Journal of Medical Internet Research

Journal Impact Factor (JIF) (2023): 5.8
Volume 22 (2020), Issue 6   ISSN 1438-8871   Editor in Chief: Gunther Eysenbach, MD, MPH

Contents

Viewpoints

Digital Health Strategies to Fight COVID-19 Worldwide: Challenges, Recommendations, and a Call for Papers (e19284)
Guy Fagherazzi, Catherine Goetzinger, Mohammed Rashid, Gloria Aguayo, Laetitia Huiart. 11

Rethinking the Use of Mobile Apps for Dietary Assessment in Medical Research (e15619)
Wael Khazen, Jean-François Jeanne, Laëtitia Demaretz, Florent Schäfer, Guy Fagherazzi. 141

Artificial Intelligence and Human Trust in Healthcare: Focus on Clinicians (e15154)
Onur Asan, Alparslan Bayrak, Avishek Choudhury. 151

Artificial Intelligence and Big Data in Diabetes Care: A Position Statement of the Italian Association of Medical Diabetologists (e16922)
Nicoletta Musacchio, Annalisa Giancaterini, Giacomo Guaita, Alessandro Ozzello, Maria Pellegrini, Paola Ponzani, Giuseppina Russo, Rita Zilich, Alberto de Micheli. 158

The Adaptive Behavioral Components (ABC) Model for Planning Longitudinal Behavioral Technology-Based Health Interventions: A Theoretical Framework (e15563)
Sean Young. 169

Digital Health Equity and COVID-19: The Innovation Curve Cannot Reinforce the Social Gradient of Health (e19361)
Allison Crawford, Eva Serhal. 1310

Considerations for an Individual-Level Population Notification System for Pandemic Response: A Review and Prototype (e19930)
Mohammad Sakib, Zahid Butt, Plinio Morita, Mark Oremus, Geoffrey Fong, Peter Hall. 1335

Why African Americans Are a Potential Target for COVID-19 Infection in the United States (e19934)
Alireza Hamidian Jahromi, Anahid Hamidianjahromi. 1401

Leveraging User Experience to Improve Video Consultations in a Cardiology Practice During the COVID-19 Pandemic: Initial Insights (e19771)
Pieter Vandekerckhove, Yves Vandekerckhove, Rene Tavernier, Kelly De Jaegher, Marleen de Mul. 1492

Reviews

The Role of Virtual Reality in Improving Health Outcomes for Community-Dwelling Older Adults: Systematic Review (e17331)

Gordana Dermody, Lisa Whitehead, Graham Wilson, Courtney Glass. . . . 21

Therapeutic Alliance in Technology-Based Interventions for the Treatment of Depression: Systematic Review (e17195)

Eileen Wehmann, Moritz Köhnen, Martin Härter, Sarah Liebherz. . . . 38

Current Evidence for Continuous Vital Signs Monitoring by Wearable Wireless Devices in Hospitalized Adults: Systematic Review (e18636)

Jobbe Leenen, Crista Leerentveld, Joris van Dijk, Henderik van Westreenen, Lisette Schoonhoven, Gijsbert Patijn. . . . 72

Engaging Children and Young People in Digital Mental Health Interventions: Systematic Review of Modes of Delivery, Facilitators, and Barriers (e16317)

Shaun Liverpool, Catarina Mota, Célia Sales, Anja uš, Sara Carletto, Camellia Hancheva, Sónia Sousa, Sonia Cerón, Patricia Moreno-Peral, Giada Pietrabissa, Bettina Moltrecht, Randi Ulberg, Nuno Ferreira, Julian Edbrooke-Childs. . . . 94

Impact of the Method of Delivering Electronic Health Behavior Change Interventions in Survivors of Cancer on Engagement, Health Behaviors, and Health Outcomes: Systematic Review and Meta-Analysis (e16112)

Kate Furness, Mitchell Sarkies, Catherine Huggins, Daniel Croagh, Terry Haines. . . . 111

The Effectiveness of Digital Health Interventions in the Management of Musculoskeletal Conditions: Systematic Literature Review (e15617)

Stephanie Hewitt, Ruth Sephton, Gillian Yeowell. . . . 209

Behavior Change Techniques Included in Reports of Social Media Interventions for Promoting Health Behaviors in Adults: Content Analysis Within a Systematic Review (e16002)

Rosiane Simeon, Omar Dewidar, Jessica Trawin, Stephanie Duench, Heather Manson, Jordi Pardo Pardo, Jennifer Petkovic, Janet Hatcher Roberts, Peter Tugwell, Manosila Yoganathan, Justin Presseau, Vivian Welch. . . . 429

Patient Work and Their Contexts: Scoping Review (e16656)

Kathleen Yin, Joshua Jung, Enrico Coiera, Liliana Laranjo, Ann Blandford, Adeel Khoja, Wan-Tien Tai, Daniel Phillips, Annie Lau. . . . 501

Electronic Data Capture Versus Conventional Data Collection Methods in Clinical Pain Studies: Systematic Review and Meta-Analysis (e16480)

Lindsay Jibb, James Khan, Puneet Seth, Chitra Lalloo, Lauren Mulrooney, Kathryn Nicholson, Dominik Nowak, Harneel Kaur, Alyssandra Chee-A-Tow, Joel Foster, Jennifer Stinson. . . . 583

Health Equity in the Effectiveness of Web-Based Health Interventions for the Self-Care of People With Chronic Health Conditions: Systematic Review (e17849)

Sophie Turnbull, Christie Cabral, Alastair Hay, Patricia Lucas. . . . 662

Technical Metrics Used to Evaluate Health Care Chatbots: Scoping Review (e18301)

Alaa Abd-Alrazaq, Zeineb Safi, Mohannad Alajlani, Jim Warren, Mowafa Househ, Kerstin Denecke. . . . 1159

Original Papers

Two Decades of Research Using Taiwan’s National Health Insurance Claims Data: Bibliometric and Text Mining Analysis on PubMed (e18457)

Sheng-Feng Sung, Cheng-Yang Hsieh, Ya-Han Hu. . . . 53

A Digital Pornography Literacy Resource Co-Designed With Vulnerable Young People: Development of "The Gist" (e15964)

Angela Davis, Cassandra Wright, Stacey Murphy, Paul Dietze, Meredith Temple-Smith, Margaret Hellard, Megan Lim. 178

A Social Media–Based Support Group for Youth Living With HIV in Nigeria (SMART Connections): Randomized Controlled Trial (e18343)

Lisa Dulli, Kathleen Ridgeway, Catherine Packer, Kate Murray, Tolulope Mumuni, Kate Plourde, Mario Chen, Adesola Olumide, Oladosu Ojengbede, Donna McCarraher. 192

Efficacy of Three Low-Intensity, Internet-Based Psychological Interventions for the Treatment of Depression in Primary Care: Randomized Controlled Trial (e15845)

Margalida Gili, Adoración Castro, Azucena García-Palacios, Javier Garcia-Campayo, Fermin Mayoral-Cleries, Cristina Botella, Miquel Roca, Alberto Barceló-Soler, María Hurtado, MªTeresa Navarro, Amelia Villena, M Pérez-Ara, Pau Riera-Serra, Rosa Baños. 222

Evaluation of Digital Technologies Tailored to Support Young People's Self-Management of Musculoskeletal Pain: Mixed Methods Study (e18315)

Helen Slater, Jennifer Stinson, Joanne Jordan, Jason Chua, Ben Low, Chitra Lalloo, Quynh Pham, Joseph Cafazzo, Andrew Briggs. 242

Coach-Facilitated Web-Based Therapy Compared With Information About Web-Based Resources in Patients Referred to Secondary Mental Health Care for Depression: Randomized Controlled Trial (e15001)

Sarah MacLean, Daniel Corsi, Sadie Litchfield, Julia Kucharski, Kira Genise, Zeynep Selaman, Valerie Testa, Simon Hatcher. 264

User-Centered Design of a Mobile Health Intervention to Enhance Exacerbation-Related Self-Management in Patients With Chronic Obstructive Pulmonary Disease (Copilot): Mixed Methods Study (e15449)

Yvonne Korpershoek, Sander Hermsen, Lisette Schoonhoven, Marieke Schuurmans, Jaap Trappenburg. 283

Challenges and Benefits of an Internet-Based Intervention With a Peer Support Component for Older Adults With Depression: Qualitative Analysis of Textual Data (e17586)

Annie Chen, Krystal Slattery, Kathryn Tomasino, Caryn Rubanovich, Leland Bardsley, David Mohr. 302

Evaluation of an On-Demand Mental Health System for Depression Symptoms: Retrospective Observational Study (e17902)

Sarah Kunkle, Manny Yip, Watson Ξ, Justin Hunt. 314

A Blended Physiotherapy Intervention for Persons With Hemophilic Arthropathy: Development Study (e16631)

Merel Timmer, Corelien Kloek, Piet de Kleijn, Isolde Kuijlaars, Roger Schutgens, Cindy Veenhof, Martijn Pisters. 326

Young People's Experience of a Long-Term Social Media–Based Intervention for First-Episode Psychosis: Qualitative Analysis (e17570)

Lee Valentine, Carla McEnery, Shaunagh O'Sullivan, John Gleeson, Sarah Bendall, Mario Alvarez-Jimenez. 335

Evaluating Engagement in a Digital and Dietetic Intervention Promoting Healthy Weight Gain in Pregnancy: Mixed Methods Study (e17845)

Jane Willcox, Daniel Chai, Lawrence Beilin, Susan Prescott, Desiree Silva, Cliff Neppe, Rae-Chi Huang. 347

A Prospective Study of Usability and Workload of Electronic Medication Adherence Products by Older Adults, Caregivers, and Health Care Providers (e18073)

Tejal Patel, Jessica Ivo, Sadaf Faisal, Aidan McDougall, Jillian Carducci, Sarah Pritchard, Feng Chang. 358

Medical Mobile App Classification Using the National Institute for Health and Care Excellence Evidence Standards Framework for Digital Health Technologies: Interrater Reliability Study (e17457)

Khine Nwe, Mark Larsen, Natalie Nelissen, David Wong. 372

Reliability of Smartphone for Diffusion-Weighted Imaging–Alberta Stroke Program Early Computed Tomography Scores in Acute Ischemic Stroke Patients: Diagnostic Test Accuracy Study (e15893)
Kenichiro Sakai, Teppei Komatsu, Yasuyuki Iguchi, Hiroyuki Takao, Toshihiro Ishibashi, Yuichi Murayama. 380

Menstrual Cycle Length and Patterns in a Global Cohort of Women Using a Mobile Phone App: Retrospective Cohort Study (e17109)
Jessica Grieger, Robert Norman. 389

Stratification of Individual Symptoms of Contact Lens–Associated Dry Eye Using the iPhone App DryEyeRhythm: Crowdsourced Cross-Sectional Study (e18996)
Takenori Inomata, Masahiro Nakamura, Masao Iwagami, Akie Midorikawa-Inomata, Jaemyoung Sung, Keiichi Fujimoto, Yuichi Okumura, Atsuko Eguchi, Nanami Iwata, Maria Miura, Kenta Fujio, Ken Nagino, Satoshi Hori, Kazuo Tsubota, Reza Dana, Akira Murakami. 404

Challenges and Successes in Raising a Child With Type 1 Diabetes and Autism Spectrum Disorder: Mixed Methods Study (e17184)
Tamara Oser, Sean Oser, Jessica Parascando, Lee Grisolano, Kanthi Krishna, Daniel Hale, Michelle Litchman, Shideh Majidi, Paul Haidet. . .
4 1 7

A Social Media Study on the Associations of Flavored Electronic Cigarettes With Health Symptoms: Observational Study (e17496)
Long Chen, Xinyi Lu, Jianbo Yuan, Joyce Luo, Jiebo Luo, Zidian Xie, Dongmei Li. 445

Association Between HIV-Related Tweets and HIV Incidence in the United States: Infodemiology Study (e17196)
Robin Stevens, Stephen Bonett, Jacqueline Bannon, Deepti Chittamuru, Barry Slaff, Safa Browne, Sarah Huang, José Bauermeister. 456

User Perceptions of Different Electronic Cigarette Flavors on Social Media: Observational Study (e17280)
Xinyi Lu, Long Chen, Jianbo Yuan, Joyce Luo, Jiebo Luo, Zidian Xie, Dongmei Li. 466

Exploring Public Awareness of Overwork Prevention With Big Data From Google Trends: Retrospective Analysis (e18181)
Ro-Ting Lin, Yawen Cheng, Yan-Cheng Jiang. 477

Impact of Age on Patients’ Communication and Technology Preferences in the Era of Meaningful Use: Mixed Methods Study (e13470)
Martina Clarke, Ann Fruhling, Marilyn Sitorius, Thomas Windle, Tamara Bernard, John Windle. 487

Physiotherapy With Telerehabilitation in Patients With Complicated Postoperative Recovery After Esophageal Cancer Surgery: Feasibility Study (e16056)
Maarten van Egmond, Raoul Engelbert, Jean Klinkenbijl, Mark van Berge Henegouwen, Marike van der Schaaf. 516

Evaluating Safety and Efficacy of Follow-up for Patients With Abdominal Pain Using Video Consultation (SAVED Study): Randomized Controlled Trial (e17417)
Dinesh Gunasekeran, Zhenghong Liu, Win Tan, Joshua Koh, Chiu Cheong, Lay Tan, Chee Lau, Gaik Phuah, Newsie Manuel, Che Chia, Gek Seng, Nancy Tong, May Huin, Suzette Dulce, Susan Yap, Kishanti Ponampalam, Hao Ying, Marcus Ong, R Ponampalam. 529

Communication Strategies Used to Obtain Clinical Histories Before Remotely Prescribing Antibiotics for Postal Treatment of Uncomplicated Genital Chlamydia: Service Evaluation (e15970)
Hannah McCulloch, Jonathan Syred, Gillian Holdsworth, Chris Howroyd, Elena Ardines, Paula Baraitser. 539

Perspectives of Psychotherapists and Psychiatrists on Mental Health Care Integration Within Primary Care Via Video Consultations: Qualitative Preimplementation Study (e17569)
Mariell Hoffmann, Michel Wensing, Frank Peters-Klimm, Joachim Szecsenyi, Mechthild Hartmann, Hans-Christoph Friederich, Markus Haun.
5 5 1

Improvements in Patient Monitoring in the Intensive Care Unit: Survey Study (e19091)
Akira-Sebastian Poncette, Lina Mosch, Claudia Spies, Malte Schmieding, Fridtjof Schiefenhövel, Henning Krampe, Felix Balzer. . . . 562

Active Surveillance of Adverse Events Following Human Papillomavirus Vaccination: Feasibility Pilot Study Based on the Regional Health Care Information Platform in the City of Ningbo, China (e17446)
Zhike Liu, Liang Zhang, Yu Yang, Ruogu Meng, Ting Fang, Ying Dong, Ning Li, Guozhang Xu, Siyan Zhan. . . . 573

Attitudes and Use of Information and Communication Technologies in Older Adults With Mild Cognitive Impairment or Early Stages of Dementia and Their Caregivers: Cross-Sectional Study (e17253)
Jose Guzman-Parra, Pilar Barnestein-Fonseca, Gloria Guerrero-Pertiñez, Peter Anderberg, Luis Jimenez-Fernandez, Esperanza Valero-Moreno, Jessica Goodman-Casanova, Antonio Cuesta-Vargas, Maite Garolera, Maria Quintana, Rebeca García-Betances, Evi Lemmens, Johan Sanmartin Berglund, Fermin Mayoral-Cleries. . . . 616

Gender and the Digital Divide Across Urban Slums of New Delhi, India: Cross-Sectional Study (e14714)
Ashish Joshi, Bhavya Malhotra, Chioma Amadi, Menka Loomba, Archa Misra, Shruti Sharma, Arushi Arora, Jaya Amatya. . . . 631

Internet and Health Information Technology Use and Psychological Distress Among Older Adults With Self-Reported Vision Impairment: Case-Control Study (e17294)
Namkee Choi, Diana DiNitto, Othelia Lee, Bryan Choi. . . . 648

Lifestyle Segmentation to Explain the Online Health Information–Seeking Behavior of Older Adults: Representative Telephone Survey (e15099)
Winja Weber, Anne Reinhardt, Constanze Rossmann. . . . 683

Views of Swedish Elder Care Personnel on Ongoing Digital Transformation: Cross-Sectional Study (e15450)
Katarina Baudin, Christine Gustafsson, Susanne Frennert. . . . 697

The Demographic Representativeness and Health Outcomes of Digital Health Station Users: Longitudinal Study (e14977)
Leah Flitcroft, Won Chen, Denny Meyer. . . . 707

Continuous Monitoring of Vital Signs in the General Ward Using Wearable Devices: Randomized Controlled Trial (e15471)
Mariska Weenk, Sebastian Bredie, Mats Koeneman, Gijs Hesselink, Harry van Goor, Tom van de Belt. . . . 722

Internet Influence of Assisted Reproduction Technology Centers in China: Qualitative Study Based on WeChat Official Accounts (e17997)
Fang Shao, Zhiqiang He, Zheng Zhu, Xiang Wang, Jianping Zhang, Jinhua Shan, Jiajia Pan, Hui Wang. . . . 733

Enhancing Patient Experience With Internet Protocol Addressable Digital Light-Emitting Diode Lighting in Imaging Environments: A Phase I Study (e11839)
Melanie Knopp, Katherine Binzel, Chadwick Wright, Jun Zhang, Michael Knopp. . . . 747

Metrics for Outpatient Portal Use Based on Log File Analysis: Algorithm Development (e16849)
Gennaro Di Tosto, Ann McAlearney, Naleef Fareed, Timothy Huerta. . . . 756

The Impact of Digital-First Consultations on Workload in General Practice: Modeling Study (e18203)
Chris Salisbury, Mairead Murphy, Polly Duncan. . . . 773

Applying Machine Learning to Daily-Life Data From the TrackYourTinnitus Mobile Health Crowdsensing Platform to Predict the Mobile Operating System Used With High Accuracy: Longitudinal Observational Study (e15547)
Rüdiger Pryss, Winfried Schlee, Burkhard Hoppenstedt, Manfred Reichert, Myra Spiliopoulou, Berthold Langguth, Marius Breitmayer, Thomas Probst. . . . 784

Modifications to Electronic Nicotine Delivery Systems: Content Analysis of YouTube Videos (e17104)

Zachary Massey, Yachao Li, Jessica Holli, Victoria Churchill, Bo Yang, Katherine Henderson, David Ashley, Jidong Huang, Lucy Popova. . . .
7 9 9

The Use of Mobile Personal Health Records for Hemoglobin A1c Regulation in Patients With Diabetes: Retrospective Observational Study (e15372)

Dongjin Seo, Yu Park, Yura Lee, Ji Kim, Joong-Yeol Park, Jae-Ho Lee. . . . 809

Comparisons Between Hypothesis- and Data-Driven Approaches for Multimorbidity Frailty Index: A Machine Learning Approach (e16213)

Li-Ning Peng, Fei-Yuan Hsiao, Wei-Ju Lee, Shih-Tsung Huang, Liang-Kung Chen. . . . 823

Facebook as a Novel Tool for Continuous Professional Education on Dementia: Pilot Randomized Controlled Trial (e16772)

Windy Chan, Angela Leung. . . . 834

Teaching the National Institutes of Health Stroke Scale to Paramedics (E-Learning vs Video): Randomized Controlled Trial (e18358)

Avinash Koka, Laurent Suppan, Philippe Cottet, Emmanuel Carrera, Loric Stuby, Mélanie Suppan. . . . 850

The Model of Gamification Principles for Digital Health Interventions: Evaluation of Validity and Potential Utility (e16506)

Mark Floryan, Philip Chow, Stephen Schueller, Lee Ritterband. . . . 858

Using Geocaching to Promote Active Aging: Qualitative Study (e15339)

Silvia Fornasini, Marco Dianti, Alessandro Bacchiega, Stefano Forti, Diego Conforti. . . . 869

Understanding Weight Loss via Online Discussions: Content Analysis of Reddit Posts Using Topic Modeling and Word Clustering Techniques (e13745)

Yang Liu, Zhijun Yin. . . . 882

Superusers' Engagement in Asthma Online Communities: Asynchronous Web-Based Interview Study (e18185)

Anna De Simoni, Anjali Shah, Olivia Fulton, Jasmine Parkinson, Aziz Sheikh, Pietro Panzarasa, Claudia Pagliari, Neil Coulson, Chris Griffiths.
8 9 6

Examining Social Capital, Social Support, and Language Use in an Online Depression Forum: Social Network and Content Analysis (e17365)

Wenjing Pan, Bo Feng, Cuihua Shen. . . . 911

Usability of a Consumer Health Informatics Tool Following Completion of a Clinical Trial: Focus Group Study (e17708)

Hwayoung Cho, Tiffany Porras, Gabriella Flynn, Rebecca Schnall. . . . 925

Facebook Recruitment Using Zip Codes to Improve Diversity in Health Research: Longitudinal Observational Study (e17554)

Cornelia Pechmann, Connor Phillips, Douglas Calder, Judith Prochaska. . . . 936

Spelling Errors and Shouting Capitalization Lead to Additive Penalties to Trustworthiness of Online Health Information: Randomized Experiment With Laypersons (e15171)

Harry Witchel, Georgina Thompson, Christopher Jones, Carina Westling, Juan Romero, Alessia Nicotra, Bruno Maag, Hugo Critchley. . . . 957

Web-Based Health Information Following the Renewal of the Cervical Screening Program in Australia: Evaluation of Readability, Understandability, and Credibility (e16701)
Olivia Mac, Amy Thayre, Shumei Tan, Rachael Dodd. 971

Cigarette Packs With URLs Leading to Tobacco Company Websites: Content Analysis (e15160)
Caitlin Weiger, Katherine Smith, Amy Hong, Joanna Cohen. 985

Privacy-Preserving Record Linkage of Deidentified Records Within a Public Health Surveillance System: Evaluation Study (e16757)
Long Nguyen, Mark Stoové, Douglas Boyle, Denton Callander, Hamish McManus, Jason Asselin, Rebecca Guy, Basil Donovan, Margaret Hellard, Carol El-Hayek. 997

Association of eHealth Literacy With Lifestyle Behaviors in University Students: Questionnaire-Based Cross-Sectional Study (e18155)
Saki Tsukahara, Satoshi Yamaguchi, Futaba Igarashi, Reiko Uruma, Naomi Ikuina, Kaori Iwakura, Keisuke Koizumi, Yasunori Sato. 1009

Disseminating the Foundations of Knowledge Translation and Patient Engagement Science Through the KnowledgeNudge Blog and Twitter Profile: Quantitative Descriptive Evaluation (e15351)
Kathryn Sibley, Masood Khan, Patricia Roche, Patrick Faucher, Carly Leggett. 1020

Prediction of (Non)Participation of Older People in Digital Health Research: Exergame Intervention Study (e17884)
Arianna Poli, Susanne Kelfve, Leonie Klompstra, Anna Strömberg, Tiny Jaarsma, Andreas Motel-Klingebiel. 1029

Physiological State and Learning Ability of Students in Normal and Virtual Reality Conditions: Complexity-Based Analysis (e17945)
Mohammad Babini, Vladimir Kulish, Hamidreza Namazi. 1041

Simulator Pre-Screening of Underprepared Drivers Prior to Licensing On-Road Examination: Clustering of Virtual Driving Test Time Series Data (e13995)
David Grethlein, Flaura Winston, Elizabeth Walshe, Sean Tanner, Venk Kandadai, Santiago Ontañón. 1050

Using Virtual Reality to Improve Apathy in Residential Aged Care: Mixed Methods Study (e17632)
Dimitrios Saredakis, Hannah Keage, Megan Corlis, Tobias Loetscher. 1064

Internet Use, eHealth Literacy, and Dietary Supplement Use Among Young Adults in Pakistan: Cross-Sectional Study (e17014)
Amina Tariq, Shanchita Khan, Amna Basharat. 1086

Factors Associated With the Actual Behavior and Intention of Rating Physicians on Physician Rating Websites: Cross-Sectional Study (e14417)
Xi Han, Bei Li, Tingting Zhang, Jiabin Qu. 1095

Associations Between Commercial App Use and Physical Activity: Cross-Sectional Study (e17152)
Jasmine Petersen, Eva Kemps, Lucy Lewis, Ivanka Prichard. 1109

Effect of BMI and Perceived Importance of Health on the Health Behavior of College Students: Cross-Sectional Study (e17640)
Wan-Chen Hsu, Chia-Hsun Chiang. 1122

Developing and Applying a Formative Evaluation Framework for Health Information Technology Implementations: Qualitative Investigation (e15068)
Kathrin Cresswell, Robin Williams, Aziz Sheikh. 1128

Patient-Centric Scheduling With the Implementation of Health Information Technology to Improve the Patient Experience and Access to Care: Retrospective Case-Control Analysis (e16451)
Sukyung Chung, Meghan Martinez, Dominick Frosch, Veena Jones, Albert Chan. 1138

Effect of Speech Recognition on Problem Solving and Recall in Consumer Digital Health Tasks: Controlled Laboratory Experiment (e14827)
Jessica Chen, David Lyell, Liliana Laranjo, Farah Magrabi. 1149

Using Blockchain Technology to Mitigate Challenges in Service Access for the Homeless and Data Exchange Between Providers: Qualitative Study (e16887)
Anjum Khurshid, Vivian Rajeswaren, Steven Andrews. 1174

An Architecture and Management Platform for Blockchain-Based Personal Health Record Exchange: Development and Usability Study (e16748)
Hsiu-An Lee, Hsin-Hua Kung, Jai Udayasankaran, Boonchai Kijsanayotin, Alvin B Marcelo, Louis Chao, Chien-Yeh Hsu. 1185

Inferring Sexually Transmitted Infection Risk From Attractiveness in Online Dating Among Adolescents and Young Adults: Exploratory Study (e14242)
Tamar Krishnamurti, Alexander Davis, Baruch Fischhoff. 1200

Toward the Development of Data Governance Standards for Using Clinical Free-Text Data in Health Research: Position Paper (e16760)
Kerina Jones, Elizabeth Ford, Nathan Lea, Lucy Griffiths, Lamiece Hassan, Sharon Heys, Emma Squires, Goran Nenadic. 1209

Healthcare Research and Analytics Data Infrastructure Solution: A Data Warehouse for Health Services Research (e18579)
Bunyamin Ozaydin, Ferhat Zengul, Nurettin Oner, Sue Feldman. 1225

Development of an Online Health Care Assessment for Preventive Medicine: A Machine Learning Approach (e18585)
Cheng-Sheng Yu, Yu-Jiun Lin, Chang-Hsien Lin, Shiyng-Yu Lin, Jenny Wu, Shy-Shin Chang. 1241

Patients' Perceptions of Barriers and Facilitators to the Adoption of E-Hospitals: Cross-Sectional Study in Western China (e17221)
Peiyi Li, Yunmei Luo, Xuexin Yu, Jin Wen, Elizabeth Mason, Weimin Li, Mohammad Jalali. 1259

An Intervention Delivered by Mobile Phone Instant Messaging to Increase Acceptability and Use of Effective Contraception Among Young Women in Bolivia: Randomized Controlled Trial (e14073)
Ona McCarthy, Carolina Aliaga, Maria Torrico Palacios, Jhonny López Gallardo, Silvia Huaynoca, Baptiste Leurent, Phil Edwards, Melissa Palmer, Irrfan Ahamed, Caroline Free. 1276

Data Validation and Verification Using Blockchain in a Clinical Trial for Breast Cancer: Regulatory Sandbox (e18938)
Tomonobu Hirano, Tomomitsu Motohashi, Kosuke Okumura, Kentaro Takajo, Taiyo Kuroki, Daisuke Ichikawa, Yutaka Matsuoka, Eisuke Ochi, Taro Ueno. 1292

Online Information Exchange and Anxiety Spread in the Early Stage of the Novel Coronavirus (COVID-19) Outbreak in South Korea: Structural Topic Model and Network Analysis (e19455)
Wonkwang Jo, Jaeho Lee, Junli Park, Yeol Kim. 1315

COVID-19-Related Information Sources and the Relationship With Confidence in People Coping with COVID-19: Facebook Survey Study in Taiwan (e20021)
Peng-Wei Wang, Wei-Hsin Lu, Nai-Ying Ko, Yi-Lung Chen, Dian-Jeng Li, Yu-Ping Chang, Cheng-Fang Yen. 1348

Telehealth in the Context of COVID-19: Changing Perspectives in Australia, the United Kingdom, and the United States (e19264)
Malcolm Fisk, Anne Livingstone, Sabrina Pit. 1356

Development of an openEHR Template for COVID-19 Based on Clinical Guidelines (e20239)
Mengyang Li, Heather Leslie, Bin Qi, Shan Nan, Hongshuo Feng, Hailing Cai, Xudong Lu, Huilong Duan. 1369

Epidemiological Observations on the Association Between Anosmia and COVID-19 Infection: Analysis of Data From a Self-Assessment Web Application (e19855)
Fabrice Denis, Simon Galmiche, Aurélien Dinh, Arnaud Fontanet, Arnaud Scherpereel, Francois Benezit, François-Xavier Lescure. 1384

Information Technology–Based Management of Clinically Healthy COVID-19 Patients: Lessons From a Living and Treatment Support Center Operated by Seoul National University Hospital (e19938)
Ye Bae, Kyung Kim, Sae Choi, Taehoon Ko, Chang Jeong, BeLong Cho, Min Kim, EunKyo Kang. 1390

Nature and Diffusion of COVID-19–related Oral Health Information on Chinese Social Media: Analysis of Tweets on Weibo (e19981)
Zhuo-Ying Tao, Guang Chu, Colman McGrath, Fang Hua, Yiu Leung, Wei-Fa Yang, Yu-Xiong Su. 1405

Internet Use, Risk Awareness, and Demographic Characteristics Associated With Engagement in Preventive Behaviors and Testing: Cross-Sectional Survey on COVID-19 in the United States (e19782)
Siyue Li, Bo Feng, Wang Liao, Wenjing Pan. 1419

Clarification of Misleading Perceptions of COVID-19 Fatality and Testing Rates in Italy: Data Analysis (e19825)
Davide Tosi, Alessandro Verde, Manuela Verde. 1431

Human Factor Considerations in Using Personal Protective Equipment in the COVID-19 Pandemic Context: Binational Survey Study (e19947)
Avi Parush, Oren Wacht, Ricardo Gomes, Amit Frenkel. 1438

Mental Health and Behavior of College Students During the Early Phases of the COVID-19 Pandemic: Longitudinal Smartphone and Ecological Momentary Assessment Study (e20185)
Jeremy Huckins, Alex daSilva, Weichen Wang, Elin Hedlund, Courtney Rogers, Subigya Nepal, Jialing Wu, Mikio Obuchi, Eilis Murphy, Meghan Meyer, Dylan Wagner, Paul Holtzheimer, Andrew Campbell. 1450

A Double Triage and Telemedicine Protocol to Optimize Infection Control in an Emergency Department in Taiwan During the COVID-19 Pandemic: Retrospective Feasibility Study (e20586)
Chien-Hao Lin, Wen-Pin Tseng, Jhong-Lin Wu, Joyce Tay, Ming-Tai Cheng, Hooi-Nee Ong, Hao-Yang Lin, Yi-Ying Chen, Chih-Hsien Wu, Jiun-Wei Chen, Shey-Ying Chen, Chang-Chuan Chan, Chien-Hua Huang, Shyr-Chyr Chen. 1469

Virtual Management of Patients With Cancer During the COVID-19 Pandemic: Web-Based Questionnaire Study (e19691)
Emad Tashkandi, Ahmed Zeeneldin, Amal AlAbdulwahab, Omima Elemam, Shereef Elsamany, Wasil Jastaniah, Shaker Abdullah, Mohammad Alfayez, Abdul Jazieh, Humaid Al-Shamsi. 1481

Framework for Managing the COVID-19 Infodemic: Methods and Results of an Online, Crowdsourced WHO Technical Consultation (e19659)
Viroj Tangcharoensathien, Neville Calleja, Tim Nguyen, Tina Purnat, Marcelo D'Agostino, Sebastian Garcia-Saiso, Mark Landry, Arash Rashidian, Clayton Hamilton, Abdelhalim AbdAllah, Ioana Ghiga, Alexandra Hill, Daniel Hougendobler, Judith van Andel, Mark Nunn, Ian Brooks, Pier Sacco, Manlio De Domenico, Philip Mai, Anatoliy Gruzd, Alexandre Alaphilippe, Sylvie Briand. 1498

COVID-19 Pneumonia Diagnosis Using a Simple 2D Deep Learning Framework With a Single Chest CT Image: Model Development and Validation (e19569)
Hoon Ko, Heewon Chung, Wu Kang, Kyung Kim, Youngbin Shin, Seung Kang, Jae Lee, Young Kim, Nan Kim, Hyunseok Jung, Jinseok Lee. .

Abstract

The coronavirus disease (COVID-19) pandemic has created an urgent need for coordinated mechanisms to respond to the outbreak across health sectors, and digital health solutions have been identified as promising approaches to address this challenge. This editorial discusses the current situation regarding digital health solutions to fight COVID-19 as well as the challenges and ethical hurdles to broad and long-term implementation of these solutions. To decrease the risk of infection, telemedicine has been used as a successful health care model in both emergency and primary care. Official communication plans should promote facile and diverse channels to inform people about the pandemic and to avoid rumors and reduce threats to public health. Social media platforms such as Twitter and Google Trends analyses are highly beneficial to model pandemic trends as well as to monitor the evolution of patients' symptoms or public reaction to the pandemic over time. However, acceptability of digital solutions may face challenges due to potential conflicts with users' cultural, moral, and religious backgrounds. Digital tools can provide collective public health benefits; however, they may be intrusive and can erode individual freedoms or leave vulnerable populations behind. The COVID-19 pandemic has demonstrated the strong potential of various digital health solutions that have been tested during the crisis. More concerted measures should be implemented to ensure that future digital health initiatives will have a greater impact on the epidemic and meet the most strategic needs to ease the life of people who are at the forefront of the crisis.

Background

Countries around the world have been affected by the COVID-19 pandemic since December 2019 [1], and the health care systems in these countries are rapidly adapting to the increasing demand. The World Health Organization (WHO) has called for coordinated mechanisms to support the response to the outbreak across health sectors, and digital health solutions have been identified as one of the most promising approaches to address this challenge in modern societies [2].

The COVID-19 pandemic is singular in many ways. First, in terms of number of people infected, transmissibility, and spectrum of clinical severity, it has had a greater impact to date than previous epidemics such as pandemic influenza, Middle East respiratory syndrome (MERS), severe acute respiratory syndrome (SARS), or Ebola virus [3]. Second, COVID-19 can be considered as the first true global epidemic of this magnitude in the digital era; digital health solutions, which have reached a certain level of maturity but are not widely deployed and accepted yet, can play a major part in our response to the crisis [4]. Indeed, the COVID-19 pandemic is occurring in an era of massive technological advancement. Digital tools can effectively support institutions during a pandemic by facilitating the immediate widespread distribution of information [5], tracking transmission in real time, creating virtual venues for meetings or day-to-day operations, and providing telemedicine visits for patients [6]. However, some digital health strategies and tools may face challenges associated with barriers to access, acceptability, and ethical issues. For instance, some governments worldwide are responding to this public health emergency with an unprecedented array of surveillance tools designed to identify and track people who may be infectious [7]. These measures have escalated existing debates regarding individual privacy and government oversight of private citizens.

The COVID-19 pandemic is providing a starting point to discuss how digital health solutions can and should be leveraged to address this unprecedented crisis [8]. This editorial offers an overview of the digital health strategies that have been employed worldwide to fight COVID-19 to date as well as a discussion of the challenges to developing more meaningful [9] and ethical solutions in the near future.

Digital Health Care Models

New health care models are needed during the COVID-19 pandemic. Due to the high transmission rate of COVID-19, most countries have ordered strict lockdowns; hence, patient-physician communication and visits are challenging. In the era of digital health technologies, the focus on new models has shifted to telehealth (virtual visits, virtual care), mobile apps (remote patient monitoring), and websites and chatbots (risk assessment, screening, triage). Figure 1 describes the main stakeholders at the forefront of the COVID_19 crisis (the population, the health care systems, and the research and health technology environment in coordination with public health agencies or governments) with significant illustrations of efficient digital health strategies that have been implemented to date at various levels.

Figure 1. The COVID-19 digital health ecosystem. AI: artifical intelligence; e-prescribing: electronic prescribing; tech: technology.

Telemedicine and Remote Patient Monitoring Systems

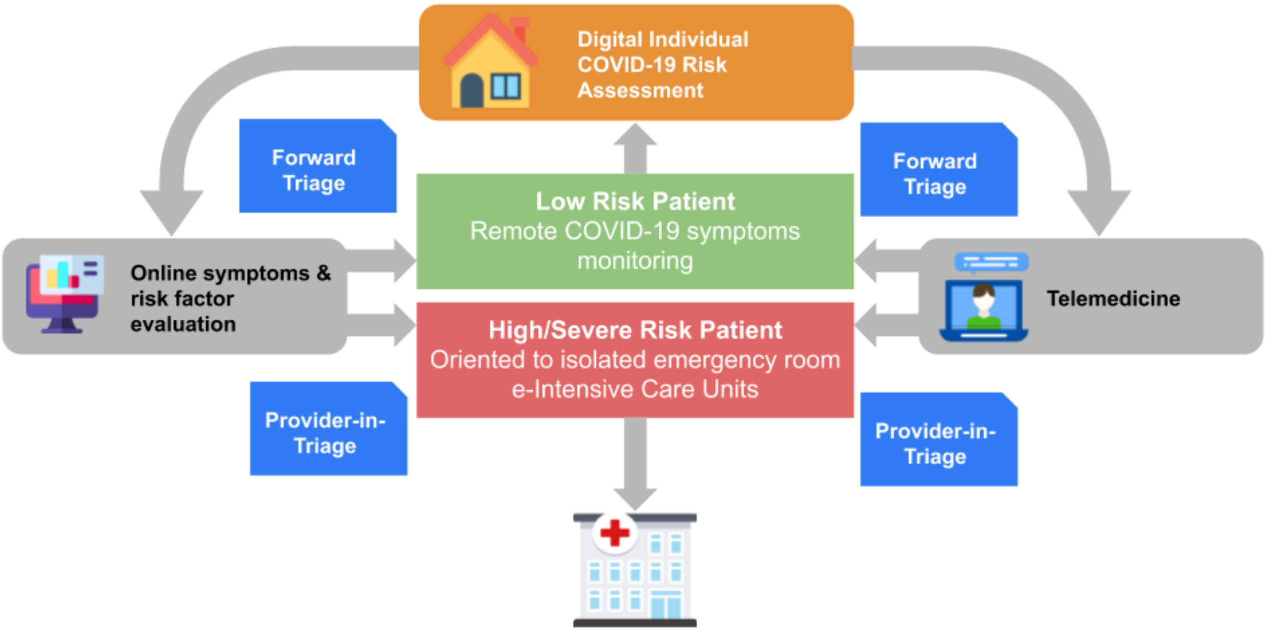
Telemedicine allows patients to receive care at home [10], thus avoiding the spread of COVID-19 in overcrowded emergency or waiting rooms [11]. Telemedicine not only supports secured care for COVID-19 patients but also allows routine primary care and electronic prescriptions (e-prescriptions). In addition, health care professionals can screen and monitor symptoms in real time, provide useful medical advice when needed, and keep stable patients at home away from overloaded hospitals [12].

Additionally, these tools can serve as useful resources to rapidly collect meaningful information on large cohorts of patients to study the evolution of their symptoms in real time; this increases understanding of the different clinical phenotypes of people infected with COVID-19 and enables the study of its long-term health consequences. Such a prospective cohort was recently established in Luxembourg (Predi-COVID) to study factors associated with COVID-19 disease severity; this study uses data from the national telesurveillance system that is used for virtually all patients who tested positive for COVID-19 and combines the data with biological sampling, electronic patient-reported outcomes, and innovative digital data collections such as smartphone-based voice recording to identify vocal biomarkers of respiratory syndromes. In another study, Wang et al [13] described armband sensors that can remotely measure the accuracy of hand hygiene based on WHO procedures.

Triage and Risk Assessment

The COVID-19 virus has caused panic and uncertainty within populations; to ensure better allocation of resources, telemedicine based on videoconferences can be used not only to comfort patients but also for triage [14]. Hollander et al [15] highlighted that telemedicine can serve as a triage system in different phases. The first stage is “forward triage;” here, patients are categorized as possibly COVID-19 infected or uninfected before they arrive at the hospital. In addition, telemedicine ensures close monitoring of less severely infected patients at home by allowing communication around the clock. The second phase of triage occurs in the hospital and is referred to as the “provider-in-triage model.” In this phase, patients at high risk for COVID-19 are screened by rapid evaluation of clinical characteristics and testing. Patients are kept in isolated emergency rooms, where they are given tablet devices to communicate with professionals [15]; the tablets are cleaned between patients. To reduce risk of infection among health care professionals, hospitals have also implemented electronic intensive care unit monitoring. For example, a few countries have launched within-hospital telemedicine programs. A robot enters the room of a patient infected with COVID-19 to monitor both vital and cardiac signs and enable communication between the patient and health care professionals where applicable. All the robot’s actions are controlled by nurses or physicians outside the room [16]. Figure 2 shows the typical path of an individual from the time they have questions about their health or symptoms potentially related to COVID-19. Digital technologies now enable online symptom checks, video consultations, and e-prescriptions and allow forward triage instead of overloading hospitals and increasing the spread of the virus. Low-risk patients can be regularly monitored from home, whereas patients with more severe symptoms can be monitored at hospitals with a provider-in-triage using digital tools.

Figure 2. Risk assessment and triage of COVID-19 in a digital health care model. COVID-19: coronavirus disease.

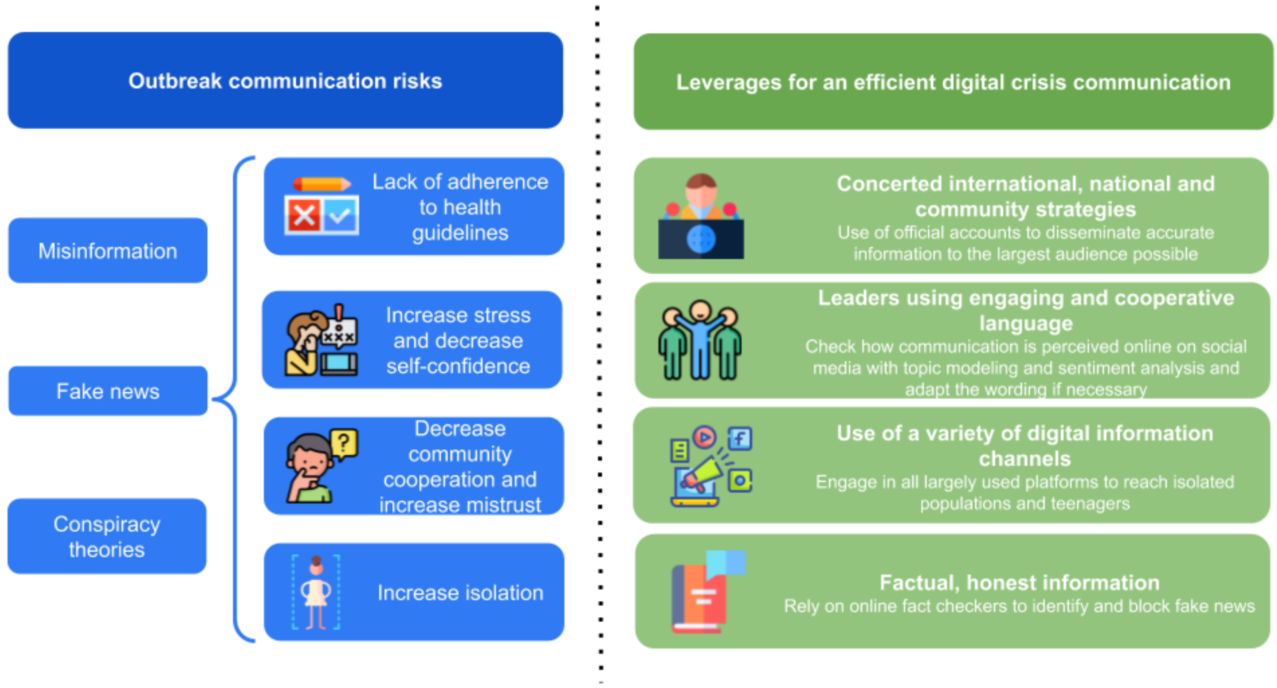


Web-based symptom trackers such as maladiecoronavirus.fr [17] in France and beatcovid19now.org [18] in Australia were rapidly established to help individuals assess their risk for COVID-19; these trackers are being updated as knowledge of COVID-19 evolves. Site users must answer several questions to feed the risk prediction algorithms; then, based on risk stratification, the website advises the user to call a hotline to receive further instructions or to stay at home and follow international guidelines. Similarly, chatbots such as Symptoma are systems that digitally assist individuals in performing risk assessment of COVID-19 [19].

Digital Communication During the Pandemic

Communication between political leaders and scientific authorities is crucial during a pandemic crisis [20] (Figure 3). Since the start of the COVID-19 pandemic, disinformation, “fake news,” and conspiracy theories about the origin, spread, and treatment of the disease have been present on the internet and in government communications, social media, and SMS text messages. These communication problems also cause confusion and mistrust; the consequences are negative at both the individual and community levels. To provide the most useful information in a timely fashion, effective digital risk communication has been established internationally by WHO as well as nationally and regionally through an active factual information campaign using several digital channels. Good communication strategies help manage people's fear and increase the likelihood that they will adhere to the measures imposed on them during the crisis. Risk communication promotes community engagement, avoids or decreases the profusion of rumors, and reduces threats to public health. However, poor risk communication can create a great deal of confusion, frustration, and future mistrust of leaders. Communication in epidemics must not only be clear and unambiguous but must also reach the target population quickly (health workers, local authorities, and the public). For instance, guidelines around practicing social distancing have been judged to be unclear and prone to misunderstanding. These guidelines should be followed with more direct messages, such as “stay at home,” especially to clarify the concept of social distancing for vulnerable populations or younger people. The WHO webpage uses the phrase “physical distance” in addition to “social distance” to emphasize this necessity. However, social contact must be stimulated, especially for older persons [21]. Digital methods appear to be promising solutions, as they enable people to maintain physical distance while keeping informed or maintaining contact with others; for example, the WhatsApp messaging platform provides health alerts in different languages [22].

Figure 3. Communication risks and strategies during disease outbreaks.



In addition, digital health can play a major role at a governmental level. Government initiatives have been taken to provide guidelines and information on government websites to inform the population about appropriate behavior during the lockdown period, hand hygiene, etc. Most of these initiatives were supported by international guidelines from WHO or the US Centers for Disease Control and Prevention (CDC).

The use of apps or instant messaging services to enable ministries or health agencies to contact health workers remotely and to inform government officials about the number of cases, symptoms, and prevention measures are just a few examples of measures that have been efficiently used in previous pandemics [23] or early in the COVID-19 crisis [22]. A crucial consequence of a bad risk communication strategy is the likelihood of increased levels of anxiety within the population. Contradictory information and overexposure to sensationalist headlines from mass media and social media can affect people’s mental health and increase the general level of fear. Lockdown can amplify the problem due to increased exposure to social media and rumors as well as lack of confrontation of ideas and debate in the real world [24]. Consequently, lockdown reinforces the importance of institutional development of digital strategies. Therefore, during the outbreak, official communication plans should promote easily accessible and diverse channels of digital communication at all stages and for different purposes (global, regional, and community-based communication). These channels should be integrated as an information system, as a communication tool, and for detecting and supporting people at risk [25]. An example of a communication strategy that was developed very quickly and effectively to fight fear and rumors among a population is the sending of messages by the government of Singapore through WhatsApp [26]. Finally, a strategy to include marginalized and vulnerable populations should be planned. Such a strategy should involve establishing multiple means of communication, including digital platforms; using adequate, simple, and nondiscriminatory language; and taking differences in health literacy into account [27].

Digital Data to Model COVID-19 Spread, Evolution, and Perception

The monitoring of online or social media activities for public health purposes has been investigated since the first days of the digital epidemiology field in the early 2010s, with the objective of capturing health-related trends and modeling disease outbreaks. The most famous examples of internet health surveillance were developed to predict the incidence of influenza, such as Google Flu Trends, or to obtain insights from social media platforms such as Twitter about influenza A/H1N1 [28], measles [29], the Zika virus [30], and the Ebola virus [31,32]. Despite their high potential in public health, these studies have been criticized for their lack of theorization and appropriate standard methodology [33], which can prevent comparison of their results and raises questions regarding the safety of relying on their findings to design targeted public health measures in the real world. To move beyond the simplistic thought that Twitter is a “giant playground” for data scientists, ongoing initiatives to use Twitter data to study the COVID-19 outbreak should build upon previous mistakes, with a more rigorous approach as well as an open source/open data mentality.

Online activities are very good indicators of trends in society. Exploiting data such as Google Trends [34], Wikipedia searches, or the Baidu Index and Weibo Index in China has already proved useful. In China, internet searches and social media data related to COVID-19 have been shown to be highly correlated with daily disease incidence and exhibit an online peak 10 to 14 days before the peak of daily incidences in the real world [35]. Although there are few reports to date, such data sources could also prove useful for early identification of less common symptoms related to COVID-19 using a similar approach to that used to detect weak pharmacovigilance signals from social media and identify side effects of drugs [36]. The main advantage of these data sources is that they can be accessed early in the epidemic and at low cost.

However, predicting disease incidence from online activities or social media data has never been used in a real time prospective fashion for public health guidance on a large scale; rather, such predictions are performed retrospectively by training algorithms to replicate gold-standard data, such as those obtained from the CDC [37], as closely as possible. COVID-19 may be the first outbreak where such a prospective analysis occurs, combining data from standard sources of disease surveillance with social media data or activity trackers [38] to improve overall accuracy.

Social media data analysis is also relevant during the COVID-19 outbreak to monitor how people react to the pandemic evolution over time (sentiment, anxiety, level of stress) as well as common beliefs, opinions [39,40], fears, or hopes regarding treatment or vaccines. Perhaps most importantly, identifying and combating the spread of “fake news” about COVID-19 is highly necessary in our modern digital society [41,42]. This could help to rationalize the debates and actions around COVID-19 and should be further extended [43].

Discussion

Challenges Related to Digital Health Implementation

The COVID-19 crisis is a typical example of the impossibility of establishing a single global technological solution to a given problem. To increase acceptability of digital technologies, the different cultural, moral, and religious backgrounds of users should be considered. With priority given to collective public health benefit and maintaining local social order during the current emergency [44], digital measures can be intrusive and can erode individual freedoms. In some countries, a strong digital divide persists today, and vulnerable populations may be overlooked during the implementation of digital approaches [45-47]. Digital solutions may be less frequently understood and used by people with low health literacy levels or by specific subgroups such as minorities, older individuals, or people who live in rural or low-income areas [48]. For all these reasons, digital approaches can be received in very different ways when they are applied in high-income, medium-income, or low-income areas or when they are deployed in individualistic versus collectivistic countries [49].

In Singapore, an app called TraceTogether has been used to track patients infected with COVID-19. Based on Bluetooth signaling, Singaporean health authorities can track individuals and inform them if they have been in contact with a patient infected with COVID-19 [50]. This patient monitoring system may be beneficial in disease surveillance and outbreak management; however, in European countries, it would not be possible to use it due to individual data protection laws. France conceived the CoronApp, which is based on similar standards [51]. Individuals need to register on the app and provide information on their health status and whether they have symptoms. A geolocation system is used to trace this information and is updated every hour. King's College London conceived the COVID Symptom Tracker app, which aims to help patients monitor their own symptoms [52]. The app gained such popularity that it is now also used in the United States. In addition to its individual benefits, the app can be used for research purposes to study the epidemiology of COVID-19.

Urged by the European Commission, an unprecedented consortium of eight giant telecommunications companies recently agreed to share aggregated and anonymized geolocation data from their clients to track their movements and activities. This raises numerous questions around data privacy [53] and ethics in Western and African countries [54], despite the availability of privacy-preserving proximity tracing technology such as the Decentralized Privacy-Preserving Proximity Tracing (DP-3T) protocol [55]. In Asia, the response to the COVID-19 crisis in South Korea has received much attention and has been widely cited as an exemplary model. With the increased flexibility in South Korea’s digital privacy laws since the MERS crisis in 2015, numerous aggressive digital solutions have been used, such as a national smartphone app, GPS tracking of infected people, and detailed emergency alerts when a positive case has been identified in a person’s geographical area. However, it was proved that this approach was only efficient to reduce the number of new daily cases due to a vast parallel testing campaign to identify COVID-19 hotspots combined with strong isolation and quarantine measures. In Europe, where testing is not as widespread as in South Asia, the use of such monitoring using GPS coordinates is therefore ethically questionable.

Regarding telehealth, the challenge of implementing feasible systems lies with governments in most cases [56], as billing systems must be adapted [15]. Telemedicine consultations must also ensure patient security in terms of data protection. Hence, close collaborations between different actors, such as health care professionals, health technology companies, and health politicians, must be ensured [15]. Once such a system is running, both patients and health care professionals can benefit from better allocation of resources and adequate care, all with reduced risk of exposure. Telemedicine and digital technologies such as apps can also play larger roles in the present crisis not only to fight COVID-19 but also to address the frequent health issues associated with isolation or quarantine, such as psychological needs [57], mental health conditions [58], and physical inactivity

[59]. Lastly, some developing countries face major obstacles to the effective delivery of digital health solutions in rural and remote locations, such as incomplete or insufficient basic digital infrastructures (eg, computers, internet networks, and electricity), lack of sustainable funding to develop, operate, and maintain digital platforms, and high telecommunication costs [4,60,61].

Recommendations to Improve Future Digital Health Systems

In France, where the COVID-19 epidemic is growing at a rapid pace, the health technology ecosystem has rapidly and generously contributed to management of the crisis. Numerous telemedicine and telemonitoring platforms have been locally deployed in hospitals or general practices. However, a lack of coordination between operators has led to issues such as an absence of consensus about the symptoms to monitor and the alert systems to establish. We could argue that some telemonitoring is better than no monitoring; however, given the rapidly evolving body of knowledge around COVID-19, more transparent communication and greater comparability should be pursued to rapidly and homogeneously update the different solutions. Otherwise, some populations will lose the opportunity to gather this data and later use it for research or evaluation.

In previous emergency situations such as the Ebola virus outbreak, Hurricane Harvey, and Hurricane Irma, as well as currently during the COVID-19 pandemic, telehealth has been explored to support patient-physician communication and, hence, improved health outcomes. It must be ensured that outside of emergency situations, telehealth will be appropriately implemented into national health care systems in the long term. This would facilitate use of telehealth systems during outbreaks [62]. Germany is an example of a country where early implementation of telemedicine and mobile apps into the health care sector since 2018 have shown short-term benefits during the COVID-19 pandemic [63]. The German health ministry even claims that they now aim to accelerate the digitization of health care in Germany and help to translate new laws into practical solutions.

Digital initiatives to fight COVID-19 should be relevant to both hospital and public health systems, adapted to the population, rapidly deployable, and capable of evolving with the growth of the body of knowledge related to COVID-19. Regarding common standards for data collection in digital COVID-19 solutions, future initiatives should consider the example of ISARIC (the International Severe Acute Respiratory and emerging Infection Consortium [64]), who successfully organized clinical research on COVID-19 by providing standardized but customizable clinical research forms in several languages, ensuring a harmonized core set of international and comparable data, or the DP-3T initiative, an open implementation of a decentralized privacy-preserving proximity tracing solution [65].

Conclusion

Time is key to fight COVID-19, and digital health solutions provide the opportunity to buy time and human resources. As the COVID-19 pandemic is the first true global health crisis in the digital era, we have observed and will observe a plethora of digital solutions. This pandemic has at least demonstrated the usefulness and reactivity of digital health solutions and constitutes an opportunity to insert these solutions into our health care systems in the long term. This creates an urgent need for policy makers, researchers, and health professionals to collectively and efficiently implement digital solutions into practice without further fragmenting the existing landscapes of care. We now call for more concerted measures to have an optimal impact on the epidemic and to address the most strategic needs to ease the life of people who are at the forefront of the COVID-19 crisis [66].

Abstract

Background: Virtual reality (VR) delivered through immersive headsets creates an opportunity to deliver interventions to improve physical, mental, and psychosocial health outcomes. VR app studies with older adults have primarily focused on rehabilitation and physical function including gait, balance, fall prevention, pain management, and cognition. Several systematic reviews have previously been conducted, but much of the extant literature is focused on rehabilitation or other institutional settings, and little is known about the effectiveness of VR apps using immersive headsets to target health outcomes among community-dwelling older adults.

Objective: The objective of this review was to evaluate the effectiveness of VR apps delivered using commercially available immersive headsets to improve physical, mental, or psychosocial health outcomes in community-dwelling older adults.

Methods: Peer-reviewed publications that included community-dwelling older adults aged ≥60 years residing in residential aged care settings and nursing homes were included. This systematic review was conducted in accordance with the Joanna Briggs Institute (JBI) methodology for systematic reviews of effectiveness evidence. The title of this review was registered with JBI, and the systematic review protocol was registered with the International Prospective Register of Systematic Reviews.

Results: In total, 7 studies that specifically included community-dwelling older adults were included in this review. VR apps using a head-mounted display led to improvements in a number of health outcomes, including pain management, posture, cognitive functioning specifically related to Alzheimer disease, and a decreased risk of falls. A total of 6 studies reported a statistically significant difference post VR intervention, and 1 study reported an improvement in cognitive function to reduce navigational errors. Only one study reported on the usability and acceptability of the interventions delivered through VR. While one study used a distraction mechanism for pain management, none of the studies used gaming technology to promote enjoyment.

Conclusions: Interventions to improve health outcomes through VR have demonstrated potential; however, the ability to synthesize findings by primary outcome for the older adult population is not possible. A number of factors, especially related to frailty, usability, and acceptability, also need to be explored before more substantial recommendations on the effectiveness of VR interventions for older adults can be made.

virtual reality; aged; aged, 80 and over; outcome assessment, health care; independent living; systematic review

Introduction

Background

Understanding how to best support the health and well-being of older adults is an important societal question. With increasing age, natural age-related physical, cognitive, and social changes are often compounded by physical and cognitive comorbidities [1-3]. A primary desire of older people as they age is that they are able to remain living as independently as possible [1-3]. However, the majority of older people live with at least one chronic disease with subsequent impact on physical, mental, or psychosocial health [1-3]. This can impact the ability to live independently or maintain social connectivity [1-3]. Prominent musculoskeletal changes include muscle loss and weakness, which impact gait and balance, increasing the risk of falls [4]. Falls among older adults is a global health issue affecting nearly 35% of people aged 65 years and older every year [5]. As age increases, so does the prevalence of falls [6]. Falls are costly to the health care systems and usually impact the quality of life (QoL) and independence of the older person [7]. Psychological and behavioral responses are common in people who have sustained a fall [8]. In addition, normal neurocognitive changes that occur in healthy aging can impact processing speed and motor responses, potentially increasing the risk of falls [9].

Changes in neurocognitive function are prevalent among older adults. Worldwide, 50 million people are diagnosed with dementia, and Alzheimer disease (AD) is the most common form of dementia, contributing nearly 70% to the dementia diagnoses [10]. The brain changes that accompany AD result in memory loss that can disrupt a person’s daily life [11], for example, difficulty in solving problems and completing everyday tasks at home, misplacing things, and getting lost outside the home, which can have a significant impact on the ability to navigate daily life. Frequently, people who experience memory problems withdraw from social activities because the changes they have experienced impact social interaction [12]. Furthermore, the QoL of older adults with dementia may be adversely affected by chronic pain, which is associated with depression [13]. As people with dementia such as AD may have vision and perception problems, they are at a greater risk of sustaining a fall and three times more likely to suffer from injuries such as hip fracture [14]. Interventions to facilitate healthy aging, adaptation, and strengthening in older adults with normal age-related changes that are intertwined with chronic disease are important in working to support older adults to remain in their own homes for as long as possible and to promote well-being. Exploring interventions that use virtual reality (VR) may offer unique opportunities to address areas of health need. VR is evolving at a rapid rate and presents an opportunity to enhance and support older adults’ physical and cognitive issues to promote engagement in physical activity, travel, or interactions with others [15]. The term *virtual reality* was first coined in the late 1980s. In the last 30 years, a vast range of VR devices have been developed, and the technology has been used across various domains, including education, athlete training, architecture, and notably in health-related research including physical, mental, and psychosocial health [15].

The term *virtual reality* has been used in health research to refer to various forms of onscreen digital representation of real objects or environments, such as showing a silhouette of an individual on a TV screen that mimics their physical rehabilitation movements [16]. However, VR is now predominantly used to refer to what was previously qualified as *immersive virtual reality*, which is understood to be viewing a stereoscopic virtual environment through a motion-tracked head-mounted display (HMD) [16]. A stereoscopic display encompasses the field of view and is able to track the motion of the head [16]. VR using an HMD not only provides the user with a particular artificial environment to view but also allows the user to engage with the virtual environment as they can look around by moving the head and by moving around the virtual environment by moving the body [16]. Definitions of what constitutes *immersion* both within and outside VR research vary, but a concept that arises from motion-tracked VR is *presence*, also known as an illusory experience of being in another place [16]. Deeper conceptualizations of presence include illusions of *place* or being in another location and *plausibility*, where events viewed by a person in VR are convincing [17]. Within the virtual world, the events seen within it are felt as if the user is really there or the events are actually taking place [18]. By allowing the user to interact with the VR environment naturally (eg, walking up to it and using a hand to pick up objects), the experience appears real for the user [18]. These attributes make a number of VR apps such as exposure therapy treatment for anxiety highly effective [18].

The degree of *presence* (or place illusion) that a user experiences is largely dependent on the characteristics of the VR technology being used [17,19]. Earlier VR research utilized HMDs with poor immersive qualities and limited technical capabilities, such as a lack of head-tracking, a small field of view, or the use of transparent displays (something closer to augmented reality) [19]. Greater presence is felt when the VR device has a stereoscopic display, has a wider field of view, and has greater amounts of tracked user movement [19]. Real-world health settings are likely to use these commercial headsets, as they are relatively affordable, easy to set up, and they support VR apps development through software such as Unity or Unreal Engine [20,21]. Although nonimmersive systems are interesting and beneficial, many community-dwelling older adults with natural age-related changes may not have the mental and physical capacity that may be needed in a nonimmersive environment.

Immersive headsets, or those that incorporate motion-tracked stereoscopic HMDs, and potentially motion controllers are known to induce a stronger sense of presence and potentially a sense of realism, embodiment, memory, and spatial understanding than nonimmersive devices [17,19,22,23]. Older adults have natural age-related changes that impact cognitive function; the literature discusses that increasing the immersive properties can be beneficial to increasing the sense of presence and place illusion, which is critical to achieve high intrinsic motivation to participate in the VR experience and achieve the health benefits desired [17,24].

Some community-dwelling older adults with cognitive and physical changes may find it challenging to concentrate on images on a wall-mounted flat screen or a handheld tablet while using an exercise bike. Furthermore, spatial cognition and ability are common changes that occur as a result of aging [25]. Given these issues, the participant may experience increased levels of stress during the intervention, and the sense of presence may be diminished as the participant tries to cognitively and physically navigate the intervention [17,24,25]. The task environment (flat screen, computer screen, and tablet) may have several display elements including passive crystal displays and light-emitting diodes [25]. Lighting levels for reading passive liquid crystal displays (nonbacklit) may be adequate for office or research environments; however, they are not adequate when used with older adults who may have visual acuity changes and who will be using the VR HMD in the home environment [25].

Using nonimmersive displays is further compounded by the angle from which the participant may need to view the display and potentially the glare of the screens that are used, which can alter the ability to visualize [25]. Due to these factors, immersive headsets are considered a distinct category of device with unique potential benefits for community-dwelling older adults. Accordingly, VR experiences in health apps for community-dwelling older adults using HMDs with stereoscopic displays that encompass the field of view and track the motion of at least the head, but also additional parts of the body, were examined in this systematic review.

Therefore, a number of papers have evaluated or systematically reviewed literature based on *virtual reality* in the health of older adults; however, as discussed earlier, the definition of *virtual reality* varies widely. The majority of these papers focused on nonimmersive digital games technology such as the Nintendo Wii, Microsoft Kinect, or custom activities where player movement is shown on a flat TV or monitor screen. Common topics of inquiry into this form of *virtual reality* used with older adults include one or more aspects of physical activity such as balance, rehabilitation, gait function, and falls [26-36]. Serious mental illness [37] and cognitive intervention and training [27,38-40] have also been the focus of reviews; however, very few papers have examined immersive VR, the area of interest in this paper. Duque [41] reported using *3D virtual-reality goggles* for visual-vestibular balance training exercises, although it is not clear if these constitute an immersive display or headset. However, recent research has begun to use immersive HMDs in the assessment of physical [42,43] or cognitive function [44] in older adults as well as providing enjoyable travel experiences [45].

In addition to the effectiveness of VR and digital games on chosen outcomes, it is important to understand the usability and acceptability of technology. When a technology such as VR is used, researchers need to be aware that older adults may not be familiar with the technology or they may have unique aging-related physical or cognitive changes that could make participation difficult. Silva [46] conducted a systematic review to identify the study characteristics of VR research with older adults and how VR impacted older adult end users. Silva [46] concluded that design characteristics could be modified to aid older adult users' experience in using the VR apps. A further systematic review [33] reported evidence on the effectiveness and feasibility of using digital gaming systems within older adults to enable physical activity is weak, with a high risk of bias. Although the authors use the term *virtual reality*, none of the studies used immersive VR HMDs, only traditional flat screen gaming technologies or augmented reality glasses (a transparent display with digital overlay). The acceptance of HMD VR, possible cybersickness, and attitudes toward technology have also been investigated [47]. There was no evidence to suggest that negative attitudes toward VR apps or cybersickness would be barriers to using VR apps with older adults.

Objectives

Although research using VR and immersive headsets is increasing, more knowledge is needed about the types of VR apps using immersive headsets, the health outcomes targeted, outcomes, and transferability to real-world settings for community-dwelling older adults. The aim of this systematic review was to evaluate the effectiveness of VR apps delivered using commercially available immersive headsets in improving physical, mental, and psychosocial health outcomes in community-dwelling older adults.

Methods

Inclusion Criteria

Types of Participants

This review included specifically community-dwelling older adults aged 60 years or older. Initial searches of the existing literature demonstrated that the classification of what constituted *older adult* varied. Accordingly, the United Nations definition of older populations as 60 years and over was used because this classification provided a more realistic representation of older adults across different countries with varying life expectancies [48]. Older adults residing in residential aged care settings and nursing homes were included, and hospitalized older adults were excluded from the review. Studies that included participants aged under 60 years in the control group were also included.

Interventions

Studies that evaluated the use of VR apps delivered via immersive headsets including a combination of VR delivery, employing immersive headsets with incorporation of projector screens to create other forms of immersive VR experiences, were included in this review. Accordingly, commercial headsets including Rift or Vive and older models that encompass the field of view and have motion tracking were included. Studies that did not use VR headsets were excluded.

Comparators

This review considered studies that compared the intervention with conventional therapy and studies that did not use comparisons such as case studies.

Outcomes

This review considered studies that included the following outcomes: effectiveness of the VR apps intervention via immersive headset using physical, mental, or psychosocial outcome measures. These outcomes were measured using kinematic and kinetic computer apps and/or statistical software as well as Likert-based questionnaires.

Types of Studies

This review considered both experimental and quasi-experimental study designs, including, but not limited to, randomized controlled trials (RCTs), nonrandomized controlled trials, before and after studies, and interrupted time-series studies. In addition, analytical observational studies including prospective and retrospective cohort studies, case-control studies, and analytical cross-sectional studies were considered for inclusion. This review also considered descriptive observational study designs including case series, individual case reports, and descriptive cross-sectional studies for inclusion. Human studies published in English between 1997 and 2019 were included. This time frame was chosen to capture the most recent advances of VR technology in health practice.

Review Registration and Approach

The inclusion criteria, methods, and analysis were registered in the Joanna Briggs Institute (JBI) Systematic Review Register, and the protocol was registered with the International Prospective Register of Systematic Reviews (PROSPERO, CRD42019143504) a priori to the commencement of data extraction. The systematic review was conducted in accordance with the JBI methodology for systematic reviews of effectiveness evidence. This review followed the preferred reporting items for systematic reviews and meta-analyses (PRISMA) recommendations for systematic review reporting [49].

Search Strategy

To identify published studies, a 3-step search strategy was employed between April and June 2019. An initial limited search of the Medical Literature Analysis and Retrieval System Online (MEDLINE, using EbscoHost) and Google Scholar was undertaken to identify articles on the topic, using search terms “virtual reality,” “older adult*,” “community setting,” “health,” and “wellbeing.” The text words contained in the titles and abstracts of relevant articles and the index terms used to describe the articles were used to develop a full search strategy for MEDLINE, Cyberpsychology and Behavior, Cumulative Index of Nursing and Allied Health Literature (CINAHL), Exerpta Medica DataBASE Guide (EMBASE), Web of Science, JBI, the Cochrane Library, IEEExplore, Lancet Psychiatry, Association for Computing Machinery (ACM) Digital Library, Science Direct, and PsycINFO. The search strategy, including all identified keywords and index terms, was adapted for each database to account for appropriate Medical Subject Headings (MeSH) terms. Multimedia Appendix 1 shows the search strategies used for each database, with concepts combined with Boolean operators *AND* and *OR*. Hand searches were conducted when necessary. The reference list of all relevant systematic reviews was screened for additional studies. Multimedia Appendix 2 illustrates the PRISMA flow diagram.

Study Selection

Following the search, all identified citations were collated and uploaded into Endnote X9, and duplicates were removed [50]. Titles and abstracts were screened by 2 independent reviewers for assessment against the inclusion criteria for the review (GD and CG). The full text of selected citations was assessed in detail against the inclusion criteria by at least two independent reviewers (GD, LW, GW, and CG). Reasons for exclusion of full-text studies were as follows: participants in the intervention group being younger than 60 years, VR apps not utilizing HMDs, studies using qualitative designs, and not addressing the effectiveness of VR apps. Disagreements arising between the reviewers at any stage of the study selection process were resolved through team discussions or with a third reviewer.

Assessment of Methodological Quality and Certainty of the Findings

Eligible studies were critically appraised and methodological quality was assessed by 2 independent reviewers (GD, LW, GW, and CG), using the standardized critical appraisal instruments from the JBI [51]. This allowed the reviewers to gain greater insight into the methodological strengths and limitations of the selected studies. Blinding treatment groups was not always conceivable given the nature of the intervention; hence, it was not considered a criterion for inclusion. Any incongruities in appraisal that arose between reviewers were discussed and resolved by all authors. The author of one of the studies considered for inclusion in this review was contacted to request clarification of the randomization techniques used.

The grading of recommendations, assessment, development, and evaluation (GRADE) approach for assessing the certainty of evidence for an effect, summarized in a narrative form, was used to assess the overall quality of the findings [52]. The GRADE assessment evaluates the limitations of the studies, indirectness, imprecision, inconsistency, and publication bias [52]. The overall quality of the evidence was categorized as high, moderate, low, or very low. At least two reviewers (GD, LW, GW, and CG) independently completed the GRADE assessments for each article.

Data Extraction

Data were extracted from studies by 2 independent reviewers (GD, LW, GW, and CG) using an adapted version of the JBI standardized data extraction tool. The data extracted included specific details about the populations; study methods; interventions; outcomes of significance to the review objective, including the effectiveness of the VR intervention on physical, mental, and psychosocial outcomes; types of VR apps used; and specific health outcomes targeted in community-dwelling older adults. Disagreements between the reviewers were resolved through team discussions or with a third reviewer.

Data Synthesis

Findings from the selected studies were narratively synthesized to demonstrate the effectiveness of the VR app intervention via immersive headsets on physical, mental, or psychosocial outcomes.

Results

Summary of the Search Results

The initial search (Multimedia Appendix 1) from 12 databases resulted in 416 references. Additional records were identified (n=74) through manual searching, including searching for systematic review reference lists. After duplicates were removed, titles of a total of 464 studies were assessed.

After the title search was completed, the abstracts of 216 articles were assessed for inclusion by 2 authors (GD and CG). A total of 17 full-text papers were comprehensively assessed for inclusion. Of which, 10 full-text manuscripts were excluded for reasons previously stated, and 7 manuscripts were included in this systematic review, with 2 papers reporting on the same sample. To compare data, Table 1 and Table 2 present the characteristics of the studies and the key findings extracted.

Table 1. Details of study design, virtual reality therapy, and health outcomes.

Study	Study design	Sample size	Sample characteristics	Virtual reality application	Virtual reality exposure	Outcomes assessed	Outcomes measured
Benham [53]	Mixed methods exploratory study	12	8 female, 4 male, majority of the sample were white, majority had exposure to technology weekly, 8 participants had musculoskeletal pain, and 4 had neurological pain	The immersive VR[a] system utilized the HTC[b] Vive HMD[c] with 2 hand controllers. A variety of games could be played, although those using movements or standing were excluded for safety reasons. Popular games included interactions with animals, music, and travel. Used range of commercially available VR apps	Participants completed 12 VR sessions over a 6-week period. These ranged from 15 to 45 min long.	Pain management, QoL[d], depression, overall physical health, overall psychological health, and social life	Patient-reported outcomes, measurement information system, Item Bank v. 1.0–emotional distress–depression, World Health Organization Quality of Life Scale Brief Version (assessing overall health, physical, psychological, and social health), numeric pain rating scale
Gago [54]	Quasi-experimental	39	20 participants with AD[e] (11 fallers and 9 nonfallers) and 19 control participants. Groups were equally matched for demographic and anthropometric data.	Immersive Oculus Rift VR headset showed a view as if the person was standing at the top of a staircase. The perspective in the headset was shifted forward down the stairs to mimic the displacement during a fall. Used the commercially released “Tuscan Villa” demo from Unity, which is no longer available	One session with a total of five 10-second trials per subject, with each trial involving 1 shift in perspective down the stairs (approximate distance of 1.17 m)	Posture and falls in AD	Kinematic and time-frequency distribution sensor data to assess posture and falls

Study	Study design	Sample size	Sample characteristics	Virtual reality application	Virtual reality exposure	Outcomes assessed	Outcomes measured
Levy [55]	RCT[f]	16	10 women and 6 men, randomly assigned to a treatment (6 women and 3 men) and control (4 women and 3 men) group. Their fear of falling developed after falling themselves.	Immersive V8 VR HMD was used with wireless mouse for exposure therapy, followed by the use of serious games. Participants were asked to walk during the VR exposure in different settings on different difficulty levels (city, castle, island, and underground). A 3-dimensional electromagnetic sensor was fixed to the helmet to measure head and body motion during walking periods. Used bespoke research software.	12 weekly sessions lasting 40 min (VR exposure=15 min)	Falls, depression, anxiety, and social life impact from functional impairment	Fear of falling measure, Beck depression inventory, Spielberger state-trait anxiety inventory, and Sheehan disability scale
Optale [56]	RCT	36	24 female and 12 male; from local rest-care home	Compare face-to-face music therapy (control) with VR therapy that includes the music from control condition. Custom virtual environments including outdoor areas with paths, childhood homes, or modern city. Navigated using joystick and viewed through motion-tracked V6 headset. User navigates through the environment and views video clips at certain points. Music plays during the experience. Used bespoke research software.	The experimental group completed 6 months of VR memory training. 3 VR sessions every fortnight within the first 3 months. During the next 3-month booster training phase, there was 1 weekly VR session. VR sessions lasted approximately 15 min.	General cognitive ability and memory, depression, and daily living	General cognitive abilities were assessed using the mini-mental state examination and mental status in neurology tests; the digital span test assessed short-term verbal memory abilities; verbal story recall test assessed long-term verbal memory; phonemic verbal fluency test, dual task performance test, and cognitive estimation test were used to assess executive function; clock drawing test assessed visuospatial processing; activities of daily living functions and mobility and the instrumental activities of daily living assessed daily living activities; the geriatric depression scale assessed depression.

Study	Study design	Sample size	Sample characteristics	Virtual reality application	Virtual reality exposure	Outcomes assessed	Outcomes measured
Parijat [57,58]	RCT	24	12 male and 12 female; 12 control and 12 experimental; closely age matched (±4 years); closely matched for physical characteristics.	Participants viewed a custom city-street VR environment that moved as if the person was walking, through an immersive motion-tracked Sony headset. The visual scene showed that the person was slipping, to induce slip recovery behavior. Used bespoke research software.	One session of VR exposure of 45 to 55 min, with pre- and postslip training and assessments in separate sessions.	Falls	Kinematic and kinetic data were filtered before angular kinematics and muscle activations were assessed at 5-min time intervals.
White [59]	Case study	1	74-year-old male living at home with his wife. Diagnosed with mild cognitive impairment with probable development of AD. Scored 24/30 on Montreal Cognitive Assessment.	Bespoke 3-story virtual building that is navigated via a wheelchair in a 2-dimensional physical space and viewed through oculus Rift DK2. Virtual elevators move the user between floors. Task involves moving to the correct window of 12 in the building. Used bespoke research software.	3×45-min training sessions per week for 7 weeks	Cognitive ability in AD	Cognitive ability and spatial trajectories were assessed

Table 2. Summary of findings table.

Outcomes assessed; study	Key findings	Grading of recommendations, assessment, development, and evaluation[a]
Pain management; Benham [53]	Between presession 1 and postsession 12 VR[b] sessions, there were significant improvements in pain scores with a large effect size (−1.54, 95% CI −2.50 to −0.58; *P*=.002; Effect size >0.8=large effect).	Moderate
Quality of life; Benham [53]	WHOQOL-BREF[c] did not find any significant differences over 6 weeks of VR therapy on overall health (−0.06, 95% CI −0.91 to 0.78; *P*=.66), no significant differences on overall physical health (0.41, −0.45 to 1.26; *P*=.08), no significant differences on social life (0.08, 95% CI −0.77 to 0.93; *P*=.87), and no significant differences on overall psychological health (0.33, 95% CI −0.52 to 1.18; *P*=.15).	Moderate
Posture; Gago [54]	The AD[d] faller group had a higher power regarding use of mechanical properties of oscillation for postural adjustments compared with the control group, alluding to worse postural stability in this group (−4 to 0s: *P*=.02; 0 to 4s: *P*=.01; and 4 to 8s: *P*=.008). AD participants had a time lag in cognitive strategies for postural correction compared with healthy subjects (−4 to 0s: *P*=.002; 0 to 4s: *P*=.01).	Moderate
Falls; Gago [54]	The AD fallers groups had a delayed reaction time for changes in power compared with the control group, with a change in power seen only in the last interval (0 to 4s vs 4 to 8s; LB[e]*P*=.008; HB[f]*P*=.01).	Moderate
Falls; Levy [55]	There were statistically significant differences between the 2 groups for fear of falling scores. Fear of falling scores over the 12 weeks reduced by 2.78 (SD 4.82) in the VR group and increased by 4.14 (SD 4.30) in the control group (*P*=.007).	Moderate
Falls; Parijat [57,58]	VR training led to significantly better balance on slippery surfaces with VR therapy reducing slip distance (slip distance 1: $F_{1,18}$=10.34, *P*=.01; slip distance 2: $F_{1,18}$=5.27, *P*=.03), reducing peak slide heel velocity ($F_{1,18}$=4.54, *P*=.05), and reducing peak trunk extension post slip ($F_{1,18}$=12.46, *P*=.01). Slip distance 1 and 2 are the anterior-posterior distance traveled (in cm, based on the location of the heel) from the start of the slip to when heel acceleration peaks (slip distance 1) and then from this point until the heel velocity peaks (distance 2) VR with the treadmill supported realistic walking gait after 15 to 20 min (step duration: $F_{6,76}$=10.56, *P*=.002; step width: $F_{6,76}$=9.56, *P*=.02). There were no significant effects on ankle, hip, or knee kinematics.	Moderate
Memory and cognitive function; Optale [56]	Combining music therapy with exploration of spatial and personally relevant environments in VR led to improved memory ($F_{2,58}$=17.40; *P*<.001) and general cognitive functions (MMSE[g] scores $F_{2,58}$=23.01, *P*<.001; mental status in neurology score $F_{2,58}$=30.16, *P*<.001); executive function (cognitive estimation test group difference: $F_{1,29}$=11.12, *P*=.002; dual task performance test group and time interaction: $F_{2,58}$=10.92, *P*<.001; phonemic verbal fluency test group and time interaction: $F_{2,58}$=14.6, *P*<.001); verbal memory (digital span test group and time interaction $F_{2,58}$=17.4, *P*<.001; verbal story recall test group and time interaction $F_{2,58}$=36.66, *P*<.001), but not in spatial abilities ($F_{2,58}$=3.14, *P*=.05).	Low
Memory and cognitive function; White [59]	Navigation errors reduced during VR training, but there may be no strong positive effect on overall cognitive ability.	Low
Disability; Levy [55]	There were no significant differences in social life (*P*=.18) or family life (*P*=.12) impact from functional impairment between the VR exposure therapy group and the waiting-list group.	Moderate
Daily living; Optale [56]	There were no significant differences of VR therapy on daily living tasks (Activities of Daily living $_{2,58}$=1.5, *P*=.23; Instrumental Activities of Daily Living $F_{2,58}$=1.05, *P*=.36).	Moderate
Anxiety; Levy [55]	There were statistically significant differences between the 2 groups' mean state anxiety scores. The mean state anxiety score reduced by 8.86 (SD 14.46) in the VR group and increased by 9.80 (4.66) in the control group (*P*=.005). There were no significant differences in trait anxiety scores between the groups (*P*=.24).	Moderate
Depression; Benham [53]	There were no significant differences in PROMIS[h] scores (0.29, 95% CI −1.14 to 0.56; *P*=.33).	Moderate
Depression; Levy [55]	There were no significant differences in Beck Depression Inventory scores between the VR and control groups (*P*=.47).	Moderate

Outcomes assessed; study	Key findings	Grading of recommendations, assessment, development, and evaluation[a]
Depression; Optale [56]	The participants receiving VR therapy had a reduced depression value on the Geriatric Depression Scale after the initial VR session ($F_{1,29}$=5.61; P=.02), but not after the booster VR session ($F_{1,29}$=1.35; P=.25).	Moderate

Populations Included in the Review

The populations recruited were highly variable. Although all were 60 years and older, the populations recruited into the studies in this review were older adults experiencing musculoskeletal or neurological pain, with a fear of falling, living in residential aged care, diagnosed with AD, and diagnosed with mild cognitive impairment [53-59]. Therefore, the results could not be synthesized across defined populations, for example, older adults at risk of falls.

Virtual Reality Application

VR apps were used to view a stereoscopic virtual environment through a motion-tracked HMD. Each of the studies in this review used an immersive virtual environment intervention [53-59]. This included differently manufactured devices with varying frames per second, field of view, degrees of freedom, latency, and tracking, which influence the immersive sense of presence [19]. The frequency and duration of VR exposure varied considerably between studies. VR exposure ranged from five 10-second displays of stereoscopic 3D images to 55 min of serious gaming, with 15 min being the most common exposure time [53-59]. VR therapy was administered as a singular session in 3 studies [54,57,58]. Other studies completed VR therapy more regularly, with Levy [55] administering it weekly over a 12-week period, Benham [53] completing it twice weekly for 6 weeks, White [59] completing it 3 times per week over a 7-week period, and Optale [56] completing 3 sessions per fortnight. Across the 7 papers, VR was used for 2 general categories of health care application: *treatment* for a particular condition or symptom and *assessment* of physical ability (although there was also a component of training) [53-59]. A total of 2 papers used VR apps that were commercially available at the time: Benham [53] allowed participants to use apps from VivePort, an web-based software portal (www.viveport.com), whereas Gago [54] made use of the *Tuscan Villa* demonstration environment that was provided in the Unity game engine software (which is no longer available) [20]. All other papers utilized bespoke software designed and created for the purposes of the research.

The papers in the review shared few commonalities, as a number of different health outcomes were addressed and a range of VR headsets and apps were utilized. Despite this, VR was often found to be effective or beneficial in addressing health in older adults, as it has with pain and physical activity [53-59]. This suggests that it can be a flexible and effective means of intervention delivery.

Health Outcomes Targeted in the Interventions

Physical Health Outcomes

Physical health outcomes are important for community-dwelling older adults to remain living in the community as independently as possible. However, due to the complex multimorbid chronic disease, many community-dwelling older people are at risk of declining physical health as they age [60,61]. For example, older adults living in the community are at greater risk for falls due to increasing functional decline and subsequent muscle loss and weakness. Several studies focused on falls, including participants who were either at risk of falls or with a history of falls [54,55,57,58]. Some overlap in health outcomes existed where 2 studies focused on health outcomes that transect physical, mental, and social aspects [53,55]. For example, the paper by Levy [55] had a primary objective focused on assessing VR therapy in the treatment of fear of falling. In total, 2 studies evaluated the use of VR training apps to improve postural and muscular adjustment with the goal of enabling the older person to compensate for induced perturbation (balance-recovery) or slips with the goal of fall prevention [54,57]. In perturbation-balance training, a balance-recovery approach is used to improve the recovery reaction to a person losing his or her balance. Gago [54] developed VR training that introduced visual perturbation with the goal of studying the postural adjustment mechanisms in participants with AD with and without a history of falls and a control group. A key finding of this study was that older adults with AD who had a history of falling needed greater compensatory postural adjustment compared with participants with AD who did not have a history of falling and the control group (−4 to 0s: P=.02; 0 to 4s: P=.01; and 4 to 8s: P=.008) [54]. This may be due to visual and perceptual problems that are often common in people with AD. However, the participants with AD who had a history of falls were able to make adjustments to visual perturbation [54].

Parijat et al [57,58] conducted 2 separate studies using the same sample and dataset. In the study by Parijat et al [58], the design and effectiveness of VR training to improve recovery reactions of healthy older adults, with the aim of reducing fall frequency, was investigated. Parijat et al [58] found that VR training of motor skills to recover from a slip-induced fall led to significantly better balance minutes (step duration: $F_{6,76}$=10.56, P=.002; step width: $F_{6,76}$= 9.56, P=.02) and recovery reactions (slip distance 1: $F_{1,18}$=10.34, P=.01; slip distance 2: $F_{1,18}$=5.27, P=.03; peak slide heel velocity: F1,18=4.54, P=.05) on actual slippery surfaces. However, because participants were able to adapt to virtual slips fairly quickly, visually inducing physical responses may not be effective long term. In the paper, slip distances 1 and 2 are the anterior-posterior distance traveled (in cm, based on the location of the heel) from the start of the slip to when heel acceleration peaks (slip distance 1) and then from this point until the heel velocity peaks (slip distance 2) [58]. In the study by Parijat et al [57], the objective was to improve the recovery reaction and improve angular and muscular responses when participants were exposed to a slippery surface. The authors also quantified the kinematics of angular and muscular changes [57]. Kinematics is a way of describing the geometric mechanics of motion and velocity without considering the force that caused the motion. The key findings of this study were that VR with the treadmill supported both realistic walking gait and significant improvements in slip recovery kinematics [57]. The authors concluded that slip training was more effective using VR training compared with conventional movable platform training [57]. The kinematic angular differences varied only in the trunk measurements between the 2 groups. Peak trunk extensions decreased more in the VR training group compared with the control group ($F_{1,18}$=12.46; P=.01) [57]. In the second slip trial, the VR training group was able to quickly reverse the forward trunk rotation, which is a key ability for regaining balance [57].

Mental and Psychosocial Health Outcomes

A total of 3 studies implemented VR to improve cognition, memory, and/or psychologic aspects in older adults [55,56,59]. In the study by Levy [55], older adult participants who exhibited fear of falling were included. The objective of this study was to use a VR app to treat the pathology of the phobic reactions to walking experienced by the participants [55]. Notably, all participants had moderate to severe social limitations as a result of their traumatic fall history, in addition to having a variety of comorbidities that were not related to walking difficulties [55]. The findings of this study showed a significant decrease in the fear of falling measure in the intervention group (−2.78; SD 4.82) compared with the control group after VR exposure (4.14; SD 4.30; P=.007) [55]. Although there was no difference in social life or depression, anxiety in the intervention group was significantly lower (−8.86; SD 14.46) than that in the control group (9.80; SD 4.66; P=.005) [55]. Optale [56] and White [59] studied the use of VR apps to improve cognition and memory function in older adults with memory deficits. Optale [56] used VR immersion and interaction as a treatment intervention for older adults with memory deficits. Several outcomes were measured, including general cognitive abilities, verbal memory, executive functions, and visuospatial processing. The study findings show that VR therapy led to significant improvements in cognitive functioning and verbal memory (pretraining to posttraining MMSE score: $F_{1,29}$=6.85; P=.01 and posttraining to postbooster evaluation: $F_{1,29}$=4.46; P=.04), particularly long-term memory improved in the intervention group [56]. A significant change was observed in the experimental group for all 3 executive functions measured [56]. However, visuospatial abilities or daily living were not affected [56]. A descriptive case study by White [59] used VR app intervention to strengthen the cognitive reserve in one participant with early AD to improve and maintain cognition, and in particular, spatial cognition. The participant's navigational ability improved in response to the training given [59]. Although navigation errors were present, a reduction was evident overall [59]. However, it is unclear whether or not there is a positive effect on overall cognitive ability [59]. The findings of this case study suggest that people with early stages of AD can learn to navigate paths in a suitable immersive VR system [59].

In the remaining study, Benham [53] conducted a mixed methods study at a senior day-center to identify the efficacy of VR interventions on pain, depression, and QoL in community-dwelling older adults who self-reported acute or chronic pain that was bothersome at least two days per week. The VR therapy appears to have improved pain management in community-dwelling older adults [53]. VR intervention significantly reduced the report of pain (−1.54, 95% CI−2.50 to −0.58; P=.002) [53]. Participants also reported that the VR intervention was able to distract them from their pain [53].

Discussion

Principal Findings

The incorporation of VR in health care is promising in its ability to support older adults in managing age-related changes, for example, musculoskeletal changes and those related to chronic disease that impact physical, cognitive, and psychosocial health and well-being. The studies included in this review are examples of how technologic advances are changing the face of health care and demonstrate that certain VR interventions can be successfully used with older adults.

Fall prevention appears to be an area where immersive VR using HMD can have a significant impact. Falls contribute to injury, pain, disability, and premature death [5]. The loss of balance and slow reactions to steady state is a primary mechanism for falls [62]. A total of 2 studies evaluated the use of VR training apps to improve postural and muscular adjustment with the goal of enabling the older person to compensate for induced perturbation (balance-recovery) or slips so that a fall may be prevented [54,57]. Although there is an emphasis on the physical aspect of fall prevention, including balance, gait, and recovery reaction, sustaining a fall can have psychological and behavioral impacts on the older person. Fear of falling is common among older adults, and in some cases, this fear is disproportionate, with physical reactions to extreme anxiety including palpitations, sweating, and avoidance of walking altogether [63,64]. A total of 3 studies aimed to improve cognition, memory, and/or psychological aspects in older adults [55,56,59]. The results indicate a positive change and improvement, although several questions remain around the longevity of the impact [55,56,59].

The findings of the studies reviewed suggest that the expansion of VR for health-related interventions, while in a safe and controlled environment, may have several potential therapeutic benefits for older adults to facilitate independence and QoL [65,66]. Although the studies included in this review have mostly focused on evaluating the effectiveness of VR intervention in conventional therapy [53-59], VR intervention apps could also support therapists and clinicians to assess a person's physical, cognitive, or psychosocial status to identify potential problems [67,68]. For example, gait patterns, postural adjustment, musculoskeletal pain, and compensatory mechanisms could be assessed using VR to identify mobility issues of concern and determine a person's fall risk [69]. Tailored VR interventions could be developed to target fall prevention and to promote increased physical activity, which has a protective effect on age-related musculoskeletal changes [54,57,58].

Furthermore, using VR to assess, develop, and implement cognitive interventions to improve cognition, memory, and psychological aspects could make VR a competitor to traditional cognitive rehabilitation [70]. For example, stroke is common among older adults, and many require cognitive rehabilitation along with physical rehabilitation. Clinicians could use VR as an individualized intervention to determine cognitive and decision-making problems and develop individualized VR-based interventions [70,71]. Chronic pain is common in older adults, limiting independence, physical movement, and social activity [53,72]. Although more knowledge is needed about VR interventions to reduce or manage pain in older adults, VR has been used extensively in other age groups, and there is scientific evidence that VR can reduce the pain that is experienced [73,74]. VR exposure therapy interventions have been applied to reduce extreme fears such as phobias [73-75]. After a fall or similar accident, older adults often suffer from extreme fear of falling, which could be very limiting to staying physically active [76]. The study by Levy [55] was able to demonstrate significant reductions in the fear of falling. One of the unique benefits of VR use in health care with older adults is the potential to meet more than one need, as VR apps may span the physical, mental, and psychosocial needs of a person [77,78].

Although some studies under review reported indication of positive outcomes regarding VR use in older adults [53,55,59], it is important to highlight several practical aspects that are challenges to implementing VR interventions with older adults, who are often in a vulnerable state, and to translate the use of VR interventions as a standard of care in the aged care sector. The majority of participants were healthy enough to fully participate in the intervention studies [57-59]. Investigations into using VR interventions with older adults who are frail or unwell are needed. For example, a better understanding of the severity of cognitive impairment and the applicability of VR has not been explored. People with increased levels of frailty who are at greater risk for functional decline and falls may benefit from VR interventions; however, it is unclear whether frail older adults can engage with the VR interventions described in this review.

Strengths and Limitations

Visual and auditory changes could make it challenging for some older adults to engage with the technology. It is important to consider natural age-related changes in the design of VR apps for older adults [79]. Only Parijat et al [57,58] explicitly assessed visual acuity, via Snellen's chart; Benham [53], Gago [54], Levy [55], and Optale [56] excluded participants if they self-reported uncorrected vision or serious/significant sensory impairment. None of the authors administered hearing tests [53-59]. Only Benham [53] and Parijat et al [57,58] took any measurement of cybersickness [80]. In most of the studies, it was unclear whether the researchers used a participatory approach by inviting older adults to contribute to the design and conduct of the intervention [81]. Although some literature indicates that older adults are open to using VR interventions, not much is known about the acceptance of HMD VR use in older adults [66,82]. For example, only 1 study included a survey question about the overall experience with VR [53]. None of the other studies discussed how well older adults accepted the VR and HMD and whether they were able to engage with and adapt to the physical aspects of the VR device and the VR environment or their experience with *presence*. Unless there is some adaptation to vision and hearing abnormalities and dexterity, older adults may be reluctant to adopt VR as a consistent health care–related intervention. In using VR exposure therapy with older people with anxiety and phobias, there is some debate on the outcome expectancy of treatment outcomes induced by *presence* (or immersion in the VR environment) because this relationship could be influenced by anxiety that may be inadvertently created by *presence* [55]. Subsequently, clinicians and industry providers may be reluctant to adopt VR for exposure therapy.

We noted that several studies in this review used a VR intervention as a means to impact another outcome that was not measured at the time of the study [54,57,58]. For example, although some of the studies implemented VR training with the aim of preventing falls, fall prevention was an indirect outcome variable, and although postural adjustment may have improved during the study, it is unclear how long this benefit lasts for and whether any longer-term impact on falls was experienced. Furthermore, some authors noted that VR interventions that induce slips need to make each slip novel in some way to reduce the likelihood that participants adapt to the stimulus and inadvertently limit the desired postural improvement [57,58].

Interestingly, no study designed or incorporated gaming technology in VR to support engagement and promote enjoyment for participants [26]. This would bring the technology *full circle* with its beginnings as a gaming technology [83]. The participants in the study by Benham [53] were able to play a game if they desired, but many seemed to choose other activities such as traveling or interacting with animals, and gaming/gamification was not a deliberate or controlled part of the intervention design or evaluation. Longitudinal studies should be conducted to determine the long-term effect on the outcome variable under study. All studies in this review included a small sample size, which impacted the generalizability of the findings [53-59]. Powered RCTs are needed to determine the effectiveness of VR therapy compared with standard care practices.

It is important to note that none of the papers included in the review reached a *High* level of GRADE certainty and quality. White [59] was judged to have a very low GRADE judgment, as it constituted a single case study with no blinding or randomization. The remaining papers were rated as *Moderate*, as they employed randomized designs, blinding, patient-reported outcomes, or RCTs [53-58]. Therefore, there is convincing evidence that VR interventions can be effective; however, it is clear that more research needs to be done. A recent review paper highlighted a similar shortcoming in scientific rigor in other fields of VR research [84]. So, although this suggests that it is not a problem particular to the health domain, it also emphasizes that more rigorous scientific methods need to be used to robustly evaluate and validate the technology.

Conclusions

In conclusion, the wider literature suggests that VR interventions have the potential for wide-scale adoption to promote health and wellness among older adults. This review demonstrates that interventional research using VR with older adults in varying states of health is in the early stages of development. In particular, evidence around the potential adoption of VR interventions in applied clinical or therapeutic settings is limited and requires further understanding of logistics, financial costs, and the acceptability and usability of immersive VR in older adults from the perspective of older adults and clinicians. The review also indicated the need for a greater understanding of the design features of immersive VR apps that can promote and improve health for older adults, including those with audio-visual deficits.

Acknowledgments

This study was not funded. GD and CG completed the title and abstract search. Review of full-text papers, data extraction, interpretation of results, and writing of the manuscript was completed by all authors (GD, LW, GW, and CG).

Conflicts of Interest

None declared.

Abstract

Background: There is growing evidence that technology-based interventions (TBIs) are effective for the treatment of depression. As TBIs are gaining acceptance, a question arises whether good therapeutic alliance, considered a key aspect of psychotherapy, can be established without or with minimal face-to-face contact or rather changes if blended concepts are applied. While therapeutic alliance has been studied extensively in the context of face-to-face therapy, only few studies have reviewed evidence on alliance ratings in TBIs.

Objective: The purpose of this study was to examine therapeutic alliance in technology-based psychological interventions for the treatment of depression.

Methods: We searched Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, PsycINFO, PSYNDEX, CINAHL, clinical trial registers, and sources of grey literature for randomized controlled trials on TBIs in the treatment of adults with unipolar depression. All publications were selected according to prespecified criteria. Data were extracted by two independent reviewers.

Results: A total of eight out of 98 studies (9.5%) included in the review on TBIs for depression considered therapeutic alliance as part of their evaluation. The available data covered eight different treatment conditions, including four stand-alone treatments (face-to-face psychotherapy, email, telephone, and internet program) and four combined treatments (face-to-face psychotherapy plus a smartphone app and an internet program combined with face-to-face psychotherapy, treatment as usual, or email/telephone). On average, patients rated the alliance positively across all groups. Importantly, no relevant group differences regarding therapeutic alliance sum scores were found in any of the studies. Five studies investigated the relationship between patients' alliance ratings and treatment outcome, revealing mixed results.

Conclusions: Our results suggest that it is possible to establish a positive therapeutic alliance across a variety of different TBIs for depression, but this is based on a small number of studies. Future research needs to determine on what basis therapeutic alliance is formed in settings that do not allow for additional nonverbal cues, perhaps with adapted instruments to measure therapeutic alliance.

therapeutic alliance; depression; technology-based intervention; treatment

Introduction

Background

Globally, over 300 million people (point prevalence in 2015) are estimated to have depression, accounting for 4.4% of the world population [1]. Depression is the greatest contributor for both disability and suicide [1] and is associated with greatly increased health care costs [2]. Treatment of depression with face-to-face psychotherapy has been shown to be effective over the last decades [3]. There is growing evidence that technology-based interventions (TBIs) are also effective for the treatment of depression, with great clinical improvement and recovery after treatment [4-9].

TBIs differ according to various aspects, including the type of technology (eg, computer and smartphone), therapeutic rationale (eg, cognitive behavior therapy and behavioral activation), the clinical phase of depression management (waiting period, acute treatment, and aftercare), and the amount of human support [10]. The degree of support as well as the delivery mode can range from a stand-alone self-administered treatment with no therapist contact at all to a blended treatment with active involvement of a therapist and regular face-to-face meetings.

Besides lowering the threshold to access treatment (eg, providing geographic and time-related flexibility) [11], TBIs, such as online therapy, provide an opportunity to reach people who refuse to seek traditional services, especially those who wish to remain anonymous [11,12].

Considering these aspects as well as the increasing interest in TBIs, a question arises whether adequate therapeutic alliance, considered a key aspect of psychotherapy, can be established without or with minimal face-to-face contact or rather changes when blended concepts are applied.

Therapeutic alliance can be viewed as the “quality of partnership and mutual collaboration between a therapist and client” [13], albeit a generally valid definition of the construct does not exist. According to Bordin [14], good therapeutic alliance is characterized by an agreement between the therapist and patient on the goals of the therapy, the tasks to be performed, and their emotional bond (eg, if the patient feels respected and appreciated by the therapist). Depending on the type of technology, the communication between the therapist and patient can be synchronous (telephone or video conference) or asynchronous (email or web-based program). Moreover, different technologies provide different cues about the therapist, such as visual (video conference) and auditory (telephone) cues, which may influence the emotional bond. This complexity needs to be incorporated when describing findings concerning therapeutic alliance, as pointed out in a recent review by Berger [15].

There are different instruments to assess therapeutic alliance, and the most frequently used instrument is the Working Alliance Inventory (WAI) [16,17], which includes the three aspects of *goal*, *task*, and *bond*. These instruments can be administered at different time points and are based on the patient’s, the therapist’s, or an observer’s point of view.

Positive alliance ratings are good predictors of treatment success in traditional face-to-face psychotherapy, even when controlling for other possible confounders, such as prior symptom change [13,18,19].

While therapeutic alliance has been studied extensively in the context of face-to-face therapy [13], only few studies have reviewed the evidence on alliance ratings in TBIs [17,20]. In a meta-analysis of 295 studies, Flückiger et al [17] recently showed that alliance ratings in internet-based programs are similar to those in face-to-face settings. They further revealed that the effect size of the relationship between alliance and treatment outcome is comparable in TBIs and face-to-face settings. The authors reported that most of the studies investigating alliance in internet-based interventions relied on the WAI. However, this review focused on internet-based interventions only and did not refer specifically to people diagnosed with depression. There are randomized controlled trials (RCTs) addressing therapeutic alliance in TBIs for people with depression [21,22]. However, there is no published systematic review on this topic.

Aim

The purpose of this study was to examine therapeutic alliance in TBIs for the treatment of depression in a systematic review, considering the following research questions: (1) How many of the studies included in the review consider therapeutic alliance in their evaluation? (2) How is therapeutic alliance assessed? (3) How is the quality of therapeutic alliance rated across different interventions? (4) Is there a relationship between therapeutic alliance and treatment outcome?

Methods

Design

This study is part of a preregistered systematic review (PROSPERO registration number: CRD42016050413) on the comparative effectiveness of *T*echnology-based *I*nterventions in different steps of *De*pression *Ca*re (TIDECA). The corresponding protocol has been published [23] and includes more detailed descriptions. This review is in accordance with the standards of the Cochrane Collaboration [24] and is reported in line with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement [25].

Search Strategy

We searched the following key databases: Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, PsycINFO, PSYNDEX, and CINAHL. The search was not limited by date, language, or publication status. Supplementary material of the study protocol [23] includes applied search strategies of key databases. We further searched clinical trial registers (ClinicalTrials.gov, International Clinical Trial Registry Platform, and German Clinical Trial Register) and sources of grey literature (Open Grey, Trip Database, ProQuest Dissertations & Theses Abstract and Indexing, and specialized registers of Institute for Scientific Information Web of Science). Additionally, all first authors of the included publications were contacted for supplementary information on further published and unpublished trials and specific study information or the status of on-going studies, which were identified as published study protocols or preregistered trials.

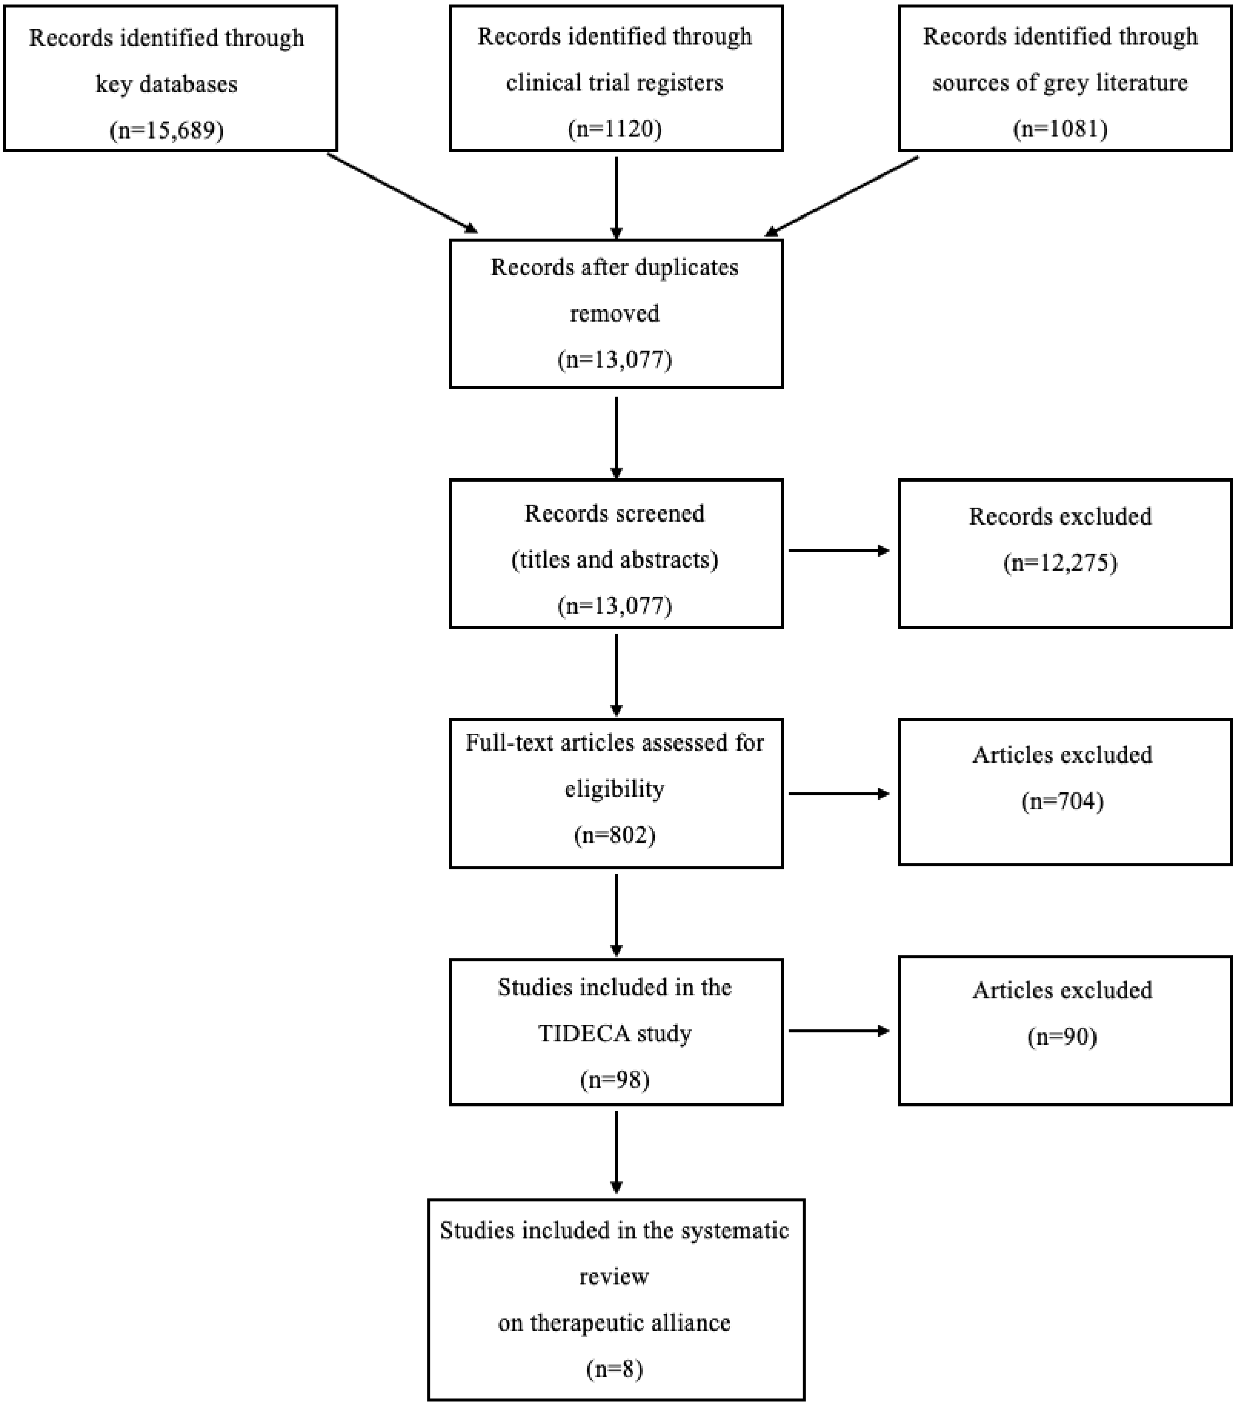
Inclusion and Exclusion Criteria

We applied PICOS categories (Population; Intervention; Comparator; Outcome; Study design) [24,26] to define the inclusion and exclusion criteria for our study. All abstracts were screened according to prespecified criteria. We included studies only if (1) they were cluster RCTs, (2) participants were 18 years or older, (3) participants had a diagnosis of unipolar depression based on a formal classification system, (4) mental or somatic comorbidities were not the main focus of the intervention or study, and (5) the active intervention included a TBI based on an explicit psychotherapeutic theory and aimed to improve depressive symptoms. For more details, refer to the study protocol [23].

Selection Procedure

The selection process is presented in Figure 1. The search yielded at total of 13,077 records after duplicates were removed. Two authors (MK and SL) independently screened the first 100 records for inclusion. Since the interrater reliability for this sample was high (98%), one author (MK) screened the remaining records in the course of the title/abstract screening and the second author (SL) assessed publications labelled as “unclear.” Selected full-text publications (n=802) were subsequently screened for inclusion by two independent reviewers (MK and MD). Discrepancies were resolved by discussion with a third reviewer (SL). A total of 98 publications fulfilled all inclusion criteria for the TIDECA study and were finally screened to determine whether they included data on the *therapeutic working alliance relationship*. Eight publications were included in this review.

Figure 1. PRISMA flow diagram. TIDECA: Technology-based Interventions in different steps of Depression Care.



Data Extraction

We developed a standardized data collection sheet, which was piloted on three studies. The sheet collected the following data: (1) general data (eg, year of publication), (2) methodological information (including risk of bias assessment), (3) demographic and clinical sample characteristics, (4) classification of the clinical phase of depression management (waiting period, acute treatment, and aftercare), (5) delivery mode (eg, blended treatment), (6) treatment characteristics, (7) sample size and study flow, (8) primary and secondary outcome data, and (9) data on therapeutic alliance, including measuring instrument, rating of therapeutic alliance for all included groups (means, standard deviations, and *P* values for available group differences), and data on the relationship between therapeutic alliance and treatment outcomes (*P* values). Data were extracted by two independent reviewers (EW and MK), and inconsistencies were resolved by discussion or by involving a third reviewer (SL).

Data Analysis

Given the heterogeneity of the studies included, qualitative (respectively descriptive) synthesis of the evidence was performed, rather than a meta-analysis.

Descriptive statistics were used to present means, standard deviations, and percentage scores. Standard deviations were derived from standard errors, if not provided otherwise. We decided to focus on alliance ratings after the treatment had started (instead of pretreatment ratings) in order to detect possible group differences based on the different interventions. If several time points after the start of treatment were reported in the studies, we selected the earliest alliance ratings, in line with previous findings showing that therapeutic alliance is established at an early stage of therapy [27]. Given that only a small number of studies provided the therapists' ratings of therapeutic alliance and all studies provided the patients' ratings, the results focused on the patients' ratings.

Quality Appraisal

The risk of bias assessment was evaluated by two independent reviewers (EW and MK) for the included studies according to the Risk of Bias Tool of the Cochrane Handbook for Systematic Reviews [24] (including the domains random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data, selective outcome reporting, and other bias). In line with a previous operationalization [28], we specified the domain "other bias" using the following three additional categories: insufficient treatment adherence, allegiance bias, and attention bias. Interrater reliability was calculated to be 77%. Discrepancies were resolved by discussions between the reviewers (EW and MK) or by involving a third reviewer (SL).

Protocol Changes

Since the applied literature search was very comprehensive, we did not perform an additional systematic forward and backward reference search.

Results

Study Characteristics

Among the selected studies in the TIDECA review, 9.5% (8/98) considered therapeutic alliance as part of their evaluation. As displayed in Table 1, studies examining therapeutic alliance were published within the last decade and were mainly located in Europe, except for one study from the United States [29-36]. The sample size of these studies ranged from 38 to 325 participants. The technological delivery modes in the intervention groups included email, web-based programs, telephone, and a smartphone app. Waitlists, face-to-face psychotherapy, treatment as usual (TAU) combined with a waitlist, and an active control group with TAU were used as controls. Among the studies, four used a TBI as a stand-alone intervention, three implemented a blended treatment (ie, combining TBIs with face-to-face therapy), and one conducted enhanced stand-alone interventions (ie, combining TBIs with TAU without following a specific concept). The therapeutic rationale of applied TBIs was based on behavioral psychotherapy in all studies. The length of the treatment ranged from 8 to 18 weeks. The qualifications of the therapists varied from MSc students of clinical psychology and licensed psychotherapists to PhD-level psychologists.

Notable differences were observed with regard to the degree of therapist guidance. Therapists in predominantly self-help interventions focused on providing feedback, validation, reinforcement, and encouragement to continue with the program. In predominantly therapist-administered interventions, the therapy was delivered by therapists, whereas interventions based on self-help did not involve any therapists.

Table 1. Study characteristics.

Study, authors (publication year)	Study location	N[a]	Study arms	Delivery mode	Therapeutic rational of TBI[b]	Length (weeks)	Qualification of the therapists	Degree of guidance[c]
Andersson et al (2012) [29]	Sweden	88	Email support vs internet program vs waitlist	Stand-alone intervention	CBT[d]	8	MSc students of clinical psychology	Predominantly therapist administered (email) and predominantly self-help (internet)
Berger et al (2018) [30]	Germany	98	Internet program + F2F[e] vs F2F	Blended treatment	CBT	12	Licensed psychotherapists	Predominantly therapist administered
Lindner et al (2014) [31]	Sweden	38	internet program + telephone support vs internet program + email support	Stand-alone intervention	BA[f] + ACT[g]	8	MSc students of clinical psychology	Predominantly self-help
Ly et al (2015) [32]	Sweden	93	Smartphone + F2F vs F2F	Blended treatment	BA	9 (blended) and 10 (control)	MSc students of clinical psychology	Predominantly self-help
Meyer et al (2015) [33]	Germany	163	Internet program + TAU[h] vs TAU + waitlist	Enhanced stand-alone intervention	CBT	13.05	No therapists involved	Self-administered
Steinmann et al (2019) [34]	Germany	59	Telephone + F2F + letters vs telephone + F2F	Stand-alone intervention	CBT	9-13	Licensed psychotherapists	Predominantly therapist administered
Stiles-Shields et al (2014) [35]	USA	325	Telephone vs F2F	Stand-alone intervention	CBT	18	PhD-level psychologists	Predominantly therapist administered
Zwerenz et al (2017) [36]	Germany	229	Internet program + TAU vs active control + TAU	Blended treatment	CBT	12	No therapists involved	Self-administered

[a] N: number of participants randomized.

[b] TBI: technology-based intervention.

[c] Based on the study by Newman et al [37].

[d] CBT: cognitive behavioral therapy.

[e] F2F: regular face-to-face psychotherapy.

[f] BA: behavioral activation.

[g] ACT: acceptance and commitment therapy.

[h] TAU: treatment as usual.

Risk of Bias Assessment

Overall, the risk of bias assessment showed a low risk of bias for selection bias, detection bias, and attrition bias (Figure 2). Given the nature of the studies, blinding of participants and personnel was not possible, thus creating a high risk for performance bias. Selective reporting (reporting bias) was unclear or high in all but one study, mainly due to unexplained or unjustified discrepancies between the protocol or the trial registration and the reported measures. Other sources of bias were unclear or high in all but two studies.

Figure 2. Risk of bias assessment. Other sources involved insufficient treatment adherence, allegiance bias or conflict of interest, and attention bias.

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias)	Blinding of outcome assessment (detection bias)	Incomplete outcome data (attrition bias)	Selective reporting (reporting bias)	Other sources of bias

Sample Characteristics

Table 2 provides an overview of the sociodemographic characteristics of the sample. The sample is rather typical for psychotherapeutic studies, with a mean participant age of 43.9 (SD 13.9) years and the majority of participants being female (769/1,093, 70.4%), being employed (554/941, 58.9%), and having a high level of education (672/1034, 65.0%). All studies included only participants who had a clinical diagnosis of depression, except for the study by Meyer et al [33], which had a sample with 84% (137/163) of patients having depression.

Table 2. Sample sociodemographic characteristics.

Characteristic	Value[a] (N=1093[b])
Age (years)	43.9 (13.9)
Sex (females)	769 (70.4%)
Occupation	
Employed (full and part time)	554 (58.9%)
Unemployed (including retired and disabled)	303 (29.3%)
Undergoing training (students and trainees)	41 (9.0%)
Education	
Low educational level (<9 years)	42 (4.1%)
Middle educational level (9-11 years)	297 (28.7%)
High educational level (≥12 years)	672 (65.0%)
Marital status	
Married/with partner	480 (46.4%)
Single/without partner (including divorced and widowed)	329 (46.4%)

[a] Data are presented as mean (SD) or n (%).

[b] Values refer to the available data. Some studies did not report in line with our subcategories (missing data: occupation, four studies; education, one study; marital status, two studies).

Assessment of Therapeutic Alliance

Table 3 summarizes how therapeutic alliance was assessed in the included studies. Five studies [29-32,35] relied on the WAI in its original format of 36 items (7-point Likert scale) [16], the short form version (WAI-S) with 12 items (7-point Likert scale) [38], or the short form-revised version (WAI-SR) with only positively worded items (5-point Likert scale) [39]. All five studies reported the total score, and three studies [29,30,35] further reported the subscores of the WAI (task, goal, and bond).

Two studies relied on the original Helping Alliance Questionnaire [40]; one reported the total score [36], whereas the other reported the subscore for collaboration or bond [34]. One study [33] assessed therapeutic alliance using the 11-item Helping Alliance Questionnaire (HAQ-11) [41], with a 6-point response score. The mean total score of the HAQ-11 was converted to a percentage score that indicated how many participants viewed the alliance as positive.

All studies used the client-rated version of the assessment tools, and three studies [30,35,36] also utilized therapist ratings. While all studies scheduled an early or mid-treatment assessment of the alliance, ranging from 2 to 6 weeks of treatment, some studies included pretreatment and follow-up evaluations as well. Notably, Steinmann et al [34] reported alliance ratings at study intake only, and Zwerenz et al [36] administered the HAQ to measure therapeutic alliance in the TAU arm but not in the TBI arm. Therefore, these data were not considered in the subsequent results.

Table 3. Assessment of therapeutic alliance.

Study, authors (publication year)	Assessment tool	Measures reported	Rater	Time of assessment	Total treatment length
Andersson et al (2012) [29]	WAI[a]	Total score + 3 subscores (task, goal, and bond)	Client	After 3 weeks	8 weeks
Berger et al (2018) [30]	WAI-Short Revised	Total score + 3 subscores (task, goal, and bond)	Client + therapist	After 6/12 weeks	12 weeks
Lindner et al (2014) [31]	WAI-Short Form	Total score	Client	After 2/8/12 weeks	8 weeks
Ly et al (2015) [32]	WAI-Short Form	Total score	Client	Pre-treatment/after 3 weeks	9 weeks (10 weeks control)
Meyer et al (2015) [33]	HAQ-11[b]	Total score	Client	After 3 weeks	13.05 weeks[c]
Steinmann et al (2019) [34]	HAQ[d]	Subscore (collaboration or bonding)	Client	Study intake	9-13 weeks
Stiles-Shields et al (2014) [35]	WAI-Short Revised	Total score + 3 subscores (task, goal, and bond)	Client + therapist	At 4/14 weeks	18 weeks
Zwerenz et al (2017) [36]	HAQ	Total score	Client + therapist	Study intake/end of TAU[e]	12 weeks

[a] WAI: Working Alliance Inventory.

[b] HAQ-11: 11-item Helping Alliance Questionnaire.

[c] A period of 3 months was converted to weeks with a factor of 4.35 weeks per month for comparability.

[d] HAQ: Helping Alliance Questionnaire.

[e] TAU: treatment as usual.

Ratings of Therapeutic Alliance

The patients' ratings of therapeutic alliance (between week 2 and 6) are displayed in Table 4. The available data cover eight different treatment conditions, including four *stand-alone treatments* (face-to-face psychotherapy, email, telephone, and internet program) and four *combined treatments* (face-to-face psychotherapy plus a smartphone app and an internet program combined with face-to-face psychotherapy, treatment as usual, or email/telephone).

On average, patients rated the alliance positively across all groups. Importantly, no relevant group differences regarding therapeutic alliance sum scores were found in any of the studies. Andersson et al [29] found a significant difference (P=.04) between email-based therapy and the use of a self-help internet program when comparing the subscore *goal*, with higher scores in the email condition. However, no relevant group differences regarding the other subscores where found.

Berger et al [30] and Stiles-Shields et al [35] further analyzed therapists' alliance ratings and found no statistically significant group differences between face-to-face psychotherapy and face-to-face psychotherapy combined with an internet program (P>.09) or between face-to-face psychotherapy and telephone treatment (P>.05).

Table 4. Patients' ratings for therapeutic alliance.

Study, authors (publication year) and subscale	Alliance ratings[a], mean (SD)								Group differences[d]
	F2F[b]	F2F + smartphone	Internet program	Internet program + F2F	Internet program + TAU[c]	Email	Internet program + email/phone	Telephone	
Andersson et al (2012) [29]

[a] Means and standard deviations are displayed, except for the study by Meyer et al, where the percentage of participants rating the alliance as positive is displayed.

[b] F2F: regular face-to-face psychotherapy.

[c] TAU: treatment as usual.

[d] P values based on t tests (Andersson et al and Ly et al), Mann-Whitney U tests (Berger et al), repeated measures analysis of variance (Lindner et al), and least square estimated means (Stiles-Shields et al).

[e] N/A: not applicable.

[f] Statistically significant.

[g] Not statistically significant after Bonferroni correction.

Relationship Between Therapeutic Alliance and Treatment Outcome

Five studies [29,30,32,33,35] investigated the relationship between patients' alliance ratings and treatment outcome (Table 5).

Berger et al [30] found a statistically significant positive association between patients' alliance ratings at 6 weeks and treatment outcome in the face-to-face psychotherapy group ($P<.05$) but not in the combined treatment group. They further showed that residual gain scores of depression were predicted by the patients' alliance rating at 12 weeks in both the regular face-to-face therapy group ($P<.05$) and combined group ($P<.01$). The therapists' ratings at 6 weeks showed no significant association with treatment outcome for either the regular ($P=.61$) or combined treatment ($P=.08$). The therapists' ratings at 12 weeks were significantly associated with treatment outcome in the combined group ($P<.05$) but not in the regular face-to-face therapy group ($P=.60$).

Ly et al [32] reported a significant positive association between patients' working alliance scores and changes in treatment outcome for the blended treatment (*P*<.05) but not for the regular face-to-face psychotherapy.

Meyer et al [33] found a positive correlation between the patients' HAQ-11 scores after 3 weeks of treatment with the internet program plus treatment as usual and symptom reduction. This correlation remained significant (*P*<.02) when controlling for early symptom change.

Anderson et al [29] and Stiles-Shields et al [35] found no relevant relationship between patients' alliance ratings and treatment outcome.

Table 5. Relationship between patients' therapeutic alliance ratings and treatment outcome.

Study, authors (publication year)	F2F[a]	F2F + smartphone	Internet program	Internet program + F2F	Internet program + TAU[b]	Email	Internet program + email/phone	Telephone

[a] F2F: regular face-to-face psychotherapy.

[b] TAU: treatment as usual.

[c] N/A: not applicable.

[d] No significant relationship between therapeutic alliance and treatment outcome.

[e] Statistically significant positive relationship between therapeutic alliance and treatment outcome. Significance based on Spearman correlation (Berger et al, *P*<.01) and mixed effects models (Ly et al, *P*=.00-.05; Meyer et al, *P*<.01).

Discussion

Principal Findings

This study investigated if and how therapeutic alliance ratings were considered in RCTs on different technology-based psychological interventions for depression. Out of the 98 studies included in the TIDECA review, 8 (9.5%) investigated therapeutic alliance. A previous review on e-therapy for different mental health diagnoses found that 1.3% of the included studies considered measures of therapeutic alliance [20]. Notably, the studies included in that review were published between 2002 and 2010, whereas the studies in our review were published between 2012 and 2019. This result may suggest an increased interest in the subject matter; however, it is difficult to directly compare the numbers, since the inclusion criteria of both studies were not identical. Our results showed that the assessment of therapeutic alliance was based on either the WAI or HAQ and that all studies used the patients' ratings, whereas only three studies reported the therapists' ratings as well. Furthermore, this study analyzed therapeutic alliance ratings across different interventions considering factors (eg, the degree of therapeutic guidance) that may affect therapeutic alliance, as well as the relationship between therapeutic alliance and treatment outcome.

It was shown that in a face-to-face psychotherapy setting, the therapeutic relationship was not rated differently when adding an internet-based program as an adjunctive treatment tool. Further, a setting with reduced (four instead of 10) face-to-face sessions and a supportive smartphone app also showed no relevant differences compared with a control setting (10 face-to-face sessions and no smartphone app) regarding therapeutic alliance. Replacing all face-to-face sessions with telephone therapy revealed no relevant difference in alliance ratings. This is especially notable as telephone communication eliminates all visual cues.

In guided internet-based programs, no difference regarding therapeutic alliance was found between guidance via email and guidance via telephone. Thus, in this specific setting, vocal cues and synchronous communication, as provided by the telephone, did not result in other therapeutic alliance ratings compared with asynchronous communication and missing vocal cues. Further, guided internet programs showed alliance ratings similar to those for individualized email therapy.

Overall, therapeutic alliance was rated positively, regardless of the type of technology applied. Notably, this also applied to a setting with no therapist contact at all [33], although it is unclear what exactly is reflected by alliance measures between a person and a program.

Our results are based on one study for each treatment comparison; thus, conclusions need to be considered with caution. Further, therapeutic alliance was assessed at different time points, ranging from 2 to 6 weeks after baseline, which adds heterogeneity to the sample. Thus, different alliance ratings may relate to how the relationship was perceived at a specific time point during the treatment, rather than reflecting differences between the interventions themselves. With this in mind, our results suggest that in the context of TBIs for depression, visual and vocal cues, synchronous communication, and physical presence of the therapist are not requirements for developing good therapeutic alliance. This finding is especially interesting in light of the idea that nonverbal behavior is a key factor of relationship formation between patients and therapists [42]. Possibly, there are other factors that compensate for the lack of nonverbal cues, such as more flexibility when accessing therapeutic modules in web-based programs or smartphone apps. Additionally, there are limited studies about the influence of nonverbal cues on the therapeutic relationship [43]; thus, the relevance of these cues for building an adequate alliance is unclear.

We found mixed results concerning the relationship between therapeutic alliance and treatment outcome (eg, alliance ratings in face-to-face therapy were closely related to the treatment outcome in one study but not in another). It has been argued that alliance ratings are not directly related to treatment outcome, but rather represent a third variable, such as early improvement and treatment motivation [44]. This notion was not confirmed by the results of the study by Meyer et al [33], which showed that early alliance ratings predicted treatment outcome, even when controlling for early symptom change.

Strengths and Limitations

Our review was conducted in line with the Cochrane guidelines, and studies were selected according to prespecified criteria, which were previously published in the study protocol, reflecting high methodological standards. The strict application of inclusion and exclusion criteria reduced the overall number of studies considered in this review. All studies were conducted in Western countries, mainly Europe (Sweden and Germany), and one study was conducted in the United States. These countries share similar communication patterns (eg, relying highly on semantic meaning rather than contextual and nonverbal cues) [45]. Thus, it is unclear whether our results can be extended to non-Western countries, especially in the context of TBIs, where visual and vocal cues are eliminated (eg, email and web-based programs).

There are some additional considerations when interpreting our results. First, the majority of the studies relied upon the WAI for the assessment of therapeutic alliance. As recently pointed out [46], this instrument has not been developed and tested for use in technology-based interventions and may need some adaptions to identify setting-specific influences. This may apply to the specific wording of the instrument (eg, *program* instead of *therapist*), as well as the content of the questions (eg, the goals of the treatment are usually not discussed in a self-help program). Thus, it is possible that future studies utilizing a tool that is specifically developed and validated in this context may show divergent results.

Second, not all studies specifically reported whether any additional contact between therapists and patients occurred outside of the treatment setting. For example, if a patient is assigned to an email therapy group but meets the therapist during the recruitment or initial assessment process, additional exposure to visual and vocal cues could influence the formation of a therapeutic bond. Thus, we encourage future studies to take this point into consideration by reporting all contacts between therapists and patients.

Third, most patients were recruited via advertisements. Previous research has shown that patients recruited from nonclinical settings have a more positive attitude toward internet interventions for the treatment of depression than patients recruited from clinical settings [47]. Further, therapists that agreed to participate in the studies may have been subject to a similar selection bias. Thus, the results may not be transferrable to clinical practice, where more skeptical individuals (concerning TBIs) are present.

Fourth, only three out of eight studies took the therapists' perception of therapeutic alliance into consideration. Previous studies have shown that therapists and patients may judge the alliance differently [13]; thus, it would be favorable to include both measures in future studies.

Implications for Clinical Practice and Future Research

As the field may continue to expand and more therapists may consider technology-based treatment options, it is important to further investigate on what basis the alliance is formed in settings that do not allow for additional cues, such as facial expression and tone. For example, in an RCT with several arms, each eliminating a different component of face-to-face communication (eg, visual or auditory cues), researchers could investigate if and how therapeutic alliance is affected. Importantly, these studies should include both the therapists' and patients' perspectives. Further, it will be important to replicate the finding that early alliance ratings may predict treatment outcome independently from early symptom change. Such studies will require more frequent measurements of therapeutic alliance, symptom change, and alternative factors that could relate to treatment outcome, such as pretreatment motivation, in order to establish the relation of these aspects. Moreover, research needs to address how personal preferences and attitudes toward TBIs may interact with the formation of a therapeutic alliance, both from the patient's and therapist's perspective. Finally, it remains unclear what exactly is measured in settings without any therapist contact at all. Possibly, the alliance between a person and a technology-based program reflects less of the emotional aspect of therapeutic alliance and is more related to how the program matches an individual's goals and expectations of the tasks required.

Conclusion

This review shows that studies on therapeutic alliance in TBIs for the treatment of depression are still limited, especially regarding therapists' alliance ratings. Taking into account different degrees of therapeutic guidance, qualifications of therapists, modes of delivery, and types of technologies, the results of this review suggest that a positive therapeutic alliance can be established in TBIs for people with depression.

Acknowledgments

The Federal Ministry of Education and Research (in German: Bundesministerium für Bildung und Forschung; BMBF) funded the systematic review on the comparative effectiveness of *T*echnology-based *I*nterventions in different steps of *De*pression *Ca*re (TIDECA; funding code: 01KG1705, funding period: August 2017 to October 2019). The funding institution had no role in the design of this study and no role during its execution, the analysis and interpretation of data, or the decision to submit the results. The review on therapeutic alliance was conducted as part of a doctoral degree (medicine) and did not receive any additional funding. We thank Mareike Dreier (MD) for her assistance in screening the full-text publications for inclusion.

Abstract

Background: Studies using Taiwan’s National Health Insurance (NHI) claims data have expanded rapidly both in quantity and quality during the first decade following the first study published in 2000. However, some of these studies were criticized for being merely data-dredging studies rather than hypothesis-driven. In addition, the use of claims data without the explicit authorization from individual patients has incurred litigation.

Objective: This study aimed to investigate whether the research output during the second decade after the release of the NHI claims database continues growing, to explore how the emergence of open access mega journals (OAMJs) and lawsuit against the use of this database affect the research topics and publication volume and to discuss the underlying reasons.

Methods: PubMed was used to locate publications based on NHI claims data between 1996 and 2017. Concept extraction using MetaMap was employed to mine research topics from article titles. Research trends were analyzed from various aspects, including publication amount, journals, research topics and types, and cooperation between authors.

Results: A total of 4473 articles were identified. A rapid growth in publications was witnessed from 2000 to 2015, followed by a plateau. Diabetes, stroke, and dementia were the top 3 most popular research topics whereas statin therapy, metformin, and Chinese herbal medicine were the most investigated interventions. Approximately one-third of the articles were published in open access journals. Studies with two or more medical conditions, but without any intervention, were the most common study type. Studies of this type tended to be contributed by prolific authors and published in OAMJs.

Conclusions: The growth in publication volume during the second decade after the release of the NHI claims database was different from that during the first decade. OAMJs appeared to provide fertile soil for the rapid growth of research based on NHI claims data, in particular for those studies with two or medical conditions in the article title. A halt in the growth of publication volume was observed after the use of NHI claims data for research purposes had been restricted in response to legal controversy. More efforts are needed to improve the impact of knowledge gained from NHI claims data on medical decisions and policy making.

KEYWORDS

administrative claims data; bibliometric analysis; National Health Insurance; text mining; open access journals; PubMed

Introduction

Health care administrative data, also known as administrative claims data, [1], are derived from claims for reimbursement for routine health care services. They are relatively inexpensive to procure and, in general, readily available in electronic format [2]. Therefore, they are widely used for medical and public health research [1,3,4]. Such claims-based studies may cover a variety of research types, such as disease surveillance, health service utilization, validity analysis, and association between exposure and health outcomes [5].

Taiwan's National Health Insurance Research Database (NHIRD), one of the largest health care administrative databases in the world, has provided a great opportunity for researchers to perform population-based studies [6]. Since 1995, residents in Taiwan have enjoyed a universal single-payer health care system operated by the National Health Insurance (NHI). The program covered virtually all of Taiwan's population (99.5%) by 2010. The coverage of the whole population in the database has the advantages of an enormous sample size and lack of participation bias [6]. In 2000, Taiwan's National Health Research Institutes compiled NHI claims data into the NHIRD and made it publicly available to the academic community. Low-cost updates of the NHIRD are possible because its data collection is carried out routinely for purposes inherent in the process of medical care and insurance reimbursement [6]. The public release of this large population-based database enables collaboration and knowledge sharing among researchers and boosts scientific production [6,7]. A bibliometric study conducted by Chen et al [8] to investigate the trend of using the NHIRD as research material found that the number of these studies had increased significantly from 2000 to 2009, with an average annual growth rate of 45.8%.

While more and more authors have successfully published studies using NHI claims data as the data source, some of these studies were criticized for being merely data-dredging studies rather than hypothesis-driven [9]. For example, as described by Hampson et al [9], increased risks of 5 different medical conditions following carbon monoxide poisoning were reported in 5 individual articles using the same research model. In addition, the emergence of open access mega journals (OAMJs) since 2006 [10] may have played a role. OAMJs, as a new business model for publication, are characterized by a large publication volume and broad disciplinary scope. They generally accept research articles as long as the requirements of "scientific soundness" are met, regardless of their contributions to a research field or academic interest [10]. It is believed, justified or not, that Journal Citation Reports (JCR)-indexed OAMJs are especially attractive to some researchers in Taiwan [10,11].

On the other hand, with the widespread use of the NHIRD in research, several human rights groups protested the use of claims data without the explicit authorization from individual patients and launched a lawsuit against the NHI Administration in 2012 [12,13]. As a result, the National Health Research Institutes stopped accepting applications for the NHIRD from researchers at the end of 2015 and terminated the NHIRD service in mid-2016 [14]. Thereafter, researchers can only access NHI claims data on site at the Data Science Center or via a virtual private network connection at its branch offices [15].

Studies based on the NHIRD have expanded substantially in both quantity and quality during the period of 2000 to 2009 [8]. However, whether the recently burgeoning OAMJs or lawsuit would affect the research output from NHI claims data remained undetermined. Since Asian countries like Japan and South Korea are also developing their own nationwide claim databases [16], the lessons regarding how Taiwan's NHI claims database contributed to academic production may help researchers in other countries to develop their own policy and strategy on how to use claims databases in research. Accordingly, we formulated the following research questions: (1) With the widespread use of NHI claims data as research material, does the number of research articles in the second decade keep growing at a similar pace to that observed in the first decade since the release of NHI claims data? What is the effect of the lawsuit against the secondary use of health insurance data for research on research output? (2) What are the most common research topics of articles using NHI claims data? Do the types of research topics correlate with the volume of research output? (3) Which journals published the most articles using NHI claims data? (4) What is the role of open access journals in the proliferation of research output? (5) Who are the most prolific authors and research groups?

Methods

Data Source

This study used PubMed to locate publications that may have used NHI claims data as the primary data source because PubMed is the most widely used database for searching medical literature. Articles published in English that entered PubMed between Jan 1, 1996 and Dec 31, 2017 with "journal article" as their publication type were included. Following the work by Chen et al [8], a broad search strategy was employed to permit inclusion of as many articles as possible. Articles had to mention "Taiwan" in any of the textual fields including title, abstract, medical subject heading (MeSH) index terms, and author's affiliation address and meet any of the following criteria: (1) indexed with the MeSH term "insurance, health" or "national health programs;" (2) either "nationwide" or "population" in the title field; (3) any of the following terms appearing in the title or abstract: "health insurance," "national insurance," "claims data*," "claim data*," "insurance claim*," "insurance data*," "administrative data*," "nationwide data*," "national data*," "NHIRD," "LHID," "NHI," and "BNHI." The asterisk (*) is the truncation symbol used by PubMed that indicates to find all terms that begin with the string preceding the asterisk.

Articles classified under the categories of comment, letter, editorial, or review and those published without an abstract were excluded. The search was done on June 24, 2018 and resulted in 5105 articles for further evaluation (See Multimedia Appendix 1).

Because journals may change their titles or even merge, this study always adopted the last title of a journal. JCR Science Edition and Social Sciences Edition (Clarivate Analytics, 2018) was used to retrieve 2017 Journal Impact Factors and journal categories. Journals were classified from Q1 to Q4 according to the impact factor quartiles in the specific journal category, where Q1 journals stand for journals with higher impact factors. Journals not indexed by the JCR were classified as other. Open access journals were identified through the Directory of Open Access Journals. OAMJs were defined as described in a previous study [10].

Ascertainment of Studies

All the articles were downloaded from PubMed and preprocessed using the "easyPubMed" package in R. Because the list of potential articles was quite lengthy, several heuristic rules were applied to determine whether an article used NHI claims data as the primary data source. Basically, regular expression pattern matching was used to detect the mentioning of using NHI claims data in article abstracts and adjusted the matching patterns by trial and error. This study finally found two inclusion rules and one exclusion rule. The rules are shown in Textbox 1. These rules identified 3059 articles as using NHI claims data and achieved 100% precision (positive predictive value) by manually examining a random sample of 500 articles.

The remaining 2046 articles were reviewed by the first and second authors. Each author independently classified an article as "using NHI claims data," "not using NHI claims data," or "using data from undetermined source" by examining its abstract or full text, when necessary. This process achieved an agreement of 99.1% (kappa=0.978), and discrepancies (19 articles) were resolved by consensus. Among them, 632 articles were considered not using NHI claims data and thus excluded. In the end, a total of 4473 articles were included in this study (Multimedia Appendix 1).

Textbox 1. Heuristic rules used to determine whether an article used National Health Insurance claims data.

Inclusion rules

1. (from|data|study|using|cohort|used|based|patients|identified|population|obtained|

claim|conducted|retrieved|collected|selected|analyz)[[:print:]]{1,20}(National Health Insurance|NHI|Longitudinal Health Insurance|insurance claims|Registry for Catastrophic Illness Patient)[[:print:]]{1,20}(claim|data|file)")

2. (National Health Insurance|NHI|Longitudinal Health Insurance|insurance claims|Registry for Catastrophic Illness Patients)[[:print;]]{1,20}(claim|data|file)[[:print:]]{1,20}(from|

used|patients|identified)

Exclusion rule

1. (Korea)[[:print:]]{1,20}(National Health Insurance|NHI)

Text Mining

This study used MetaMap as the tool to mine medical entities, such as symptoms, clinical findings, diseases, and medications, from article titles. MetaMap is a natural language processing tool developed by the National Library of Medicine. It analyzes input text through tokenization, sentence boundary determination, part-of-speech tagging, and parsing and generates variants of resulting phrases or words [17]. By evaluating measures of centrality, variation, coverage, and cohesiveness, MetaMap locates each matched medical entity in the Unified Medical Language System (UMLS) Metathesaurus, assigns it a semantic type, and returns a concept unique identifier and score between 0 and 1000, with a higher value representing a closer match [18]. This study used UMLS Metathesaurus version 2016AA.

Because an article title typically indicates what the article is about, this study attempted to mine knowledge from article titles. Although MeSH terms are also used in PubMed to describe what an article is about, we analyzed MetaMap-derived concepts instead of MeSH concepts for two reasons. First, we focused on the article title, but the MeSH concepts were determined by examining the whole article; second, the UMLS Metathesaurus contains far more medical concepts than the MeSH vocabulary. This study focused on two categories of medical entities: (1) medical conditions including diseases, symptoms and signs, and findings and (2) interventions, including medications, procedures, and surgery. Specifically, medical entities were categorized based on their UMLS semantic types (see Multimedia Appendix 2). Because MetaMap may generate multiple UMLS semantic types and concepts from the same phrase [18], this study relied on the order output by MetaMap and accepted only the first returned semantic type and concept. Furthermore, MetaMap might retrieve general terms that are not the medical entities the researchers were interested in, such as "adopt," "75+ years," and "ambulatory visit". Therefore, this study collected these terms in a stop word list by manually reviewing an aggregate list of the concepts returned by MetaMap. The terms in the stop word list were then excluded from analysis.

Researchers may have different preferences for research topics when using administrative databases as the primary data source [5]. Descriptive studies may investigate only one medical condition whereas analytical studies generally focus on the association between an exposure (either a medical condition or an intervention) and an outcome (a medical condition) [19]. Some studies that used NHI claims data were considered to replicate the same research model of examining the association between two medical conditions [9]. Motivated by this criticism, this study classified articles into 4 study types based on medical entities mentioned in the title as follows: (1) with ≥1 intervention regardless of the number of medical conditions, (2) with ≥2 medical conditions but without any intervention, (3) with only 1 medical condition but without any intervention, and (4) others. Each article was assigned to only 1 of the 4 study types. For example, in the article title "Tamoxifen and the risk of Parkinson's disease in female patients with breast cancer in Asian people," tamoxifen is an intervention whereas Parkinson's disease and breast cancer are both medical conditions. This article is classified as the type with ≥1 intervention. An article with the title "Increased risk of stroke in patients with chronic kidney disease after recurrent hypoglycemia" mentions three medical conditions and is classified as the type with ≥2 medical conditions but without any intervention.

In order to offer background statistics, PubMed was queried to identify the number of articles published in English that entered PubMed between 2000 and 2017 with "journal article" as their publication type. The number of articles published between 2000 and 2017 in the top 20 journals that have published the most studies using NHI claims data were also obtained. Furthermore, the titles of the articles in PubMed and the top 20 journals were screened for presence of the top 10 medical conditions and top 10 interventions that were the most prevalent among studies using NHI claims data. The percentage of each medical condition or intervention among published articles was calculated.

Statistical Analysis and Data Visualization

Categorical variables are reported as counts (percentages). Comparisons between groups used chi-square tests. Trends in continuous variables were assessed using the Cuzick test. Trends in categorical outcomes were evaluated using the Cochran-Armitage trend test for binomial proportions and the multinomial Cochran-Armitage Trend Test implemented in the R package "multiCA" [20] for multinomial proportions. Social network analysis was applied to explore the cooperation between authors and the relationships between medical entities. The "igraph" package in R was used to produce the network graph. Each node represents an author or a medical entity. The nodes are joined by weighted links, in which the width of a link indicates the frequency of relationships between two nodes. The size of a node is proportional to the weighted degree centrality of the node, which is computed by summing the weights of links to the node.

Statistical analyses and visualizations were performed using Stata 15.1 (StataCorp, College Station, Texas) and R version 3.5.0 (R Foundation for Statistical Computing, Vienna, Austria). Two-tailed *P* values were considered statistically significant at <.05.

Results

Trends in Research Output

Since the first article appeared in 2000, the number of publications grew tremendously until 2015, when the publication output seemed to reach a plateau (Figure 1). In contrast, the number of publications in PubMed and the top 20 journals that have published the most studies using NHI claims data continued to increase after 2015 (Figure 1). By 2015, the average annual growth rate of published articles was 77.4%, with a doubling time of 1.7 years. Almost all the articles (97.0%) were published in journals indexed in the JCR Science Edition or Social Sciences Edition. Among the articles indexed in the JCR, 46.4%, 38.3%, 11.5%, and 3.8% were published in Q1, Q2, Q3, and Q4 journals, respectively. Figure 1 illustrates the distribution of articles across the four quartiles of journals in the JCR each year. Table 1 gives the characteristics of articles, authors, and journals across 3 time periods and the results of the trend analysis by year. Based on the affiliation of the first author, we determined that researchers in nonhospital institutions published most of the articles initially, which were gradually outnumbered by those produced by hospital researchers in recent years. Articles were increasingly published in open access journals, in particular OAMJs. Articles were published in an increasing number of journals and were more widely distributed across disciplines.

Figure 1. Annual number of publications between 2000 and 2017 (A) in PubMed, (B) in the top 20 journals that have published the most studies using National Health Insurance (NHI) claims data, and (C) based on NHI claims data, separated by JCR (2017 edition) ranking (Q1, Q2, Q3, Q4). The first year of each major OAMJ is indicated. The release of the National Health Insurance Research Databases (NHIRD) began in 2000 and ended in 2015. The Health and Welfare Database (HWD) was created in 2009 and is still available for research use.

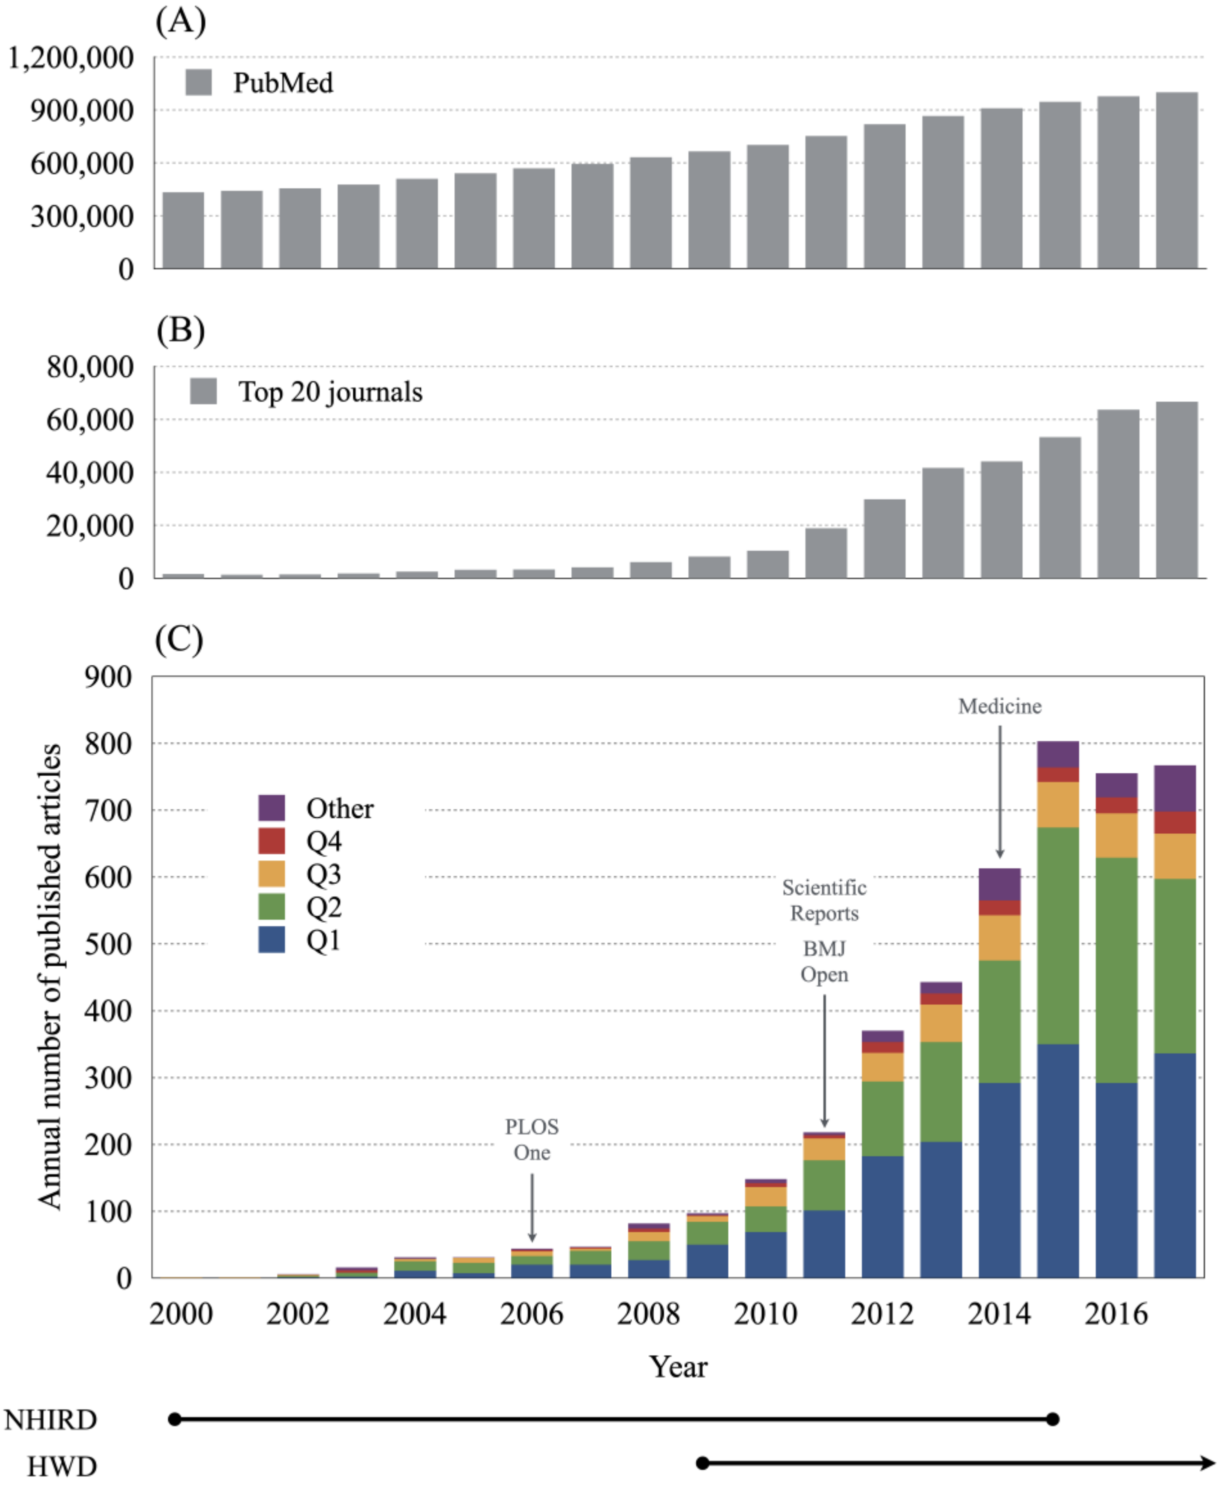

Table 1. Characteristics of and trends for articles and journals.

Research Topics of Articles

A total of 1763 medical entities were retrieved from article titles using MetaMap. Among these, 1132 entities belonged to the category of medical conditions, and 631 belonged to the category of interventions. The most commonly investigated medical conditions were diabetes (n=263), stroke (n=189), and dementia (n=139), whereas the most commonly studied interventions were statin (n=100), metformin (n=40), and Chinese herbal medicine (n=38). The top 50 medical conditions and interventions are listed in Table 2.

Table 3 gives the number and percentage of articles with one of the top 10 medical conditions or the top 10 interventions in the article title during the same period (2000 to 2017). Apparently, the top 10 medical conditions and top 10 interventions were not so prevalent in the titles among articles in PubMed or the top 20 journals.

Figure 2 illustrates the distribution of study types over the years. A significant trend in the proportions of study types was found ($P<.001$). In particular, the number of articles with ≥2 medical conditions in the title grew extensively whereas the number of articles with only one medical condition or without any medical entities in the title decreased considerably (Table 1). Figure 3 shows the most common condition-condition pairs and condition-intervention pairs in article titles. Diabetes, stroke, and dementia remained the top three medical conditions that were extensively studied in association with other medical conditions. They co-occurred with 118, 111, and 80 other medical conditions in article titles, respectively. Among the most studied interventions, statin, metformin, and Chinese herbal medicine co-occurred with 70, 31, and 28 medical conditions in article titles, respectively.

Scattering of Articles in Journals

Until the end of 2017, 4473 articles were published in 841 journals, with an average of 5.3 articles per journal. Among these journals, 791 were indexed in the JCR Science Edition or Social Sciences Edition and were spread across 68 disciplines. The journals PLOS ONE and Medicine ranked first and second, respectively, in the number of publications and yielded 18.0% (804/4473) of the articles, whereas 333 journals published only one article each. This study applied Bradford's law and divided journals into three groups by the rank of journals, with each group of journals publishing approximately the same number of articles (Table 4). The top 20 journals represented one-third of all articles. In contrast, 113 and 708 journals contributed to the next two one-third proportions, respectively. The ratio of journal numbers among these three groups is 20:113:708 (1:5.7:35.4), which is quite close to 1:5.7:5.7^2 (32.5).

Table 4. Scattering of articles in journals.

Group	Journals (n=841), n	Articles (n=4473), n	Cumulative, n (%)	Description
Top third	20	1504	1504 (33.6)	Publishing 26-419 articles
Middle third	113	1315	2819 (63.0)	Publishing 8-25 articles
Bottom third	708	1654	4473 (100.0)	Publishing 1-7 articles

Role of Open Access Mega Journals

Open access journals published 35% of the studies, whereas OAMJs published around one-fifth of the studies (Table 1). Half of the top 20 journals are open access journals, with 4 journals considered to be OAMJs (Table 5). The four OAMJs (ie, PLOS ONE, Medicine, Scientific Reports, and BMJ Open) ranked first, second, seventh, and ninth, respectively, in terms of the number of publications. Table 6 shows the distribution of study types per article title across journal types. The proportions of study types were similar between open access journals and non-open access journals (*P*=.266). In contrast, OAMJs had a different distribution of study types than non-OAMJs (*P*<.001). They tended to publish articles with ≥2 medical conditions in the title.

Table 5. Top 20 journals ranked by published articles between 2000 and 2017.

Journal name	IF[a]	Rank in JCR[b] in 2017	Articles, n (%)	OAJ[c]	OAMJ[d]

Table 6. Distribution of study types per article title across journal types.

Study type	Open access journal, n (%)		Open access mega journal, n (%)	
	Yes (n=1566)	No (n=2907)	Yes (n=906)	No (n=276)
With ≥1 intervention	552 (35.2)	994 (34.2)	308 (34.0)	1238 (34.7)
With ≥2 conditions	537 (34.3)	1038 (35.7)	400 (44.2)	1175 (32.9)
With only 1 condition	353 (22.5)	684 (23.5)	159 (17.5)	878 (24.6)
Others	124 (7.9)	191 (6.6)	39 (4.3)	276 (7.7)

Prolific Authors and Research Groups

The visualization in Figure 4 presents the networks of co-authorships during 2000 to 2005, 2006 to 2011, and 2012 to 2017. To avoid cluttering the figure, only author pairs who had collaborations in more than 2, 5, and 20 articles in the 3 time periods, respectively, were depicted. From 2000 to 2005, the social network analysis identified three main research groups. Herng-Ching Lin from Taipei Medical University was the most productive author and published at least 10 articles. Between 2006 and 2011, Herng-Ching Lin still produced the highest volume of publications (≥100). However, several other research groups emerged during this period. From 2012 to 2017, a total of 7 productive authors were identified, and each published at least 100 articles. Two large research groups can be readily observed in the network graph, including authors mainly from China Medical University Hospital (Cheng-Li Lin, Chia-Hung Kao, Fung-Chang Sung, et al) and Taipei Veterans General Hospital (Tseng-Ji Chen, Chia-Jen Liu, et al).

When a prolific author was defined as one who had at least 100 articles published between 2000 and 2017, a total of 8 authors were qualified as prolific. Table 7 shows that study types were significantly different between studies authored by at least one of the prolific authors and those that were not ($P<.001$). The most common type of studies contributed by prolific authors were studies with two or more medical conditions in the article title, whereas studies by nonprolific authors were more likely to mention at least one intervention in the article title.

Figure 4. Co-authorship networks during (A) 2000-2005, (B) 2006-2011, and (C) 2012-2017.

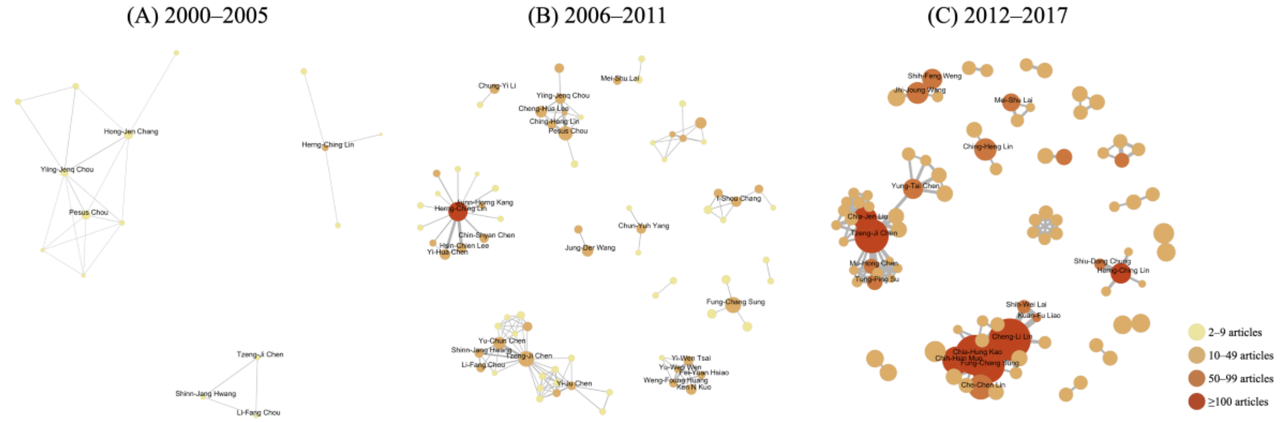

Table 7. Distribution of study types per article title between studies authored by prolific authors and those authored by others.

Study type	Prolific author (≥100 articles), n (%)	
	Yes (n=1399)	No (n=3074)
With ≥1 intervention	385 (27.5)	1161 (37.8)
With ≥2 conditions	707 (50.5)	868 (28.2)
With only 1 condition	250 (17.9)	787 (25.6)
Others	57 (4.1)	258 (8.4)

Discussion

Principal Findings

This study yielded several interesting findings. First, a rapid growth in publications was observed from 2009 to 2015, just as it was between 2000 and 2009. However, the growth dramatically ceased after 2015. Second, certain medical conditions, such as diabetes, stroke, and dementia, and certain interventions such as statin therapy, metformin, and Chinese herbal medicine, received more attention from researchers using NHI claims data as the study material. Third, almost all the studies were published in JCR-indexed journals, most ranking as Q1 or Q2 in their corresponding JCR categories. OAMJs appeared to provide fertile soil for the rapid growth of research based on NHI claims data, particularly studies with ≥2 medical conditions in the article title. Fourth, while the top 8 most prolific authors contributed nearly one-third of all studies, they published more studies with ≥2 medical conditions in the article title than nonprolific authors. These studies mainly investigated the association between two medical conditions and might be easier to conduct than studies examining the effect of an intervention on a medical condition.

Publication Volume

As described by Chen et al [8], the growth of literature using NHI claims data generally followed the proposed model of scientific growth [21] before 2015. The sudden halt of the growth trend after 2015 is quite unexpected. Although the underlying reasons are not fully understood, it is speculated to be related to the 2012 lawsuit against the secondary use of health insurance data [12,13]. Later, in reaction to the legal controversy, more precautionary measures for accessing NHI claims data were enforced [13]. Consequently, the National Health Research Institutes stopped the acceptance of new applications for procuring data from the NHIRD from December 2015 onwards. Moreover, permission to use a local copy of the NHIRD typically expires after 3 years. Therefore, after December 2018, researchers were allowed to access NHI claims data, which is now a part of the Health and Welfare Database, only within the Data Science Center of the Ministry of Health and Welfare or via a virtual private network from local branch offices of the Data Science Center across the country [22]. These measures definitely increased the barriers to conducting research using the NHI claims data. The question of whether the research output will decline from the present level awaits further observation.

Research Topics

Diabetes, stroke, and dementia represented the most commonly investigated medical conditions. All these conditions are highly prevalent diseases that naturally attract more attention from researchers. Furthermore, their high prevalence enabled researchers to study these diseases using merely the Longitudinal Health Insurance Database, which is the 1 million–person subset of the NHIRD that entails a lower cost than the whole dataset of the NHIRD. In particular, because the diagnostic codes for diabetes and stroke have been validated within NHI claims data [23-25], researchers might be more confident performing research on these diseases. This again emphasizes the importance of case validation in secondary data analysis [26].

As for interventions, statins and metformin are commonly prescribed to patients with stroke and diabetes, respectively. Naturally, they were among the most frequently investigated interventions. In addition, the pleiotropic effects of statins and metformin might also intrigue researchers to test their effects on other diseases using large health care databases like the NHIRD [27,28]. Last but not least, the NHI program reimburses Chinese herbal medicine; therefore, NHI claims data provide researchers a unique opportunity to study the effectiveness of Chinese herbal medicine [29].

Implications

Writing for publication is essential for academics. Currently, not only are academics evaluated against how well they publish but universities are also ranked according to their academic publication rates. The long-existing “publish or perish” culture of academia has now prevailed in Taiwan’s hospitals. Taiwan’s hospital accreditation system, in addition to assessing the quality of health care, also aims to determine the teaching status of a hospital [30]. Therefore, hospitals are putting more pressure on their staff to publish in JCR-indexed journals in order to meet the accreditation standards. The pressure to publish is reflected in the increasing trend of first authors coming from hospitals (Table 1).

In addition to these internal factors, the external environment is just suitable for catalyzing the growth of publications. The increasing availability of open access journals, in particular OAMJs, provides unprecedented capacity to accommodate a large volume of publications. Furthermore, several OAMJs (eg, PLOS ONE, Medicine, Scientific Reports, and BMJ Open) have decent impact factors and above-average JCR ranking (Q1 or Q2). All these factors have driven researchers to utilize secondary data analysis to augment their research output. Although the current system might have misdirected some hospital practitioners to “shallow research,” it has also encouraged positive involvement of practitioners in academic research.

Based on the text mining analysis, prolific authors tended to produce articles with ≥2 medical conditions in the title, while such articles were more likely to be published in OAMJs. From the pragmatic point of view, it is easier to investigate the association between two medical conditions than to study the effect of an intervention on a medical condition, in particular when the intervention, such as a medication, is time-dependent. Testing multiple hypotheses at the same time definitely increases the likelihood of finding an association [31]. Therefore, conducting studies investigating the association between two medical conditions within a large database appears to be a shortcut to increase research output. A typical approach is to examine whether condition A increases the risk of condition B. Some of these studies are criticized as “templated and non-hypothesis driven” and have raised concerns and disputes regarding the misuse of data analysis [9,32,33]. In addition, due to Berkson’s bias, such association studies may generate significant but spurious associations caused by inappropriate conditional factors such as hospitalization [34]. All these criticisms may give an impression that findings from studies using NHI claims data are useless to either clinical practitioners or policy makers.

Future Directions

Despite the negative impression, the following strategies were proposed to increase the impact of research based on NHI claims data. First, the percentage of first authors who are not Taiwanese citizens was very low (Table 1). As compared to studies using the United Kingdom’s electronic health database [35], international collaboration is relatively uncommon in studies using NHI claims data. In addition to seeking collaboration with foreign partners, the integration of databases from multiple countries can provide opportunities to compare disease prevalence and treatment effects across countries [36], hopefully producing more generalizable knowledge. Second, apart from formulating a hypothesis before conducting a study, researchers should focus on generating research questions with a real impact on clinical decision making rather than producing articles acceptable by journals with an impact factor. In this respect, studies using the United Kingdom's electronic health database have set good examples of providing real-world evidence to inform clinical practice [37]. Future research should be directed towards clinically relevant and actionable study outcomes. Third, NHI claims data, like other administrative claims data, have been questioned about their data validity because claims data typically lack clinical information. Record linkage between NHI claims data and various clinical registries may be a promising approach to complement the advantages of each data source. The combination of detailed clinical information from registry databases and long-term outcome data from claims databases offers opportunities to enhance the validity of outcomes research [38]. Finally, as for the litigation from human rights groups against the use of NHI claims data, researchers should take this as an opportunity to meet the need for more dialogue and proactive participation from such groups.

Limitations

This study has the following limitations. First, this study included only articles written in English and indexed in the PubMed database to make the results comparable with the study by Chen et al [8]. This undoubtedly limited the scope of this work to health-related publications. However, because the purpose of NHI claims data is to track payments for health care utilization, it is believed that most of these articles, if not all, were published in PubMed-indexed journals. Second, even though journal rankings change year by year, this study used 2017 JCR Journal Impact Factors and journal categories for journal ranking to simplify the analysis. Third, the analysis of article titles was based on automated natural language processing algorithms provided by MetaMap. Although MetaMap can effectively extract medical concepts from biomedical texts, the semantic relationships between the identified medical concepts are not readily discernible [39]. For example, it was difficult to determine whether a study truly investigated the association between two medical conditions simply based on the co-occurrence of the two conditions in the article title.

Conclusions

As Taiwan has recently become an aged society and is expected to become a super-aged society by 2025 [40,41], health care expenditure will inevitably increase as the size of the elderly population grows. Therefore, knowledge of the burden of various diseases as well as the cost effectiveness of different diagnostic and treatment strategies is of paramount importance. Although nationwide disease registration and population-based surveys can provide valuable information to facilitate medical decisions and policy making, the processes of registration and surveys may themselves entail extra costs. In this regard, analysis of secondary data, such as NHI claims data, may continue to provide an affordable, alternative means of gaining knowledge.

Acknowledgments

We would like to thank Ms. Li-Ying Sung for English language editing. This research was supported in part by the Ministry of Science and Technology (grant number MOST 107-2314-B-705-001) and the Center for Innovative Research on Aging Society from The Featured Areas Research Center Program within the framework of the Higher Education Sprout Project by the Ministry of Education in Taiwan.

Abstract

Background: Continuous monitoring of vital signs by using wearable wireless devices may allow for timely detection of clinical deterioration in patients in general wards in comparison to detection by standard intermittent vital signs measurements. A large number of studies on many different wearable devices have been reported in recent years, but a systematic review is not yet available to date.

Objective: The aim of this study was to provide a systematic review for health care professionals regarding the current evidence about the validation, feasibility, clinical outcomes, and costs of wearable wireless devices for continuous monitoring of vital signs.

Methods: A systematic and comprehensive search was performed using PubMed/MEDLINE, EMBASE, and Cochrane Central Register of Controlled Trials from January 2009 to September 2019 for studies that evaluated wearable wireless devices for continuous monitoring of vital signs in adults. Outcomes were structured by validation, feasibility, clinical outcomes, and costs. Risk of bias was determined by using the Mixed Methods Appraisal Tool, quality assessment of diagnostic accuracy studies 2nd edition, or quality of health economic studies tool.

Results: In this review, 27 studies evaluating 13 different wearable wireless devices were included. These studies predominantly evaluated the validation or the feasibility outcomes of these devices. Only a few studies reported the clinical outcomes with these devices and they did not report a significantly better clinical outcome than the standard tools used for measuring vital signs. Cost outcomes were not reported in any study. The quality of the included studies was predominantly rated as low or moderate.

Conclusions: Wearable wireless continuous monitoring devices are mostly still in the clinical validation and feasibility testing phases. To date, there are no high quality large well-controlled studies of wearable wireless devices available that show a significant clinical benefit or cost-effectiveness. Such studies are needed to help health care professionals and administrators in their decision making regarding implementation of these devices on a large scale in clinical practice or in-home monitoring.

continuous monitoring; patient monitoring; vital signs; clinical deterioration; early deterioration; wearable wireless device; systematic review; monitoring

Introduction

Continuous monitoring of vital signs of inpatients is a common practice in intensive care, medium care, operation theatre, and recovery ward settings [1]. The goal of continuous vital signs monitoring in these settings is early detection of the clinical deterioration, thereby allowing timely intervention [2,3]. However, once patients are discharged to the general ward, vital signs are only monitored intermittently, often just once or twice daily. Early warning scores have been implemented to guide clinical interpretation, but this value is limited by the intermittent nature of the measurements [4-6]. Serious unexpected adverse events do occur regularly in general wards, especially in high-risk postsurgical or elderly frail patients [7-13]. This incidence of adverse events is expected to increase owing to the aging population, increasing complexity of in-hospital care, increasing pressure to limit health care costs, and increasing shortage of nursing staff. These adverse events may be prevented or mitigated if continuous monitoring of vital signs would be available to facilitate early detection of the deteriorating trends in vital signs, thereby allowing timely interventions [14-16]. An important advantage of continuous monitoring may be the insight in the trends, which can be much more informative and predictive than single deviating values [17-19].

Recent studies have shown that continuous monitoring in combination with automated alerts in case of deterioration improves patient outcomes [17,20-23]. However, for continuous monitoring to be applicable in general wards, it should not lead to decreased mobility of the patient. Therefore, continuous monitoring devices should preferably be portable, wireless, and wearable on an easily accessible body part [18,24]. Such wearable devices also have the potential to be used for continuous monitoring of the vital signs of the patients at home or in rehabilitation centers, thereby possibly leading to reduced length of hospital stay and preventing unplanned readmissions [25].

The technology of wearable wireless sensors for vital signs monitoring is advancing rapidly [26]. Many manufacturers are now developing wearable sensors with different capabilities and different underlying technical specifications and algorithms [27]. The reliability and the accuracy of these devices have often only been demonstrated in healthy volunteers instead of in patients with deviating values [17]. In addition, the scientific evidence regarding the feasibility, effectiveness, and costs of these wearable sensors in clinical practice is still very limited [17,28,29]. Previous reviews on continuous monitoring of vital signs did not focus on wearable wireless devices but rather on conventional nonambulant monitoring [14]. The aim of this study was to systematically review the current evidence on wearable wireless devices for continuous vital signs monitoring by providing a thorough overview of the currently available studies.

Methods

Design

We conducted a systematic review of the literature by following the guidelines as outlined in the Cochrane Handbook for Systematic Reviews of Interventions version 6.0 and reported according the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement [30,31].

Eligibility Criteria

Studies were considered eligible for inclusion when they met the following criteria: consisted of participants older than 18 years; evaluated a continuous monitoring device that measured vital signs such as heart rate (HR), respiratory rate (RR), blood pressure (BP), temperature, and blood oxygen saturation (SpO_2) [16]; used a device that measured ≥2 vital signs; used a device that was wireless and wearable; and published after 2009. This timeframe was chosen to prevent the inclusion of papers on outdated technology. Studies were excluded when the device was not wearable by the patient and the device had no formal approval as a medical device through the Conformité Européenne (CE) mark or Food and Drug Administration (FDA) clearance or both. Furthermore, conference abstracts, review articles, letters, editorials, articles without full texts, and non-English or non-Dutch articles were excluded.

The outcomes of interest were as follows: validation (eg, sensitivity, specificity, limits of agreement [LoA]), feasibility (eg, acceptability, user experiences, system fidelity), clinical outcomes (eg, mortality, length of stay, fail-to-rescue [FTR], intensive care unit [ICU] admission), and costs (eg, cost-minimization, cost-benefit, cost-effectiveness, or cost-utility outcomes) [25,32-35].

For validation studies, the prespecified clinically relevant mean difference and LoA were 10±10 beats per minute for HR, 3±3 breaths per minute for RR, 0.5°C±1.0°C for temperature, 10±20 mmHg for systolic BP, and 3%±5% for SpO_2. The guidelines for the acceptable mean differences and LoA for continuous monitoring of vital signs are unfortunately lacking.

Search Strategy

A systematic literature search of PubMed/MEDLINE, EMBASE, and the Cochrane Central Register of Controlled Trials was performed with the last search run on September 6, 2019. In addition, the references of the retrieved studies were manually screened to obtain additional relevant studies. The following keywords were used: vital signs, clinical deterioration, and wireless continuous monitoring. Keywords on outcomes were based on terms about validation, feasibility, clinical outcomes, and cost outcomes. The full search strategy is available in Multimedia Appendix 1. The search string was audited by a clinical librarian and adapted for the individual databases and interfaces as needed. The information about the specifications of the wearable devices was obtained from the manuals and fact sheets of the manufacturers.

Study Selection

All identified references were checked for duplicates and consolidated in the reference manager software (Mendeley 1.19.5). Titles and abstracts of references were independently screened by 2 researchers against the inclusion and exclusion criteria. Full-text articles of references that matched the inclusion criteria were read independently to determine eligibility. Disagreements were resolved by discussion between the 2 review authors; if no agreement could be reached, the third author was consulted.

Data Collection Process

A data extraction sheet was developed based on the Cochrane Consumers and Communication review group's data extraction template and was pilot tested using 5 randomly selected included studies and refined accordingly [31]. One review author extracted the data from the included studies and the second author checked the extracted data. Disagreements were resolved by discussion between the 2 review authors; if no agreement could be reached, the third author was consulted.

Data Extraction and Synthesis

The following data were extracted for each study: (1) first author, country, year of publishing, aim, design, setting, patient population, sample size, and conflicts of interest; (2) manufacturer and name of the device and type of vital signs measured by the device; and (3) outcomes of the studies divided in previously defined categories: validation, feasibility, clinical, and cost outcomes. The study outcomes were presented for each device.

Risk of Bias of Individual Studies

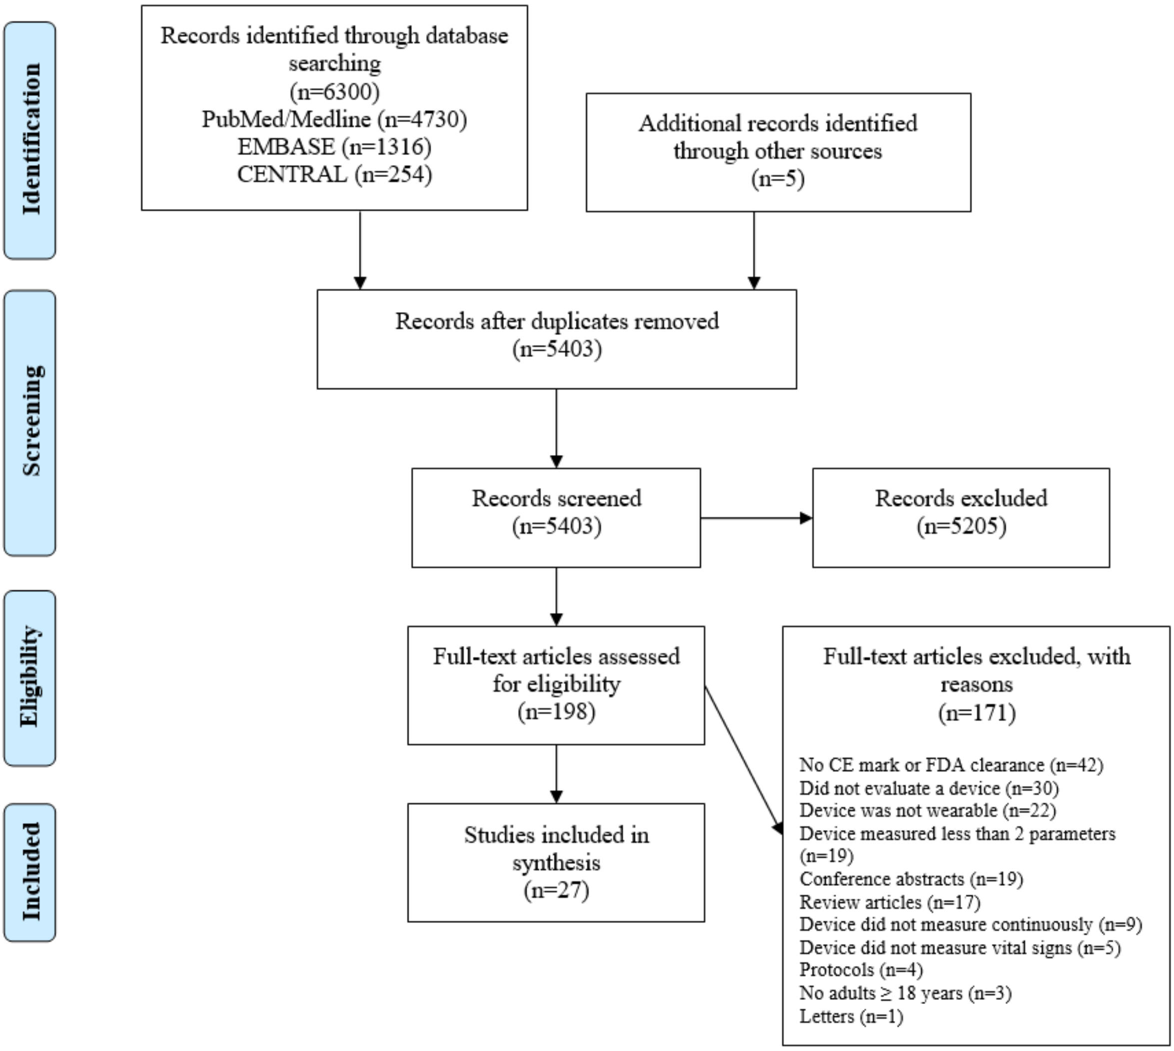
For assessing the risk of bias of individual studies, 2 authors independently appraised each study critically. Disagreements in the quality assessment between the authors were solved by discussion until consensus was reached. Owing to the large diversity of the included study designs, 3 different instruments were used. The 2018 version of the Mixed Methods Appraisal Tool (MMAT) was utilized for 5 study designs: qualitative, quantitative randomized controlled, quantitative nonrandomized, quantitative descriptive, and mixed methods [36]. Each category contained 5 criteria with the score range from 0 to 5 of the criteria met. For mixed methods studies, scores were calculated as the lowest score from among the 3 relevant designs (quantitative, qualitative, and mixed methods). A score of 0 to 2 was considered as low, a score of 3 and 4 was considered as moderate, and a score of 5 was considered as high. For diagnostic accuracy study designs, the quality assessment of diagnostic accuracy studies 2nd edition (QUADAS-2) was utilized to assess the risk of bias [37]. QUADAS‐2 consists of 4 domains: patient selection, index test, reference standard, and flow and timing. All domains were assessed for the potential for risk of bias and the first 3 domains, that is, patient selection, index test, and reference standard were assessed for concerns regarding applicability. For economic evaluation studies, the quality of health economic studies (QHES) tool was utilized to assess the quality [38]. The QHES instrument is a validated method for assessing the quality of health economic analyses. It consists of 16 items, each with specific weight values ranging from 1 to 9. Each score is multiplied by the weight to produce a total score, with a maximum score of 100.

Results

Study Selection

We identified 5403 potentially relevant studies in our literature search after duplicate removal, of which 5 studies were accessed from the reference list of the potentially relevant studies. Screening of titles and abstracts resulted in 198 studies, which were read full text. Eventually, 27 studies that met the eligibility criteria were included [39-65]. A PRISMA flowchart of the search is presented in Figure 1.

Figure 1. PRISMA flowchart. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses; CENTRAL: Cochrane Central Register of Controlled Trials; CE: Conformité Européenne; FDA: Food and Drug Administration.



Study Characteristics

In this study, 13 different devices of 10 manufacturers were studied in 2717 subjects (median 43, range 6-736). Subjects were healthy patients, trauma patients, surgical patients, or neurological/neurosurgical patients (Table 1). The 13 devices were as follows: ViSi Mobile, SensiumVitals, HealthPatch MD, VitalPatch, Wireless Vital Signs Monitor (WVSM) device, MiniMedic, Zephyr BioPatch, Biosensor, IntelliVue Cableless Measurement Solution, Wavelet Wristband, Proteus patch, Alarm Management System, and EQ02 Lifemonitor (Table 2).

Of the 27 included studies, 15 were from the United States and the remaining were from the United Kingdom (N=6), the Netherlands (N=2), Canada (N=1), China (N=1), Australia (N=1), and Austria (N=1). Among these, 13 were validation studies, 6 were cohort studies, 2 were case-control studies, 3 were mixed methods studies, 1 was a qualitative study, and 2 were pilot randomized controlled trials. The reported outcomes were validation (N=15), feasibility (N=15), and clinical outcomes (N=6; Table 3). Seventeen studies declared that they had no conflicts of interest. In 6 studies, one or more authors were employees of the manufacturing company of the studied device. The remaining 4 studies did not declare any possible conflicts of interest (Table 1).

Devices

ViSi Mobile

Five studies (N=1308) have been published about the ViSi Mobile (Sotera Wireless; Table 1) [39,40,51,59,60]. This device is worn on the wrist, upper arm, or chest, and it measures HR, RR, BP, SpO_2, and skin temperature (Table 2) [66].

Validation outcomes: This device was validated in 1 study, which reported an acceptable mean difference but wide LoA between the device and manual nurse measurements for HR, RR, and BP (Table 4) [59]. SpO_2 had an acceptable mean difference and LoA.

Of the 27 included studies, 15 were from the United States and the remaining were from the United Kingdom (N=6), the Netherlands (N=2), Canada (N=1), China (N=1), Australia (N=1), and Austria (N=1). Among these, 13 were validation studies, 6 were cohort studies, 2 were case-control studies, 3

were mixed methods studies, 1 was a qualitative study, and 2 were pilot randomized controlled trials. The reported outcomes were validation (N=15), feasibility (N=15), and clinical outcomes (N=6; Table 3). Seventeen studies declared that they had no conflicts of interest. In 6 studies, one or more authors were employees of the manufacturing company of the studied device. The remaining 4 studies did not declare any possible conflicts of interest (Table 1).

Feasibility outcomes: Patients reported the wristband as big or heavy. Four studies reported the perceptions of the health care professionals [39,51,59,60]. Nurses mentioned that this device had a short battery life and poor connection but it reported better insight into the vital signs [59]. Both nurses and physicians felt confident about their ability to identify patients at risk of deterioration but were concerned about the accuracy of the device [39,59]. Besides, physicians were positive about the potential of continuous monitoring, as this device provided reassurance to patients and supported interdisciplinary communication between nurses and physicians [39]. Another study stated that 67% of the nurses were positive about the deployment of continuous monitoring in the ward [51]. All nurses were positive that the monitor provided valuable patient data that increased patient safety [60]. However, they had certain reservations, including the potential decrease in the bedside nurse-patient contact, increase in inappropriate rapid response team (RRT) calls, and possible discomfort for patients wearing the device [39]. Two studies reported system fidelity. The system generated 2 to 10 alarms per patient in a day [40,60], of which one study [60] reported that 92% of the nurses indicated that the number of alarms were appropriate. One study showed that 70% of the artefacts, defined as the noncollected parameters, were caused by connection failure and 74% lasted less than 5 minutes [59].

Clinical outcomes: RRT calls, FTR, unexpected deaths, and ICU transfers were not significantly reduced by continuous monitoring [40,51]. The complication rate was higher in the intermittent monitoring group than in the continuous monitoring group [51]. One study described only 4 alert-initiated interventions in 236 patients [60]. The quality of these studies ranged from low to moderate, as assessed by the MMAT tool, thereby indicating that these studies are subject to bias (Figure 2).

Cost outcomes: None of the studies reported this type of outcome.

SensiumVitals

Five studies (N=371) have been published about the SensiumVitals (Sensium Healthcare; Table 1) [56,61-64]. This is a patch device attached to the chest for continuous monitoring of the HR, RR, and axillary temperature (Table 2) [67].

Validation outcomes: This device was validated in 3 studies. Two studies included surgical patients [63,64] and 1 included healthy volunteers [61]. The results were conflicting. The mean difference between the device and reference standard was acceptable for HR and RR (Table 4). For HR, LoA was acceptable in 2 studies and outside acceptable limits for 1 study. For RR, LoA was wide for all studies. One study [64] reported temperatures outside acceptable ranges. Furthermore, RR was frequently rejected by the algorithm owing to the inaccuracy of the measurement [61,63]. However, the results may be biased owing to the high risk of bias at the reference standards and patient selection (Figure 2). In addition, 2 of the 3 studies [61,63] were authored by the employees of the SensiumVitals manufacturing company and one study was also funded by the manufacturer [61].

Feasibility outcomes: Two studies described the feasibility of this device. One qualitative study showed the patient perceptions [56]. Six themes emerged from the interviews: (1) patients emphasized the importance of nursing contact, (2) patients indicated that they hoped to be disturbed less for night-time observations with the new monitoring system, (3) patients reported high comfort, (4) patients experienced a high sense of security, (5) patients expressed that monitoring could be a solution for the busy nursing staff, and (6) patients expressed reservations about the reliability of the technology such as the data security and system failure. The second study reported that patients were comfortable with the patch and that it enhanced the feeling of safety although 16.4% discontinued the intervention owing to the discomfort before the end of the study [62].

Clinical outcomes: Only one study reported the clinical outcome. In that study, no statistically significant better clinical outcomes for the patch group were seen, possibly owing to the sample size [62]. Notably, the authors reported that an unacceptable high number of alerts were sent to the nurses before adjusting the alarm thresholds. Since the quality of these studies was rated from low to high by the MMAT tool, possible bias is introduced (Figure 2).

Cost outcomes: None of the studies reported this type of outcome.

VitalPatch and HealthPatch MD

Five studies (N=133) have been published on the VitalPatch and its previous version HealthPatch MD, which is not available anymore (VitalConnect; Table 1) [41-43,65]. Of them, one mixed methods study compared the HealthPatch with the ViSi Mobile [59]. This patch device is applied to the chest and measures HR, RR, and ST (Table 2) [68].

Validation outcomes: This device was validated in 4 studies. For HR, the mean difference was acceptable for all studies and LoA was acceptable for 2 studies (Table 4). The mean difference for RR was acceptable; however, all studies reported LoA outside of the preset acceptable range. One study reported a mean absolute error of less than 3 for HR and 1 for RR [65]. All studies were subject to potential bias at patient selection and the reference standard (Table 4).

Feasibility outcomes: The acceptability of this device was reported as high by the majority of the nurses [41]. However, the exact numbers were not reported. Besides, the health care professionals recommended that it was necessary to gain experience with use of the device in clinical practice [41]. Patients reported that the HealthPatch did not restrict them in daily activities. The fidelity of the system was reported in 2 studies, of which one study reported a loss of data of 6% [42].

They compared several thresholds; 63% of the measurements were performed without data loss greater than 2 minutes. In addition, another study reported that more than 50% of all the artefacts lasted for less than 1 minute, and 43% of them lasted for less than 5 minutes [59]. The reasons for these artefacts were wireless signal connection problems or losing skin contact.

None of the studies reported the clinical and cost outcomes.

WVSM Device

Two studies (N=305) evaluated the WVSM device (Athena GTX) in trauma patients (Table 1) [45,69]. This device measures the HR, BP, RR, and SpO_2 continuously and is worn on the chest, upper arm, and fingertips (Table 2) [70].

Feasibility outcomes: One study reported the feasibility outcomes [45]. This study was a posthoc analysis of the previous study of Liu et al [69]. They found at least 75% adequate data for BP, HR, and RR for predicting life-saving interventions (LSIs) [45]. However, the results were subject to bias because of a high risk of bias in the following categories: patient selection and flow and timing (Figure 2).

Clinical outcomes: One study reported the clinical outcomes and showed that the data of this device were accurate in comparison with that shown in a conventional monitor for the determination of LSIs, without periodic loss of signals or other errors [69]. The authors learned during the study that new medical devices to be used for prehospital studies require integration into the local information technology infrastructure. The quality of this study was rated as high (Figure 2).

None of the studies reported the validation and cost outcomes.

MiniMedic

Two studies (N=155) evaluated the MiniMedic (Athena GTX) in trauma patients (Table 1) [49,50]. This device measures the HR, SpO_2, and ST both at the fingertip and in the forehead (Table 2). In addition, a Murphy factor, an injury acuity algorithm that generates a score, can be calculated for triaged patients in need of LSIs [71].

Validation outcomes: One study compared the pulse-wave transit time, a derivate of BP, reported in the device with the BP reported in the conventional monitor and found correlations between them (R^2=0.036, P<.001; Table 3) [50]. Temperature measurements were significantly different between the device and the reference standard and between the fingertip and the forehead sensor of the device. For HR, a mean difference of 3 beats per minute was found between the device and the reference standard (P<.001). For SpO_2, the median difference between the conventional monitor and the fingertip sensor was 0% and that between the conventional monitor and the forehead sensor was 7% (P<.001). However, this study had a high possibility of bias at patient selection (Figure 2). The second study demonstrated that the MiniMedic was capable of computing a single numeric value, the Murphy factor, to summarize the overall patient status and to identify prehospital trauma patients who need LSIs [49].

None of these studies reported the feasibility, clinical, and cost outcomes.

Zephyr BioPatch

Three studies (N=85) have been published about the Zephyr BioPatch (Medtronic Annapolis; Table 1) [46-48]. This is a patch or a patch fixed by a harness on the chest and it measures the HR, RR, and the estimated core temperature (Table 2) [72].

Validation outcomes: Two studies reported the validation outcomes (Table 3). One study was conducted in healthy volunteers during graded exercise and in a hot environment and one was conducted in full-term pregnant women [47,48]. For HR, both studies reported acceptable mean differences but nonacceptable LoA. For RR, one study [47] reported acceptable mean differences but nonacceptable LoA for RR but the other study [48] that also reported acceptable mean differences but nonacceptable LoA for RR was subjected to a high risk of bias at patient selection (Figure 2). Therefore, Boatin et al [47] are the only researchers who have reported acceptable mean differences but nonacceptable LoA for RR.

Feasibility outcomes: Considering the feasibility outcomes, the participants found the patch comfortable (78%), likeable (81%), and useful (97%). Among nurses, 80% of the nurses found the monitor easy to use and 84% would recommend it to patients [47]. Another study reported a retention rate of 88.6% at the end of the 24-hour monitoring period after exclusion of 2 patients with poor electrocardiogram (ECG) signals [46]. Furthermore, the authors interviewed patients and nurses about any challenges wearing the sensors. Both groups did not report any challenges. The quality of the studies was rated as moderate and high (Figure 2).

None of the included studies reported the clinical and cost outcomes.

Biosensor

One study (N=17) reported about the Philips Biosensor, which is a rebrand of the VitalConnect's HealthPatch (Table 1) [57]. This device is able to measure HR, RR, and ST (Table 2) [73].

Validation outcomes: This study only compared the RR of the device with a reference standard. This resulted in acceptable limits of mean difference of 3.5±5.2 breaths per minute and a statistically significant correlation of Spearman's ρ of 0.86. However, results may be biased due to the high risk of bias regarding patient selection and flow and timing (Figure 2). In addition, 2 authors were employees of Philips and the study was funded by the manufacturer.

This study did not report the feasibility, clinical, and cost outcomes.

Wavelet Wristband

One study (N=35) reported about the Wavelet Wristband (Wavelet Health), a watch that monitors HR and RR (Table 1 and Table 2) [52,74].

Validation outcomes: For HR, acceptable mean differences and LoA were found (Table 4). For RR, the LoA was outside of the acceptable limits. However, all aspects of risk of bias were either unclear or high and applicability was low (Figure 2). Besides, 4 authors were former or current employees of the manufacturing company.

This study did not report the feasibility, clinical, and cost outcomes.

Proteus Patch

We found 1 study (N=13) that reported about the Proteus patch (Proteus Digital Health; Table 1) [53]. This device monitors HR, RR, and ST (Table 2) [75].

Feasibility outcomes: In the feasibility study, the patch was able to monitor for over 5 days at home. However, data of 2 patients was insufficient for performing the analysis and were excluded. The quality of the study was rated as low (Figure 2).

This study did not report the validation, clinical, or cost outcomes.

IntelliVue Cableless Measurement Solution

We found about the IntelliVue Cableless Measurement Solution (Philips) in 1 study on clinical patients (N=226; Table 1) [54]. This is a device for monitoring the HR, RR, BP, and SpO_2 (Table 2) [76].

Feasibility outcomes: There was an overall good acceptance by patients and health care professionals. No data was lost due to technical difficulties over a median monitoring period of 178 minutes per patient. The quality of the study was rated as high (Figure 2).

This study did not report the validation, clinical, or cost outcomes.

Equivital EQ02 Lifemonitor

We found 1 study (N=6) that reported about the Equivital EQ02 Lifemonitor (Hidalgo Ltd) for measuring the HR, RR, ST, and core temperature by using a chest-worn belt monitor (Table 1 and Table 2) [55]. The core temperature was measured using an ingestible pill [77].

Validation outcomes: Acceptable results were found for HR and RR (Figure 2). Skin temperature was outside of the acceptable limits for mean difference and LoA, but the core temperature measurement was considered as acceptable. However, these results were subjected to a high risk of bias at patient selection and reference standard (Figure 2).

This study did not report the feasibility, clinical, and cost outcomes.

Alarm Management System

We found 1 study (N=250) that reported about the Alarm Management System (Covidien; Table 1) [58]. This device was worn at the fingertip and it measures HR and SpO_2 (Table 2).

Feasibility outcomes: The authors reported that 86.6% of the patients completed the monitoring period in the study. Besides, a mean of 4 alarms per week was reported due to decreased SpO_2 in about 75% of the alarms.

Clinical outcomes: The authors reported respiratory event rates, ICU transfer, and RRT calls. However, this occurred 0 times in the control and 1 time in the intervention group. Eventually, the quality of this study was rated as high (Figure 2).

This study did not report about the validation or cost outcomes.

Discussion

Summary of Evidence

In this study, we aimed to provide a systematic review of the current evidence on wearable wireless continuous monitoring devices for vital signs monitoring. We included 27 studies, which evaluated 13 different wearable devices. Overall, the studies predominantly evaluated the validation of the recorded data (N=15) or the feasibility (N=15) of these devices. Clinical outcomes were only reported in 6 studies, and studies describing the cost outcomes are still lacking. Although 13 different devices were included in this review, these devices did not share the same indication in terms of monitoring. In general, 2 main target indications could be identified. First, the ViSi Mobile, WVSM Device, MiniMedic, and IntelliVue Cableless Measurement Solution were designed for more extensive prehospital (ambulance) or clinical physiological monitoring. This monitoring level may be comparable to standard ICU monitoring, and therefore, these devices are usually bulkier wearable devices. Second, patch, wristband, and harness devices such as the SensiumVitals, VitalPatch, Philips Biosensor, Zephyr BioPatch, EQ02 Lifemonitor, Alarm Management System, Wavelet Wristband, and the Proteus patch were designed for ambulant wireless clinical monitoring of only a few basic vital signs. These devices are possibly more suitable for patients in the general ward and for monitoring the vital signs at home.

Regarding the validation of the devices, a few considerations should be taken into account. Many of these studies were conducted in healthy volunteers, which may introduce a bias owing to the lack of deviating vital signs values when compared to the vital signs of the actual patients. Further, for technical reasons, vital signs cannot be measured continuously by wearable sensors with equal accuracy. In particular, the RR and temperatures still appear to be difficult to be measured reliably in several included studies. In fact, the optimal reference standard for measuring RR has still not been found, although it is considered to be the most important parameter for predicting clinical deterioration [78-81]. In addition, the optimal method for measuring temperature by using wearable wireless devices has yet to be found. Most devices measure the skin temperature, which is known to be unreliable as equivalent for core temperature [82-84].

Feasibility outcomes were focused on acceptability by health care professionals and patients. In general, both groups were positive about the deployment of the devices. In addition, the operation of the system was evaluated, such as the completeness of the measurements and the number and appropriateness of the alarms. Both outcomes were assessed as feasible.

The impact of these devices on clinical outcomes is still unclear because most included studies were underpowered to demonstrate any significant effect. However, multiple studies described cases wherein a complication was recognized earlier by the device and acted upon in a timely manner.

Regarding costs, no outcomes were reported about the devices in the included studies. Such data may however be essential for preparing future business cases for large-scale implementation, considering the relatively high cost of such monitoring devices and platforms [85].

Previously published reviews on continuous monitoring did not focus on wearable devices, except for one, but this was not a systematic review [32]. We found comparable but also contrasting results in that study [32]. The review of Joshi et al [32] reported the same devices as those reported by us as well as some other devices that we excluded since there were no published studies about those devices or they were published before 2009. In line with our results, they also concluded that the diagnostic accuracy of the devices was suboptimal, especially the alarm rates and the false alarms. In addition, they also indicated that there were no sufficiently powered studies to show beneficial clinical effects or cost-effectiveness.

In a review of nonwearable devices, Cardona-Morrell et al [14] found that early detection of deterioration was enhanced but there were no significant improvements in the clinical outcomes, which is in line with our findings regarding wearable devices. This could be explained by the heterogeneous and underpowered character of the included studies [14]. Downey et al [86] also came to this conclusion and further stated that continuous monitoring seems to be feasible in terms of the frequency of implementation in hospitals; they found that patient and nurse perceptions were positive and that continuous monitoring may be cost-efficient.

Limitations

This systematic review had several limitations. First, the quality varied across the included studies. Several accuracy studies contained high risk of bias regarding patient selection as well as the applicability. Further, the reference standard was often not free from potential bias. Considering the studies assessed with the MMAT tool, quality was predominantly rated 2 or 3 out of 5; therefore, bias is present. Moreover, assessing the quality of the studies and comparing these studies was difficult owing to the heterogeneity of the included studies. Therefore, performing a meta-analysis was not possible owing to the heterogeneity in the devices and the outcomes. Second, 5 of the included studies had possible conflicts of interest owing to funding by the manufacturer or because employees of the manufacturing companies of the devices played a role in the conduct of the study. This highlights the possible risk of reporting and publication bias within this field of research. Third, there were some limitations about the search. We only focused on devices that measured at least two vital signs. However, this cut-off was based on previous studies about the predictive value for clinical deterioration. These studies found that the more vital signs are monitored, the more accurate the detection is [87,88]. Besides, we only focused on off-the-shelf devices with a clearance by the CE mark or FDA as a medical device for clinical use. We excluded 42 prototype studies that were considered to be less clinically relevant for health care professionals. However, this indicates that there may be many more monitoring devices that will be launched in the health care market in the future. Besides, the review was restricted to English and Dutch publications published from 2009 and after. Only a few studies were excluded based on language and the older studies were considered be less clinically relevant owing to outdated technology. Fourth, we prespecified the clinically relevant mean difference and LoA for vital signs. It may be clinically desirable to redefine acceptable accuracy limits depending on the value of the vital signs measured and the patient population. For example, a difference of 3 breaths per minute is more clinically relevant in a range of 5-8 breaths per minute than with 30-33 breaths per minute. However, reliable evidence or guidelines for continuous monitoring of vital signs are currently lacking.

Clinical Implications

This review outlines several important clinical implications before health systems may proceed to large-scale implementation of wearable wireless continuous monitoring devices for vital signs monitoring for patients in the hospital and at home. For both settings, vital signs data measurements should be accurate, reliable, and validated in clinical studies. This is especially important for the home setting, wherein a health care professional is not readily available to assess the clinical condition of the patient. For further optimization, the monitoring measurements should preferably be incorporated into an early warning score system supported by a validated decision support algorithm [89]. These analysis algorithms should be further enhanced to prevent too many alarms in order to avoid alarm fatigue [90]. Further, for optimal adoption into clinical workflows, the vital signs measurements should preferably be integrated into the electronic medical record. This will likely improve commitment and compliance from nurses and doctors and will also allow for the summarized monitoring data to be archived in the patient records [32]. When all such factors are optimized, it is anticipated that studies will be able to show a significant effect on clinical outcomes. For monitoring patients at home, the patient data need to be sent to health care professionals through a stable and secure wireless connection. Such a system will need to be embedded in a validated care work flow, thereby providing alarm reviews by care professionals who will assess, make an initial phone call, and then escalate to a home visit by a nurse or direct the patient to the emergency department when needed [91]. Furthermore, for home monitoring, the devices should be small, flexible, and hypoallergenic and not bother patients during their daily activities [18,24]. Battery life, which currently ranges from 3 to 7 days in most devices, may be further extended especially for long-term monitoring of patients with chronic diseases such as heart failure [18,19]. Eventually, when all the conditions are optimized, larger studies may be able to demonstrate that continuous home monitoring safely allows for routine early discharge from the hospital. Further, such a system may potentially provide timely detection of complications, and thereby prevent readmissions, improve overall outcomes, and decrease health care costs [21,92].

Conclusions

Continuous monitoring devices are mostly still in the validation and feasibility phases. Besides, studies reporting clinical outcomes are still sparse and cost outcome studies are still lacking. Such studies are needed to help health care professionals and administrators in their decision making regarding the implementation of these devices on a large scale in clinical practice or in home monitoring.

Acknowledgments

This study was funded by the Innovation and Science Fund of Isala (grant number: INNO 1915).

Authors' Contributions

JL conceived the presented idea. JL, CH, HvW, LS, and GP designed the methods. JL conducted the search, JL and CH independently included the studies, extracted the data, and were responsible for the quality assessment whereas HvW, LS, and GP provided supervision during all the stages. All authors discussed the results and contributed to the final manuscript.

Abstract

Background: There is a high prevalence of children and young people (CYP) experiencing mental health (MH) problems. Owing to accessibility, affordability, and scalability, an increasing number of digital health interventions (DHIs) have been developed and incorporated into MH treatment. Studies have shown the potential of DHIs to improve MH outcomes. However, the modes of delivery used to engage CYP in digital MH interventions may differ, with implications for the extent to which findings pertain to the level of engagement with the DHI. Knowledge of the various modalities could aid in the development of interventions that are acceptable and feasible.

Objective: This review aimed to (1) identify modes of delivery used in CYP digital MH interventions, (2) explore influencing factors to usage and implementation, and (3) investigate ways in which the interventions have been evaluated and whether CYP engage in DHIs.

Methods: A literature search was performed in the Cochrane Library, Excerpta Medica dataBASE (EMBASE), Medical Literature Analysis and Retrieval System Online (MEDLINE), and PsycINFO databases using 3 key concepts “child and adolescent mental health,” “digital intervention,” and “engagement.” Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines were followed using rigorous inclusion criteria and screening by at least two reviewers. The selected articles were assessed for quality using the mixed methods appraisal tool, and data were extracted to address the review aims. Data aggregation and synthesis were conducted and presented as descriptive numerical summaries and a narrative synthesis, respectively.

Results: This study identified 6 modes of delivery from 83 articles and 71 interventions for engaging CYP: (1) websites, (2) games and computer-assisted programs, (3) apps, (4) robots and digital devices, (5) virtual reality, and (6) mobile text messaging. Overall, 2 themes emerged highlighting intervention-specific and person-specific barriers and facilitators to CYP's engagement. These themes encompassed factors such as suitability, usability, and acceptability of the DHIs and motivation, capability, and opportunity for the CYP using DHIs. The literature highlighted that CYP prefer DHIs with features such as videos, limited text, ability to personalize, ability to connect with others, and options to receive text message reminders. The findings of this review suggest a high average retention rate of 79% in studies involving various DHIs.

Conclusions: The development of DHIs is increasing and may be of interest to CYP, particularly in the area of MH treatment. With continuous technological advancements, it is important to know which modalities may increase engagement and help CYP who are facing MH problems. This review identified the existing modalities and highlighted the influencing factors from the perspective of CYP. This knowledge provides information that can be used to design and evaluate new interventions and offers important theoretical insights into how and why CYP engage in DHIs.

Introduction

Prevalence of Mental Health Problems in Children and Young People

Mental health (MH) problems in childhood and adolescence are of great importance because of their prevalence, early onset, and impact on different areas of the child's life [1]. The number of children and young people (CYP) who experience MH problems ranges from 10% to 20% worldwide [2]. An international study conducted in 27 countries estimated the worldwide pooled prevalence of MH problems to be 13.4% among CYP [3]. Specifically, anxiety and disruptive behavior disorders seem to be the most frequent presentations (Table 1) [3]. Estimates further suggest that approximately 1 in every 3 adolescents will meet the criteria for anxiety and depressive disorders [2], while 1 in 4 young people aged 16 to 24 years has experienced at least one MH problem in the past year [3].

Table 1. Prevalence of mental health problems in children and young people.

Mental health problem	Prevalence (%) (adapted from Polanczyk et al [3])
Anxiety	6.5
Disruptive behavior	5.7
Oppositional defiance disorder	3.6
Attention-deficit hyperactivity	3.4
Depression	2.6
Conduct	2.1

Benefits of Digital Health Interventions

Addressing MH problems in CYP is a major public health concern [4,5], which has been impaired by low levels of youth help-seeking behavior [6]. Concerns about stigma and confidentiality, shame or embarrassment in discussing personal issues, financial costs, and/or limited access to services are among the many barriers to accessing help in this population [6-8]. In many instances, existing efficacious face-to-face interventions are adapted using digital technology as a means of addressing these barriers [9]. Digital health interventions (DHIs; eg, internet programs, apps, virtual reality environments, robotic systems) have the potential to be effective, with advantages of accessibility, anonymity, prompt feedback, cost-effectiveness, applicability in real-life contexts, and high treatment fidelity [7,10-15]. Therefore, considering the increased digital literacy and internet use among youth [16], DHIs may serve as a new way to increase accessibility to MH interventions in this population [17,18].

Efficacy of Digital Health Interventions

The World Health Organization (WHO), the United Kingdom's National Health Service, and the US National Institute of Mental Health have identified MH apps as cost-effective and scalable solutions for addressing the MH treatment gap [19]. The efficacy of web-based therapies is well established in the treatment of several MH problems, including depression, anxiety, and substance misuse among adolescents [20-22]. Web-based treatment programs have also demonstrated comparable efficacy to face-to-face psychotherapy [23,24]. In addition, smartphone-based MH interventions have been shown to be a promising self-management tool for depression [25] by reducing symptoms, similar to face-to-face interventions. Equivalent results were also found for anxiety-focused mobile apps [26]. Recent systematic reviews have shown that interventions based on computerized cognitive behavioral therapy are a promising and acceptable way to reduce anxiety and depression in CYP [17,18]. The findings also support the clinical benefits of DHIs for other symptoms and disorders such as autism spectrum disorders, attention deficit, and behavioral disorders [27].

Research on Digital Mental Health Interventions for Children and Young People

Despite the growing interest in using mobile apps to deliver interventions, more research evidence is needed to support implementation in children and young people’s mental health (CYPMH) services [27-29]. For instance, the evaluation of DHIs is increasingly discussed in electronic health research. A recent review showed that the majority of registered DHI evaluation trials employ common methods, such as the randomized controlled trial (RCT) study design [30]. There is much debate in the literature on appropriate methods for evaluating the impact of DHIs [31]. For instance, given the speed at which technologies advance, adaptive research designs may be more useful for increasing usability and ability to respond in a timely manner to users’ experiences [32]. Considering the limitations of traditional research designs, new methodological frameworks and research designs have been developed (eg, continuous evaluation of evolving behavioral intervention technologies [33] and microrandomized trials [34]). To develop DHIs that are more useful and thereby more engaging for users, researchers agree that the impact of different functionalities on levels of engagement is important [35]. Engagement with digital behavior change interventions has been defined in the literature as a subjective experience (the user-perceived state of *flow*, characterized by temporal dissociation, focused attention, interest, and enjoyment) or as a behavior (extent of usage of the DHI over time or adherence) [36]. Perski et al [36] proposed an integrated conceptualization of engagement that includes both the extent (eg, amount, frequency, duration, and depth) of usage and the subjective experience of “what it feels” to be engaged (eg, attention, interest, and affect). However, engagement is usually assessed through the evaluation of the user interaction with the DHI, either by user-reported tools (eg, questionnaires, interviews, or think-aloud studies), by automated recordings of use (eg, log-ins, page views), or by recording physiological or psychophysical correlates of DHI interaction [36].

Despite the potential of DHIs, researchers have identified several limitations that influence practicality [37]. The main limitations identified were restricted tailoring to patient needs, challenges with managing comorbidity and acute crisis [38], low patient engagement and high dropout rates [39]. Although efforts have been made to reduce these occurrences with strategies such as gamification, tailoring, and guided self-help, the aforementioned difficulties remain [27,38,39]. In addition, further challenges arise from cautious attitudes of professionals toward DHIs, such as failure to address important aspects of the disease, data security, and accessibility [40].

Rationale for This Review

The rapid advancement of technology [41] and the increasing interest of CYP in technology [16] calls for a better understanding and evaluation of DHIs used to *engage* CYP with MH problems [42,43]. Engagement is commonly referred to as the active involvement of participants with the intervention, also described in previous literature as *participation*, *adherence*, *noncompliance*, or *resistance* [44]. This knowledge is crucial to support the development and evaluation of DHIs that are acceptable and feasible in CYPMH settings. This review sets out to contribute to the growing body of knowledge on digital CYPMH interventions by investigating modes of delivery used in DHIs. Although recent meta-analyses highlighted the potential effectiveness of CYPMH DHIs [17,18,45], this review aimed to present information that might be of use in the development of real-world interventions that are more likely to increase engagement from CYP.

Aims

The primary aim of this study was to review the literature to identify modes of delivery used to engage CYP in digital MH interventions. Second, we explored barriers and facilitators for the usage and implementation of DHIs. The authors also aimed to investigate the ways in which these interventions have been evaluated and whether CYP engage in DHI research. The following questions were addressed:

1. What modes of delivery are used for engaging CYP in digital MH interventions?
2. What are the barriers and facilitators to engaging CYP in digital MH interventions?
3. How do retention rates vary in CYP digital MH intervention research?

Methods

Literature Search and Search Strategy

A literature search was conducted using the Cochrane Library, EMBASE, MEDLINE, and PsycINFO databases. All searches were carried out on the same day (December 27, 2018) to control for daily updates. Overall, 3 key concepts informed the search strategy: *child and adolescent mental health*, *digital intervention*, and *engagement*. Terms within similar categories were combined with *OR* and then the results from each category were combined with *AND* (see Multimedia Appendix 1). The search strategy was guided by similar reviews exploring technology or engagement in child and family MH treatment [44-46], the review team discussions, and input from the University College London Institute of Child Health librarian. Reference lists of relevant articles were also scanned for additional potential studies. An initial sample of articles identified through database searching was screened first by titles and abstracts. Next, the full-text versions of potentially relevant studies were retrieved and examined in detail for eligibility at the review team meetings. Differences regarding study selection were resolved by discussion among the authors.

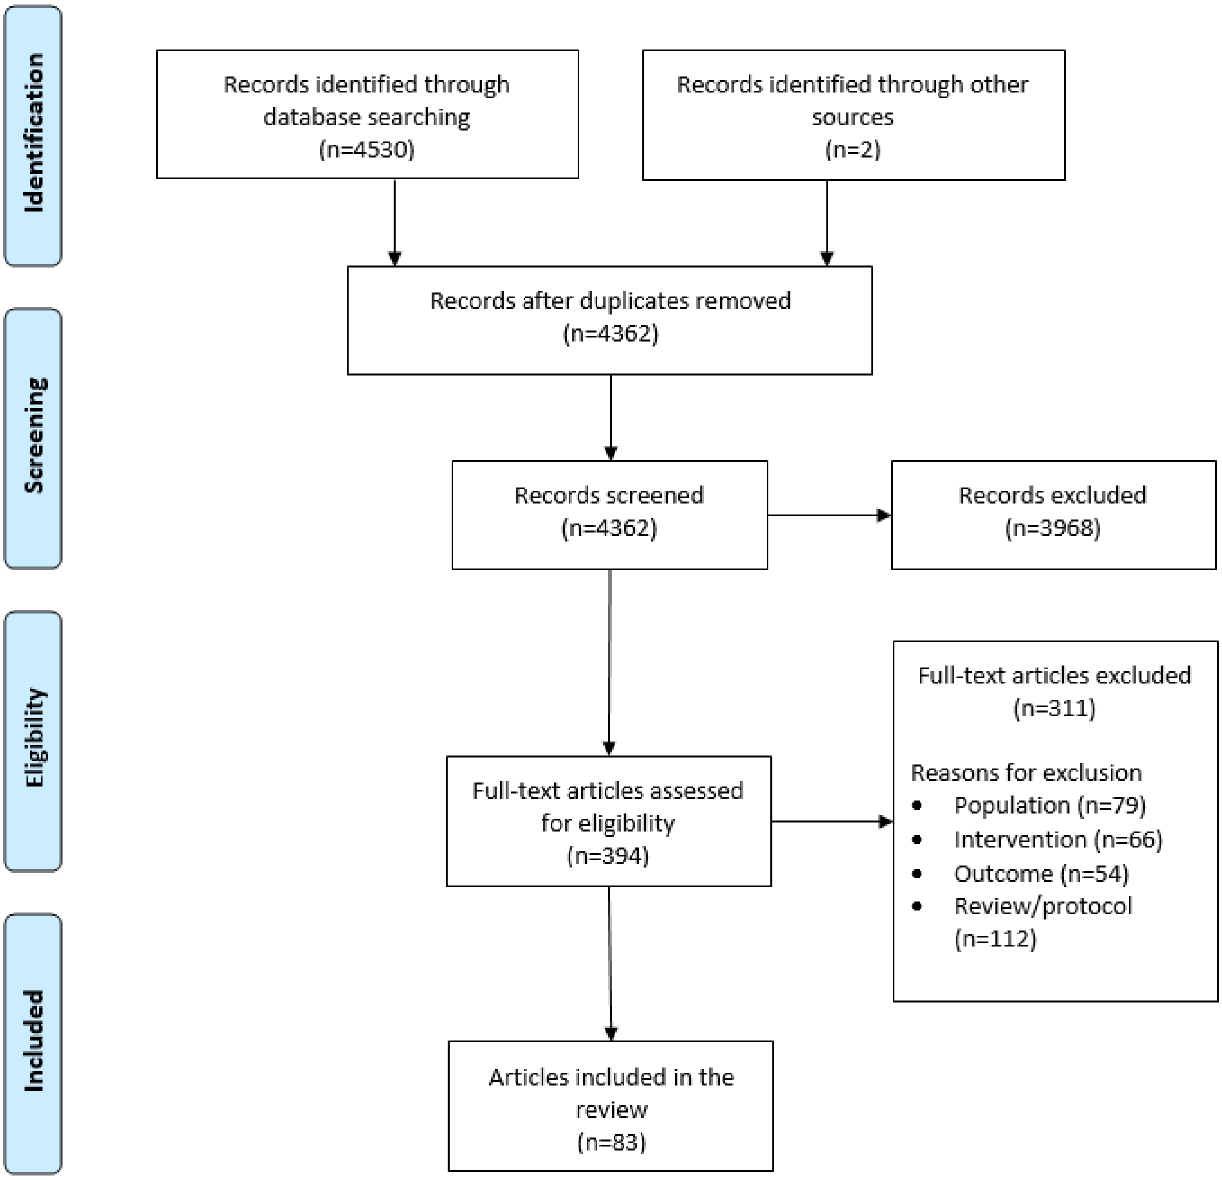
Inclusion and Exclusion Criteria

Screened articles were included if (1) the study targeted a CYP sample with a mean age less than 25 years; (2) the article described a DHI targeting an MH symptom (related to a primary physical/somatic condition) or the intervention was being used by CYP with MH problems; and (3) the study explored the development or testing of a DHI resulting in data on adherence, acceptability, or barriers and facilitators to engagement. Any study design was deemed acceptable for inclusion. Articles were excluded if (1) the age of the participants was not defined or if the mean age of the sample was 25 years and above, (2) the intervention was for the sole purpose of communicating between a health care professional and the CYP (eg, Skype, email, teleconference, or messages for appointment reminders), (3) the outcome of the study was not clearly defined or did not provide sufficient details to determine if the outcome was directly related to the intervention, and (4) the study had no human participants (eg, discussion articles describing a novel intervention).

Study Selection Process

In accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines [47], the flowchart presented in Figure 1 provides step-by-step details of our study selection process. After duplicates were removed, at least two members of the review team independently screened the titles and abstracts against the inclusion criteria. The full-text versions of the remaining potential articles were further examined by at least two reviewers for final inclusion. Articles excluded at this stage described interventions that were being used for communication purposes only, did not provide sufficient details of the intervention, were reviews or study protocols, were those in which the age range was not specified or was above the cutoff, targeted a non-MH condition only or targeted parents or clinicians, or had an outcome that was not related to the intervention. Any disagreements were resolved through discussions.

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses flow chart of the study selection process.



Data Extraction and Quality Assessment

A standardized form [48] that was adapted and piloted by the review team was used to extract relevant information from each article, including the following: reference, year, country, study aims, study design, sample size, setting, clinical characteristics, type of support including therapeutic treatment, retention rate, outcome, and descriptive characteristics of the sample and the intervention. Study-specific data for the second review question were also extracted at this stage to inform the thematic framework [49]. The mixed methods appraisal tool (MMAT-v2018) [50] was used to assess the methodological quality of each selected study. This tool was discussed in detail and selected based on its ability to report on the quality of varying study designs. Responses were rated on a categorical scale as "no," "can't tell," or "yes" to any of the methodological quality criteria. The number of items rated "yes" was counted to provide an overall score out of a possible 5 [51]. If at least one of the MMAT quality criteria was met, the methodological quality of the study was considered acceptable and the record was included. SL and a second member of the review team independently extracted all data and independently conducted the quality assessment. The 2 reviewers discussed any discrepancies and, if necessary, consulted a third team member to reach a final decision.

Data Aggregation and Synthesis

The extracted data were collated and summarized to produce a narrative summary of the study characteristics that addressed the first review question. A descriptive numerical summary was presented to group articles by the primary digital platform used to deliver the intervention. SL completed a qualitative data-driven thematic analysis [52] in addition to inductive analysis informed by the Digital Behaviour Change Framework [53] to address the second review question. Moreover, this framework and the capability, opportunity, motivation, and behavior (COM-B) model [54] were used to explore the factors influencing behavior change and intervention design. The coding process involved moving backward and forward between the data and emerging concepts. The first step generated initial codes from open coding, in which units of meanings were derived from a line-by-line analysis followed by axial coding to integrate and differentiate among subcategories. Qualitative findings relating to barriers and facilitators were coded in NVivo [55]. The review team reviewed the coding process, and any disagreements were discussed before reaching a consensus. There were no major disagreements, and consequently, the codes were developed into themes. For the purpose of addressing the third review question, the retention rate was defined as the percentage of participants completing outcome measures for at least one follow-up time point. In studies where this was not explicitly mentioned, we used the percentage of participants continuing to engage with the intervention after a specified period (ie, a time period identified by the original author).

Changes to the Protocol

Initially, the review team planned to investigate recruitment rates. However, the identified studies varied in recruitment strategies and did not provide sufficient details to address this research question. In addition, although the review team acknowledged the potential of gray literature (eg, research not published in peer-reviewed journals) to broaden the scope of systematic reviews, the team agreed to only include articles published in peer-reviewed journals. This decision was because of various reasons: (1) the popularity of technological advancements in health care; (2) the resource constraints of this study; (3) some evidence of the limited contribution of unpublished studies to the results of meta-analyses in child-relevant reviews [56]; and (4) the consideration that the aim of this systematic review was not related to efficacy and safety, which could be amenable to publication bias. No other substantial deviations from the registered protocol were made. The review protocol was registered in the International Register of Systematic Reviews (PROSPERO) [CRD42018094815].

Results

Overview of the Included Articles

The results of this systematic review are presented as a narrative synthesis [57] and, where applicable, descriptive numerical summaries are provided. A total of 83 articles published between 2001 and 2018 met the inclusion criteria (Multimedia Appendix 2) identifying 71 interventions (Multimedia Appendix 3). Of the 83 articles reviewed, almost two-third were conducted in the United States and Canada or in Australia and New Zealand. The most common type of intervention incorporated cognitive behavioral therapy as the main therapeutic modality. The mean age of the included samples was between 2 years to 24 years. Affective disorders (ie, anxiety and depression, including suicidality) were the most common presentation targets of the DHIs reviewed. Multimedia Appendix 4 provides details of the reviewed articles and Table 2 provides a summary of these findings.

A broad range of recruitment strategies were used to develop and test these DHIs, including referrals from health or school professionals; self-referrals through social media and web-based advertising; university email lists; recruitment software; or in-person advertising through posters, flyers, newspaper advertisements, word of mouth, and existing research and support groups. The following section presents the modes of delivery for DHIs, highlighting how they have been evaluated and their main features and purpose. Table 3 provides a summary of the 6 DHI categories identified in this review, the corresponding features, and the study designs adopted.

Table 2. Characteristics of the included articles (N=83).

Characteristics	Values, n (%)
Country	
United States and Canada	31 (37)
Australia and New Zealand	23 (28)
Europe	21 (25)
Asia	7 (8)
Brazil	1 (1)
Therapeutic modality	
Cognitive behavioral therapy	39 (47)
Cognitive skills training mechanisms	9 (11)
Social skills training or social support	7 (8)
Applied behavior analysis concepts	3 (4)
Single component or combinations[a]	25 (30)
Disorders	
Affective[b]	38 (46)
Attention deficit and hyperactivity	7 (8)
Autism spectrum	12 (15)
Eating disorders	4 (5)
Behavioral disorders[c]	10 (12)
Nonspecific or multiple disorders	12 (15)

[a] Combinations of the following strategies: therapeutic support embedded in positive psychology, behavior activation, self-regulation, learning theories, motivational interviewing, and mindfulness.

[b] Depression, anxiety, or suicidality.

[c] Obsessive compulsive disorder, substance abuse, selective mutism, social difficulties, and psychosis or schizophrenia.

Table 3. Summary of digital modes of delivery used in children and young people's mental health intervention.

Mode of delivery (number of articles)	Goals: features	Study design, n
Website interventions (n=43)	• Communication: emails, text messages, social networking, web-based message boards, discussion forums • Dissemination of information: text and multimedia channels (videos, animations, and audio), games and quizzes, homework tasks, and web-based profile set up with customizations	RCT[a] (n=22), pre- to posttest (n=11), observational study—qualitative, quantitative, or mixed methods approaches (n=10)
Games or computer-assisted interventions (n=23)	• Dissemination of information, skills development, psychoeducation: photos, stories, animations, quizzes, text messages, and multimedia (audio and videos)	RCT (n=11), pre- to posttest (n=8), observational study—quantitative or mixed methods approaches (n=4)
Apps: web or mobile (n=10)	• Dissemination of information, skills development, peer-to-peer communication: text message reminders, text, photos and multimedia (audio and videos) plus an opportunity to upload content	RCT (n=4), pre- to posttest (n=1), observational study—qualitative, quantitative, or mixed methods approaches (n=5)
Robots and digital devices (n=3)	• Dissemination of information: audio and movement • Peer-to-peer communication: email reminders	RCT (n=1), feasibility study (n=1), mixed methods design (n=1)
Virtual reality experiences (n=3)	• Dissemination of information, skills development, therapeutic support: Gamification using multimedia (audio and images)	Pre- to posttest (n=2), posttest (n=1)
Mobile text messages (n=1)	• Dissemination of information, skills development, social support: Text	RCT (n=1)

[a] RCT: randomized controlled trial.

What Modes of Delivery Are Used for Engaging Children and Young People in Digital Mental Health Interventions?

Website Interventions

Overall, 33 of the 43 articles adopted an interventional study design (22 RCTs and 11 pre- to poststudy designs). The remaining 10 studies adopted observational study designs utilizing qualitative, quantitative, or mixed methods approaches. The methodological quality of the included studies was acceptable. Qualitative studies scores ranged from 2 to 5 points, RCTs and nonrandomized quantitative studies also ranged 2 to 5 points, and mixed methods studies ranged 2 to 4 points.

The primary goal of the majority of the interventions (n=40) was to transmit specific MH information to a targeted population. In addition, 12 of the 40 articles described interventions that were multipurpose, providing an additional opportunity for peer communication (n=7) or for personal health tracking (n=4). YouthCHAT (see Multimedia Appendix 3 for definitions and descriptions of the interventions) provided general information in addition to providing an opportunity for personal health tracking. However, SharpTalk's primary focus was to facilitate peer-to-peer communication through discussion forums, and Manage Your Life Online functioned as a communication aid that provided an opportunity for personal health tracking.

Various features were adopted to achieve the above goals. Communication occurred digitally using emails, text messages, social networking, web-based message boards, and discussion forums. Dissemination of information occurred through text and multimedia channels (eg, videos, animations, and audio). Some interventions also utilized games and quizzes, homework tasks, and a web-based profile set up with customizations.

Games or Computer-Assisted Interventions

Overall, 20 of the 23 articles adopted an interventional study design (11 RCTs and 8 pre- to poststudy designs). The remaining 4 studies adopted observational study designs utilizing quantitative or mixed method approaches. The methodological quality of the included studies varied. RCTs scores ranged 2 to 5 points, nonrandomized quantitative studies ranged 2 to 4 points, and mixed methods ranged 3 to 5 points. No articles used qualitative methods only.

The primary goal of the majority of the interventions (n=18) was to transmit specific MH information to a targeted population. Of the 18 interventions, 4 were multipurpose, providing additional general information to the public (n=1) or an opportunity for personal health tracking (n=4). In addition, 8 interventions focused on cognitive training tasks. The computer-assisted instruction intervention was used as a facilitator to assist children in developing reading skills. The social stories accessed via tablets were also used for psychoeducational purposes.

The gamification approach used to achieve the above goals was accessed either on the web or offline and incorporated photos, stories, animations, quizzes, text messages, and videos.

Apps

Of the 10 articles, 5 adopted an interventional study design (4 RCTs and 1 pre- to poststudy design). The remaining 5 articles adopted observational study designs utilizing qualitative, quantitative, or mixed methods approaches. The methodological quality of the included studies varied. Qualitative studies scored either 4 or 5 points, RCTs scores ranged 1 to 4 points, the 1 nonrandomized quantitative study scored 4 points, whereas the 2 mixed methods studies scored 3 points.

The primary goal of most apps was to transmit specific MH information to a targeted population. Furthermore, 3 apps were multipurpose, providing an additional opportunity for personal health tracking. The TECH app further included peer-to-peer communication.

The included apps were either web apps or mobile apps and included text message reminders, text, photos, and multimedia (videos and audio). Users also had the opportunity to upload content such as videos and photos.

Robots and Digital Devices

Of the 3 studies, 2 adopted an interventional study design, of which one (CommU) was an RCT. The study on the Fitbit Flex and Facebook adopted a mixed methods design. The study on ARIA adopted an observational study design as a pilot usability study. The methodological quality of the included studies was acceptable. The ARIA study scored 3 points, CommU scored 3 points, and the Fitbit Flex and Facebook intervention study scored 5 points.

The primary goal of ARIA and CommU was to transmit specific MH information to a targeted population, whereas the Fitbit Flex and Facebook intervention additionally provided an opportunity for peer communication.

ARIA and CommU utilized audio and movement to achieve the above purpose. The Fitbit Flex and Facebook synced with 2 other approaches, an app and a website, and included email reminders to achieve its purpose.

Virtual Reality Experiences

Furthermore, of the 3 studies, 2 interventions adopted pre- to posttest designs, whereas one adopted a posttest-only design (Virtual Dolphin Interaction). No RCTs were found to evaluate the identified interventions. Cave Automatic Virtual Environment also incorporated a mixed methods approach and obtained qualitative data. The methodological quality was acceptable. The Cave Automatic Virtual Environment and Collaborative Virtual Environment studies scored 3 points and the Virtual Dolphin Interaction study scored 4 points.

The primary goal of all 3 interventions was to transmit specific MH information to a targeted group or to facilitate skills training or provide therapeutic support. Collaborative Virtual Environment also functioned as a communication aid to facilitate collaboration within the virtual reality environment.

Cave Automatic Virtual Environment, Collaborative Virtual Environment, and Virtual Dolphin Interaction utilized features of the gamification approach to engage CYP in a more real-life experience, allowing for more immersion and movement.

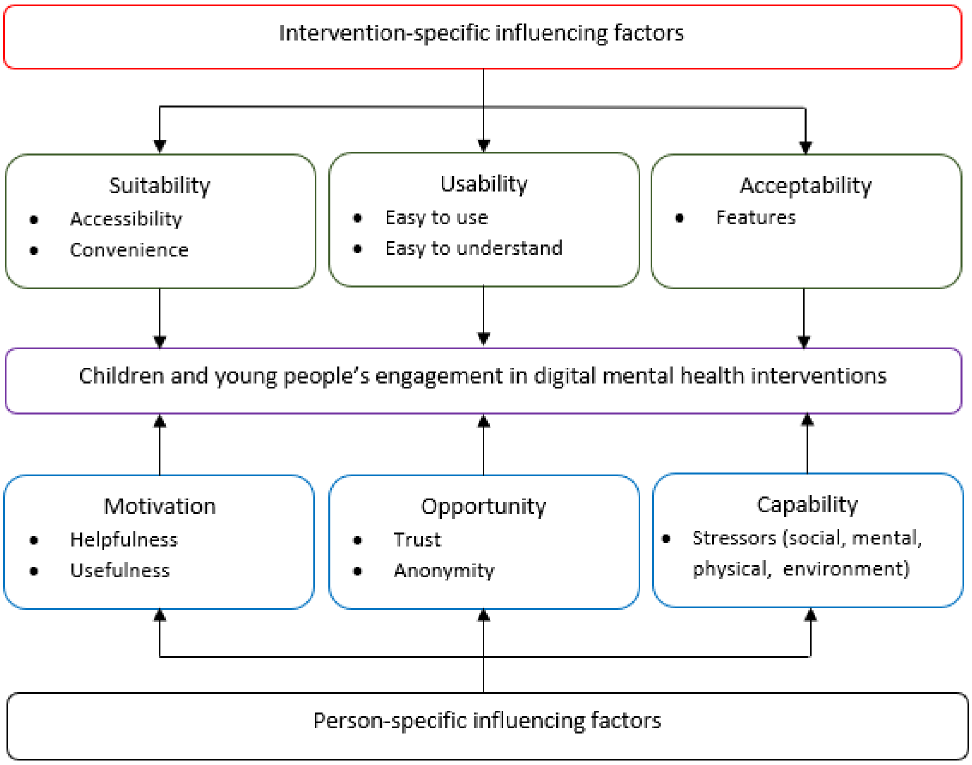
Mobile Text Messages

In addition, 1 text messaging intervention was identified and evaluated in an RCT. The methodological quality score was 3. The Educating and Supporting Inquisitive Youth in Recovery program aimed to transmit specific MH information to a targeted audience, to facilitate skills training or offer therapeutic support, to provide the opportunity for personal health tracking, and to signpost CYP to additional social support websites. No additional features, apart from text, were described in the study. However, participants were contacted via phone as part of the study.

What Are the Barriers and Facilitators to Engaging Children and Young People in Digital Mental Health Interventions?

Influencing factors presented as barriers and facilitators to engagement emerged as 2 broad themes encompassing 6 factors: intervention-specific influences (suitability, usability, and acceptability) and person-specific influences (motivation, capability, and opportunity). Overall, 29% (24/83) of the included articles provided data to support these themes, 13 studies provided data for suitability, 13 for usability, and 14 provided data for acceptability. Of the 24 articles, 8 provided data to inform motivation, 4 for capability, and 13 for opportunity. A summary of concepts corresponding to the individual factors within the major themes is presented in Multimedia Appendix 5. On the basis of these findings, a conceptual framework (Figure 2) was developed, highlighting the specific components impacting engagement in CYP digital MH interventions, which can inform the development of, and research into, CYP DHIs.

Figure 2. A framework of factors influencing engagement in children and young people's mental health digital intervention.



Theme 1: Intervention-Specific Influences

CYP highlighted factors related to the development of the intervention, which influenced whether they used the intervention or not. A prominent factor influencing the acceptability (ie, willingness to use) of the intervention was the features, whereby CYP highlighted certain images, specific language, and interfaces that were unappealing to them. They made suggestions and highlighted features such as videos, having less text, ability to personalize or create a profile, and ability to connect with others or receive text message reminders as encouraging their use of the intervention. CYP also suggested that providing rewards could also be a motivating factor for engaging with DHIs. Similarly, usability (ie, the degree to which the DHI was able to be used) was important for promoting engagement. Interventions that CYP favored were described as self-paced, user friendly, age appropriate, simple, and straightforward. However, in situations where CYP had problems understanding the task, or if the intervention did not provide sufficient instructions on usage, they were less inclined to continue using the DHI.

Another main factor was the suitability (ie, the degree to which the DHI is in line with daily activities) of the intervention to the lifestyle of CYP. Although CYP liked not having to travel to access the intervention and the ability to use it while at home, they were *put off* by technical issues or having to use media such as emails or desktop computers that they used less frequently in their daily lives. Many CYP highlighted not participating in the intervention because of a lack of time and inability to integrate the task into their everyday life. They suggested that flexibility concerning time and ability to bypass long waiting lists encouraged usage. In addition, they highlighted that DHIs were convenient and welcomed as they spend most of their time on the web.

Theme 2: Person-Specific Influences

Of the 6 factors, 3 were associated with person-specific barriers and facilitators to behavior change, which is in line with the COM-B model [54]. The opportunity for the intervention to be adopted was highlighted in 3 areas. First, feeling a sense of connectedness was important to CYP. They were more likely to use the intervention if it facilitated conversations with others because they wanted to know that others had similar experiences. Some CYP even indicated that they “felt alone” on the web without the support of a therapist. Trust was also of great importance to CYP, and they were reluctant to accept DHIs because of privacy concerns or uncertainties around its validity. CYP made suggestions to use trusted *brand names* that they were familiar with. They were also more inclined to use the interventions if there was transparency or evidence provided to support its credibility. The concerns around trust also extended to their preference for anonymity. They highlighted that anonymity made it easier to talk to a stranger on the web without feelings of embarrassment.

The second major factor identified as a person-specific influence was motivation. Some tasks were of less interest to CYP, and sometimes, they would have forgotten the existence of the intervention. However, they highlighted that curiosity and perceived need influenced their usage. Perceived usefulness of the intervention to address their needs was a major motivating factor; therefore, if the resource was viewed as unhelpful or too general, CYP were less interested in using it. However, although CYP were eager to use DHIs, the capability to engage with the intervention was sometimes affected by physical, environmental, and MH stressors, representing another major influencing factor.

How Do Retention Rates Vary in Children and Young People Digital Mental Health Intervention Research?

Owing to the heterogeneity in study design and intervention type, not all articles provided sufficient detail to estimate retention rates. Therefore, we were unable to include estimates for 16 of the included articles. The average retention rate across the remaining 67 articles showed almost 80% of CYP using DHIs or completing the follow-up measures. Results showed that the retention rates varied, with 11.9% (8/67) of articles achieving 100% retention and 8.95% (6/67) reporting less than 50% retention. Overall, 83.58% (56/67) of the included articles had a retention rate of at least 70%. Subgroup analyses for approaches with a larger number of articles indicated that the average retention rate for games and computer-assisted intervention studies was 86.95%, followed by websites interventions with 78.87%, and apps with 78.45%. Multimedia Appendix 4 shows the distribution of retention rates across studies.

Discussion

Overview

This review identified 6 modes of delivery of DHIs for CYP with MH issues: websites, games and computer-assisted programs, apps, robots and digital devices, virtual reality, and mobile text messaging. Overall, 2 themes emerged, highlighting intervention-specific and person-specific barriers and facilitators to engagement in DHIs. In addition, the findings of this review suggest a high average retention rate of almost 80% when the identified modalities were evaluated. Knowledge of these approaches, including influencing factors to usage from the perspective of the CYP, provided information that can be used to design and evaluate new DHIs.

Explanation of the Overall Findings

From the articles reviewed, 59 contributions were published between 2013 and 2018, with 15 records published in 2018. This is consistent with the fact that interest in applying digital technologies to MH practice has been increasing since the early 2000s, and recommendations for research in this field were issued only in 2013 [58,59]. With most of the studies reviewed being conducted in developed countries, digital responses to CYPMH seem unbalanced. Previous research [60-62] highlighted the paucity of access to DHIs in low- and middle-income countries. This inequality could be because of limited resources (both financial and human), shortage of skilled personnel, infrastructure problems leading to poor internet penetration and connectivity [63], or the absence of a specific CYPMH policy [64]. However, a strong association between the severity of risk for mood disorders and social disadvantage has been documented [65,66]. Anxiety is the most common psychiatric condition affecting CYP in all societies [45,67-69]. It may also co-occur with other disorders, both concurrently and sequentially, leading to further health problems [68]. Therefore, it is not surprising, that 46% of articles resulting from our literature search targeted CYP with affective disorders.

The modes of delivery identified in this review are similar to those identified in other reviews exploring adolescent physical health [70,71] and MH [45]. The purpose of the interventions is also in line with WHO’s classification of DHIs [72]. The intervention-specific and person-specific influences on CYP engagement identified in the present review mirror those of previous research on the broader technology acceptance model [73-75], the conceptual framework for engagement in Digital Behavior Change Interventions in adults [36,53], and more recently, the application of social cognitive theory to understand engagement with DHIs for trauma recovery [35]. For these models, predictors included perceived need, engagement self-efficacy, outcome expectations, and symptom severity. The proposed model of CYP engagement in digital MH interventions, based on the findings of the present review, builds on these models by highlighting the importance of the social context in which young people engage with DHIs. It also highlights major factors for researchers and developers in CYPMH to facilitate opportunities for a sense of connectedness. *Peer -connectedness* may be challenged by the necessary application of safeguarding measures. Indirect peer connectedness where CYP can access appropriately anonymous and asynchronous stories from real CYP with similar experiences may be one such approach, as in SharpTalk [76]. Similarly, options for anonymous usage may be particularly important for CYP's *self-connectedness* in terms of sharing experience in a manner that mitigates the role of stigma and shame [77,78]. *Professional connectedness* was particularly important in DHIs as CYP wanted to connect with a trusted support provider in lieu of connecting with a professional in real life. A key facilitator of professional connectedness was credibility in relation to evidence of the intervention's effectiveness and trust in the privacy and data security, which could be facilitated by using familiar *brand names*. Although characterized as an intervention-specific factor in other models [53], we characterized this as part of opportunities for connectedness and, therefore, as a person-specific factor. Future studies should explore the impact of new modes of delivery to promote a sense of connectedness in DHIs (eg, more usage of features such as ChatBots, as in the Manage Your Life Online intervention).

Other barriers and facilitators that were identified in this review also emphasize the importance of user-centered design methods when developing DHIs for CYP [53]. Through co-design workshops and focus groups with CYP, developers can ensure that a DHI's design is age appropriate, (eg, little text and using youth-engaging language) by putting a greater focus on videos and pictures, while keeping the platform user friendly. Moreover, CYP mentioned factors such as reward systems and reminders, which fall under the umbrella of persuasive design methods and have been explored in previous research [36,79]. The positive influence of these methods on user engagement and adherence to DHIs has been supported; however, quantifiable evidence from trials is still lacking [36,79]. With respect to reminders, past research has indicated a positive impact on engagement. However, excessive and undue reminders have also been shown to have opposing effects [80]. Evidence from previous studies has suggested that specific behavior change techniques, such as goal setting or self-monitoring tools, relate to higher engagement [81]. This review did not extensively investigate these techniques and therefore cannot fully suggest their potential positive effects on the engagement of CYP. However, the findings of this review justify that designing DHIs with CYP in mind would be ideal to promote usage, adherence, and positive user experience and to address the barriers that some of the reviewed studies suggest.

Comparison of Research Retention Rates With Other Studies

Our findings suggest that the retention rate of CYP in digital MH interventions (mean retention rate of 79.2%) was superior to that reported in face-to-face CYP MH outpatient care, where dropout affects 20% to 60% of the cases [82]. However, a direct comparison with other studies is not clear, given the diversity of criteria used for defining dropout. For instance, dropout percentages are lower when dropout is defined by the therapist's opinion than when dropout is defined by the completion of a certain number of sessions [83-85]. Our definition of retention relied on completion of the first follow-up measure or engagement for a specified period, which may explain the higher retention found. In this review, retention rates also varied widely across the studies (range 15.79%-100%). A similar heterogeneity in retention rates was found in previous reviews of studies with adults receiving internet-based MH programs (17%-98%) [82], as well as in face-to-face MH interventions with CYP [83], and the adult population (varying between 17%-72% and 17%-98%, respectively) [86]. Efficacy studies tend to present lower dropout rates than studies conducted in naturalistic settings [83]. Our review included a variety of empirical studies, which may have contributed to the diversity of retention rates found. Finally, the average retention rate for games and computer-assisted intervention studies was almost 10% higher than that of the other modalities, which may reflect the preference of children for interventions in game formats [87,88].

Digital Mental Health Care and Support of Children and Young People

DHIs were included at various stages of the provision of psychological support. Technology-mediated programs and tools were part of prevention, assessment, treatment (psychoeducation and psychotherapy) and follow-up of MH care. This extensive potential of DHIs can support the WHO's initiative to identify and intervene to lessen the MH treatment gap [89]. When used as part of the initial assessment, support for shared decision making, personalized goal setting, progression, or management of transitions, DHIs are able to support CYP by enhancing their sense of agency and control. This may in turn promote greater involvement in the treatment process [90]. In several of the reviewed studies, DHIs targeting social skills training and joint attention training were used in the initial phase as a facilitator of the therapeutic process. For some specific conditions such as social anxiety, selective mutism, autism spectrum disorders, and attention-deficit conditions, the involvement of digitized programs in the preliminary phase of therapy may be an important facilitator for therapeutic success [91,92]. DHIs as part of the therapeutic process can be used in the periods between face-to-face treatment for interactive homework assignments, reminders, self-monitoring tools, individualized exercises, and real-time symptom assessment.

Implications and Recommendations

DHIs can be a helpful way to support and treat MH problems. Such tools can complement the various stages of the provision of psychological support or psychotherapy among CYP with MH problems. However, effective implementation and sustained usage will rely on the extent to which the design is appropriate for the intended purpose and how it will be used in practice. This understanding may help to minimize the risks associated with fear of usage that some end users experience by providing useful directions on how to design technologically responsible therapeutic approaches [93]. As a result, the findings of this review suggest that the development of DHIs should be suitable for CYP's lifestyle, focusing on ease of access, such as the ability to be used on their mobile devices at their convenience. Attention should also be given to the design of DHIs to ensure that it is not too complex and that the features are attractive to CYP. In addition, incorporating concepts that provide the CYP with a level of trust for the DHI and the ability to connect with others should be carefully considered. To target concerns about usefulness, developers should work with clinicians and CYP to ensure that suitable information is provided through the intervention. This collaborative approach can highlight specific ways to encourage CYP to continue engaging or increasing engagement during stressful periods.

Although this study provides insight that is valuable for the development of new interventions, future research should (1) not only focus on the effectiveness but also investigate engagement, taking into account influencing factors, as an important component of research; (2) arrive at a consensus on defining engagement and how it should be measured; (3) provide adequate reporting of recruitment and retention rates; and (4) compare CYP preferences for various modes of delivery or therapeutic approaches. Finally, this study also acknowledges the implications for practice. The findings suggest CYP interest in DHIs, and therefore, (1) efforts to improve engagement may be beneficial to CYPMH outcomes and (2) families including the CYP and clinicians should work together to identify DHIs that are suitable to the CYP's lifestyle.

Strengths and Limitations

This review adhered to established guidelines for systematic reviews [94] and adopted a comprehensive study design carried out by a team of researchers, allowing each stage of the review to be undertaken by at least two independent reviewers. Most importantly, this review highlighted the range of modes of delivery, factors influencing usage, and the variation in study types and retention of CYP in digital MH intervention studies. Our findings contribute to a broader understanding of the CYP DHI literature. However, this review is not devoid of limitations. The review team attempted to identify and include as many articles as possible; however, unknowingly and unintentionally, some papers may have been missed. This can be partly because of the challenges and inconsistencies when defining the construct of engagement resulting in a wide variety of terms used [44]. In addition, unpublished data were not included in the search strategy, which may have impacted the results of this review. Nevertheless, this approach was also seen as a further strength by ensuring that only peer-reviewed interventions were included. Moreover, the study team attempted to group interventions based on digital platforms to describe each approach. However, there may still be some variation within these groupings that make it difficult to categorize. This review was also limited as only subsamples of the total number of included articles contributed to addressing research questions 2 and 3. Therefore, caution was taken when generalizing the findings and drawing overall conclusions. In addition, because of the variability in study designs, we were prudent when averaging retention rates for this review, as follow-up measures were collected at varying time points across the selected records.

Conclusions

DHIs may be of interest to CYP, particularly in the area of MH treatment. Research on retention rates suggests high engagement of CYP in digital MH interventions that may encourage further development of DHIs in the near future. CYPMH services could benefit from this development as the included studies indicate. However, the results of this review highlighted intervention-specific and person-specific factors that influence CYP usage of digital MH interventions that should be considered. With continuous technological advancements, it is desirable to know which modalities may increase usability and adherence to better support CYP facing MH challenges.

Acknowledgments

This study was funded by the European Union's Horizon 2020 research and innovation program under the Marie Skłodowska-Curie grant agreement number 722561; TREATme, a European Network on Individualized Psychotherapy Treatment of Young People with Mental Health Disorders under the European Cooperation in Science and Technology which is supported by the EU Framework Programme Horizon 2020 action CA16102; European COMPETE2020 (POCI-01-0145-FEDER-030980); Estonian Research Council grant PUT1518; and Portuguese National funds FCT—Fundação para a Ciência e a Tecnologia, I P (PTDC/PSI-ESP/30980/2017).

Authors' Contributions

SL and JE-C conceptualized the paper. SL, CPM, CMDS, AC, S Carletto, CH, SS, S Cerón, PMP, GP, BM, and JE-C carried out selection of articles, data extraction, data analysis, and writing of the original draft. SL, CPM, CMDS, AC, S Carletto, CH, SS, S Cerón, PMP, GP, BM, RU, NF, and JE-C were involved in the writing, review, and editing.

Conflicts of Interest

JE-C is an author of one of the reviewed articles.

Abstract

Background: Increased accessibility to the internet and mobile devices has seen a rapid expansion in electronic health (eHealth) behavior change interventions delivered to patients with cancer and survivors using synchronous, asynchronous, and combined delivery methods. Characterizing effective delivery methods of eHealth interventions is required to enable improved design and implementation of evidence-based health behavior change interventions.

Objective: This study aims to systematically review the literature and synthesize evidence on the success of eHealth behavior change interventions in patients with cancer and survivors delivered by synchronous, asynchronous, or combined methods compared with a control group. Engagement with the intervention, behavior change, and health outcomes, including quality of life, fatigue, depression, and anxiety, were examined.

Methods: A search of Scopus, Ovid MEDLINE, Excerpta Medica dataBASE, Cumulative Index to Nursing and Allied Health Literature Plus, PsycINFO, Cochrane CENTRAL, and PubMed was conducted for studies published between March 2007 and March 2019. We looked for randomized controlled trials (RCTs) examining interventions delivered to adult cancer survivors via eHealth methods with a measure of health behavior change. Random-effects meta-analysis was performed to examine whether the method of eHealth delivery impacted the level of engagement, behavior change, and health outcomes.

Results: A total of 24 RCTs were included predominantly examining dietary and physical activity behavior change interventions. There were 11 studies that used a synchronous approach and 11 studies that used an asynchronous approach, whereas 2 studies used a combined delivery method. Use of eHealth interventions improved exercise behavior (standardized mean difference [SMD]

0.34, 95% CI 0.21-0.48), diet behavior (SMD 0.44, 95% CI 0.18-0.70), fatigue (SMD 0.21, 95% CI −0.08 to 0.50; SMD change 0.22, 95% CI 0.09-0.35), anxiety (SMD 1.21, 95% CI: 0.36-2.07; SMD change 0.15, 95% CI −0.09 to 0.40), depression (SMD 0.15, 95% CI 0.00-0.30), and quality of life (SMD 0.12, 95% CI −0.10 to 0.34; SMD change 0.14, 95% CI 0.04-0.24). The mode of delivery did not influence the amount of dietary and physical activity behavior change observed.

Conclusions: Physical activity and dietary behavior change eHealth interventions delivered to patients with cancer or survivors have a small to moderate impact on behavior change and a small to very small benefit to quality of life, fatigue, depression, and anxiety. There is insufficient evidence to determine whether asynchronous or synchronous delivery modes yield superior results. Three-arm RCTs comparing delivery modes with a control with robust engagement reporting are required to determine the most successful delivery method for promoting behavior change and ultimately favorable health outcomes.

Introduction

Background

The World Health Organization describes electronic health (eHealth) as a cost-effective and secure way to use information and communication technologies for health [1]. eHealth broadly encompasses the provision of health care services, education, allows surveillance, and the development of knowledge and research through technology [1]. Mobile health (mHealth) is a subset of eHealth, where mobile devices support the delivery of medical and public health care to individuals and populations [2]. In 2007, the number of individuals using the internet around the world was approximately 1.3 billion [3]. Furthermore, in 2018, this number had trebled to 3.9 billion people with internet access (51.2% of the world’s population) [3,4]. The use of mHealth in the delivery of health interventions is increasing worldwide because of the rapid growth of internet use and leaps in technological advancements. Its potential to target previously hard-to-reach populations and the need for innovative approaches to deliver health promotion and interventions in the face of aging populations and health care budget constraints make it an attractive delivery method [2,5-8].

Behavior change interventions can be defined as “coordinated sets of activities designed to change specified behaviour patterns” [9]. The effectiveness of digital behavior change interventions to promote behavior change is likely to be dependent on a complex interplay of factors, which are still in their infancy in terms of understanding. A systematic review of behavior change interventions delivered via the internet found that more extensive use of underlying behavior change theory and utilization of more behavior change techniques were important factors in overall intervention effectiveness [10]. Although eHealth interventions offer the promise of enhancing health care to populations in rural and regional settings and overcoming some of the challenges associated with accessing traditional health care delivery modes, there has been concern that in some segments of the community, provision of eHealth may exacerbate already prominent inequalities [11]. Of particular concern are individuals who have low health literacy, access to technology, and familiarity and confidence in the use of technology [11-14].

eHealth interventions, focusing on behavior change, are being increasingly used in patients with cancer and survivors. In 2018, cancer rates around the world increased to 18.1 million cases per year with 1 in 6 women and 1 in 5 men receiving a diagnosis in their lifetime [15]. Cancer survivorship also increased, with 43.8 million people surviving up to 5 years [15]. Many of these individuals live with long-term treatment side effects, including cardiac dysfunction, functional decline often precipitated by chronic pain and fatigue syndromes, obesity, diabetes, osteoporosis, premature menopause, neurocognitive deficits, and risks associated with primary recurrence and second cancers [16-18]. There are well-established guidelines and recommendations to modify risks associated with physical activity and healthy eating behavioral patterns post cancer diagnosis [19-21]. Studies of behavior change interventions in this population often use a guideline as a basis to improve physical activity and healthy eating behaviors. A recent review of self-guided technology-supported nutrition and physical activity interventions in adults with cancer found benefits in physical activity and fatigue with some modest effect on dietary behaviors and health-related quality of life [22]. Another review looked at telephone, print, and web-based interventions and found that improvements were reported in 76% of the studies included for physical activity, dietary behaviors, or weight [23]. However, these reviews did not contrast the relative effectiveness of different approaches to delivering eHealth behavior change interventions. There are 3 important categories that eHealth interventions can be described: synchronous, asynchronous, and combined. Synchronous eHealth interventions are delivered via real-time interactions between the person and health care provider, encompassing face-to-face contact through teleconferencing equipment, telephone (telehealth), and live chat via web-based [24-26]. Asynchronous techniques include store-and-forward methods such as email and automated messaging systems without a live interaction component [24-26]. Combination approaches use both synchronous and asynchronous elements. These distinctions are important because they impact how health services need to structure and staff services that use these approaches and dictate whether or not health services have to rely on technology-based platforms to enable delivery.

Objectives

There is a need to characterize effective eHealth interventions to enable improved design and implementation of evidence-based cancer health behavior change interventions, which will translate into the ability to scale up to affect health behavior change in a wide range of health promotion and health care management situations. This systematic literature review seeks to compare synchronous with asynchronous delivery modes and contrast their impact on behavior change and quality of life outcomes in adult patients with cancer or survivors. It also seeks to examine whether the degree of behavior change influences the amount of change in quality of life and to describe the behavior change theories and techniques used in the field.

Methods

In conducting this review, we recognized that increased access to mobile internet technologies, and increased availability of health information on the web, combined with changing behaviors in accessing health information [27,28] means that people who previously may have relied on health professionals to provide them with information are now better enabled and more likely to find information on their own. We chose to restrict study selection to being from a contemporary period (from 2007 onward) under the justification that the substantial increase in availability of information about health behaviors and managing the lifestyle consequences of cancer through the internet has evidently changed how people may seek and find information about their health issues and respond to behavior change interventions delivered by distance.

Reporting Guidelines

This systematic review follows the Cochrane Collaboration's Handbook of Systematic Reviews of Interventions [29]. This systematic review was registered with The International Prospective Register of Systematic Reviews (PROSPERO) CRD42018103855. The methods used in this systematic review are in line with the preferred reporting items for systematic reviews and meta-analysis (PRISMA) guidelines. A completed copy of the PRISMA checklist is attached (Multimedia Appendix 1).

Search Strategy

A three-part search strategy was used to identify studies that met the following inclusion criteria: (1) we searched electronic bibliographic databases for published work including SCOPUS, Ovid MEDLINE, Excerpta Medica dataBASE (EMBASE), Cumulative Index to Nursing and Allied Health Literature (CINAHL) Plus, PsycINFO, and Cochrane CENTRAL; and (2) we searched the reference lists of the primary studies included in the review. We undertook a second phase of study identification where we completed a hand search of the *Journal of Medical Internet Research Cancer* and expanded the database search to include PubMed with the additional search term "website" (Multimedia Appendix 2).

Search Terms

Example Search Strategy

Mobile app*, electronic mail, internet, mhealth, mobile health, ehealth, electronic health, telehealth, telemedicine, telenursing, telemonitoring, telerehabilitation, telephone, cell* phone*, cell* telephone*, mobile telephone, mobile phone*, smartphone*, email*, electronic messag*, electronic mail, text messag*, short messag* service*, SMS, MMS, interactive voice response, multimedia, web-based, automat* reminder*, videoconferenc*, online*

AND

behavio* chang*, health behavio* chang*, behavio* theory, behavio* modifi*, health promotion

AND

NOT child*, adolescen*, teen*, preschool*, infant*, toddler*

AND

specific validated database filters for randomised controlled trials

AND

English language, 2007 to current

The asterisk truncates the search term so that alternative terms are also identified (eg, behavio* will find behavior and behavioral).

Titles and abstracts were retrieved using the search strategy. Reference lists were then exported into Clarivate Analytics EndNote X8 and duplicates were removed. References were then exported into Covidence where further *deduplication* occurred. Abstracts were reviewed by the author (KF), and an independent author (MS) performed a parallel review. The overall review was limited to the population of people with cancer when the abstract screening resulted in over 400 studies to be reviewed. Papers where reviewers disagreed on the rating of eligibility criteria were re-examined and discussed to reach consensus. The full-text papers were then retrieved and independently assessed by 2 reviewers (KF and MS). Hand searching for primary studies included in the review resulted in a further 23 studies for review.

Selection Criteria

Studies were limited to those relating to cancer patients or survivors, published with one or more search terms, were subjected to peer review, published in the English language, involved human adult subjects aged 18 years and over, and dated from 2007 to March 2019. The primary intervention was delivered through an eHealth delivery method such as telephone or internet, either asynchronous or synchronous or combined interventions against a control (including usual care or wait list control or no intervention), random assignment of participants to treatment or comparison groups, and a measure of health behavior change must have been taken after the intervention. Studies were excluded if there was any face-to-face component, as we sought to examine interventions purely delivered via eHealth approaches.

Outcomes

The Kirkpatrick model [30] is an internationally recognized tool to evaluate the effectiveness of training interventions. In this review, training is defined as the health behavior change intervention. We sought to examine relationships between the intervention delivery mechanism (synchronous or asynchronous) and the 4 different levels of the Kirkpatrick model. The 4 levels of the model are as follows:

- Level 1 (reaction): This is how participants responded to the training. This review focuses on participant user engagement metrics to assess reaction.
- Level 2 (learning): This is the content learned from the training provided and is usually knowledge tests completed pre- and postintervention.
- Level 3 (behavior): This level examines the participants' application of learning. We review the participants' ability to translate the intervention into health-related behavior change.
- Level 4 (results): This is the degree to which targeted outcomes have occurred as a result of the training provided. This review looks at health outcomes as described by previous studies.

This review examined how the different delivery mechanisms of behavior change intervention not only impact the individual levels of this model but also impact the interaction between these levels. We did not extract data related to the second level of the Kirkpatrick hierarchy (learning) as behavior change interventions do not necessarily require new information to be learned to change behaviors (this is a minor limitation in applying an educational framework in a behavior change context).

Primary Outcomes

The primary outcome for this review was defined as a change in health behaviors (eg, increases in moderate-to-vigorous physical activity or fruit and vegetable consumption) from baseline to the conclusion of the active intervention. This was chosen as it was most likely to be the time of greatest compliance with the intervention.

Secondary Outcomes

The secondary outcomes for this review were engagement in the eHealth interventions and changes in quality of life, fatigue, anxiety, and depression. We sought to measure the proportion of participant initiation of the intervention, the frequency of intervention delivery per week, and duration of intervention delivery in minutes. Changes in quality of life, fatigue, anxiety, and depression were measured relative to the measure taken as close to the conclusion of the active intervention as possible, not after any period of follow-up.

Other Descriptive Data

We sought to describe the behavior change theories used and behavior change techniques employed in eHealth interventions.

Data Extraction

One (KF) and either of the 2 reviewers (MS or KH) independently extracted data including study identifiers, study design, population characteristics, consent and retention rate, intervention, behavior change and health outcomes of interest, behavior change theory and techniques used, intervention participation rates, control condition details, length of follow-up, and information to complete a risk of bias assessment into a standardized data extraction table. Data were extracted on the key outcomes (objective or self-reported) defined by the study, including those that reported on multiple behavior change outcomes (eg, diet and physical activity). Where this was not clear, 2 reviewers independently chose the most relevant behavior change outcome to the study. Where data were incompatible for meta-analysis, authors were contacted twice via email, and 2 out of 9 authors who were contacted responded with forthcoming information. Engagement data were also extracted by 2 reviewers.

Risk of Bias Assessment

Two review authors (KF and KH) independently assessed the risk of bias for randomized controlled trials (RCTs) using the Cochrane Collaboration's tool for assessing bias [31]. Differences of opinion were discussed and agreed upon between the 2 reviewers.

Analysis

Behavior Change and Health Outcomes

Data were separated into groups of similar outcomes to perform pooled random effects meta-analysis using standardized mean difference (SMD) of summative level data. Standardized effect sizes were considered small at 0.2, moderate at 0.5, and large at 0.8 [32]. A random effects metaregression analysis was undertaken to determine if the mode of delivery influenced the amount of behavior change observed. The SD of the effect size was imputed for one study [33], as variance data were not available. The imputation method was used to borrow a particular value from other studies using the same outcome measure [34]. The functional assessment of chronic illness therapy-fatigue, used in 3 studies [35-37], was transformed by multiplying the mean values by −1 to ensure that all scales were in the same direction [29]. For visual representation and ease of interpretation, fatigue, depression, and anxiety were transformed to allow lower scores to represent improved outcomes.

Initiation of Engagement Data

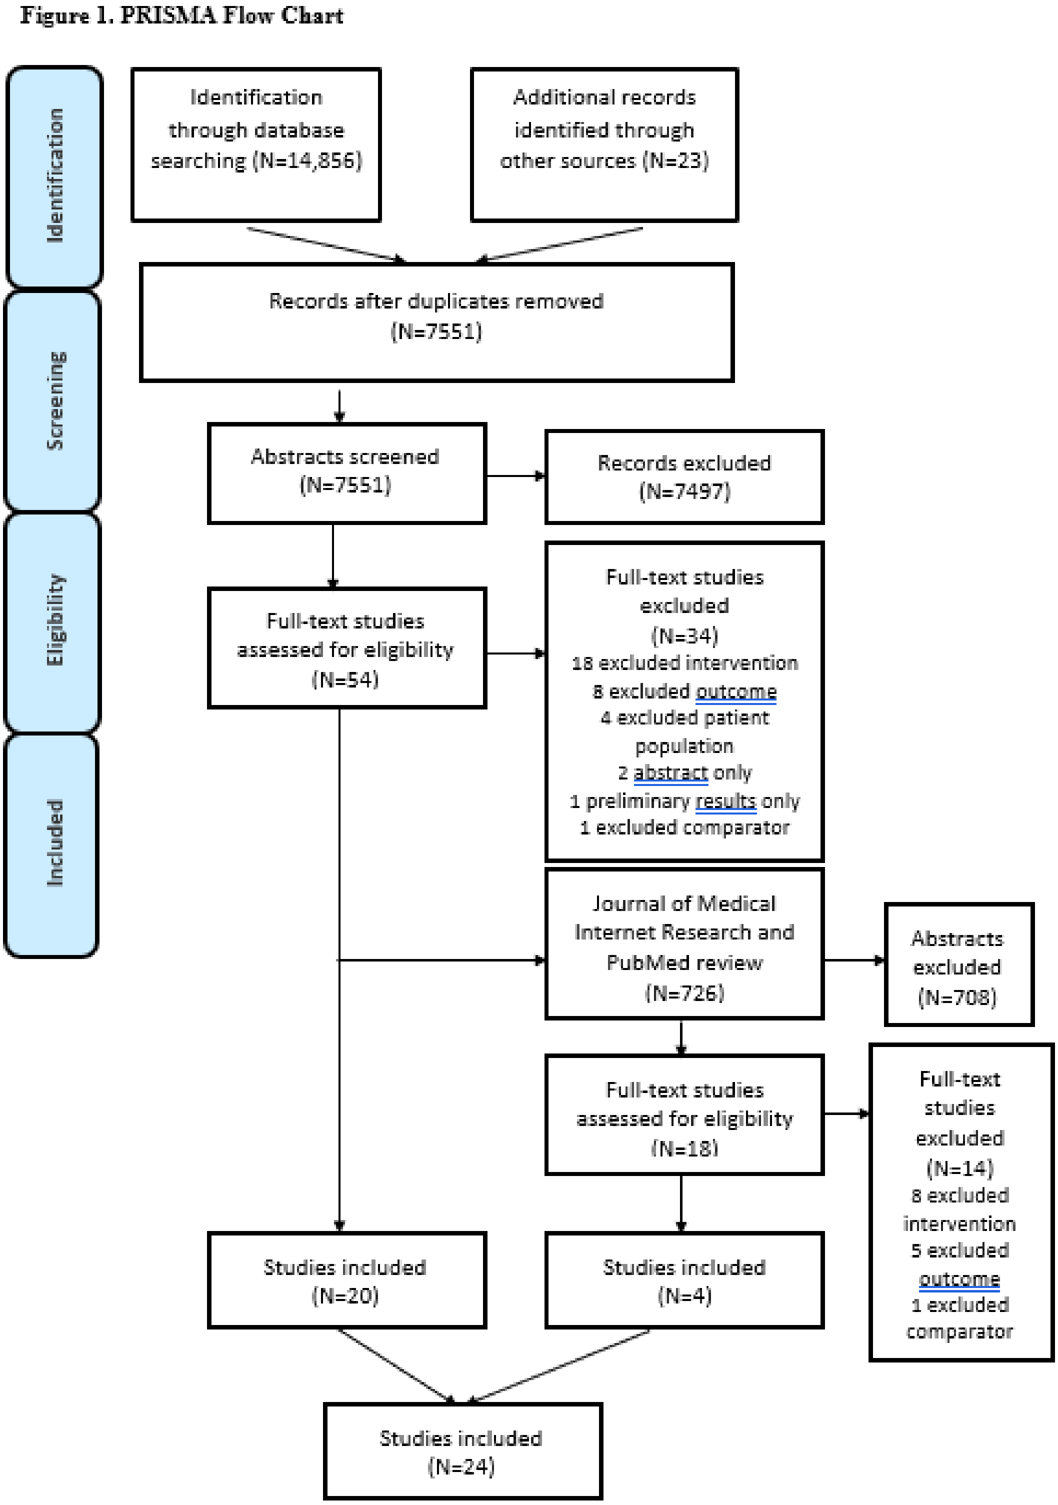
Variances of raw proportion data were transformed using the Freeman-Tukey arcsine square root transformation [38]. The DerSimonian-Laird random effects model [39] was then used to pool these transformed proportions to provide a measure of the extent of between-study heterogeneity. The Wilson score was then used to provide CIs for the pooled estimate [40]. A random effects plot was then created. Random effects metaregression analyses were then performed to determine whether any of the different delivery modes influenced the amount of engagement initiation.

Results

Summary

The literature search identified a total of 15,582 studies with a further 23 studies identified through reference list searching of relevant papers. After EndNote X8 and Covidence deduplication, a total of 8259 studies were screened, with 72 s remaining for full-text screening. A total of 24 studies were included in this review; 11 studies were delivered via synchronous and asynchronous methods, respectively, with 2 studies using a combined approach (Figure 1). The studies were predominantly delivered in the United States with 13 studies [37,41-52]; 3 in Australia [35,36,53], South Korea [33,54,55], and the Netherlands [56-58]; and 1 in Canada [59] and France [60]. The total sample size was 4583, ranging from n=18 to n=641. There were a range of different cancer types targeted during the study interventions: 7 unspecified cancer types [45,49,50,52,55-57,60]; 6 breast cancer [33,35,42,51,54,61]; 2 colon or colorectal [36,43]; 2 breast, prostate, or colorectal [44,59]; 2 melanoma [41,53]; and 1 each of breast/colon or rectal [37], colorectal or prostate [58], prostate [46], and urothelial cell carcinoma [47]. The majority of studies focused on posttreatment (also reported as survivors) with 17 studies [33,36,37,41,43-45,49-56,59,61], 6 studies included patients during active cancer treatment (2 used survivors and active cancer treatment) [35,42,47,57,58,60], and 1 study included patients undergoing surveillance for their cancer [46]. Of the 24 studies included in this review, 19 provided data on a measure of physical activity behavior change [33,35-37,42-45,48-50,54-57,59] and 9 studies provided data on a measure of dietary behavior change [33,36,42,44-47,54,56]; 2 studies provided data on skin self-examination during melanoma-related interventions [41,53]; 2 studies provided data on smoking cessation [52,56], whereas another study provided information on alcohol intake [36]. Interventions delivered via synchronous modes included telephone, Skype, and videoconferencing, whereas those delivered via asynchronous modes used combinations of custom or existing websites and mobile apps, with short messaging and email. Studies that used combined methods used web-based intervention and an online moderated forum, and telephone and SMS text messaging. Many studies in any of the delivery method intervention groups used adjunct features, including pedometers and written workbooks (Multimedia Appendix 3).

Figure 1. Preferred reporting items for systematic reviews and meta-analysis flowchart.



Behavior Change Techniques

The use of behavior change techniques varied significantly between studies; studies used between 2 and 17 (median 8) different techniques. The most popular behavior change techniques used across the studies were goal setting (behavior; 87%) and self-monitoring of behavior (85%), information about health consequences (70%), problem solving (67%), action planning (62%), feedback on behavior (61%), and instructions on how to perform behavior (61%). Out of the 93 hierarchically set behavior change techniques from the Michie et al [62] taxonomy, only 33 were used across the 24 studies included in this review (Multimedia Appendix 4).

Behavior Change Theory

A total of 20 studies reported on the use of behavior change theory. Within the studies that reported on behavior change theory, social cognitive theory and the transtheoretical model of change were the 2 most popular theories used, with 60% and 39% of papers reporting on these, respectively. A total of 8 studies (33%) used more than one theory to underpin their interventions (Multimedia Appendix 4).

Risk of Bias Assessment

The outcome of the risk of bias assessment is presented in Figures 2 and 3. Attrition bias was considered to be low across most studies. There was a high degree of risk associated with blinding of personnel, participants, and outcome assessment. The reporting of study-related processes was highly variable, which led to many areas of the risk of bias being assigned as unclear.

Figure 2. Risk of bias summary of the included randomized control trials using the Cochrane Collaboration risk of bias tool.

Behavior Change: Physical Activity

Of the 19 studies in this review that presented data on physical activity as a behavior change outcome, 15 studies were included in this meta-analysis [35-37,42,44,45,48-51,54,57-60] and a further 4 could not be included as the data were presented in a format incompatible with meta-analysis [33,43,55,56]. There was a finding in favor of eHealth interventions (SMD 0.34; 95% CI 0.21 to 0.48) for increasing physical activity behaviors (Figure 4).

When analyzed by delivery method, the intervention delivery mode of synchronous, asynchronous, or combined did not impact the overall positive outcome effect (Table 1).

Figure 4. Effect of electronic health interventions compared with a control on physical activity interventions, analyzed using standardized mean difference. SMD: standardized mean difference.

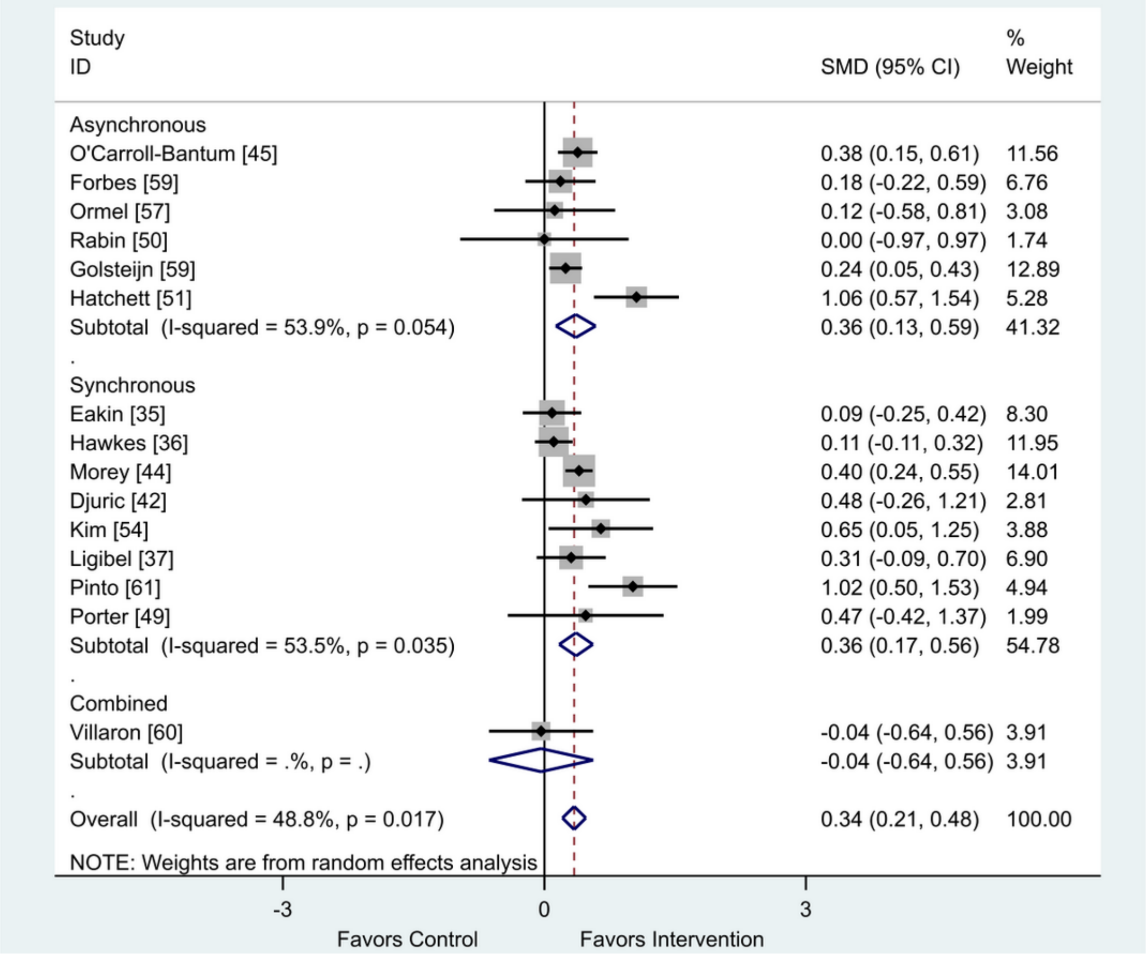

Table 1. Metaregression comparing the effect of synchronous versus asynchronous versus combined electronic health interventions on physical activity behavior change, analyzed using standardized effect size.

Standardized effect size	Coefficient	95% CI	*P* value
Asynchronous	−0.01	−0.38 to 0.35	.95
Combined	−0.41	−1.27 to 0.45	.32
Constant	0.37	0.13-0.61	.005

The 4 studies examining asynchronous interventions provided data that were presented in a format incompatible with meta-analysis. One reported a significant increase in moderate physical activity in their intervention group (*P*=.04); however, the authors reported that this did not remain significant after controlling for multiple testing [56]. Another study reported that the intervention increased the proportion of participants who undertook moderate intensity aerobic exercise for at least 150 min per week to a greater extent than the control (*P*=.001) [33]. These outcomes contrasted with 2 other studies that reported no effect in improving the secondary outcome of metabolic equivalent of task (*P*=.48) [55] and the proportion of participants who undertook moderate-to-vigorous physical activity (*P*=.12) [43].

Behavior Change: Dietary

A total of 9 studies included in this review provided data on diet as a behavior change outcome; 6 studies were included in this meta-analysis [36,42,44,45,47,54] and a further 3 could not be included as the data were presented in a format incompatible with meta-analysis [33,46,56]. There was a finding that diet interventions delivered via eHealth can improve behavior change compared with control (SMD 0.44; 95% CI 0.18 to 0.70; Figure 5).

When analyzed by delivery method, the intervention delivery mode of synchronous or asynchronous did not impact the overall positive outcome effect (Table 2).

Figure 5. Effect of electronic health interventions compared with control on dietary interventions, analyzed using standardized mean difference. SMD: standardized mean difference.

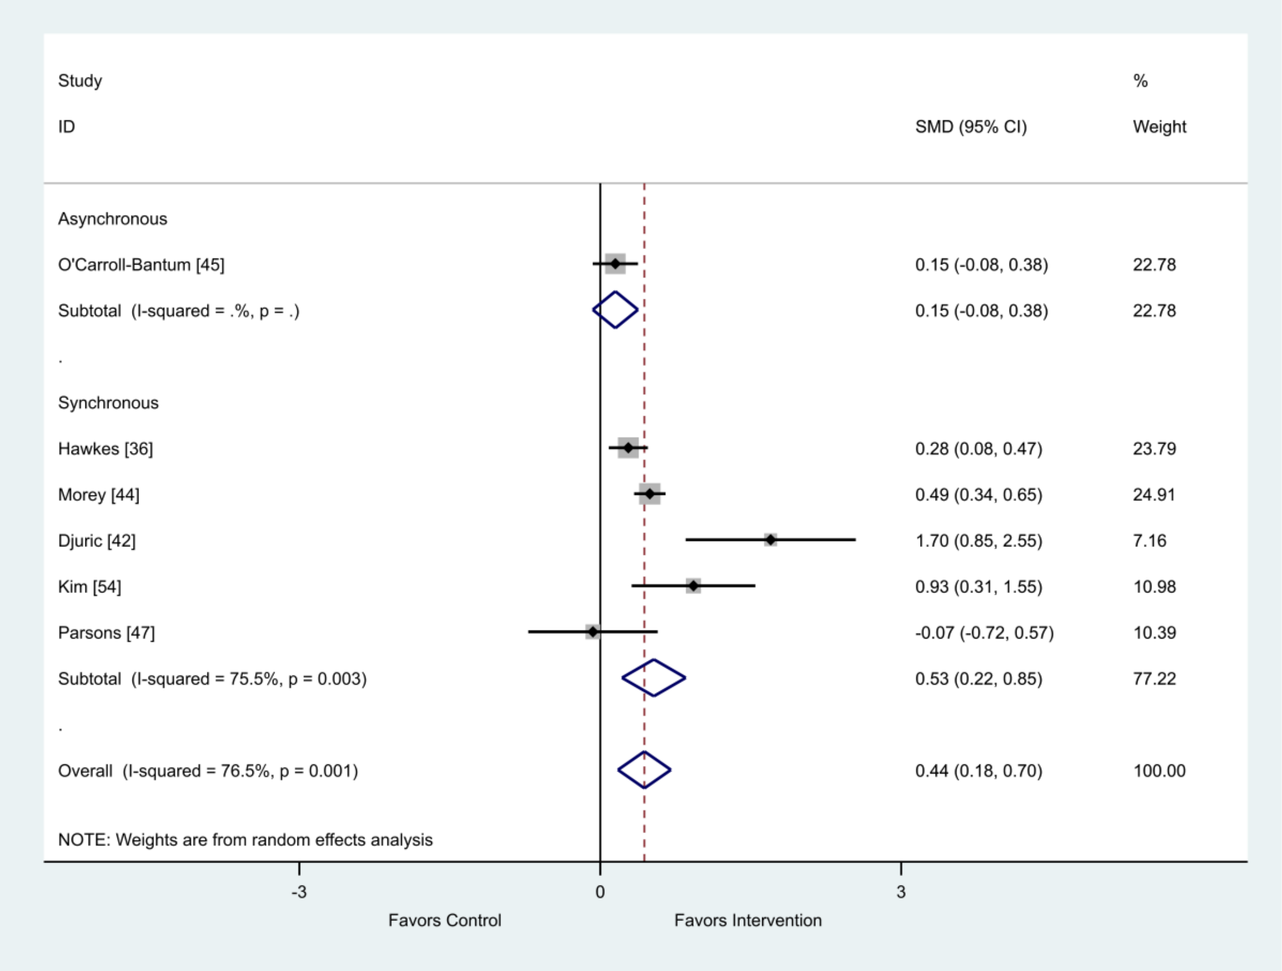

Table 2. Metaregression of synchronous and asynchronous dietary interventions on behavior change outcome, analyzed using standardized effect size.

Standardized effect size	Coefficient	95% CI	*P* value
Asynchronous	−0.44	−2.18 to 1.29	.52
Constant	0.60	−0.17 to 1.36	.10

In total, 3 studies provided data incompatible with the meta-analysis. The 2 studies using asynchronous delivery approaches reported significantly higher vegetable consumption in participants accessing a web-based guide (*P*=.02), which the authors reported did not remain significant after accounting for multiple testing [56], whereas dietary quality index was greater in the intervention compared with the control in the other study (*P*=.001) [33]. One synchronous intervention reported a significant increase in alpha-carotenoid concentrations compared with controls (*P*<.05) [47].

Other Behavior Change Outcomes

A total of 5 studies provided data on other primary behavior change outcomes, including smoking cessation, alcohol intake, and skin self-assessment. A study examining asynchronous interventions reported no effect on smoking cessation (*P*=.28; odds ratio [OR] 2.61) [56]. Similarly, no improvement in smoking cessation rates was found in a study using a combined delivery mode approach [52]. A separate trial using an asynchronous delivery mode to encourage skin self-examination was effective (OR derived from percentage data provided 1.90, 95% CI 2.23-2.94) [41]. Conversely, another study examining the effect of an intervention (delivered synchronously) to encourage skin self-examination reported a decrease in the reported rate of skin self-examination in the intervention group compared with control (adjusted between-group difference −0.13; 95% CI −0.4 to 0.2; *P*=.40); however, this outcome was measured at 6 months follow-up rather than immediately post intervention at 1 month. This study also presented information about melanoma-related knowledge change and was the only study included in this review that presented any data on knowledge change. They found an improvement in melanoma-related knowledge in the intervention group at 6 months using an adjusted between-group difference (1.7; 95% CI 0.8-2.6; *P*<.001) [53]. The final study examining a synchronously delivered intervention revealed no significant difference between groups on alcohol intake (grams per day; *P*=.26) [36].

Health Outcome: Quality of Life

There were 13 studies that provided data on quality of life [33,35-37,42-44,49,54,55,58-60]; 2 meta-analyses were performed as data were presented as a combination of final scores and change scores. Of the 7 studies that provided final scores, there was a favorable impact of the intervention for the synchronous (SMD 0.25; 95% CI −0.36 to 0.87) and combined (SMD 0.35; 95% CI −0.25 to 0.95) eHealth interventions on quality of life. The 3 studies using an asynchronous mode for intervention delivery reported no improvement in quality of life compared with control conditions (SMD 0.01; 95% CI −0.15 to 0.17; Figure 6).

Of the 5 studies that provided change scores, there was a favorable impact of the intervention for both asynchronous (SMD 0.12; 95% CI 0.01-0.23) and synchronous (SMD 0.26; 95% CI 0.02-0.49) eHealth interventions on quality of life (Figure 7).

Figure 6. Effect of electronic health interventions compared with a control on quality of life interventions, analyzed using standardized mean difference (postintervention mean and SD). SMD: standardized mean difference.

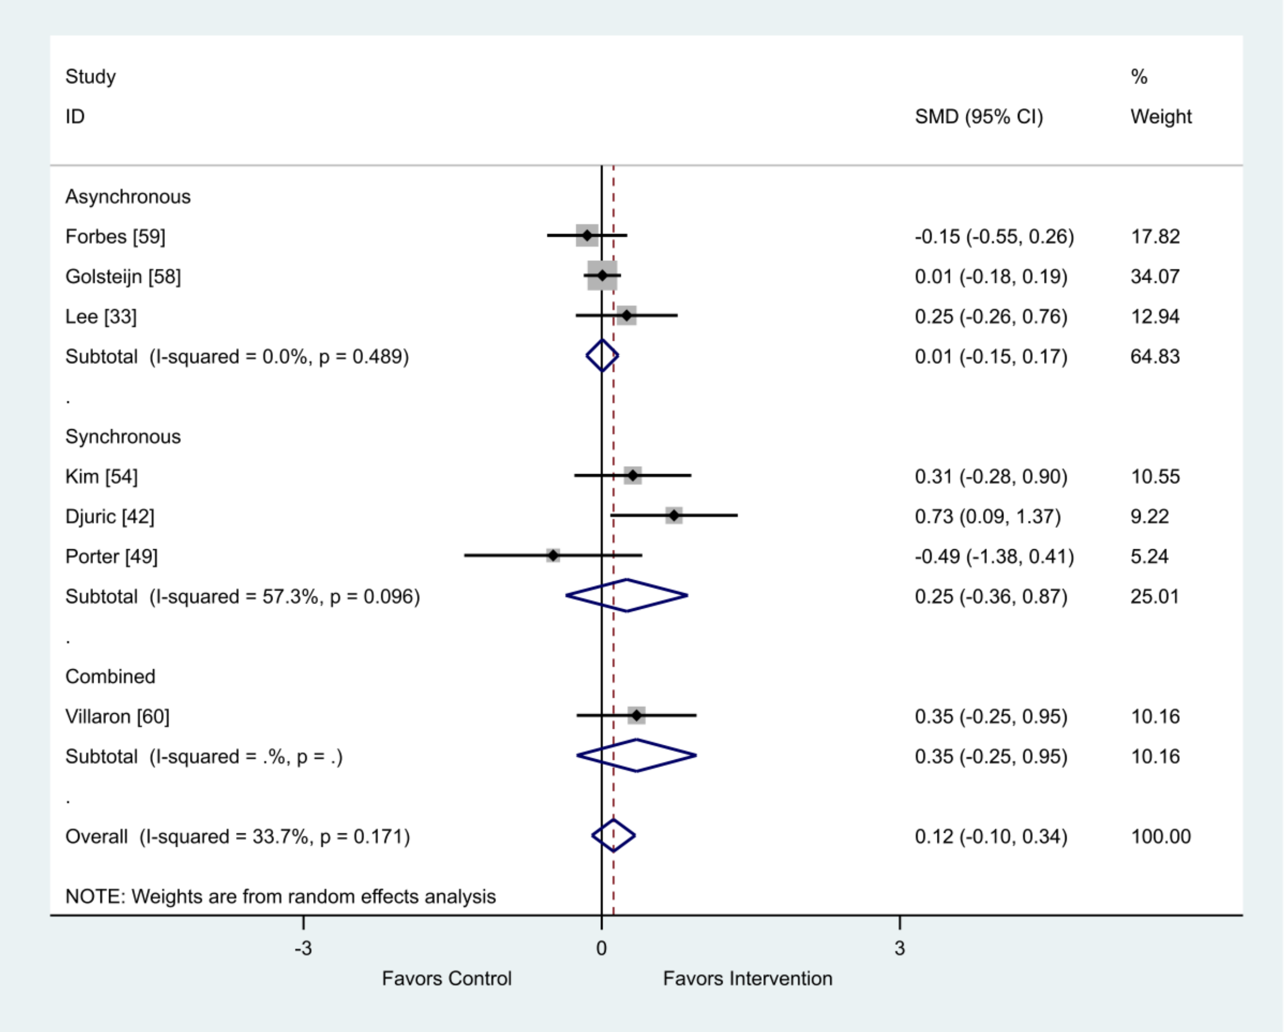

Figure 7. Effect of electronic health interventions with a control on quality of life interventions, analyzed using standardized mean difference (postintervention mean and SD change scores). SMD: standardized mean difference.

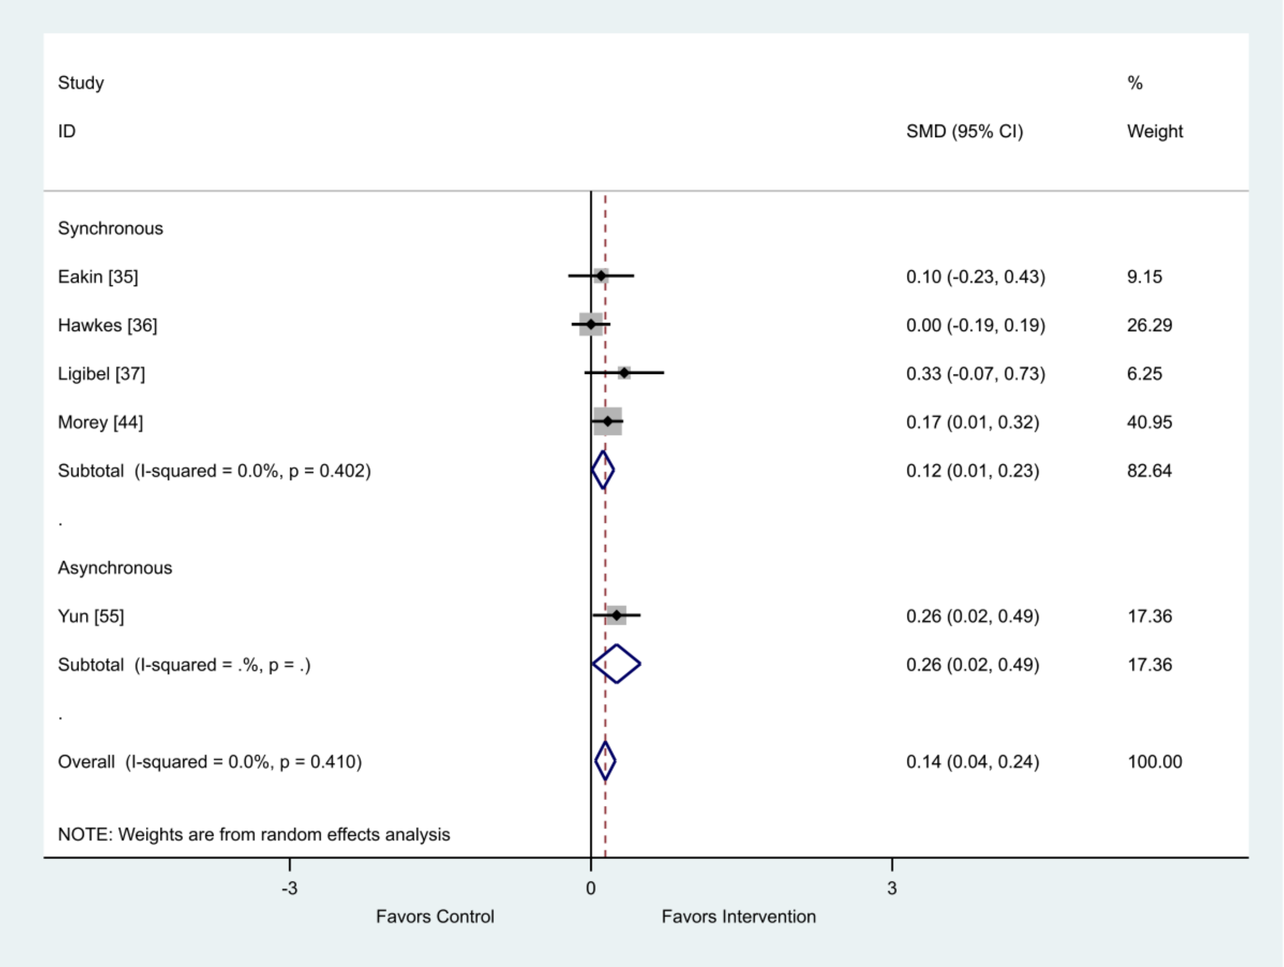

One study provided data that were incompatible with the meta-analysis. It was found that quality of life was not significantly different between the asynchronous intervention group and the no intervention control group over the intervention period. The intervention group baseline outcome score was 105 versus the postintervention outcome score of 109.1 and the control group baseline outcome score of 103.3 versus the postintervention outcome score of 106.5 [43].

When analyzed by delivery method, the intervention delivery mode of synchronous or asynchronous did not impact the overall positive outcome effect (Table 3).

When analyzed by delivery method, the intervention delivery mode of synchronous or asynchronous did not impact the overall positive outcome effect (Table 4).

Table 3. Metaregression of synchronous and asynchronous interventions on quality of life outcome, analyzed using standardized effect size.

Standardized effect size	Coefficient	95% CI	*P* value
Asynchronous	−0.31	−1.05 to 0.43	.31
Combined	0.04	−1.22 to 1.29	.94
Constant	0.31	−0.37 to 1.0	.27

Table 4. Metaregression of synchronous and asynchronous interventions on quality of life outcome, analyzed using standardized effect size (postintervention mean and SD change scores).

Standardized effect size	Coefficient	95% CI	*P* value
Asynchronous	0.14	−0.31 to 0.58	.40
Constant	0.12	−0.70 to 0.31	.14

Health Outcome: Fatigue

There were a total of 10 studies that presented data on fatigue [33,35-37,45,50,54,55,58,60,63]. Of the 6 studies using final scores, synchronous (SMD 1.03; 95% CI 0.41-1.66) and combined (SMD 0.23; 95% CI −0.37 to 0.83) interventions showed a favorable impact on fatigue. The asynchronous group reported no intervention effect on fatigue (SMD 0.03; 95% CI −0.18 to 0.24; Figure 8).

Of the 4 studies that provided change scores, both synchronous (SMD 0.19; 95% CI 0.03-0.34) and asynchronous (SMD 0.29; 95% CI 0.05-0.53) eHealth interventions showed a favorable impact on fatigue (Figure 9).

When analyzed by delivery method, the intervention delivery mode of synchronous, asynchronous, or combined did not impact the overall positive outcome effect (Table 5).

When analyzed by delivery method, the intervention delivery mode of synchronous or asynchronous did not impact the overall positive outcome effect (Table 6).

Figure 8. Effect of electronic health interventions with a control on fatigue interventions, analyzed using standardized mean difference (postintervention mean and SD). Lower scores indicate improved fatigue. SMD: standardized mean difference.

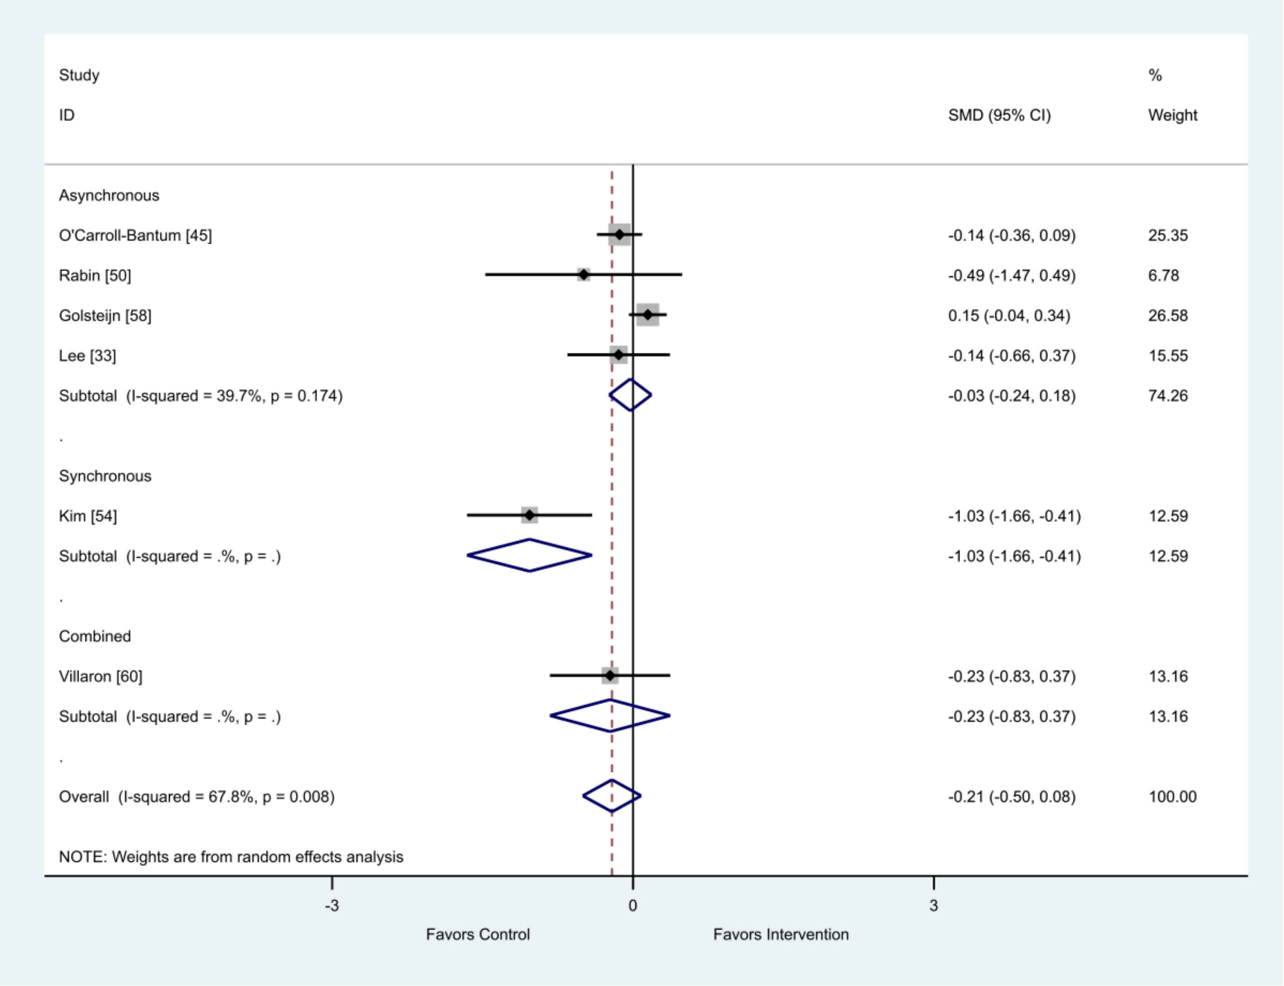

Figure 9. Effect of electronic health interventions with a control on fatigue interventions, analyzed using standardized mean difference (postintervention mean and SD change scores). Lower scores indicate improved fatigue. SMD: standardized mean difference.

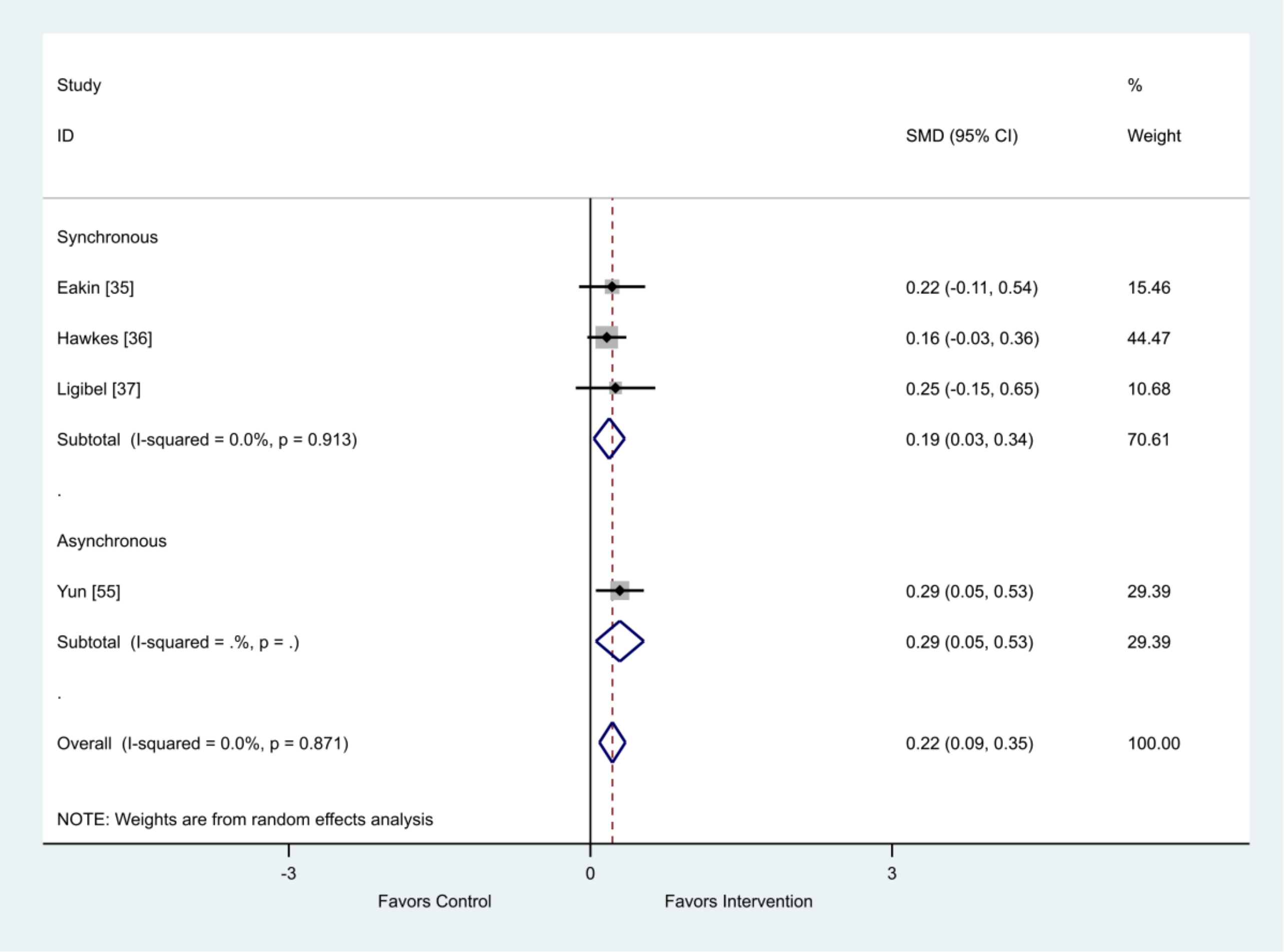

Table 5. Metaregression of synchronous and asynchronous interventions on fatigue outcome, analyzed using standardized effect size.

Standardized effect size	Coefficient	95% CI	*P* value
Asynchronous	1.00	−0.16 to 2.17	.07
Combined	0.80	−0.74 to 2.35	.20
Constant	−1.03	−2.14 to 0.77	.08

Table 6. Metaregression of synchronous and asynchronous interventions on fatigue outcome, analyzed using standardized effect size.

Standardized effect size	Coefficient	95% CI	*P* value
Asynchronous	0.11	−0.51 to 0.73	.54
Constant	0.19	−0.15 to 0.53	.14

Health Outcome: Depression

There were a total of 6 studies that presented data on health outcome depression [33,45,53-55,58]. Of the 5 studies’ final scores, the synchronous intervention showed a favorable impact on depression (SMD 0.80; 95% CI 0.19-1.41). The asynchronous group reported no intervention effect on depression (SMD 0.11; 95% CI −0.01 to 0.22; Figure 10). The one that compared asynchronous study with a no intervention control that reported change scores found no intervention effect on depression (group difference −1.0; 95% CI −2.8 to 0.8; *P*=.40).

When analyzed by delivery method, the intervention delivery mode of synchronous or asynchronous did not impact the overall positive outcome effect (Table 7).

Figure 10. Effect of electronic health interventions with a control on depression interventions, analyzed using standardized mean difference (postintervention mean and SD). Lower scores indicate improved depression. SMD: standardized mean difference.

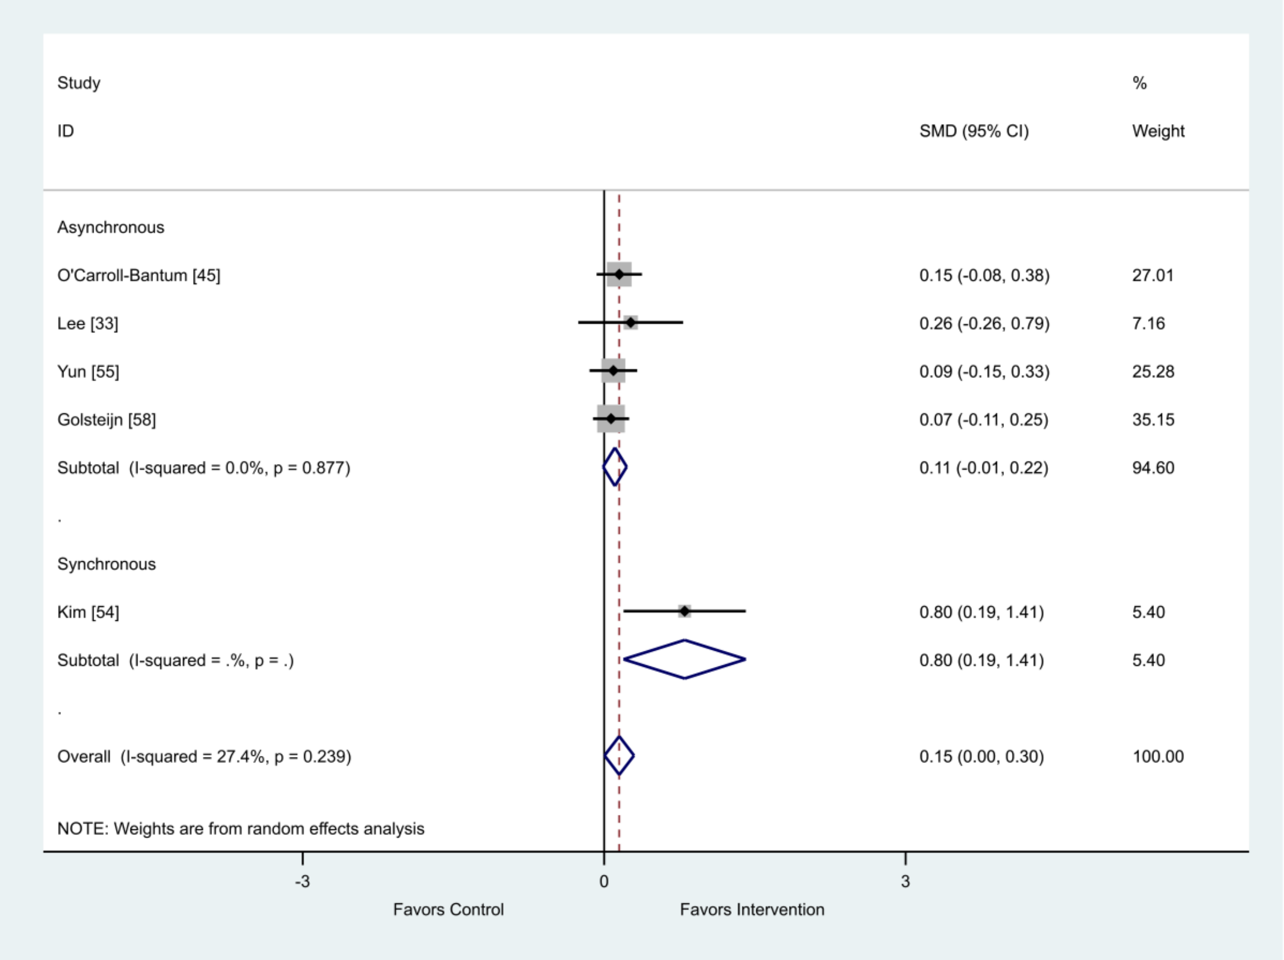

Table 7. Metaregression of synchronous and asynchronous interventions on depression outcome, analyzed using standardized effect size.

Standardized effect size	Coefficient	95% CI	*P* value
Asynchronous	−0.69	−1.70 to 0.32	.12
Constant	0.80	−0.19 to 1.79	.08

Health Outcome: Anxiety

There were 6 studies that provided health outcome data on anxiety [33,35,53-55,58].

Of the 4 studies that provided final scores, both synchronous (SMD 2.78; 95% CI 1.95-3.61) and asynchronous (SMD 0.74; 95% CI −0.01 to 1.48) modes showed a favorable impact on anxiety (Figure 11).

Of the 2 studies that provided change scores comparing synchronous interventions with usual care control groups, there was a very small favorable intervention effect on anxiety (SMD 0.15; 95% CI −0.09 to 0.40; Figure 12).

When analyzed by delivery method, the intervention delivery mode of synchronous or asynchronous did not impact the overall positive outcome effect (Table 8).

Figure 11. Effect of electronic health interventions versus control group on anxiety interventions, analyzed using standardized mean difference (postintervention mean and SD). Lower scores indicate improved anxiety. SMD: standardized mean difference.

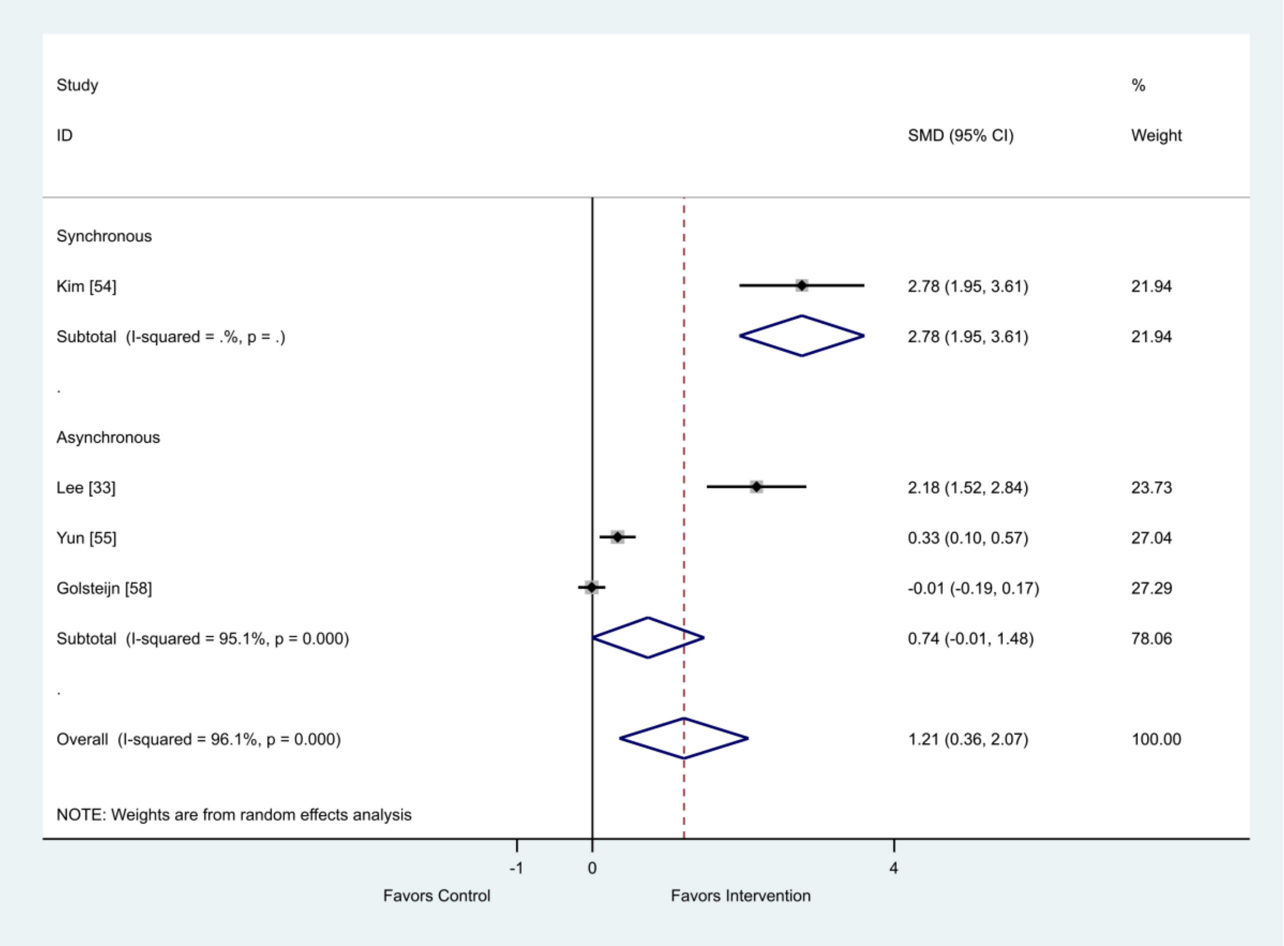

Figure 12. Effect of electronic health interventions with a control on anxiety interventions, analyzed using standardized mean difference (postintervention mean and SD change scores). Lower scores indicate improved anxiety. SMD: standardized mean difference.

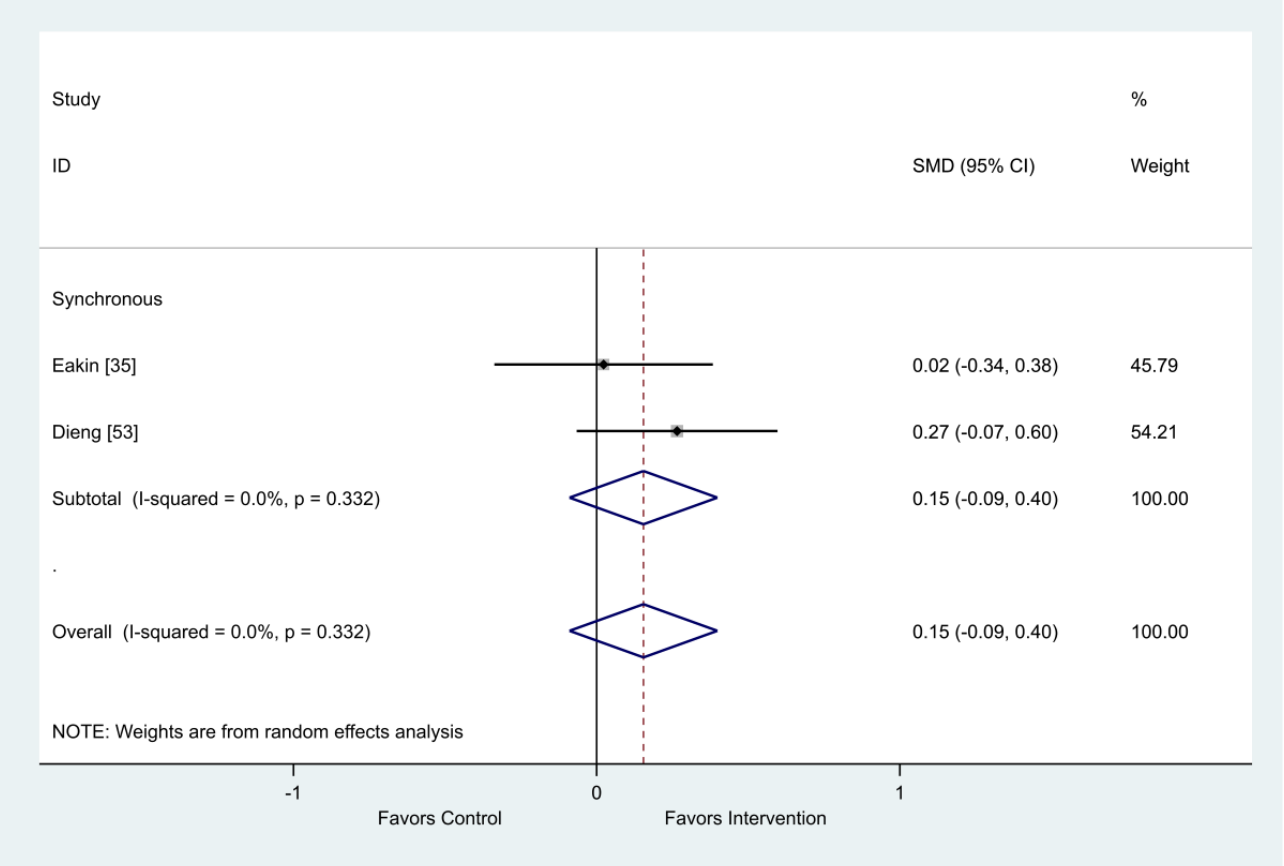

Table 8. Metaregression of synchronous and asynchronous interventions on anxiety outcome, analyzed using standardized effect size.

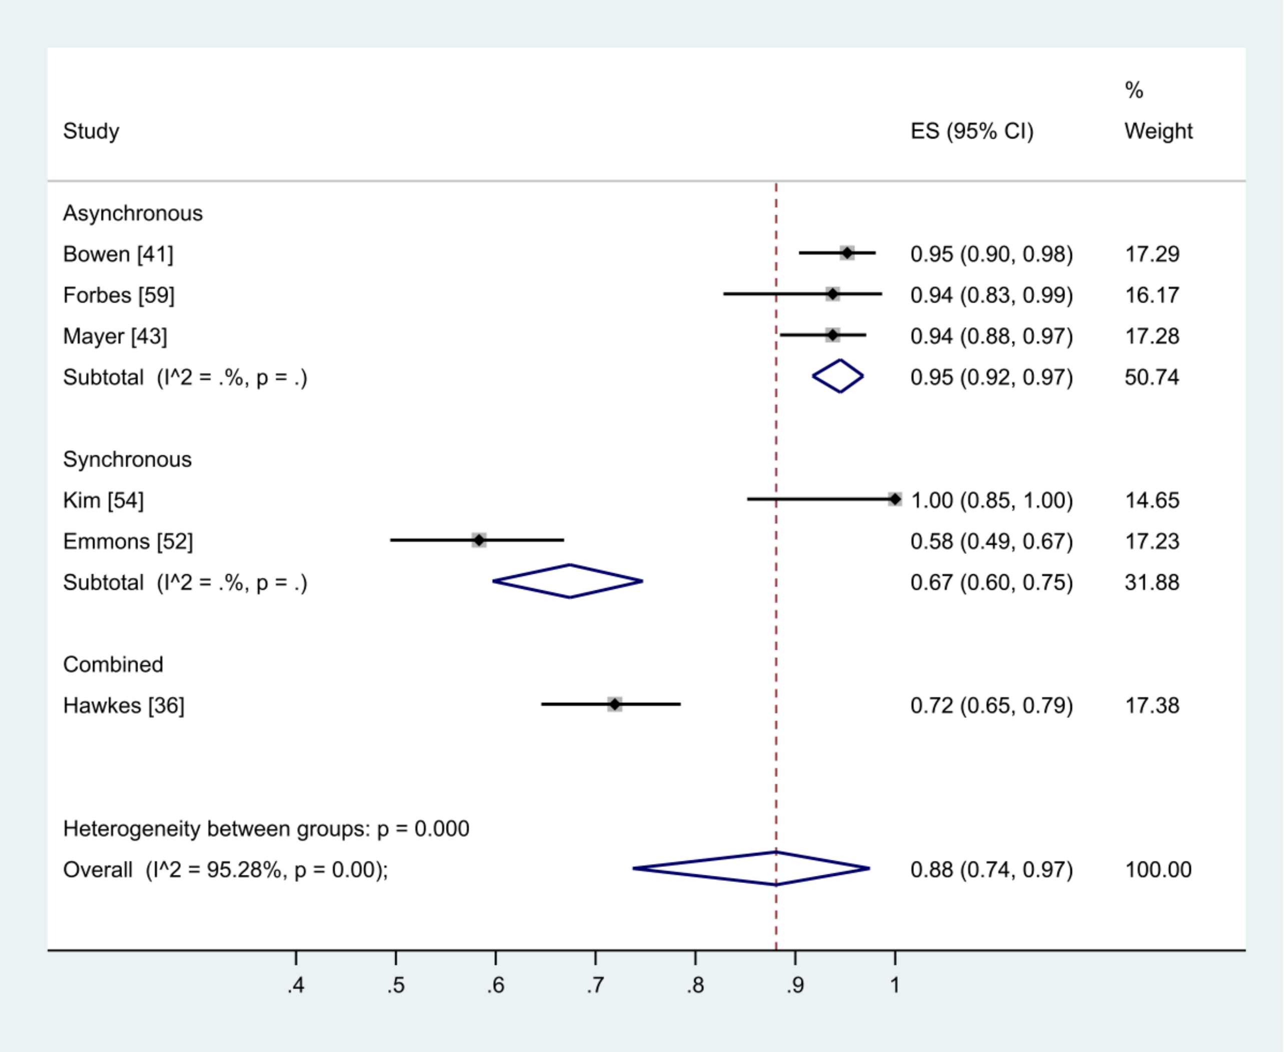
Standardized effect size	Coefficient	95% CI	*P* value
Asynchronous	−1.98	−7.96 to 4.01	.29
Constant	2.77	−2.47 to 8.02	.15

We were unable to perform metaregression to examine the association between mode of delivery and change in anxiety, as there was only 1 delivery mode (synchronous) included in this meta-analysis.

Initiation of Engagement Data

A total of 5 studies did not provide any information about engagement or participation in their intervention [46,48,51,57,58]. Only 6 studies provided data on the initiation of participants to their interventions [36,41,43,52,54,59]. Other data pertaining to participant engagement or participation in interventions are shown in Table 1. The pooled effect of the proportion of initiation engagement found that 88% of participants commenced the intervention (Figure 13). Of the 11 synchronously delivered interventions, 9 studies reported on completion of telephone or videoconference sessions. In all, 7 studies reported that participants completed between 62% and 100% of all planned intervention sessions [33,36,42,45,49,53]. One study reported that 79% completed >75% of telephone calls [35] and another reported a median 9 out of 10 to 11 planned telephone calls completed [37]. Comparison of engagement and participation was made particularly challenging in the asynchronous group due to the heterogeneous nature of the reporting. Studies presented a range of data that included initiation, content accessed, log-in averages, and intervention fidelity or adherence.

Figure 13. The effect of mode of delivery (synchronous or asynchronous) interventions on initiation engagement, analyzed using proportion.



Discussion

Principal Findings

The use of eHealth interventions improved physical activity, diet behaviors, quality of life, fatigue, depression, and anxiety in studies conducted across people who had been treated for a range of cancer types compared with control conditions. The overall impact appeared to be greater for the behavior change outcomes than the health outcomes. It did not appear that the mode of delivery (synchronous vs asynchronous vs combined) affected how much improvement the eHealth interventions generated. There was insufficient evidence to identify that the amount of behavior change was associated with the amount of change in health outcomes, although this may yet be identified as further studies report on both outcomes. These findings indicate that eHealth interventions may be beneficial for improving health behaviors and health outcomes when provided to cancer patients and/or survivors. However, there was one behavior change area where a negative impact on a health behavior (skin self-examination for melanoma) was reported, indicating that not all health behaviors may be improved from exposure to eHealth interventions.

At this stage, there is insufficient evidence to determine what delivery methods work for who, in what context, at what time. Therefore, the decision as to whether health services should provide synchronous or asynchronous eHealth behavior change interventions cannot yet be answered. None of the studies in this review compared synchronous with asynchronous eHealth approaches in the same population, using the same behavior change theory and techniques. A study that examined a telephone-delivered versus an internet-delivered weight loss intervention in cancer survivors found that the telephone group not only had greater losses in waist circumference (−0.75 vs −0.09; *P*=.03) but also had higher levels of engagement (80% completed calls vs 27% web log-ins) [64]. Other considerations, such as the cost-effectiveness and reliability of the different delivery approaches, should also come into play when making this decision. These issues were beyond the scope of this review but should be examined in future work to help inform this decision making.

We identified that initial engagement was high across the few studies that reported this outcome. We would also have liked to examine long-term engagement and the effect of this on intervention success, but the highly inconsistent and sporadic reporting of long-term engagement within included studies made synthesizing this information impossible in this review. There is no consensus regarding the definition of engagement in the context of eHealth and how to measure it, as many studies of behavior change interventions do not report at all on their participant engagement characteristics, yet report on attrition [65-69]. People could report absolute frequencies of contact, and where relevant, duration of contact. However, a recent new concept of effective engagement outlines that for each different intervention delivered, and for each individual person receiving the intervention, their requirement to engage and over what period of time will be different to achieve the intended outcome [70]. This concept indicates that *absolute* measures of engagement in eHealth interventions may not tell the full story as to whether the individual has engaged to a degree that is optimal for them. Perski et al [71] proposed that engagement with digital behavior change interventions occurs through specific direct and indirect mechanisms of action. Constructs of content, delivery, context, target behavior, population, and setting were proposed as important mechanisms to understand and report on when understanding engagement.

Our findings contrast with a previous review that looked at telephone interventions on physical activity and dietary behavior change in the population without cancer [72], in that the magnitude of effect appears to be lower than previously pooled analysis of behavior change outcomes using telephone interventions (effect size 0.60; 95% CI 0.24 to 1.19). It is plausible that the benefit of eHealth interventions in cancer populations may be diminished compared with populations without cancer because of concurrent treatment side effects and the impact that a cancer diagnosis can have on the capacity of patients to absorb new information [73]. A systematic review [74] of the effectiveness of mHealth technology use in behavior change interventions demonstrated mixed results. Studies reporting benefits described small effect sizes that were retained only in the short term. An older review [10] of interventions promoting health behavior change via the internet also examined the mode of delivery on efficacy and included 3 categories: automated functions, communicative functions, and supplementary modes. This review found that interventions were more effective in eliciting behavior change when there was more extensive use of underlying behavior change theory, more techniques of behavior change used in the delivery of the intervention, and additional methods of interacting with participants (combined techniques). This review found that between 2 and 17 behavior change techniques were used in each study, and a range of theoretical underpinnings was employed. This variability may also have contributed to the variability seen in the results of this review. These previous reviews were limited by not examining the potential mechanisms of action leading to the behavior change or the moderating effect of how the interventions were delivered.

We acknowledge a number of limitations on how we decided to undertake this review. Many of the studies included in this review used self-reported outcome measures with many failing to also include objective measures to corroborate data. We also combined both objective and subjective measures of behavior in the same meta-analysis. The small number of studies and high heterogeneity of data precluded a multiple metaregression to assess the interaction between behavior change and intervention delivery mode on health outcomes. Response bias, including social desirability bias, occurs frequently where self-reported outcome measures are used in research [75]. Ecological fallacy could also explain why we did not find a relationship between the amount of behavior change and the amount of change in quality of life. This could have been brought about by the examination of study level comparisons of analytic approaches and relationships rather than at the person level. We need to be able to trace the health behavior change data to the individual participants to understand the impact of the intervention.

Many of the studies reported multiple outcome measures, each with differing results. In this review, we chose to use data from the primary outcome measures (where reported) as the outcome of choice for behavior change and health outcomes. Where this was not reported, we decided to choose the outcome that we believed to be the most relevant outcome to the intervention examined in that particular study. We chose not to conduct metaregression analyses comparing synchronous and asynchronous eHealth approaches for outcomes where only one study was available in either of these subgroups. Such analyses would arguably have had limited generalizability and were at high risk of committing a type II statistical error. We chose to include studies within this synthesis regardless of the type of cancer involved or of the behavior change theories and techniques employed. Each theory and technique may have a different effect on the outcomes we examined and may be a source of confounding for our comparisons of synchronous and asynchronous eHealth approaches. Similarly, the type of patient population may have a moderating effect on the efficacy of synchronous and asynchronous eHealth interventions. Ideally, a comparison of synchronous and asynchronous eHealth approaches would be undertaken in the same populations, using the same behavior change theories and techniques. However, no such studies were identified in this review.

Effective health behavior change has been ascribed to rely on the use of behavior change theory. In all, 83% (n=20/24) of studies included in this review reported on the use of behavior change theory. It was beyond the scope of this review to detail how behavior change theory was used to develop the various interventions used in the included studies. This is an area of great interest and could be pursued in future reviews seeking to identify how interventions are constructed, using the methods of Michie and Prestwich [76].

There are a range of studies that looked at synchronous and asynchronous methods in health behavior change interventions in cancer patients and/or survivors, but there is a complete absence of RCTs that compared the differences in the delivery methods within one specific trial. This is where the gap in evidence lies. This systematic review highlights the need for further 3-arm studies comparing both synchronous and asynchronous interventions compared with a standard care group. There should also be an economic evaluation to determine which is also the most cost-effective intervention. Robust reporting of engagement, not only at the initiation of the trial but throughout, is also essential to gain a greater understanding of the complexity of participant engagement in study efficacy and how to replicate this in future implementation of eHealth interventions. Trials of this nature will enable the determination of the most successful method of delivery in terms of effectiveness, acceptability, user engagement, cost-effectiveness, successful behavior change, and ultimately translation into health outcomes.

Conclusions

This systematic review and meta-analysis provides evidence that behavior change interventions delivered via eHealth, particularly on physical activity and diet modification delivered to cancer patients or survivors, show benefit. There is insufficient evidence to determine whether the specific delivery mode of eHealth (synchronous, asynchronous, or combined) modulates this effectiveness. Three-arm RCTs comparing asynchronous and synchronous delivery modes with a control with robust engagement reporting are required to determine the most successful delivery method for promoting behavior change and ultimately favorable health outcomes.

Acknowledgments

The authors wish to thank Monash Health for providing support for this project.

Authors' Contributions

KF was the lead reviewer and drafted the manuscript. MS was the secondary reviewer for full-text screening. MS and KH were secondary reviewers for data extraction. KH was the secondary reviewer for the risk of bias assessment. KF completed the data analysis and TH reviewed for accuracy. All authors (MS, KH, TH, and DC) provided feedback on the draft manuscript. All authors (MS, KH, TH, and DC) reviewed the final manuscript before submission.

Conflicts of Interest

None declared.

Abstract

In this issue of the *Journal of Medical Internet Research*, the World Health Organization (WHO) is presenting a framework for managing the coronavirus disease (COVID-19) infodemic. Infodemiology is now acknowledged by public health organizations and the WHO as an important emerging scientific field and critical area of practice during a pandemic. From the perspective of being the first “infodemiologist” who originally coined the term almost two decades ago, I am positing four pillars of infodemic management: (1) information monitoring (infoveillance); (2) building eHealth Literacy and science literacy capacity; (3) encouraging knowledge refinement and quality improvement processes such as fact checking and peer-review; and (4) accurate and timely knowledge translation, minimizing distorting factors such as political or commercial influences. In the current COVID-19 pandemic, the United Nations has advocated that facts and science should be promoted and that these constitute the antidote to the current infodemic. This is in stark contrast to the realities of infodemic mismanagement and misguided upstream filtering, where social media platforms such as Twitter have advertising policies that sideline science organizations and science publishers, treating peer-reviewed science as “inappropriate content.”

The World Health Organization Declares an Infodemic and Crowdsources a Framework

In this issue of the *Journal of Medical Internet Research*, a high-profile group of authors associated with the World Health Organization (WHO) have published a paper entitled “Framework for Managing the COVID-19 Infodemic: Methods and Results of an Online, Crowdsourced WHO Technical Consultation” [1]. In the paper, the authors collected and organized global ideas to fight the current coronavirus disease (COVID-19) infodemic declared by the WHO on February 15, 2020. Impressively, this consultation meeting was entirely conducted online, and, as noted by the authors, turned out to be one of the largest meetings ever convened by the WHO.

In my capacity as the Editor of the *Journal of Medical Internet Research*, I had the honor of attending the meeting as an invited panelist to talk about the responsibility and potential approaches for scholarly publishers to combat the infodemic. A summary of my presentation and a project proposal for scientists, editors, and science communicators will be the subject of a separate, forthcoming editorial.

I also attended the meeting as one of the early researchers in this field. In fact, I coined the terms *infodemiology* [2,3], *infodemic*, and *infoveillance* [4] over the course of the past 20 years. It is not without pride that I witnessed how this line of research is now formally acknowledged by public health organizations and the WHO as a novel, emerging scientific field and critical area of practice during a pandemic [1]. It should also be noted that this journal has been a pioneer in encouraging and disseminating this line of research and has provided a central forum for researchers to discuss and publish their infodemiology work in a high-impact journal [5-7].

A Brief History of Infodemiology

Although the term *infodemiology* was coined in 2002 [2], concerns over infodemics or outbreaks of misinformation are almost as old as the World Wide Web itself. A widely cited paper published in 1997 in the *BMJ* drew attention to the, now seemingly trivial, finding that medical information found on the internet is not always reliable [8]. This paper sparked an avalanche of publications describing and analyzing the quality of medical information on different topics, which I, together with my colleagues, synthesized in a comprehensive systematic review published in *JAMA* in 2002 [9]. At the time, I was also leading major EU-funded projects (MedCERTAIN and MedCIRCLE) attempting to label health information on the internet with machine-readable metadata [10,11], an ambitious project with the goal to create something akin to a digital “immune system” for misinformation [12], with distributed descriptive and evaluative metadata as machine-processable “antibodies.” The metadata (evaluative or descriptive, supplied by third parties or the providers themselves) are perhaps conceptually comparable to contemporary efforts by Facebook and Twitter to fact-check information and label social media posts that are problematic [13], although these tags are not necessarily machine processable and cannot be harvested by third-party applications, which was the underlying idea of the MedCERTAIN/MedCIRCLE projects [10,11]. The goal was to create a global infrastructure for such machine-processable annotations that would allow humans and machines to attain a more complete picture about what other people and institutions have to say or think about a certain information provider or piece of information. The vast amount of information on the web, the dynamic nature of the web, and questions on the scalability of this approach were obvious limitations, but, perhaps it is time, for the sake of future infodemic preparedness, to revisit some of these “semantic web” ideas articulated over 20 years ago and to combine them with today’s powerful artificial intelligence tools, because, given the advances in natural language processing, many of these metadata labels could now be generated automatically. My former project partner Dan Brickley is now working with Google and is running schema.org [14], which organizes community vocabularies to enable such applications.

I coined the term “infodemiology” in 2002 in a short guest editorial in the *American Journal of Medicine* [2], defining “infodemiology” as a “new emerging research discipline and methodology” comprising the “the study of the determinants and distribution of health information and misinformation—which may be useful in guiding health professionals and patients to quality health information on the Internet.” Equipped with the awareness that “quality of health information” as well as “misinformation” is often hard to define (as quality is in the eye of the beholder, and a “fact” in medicine requires more than one patient or study), I framed infodemiology as a method to “identify areas where there is a knowledge translation gap between best evidence (what some experts know) and practice (what most people do or believe)” [2]. While this early work focused on information *supply* (what is published on the internet), I added, in 2006, analysis of information *demand* (search queries) to the concept, realizing that harvesting what people are searching for on the internet could inform areas of public health such as surveillance. I illustrated this with demonstrating the predictive power of Internet searches to predict flu outbreaks [3,4]; an idea that inspired Google Flu Trends [15]. With the emergence of Twitter, more “social listening” infoveillance studies became possible, and H1N1 (SwineFlue) became the first pandemic where this approach could be demonstrated; my graduate student Cynthia Chew and I, analyzed the content of pandemic tweets and determined, among other interesting findings, a prevalence of misinformation of 4.5% [16].

In a tweet posted on April 14, 2020, Secretary General of the United Nations (UN) António Guterres announced a UN communications response initiative countering the infodemic with facts and evidence [17]; however, what we have learned in 20 years of infodemiology research is that the quality of health information is an elusive concept, as in medicine, the truth is not always easy to determine, especially in a rapidly evolving situation.

While certain technical quality criteria, readibility scores, and the compliance with ethical quality criteria (such as the presence of disclosure of who owns the site and conflicts of interests, all aspects that are important to determine the source credibility) are relatively easy to measure, the concepts of *accuracy*, *facts*, and *truth* usually require the presence of evidence-based guidelines or systematic reviews as a gold standard to determine what works and what does not. In a rapidly evolving situation such as the COVID-19 pandemic, some of the problems are the rapid rate of new scientific information published and the inability of researchers, policy makers, journalists, and ordinary citizens to keep up with quickly changing facts. In other words, the current pandemic is partly a challenge to filter (in real time) the sheer quantity of information published on a daily basis. The founder of the website Retraction Watch, Ivan Oransky, stresses that science is a conversation [18]. Even a publication of a clinical study is not the last word and studies may be contradicted or proven wrong. In the early phases of a pandemic, "facts" are perhaps more accurately referred to as "BETs" (best evidence at the time). Facts are sparse and recommendations based on BETs are subject to change. The COVID-19 pandemic has illustrated this with examples such as mask-wearing recommendations, use of certain drugs such as hydroxychloroquine, and social distancing or school opening guidelines. The public health and medical evidence also needs to be integrated with economic and political considerations and may be subject to cultural variations and influences. Thus, the proposal to fight the infodemic by spreading “facts” is easier said than done when it is not clear what the exact facts are.

The Information “Cake” Model

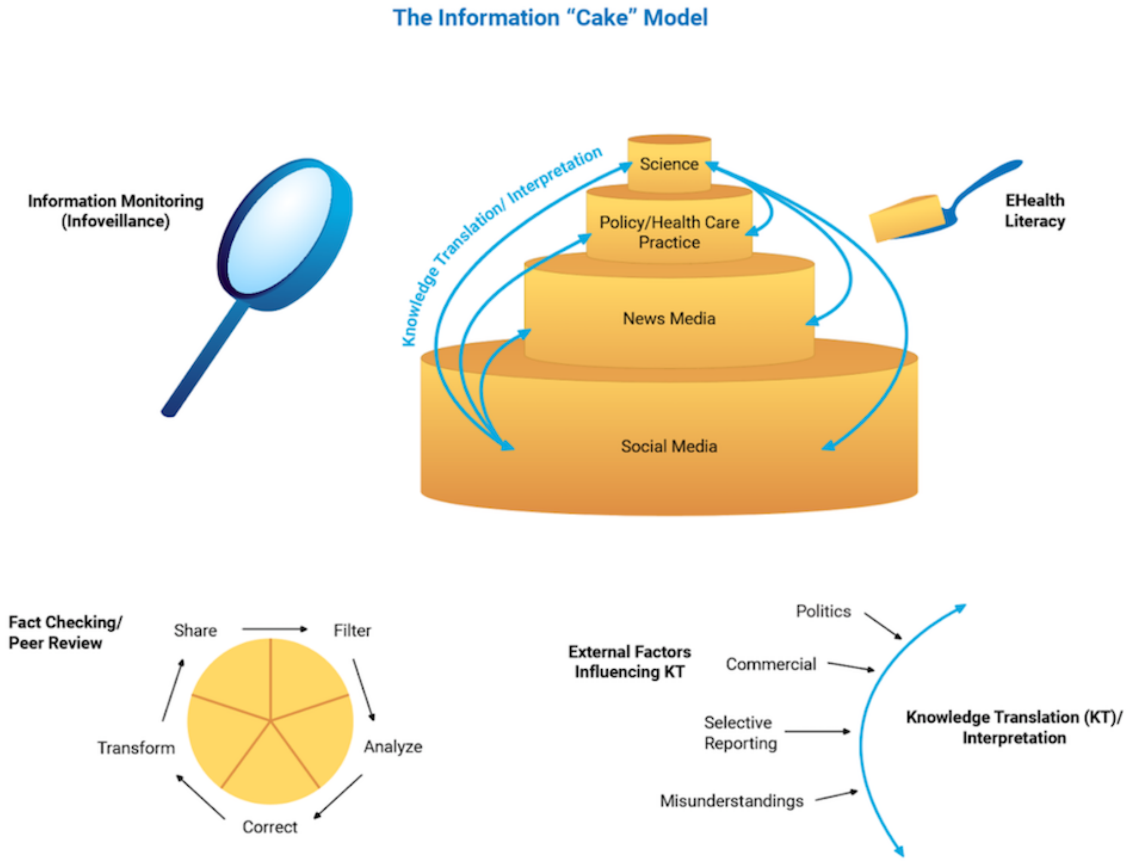
The following model is not the framework presented in the WHO paper in this journal. It is an "expert opinion" (to the degree as somebody - and probably the first - who has "Infodemiologist" in his LinkedIn profile can be considered an "expert"). It supplements the WHO framework by providing a first broad roadmap on how to fight an infodemic.

The current infodemic is a crisis to distill the sheer quantity of information, which is occurring on four levels: (1) science, (2) policy and practice, (3) news media, and (4) social media.

The wedding cake model (Figure 1) illustrates these four levels as layers. The size of the layers is proportional to the amount of information generated by these four groups of actors. The model also shows some information flows and knowledge translation activities that take place between these different levels. Science is the smallest layer of the wedding cake in terms of the amount of information, and it is depicted at the top of the information wedding cake, which represents rigorous and selective information production cycles. Clearly, misinformation can be found here as well, perhaps measured by the number of retractions, which, as of June 2020, stands at less than two dozen retracted articles [19], but this number is certain to increase. With over 26,000 COVID-19 articles indexed in Pubmed, this represents less than 0.1% of the published research, even though there may be a higher rate within the segment of unreviewed preprints, some of which may never see the light of journal publication, which may be another metric for the prevalence of scientific misinformation (somebody please do a study on this and submit it to the *Journal of Medical Internet Research*!). The main problem is not so much the prevalence of misinformation in the science layer, but the challenge of translating this information into actionable recommendations and conveying conclusions for different audiences and stakeholders in other layers, illustrated by the knowledge translation arrows in Figure 1.

Social media is depicted as the largest and last segment of the wedding cake, representing the vast amount of nearly unfiltered and uncontrolled information generated or amplified by the public. Information in social media is, of course, also generated by science organizations, policy makers, health care organizations, and journalists.

Figure 1. The Information "Cake" Model. The four pillars of infodemic management are information monitoring (infoveillance; top left); building eHealth Literacy and science literacy (top right); encouraging knowledge refinement and quality improvement processes for information providers, such as fact checking and peer review (bottom left); and Knowledge Translation, meaning to translate knowledge from one layer to another, while minimizing distorting factors (bottom right). eHealth: electronic health; KT: knowledge translation.



First Pillar: Facilitate Accurate Knowledge Translation

Between the levels, knowledge translation processes need to take place to translate the information from one audience to another, and these knowledge translation processes are, perhaps, the main mechanisms where information becomes misinformation, as the interpretation of "facts" is subject to multiple potentially influencing factors such as politics, commercial interests, selective reporting, and misunderstandings. These knowledge translation processes take place between all four layers of the cake, for example, between public health policy recommendations and news media (to keep the figure simple, not all possible knowledge translation arrows between the different layers are shown in Figure 1). *The first* *pillar of infodemic management is to support, facilitate, and strengthen accurate knowledge translation*. In the WHO paper, authors hint at that when they write “knowledge should be translated into actionable behaviour-change messages presented in ways that are understood by and accessible to all individuals” [1], but this is of course just one example for a KT problem, while there are also other KT challenges, e.g. between science and policy makers. Realizing that knowledge translation is subject to political, commercial, or other influences that distort the scientific message, the influencing factors should be minimized or, if present, at least clearly disclosed and called out.

Second Pillar: Knowledge Refinement, Filtering, and Fact-Checking

The FACTS model [20], depicted as an insert in Figure 1, is an example for a fact checking workflow, and reminds us that within each layer, there are knowledge refinement processes such as fact checking and quality assurance mechanisms at play, which are sometimes visible and sometimes invisible to the end user. For example, on the science level, the process of peer reviewing and publishing scholarly work is a method to constantly filter, refine, and improve the information generated by previous scholars. This also means that within each layer, there is a continuum ranging from raw, tentative, and possibly problematic information to highly refined and trustworthy information. *The second pillar of infodemic management is to encourage, facilitate, and strengthen knowledge refinement and filtering processes on each level, to accelerate internal quality improvement processes.* Within each layer, information in different stages of this "refinement" process can be found (for example, in the science layer, unreviewed preprints, laying right next to peer-reviewed scholarly communications); thus, clearly labelling the provenance of the information at the different knowledge production stages is equally as important as facilitating and accelerating them..

Third pillar: Build eHealth Literacy

The cake-serving utensil illustrates that in the age of the internet and openness, the end user is able to (but not always equipped) to consume information from any level, in any refinement stage, making eHealth literacy an essential skill in a networked world. eHealth literacy is defined as "the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to addressing or solving a health problem." [21,22]. In the information age (which is now perhaps shifting to the infodemic age!), the user carries a significant part of the responsibility to select and downstream-filter trustworthy health information. For example, nothing stops a user from tapping into the vast array of unreviewed preprints published in preprint servers such as medRxiv, but interpreting and contextualizing the information found here requires significant eHealth literacy (which includes science literacy) skills. Thus, *the third pillar of infodemic management is to enhance the capacity of all stakeholders to build eHealth literacy, to select and assess health and science information found on the different layers of the information cake*. This aspect is notably underdeveloped in the WHO paper’s taxonomy but can be seen as part of WHO’s “identify evidence” category.

Fourth Pillar: Monitoring, Infodemiology, Infoveillance, and Social Listening

The fourth pillar of infodemic management is continuous monitoring and analysis of data and information exchange patterns on the internet, a field I have called *infodemiology and infoveillance* [4]. My idea was that similar to surveillance in pandemics we want to be able to detect outbreaks of misinformation, rumors, falsehoods, to counter them with facts or other interventions. Infoveillance requires generating metrics on information supply on the internet, including its quality (for example incidence of anti-vaccination tweets), as well as information demand metrics, such as search queries or questions posed on social media or other web 2.0 platforms. In Figure 1, infoveillance is illustrated as a lens magnifying the information exchange patterns within different communities and for different subtopics.

Conclusions

Poorly executed and uncoordinated infodemic management may lead to unintended consequences such as the sidelining and suppression of science in favor of political and commercial interests.

Such an unintended consequence is demonstrated, for example, by the poorly thought-through advertising policy of Twitter [23], which only allows governments and selected news media, but not science organization or science publishers, to amplify messages. Under this “inappropriate content” policy of Twitter, only the following kinds of tweets are allowed to be amplified and promoted [23]:

- *Public service announcements related to COVID-19 from governments and supranational entities (for example, World Health Organization) as well as trusted partners approved by the Public Policy team*
- *News related to COVID-19 from media publishers who have been exempted under the Political Ads policy.*

Notably missing from Twitters' exemption list are science organizations and science publishers. Is this indicative of a sidelining of science in favor of politics, or just an oversight? JMIR Publications (as science publisher) ran into this problem first-hand when we were prevented by Twitter from disseminating COVID-19 peer-reviewed research, promoting our virtual COVID-19 preprint journal clubs, etc. Therefore, if the UN declares an infodemic and promotes science and “facts” as the antidote, then the suppression of science as “inappropriate content” by private social media platforms should be an alarming sign that indicates that there is ample room of improvement in how the current infodemic is managed and coordinated by different stakeholders.

The current COVID-19 pandemic is a 9/11 for public health, but also an opportunity to develop and formalize tools and approaches for future infodemic management. It is also an opportunity to re-engineer certain knowledge refinement processes such as scholarly publishing and peer-review (stayed tuned to what we are doing with JMIRx.org). Much as improvements in information flows between government agencies post-9/11 helped to prevent another major act of terrorism in the United States, improved and preventive infodemic prevention and management can mitigate the next infodemic, which we will face as soon as a vaccine is available. The price for freedom of speech and improved information technology is an increased susceptibility to infodemics. We are entering the age of infodemics.

Conflicts of Interest

The author is founder and president of JMIR Publications.

Abstract

Food intake and usual dietary intake are among the key determinants of health to be assessed in medical research and important confounding factors to be accounted for in clinical studies. Although various methods are available for gathering dietary data, those based on innovative technologies are particularly promising. With combined cost-effectiveness and ease of use, it is safe to assume that mobile technologies can now optimize tracking of eating occasions and dietary behaviors. Yet, choosing a dietary assessment tool that meets research objectives and data quality standards remains challenging. In this paper, we describe the purposes of collecting dietary data in medical research and outline the main considerations for using mobile dietary assessment tools based on participant and researcher expectations.

Diet Assessment in Clinical Studies: Purposes and Limitations

In which situations should diet be assessed in clinical research? Which considerations should drive the selection of a dietary assessment tool (DAT)? This paper addresses these two questions, emphasizing that one should consider not only the research objectives and study setting, but also the opportunities and limitations of available methods for acquiring and analyzing dietary data.

In epidemiological and clinical observational studies, dietary parameters are adequately considered when information on usual dietary intake is needed at a population level [1] or when diet-disease relationships are being explored [2]. In these settings, evaluating dietary intake over time has proved efficient for investigating diet-disease associations at the population level, especially in chronic conditions [2]. Tracking participant lifestyle was needed to understand the role of unhealthy food and diet in the development of overweight, obesity, type 2 diabetes [3], cardiovascular diseases [3,4], and cancer [5]. However, despite the availability of scientifically validated methods to assess dietary intake and usual intake, their use in establishing diet-disease relationships remains controversial [6,7].

In interventional settings, dietary parameters need to be considered for efficacy assessments or to control confounding effects, irrespective of the nature (dietary, drug, or other) of the intervention [8]. However, background diet is, to our knowledge, not systematically assessed in drug development studies despite evidence of the presence of food-drug interactions.

Food-drug interaction is also an important factor to consider during clinical development, as some chemical compounds in foods can potentially affect the pharmacokinetic, pharmacodynamic, or metabolic pathways of some drugs [9]. For example, it is known that leafy green vegetables such as kale and spinach, which contain high levels of vitamin K, can reduce the effectiveness of some oral anticoagulants, such as warfarin [10]. In parallel, we must not neglect how the side effects of medicinal products can influence appetite [11].

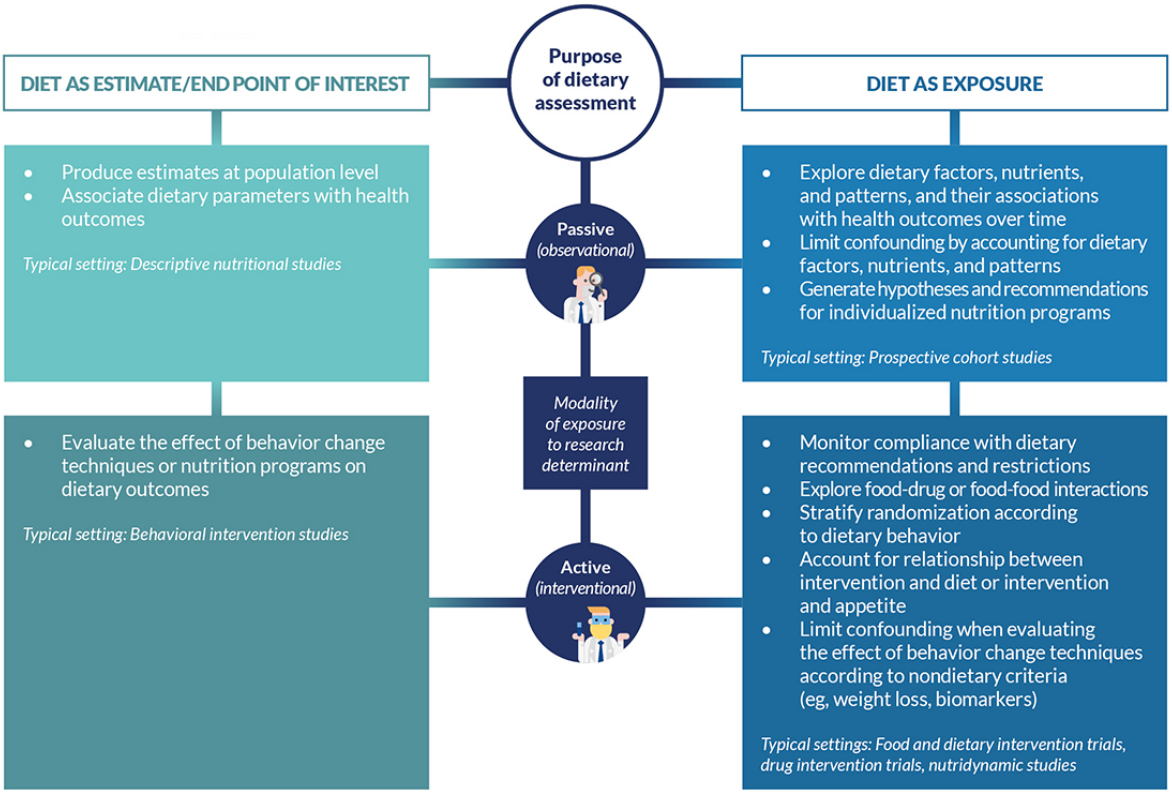
Choosing the Optimal DAT

Selecting a DAT adapted to a research question is usually a matter of compromise. Current methods to assess diet are available in various formats (paper or electronic), to obtain data on dietary intake (prospectively or retrospectively) or usual intake [12]. In a comprehensive resource guide issued by the Food and Agriculture Organization of the United Nations [13] and as explained by other authors [14], various available DATs can be distinguished based on technology (including data acquisition):

- Conventional methods for dietary data collection, which include food records, food frequency questionnaires, 24-hour dietary recalls and diet history, which are widely used in research, with known strengths and limitations
- DATs based on innovative technologies, which are divided into 5 categories according to the acquisition method: personal digital assistant, image-assisted methods (ie, digital cameras), mobile-based technology, interactive computer and web-based technologies, and scan and sensor-based technologies. It must be noted that DATs based on innovative technologies can be digitized versions of the above-mentioned conventional methods.

Collecting dietary data is, however, not always needed for primary study analyses, as one may only be interested in monitoring the background diet or compliance with dietary restrictions while focusing on many other clinical and nonclinical parameters (Figure 1).

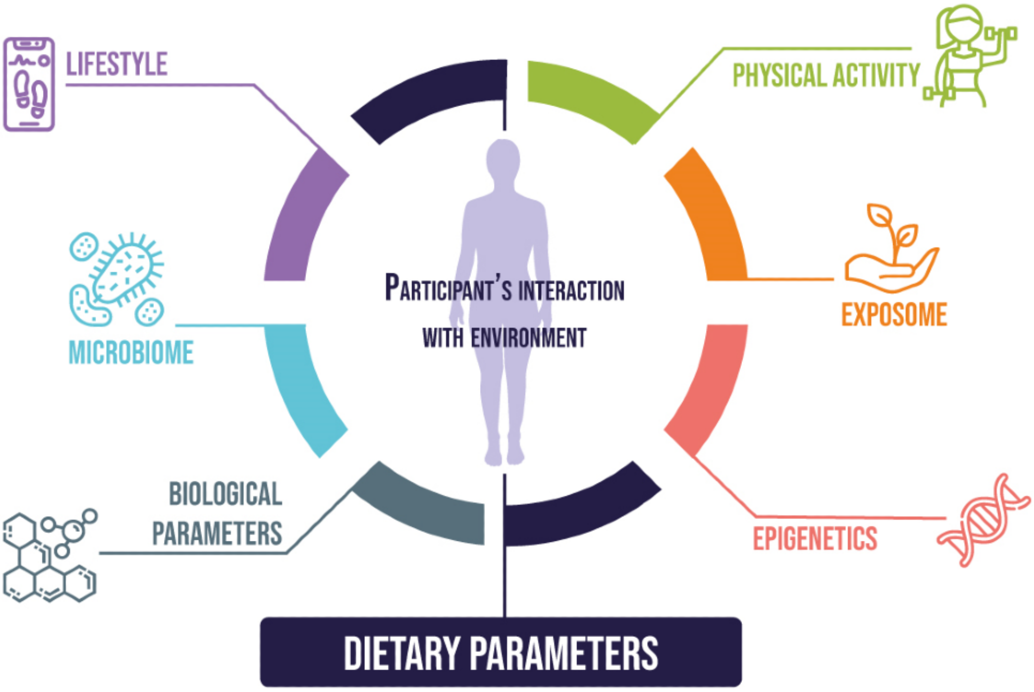
Figure 1. Relevant frameworks for using dietary assessment tools in human studies.



Because collecting dietary information usually requires substantial involvement from clinical study participants, selecting an appropriate DAT represents a trade-off between participant burden and the volume or accuracy of the collected information. Compromises may include collecting dietary intake data at specific time points rather than tracking each eating occasion, and choosing a reasonable frequency for assessing food intake throughout the research studies.

However, limiting the dietary assessment to habitual food intake (evaluated using food frequency questionnaires) is not relevant for every study, especially when associations between dietary and biological parameters are investigated, as outlined in Figure 2.

Figure 2. Parameters that can be measured or accounted for along with dietary parameters in medical research.



Instead of evaluating habitual food intake, daily tracking of each eating occasion may be needed. One example is the daily variation of gut microbiota composition, known to be related to food choice [15], requiring, when investigated, exhaustive and daily tracking of a participant's dietary intake. Handling temporality, therefore, represents a major challenge when selecting a relevant DAT, in case there is important intrasubject variability of parameters over time. We believe that a focus is needed for identifying or developing solutions that can effectively track participants' background diet throughout their participation in research studies (observational or interventional), irrespective of the intervention (drug, food, or dietary) while limiting the associated participant burden. DATs based on new technologies offer opportunities to facilitate traditional food intake measures, and mobile apps have demonstrated being adequate for both participants and researchers. For participants, mobile apps represent an acquisition method that is acceptable, accessible, ubiquitous, and one that can be used by participants alone [16-18]. For the study sponsors or researchers, these apps offer other opportunities in terms of cost-effectiveness, reducing time between the collection and reporting of dietary data, and improving data quality with an accurate, comprehensive, and relevant food composition data set [14].

Mobile apps, therefore, represent a good compromise for researchers (investigators and sponsors) when the collection of dietary data is needed.

The Need to Explore the True Potential of Mobile Apps as DATs

When navigating the astronomical number of mobile diet apps (approximately 30,000 diet and physical activity mobile apps are currently available on Google Play and the App Store), selecting a DAT that fits with research purposes remains a key challenge. This selection should be based on multiple parameters, including the suitability of user experience and interface, the reliability of the food composition database (FCD), the relevance of the data acquisition method (identification and quantification of foods), and the quality of nutritional outputs.

To compare these mobile diet apps in terms of reliability, quality, and effectiveness, we cannot consider the number of downloads as a reliable evaluation parameter, as the most frequently downloaded apps are not necessarily the most usable or efficient in medical research [19]. Neither can we assess these tools based on user ratings (ie, stars), which are known to be biased [20]. Currently, no official standards exist for evaluating health-related mobile apps, making the evaluation of the strengths and weaknesses of these apps complex for researchers when choosing a relevant tool [21].

High-quality reviews and meta-analyses are few, and there is limited comparability between the evaluation methods used. Some of the reviews evaluate functionality, information quality, esthetics, and engagement [22]; others evaluate the accountability, usability, scientific coverage, and technology-enhanced features based on the opinions of nutrition experts who had tested different apps for 5 days [23]. In parallel, other experts have developed their own scales for a qualitative assessment of mobile health apps, including the following:

- Mobile App Rating Scale, which focuses on 4 evaluation parameters by an expert panel, including engagement, functionality, aesthetics, and quality of the information provided by the app [24]
- App Quality Evaluation, which evaluates the educational quality and technical functionality of nutrition apps by nutrition professionals and app users, based on several parameters, including app function, purpose, behavior change potential, support of knowledge acquisition, and skill development [25]

To our knowledge, only 3 studies have compared the nutritional values provided by different mobile diet apps based on quantitative parameters. One research team evaluated the accuracy of 7 diet apps in providing nutrient values. In their study, the nutrient labels of 100 food products available in the Netherlands were compared to the nutrient values provided in the nutrition facts in each app. The researchers concluded that the accuracy of nutrient values varied enormously between these apps, and energy was the most reliable value [26]. Another research team compared the nutrient intake calculations of 5 consumer-grade mobile diet apps to the Nutrition Data System for Research dietary analysis program, concluding that most of the nutritional values (except energy and some macronutrients) provided in these apps are generally underestimated, and that some apps are more accurate than others [27].

More recently, another team evaluated energy, macronutrient, and available micronutrient values provided by 5 popular nutrition apps against a UK reference method (Dietplan6 [28]). The authors concluded that the values of energy, carbohydrates, saturated fats, total fat, and fiber reported by these apps (except for 1 app) were rather reliable, while the values of protein, sodium, and micronutrients were inconsistent and less reliable [29].

Academic and Consumer-Grade Mobile Diet Apps

Two Main Categories of Mobile Diet Apps

Even though mobile diet apps are emerging tools, 2 main categories can be distinguished based on the affiliation of the developers and their objectives:

- Academic apps, developed by experts in nutrition or dietetics to provide a reliable, scientifically validated tool; these are mainly developed for research purposes. Known examples include Technology Assisted Dietary Assessment [30], DietCam [31], and My Meal Mate [32].
- Consumer-grade apps that are service-oriented, typically developed by private entities specialized in digital development [33]. These apps are intended to be used by the lay public, and their purpose is mainly commercial. Popular examples include MyFitnessPal, FatSecret, and Lifesum. Weight management is usually the main feature of this second category of apps.

The main strengths and limitations of each category, from the participant and researcher perspective, are outlined in Figure 3.

Academic Apps: A Focus on Scientific Validation

From a researcher's point of view, academic apps offer more advantages than consumer-grade apps, as they are usually developed with identifiable scientific input and compared with a standard method for validation purposes. Typical examples of academic apps include Electronic Dietary Intake Assessment (e-DIA) [34] and My Meal Mate [32]. Academic apps are primarily focused on research and do not aim to be popular. For most of these apps, the number of users is unknown (as they are usually not referenced in Google Play or the App Store), but we assume it is lower than the number of users of consumer-grade apps, which aim to be visible in the stores.

Another main advantage of academic apps is the absence of any constraints in terms of advertising and commercial incentives for users. We also believe that these apps are safer in terms of privacy and confidentiality than those designed for consumer use.

A recent systematic assessment of technology-based DATs [35] compared the features of research and consumer tools. The authors concluded that features facilitating data entry (including voice, digital images, and bar code scan) were more frequently available in “consumer” apps, such as DietCam or My Meal Mate. This work, however, did not consider the “consumer-grade” apps that are discussed in this paper. Other examples of academic apps or apps developed with identifiable academic input that include such features are MyFoodRepo (which includes an image recognition algorithm) [36] and FODMAP App for people with irritable bowel syndrome (FoodMaestro bar code scan, a commercial app) [37]. Most academic apps are not designed for universal use as they are validated for specific homogenous populations, which prevents their use in an international clinical study. Similarly, another important difference between these 2 categories is the number of available languages, as most academic apps are usually available in 1 or 2 languages at most (myfood24 [38] is available in English, German, and Danish, and developers are currently working on the release of an Arabic version).

The question of the scientific validation of academic apps remains a matter of debate. In general, academic apps are evaluated using another self-report instrument thought to capture diet as a reference, such as 24-hour dietary recalls. The choice of the reference method can be controversial, as stated by the National Cancer Institute, which considers that data collected using this method contain errors, including intake-related bias [39]. It should be noted that the e-DIA app was validated by comparison to 24-hour dietary recall as a reference [34], and the same reference method was used to validate My Meal Mate app [32]. Results of validation studies must, therefore, be interpreted with caution when scientific validation is relative and not absolute. These validation methods are less reliable than using gold-standard reference measures, such as biomarker recovery, or methods to capture true intake without systematic errors, such as direct observation and feeding studies [39].

Consumer-Grade Apps: Volume of FCD Data and User Experience

Given the lucrative purpose of consumer-grade apps, an app must be attractive to appeal to a maximum number of users. Even though this environment is competitive, some of these apps are very popular and are downloaded tens of millions of times around the world (such as MyFitnessPal, FatSecret, and Lose It!). For the end user, the apps designed as a service usually offer an appealing user interface and experience: their design is attractive, which facilitates the identification of a meal and may reduce the time required to enter data compared to some academic apps. Another major difference between these 2 categories is the number of languages available (for example, MyFitnessPal is available in 19 languages [26]). The use of a very rich and international FCD is usually a key differentiator among these apps. However, the quality of the FCDs, regularly pointed at as a major issue with consumer-grade apps, is discussed later in this article.

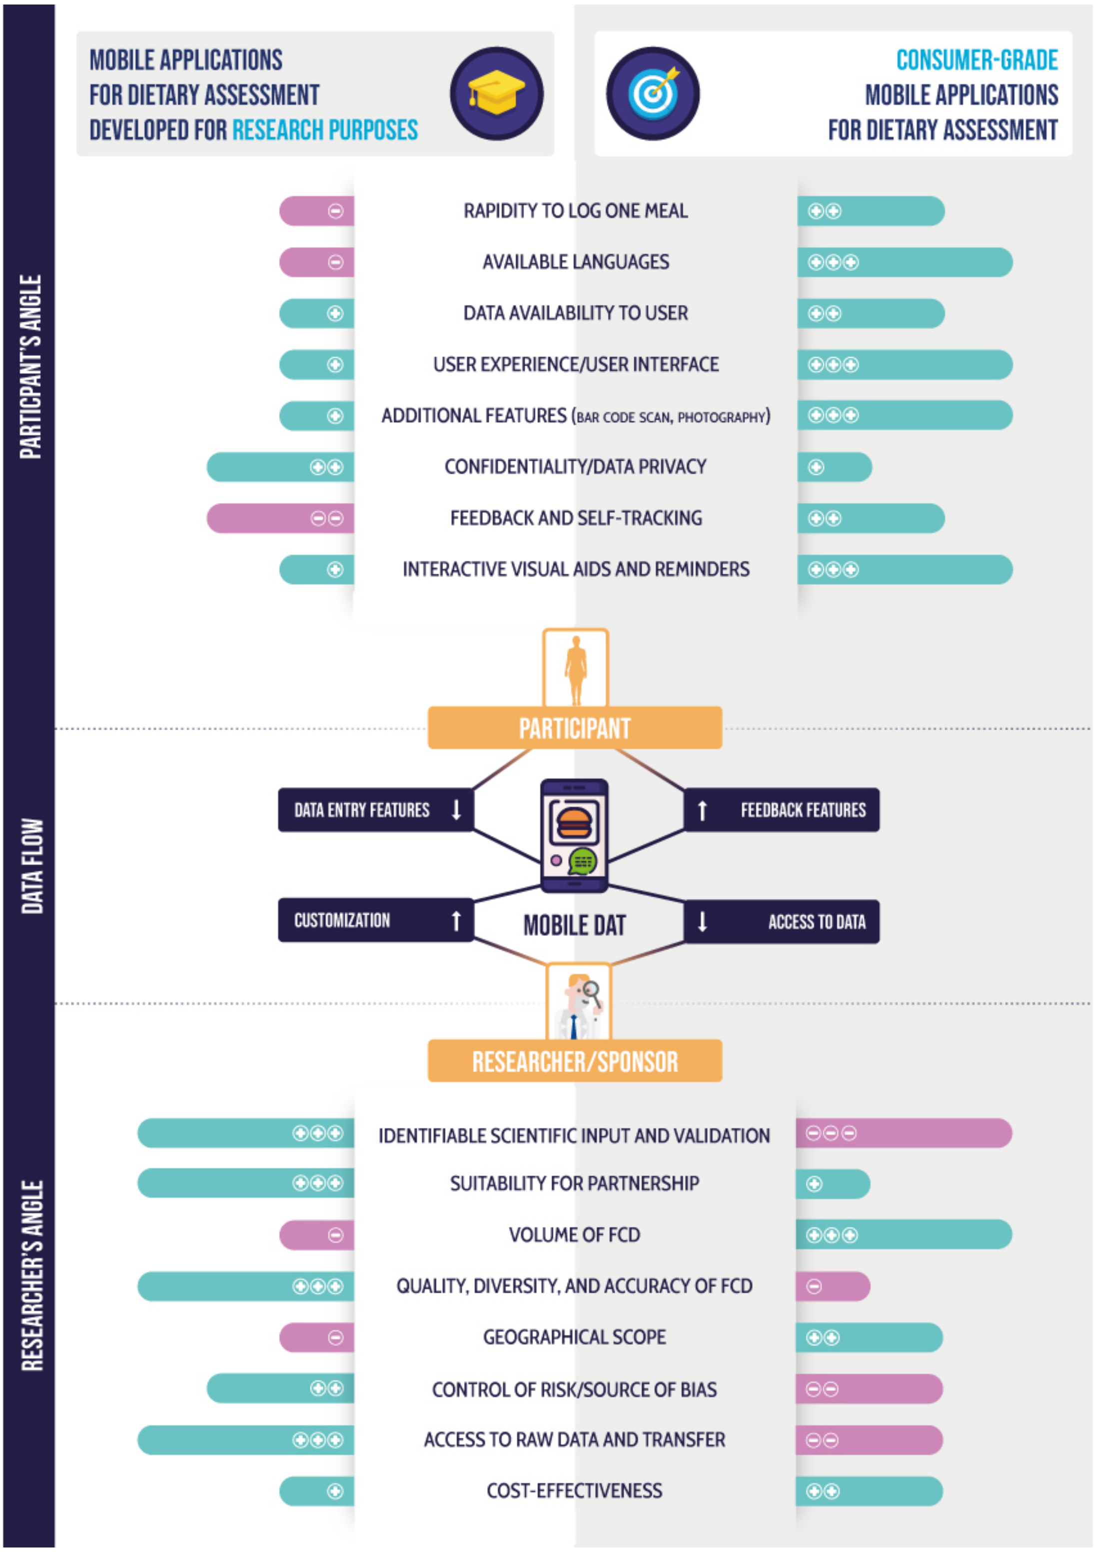
The usability of consumer-grade apps is now being explored but is difficult to assess. A recent review [40] concluded that the features available in consumer apps vary greatly, and there are additional variations between Android and iOS versions. The key features of these apps usually include interactive visual aids and reminders, which are available in basic free versions (even though some apps require subscriptions) to help users achieve their goals. Thus, to further engage users in improving these apps, end-users can add new food products that are not available in the FCD, including energy and nutrient values, or to correct inaccurate information [41]. This may be beneficial for FCD enrichment, but it may also be a major and dangerous source of error in data entry. The addition of new food products and associated nutrient values by lay users can lead to input errors, especially when the developers of these apps do not control the quality and integrity of the data sets, and this is one of the most important negative features of consumer-grade apps.

On the other hand, the use of these consumer-grade apps in medical research has certain limitations and risks, especially with regard to data privacy and confidentiality. The lack of documentation regarding the privacy of user data may represent a major challenge for the legal and ethical integrity of personal and food data [42]. A recent example is the data breach of 150 million accounts of MyFitnessPal [43], which is considered the world's no. 1 app in the field of consumer-grade diet-tracking apps. Another major limitation of these apps is the strong incentive to purchase a paid version through advertisements and recurring notifications: these may cause annoyance to the users of a basic free version and represent a bias in research when too many recommendations are provided as they may interfere with evaluation of the parameters.

We can safely assume that most consumer-grade apps have been developed without rigorous scientific validation and do not systematically involve nutrition experts during development. A recent review of 28 905 relevant health-oriented mobile apps showed that only 17 apps (0.05%) were developed with identifiable professional input [44]; other analyses showed that only 0.8% (3/393) of weight management apps have been scientifically evaluated [45].

Consumer-grade apps may, however, offer some benefits to researchers, such as FCD data volume, as it differs hugely between these 2 categories of apps. In academic apps, the approximate number of food items in the FCD is tens of thousands at most (8500 for DietCam [31] and 40,000 for My Meal Mate [35]), while this number is much higher in several consumer-grade apps (eg, 18 million foods claimed by MyFitnessPal developers [46]).

Figure 3. Key aspects of mobile dietary assessment tools (DATs) developed for research purposes and consumer use from the participant and researcher perspectives. FCD: food composition database.



Room for Improvement of Consumer-Grade Apps

If the volume of FCD data is a key differentiator for these 2 categories of apps, the quality, diversity, and accuracy of FCDs is widely in favor of academic apps. Indeed, the quality of FCDs of consumer-grade apps remains questionable, as explained by several authors [26,27,29] who have concluded that these apps lack a reliable FCD; provide a limited set of nutrients to users; are too focused on energy and macronutrient intake, with a lot of missing data; and underestimate macronutrient and micronutrient values.

Several developers assume that some food information in their database is inaccurate, and some of them, such as MyFitnessPal [41] or Lose It! [47], invite users to correct these errors using crowdsourcing techniques.

Academic apps are regarded as more reliable in their FCD, based on objective measurements and scientific studies [48,49]. For researchers and sponsors, other benefits are in favor of academic apps, including the suitability for partnership, as the developers of these types of apps are usually more open to share information about the development and validation of these tools. Considering that these apps are primarily designed for research, the access to and transfer of raw data are facilitated for researchers with dedicated access. For apps focused on consumers, the access to data is mainly provided to users, especially those who subscribe to optional features. In addition, the absence of feedback features in academic apps reduces the risk of bias in the tracking of eating occasions. However, it should be noted that the geographic scope of consumer-grade apps, which are developed and available worldwide, is far more significant than that of academic apps, which are usually limited to one or two countries.

Discussion

In summary, we can surmise that researchers will usually favor using academic mobile apps, while end users may be more attracted to the features offered by consumer-grade mobile apps. Based on our experience and the cited opinions of experts in the field of nutrition, we understand that currently, there is no one-size-fits-all solution for tracking dietary intake that can be used in every type of medical research, as each available tool has its limitations [35,50] due to language availability, validation in specific populations, and the reliability of FCDs. The ideal option would be to develop a mobile app for tracking the diet that has the strengths of both types of apps: an efficient, user-friendly interface and experience, coupled with an FCD that is as rich as it is reliable. In the absence of such a tool, or in developing one soon, we must select the most appropriate one for each type of study according to its objectives. The landmark DIET@NET (DIETary Assessment Tool NETwork) suggests considering 5 steps before choosing the appropriate type of DAT, and the first step is, of course, to define the research question well [50].

If the daily use of consumer apps by millions of people worldwide can generate big data on food consumption, this information can be used by researchers (while complying with data privacy requirements) to study health, diet, and dietary behavior parameters. This can be done by considering cultural aspects of populations at different levels (country, household, or individual) while integrating potential key cofactors such as physical activity level, sleep, weight, or location data, which can often be collected simultaneously. It has also been highlighted that the most frequently downloaded consumer-grade apps lack features relating to emotions, even though emotions are known to be associated with diet [40]. Using these diet apps as a reliable food-tracking tool in clinical trials or research, in general, is a major challenge, considering their limitations; despite the popularity of these apps, the lack of evidence and scientific validation of their use remains the major issue [51]. Little information is available on the quality of these mobile apps, other than what can be gathered from users' ratings published on mobile app stores. The lack of reliability of the data these apps provide, especially in the FCD, is a real barrier for researchers who want to utilize the user data. It should also be noted that the legal and ethical concerns related to user data for consumer-grade mobile health apps are well documented in the literature [52-54]. A recent review showed that most mobile diet apps do not provide terms of use or privacy policy documents [42].

The use of consumer diet apps in studies should be done with caution: given the nature and suboptimal quality of their FCDs, their use should be limited to the tracking of some macroelements such as energy intake. Energy intake is considered the most consistently and accurately value reported by these apps compared to other macro- and micronutrients [23,26], which are generally underestimated [27,29,55]. Recent studies have also shown that different consumer apps, such as Samsung Health, MyFitnessPal, and FatSecret, provide an acceptable estimate of energy, carbohydrate, and fat intake [29], and that MyFitnessPal offers a good relative validity for energy and fiber tracking [55]. Many dieticians (in the United Kingdom, New Zealand, and Australia) use nutrition apps in their practice [56]. However, for many experts in the field of nutrition, mobile apps designed for consumer awareness are an unreliable source of nutritional values due to the crowdsourcing nature of the FCD. This issue is leading to a lack of interest in using these new tools for nutritional and clinical studies.

Perspectives

Our opinion is that the potential of mobile apps designed for consumer use has not been sufficiently evaluated, especially in clinical settings. Despite the limitations that have been outlined above, we believe that the data collected by these apps represent a source of information we cannot ignore, as it may be sufficient in some epidemiological or clinical studies, when the assessment of diet is not the primary objective of a research study. Potential uses of these tools include segmenting participant populations into subgroups according to usual dietary intake or associating specific meal patterns with biological parameters during a short time frame. However, in our view, further work is needed to assess this potential. We should also consider the potential of other features that are now included in several mobile apps, such as automated, image-based recognition. This feature, while promising, is only in an early stage of development, and there is still room for improvement until it can be used regularly by clinical study participants. However, when relevant, analytical methods offered by artificial intelligence may soon be used to obtain both qualitative (ie, composition of meals) and quantitative (ie, portion sizes) outputs. We believe that such features may one day be the bridge that accommodates participants and researchers, filling the gap between academic and consumer-grade apps once they are available in both types of solutions.

Acknowledgments

WK, FS, and GF authored the manuscript and created the figures. LD and JFJ reviewed the manuscript. All authors validated the final version of the manuscript and agreed to be accountable for the accuracy of the work. The authors thank Mrs Livia Recchia for the graphic design of the figures and Mrs Debjani Roy for her thorough proofreading of the manuscript.

Conflicts of Interest

WK is employed by a contractor of Danone Nutricia Research. JFJ, LD, and FS are employed by Danone Nutricia Research. GF has received consulting fees from Danone Nutricia Research.

Abstract

Artificial intelligence (AI) can transform health care practices with its increasing ability to translate the uncertainty and complexity in data into actionable—though imperfect—clinical decisions or suggestions. In the evolving relationship between humans and AI, trust is the one mechanism that shapes clinicians' use and adoption of AI. Trust is a psychological mechanism to deal with the uncertainty between what is known and unknown. Several research studies have highlighted the need for improving AI-based systems and enhancing their capabilities to help clinicians. However, assessing the magnitude and impact of human trust on AI technology demands substantial attention. Will a clinician trust an AI-based system? What are the factors that influence human trust in AI? Can trust in AI be optimized to improve decision-making processes? In this paper, we focus on clinicians as the primary users of AI systems in health care and present factors shaping trust between clinicians and AI. We highlight critical challenges related to trust that should be considered during the development of any AI system for clinical use.

KEYWORDS

human-AI collaboration; trust; technology adoption; FDA policy; bias; health care

Introduction

Artificial intelligence (AI), which has been introduced as a technology to improve decision-making involving uncertainty and complexity in systems, has the potential to transform health care practices [1,2]. The role of humans in the practical applications of AI is often overlooked. The development of automated systems to augment human decision-making dates to the 1950s with the Fitts list, which identifies the complementary capabilities of humans and automated systems [3]. The Fitts list includes 11 statements asserting that humans are better at detection, perception, judgment, induction, improvisation, and long-term memory, while automated systems are better at power/speed, computation, replication, simultaneous operation, and short-term memory [4]. Several studies have shown that automated systems may or may not improve human decision-making, depending on whether or how human factors are accounted for in their design [5].

As AI is rapidly developing, unlike other technologies, there is an absence of a clear definition of the process, functioning, and role of AI [6]. Trust is a crucial factor influencing interactions between human beings, including their interactions with AI. Understanding the trust dynamics between AI and humans is crucial, particularly in the field of healthcare, where life is at risk. In this paper, we discuss the impact of trust on the dynamic interactions between AI and clinicians, highlight the key factors that influence trust relationships and identify key challenges and future research directions in the health care domain. While the users of AI systems can be diverse, including patients and insurance providers, the focus of this paper is limited to the domain experts in healthcare, ie, clinicians. We acknowledge that trust relationships could significantly differ for patients and insurance providers.

Definitions

What Is AI?

The term AI has been used in many ways in computer science, engineering, and healthcare. Broadly, it can be defined as a computer program that can make intelligent decisions [7]. This definition includes computer programs that operate with predefined rules and data-driven models. This paper distinguishes these two by referring to the former as *automation*, which can be used to make well-defined and repetitive decisions. While automated systems have been used to augment or replace human operation in health care [8], the generalizability of the process and existence of intelligence in automation can be questionable. The focus of this research is the latter, which is a process to make health care decisions using a mathematical model built on prior or real-time data. Existing literature in the machine learning field provides relatively successful methods to train such mathematical models that learn useful knowledge from data [9-11]. In this paper, we refer to *a computer process that algorithmically makes optimal decisions based on multiple criteria using one or more machine learning-based models* as AI. While trust has been studied in the context of automation [12], the deterministic (ie, consistently providing the same output for a particular input) and relatively predictable nature of automation is an important distinction from our definition of AI, which has implications for trust research.

What Is Trust?

Interpersonal trust is a human belief (or referred to as an attitude in some sources [12]) that is broadly defined based on three main dimensions, namely, benevolence, integrity, and ability [13]. This attitude may be intrinsically formed based on the user's own experience with the system of interest or may stem from an extrinsic source such as the reputation of the system in the user's social circle [14]. Studies highlight some differences between interpersonal trust and trust in technical systems because technical systems may lack intentionality, which is relevant to honesty and benevolence [12]. A user's perception of an AI system's ability remains a significant dimension for trust in AI systems, which depends on the quality of the input data, the mathematical problem representation, and the algorithms used in the decision-making. The level of trust in AI has a significant impact on how much users rely on AI [12], and hence the efficacy of health care decisions. However, the level of trust in AI may not necessarily have a positive correlation with clinical or patient outcomes.

AI in Health Care

AI has shown significant potential in the area of mining medical records, designing treatment plans [15], robotics mediated surgeries [16], medical management and supporting hospital operations, clinical data interpretation [17], clinical trial participation [18,19], image-based diagnosis [20], preliminary diagnosis [21], virtual nursing [22], and connected health care devices [23]. In addition to these applications, significant investments in AI research [24], as well as recent efforts on regulating the use of AI in the medical domain [24], suggest that AI could become an essential technology to assist decision-making in the medical domain in the foreseeable future.

AI research in health care poses unique challenges compared to other technical domains. Physical system models mathematically describe the underlying technical behavior in engineering applications. However, the lack of such quantitative models in many health care applications such as medical diagnostics (eg, the precise relationships between diseases and their causes) creates a significant challenge. The responses from clinicians for the same clinical cases vary significantly. Therefore, it would be a challenge to train AI-based tools on the subjective responses that carry over individual biases from clinicians without any knowledge of the ground truth. Also, AI research must account for the distinct medical problem characteristics across different health care applications. It may not be possible to generalize a process to train a mathematical model for an AI tailored to the needs of cancer applications to cardiovascular applications, for instance. Further, vulnerable groups such as minorities and patients with disabilities may not be sufficiently represented in the data, and their needs may not be adequately accounted for if these groups are not carefully considered during the design of the AI system. A customized AI process might be necessary for each application depending on the type and amount of data available, the target patient population, the amount of variability and useful information in the data, and the nature of the health care decisions to be made.

Further, health care is a highly regulated space where developing an adaptive AI technology to meet regulatory requirements is an additional challenge. The US Food and Drug Administration (FDA) categorizes Software into three classes: (a) Software as a Medical Device (SaMD), (b) software in a medical device, and (c) software used in the manufacture or maintenance of a medical device. FDA defines SaMD as "… AI/ML-based Software, when intended to treat, diagnose, cure, mitigate, or prevent disease or other conditions, are medical devices under the FD&C Act and called Software as a Medical Device" [25]. SaMD ranges from smartphone applications to view radiologic images for diagnostic purposes to Computer-Aided Detection software to post-processing of images to detect breast cancer [26]. FDA has approved several AI-based SaMDs with "locked" algorithms that generate the same result each time for the same input; these algorithms are adaptable but require a manual process for the updates [25,27].

Unlike the standard SaMD model, an adaptive algorithm changes its behavior using a definitive learning process without requiring any manual input. An adaptive algorithm might generate different outputs each time a given set of inputs is received due to learning and updating. A credible validation and verification plan that ensures safe and reliable operation under adaptive behaviors must be a part of the AI design.

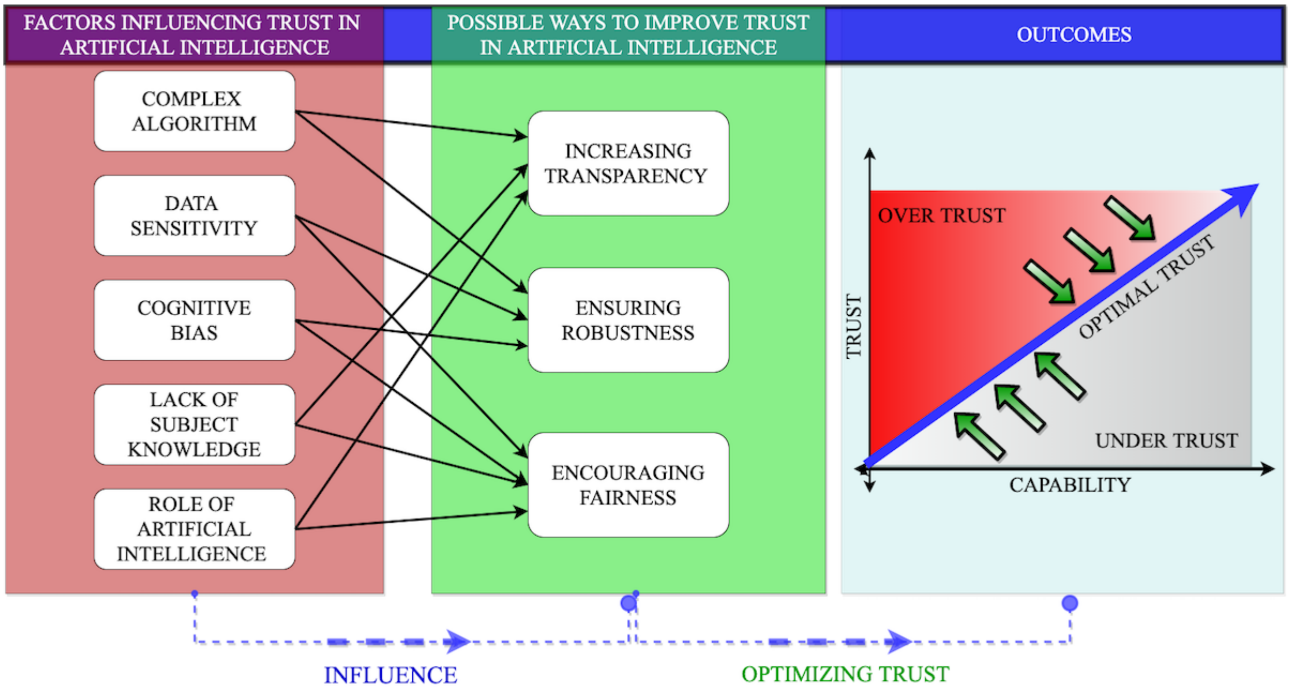
AI in health care has two potential advantages to human performance. First, AI can learn from big data (such as incommunicable silos of unstructured information stored in an electronic health record) more efficiently than clinicians. A successful AI system can efficiently extract relevant information from offline or real-time data to assist in improving organizational performance and help clinicians in making informed decisions in real time. Second, AI systems can perform predefined tasks with higher precision. AI can be in a continuous active state without compromising its performance—it does not suffer from burnout as humans do. This feature of AI technology has the potential to revolutionize complicated surgeries. The Da Vinci robotic surgical system can mimic a surgeon's hand movements with greater precision [28]. Further, existing applications of AI in various domains such as AlphaStar (an AI bot that outperforms an expert player in a video game) and LYNA (an AI capable of detecting breast cancer using images from lymph node biopsies) report successful outcomes comparable to human decision-making [29,30].

There are limitations of AI that might restrict its application in life-critical areas such as healthcare. AI methods require data inputs to be in a structured form, which limits the type of information that can be provided for medical decisions. Even the deep learning methods, which can find a suitable mathematical representation from a given dataset automatically, are trained for a given input type (eg, medical image data) and, once developed, they cannot accept another input type (eg, statements from patients). Also, AI methods generally lack "common sense," making them unable to identify simple mistakes in data or decisions that would otherwise be obvious to a human being [31]. Therefore, there is significant potential and need for improvement by combining the intuitive and analytical thinking of medical experts [32] with the computational power of AI in a proper human-AI collaboration architecture.

Trust in Human-AI Collaboration

Advances in the capabilities of AI will expand the role of this technology from the automation of repetitive and well-defined tasks to guiding decision-making under uncertainty that is currently done exclusively by medical professionals. As health care providers rely more on AI, a proper trust relationship, also referred to as *calibrated* trust [33], becomes a requirement for effective decisions. The deterministic and relatively predictable nature of a typical rule-based software system is an essential factor contributing to the development of user trust. The resulting behavior of a deterministic system can entirely be determined by its initial state and inputs. However, the nondeterministic nature of AI, where an algorithm can exhibit different behaviors in different iterations for the same input, might introduce unique dimensions to the concept of trust. Figure 1 presents our overview of some important factors influencing trust in AI for health care, possible ways to improve trust relationships, and their impact on trust. Note that the purpose of the figure is not to provide an exhaustive list but rather to highlight important issues relevant to trust in AI for health care applications.

Figure 1. Human factors and trust in artificial intelligence.



Currently, a lack of trust in the AI systems is a significant drawback in the adoption of this technology in healthcare. Trust in AI can be influenced by several human factors such as user education, past experiences, user biases, and perception towards automation, as well as properties of the AI system, including controllability, transparency, and complexity of the model, associated risks, and many others. Among these factors, reliability, which refers to whether the AI technology can perform a task predictably and consistently [34], might be particularly concerning in health care due to the changes in the reliability of AI in the presence of new data [35]. The reliability of an AI technology is conditioned on the user and input data. Considering that an AI system might be trained with insufficient and subjective data from multiple sources, AI could generate biased or overfitted outcomes of which the clinical user might not be aware. These concerns hinder the performance of this technology [36], thus deterring the user's trust and acceptance of AI systems.

It is also important to note that *maximizing the user's trust* does not necessarily yield the best decisions from a human-AI collaboration. When trust is at maximum, the user accepts or believes all the recommendations and outcomes generated by the AI system. While in some applications, AI can outperform human decision-making by incorporating data from multiple sources [29,30], the limitations above suggest that unnecessarily high trust in AI may have catastrophic consequences, especially in life-critical applications. Therefore, our study supports the concept of *optimal trust* in which both humans and AI each have some level of skepticism regarding the other's decisions since both are capable of making mistakes. The amount of skepticism necessary for the most accurate clinical decisions depends on the capability of the human user and the AI system. The development of AI must incorporate mechanisms that will establish and maintain a properly balanced, optimal level of trust from and to the user that matches the capability of the AI system [12].

Developing a healthy trust relationship in human-AI collaboration is a challenge due to the uncertain behavior of a knowledge-based evolving AI system. We posit that the following factors should be incorporated into the development of AI to achieve an optimal level of trust: fairness, transparency, and robustness (Figure 1). It is often assumed that algorithmic decision-making might lead to fairer and more robust outcomes than human judgment [37]. However, algorithms intrinsically discriminate and assign a weight to some factors over others. Moreover, the properties of machine learning algorithms bear the risk to reflect and aggravate underlying data bias, which might unfairly affect members of protected groups based on sensitive categories such as gender, race, and sexual orientation. For instance, a study [38] that implemented machine learning to detect skin cancer used less than 5% data from a dark-skinned patient population to train the model, potentially leading to bias against dark-skinned patients [39]. According to the UK International Commissioner's Office, AI fairness depends on the effects of the data processing on users (care providers and patients), their expectations as to how their data will be used (clinical and personal data) and the level of transparency provided [40,41] (sharing with other care providers and insurance). Fairness in an AI process is concurrent with bias minimization. Bias, a mismatch between the distribution of training data and a preferred fair distribution, can yield unfair outcomes (prediction/classification). In order to establish fairness in AI systems, biases originating from the subjective responses of clinicians should be identified and curtailed during validation and verification.

Achieving fairness through awareness or transparency can also improve trust [42,43]. Facilitating secured access to patient data can improve transparency [44] in the data and allow patients to validate their information. In our view, transparency fosters an understanding not only of the working principles of AI algorithms but also the algorithmic biases and biases due to underrepresentation. Depending on data availability and quality, an AI system might perform remarkably well at some tasks while performing poorly in others. Revisiting the 'skin cancer example' cited above [38], if clinicians are informed about the bias in the training data (eg, underrepresentation of minorities), then it will be easier for them to identify the suitable patient population (eg, Caucasians) on which the AI algorithm can be implemented. Explainable AI is another route to AI transparency that might help clinicians arrive at clinically meaningful explanations about the outcome of AI applications and make informed judgments. However, there are tradeoffs between the explainability and sophistication of an AI algorithm. Explainable AI models such as decision trees intuitively tend to be simple and might not be accurate, especially when dealing with big and complex data. Determining the precise balance between explainability and sophistication is crucial to enhance trust in AI. Finally, robustness is the sensitivity of the decisions made by the AI models to the input dataset. Poor robustness can lead to significant changes in the outcome of an AI model with small perturbations in the input data. Insufficient or erroneous data can impede AI robustness. Proofing AI models against such volatilities can help to build trust in AI systems.

Future Research Directions

The efficacy of human-AI collaboration is not only a function of the accuracy of the underlying mathematical process behind the AI system but also human factors, including trust. A holistic approach recognizing health care as a dynamic socio-technical system in which sub-elements interact with each other is necessary to understand trust relationships in human-AI collaboration. For instance, trust in AI systems might be affected by organizational policies, culture, specific tasks assigned to the health care providers, other similar computational tools used by the providers, providers' interaction with other individuals such as patients and other providers, as well as internal and external environmental factors. This viewpoint is consistent with and complementary to the research roadmaps proposed in the systems engineering literature on AI [45]. Applying human factors methodologies such as the SEIPS model [46] to the health care domain can assist researchers in capturing the entire socio-technical work system. These holistic human factors models provide a useful conceptual framework for researchers to capture contemporary and dynamic issues relevant to trust modeling in healthcare.

Second, recent approvals of AI algorithms reveal the limitations of existing regulatory standards. In early 2018, the FDA authorized the WAVE Clinical Platform, an early-warning system that utilizes vital sign data to identify high-risk patients [35]. FDA standards, designed for traditional rule-based algorithms, do not apply to advanced AI systems whose predictive performance might change when exposed to new data [35]. To measure the impact of AI systems, FDA should benchmark the predictive model and ensure clinically meaningful outcomes. As it does for drug approvals, FDA should rigorously confirm and test surrogate endpoints in potential evaluations of AI systems. Recently, the FDA announced that it is developing a framework for regulating AI systems that self-update on new data and seeking comments on how to regulate self-updating algorithms [47].

AI raises profound concerns regarding medical responsibility. Under current practice, clinicians are only responsible when they deviate from the standard care procedure for a given health condition (irrespective of patient health outcome) [48]. However, clinicians will be held responsible if they follow the AI recommendation when it is different from the standard care process and negatively affects patient health outcomes [48]. What would this mean for an AI system and trust between AI and users? Clinicians using AI systems are expected to use them for decision support, not as a replacement for trained clinical decision-making. In this sense, clinicians are still responsible for any medical errors that may occur as humans remain the final decision-makers. Then, in what capacity can AI assist clinicians and will clinicians be able to use and assess the reliability of an AI system? The influence of these factors on clinicians' trust in AI applications needs further study.

Considering the limitations of both human cognition and AI approaches, a quantitative measure for the optimal level of trust between clinicians and AI systems to make the most accurate and reliable clinical decisions remains unknown. Linking this optimal level of trust to specific design attributes in an AI system is another unknown. An analysis of that problem should account for the individual human factors specific to the user of the system, including the sizeable aleatory variability associated with it and continuously evolving capabilities of AI methods. The results of such an analysis should inform the regulatory policy decisions.

Finally, trust in AI is expected to have completely different characteristics for patients compared to clinicians. First, patients generally do not have expertise in the medical field, as opposed to clinicians. Further, patients, regardless of whether they are the users of the AI system or not, will be directly impacted by the clinical decisions (or suggestions) that the AI system provides. With the increased patient involvement in a patient-centered health care model, especially educated patients might question clinicians' decisions and want to be informed whether the decisions are based on AI recommendations or not. If AI systems are an essential part of this shared decision-making process between patients and clinicians, trust relationships between patients and AI systems deserve further in-depth research.

Abstract

Since the last decade, most of our daily activities have become digital. Digital health takes into account the ever-increasing synergy between advanced medical technologies, innovation, and digital communication. Thanks to machine learning, we are not limited anymore to a descriptive analysis of the data, as we can obtain greater value by identifying and predicting patterns resulting from inductive reasoning. Machine learning software programs that disclose the reasoning behind a prediction allow for "what-if" models by which it is possible to understand if and how, by changing certain factors, one may improve the outcomes, thereby identifying the optimal behavior. Currently, diabetes care is facing several challenges: the decreasing number of diabetologists, the increasing number of patients, the reduced time allowed for medical visits, the growing complexity of the disease both from the standpoints of clinical and patient care, the difficulty of achieving the relevant clinical targets, the growing burden of disease management for both the health care professional and the patient, and the health care accessibility and sustainability. In this context, new digital technologies and the use of artificial intelligence are certainly a great opportunity. Herein, we report the results of a careful analysis of the current literature and represent the vision of the Italian Association of Medical Diabetologists (AMD) on this controversial topic that, if well used, may be the key for a great scientific innovation. AMD believes that the use of artificial intelligence will enable the conversion of data (descriptive) into knowledge of the factors that "affect" the behavior and correlations (predictive), thereby identifying the key aspects that may establish an improvement of the expected results (prescriptive). Artificial intelligence can therefore become a tool of great technical support to help diabetologists become fully responsible of the individual patient, thereby assuring customized and precise medicine. This, in turn, will allow for comprehensive therapies to be built in accordance with the evidence criteria that should always be the ground for any therapeutic choice.

KEYWORDS

artificial intelligence; big data analytics; clinical decision making; diabetes management; health care

Introduction

The ongoing evolution in medicine and, in particular, in the field of diabetology is strongly intertwined to a series of changes and innovations [1-3]. The term “digital health” is a “container,” grouping together informatics and telecommunications that have the common objectives of diagnosis, treatment, or monitoring of diseases, maintenance of health and well-being, and support for healthy lifestyles. The US Food and Drug Administration has compiled a list of software programs with medical device functions (apps for smartphones and personal computers with diagnostic, monitoring, or therapeutic objectives), advanced business intelligence data analysis tools, artificial intelligence (AI), cloud, cyber security, and innovative health technologies [4]. These tools belong to an evolving reality; they are still unclear but they are potentially leading to challenging and promising scenarios [5,6].

The scope of this position statement is to analyze the most relevant aspects and describe the changes that have already occurred or those that will take place shortly by exploring the possibilities of application and development in the field of diabetology. Indeed, the digital world is constantly expanding and it has already become an integral part of our personal and professional life [7,8]. Smartphones, personal computers, and network access are now essential tools for almost all populations and for many diabetologists, both as individuals and professionals.

Digitalization

Almost every daily activity of the diabetologist has to deal with digitalization, from electronic medical records to imaging diagnostics, from laboratory references to the various software programs for administrative practices and certifications, and from glucose level data downloaded from glucometers to sensors for continuous glucose monitoring and insulin pumps. Through the analysis of these data, the diabetologists make therapeutic decisions, and the more complete and numerous the data, the more they need informatics tools to guide them in the analysis, help them identify specific patterns for detecting glycemic abnormalities, understand the possible causes, and adopt the appropriate therapeutic strategies to correct these abnormalities [9,10].

Data Management and Connectivity

In the early days, data collection and management for each individual patient occurred manually at the hospital by physically connecting cables or wireless devices to the local software/network. Currently, thanks to the technological evolution, these data can be transmitted automatically from the glucometers via “cloud” or on data integration platforms that collect elements from different devices and provide standardized reports [11,12]. If not properly managed, this large amount of data is likely to overwhelm both the patient and the health care professional, and the professionals’ experience in reading these reports is certainly the added value that increases their potential. Advanced informatics tools can simplify the analysis and provide suggestions to guide the clinical decisions of the physician [13]. With experience and technology coming together, the analysis time can be increasingly reduced and more appropriate and correct data-driven therapeutic decisions can be made, thanks to the greater customization strategies of the therapy [14-21].

AI and Individualized Care

In this context, the use of AI, and in particular, the use of machine learning allows an important step forward compared with the traditional data analysis techniques (ie, graphs representing a picture of reality, which are very useful and precise but are static and outdated). Through the automatic identification of specific patterns within the data and through inductive reasoning typical of the human mind, machine learning can highlight correlations that lead to “predictions,” without being programmed in advance to carry out this activity [19].

In a not too distant future, AI, thanks to algorithms that can enable learning and improving the machine’s own abilities independently, will offer effective solutions to satisfy the most disparate needs and will be able to deal with problems that today may seem insurmountable obstacles, for the benefit of the community [22]. In the field of clinical diabetology, these tools could have multiple potential implications, including the identification of new risk factors for the onset of diabetes (through the evaluation of large databases related to the general population) or revealing unsuspected subjects who are at a high risk of complications (by cross-checking clinical and administrative records of patients with diabetes) and identifying the behavioral and therapeutic variables that are most closely related to the progression of a specific complication.

There are many examples of collaboration between pharmaceutical companies, information technology companies, scientific institutes, and universities that exploit large complex datasets (the so-called big data) with the aim of improving the treatment of type 2 diabetes mellitus (T2DM) and of unraveling physiopathological mechanisms through the integration of data from biological, demographic, clinical, environmental, and genomic sources [23].

Risk Stratification and Personalized Medicine

The ability to elaborate a large and heterogeneous amount of data, even in real time, through increasingly powerful algorithms, allows us to extract knowledge and exponentially make predictive assessments on the behavior of individuals as well as, more generally, assume decisions for the entire community [24,25]. This means that the use of AI will make it possible to transform the immediate data (descriptive) into knowledge of the factors that “condition” behavior and correlations (predictive) [25-27] up to the identification of the key factors that can facilitate an improvement in the expected results (prescriptive) [28,29]. In this scenario, one of the most interesting applications would be to identify the variables that could be related to greater responsiveness to a specific drug because this approach would open the door to a truly personalized medicine that uses the right drug for the right person, with obviously greater efficacy, improved outcomes, and containment of costs. Furthermore, predictive analysis techniques based on AI could be used to identify which group of patients would require more attention and which strategies would be more effective, depending on the individual patient, thereby allowing more efficient methods of personal care with lower costs and better outcomes. This concept of risk stratification, which considers all the individual characteristics of the patient (ie, clinical aspects, genetic data, lifestyle, environmental factors), is the basis of the modern model of clinical governance called “population health management.” Today, the risk stratification of the population results from the extraction of historical expenditure data (eg, inpatient and outpatient admissions, diagnosis, pharmaceutical expenditure) and this presents the following series of biases: weak clinical validity; temporal misalignment between the extraction, the analysis, and the health status; and absence of information on the real socioeconomic condition and behavioral health. In this way, the data represent “satisfied demand” rather than “real needs.” The new challenge is the use of big data and business analytics systems to activate risk stratification models based on real health status, integrated use of multiple sources, and collaboration between professionals (ie, care team and data manager in a data mining process) [30,31].

Biotechnologies and Omics

Another aspect that characterizes the ongoing medical revolution is the development and increasing importance of biotechnologies used in genetics and in the so-called “omics” sciences. These new techniques have been showing that the complex pathophysiological processes underlying type 1 diabetes mellitus (T1DM), T2DM, and gestational diabetes mellitus are caused by disturbances in the gene expression that lead to alterations in the processes within the organs involved in glucose homeostasis [32]. The complexity of the system is exacerbated by the fact that the relative contribution of each component is highly individual. Understanding the molecular mechanisms underlying these interactions is crucial for developing new personalized prevention and treatment strategies [32,33].

Social Networks and Apps

Finally, the ever-increasing use of social networks and apps has major implications in the diabetes care. On one hand, health professionals must change the way they communicate and keep up with the times by always acquiring new technological and communication skills to deal with and manage the changes taking place, while on the other hand, the new technologies could be used as motivational and coaching tools in support of the traditional educational activities and as an alternative data source. Notably, the areas that influence the state of health are only 10% due to the medical care and health status, whereas the major role is instead played by lifestyle and behaviors as well as by genetics [34-36]. For this reason, to obtain a more precise picture of the state of health of the general population or of specific subgroups, we cannot limit ourselves to collecting and analyzing only health data, but we must consider what comes from the world of social networking and smartphone apps, despite all the known limitations and criticalities.

Evolution of the Role of Health Care Professionals

The exponential increase in knowledge and technologies, the increased complexity of the tasks, and the increasingly diversified needs of the patients are flooding health care professionals with increasingly greater tasks and aspects to be addressed and managed. It is necessary to reflect on what the true essence of medical care is and to reassess the meaning of this profession. The ability to change, juggle the new technology tools, and exploit the potential of new information technology and business analytics techniques will enable health care professionals to have a great support in their choices and reduce the time spent collecting data or using the machines so that they can concentrate more on the decision-making process, thereby rendering each intervention more effective and efficient. As a proof of concept, it has been recently reported that the costs for care of patients were steadily diminished by the active use of technology, which supplied a real time feedback about their blood glucose levels and connected them to clinical support [37]. These reductions were primarily attributable to reduced diabetes-related and office-based services, independent of the specific condition, and they were proportional to the frequency of use of the digital tools [37].

Data from Diabetology Literature

Diabetology is facing different challenges: the ever-decreasing number of diabetologists, the increasing number of patients, the reduction of visitation time, the increasing complexity of the pathology both from the clinical and welfare point of view, the difficulty in achieving the objectives, the growing burden of pathology management for health care professionals and patients, and the decreased accessibility to care and sustainability. New digital technologies and the use of AI are certainly a great opportunity. The current panorama of international scientific literature with respect to the use of big data and AI in diabetology offers various hints and in-depth analyses, which are applicable to different fields.

The Epidemiological Area

Cases of diabetes have been identified within large heterogeneous databases, and new risk factors for diabetes have been identified. An interesting multi-database retrospective study on the identification of cases of T2DM [17] strategically used the European Medical Information Framework Project database, a European project for the efficient reuse of health data for epidemiological research [38]. This database collects health information of about 52 million European citizens by using heterogeneous sources and by acting as a support for the execution of high-quality multinational observational studies, based on populations with large sample sizes and otherwise inconceivable follow-ups. Subjects with T2DM were identified using a complex algorithm strategy in 8 different health data sources, and the strengths and limitations of each data source were revealed during the creation of a model that ensures the interoperability of systems of heterogeneous electronic medical records. These efforts represent a methodological advancement for carrying out studies of multinational and multi-data sources, thereby providing sufficient information for the contextualization and correct interpretation of the results and generating transparent and reusable documentation.

Additionally, a study conducted by researchers from the University of New York and Philadelphia described a new "data-driven" approach of population health management based on the use of machine learning techniques to develop predictive models and identify risk factors for the onset of T2DM [39]. They based this model on administrative data concerning health services, pharmaceutical records, insurance databases, citizens' access to the different care facilities, and laboratory results from 4.1 million individuals over a period of 4 years and a total of 42,000 variables. This model has been able to identify new risk factors for the appearance of diabetes with a predictive probability of at least 50% higher than the models based on the known traditional risk factors, thereby avoiding the costs of performing a screening. The identification through new predictive models based on machine learning of the part of the population that is at the highest risk of developing diabetes will be able to generate clinical hypotheses for the identification of new risk factors and to implement more targeted cost-effective interventions.

Phenotyping and Risk Stratification

A study of 65,000 newly diagnosed patients with T2DM [40] estimated that 10% of the subjects absorb 68% of the resources. The task of predictive analytical methods based on big data is precisely that of identifying the 10% of the subjects most at risk, on whom the treatment needs to be intensified in order to improve the health outcomes at lower costs.

An interesting Japanese study [41] has developed a practical framework for phenotyping T2DM by using both specialized knowledge and an approach based on machine learning (in particular, the support vector machine) to develop 2 phenotyping algorithms with data extracted from electronic medical records: one with high sensitivity for screening and the other to identify the subjects for research. Both algorithms showed superior performance compared to the basic algorithms, thus suggesting the possibility of using the proposed framework to conduct appropriate research depending on the objective.

The Diagnostic Area

The use of predictive models based on AI has demonstrated the feasibility of identifying individuals with the highest probability of having undiagnosed diabetes through clinical data that can be easily obtained from different databases [42], thereby exploiting the potential of machine learning algorithms, including neural networks, as tools for diagnosing diabetes [43]. Machine learning and pattern recognition are tools of enormous interest as they are promising in improving the sensitivity and specificity of disease detection and diagnosis, and they appear to be able to reduce the potential for human error in decision-making. An exemplar application is the creation of surveillance algorithms that are able to detect diabetes and, in particular, to distinguish T1DM from T2DM by using structured electronic medical records [14]. The extraction of data from the electronic database of a 4-year long, multi-sectorial, and multi-specialist outpatient practice allowed the inclusion of approximately 700,000 patients. Possible cases of diabetes were reported using laboratory test results, diagnostic codes, and prescriptions. More cases of diabetes were captured by taking advantage of the entire range of data acquired from the records compared to that captured by the analysis of only administrative databases, thus increasing the sensitivity of the method. The application of these algorithms to electronic folders has the potential to provide timely and clinically detailed information on large numbers at low cost and nearly in real time. Electronic records will probably become increasingly important sources for the surveillance of public health and for the definition of more targeted health policies [15,44].

Field of Automatic Reporting

Diabetic retinopathy, in particular, is a chronic complication of diabetes. The automated classification of diabetic retinopathy has potential benefits such as increasing the efficiency, reproducibility, and coverage of screening programs; reducing obstacles to accessing and improving results; and providing early diagnosis and treatment. To maximize the clinical utility of the automated classification, an algorithm designed to detect specific lesions or to predict the presence of any level of diabetic retinopathy was recently developed [45]. In this study, deep learning, together with visual and pattern recognition techniques, has allowed the identification of the desired features with the highest predictive value directly from the images on a large set of labeled example data. These results show that deep neural networks can be "trained" by using large data sets and without having to specify lesion-based features to identify diabetic retinopathy or diabetic macular edema in fundus images with high sensitivity and high specificity.

Economic Field

Cost-effectiveness studies of health interventions have been performed previously. An Italian group performed a retrospective analysis through the cross-examination of large clinical and administrative databases with the aim of quantifying the relationship between health care costs attributable to diabetes and the level of glucose control [46]. The results indicated that glycemic control (expressed by hemoglobin A_{1c} [HbA_{1c}] levels) is a useful surrogate not only to estimate the odds of developing diabetes-related complications but also to estimate the costs associated with health care. The integration of administrative and clinical databases seems to be suitable to show that an appropriate management of diabetes can allow a better allocation of resources.

Expected Advantages in Diabetology

The ongoing medical revolution is strongly linked to the spread of digital health, the new software for AI, the use of big data to make more appropriate data-driven decisions, and the even greater focus on predictive, preventive, personalized, and participatory medicine [6]. Each of these elements has important repercussions in the management of complex and widespread chronic diseases such as diabetes. Table 1 summarizes the advantages and weaknesses attributed to each area of application, especially considering the challenges that diabetology faces, according to our professional experience and opinion.

Table 1. Advantages and weaknesses of the use of new technologies in diabetology (our opinion).

New technology in diabetology	Advantages	Issues
Digital data management (glucometers and continuous glucose monitoring connected to the cloud and data integration platforms)	• Support for doctors' decisions • Reduced analysis time • Graphs and images easy to understand and interpret • Correct management, supported by data, even remotely • Sharing with caregivers or family members possible • Simultaneous analysis of data from different devices • Integration of glycemic values with alternative data for better understanding (eg, carbohydrate intake, physical activity) • Possibility of intervening in the intervals between visits • Overcomes geographical barriers • Motivational tool	• Difficult to integrate with computerized clinical records • Different software programs for different devices • Time spent learning the software and gaining experience • Risk of data "flooding" the professional and the patient • Lack of significant evidences on the improvement of the outcomes • Limited number of patients currently accessing this technology • Lack of recognition for time spent and medical services • Requirement of organizational changes
Mobile app (medical device with CE[a] marking)	• Therapeutic instrument (eg, bolus calculator) • Easy visualization of data and management of corrective actions • Overview of trends over time • Greater patient involvement • Convenient for the patient • Motivational and educational support tool	• New skills and time for patient training • Reliability of the instruments
Telemedicine	• Overcomes geographical barriers • Greater accessibility to care • Reduced administrative burden (if structured) • Lower costs and inconvenience to the patient • Integration with traditional management in the clinic • Strong potential for cost reduction	• Nonrecognition of medical services • Structural difficulties • Need for institutional and organizational changes
Machine learning	• Performance of descriptive, predictive, and prescriptive analyses • Analysis of large databases of different sources that cannot be analyzed with traditional statistics • Better epidemiological risk assessment of the disease • Identification of new variables and new risk factors for the development of diabetes and its complications • Possibility of identifying the most effective patient-tailored therapeutic strategy • Minimizing adverse drug events by increasing safety • Possibility of phenotype/genotype integration	• Data quality • Heterogeneity of unstructured data • Correct use of data • Integration of data from different sources • Respect for privacy • Ethical problems • Possibility of reducing the professional skills of doctors • Replacing the professional with the machine • Difficulty in knowing and interpreting new analysis models different from the traditional clinical epidemiology of evidence-based medicine

Importance of the Chronic Care Model

A very interesting field of application concerns the Chronic Care Model (CCM), a medical assistance model for patients with chronic diseases. The CCM is a model for sustainable chronicity [47], in which the scope is to achieve a "personalized and effective care," with an active participation of the person, integrating the different professionals involved in assistance, to concretely improve the life of the person with a chronic pathology. The CCM in the declination of its various dimensions (health care organization, delivery system design, decision support, clinical information systems, self-management support, and community resources) brings a huge amount of the so-called "real world data." Such real world data are data collected in the normal clinical practice (not from controlled clinical trials), which allow the description of the patient's care pathways through the integration of different sources, consistent with what usually happens in reality. Each step of the care and assistance pathway—from diagnosis to treatment and follow-up—generates a large amount of data and images (big data) that often reside within health facilities in separate and independent databases. To obtain an integrated view of the diagnostic-therapeutic pathways for individual patients and to trace their complexity, it is necessary that these flows are integrated.

An interesting Australian study on CCM [48] shows how the use of electronic medical records and informatics-integrated assistance can improve the management of chronic diseases. The benefits for health care professionals and service users through an accurate and timely exchange of information are better work efficiency, prevention of repetition of data and information collection, as well as a better decision-making process.

Perspective of AMD

In Italy, in total, about 5 million people have diabetes (about 1 in 12 residents), and the number will probably rise to 7 million in 15-20 years. Italian epidemiological data suggest that around 250,000 new diagnoses of T2DM and around 25,000 new diagnoses of T1DM are reported each year [49]. Since the 1970s, an articulated network of diabetes centers has developed—some operating independently as simple, complex, departmental, or territorial structures, while others with outpatient activities are attached to the Internal Medicine and Geriatrics Operative Units. The social and health relevance of diabetes has been sanctioned by a law (n. 115 of 1987) that has enhanced the role of diabetes centers and inspired numerous national and regional documents for the following 30 years and the approval of the National Diabetic Disease Plan in 2013 by the Ministry of Health. This model encompasses family doctors and a widespread network of specialist centers throughout the national territory, based on multi-professional skills (eg, diabetologist, nurse, dietitian, sometimes psychologist or podiatrist, and eventually cardiologist, nephrologist, neurologist, ophthalmologist) and regularly serving about 50% of the people with diabetes. As a result of this network, Italy has the lowest average level of HbA_{1c} and the lowest rates of chronic complications and excess mortality among the western countries [50,51]. In this regard, the role of diabetes care in reducing mortality in people with diabetes must be underlined; those who are assisted in diabetes centers have lower total and cardiovascular mortality than those who do not attend the diabetes centers [50,51].

The mission of the Italian Association of Medical Diabetologists (AMD) is to promote the professional development of its members and to ensure the continuous improvement of the quality of assistance to all people with diabetes. In ancient times, AMD had already grasped the importance of standardizing the recording of daily clinical work in an electronic folder, followed by the collection and processing of real life information on care, examinations, complications, and therapy for a qualitative interpretation of real assistance in the national territory. This intuition of the use of variables with an intrinsic clinical and professional integrated meaning, which imply the doctor's reasoning in predictive and prescriptive choices has in fact realized the first model of decisional learning, thanks to the use of statistical algorithms.

Experience of the Annals

The AMD Annals represent a periodic publication that has allowed, annually since 2006, to assess the care profiles of people with T1DM and T2DM who have been admitted in Italian diabetes care centers. A wide network of diabetology services equipped with a computerized clinical record system, used for the normal management of patients in charge, has a software program provided by AMD that allows the extraction of a standardized set of clinical information (ie, Data File AMD). The database obtained is used to calculate the quality of the care indicators, both centrally and locally. In this way, a benchmarking activity is promoted based on the comparison of one's own performance with that recorded at the national level (best performers approach). This activity reflects the professional performance of the diabetologists—it is perfectly in line with the recommendations of the National Diabetes Plan. It is very cost-effective and has produced a systematic improvement over the years of all the indicators considered [52].

In addition, the AMD Annals database represents a valuable source of observational research data. In fact, it has allowed the investigation of many key aspects over time, such as the care of the elderly patients, gender medicine, cardiovascular, renal, and hepatic issues, the appropriateness of the use of drugs, and glycemic self-control, thereby providing a realistic picture of the work of the diabetology services. Notably, the analysis of the Annals database has allowed the identification of critical areas and, therefore, the timely activation of processes of improvement, in a logic of continuous quality enhancement, that is, a process of periodical performance assessment of diabetes centers on data collection and quality of care according to standardized indicators [53-57]. It is easy, at this point, to visualize that the Annals project "photographs" the history of the evolution of clinical diabetology and has allowed, for its own conception and structuring, each individual center to self-evaluate and improve in real time. Precisely, this careful measurement of behaviors and results is capable of triggering a dynamic evolution of an entire class of professionals, thus representing an irreplaceable benefit.

With innovative and far-sighted thinking, AMD has created this database, which today represents an unparalleled heritage in a cultural civilization that is increasingly aware of the importance of information and the value of a large and accurate collection of data. In this new era, the world is being organized to take advantage of the ever-increasing databases to rely on technology and use them as assets to be interpreted to facilitate and accelerate important decisions in every field. It is clear that it is increasingly important to have a quality data collection that is increasingly "clean," and it is fundamental to highlight the need for all professionals to be trained in the culture of big data and its correct recording. In fact, given that decisions can be made on the results of data processing, it is essential to raise the problem of the truthfulness of the data on which the analyses are based, to have a measure of the reliability of the results, and to be aware of them. Further, in this area, AMD has invested time and resources in activating a process—born more than 10 years ago—of culture on the quality of the data, which involved many partners who participated in the Annals project [53-57]. This is why AMD feels ready to investigate the topic, as it has an advantageous background, and it wants to project itself in a competent and proactive way in the world of big data and AIs that represent a new cultural challenge in the scientific field.

Diabetes Intelligence, the Value of the Diabetologist: Structured Skills and Prioritized Activities

The DIA&INT (Diabetes Intelligence) is an AMD project that rises in the setting of exploring new methods of analysis of unconventional data, and it can be considered as the first experiment in analyzing unstructured data by using the business intelligence method (a precursor of machine learning systems).

In a comprehensive vision of clinical activity, AMD focuses on the value of the skills that identify a diabetologist and make it a decisive tool in the care process. To achieve this objective, AMD implemented a business intelligence project called DIA&INT [47]. This project was mainly aimed at encouraging the implementation of the CCM in an "evidence-based" way by highlighting the direct link between the activities carried out by the diabetologist and their expected outcomes in order to highlight those activities that are essential to obtain the best outcomes in modern diabetology. Furthermore, this method may contribute to extrapolating the actions that could optimize the scarce resources and it may represent a valid support for the institutional choices in the current health system revision.

Admittedly, DIA&INT has been designed to respond to the need for establishing the qualitative dimension of the diabetologist's performance and the specific contribution of the many factors participating in the clinical decision in the real world. To do this, AMD has chosen to use the following accredited tools.

1. Organizational analysis to measure and enhance the role of diabetes care with specific tools (social return on investment).
2. Data management with advanced tools (business intelligence).

The resulting "program" has been structured to standardize the information and define activities and competences, as implicitly described in the official guidelines, which are measurable and comparable, with processing methods different from those of classical epidemiology, but necessary to perform predictive and prescriptive assessments. The methodology used [47] exploited the collective intelligence of the diabetologists who participated in a survey, expressing their opinion on a complex node such as the definition of the integrated benefit of certain activities in a personalized and weighted way. The intention was to "display" how diabetologists think when carrying out clinical judgment.

Through this approach, 2 main concepts were outlined: the requirements (priority, specificity, frequency, and multidimensional analysis) and the decision-making elements for "if…then" choices based on a priori knowledge (medical, regulatory, ethical, psychosocial, etc) and the ability to propose a dynamic personalized treatment project to the person with diabetes that does not yet involve healing and that requires an active personal effort. By doing so, DIA&INT has selected the necessary skills and activities in medical practice, which have an impact on the evolution of the quality of the "health product" and the outcomes. DIA&INT produced the Core Competence curriculum of the diabetologist [58] and measured the impact of the activities on the experiences [47].

Discussion

The changes offered by technological innovation have generated an unprecedented level of data collection and processing that is destined to undergo further expansion with the new applications of robotics and augmented reality, crossing a new frontier and entering the era of big data and cognitive systems. A new category of technologies is born, which uses natural language processing and machine learning and is able to amplify and accelerate the digital transformation process to allow people and machines to interact in a more natural way, extending and enhancing cognitive skills and abilities. The possibility of extracting information that has a meaning and is functional, in fact, requires the development of sophisticated technologies and interdisciplinary skills to operate closely together. In particular, in medicine, health care systems require consistent, appropriate, and sustainable choices.

Today, the complexity of medicine certainly goes beyond the capacity of the human mind. The patients themselves are increasingly complex and we know that the long-term effectiveness of a treatment depends on variables that are no longer just "numerical," but also on other information that is difficult to structure [2]. In this framework, advances in computing power play a central role in the acquisition of knowledge. It is essential to collect and use the key information in a coherent way, out of its abundance by using effective and reliable analysis tools that are represented by the new techniques of AI already available today. These techniques recognize and use machine learning systems that are able to "extricate themselves" and learn from these immense amounts of data, even with intrinsic systems of recognition and error management. In essence, AI is a machine capable of solving problems and reproducing activities typical of human intelligence [59].

However, at this stage, it is important to remind our readers that even though the data are processed through algorithms, the final decision rests with the physician, and the fact that still a huge part of this category is reluctant to computerization should not be overlooked. In addition, more research is needed to assess how clinicians currently incorporate digital tools into their practice and the prevalence of digital platform use in various health care systems. AMD has already set the basis of culture and tools on the importance of collecting data, but now, it is necessary to go further. The strong potential of the large amount of data collected in more than 10 years of observation in the AMD Annals initiative may contain a significant "hidden" knowledge that, analyzed through different tools, may show new patterns that can help us to make better decisions in the prevention and management of diabetes and its complications. For example, this type of analysis may not only amplify our notions on the risk factors for diabetes complications but may also unravel new and unsuspected connections between them, indicating the probability with which they can affect the evolution of the disease on specific groups of subjects. Properly "trained" machine learning algorithms are able to efficiently evaluate millions of data while seeking probabilistic risk correlations, and they are not limited to tracking the spread of an epidemic but has the scope of identifying new personalized therapies. We could also imagine going further, in the increasingly realistic hypothesis of linkage between the various health care databases (administrative data, assistance process, intermediate and final results, costs, etc), which will allow us to make comprehensive assessments of the whole process of care in an even more individualized way in terms of clinical effectiveness, organizational effectiveness, sustainability, and equity.

The field of big data is already a reality and this systematic revision and position statement was made to offer the basis of knowledge for a constructive debate on the next steps that the AMD as an association and, more in general, diabetology would follow in the very next future. It is time to choose to be proactive players in this complex system and take responsibility for these new processes aimed at improving the care of people with diabetes, which is and remains our “mission.”

In conclusion, the incessant progress of these changes brings into question many established paradigms, also in the scientific sphere, and this position statement represents the first document of careful analysis of this new world, which we must make our own in a logic of constructive comparison. We must reflect on the current scenarios, ask ourselves about the effects produced by these transformations to understand the consequences in our lives induced by the automated decisions, and become able of integrating the traditional route into the new systems.

The diabetologist, more than any other health care professional, already has the right mentality of being ready to take up this innovation. The culture of the data is in our DNA, the need to phenotype the patient and personalize the care and therapeutic approach have long been our priorities, the skills to manage a complex disease such as diabetes have been refined over time—ranging from technological to communicative and from educational and andragogical to managerial abilities. Thanks to all this progress made over the years and strongly desired by AMD, we are ready for a new challenge in the management of diabetology that must see us as protagonists. The “digital diabetes” is coming, and AI and big data are opening a window on new scenarios. Today’s diabetologists must acquire new skills to be able to lead these changes, be proactive in exploiting their potential and advantages, and limit their risks and guard the essential elements of the professions of doctors and health care professionals managing patients with complex chronic conditions.

Acknowledgments

No funding was received for the preparation of this manuscript. This document was approved and validated by the following members of the National Executive Board of AMD 2015-2017: N Musacchio, D Mannino, A Botta, M Calabrese, F Calcaterra, R Candido, A Gigante, G Guaita, G La Penna, S Leotta, A Lo Presti, MC Ponziani, and M Ragonese.

Authors' Contributions

NM conceptualized and drafted the manuscript. AdM directed the “BIG DATA and AI” Position Statement group of AMD, coordinated the writing of the manuscript, and reviewed it. AG, GG, AO, MP, PP, GR, and RZ contributed to the writing, editing, and reviewing of the manuscript.

Conflicts of Interest

None declared.

Abstract

A growing number of interventions incorporate digital and social technologies (eg, social media, mobile phone apps, and wearable devices) into their design for behavior change. However, because of a number of factors, including changing trends in the use of technology over time, results on the efficacy of these interventions have been mixed. An updated framework is needed to help researchers better plan behavioral technology interventions by anticipating the needed resources and potential changes in trends that may affect interventions over time. Focusing on the domain of health interventions as a use case, we present the Adaptive Behavioral Components (ABC) model for technology-based behavioral interventions. ABC is composed of five components: basic behavior change; intervention, or problem-focused characteristics; population, social, and behavioral characteristics; individual-level and personality characteristics; and technology characteristics. ABC was designed with the goals of (1) guiding high-level development for digital technology–based interventions; (2) helping interventionists consider, plan for, and adapt to potential barriers that may arise during longitudinal interventions; and (3) providing a framework to potentially help increase the consistency of findings among digital technology intervention studies. We describe the planning of an HIV prevention intervention as a case study for how to implement ABC into intervention design. Using the ABC model to plan future interventions might help to improve the design of and adherence to longitudinal behavior change intervention protocols; allow these interventions to adapt, anticipate, and prepare for changes that may arise over time; and help to potentially improve intervention behavior change outcomes. Additional research is needed on the influence of each of ABC's components to help improve intervention design and implementation.

Introduction

Digital and social technologies (eg, social media, smartphone apps, and wearable devices) have promising potential for achieving rapid and widespread health behavior change. Social media has been used to change and predict a number of health-related behaviors, including HIV testing and sexually transmitted diseases, suicide prevention, car crashes, and opioid-related emergency department visits [1-7]; Fitbits and self-tracking devices have been proposed as intervention tools to increase exercise [8,9] and reduce stress; health systems and insurers have integrated wearable device, social media and patient health/medical data to try to improve clinical outcomes [10,11]; and smartphone apps have be studied for their potential to improve a variety of health behaviors and outcomes, such as weight loss and diabetes self-management [12-14].

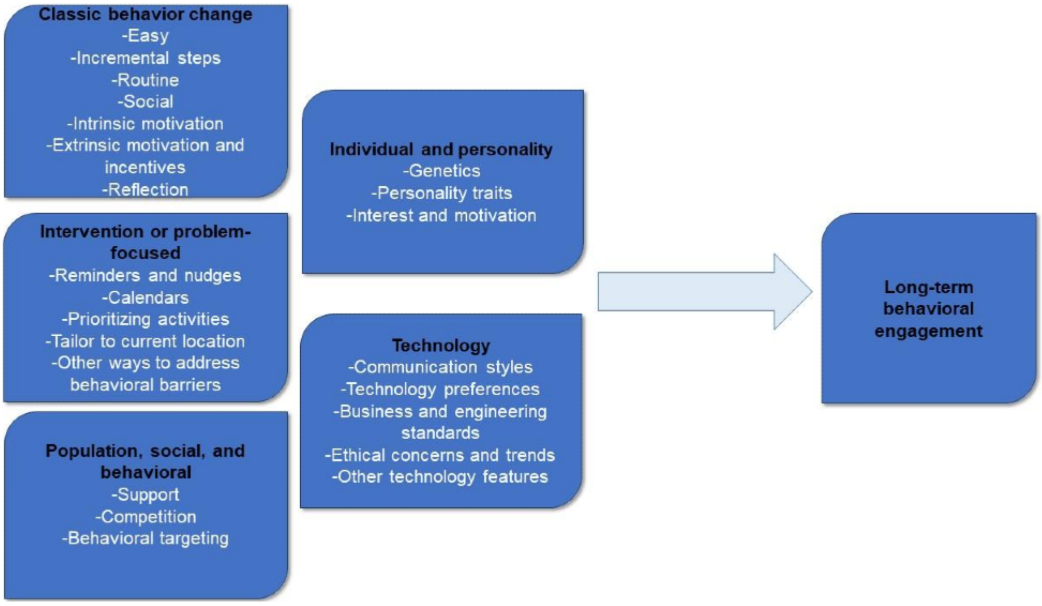
However, results have been mixed on whether and how digital technologies might change people's health behaviors [15-20]. Although some of these differences may be related to common methodological and study assessment–related reasons (eg, differences in study duration or outcomes), there are also a number of potential intervention design–related reasons for these inconsistences. For example, a large volume of behavioral psychology research suggests that small contextual changes have a dramatic effect on behavior [21-24], such as the size of a button on a website, or the way in which information is communicated and displayed. Although contextual issues can and have been found to impact intervention success regardless of whether it is an online or offline study (eg, age, race/ethnicity, and sex of experimenter may affect participant adherence and engagement), these issues become more complicated when delivering interventions digitally because of the frequency and ease of changing variables in digital technologies compared with offline interventions (eg, placement of buttons and text, inclusion of social interaction, and gamification), as well as reliance on technology companies (eg, Facebook and Twitter) to maintain similar and stable versions of their products. These issues have become increasingly important with the current COVID-19 pandemic, as there is growing need to integrate new technologies into research and clinical care to address COVID-19 policies, such as social distancing and stay-at-home orders.

Due to changing trends in design and use of digital technologies, it is, therefore, extremely difficult to exactly replicate a technology-based intervention study, as the earlier study might have occurred on a now outdated software platform. This creates an additional problem as grant applications often require planning 3- to 5-year studies in advance despite the potential technological changes that may occur during that period. How can researchers designing digital technology–based interventions address, or at least anticipate, these issues? New theories are needed to build on existing health informatics and behavioral technology-based intervention models [25].

This manuscript proposes a theoretical framework, called the Adaptive Behavioral Components (ABC) theory for technology-based interventions, with the goals of (1) guiding high-level development for digital health technology–based interventions; (2) helping interventionists consider, plan for, and adapt to potential barriers that may arise during longitudinal interventions; and (3) providing a framework to potentially help increase consistency of findings among digital technology intervention studies. We seek to describe and synthesize categories of prior research (below) into a new theory to help researchers design digital health technology–based interventions.

ABC incorporates research across the fields of social and behavioral psychology, informatics, and marketing to develop a model tailored to the needs of digital technology interventionists. The model is based on five overarching factors needed for guiding a sustainable technology-based intervention: (1) basic behavior change components; (2) intervention and problem-focused characteristics; (3) population, social, and behavioral characteristics; (4) individual-level and personality characteristics; and (5) technology characteristics (Figure 1).

Figure 1. Adaptive Behavioral Components Theory (ABC) for Technology-based Interventions. By helping researchers to consider these five high-level components, the model provides guidance on how to plan for the needs and potential changes during a technology-based health intervention.



A large body of research, including theoretical modeling, has been conducted on many of these five areas. ABC is not meant to replace existing theories specific to one or more of these components, but rather to provide a guide for when and how to think about the inter-related, diverse, and overarching concepts affecting behavior change that are often not considered within behavioral interventions. The first four components of ABC can apply broadly to behavioral interventions, whereas the last component is specific to digital technology–based interventions. Although the model might also be applied outside of health, this manuscript focuses on health applications to narrow the scope of discussion and provide context. The five components of ABC are described in more detail below, along with a case study of how it has been learned and might be applied in research settings.

The ABC Framework

Basic Behavior Change Components

There are a number of behavior change methods and theories, such as social normative and social cognitive theory–based interventions, that have been broadly and successfully applied to change health behaviors, including HIV risk behaviors [26] and smoking cessation [27]. These methods are typically rooted in social and behavioral psychological theory [20] and broadly suggest that interventions will be more efficacious if they (1) make it easy to engage in the target behavior [28-32], (2) make the behavior routine rather than infrequent and unpredictable [33,34], (3) incorporate social components such as support and/or competition [2,35-37], (4) build change incrementally (eg, dieters who focused on the daily steps of eating healthy were more likely to adhere to their healthy eating routine compared with those who focused on the end goal of losing weight [and these individuals actually gained more weight at follow-up]) [38], (5) develop intrinsic [39-41] and (6) extrinsic motivation (being cautious about the sometimes negative effects of incentives on behavior) [42,43], and (7) provide ways for people to reflect on their progress [44,45]. Integration of these basic behavior change components may help to improve intervention behavior change–related outcomes.

Intervention/Problem-Focused Characteristics

Interventions may benefit from further tailoring to address the *specific* behavioral barriers preventing people from conducting the intended behavior. These intervention or problem-focused characteristics are typically contextual factors that affect people’s willingness and ability to participate and remain engaged in an intervention. For example, people might not engage in behaviors because of a variety of reasons, including lack of remembering, interest, or time; belief that the intervention is unlikely to help or may harm them; cost; or that the intervention is ill-suited to their lifestyle, values, or expectations. The specific intervention framework should be guided by these needs [46]. For example, an intervention designed to send mobile-delivered medication reminders would likely be more beneficial to individuals who are forgetting to take their medication compared with individuals who fear the side effects of the medication. Similarly, environmental and immediate contextual-level tailoring (eg, just-in-time interventions) may benefit individuals who need to be reminded to engage in activities at certain times or in certain locations [47]. For example, a text message reminder can be sent as a reminder tool to attempt to prevent drug use for a substance-using individual who is walking in an area detected by the phone to be a high-risk area for substance use, an example of timecasting [48]. By understanding the reasons why people are not engaging in a specific behavior, intervention characteristics can be tailored to optimize addressing that barrier to behavior change.

Population/Social/Behavioral Characteristics

Tailoring interventions to people’s differences in population, social, and behavioral characteristics may help to further improve intervention efficacy. For example, tailoring intervention content to the target population (eg, creating racially and culturally tailored online recruitment advertisements for a study among African Americans) may increase recruitment efficiency [49]. In a study demonstrating this approach, African American men had increased odds of clicking on a Web-based advertisement that included an image of an African American model vs a white model [50]. Similarly, tailoring interventions to include individuals who share similar demographic characteristics and preferences (ie, peers) may be more efficacious compared with interventions that do not tailor for these factors [51]. Tailoring interventions to an individual’s behavioral state might also lead to higher engagement compared with not including this tailoring. For example, online smoking cessation health information may have higher click-through and engagement rates if delivered to people who have been searching on Google for ways to quit smoking compared with individuals browsing on Facebook to talk with friends.

Individual-Level/Personality Characteristics

Despite the success of social- and community-based interventions, many people within these interventions do not follow the group norm because of individual-level differences, such as differences in experience, genetics, personality, and disposition [52]. For example, in a study on factors affecting health, the personality factor, that is, conscientiousness, predicted all study outcomes, with individuals identified as being less responsible and less self-controlled tending to report poorer health, be more overweight, and engage in more substance use. Tailoring interventions at these individual levels, such as by targeting familial, genetic, and/or personality characteristics, might increase intervention efficacy. For example, participants who have personality traits identifying them as “more social” might be targeted as peer role models for peer-led interventions [53-55]. Similarly, individuals with genetic predisposition for alcohol use disorder [56] might be targeted for an alcohol-related intervention to help researchers learn more about genetic factors/predisposition and improve targeting of at-risk individuals. However, research on the role and methods of developing interventions based on individual-level/personality characteristics has been limited, leading researchers to call for additional research on this topic [57].

Technology Characteristics

Although the above four factors affect and should be considered when conducting any type of behavior change intervention, the technology characteristics component is specific and critical to the success of *digital technology* interventions. It is also perhaps the component that requires the most planning of all the five factors, because of the changing needs and trends in technology use. Intervention engagement can be affected by a variety of technology characteristics, such as current trends in popular communication style (eg, use of video as a preferred communication medium vs text), changes in features of a technology (eg, adding an online community feature to a software app may change user engagement rates), and changes in ethical concerns (eg, social media engagement may decline after a recent security breach on that social media platform) [58]. These factors might have a large impact on intervention efficacy. Understanding and preparing for technology characteristics and potential adaptations is, therefore, essential for the delivery of effective longitudinal technology-based interventions.

Discussion

Lessons Learned and How to Apply

As a case study identifying the five components of ABC and how to apply them, we will describe the process for planning an intervention to increase the initiation of pre-exposure prophylaxsis (PrEP) as a method of HIV prevention among African American and Latino men who have sex with men (MSM) who are aged 18 years or older and living in Los Angeles. The primary behavior we wish to change is, therefore, to increase the number of participants initiating PrEP. Table 1 can be used as a reference for when and how the ABC framework can be incorporated into planning this intervention.

Table 1. Applying the Adaptive Behavioral Components (ABC) model for technology-based interventions. This table provides an example of how a researcher might apply the ABC framework in an intervention designed to increase uptake of pre-exposure prophylaxis among African American and Latino men who have sex with men at risk for HIV. The examples below are not exhaustive but are meant to assist readers in understanding how to integrate ABC into intervention design.

Category and subcategory	Example
Classic behavior change	
Easy	Provide online diagnosis and prescription referral as an option to increase PrEP[a] accessibility
Incremental steps	Gradually discuss and promote PrEP with participants, beginning with friendly topics first to gain trust
Routine	Routine (eg, weekly) communications with study participants
Social	Encourage discussions and social interaction among participants
Intrinsic motivation	Educate participants on the importance of prevention and safe sex
Extrinsic motivation	Provide products/services that have tangible value to participants (eg, free PrEP and HIV self-test)
Reflection	Encourage participants to talk about their experiences using PrEP so that they reflect on and think about it
Intervention/problem-focused	
Reminders/nudges	Remind participants to make an appointment and use PrEP
Calendars	Codevelop a calendar with them with dates for when they will schedule an appointment
Prioritizing activities	Cocreate a list of priorities with them to help them fit a PrEP medical visit and use into their priorities
Tailor to current location	Discuss PrEP when participants are available based on their location and schedule
Population/social/behavioral	
Social support	Develop a peer support network where peer role models deliver the intervention
Competition	Integrate friendly games
Behavioral targeting	Provide recruitment advertisements and/or HIV prevention information to participants at the right time and context (eg, when participants are requesting or searching for information about safe sex)
Individual/personality	
Genetics	Tailor the intervention based on genetic differences in response found in research
Personality traits	Tailor the intervention based on personality differences in response found in research
Interest/motivation	Tailor the intervention based on interest/motivation (eg, individuals who are less interested may need greater financial incentives)
Technology	
Communication styles	Offer multiple methods of communication (eg, chat, video, and text message)
Technology preferences	Deliver the intervention on platforms that are already being used by minority men who have sex with men (ie, the target population)
Business/engineering standards	Awareness and planning based on current and potential future changing trends in the technology platforms being used
Ethical considerations/trends	Awareness and planning technology features that address current and potential future ethical considerations (eg, for an HIV prevention intervention, private communication is important to reduce experience of stigma)
Other technology features	Deliver the intervention on multiple technology platforms to avoid risks from one platform

[a] PrEP: pre-exposure prophylaxsis.

Although there are numerous reasons why individuals do not take PrEP, using the ABC framework to analyze the intervention/problem-focused characteristics teaches us that we need to narrow to focus on only one of these reasons (stigma) and develop an intervention designed to decrease stigma to increase PrEP use. As stigma is a social construct (created and perpetuated by one's peers) [59], we seek to counteract stigma that prevents people from using PrEP by creating an intervention that will leverage peers to promote PrEP uptake (ie, we will deliver a peer-led, community-based intervention). Within the intervention framework, we will attempt to include many of the basic behavior change components. For example, we will make it easy for participants to request PrEP by allowing them to receive an online tele-consultation and request PrEP online, making it easier (and less stigmatizing) than typical methods of having to visit and get tested at in-person clinics. We will also hire peer leaders to gradually become friends and then promote PrEP behavior change with participants each week, incentivizing routine discussions with the peer leaders.

We will integrate the population/social/behavioral characteristics of ABC by designing recruitment materials, intervention content, and processes that are tailored for this population (eg, recruitment advertisements include sexually provocative images of minority MSM; advertisements will be placed on websites where minority MSM are already searching for safe sex information [eg, Google ad words]; and HIV prevention conversations will be delivered by minority MSM peer leaders and focused on issues relevant to minority MSM).

Although the intervention is designed for African American and Latino MSM, we anticipate individual differences such that not all individuals will respond to the intervention as planned. To address this, we will meet peer leaders each week to learn about the barriers and facilitators in promoting PrEP uptake among each individual participant, to refine and further tailor the intervention to individuals who are not responsive to the intervention (eg, some participants may require more personal time/education than the average group member).

Finally, we wish to use technologies to scale the peer-led PrEP uptake intervention because of a technology-based intervention's potential for rapidly and cost-effectively scaling behavior change. We seek to use social media and mobile social technologies to deliver the intervention because of their alignment with and ability to meet the requirements stated above (eg, social media technologies allow African American and Latino MSM peer community leaders to communicate with and spread PrEP uptake–related behavior change information to other African American and Latino MSM both within a [private] group and/or individually). The Harnessing Online Peer Education (HOPE) intervention, a peer-led online community-based behavior change intervention, is one example of this type of intervention and one that we seek to use. Although HOPE interventions have been focused on different populations and behavioral outcomes, including HIV testing (HOPE HIV), mental health, and opioid misuse, with efficacy demonstrated in changing primary behavioral outcomes [2,51,60,61], all members of this family of intervention rely on using social technologies as a method for delivering a social normative (eg, peer-based) intervention. However, deciding the specific technology component(s) to be used in HOPE is perhaps the most important and difficult aspect in our study plan because of the changing trends in technologies.

For example, a multiwave, 5-year HOPE HIV testing intervention was funded in 2014 based on earlier methods and results from HOPE interventions conducted in 2010 and 2012 that showed success in using Facebook groups as an intervention delivery platform [2,51]. However, from 2010 to 2014, and throughout the 5 years following 2014, a large number of changes have occurred on social media, including Facebook no longer being the sole dominant technology used for online communities or forums among all age groups and populations. With the introduction of other platforms, such as Snapchat and Instagram, use of Facebook has waned, especially among youth [62], which might reduce the engagement and potential efficacy of interventions delivered on Facebook that rely on previous rates of engagement. Similarly, throughout a 5-year period, Facebook has made a number of changes to their interface, affecting HOPE intervention engagement.

For example, in 2018, Facebook's Mark Zuckerberg made a public statement that Facebook would be changing the way their algorithm displayed content, upsetting many individuals and businesses who had relied on previous methods for posting on Facebook that might no longer work [63]. Previous longitudinal behavioral interventions on Facebook were impacted by these changes. For example, in an HIV prevention intervention run by our team using Facebook groups during this period, we have been finding that Facebook platform changes have resulted in intervention participants receiving fewer notifications about HIV prevention and testing compared with control (Facebook) group participants. Although the intervention group remains significantly more engaged in posting compared with the control group (as intended by the intervention), the large number of posts within the intervention group combined with the changes to the way Facebook groups and the Facebook algorithm are used initially resulted in fewer testing-related posts being viewed by the intervention group compared with the control group. As a result, our team has learned the importance of delivering technology-based interventions through multiple technology platforms to minimize the impact on the intervention because of changes that may occur on one of the technology platforms or by changing trends in the types of technologies used by participants.

We responded to these experiences by learning that we need to modify the way technology-based interventions are designed and delivered. In the future, we seek to develop a HOPE intervention that leverages multiple platforms, including Facebook, Instagram, Snapchat, and YouTube (or whichever platforms that are dominant at that time), and ensures that the elements of ABC can be integrated into one or more of these platforms. By delivering the intervention across multiple platforms, we seek to (1) reduce the risk that changes in one or more of the technology platforms alters intervention delivery; (2) reduce the risk that major changes to the study protocol might be needed at a later period; (3) allow flexibility within the study protocol for it to be tailored to incorporate additional social technologies in the future (eg, by leveraging multiple technologies to deliver the intervention, each of these play a smaller role and allows for technologies to be replaced over time as needed with trends while keeping the scope of work intact); (4) allow the ability to simultaneously tailor the intervention to different subdemographic groups and populations (ie, tailoring for age, race, and ethnicity based on the social technologies used most frequently by those groups); and (5) allow the ability to incorporate multimedia methods and trends in communication, such as use of social technologies that are designed for sharing of text, images, videos, and/or other methods such as virtual reality.

We also recommend to our own team and other researchers to track every available relevant digital metric (eg, click-through rates, downloads, and likes) and to conduct a pilot study before proceeding with an intervention. These digital data can be very useful in informing potential unknown problems that might occur during an intervention [64]. They are also important as they can help monitor and address unforeseen circumstances that may occur in the middle of a digital intervention (eg, a prolonged drop in engagement on a digital platform may be a signal for the need to shift the intervention methods/content to a different digital platform). Taken together, we have learned the importance of both accounting for changes in technology use and the need to anticipate and adapt various behavior change components across technologies to improve the efficacy and durability of digital behavioral interventions.

Conclusions

The ABC model was designed as a guide both to assist in planning digitally delivered behavior change interventions and to help anticipate the needed resources and potential changes in trends that may affect an intervention over time. Using the ABC model to plan future interventions may help to improve the design of and adherence to longitudinal behavior change intervention protocols; allow these interventions to adapt, anticipate, and prepare for changes that may arise over time; and help to potentially improve intervention behavior change outcomes.

Acknowledgments

The authors would like to thank Hendricks Brown for feedback on previous versions of this manuscript. The authors wish to thank the National Institute on Mental Health (5R01MH106415), National Institute on Drug Abuse (C-PIM grant), National Human Genome Research Institute (U01), and National Institute for Allergy and Infectious Diseases (7R01AI132030) for funding this work. This manuscript does not reflect the opinions or views of the funders.

Authors' Contributions

SDY developed the theory and wrote the manuscript.

Conflicts of Interest

SDY receives royalties from Harper Collins Publishers (US edition), Penguin (UK edition), and other publishers for the book, Stick with It. He is also an advisor/consultant (receiving compensation) to companies and startups related to behavior change.

Abstract

Background: The impact of viewing pornography at a young age on the sexual health of subgroups of young people is an important public health issue. However, the topic is complex and extremely sensitive, and best practices for research and harm reduction are yet to be defined. Drawing on cross-disciplinary approaches, such as co-design, is one way to achieve a better understanding of the issue among vulnerable young people and to create needs-based and evidence-informed digital resources to promote pornography literacy.

Objective: The objective of this study was to co-design a relevant, usable, and acceptable digital prototype to address the pornography literacy needs of vulnerable young people.

Methods: In total, 17 young people aged between 14 and 23 years who were engaged in youth services programs or alternative education programs were recruited to participate in 4 co-design workshops with a multidisciplinary design team.

Results: Although the participants could identify problems with pornography and critique its messages, they lacked the information to understand alternative healthy attitudes and behaviors. A digital resource that provides detailed and practical information about sex, sexual ethics, and relationships may help vulnerable young people to identify and contrast with any problematic messages they receive from both pornography and society. Embedding this information with pornography literacy messages may be a more effective way of addressing underlying attitudes. Acknowledging information-seeking patterns and leveraging user interaction patterns from commonly used digital platforms among users may enhance engagement with resources. Importantly, digital platforms are perceived among this group as a source of anonymous secondary information but would not be organically accessed among this group without face-to-face conversations as an access point.

Conclusions: This paper highlights the potential for pornography literacy to be embedded within real and practical information about having sex, navigating sexuality, and healthy relationships. The study findings include important recommendations for the conceptualization of digital pornography literacy programs and opportunities for cross-disciplinary co-design research to address complex and emerging health issues.

KEYWORDS

co-design; pornography literacy; sexual health; sex education

Introduction

Background

Young people's increasing access to free web-based pornography has led to concerns over its impact on their attitudes and behavior [1]. Pornography is defined as sexually explicit pictures, texts, or other material created to cause sexual arousal [2]. However, in reality, web-based pornography includes a wide variety of material and genres that depict diverse sexual scenes [3-5]. The literature suggests that condom use in heterosexual pornography is rare (2%-3%) and that gender inequality in mainstream online videos is common [3,5,6]. For instance, female actors were found to be significantly more likely to be shown being dominated or degraded [3] and were four times less likely than male actors to be shown achieving orgasm [4]. Recent research with 15- to 29-year-old Australians found that 90% had ever viewed pornography, with 81% of young men and 22% of young women reporting at least weekly use [7]. Pornography exposure is associated with sexual risk factors, including decreased age of first sexual experience, more lifetime sexual partners, and not using a condom during the last sexual encounter [8-10]. Exposure has been associated with increased sexual aggression and sexist attitudes [11], and cross-sectional studies report links with relationship problems and depression [12-16]. However, harmful effects have not consistently been reported in research, with some studies showing mixed findings [17]. Given the scale of the issue, it is a public health imperative to better understand how viewing this content frequently and from a young age may impact on sexual scripts, which include the knowledge, beliefs, and attitudes that guide sexual decision making [18,19]. However, the topic is evolving, complex, and extremely sensitive, and best practices for research and harm reduction are yet to be defined. Drawing on cross-disciplinary approaches, such as co-design, is one way to achieve a better understanding of the issue among young people and to create needs-based and evidence-informed responses.

Vulnerable Young People at Risk

Pornography is not homogenous, nor are its audiences [20]. Informed by the social cognitive theory, researchers have suggested that there may be differential effects of viewing pornography, influenced by factors such as the type of pornography viewed; the viewer's age, gender, and sexuality; preheld beliefs; and access to alternative sources of information [10,16,21,22]. How these factors influence the impact of pornography on knowledge, attitudes, and behaviors is beginning to be explored among subgroups of young people to understand risk factors for harm. A 2018 cross-sectional survey of 15- to 29-year-old heterosexual Australians (n=517) by our group found that young women (n=320) were significantly more likely than young men (n=197) to report having seen violent or degrading behaviors toward women [23]. We hypothesized that gendered experiences may influence how young audiences interpret pornographic images rather than indicate pornography preferences [23]. A 2015 study of economically disadvantaged, urban-residing black and Hispanic youth (n=72) identified an association between regular pornography use and dating violence [10]. Other studies have found that pornography can play an important role in the sexual development of lesbian, gay, bisexual, transsexual, queer, and intersex plus (LGBTQI+) young people in the context of limited access to alternative representations and overrepresentation of heteronormative sex [24,25]. However, few studies have explored how this may negatively influence ideas about sex, gender, and sexuality for young LGBTQI+ people exposed to fetishized representations of sexuality [26]. In summary, there may be young people who are at greater risk of harms from pornography as a result of the sociocultural and environmental contexts in which they view it. For instance, young people who do not consistently attend school, experience family conflict, identify as gender or sexuality diverse, or are from culturally and linguistically diverse backgrounds may have specific experiences and less access to relevant sexuality and relationships education, including pornography literacy. Understanding how these subgroups of young people experience pornography and its effects is vital to creating effective health promotion responses.

Pornography Literacy

Despite the evidence of the impacts of pornography on young people being underdeveloped, interventions to reduce its potential harms are being funded and produced [27-30]. Pornography literacy has been advocated as a harm reduction approach. On the basis of the media literacy theory [31], the key aims of pornography literacy approaches are to teach young people skills to critically analyze the messages in pornography, to increase their understanding of risks of exposure, and to encourage them to hold critical attitudes toward viewing the content and its messages [21,29,31,32]. However, there is little consensus about what pornography literacy education programs should include or how they should be delivered [33]. One of the few studies that explored the pornography literacy needs of young people used participatory research methods to identify information needs among Irish young adults aged 18 to 29 years [33]. Dawson identified pornography literacy priorities, including communication and consent, body image, reality of real-life sex, pleasure, information about the fetishization of gender and sexually diverse groups, and reducing shame over pornography use [33].

Importantly, current literature is inconclusive about the effectiveness of pornography literacy to reduce pornography-related harms among young people [32,34,35]. A small body of the literature suggests that participation in media literacy may help young people to develop skills to critique media messages and develop realistic expectations [33]. For instance, a representative panel survey of Dutch adolescents found an association between receiving school-based pornography literacy education and reduced strength in the relationship between pornography and stereotypical sexual attitudes [35]. However, the study did not define pornography literacy, relying on self-reporting of receiving any school-based education about pornography [35]. A recent preliminary study of 24 college students (aged 15-24 years) assessed the feasibility and effectiveness of a class-based pornography literacy program; it found that pornography-related knowledge increased posttest and some attitudinal shifts resulted [32]. These programs have been implemented and evaluated among young people engaged through formal in-person education and, thus, may not be applicable to those not in formal education settings. To date, there are no publicly available online or digital pornography literacy resources that specifically target vulnerable young people. Research has suggested that online resources could complement and enhance information engagement [33] and are most valuable to young people who lack alternative information, including those with diverse gender and sexual identities [36]. As such, understanding the experience, needs, and wants of subgroups that may be particularly vulnerable to the effects of viewing pornography will assist in developing responsive and equitable digital resources.

Human-Centered Design

Human-centered design and design thinking approaches involve prioritizing users throughout the creation of a product or service rather than at the start or end [37,38]. As a tool of human-centered design and design thinking, co-design methods involve bringing together key users, designers, and subject matter experts who participate in iterative workshops to understand and empathize with users. This enables them to define key issues and opportunities, to develop ideas to overcome issues, and to design solutions. Using creative and generative activities enables engagement with lived experiences and perspectives in ways that can overcome limitations of verbal communication where topics are complex or sensitive [39,40]. If implemented well, co-design methods can provide participants with time and space to actually think about the issue as they create, form, and question opinions and reflect on theirs and others' experiences in a safe and productive setting. Creating, role playing, and interaction between facilitators and participants can shift power dynamics and create trust and mutuality to understand and define sensitive issues. Importantly, involving users who are experts of their own experience as co-designers of potential solutions can help overcome the limitations of relying on traditional formative research methods to create health interventions [41].

Despite the seemingly obvious alignment of design and health disciplines, recognized challenges for cross-disciplinary collaboration exist [40,42]. For instance, it has been acknowledged that health research principles such as control, generalizability, reduction of bias, and replicability are in contrast with co-design processes that are necessarily creative, iterative, and flexible to account for the needs of users [40]. Furthermore, challenges of bringing together cross-disciplinary expertise central to co-design processes, such as time, resources, and willingness to compromise on disciplinary approaches could influence those considering this approach. Even the process of communicating co-design processes and findings falls outside of qualitative research conventions. Despite these challenges, the potential for the co-design method to radically contribute to the field of public health and health promotion is immense. For instance, there has been growing recognition of the potential for this method to increase the effectiveness of health promotion practices, particularly where issues are complex, sensitive, and ill-defined [37,39,42,43]. This being the case, these methods are particularly relevant for addressing the impact of web-based pornography on vulnerable young people's sexual health and their preferences for pornography literacy education.

This Study

This study aimed to co-design a relevant, usable, and acceptable digital prototype to improve pornography literacy among vulnerable young people. The project involved a cross-disciplinary co-design, including vulnerable young people, service providers, public health researchers, design researchers, user interface designers, and web developers.

Methods

Participants

A total of 17 young people aged between 14 and 23 years participated in the multiphase co-design workshops. The participants included 5 young women, 1 gender nonbinary person, and 11 young men.

Procedure

Young people were eligible if they were currently engaged with one of our partner youth service providers, were aged 14 to 24 years, and had experiences or identified with of at least one of the following: fragmented school attendance or disengagement from mainstream education (irregular attendance or participation in alternative curriculums such as vocational or applied learning); limited access to relevant education on sex, sexuality, and relationships (ie, for young people who identify as LGBTQI+); experience of family conflict or breakdown; and culturally and linguistically diverse (CALD) backgrounds.

We partnered with youth services, education providers, and primary health care providers to embed us in their existing programs for young people. This included youth groups and alternative education programs for young people disengaged from mainstream schools. A written information and consent form was developed and was accompanied by a short video to facilitate information and consent for people with low literacy skills. Project information was housed on a website to ensure that community members and potential co-designers could access further information about the project or contact our team. Informed consent was obtained from participants aged 16 years and older. For participants aged 15 years, we followed consenting practices for mature minors [44] of partner organizations, which involved independently consenting those deemed mature minors and seeking parental consent for others. Parental consent was obtained for participants younger than 15 years. The participants received an Aus $40 (US $29) gift voucher for every 3-hour workshop, with a bonus Aus $20 (US $12.11) voucher for those who attended all workshops. Facilitators, participants, and youth workers communicated about any sensitive or traumatic issues that may have emerged during activities. Participants were given the opportunity to change activities, observe, or leave it any time and to debrief or access relevant services after each workshop. Ethics approval for the research was granted by the Alfred Health Human Research Ethics Committee (373/18).

Participant Characteristics

A total of 17 young people participated in the co-design workshops, including 5 females, 1 gender nonbinary person, and 11 males. Participants ranged in age from 14 to 23 years (mean 16.5 years). Furthermore, 6 participants were from CALD backgrounds (English as a second language), 5 identified as LGBTQI+, and 2 were living with an intellectual disability. Over one-third of our sample was disengaged from mainstream schooling and had experiences of fragmented education. A similar proportion had experiences of family conflict or breakdown.

Co-Design Workshops

We conducted a total of 12 co-design workshops across 3 groups. Workshops were designed across 4 phases adapted from design thinking [37]: *understand*, *define*, *ideate*, and *design*. Workshops were conducted in known and safe spaces, including schools, community centers, and youth services. Two design researchers (1 male and 1 female) and a public health researcher (female) facilitated all the workshops. Youth workers and teachers were present on site but not in the room during the workshops. Each workshop ran for 3 hours. Workshops were audio-recorded, and note-takers recorded key conversations, observations, and interactions.

The first workshop focused on introducing the process, building trust and rapport, creating shared boundaries and safety, and beginning the process of getting to know our users and their information preferences. Activities were designed to create opportunities even during the introduction and icebreakers to understand more about our user's lives, aspirations, motivations, and challenges to help us walk in their shoes. The second workshop focused on creating opportunities for our participants to reflect on their thoughts, feelings, and experiences of sex, relationships, and pornography and to enable them to define key issues or problems, hence identifying information needs. We were conscious of creating space for participants to speak openly, using their own language about issues they may feel unsafe or embarrassed to talk about in the workshop setting. We designed activities that could be fully engaged with either anonymously or in the third person. The aim of the third workshop was to review young participants' definition of the problem and position our participants as *solution designers*. This involved building participants' understanding of design processes and tools and belief in themselves as *designers*, while simultaneously exploring their preferences for solutions. Activities facilitated the ideation of *blue-sky* ideas to help address issues defined throughout the previous workshops. The aim of the fourth workshop was to enable participants to develop their ideas into digital design solutions and to understand their brand values and aesthetic preferences for the user interface design. Participants used digital wireframes to map out their solution, features, and interactivity.

Workshop Activities

During activity design, we considered our participants' interests, abilities, and challenges and, our design practices. Activities prioritized creativity, shared understanding, empathy, and safety. In the first workshop, participants created personas of other young people that could be used for third-person discussions to avoid over disclosure. Across the workshops, each activity was built on the topics and outcomes from previous activities. This allowed participants to work into this complex issue and to increase trust and engagement as the activities progressed. Activities were generative to create spaces for participants to embrace creativity and to reflect on the issues [45]. Informed by previous co-design projects engaging with young people [39,43], we used a range of creative tools, including Lego, collage (Figure 1), community-mapping, drawing, music, and movie making. For instance, one activity involved participants creating a storyboard based on a scenario related to sex, relationships, or porn. They used personas to explore what the people in the scenario thought, felt, and did. Participants used Lego to create each scene of their movie along with speech bubbles. Each small group used a preloaded *stop motion* video app [46] to create a short movie, which they recorded and played back to the group for discussion. Activities positioned participants as designers throughout the process from understanding and defining the issue right through to the design of actual solutions. We conducted solution prototyping using pop culture references, such as superheroes, to leverage universal recognition and engagement with the Marvel comic franchise. A full description of our activity development and implementation is described in a research protocol and can be accessed on request.

Figure 1. Hot or Not? Collage.

Data Analysis

Data generated from activities included (1) the products of these activities that were considered *assets* that we could analyze; (2) our debrief notes that recorded conversations, interactions, and observations; and (3) verbal recordings of participants' discussions during the activities. All findings are developed based on insights drawn from across activities.

Co-Design Synthesis

An iterative human-centered design data synthesis using *affinity mapping* guided the analysis of data [47]. Step 1 involved extracting data from the assets the participants created, workshop recordings, transcription notes, and debrief notes. Step 2 involved sorting the data into several deductive themes that were clustered and coded together to establish subthemes. This step involved building consensus among the team through disagreement and debate. Step 3 involved *collaborative sense-making* where the research team interpreted the themes and subthemes into design insights [47]. For instance, the theme of youth trauma was evident across the workshop; in our data synthesis phase, we translated this into a design recommendation of needing our resource to be trauma-informed, which we placed under the *information preferences* branch of design considerations. We identified how our insights were connected to create a picture of our users' needs and challenges for the design. Each stage of the synthesis process included researchers AD and SM, and the final steps also included researcher CW and members of the design team.

Prototype Design

Human-centered design practices guided our process for bringing together the needs and wants of our users with best practice in accessible design and health promotion. The multidisciplinary team of designers and researchers were involved in the final stages of the synthesis and then participated in a process called Design Sprints. The process included ideating solutions based on user personas (available on request), on participants' design solutions created during co-design workshops, and on the response to the information needs and preferences of each user persona. Multiple rounds of ideation and design took place before a set of design recommendations for the prototype was developed. On the basis of the feedback from participants, key stakeholders, and external subject matter experts, these recommendations were developed into a functioning digital prototype of the solution for testing and evaluation (to take place in an independent study).

Results

Design Considerations

A summary of key design considerations (*information needs* and *information preferences)* identified through data synthesis and translation of co-design insights have been outlined as follows, after which the full description of the final prototype design has been provided.

Information Needs

Pornography Literacy

Participants defined pornography as *anything you can see on a porn site*, including porn videos, images, explicit pop-up advertisements (eg, for penis enlargements), and third-party services (eg, for paid sex). Activities and discussion among our users illustrated that they understood pornography as obviously unrealistic and could already critique its messages. Young women identified concerns over the representation of women's bodies, gender stereotypes such as *women who like sex are sluts*, and the reinforcement of rape myth acceptance. In contrast, young men and young transmen commonly identified problematic messages about bodies, including male bodies, male sexual performance, and normalization of the objectification of women, such as their representation as *i* (Figure 2). Despite being able to identify problematic messages, young men did not link them to their own attitudes or behaviors. Rather, some explicitly stated that knowing pornography was "fake" made them "porn proof." Others explained "we don't all watch Harry Potter and want to become wizards" to articulate to the group how their understanding of pornography as *fantasy* meant that they could watch it without having their attitudes or behaviors affected.

In contrast to these claims, young men created scenarios in which watching pornography did impact their behavior. For instance, a pair of participants created a stop-motion Lego movie illustrating how a character watched pornography and, after viewing anal sex, decides to try it with his girlfriend who is uncertain about it (Figure 3). In the scenario, the girl asks the guy to stop because she does not feel comfortable. He complies, only saying "I saw it online," and no harm is perceived to be done. The scenario and subsequent discussions revealed a contradiction to our participants' statements that watching porn did not affect their attitudes or behavior in any way and potential barriers to addressing impacts by focusing on the potential harms from porn.

Figure 2. Porn world vs. real world activity creation.

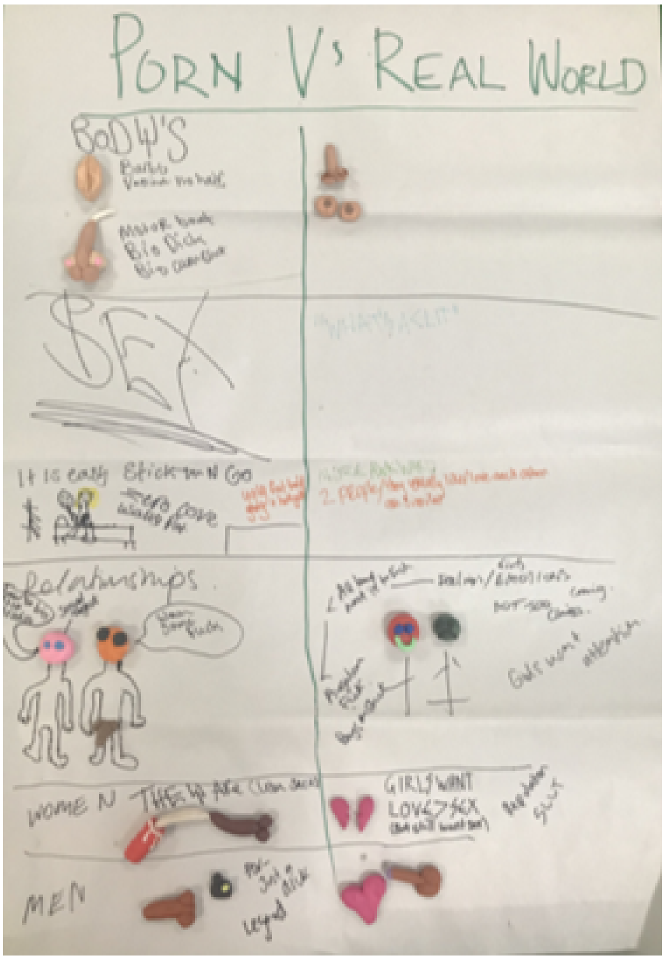

Figure 3. Stop motion movie scene and storyboard activity creation.

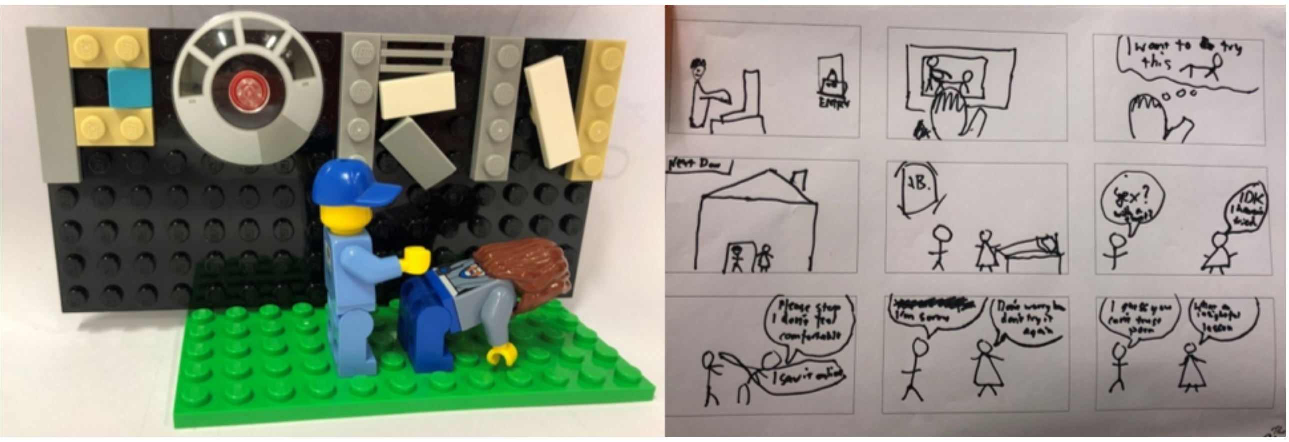


Beyond a Problem With Porn

Activities revealed that our users lacked information and skills to be able to contrast problematic messages from pornography with alternative ways of thinking or behaving. For instance, although participants could identify that representations of pleasure and consent in pornography were limited, there was little consensus among the groups about how to make sex pleasurable for all people and what constitutes consent or ethical sexual practices. This was particularly problematic for LGBTQI+ young people who experienced even less access to relevant representations of sex and sexuality outside of porn. Specific information gaps identified across groups included pleasurable sex positions, sexual pleasure for young women and trans young people, sexual pressure, consent, safe sex, and healthy relationships. Without alternative information and frameworks to guide their decision making and preferences, our participants were concerned with their ability to navigate both the "basics" and the "grey" areas of sex and relationships.

Furthermore, our users identified how messages from pornography can be compounded by messages they are exposed to in other domains. For young women in particular, problematic messages that they are exposed to in pornography are not always different from those in popular culture and society. For instance, some talked about the messages they are exposed to on Instagram about the ideal female body and sexuality. Some young men also articulated concerns about unhealthy behaviors they had seen modeled by family members such as a "drunk uncle" who makes people feel uncomfortable with his behavior. These insights highlight potential problems with creating a resource centered on pornography as an issue without addressing the information gaps and underlying social norms that permeate young people's lives.

Information Preferences

Reactive Information Seeking

In general, our users were unlikely to proactively seek out information, especially about sex, relationships, and porn, unless prompted by experience or contradiction to preheld knowledge. Rather, they wait until they have a negative or confusing experience or until their beliefs are contradicted to *Google it* This was illustrated during workshops when participants would often talk to each other about the issues raised through activities. On one occasion, 2 participants debated if girls can orgasm during penetrative sex. After discussion and disagreement, they pulled out their phones and searched for an answer. Both confirmed their own assumptions by finding something online to illustrate their point, highlighting that once they seek out information, many look to confirm or validate their existing opinions or beliefs. Importantly, neither participant found quality or evidence-based information; we found that few participants had the knowledge or skills to research high-quality information in practice. This has important implications for designing a resource on this topic.

Trauma-Informed

Participant's experiences of trauma affected their engagement with these sensitive topics. Some who had experienced sexually related trauma found overtly sex-positive sex education content retraumatizing. Other participants specified finding visual and descriptive content about sexually transmitted infections and detailed real-life stories of sexual violence to be traumatizing. As stated by a young man who said:

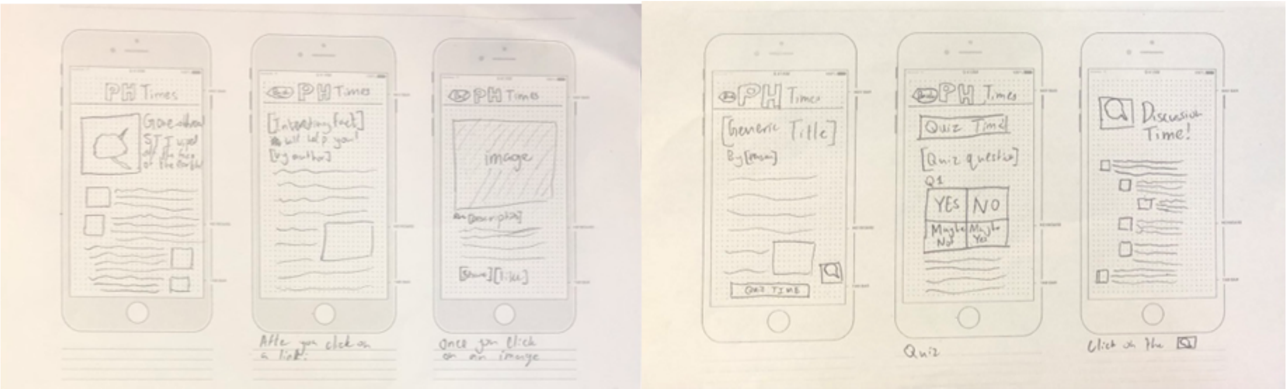
> *You don't want to see like diseased bodies (sic). It's just gross. But at the same time, you want to know about what happens. It's the same with like stories about sexual assault. I'm sorry but they are just hard to read sometimes.*

Although there was an understanding of the need to be aware of behaviors and consequences, young people's personal and online experiences of this educational content sometimes resulted in them withdrawing from engagement altogether. The sentiments demonstrated the fine balance between being direct and positive about sex without traumatizing or downplaying the sometimes negative experiences of sex among our users.

Prototype

On the basis of the results described earlier, a high-fidelity digital prototype was designed by a cross-disciplinary team of researchers and designers. A digital prototype is a way of creating a working example of a product that is tangible enough that it can be tested with a larger population and further developed based on new learnings. The design processes leveraged the solution designs (Figure 4), needs, and wants of co-design participants that were aligned with health promotion and design accessibility best practice [48]. The digital prototype developed, called *The Gist,* is described in the following sections with reference to the rationale for content (relevance and acceptability) and design (usability and accessibility).

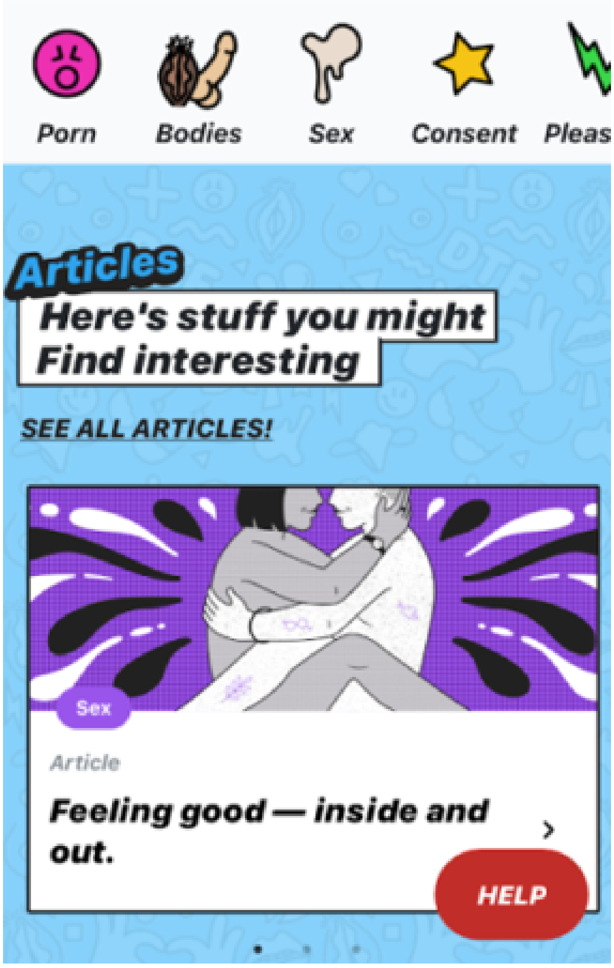
Figure 4. A digital wireframe of a solution concept created by a young co-designer during prototyping.



The Gist

The Gist (Figure 5) is an interactive mobile-first web-based app prototype. The aim of the design is to provide vulnerable young people with an interesting and easy way to take control of their sexual health and well-being in the context of normalized pornography use.

Figure 5. The Gist web-based mobile application prototype home screen.



Here's stuff you might Find interesting

Feeling good — inside and out.

Content

The Gist content provides alternative information that our users want and are not getting from porn, society, or mainstream education; it aims to develop healthy ideas about relationships, sex, and bodies. Drawing on concepts underpinning ethical sex, as described by Carmody and Ovendon [49], the resource aims to provide practical steps that users can follow to develop skills and preferences and help them to consider how their choices impact on themselves and others. For instance, practical information about sex is provided to help them develop an understanding of their own needs and their partners' needs. This content is linked with steps they can take to identify, understand,

and communicate these needs. Critical pornography literacy is built into messages by contrasting this alternative information with problematic messages present in pornography and society. This shifts the focus away from the *problems with porn* toward meeting our users' identified needs, while still enhancing the critical literacy of problematic representations of sex, sexuality, and gender. This includes information about sex positions, finding out what you like, sexual pleasure, sexual arousal, bodies, relationships, consent, and porn. The content balances direct, challenging, and informative articles with opportunities to build and test skills through interactive elements such as quizzes (Figure 6). Content is presented in gender- and sexuality-neutral ways in response to enable young people to explore information in an inclusive environment.

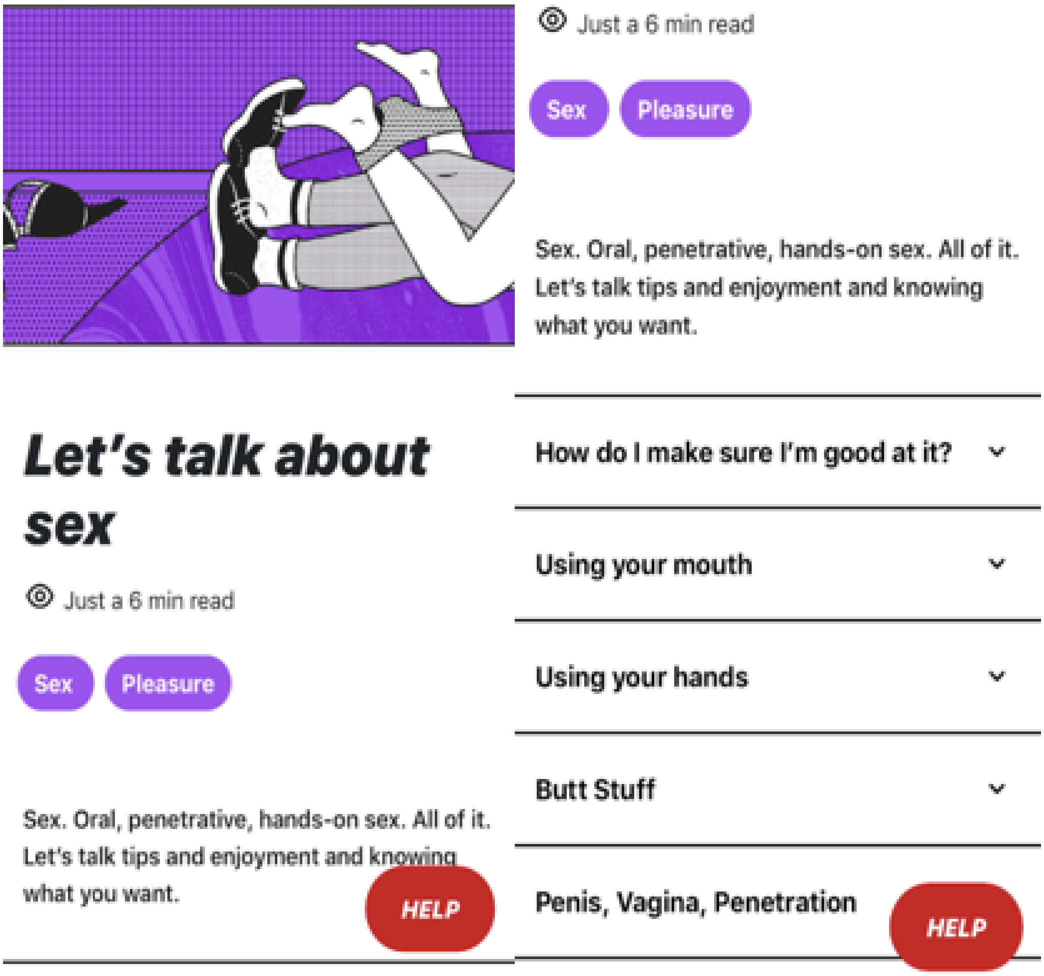
Figure 6. The Gist 'Debunked' activity to challenge pre-held knowledge and attitudes.

User Interface and Experience Design

The Gist brand is designed with a bold typography in keeping with our audiences' desire for alternative and nonmainstream products, and a *retro* 90s design feel. The name, *The Gist*, refers to the process of getting to know the idea or main point of a concept. It was selected for the prototype through testing with co-design participants. The user interface leverages our users' reactive information-seeking habits, and quick content for browsing aims to surprise or contradict our users' ideas and experiences motivating them to seek out more information. Short *gists* or facts are linked through to deeper exploration of the issues to enable in-app learning to progress once a user is engaged. Multiformat content also leverages user experience (UX) and interaction patterns from apps our users frequently engage with such as Spotify, Instagram Stories, and YouTube. This enhances the familiarity and usability of The Gist for our target population. Capitalizing on our users current UX patterns, the app enables continuous scrolling for breadth of engagement and continuous links to further content for depth of engagement [48]. Detailed articles utilize progressive disclosure (informative headlines with expandable information sections; for example, Figure 7). Users are provided with staggered content that can be engaged with if elected. This allows young people to take control of what they see and to elect not be exposed to information that they are uncomfortable with. This is based on insights from the co-design that suggest that lived experience and developmental stage are more important factors than age in relation to information needs, relevance, and acceptability.

The Gist web-based app does not include commenting features or social media integration other than sharing a quiz or an article directly with someone. This reduces the capacity for young people to interact negatively with each other and reflects our co-design research and previous studies suggesting that young people are unlikely to actively share any content relating to sexual health on social media [41]. Although the prototype design can be developed as a standalone, direct-to-consumer digital resource; we recommended that implementation be embedded within a multipronged health promotion approach such as service-delivered workshops. This is in response to the positive reaction that our co-design workshops were met with and the participants explicitly stating that they valued the opportunity to direct conversations with adults on sex and relationships. Scaffolding the digital product with service-delivered face-to-face workshops would also act as an entry point to the digital solution to enhance reach and engagement, making a digital solution more feasible.

Figure 7. The Gist article structure utilizing progressive disclosure to increase user control.



Let's talk about sex

Discussion

Principal Findings

The findings of our co-design workshops identify unmet sexual health and pornography literacy information needs among our users, their information-seeking patterns, and preferences for a digital resource. Through this process, we were able to develop The Gist prototype with young co-designers. The detailed and revealing nature of our findings suggests that using participatory research methods such as co-design can overcome sociocultural and structural barriers to engaging vulnerable young people in research on sensitive health issues. Some notable findings from this cross-disciplinary approach are discussed in the following sections in the context of current literature and directions for future research.

Unmet Information Needs and the Limitations of Current Pornography Literacy Approaches

Most formal pornography literacy programs focus on the critical awareness of pornographic content and the industry [32]. We found that our users understood pornography as obviously unrealistic and could already critique its messages. Consistent with findings from the study by Dawson et al [33], a key message of this study is that effective pornography literacy programs must expand their focus on problematic messages from pornography and go beyond critical media literacy to include alternative information to help young audiences to navigate sexuality and relationships in their lives.

Few resources exist that directly contrast information about sex with messages from pornography and society [50-52]. There are some notable exceptions that include a cross-section of relevant topics [53]. However, the usability and acceptability of the resource among subgroups of young people are unknown. Our findings suggest that there is potential to embed pornography literacy within practical information about ethical sex and relationships to help young people transfer critical literacy into alternate choices and preferences in real life, but that this approach must be evaluated [49]. Any approach must balance sex-positive language and framing with acknowledgment of the negative lived experiences of some young people who require sensitively delivered information acknowledging these experiences. Although we included safeguarding approaches such as progressive disclosure and trauma-informed language, further research would strengthen the approach to pornography literacy programs.

A large body of the literature has identified the information deficit that young people experience as a result of current education approaches that fail to adequately teach about pleasure, sexual discovery, or self-representation [21,54,55]. We found that for vulnerable young people, there were critical unmet information needs in relation to the basics of navigating sex and relationships that compounded fetishized representations in pornography [33]. Thus, having relevant and accessible alternative information may be even more vital for vulnerable young people whose basic needs may not be met by schools, parents, or peers [25]. Importantly, our findings reinforce the need for longitudinal research to understand the specific impacts of pornography on the lives of subgroups of young people, including disengaged LGBTQI+ and CALD groups, if their needs are to be met.

Co-Design and Digital Health Promotion

Research has illustrated limitations to traditional approaches to intervention design, which involve engagement with target users in research to inform content development by subject matter or technical experts rather than by engaging end users throughout the process as equal partners in design [39,56,57]. Where topics are particularly complex or sensitive, asking young people to engage in one-on-one interviews or even focus groups may be ethically sensitive and/or increase social desirability bias. Using creative and generative activities, we observed an extremely high level of engagement among young people, even on difficult topics that sometimes included traumatic experiences. Creating a safe space where participants could use creation to express an experience, rather than having to speak directly about it, enabled them to have their perspectives included and to better understand the underlying issues and design a more inclusive solution. The study provides an example of how co-design methods are responsive to sensitive and complex health issues and are particularly suitable for designing with rather than for young people [40,43]. More work needs to be done evaluating the effectiveness of co-designed interventions compared with evidence-based expert-designed approaches.

Limitations

These findings should be considered within the context of study limitations. Co-design with *extreme* or *hard-to-reach* users generates products that can appeal to broader populations [39,43,58]; however, co-design research needs to be undertaken to test and adapt the prototype for specific audiences. We could not report quotes and attributions in this publication because of ethical concerns that service providers who helped with recruitment may be able to identify participants. Despite these limitations, the study provides important findings relating to pornography literacy and intervention design because of high-quality, in-depth, and reoccurring engagement with this vulnerable population.

Conclusions

The study findings include important recommendations for the conceptualization of online pornography literacy programs and opportunities for cross-disciplinary research to address complex and emerging health issues. If pornography literacy programs focus on pornography without providing young people with alternative information about sex and relationships, they may not be effective in reducing harm. This study highlights the potential for pornography literacy to be embedded within real and practical information about having sex, navigating sexuality, and healthy relationships. The cross-disciplinary approach reported in this study demonstrates that it is possible to collaboratively co-design a pornography literacy resource combining the needs and wants of vulnerable young people with best practice in design and health promotion.

Acknowledgments

The project was funded by the Victorian Health Promotion Foundation, Melbourne, Australia. Prototype content was developed with technical expertise from Jenny Walsh. Illustration and production were delivered in partnership with Cat Wall and Bonnie Eichelberger. AD was supported by the National Health and Medical Research Council postdoctoral scholarship. CW, ML, PD, and MH were supported by the National Health and Medical Research Council fellowships. The project was delivered with collaboration between the Burnet Institute and Sheda and in partnership with Stonnington Youth Services, Hester Hornbrook Academy, and Star Health. The authors gratefully acknowledge the contribution to this work of the Victorian Operational Infrastructure Support Program received by the Burnet Institute.

Abstract

Background: Youth living with HIV (YLHIV) enrolled in HIV treatment experience higher loss to follow-up, suboptimal treatment adherence, and greater HIV-related mortality compared with younger children or adults. Despite poorer health outcomes, few interventions target youth specifically. Expanding access to mobile phone technology, in low- and middle-income countries (LMICs) in particular, has increased interest in using this technology to improve health outcomes. mHealth interventions may present innovative opportunities to improve adherence and retention among YLHIV in LMICs.

Objective: This study aimed to test the effectiveness of a structured support group intervention, Social Media to promote Adherence and Retention in Treatment (SMART) Connections, delivered through a social media platform, on HIV treatment retention among YLHIV aged 15 to 24 years and on secondary outcomes of antiretroviral therapy (ART) adherence, HIV knowledge, and social support.

Methods: We conducted a parallel, unblinded randomized controlled trial. YLHIV enrolled in HIV treatment for less than 12 months were randomized in a 1:1 ratio to receive SMART Connections (intervention) or standard of care alone (control). We collected data at baseline and endline through structured interviews and medical record extraction. We also conducted in-depth interviews with subsets of intervention group participants. The primary outcome was retention in HIV treatment. We conducted a time-to-event analysis examining time retained in treatment from study enrollment to the date the participant was no longer classified as active-on-treatment.

Results: A total of 349 YLHIV enrolled in the study and were randomly allocated to the intervention group (n=177) or control group (n=172). Our primary analysis included data from 324 participants at endline. The probability of being retained in treatment did not differ significantly between the 2 study arms during the study. Retention was high at endline, with 75.7% (112/163) of intervention group participants and 83.4% (126/161) of control group participants active on treatment. HIV-related knowledge was significantly better in the intervention group at endline, but no statistically significant differences were found for ART adherence or social support. Intervention group participants overwhelmingly reported that the intervention was useful, that they enjoyed taking part, and that they would recommend it to other YLHIV.

Conclusions: Our findings of improved HIV knowledge and high acceptability are encouraging, despite a lack of measurable effect on retention. Retention was greater than anticipated in both groups, likely a result of external efforts that began partway through the study. Qualitative data indicate that the SMART Connections intervention may have contributed to retention, adherence, and social support in ways that were not captured quantitatively. Web-based delivery of support group interventions can permit people to access information and other group members privately, when convenient, and without travel. Such digital health interventions may help fill critical gaps in services available for YLHIV.

Trial Registration: ClinicalTrials.gov NCT03516318; https://clinicaltrials.gov/ct2/show/NCT03516318

KEYWORDS

HIV; treatment adherence and compliance; youth; social support; mHealth; medication adherence; mobile phone

Introduction

Globally, young people aged 15 to 24 years account for more than 30% of new HIV infections, over 80% of whom live in sub-Saharan Africa (SSA); AIDS remains the leading cause of death among youth in SSA [1-6]. Despite a lack of age-disaggregated data on antiretroviral therapy (ART) coverage for youth, available data show that youth living with HIV (YLHIV) enrolled in HIV care experience higher loss to follow-up and suboptimal treatment adherence compared with younger children or adults [7-10]. YLHIV face many challenges to effective treatment, including stigma and fear of disclosure to others, lack of social support, lack of services designed to comprehensively meet their unique needs, and limited knowledge about the disease [7-10]. To achieve the Joint United Nations Programme on HIV and AIDS 95-95-95 goals by 2030, understanding and addressing the unique needs of YLHIV will be critical [11].

Although YLHIV experience poorer health outcomes, few interventions to improve these outcomes target youth specifically. Interventions to improve HIV-related outcomes implemented in low- and middle-income countries (LMICs) largely target adults and aim to improve ART adherence; fewer interventions target retention in care [12-14]. Support groups to improve health outcomes among people living with HIV (PLHIV), including YLHIV, are supported by some evidence to improve retention in care [15-22].

Expanding access to mobile phone technology has increased interest in using this technology to improve health outcomes. Digital health interventions such as mobile reminders and interactive voice or SMS responses have shown some effectiveness in improving adherence or retention among PLHIV in LMICs [23-31]. Although research has not examined these interventions specifically among YLHIV in LMICs, preliminary evidence in high-income countries suggests that such interventions are feasible and may impact ART adherence [32-35]. Furthermore, 2 recent studies in South Africa integrated social media into interventions for YLHIV to improve social support and found them to be acceptable and feasible [36,37]. Increasing internet use, feature phone, and smartphone availability in LMICs makes these interventions possible. Developing and testing interventions to improve YLHIV outcomes in SSA is urgently needed, and digital health interventions may present innovative opportunities to improve adherence and retention among youth in LMICs [12-14,38-40].

Nigeria is experiencing a generalized HIV epidemic and has the second largest global burden of the disease, with an estimated 3,438,442 people currently living with HIV [41]. As with other countries in the region, YLHIV in Nigeria experience high loss to follow-up from HIV treatment services, with the greatest losses occurring early in treatment [39,42]. Given increasing access to and use of mobile phone technology in Nigeria, digital health strategies have potential to help meet YLHIV informational and social support needs [43,44].

In response, we developed a structured support group intervention— Social Media to promote Adherence and Retention in Treatment (SMART) Connections—delivered through a social media platform. The intervention's aim is to improve HIV-related knowledge, social support, and ultimately, retention in HIV treatment and ART adherence among YLHIV. We conducted workshops with local stakeholders and youths to inform intervention design, followed by a feasibility and acceptability study with 41 adolescents aged 15 to 19 years in south-central Nigeria (results published elsewhere) [45]. In this study, we set out to test the effectiveness of the SMART Connections intervention on HIV treatment retention among youth aged 15 to 24 years. We also examined the effects of SMART Connections on secondary outcomes of ART adherence, HIV knowledge, and social support.

Methods

Design

We conducted a two-arm, parallel, randomized controlled trial. Participants were individually randomized in a 1:1 ratio to either the SMART Connections intervention (intervention group) or standard of care (control group). This was an open-label study with no blinding of the study staff or participants. We conducted face-to-face structured interviews with participants and extracted data from medical records at enrollment (baseline) and again at the completion of the intervention period (endline), approximately 6-9 months after enrollment. We also conducted in-depth interviews (IDIs) at endline with 2 subsets of intervention group participants: participants with high group participation and those with low group participation (classified by group facilitators). We obtained informed consent from youth aged 18 years and older; for youth aged 15 to 17 years, we obtained parental permission and adolescent assent at enrollment. This study was reviewed and approved by FHI 360's Protection of Human Subjects Committee, the University of Uyo Teaching Hospital's Institutional Health Research Ethical Committee, and the Cross River State Health Research Ethics Committee.

Intervention Description

SMART Connections was informed through workshops conducted with stakeholders and YLHIV in Akwa Ibom State, Nigeria, to gather input for design and content [12,13]. The intervention was designed to promote retention in HIV care by leveraging social support and improving HIV-related knowledge and treatment literacy [46,47]. The content of the structured support groups was adapted from an existing support group guide, Positive Connections, and delivered through secret Facebook groups [48]. The intervention was delivered over approximately 22 weeks (2 weeks per session) to groups of about 15 to 25 youths, with nearly daily activities (Figure 1).

The intervention guide is attached as a Multimedia Appendix 1.

Two community-based organizations were engaged to recruit support group facilitators and assist study staff in training them to deliver the intervention. Selected facilitators had received prior training to facilitate in-person support groups and were living with HIV themselves. Facilitators underwent a 5-day training and received an implementation guide, smartphone and monthly data allowance. Facilitators met monthly with the study staff to debrief on challenges they had encountered and provided support to one another.

Once a sufficient number of participants were recruited and randomized to form a support group, each group began with an in-person meeting, during which participants met one another and the facilitator and agreed-upon ground rules for participation. Facilitators also instructed participants on how to secure their phones (using a password or passcode), turn off Facebook notifications so that messages and posts would not show up on their phones and to log out of Facebook after each use to keep others from accessing their Facebook accounts.

Figure 1. Intervention design overview. YLHIV: youth living with HIV.

How it works

Safe Space: YLHIV ages 15 to 19 form secret Facebook groups.

Supportive Adult Role Model: Groups are led by a trained adult facilitator with lived HIV experience.

Social Activities: Including riddles, puzzles, and discussion about nonhealth topics to promote bonding.

Interactive Polls and Facilitated Discussions test knowledge and reinforce learning.

Word-of-the-Week and Key Message: Images provide definitions of core concepts.

11 Key Topics Covered: Disclosure, exploring feelings, nutrition and health, reproductive rights, positive health dignity and prevention, discrimination and rights, violence, communication and problem solving, and planning for your future.

Standard of Care Services

All study participants continued to receive standard services available to YLHIV in study facilities and communities. Standard health services included routine clinical care for HIV treatment, including viral load tests, active case management by community volunteers with intensive adherence support during the first 4 weeks of ART, and enhanced adherence counseling for patients with unsuppressed viral loads.

All study participants received a smartphone (valued at US $65) and a monthly data bundle (US $3.5 equivalent to 1 gigabyte of data) for the duration of the intervention.

Study Setting, Population, and Eligibility

The study was implemented in 14 health facilities located in Akwa Ibom State and Cross River State. The 2 states lie adjacent to each other in south-central Nigeria and share many sociocultural similarities. The population of interest was YLHIV aged 15 to 24 years who had been on ART for less than 12 months. In addition to age and ART eligibility criteria, participants had to demonstrate basic literacy for web-based chats, which was assessed at enrollment by asking the participant to read 3 short messages from intervention materials. We excluded individuals who were unable to attend the initial intervention group meeting if randomized to the intervention group, who were enrolled in another research study related to HIV retention or ART adherence, or who were severely ill and unable to provide informed consent at the time of recruitment. For IDIs, facilitators identified group members with high and low participation from whom participants were purposively selected to achieve representativeness by group participation, sex, and age.

Study Power

The study was powered to detect at least a 0.125 difference in the cumulative probability of retention at endline (0.45 in the control group and 0.575 in the intervention group), corresponding to a hazard ratio of 0.69, with 80% power and 5% significance level for a two-sided comparison using the log-rank test. This resulted in a total sample size of 500 (250 per study arm). Calculations also assumed exponential times to event and a 10% loss to study follow-up. Our estimate of retention was based on program data for the prior year from the United States Agency for International Development (USAID)–funded bilateral HIV services delivery (Strengthening Integrated Delivery of HIV/AIDS Services; SIDHAS) project, which supported HIV services in the facilities selected for this study.

Changes to the Study Protocol and Implementation

We originally planned to recruit YLHIV aged 15 to 22 years on ART for 6 months or less and expected to achieve our sample size within 3 months. Due to substantially lower than expected numbers of YLHIV enrolling in HIV treatment, we amended the study protocol and expanded the eligibility criteria to include YLHIV aged up to 24 years and on ART for 12 months or less. We also extended enrollment from 3 to 8 months and added 3 facilities (originally 11).

Finally, we intended to collect outcome data from participants after the intervention was completed and at 1 year from enrollment (approximately 6 months later) but were unable to collect a second round of outcome data because of prolonged recruitment—the funding project came to an end before the final round of data collection could take place.

Recruitment and Randomization

Eligible participants were sequentially recruited from patients attending clinic visits at the study facilities. Health care staff informed eligible participants of the study and directed those interested to a data collector who was stationed in the facility. Data collectors met with potential participants in a private setting in the facility, provided additional details on the study, then proceeded to obtain informed consent and enroll participants. Data collectors assigned participants to study arms using randomization envelopes. Randomization groups were concealed in sequentially numbered sealed opaque envelopes. The allocation sequence was generated using permuted blocks and stratified by local government areas (LGA), which are administrative subunits of the state, by a biostatistician otherwise uninvolved in the study using a validated SAS macro (SAS version 9.4) [49]. Recruitment occurred at health facilities, but randomization was managed from a central location for all facilities within an LGA. This was an open-label study with no blinding of the study staff or participants.

Measures

We collected demographic information (sex, age, relationship status, education, occupation, and religion) and information on HIV history, including date of HIV diagnosis, ART start date, disclosure of HIV status to others, and viral load testing. Additionally, we collected data on secondary outcomes of ART adherence, HIV-related knowledge, and social support as well as psychosocial factors associated with poor retention, including social isolation, depression, and perceived and experienced stigma.

Retention: For our primary time-to-event analysis, we computed the time retained in care from study enrollment to the date the participant was no longer classified as active on treatment, consistent with the President’s Emergency Plan for AIDS Relief (PEPFAR) indicator definitions [50]. We recorded dates for all scheduled clinic visits from patient medical records for each participant from study enrollment until the end of the study. If a participant failed to return after a scheduled visit for more than 28 days, the date of the missed visit was the date of loss to care recorded, unless death or transfer of service was documented before the missed visit. For a small number of patients, their first missed scheduled visit was scheduled on or within 28 days before study enrollment. If the participant missed this first scheduled visit by more than 28 days, he or she was assigned a retention time of 0.

We also reported on treatment status at endline. To be considered active on treatment at endline, an individual must have attended a visit or had a follow-up visit scheduled within 28 days of the date of their endline questionnaire. For those who did not complete an endline questionnaire, an approximate endline date was used (based on the median time in the study of those enrolled the same month). Participants who died or transferred facilities were categorized accordingly.

Measurement of secondary outcomes and other psychosocial variables are summarized in Table 1.

Data Collection

Structured questionnaires programmed into password-protected computer tablets were used to collect data from participants at both baseline and endline. We also extracted medical record data (MRE) from patient charts at both time points into a separate form programmed into the tablets. Data from tablets were uploaded daily to a secure computer server. Trained interviewers administered a semistructured IDI guide. IDIs were audio recorded and transcribed verbatim.

Data Analyses

All analyses used an intent-to-treat approach, in which all randomized participants were included in the statistical analysis and analyzed according to the group to which they were originally assigned, regardless of the treatment they received during the study. The primary hypothesis was that *YLHIV enrolled in HIV treatment services who participate in SMART Connections will be more likely to be retained in HIV care than YLHIV enrolled in HIV treatment services who do not participate in the intervention.*

Kaplan-Meier cumulative retention probabilities are reported with 95% CIs and plotted by study arm. Participants who were confirmed to have died or transferred to a facility outside the study facilities were considered censored. Participants who had elected to drop out of the study (n=8), or for whom all MRE were missing because of missing charts (n=14) or all visit data were missing data in charts (n=3), were excluded from the analysis.

The retention probabilities between the groups were compared using a log-rank test stratified by LGA with a two-sided α of .05. We also report on retention descriptively, examining lapses in care, and return to treatment over the course of study follow-up. The relationships between treatment exposure and secondary outcomes (ART adherence, HIV knowledge, and social support) as well as social isolation, depression, and HIV-related stigma were explored with *t* tests for continuous outcomes and chi-square test for categorical outcomes, using two-sided tests, with a significance level of 0.05.

We applied thematic analysis to the IDI data. A structured codebook was developed *a priori* based on the interview guide; emergent thematic codes were added during the analysis. To assess intercoder consistency, 2 analysts independently coded 3 transcripts, compared coding, and resolved differences through discussion. Coding was conducted using NVivo 12 [56]. Once all transcripts were coded, textual coding reports were produced.

Table 1. Secondary outcomes and related psychosocial variables and their measurement.

Concept	Measurement
HIV knowledge and treatment literacy	A set of 14 knowledge-based questions covering HIV transmission, diagnosis, treatment, and treatment monitoring based on topics covered in the SMART[a] Connections curriculum. Each item is scored 1 if answered correctly and 0 if answered incorrectly. A total knowledge score was calculated based on the proportion of items correctly answered.
Social support	Medical Outcomes Study-Social Support Survey, a 19-item scale that covers the dimensions of emotional, information, affectionate, and tangible social support in addition to positive social interaction [51]. Scores for each item were summed, then averaged. Range of possible scores: 0-5, with a higher score indicating a greater level of social support.
Adherence to antiretroviral treatment	Self-report using the AIDS Clinical Trials Group adherence questionnaire [52]. For these analyses, we limited our analysis to a single item that recorded self-reported ART[b] adherence for the 3 days before the interview. Values included 0 for no missed doses, and 1 for 1 or more missed doses.
Social isolation	4-item PROMIS[c] Social Isolation Scale [53]. Participants are asked how often they feel each of 4 different situations occurs in their lives. Responses options include 1=Never, 2=Rarely, 3=Sometimes, 4=Usually, and 5=Always. For this analysis, the total score was a sum of the responses for the 4 items.
Depression	Stanford Patient Education Research Center's PHQ-8[d] [54]. The PHQ-8 asks respondents on how many days over the prior 2 weeks they experienced 8 possible symptoms, with response options of *not at all*=0, *a few days*=1, *more than half the days*=2, and *most all of the days*=3. The score for each item is summed, and a total score that ranges from 0 to 24 is assigned. Respondents with scores <10 are classified as not depressed. Respondents who score 10-19 points are considered to have major depression, and those who score 20 or more have severe depression [54]. For these analyses, a categorical variable was created: 1=no depression, 2=major depression, and 3=severe depression.
HIV-related stigma	12-item scale adapted by Reinius and colleagues from the 40-item HIV stigma scale [55]. This shortened stigma scale covers 4 dimensions of stigma: personalized stigma, disclosure concerns, concerns about public attitudes, and negative self-image. Each item is scored on a 4-point Likert-type scale, and the scores added within dimensions with possible scores ranging from 3 to 12 [55]. A higher score indicates a greater level of perceived HIV-related stigma.

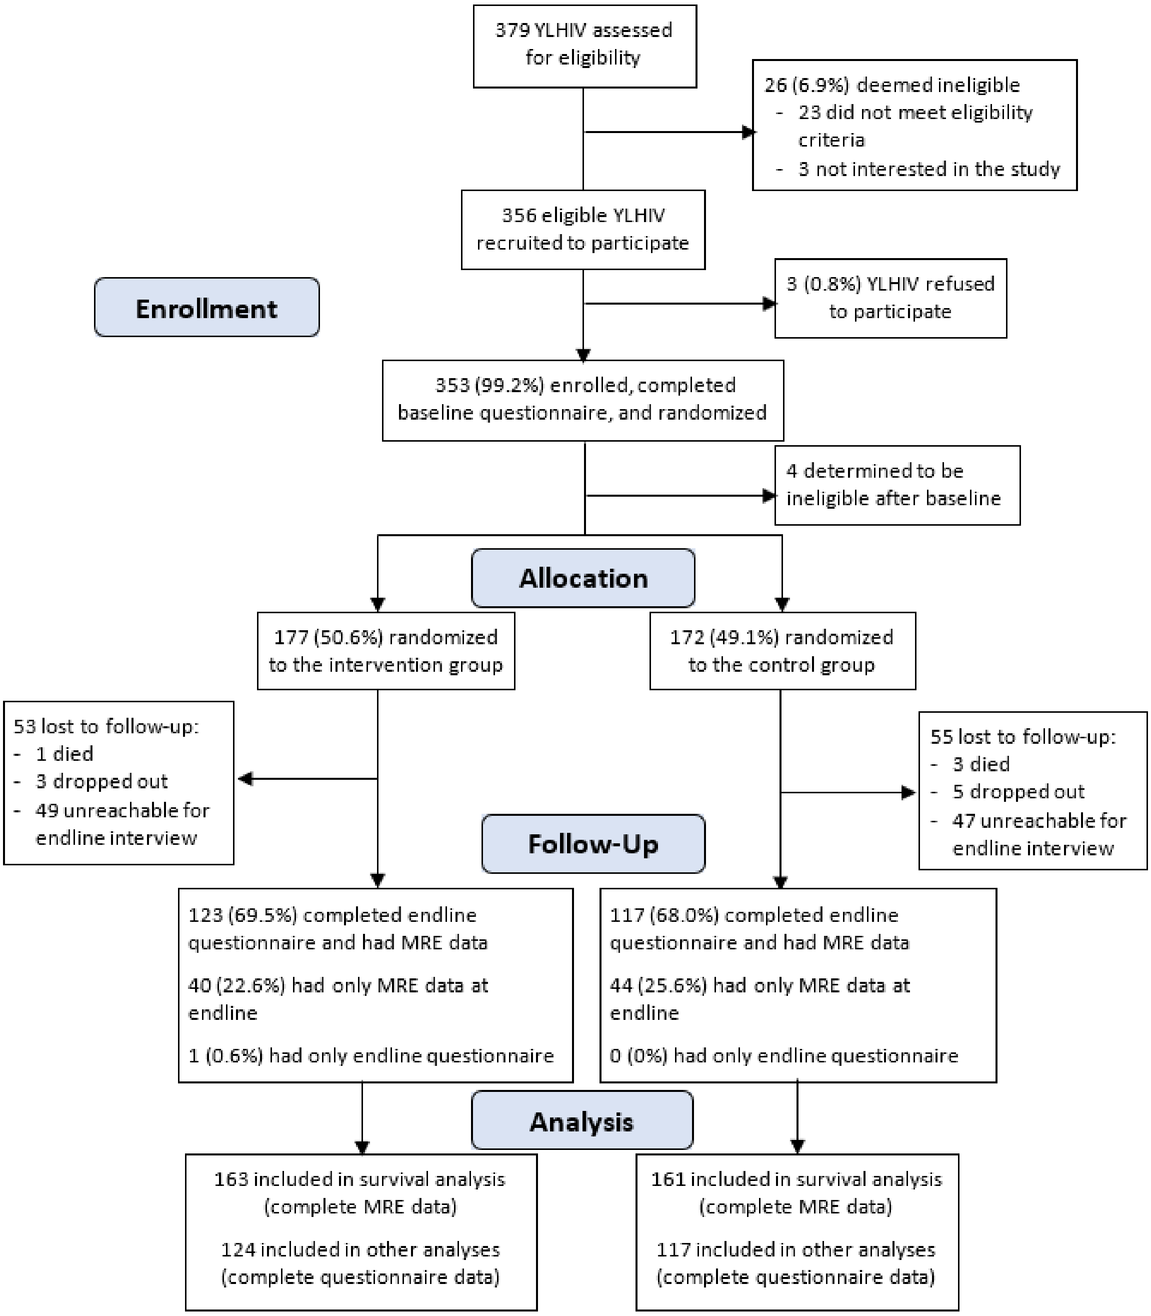
Results

Overview

We recruited 356 youths between September 2018 and April 2019, 353 (99.2%) of whom enrolled in the study (Figure 2). A total of 4 participants were removed after enrollment, as they provided false eligibility information, and were deemed ineligible. Participants were then randomly allocated to the intervention group (n=177) or control group (n=172). At endline (June to November 2019), 108 participants were lost to follow-up from the study, including 4 who died, 8 who discontinued study participation, and 96 who were not reachable for an endline interview. Endline interviews and MRE data were completed for 241 participants. MRE data were collected for an additional 84 participants who were not reachable for an endline interview but who had not elected to END study participation. We conducted IDIs with 21 intervention participants following the endline survey, of whom 16 were female and ranged in age from 17 to 24 years; 13 were classified as high participation and 8 as low participation.

A total of 10 randomization errors occurred during the study: 6 participants randomized to the control group were erroneously recorded by data collectors to be the intervention group and took part in the intervention; 4 participants randomized to the intervention group were erroneously recorded as in the control group and did not participate in the intervention. Two other participants, randomized to and recorded as in the control group, were erroneously contacted to participate in the intervention. In addition, 14 people randomized to the intervention group chose not to participate in the intervention. Thus, a total of 167 participants joined an online support group during the study: 160 randomized to the intervention group, 5 due to randomization errors, and 2 control group participants erroneously contacted.

Figure 2. Study flowchart. MRE: medical record data; YLHIV: youth living with HIV.



To assess the potential effects of loss to follow-up, we examined differences between those who did and did not complete an endline interview. There were no statistically significant differences in any background characteristic or baseline values of secondary outcomes between those who completed endline interviews and those lost to study follow-up (results not shown).

Background

Both study arms were similar in all baseline demographic characteristics (Table 2). Most participants were female 87.7% (306/349) and had completed some secondary school or more; the mean age was 21 years (SD 2.3). More than half of the respondents reported being married or in a relationship. Among those in a relationship (including married), fewer than half reported that their partner knew their HIV status, and about half knew their partner's HIV status. Most participants reported having access to a mobile phone in their household (303/349, 86.8%), with 67.1% (234/349) reporting that they owned their own mobile phone.

Table 2. Background characteristics of study participants at baseline (N=349).

Characteristic	Intervention (n=177)	Control (n=172)
Sex, n (%)		
Female	151 (85.3)	155 (90.1)
Male	26 (14.7)	17 (9.9)
Age (years), mean (SD)	21.3 (2.3)	21.0 (2.3)
Relationship status, n (%)[a]		
Married	37 (20.9)	40 (23.3)
Unmarried or in a relationship	83 (46.9)	85 (50.3)
Single	57 (32.2)	44 (26.0)
Among those married or in a relationship, n (%)		
Partner knows participant's HIV status[b]	42 (35.3)[c]	57 (45.6)[d]
Partner has HIV[e]	20 (16.7)[c]	26 (30.0)[d]
Partner does not have HIV	39 (32.5)[c]	40 (32.3)[d]
Does not know partner's HIV status	61 (50.8)[c]	58 (46.8)[d]
Education level, n (%)[e]

Retention in HIV Care

The probability of being retained in HIV care, defined as not having missed a scheduled appointment by more than 28 days, was similar between the intervention and control groups (Figure 3).

The probability of remaining in care without more than a 28-day gap was slightly higher in the intervention group than in the control group at each time point, except at 120 days; however, 95% CIs overlapped between the 2 study arms at all time points (Table 3).

Figure 3. Cumulative probability of retention in care (n=324).

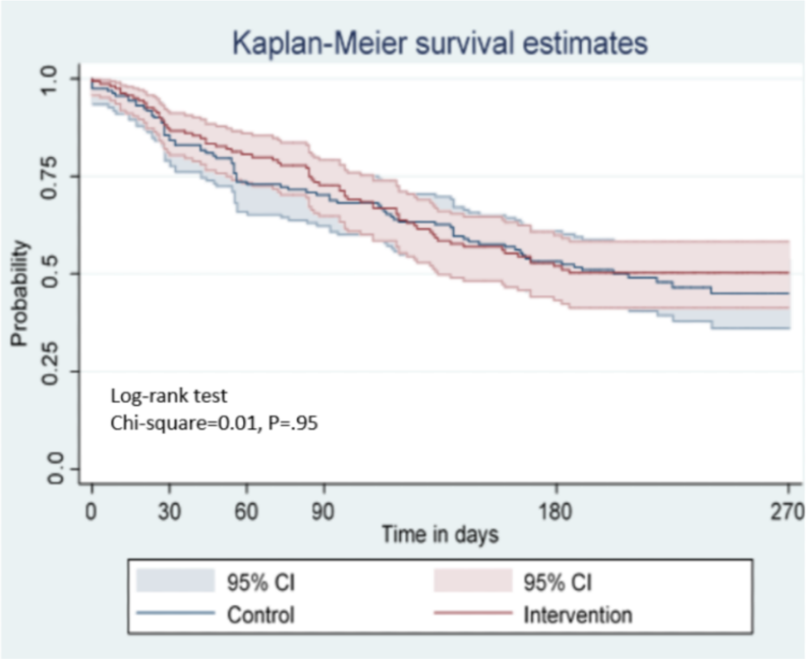

Table 3. Probabilities of remaining in care, without a gap of more than 28 days at 30, 60, 90, 180, and 270 days (n=324; 163 intervention and 161 control).

Time	Total at risk	Failures	Probability of being retained in care	SE	95% CI	
					Lower limit	Upper limit
Intervention						
0	163	1	0.99	0.01	0.96	1.00
30	129	21	0.87	0.03	0.80	0.91
60	116	9	0.81	0.03	0.73	0.86
90	102	11	0.73	0.04	0.65	0.79
180	59	27	0.52	0.04	0.43	0.60
270	8	2	0.50	0.04	0.41	0.58
Control

90	103	4	0.70	0.04	0.62	0.77
180	72	24	0.53	0.04	0.45	0.61
270	12	8	0.45	0.04	0.36	0.54

Retention, measured as not having missed any scheduled visit by more than 28 days, did not reflect the participant's treatment status at endline (Table 4). Almost half of all participants missed at least one scheduled visit by more than 28 days during the 6 to 9 months of follow-up and were classified as lost to care at some point; however, most participants were active on treatment at endline. A total of 40.0% (65/163) in the treatment arm and 46.0% (74/161) in the control arm were counted as having been lost-to-care in the time-to-event analysis but were active on treatment at the end of the study.

Table 4. Clinic visits and retention over the study period for participants included in the retention analysis, intention to treat (n=324: 163 intervention and 161 control).

Characteristics	Intervention (n=163)	Control (n=161)
Number of clinic visits during study, mean (range, SD)	3.4 (0-10, 1.9)	3.9 (0-10, 1.9)
Missed at least one visit by >28 days, n (%)	70 (42.9)	78 (48.5)
Time between scheduled visits (months), n (%)[a]		
1	111 (72.1)	118 (75.6)
2	33 (21.4)	30 (19.2)
3	7 (4.5)	5 (3.2)
4	1 (0.6)	2 (1.3)
>5	2 (1.3)	1 (0.6)
Treatment status at endline, n (%)[b]		
Active on treatment	112 (75.7)	126 (83.4)
Lost to care	22 (14.9)	15 (9.9)
Transferred out	13 (8.8)	7 (4.6)
Deceased	1 (0.7)	3 (2.0)
Of those active on treatment at endline, n (%) who missed at least one scheduled visit by >28 days	45 (40.2)	58 (46.0)

[a] 9 missing from intervention group, and 5 missing from control group.

[b] 15 missing from intervention group, and 10 missing from control group.

The average number of clinic visits during the study varied by participant, in part because of variation in the length of time between scheduled visits. The average time between schedule visits was 1 month for most, but one-quarter of participants had an average time between visits ranging from 2 to more than five months.

Barriers to clinic attendance, as described in IDIs, included traveling away from home, anticipating stigma at the clinic, and competing obligations. When asked how easy it was to attend scheduled appointments, one participant described it as follows:

> *When you go to the hospital and they saw you…they will tell people about you, this is the kind of sickness that this person has, so that makes me very difficult to go.* [24-year-old female, high participation]

A few participants described hesitation leaving school, work, or family to attend appointments if it required disclosing their HIV status. Findings were similar in endline questionnaire open-ended data; among 79 participants who reported missing an appointment by one week or more, reasons for doing so included traveling (33/79, 42%), transportation issues (20/79, 25%), or were busy (13/79, 16.5%).

Most IDI participants described that the intervention impacted their attitudes and behaviors toward attending scheduled appointments. Some described that the intervention reinforced the importance of attending appointments to prevent gaps in medication and taught them to "take your drugs so that you'll feel okay " (21-year-old female, high participation). Others described learning strategies to avoid missing appointments, such as asking someone to collect refills if they could not. A few reported that the intervention served as a reminder to attend scheduled appointments; one participant mentioned receiving reminders from group members on their appointment day. Another described that being part of the group:

> *Something was there telling me to always don't miss appointment, to take my drugs, it was important, so I think the group was a reminder.* [19-year-old female, low participation]

In contrast, a few participants, most categorized as low group participation, felt that the intervention did not affect their retention in care.

Secondary Outcomes

HIV-related knowledge was high in both groups at endline but significantly higher in the intervention group compared with the control group (Table 5). No other statistically significant differences between study arms were observed for ART adherence, social support, social isolation, HIV-related stigma, or depression.

Table 5. Bivariate relationships between treatment group and endline HIV knowledge, psychosocial variables (*t* test), and self-reported adherence (chi-square test) among participants who responded to the endline questionnaire (n=241).

Outcomes	*t* value (*df*)	Chi-sqaure (*df*=1)	*P* value
HIV knowledge score	-2.96 (239)	N/A[a]	.003
Social isolation score	-0.79 (239)	N/A	.43
Social support score			
Total score[b]	-0.95 (238)	N/A	.34
Tangible subscore	-0.38 (239)	N/A	.70
Emotional/informational subscore[b]	-0.67 (238)	N/A	.51
Affectionate subscore[b]	-0.64 (238)	N/A	.53
Positive social interaction subscore	-1.57 (239)	N/A	.12
Stigma score			
Total score[c]	0.34 (196)	N/A	.73
Personalized stigma subscore[d]	-0.51 (209)	N/A	.61
Disclosure concerns subscore[e]	0.77 (235)	N/A	.44
Concerns about public attitudes subscore[f]	-0.54 (213)	N/A	.59
Negative self-image subscore[g]	0.02 (229)	N/A	.98
Depression[h]	N/A	0.15	.70
Adherence[b]	N/A	0.32	.57

[a] N/A: not applicable.

[b] 1 missing from the intervention group.

[c] 23 missing from the intervention group, 20 missing from the control group.

[d] 17 missing from the intervention group, 13 missing from the control group.

[e] 4 missing from the control group.

[f] 13 missing from the intervention group, 13 missing from the control group.

[g] 4 missing from the intervention group, 6 missing from the control group.

[h] 1 missing from the intervention group, 1 missing from the control group.

Although the 2 study arms did not differ significantly on social support, nearly all IDI participants, including those with low intervention participation, stated they received social support from facilitators and other group members. These participants described receiving encouragement and advice, having people to “share my feelings with” or “someone to talk to,” and receiving answers to factual and personal questions. One participant described the following:

> *I felt like I was not alone in the journey and it was really cool...it was amazing. I don't know how to say it in words but it's something to build (us up) because sometimes we can't just do it by ourselves. We need to find people in the situations with us for us get stronger, so the group actually made me stronger.* [19-year-old female, low participation]

Some support was related to self-management, such as encouragement to adhere to ART. For example, one participant described group members as:

> *…people that would encourage you no matter anything, they tell you no matter anything, that they’re okay with the drugs,… [they] encourage you to take the ART.* [22-year-old male, low participation]

Participants frequently received multiple types of support and often supported other group members by sharing their own experiences or providing emotional support and advice.

Nearly all IDI participants stated they felt a sense of connectedness with the group, sometimes described feeling as if they were “a family” or that participants got along “as brother and sister.” This feeling was often attributed to having group members of the same age range and HIV status and conferred a sense of safety and confidentiality within the group. In endline questionnaires, when asked what they liked most about the intervention, the most common responses included receiving encouragement and support, the ability to share their problems, and feeling a sense of unity or belonging.

When asked about sources of social support outside of the intervention group, most said they did not receive social support outside of the group, sometimes elaborating that they preferred not to disclose their HIV status to family and friends due to fear of stigma:

> *I don't like disclosing… I don’t know if that person is a victim of HIV…the person may start broadcasting me. Things like that so that’s why I don’t tell her, I didn’t tell people… They will not be able to encourage me since they don’t know what I’m passing through … I keep it [my status] to myself.* [19-year-old male, high participation]

Only a couple of IDI participants stated that they received support from family members; a few mentioned a health care provider.

Participant Perspectives on the Intervention

Nearly all who took part in the intervention (as treated) and completed an endline interview agreed that the intervention was useful to them, they enjoyed the intervention and felt comfortable interacting with the facilitators and other group members, and they would recommend the intervention to other YLHIV (Table 6). Nearly all also reported that connecting to the groups on Facebook was somewhat or very easy.

Table 6. Intervention participant perspectives on the web-based intervention at endline (n=127).

Characteristic	Intervention (n=127)[a]
Agree with the following statements, n (%)	
I enjoyed being a member of the online support group[b]	122 (97.6)
I received information during the support group that was useful to me[b]	124 (99.2)
Participating in the support group helped me better understand HIV infection[b]	124 (99.2)
I felt comfortable interacting with other group members[b]	116 (92.8)
I felt comfortable interacting with the group facilitator[c]	118 (95.2)
I made new friends in the group[b]	94 (75.2)
I would like to continue to be part of this group[b]	121 (96.8)
I think Facebook groups are a good way for young people on ART to interact with each other[b]	124 (99.2)
I think Facebook groups are a good way for support group leaders to get information to people on ART[d]	119 (99.2)
I would recommend this Facebook group to other young people living with HIV[b]	121 (96.8)
Ease of connecting to Facebook group, n (%)	
Very easy	80 (63.0)
Somewhat easy	32 (25.2)
Somewhat difficult	13 (10.2)
Very difficult	2 (1.6)

[a] This number includes the 6 participants assigned to the control group who took part in the intervention (as treated).

[b] 2 missing.

[c] 3 missing.

[d] 7 missing.

IDI participants often conveyed appreciation for learning about practical aspects of managing HIV, such as taking ART at consistent times during the day and eating “a balanced diet” to support overall health. Many participants also enjoyed learning why medication adherence is important. Participants recalled learning that ART adherence would help them feel healthier and achieve a longer life. One participant described as follows:

> *by taking the drugs and eating your food every day, your body will be okay … but if you avoid taking that drugs and you are not doing anything, you don’t go for test, you might die at any point in time and nobody will know the purpose of your death.* [22-year-old female, high participation]

Many IDI participants also expressed enthusiasm for the social and interactive elements of the intervention, such as riddles posed by the facilitator. Most felt the Facebook platform was acceptable, reporting that the “secret” groups ensured their privacy, and the web-based format allowed them to interact with the group at their convenience. One participant described as follows:

> *you’ll use it [the group] at the comfort of your home, not pressing you to go out, do this, every time to hear about the new information that you need to learn. Peacefully, you’ll just learn inside your room, inside your, the comfort of your own home. So, I was very happy about that one.* [17-year-old male, high participation]

Discussion

The SMART Connections intervention was designed to improve treatment retention among YLHIV by improving HIV-related knowledge and social support. Our findings indicate that the intervention did not significantly improve retention or social support; however, HIV-related knowledge did improve significantly. Data from IDIs provided evidence of perceived improvements in social support. Intervention participants also overwhelmingly found the intervention acceptable, liked the web-based platform, and reported it had helped them in their HIV treatment.

Our study adds to a small yet growing number of studies targeting YLHIV in LMICs. A 2019 literature review identified only 10 studies between 2016 and 2018 focused on adolescents (10-19 years) and/or YLHIV (15-24 years) in LMICs [36]. Among the 10 studies, 5 tested variations of youth-friendly services, 3 examined different community-based services to ALHIV/YLHIV, and 1 examined an SMS reminder system. Similar to our results, half of the studies reviewed—3 studies on youth-friendly services, 1 on community-based adherence clubs, and 1 on SMS reminders—showed no effects on retention [14]. Five studies found significant associations between youth-focused interventions and retention in HIV services; however, all were retrospective cohort studies, with limitations inherent to observational studies [14].

To date, most research on digital health interventions among PLHIV remains focused on high-income country settings, with a few exceptions [57-61]. A 2016 South African study examined the feasibility and acceptability of a web-based social media platform, MXit, to support YLHIV aged 12 to 25 years. Similar to our research, investigators found that the majority of youths in the study (84%) felt that offering a service outside of in-person meetings was useful [37]. A second South African study recently examined using mobile phones to provide peer mentorship for youths newly diagnosed with HIV [62]. This small case-control study also found no differences in 6- and 12-month retention or viral suppression between the groups [62]. Looking forward, interest in the use of digital health interventions to help meet the needs of YLHIV is growing. We identified published protocols of current studies examining interventions targeting youths; however, all 3 are being conducted in the United States [63-65].

SMART Connections was originally designed for adolescents aged 15 to 19 years living with HIV. The practical reality of ART initiation in our study settings, despite being among the highest HIV prevalence in Nigeria, led us to expand the age range for this study [66]. Most study participants were aged >19 years and although much of the content is relevant to the people of all ages, we believe future research should explore if some of the intervention content should be tailored to the differing developmental needs of those aged 15 to 19 years and those aged 20 to 24 years. We also noted that most (88%) of study participants were female. Although HIV prevalence among females in this age group is, on average, twice that of males in the age group, other research has demonstrated that the high ratio of females to males is not unusual in this setting [2]. A 2014 study examining the characteristics of YLHIV initiating ART in Nigeria found that from 2004 to 2013, 92% of new ART patients aged 15 to 24 years were female [42]. Given the high ratio of females to males, it may be worth exploring if and how the intervention could be better tailored to meet the gender-specific needs of young women.

Retention can be difficult to define and measure. Medical records, the source for our primary outcome, posed a particular problem as records contained errors, conflicting information, and missing data. In addition, most participants in care at endline had missed at least one appointment by more than 28 days, suggesting that, although missed visits and ART refills are problematic for effective treatment, they are a reality for many YLHIV, and missing visits does not necessarily translate to categorical loss to follow-up.

Measuring ART adherence is similarly difficult; self-reported gaps in adherence are underreported [67]. We originally considered using viral load as a marker for adherence; however, viral load test results were not widely available for participants, either because testing was not happening or results were not being recorded reliably. The study lacked sufficient resources to pay for testing for all participants. Future research should include viral load as a primary outcome for interventions designed to improve health outcomes among PLHIV.

Although we did not find a statistically significant intervention effect on social support, results from qualitative data indicate that participants developed friendships with, received support from, and grew close to other group participants despite interacting almost entirely on the web. One possible reason for the lack of an intervention effect on social support may have been that the measure we used was not HIV-specific; we may not have captured the type of social support participants felt they received through the intervention. Given challenges related to stigma and disclosure, further research is needed to operationalize and measure social support associated with HIV.

Limitations

Despite many strengths, including the use of rigorous experimental study design, the study had a number of limitations. Several factors limited the study implementation and perhaps the interpretation of results. First, the results may not be generalizable to other youths outside our study areas. In addition, recruitment lagged, taking more than twice as long as planned because YLHIV enrollment in ART was substantially lower than estimated using HIV service data before the study. Despite protocol modifications, we were only able to enroll 69.8% (349/500) of the planned participants, reducing the study’s power. Slow enrollment also prolonged the time necessary to enroll enough intervention participants to form a support group in many cases. Thus, participants contributed different amounts of time to the study, and some intervention group participants waited months before their support group could begin. This may have added to their risk of loss to follow up before initiating the intervention.

The context of HIV service delivery also changed during the study implementation. A dedicated *surge* in PEPFAR-supported HIV services aimed to increase the number of PLHIV enrolled on treatment and retained in care began in the study sites partway through the study [68]. This surge entailed intensive efforts to better support HIV treatment services and PLHIV in their care and treatment. Strategies including community-based

ART initiation, multimonth ART dispensing for stable patients, and community-delivered ART refills were implemented to increase ART initiation and to improve treatment adherence and retention [68]. These changes meant that the average time between clinic visits and the number of visits participants had during the study varied. Although participants in both study arms were exposed to this changing context, retention increased dramatically during the surge; retention at endline was considerably higher in both study arms compared with retention rates indicated by the presurge programmatic data used to calculate effect size estimates. These external efforts may have masked any possible impact that the intervention had on retention.

Conclusions

Our findings of improved HIV knowledge and high acceptability are encouraging despite a lack of measurable effect on retention. No single psychosocial intervention is likely to meet the varying needs of YLHIV, but the SMART Connections intervention appears to contribute to some of those needs. Digital health support groups may fill critical gaps in the services available for YLHIV. Given the increasing use of social media by youth, the platform may be a preferred resource for some aspects of HIV-related support. Web-based delivery of support group interventions through platforms such as Facebook can permit people to access information and other group members privately, when convenient, and without travel.

Moving forward, we suggest a few adaptations to the SMART Connections intervention and to continue to examine its potential effects. Expanding groups to include YLHIV on ART for more than 1 year may provide better support to those newly initiating treatment and help meet their own informational and support needs. Findings from the IDIs suggest that the intervention had a perceived effect on social support. We believe that the tool we used to measure social support may not have adequately distinguished between more general social support and social support related to HIV. Further work to develop and test measures of social support that better reflect the support given/provided in the context of HIV should be pursued. Finally, focusing on more reliable outcome measures, such as viral load, is strongly recommended for interventions attempting to improve HIV-related health outcomes.

Acknowledgments

The authors would like to acknowledge the contributions of several individuals to the successful implementation of the study. The USAID–funded SIDHAS project was essential for the successful implementation of the intervention under study. Drs Hadiza Khamofu and Tosin Idaboh of FHI 360 ensured the coordination of intervention implementation with the SIDHAS project. Dr Oluwasanmi Adedokun from FHI 360 provided key information and direct support for selecting study sites and informing sampling through the use of the SIDHAS program data. The authors would also like to thank Nnamdi Ike from FHI 360, who played a pivotal role in coordinating the logistics for study-related training and liaising between the health facilities, the study team, and the local partners. Mr Ike also was key to coordinating efforts with the community-based organizations and monitoring the implementation of the intervention under study.

The authors would like to acknowledge the Center for Population and Reproductive Health study team and their efforts to successfully carry out data collection and enroll study participants in the intervention. The authors especially would also like to thank Ms Hannah Silverstein from the University of North Carolina for her creative efforts in illustrating the intervention and contributions to content development. Finally, the authors would like to thank the facilitators and youths who took part in the study, without whom this research would not have been possible.

This study was funded by the USAID through the US PEPFAR, under task order contract number AID-OAA-TO-15-00003 and YouthPower Action, under Indefinite Delivery, Indefinite Quantity contract number AID-OAA-I-15-00009, YouthPower: Implementation. The contents of this publication are the sole responsibility of FHI 360 and do not necessarily reflect the views of the USAID or the US Government.

Abstract

Background: Musculoskeletal conditions are the second greatest contributor to disability worldwide and have significant individual, societal, and economic implications. Due to the growing burden of musculoskeletal disability, an integrated and strategic response is urgently required. Digital health interventions provide high-reach, low-cost, readily accessible, and scalable interventions for large patient populations that address time and resource constraints.

Objective: This review aimed to investigate if digital health interventions are effective in reducing pain and functional disability in patients with musculoskeletal conditions.

Methods: A systematic review was undertaken to address the research objective. The review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. The review protocol was registered with the International Prospective Register of Systematic Reviews before commencement of the study. The following databases were searched: Medical Literature Analysis and Retrieval System Online (MEDLINE), Excerpta Medica database (EMBASE), Cumulative Index to Nursing and Allied Health Literature, and Scopus from January 1, 2000, to November 15, 2019, using search terms and database specific−medical subject headings terms in various combinations appropriate to the research objective.

Results: A total of 19 English language studies were eligible for inclusion. Of the 19 studies that assessed musculoskeletal pain, 9 reported statistically significant reductions following digital intervention. In all, 16 studies investigated functional disability; 10 studies showed a statistically significant improvement. Significant improvements were also found in a range of additional outcomes. Due to the heterogeneity of the results, a meta-analysis was not feasible.

Conclusions: This review has demonstrated that digital health interventions have some clinical benefits in the management of musculoskeletal conditions for pain and functional disability. Digital health interventions have the potential to contribute positively toward reducing the multifaceted burden of musculoskeletal conditions to the individual, economy, and society.

Introduction

Background

Musculoskeletal conditions are the second greatest contributor to disability worldwide and have substantial individual, societal, and economic implications [1,2]. The term musculoskeletal conditions is a broad term used to describe a large number of conditions that affect bones, joints, and soft tissues [3]. Musculoskeletal conditions comprise over 100 different disorders, diseases, and syndromes, most of which affect people's ability to carry out normal activities and impact their quality of life. The most prevalent of these conditions are low back pain (LBP) and osteoarthritis (OA) [3]. Musculoskeletal conditions account for 30% of general practitioner consultations in England and are associated with related comorbidities, including diabetes, depression, and obesity [4]. For the individual, the most common symptoms include pain, aching, stiffness, fatigue, reduced physical functioning, and loss of dexterity [3]. Treating musculoskeletal conditions is estimated to cost the United States US $213 billion [5] and costs the UK economy £10.2 billion (US $12.62 billion) in direct costs to the National Health Service [3].

Due to the prevalence and growing burden of musculoskeletal disability, an integrated, strategic approach that provides effective and accessible models of health service delivery on a population level is urgently required [2,6]. The use of mobile and wireless digital health interventions is one possible solution to deliver this objective [7]. Digital health interventions provide opportunities to tackle health system challenges and offer the potential to enhance the quality and sustainability of musculoskeletal health services [8]. The World Health Organization has recently published guidelines that classify digital health interventions in an attempt to standardize the vocabulary used within the diverse communities working in digital health [8]. In cognizance of this, digital health interventions in this study applies to interventions for clients, with all digital health interventions being delivered as apps, via websites or via web-based software [8].

Digital health interventions can provide high-reach, low-cost, readily accessible, and scalable patient education and self-management interventions that address time and resource constraints for musculoskeletal populations, delivered via apps or web-based platforms [6]. However, there are problems facing the implementation of digital health interventions [9]. A common problem is the failure of agreement on what constitutes appropriate evaluation before widespread rollout [9,10]. In addition, there is tension between the dynamic development of digital interventions and the slow transition into clinical practice from more conventional clinical trial outcomes [9-11]. If digital interventions are to be utilized as therapeutic interventions for musculoskeletal conditions, clinicians and service users need to have confidence in their effectiveness [10,11]. Ultimately, the development and utilization of digital health interventions in a therapeutic capacity for musculoskeletal conditions need to work toward reducing the burden of musculoskeletal-related disability.

Objective

The primary aim of this systematic review was to assess if digital health interventions are clinically effective in reducing pain and functional disability in patients with musculoskeletal conditions. The secondary aim was to explore the content, characteristics, and delivery of digital health interventions in the studies identified to ascertain if there were specific aspects of the interventions, or the population they were targeting, that were associated with beneficial outcomes. To the best of our knowledge, no systematic review has examined the effectiveness of digital health interventions in the management of musculoskeletal conditions.

Methods

Overview

A systematic review was undertaken to address the aims of the study. The authors (SH and RS) were assisted in the literature search by an experienced librarian, proficient in searching medical databases. The review was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines [12]. The review protocol was registered with the International Prospective Register of Systematic Reviews (PROSPERO reference: CRD42018093343) before commencement of the study. However, deviations from the protocol were required following the pilot study. This was related to the inclusion of the PsycINFO database, which yielded no useful results and, as such, was not included in the main search.

Search Strategy

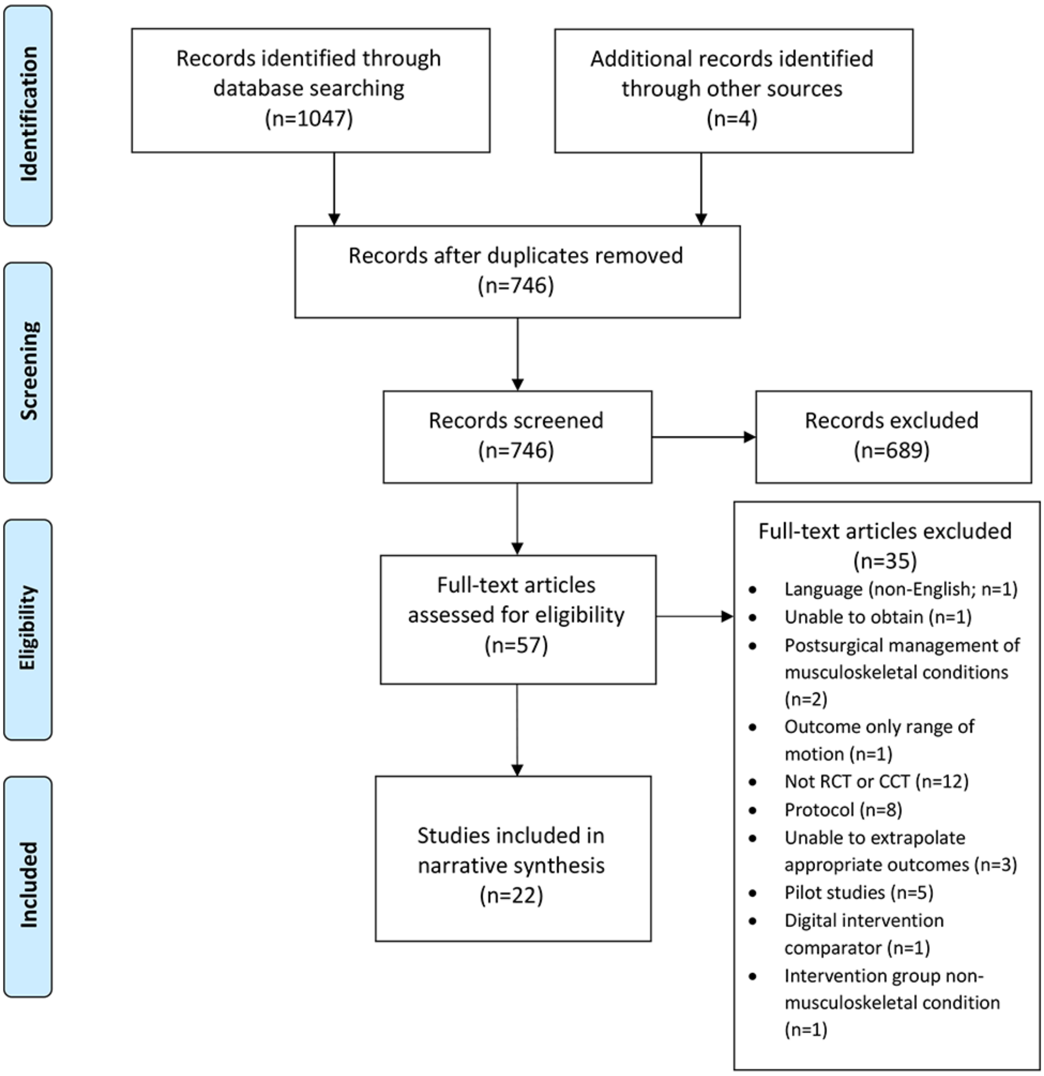
A systematic search of the following databases was conducted: MEDLINE, EMBASE, Cumulative Index to Nursing and Allied Health Literature, and Scopus from January 1, 2000 to November 15, 2019. The search was conducted on November 15, 2019. Abstract and subject-heading search terms pertinent to the study aims were developed and finalized jointly by the 3 authors (SH, RS, and GY) following background literature searches and a pilot study. Search terms and database specific−medical subject heading terms were used in various combinations (Multimedia Appendix 1). Boolean operators "OR" and "AND" were used to combine search terms.

Eligibility criteria were guided by the population, intervention, comparator, outcome, and study design framework [13] (Textbox 1). Titles and abstracts were reviewed for eligibility by 2 reviewers (SH and RS). Full-text papers were obtained and independently screened against the eligibility criteria by the same reviewers (SH and RS), and any disagreements were resolved through discussion. A third reviewer (GY) was available to resolve disagreements; however, this was not required. Manual searching of the reference lists was undertaken to identify any additional studies. The PRISMA flowchart details the search strategy for this review (Figure 1).

Textbox 1. Eligibility criteria.

- Inclusion criteria
    - Population
        - Adults (older than 18 years) with musculoskeletal conditions (acute, subacute, and chronic)
        - Setting: Anywhere patient has access to the internet
    - Intervention
        - Any form of digital-based intervention/treatment delivered by any digital means (eg, website or app) over any time frame.
        - Digital health intervention: For the purpose of this review, *digital health interventions* refers to *interventions for clients*, including targeted client communication; personal health tracking; and on-demand information services delivered by apps, web-based software, or websites. It includes any intervention accessed through a computer (work or home), or smartphone, or other hand-held device, and it includes desktop computer programs or apps that provide self-management information and can be used online or offline. The intervention must function without the need for directive input from a health professional. They must also be *interactive*, which we define as requiring contributions from program users (eg, entering personal data and making choices), which alter pathways within programs to produce tailored material and feedback that is personally relevant to users.
    - Comparator
        - The stated intervention(s) compared with waiting list control (no intervention) or alternative (*standard*) means of delivery (eg, face-to-face, class-based, and printed materials/hand-outs), nondigital self-management interventions (eg, leaflets), and noninteractive digital (eg, web page of flat copy).
    - Outcomes
        - Any positive or adverse health-based outcome and/or predictive indicators assessing pain and/or physical functioning/disability.
    - Secondary outcomes
        - Any positive or adverse health-based outcome and/or predictive indicators assessing patient knowledge and understanding, self-efficacy, catastrophizing, and empowerment. In addition, assess for any correlation between specific aspects of digital interventions and specific outcomes.
    - Study design
        - Randomized controlled trials in English.
- Exclusion criteria
    - Population
        - Nonmusculoskeletal pathology; postsurgical management, for example, following anterior cruciate ligament repair; and post knee replacement
        - Papers pertaining to (chronic) pain, where it is not possible to extrapolate information specifically relating to (chronic) pain of musculoskeletal origin
        - Papers that examined musculoskeletal pain as a *result* of computer use
    - Intervention
        - Papers where digital interventions are used in combination with other methods of intervention of nondigital origin and it is not possible to extrapolate the information pertaining specifically to digital interventions
    - Comparator
        - Any form of digital-based intervention/treatment
    - Outcome
        - Do not assess pain and/or physical functioning/disability
    - Study design
        - Study protocols, case studies/discussion papers, nonrandomized control trials, pilot studies, conference abstracts, and non-English language

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses flow diagram indicating search strategy. CCT: controlled clinical trial; RCT: randomized controlled trial.



Data Extraction

Data relating to the research aims were independently extracted by the authors (SH,GY, RS). The data extracted included the study setting details (authors, year, and country of origin), the study population (number of participants, age, and gender), intervention details, duration/follow-up period, and outcome measures used (Table 1 and Multimedia Appendix 2). Any misunderstandings and disagreements were addressed through consultation.

All outcome measures and predictive tools (Multimedia Appendix 6) were acknowledged. There were numerous clinical outcome measures, with considerable disparity across the time frames over which interventions were assessed. In addition, a wide range of digital health interventions were used in the studies. According to Cochrane, this diversity across interventions and comparators is not compatible with statistical assessment via meta-analysis; instead, it is more suitable for narrative interpretation [13]. Attempting a meta-analysis with clinically diverse studies risks obscuring genuine differences in effects, resulting in inappropriate conclusions [13]. Furthermore, undertaking a meta-analysis of studies that are at risk of bias may be misleading, as this will compound the errors and produce results that may be interpreted inappropriately as having more credibility [13]. Therefore, for this review, a meta-analysis was not undertaken.

The results are presented in Multimedia Appendix 4. In line with the review’s primary aim, full details of study results are included in the table for all pain and functional disability outcomes. For additional outcomes, only significant between-group differences that were measured at the final time point in the study, are presented.

[j] FLIP: facsimile lesson with instructional pictures (hard copy).

[k] iCBT: internet-delivered cognitive behavioral therapy.

[l] PPI: positive psychology intervention.

Quality Assessment

Methodological quality of the included studies was assessed by the lead researcher (SH) using the Cochrane risk of bias tool (modified) for quality assessment of randomized controlled trials (RCTs) [35]. This tool examines different subsets of bias, including performance, selection, detection, and attrition [36]. In total, 40% of the papers were independently assessed by a second reviewer (RS), and any disagreements were resolved through discussion. A third author was available (GY) should disagreements not be resolved but was not required.

Results

Search Results

A total of 1047 papers of potential interest were identified (Figure 1 and Multimedia Appendix 3). Of these, 301 were excluded as duplicates, leaving 746 for title and abstract screening. Following screening, the full texts of 57 papers were obtained and screened for eligibility, resulting in 22 papers eligible for inclusion.

Description of the Included Studies

Of the 22 papers identified (Figure 1), 3 papers were published in 1 study [23-25], whereas another study published 2 papers [18,19]. Although the study population and intervention were the same in Del Pozo et al's [23-25], Calner et al's, and Nordin et al's [18,19] papers, different outcomes were reported in each publication. Therefore, for the quality assessment, each of these papers was assessed individually using the designated assessment tool. However, for data extraction, the 3 Del Pozo et al's papers [23-25], and the Calner et al and Nordin et al's [18,19] papers, have been combined to avoid duplication of the participant outcomes, thus leaving 19 individual studies included in the data extraction and results tables (Table 1, and Multimedia Appendices 2, and 4). Of the 19 included studies, most were from the United States (n=8) [14,20,22,26-29,32]; 3 were from Australia [6,15,31]; 3 were from the Netherlands [16,30,34]; 2 were from Sweden [17-19]; and 1 each from Spain [23-25], Germany [33], and India [21]. One study was published in 2003 [34]; otherwise, all other studies were published between 2010 and 2019.

Of the studies that reported on the gender of participants, all studies except 3 [27,29,32] had a greater number of female participants. All studies included participants with an average age of 35 to 69 years. A wide variety of musculoskeletal conditions were examined by the included studies. In total, 10 studies investigated digital health interventions for LBP [17,20-27,31-33], 3 studies examined musculoskeletal pain [18,19,28,30], 3 studies investigated knee pain [6,14,29], 2 studies examined hip pain only or both knee and hip pain [15,16], and 1 investigated neck/upper limb pain [34].

Quality Assessment and Risk of Bias

Risk of bias was assessed using the modified Cochrane collaboration tool for assessing risk of bias [35]. Bias is assessed as a judgment (high, low, or unclear) for individual elements (7 domains) from 5 categories: selection (allocation concealment and randomization procedure), blinding (participants/personal and outcome assessors), completeness of data, selective outcome reporting, and other potential sources of bias [35]. Overall, the methodological quality of the included studies was variable (Table 2; refer to the judging criteria described in Multimedia Appendix 5). Of the 22 included studies, 1 achieved a low risk of bias across all 7 domains [15]. A further 6 were unable to blind the participants [6,14,21,23-25,27,31] but achieved a low risk of bias over the remaining 6 domains. Of the remaining 13 studies, a low risk of bias was achieved in 5 or fewer domains. The most consistent domain that failed to achieve a low risk of bias was the blinding of the study participants. The only study that was able to achieve blinding of participants [15] is one where both the control and the experimental group were told they would receive web-based resources and physiotherapy. However, 1 of the groups received only 8 information sheets on the web (flat copies; see Textbox 1) as opposed to the experimental group, which received an interactive digital intervention—pain coping skills training.

Table 2. Modified Cochrane collaboration tool for assessing risk of bias (For all domains, if reported Yes, this would indicate a low risk of bias, No would indicate a high risk of bias, and Unclear would indicate an unclear risk of bias).

Pain

All 19 included studies used outcomes that assessed pain. Of these, 9 reported statistically significant improvements in pain [6,15,16,23-26,28,29,32,33], 4 studies [6,15,16,26] assessed pain at more than one time point, and in 2 studies [15,16], improvement was not maintained at the last time point measured. In all, 4 studies [15,16,23-26] reported effect sizes, measured by odds ratio, eta squared, or Cohen d (Multimedia Appendix 4). The findings in 1 study indicated a large effect size [23-25], 2 studies reported moderate effect sizes [15,26], and 1 study reported a small effect size [16]. In relation to the quality of the studies, 3 out of the 9 studies with positive outcomes [6,15,23-25] were within those classified as low risk of bias or those that had low risk of bias in 6 out of 7 categories, with the exception of blinding [6,23-25] (Table 2).

Of the 9 studies that demonstrated statistically significant improvement in pain, 1 was on participants with hip OA, 1 was on chronic knee and hip OA, 1 was on knee pain, and 5 were on LBP. Of the 10 studies that did not demonstrate improvement, 1 was on OA knee, 6 were on chronic LBP, 2 were on chronic musculoskeletal pain, and 1 was on work-related neck and upper limb disorders. The duration of the interventions varied from 3 weeks to 9 months in the studies that showed improvement and 3 weeks to 12 months in those studies that did not show positive outcomes.

Functional Disability

In all, 16 of the included studies [6,14-16,18-27,29-33] used outcomes that assessed functional disability. Of these, 10 reported statistically significant improvements [6,15,16,20,21,23-27,29,32] (Multimedia Appendix 4); 5 of these studies [6,15,16,26,27] assessed outcomes at more than one time point, and in 2 studies [15,27], improvement was not maintained at the last time point measured. A total of 6 studies [15,16,20,21,23-26] reported effect sizes. In total, 3 studies reported a large effect size [15,16,23-25], 2 studies reported a moderate effect size [20,21], and 1 study reported a small effect size [26] (Multimedia Appendix 4). In relation to the quality of the studies, 5 out of the 10 studies with positive outcomes [6,15,21,23-25,27] had a low or relatively low risk of bias (Table 2).

Of the 10 studies that demonstrated statistically significant improvement in functional disability, 2 studies were on participants with chronic knee pain, 1 was on hip OA, 1 was on chronic knee and hip OA, 3 were on LBP, and 3 were on chronic LBP. Of the 6 studies that did not demonstrate improvement, 1 was on OA knee, 1 was on LBP, 2 were on chronic LBP, and 2 were on chronic musculoskeletal pain [14,18,19,22,30,31,33]. The duration of the interventions varied from 3 weeks to 9 months in the studies that showed improvement and 4 weeks to 4 months in those studies that did not show positive outcomes.

Additional Outcome Measures

Several additional outcomes were measured across the studies including measures of quality of life, psychosocial distress, work, and surgery interest. Multimedia Appendix 2 gives details of all outcomes, and Multimedia Appendix 4 shows statistically significant results at the last measured time point for each study. The most frequent additional outcomes across the studies were catastrophizing, self-efficacy, quality of life, and coping strategies.

Of the 7 studies reporting on catastrophizing [6,15,17,20,22,31,33], 4 reported statistically significant improvements [6,15,17,20]. Moreover, 7 studies examined self-efficacy [6,15,16,18-20,22,31], 2 of which reported statistically significant improvements [6,20]. In all, 6 studies reported on health-related quality of life [6,15,17-19,23-26], of which 3 [6,17,23-25] reported statistically significant improvements. In total, 6 studies reported on coping ability [6,15,16,18,19,22,30], of which 4 [6,15,16,22] showed significant improvement. A total of 2 studies examined self-reported interest in surgery post intervention [29,32], and both the studies showed significant reductions in pursuing surgical intervention.

Discussion

Principal Findings

The primary aim of this systematic review was to assess if digital health interventions were clinically effective in impacting musculoskeletal pain and functional disability in patients with musculoskeletal conditions. The results of the analysis show that there is some evidence to support the effectiveness of digital health interventions in improving pain, with 9 out of 19 studies reporting significant improvements. There was stronger evidence to support the role of digital health interventions in improving functional disability, with 10 out of 16 studies reporting significant improvements. There were also positive results shown in several additional outcomes, most notably catastrophizing and coping strategies, with 4 out of 7 and 4 out of 6 studies, respectively, reporting significant improvements.

In terms of musculoskeletal conditions treated, both peripheral and spinal conditions showed improvement in pain and/or functional disability. However, pain outcomes in all studies with a study population of chronic musculoskeletal conditions (chronic low back and chronic musculoskeletal pain) did not show any significant improvements. This is not a surprising finding, as generally interventions for chronic low back and chronic musculoskeletal pain are likely to have a greater effect on function, quality of life, and psychosocial factors rather than pain [37], as was found in this review. The positive outcomes for the majority of studies that considered coping strategies and catastrophizing may indicate that digital education and management strategies enable patients to better understand and cope with their musculoskeletal condition. The reduction in interest in surgery found in 2 studies [29,32] supports this.

Overall, the methodological quality of the included trials was variable. Only 1 study [15] had a low risk of bias across all domains. In total, 6 further studies were unable to blind the study participants [6,14,21,23-25,27,31], which is a common challenge facing researchers developing pragmatic clinical trials with comparative interventions [36]. Therefore, the potential risk of performance bias is elevated [36]. However, there was no observed direct relationship between the quality of trials and positive or negative outcomes; 3 of the 7 studies with low or relatively low risk of bias demonstrated significant improvements in pain, and 5 studies demonstrated significant improvements in functional disability. The large number of outcome measures used by the included studies made direct comparisons between studies difficult. This is a common problem in musculoskeletal research and is a reflection of the large number of outcome measures used in musculoskeletal conditions. The digital health interventions also varied considerably in many aspects including duration, program features, and targeted musculoskeletal condition, meaning a meta-analysis was not possible.

The secondary aim of the study was to explore the content, characteristics, and delivery of digital health interventions to ascertain if there are specific aspects of the interventions, or the population they are targeting, that are associated with beneficial outcomes. In relation to this aim, we looked across all studies in an attempt to identify characteristics related to positive or negative outcomes. Several features emerged following the analysis of the studies.

It appears important to match the digital health intervention to known evidence-based approaches for the condition. Examples of this can be seen in the studies where the population had chronic LBP or chronic musculoskeletal pain. In 3 of the studies that did not show any significant improvements in functional disability [17,22,30], interventions were not matched to what would be considered the best evidence-based practice. It is widely recognized that chronic musculoskeletal conditions, particularly LBP, are optimally managed using a biopsychosocial approach [38] incorporating both physical and psychosocial elements in the rehabilitation program. Chiauzzi et al [22], Peters et al [30], and Buhrman et al [17] utilized components of a psychosocial approach within their digital health interventions, but they did not specify an exercise or physical activity component. None of these studies demonstrated improvement in pain or functional disability. In contrast, 3 studies [20,21,26] did achieve statistically significant improvements in functional disability when including an exercise/physical activity component alongside a psychosocial component within their digital health intervention. In total, 2 studies [18,19,31] demonstrated the inclusion of all components of a biopsychosocial approach but achieved no statistically significant improvement in functional disability; however, this can be explained to an extent by the nature of the studies. In Calner et al's and Nordin et al's studies [18,19], the control group received multimodal rehabilitation (MMR) treatment from a minimum of 3 different health care professionals, including physiotherapists, psychologists, physicians, occupational therapists, and nurses. The experimental group also received MMR plus a web-based behavior change program; therefore, both the experimental and control groups had access to extensive psychosocial and physical intervention. Petrozzi et al [31] conducted an established internet-delivered program designed for the prevention and management of depressive symptoms (MoodGYM) and conducted a single-blinded study to examine the effectiveness of this in combination with physical treatments for patients with chronic LBP. The lack of significant improvement may be a reflection of the mismatch of content to the target population. The population for this study had moderate levels of back pain, low levels of disability, high levels of self-efficacy, and normal to mild levels of psychological distress (as assessed by STarTBack screening tool). However, MoodGYM is targeted toward those with higher levels of psychological distress and at higher risk of ongoing disability. The authors themselves acknowledge this as a limitation of their study. This highlights the importance of content being appropriately targeted toward the intended audience.

Another feature we identified was that all the digital health interventions delivered on an app [21,26,29,32,33], as opposed to a web-based program, produced positive results in pain and/or functional disability. In the context of this review, apps appear to have gained popularity in recent years. Of the 5 studies using apps, 1 was published in 2015 and the remaining 4 in 2018-2019. A number of reasons can be hypothesized as to why apps may provide successful digital health interventions. All the apps had in-app functions that facilitated greater engagement with study participants, for example, sensor-guided exercise features, notifications, and daily activity goals. Additionally, the success of apps may be related to other factors, including ease of access, portability, and convenience in comparison to web-based interventions.

In several studies, additional efforts were made to encourage engagement with the digital intervention. Various forms of multimedia additional support were included in 10 studies, such as phone calls, email reminders, and text messages [6,14-17,23-26,29-31]. In total, 6 of these studies demonstrated positive results for either pain and/or functional disability. Therefore, there is some indication that these additional forms of support may be linked to positive outcomes; however, the frequency and delivery modes were variable; as such, it is difficult to quantify the extent to which additional forms of support improve the effectiveness of a digital health intervention.

Due to the different features within each intervention, it was difficult to draw any firm conclusions regarding which components of digital intervention create the most engaging digital interface. The number of participant-interactive components within web-based interventions (eg, exercise trackers, web-based coaching, and quizzes) did not appear to definitively influence the success of the intervention. Both significant and nonsignificant outcomes were seen in trials with multiple interactive elements (Multimedia Appendix 2). An RCT by Riva et al [39] was designed to specifically evaluate the addition of interactive features to a well-established internet intervention for chronic back pain; the results of this study showed no difference between the group with multiple interactive features and the control in relation to pain and physical activity. It is also unclear if tailoring the intervention offers additional benefits. One of the studies included in this review [26] was a 3-arm study comparing a control group, tailored mobile-web intervention, and an alternative care group that received emails directing participants to nontailored web-based resources. Significant reductions in function were reported at 16-week follow-up for both intervention groups compared with the control; however, there was no significant difference between the groups.

In all studies reviewed, there was minimal reference to patient involvement in the development of the digital health intervention. Many studies on such interventions appear to use content developed by the medical/research team, with little reference to patient involvement in the design phase of the intervention [40]. Involving patients early in the development process may help inform key features of the design, including what constitutes an engaging interface.

In 6 studies [6,15,18,19,29,31,33], digital health interventions were used as an adjunct to face-to-face intervention with a health care practitioner, that is, physiotherapist or multidisciplinary team; 4 of these studies [6,15,29,33] showed improvements in pain and/or functional disability. In the 2 studies in which digital intervention did not show any improvement [18,19,31], the studies by Calner et al and Nordin et al [18,19] involved extensive MDT rehabilitation in both groups, and the addition of web-based intervention did not improve outcomes. This may reflect the intensity of face-to-face treatment received by the study participants in both groups. Petrozzi et al's study [31] was targeted at patients with high levels of psychosocial distress that did not match the presentation of the patients in the study group; the mismatch of the intervention to the target group may have influenced the results. As such, there is some support that digital health interventions may improve outcomes as an adjunct to face-to-face treatment with a health care practitioner. Importantly, in no cases were digital health interventions inferior to an interventional control in relation to pain or functional disability, and no trials reported adverse events. This, in itself, is an important finding, as although not always superior to interventional controls (usual care), digital health interventions have the ability to deliver safe, high-reach, low-cost, readily accessible, and scalable care. They could also help address physical access issues, as a result of the nature of a patient's pain, comorbidities, travel distances, and costs. Therefore, the use of digital interventions as an alternative to usual care may have a substantial impact on helping to manage the growing burden of musculoskeletal functional disability. This is particularly pertinent in health care systems currently stretched to such an extent that the frequency of delivery of face-to-face appointments is suboptimal. Digital health interventions may ultimately result in patients accessing more health care than they would in a solely face-to-face scenario.

From the review, no conclusions can be drawn regarding the duration of intervention for both pain and functional disability. Significant and nonsignificant outcomes were found in both short duration (3 weeks) and longer duration studies (up to 12 months). Due to the heterogeneity of the interventions and the lack of detail in the studies, it is also difficult to draw conclusions on the optimal dose or exposure to digital health interventions required to gain meaningful benefits. Many studies did not quantify how long patients engaged with the digital intervention; therefore, it is not possible to conclude if patients who engaged for longer durations with the intervention did better or worse. Further research is needed in both areas.

In what is perhaps a reflection of the emerging role of digital health interventions in the management of musculoskeletal conditions, there was a lack of long-term follow-up, particularly for patients with chronic musculoskeletal conditions in the majority of studies. It would be beneficial to assess the impact of successful websites and apps over a longer duration, as this has potential implications for patients, services, and health care resources if acute exacerbations of chronic conditions can be, at least in part, managed remotely.

There are certain limitations to this systematic review. Only English language studies were included; therefore, it is possible that relevant literature published in other languages may have been excluded. In addition, this review only included RCT study designs; however, this was to ensure that higher levels of evidence were used to address the aim of the review [41]. Finally, it was not possible to undertake a meta-analysis due to the diversity across interventions and comparators in the reviewed trials [13].

Conclusions

This review has demonstrated that digital health interventions have some clinical benefits in the management of musculoskeletal conditions. There is evidence to support the effectiveness of digital health interventions in improving pain. There is stronger evidence to support the effectiveness of digital health interventions in improving functional disability. There are also positive results shown in several additional outcomes, notably catastrophizing and coping strategies. This review demonstrates the potential of digital health interventions to contribute positively toward diminishing the personal, societal, and economic impact of musculoskeletal conditions, which, as our population ages, is only set to grow. Further research is needed to identify the patient subgroups that respond most positively to digital health interventions and also to determine the pertinent features of the interventions that are likely to achieve more successful patient outcomes.

Abstract

Background: Primary care is a major access point for the initial treatment of depression, but the management of these patients is far from optimal. The lack of time in primary care is one of the major difficulties for the delivery of evidence-based psychotherapy. During the last decade, research has focused on the development of brief psychotherapy and cost-effective internet-based interventions mostly based on cognitive behavioral therapy (CBT). Very little research has focused on alternative methods of treatment for depression using CBT. Thus, there is a need for research into other therapeutic approaches.

Objective: This study aimed to assess the effectiveness of 3 low-intensity, internet-based psychological interventions (healthy lifestyle psychoeducational program [HLP], focused program on positive affect promotion [PAPP], and brief intervention based on mindfulness [MP]) compared with a control condition (improved treatment as usual [iTAU]).

Methods: A multicenter, 4-arm, parallel randomized controlled trial was conducted between March 2015 and March 2016, with a follow-up of 12 months. In total, 221 adults with mild or moderate major depression were recruited in primary care settings from 3 Spanish regions. Patients were randomly distributed to iTAU (n=57), HLP (n=54), PAPP (n=56), and MP (n=54). All patients received iTAU from their general practitioners. The main outcome was the Spanish version of the Patient Health Questionnaire-9 (PHQ-9) from pretreatment (time 1) to posttreatment (time 2) and up to 6 (time 3) and 12 (time 4) months' follow-up. Secondary outcomes included the visual analog scale of the EuroQol, the Short-Form Health Survey (SF-12), the Positive and Negative Affect Schedule (PANAS), and the Pemberton Happiness Index (PHI). We conducted regression models to estimate outcome differences along study stages.

Results: A moderate decrease was detected in PHQ-9 scores from HLP (β=–3.05; *P*=.01) and MP (β=–3.00; *P*=.01) compared with iTAU at posttreatment. There were significant differences between all intervention groups and iTAU in physical SF-12 scores at 6 months after treatment. Regarding well-being, MP and PAPP reported better PHI results than iTAU at 6 months post treatment. PAPP intervention significantly decreased PANAS negative affect scores compared with iTAU 12 months after treatment.

Conclusions: The low-intensity, internet-based psychological interventions (HLP and MP) for the treatment of depression in primary care are more effective than iTAU at posttreatment. Moreover, all low-intensity psychological interventions are also effective in improving medium- and long-term quality of life. PAPP is effective for improving health-related quality of life, negative affect, and well-being in patients with depression. Nevertheless, it is important to examine possible reasons that could be implicated for PAPP not being effective in reducing depressive symptomatology; in addition, more research is still needed to assess the cost-effectiveness analysis of these interventions.

KEYWORDS

depression; primary care; internet-based interventions; randomized controlled trial

Introduction

Background

Depression represents a significant personal, economic, and societal burden [1-3]. Primary care remains a major access point for initial treatment of depression [4,5]. Previous studies reveal that more than 80% of patients with depression are being managed in general practice [6,7]. However, management of these patients is far from optimal, and it has been reported that only one-half of the patients receive adequate care, whether pharmacological or psychological [5]. Pence et al [4] estimated that only 47% of primary care patients with depression are clinically recognized, 24% receive treatment, and 9% receive adequate treatment.

Multiple and complex facilitators and barriers to treatment have been described [8,9], and access to evidence-based psychotherapy is one of these difficulties. Different factors such as professionals' training, time needed, costs or work overload, professionals' attitudes and organization, and geographical and logistic difficulties are some of the reasons that make the integration of psychotherapy in primary care difficult. New forms and models for delivering psychotherapy in primary care have been proposed to overcome these problems. The implementation of stepped and collaborative care models in primary care settings that provide time-limited psychotherapy have been found to improve the management of depression [10]. One of the most important difficulties for integrating psychotherapy into primary care is the lack of time and resources. Many empirically tested treatment protocols last 1 hour on a weekly basis for 15-20 sessions. (Extensive time and resources imply important difficulties for the application of this type of therapy.) For these reasons, and in an effort to reduce the high medical costs of depression treatment and overcome the difficulties of traditional treatments in primary care, brief psychotherapy for depression effective and cost-effective internet-based interventions have been extensively developed during the last decade [11,12]. Low-intensity, internet-based interventions could be a simple, cost-effective method for treating depression in primary care settings [13]. In fact, meta-analyses suggest that depression can be effectively treated with brief psychotherapy (6-8 sessions), specifically with cognitive behavioral therapy (CBT), problem-solving therapy [14], and counseling approaches [15].

Most of the internet interventions aiming at the treatment of depression are based on CBT. Previous findings for other forms of face-to face psychotherapy suggest that there is no *one-fits-all* solution [16], but few studies have analyzed web-based interventions based on other types of treatments. First results are promising, but more research is needed to determine the efficacy of alternative programs than internet-delivery CBT [17].

In a previous study, our group shows the efficacy of an internet intervention for depression in primary care (smiling is fun) [18]. The program follows a transdiagnostic perspective, and it is based on CBT techniques but also includes other psychological strategies to improve depressive symptoms such as promotion of healthy lifestyles, positive affect, and mindfulness. The treatment protocol is composed of 10 modules and lasts about 3 months. The program proved to be more effective than treatment as usual alone, but the attrition rate at follow-up was significant and the retention rate was not as good as we expected. These results led us to design a new protocol with the objective to identify which of the alternative therapeutic approaches was more effective and, also, to shorten the duration of the program to achieve better rates of attrition and retention.

Evidence of the benefits for treating depression of positive psychology, mindfulness, and lifestyle habits delivered using internet is growing as a result of increase in research studies over the last 10 years [19-22]. Meta-analyses of positive psychological interventions delivered to clinical and community samples have reported small but significant effects for reducing depressive symptoms [23] and comparable efficacy and lasting effects to traditional psychotherapy and pharmacotherapy [24,25]. Web-based positive emotion skills training for depression have shown preliminary good results [19,26] but warrant additional study. There is growing evidence for positive benefits of mindfulness interventions in clinically depressed individuals [27,28]. Recent reviews and meta-analysis of mindfulness-based CBT suggest that internet-based approaches have potential to contribute to improving depression [29,30], but there is a need for research into this therapeutic approach. Finally, lifestyle web-based interventions can be an effective and inexpensive alternative or supplement to depression therapy that is delivered using more traditional modes, overcoming barriers that make people from accessing treatment difficult. The results of a recent review [31] highlight the potential of web-based lifestyle interventions as adjunctive treatments for depression and the possibility of achieving significant improvements in depressive symptoms when targeting lifestyle behavior change. But the limited number of studies requires further clinical trials to achieve better understanding.

Objectives

Considering the scarcity of these studies and the fact that low-intensity, internet-based psychological interventions could be an efficacious and cost-effective therapeutic option for the treatment of depression, the aim of this study was to assess the effectiveness of 3 low-intensity, internet-based psychological interventions (psychoeducational program for the promotion of a healthy lifestyle (HLP), psychological intervention for the promotion of positive affect (PAPP), and brief intervention based on mindfulness [MP]) compared with a control condition.

Methods

Study Design

This study was a multicenter, 4-arm, parallel randomized controlled trial. Adults with depressive symptoms in primary care were randomly assigned to one of the following groups: (1) HLP + improved treatment as usual (iTAU), (2) PAPP + iTAU, (3) MP + iTAU, or (4) iTAU.

Trial registration number of this study was ISRCTN82388279. Research protocol of the study has been described elsewhere [32].

Recruitment of Participants and Baseline Assessment

We recruited patients with major depression or dysthymia, older than 18 years, able to understand and read Spanish, with mild or moderate depression according to the Patient Health Questionnaire-9 (PHQ-9; 5-9: mild depression; 10-14: moderate depression) [33], and with symptoms lasting longer than 2 weeks. Major depression and dysthymia were identified using the MINI International Neuropsychiatric Interview 5.0. We excluded patients with a diagnosis of any disease that may affect the central nervous system (brain pathology, traumatic brain injury, dementia, etc); with any psychiatric disorder other than major depression, dysthymia, anxiety disorders, or personality disorders; with any medical, infectious, or degenerative disease that may affect mood; with presence of delusional ideas or hallucinations consistent or not with mood; and with suicide risk.

Participants were recruited in primary care settings, between March 2015 and March 2016, in the Spanish regions of Aragon, Andalusia, and the Balearic Islands. When the general practitioner identifies a potential participant during a routine visit, he or she explained to the patient the characteristics of the study. When the patient was interested in participating, he or she signed an informed consent form and the general practitioner filled a referral form describing the sociodemographic characteristics of the patient and a checklist for inclusion and exclusion criteria and gave him or her the patient's information sheet and a handout describing the study. The general practitioner sent these documents by fax to the local researcher. Participants were interviewed in the next 3 days by the researcher, which administered psychological assessment instruments related with inclusion and exclusion criteria by phone. Included participants were randomized to 1 of the 4 groups by an independent researcher. Patient safety was systematically monitored. The Ethical Review Board of the regional health authority approved the study (Ref: IB 2144/13PI).

Randomization, Concealment, and Blinding

The sequence was concealed until interventions were assigned. Participants agreed to participate before the random allocation without knowing which treatment they were being allocated to. Study personnel conducting psychological assessment were masked to participants' treatment conditions. The researcher that administered baseline assessments was unaware of the treatment group to which the participant belonged. This researcher was different from the one that administered the questionnaires over the study. General practitioners were also unaware, as far as possible, of the arm to which each patient had been randomized, as their treatment needed to be exclusively based on the recommendations of the treatment of depression guidelines.

Follow-Up

Follow-up data collection took place between April 2015 and June 2017. Participants were assessed on web at pretreatment (time 1), posttreatment (time 2), and 6- (time 3) and 12- (time 4) month posttreatment assessments. The web-based platform hosted the questionnaires. Participants were sent an email with a link to that platform. No other protocols were used to increase compliance with the research data collection, but a phone call was made before each wave assessment to increase response rates.

Improved Treatment as Usual

All the patients included in the study (irrespective of the treatment group randomly assigned) received iTAU. This treatment was provided by their general practitioners, who had previously received a training program to update their knowledge on how to diagnose and treat depression in primary care and optimized by the recommendations based on the Spanish Guide for the Treatment of Depression in Primary Care [34,35]. In case of suicide risk or severe social dysfunction or worsening of symptoms being detected, patients were referred to mental health facilities.

Intervention Groups

All interventions (except iTAU) were composed of one face-to-face group session and 4 web-based, individual, and interactive therapeutic modules.

The face-to-face session, which took place in primary care centers, involved up to 5 patients and was 90 min long. The aim of this session was to explain the program structure and main components of treatment and to motivate participants for change.

The web-based therapeutic modules are oriented to work on different psychological techniques, and the duration of each module is approximately between 40 and 60 min. All modules include an explanation of the module contents, check questions to test if they understand the contents, and exercises to practice the techniques. These modules are sequential, to move step by step, throughout the program. However, users can review the module contents once they are finished. Although the duration of the program can vary among users, it is estimated that for most people, it lasted between 4 and 8 weeks. Regarding the therapeutic content, all intervention groups are composed of 4 intervention modules based on different psychological techniques, as shown in Table 1. A more specific and detailed description of the module contents can be found elsewhere [32].

To maximize adherence, participants received 2 weekly automated mobile phone messages, encouraging them to proceed with the program and reminding them of the importance of doing the tasks in each module. If participants did not access the program for a week, they received an automated email encouraging them to continue with the modules. Furthermore, the program also offers continued feedback to users through the assessment tools showing them their progress throughout the entire treatment process. All groups of patients received a participant manual with information about the technical aspects of the web-based program.

Table 1. Intervention modules and main objectives.

Intervention and modules	Main objective
Psychoeducational program for the promotion of a healthy lifestyle	
Beginning of a lifestyle change	To teach the importance of healthy lifestyle to improve emotional health and general well-being and to give structured hygienic-dietary recommendations.
Physical activity. Learning to move on	To give information about the most recommended exercises to improve mood, and to train the patient in learning procedures to increase motivation, to start being more active, and to maintain this physical activity regularly.
Diet. Learning to eat	To teach the importance of diet to achieve a good physical and mental health, and the role of the Mediterranean diet in the prevention and treatment of depression.
Sleep. The importance of good sleep	To understand the relationship between sleep and general health.
Psychological intervention for the promotion of positive affect	
Learning to live	To teach the importance of establishing and maintaining an adequate activity level and the relevance of choosing activities that are significant, with a personal meaning for the individual.
Learning to enjoy	To give education about the effect of positive emotions and to train the patient in learning procedures to increase the likelihood of experiencing positive emotions, promoting the occurrence of pleasant activities to learn to enjoy the present moment.
Accepting to life	To train the patient in focusing on positive emotions related with the past (such as gratitude) or the future (such as optimism).
Living and learning	To train the patient in understanding life as a continuous process of learning and personal growth, emphasizing the training in strategies to promote psychological strengths, resilience, and meaningful goals linked to important values.
Brief intervention based on mindfulness	
Getting to know mindfulness	To show what mindfulness is, prejudices about it, the inattention problem, and some of its main benefits and recommendations to practice it.
Establishing formal and informal practices	To teach the importance of the establishment not only of formal but also of informal practice.
Through management, body scan practice and values	To help people to see the importance of values to keep a regular mindfulness practice.
Self-compassion. Integrating mindfulness in everyday life	To establish a regular practice of mindfulness to be indefinitely kept.

Instruments

Demographic Variables

We gathered sociodemographic data such as gender, age, place of residence, family status, living with family or alone, level of studies, work status, and income level according to national minimum wage (NMW) as well as clinical variables such as taking psychopharmacological medication (yes vs no) and the number of general practitioners visits in the previous 12 months.

Outcomes

The Spanish version of PHQ-9 [36], as a continuous variable, was used as the primary outcome measure in all 4 assessments, from pretreatment (time 1) to 12-month follow-up (time 4). PHQ-9 is one of the most widely used instruments to evaluate the presence and severity of depressive symptoms. Participants describe their mood according to the last 2 weeks before evaluation. Items range from 0 to 3 denoting *not at all*, *several days*, *more than half the days*, and *nearly every day*, respectively. Total scores range from 0 to 27. The Spanish version has been shown to have good psychometric properties (for the diagnosis of any disorder, k=0.74; overall accuracy, 88%; sensitivity, 87%; and specificity, 88%).

Secondary outcomes included the visual analog scale (VAS) of the EuroQol (*EuroQol—a new facility for the measurement of health-related quality of life*, 1990), in its Spanish version [37]; the Short-Form Health Survey (SF-12) [38], in its Spanish version [39], as a measure of health-related quality of life and functioning; the Positive and Negative Affect Schedule (PANAS) [40], in its Spanish version [41], as a measure of positive and negative affect; and the Pemberton Happiness Index (PHI) [42] as a measure of general well-being.

The VAS is a vertical line on which the best and worst possible health states are scored, 100 or 0, respectively. The SF-12 scoring algorithm yields a physical and mental component scale, and both were used as continuous variables applying Spanish norms. The PANAS evaluates 2 independent dimensions: positive affect and negative affect and were used as continuous variables. *Trait* version was used in this study. The overall PHI index was used as a continuous measure of general well-being, and the scores ranged from 0 to 10.

Sample Size

Required sample size was 240 participants, 60 participants in each condition [32]. This estimation was calculated according to the literature, with a SD of 9.2 and a mean of 16.2 in the iTAU group [43], 14.59 in PAPP group [44], 16.12 in HLP group [45], and 10.3 in the MP group [43], accepting an α of .05 and a β risk<0.2 in a bilateral contrast and assuming a 25.0% (60/240) patient loss to follow-up. This sample size also allows for the calculation of the clinically significant difference in the main outcome variable, PHQ-9 [36], and this difference has been placed at 5 points.

Data Analysis

First, demographic and outcome variables were characterized through descriptive exploratory analysis. Database scrutiny revealed increasing percentages of whole wave missingness in primary and secondary outcome variables along the follow-up. Missingness effects were, thereafter, assessed through sensitivity analyses for demographic variables, intervention groups, and baseline outcomes, considering dropout as study abandonment, with or without subject return, at any assessment period. Although an association between collected variables and study attrition had been detected, no association was reported between outcome values and follow-up missingness; hence, missing at random was assumed for primary and secondary outcome variables. Finally, we implemented Multiple Imputation with Chained Equations (MICE) to replace the outcome missing values, performing 100 imputation models with 100 iterations per model.

We conducted paired *t*-tests and Wilcoxon Signed Rank tests to estimate PHQ-9 primary outcome differences between study stages. Analysis of variance and Tukey's range test were also displayed to examine outcome differences between intervention groups at each time point. In addition, unadjusted and adjusted to sex and age linear regression models were performed. Consecutively, Hedge's (g) effect size index was calculated for each unadjusted regression model. The same approach was used compare secondary results from SF-12 Mental and Physical subscales scores, EuroQol (VAS) scores, and PHI global scores. We used a Complier Average Causal Effect (CACE) analysis to determine the number of completed modules effect on PHQ-9 posttreatment scores, defining compliance as 4 completed modules (100%) and analyzing these same effects per module. In all the analyses, we used a 2-sided test at 5% significance level. Data analyses were implemented with R (3.15.) and Stata 15 (StataCorp).

Results

Baseline Characteristics and Attrition Rates

A total of 221 recruited participants met inclusion criteria and agreed to participate after baseline assessments (Figure 1). The number of recruited participants varied across regions: 75 from Zaragoza, 76 from Málaga, and 70 from Mallorca. A total of 57 participants were designated to iTAU, 54 to HLP, 54 to MP, and the remaining 56 to PAPP. Although all participants did not provide their complete baseline sociodemographic data, no statistically significant differences were found between intervention groups after randomization (Table 2).

Attrition rates increased significantly as study went forward: primary outcome PHQ-9 data were collected for the 72.4% (160/221) of participants at time 1, 57.5% (127/221) at time 2, 46.2% (102/221) at time 3, and 43.9% (97/221) at time 4. Missingness analysis does not report outcome baseline significant differences between dropout and nondropout groups. Conversely, differences in missingness were found between intervention groups, with 28% (15/54) in HLP and 24% (13/54) in MP presenting significative less dropout subjects (*P*<.01) than 45% (25/56) in PAPP and 63% (36/57) in iTAU groups. Baseline age differences were also detected between dropout and nondropout groups at time 2 (*P*=.04) and time 3 (*P*=.03). After MICE, mean depression severity assessed by PHQ-9 score at pretreatment stage (time 1) was 15.33 (SD 5.76) with a median of 15.5, which agrees for a moderate depression level.

[j] PANAS: Positive and Negative Affect Schedule.

Primary Analysis

All our primary and secondary results were extracted from databases with high rates of attrition, 44.7% (395/884), which were thereafter imputed. Thus, the following results should be considered more as suggestive hypothesis rather than empirical statements. To this extent, we found significant decreases of PHQ-9 scores (*P*<.001) in all interventions (iTAU included) from pretreatment (mean 15.33, SD 5.76) to posttreatment (mean 10.19, SD 6.42) and up to 6 and 12 months (time 3: mean 9.39, SD 6.59 and time 4: mean 9.68, SD 6.14). After treatment, a moderate decrease was detected in PHQ scores from HLP and MP relative to iTAU: iTAU versus HLP (β=–3.05; *P*=.01) and iTAU versus MP (β=–3.00; *P*=.01; Table 3). In contrast, we observed no significant PHQ-9 differences between PAPP and iTAU, nor between any psychotherapeutic strategies, throughout the study (Table 3). Adjusted regression models replicated these same findings with poor variation (Multimedia Appendix 1). CACE analysis reported posttreatment dose-response significant decrease in PHQ-9 scores in HLP and PAPP in both imputed and adjusted models (Table 4, Multimedia Appendix 2). Despite the fact that the compliance effects (4 modules vs >4 modules) tended to disappear in the long term, the effects per module remained conserved (Table 4).

Table 3. Primary outcome analysis with imputed data (N=221): intervention comparisons along the follow-up.

Primary outcome	Time 1 (pretreatment)	Time 2 (posttreatment)	Time 3 (6 months)	Time 4 (12 months)

Secondary Analysis

Imputed Mental and Physical SF-12 scores significantly increased in all intervention groups (iTAU included) from pretreatment to posttreatment (Mental SF-12: *P*<.001; Physical SF-12: *P*<.001) and from posttreatment to 6 months after treatment (Mental SF-12: *P*<.001; Physical SF-12: *P*=.02). Although differences between these intervention groups disappeared in the long term (Table 5), iTAU Mental SF-12 scores were higher than HLP scores (β=–5.32; *P*=.02) and PAPP scores (β=–7.72; *P*=.001) at posttreatment. Conversely, we determined posttreatment increases in HLP Physical SF-12 scores relative to iTAU (β=4.58; *P*=.047) and from MP group compared with iTAU (β=5.32; *P*=.02). Physical SF-12 HLP, MP, and PAPP group differences relative to iTAU were observed up to 6 months after treatment (Table 5). These results were replicated similarly by adjusted regression coefficients (Multimedia Appendix 3).

Although EuroQol (VAS) significant differences were detected from pretreatment to 6 months (*P*<.001) and up to 12 months after treatment (*P*<.001) in all intervention groups, no meaningful differences among the groups were observed at any time (Table 6). Otherwise, PHI scores rose significantly at 6 and 12-months after treatment relative to pretreatment (*P*<.001), and all psychotherapy interventions, except HLP, reported better PHI results than iTAU treatment at time 3 (Table 6). These results were replicated similarly by adjusted regression coefficients (Multimedia Appendix 4). PANAS negative affect scale decreased in all intervention groups at posttreatment (*P*<.001), at 6 months (*P*<.001), and at 12 months (*P*<.001) compared with pretreatment. In contrast, all PANAS positive affect scores increased significantly throughout study time relative to pretreatment (*P*<.001). However, we found no significant PANAS positive affect differences between intervention groups throughout the study (Table 7). Regarding PANAS negative scale, only PAPP intervention was significantly lower than iTAU when were compared 12 months after treatment (Table 7). These results were replicated similarly by adjusted regression coefficients (Multimedia Appendix 5).

Internet-Based Program Usage

A total of 81.1% (133/164) participants attended the initial face-to-face session. In HLP, 44% (24/54) of participants completed all web-based modules, in MP, 52% (28/54), and in PAPP, 32% (18/56; χ^2_2=4.4; *P*=.11). In HLP, the median number of sessions completed was 2 (range: 0-4). In MP, the median number of sessions completed was 4 (range: 0-4), and in PAPP, 2 (range: 0-4). There were no significant differences between intervention groups in terms of sessions completed (F_2=1.775; *P*=.17).

Discussion

Principal Findings

The main objective of our study was to examine the efficacy of 3 low-intensity, internet-based psychological interventions when compared with that of the control condition (iTAU) in primary care in Spain.

Our main finding was that there were differences in the short term in favor of internet-based psychological interventions, specifically HLP and MP. This finding is consistent with the literature that has shown that brief psychotherapy is efficacious for the treatment of depression in primary care [12] and is also in line with the previous literature that has demonstrated that internet-based intervention programs are effective for the treatment of depression [18,46-48]. However, no differences were found in depression severity between PAPP and iTAU. This finding is not in line with the previous literature that has shown that this psychotherapy is effective in reducing depression [49]. Moreover, there were no differences found in the medium and long term between intervention and control groups. This result differs from findings of previous systematic reviews and meta-analysis that have evidenced that electronic health interventions effectively reduce depressive symptoms [11,50,51]. However, differences between populations may affect the generalizability of these studies [52]. It has been argued that psychotherapy may be less effective in primary care than in other settings, mainly due to the considerable heterogeneity in the severity of symptoms and the lower motivation among patients in primary care settings [53]. Our findings also show the faster effect of our interventions, with moderate effect size at posttreatment. The lack of mid- and long-term efficacy could be explained by a floor effect. Care as usual is not a clearly defined treatment, entailing different interventions [52]. Given that the usual care was improved before the interventions and that pharmacological treatment were offered to all groups, no major effects can be expected when web-based interventions were given. Our results also show that there were no differences between interventions throughout the study regarding depressive symptomatology. This finding is in line with that of the study by Cuijpers et al [54] who found that all therapies are equally effective in the treatment of depression.

Furthermore, we found differences between the 3 interventions groups and control group (iTAU) regarding health-related quality of life. In particular, we observed short- and medium-term differences in favor of HLP and MP in physical health status, and in medium term for PAPP. These results demonstrated that the 3 low-intensity, internet-based psychological interventions in primary care are also effective in improving medium- and long-term quality of life. This finding is highly important, for, as is well known, depression is associated with serious disability and loss in quality of life [55,56], suggesting that it could be a useful tool to improve quality of life of patients with depression.

Differences were also found in well-being and affect between intervention and control groups. In particular, we observed differences in medium term regarding well-being in MP compared with that in iTAU. In PAPP, differences were found in medium and long term with regard to well-being and, in long term, with regard to negative affect in favor of psychotherapy. This finding shows us that although PAPP seems to be ineffective in reducing depressive symptomatology, it could be effective in improving health-related quality of life and well-being in patients with depression.

Regarding treatment adherence, our completion treatment rates were relatively low in each intervention group. Dropout treatment is common in internet intervention programs, although rates vary depending on the support provided along the intervention or the context [47]. Regarding primary care, our adherence rates are higher than those reported in a previous study, in which participants completing all treatment sessions did not exceed 20% [57].

A possible explanation could be that in our study, there was an initial face-to-face group session, in which the final goal was to reinforce commitment and adherence to treatment, as well as, to explain the program structure and main components of treatment, clarify the instructions for the use of the web-based platform, and motivate participants to change. Thus, perhaps these measures could have increased our completion rates.

Limitations and Strengths

This trial presents several limitations, which should be mentioned. First, not all participants completed posttest measurements, and a high attrition rate at follow-up was found. Although missing values were corrected by using multiple imputations, the results should be interpreted with caution. Second, just as difficulties in recruiting patients is an important issue in clinical trials [58-60], general practitioners may also experience problems in recruiting patients owing to their overload schedule, and our sample size is slightly lower than the expected. Finally, treatment directed to depression problems with the general practitioners in the iTAU group was not recorded. It would be necessary to consider these variables in the future to analyze possible influences on between-group results.

Our study has a significant strength: to the best of our knowledge, this is the first trial in Spain aimed at improving the symptomatology and quality of life of patients with depression using low-intensity interventions applied by the information and communication technologies. The treatment programs used in this study include therapeutic strategies based on mindfulness, healthy lifestyle, and positive affect, which have proven their efficacy for the treatment of depression; nevertheless, it is still the first study that adapts these interventions to information and communication technologies.

Conclusions

This study has 3 important conclusions. First, 2 low-intensity, internet-based psychological interventions (HLP and MP) for the treatment of depression in primary care were more effective than iTAU at posttreatment. Second, all low-intensity, internet-based psychological interventions were also effective in improving medium- and long-term quality of life. Finally, PAPP was effective for improving health-related quality of life and well-being in patients with depression. Nevertheless, it is important to examine possible reasons that could be implicated in the ineffectiveness of PAPP in reducing depressive symptomatology, such as the intervention length, population, and treatment adherence, to increase its effectiveness in future studies of internet-based interventions programs for depression. Overall, our results suggest that although low-intensity, internet-based psychological programs are an efficacious therapeutic option for the treatment of depression in primary care, subsequent and more complex analyses are necessary to explain the reasons why some interventions appeared to affect some outcomes but not others. Furthermore, more research is still needed to assess the cost-effectiveness analysis of these interventions.

Acknowledgments

This study was financed by the Instituto de Salud Carlos III of the Spanish Ministry of Economy and Competitiveness with the PI13/01171 grant (Efficacy and cost-effectiveness of the low-intensity psychological interventions applied by ICTs for the treatment of depression in primary care: a controlled trial). The authors would like to thank the Institut d'Investigació Sanitaria de les Illes Balears (IdiSBa) for the assistance received on statistical analysis queries.

Abstract

Background: Digital technologies connect young people with health services and resources that support their self-care. The lack of accessible, reliable digital resources tailored to young people with persistent musculoskeletal pain is a significant gap in the health services in Australia. Recognizing the intense resourcing required to develop and implement effective electronic health (eHealth) interventions, the adaptation of extant, proven digital technologies may improve access to pain care with cost and time efficiencies.

Objective: This study aimed to test the acceptability and need for adaptation of extant digital technologies, the pain*HEALTH* website and the *iCanCope with Pain* app, for use by young Australians with musculoskeletal pain.

Methods: A 3-phased, mixed methods evaluation was undertaken from May 2019 to August 2019 in Australia. Young people aged 15 to 25 years with musculoskeletal pain for >3 months were recruited. Phases were sequential: (1) phase 1, participant testing (3 groups, each of n=5) of co-designed website prototypes compared with a control website (pain*HEALTH*), with user tasks mapped to eHealth quality and engagement criteria; (2) phase 2, participants' week-long use of the *iCanCope with Pain* app with engagement data captured using a real-time analytic platform (daily check-ins for pain, interference, sleep, mood, physical activity, and energy levels; goal setting; and accessing resources); and (3) phase 3, semistructured interviews were conducted to gain insights into participants' experiences of using these digital technologies.

Results: Fifteen young people (12/15, 80% female; mean age 20.5 [SD 3.3] years; range 15-25 years) participated in all 3 phases. The phase 1 aggregated group data informed the recommendations used to guide 3 rapid cycles of prototype iteration. Adaptations included optimizing navigation, improving usability (functionality), and enhancing content to promote user engagement and acceptability. In phase 2, all participants checked in, with the highest frequency of full check-ins attributed to pain intensity (183/183, 100.0%), pain interference (175/183, 95.6%), and mood (152/183, 83.1%), respectively. Individual variability was evident for monitoring progress with the highest frequency of history views for pain intensity (51/183, 32.3%), followed by pain interference (24/183, 15.2%). For the goals set feature, 87% (13/15) of participants set a total of 42 goals covering 5 areas, most frequently for activity (35/42, 83%). For phase 3, metasynthesis of qualitative data highlighted that these digital tools were perceived as youth-focused and acceptable. A total of 4 metathemes emerged: (1) importance of user-centered design to leverage user engagement; (2) website design (features) promoting user acceptability and engagement; (3) app functionality supporting self-management; and (4) the role of wider promotion, health professional digital prescriptions, and strategies to ensure longer-term engagement.

Conclusions: Leveraging extant digital tools, with appropriate user-informed adaptations, can help to build capacity tailored to support young people's self-management of musculoskeletal pain.

Introduction

Background

Young people want access to health services that are tailored and responsive to their specific health needs, especially for those with chronic health conditions such as persistent musculoskeletal pain [1-3]. Digital technologies connect young people with health services and resources to support their self-care and promote positive health habits [4-6]. Furthermore, digital technologies are portable, customizable, and readily assimilate into young people's daily routines [5].

This capability to connect is especially important for young people with chronic health conditions, including pain, during the critical transition from childhood to young adulthood [1,7]. Persistent pain can impose a significant and enduring health and economic burden on young people and their communities [8,9]. Australian data suggest persistent pain rates for young people approach those of adults (ie, approximately 20%) [8,10], whereas international data indicate higher rates for musculoskeletal pain (eg, 37% for back pain) [11-13]. Young people often fall through gaps during this developmental transition, with many failing to seek care and adopting unhelpful habits that increase the risk of ongoing health and social issues [6]. In Australia, this risk is compounded by young people exiting pediatric health services around the age of 16 years and failing to seamlessly integrate into adult health services, despite transitional frameworks [1,14,15]. Digital technologies may help to drive engagement, enabling timely access and broader reach to the *right* health care [1,14,16,17]. Currently, the lack of accessible, reliable digital resources tailored to the needs and preferences of young Australians with persistent musculoskeletal pain remains a health services gap [14,18]. Recognizing the intense resourcing required to develop and implement effective electronic health (eHealth) interventions, adaptation of proven digital technologies may be a more cost- and time-efficient approach [19].

To accelerate the implementation of digital technologies into the care of young Australians with musculoskeletal pain, we established a transnational partnership to leverage digital technologies already developed and tested for pain care. Both platforms were co-designed using best practice recommendations for eHealth design and implementation [20]. First, in Australia, we developed a digital resource, pain*HEALTH*, to support improved musculoskeletal pain care for adults [21-27]. Co-designed with consumers, using a policy-into-practice approach [28], aligned to contemporary musculoskeletal models of care and strategic health frameworks (the chronic conditions framework [29] and the national pain strategy [15]), pain*HEALTH* supports consumers accessing the right care, at the right time, by the right team. Impact evaluation demonstrated that consumers/caregivers and health professionals perceived pain*HEALTH* as supporting holistic self-management and cocare of musculoskeletal pain [30]. Second, in Canada, an integrated smartphone and web-based self-management program, *iCanCope with Pain*, was developed [16,31]. This digital platform addresses the self-management needs of young people with persistent pain by improving access to contemporary tailored pain education; providing practical strategies to manage pain, psychological well-being, and sleep hygiene; encouraging physical activity; and providing peer social support [3,16]. The platform is undergoing cultural adaptation and usability testing evaluation in Norway [32].

Trial evaluation in Canada is also underway to assess implementation success and effectiveness (such as pain intensity, pain-related activity limitations, and health-related quality of life) outcomes (clinical trial number: NCT02601755).

Objective

Therefore, to avoid research waste and technology duplication, this study aimed to test the acceptability and need for adaptation of these two extant digital technologies for young Australians with musculoskeletal pain. The specific aims were as follows:

1. To test the acceptability and usability of a prototype derivative of pain*HEALTH* for young people with musculoskeletal pain
2. To test the acceptability and usability of the *iCanCope with Pain* app [16] for young people with musculoskeletal pain.

Methods

Study Design

This 3-phased, mixed methods evaluation was undertaken in Australia between May 2019 and August 2019. Phases were sequential, with phase 1 involving participant (user) testing of website prototypes (research aim 1). In phase 2, participants utilized the *iCanCope with Pain* app (hereafter *app*) over a 1-week engagement period (research aim 2). Finally, in phase 3, semistructured interviews were conducted to provide insights into the participants' experiences of using these digital technologies (Figure 1). The study had institutional ethics approval, adhered to the Declaration of Helsinki, and aligned with reporting recommendations from the consolidated criteria for reporting qualitative studies: 32-item criteria (Multimedia Appendix 1) [33].

Figure 1. A 3-phased approach to the user testing was adopted, with all participants undertaking user testing of website prototypes (phase 1), pain app user testing (phase 2), and semistructured interviews on their experiences of using these digital technologies (phase 3).

Eligibility Criteria

Young people aged 15 to 25 years with musculoskeletal pain for >3 months and currently living in Australia were eligible to participate. Musculoskeletal pain included recurrent or persistent pain; however, pain at the time of enrollment was not a prerequisite for participation. These eligibility criteria were aligned to our previous research [1] and applied across all 3 study phases.

Recruitment and Sampling

Participants were recruited from community sources, including arthritis consumer organizations, private health care practices, youth mental health services, via social media, electronic newsletters, flyers, and emails. Initial eligibility screening was undertaken using a web-based survey platform Qualtrics. The survey instrument was informed by our previous research on young people with musculoskeletal pain [1,16], with minor iterations, and was piloted by members of the research team (HS, AMB, J Chua, and JNS) before deployment to the field. No researcher had an existing relationship with any participant.

Consent

Young people meeting all 3 inclusion criteria were requested to provide consent directly through the Qualtrics web platform. Participants aged 15 to 17 years were advised to discuss consent with their guardian/parent before consenting to participate and were also invited to have a guardian/parent present for any, or all, phases of the study.

Protocol

The participants meeting the inclusion criteria and providing consent completed an initial web-based survey to capture demographics and clinical characteristics, including area(s) of their pain, pain duration, and pain diagnosis. The Örebro Musculoskeletal Pain Screening Questionnaire-Short Form (ÖMPSQ-SF) [34] was included as a measure of pain-related disability. The ÖMPSQ-SF has been validated for use in primary care [35] and used for previous clinical pain research in this age group [1]. Items are scored 0 to 10; 0 refers to the absence of impairment and 10 to severe impairment. A total of 3 items are reversed in order for all the questions to be oriented in the same direction. Total scores range between 1 and 100, with a score >50 indicating higher estimated risk for future (work) disability. Given the age range for our cohort, we modified the wording for items where *work* was mentioned to include *work/study*. Once participants completed the web-based survey, they were contacted to schedule a time for phase 1 of the user testing.

Participants were allocated sequentially to 3 testing groups (each comprising 5 participants). Groups were run in series, with group allocations remaining consistent across all 3 phases of testing (as all participants consented to complete all 3 phases). The purpose of serial testing in phase 1 was to enable iterative cycles of formative feedback used to guide prototype refinements before the subsequent testing group, an approach consistent with best practice recommendations for digital user testing [16,20]. The period of testing across all 3 phases for a group ranged from 11 to 26 days. At the completion of phase 3, all participants received an AUD $100 (US $65) gift voucher.

Phase 1. painHEALTH and Prototype Website User Testing

For this phase of user testing, the existing pain*HEALTH* platform was used as a *control* website. This allowed users to evaluate 2 newly developed website prototypes against a fully functional comparator. As pain*HEALTH* was co-designed with adults, rather than younger Australians, we did not expect participants to easily relate to this website, but rather to consider features and content that might be helpful on a youth-focused platform. The prototypes were informed from our previous research using insights from young people with musculoskeletal pain about their needs and preferences for digital tools [1]. The specific tasks are outlined later in the paper.

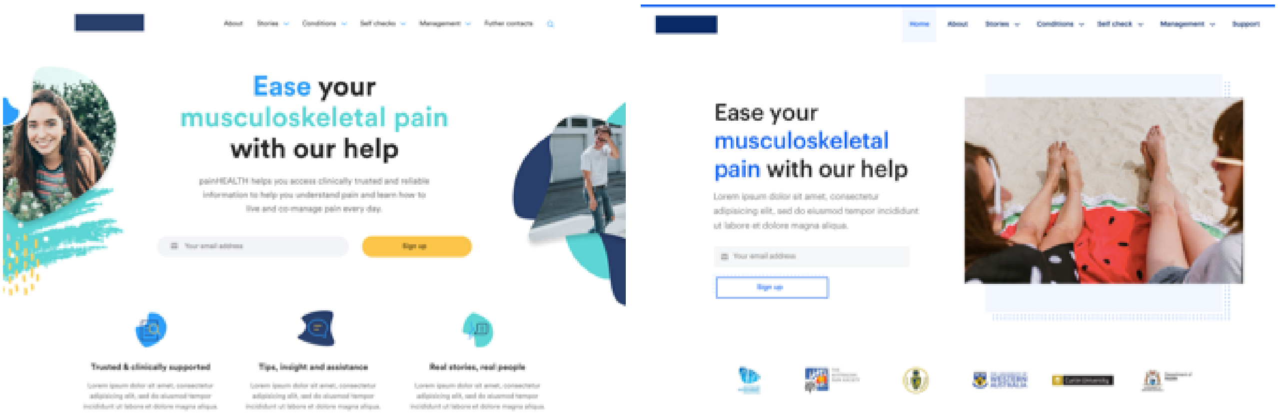
We implemented *Lookback* as the test platform, using the *LookBack Live* option. *LookBack Live* allows users and researchers to engage and communicate together in real time with a website (in this case, pain*HEALTH* and website prototypes) via a shared screen, with reactions, comments, behaviors, and interactions captured via downloadable audiovisual recording. This platform provided a good *fit for purpose*, enabling flexible scheduling, remote user access, and participants use of their own computers or mobile devices without the need for additional cables or cameras. User insights are denoted by a researcher's use of *time stamps*, with additional capacity for taking technical notes within the test platform that can later be extracted in text and recorded form. A rapid cycle of prototype iteration was undertaken at each group's completion of user testing.

Before implementing the user testing, the LookBack Live platform and user tasks were piloted by members of the research team (HS, AMB, JNS, and CL). Minor amendments were made to the user tasks to improve clarity regarding tasks. Participants were scheduled to a time slot, emailed a unique LookBack Live invitation link, and provided with instructions for the session. Participants were informed that the user testing was about the prototypes (and not themselves) and they "can't do or say anything wrong" and to "think aloud" as much as possible. The total mean duration of the web-based prototype testing was between 60 and 90 min.

Participants were tasked with evaluation in the following order:

- The pain*HEALTH* website: This website was used as a control site to help orient participants toward the look and feel, functionality, and content of a contemporary, consumer-focused, Australian musculoskeletal pain website [30]. Users were guided through 4 tasks covering interactive content (pain conditions and stories, self-checks, and pain management) on musculoskeletal pain care.
- Two newly developed prototype websites (Figure 2): Prototype 1 was characterized by soft round shapes with a palette of purple/yellow/pink, and prototype 2 featured a geometric design with a blue/black palette). Content for the prototypes was adapted from the pain*HEALTH* website for the evaluation tasks. The prototype websites were powered by InVision (digital product design).

Figure 2. Screenshots of the 2 prototype websites: to the left, the round, soft version is shown, and to the right, the geometric version.



Participants completed the same 4 tasks across each of the 3 websites (Multimedia Appendix 2). Each test task was contextualized by: (1) a background statement about the nature of the task, (2) instructions to guide the specific task required, (3) specific questions about each task to gauge feedback, and (4) any additional feedback. The 4 test tasks were as follows

1. Find and watch *Daniel's pain story*: This video/text content captured a young person's narrative around their experiences with low back pain.
2. Find and complete the '*Örebro Musculoskeletal Pain Self-Check*': This self-check questionnaire is designed for use across musculoskeletal pain conditions to predict the risk of higher estimated disability [34], and users can print out their score to share with health professionals.
3. Find and read the *Making Sense of Pain* management module: This content is focused on reasons why pain can persist beyond normal tissue healing times and the need for tailored holistic and integrated pain care.
4. Find *Further assistance*: This page provides a list of West Australian pain services and links to a cross-discipline health professional listing managed by the Australian Pain Society.

These test tasks were designed to reflect user-centered eHealth design principles [20] and criteria that predict real-world user engagement [20,36,37], specifically:

- Navigation
- Usability (functionality and ease of utilization)
- User engagement (content presentation, interactive, not irritating, targeted/tailored/personalized, captivating, and relatability)
- Content (appropriate level of literacy, credible, clear, and concise)
- Acceptability (design look and feel, meets the expectations of young people with musculoskeletal pain, motivating, and likability).

Engagement criteria were intentionally mapped across the task tests, with some overlapping of criteria (Table 1) to enable meaningful interpretation of outcomes and inform prototype iteration.

Table 1. Four test tasks were mapped, as per ticks, to reflect specific electronic health evaluation criteria.

Design and quality criteria	Test tasks			
	Daniel's story	Self-check[a]	Making sense of pain	Further support
Navigation	✓	N/A[b]	N/A	✓
Usability	N/A	✓	N/A	✓
User engagement	✓	✓	✓	✓
Content	✓	✓	✓	✓
Acceptability	✓	✓	✓	✓

[a] Self-check refers to validated self-report questionnaires.

[b] N/A: not applicable.

Phase 2. iCanCope With Pain App User Testing

For phase 2, we adapted the framework developed by Stinson et al [16] for guiding young people's use of the *iCanCope with Pain* integrated web- and smartphone-based app [16,31]. The specific app features [16] tested included:

- Symptom(s) check-in
- Structured goal setting to improve pain and function
- An interactive toolbox for pain coping strategies
- Access to papers to support users understand and manage their pain, mood, sleep, activity, and social function.

Participants were contacted by email within 2 days of completion of phase 1 and provided with the following standardized information (Multimedia Appendix 3):

- An overview of the *iCanCope with Pain* app (why it was developed, how it is currently being used, and by whom) and a link to the *iCanCope with Pain* website
- Features of the app used to support the self-management of pain (tracking and monitoring function; tracking your sleep, mood, physical activity, and energy levels; setting realistic goals; coping tools; and resources to support care)
- Instructions on how to access the app (via the app store) and sign in using their unique independently generated user name and password.

Instructions also outlined 4 key tasks for participants to complete:

1. Setting up their individual user profile (pain areas, triggers, pain intensity, interference, mood, sleep, physical activity, and energy)
2. Setting up their individualized goals aimed at improving their functioning in 5 main areas (physical activity, sleep, social, mood, and energy) and monitoring their progress against these goals
3. Symptom tracking over the 7 days to self-monitor progress (including pain, interference, mood, sleep, physical activity, and energy) and captured in the form of daily *check-in* reports
4. Accessing and exploring the library and the community resources designed to support their pain management (topics including nutrition, mood, sleep, work and study, social activities, self-worth, coping with pain, dealing with setbacks, talking to friends, employers, and teachers about pain).

Once set up and having completed these initial tasks, participants were encouraged to use the app daily to self-track and monitor their progress over the following 7-day period, while also using the app as they wished. Data extraction was performed by a team member (QP) blinded to phase 1 outcomes.

Phase 3: Semistructured Interviews

In the final phase, individual in-depth interviews were undertaken with participants about their experiences of using these 2 digital tools (website and app). The interview schedule was developed by a multidisciplinary research team (including clinical researchers with experience of musculoskeletal pain [HS, JNS, AMB]) and informed by prior user testing of these digital platforms [16,30] and our research on young people experiencing musculoskeletal pain [1,14] (Multimedia Appendix 4). Before the interview, participants were contacted (JEJ) to outline the interview process and schedule a time for the interview, in a quiet location chosen by the participant. All 15 interviews were conducted via teleconferencing by a senior qualitative researcher (JEJ) with experience in interviewing young people with musculoskeletal pain and who was independent of phase 1 and 2. No participant requested a support person during the interview. Interviews were audio recorded (duration ranged between 14 and 36 min, mean duration 21 min) and transcribed verbatim. Verbatim transcripts were checked for accuracy.

Data Analysis

Phase 1

User insights and feedback were extracted at the completion of each group's cycle of testing. These text-based group data were recorded in an Excel spreadsheet, aggregated (BL), and mapped against the established eHealth criteria (HS; Table 1). These data were discussed by members of the team (HS and BL), and a consensus reached about what iterations should be implemented. Rapid cycles of prototype iteration were then undertaken and implemented before the next cycle of group testing. Therefore, 3 cycles of prototype iteration were undertaken and implemented (between groups 1 and 2, between groups 2 and 3, and 1 final cycle at the completion of group 3 testing).

Phase 2

Participant engagement over the 7 days of testing was captured and evaluated through an Analytics Platform to Evaluate Effective Engagement (APEEE) with digital health interventions [38]. APEEE is a dynamic, real-time analytic platform that captures and characterizes user app engagement. Outcomes from APEEE included the following:

- Total number of full check-ins (completion of all relevant domains), time taken to check-in (min/second), check-in by domain (pain activity, mood, physical activity, sleep, and energy). Note that sleep can only be logged once per day.
- History views (number of times each symptom domain was reviewed: pain, interference, activity, mood, sleep, and energy). Note that pain intensity is the default history domain, with users having to toggle to view other domains.
- Goals set (number and domain: activity, sleep, energy, mood, social).
- Library articles accessed (number and type).

Phase 3

The 15 verbatim transcripts were analyzed (coded) by 1 researcher (JEJ) in 3 sequential stages (ie, 3 sets of 5 transcripts) using inductive and deductive approaches. In the first stage, 5 transcripts were analyzed using a general inductive analytical approach, where codes were directly derived from the data or from *the ground up*, without starting from a prior theoretical understanding of the issue being explored. For the second stage, the coding framework inductively derived from the first five 5 transcripts was then utilized to deductively code the second set of 5 transcripts. When a new topic emerged from the data, a corresponding code was developed inductively. In the third stage, to verify data redundancy, the revised coding framework was applied to the final set of 5 transcripts. No new codes were added to the framework in this final stage of the analysis. By utilizing a combined inductive and deductive analytical approach, which involved a constant comparison of data over a period until no new topics emerged (data redundancy), a comprehensive profile of participant preferences and experiences was developed. Following the finalization of the coding framework, codes were reviewed, and key themes and corresponding subthemes were developed through an iterative process of grouping codes into concepts, reviewing transcripts, and refining themes. The interview schedule was intentionally divided into 4 parts: (1) general background/context (questions 1 and 2); (2) perceptions of the pain*HEALTH* website functionality (question 3); (3) perceptions of the *iCanCopewith Pain* app functionality (question 4); and (4) perceptions related to the acceptability, use, and implementation of the 2 digital tools generally (questions 5-13). This enabled the analysis of transcripts to be undertaken for each part of the schedule as mutually exclusive categories. Key themes and subthemes aligning to each part of the interview schedule were then reviewed (HS, AMB, and JEJ) and grouped under overarching (meta) themes [39]. One-third of the interview transcripts (n=5) were independently analyzed (JNS and CL) to confirm themes identified, and where necessary, refined to reach consensus, and confirm the construct validity. Data were structurally organized to present themes in a logical explanatory scheme [40].

We evaluated the extent to which our inductively derived data mapped to an evidence-based eHealth roadmap (the latter, extensively reviewed elsewhere) [20]. The roadmap takes a holistic approach to the development of eHealth technologies, integrating persuasive health technology theories with business modeling (efficient, effective, and sustainable) to improve the uptake and impact of eHealth technologies in practice. The roadmap is agnostic to digital platforms, is inherently fluid, interactive, and allows for a cyclical approach to the co-design (acceptability, functionality, and usability) and implementation of digital technologies in real-world settings. The roadmap provided a good *fit for purpose*, the plurality allowing for analysis of content relevant across both digital platforms (specifically, contextual inquiry, user requirements, value specification, co-design, and operationalization, referred to here as implementation).

Results

Demographic and Clinical Characteristics

A total of 20 potential participants met the inclusion criteria and consented to participate (Table 2). Of these 20, 15 (75%) participated and completed all 3 phases of the study, and 5 recruits did not start the study for various reasons (2 unwell, 2 for personal reasons, and 1 did not respond to email contacts or phone follow-up). The majority of these 15 participants were female (12/15, 80%) and resided in Western Australia (13/15, 87%). The mean age of these participants was 20.5 (SD 3.3) years.

For those participants with a confirmed medical diagnosis (10/15, 67%), musculoskeletal conditions included Ehlers-Danlos Syndrome (n=2), fibromyalgia (n=4), endometriosis (n=1; comorbid with back pain), rheumatoid arthritis (n=1), scoliosis (n=1), sacroiliitis (n=1), hip labral tear (n=1), and low back pain with nerve-related leg pain (n=1). For those reporting no confirmed diagnosis, conditions primarily related to low back/neck pain or upper/lower limb muscle or joint pain.

Table 2. Demographic and clinical pain characteristics of consenting participants (N=20).

[a] TAFE: Technical and Further Education Institutions.

[b] Pathway for university entrance.

[c] ÖMPSQ-SF: Örebro Musculoskeletal Pain Screening Questionnaire-Short Form, possible score 1 to 100.

[d] Total count may be greater than the number of participants as more than one area of pain could be nominated.

[e] Areas of pain nominated in free text included abdominal pain (n=3), coccygeal pain (n=1), migraine (n=3), gastrointestinal issues (n=2), dysmenorrhea

(n=1), and nerve pain (n=1).

Phase 1: pain*HEALTH* and Prototype Website User Testing Outcomes

Outcomes from user testing of websites provided rich insights across the 3 groups. Outcomes are summarized sequentially by groups (1, 2, and 3) with recommendations derived to inform each cycle of prototype iteration, shown in Textboxes 1 to 3, respectively. A comprehensive tabulation of these data mapped by group to design criteria (navigation, usability, user engagement, content, and acceptability) with supporting user insights and quotes is provided in Multimedia Appendix 5.

For group 1, outcomes are summarized in Textbox 1. Participants leaned more strongly toward preferring the *round and bright* prototype variation. Compared with the control site, participants liked the use of dropdowns (easier navigation) and self-check functionality enhancements (better user experience for quiz completion). The *Further Support* menu did not resonate well with participant expectations, as this suggested *technical support* for some. Simplifying language and the use of a glossary were perceived as enhancements that would improve user engagement. On the basis of these outcomes and discussions with members of the team (AMB, JNS, BL, and HS), a consensus decision was reached to proceed with the *round and bright* prototype only. Collectively, these data informed the first rapid cycle of prototype iteration, implemented before group 2 testing.

Textbox 1. Recommendations for prototype iteration based on insights from group 1 participants.

- Navigation: add drop-down menus throughout the prototype website to facilitate navigation and improve user engagement.
- Usability: *self-check* improvements included providing an explanation about what the self-check results mean to help reduce anxiety and fear about the results and the addition of explanatory text about who to see (health professional) and why.
- Content and user engagement: simplifying text, chunking text, and use of bold quotes to highlight key messages.
- Acceptability: *Further Assistance* changed to *Further Help* to capture both the listing of resources, services, and links to health professionals.

Group 2 insights indicated overall positive responses to the colorful prototype iterations and informed further recommendations for iteration (Textbox 2; Multimedia Appendix 5). Participant insights highlighted the ease of navigation, usability (functionality), engagement, content, and acceptability compared with the pain*HEALTH* website. Recommendations to inform the second cycle of prototype iteration were implemented before group 3 testing.

Textbox 2. Recommendations for prototype iteration based on insights from group 2 participants.

- Navigation: enhance the navigation bar to ensure it is *sticky* on every page (ie, the navigation bar follows the user as they move up and down a page); implement hyperlinks to open external websites in a new tab; improve identification of external hyperlinks versus internal; add global navigation to the self-check, with the removal of progression steps; inclusion of a progress bar/percentage; remove lifestyle image on self-check start page; and use a smaller icon to reduce the need for users to scroll to start the self-check quiz.
- Usability: for the self-check, revise the text to better explain what the self-check is, why a user would complete it, and how they can use this information.
- User engagement: introduce categories within the management modules to better direct users to relevant content and further optimize and enhance user engagement and acceptability.
- Content: review website content and optimize for a younger reading audience (the appropriate level of health literacy) with even more *chunked content* and amend *Further Contacts* further, adding 3 tabs to be meet user expectation about related page content and to reduce the volume of contacts listed on the page into clear groupings to be easily scannable.
- Acceptability: color palette optimization to improve the relatability for the targeted age range using a softer palette of welcoming blues and engaging yellows that still *feels* young; drop the pinks and purples to ensure accessibility for color-blind individuals.

Group 3 participants indicated a positive overall response to the prototype compared with the control site (Textbox 3; Multimedia Appendix 5), with all indicating that the color palette was engaging and fun and nicely targeted toward a younger demographic. Feedback highlighted an improved user experience in navigation, with no further issues reported. Self-check functionality enhancements were well received. One participant raised the possibility of implementing screen reader functionality to help improve readability (when required). Compared with the control site, the use of chunked information and larger font size made for easier readability. Compared with the control website, this prototype was perceived by group 3 participants as providing a good example of a holistic, integrated approach to young people’s pain, making it easy to find, research and understand their pain. To further support and explain content, the use of more illustrations/videos within the management modules was proposed. Overall, participants found the website acceptable, reporting the look and feel as engaging, fun, relatable, and appropriate to their demographic. Collectively, group 3 insights guided the final prototype iteration recommendations.

Textbox 3. Final recommendations for prototype iteration based on insights from group 3 participants.

- Usability: consider screen reader functionality to support users or consider extracting the audio from website videos, loading these as audio files. For longer form content, capturing readings of content, to then create downloadable audio files.
- Content: the use of a sidebar section that can act as an *anchor link* that is sticky and follows the user up/down the screen and scrolls their viewpoint to the contact area to further assist finding relevant contacts.
- User engagement: embed images that are resonant of the specific pain management module the content is about (eg, an image or icon of an activity or walking for *Movement with Pain*) to help differentiate the management module content and better assist, engage, motivate, and relate to the user.

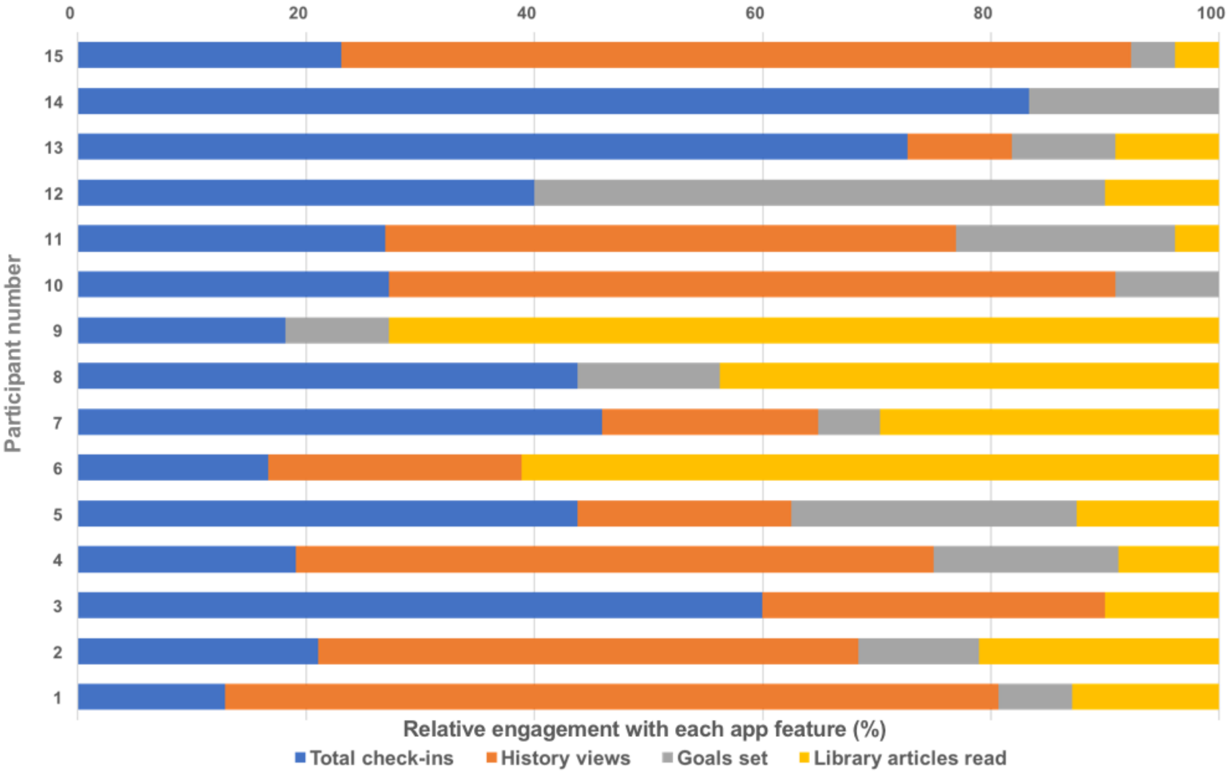
Phase 2 Outcomes: *iCanCope with Pain* App

Participants' engagement data for the use of the *iCanCope with Pain* app are summarized in Table 3 and Figure 3. The group mean (SD) and median frequencies for specific app features were: check-ins, 7.3 (4.0), 7.0; history views, 10.5 (12.8), 4.0; goals set, 2.8 (2.8), 2.0; and articles accessed, 4.2 (3.9), 2.0. Over the week of app use, all participants checked in, with 183 check-ins initiated. Of these, 59.6% (109/183) were full check-ins, meaning completion of all 5 domains (sleep, mood, physical activity, and energy levels). The highest frequency of full check-ins was attributed to pain intensity (183/183, 100.0%), followed by pain interference (175/183, 95.6%), and then mood (152/183, 83.1%). Attrition for check-ins was more common for domains covering physical activity (120/183, 65.6%) and energy (109/183, 59.6%). Note that the sleep domain is only asked once per day regardless of the number of times participants checked in each day (therefore, no denominator provided), which explains the lower number relative to other domains (n=72).

Table 3. Individual participant engagement data for the use of the *iCanCope with Pain* app over 7 days.

Participant ID	Full check-ins, n	History views, n	Goals set, n	Library articles accessed, n
1	4	21	2	4
2	8	18	4	8
3	6	3	0	1
4	13	38	11	6
5	7	3	4	2
6	3	4	0	11
7	17	7	2	11
8	7	0	2	7
9	2	0	1	8
10	6	14	2	0
11	7	13	5	1
12	4	0	5	1
13	8	1	1	1
14	5	0	1	0
15	12	36	2	2

Figure 3. Individual-level data are shown for participants 1 to 15 (vertical axis). Relative user engagement (horizontal axis, proportional frequencies, and ranges for each domain) is presented across 4 key domains: (1) total (full) check-ins (blue), range 2-17; (2) history views (bright orange), range 0-38; (3) goals set (gray), 0-11; and (4) library articles accessed (light orange), range 0-11. Note that it is the variable relative engagement of each individual with the features of the app.



A total of 73.3% (11/15) participants completed a total of 158 history views over the week of app use (ie, monitoring their progress over time), with a variable frequency of views for each domain. The highest frequency of domain history views related to pain intensity (51/158, 32.3%), followed by pain interference (24/158, 15.2%), activity (22/158, 13.9%), mood (21/158, 13.3%), sleep (19/158, 12.0%), and energy (18/158, 11.4%).

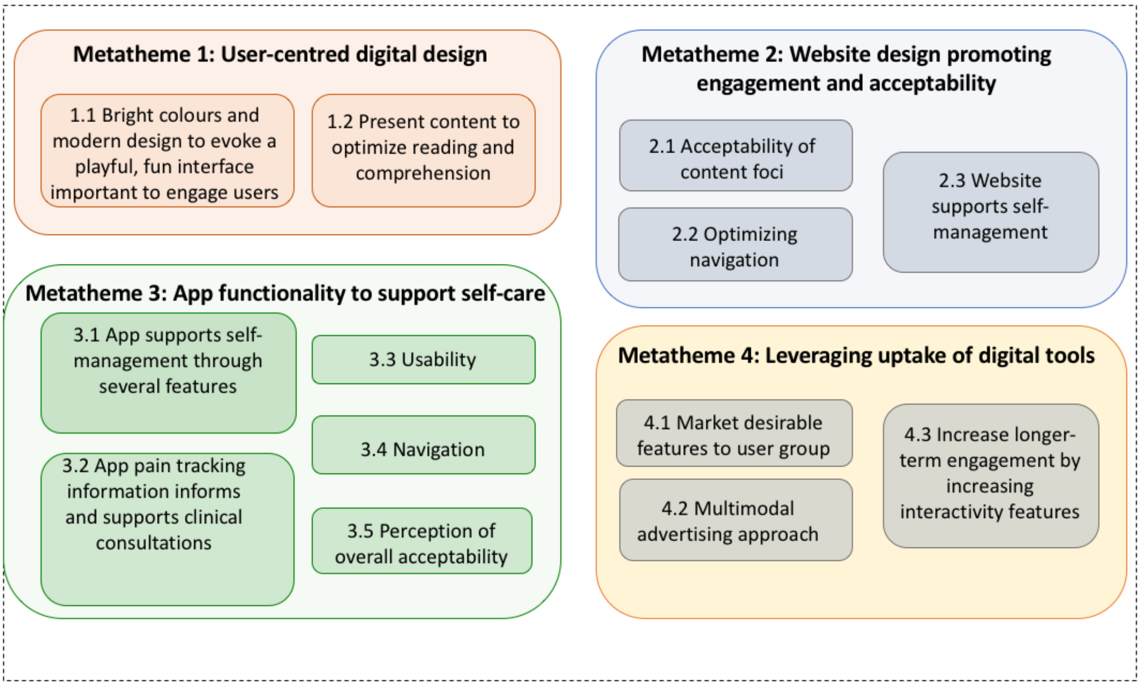
For the *goals set* feature, 86.7% (13/15) of participants set a total of 42 goals covering 5 areas. The most frequently set goals were for activity (35/42, 83.3%), with fewer for sleep (4/42, 9.5%), energy, mood, and social activity (1/42 for each, 2.4%). Over the week of app use, 63 articles were accessed through the app library by 11 (73.3%) participants. Articles focused on the following content areas (listed most to least frequently accessed; note *n* may be greater than participant numbers, as more than one article could be categorized within 1 content area):

- Making sense of pain (16/63, 25%)
- Sleep hygiene (14/63, 22%)
- Behavioral approaches to pain (coping and mood management; 10/63,16%)
- Activity planning, pacing, and goal setting (8/63, 13%)
- Communicating pain (4/63, 6%)
- Exercising with pain (4/63, 6%)
- Managing fatigue with pain (2/63, 3%)
- Condition-specific care (neuropathic pain; 1/63, 2%)
- Motivation and adherence (1/63, 2%)
- Nutrition (healthy eating habits; 1/63, 2%).

Phase 3: Qualitative Interview Findings

Findings are presented according to a hierarchical structure aligned to the qualitative data analysis methods, with 4 overarching metathemes identified, supported by themes and subthemes (Figure 4). An overarching summative statement for each metatheme is provided in the text later in the paper. Further details for metathemes, including specific themes and subthemes with supporting quotes, are summarized in Textboxes 4 to 7, respectively. A comprehensive tabulation of all findings is provided in Multimedia Appendix 6.

Figure 4. Graphic summary of metathemes and themes derived from qualitative interviews. Metathemes were as follows: user-centered digital design (orange), website design promoting engagement and acceptability (blue), app functionality to support self-care (green), and leveraging uptake of digital tools (yellow).



Metatheme 1: User-Centered Design Features Resonating With Young People's Needs

User-centered design features perceived by participants across both digital platforms as reflecting specific youth-focused digital tools included vibrant color palettes, playful nonlinear shapes, and engaging interfaces that motivated them to interact with the digital tools. Participants described content across both platforms in a manner that was relatable and engaging for young people, with the use of simple language, a variety of formats to deliver information, and chunking of text, rated as preferred features (Textbox 4).

Textbox 4. Metatheme 1: user-centered digital design.

Bright colors and modern design that evoke a playful and fun interface are important features of digital tools (website and app) to engage users

- Vibrant colors associated with being youth-focused

  "I felt like the colours were good. I felt like the design was youth-focused, but not necessarily exclusively youth-focused, if you know what I mean? If a 50-something year old were to look at it [the app], they wouldn't just be like, 'Oh, this is dodgy.'" [Participant number 11; app]

- Vibrant colors associated with eliciting positive emotions

  "I really enjoyed the bright colour scheme with the blues and the purple and the pinks. I thought it was really calming and really interesting, as well, for a young audience." [Participant number 9; website prototype 1]

- Different shapes, curved edges, lots of images, and illustrations are modern design features that appeal to users

  "I really enjoyed how the layout was all the bubbles instead of being just straight text or in boxes, it seemed really interesting and fun." [Participant number 9; app and website]

Present content to optimize reading and comprehension

- Use of different formats to deliver information (eg, video, audio, text, illustrations)

  "I found it all very easy to read. It was nice big font with a good balance between images to break up the text, as well as videos and stuff like that as well." [Participant number 3; prototype websites]

- Careful attention to font—the size, type, and color all impact readability (particularly if user is feeling unwell/fatigued)

  "But the writing itself is a decent size, so for anyone that does have a bit more trouble with that, like if they do have a headache, the fact that it's a bit bigger is better as well." [Participant number 1; app and websites]

- Using positive, nontechnical language, and less formal wording to enhance engagement

  > *"I guess the thing that struck me the most, I guess, in a good way was how it was sort of almost unprofessional, like it was just asking these questions with almost like childish cartoony images."* [Participant number 3; app]
  >
  > *"It's not 'for kids,' there's no being spoken down to at any point with this site."* [Participant number 10; website]

- Short and concise information with links to additional information/external resources

  > *"The shortness of them, the conciseness is pretty helpful as well, so I can just sit down for 5 minutes, read it and then take it on, see if it works and if it doesn't work, find another one, like, find a method to suit me better."* [Participant number 14; app and prototype website]

Metatheme 2: Website Design Promoting User Acceptability and Engagement

Participants identified features of the website prototypes that aligned with their preferences for acceptability, ease of navigation, and usability of digital tools. Acceptability here referred mainly to the information being relevant to participants (Textbox 5). Where content was too text-heavy (ie, pain*HEALTH* website), participants suggested modifying density by *chunking information*, using *callouts*, and greater use of supporting images/interactive features (such as video content). Participants liked the use of real-world patient stories on the websites, which resonated with their individual experiences of pain, reduced feelings of isolation, and showed how others had learned to cope with their pain. Navigation features that motivated participants to engage with the website included drop-down menus, clear website layout, simple design, use of a search bar, and minimal clicks to get to relevant content. Participants expressed enthusiasm for a tailored website specific to the needs of young people with pain. Features including meaningful pain management information, practical tips, real-world pain stories, and insights into condition-specific care were positively perceived to support their pain self-management.

Textbox 5. Metatheme 2: website co-design promoting user acceptability and engagement.

Acceptability of content foci

- Information matches user needs

  > *"It's got plenty of information on different types of pain, things like sleep, which is really helpful as well 'cos that's a big part of it, and also information on who you could speak to if you're having further issues, which is really nice as well because there's not a lot of that information elsewhere."* [Participant number 11; pain*HEALTH*]
  >
  > *"Also, I found that the stories themselves are pretty handy… I think it shows me that I'm not the only one doing it, but they're also demonstrated methods of coping with it within their everyday life. That was the key bit."* [Participant number 14; pain*HEALTH*]

- Information pages too text-heavy and need to be broken up with the use of images, diagrams, and callout text features

  > *"I felt further work could be done to improve things like having a lot more figures and images in the text, so like the articles or explanations, having a lot more diagrams that are explaining some of the science."* [Participant number 22; pain*HEALTH*]

- More information wanted on services available and how to access help

  > *"...I think the Help section, where it gave the list of the hospitals and healthcare centres, that needs to be a bit more refined so that it's easier to see what you were looking for. I'd like to see a website, like a hospital website and then further contact details on that website or instructions on how to get to the details on the service and what they can do."* [Participant number 6; website prototype 1]

Optimizing navigation

- Drop-down menu feature widely liked and assisted easy navigation

  > *"Everything is easy to find because it's labelled very nicely at the top there for you and it's all dropdown, so it's really easy to go into what you're looking for."* [Participant number 1; website prototype 1 and 2, version 1]

- Website layout design clear and easy to use

  > *"It's very clearly laid out and really easy to navigate without being, I don't know, patronising. I've been on patronising information sites before."* [Participant number 10; website prototype 1]

- Search bar considered an important feature that would assist looking for specific information

  > *"The search bar would make it easier, but it was pretty straightforward and I was able to find what I was looking for."* [Participant number 4; website prototype 1 and 2, version 1]

- Preference for minimal clicks to access information

  > *"Probably an update to the home page so when you click on the menu bar you don't go to another page that's got all the links there, you actually just go directly to the page that you're looking for from the menu bar."* [Participant number 14; website prototype 1]

Website supports self-management

> *"It's amazing to think that things like this are coming out because when you first get diagnosed or whatever there really aren't places like this. So it's exciting to see that people are starting to think about this. It's great."* [Participant number 12; website prototype 1]

Metatheme 3: App Functionality Supporting Pain Self-Management

Participants identified multiple app functionalities that they perceived supported active self-management of their pain. Notably, the daily check-in was seen as encouraging self-reflection and identification of broader factors that may impact their pain, whereas pain tracking information was useful in supporting their pain care through positive behavioral change and guiding clinical pain encounters (Textbox 6).

Usability features that motivated participants to engage with the app included the daily check-in (easy to use), content prompts based on input from check-ins (eg, mood management), and being able to connect with young peers. Participants identified several app functionalities that could enhance daily check-ins, including:

- Ability to set a flexible check-in time that suited their daily routines (versus the standard midday check-in)
- Functionality that allows for mapping output from daily activities and personal diary functionality for reflection/reminders
- Retrospective diary entry capability (in case of missing a day of entry)
- Capacity for entries in different pain areas (ie, pain intensity)
- Alternate mechanisms for ratings at check-in (versus spin a dial)
- Reminder notifications remain active until you have completed a task.

Enhanced functionality to improve self-management included enabling more specific alignment of user goals with measurable outcomes (ie, what goal did you set? did you achieve the goal?) and a metric to map outcome (eg, how much exercise did you achieve?) tailored to the individual. Some participants suggested improved functionality to enable printing and emailing of pain tracking information would be beneficial, as would the ability to personalize an avatar. Participants were largely positive about app navigation functionality, with features indicating strong usability highlighted as intuitive design, ease of use, and accessible content. A majority of participants (10/15, 67%) disliked the app icon *Copey*, indicating that it was more appropriate for younger users. Overall, the app was acceptable to all participants and perceived as a valuable digital tool to promote self-management of pain, with 24-hour access via their smartphones, enabling a flexible fit within their daily routines.

Textbox 6. Metatheme 3: app functionality to support young people's pain self-management.

***iCanCope with Pain* app supports self-management through several features**

- Daily check-in encourages self-reflection and identification of broader factors that may impact on pain

  > *"So I think it was good for bringing to light some of those things, because normally you wouldn't typically finish your day and be like, 'I was in a lot of pain today. Why was I in a lot of pain?' and this helps to start those, I suppose."* [Participant number 3]

- Pain tracking supports positive pain care behaviors (monitoring, self-reflection, goal setting, coping, and progress over time)

  > *"It was interesting to see how much sleep I got related to my pain and my mood etc... It's like, maybe I should sleep more."* [Participant number 6]

- Encourages setting of goals and monitoring progress

> *"That was awesome. That part was really good because you can track personally what your goals are, when you've completed them, whether they're short-term goals or long-term goals."* [Participant number 13]

Utilize pain tracking information to inform and support clinical consultations

> *"I think it could be used for both, like for just monitoring it yourself. If health professionals need to see how it's changing, that would be a good tool for them to use."* [Participant number 4]

Usability

- Daily check-in feature engaging and easy to use

> *"I just like how easy it is. It doesn't take very long to check-in and it's very easy to see how it's changing and what's impacting it."* [Participant number 4]

- Information interactivity features appealing

> *"I think after you enter it for three days it starts giving you some recommendations and patterns, which was nice. It gives you feedback and I think it was giving some suggestions of articles, which was good, then you click on them and start reading."* [Participant number 7]

- Copey, a divisive character—mixed perceptions regarding the acceptability of the app icon for the target user group

> *"I quite liked it, but I think it might be a bit too childish for my demographic. The icon is iconic, but I think that's what is making it childish for the younger group."* [Participant number 6]
>
> *"I think it is. I think it's a little childish, but I think that young adults are returning to enjoying more childish things...maybe having the icons be a little bit more adult."* [Participant number 9]

- Multifaceted improvements for daily check-in feature

> *"Yeah, it doesn't have anything that specifies [what time] I'm checking in and also it seems to let me check in multiple times a day."* [Participant number 10]

- Greater functionality (design features) to support end user self-management

> *"Also with the 'My Goals', I think it would be important to link that to your normal check in every day. The information that you provide in your 'My Goals' may be relevant to your check in in terms of exercise, sleep, or how you're feeling today."* [Participant number 7]

- Provide different mode settings to enable tailoring the app 'look and feel' to each user

> *"The only thing I would suggest would be a change of background or some personalized settings so people can really make it their own and keep it engaging."* [Participant number 12]

- Scales used to rate physical activity need to be revised - not considered intuitive

> *"Physical activity levels being levelled from 'great' to 'the worst' doesn't really make a lot of sense. If it were in terms of minutes, that would, I think, be easier to navigate."* [Participant number 10]

Navigation

- Easy to use and intuitive

> *"The navigation around the app was, I felt, really intuitive and really easy."* [Participant number 2]

- More guidance on how to utilize functions not related to check-in

> *"So, I think the main ones obviously that I was using were doing the pain every day, but the other sections I wasn't too familiar with or understanding well. Yes [more guidance on other sections], because I think the reason I stuck to the first one was because I was instructed how to use it."* [Participant number 15]

Perception of overall acceptability

- App was considered a valuable resource for monitoring and managing pain

> *"Yeah, I think the app I would probably use on a daily basis. The app I really, really liked. I don't know whether I'm still able to use it but yeah, if I'm still able to use it now then I'd love to. I think the app is just amazing."* [Participant number 13]

- App readily available using phone

> *"I thought that was so nice and I wish I had that when I was younger… as I said, it would just be so nice because you always have an information source on your phone and you could just use it whenever you needed it."* [Participant number 9]

Metatheme 4: Leveraging Uptake of Digital Tools

Participants provided rich insights into how both these digital tools could be leveraged to extend reach into the community and drive uptake by young people with pain. Key themes included marketing the app to potential users, highlighting key functionalities and features that enable tailoring the app to support their self-management (Textbox 7). Testimonials from current users were perceived as marketing opportunities, especially where the testimonial was linked to a social media account identifying a real-world person who had lived experience of pain. Marketing strategies that included wider promotion through health services or referral by health professionals were perceived by participants as effective ways to increase awareness about these digital tools and their value for self-management of pain. Social media was also advocated as a valuable platform to promote awareness and drive the dissemination of digital tools as well as linking (push) between the app and the (new) website. Some participants suggested promotion via not-for-profit arthritis organizations and educational institutions (schools and universities). To encourage sustained user engagement with digital tools, a few participants recommended a rewards-based design (ie, achieving levels of performance).

Textbox 7. Metatheme 4: leveraging uptake of digital tools.

Market desirable features to the user group

- How the tools can help the user

> *"I think curiosity drives young people. If you make it available and say that it'll help you track your pain and so on, I think that might motivate them for people who want to track or monitor what they did."* [Participant number 14; app]

- Testimonials from users

> *"I think people do often read what other people have to say about it, so I think that definitely [testimonials] would make a difference."* [Participant number 12; app and website]

Multimodal advertising approach

- Referral from a health professional which can be utilized both within and external to the clinical consultation

> *"…having that a doctors' surgeries or having doctors or other allied health, like physios or anything like that, refer it."* [Participant number 8; app and website]

- Social media advertising

> *"I think social media could be a big way. Particularly through Facebook or Instagram, having ads that pop up I think could be a good way."* [Participant number 8]

- Links through other websites

> *"But if it popped up on certain websites, like Beyond Blue or something like that as well, because I feel like a lot of them probably go onto those sorts of spaces to look for support... Yeah, because it makes it seem like it is more reliable and a better source of information if it is popping up on something like the government websites."* [Participant number 1]

- Promotion through educational institutions

> *"I think you've got to put the information out there and I think one way could be through maybe schools…'If you experience this pain, we've got these websites, we've got these apps, there are tools available'. I guess the same could go at a university or education system..."* [Participant number 8]

- Promotion through specific age relevant chronic disease organizations

> *"In WA, I know there's a thing called Camp Freedom, which is an arthritis camp with the JIA, but they talk about quite a lot of different apps, they hand out brochures and that kind of thing. So that is a really helpful way to get in as well, because all these kids are dealing with pain."* [Participant number 13]

Increase longer-term engagement with digital tools by increasing interactivity features

> *"I think there's a lot of really valuable information on the website and in the app, but I think it's that linking to actions and helping to guide people through thought processes, rather than just being information or data tallying. Because it will help engage people for longer with the website and with the services and with the app if they feel like they're making progress via the engagement with those online and app mediums..."* [Participant number 2]

Discussion

Principal Findings

This study aimed to test the acceptability, usability, and need for adaptation of 2 extant digital technologies to support the needs of young Australians with musculoskeletal pain. Overall, the participants' perspectives were positive on the acceptability and usability of both the final prototype pain website and the *iCanCope with Pain* app. In using these digital technologies, participants articulated the critical importance of designs being youth-focused, with colorful, fun interfaces that were relatable to promote young people's engagement in self-management of their musculoskeletal pain. Adaptation of the website prototype was required and informed by rapid cycles of iteration with a focus on improving user engagement. For the app, participant engagement highlighted the value of tailoring capabilities to support individualized pain self-management. Recommendations for app adaptations were modest and primarily related to enhancing functionality (more capacity to personalize the *look and feel*), improved flexibility (check-in time), and capacity to monitor outcomes from goal setting. Participant insights on leveraging these digital technologies to support young people's self-management emphasized the need for wider promotion, health professional *digital prescriptions*, and strategies to ensure longer-term engagement.

Strengths and Limitations

Strengths of this 3-phased mixed methods study included the following: (1) adherence to a user-centered eHealth design roadmap [20] reflecting value specifications, co-design principles, iterative cycles of prototype testing, and identification of factors relevant to implementation; (2) evaluation criteria that predict real-world user engagement [20,36,37]; (3) use of an innovative web-based testing platform *fit for purpose*, allowing remote user testing and reach across geographic barriers; (4) rapid cycles of website prototype design, testing, and iteration; (5) use of an analytics platform to evaluate engagement with capture extended over 1 week (user testing often conducted as a short, single session under laboratory conditions); and (6) mixed methods design, using a larger (user testing) sample, thereby providing rich insights on the acceptability and usability of these digital technologies and informing recommendations on the need for adaptation and suggestions to enable implementation.

Limitations included (1) the potential for gender bias given the dominantly female sample; (2) potential participation bias, with recruitment of young people who felt confident in sharing their experiences or who had directly experienced health services/resource gaps; and (3) although our sample is representative of young people from Australia (a developed country with a high-quality health care system), findings are not necessarily transferable to different health care systems, including those of middle or low-income economies.

Leveraging Digital Technologies to Support Young People's Self-Management of Musculoskeletal Pain

Leveraging these 2 digital tools (app and web-based) for pain that we have previously co-designed, developed, and evaluated [16,30], enabled us to rapidly create a digital test bed in Australia. Advantages included time and cost efficiencies, maximizing the use of current resources, and avoiding unnecessary duplication [19]. Accelerating this phase of our research program to support young Australian people with musculoskeletal pain [1,2,16] is critical [17,41], given the increasing burden imposed by musculoskeletal pain and the lack of an appropriately skilled health workforce [9,15,17]. Digital technologies such as those we have tested in this study provide an innovative approach to improving timely access to credible and practical self-management for young people with musculoskeletal pain and other chronic noncommunicable conditions [2,42,43], regardless of where they live [1]. This is particularly relevant in the current Australian digital landscape given the implementation of the National Digital Health Strategy [44] and the drive for innovative, sustainable digital technologies to support the implementation of health services and self-care of chronic health conditions [29,44].

User-Centered Co-Design Critical to Optimizing Acceptability, Usability, and Engagement

Collectively, the findings from our study highlight the importance of user-centered co-design from inception. Our approach is consistent with evidence derived from our recent systematic review of mobile health technologies for chronic noncommunicable disease management in young people, specifically recommendations on effective implementation [2] and the use of an evidence-based roadmap to increase the uptake and impact of eHealth technologies [20]. Our digital tools were perceived as being youth-focused, with a visual design that elicited positive user emotions and promoted active engagement, outcomes aligned with our primary study aims. The positive perceptions of young people on acceptability, usability, and potential engagement are consistent with qualities of product design that predict real-world user engagement with (app and web-based) eHealth interventions [36]. Furthermore, a recent study on design qualities that may predict user adherence to behavioral eHealth interventions in real-world use, found therapeutic persuasiveness (defined as *the incorporation of persuasive design/behavior change principles*) to be the most robust predictor of adherence (ie, duration of use and number of unique sessions), suggesting the importance of persuasive design and behavior change techniques incorporation during the design and evaluation of digital behavioral interventions [45].

Regarding adaptations, the optimization of the app was primarily related to enhancements in functionality (capacity to personalize the *look and feel*, scales for goal setting and monitoring of goals/outcomes, and time flexibility for check-ins). Use of the app over the week varied with individual participant engagement data, highlighting the value of flexible daily check-ins and tailoring capabilities to support individualized self-reflection and monitoring. A similar approach to testing cultural appropriateness, usability, and the need for adaptation of the *iCanCope with Pain* app has recently been undertaken in Norway [32], with preliminary outcomes indicating high levels of acceptability and usability, the only adaptations being the need for optimizing user interaction of the social support feature [32]. The app is currently being evaluated in a randomized controlled trial with a larger sample with chronic pain and juvenile inflammatory arthritis. Other derivatives of the *iCanCope with Pain* app have also been developed for various conditions in children and adolescents, including self-management of postoperative pain [46], sickle cell pain [47], and juvenile idiopathic arthritis [48], with the latter 2 currently undergoing evaluation [46].

Adaptation of the website prototype was guided by rounds of participant feedback, informing rapid cycles of iteration with a focus on improving user engagement. Recommendations for adaptation are mainly related to greater use of chunked information and call outs (key messages in large font that function as calls to action), optimizing navigation (sticky bars, search functions, and drop-down menus), and improving the information on accessing other services and resources to their support care (what services, what they offer, how to access them). These design recommendations were implemented in the final website prototype in preparation for the current (ongoing) phase of finalizing text and audiovisual content in collaboration with young people. This approach to co-design of content will ensure alignment to Australian user needs and preferences [1,14], while also ensuring consistent messaging and self-management domains between the website and the *iCanCope with Pain* app.

Operationally, the intention for future use of these 2 digital platforms in Australia is to offer complementary digital tools with different functions that can interact bidirectionally (eg, by use of push notifications). Such an approach offers flexibility in supporting both individualized tailored self-management (app), while concurrently providing the capacity for richer audiovisual content and resources specifically codeveloped with and for young Australians (website) and critically, explicitly linked to Australian health services and systems [2]. On the basis of our impact evaluation of the adult pain*HEALTH* website [30], digital platforms can operate as an important health strengthening tool [49], linking consumers/caregivers with their clinicians, services, and systems. We have also demonstrated that this approach promotes more holistic integrated pain care models [17,30] and enables consistency of messaging between consumers and their clinicians (eg, sharing of short targeted audiovisual content during clinical consultations about other people's pain experiences, and how they have implemented positive evidence-based behaviors to improve their pain care). The web-based platform will also include contemporary, evidence-based condition-specific musculoskeletal knowledge (eg, about low back pain and juvenile inflammatory arthritis) with links to best practice pain self-management (eg, making sense of pain, pain education, coping skills and behavioral approaches to pain, encouraging movement, activity and exercise with pain (pacing), appropriate use of medicines) [16,50]. Additional advantages of a web-based platform include the capacity for real-time updating at lower resourcing and cost than app-based technologies, multiple-platform compliance (ie, capacity for use on various devices), easy access, and linking to other entities (eg, consumer, tertiary educational, and health professional bodies). Advantages of the app included empowering young people to take *their health in their hands*, supported by individual tailoring abilities of the app, informed by check-ins, with self-monitoring and self-reflection supporting helpful habits (behavior change) and complementing clinical care.

Conclusions: Insights and the Next Steps

Outcomes from current, ongoing trials of the effectiveness of the *iCanCope with Pain* app will help to inform our decision on the most appropriate approach to evaluate the implementation of these digital technologies in Australian pediatric pain care settings. We envisage the use of a contemporary and flexible evaluation approach that moves beyond traditional effectiveness designs to consider alterative hybrid trial designs [51] or multidimensional and whole-of-system evaluation approaches, such as a *benefits evaluation* [52] that is best aligned to the Australian digital ecosystem and positions these digital tools for real-world implementation [51]. The adaptation of user-centered design and implementation science methods from inception (such as done here) can mitigate the risk of low rates of implementation and the associated research waste [19]. In this context, we gained valuable insights from young people to support and enable implementation, including taking a *whole-of-health* (systems, services, and clinical-level) approach to facilitate real-world dissemination and embedding. These findings are in accordance with recommendations from our recent systematic review of mHealth technologies for noncommunicable chronic disease management in young adults [2].

Digital technologies are positioned to enable the rapid transformation of health care, with their critical role highlighted by the release of the first World Health Organization guideline establishing recommendations on digital interventions for health system strengthening [53], and more recently, local recommendations for transforming health in Australia [54]. The outcomes from this study are, therefore, timely considering the reorientation of health services and system reform toward better integrated management of chronic health conditions [55], healthy aging across the life course [56], and the expectations of young people with chronic musculoskeletal pain for access to evidence-based digital tools to support their self-management [1]. Although we are cautious and thoughtful about the many broader research questions that remain on the evidence for the use of digital technologies in health care innovation (consumer needs and preferences; synergy with current services and systems; capacity to interface with current health systems, services, and workflows; achievement of broader system goals; and stability and sustainability), we suggest that this should not be a reason to accept the current default position in Australia, where many young people with musculoskeletal pain do not have timely access to reliable evidence-based services and resources that promote and support helpful behaviors and improved well-being.

Acknowledgments

This research was supported by grant cofunding awarded from the Government of Western Australia, Department of Health, Health Networks (2018_2436) and Arthritis and Osteoporosis WA, with in-kind support from the School of Physiotherapy and Exercise Science, Faculty of Health Sciences, Curtin University. The funding organization had no influence on the study design, collection, analysis, and interpretation of data or on the writing of the manuscript and the decision to submit the manuscript for publication. The authors wish to thank the staff at Improving Outcomes in Child Health through Technology Laboratory, SickKids Hospital, Toronto, Canada, for assistance with providing codes for access to the *iCanCope with Pain* app and for piloting use of the LookBack platform. The authors also acknowledge the support from the Institute of Health Policy, Management and Evaluation, Dalla Lana School of Public Health, University of Toronto, and the Centre for Global eHealth Innovation, Techna Institute, University Health Network, Toronto, Ontario, Canada, for the use of APEEE.

Authors' Contributions

HS, JNS, and AMB conceived and led the study. HS, AMB, JNS, and J Cafazzo procured the funding, and HS, JNS, JEJ, AMB, BL, J Chua, CL, QP, and J Cafazzo contributed to the study methods. BL, J Chua, and HS analyzed the web-based phase 1 data, and QP analyzed the phase 2 engagement data (APEEE). JEJ collected and analyzed the phase 3 qualitative interview data and developed the coding framework with review by HS, AMB, JNS, and CL. JNS and CL provided external validation. All authors (HS, JEJ, JNS, J Chua, BL, CL, QP, J Cafazzo, and AMB) contributed to the drafting and review of the final manuscript.

Conflicts of Interest

HS, AMB, J Chua, and BL were involved in the co-design, development, implementation, and evaluation of pain*HEALTH*; JEJ was involved in the evaluation of pain*HEALTH*. JNS, CL, and J Cafazzo were involved in the co-design and evaluation of the *iCanCope with Pain* app; QP, J Cafazzo, JNS, and CL were involved in the co-design, development, and evaluation of APEEE. Grant funding for this project supported the research activities of J Chua, BL, and JEJ and was administered by Curtin University. The remaining authors (HS, JNS, JEJ, J Chua, CL, BL, QP, J Cafazzo, and AMB) have no other conflicts of interest to declare.

Abstract

Background: Depression is a common mental disorder with a high social burden and significant impact on suicidality and quality of life. Treatment is often limited to drug therapies because of long waiting times to see psychological therapists face to face, despite several guidelines recommending that psychological treatments should be first-line interventions for mild to moderate depression.

Objective: We aimed to evaluate, among patients on a waitlist to receive secondary mental health care services for depression, how effective coach-guided web-based therapy (*The Journal*) is, compared with an information-only waitlist control group, in reducing depression symptoms after 12 weeks.

Methods: We conducted a randomized controlled trial with 2 parallel arms and a process evaluation, which included interviews with study participants. Participants assigned to the intervention group received 12 weeks of web-based therapy guided by a coach who had a background in social work. Patients in the control group receive a leaflet of mental health resources they could access. The primary outcome measure was a change in depression scores, as measured by the Patient-Health Questionnaire (PHQ-9).

Results: A total of 95 participants were enrolled (intervention, n=47; control, n=48). The mean change in PHQ-9 scores from baseline to week 12 was −3.6 (SD 6.6) in the intervention group and −3.1 (SD 6.2) in the control group, which was not a statistically significant difference with a two-sided alpha of .05 ($t_{91}=-0.37$; *P*=.72, 95% CI −3.1 to 2.2). At 12 weeks, participants in the intervention group reported higher health-related quality of life (mean EuroQol 5 dimensions visual analogue scale [EQ-5D-VAS] score 66.8, SD 18.0) compared with the control group (mean EQ-5D VAS score 55.9, SD 19.2; $t_{84}=-2.73$; *P*=.01). There were no statistically significant differences between the two groups in health service use following their initial consultation with a psychiatrist. The process evaluation showed that participants in the intervention group completed a mean of 5.0 (SD 2.3) lessons in *The Journal* and 8.8 (SD 3.1) sessions with the coach. Most participants (29/47, 62%) in the intervention group who completed the full dose of the intervention, by finishing 6 or more lessons in *The Journal*, were more likely to have a clinically important reduction in depressive symptoms at 12 weeks compared with the control group (X^2_1=6.3; *P*=.01, Φ=0.37). Participants who completed the interviews reported that the role played by the coach was a major factor in adherence to the study intervention.

Conclusions: The results demonstrate that the use of guided web-based therapy for the treatment of depression is not more effective than information-only waitlist control. However, it showed that the coach has the potential to increase adherence and engagement with web-based depression treatment protocols. Further research is needed on what makes the coach effective.

Introduction

Background

Depression is a common mental disorder [1] with a high social burden [2] and significant impact on suicidality [3] and quality of life. Most treatment for depression occurs in primary care. In secondary care, treatment is often limited to drug therapies, in part, due to long waiting lists to see psychological therapists face-to-face. This is contrary to recommendations about the importance of nondrug therapies by the National Institute for Health and Care Excellence (NICE), based in the United Kingdom, and other institutions [4]. In secondary and tertiary mental health care centers in Ontario, at the time of this trial, the waiting time to be seen by a psychiatrist for depression was between 9 months and 1 year.

Use of Electronic Therapies in Treating Depression

There is evidence that web-based therapies can reduce the symptoms of depression [5]. Randomized controlled trials (RCTs) have demonstrated the effectiveness of web-based cognitive behavior therapy (CBT) [6,7], problem-solving therapy [8], interpersonal therapy [9], and psychodynamic therapy. Computerized CBT is also recommended in the NICE guidelines for the treatment of mild to moderate depression [4]. However, most of the RCTs of web-based therapies have been conducted in community samples, often recruited from the internet. These populations are self-selecting and, although their scores on depression rating scales may be comparable with clinical populations, they often differ in terms of comorbidity, duration of symptoms, and impact on daily functioning.

Guided Electronic Therapy in the Treatment of Depression

The delivery of web-based therapy as a treatment for depression can be performed in one of two ways: through the use of supports to assist patients through the web-based therapy (guided model) or through the self-help use of computerized treatment (unguided model). In the guided model, patients are provided support as they progress through web-based therapy. In some cases, highly trained clinicians have been used to fill this role [10]; however, their advanced training is costly and does not appear to provide any added benefit. For instance, despite the use of a clinician in the delivery of web-based therapy for the treatment of depression and anxiety among young adults, Dear et al [11] did not find any significant differences in symptomatology when compared with the unguided condition. One solution that has been implemented to mitigate this issue is the use of coaches to support patients progressing through web-based therapy, answering both technical questions about how the program works as well as providing support and encouragement. To date, coaches have included both students [12] and licensed professionals from a variety of backgrounds, including psychology [13], counseling [14], and social work [15,16]. The components of effective coaching are still uncertain [17], with most of the literature emphasizing the technical aspects of an internet intervention. It is not clear whether the professional background of the coach, the frequency of contact, or the content of the coaching sessions affects treatment outcomes.

Several systematic reviews have demonstrated that internet-based interventions for depression have effect sizes that are comparable with face-to-face interventions, whereas unguided interventions have smaller effect sizes [7,18,19]. However, the evidence is inconsistent, with head-to-head comparisons of guided versus unguided interventions showing mixed results. The largest study of guided web-based therapy compared with usual care has been the Randomised Evaluation of the Effectiveness and Acceptability of Computerised Therapy (REEACT) study [20], which was a UK-based RCT of 691 patients with depression in primary care. Participants were randomized to one of three treatment groups: (1) usual care; (2) *Beating the Blues*, a guided commercial web-based program; or (3) *MoodGYM*, a guided free web-based program. The study found no difference in depression outcomes between the three groups. Similarly, Kenter et al [21] compared student-assisted internet-based problem-solving therapy with an information-only waitlist control and found minimal differences in depression severity (Cohen *d*=0.07), as measured by the Centre for Epidemiology Studies Depression scale.

Adherence to Web-Based Therapy Treatment Protocols

Web-based interventions for depression struggle with engagement and adherence to treatment protocols. For example, in the *Beating the Blues* and *MoodGYM* arms of the REEACT trial, participants completed only a median of 1 to 2 sessions and received only 6 min of technical support time, 5 emails, and almost no text messages from the telephone support workers. Further, approximately 1 in 5 participants randomized to either of the web-based therapy conditions did not access the programs at all. Similar problems were encountered in the study conducted by Kenter et al [21], with only 36% of participants receiving an adequate dosage of the intervention, defined by the authors as 4 of 5 lessons of web-based therapy. From a public health perspective, low adherence to web-based therapies dilutes their effectiveness. However, it is unclear if, for individual patients, adhering to a complete course of web-based therapy is better than control treatments.

This Study

We have previously reported on an RCT of *The Journal* comparing guided web-based therapy with an information-only waitlist control in patients with depression referred to secondary mental health services in New Zealand [22]. Participants were recruited face-to-face during their triage visit at community mental health centers, and the study found no difference in depression or service use after 12 weeks. However, all participants in this study were also receiving mental health care from clinicians, which may have outweighed any effect of the web-based therapy. In this study, we report on an RCT of *The Journal* [23], facilitated by a coach, compared with an information-only waitlist control group for the treatment of depression in patients referred to secondary mental health services in Canada. In this setting, access is a significant issue, with patients often waiting for over a year to access mental health services. During this time, patients on the waiting list do not receive any other mental health care other than routine follow-up from their family physician; therefore, the provision of web-based therapy could potentially be used as an alternative to referral to specialized mental health services. This study gave us an opportunity to refine the study intervention. In contrast to the New Zealand study, we opted to use an information-only control group as it is a low-cost, low-risk alternative that could easily be implemented in clinical practice. Similarly, we were able to refine the coaching aspect of the intervention. We hypothesized that, after 12 weeks of treatment, participants receiving coach-guided web-based therapy would experience a greater reduction in depressive symptoms and health service use.

Methods

Trial Design

The design of the trial was an RCT with two parallel groups. This trial has been reported according to the Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth (CONSORT-EHEALTH; Multimedia Appendix 1).

Recruitment

Potential participants were patients referred to the Royal Ottawa Mental Health Centre (ROMHC, Ottawa, Canada) with symptoms of depression or dysthymia who were on a waiting list for treatment in the following psychiatric programs: Mood and Anxiety, Geriatric Psychiatry and Youth Psychiatry. The ROMHC has 284 inpatient beds and acts as a specialized mental health facility for residents of communities across Eastern Ontario. These programs are aimed at treating people with complex and serious mental illnesses that are often resistant to treatment. Patients are referred to treatment in these programs directly by their family physicians. The first appointment in the programs is with a psychiatrist who then decides on a treatment plan with the patient. At the time of this clinical trial, the waitlist for the Mood and Anxiety Program was between 9 months and 1 year.

Eligibility criteria for participation in the trial are outlined in Textbox 1. Potentially eligible patients were contacted using the following methods: patients who had completed a consent to be contacted for research as part of their referral documentation were contacted by telephone. Those who did not complete the consent to be contacted for the research section of the referral were contacted by mail, as per institutional policies. Interested patients were preliminarily screened by a research assistant for eligibility to participate in the study. Eligible patients were then asked to attend a face-to-face consenting appointment with a research assistant. A minority of patients who could not travel to the clinic were asked to consent via mail (n=3).

Textbox 1. Participant eligibility criteria.

Inclusion criteria:

- 16 years of age or older.
- Referred and triaged to the Mood and Anxiety, Youth Psychiatry, or Geriatric Psychiatry Program at the Royal Ottawa Mental Health Centre for any depressive symptoms.
- Willing to attend electronic therapy sessions for up to 12 weeks.
- Able and willing to provide informed consent.
- Willing to be randomized.
- Willing to comply with all study procedures.

Exclusion criteria:

- Is unable to read or write in English.
- Does not have an Ontario Health Insurance Plan number.
- Has cognitive impairments that render them unable to use a computer.
- There is another participant enrolled in the study who lives at their address.

Interventions

The Journal

The Journal [23] is an evidence-based free web-based therapy program developed in New Zealand for the self-management of depression that utilizes the cognitive behavioral techniques of behavioral activation and problem solving (Multimedia Appendix 2). The problem-solving approach was derived from a large RCT of face-to-face problem-solving used in people who presented to emergency departments with intentional self-harm [24].

As described in Table 1, there are a total of 9 modules in *The Journal*, 6 of which must be done for patients to complete the program. Participants progressed through the web-based therapy as follows: (1) positivity module (1 lesson); (2) lifestyle modules (4 lessons, 1 of which must be completed); and (3) problem-solving module (4 lessons). At the start of each lesson, users are asked to watch a video featuring Sir John Kirwan, a former All-Blacks rugby player, who has been very public about his own struggles with depression in an effort to reduce stigmatization.

Table 1. Breakdown of participant progress through The Journal.

Lessons	Description	Tasks to be completed by participants
Positivity module	Learn the importance of staying positive and planning regular activities that they enjoy	• Watch video on staying positive; • Select 2 enjoyable activities; • Select dates to complete activities.
Lifestyle module[a]		
Eating right	Explore the link between diet and mood.	• Watch video on eating right; • Browse and select a healthy recipe; • Create a shopping plan.
Getting active	Review benefits of being active on mood.	• Watch video on getting active; • Pick 2 activities to complete; • Make a plan for getting active.
Learning to relax	Highlights the importance of stress management.	• Watch video on learning to relax; • Practice relaxation and breathing; • Make a plan for relaxing exercises.
Sleeping better	Discuss the importance of good sleep habits to mood.	• Watch video on sleeping better; • Set a nighttime routine; • Set a morning routine; • Keep a sleep diary; • Make a plan to practice sleep hygiene.
Problem-solving module		
Identify problems	Learn how depression impacts problem-solving abilities.	• Watch video on identifying problems; • Create a problem list; • Pick a problem to work on; • Define the problem; • Make a plan to create a problem list and statement.
Find solutions	Explore how to use both logical and creative parts of the brain to brainstorm problem solutions.	• Watch video on brainstorming solutions; • Create a solutions list; • Select a solution to implement; • Evaluate solutions; • Make a plan to list and evaluate solutions.
Create a plan	Review how to create SMART[b] plan.	• Watch video on brainstorming solutions; • Review the selected solution to make sure it is SMART; • Write a detailed step-by-step plan; • Review plan.
Review your plan	Highlights the importance of assessing progress and updating the SMART plan.	• Watch video on reviewing the SMART plan; • Review progress on plan; • Revise plan as needed; • Complete self-test.

[a] Participants are only required to complete 1 of the 4 lifestyle lessons.

[b] SMART: specific, measurable, achievable, relevant, time-bound.

Study Intervention

Both groups received usual care while on the waitlist, which included management by a family physician and use of community resources, such as access to distress center lines and counseling services. Once participants are called off the waitlist, they receive an initial appointment with a psychiatrist, at which point adjustments are made to the patient's care plan. They are then referred back to their family physician, or they receive further psychiatric treatment (eg, regular care from a psychiatrist, social worker, nurse, occupational therapist, and so on).

Following the consent appointment, participants were randomized to one of two treatment groups. In addition to usual care, participants assigned to the control group received an information leaflet with web-based resources, including *The Journal*, and told that they could decide for themselves the best way to use this information while on the waitlist. Participants had been previously informed by their clinical team that the estimated wait time to be seen by a psychiatrist was between 9 and 12 months.

For those participants assigned to the intervention group, the intervention consisted of the following:

1. An information leaflet of web-based depression resources.
2. An invitation to use *The Journal*.
3. 12-weekly telephone coaching sessions with a coach (SL), who had a guideline script for each coaching session, reinforced the topic of each lesson in *The Journal*, helped identify and support participants in goal setting and the techniques of problem-solving. Each session lasted between 30 and 60 min. The coach had a background in social work and received weekly supervision from the principal investigator (SH).
4. Text message or email contact between appointments, as per the participant's preference.

Outcomes

Primary Outcome

The primary outcome measure was the Patient Health Questionnaire (PHQ-9) [25], a 9-item questionnaire that assesses the severity of depression symptoms experienced within the preceding 2 weeks. Participants are asked to rate each symptom of depression on a Likert scale from 0 (not at all) to 3 (nearly every day), with total scores ranging from 0 (minimal depression) to 27 (severe depression). The PHQ-9 has strong methodological properties, with an internal consistency of 0.89 and strong test-retest reliability [26]. Increasing scores on the PHQ-9 have also been found to be correlated with deteriorating scores on all 6 subscales of the Medical Outcomes Survey Short Form-20 [27]. The PHQ-9 was selected not only for its strong psychometric properties but also for its commonality. The PHQ-9 is often used as a screening tool for major depressive disorder in primary care practice [28].

Secondary Outcomes

Suicidal thoughts were assessed by question 9 of the PHQ-9, in which respondents were asked *Over the last 2 weeks how often have you been bothered by thoughts that you would be better off dead or of hurting yourself in some way*? [26]. This variable was dichotomized as follows: participants who responded *Not at All* (0) were categorized as *no* (0), and participants who reported any degree of suicidality (1, 2, or 3) were categorized as *yes* (1).

Health-related quality of life was assessed using the EuroQol-5 dimension (3 levels) questionnaire (EQ-5D-3L). This is a 5-item questionnaire that assesses health-related quality of life, including mobility, self-care, ability to participate in one's usual activities, pain or discomfort, and anxiety or depression. The EQ-5D-3L asks participants to assess their health-related quality of life on a 3-point scale from no dysfunction to extreme dysfunction, with the following response categories:

- Level 1: indicating no problem.
- Level 2: indicating some problems.
- Level 3: indicating extreme problems.

The EQ-5D-3L is then able to define a unique health state based on the responses to each of the 5 dimensions of health described above. Respondents fall into 1 of 243 different health states, depending on their responses to the questionnaire [28]. For instance, an overall score of 11111 indicates no problems in any of the 5 health dimensions, whereas a score of 12312 indicates that a respondent has no problems with mobility, some problems with washing or dressing, extreme problems with doing usual activities, no pain or discomfort, and some anxiety or depression. The measure also includes a visual analogue scale (VAS), which asks participants to evaluate their overall health on a scale from 0 to 100. The EQ-5D-3L has strong psychometric properties and has been found to be moderately to highly correlated with other measures of impairment and disability [29,30].

Service use was measured using data extracted from participants' electronic medical records (EMR), including, time to first consultation appointment at the ROMHC and the total number of outpatient mental health follow-up appointments after the first consultation completed at the ROMHC. These measures were administered as shown in Table 2.

Baseline assessments were administered in-person following the consent appointment, and all other time point assessments were conducted by telephone either by the coach (intervention group) or a research assistant (control group). Patients who missed appointments or were lost to follow-up were also sent questionnaires by mail. Service use at the ROMHC was obtained from the EMR of each participant. Five participants in the control group were excluded ad hoc to prevent confounding as they accessed *The Journal* during the treatment period.

Table 2. Outcome measures and timing of assessments.

Variable	Outcome measure	Time point
Primary outcome		
Depressive symptoms	PHQ-9[a]	Baseline, week 2, week 6, week 12
Secondary outcomes		
Suicidal thoughts	PHQ-9 Q9[b]	Baseline, week 2, week 6, week 12
Health-related quality of life	EQ-5D-3L[c], EQ-5D-VAS[d]	Baseline, week 6, week 12
Health service use	ROMHC EMR[e]	One year following the initial consultation appointment at the ROMHC

[a] PHQ-9: Patient Health Questionnaire.

[b] PHQ-9 Q9: Patient Health Questionnaire question 9.

[c] EQ-5D-3L: EuroQol 5 dimensions (3 levels) questionnaire.

[d] EQ-5D-VAS: EuroQol 5 dimensions visual analogue scale.

[e] ROMHC EMR: Royal Ottawa Mental Health Center electronic medical record.

Sample Size

Based on the previous studies that used the PHQ-9 as their primary outcome measure, we expected the mean pretreatment score to be 17.0 (SD 4.0). To detect a difference in PHQ-9 scores between the two groups of at least 3 points, an established minimal clinically important difference [31], we would need 44 participants in each group with a 2-sided alpha of .05, and a power of 80.0% (effect size of 0.6). Allowing for a 25.0% dropout rate, we aimed to recruit a total of 110 participants.

Randomization

Randomization was completed by the Ottawa Methods Centre at the Ottawa Hospital Research Institute, with allocations kept in sequential sealed envelopes at the study base. Participants were randomized in a 1:1 allocation, and there were no restrictions. After providing consent, participants were randomized by a research assistant according to the allocation in the sealed envelopes.

Blinding

Owing to the nature of the intervention, neither participants nor study staff were blinded to the treatment allocation. Outcome assessments were collected by delegated study staff who were not blinded to the treatment allocation.

Statistical Analyses

Group differences in demographic and pretreatment measures were analyzed using independent samples *t* tests. Changes in participants' scores from pretreatment to follow-up at 12 weeks were assessed using repeated measures analysis of variance with mixed linear modeling to account for missing variables. This model included the following variables: treatment group (control or intervention), PHQ-9 scores at 4 different time points (baseline, week 2, week 6, and week 12), gender (male or female), and age. PHQ-9 scores were entered as within-subject variables, treatment group as between-subject factors, and age and gender as covariates. Statistical analyses were conducted using the general linear modeling repeated measures procedure in IBM SPSS Statistics 25 for Windows. To assess significant differences in outcome measures, the last observations for the PHQ-9, EQ-5D-3L and EQ-5D-VAS were carried forward for the 6- and 12-week time points.

Differences in suicidal thoughts between the two groups were assessed using an independent samples *t* test. Differences in proportions of service use were assessed using chi-square tests. In addition, we also assessed whether participants experienced a clinically important reduction in depression symptoms defined as a PHQ-9 score of 9 or less or a 50.0% reduction in scores [31]. This was described using percentages and frequencies, and chi-square was used to assess the significance of the differences in proportions. Assessments of normality were completed using the Shapiro-Wilk test for continuous data, and the Mann-Whitney U test for nonparametric data.

Process Evaluation

As per the recommendations outlined in the Medical Research Council's guidelines for the assessment of complex interventions [32], we conducted a process evaluation to assess the context, implementation, and mechanisms of impact of the study intervention. The process evaluation outcome measures are outlined in Table 3. We also conducted semistructured interviews with participants within 6 months of study completion to assess their experience of the study intervention, including access to and functionality of *The Journal*, the therapeutic content and value of *The Journal*, and the experience of working with a coach. Interviewees were identified using a purposive sampling approach and were stratified to include participants in both arms of the trial and varying levels of engagement (eg, not engaged, moderately engaged, and highly engaged). Interviews were conducted until data saturation was reached (n=15).

Table 3. Process evaluation outcome measures.

Evaluation critierion and outcome measure	Description
Context	
Facilitators of and barriers to study completion	- Qualitative interviews with participants
Implementation	
Reach	- Total number of participants reached - Comparison of sample to Ontarian and Canadian populations.
Fidelity	- Mean length of weekly coaching calls - Mean number of contacts with the coach - Mean number of weekly coaching sessions completed - Mean number of lessons in *The Journal*[a]
Dose	- Total number of participants to complete 6 lessons in *The Journal*
Mechanisms of impact	
Role of the coach	- Qualitative interviews with participants

[a] All usage data from *The Journal* were assessed via participant self-report.

Individual interviews were conducted by two female University of Ottawa Department of Psychiatry residents (JK and ZS) who were independent of the research team that conducted the RCT. Following transcription, two independent coders (JK and KG) analyzed the material using a thematic, grounded theory approach. The coding took place in two stages, with coders meeting during the first stage to discuss emergent codes, reconcile definitions, and compare coding rationales. The two coders had not been involved in delivering the treatment or any of the previous study contacts.

Ethics

The study received approval from the Royal Research Ethics Board (Protocol 2014001). All participants provided informed consent before participation in both the RCT and qualitative interviews.

Results

Participants

Recruitment for this study took place over 11 months, from May 2015 to April 2016, and a total of 1316 patients were preliminarily screened for eligibility by examining their referral documentation (Figure 1). Of these, 45.9% (605/1316) could not be reached to complete a full screening for eligibility; 40.4% (532/1316) could be contacted were not eligible to participate, and 13.6% (179/1316) were eligible and could be contacted.

Of the 45.9% (605/1316) of patients who could not be contacted to complete a full eligibility screen, 25.4% (154/605) provided consent to be approached about research studies but did not reply to telephone or mail invitations; 63.1% (382/605) were invited to discuss the study by mail with no response, and 11.3% (69/606) had incomplete mailing information listed on their referral documents.

Of the 40.4% (532/1316) of patients who could be contacted but were ineligible to participate, 84.9% (452/532) were referred for a reason other than depressive symptoms; 5.6% (30/532) had cognitive impairments rendering them unable to use a computer; 4.5% (24/532) were no longer on the waitlist at the time of screening; 2.6% (14/532) were under 16 years of age at the time of screening; 1.12% (6/532) were unable to read and write in English; and, 1.12% (6/532) did not have a valid Ontario Health Insurance Plan number.

Of the 13.6% (179/1316) of patients who were eligible to participate, 46.9% (84/179) declined to participate, and 53.1% (95/179) consented to participate in the study. Table 4 lists the reasons for patients declining to participate.

The majority of participants enrolled in the study were recruited from the Mood and Anxiety Outpatient Clinic (n=92), and 3 were recruited from the Geriatric Psychiatry Program at the ROMHC. No participants were enrolled from the Youth Psychiatry Program. Table 5 describes the demographic characteristics of the participants. There were significantly more women in the intervention group and more men in the control group (X^2_1=6.6; P=.01).

Participants in the intervention group completed a mean number of 5.0 (SD 2.3) lessons in *The Journal* and 8.8 (SD 3.1) sessions with the coach. In the control group, 10% (5/48) of participants reported accessing *The Journal*. In the control group, 17% (8/48) of participants scored 9 or below on the PHQ-9 at baseline compared with 23% (11/47) of participants in the intervention group. Owing to gender imbalances between the groups, we also conducted a post hoc gender analysis of changes in PHQ-9 scores and health service use.

Unemployed	11 (12)	7 (15)	4 (8)

[a] n=1 transgender participant removed from the analysis.

[b] *P*=.01.

Primary Outcome

The mean PHQ-9 score was lower in the intervention group than in the control group at all study time points (Table 6). The proportions of missing values were comparable between the 2 groups at all assessment points, with the exception of week 12 (2/46 , 4% in the control group compared with 0/47, 0% in the intervention group). The Shapiro-Wilk test of normality revealed that all data were normally distributed with the exception of the control group at the week 12 study time point (W_{46}=0.95; *P*=.04).

At 12 weeks, the mean PHQ-9 score in the intervention group was 11.3 (SD 6.4) and was 12.4 (SD 6.4) in the control group (t_{86}=0.76; *P*=.45, 95% CI −1.9 to 3.8). To account for the non-normality in scores at week 12, mean differences (MDs) at this time were also assessed using a Mann-Whitney U test of significance, which confirmed that the difference between the two groups was not statistically significant (Mann-Whitney U statistic=862.0; Z=−0.85; *P*=.40). The mean change in PHQ-9 scores from baseline to week 12 was −3.6 (SD 6.6) in the intervention group and −3.1 (SD 6.2) in the control group, which was not statistically significant (t_{91}=−0.37; *P*=.72, 95% CI −3.1 to 2.2).

Excluding the 10% (5/48) of participants in the control group who also accessed *The Journal* did not result in any statistically significant differences in mean PHQ-9 scores compared with the intervention group. The mean score at week 12 for the control group excluding those who accessed *The Journal* (n=41) was 12.4 (SD 6.2) compared with 10.7 in the intervention group (t_{86}=0.76; *P*=.45, 95% CI −0.9 to 4.3).

Table 6. Mean and median scores on the Patient-Health Questionnaire-9 (n=95).

Study time point	Mean (SD)	Median	Missing values, n (%)	Mean difference (95% CI)	Independent samples *t* test (*df*)	*P* value
Baseline				**0.5 (−1.8 to 2.9)**	**0.45 (93)**	**.66**
Control (n=48)	15.4 (5.4)	16.5	0 (0)			
Intervention (n=47)	14.9 (6.0)	16.0	0 (0)			
Week 2				**1.1 (−1.3 to 3.5)**	**0.92 (89)**	**.36**
Control (n=46)	12.6 (5.5)	11.5	2 (4)			
Intervention (n=45)	11.5 (5.9)	12.0	2 (4)			
Week 6				**1.7 (−0.9 to 4.3)**	**1.29 (89)**	**.19**
Control (n=46)	12.4 (6.2)	12.0	2 (4)			
Intervention (n=45)	10.7 (6.1)	10.0	2 (4)			
Week 12				**1.0 (−1.9 to 3.8)**	**0.76 (89)**	**.45**
Control (n=46)	12.4 (6.4)	11.5	2 (4)			
Intervention (n=47)	11.3 (6.4)	10	0 (0)			

The repeated measures modeling found that scores on the PHQ-9 differed significantly by study time point, irrespective of group allocation ($F_{2.6,222.8}$=11.59, *P*<.001). However, this relationship was not sustained once treatment group was taken into account ($F_{1,87}$=1.46, *P*=.23). Similarly, modeling found that scores on the PHQ-9 were not significantly associated with gender ($F_{1,87}$=0.33, *P*=.57) or the interaction between treatment group and PHQ-9 scores ($F_{1,87}$=0.70; *P*=.53). However, results were significantly associated with age of participants ($F_{1,87}$=5.97, *P*=.02, η^2=0.06).

Secondary Outcomes

Health-Related Quality of Life

After 12 weeks of treatment, participants in the intervention group reported higher health-related quality of life, with mean index scores on the EQ-5D-3L of 0.7 (SD 0.7) for the intervention group and 0.6 (SD 0.5) for the control group (t_{86}=−2.30; *P*=.02, CI 95% −0.2 to −0.1; Multimedia Appendix 3). Similarly, at 12 weeks, the mean EQ-5D-VAS score was significantly greater in the intervention group (mean 66.8, SD 18.0) than in the control group (mean 55.9, SD 19.2; t_{84}=−2.73; *P*=.01).

Changes in Suicidality

At 12 weeks, of the 47 participants in the intervention group, 66% (31/47) reported no suicidality, 28% (13/47) reported suicidality several days in the preceding 12 weeks, 2% (1/47) reported suicidality nearly half the days, and 4% (2/47) reported suicidality nearly every day. In comparison, of the 46 participants in the control group, 69% (33/46) reported no suicidality, 17% (8/46) reported suicidality several days, 6% (3/46) reported suicidality more than half the days, and 4% (2/46) reported suicidality nearly every day (Table 7). These differences in suicidality were not statistically significant (X^2_3=2.2; *P*=.52).

Table 7. Mean and median scores on the Patient-Health Questionnaire -9, Question 9 (n=95).

Hospital Service Use

Participants in both groups received similar levels of face-to-face follow-up care, with 25.0% of participants in the intervention group receiving any follow-up in the next 12 months at the hospital after their initial outpatient appointment with a psychiatrist compared with 21.3% of the control group (X^2_1=0.7; *P*=.80; Table 8). Participants in the intervention group attended a mean number of 4.8 (SD 8.5) face-to-face follow-up appointments compared with 3.6 (SD 5.6) in the control group (Mann-Whitney U statistic=255.50; Z=−0.11; *P*=.91).

Table 8. Hospital service use.

Health service use indicator	Control	Intervention	Tests of association	*P* value
Number of days from referral to first appointment[a], mean (SD)	213.6 (54.6)	219.3 (57.0)	t_{69}=−0.43 *P*	.67

Process Evaluation

Implementation

Reach

As reported above, only 13.4% (95/711) of potentially eligible patients (eg, those who could be contacted and were on the waitlist for mental health treatment) agreed to participate in the trial. Of particular note is that 8.9% (16/179) eligible participants declined to participate because they did not have computer or internet access at home. This is comparable with 14% of the Canadian population [33]. Similarly, among participants who were randomized to one of the trial arms, 42% (40/95) were university-educated compared with 33.3% of residents of Ottawa [34].

Fidelity

Analysis of trial records demonstrated that the study intervention was implemented as intended in the study protocol. Participants in the intervention group completed a mean of 5.0 (SD 2.3) lessons in *The Journal*. Similarly, throughout the course of the study, participants completed a mean of 8.8 (SD 3.1) telephone coaching sessions, ranging from a mean of 9.6 to 61.6 min in duration, and a mean of 21.6 (SD 10.8) contacts with the coach (mean 13.1 (SD 4.0) telephone calls, 2.0 (SD 2.5) emails, and mean 25.7 (SD 15.4) text messages. All fidelity measures were significantly associated with PHQ-9 scores at 12 weeks, with the exception of the types of contact with the coach (Table 9). Total lessons completed in *The Journal*, total number of coaching sessions completed, and average length of coaching calls were all inversely related to PHQ-9 scores at 12 weeks, with those having completed more lessons in *The Journal*, a higher number of sessions with the coach and longer coaching calls reporting lower levels of depression after 12 weeks of treatment (Table 9).

Table 9. Relationship between fidelity measures and Patient-Health Questionnaire scores at 12 weeks (n=47).

Fidelity Measures	Mean (SD)	Median	Pearson’s correlation with PHQ-9[a] scores at week 12, (n=47)	
			r	*P* value
Total lessons completed in *The Journal*	5.0 (2.3)	6.0	−0.436	.002
Total sessions with the coach	8.8 (3.1)	10.0	−0.435	.002
Average length of coaching calls (min)	30.8 (12.9)	27.7	−0.360	.01
Total contacts with coach by type				
Telephone	13.1 (4.0)	13.0	0.061	.68
Email	2.0 (2.5)	1.0	−0.163	.27
Text message	25.7(15.4)	26.0	−0.073	.62

[a] PHQ-9: Patient Health Questionnaire.

Dose

For those participants in the intervention group who received a full *dose* of the study intervention, completing 6 or more lessons from *The Journal* (n=29), the mean PHQ-9 scores at 12 weeks was 9.5 (SD 5.7) compared with 14.2 (SD 6.6) among those who completed 5 lessons or less in *The Journal* and 12.4 (SD 6.4) in the control group ($F_{2,85}$=3.5; *P*=.04). Post hoc comparisons using the Tukey Honestly Significant Difference test indicated that the MD among those who completed at least 6 lessons in *The Journal* was significantly different from those who completed 5 or fewer lessons in *The Journal* (MD=−4.7, *P*=.04). However, the MDs between the control group and both experimental groups were not statistically significant ($MD_{\geq 6\ Lessons}$=−2.8; *P*=.15; $MD_{\leq 5\ Lessons=}$1.86; *P*=.55). Similarly, those who completed at least six or more lessons in *The Journal* were more likely to demonstrate a clinically significant reduction in symptoms, with 65.5% reporting a significant reduction in symptoms compared with 27.8% of those who completed less than 5 or fewer lessons and 37.0% of the control group (X^2_2=8.2; *P*=.02; Φ=0.30).

Similarly, by week 12 in the intervention group, 51% (24/47) of participants had a clinically important reduction in depressive symptoms (PHQ-9 score of 9 or less or a 50% or more improvement in scores) compared with 37% (17/46) of participants in the control group. However, this difference was not statistically significant (X^2_1=1.8; *P*=.17). Among participants in the intervention group who completed the full *dose* of the intervention by finishing 6 or more *Journal* sessions, 66% (19/29) had clinically important reductions in depression at 12 weeks compared with 37% (17/46) in the control group (X^2_1=6.3; *P*=.01; Φ=0.37).

Context and Mechanisms of Impact

A total of 15 qualitative interviews were conducted (10 intervention, 5 control) with 4 male (2 intervention group, 2 control group), 10 female (7 intervention group, 3 control group), and 1 transgender person (intervention group). Interviews took place at the ROMHC at a time that was mutually convenient for both participants and interviewers. Themes that arose from the interviewers were categorized in terms of whether there were positive facilitators of or negative barriers to engagement with the study intervention.

Facilitators to Engagement With The Journal

Participants identified Sir John Kirwan's relatability as a positive facilitator through his sharing of his personal experience with depression. For instance, a participant commented on the videos that begin each lesson in *The Journal*, explaining the following:

> *…I just like the way that they interacted with each other and how casual it was, so it didn't feel like I was doing homework, and it didn't feel like I was doing medical stuff…It was just, watching two people sitting on a bench in a park and they were talking, and I really liked how the narrator came right out and said, you know, when I was depressed, you know, I couldn't get out of bed, or I, I didn't want to take a shower, it was, like, wow somebody else feels the way I do. So, it helped me to feel like I wasn't all, all alone. And he was, he seemed to be very honest about his experience.* [P040]

Similarly, participants expressed an appreciation for the structure and layout of *The Journal*, specifically commenting on the usefulness of the Problem-Solving modules:

> *Interviewer: …what did you like about the problem-solving lesson?*
>
> *Participant: … it was in a new, new approaches. It gave me a new technique or I found a new technique in there in terms of outlining problems, and thinking about them and, that I hadn't.* [P095]

Barriers to Engagement With The Journal

Participants also reported frustrations with some aspects of *The Journal*, specifically relating to the technical issues they encountered. At the time of the trial, *The Journal* was not available on mobile devices, such as smartphones or tablets, which may have limited participants' ability to access it. Similarly, technical issues presented themselves within the web-based program as well. For instance, in each lesson, participants must set deadlines for tasks that they are required to complete and are unable to move forward in *The Journal* until these deadlines pass. Participants also identified issues with motivation and questioned whether *The Journal* would be most appropriate for patients who are only mildly depressed. For instance, one participant explained:

> *Participant: Yeah, lifestyle one…was little bit of a challenge.*
>
> *Interviewer: Yeah? In what way?*
>
> *Participant: … just trying to find motivation…it's just hard to change some things about lifestyle, but it came with time"* [P002]

Similarly, a participant in the control group commented on how some depressive symptoms, such as difficulty with concentration, may act as barriers to engagement with treatment:

> *Interviewer: … Were there any barriers or challenges to using the brochure?*
>
> *Participant: …not really because it's short and sweet…my only barrier was time, you know, time and, and energy. Because at the time, and it was almost an opportune time that I was doing this because I was low at the time… so when you are depressed the last thing you want to do it read, so you can't even. And that's why I was saying that if this was little bullet chunks, you know, you don't have to read it so much, cause I can't read a book when I'm down. Like I start to read a paragraph and I'm like, no I have to close it.* [P014]

Coach as a Mechanism of Change

Numerous participants in the intervention group also identified the coach as key to their success with the program, highlighting the importance of accountability:

> *Interviewer: …what would you say made the biggest difference to your participation in the study? ...was it the journal, was it the coach?*
>
> *Participant: It was the coach, oh my god. I would not have stayed with that journal unless [SL] was calling me… cause then I wouldn't really have anybody to be like, hey did you do that thing?* [P038]

Similarly, another participant questioned whether they would have been as successful in completing the program had they not had someone following-up on their goals:

> *…if it was by myself, I might have just kept postponing it or not doing it or, so I found it quite helpful. She's a pretty great coach.* [P068]

Similarly, another participant highlighted the importance of continuity between the lessons in *The Journal* and the content of the coaching sessions:

> *I like the conversations the following week with the homework that we did. I liked that it was continuous.* [P069]

Accountability also emerged as important for participants in the control group. For instance, 1 participant who accessed *The Journal* expressed a lack of follow-up by a third party as a barrier to completing the program, suggesting that:

> *…you guys can follow-up and see if they're.. If people are using it or not…just to say, somebody is following me, I should probably do a little bit more of this...* [P066]

This was echoed by another participant in the control group who struggled with the limited follow-up they received from the research team:

> *taking not even five minutes to say "how are you doing right now?"… So in a way it gauges their, their level of health, of mental health at the time, and if they do appear to need resources then [the Research Assistant] could say "look I'm not a doctor, I'm not a psychiatrist, but do you remember the flyer that I gave you, on it there was this thing that might be helpful for you right now, you might want to give it a thought"… so, that's just like extra, like value added for resourcefulness.* [P014]

Discussion

Principal Findings

Among patients on a waiting list referred to secondary care for depressive symptoms, a trial of usual care plus coach-facilitated web-based therapy compared with usual care plus information-only waitlist control group found no statistically significant differences in mean depression scores after 12 weeks. However, participants who completed 6 or more lessons in *The Journal* reported significantly greater reductions in symptoms compared with controls. Participants in the intervention group also reported better quality of life after 12 weeks of treatment. There was no difference in service use between the two groups. During the qualitative interviews conducted as part of the process evaluation, participants identified the role of the coach as a major factor in their completion of the web-based therapy program.

Strengths and Limitations

The major strength of this study is that it is the first study of coach-assisted web-based therapy in a secondary care setting in Canada. This study demonstrated that it is possible to incorporate the use of a coach within this clinical setting. However, due to limitations imposed by institutional policies, study staff were restricted in their ability to recruit participants, with only 12% (95/784) of potentially eligible patients agreeing to participate in the trial. It is reasonable to expect greater reach if this intervention was rolled out by a clinical service that could approach people directly at the time of referral.

There was also a possibility of contamination between the arms of the trial. Given that *The Journal* is a publicly accessible website, any participant was able to access it, and there was little that could be done by the study team to prevent this. However, our experience is that patients in secondary care do not widely use *The Journal*, with only 10% (5/48) participants in the control group reporting use of *The Journal* during the treatment period. Furthermore, contamination is likely to bias the study to showing no difference (as the control group could use *The Journal* unguided), so any differences that are found are likely to be more *believable*. Finally, the ability to generalize study findings to the larger Canadian population may be limited as a result of our highly educated population.

Some participants who were interviewed as part of the process evaluation expressed issues with recall given that the interviews took place 6 months after study completion. It is possible that interviews conducted closer to study completion would have yielded richer qualitative data.

Comparison With Prior Work

A key contribution of this study is that participant engagement with and adherence to the intervention was much higher than that reported in previous work, with 62% (29/47) of participants in the intervention group receiving a full *dose* of treatment, completing an average of 5 out of 6 lessons in *The Journal* and 8.8 telephone coaching sessions with the coach. Comparatively, in the REEACT trial, participants only completed a median of 2 sessions of web-based therapy. Similarly, in the study by Kenter et al [21], only 36% of participants received the required 4 to 5 sessions of internet-based psychotherapy. This was found in spite of difficulties with ease of access, as *The Journal* was not available on mobile or tablet devices at the time of the study. This trial also highlights the importance of the uptake of the intervention to clinical outcomes, with participants who completed at least 6 lessons in *The Journal* experiencing a significantly greater reduction in depression symptoms than those who did not.

The previous trial of a guided version of *The Journal* in New Zealand secondary care showed no differences in clinical outcomes or service use. However, the patients in the New Zealand study had higher baseline depression scores, a mean PHQ-9 of 17.0, and were less engaged with the study intervention, completing only a mean of 2.5 lessons in *The Journal*. The magnitude of change in PHQ-9 scores was also different, with an intervention group change in PHQ-9 scores of 3.5 in Canada compared with 9.4 in New Zealand. This presumably reflects differences in usual care, with participants in New Zealand receiving mental health care, whereas Canadian participants received care from their primary care physicians while on a waiting list.

Clinical Implications

Web-based therapies are often promoted as a way to address long waiting lists for mental health care services. However, in this study, even though participants in the intervention group with more exposure to the study intervention were more likely to experience a significant reduction in symptoms, this had little impact on subsequent service use. Web-based therapies are part of a complex socio-technological system and, as such, cannot exist in a vacuum. To achieve improvement in patient outcomes, they must be integrated into a larger system of care. This could be achieved with a more explicit stepped care system supported by web-based therapies, with a more flexible response from providers based on patient need.

Unanswered Questions and Future Research

This study provides limited support for the potential use of web-based therapies within a stepped-care approach to the treatment of depression. However, an RCT is needed to determine the effectiveness of such an approach. The impact of providing digital services to those in greatest need, who are also the least likely to have access to high-speed connections, also needs to be taken into account. Future research on internet-based psychotherapy for depression needs to include the system of care in which it is used. This can be done through implementation science tools, which not only evaluate the effectiveness of web-based therapies but also the factors central to their uptake, such as reach, adoption, and sustainability.

Conclusions

The results of this study demonstrated that the use of guided web-based therapy for the treatment of depression is not more effective than information-only waitlist control. However, it showed that coach-guided web-based therapy has the potential to increase adherence and engagement with depression treatment protocols. Greater adherence resulted in greater effectiveness. More research is needed on the human component of coaching in conjunction with web-based therapy to examine what factors lead to greater adherence. Researchers also need to consider when and how web-based therapies should be integrated into existing clinical pathways.

Acknowledgments

This work was supported by a Canadian Institutes for Health Research Catalyst grant (funding reference number: 134160) and the Royal’s University Medical Research Fund. The funders had no role in the review or approval of the manuscript for publication.

The research team would like to recognize the following psychiatric programs at the ROMHC: Mood and Anxiety, Geriatric Psychiatry, and Youth Psychiatry, as well as the service users who participated in our study.

Authors' Contributions

SH conceived of the study and was the grant holder. SM took the lead in drafting of the manuscript, completed participant recruitment, and data collection activities. DJC conducted all statistical analyses. SL completed participant follow-up and data collection activities. JK and ZS completed the process evaluation of qualitative interviews. JK and KG conducted qualitative analysis of the process. All authors reviewed and approved the final manuscript.

Abstract

Background: Adequate self-management skills are of great importance for patients with chronic obstructive pulmonary disease (COPD) to reduce the impact of COPD exacerbations. Using mobile health (mHealth) to support exacerbation-related self-management could be promising in engaging patients in their own health and changing health behaviors. However, there is limited knowledge on how to design mHealth interventions that are effective, meet the needs of end users, and are perceived as useful. By following an iterative user-centered design (UCD) process, an evidence-driven and usable mHealth intervention was developed to enhance exacerbation-related self-management in patients with COPD.

Objective: This study aimed to describe in detail the full UCD and development process of an evidence-driven and usable mHealth intervention to enhance exacerbation-related self-management in patients with COPD.

Methods: The UCD process consisted of four iterative phases: (1) background analysis and design conceptualization, (2) alpha usability testing, (3) iterative software development, and (4) field usability testing. Patients with COPD, health care providers, COPD experts, designers, software developers, and a behavioral scientist were involved throughout the design and development process. The intervention was developed using the behavior change wheel (BCW), a theoretically based approach for designing behavior change interventions, and logic modeling was used to map out the potential working mechanism of the intervention. Furthermore, the principles of design thinking were used for the creative design of the intervention. Qualitative and quantitative research methods were used throughout the design and development process.

Results: The background analysis and design conceptualization phase resulted in final guiding principles for the intervention, a logic model to underpin the working mechanism of the intervention, and design requirements. Usability requirements were obtained from the usability testing phases. The iterative software development resulted in an evidence-driven and usable mHealth intervention—Copilot, a mobile app consisting of a symptom-monitoring module, and a personalized COPD action plan.

Conclusions: By following a UCD process, an mHealth intervention was developed that meets the needs and preferences of patients with COPD, is likely to be used by patients with COPD, and has a high potential to be effective in reducing exacerbation impact. This extensive report of the intervention development process contributes to more transparency in the development of complex interventions in health care and can be used by researchers and designers as guidance for the development of future mHealth interventions.

Introduction

Background

Chronic obstructive pulmonary disease (COPD) is a highly prevalent chronic disease and is predicted to be the third leading cause of mortality worldwide in 2030 [1,2]. Exacerbations are important events in the course of COPD, as they accelerate the decline in lung function [3], negatively affect the quality of life [4,5], and lead to increased mortality and high socioeconomic costs [6,7]. An exacerbation is defined as *a sustained worsening of patients'respiratory symptoms, which are beyond normal day-to-day variability and may warrant medical treatment* [8]. The absence of an adequate imminent exacerbation marker requires a focus on supporting patients with COPD in developing self-management skills to reduce the impact of exacerbations [9]. Self-management is defined as *an individual's ability to detect and manage symptoms, treatment, physical and psychosocial consequences, and lifestyle changes inherent in living with a chronic condition* [10].

Recent interventions focusing on exacerbation-related self-management (including the use of action plans) have shown positive outcomes on quality of life and hospital admissions [11,12]. However, there is still a substantial proportion of patients with COPD who barely benefit from these kinds of interventions [11-13]. This might be explained by the *one-size-fits-all* and static approach regarding design, intensity, and mode of delivery without a focus on individual exacerbation patterns and actions. Moreover, recent interventions have a strict focus on exacerbation detection and taking action and the use is suboptimal [11,14,15]. To further reduce the impact of exacerbations, more comprehensive, dynamic, and individualized strategies are needed to improve the full spectrum of exacerbation-related self-management behavior that meet patients' needs, perceptions, and capabilities [12,16].

Mobile health (mHealth) is considered promising in engaging patients in their own health and changing health behaviors [17,18]. The rapidly evolving nature and increased uptake of mHealth are bound to influence the accessibility and the way self-management support will be provided in the future, also in patients with COPD [19-21]. Recent studies suggest that mHealth interventions focusing on COPD self-management lead to positive outcomes, although no firm conclusions could be drawn because of poor quality and heterogeneity among the studies [19,20]. Nonetheless, the use of mHealth creates opportunities to strongly individualize interventions and to provide more dynamic and intensive therapeutic stimuli that fit with real-time health status and individual exacerbation patterns. As a result, mHealth can reach patients at the right moment and can provide tailored support anytime and anywhere, which could stimulate the development of effective self-management skills and change health behaviors.

To date, there is limited knowledge on how to design mHealth interventions that are effective, meet the needs of intended end users, and are perceived as useful [17,22]. Designing mHealth interventions to change health behaviors is complex and needs theoretical grounding to increase the design's efficacy. In current thinking about the development of behavior change interventions, the importance of theory is clear [23-26], but the way in which theory should be incorporated in the design process is not [24,27,28]. Furthermore, specific steps in the development of evidence- and theory-driven interventions that involve the end users are rarely described transparently in literature [22,29].

Objectives

During a 4-year period, our research team has developed an evidence-driven and usable mHealth intervention to enhance exacerbation-related self-management in patients with COPD. By following an iterative user-centered design (UCD) process, several studies were performed to increase the likelihood of developing an mHealth intervention that is effective, fits with patients' needs and preferences, and can be successfully implemented in routine COPD care. Some of these studies have recently been published [15,30,31]. This paper underpins the design and working mechanism of this COPD-specific mHealth intervention and offers a novel and potentially effective method to use evidence and theory to inform the design of mHealth interventions in general.

The aim of this paper was to describe in detail the full UCD and development process of an evidence-driven and usable mHealth intervention to enhance exacerbation-related self-management in patients with COPD, including the design, iterative software development, and usability testing.

Methods

User-Centered Design Process

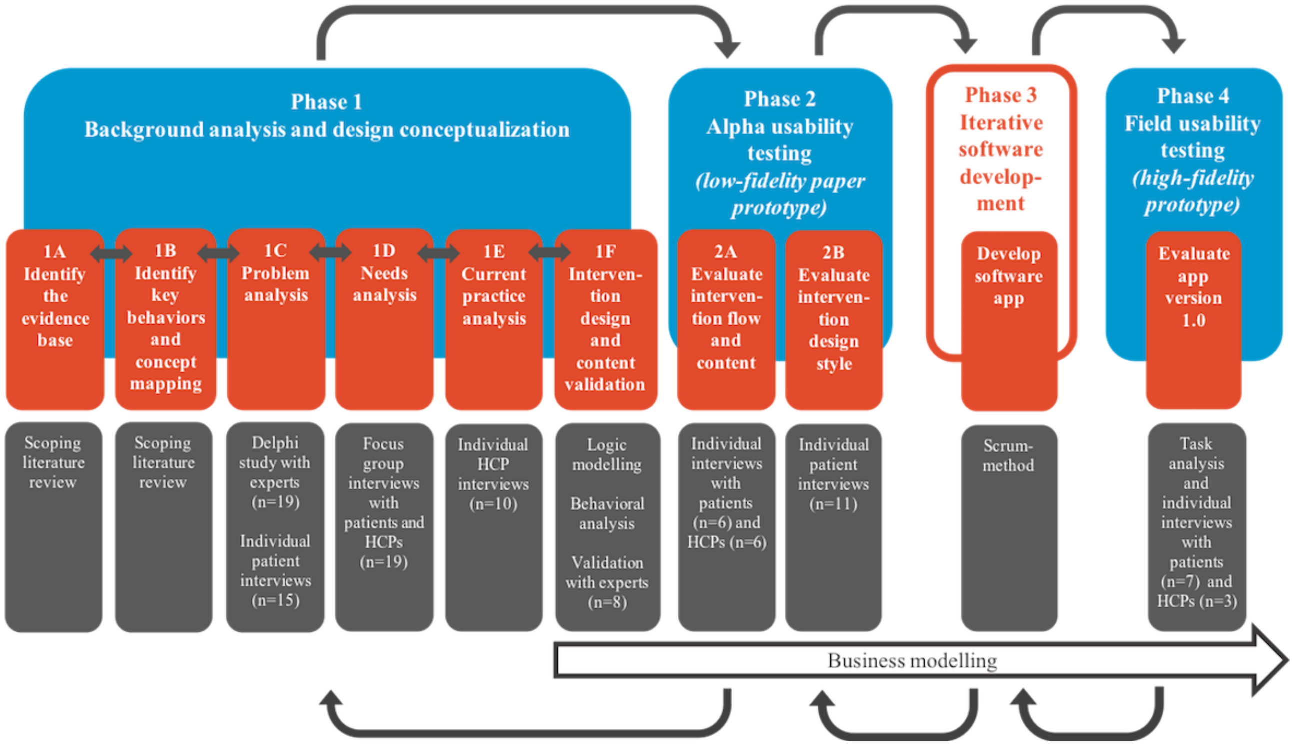
Guiding principles for the mHealth intervention were formulated by the research team at an early stage to provide a framework for making decisions during intervention development (Textbox 1) [32]. The guiding principles were based on recent evidence regarding COPD self-management and were progressively refined as the intervention development proceeded based on outcomes of specific development steps that we described in this paper. The mHealth intervention was developed by following a UCD process involving patients with COPD, health care providers (HCPs), COPD experts, designers, software developers, and a behavioral scientist. The UCD was based on the methodology as described by Johnston et al [33] consisting of four iterative phases: (1) background analysis and design conceptualization, (2) alpha usability testing, (3) iterative software development, and (4) field usability testing (Figure 1) [33]. Johnston et al [33] provide limited guidance on the specific steps needed to develop an effective mHealth intervention that meets patients' needs and preferences and fits with current COPD care. Therefore, we extended the first phase of the UCD with subphases based on a comprehensive approach that combines elements of the Medical Research Council (MRC) framework development phase with elements of existing development models (Figure 1) [34]. The MRC framework is a well-known and often used framework for the development and evaluation of complex interventions in health care with a specific focus on developing theory- and evidence-driven interventions. The whole design and development process was carried out between 2015 and 2019. The methods of each phase are chronologically described in the following paragraphs. The results of each phase are detailed in the Results section.

Textbox 1. Guiding principles for a mobile health intervention to enhance exacerbation-related self-management in patients with chronic obstructive pulmonary disease.

The mobile health intervention should:

- meet individual patient needs, perceptions, and preferences regarding exacerbation-related self-management;
- synchronize with current health status and anticipate on the heterogeneity of exacerbations in and between patients;
- focus on target behaviors in the full spectrum of exacerbation-related self-management;
- include a chronic obstructive pulmonary disease (COPD) action plan along with ongoing self-management support;
- focus on the continuous development of self-management skills and behavior change;
- stimulate proactive self-monitoring;
- be safe, literacy-sensitive, and patient-friendly;
- be feasible in current Dutch COPD care; and
- meet the conceptual definition of a COPD self-management intervention: *A COPD self-management intervention should be structured but personalized and often multicomponent, with goals of motivating, engaging and supporting the patients to positively adapt their health behavior(s) and develop skills to better manage their disease* [16].

Figure 1. User-centered design for the development of the mobile health intervention. HCP: health care provider.



Phase 1: Background Analysis and Design Conceptualization

The aim of the first phase was to identify the evidence base and to achieve a theoretical understanding of the underlying process of change for the intervention [35].

1A: Identify the Evidence Base

In phase 1A, a scoping literature review was performed in Medical Literature Analysis and Retrieval System Online (MEDLINE) to explore current systematic reviews on interventions that focus on enhancing exacerbation-related self-management in patients with COPD, including mHealth interventions, and to identify potential effective intervention components (Figure 1; phase 1A). Literature review on interventions was an ongoing process during the whole intervention development process, to stay up to date on developments about (mHealth) interventions focusing on exacerbation-related self-management.

1B: Identify Key Behaviors and Concept Mapping

In phase 1B, a scoping literature review was performed in MEDLINE to specify symptom fluctuation phases during the course of COPD and to identify relevant self-management behaviors that can reduce exacerbation impact (Figure 1; phase 1B). Two researchers (YK and JT) developed a conceptual model of patients' fluctuations in symptoms during the course of COPD. Then, an initial set of relevant self-management behaviors was generated and added to the conceptual model. The methods of the scoping review and stepwise development of the conceptual model are published elsewhere [15].

1C: Problem Analysis

A problem analysis was included to provide insight into the problems experienced by patients and identified by experts to determine the intervention targets and to set boundaries of the intervention (Figure 1; phase 1C). A two-round Delphi study with 19 international respiratory experts (medical doctors and key researchers in the field of COPD) was performed. In this study, insight into expert opinion was provided on the most relevant set of self-management behaviors that have the potential to maximally reduce the impact of exacerbations and is feasible to target and influence before, during, and after an exacerbation. The methodology is described in depth in the publication of this study [15]. Furthermore, a grounded theory study using individual in-depth interviews with patients with COPD (n=15) was performed [36]. In this study, patient perceptions, capabilities, and needs with regard to exacerbation-related self-management were explored to identify and explain the underlying process of exacerbation-related self-management behavior in patients with COPD. The methodology is described in depth elsewhere [30].

1D: Needs Analysis

Patients' needs regarding exacerbation-related self-management were partially identified in phase 1C because these needs flowed naturally from the problems perceived by patients [37]. An additional needs analysis was performed to further investigate specific needs and explicit requests for care with regard to using mHealth for self-management (Figure 1; phase 1D) [37]. To develop an mHealth intervention with optimal usability and feasibility, a deep and early understanding of both patients' and HCPs' perspectives was considered to be important [38]. Therefore, a qualitative study using focus group interviews with both patients with COPD (n=13) and HCPs (n=6) was performed to (1) explore their willingness to use mHealth for self-management of exacerbations, (2) identify potential benefits and barriers of using mHealth, and (3) explore needs and preferences regarding the content of an mHealth intervention [39]. The methods of this step are further described in the paper of this study [31].

1E: Current Practice Analysis

An analysis of COPD guidelines and current practice was performed to gain insight into current exacerbation-related self-management support and to explore the added value of the intended intervention compared with regular care (Figure 1; phase 1E). Individual semistructured interviews with HCPs (n=10) were performed to identify HCPs' perspectives with regard to care provided and their role in providing self-management support. Purposive sampling was performed in primary and secondary care settings. The following topics were discussed: current interventions to support exacerbation-related self-management, HCP experiences with providing self-management support, perceptions toward HCPs' roles and responsibilities, barriers in providing self-management support, and the potential to use mHealth for self-management support. All interviews were audiotaped, transcribed verbatim, and analyzed by open, axial, and selective coding [40].

1F: Intervention Design

The aim of the intervention design phase (Figure 1; phase 1F) was twofold: (1) to map out the potential working mechanisms triggered by the intervention and (2) to develop the flow and content of the intervention. During this phase, a decision was made on the target behaviors of the intervention. The behavior change wheel (BCW) method was used to analyze the target behaviors and to design intervention components [41]. First, based on the literature, behavioral analysis was performed by two researchers (YK and SH) to identify what needs to change in patients' capability, opportunity, and motivation to improve each target behavior (capability, opportunity, and motivation model of behavior [COM-B] analysis) [41]. Second, the theoretical domains framework (TDF) was used to elaborate on the behavioral analysis by mapping the 14 domains of the framework onto the capability, opportunity, and motivation components of COM-B [41]. Third, potentially relevant intervention functions and behavior change techniques (BCTs), matching users and context, were selected using criteria provided by the BCW [41] (see Multimedia Appendix 1). Logic modeling was used to map out the potential working mechanism of the intervention by detailing all evidence and assumptions underpinning the pathway from the intervention to the long-term impact on outcomes [42,43]. The logic model starts with the target behaviors and details what needs to change in behavior (TDF), by which intervention functions and BCTs, and through which specific intervention components, including factors that could influence the working mechanism, and results in short- and long-term outcomes. The logic model components were based on the evidence gained from all previous phases, and consensus on the components was reached during research group meetings. On the basis of this model, design requirements were formulated.

Furthermore, creative ideas with regard to the intervention design were explored using methods derived from design thinking [44]. In a *pressure cooker session* with three independent creative designers, initial ideas on the design were presented by focusing on potential techniques to change health behaviors and to enhance engagement with mHealth. After this session, collaboration with a creative design agency (Panton BV, Deventer, the Netherlands) specifically focusing on health care solutions was initiated. By following an iterative design process, the flow and content of the intervention were designed, and various design styles were developed using low-fidelity prototypes—paper prototypes that visualize design solutions. In the early stages of digital user interface design, such low-fidelity paper prototypes are often used to determine requirements for the architecture and functionalities of the specific intervention to be designed [45]. The paper prototypes were tested in phase 2 of the UCD.

Moreover, the content of a symptom-monitoring module was developed during this stage. The module aimed to determine the individual COPD patient's normal day-to-day variability in symptoms to be able to set the patient's normal symptom pattern. The content validity of the module was evaluated by experts in the field of COPD (n=8) according to the Lynn method [46]. Each symptom was rated on *relevance* and *linguistics* by answering four questions. All questions about *relevance* were rated on a 4-point Likert scale (1=not relevant, 4=relevant). *Linguistics* was determined by if the interpretation was clear (*yes* or *no*). The item-content validity index (I-CVI) was calculated for each *relevance* question to determine the number of experts judging the content as valid (I-CVI>0.78=relevant). Subsequently, the scale-content validity index (S-CVI) was calculated to determine the relevance of the whole symptom-monitoring module (S-CVI>0.90=excellent) [46]. *Linguistics* was considered to be clear when at least 75% of the expert panel rated clearness of interpretation as a *yes*. A more in-depth description of the development and content validity assessment of the symptom-monitoring module is given in Multimedia Appendix 2.

Phase 2: Alpha Usability Testing

In the second phase, alpha usability tests were performed by investigating patient and HCP responses to low-fidelity paper prototypes of the intervention in two steps: (1) evaluating the intervention flow and content and (2) evaluating intervention design styles [33]. At each phase of usability testing, we only included patients who had not evaluated an earlier prototype.

2A: Evaluate Intervention Flow and Content

Perceptions, needs, and preferences regarding the intervention flow and structure were evaluated with both patients with COPD (n=6) and HCPs (n=6) to identify usability requirements (Figure 1; phase 2A). Individual semistructured interviews were held using low-fidelity paper prototypes. The following topics were discussed: experience with mHealth and written action plans, the overall flow of the intervention, symptom-monitoring/action plan scenarios, and the added value of the intervention. Purposive sampling of participants was performed in primary, secondary, and tertiary care settings. In total, 6 patients and 6 HCPs were included based on the general rule of thumb that approximately 80% of all potential usability problems could be identified by including 5 to 10 end users [47]. The inclusion and exclusion criteria of the participants during usability testing are detailed in Textboxes 2 and 3, respectively. Data were thematically analyzed by two researchers independently [48]. Data analysis was supported by NVivo 10.0 software (2012; QSR International Pty Ltd.).

Textbox 2. Inclusion criteria of participants during usability testing.

Inclusion criteria for patients with a clinical diagnosis [2] of chronic obstructive pulmonary disease (COPD)

- Age >40 years
- Spirometry forced expiratory volume in 1 second/forced vital capacity ratio <70%
- ≥1 exacerbation in the last 12 months before entering the study (defined as a period of symptom deterioration in which the use of a course of corticosteroids and/or antibiotics was required, or hospitalization was necessary)
- Adequate communication skills
- Willing and able to comply with study procedures and give written informed consent
- Patients who are judged by their health care provider to have suitable hearing and vision

Inclusion criteria for health care providers

- Having a patient–health care provider relationship with patients with COPD
- Supporting patients with COPD in self-management
- At least one year of experience with COPD care

Textbox 3. Exclusion criteria of participants during usability testing.

Exclusion criteria for patients with a clinical diagnosis of chronic obstructive pulmonary disease

- Diagnosed with cognitive impairments
- Life expectancy ≤3 months
- Primary diagnosis of asthma, cardiac disease, or other major functionally limiting diseases

Exclusion criteria for health care providers

- Not applicable

2B: Evaluate Intervention Design Style

Next, the preferences of patients with COPD regarding intervention design style were explored by individual semistructured interviews (n=11; Figure 1; phase 2B) [33]. Low-fidelity paper prototypes were used to present variations in design style and tone of voice. Purposive sampling of participants was performed in a physiotherapy practice and a rehabilitation center according to the inclusion and exclusion criteria for patients in Textboxes 2 and 3. Data were analyzed by 2 researchers independently through summarizing the advantages and disadvantages of each design style and the overall preferences regarding design style. On the basis of the results of both alpha usability steps, the intervention design was finalized for further software development.

Phase 3: Iterative Software Development

The software of the mHealth intervention was developed during a 12-week period according to a scrum-based design method consisting of five development sprints (Figure 1; phase 3) [49]. During biweekly stakeholder meetings, the research team, designers, and software developers met in person to evaluate the current stage of development and to make decisions on the further development of the first version of the mHealth intervention (minimum viable product; MVP). The mHealth intervention was built in React Native (Massachusetts Institute of Technology licenses), a software structure that is easy to adapt and suitable for both iOS and Android. This saves time and money during the initial and future development of the intervention and fits within the agile development process of the intervention.

Phase 4: Field Usability Testing

In the fourth phase, field usability tests of the MVP (ie, tests with a high-fidelity prototype within the context in which the intervention will actually be used) were performed with patients with COPD (n=7) and HCPs (n=3) using cognitive task analysis [47,50]. This mixed methods study focused on three quality components: task success, user errors/problems, and satisfaction, based on Nielsen's heuristics and the International Organization for Standardization's usability standard 9241-11 [51]. Purposive sampling of participants was performed in primary, secondary, and tertiary care settings until data saturation was reached. In line with the procedure of phase 2, a minimum of 5 patients were included according to the inclusion and exclusion criteria of Textboxes 2 and 3. Participants were observed while performing tasks with the MVP and asked to *think aloud* to clarify their decision-making process and express experienced user problems and errors [51]. After the task analysis, the validated 10-item system usability scale (SUS) was filled out by patients to get a global view of usability [52]. Each item was scored on a 5-point Likert scale, and all items were converted to a total score (range 0-100, a score>70 is considered to be acceptable) [52,53]. Furthermore, semistructured interviews were conducted. On the basis of previous research and the technology acceptance model [54,55], the following topics were formulated: the first impression of the app, ease of use, satisfaction, perceived usefulness, applicability, attitude toward using the app, and the content of the app. The whole procedure with patients was video recorded without the faces of participants being visible. The procedure with HCPs was more pragmatic in nature because the MVP did not include a specific HCP interface. However, the relevant functions for HCPs could be tested within the MVP. Therefore, only 3 HCPs were included, and the procedure was only observed by 1 researcher who simultaneously made notes.

The performance of tasks by patients was observed by two researchers independently. An observation list was used to note task success, users' errors/problems, and participants' expressions for each task. The performance of tasks was scored as successful (1 point), partially successful (0.5 points), or unsuccessful (0 points) [56]. The observation lists were discussed by the researchers to reach a consensus on the performance of tasks and the identified problems and errors. The data from the think-aloud method were used to derive a better understanding of task performance. A severity score ranging from 0 (no usability problem) to 4 (usability catastrophe) was given to each problem based on the impact and frequency of the problem [57]. Data from the semistructured interviews were analyzed by 2 researchers independently using thematic analysis [48]. The data analysis of HCPs observations was performed by only 1 researcher, and the semistructured interviews were only summarized.

The usability studies were approved by the Medical Ethics Research Committee of the University Medical Center Utrecht (17–887), and all participants gave written informed consent.

Business Modeling

Business modeling, based on the principles of *the lean startup* methodology [58], was performed parallel to phase 1F until phase 4 to ensure valorization and sustainable implementation of the mHealth intervention in its intended care practice (Figure 1) [59]. Business modeling included contextual inquiry and continuous investigation of relevant stakeholder needs (patients with COPD, HCPs, policy makers, and health care insurers) to better understand what should be accomplished with our mHealth intervention and to obtain value drivers to underpin choices in what to design [59]. The needs of patients with COPD and HCPs were investigated in phases 1C, 1D, and 1E, and individual conversations with policy makers and health care insurers were held to identify their perspectives toward the mHealth intervention. Furthermore, the best innovation and distribution routes and market opportunities were explored in conversations with stakeholders to investigate their interests and financial incentives to support self-management with mHealth. Competition analysis was performed to explore the value of our intervention with respect to existing mHealth technologies. Finally, conversations with vendors in the field were held to explore business opportunities.

Results

Phase 1: Background Analysis and Design Conceptualization

1A: Identify the Evidence Base

A total of four relevant systematic reviews on exacerbation-related self-management interventions and two systematic reviews specifically focusing on mHealth interventions to improve exacerbation-related outcomes were identified. Self-management interventions, including exacerbation action plans along with ongoing self-management support, were associated with positive outcomes on quality of life, hospital admissions, and health care use [11,12,60]. A review of self-management interventions delivered immediately following an acute exacerbation showed no significant effect on quality of life nor hospital admissions [61]. All reviews showed large heterogeneity in interventions making it hard to draw conclusions on effective components of these interventions. Furthermore, mHealth interventions facilitating, supporting, and sustaining self-management among people with COPD significantly improved quality of life, and levels of activity [19]. Smartphone interventions in patients with COPD with exacerbations, without a specific focus on self-management, were found to be useful in reducing the number of patients having a COPD exacerbation [20]. These results should also be interpreted with caution because of the heterogeneity among studies.

On the basis of these findings, it seemed promising to use mHealth strategies that specifically aim at enhancing self-management behavior. It was considered important that the mHealth intervention includes a COPD action plan along with ongoing self-management support, which confirmed our guiding principle to include an action plan. Furthermore, a conceptual definition of a COPD self-management intervention was published in 2016 [16]. Given the need for consensus on what defines a COPD self-management intervention, this definition was added to the guiding principles (Textbox 1).

1B: Identify Key Behaviors and Concept Mapping

A conceptual model picturing the event of an exacerbation was developed by distinguishing five phases before, during, and after an index event. Specific aims regarding the reduction of exacerbation impact were formulated for each phase of the conceptual model. The conceptual model is published elsewhere [15]. On the basis of the knowledge generated from the literature, an initial set of 27 relevant self-management behaviors aiming to reduce exacerbation impact was identified and assigned to the relevant phases of the conceptual model. This initial set of self-management behaviors was introduced to experts in the first round of the Delphi study (Figure 1; phase 1C) to reach a consensus on the most relevant behaviors [15].

1C: Problem Analysis

A Delphi panel of 19 international experts reached a consensus on 17 self-management behaviors that can be targeted and influenced before, during, and after an exacerbation (Figure 1; phase 1C). This set of behaviors has the potential to maximally reduce the impact of exacerbations. The self-management behaviors were related to the following broader categories: adherence to pharmacotherapy, influenza vaccination, physical activity/exercise, avoiding stimuli, smoking cessation, early detection of symptom deterioration, medical treatment of exacerbations, managing stress and anxiety, and awareness of recurrent exacerbations [15]. The 17 self-management behaviors were considered as potential target behaviors for the mHealth intervention. Our grounded theory study (Figure 1; phase 1C) has resulted in a conceptual model explaining factors that influence exacerbation-related self-management from the patients' perspective. The conceptual model is published elsewhere [30]. The conceptual model shows that exacerbation-related self-management is influenced by five generic factors: *acceptance of COPD*, *perceived severity of symptoms*, *knowledge of exacerbations*, *former experiences with exacerbations*, and *social support*. Furthermore, *heterogeneity of exacerbations* and *habituation to symptoms* were identified as specific factors influencing the capability to recognize an exacerbation. Performance of self-management actions was specifically influenced by *perceived influence on exacerbation course*, *feelings of fear*, *self-empowerment*, *trust in health care provider*, *patient beliefs*, and *ambivalence toward treatment* [30]. These factors were included as moderating and mediating factors in the working mechanism of the intervention (see also 1F: Intervention Design section).

1D: Needs Analysis

Our needs analysis (Figure 1; phase 1D) resulted in an overview of potential benefits and barriers regarding the use of mHealth to support self-management and early ideas on the content of the intervention [31]. Both patients and HCPs emphasized the need for a multicomponent and tailored mHealth intervention that focuses on improving patient self-management skills by determining health status and providing adequate information, decision support, and feedback on self-management behavior in an advisory manner. Important findings were that patients and HCPs emphasized that an mHealth intervention should never replace patients' own feelings nor undermine their own decisions. The intervention should be complementary to regular (personal) contact with HCPs and should facilitate adequate self-management support by HCPs. Discussing self-management skills with HCPs in personal consultations was believed to be essential to improve these skills. Both patients and HCPs expressed doubts regarding (real-time) the monitoring of symptoms by HCPs because of safety reasons and time constraints, although early detection of exacerbations was considered to be an important benefit. Moreover, the intervention should be attractive, straightforward, rewarding, and safe. Finally, patients emphasized that using mHealth should be their own choice and should never be enforced. On the basis of these findings, the design requirements for the intervention were formulated. Further results of the focus group interviews are published elsewhere [31].

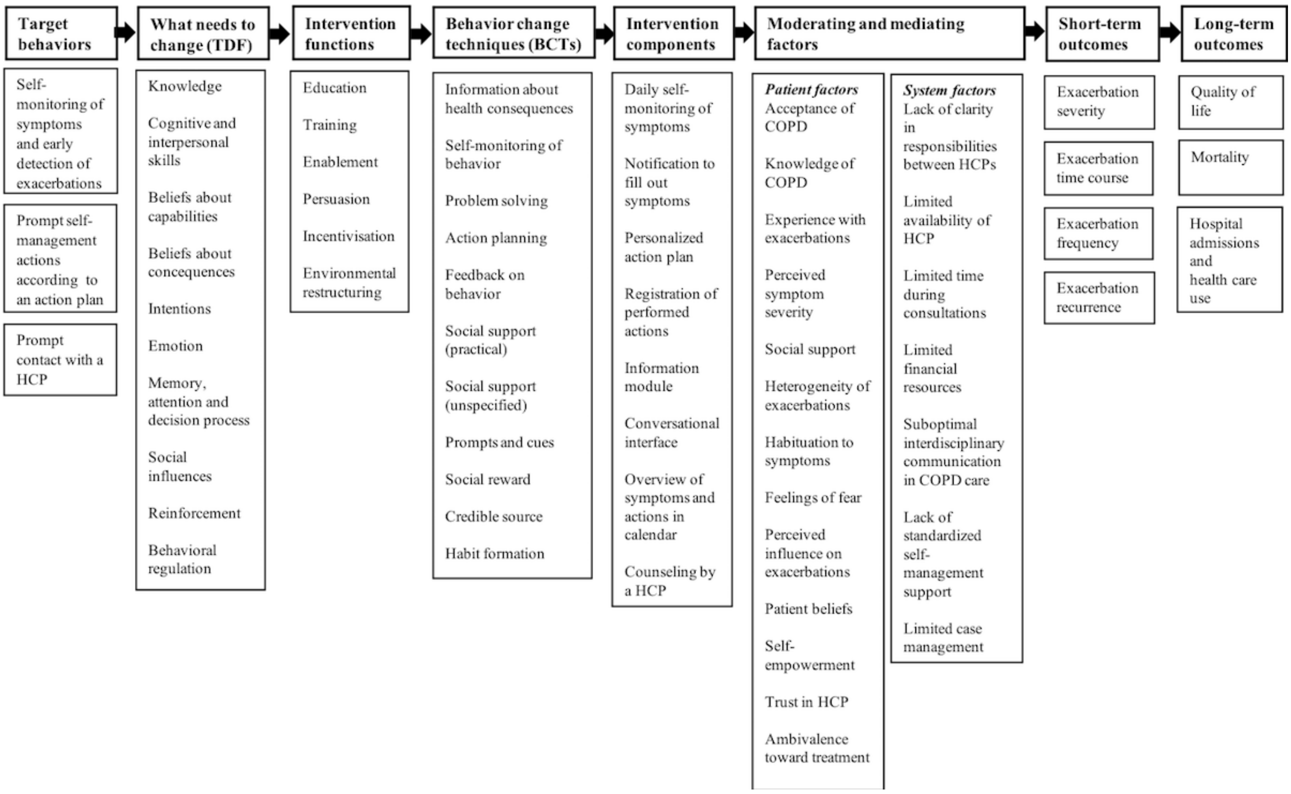
1E: Current Practice Analysis

On the basis of three Dutch health care standards focusing on COPD [62-64] and 10 interviews with HCPs, insight into current exacerbation-related self-management support was provided. Two pulmonologists, 2 nurse specialists, 2 pulmonary nurses, 2 general practitioners, and 1 primary care nurse (4 males/6 females, work experience range 3-20 years) were interviewed. An important finding was the lack of standardized self-management support and limited use of evidence-based interventions by HCPs. There was a large variation in providing information about exacerbation-related self-management with regard to timing, topics discussed, and mode of delivery. Only a few HCPs used a COPD action plan and prescribed self-treatment with prednisolone and/or antibiotics to stimulate self-management. More than half of the HCPs (n=6) expressed that patients had no specific case manager. Providing self-management support was mostly perceived as a shared responsibility between HCPs, although individual responsibilities of the HCPs involved were unclear. Most HCPs felt that there is large room for improvement in self-management support by HCPs. Barriers in providing self-management support were the lack of standardized self-management support and clarity in responsibilities between HCPs, limited availability of HCPs, limited case management, limited time during consultations, limited financial resources, and suboptimal interdisciplinary communication in COPD care. The findings from the current practice analysis were included as moderating and mediating factors in the working mechanism of the intervention (see also 1F: Intervention Design section).

1F: Intervention Design

During the intervention design phase, the research team decided to initially focus on the three target behaviors: (1) self-monitoring of symptoms and early detection of an exacerbation, (2) taking prompt individualized self-management actions, and (3) prompt contact with an HCP. On the basis of insights from phase 1C, these behaviors were expected to contribute most to the reduction of exacerbation impact, had the potential for large improvement, and were considered most feasible to influence. The choice for these three behaviors was made, given the importance of aggregating the target behaviors that fit together and are considered to have the largest impact on exacerbations [65]. On the basis of behavioral analysis of these behaviors, potential intervention functions and BCTs were selected for the intervention [41]. The behavioral analysis of the target behaviors, including the final intervention functions and BCTs is described in detail in Multimedia Appendix 1. Figure 2 shows the logic model of the intervention that synthesizes all the evidence gained in the previous phases (phase 1A until 1E), including the selection of final intervention functions and BCTs.

Figure 2. Logic model of a mobile health intervention to enhance exacerbation-related self-management in patients with chronic obstructive pulmonary disease. BCTs: behavior change techniques; COPD: chronic obstructive pulmonary disease; HCP: health care provider; TDF: theoretical domains framework.



On the basis of the results of all previous phases, design requirements for the mHealth intervention were formulated (see Textbox 4). At this stage, the research team and design agency decided to develop a mobile app to enhance exacerbation-related self-management in patients with COPD. On the basis of design requirements, a concept of the flow and content of the app and various design styles were developed using low-fidelity paper prototypes.

Textbox 4. Design requirements for the mobile health intervention.

The mobile health (mHealth) intervention should:

- at least focus on self-monitoring of symptoms and early detection of exacerbations and taking prompt self-management actions including prompt contact with a health care provider (HCP);
- support patients in developing self-management skills over time (*learning by doing*) and changing behaviors;
- focus on (aggregated) self-management behaviors before, during, and after an exacerbation;
- include a chronic obstructive pulmonary disease (COPD) action plan with an educational component along with ongoing support;
- be comprehensive/multicomponent and tailored to individual patients;
- provide adequate information, decision support, and feedback on self-management behavior (in an advisory manner);
- take into account the factors influencing exacerbation-related self-management;
- fit with current COPD care and be accessible for HCPs;
- facilitate adequate self-management support by HCPs;
- be complementary to regular (personal) contact with HCPs;
- be attractive, straightforward, rewarding, and safe;
- never replace patients' own feelings nor undermine their own decisions; and
- not be enforced to patients. Using mHealth should be the patient's own choice.

Furthermore, the symptom-monitoring module was developed during this stage. Content validity of the symptom-monitoring module was determined after two expert rounds. In total, these eight symptoms were rated as relevant (I-CVI>0.78) and clear (≥75% of the expert panel): Dyspnea, wheezing, nighttime symptoms, coughing, sputum volume, sputum purulence, sputum color, and fatigue. The relevance of the final symptom-monitoring module, determined by three questions, was considered to be high with S-CVIs of 0.93 or greater. More detailed results and the final symptom-monitoring module are shown in Multimedia Appendix 2.

Phase 2: Alpha Usability Testing

2A: Evaluate Intervention Flow and Content

Evaluation of the flow and content of the intervention with both patients with COPD and HCPs resulted in overarching themes related to the intervention flow and an overview of usability requirements. The baseline characteristics of the participants are shown in Multimedia Appendix 3. The patients recruited from tertiary care all had a written action plan, whereas the other patients only had verbal agreements with their HCPs.

The Intervention Flow and Content

Overall, all patients and HCPs were positive about the intervention flow that consisted of four steps: (1) personalization of an action plan, (2) intensive monitoring of symptoms, (3) adjusting initial action plan based on monitoring period, and (4) regular use (filling out symptoms on a regular basis and receiving support on individualized actions). However, the patients who believed that they were well aware of their symptoms did not directly perceive that they could benefit from the intensive monitoring period. Overall, patients preferred personalization of the duration of intensive monitoring and the timing of notifications. HCPs felt that they should have autonomy in determining how, and at which moment, the action plan should be reviewed and adjusted. On the basis of specific mockups used to explore preferences regarding symptom registration and determining symptoms status, the most intuitive and straightforward scenarios were identified. For example, mockup 1 was considered to be the best solution to determine symptom status by all patients (Figure 3).

Figure 3. Low-fidelity paper prototypes of 3 scenarios to determine symptoms status.

Mockup 1 Mockup 2 Mockup 3

The Added Value of the Intervention

Patients expressed that the app could create awareness into their own situation and could support early detection of symptom deterioration and taking prompt actions. The adjustability and accessibility of the app were perceived as benefits compared with using a written action plan. Furthermore, both patients and

HCPs were positive about the overview of registered symptoms and undertaken actions as a tool to start the dialog about patients' self-management behavior. Moreover, personalization and tailoring of the app were considered to be an important benefit:

> *Finally an app that is not for COPD but for me personally.* [Patient 2]

Needs With Regard to the Intervention

Patients expressed a clear need for an accessible and reliable app that provides insight into their own situation and eliminates their doubts by including reflective questions. Patients stressed the importance of an app that is straightforward, for example, by providing simple and effortless instructions in case of serious dyspnea that causes panic, such as:

> *breathe slowly or call the doctor: It has to be simple, because energy is air.* [Patient 3]

They would like to use the app to inform relatives about their situation. Both patients and HCPs emphasized that the app should stimulate prompt contact with an HCP:

> *Patients experience feelings of fear you know, like: when I am raising an alarm, I might have to take prednisolone or I might be admitted to the hospital, so therefore I won't make the call...Will that be included in the app as well?* [HCP 1]

Furthermore, HCPs explained that the app should provide insight into patient symptoms over time and realize more proactive care instead of reactive care. Most HCPs felt that a separate HCP interface to personalize the app would increase the usability of the app in daily practice.

Usability Requirements

On the basis of the results of phase 2A, usability requirements were formulated for the software development phase (see Table 1).

Table 1. Usability requirements for the mobile health intervention.

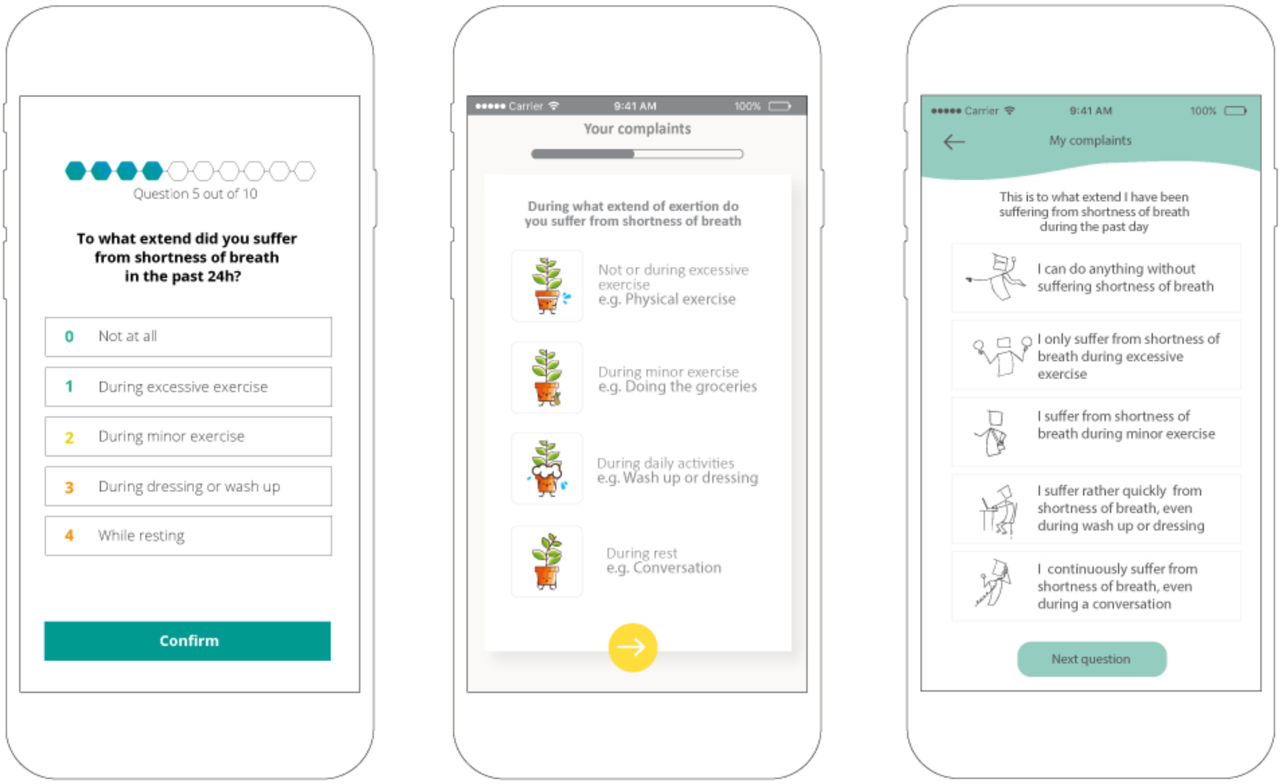
Topics of importance to users	Patients with chronic obstructive pulmonary disease (n=6) and HCPs[a] (n=6)
Content	• App should be reliable and accessible • Information should be straightforward and individualized • App should provide insight into symptoms over time • App should support prompt contact with an HCP • App should be a tool that can be used to get into dialog with HCPs about self-management behavior
Tailoring of the app	• Intensive monitoring period and timing of notifications should be personalized • HCPs should have autonomy in determining how, and at which moment in the care process, the action plan should be reviewed and adjusted
Interface	• The action plan should preferably be personalized in a separate HCP interface
Design style	• The design style should be restrained and clear without too much text.

[a] HCP: health care provider.

2B: Evaluate Intervention Design Style

In total, three potential design styles of the intervention were explored with patients with COPD (see Baseline characteristics in Multimedia Appendix 3. Mockups of the action plan, symptom registration, action registration, and the overview of symptoms and actions over time were used (see example in Figure 4). There was no consensus on a preferred design style. In general, patients preferred a restrained and clear design style without too much text. A few patients were positive about a more numerical design, whereas other patients found it hard to express their symptoms in numbers. There was a wide variety in preference regarding the tone of voice (distant vs personal tone of voice). Overall, patients were positive about using symbols. Most patients were negative about using an avatar in the app as it has no added value, and some patients considered an avatar to be childish. On the basis of these results, a restrained and clear design style without too much text was included as a usability requirement (see Table 1).

Figure 4. Low-fidelity paper prototypes of three symptom monitoring design styles.



Question 5 out of 10

To what extend did you suffer from shortness of breath in the past 24h?

0 Not at all
1 During excessive exercise
2 During minor exercise
3 During dressing or wash up
4 While resting

During what extend of exertion do you suffer from shortness of breath

Not or during excessive exercise e.g. Physical exercise
During minor exercise e.g. Doing the groceries
During daily activities e.g. Wash up or dressing
During rest e.g. Conversation

This is to what extend I have been suffering from shortness of breath during the past day

I can do anything without suffering shortness of breath
I only suffer from shortness of breath during excessive exercise
I suffer from shortness of breath during minor exercise
I suffer rather quickly from shortness of breath, even during wash up or dressing
I continuously suffer from shortness of breath, even during a conversation

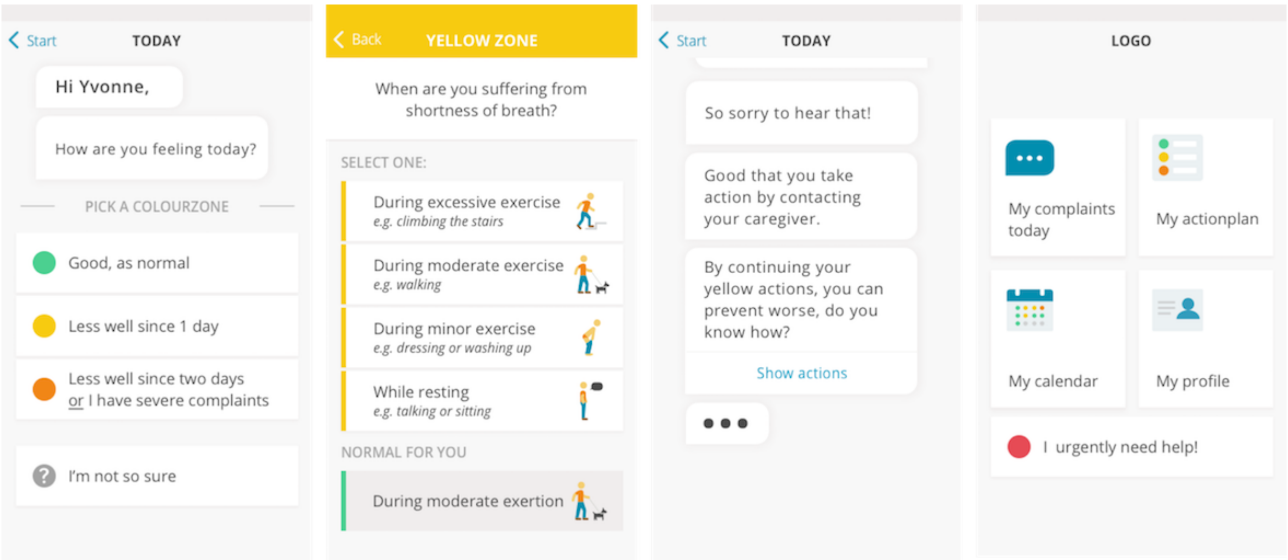
Phase 3: Iterative Software Development

Iterative software development resulted in a functional mobile app for patients (Copilot app) that can be used to (1) compose an action plan together with an HCP (based on a COPD action plan using color zones that is included in Dutch care standards)[66], (2) monitor symptoms and undertaken actions, (3) review symptoms and undertaken actions, and (4) read information about COPD and exacerbations. At this stage, the final integrated list of BCTs needed to ensure this MVP adhered to both the guiding principles (Textbox 1) and the design requirements (Textbox 4) was constructed by two researchers (YK and SH) using the BCW framework. In total, 6 intervention functions and 11 BCTs were selected for the MVP (see Figure 2 and Multimedia Appendix 1). During the iterative software development process, the research team made decisions to add steps to the flow of the app that were not thought of beforehand, such as including an onboarding program to register and personalize the patient's action plan. At the same time, owing to time and financial constraints, some steps were disregarded and moved to later versions of the intervention, such as including assistance in cases where patients are in doubt about contacting their HCP.

Phase 4: Field Usability Testing

All functionalities of the MVP were tested by patients with COPD, and all functionalities that belong to the HCP role were evaluated with HCPs (see baseline characteristics in Multimedia Appendix 3). Examples of the MVP are shown in Figure 5.

Figure 5. High-fidelity prototype of the Copilot app (minimum viable product).



Hi Yvonne,

How are you feeling today?

When are you suffering from shortness of breath?

So sorry to hear that!

Good that you take action by contacting your caregiver.

By continuing your yellow actions, you can prevent worse, do you know how?

Usability Assessment

According to patients with COPD, the general usability of the MVP was considered to be good based on the average rating of 90.7 (SD 6.7) on the SUS.

Task Success

Key tasks within the app were performed by all patients, and some tasks were performed only by a few patients because of time constraints (see Multimedia Appendix 4). Almost all patients were successful in consulting the app for HCP contact details and immediate help as well as to check self-management actions in the specific color zones. Furthermore, reviewing symptoms and undertaken actions was performed successfully overall, except for 2 participants who did not know where to find this overview. The information module was easily found by most of the patients. Most difficulties in the performance of tasks were observed during the symptom and action registration. Most patients were able to fill out their symptoms, but some patients overlooked the *save* button. One patient experienced difficulty with selecting the right color zone because of difficulty with scenario thinking. The support option for selecting a color zone (gray zone) appeared not to be intuitive, and navigation problems in the gray zone were observed. Overall, the HCPs were able to personalize the action plan and to evaluate the symptom-monitoring period. The performance of tasks by both patients and HCPs is further specified in Multimedia Appendix 4.

User Errors and Problems

On the basis of task analysis and observations during random navigation in the app, 23 user errors and problems were identified by patients with COPD. In total, seven problems were rated with the highest severity score of 4. These problems were related to saving registered symptoms, accidentally deleting symptoms and navigation in the gray zone. Moreover, five problems had a severity score of 3 and were related to the action plan overview, understanding of buttons on the home screen, and changing HCP contact details. The lowest severity scores (1 and 2) were assigned to 11 problems. Furthermore, 11 user errors and problems were observed during the use of the app by HCPs. The HCPs experienced problems with saving registered symptoms as well. Another severe problem was related to changing contact details (severity score 4). Two less severe problems were related to personalizing and changing the yellow zone of the action plan (severity score 3). The lowest severity scores (0-2) were assigned to seven problems. A more detailed overview of all user problems and errors is provided in Multimedia Appendix 4.

Patients' and Health Care Providers' Perceptions Toward Using the App

Overall, patients were positive about the app, as they found the app supportive with regard to monitoring and evaluating symptoms and taking prompt actions. On a scale from 1 to 10, patients' satisfaction rates ranged from 8 to 10 because of the ease of use and the interface being intuitive. The patients who frequently experienced exacerbations expressed an important need for the app. Two patients who rarely experienced exacerbations explained that the app will only have an added value if additional support would be provided during the stable phase (green zone). The interviews resulted in 13 themes that were categorized into feelings about the app, the added value of the app, the content of the app, and facilitators and barriers to use the app. A description of these themes and illustrative quotes is provided in Multimedia Appendix 4.

Field usability testing showed that a usable mHealth intervention has been developed. On the basis of these results, improvements for future versions of the app were revealed. The improvements were determined in collaboration with the designers and focus on the user errors and problems that were rated as most severe (severity ratings 3 and 4), problems that were observed in both patients and HCPs, or additional problems that were mentioned in the interviews. An overview of these improvements is shown in Multimedia Appendix 4.

Business Modeling

Business modeling resulted in a preliminary business plan that provided important design input during the development steps and will direct future development and implementation steps.

The business plan guided the direction to actively involve HCPs in providing the intervention to patients and the specific focus on developing self-management skills over time (learning by doing) to be distinctive from other Dutch mHealth solutions. These outcomes were added to the design requirements (Textbox 4). During business modeling, market volume, and segmentation, different innovation and distribution routes and revenue models were systematically evaluated. Given current positive developments with regard to funding of apps in the Netherlands, especially those that are evidence-driven, a distribution strategy will be chosen that includes health care insurers to ensure implementation and continued use in Dutch COPD care.

Discussion

Principal Findings

This paper provides insight into a systematic and thorough way of developing an evidence-driven and usable mHealth intervention (Copilot) for patients with COPD to enhance exacerbation-related self-management. Following an iterative UCD process, a mobile app consisting of a personalized action plan and symptom-monitoring module has been developed. The intervention was developed by following a thorough and well-underpinned process consisting of a background analysis and design conceptualization phase leading to final guiding principles, a logic model and design requirements, usability testing phases leading to usability requirements, and iterative software development of an MVP that adheres to these guiding principles and design and usability requirements. This unique approach of scientific engineering has resulted in an mHealth intervention that meets the needs and preferences of patients with COPD, is likely to be used by patients with COPD, and has a high potential to be effective in reducing exacerbation impact. Involving patients with COPD, HCPs, COPD experts, and experts from design and behavioral science throughout the development process increased the likelihood that the mHealth intervention can be successfully implemented into Dutch COPD care.

Copilot requires an active case manager role, as previous studies have shown the need for ongoing case manager support alongside the use of an action plan to achieve effective and safe self-management [11,67]. The mHealth intervention was developed as a tool to enhance patient self-management skills that is complementary to personal interaction with an HCP. This is in line with recent research underlining that a good patient-HCP relationship is important for patients to engage and take responsibility for their own health care [68,69]. The specific focus on developing self-management skills over time is distinctive from other mHealth initiatives, as research in the past decade has focused increasingly on telemonitoring strategies to decrease the impact of exacerbations [21,70,71]. The impact of telemonitoring in the COPD population is, however, still equivocal because of trial designs, unstandardized interventions, and limited follow-up [21,70]. With telemonitoring, the decision-making process is profession based. The working mechanism of Copilot focuses on enhancing patients' self-management skills over time. Therefore, no telemonitoring strategies were included in our mHealth intervention.

Although our Delphi study has shown the need for a comprehensive strategy to improve the full spectrum of exacerbation-related self-management behavior [15], the first version of our mHealth intervention focuses specifically on self-monitoring of symptoms and taking prompt individualized self-management actions. A *less is more* approach consisting of only a few strong target behaviors that fit together was considered to be imperative in creating impact [41,65]. When changing these target behaviors is proven effective, we could build upon these behaviors incrementally [41]. It is important to note that not all relevant self-management behaviors have to be addressed through mHealth, as HCPs should continue to have an essential role in providing self-management support as well [31].

Strengths and Limitations

A major strength was the systematic and thorough way of developing Copilot according to a UCD that was based on existing development models and diminished the chance of missing important steps [33,34]. We have systematically investigated and incorporated the views of end users, continuously evaluated prototypes, and involved persuasive design techniques to match user profiles and motivate patients to engage in self-management, which is in line with the *person-based approach* and the holistic framework for the development of electronic health (eHealth) technologies [32,72]. Furthermore, we used guiding principles to easily recall the principal and distinctive features of the intervention during the extensive, iterative intervention development process [32]. Another important strength was the detailed analysis of behaviors of patients with COPD using the BCW method and selection of BCTs to underpin the pathway toward behavior change [41]. Using the BCW method along with a UCD is comparable with the methodology used by Curtis et al [22] to develop a theory-driven and user-centered healthy eating app. Their work also focused on a thorough analysis of target behaviors, selection of BCTs, and exploration of user preferences to underpin the design of the app with relevant theory and evidence and ensure engagement among the target population. However, Curtis et al [22] performed no specific activities with regard to valorization and implementation of their app during their development process [22]. To make both the design and the implementation of our app value driven, we performed valorization activities throughout the development process of our app [59,72]. Business modeling helped us to identify critical success factors that will influence the sustainability and effectiveness of the app, which is often overlooked during the development process of eHealth and mHealth technologies [59].

From a health care and behavior change perspective, we chose to use the MRC framework for the development of complex interventions as a basis for our UCD, instead of a more general software development approach. The four iterative phases were inspired by the user-centered methodology used by Johnston et al [33] for the development of a Web-based interface for patients with COPD. The use of a more general software development approach as a basis for the development process might have provided more specific guidance to the software development and usability phases beforehand. However, such approaches pay less attention to the activities needed to design a theory- and evidence-driven intervention, which was an important focus in our design process.

Furthermore, it should be noted that the extensive and thorough development process increased the likelihood of developing an effective intervention, although it is questionable if this process is feasible in daily practice. The whole intervention development process took place over a 4-year period, which is quite time consuming and could increase the risk of a misfit with current market developments or that technology has moved on by the time of implementation [22,73,74]. The time-consuming development was partly because of the inclusion of all the development phases but was also related to developing an mHealth intervention from a scientific environment. Developing an intervention from science involves completing an empirical cycle at each development phase and often includes an extensive review of a study protocol by a medical ethics research committee. Pursuing the rules of science during the development process of an mHealth intervention has slowed down the process at certain points in time. Furthermore, development from a scientific environment generally means less focus on business modeling and entrepreneurship, which could delay the process of bringing the app to the market. Finally, a limitation in this study was the restricted budget available for the creative design and development of the mHealth intervention, which required us to make a selection in the development of intervention components.

Implications for Practice and Future Research

The findings of this study are important for both patients with COPD and HCPs supporting patients with COPD in self-management as well as for researchers and designers focusing on the development of mHealth interventions. For patients with COPD, an evidence-driven and usable mobile app has been developed to assist them in developing exacerbation-related self-management skills. It needs to be emphasized that, at least for the coming years, not all patients with COPD will be eligible for the mHealth intervention, especially for those with a more negative attitude toward mHealth and low digital literacy [19,31]. However, a positive change in attitudes toward mHealth and digital skills can be expected in the future, given the current trends in internet access and smartphone use [18]. For HCPs, the mHealth intervention can be used to provide more evidence-based, structured, and tailored self-management support. The mHealth intervention can be embedded in primary, secondary, and tertiary care settings, which could contribute to improving integrated care. To increase the likelihood of successful implementation in Dutch COPD care, the intervention can easily be adapted to a specific setting and context. Hereby, the intervention would be available for a wide range of health care settings in which patients with COPD are currently treated. For future practice, it is important that more intervention components will be added to the mHealth intervention to optimally address the selected target behaviors, such as adding self-treatment with prednisolone and/or antibiotics and providing assistance in case patients are in doubt about if they should contact their HCP. Furthermore, a separate dashboard for HCPs should be developed to be able to individualize the mHealth intervention and to review registered symptoms and actions during consultations without having to use the patient's own device. An essential step would then be to establish cooperation with external vendors in the field and health care insurers to ensure implementation in COPD care. In the next phase, it is important that the mHealth intervention takes into account patient comorbidities to make the intervention available for a wider population and to ensure patient safety [12]. Future steps should focus on adding target behaviors that are relevant before, during, and after an exacerbation to maximize the reduction of exacerbation impact.

For researchers and designers, the UCD in this study can be used as guidance for the development of mHealth interventions that meet end user needs and preferences, have high potential to be effective, and are likely to be used by the target population. Essential in the development is that interventions are grounded in theory and evidence and that user needs and preferences are thoroughly investigated. Moreover, valorization and implementation activities should be regarded as continuous activities throughout the development process to ensure sustainable use in its intended practice. This extensive reporting of the intervention development process enhances the reproducibility of the intervention and contributes to more transparency in the development of complex interventions in health care, which is needed to strengthen the internal and external validity of interventions and to add value to health care research [34]. All in all, it is helpful to have multiple examples and variants on how to develop evidence- and theory-driven mHealth interventions. It should be considered if the thoroughness of this UCD is needed for all mHealth interventions that will be developed in the future. Depending on the topic, decisions should be made about which phases and steps are relevant to the topic and should be included in the development process. In addition, taking time aspects into consideration, it should be questioned how thoroughly an individual step should be executed. The need for efficiency in the development of mHealth interventions is currently a highly discussed topic [75]. Our work contributes to this discussion by mapping out a state-of-the-art design and development process and showing how time consuming this is.

Future research should focus on evaluating the feasibility of the mHealth intervention in the daily practice of HCPs, as they have a key role in personalizing the mHealth intervention before patient use. In a second phase, the feasibility of the mHealth intervention should be evaluated with patients with COPD to investigate the delivery and acceptability of the intervention, compliance with the intervention, and recruitment and retention of patients. In the next phase, the effect of the mHealth intervention on the relevant patient outcomes and health care use should be evaluated. Recent studies on mHealth interventions in patients with COPD suggest the use of randomized controlled trials (RCTs) with adequately powered sample sizes and a 1-year follow-up period to be sufficient to comment on behavioral change and impact of treatment [19,20]. However, this time-consuming design may not be ideal for rapidly evolving mHealth technologies [73,76]. Using an RCT implies two or more years of research in which this mHealth intervention with high potential for effectiveness, and no expected harm will not be available for patients with COPD.

Furthermore, an RCT only enables identifying if this complex mHealth intervention as a whole work and the cost-effectiveness of it, without identifying which intervention components work in whom. Alternatively, more rapid study designs such as n-of-1 trials or observational designs could be used to understand the working mechanism of the intervention and simultaneously focus on bringing the mHealth intervention to the market as soon as possible [73,75-77]. Within these designs, it is important to evaluate self-management skills and behavior change as outcomes, and the way this is assessed should be clearly reported [19,77,78].

Conclusions

This paper described in detail the full UCD and development process of an evidence-driven and usable mHealth intervention to enhance exacerbation-related self-management in patients with COPD. By following a UCD process, an mHealth intervention was developed that meets the needs and preferences of patients with COPD, is likely to be used by patients with COPD, and has a high potential to be effective in reducing exacerbation impact. This extensive reporting of the intervention development process contributes to more transparency in the development of complex interventions in health care. The UCD process in this study can be used by researchers and designers as guidance for the development of mHealth interventions. However, taking time aspects into consideration, decisions have to be made about the thoroughness of executing individual phases.

Acknowledgments

The authors thank all patients and HCPs who participated throughout the development process for their time and sharing perceptions toward the mHealth intervention. The authors acknowledge all health care centers for recruiting patients. The authors thank Beatrijs van Hoof and Jochem Wilson from Panton BV for translating the input for the mHealth intervention into a creative design and thank developers from Inspire Innovation BV for developing the software of Copilot. Furthermore, the authors thank Annabeth van Stroe, RN, MSc, for her role in evaluating the intervention flow and content and also thank the students from the Bachelor of Nursing course of the University of Applied Sciences Utrecht for their role in examining current practice. During the development process, researchers JT and YK joined an innovation contest (Ureka Mega Challenge) at the University Medical Center of Utrecht. A grant of €50,000 (US $55,645) was received from this contest, which enabled the development of the first version of the Copilot app.

Conflicts of Interest

None declared.

Abstract

Background: Technological interventions provide many opportunities for improving the health and quality of life of older adults. However, interaction with new technologies can also cause frustration. Although these themes have been explored in extant research, much remains to be learned with regard to how the challenges of aging and technology use and the experiences of participating in a social and learning environment are interrelated.

Objective: This study aimed to perform a qualitative analysis of data collected from MoodTech, a pilot study of an internet-based intervention with a peer support component for older adults with symptoms of depression, to better understand the participants' experience of using technological interventions, including the challenges and benefits that they experienced over the course of these interventions.

Methods: We employed an inductive qualitative analysis method based on grounded theory methodology and interpretative phenomenological analysis to analyze participant textual data. These textual data were of 3 main types: (1) assignments in which participants challenged their negative thoughts, (2) status updates, and (3) comments in the peer support component of the intervention.

Results: We have presented the results through 3 main themes: (1) the challenges of aging as seen through the participants' comments, (2) the difficulties experienced by the participants in using MoodTech, and (3) the benefits they derived from participating.

Conclusions: This paper offers several contributions concerning study participants' experiences with internet-based cognitive behavioral therapy (iCBT) interventions with a peer support component and design considerations for developing complex technological interventions that support the challenges participants experience due to aging and cognitive difficulties. First, technical issues encountered by older adults within the context of the intervention can interact with and exacerbate the insecurities they experience in life, and it is important to consider how intervention components might be designed to mitigate these issues. Second, peer support can be employed as a mechanism to facilitate communication, support, and collaborative problem solving among participants in an intervention. The insights from this paper can inform the design of iCBT interventions for older adults.

Introduction

Background

Depression is a psychiatric disorder that affects a significant proportion of older adults [1,2] and can have various negative consequences, including decreased quality of life, increased disability, and increased risk of mortality [3]. In addition, depression can often go undetected or untreated [2,4]. The treatments for depression in older adults include antidepressants, behavioral treatments, cognitive behavioral therapy (CBT), cognitive bibliotherapy, problem-solving therapy, psychotherapy, and life review/reminiscence therapy [2,5,6]. In recent years, there has been interest in internet-based CBT (iCBT) for reducing depressive symptoms in older adults; however, the number, quality, and heterogeneity of extant research suggest the need for additional research to evaluate the efficacy of iCBT interventions [7].

There has also been recognition of the negative effects of social isolation among older adults, including poorer cognitive functioning, impaired sleep and daytime dysfunction, reductions in physical activity, impaired mental health, and the potential utility of technology for alleviating loneliness and social isolation [8,9]. Although studies of technological interventions for depression and loneliness among older adults are still limited, extant research suggests that these interventions can reduce the symptoms of anxiety and depression [10,11] and are helpful for the management of loneliness [8,12,13].

However, older adults may experience difficulties in learning new technologies, and it is important to provide support during the process of learning to use them [14]. Although digital technologies could be a vehicle for empowerment by facilitating greater engagement in hobbies, social support, and everyday tasks, they may also be a form of disempowerment if they are viewed with apprehension, and the inability to use them can lead to social isolation [15]. Moreover, the adoption of technology use can be mediated by cognitive abilities, computer self-efficacy, and computer anxiety [16].

Nevertheless, previous research has suggested that older adults perceive that the benefits of using these technologies may outweigh the costs [17] and that engagement with internet and digital technologies can lead to improved depression symptomatology and psychological well-being [18,19]. In recent years, there has been increased interest in the factors that influence engagement with social networking websites among older adults [20]. For example, some older adults use Facebook to connect with family, and previous research has reported that older adults who were Facebook users scored higher on assessments of social satisfaction than those who were not [21]. Taken together, the extant literature suggests that new technologies and web-based social environments may benefit older adults, but the implementation of these environments is critical.

Objectives

Although prior research on digital health interventions has examined the effect of the peer support component using quantitative measures [11,22,23], there is great potential to employ qualitative data to better understand participants' experiences of peer support interventions and iCBT interventions for older adults. In this study, we performed a qualitative secondary analysis of data from MoodTech, an internet-based intervention for depression for adults aged 65 years and above [11]. This intervention included didactic content (in the form of lessons), interactive skills–based tools, and peer support features. The primary analysis focused on quantitative analyses of engagement metrics (participant log-ins and minutes); usability; and mental health outcomes, including depression and anxiety, and reported a reduction in depression among participants compared with those waitlisted [11].

In this study, we focused on the textual data that participants produced, either as part of the activities they engaged in along with the didactic content or in the peer-support component of the website, to understand the participants' experiences of the intervention and develop recommendations for the design of internet-based interventions for older adults. We describe three themes, namely, challenges experienced by older adults in life, difficulties experienced in the intervention, and the benefits of the online social space, using the first theme of life challenges to provide context for the other two themes.

Methods

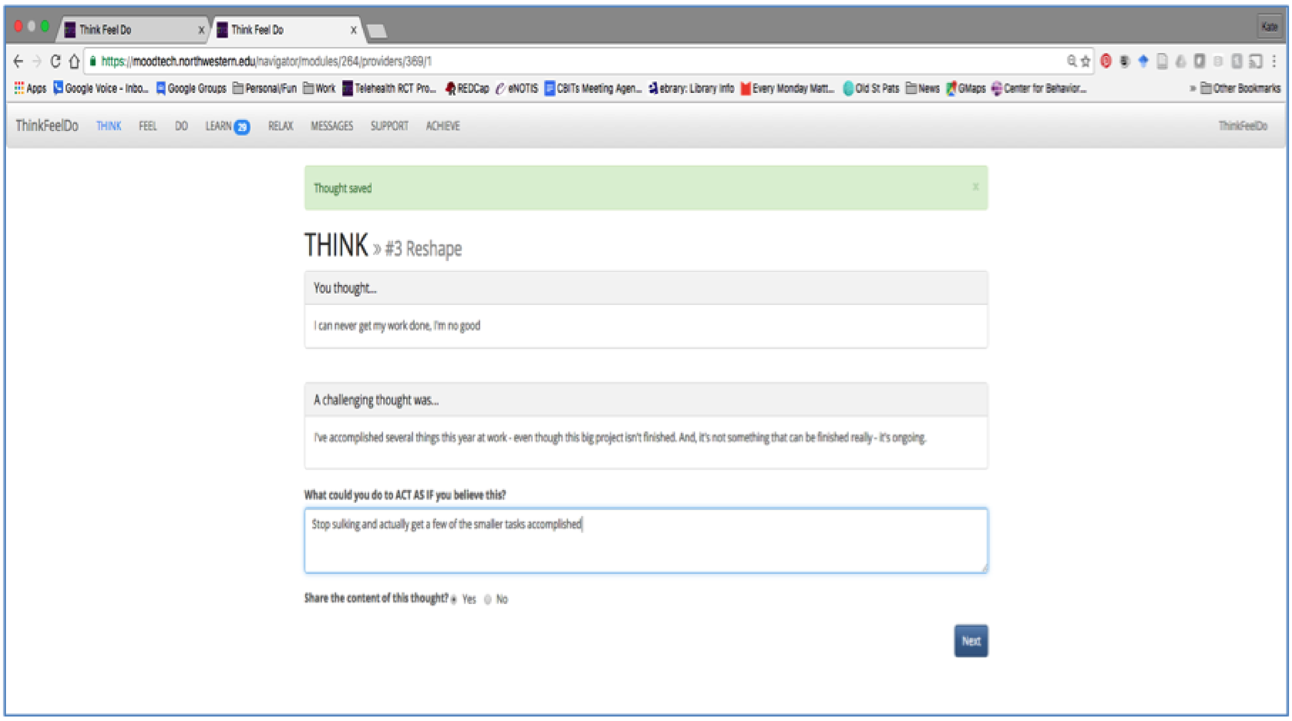
In the Methods section, we introduce the intervention, explain the data that are the focus of the analysis, and then describe the data analysis method.

MoodTech

The MoodTech study was designed to evaluate the feasibility and acceptability of an online intervention for depression based on CBT principles, developed for participants aged 65 years and above [11]. MoodTech was built on the ThinkFeelDo platform [24] and focused on five core skills: (1) cognitive restructuring (think), (2) mood and emotion monitoring (feel), (3) behavioral activation (do), (4) relaxation/mindfulness (relax), and (5) goal setting (achieve). Activities were an aspect of the *do* tool. Within the tool, participants were able to list activities completed in the last few days. Participants could plan activities to boost their mood, provide an optional prospective due date for completion, and report completion. The *think* tool asked the users to record their negative thoughts, categorize the type of cognitive distortion (eg, magnifying, minimizing and tunnel vision), reframe the thought constructively, and create an action plan (Figure 1).

The peer support version of the intervention also featured an online social environment in which the participants could interact with one another (Figure 2). This included an activity feed that automatically posted the participants' actions, including lessons read, goals set, and relaxation exercises completed. The participants could share status updates and comment on items shared by others. They also had the option of sharing thoughts they entered as part of the *think* tool and activities they completed or scheduled in the *do* tool.

Figure 1. Screenshot of harmful thoughts activity. Participants enter thoughts and create a challenging thought and action in response. The thoughts can be private or shared publicly with the peer support group, allowing peer and coach comments.



Thought saved

THINK » #3 Reshape

You thought...

I can never get my work done, I'm no good

A challenging thought was...

I've accomplished several things this year at work - even though this big project isn't finished. And, it's not something that can be finished really - it's ongoing.

What could you do to ACT AS IF you believe this?

Stop sulking and actually get a few of the smaller tasks accomplished

Share the content of this thought? ● Yes ○ No

Next

Figure 2. Screenshot of the social peer support feature displaying a portion of social media feed where a negative thought shared publicly had 3 comments and 2 likes.

[redacted]: Congrats on getting the job! :) 06/06/2016

[redacted]: Thanks for words of encouragement. The good news is that i got the job. So happy. 06/03/2016

[redacted] I have found that when I have an interview, I need to go in there with total confidence in myself. You know you can do the job or you wouldn't have applied for it. Don't let them scare you. Be friendly and make it clear that you would like the job and that you would be the best choice. 06/03/2016

The study comprised 3 treatment arms, each 8 weeks in length: 1 group received the online intervention without peer support (individual internet-based intervention), another group (divided into 2 cohorts) received the online intervention with peer support (internet-based intervention with peer support), and the final group was a waitlist control group that was evaluated with no treatment during the course of intervention before being given access to the individual internet-based intervention.

Participants were primarily recruited through clinical research registries as well as online and community advertisements and clinic referrals. To participate, individuals needed to be aged ≥65 years; to have elevated depressive symptoms at screening (score of ≥8 on the patient health questionnaire-8 or a score of

>7 on the geriatric depression scale-15); to be able to read and speak English; and to have basic internet skills and access to the internet, a telephone, and a valid email address. The exclusion criteria included current engagement or planned engagement in psychotherapy, psychiatric diagnoses for which participation could be inappropriate (eg, psychotic disorder), or cognitive impairment [11].

Data Set

The MoodTech data set comprises demographics, usage, and outcomes data collected before and during the MoodTech intervention. We report the descriptive statistics and feature usage statistics for the sample.

During the intervention, participants produced textual data incidentally through their interaction with the system. First, participants produced textual data through individual activities, such as the goals they set for themselves, and their work on challenging negative thoughts. Status updates were part of the activity feed, allowing users to post unsolicited statements to their peers on any topic. Comments and *likes* could be made in response to any material in the activity feed, including thoughts or goals that were publicly shared, user profiles, or status updates, and were visible to all participants in the intervention. Comments were the only means of direct text communication among the participants and often would resemble conversation, with multiple comments back and forth attached to an original post to the feed. The participants were also able to *nudge* (a social action resembling a physical *nudge*, which carries no verbal communication) other participants to promote engagement. The intervention also included a *messages* section, where participants could interact privately with their coach. The coach could also comment on the participants' activity on the feed.

In this study, we focused on textual data from thought activities, status updates, and comments as these tended to be longer and richer, thus providing more insight into participants' experiences. The textual data were aggregated into documents by participant ID and textual data type (activities, thoughts, status posts, and comments) for analysis, such that each document represented the textual expression of 1 participant for a given data type. For example, all status posts by ID 1523 would have been aggregated into a single document. To provide context for analysis of comments, the original status post or item (eg, harmful thought) that elicited the comment was also included in these documents. We focused on the text generated as part of the *think* section or in the social space (ie, status updates and comments), which provided the richest insight into participants' experiences of the MoodTech platform and their efforts to practice the skills taught in the intervention.

Qualitative Data Analysis

Our analytic method was informed by two qualitative approaches: interpretative phenomenological analysis (IPA) [25] and grounded theory [26-28]. At the outset, the perspective with which we viewed the data was influenced by IPA, a method that places emphasis on how individuals make sense of their world, positing a close connection between what a person says or writes and his or her cognitions [25,29]. IPA is widely used in health-related studies with a focus on patient experience [29-31]. In this study, we adopted this perspective in code development, endeavoring to create codes that illustrated participants' experiences of life and the intervention.

Our analytic procedure was based on grounded theory methodology. In grounded theory, researchers code the data line by line [26]. The codes are refined through a process involving constant comparisons and constant questioning. We identified concepts of interest, namely, health, depression, aging, technology, and participation in the social networking component of the intervention, and 1 author (KS) performed line-by-line coding, creating codes that were related to one or more of these topics. Then, 2 authors (KS and AC) worked together to iteratively refine and merge codes and to create a hierarchical code structure of themes and subthemes. After KS developed the initial codes and hierarchical structure of themes, AC reviewed the codes and structure and suggested revisions, which were then reviewed by KS. The 2 authors agreed upon the final set of codes and hierarchical code structure. The codes were compared for the same participant and across participants to ensure consistency of the coding scheme, focusing on the reduction of conceptual overlap and redundancy. The two authors consulted with a clinical expert (KT) to ensure that the interpretation of the themes was consistent with the clinical knowledge of depression in older adults and with the design of the MoodTech intervention. The data analysis was performed using the qualitative data analysis software, Atlas.ti (Cleverbridge, Inc) [32].

Although we initially included activities (data from the *do* tool) in our analysis, we found that they were usually short phrases or sentences indicating what the participants planned or had already done (eg, *ate supper*, ID 1568) and thus uninformative concerning the participants' inner mental state. Therefore, we did not report the themes from the activities in this paper. In selecting the themes to report and elaborate upon, we considered the guidelines provided by Braun and Clarke [33], with frequency and conceptual relatedness of the codes to one another being key considerations. In this paper, we focused on participants' life challenges, difficulties with the program, and benefits of the program. In our selection of quotes, we endeavored to represent the diversity of voices among the sample.

The aims of our investigation were to qualitatively understand how the participants experienced the intervention material and the peer support component. With respect to the first goal, all participants, regardless of treatment arm, received the same intervention materials; thus, we analyzed the available data from all treatment arms together. With regard to the second goal of analyzing participants' experiences with the peer support component, we only used data from the one arm that received this component, the internet-based intervention with peer support.

Results

Data Set

Sample

The MoodTech study included 47 participants. Two of the original participants (1 in the individual internet-based intervention and the other in the wait list control) were not included in this data set. One participant in the individual internet-based intervention group dropped out of the study before using the intervention, and one of the 12 participants in the wait list control decided not to use the intervention after the waiting period. Most of the participants were female, white, and retired. Overall, the sample was highly educated, with most participants having a 2-year college degree or above. The summary statistics for the sample are shown in Table 1.

Table 1. Participant characteristics.

Participant characteristic	Individual internet-based intervention	Internet-based intervention with peer support	Wait list control
Age (years), mean (SD)	69.3 (3.5)	69.5 (4.3)	70.2 (4.9)
Sex, n			
Female	7	16	7
Male	4	7	4

Some college	0	5	1
2-year college (Associate’s degree)	0	5	2
4-year college (Bachelor’s degree)	3	6	4
Master’s degree	5	5	2
Doctoral degree (PhD, MD, and JD)	3	2	2
Employment status, n			
Employed	2	3	3
Retired	9	18	7
Other	0	2	1

Feature Usage

Although most participants engaged with the features of the application they had access to, there was a great deal of variability in the extent to which the features were used (Table 2). A total of 43 out of 45 participants produced text data of at least one type. In the treatment arm with peer support, less than half of the individuals authored status updates, but almost all participants commented on at least one status post. Similarly, with nonverbal social interactions, almost all participants liked an item at least once, but only about half of the participants used the nudges. As the SDs indicate, there was substantial variability in the extent to which the participants used the features of the intervention.

Table 2. Engagement metrics for the skills and peer support components of the MoodTech intervention.

Feature used	Individual internet-based intervention (n=11)		Internet-based intervention with peer support (n=23)		Wait list control (n=11)	
	Participants, n	Participants, mean (SD)	Participants, n	Participants, mean (SD)	Participants, n	Participants, mean (SD)
Thoughts	9	9.1 (4.5)	18	11.9 (11.1)	9	10.1 (5.3)
Messages	11	11.6 (5.8)	21	9.3 (7.2)	11	10.4 (6.1)
Social interactions: verbal

Comments	N/A	N/A	19	20.3 (23.6)	N/A	N/A
Social interactions: nonverbal						
Likes	N/A	N/A	19	25.7 (52)	N/A	N/A
Nudges	N/A	N/A	9	5.7 (8.2)	N/A	N/A

[a] N/A: not applicable.

Textual Data

Our analysis focused on the textual data produced as a part of the *think* and *do* sections of the intervention and the social space. The activities and harmful thoughts features of MoodTech were available to all 45 participants, whereas status updates and comments were only available to participants in the peer support arm (n=23). Table 3 depicts how the text data were divided into documents, with each document pertaining to a unique participant-data type pairing, and imported into Atlas.ti.

Table 3. Textual data used in qualitative data analysis.

Arm	Participants, n	Intervention features (available to all)		Peer support component features		Total documents, n
		Activities	Thoughts	Status post	Comment	
Individual internet-based intervention	11	3	11	N/A[a]	N/A	14
Internet-based intervention with peer support	23	15	20	10	19	64
Wait list control	11	1	9	N/A	N/A	10
Total	45	19	40	10	19	88

[a] N/A: not applicable.

Qualitative Data Analysis

Life Challenges

As part of the didactic component of the MoodTech intervention, participants learned how to reframe and reduce harmful thoughts. We analyzed these harmful thoughts to help us understand the challenges that participants face in life, to which they endeavored to apply the skills that they were learning. We describe these life challenges to provide context and to better understand the difficulties and benefits the participants experienced, both with the MoodTech intervention and with skill application.

Health Concerns

Participants in the MoodTech intervention expressed many challenges, including health-related problems such as chronic pain, sleep, weight, physical ability, and potentially negative results from medical tests. These often left them with a sense of regret and hopelessness:

> *I have feelings of regret and grief over my health and often wish it would speed up and not take so long until it's over. The pain levels are extremely challenging.* [ID1607, harmful thought]
>
> *When I'm in pain, I feel as though it's going to last forever, that I'll never get better...* [ID1816, harmful thought]

Other Challenges

Other than health-related challenges, participants also experienced personal challenges. These could be intertwined with their recollections of the past and concerns about the future. Family played a prominent role. Participants worried about the welfare of their children and their parents, were fearful of losing loved ones, and wrote of tensions they experienced interacting with other family members. They were also concerned about financial status, professional status, and legacy:

> *I was not a good mother, my kids had to do without so much and work harder.* [ID1651, harmful thought]
>
> *I am afraid that I will not have enough money.* [ID1596, harmful thought]

Participants also had concerns about how they were perhaps perceived by others. There were various reasons for this, including feeling self-conscious about physical appearance, but some participants were also concerned about how they were perceived in terms of intellect. Participants expressed concern about cognitive difficulties and memory issues:

> *I can't get my thoughts together; I'm getting worse.* [ID1885, harmful thought]
>
> *I wish my memory was as it once was. I am ALWAYS forgetting names, words, and where I put things as three examples. I feel embarrassed and diminished in the eyes of my family.* [ID1838, harmful thought]

Difficulties That Participants Experienced in the Intervention

Technical Difficulties Leading to Self-Doubts

Participants experienced various difficulties in working with the MoodTech intervention. First, in terms of the technology, participants often encountered issues with the system, such as creating a text entry, not having the entry saved, and then having to reenter it. These issues led to confusion and frustration, which were accompanied by the participants questioning their memory and abilities:

> *The program confuses me and adds to my litany of reasons I think I am a dunce!* [ID1523, comment]
>
> *I think the software challenges on site make several of us feel like dummies and that is no help to alleviate depression.* [ID1607, harmful thought]

Being Overwhelmed by the Pace of the Intervention

Participants felt overwhelmed by the amount of work they perceived that they had as well as the pace of the intervention:

> *How will I ever get all of this work done in just 7 weeks that I have left?* [ID1599, harmful thought]
>
> *What's the matter with me that I have a hard time keeping up with the lessons in this program and not working on them as much as I should* [ID1781, harmful thought]
>
> *Anyone else finding this program overwhelming. Todays lesson is good but difficult.* [ID1596, status post]
>
> *I'm feeling overwhelmed too. The weekly/daily pressures are too fast-paced for me. I suppose the program needs a schedule but it doesn't take into account the actual pace and work of being depressed. I feel behind too.* [ID1550, comment]

The problems that participants experienced with the program compounded insecurities and anxieties that participants already had, which led to an increased sense of pressure and frustration.

The Benefits of Social Space

Despite the difficulties that the participants experienced with MoodTech, they also experienced positive interactions in the peer support space. These included affirmation and encouragement from peers and coaches, collaborative efforts at problem solving, and positive affective experiences from the social experience of the website.

Empathy and Encouragement

Participants expressed empathy and provided encouragement to one another for the difficulties they experienced in life:

> *This is just a temporary setback (having to keep off your feet for most of the week). You can do it (lost weight) – don't give up trying. Mind over matter!* [ID1816, comment]
>
> *Looks like you're on top of the problem and are looking ahead of what comes next.* [ID1813, comment]

Appreciation and Affirmation

At the outset, participants expressed appreciation for and affirmed the contributions of others on the website:

> *This is a very good insight, [ID 1607]. Although I have not posted very frequently, I feel that you have been very courageous and open during this study.* [ID1596, comment]
>
> *Dear [ID 1781], I have been thinking about your post since last week but couldn't put my feelings into words. Just wanted you to know that I admire your honesty and the courage that it must have taken to share this post.* [ID1760, comment]

Collaborative Problem Solving

Participants also engaged in collaborative discussions about the problems they were trying to address as part of the MoodTech intervention. For example, in the following exchange, 2 participants discussed the nature of their tendency to worry:

> *I worry too much – guess I feel that by worrying about all the contingencies, I can somehow control one or two of them. Anyone else have that problem...* [ID1816, status post]
>
> *I also struggle with worrying a lot. [ID 1816] ...I think you nailed it when you said that the reason is that perhaps by worrying, you can control one or two of them...* [ID1723, comment]

Participants also helped one another figure out how to utilize the website. For example, several participants were confused about how to go from the email notifications of a new comment on their post to the comments themselves. They were able to explain to one another in the social space how to navigate to the particular content that they wanted:

> *Until I figured out to go to my profile page & scroll down, I'd get the email saying someone commented to me then I'd go to the main page & scroll down through ALL comments until I found mine.* [ID1550, comment]
>
> *I just got a couple of notes that someone “”LIKED“” a couple of my comments. But it's hard to figure out who liked what -- can't I get a link directly to what was liked, so I can acknowledge it?* [ID1816, status post]
>
> *It was confusing to me at first, also. Scroll down all the things that you posted on the Feed. When you find one with a number in parenthesis behind the comment*

> *or like, click on the number. That will take you to the comment and who liked it or made a comment. HOpe this helps.* [ID1723, comment]

Discussion

Principal Findings

In this paper, we present a qualitative analysis of textual data collected from MoodTech, a pilot study of an internet-based intervention with a peer support component for older adults with symptoms of depression. We analyzed 3 main types of data from the intervention: harmful thoughts, status updates, and comments. We present the results through 3 main themes: (1) challenges that participants experienced in life, (2) difficulties that participants experienced during the course of the intervention, and (3) the benefits that they derived from participating in the social space. The thoughts section of the data (individual) provided the most insight into difficulties experienced in the intervention, whereas the status post and comment sections (peer support) provided insight into the challenges and difficulties experienced as well as the benefits of having a peer support component in an intervention.

At the outset, participants shared various life challenges that they experienced, including health concerns, self-consciousness, recollections of the past, and anxiety about the future. These concerns provide context for the difficulties that the participants experienced as they engaged in the intervention activities, including being overwhelmed by the pace of the intervention and technical issues. The difficulties they experienced with the intervention fueled the insecurities they were experiencing in life. However, the peer support component appeared to benefit the participants by providing a medium for empathy, encouragement, appreciation, and affirmation, and collaborative problem solving.

The life challenges mentioned by the participants in this study went beyond health-related challenges to include other challenges in which the effects of time and aging were clearly related. This characterization of life challenge resonates with extant literature on aging, which has noted that there is a difference between objective (health-related) and subjective perceptions of health [34]; people with multiple chronic conditions may rate themselves as healthy and active, whereas those with few or no conditions may rate their health more poorly, because of psychological and social factors, coping mechanisms, and resilience. The data collected from the social space can provide insights for researchers into the challenges experienced by the participants in the aging process as well as about how these challenges may affect the participants' experiences of the intervention.

Social Space for Information Sharing and Mutual Encouragement

The MoodTech intervention not only offered participants an opportunity to practice the skills that they were learning individually but also with the option of sharing them with others. Although the participants in this study experienced frustration and confusion due to technical difficulties, the participants' written utterances also suggested that the ability to interact in the social space was a positive experience and that they valued the support and camaraderie of others.

The interactions among the participants in the social space showed that the participants were motivated to help one another with technical issues as well as with the difficulties they experienced in life or with the intervention content. The content and shared understanding from peer interactions made it possible to brainstorm coping strategies or at least take comfort in knowing that others shared their experiences. With regard to the technology, participants understood the frustrations that others were experiencing as well as the insecurities that were perhaps triggered by age-related factors and were quick to offer advice and workarounds to reduce others' struggles. The findings thus illustrate that a social networking component within the context of a cognitive behavioral intervention can perhaps provide a synergistic contribution to the intervention and enrich and deepen the learning that participants are engaged in with the educational modules.

One question that might arise from this is if there was an optimal level of usage of the features. There was extensive variability in the extent to which the study features were used. Although not all participants posted status updates, almost all participants commented at least once and liked the items shared by others. Participants commented on others' thoughts and behaviors and expressed admiration for the courage of others who shared their experiences.

Only about half of the participants posted status updates and nudges, and we can only speculate about the causes. Although the reasons for lower usage of these features are unclear, perhaps posting a status update required more courage or effort than simply commenting on the posts of others. With regard to nudges, some possible reasons might be that the meaning of a nudge was less intuitive to participants or more personal than they wanted it to be.

Overall, these findings are consistent with prior literature, which reported that sharing of experiences on online support groups can lead to improved sentiment [35] and patient empowerment [36]. Of particular interest perhaps are contagion effects resulting from participation in a group discussion. As described in the Results, we observed various positive effects of group interactions such as being inspired by the actions of others and resonance in terms of shared experiences leading to subsequent sharing of similar experiences. In some cases, the shared experiences were related to difficulties with the intervention. One participant expressing feelings of frustration with the program can lead to others sharing similar feelings. However, the expression of negative sentiments is not necessarily undesirable. Expressing frustration gives participants a chance to release these tensions and frustrations so that they can be overcome, and, in this intervention, it also led to collaborative problem solving.

In this study, some participants were clearly more active than others, and participants also differed in terms of the nature of content they contributed. Previous research has found that members of online communities play different roles [37]. Previous research investigating lurkers (those who read but do not post) and posters has reported that posters tend to report having their expectations met more often than lurkers [38], those who received emotional support in an online support group were less likely to drop out [39], and online support group members provide different forms of support to one another [40].

On the basis of the comments made in the social space, we suspect that some participants in this study did find the content of others useful even if they did not contribute content themselves and that many perhaps had respect for those who had the courage to do so. It is likely that some participants, whether they contributed or not, benefited from the social space, in terms of both informational and social interactions. However, more research is needed to better understand how different forms of engagement with the social space may be associated with health-related outcomes.

Design Implications

Participants in this study experienced a substantial amount of frustration due to technical issues. In some but not all cases, this appeared to be exacerbated by other problems they experienced, such as cognitive issues. The problems they experienced led to uncertainty about if they or the system were the cause of the problem. Although the technical difficulties faced by the participants were those that could occur with any system, considering them in the context of age-related factors is critical for delivering effective treatment.

The idea that technological interventions for older adults should consider age-related factors is not new. Prior research, for example, has recommended that technology-based training for older adults should be well-structured, provide feedback and adaptive guidance, include metacognitive prompts, include a user interface that is simple and consistent, and take into consideration extant knowledge of cognitive load [41]. This can be difficult for complex multicomponent educational interventions.

This study provides insights into the design strategies for minimizing confusion and frustration on the part of older adults in the design of educational interventions. At the outset, one of the problems we observed was that participants felt mounting pressure due to the perception that they could not finish their assignments. With MoodTech, a potential alternative design might be to present personalized educational objectives to participants, paced to suit the needs and goals of the participants over time. For example, participants could be told that MoodTech would provide assignments that depended on how they were doing, in a manner similar to how an adaptive system would work. This way, participants would not feel despair at not being able to finish the modules. This might be more difficult in the setting of a peer-supported intervention in which participants are aiming to move through the material as a group. Presenting content in an adaptive fashion might lead to some participants referring to content that others might not have seen. Thus, there is a design tension that must be considered when providing a more personalized experience and a unified group experience that members share.

It is useful to consider the multiple factors that may be at play in the perception of pressure to finish the assignments. Lack of motivation, feeling inadequate, and feeling pressured can also be symptoms of depression, which the intervention is intended to address; it may not be in the participants’ interests to cater to their preferences completely. The design of digital mental health technologies involves a competing tension between promoting engagement and achieving improvements in symptoms and well-being. Behavior change often involves confronting problems that can, at times, be uncomfortable. Thus, the goal of addressing the issues raised in this study may be to minimize the pressure experienced by users by allowing meaningful engagement, recognizing that some users may nevertheless continue to experience some discomfort.

A second design takeaway would be to simplify the instructions and training that are provided to the participants. Previous research has also argued that the availability of support is critical as older adults are learning a technology, although this support can take various forms, including step-by-step guidance, an error-friendly space where someone is available to fix problems if they arise, and manuals [14]. Owing to the complexity of the system used in this study, the training materials that the participants received were extensive, and it may have been difficult to find what they needed at the appropriate time. Providing simpler training materials, a short summary of key actions that is accessible from anywhere in the program, and training videos could perhaps enable participants to engage with the site more easily and ameliorate the confusion and frustration experienced during the study. Having these features might also reduce the burden on coaches for providing technical support and training and preventing intervention dropout.

Although disorientation and cognitive overload are well-recognized as concerns in the interface design [42], this qualitative analysis has shown that they take a particular meaning with this population and that addressing these issues is paramount. User interface adaptations that involve the reduction of interface complexity or enhancement of assistance features can be particularly important for older adults to mitigate the effects of cognitive decline and vision loss [43] and prevent normal user interface difficulties from being interpreted as evidence of cognitive decline or lack of competence.

Limitations and Future Directions

Our analysis had various limitations that could also serve as potentially fruitful directions for subsequent research. First, one of the data types that we analyzed, reframing negative thoughts, were a skill that participants were explicitly directed to practice. As such, these thoughts were inherently negative in nature, and both the life challenges and negative aspects of the participants’ intervention experiences might be more apparent than positive aspects due to our selection of data to analyze. Second, in addition to the quantitative and qualitative analyses that have been conducted, analytical methods that model the participants’ interactions, such as network analysis, could have provided additional insight into how the participants interacted with one another and could be a fruitful direction for future research. Third, the findings are based on a secondary analysis of the content produced during the course of the intervention; we did not directly conduct an exit interview asking the participants to comment on their experiences or specific features such as nudges, which could have led to additional insights to inform the design and features of the intervention. Finally, our sample primarily comprised individuals who were female, white, and highly educated. There is a need to further explore how individuals from other backgrounds might experience this intervention.

Conclusions

In this paper, we analyzed textual data from an internet intervention with a peer support component for older adults with symptoms of depression. The textual data provided insight into the participants' experiences with the intervention as well as design considerations for developing complex technological interventions that support the challenges that participants may experience due to aging and cognitive difficulties. First, technical issues encountered by older adults within the context of the intervention can interact with and exacerbate insecurities that they may experience in life, and it is important to consider how intervention components might be designed to mitigate these issues. Second, peer support can be employed as a mechanism to facilitate communication, support, and collaborative problem solving among participants in an intervention. It is our hope that insights from this study inform the design of other iCBT interventions for older adults.

Acknowledgments

This project was supported by the National Institute of Mental Health (grants P20 MH090318 and R01 MH095753; PI: DM). Data collection used REDCap electronic data tools supported, in part, by the National Institutes of Health National Center for Advancing Translational Sciences, grant UL1TR001422.

Authors' Contributions

AC, KS, and KT were involved in the conceptualization of this secondary data analysis. CR and LB deidentified the data that was used in the analysis. AC and KS analyzed the data, and KT provided consultation in the analysis. AC and KS drafted the manuscript, and KT, CR, LB, and DM provided feedback on multiple versions of the manuscript. All authors gave permission for the final version to be published.

Conflicts of Interest

DM has accepted consulting fees from Apple Inc, Pear Therapeutics, Otsuka Pharmaceutical Inc, and has an ownership interest in Adaptive Health, Inc.

Abstract

Background: Depression is an extremely prevalent issue in the United States, with an estimated 7% of adults experiencing at least one major depressive episode in 2017. Although psychotherapy and medication management are effective treatments for depression, significant barriers in accessing care persist. Virtual care can potentially address some of these obstacles.

Objective: We conducted a preliminary investigation of utilization characteristics and effectiveness of an on-demand health system for reducing depression symptoms.

Methods: Data were analyzed from 1662 users of an on-demand mental health system that includes behavioral health coaching, clinical services (therapy and psychiatry), and self-guided content and assessments primarily via a mobile app platform. Measures included engagement characterized by mobile app data, member satisfaction scores collected via in-app surveys, and depression symptoms via the Patient Health Questionnaire-2 (PHQ-2) at baseline and 8-12 week follow-up. Descriptive statistics are reported for measures, and pre/post-PHQ-2 data were analyzed using the McNemar test. A chi-square test was used to test the association between the proportion of individuals with an improvement in PHQ-2 result and care modality (coaching, therapy, and psychiatry, or hybrid).

Results: During the study period, 65.5% of individuals (1089/1662) engaged only in coaching services, 27.6% of individuals (459/1662) were engaged in both coaching and clinical services, 3.3% of individuals (54/1662) engaged only in clinical services, and 3.7% of individuals (61/1662) only used the app. Of the 1662 individuals who completed the PHQ-2 survey, 772 (46.5%) were considered a positive screen at intake, and 890 (53.6%) were considered a negative screen at intake. At follow-up, 477 (28.7%) of individuals screened positive, and 1185 (71.3%) screened negative. A McNemar test showed that there was a statistically significant decrease in the proportion of users experiencing depressed mood and anhedonia more than half the time at follow-up (*P*<.001). A chi-square test showed there was no significant association between care modality and the proportion of individuals with an improvement in PHQ-2 score.

Conclusions: This study provides preliminary insights into which aspects of an on-demand mental health system members are utilizing and levels of engagement and satisfaction over an 8-12 week window. Additionally, there is some signal that this system may be useful for reducing depression symptoms in users over this period. Additional research is required, given the study limitations, and future research directions are discussed.

Introduction

Depression is one of the most prevalent and impactful health conditions in the United States, according to multiple data sources. Conservative estimates from national surveys show that 7%-8% of American adults are affected by major depression annually [1,2]. A national health index of more than 41 million people, compiled by one of the largest health insurance providers, ranked depression second only to hypertension in its impact on American longevity and quality of life [3]. In addition to the direct symptoms caused by depression, the majority of adults with depression report at least some difficulty with work, home, or social activities due to their symptoms [2]. Thus, the health burden of depression translates into a significant social and economic burden [4].

Existing Approaches and Barriers

Although there are effective treatments (including pharmacological and psychotherapy interventions) for depression and other mental health conditions, the current US healthcare system does not adequately address the many social, medical, and economic barriers. Access to formal behavioral health treatment remains a challenge because of a complex collection of barriers, including perceived public or social stigma, inadequate behavioral health workforce in certain geographic regions, and poor insurance coverage and related financial costs [5].

The mental health workforce shortage is more acute for some geographic regions; nearly 40 percent of Americans live in areas designated by the federal government as having a shortage of mental health professionals [6,7]. Access challenges include general barriers such as high cost, time, and transportation, but also specific obstacles like stigma and treatment preference [8]. Having access to a preferred choice of treatment improves treatment initiation, adherence, and outcomes [9,10].

Collaborative Care Model

The primary care-based collaborative care model augments the model of behavioral health care being provided in primary care and replaces it with a three-pronged team, including the primary care physician, a care manager, and a psychiatric consultant. This model helps to spread the expertise of the psychiatric consultant across a population of primary care patients through the actions of the care manager and the prescribing of the primary care provider (PCP); therefore, a larger population of primary care patients can receive evidence-based mental health care [11].

While the collaborative care model has a strong evidence base and is beginning to receive recognition from large payors such as Centers for Medicare & Medicaid Services (CMS), challenges remain in the real-world implementation of the model. In primary care settings, it remains difficult for overburdened PCPs to prescribe psychotropic medications in a 10-15 minute encounter that can often be focused on many chronic health conditions. It can also be challenging for a PCP to digest the recommendations of the care manager or psychiatric consultant team [12].

Beyond the challenges of limited time and competing priorities within a brief appointment, the collaborative care model only addresses those patients who present to primary care with behavioral health symptoms that rise to the level of a diagnosed DSM-V mental illness, such as Major Depression or Generalized Anxiety Disorder, or the symptoms are severe enough to trigger a full PHQ-9 or GAD-7. There is another “hidden” population of individuals suffering from upstream subclinical stress and behavioral health symptoms who do not present to a PCP because they do not have a comorbid medical problem, or they may not have easy geographic or financial access to a regular PCP. In fact, according to a 2018 Kaiser poll, many Millenials report not having and not even desiring a regular PCP [13].

Telehealth and Digital Interventions

The US healthcare system has attempted to close this chasm of unmet behavioral health needs and concurrent poor quality of care through a variety of different mechanisms, including telemedicine and other digital solutions. Telehealth has become the standard to address geographic barriers to care in rural regions over nearly three decades in systems such as the Department of Veteran Affairs, where evidence-based psychotherapy and medication management can be delivered at an equivalent level of quality as in-person care [14]. A 2016 systematic review showed that telephone-based interventions had promised in reducing symptoms of depression and anxiety [15]. Unfortunately, most telemental health models primarily address the geographic maldistribution of providers as opposed to the sheer lack of full-time providers across the country.

Smartphone-based treatments have also shown promise in managing depression according to a 2017 meta-analysis [16]. Given the heterogeneity of these interventions, many studies highlight the need to establish which aspects of these technologies are most active for a given population. Thus, characterizing the features, engagement, and users of specific products can help enhance our understanding of how these new technologies and systems work for different populations.

In the broader digital health landscape, there have been calls for companies to produce and publish evidence on outcomes, including engagement and clinical outcomes [17]. There are multiple dimensions for evaluating these types of products, and many organizations, including the US FDA, the UK NHS, the APA, have proposed frameworks to guide informed decision making and evaluation. Common categories of evaluation include privacy and security, evidence base, ease of use, and data integration [18].

This exploratory study aimed to investigate the initial effectiveness of a novel on-demand system by describing utilization and satisfaction measures in addition to evaluating changes in self-reported depression symptoms. Previous research has proposed some guidelines for conducting studies in real-world settings in contrast to highly controlled efficacy studies, including observing utilization, satisfaction, and outcomes in actual practice [19]. This is consistent with principles of implementation research, which seeks to understand intervention in real-world conditions, rather than trying to control for conditions or to remove their influence as causal effects [20]. Studies of other digital mental health technologies have used this approach to investigate initial effectiveness in addition to guiding future research directions [21,22].

Methods

Participants

Individuals in this study are employees or health plan members who have access to the Ginger system as part of their employer or health plan benefits. The Ginger system includes the following exclusionary criteria where telehealth is likely not appropriate:

1. Active suicidal ideation
2. Active high-risk self-harm behavior
3. Two or more hospitalizations within the past 6 months for psychiatric reasons
4. Certain symptoms of psychosis that are poorly managed (eg, the member is not med compliant, or symptoms are unresponsive to treatment), likely incompatible with telehealth
5. A primary diagnosis of a substance use disorder, or moderate to severe substance abuse issues, due to the high complexity, severity, and risk frequently associated with such members, as well as the need for specialized care
6. Active eating disorders with symptoms considered to be high risk
7. Ongoing grave disability, including bipolar patients with active mania/hypomania or mixed episodes who are unmedicated or who have poor compliance with medication regimen over time
8. Two or more medical hospitalizations in the last month due to the high likelihood that the individual has a poorly controlled medical condition that requires close monitoring

For this study, we included Ginger users aged 18 or older who downloaded the app between January 1, 2018, and December 31, 2019. This period was chosen as it reflects the approximate timing of when Ginger began to provide care to members via its employer business. Based on these criteria, 24,682 individuals were eligible for the study, 10,942 users (44.33%) completed the intake survey, and 1662 users (6.73%) completed a 12-week follow-up survey and were included in our analysis. Survey response rates are a challenge in both online studies and behavioral health practice; research has shown that the majority of participants in remote studies discontinue participation within the first week of a study and that online survey rates tend to be much lower than in-person [23,24]. The survey response rates here are lower than what is reported in the literature, which is expected given the observational nature of this study and the design of the survey system in a digital product, where users are not required to complete surveys to receive care.

Procedures

The Ginger System

Ginger provides members with behavioral health coaching, therapy, and psychiatry, along with self-guided content and assessments primarily via a mobile app platform. Members generally have access to Ginger as part of their employee or health plan benefits. After downloading the mobile app, users can start chatting with a behavioral health coach within minutes (Figures 1 and 2). Ginger coaches are full-time employees who typically have an advanced degree in a field related to mental health, and an accredited Coach Certification [25,26]. While many users solely engage with coaches, some will request or require escalation to psychotherapy services. Examples of situations that require escalation include individuals with chronic mental illness and severe trauma, the potential of harm to self or others, and significant mental instability (ie, hallucinations, delusions, and extreme mood swings). When members are escalated to therapy or psychiatry, they may continue working with a coach on an on-demand basis, provided that they also agree to seek additional care concurrently; coaching can continue supporting them in addressing day to day goals and challenges, as well as acting as an adjunct to the care plan put in place by their therapist or psychiatrist.

Welcome to Ginger

Get immediate emotional support for all your life challenges.

Already have an account? Sign in

Enter your access code

Your unique access code was delivered to your work email.

Welcome to Ginger, Dan!

Our team of coaches, therapists and psychiatrists works together to help you face life's challenges.

Before you start chatting with your coach, we have a few questions that will help us personalize your care.

How can we help?

Tell us how you're feeling. Choose all that apply:

- Overwhelmed ☐
- Stressed ☐
- Anxious ☑
- Not motivated ☐
- Depressed ☐
- Grieving ☐
- Something else ☐

What does this impact?

- Family ☐
- Personal growth ☐
- Career ☑
- Social life ☐
- Dating ☐
- Hobbies ☐
- Physical health ☐
- Personal finances ☐

We're here to help you.

Based on your answers, feelings of worry & anxiety may be getting in the way of achieving your work goals.

Your care team will work with you to create a personalized plan tailored to your needs, so you can better control your anxiety.

A dedicated care team

You'll start by chatting with your dedicated coach, who works with a team to support you 24/7. If your coach isn't available to chat, another member of your care team will step in.

Our Policies

Please read and agree to our policies.

Privacy Statement
The personal information we collect and how it is used and protected.

Notice of Privacy Practices
How your health information may be used and shared, and how you can get access to the information.

Terms of Use
The rules that govern your use of the Ginger service and mobile app.

☐ Agree to all policies

Let's Chat.

In your first conversation, your coach will get to know you and discuss how you want to work together. **This can take from 30 to 60 minutes.**

When do you want to start?

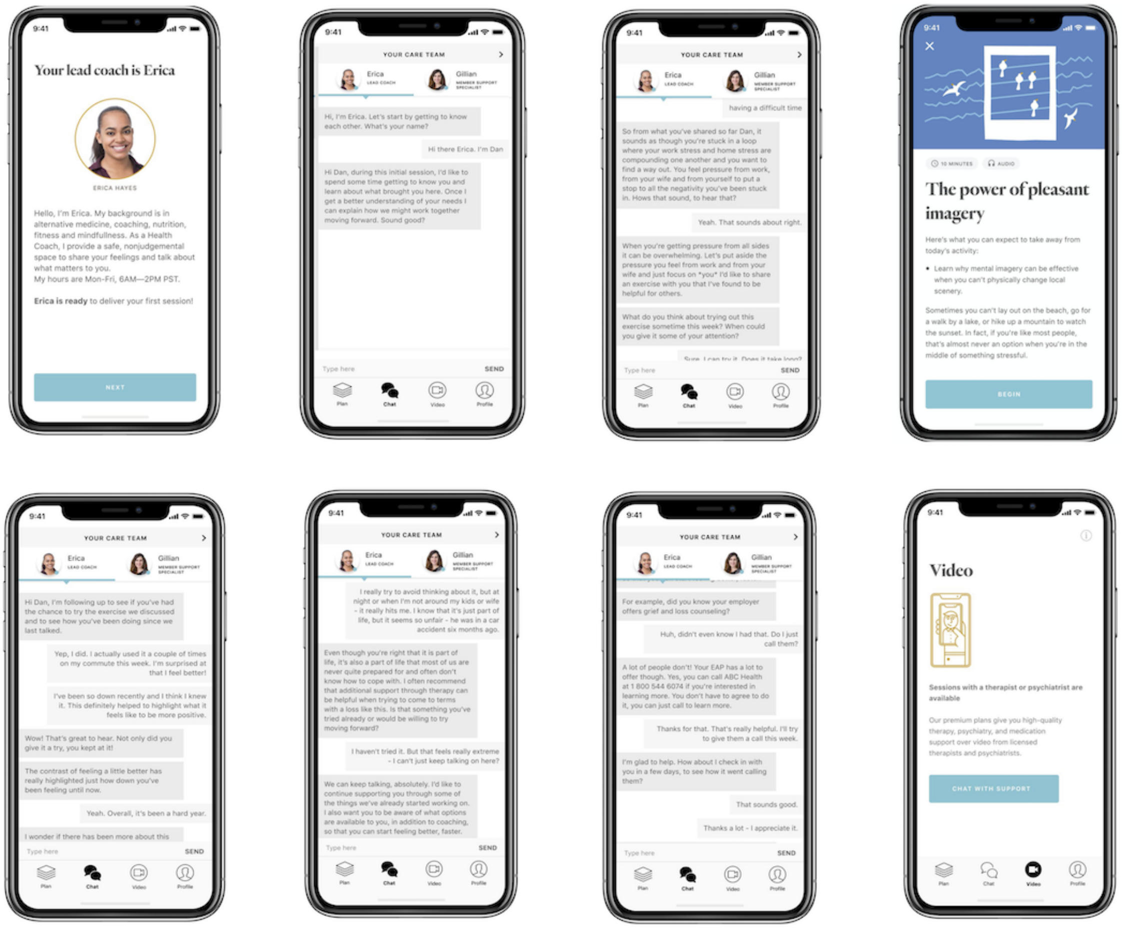
Your lead coach is Erica

ERICA HAYES

Hello, I'm Erica. My background is in alternative medicine, coaching, nutrition, fitness and mindfulness. As a Health Coach, I provide a safe, nonjudgemental space to share your feelings and talk about what matters to you.
My hours are Mon-Fri, 6AM—2PM PST.

Erica is ready to deliver your first session!

Figure 2. Ginger coach chat screens.



Your lead coach is Erica

ERICA HAYES

Hello, I'm Erica. My background is in alternative medicine, coaching, nutrition, fitness and mindfullness. As a Health Coach, I provide a safe, nonjudgemental space to share your feelings and talk about what matters to you.
My hours are Mon-Fri, 6AM—2PM PST.

Erica is ready to deliver your first session!

Hi, I'm Erica. Let's start by getting to know each other. What's your name?

Hi there Erica. I'm Dan

Hi Dan, during this initial session, I'd like to spend some time getting to know you and learn about what brought you here. Once I get a better understanding of your needs I can explain how we might work together moving forward. Sound good?

having a difficult time

So from what you've shared so far Dan, it sounds as though you're stuck in a loop where your work stress and home stress are compounding one another and you want to find a way out. You feel pressure from work, from your wife and from yourself to put a stop to all the negativity you've been stuck in. Hows that sound, to hear that?

Yeah. That sounds about right.

When you're getting pressure from all sides it can be overwhelming. Let's put aside the pressure you feel from work and from your wife and just focus on *you* I'd like to share an exercise with you that I've found to be helpful for others.

What do you think about trying out this exercise sometime this week? When could you give it some of your attention?

Sure, I can try it. Does it take long?

The power of pleasant imagery

Here's what you can expect to take away from today's activity:

- Learn why mental imagery can be effective when you can't physically change local scenery.

Sometimes you can't lay out on the beach, go for a walk by a lake, or hike up a mountain to watch the sunset. In fact, if you're like most people, that's almost never an option when you're in the middle of something stressful.

Hi Dan, I'm following up to see if you've had the chance to try the exercise we discussed and to see how you've been doing since we last talked.

Yep, I did. I actually used it a couple of times on my commute this week. I'm surprised at that I feel better!

I've been so down recently and I think I knew it. This definitely helped to highlight what it feels like to be more positive.

Wow! That's great to hear. Not only did you give it a try, you kept at it!

The contrast of feeling a little better has really highlighted just how down you've been feeling until now.

Yeah. Overall, it's been a hard year.

I wonder if there has been more about this

I really try to avoid thinking about it, but at night or when I'm not around my kids or wife - it really hits me. I know that it's just part of life, but it seems so unfair - he was in a car accident six months ago.

Even though you're right that it is part of life, it's also a part of life that most of us are never quite prepared for and often don't know how to cope with. I often recommend that additional support through therapy can be helpful when trying to come to terms with a loss like this. Is that something you've tried already or would be willing to try moving forward?

I haven't tried it. But that feels really extreme - I can't just keep talking on here?

We can keep talking, absolutely. I'd like to continue supporting you through some of the things we've already started working on. I also want you to be aware of what options are available to you, in addition to coaching, so that you can start feeling better, faster.

For example, did you know your employer offers grief and loss counseling?

Huh, didn't even know I had that. Do I just call them?

A lot of people don't! Your EAP has a lot to offer though. Yes, you can call ABC Health at 1 800 544 6074 if you're interested in learning more. You don't have to agree to do it, you can just call to learn more.

Thanks for that. That's really helpful. I'll try to give them a call this week.

I'm glad to help. How about I check in with you in a few days, to see how it went calling them?

That sounds good.

Thanks a lot - I appreciate it.

Video

Sessions with a therapist or psychiatrist are available

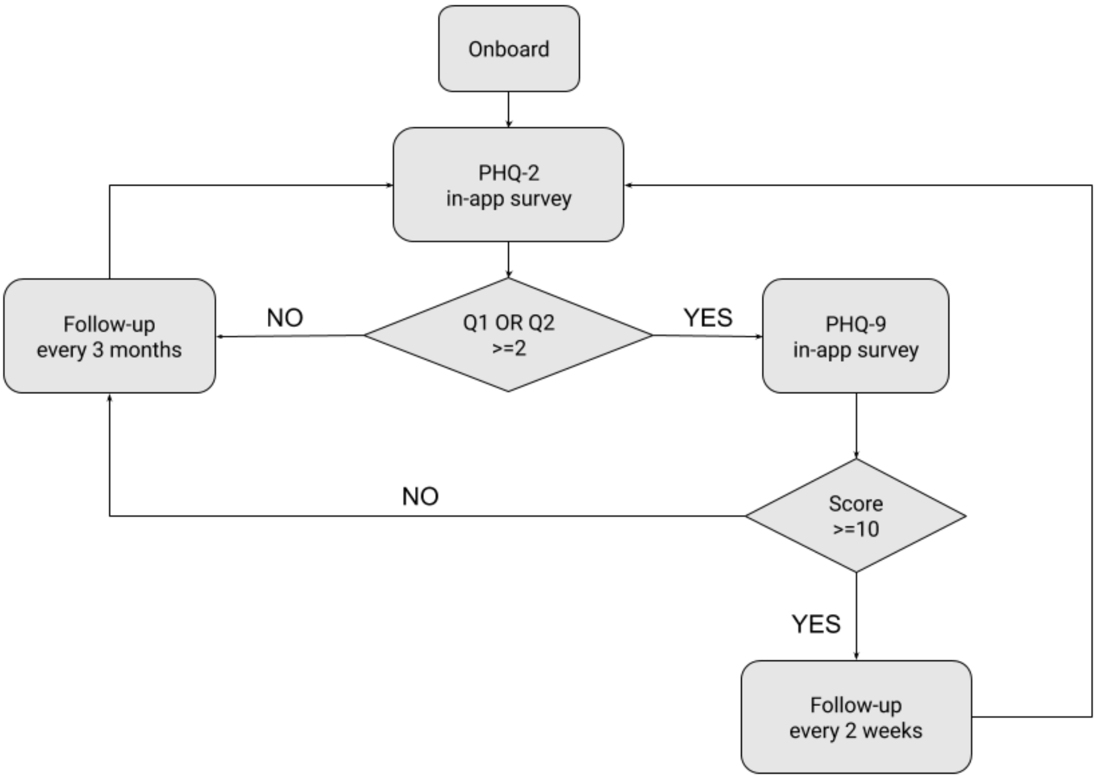
Our premium plans give you high-quality therapy, psychiatry, and medication support over video from licensed therapists and psychiatrists.

Data Collection

The Ginger system incorporates regular check-ins and feedback to understand better what solutions work for individual members, consistent with principles of measurement-based care (MBC). Although MBC has been demonstrated to enhance care, studies have shown that less than 20 percent of behavioral health practitioners integrate it into their practice [27]. Ginger assesses depression via the Patient Health Questionnaire (PHQ), delivered via the Ginger mobile app. The PHQ is one of the most validated assessments in mental health and is commonly used by clinicians in screening for and diagnosing depression in addition to monitoring treatment response [28]. When users onboard with the Ginger app (Figure 1), they are prompted first to answer the PHQ-2 questionnaire. Individuals that provide answers with a score of 2 or above for either question are considered a "positive depression screen" and then asked to complete the full PHQ-9.

There are no strict guidelines on how often to re-administer the PHQ-2 and PHQ-9; it can be re-administered as needed with a standard recommendation for monitoring and adjusting treatment every 4-6 weeks for users seeking treatment for depression [29]. Similarly, according to the US Preventive Services Task Force (USPSTF), there is little evidence regarding the optimal and interval for screening for depression. The USPSTF recommends a pragmatic approach of screening all adults who have not been screened previously and "using clinical judgment in consideration of risk factors, comorbid conditions, and life events to determine if additional screening of high-risk patients is warranted" [30,31]. Based on this guidance, Ginger administers the survey every 2 weeks for users with PHQ-9 scores ≥10 and every 3 months for users with PHQ-9 scores <10 in order to monitor symptom response and assess if additional care is warranted (Figure 3). Survey completion is not forced so as not to withhold support from members who require care.

Figure 3. Ginger PHQ survey logic.



In addition to clinical outcomes, Ginger collects and analyzes product data to understand a member's progress and journey through the system, including access, engagement, and member satisfaction.

Measures

Engagement

Engagement is characterized based on product user behavior data, including the number of coaching sessions and the number of clinical (therapy and psychiatry) appointments attended. A coaching session is defined as 25 messages exchanged. This threshold is based on an internal analysis of messaging patterns in addition to coaching team feedback on what constitutes a typical session. These measures provide insight into dropoff, adherence, and dosing, which are essential areas of study in this field [32,33].

Member Satisfaction

Member Satisfaction is measured using a 5-star survey. Ginger regularly prompts users to rate their experience via "star ratings." For coaching, this is required after the first 25 messages (ie, one text-based coaching session), and then every two weeks following. For clinical sessions, members are prompted to provide a rating after every therapy and psychiatry appointment. In addition to being a universal tool for consumers to rate products and services online (eg, Yelp, Amazon, Google), star ratings have also been used to understand provider care [34,35]. Although there are limitations associated with these consumer ratings, they can provide valuable insights for further exploration. Given the potential biases in these responses, the Ginger system includes proactive outreach from the member support team anytime there is less than a 4-star rating in addition to a clinical QA program to understand the care a member is receiving.

Depression Symptoms

Depression symptoms were assessed using the 2-item Patient Health Questionnaire (PHQ-2). The PHQ-2 comprises the first two items of the PHQ-9, assessing the degree to which an individual has experienced depressed mood and anhedonia over the preceding two weeks. A description of this survey logic is provided above. For this analysis, a negative depression screen means a user's response to each PHQ-2 question was less than 2 (ie, a response of "not at all" or "several days"). A positive depression screen means a user's response to either PHQ-2 question was ≥2 (ie, a response of "more than half the days" or "nearly every day"). Thus, a positive screen in this system can be interpreted to an individual having "little interest or pleasure in doing things" and "feeling down, depressed, or hopeless" more than half the days in the last 2 weeks. Although the PHQ-2 is generally used as a screening survey, it has a relatively high sensitivity for major depressive disorder, and previous research has utilized it as a longitudinal outcome measure [36-38]. Additionally, it provides insight into the severity of two key symptoms of depression: depressed mood and anhedonia. For this analysis, we considered a follow-up window of 8-12 weeks to reflect coaching and clinical protocols and the period in which we expect coaching and psychotherapy to have a measurable impact [32,33].

Data Management and Analysis

Data for this study were processed using Looker, business intelligence, and data analytics platform. Data were analyzed in Python and exported to spreadsheets for final analysis and review. We first assessed descriptive statistics for eligible users and those who completed follow-up. We then looked at the percentage of users demonstrating a change in PHQ-2 screen from baseline to follow-up for those who completed in-app surveys. We further evaluated these changes from baseline to follow-up using the McNemar test. The McNemar test compares dependent samples in terms of a dichotomous variable and is used for pretest/posttest designs or in time series data where the same sample is tested at least in two points in time [39]. We determined this to be the most appropriate test given the study design and nature of the outcome variable (comparing PHQ-2 screen outcomes at baseline and follow-up).

To evaluate outcomes by care modality (coaching only, therapy + psychiatry, hybrid) for users who screened positive at intake, we performed a chi-squared test to see if the proportion of individuals with reduced depression symptoms (change from a positive screen at intake to negative at follow-up) differed between these groups.

Ethics Statement

This study represents a secondary analysis of pre-existing de-identified data. The study team does not have access to the participants or participant identifying information and does not intend to recontact participants. This study protocol was reviewed by Advarra IRB and determined to be exempt from IRB oversight as de-identified secondary data analysis is generally not regarded as human subjects research.

Results

Table 1 reports descriptive characteristics of the sample who completed follow-up. Of 1662 individuals included in this analysis, 46.5% (772/1662) screened positive for depression at intake, and 53.6% (890/1662) screened negative according to the PHQ-2 questionnaire.

Gender and demographic data were missing for a large portion of the sample, as this has historically been optional information provided in employer eligibility files. For those users who did have data reported (N=678), 68.7% (466/678) were female, and 30.8% (209/678) were male. Of the individuals that reported age information, 11.5% (122/1064) were 18-24, 51.3% (546/1064) were 25-34, 22.7% (242/1064) were 35-44, 14.3% (152/1064) were 45-64, and 0.1% (2/1064) were 65 or older. When looking at the modality of care in which individuals were engaged, 65.5% (1089/1662) were only engaged in coaching, 27.6% (458/1662) were engaged in both coaching and clinical (therapy or psychiatry) services, 3.3% (54/1662) were only engaged in clinical services, and 3.7% (61/1662) used the app but did not engage in coaching or clinical services.

For those individuals engaged in coaching, the average number of sessions was 6 over the study period. For those individuals engaged in any clinical service (therapy or psychiatry), the average number of appointments was 6 over the period. The average number of therapy appointments for those engaged in therapy services was 6. The average number of psychiatry appointments for those engaged in psychiatry services was 3.

Table 2 shows the frequency and percentage of users by PHQ-2 result at intake and follow-up. Of the 1662 individuals who completed follow-up, 772 (46.5%) were considered a positive screen at intake, and 890 (53.6%) were considered a negative screen at intake. At the follow-up window, 477 (28.7%) of individuals screened positive, and 1185 (71.3%) screened negative. Using the McNemar test, we concluded that there was a statistically significant difference in the proportion of users with a positive PHQ-2 result at baseline and follow-up, $P<.001$.

Table 1. Characteristics of the study cohort.

Characteristic	Value
Gender, n (%)	
Female	466 (28.04)
Male	209 (12.58)
Other	3 (0.18)
No response	984 (59.21)
Age, n (%)	
18-24 years old	122 (7.34)
25-34 years old	546 (32.85)
35-44 years old	242 (14.56)
45-64 years old	152 (9.15)
65 or older	2 (0.12)
No response	598 (35.98)
Care modality, n (%)	
Coaching only	1089 (65.52)
Hybrid (coaching + clinical)	458 (27.56)
Clinical only	54 (3.25)
App only	61 (3.67)
Engagement, mean (SD)	
Coaching sessions	6.14 (5.44)
Clinical appointments	5.79 (3.12)
Therapy appointments	5.54 (2.8)
Psychiatry appointments	2.71 (1.7)
Member satisfaction, mean (SD)	
Coach star rating	4.63 (0.6)
Clinical star rating	4.74 (0.61)
Patient Health Questionnaire intake screen, n (%)	
Positive	772 (46.45)
Negative	890 (53.55)

Table 2. Patient Health Questionnaire-2 (PHQ-2) results at intake and follow-up (N=1662).

PHQ-2 screen result (pre)	Post		Count, n	X^2 (*df*)	*P* value
	Positive, n (%)	Negative, n (%)			
Positive	312 (18.77)	460 (27.68)	1662	139.24 (1)	<.001
Negative	165 (9.93)	725 (43.62)			

[a] McNemar chi-squared test.

Table 3 shows the frequency and percentage of users who experienced a change in their PHQ-2 result by care modality for the users who screened positive at intake (N=748). Using a chi-square test, we concluded that there was not a significant association between the proportion of individuals with a positive screen at intake who improved at follow-up and care modality (*P*=.77).

Table 3. Association between PHQ-2 improvements and care modality (N=748).

Variable (care modality)	Change, n (%)	No change, n (%)	Count, n	X^2 (*df*)	*P* value[a]
Coaching only	281 (58.54)	199 (41.46)	480	1.1289 (2)	.770
Therapy only	16 (61.54)	10 (38.46)	26		
Hybrid	150 (61.98)	92 (38.02)	242		

[a] Chi-square test for independence.

Discussion

Principal Findings

Although there is growing evidence that digital and virtual mental health interventions show promise in improving clinical outcomes for individuals with depression, many studies have highlighted the need to study further the features of specific technologies and the populations that use them. This study adds to this literature by describing a specific virtual on-demand mental health system and providing some preliminary results on user characteristics, engagement, and depression symptoms to guide future research.

Descriptive statistics showed that a majority of individuals were only utilizing coaching services (65.52%), and a minority of individuals were only utilizing clinical services (3.25%). The average coach and clinician star rating was >4.5, which provides some signal that members receiving care are satisfied with the care they are receiving, although more research is required to understand satisfaction with specific aspects of the system.

A McNemar test showed that the proportion of individuals with a positive PHQ-2 screen significantly decreased at follow-up, thus providing preliminary evidence that the Ginger system has an impact on decreasing depression symptom severity. A chi-square test concluded that there was not a significant association between care modality and the proportion of individuals with a positive screen improving at follow-up. While further research is required, this suggests that text-based behavioral health coaching alone can be an effective modality for reducing depression symptoms in addition to traditional clinical services like therapy and psychiatry. Based on the operationalization of our outcome variable, it is important to note that this analysis only evaluated change in PHQ-2 screen results; thus, we are underestimating the proportion of individuals who improved because we are not capturing individuals who screened positive at follow-up according to the PHQ-2 but still experienced a full symptom response according to PHQ-9.

Limitations

This analysis has various limitations based on historical product and clinical design of the system that generated these observational data. First, PHQ survey completion is not required for all users. Thus, the cohort we were able to study was limited, and these outcomes are not necessarily generalizable to the overall user base due to bias in the users who complete the survey. Efforts to improve the product design, user experience, and integrations with clinical workflows will also allow us to study a broader cohort in the future and make more generalizable conclusions.

Given the historical survey design of this system, clinical outcomes were operationalized as a binary variable using PHQ-2, which can be interpreted as a positive or negative depression screen or severity of anhedonia and depressed mood. Thus, we could only measure outcomes as a dichotomous variable and did not assess the extent of symptom response on a continuous scale. Although the PHQ-2 is generally intended to be a screening survey, it has a relatively high sensitivity for major depressive disorder, and there is precedent for using it as a longitudinal outcome [36-38]. Furthermore, it explicitly measures the severity of two key symptoms of depression: anhedonia and depressed mood.

Although we have some demographic data on users via employer eligibility files, missing data meant we were not able to stratify our analyses or control for specific demographic variables since users are not currently required to provide this information directly to Ginger. Future product updates will address this missing data issue and allow stratified analyses of outcomes by demographics (gender, age, socioeconomic status) to help us better understand how outcomes differ for specific populations.

Finally, because we lacked a control group, we are unable to understand the significance of these outcomes versus usual care or no care. Given ethical challenges, few prospective non-intervention studies following the natural course of untreated depression exist [37]. Prior research looking at wait-list control groups has suggested that 20-25 percent of untreated depression cases will remit within 3 months [40,41].

Collectively, these limitations point to many directions for future research. By using this dataset, follow-up studies could examine which aspects of this system are associated with changes in clinical outcomes, eg, different types of coaching and therapy, different thresholds of engagement, frequency of coach and clinical interaction, and different types of in-app content. New measurements and survey tools such as productivity, quality of life, and functional outcomes will also help evaluate impact in a broader cohort of users where the PHQ survey is not the most appropriate measure of progress, eg, those who screen negatively for depression. Finally, randomized controlled studies could also build upon this research and further test hypotheses on the efficacy of specific interventions in this system.

Conclusion

There is growing evidence that telehealth and other digital interventions can be useful in reducing symptoms of depression and other mental health conditions. This study adds to the literature by describing a specific on-demand mental health system and investigating utilization patterns and impact. The results of this exploratory study show a significant decrease in the proportion of users experiencing depressed mood and anhedonia at follow-up. Limitations with this study design mean that these results are not generalizable to the entire user base nor attributable to a specific intervention. Future studies can address these limitations and provide additional insight into which features of the system are most associated with outcomes in different populations.

Abstract

Background: Joint bleeds are the hallmark of hemophilia, leading to a painful arthritic condition called as hemophilic arthropathy (HA). Exercise programs are frequently used to improve the physical functioning in persons with HA. As hemophilia is a rare disease, there are not many physiotherapists who are experienced in the field of hemophilia, and regular physiotherapy sessions with an experienced physiotherapist in the field of hemophilia are not feasible for persons with HA. Blended care is an innovative intervention that can support persons with HA at home to perform the advised physical activities and exercises and provide self-management information.

Objective: The aim of this study was to develop a blended physiotherapy intervention for persons with HA.

Methods: The blended physiotherapy intervention, namely, e-Exercise HA was developed by cocreation with physiotherapists, persons with HA, software developers, and researchers. The content of e-Exercise HA was compiled using the first 3 steps of the Center for eHealth Research roadmap model (ie, contextual inquiry, value specification, and design), including people with experience in the development of previous blended physiotherapy interventions, a literature search, and focus groups.

Results: A 12-week blended intervention was developed, integrating face-to-face physiotherapy sessions with a web-based app. The intervention consists of information modules for persons with HA and information modules for physiotherapists, a graded activity program using a self-chosen activity, and personalized video-supported exercises. The information modules consist of text blocks, videos, and reflective questions. The patients can receive pop-ups as reminders and give feedback on the performance of the prescribed activities.

Conclusions: In this study, we developed a blended physiotherapy intervention for persons with HA, which consists of information modules, a graded activity program, and personalized video-supported exercises.

Introduction

Hemophilia is an X-linked congenital disorder that impairs the body's ability to make blood clots [1]. It is a rare disease, with a prevalence of 1 in 10,000 persons. Hemophilia is characterized by prolonged bleeding after injuries, easy bruising, and an increased risk of bleeding in the joints and muscles. When untreated, persons with severe hemophilia (<1% blood clotting factors) experience spontaneous bleeding, whereas persons with mild hemophilia (>5% blood clotting factors) experience bleeding only after a trauma [1]. Despite the introduction of prophylactic clotting factor replacement therapy in developed countries in the 1970s, approximately 2 joint bleeds per year are still observed in persons with severe hemophilia receiving prophylactic treatment [2]. The most affected body parts in persons with hemophilia are the ankle joints (42%), knees (20%), and elbows (20%) [3].

Recurrent bleeding in the joints eventually causes hemophilic arthropathy (HA). The pathogenesis of HA has certain features in common with inflammatory joint diseases, but HA is predominantly a degenerative joint disease, which is comparable to osteoarthritis (OA) [4]. The clinical symptoms of pain and the limited range of motion of the joints and atrophy of the surrounding muscles in HA are similar to those reported in OA. Furthermore, people with HA and OA experience limitations in their activities and participation and they are less active than their healthy peers [5].

A wide variety of exercise programs have been developed for persons with hemophilia [6]. However, since these interventions have shown mixed success, a preferred exercise intervention for persons with HA is still undecided. Moreover, regular physiotherapy is not feasible for many persons with hemophilia because physiotherapy treatment is often not covered by health insurance and physiotherapists experienced in hemophilia care are scarce. Since the symptoms and pathogenesis of HA are similar to those of OA, it can be hypothesized that increasing physical activity in daily life has the potential to improve the physical functioning in persons with HA, as previously shown in persons with OA [7]. To our knowledge, no interventions that target the daily movement behavior of persons with hemophilia have been described to date.

Medical apps in smartphones are an upcoming phenomenon in health care and they offer unique possibilities for providing information, supporting behavioral change, and encouraging self-control. Integrating a medical app in smartphones with regular face-to-face physiotherapy sessions can support the participants in performing the advised physical activity behavior and prescribed home exercises and support self-management beyond the walls of the physiotherapy practice. Previously developed electronic health (eHealth) apps for persons with hemophilia include videoconferencing apps and apps that report bleeding events and the use of clotting factor replacement therapy [8,9]. An eHealth intervention directed at changing the movement behavior and improving physical functioning is not yet available for persons with hemophilia.

Recently, a blended exercise program “e-Exercise” was developed for persons with OA, integrating face-to-face physiotherapy with a smartphone app [10]. This program consists of information modules on increasing self-management, personalized exercises, and a behavioral graded activity approach. A clustered randomized controlled trial showed that the effectiveness of e-Exercise in patients with OA was comparable to that of the usual physiotherapy in these patients [11]. Moreover, patients with OA in the e-Exercise group needed only 5 face-to-face sessions, whereas patients in the usual physiotherapy group needed 12 face-to-face sessions.

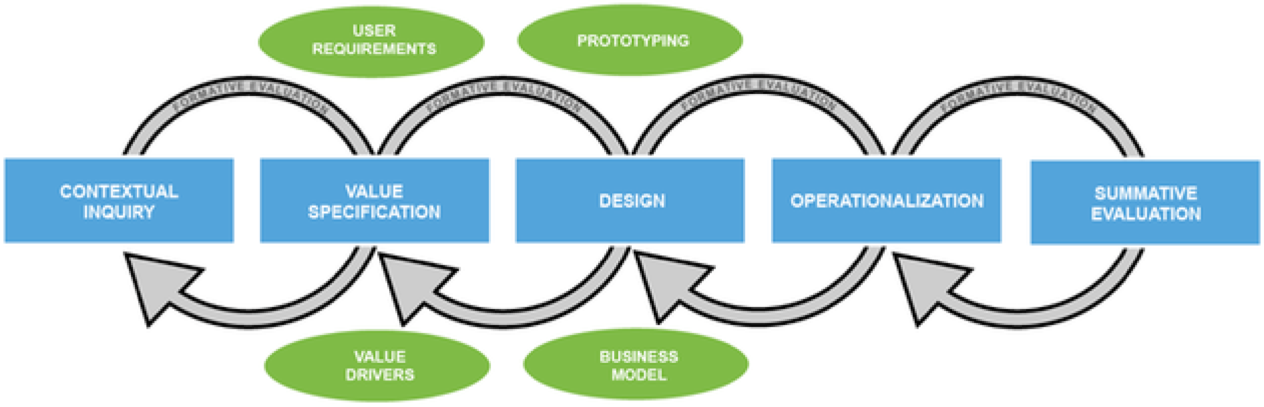
A blended physiotherapy intervention is expected to be beneficial for persons with HA because it has the potential to support behavioral change and it creates the opportunity to treat patients who have limited access to specialized physiotherapy. Furthermore, it could be used to support physiotherapists in primary health care, who are less familiar and not experienced in treating persons with HA. We hypothesized that certain aspects of the previously developed e-Exercise OA intervention could be suitable for persons with HA as well, given the previously mentioned similarities between the two disorders. However, significant changes might be needed in the intervention for HA because of the differences in the congenital character of hemophilia, possible fear of bleeding, involvement of multiple joints, and involvement of other joints (eg, ankles). The aim of this study was to develop a blended physiotherapy intervention for persons with HA. The proposed program was developed upon the existing e-Exercise intervention for persons with OA. During the development of this program, the similarities and differences in the treatment of persons with OA and HA were investigated.

Methods

Theoretical Model Roadmap

The theoretical Center for eHealth Research (CeHRes) roadmap model was used to develop e-Exercise HA [12]. The CeHRes roadmap is designed for the development and research of eHealth technologies. Cocreation plays a central role in this approach because it anticipates the needs and values of the stakeholders to improve the uptake and the effect of the intervention. Figure 1 shows the 5 stages of the CeHRes roadmap, which consists of connecting formative evaluation cycles. This study focused on the following first 3 stages of the model: contextual inquiry, value specification, and design.

Figure 1. CeHRes roadmap. CeHRes: Center for eHealth Research.



Stages 1 and 2: Contextual Inquiry and Value Specification

The aim of contextual inquiry and value specification is to establish the most important needs, values, and requirements of the stakeholders in relation to a blended physiotherapy intervention for persons with HA. The input in this step was based on (1) a literature search, (2) experience with the development and implementation of the e-Exercise OA intervention, and (3) focus groups with persons with HA and physiotherapists experienced in the field of hemophilia. These 3 points have been described in detail as follows.

First, a literature search was performed for studies published in PubMed till April 2019 using the search terms “hemophilia” AND “exercise” OR “physiotherapy.” Additionally, we searched for national and international physiotherapy guidelines on hemophilia and OA through patient societies and professional associations and by using search terms “physiotherapy” AND “guidelines and hemophilia” OR “osteoarthritis.”

Second, experience with the development and implementation of the e-Exercise OA intervention was established from previous studies [10,13,14] and by involving the authors of these previous studies in the development process.

Third, 2 focus groups were formed: one group consisted of 5 persons with HA and the other group consisted of 5 physiotherapists experienced in the field of hemophilia. Sessions with the focus groups lasted for around 1 hour and were moderated by MAT. A topic guide was used to discuss the following subjects: the preferred content of physiotherapy for persons with HA, advantages and barriers of usual physiotherapy, information provided and needed, thoughts and beliefs around physical activity (only persons with hemophilia), possible subgroups of persons with HA (only physiotherapists), and advantages and barriers to the use of eHealth. All focus groups were audio recorded and transcribed verbatim. The results were analyzed using a thematic analysis. The data analysis involved reading the transcripts, mapping quotes into codes with the open coding process, and summarizing the codes into themes iteratively.

Thus, information acquired by literature research, experience with a previously developed blended intervention for patients with OA, and focus groups were used to compile the content of the intervention. The authors compiled the first draft of the program. Consequently, all the members of the focus groups individually provided feedback on the draft. Patients were invited to give feedback on the information modules for patients, while physiotherapists were invited to comment on the information modules for physiotherapists. In addition, a hematologist and a social worker commented on the information modules. The physiotherapists collected the feedback with their coworkers in primary care, while patients discussed with their partners or their significant other. The comments were processed by the authors and a second draft was presented to the stakeholders. This process continued until all the members were satisfied.

Stage 3: Design

During the design phase, the researchers cooperated with “The Health Train,” a commercial eHealth entrepreneur, which was already involved in the previous developed e-Exercise OA app. Currently, e-Exercise interventions are also being developed and studied for low back pain, medically unexplained physical symptoms, and complaints of the neck and shoulder. Knowledge about the design and the functionality of the app studied during the development of other e-Exercise interventions were used for the development of e-Exercise HA. The collaboration with a commercial eHealth entrepreneur can facilitate a long-term implementation of the e-Exercise interventions in physiotherapy care, irrespective of research funding. The possibility of using the same platform for interventions for different patient populations and connecting e-Exercise with the most widely used electronic medical record by physiotherapists in primary care will facilitate the use of e-Exercise by physiotherapists. The research team provided input for the content of the web-based app, and “The Health Train” integrated this content into their platform.

Results

Stages 1 and 2: Contextual Inquiry and Value Specification

A recent Cochrane systematic literature review in 2016 [6] provided information on the effectiveness and safety of several exercise protocols for persons with hemophilia, including resistance exercises, isometric exercises, bicycle ergometry, treadmill walking, and hydrotherapy. Most interventions improved one of the following outcomes: pain, range of motion, strength, or walking tolerance. Functional exercises seemed more effective than static exercises for improving strength. No adverse events were reported as a result of any of the interventions. An additional literature search between December 2016 and April 2019 with the search terms “hemophilia” AND “exercise” OR “physiotherapy” yielded 4 original papers that reported similar results after different forms of exercise therapy and manual therapy [15-19]. No guidelines on physiotherapy for persons with HA were available. Instead, parts of the general guidelines for the treatment of hemophilia and parts of the Dutch physiotherapy guidelines for OA were used [1,20]. The demographic characteristics of the participants in both the focus groups are shown in Table 1 and Table 2.

The focus groups provided information on the following themes: current treatment for HA, attitude toward physical activity with HA, information requirements for HA, and values and requirements of e-Exercise for HA.

Table 1. Focus Group 1: Demographic characteristics of the participating patients.

Participants with HA[a]	Age (years)	Severity	Hemophilia A/B	Hemophilia joint health score[b]	Hemophilia activity list[c]
Participant 1	56	Severe	A	38	59
Participant 2	54	Severe	A	12	72
Participant 3	67	Severe	A	50	40
Participant 4	40	Severe	A	31	94
Participant 5	76	Severe	A	n.a.[d]	n.a.

[a] HA: hemophilic arthropathy.

[b] High score indicates worse joint status.

[c] High score indicates less limitations in activities, maximum score =100.

[d] n.a.: not assessed.

Table 2. Focus Group 2: Demographic characteristics of the participating physiotherapists.

Participants	Overall experience (years)	Experience with hemophilia (years)	Number of persons with hemophilia (n) that were treated	Work setting	Specialization
Physiotherapist 1	30	>10	>10	Primary care	Manual therapy
Physiotherapist 2	26	>10	0-5	Primary care	General
Physiotherapist 3	18	>10	0-5	Primary care	General
Physiotherapist 4	38	>10	>10	Primary care	Manual therapy
Physiotherapist 5	40	>10	>10	Hemophilia treatment center	Manual therapy

Current Treatment for Hemophilic Arthropathy

According to the physiotherapists, the basis of the treatment for persons with HA is similar to that of the treatment for patients with OA, and the same physiological principle in OA treatment should be used in HA physiotherapy treatment. The focus group session with the physiotherapists directed at the similarities and the differences between the preferred treatments for OA and HA. This focus group revealed that the treatment for both OA and HA has changed over the last few years from a hands-on approach to a coaching-based therapy, thereby enabling patients to achieve more self-control. The most important difference between OA and HA is that the physiotherapists need to be aware of the symptoms that can indicate a bleeding event while treating a person with HA. Another difference is that persons with HA have more knowledge about their condition—often even more than their primary care physiotherapist. This knowledge plays an important role in their coaching roles. Furthermore, persons with OA have to be motivated to be more active while persons with HA need to learn how to increase the intensity and the duration of the activities and exercises slowly and to avoid peak loads. Patients stated that they benefitted from the exercises and advice on movement behavior as well as the manual therapy. Focus group sessions with persons with HA revealed that the most critical barriers to adhering to physiotherapy were the limited reimbursement by the health insurance, execution of boring exercises, and stubbornness of the patients to accept advise. The patients mentioned that a good relationship with their physiotherapist facilitated their adherence to the physiotherapy treatment.

Attitude Toward Physical Activity

Persons with HA explained that they continuously balanced the risk of increasing complaints with the benefits of performing an activity. Patients preferred to do meaningful activities such as walking or cycling in their daily life. They stated that the proud feeling after accomplishing an activity goal motivated them to continue to be active. Some patients mentioned that they preferred to do exercises as well. The important conditions for achieving an activity goal are the choice of the type of activity and tailoring the increase in the intensity and duration with professional guidance. Patients were motivated to perform an activity if they received encouragement but they were demotivated when their complaints were not empathized by others. Patients expressed different opinions about consuming painkillers. Some stated that painkillers enabled them to be active and to relax, while others were afraid that the consumption of painkillers would make them overuse the joint and consequently increase the joint damage.

Requirement of Specific Information on Hemophilic Arthropathy

Both persons with HA and physiotherapists in primary care emphasized the need for specific information for physiotherapists in primary care. Physiotherapists in primary care need to know the basic information about hemophilia along with the specific dos and don'ts. Patients did not specify the need for more information for themselves. The physiotherapists stated that basic information about hemophilia need not be provided for such patients. Instead, the patients could benefit from information on the course of their complaints, differences between joint bleeding and arthropathic complaints, how to actively manage HA, and how to cope with the limitations in their daily activities and participation. Short videos were considered as the preferable mode of conveying information to persons with HA and physiotherapists. Information for patients must be provided in a simple language. Physiotherapists were prepared to spend no more than 30 minutes to read or hear all the information that was required. The patients appreciated the communication about their specific situation between the hemophilia treatment center and the primary care physiotherapist.

Values and Requirements of Blended Physiotherapy for Persons With Hemophilic Arthropathy

Both physiotherapists and persons with HA believed that an e-Exercise app could add positively to the current physiotherapy treatment for persons with HA. The physiotherapists stated that the frequency of face-to-face visits in this program should be high initially and then decreased during the intervention. The overall number of face-to-face visits should be personalized, which can be determined by the self-management skills and the restraining factors of the patient. The patients stated that the e-Exercise app should include choices for exercises and a variability in the exercises. The patients preferred to set a goal, perform meaningful activities (walking or biking), give feedback on how well they were able to follow the program, and receive pop-ups and an exercise scheme to increase adherence. Physiotherapists stated that they could benefit from a feature in the app through which they could communicate with the patients and be able to consult the hemophilia treatment center for questions. The illustrative quotes for the different themes are presented in Table 3.

Table 3. Quotes from physiotherapists and persons with HA[a].

Theme	Illustrative quote
Current treatment for HA	*…We have our principles of physiology and training. In strength training, overload is needed to make gains for the muscle fibers. This is no different for a person with hemophilia; however, you need to be more careful with increasing intensity.* [Physiotherapist]
Attitude toward physical activity with HA	*…When you have hemophilia, physical activity needs to involve mainly natural movements and things that I just do myself. I try that, I ride my bike, I walk, and I do not take the elevator but the stairs.* [Patient]
Information requirements	*…The difference between patients with OA and those with HA is that because persons with HA have had hemophilia all their life, they have more knowledge about their disease than their 63-year-old neighbor with a painful knee."* [Physiotherapist]
Values and requirements of e-Exercise	*…So you have complaints and you cannot do certain things. ...the physiotherapist asks what your most important feasible goal is. "…" if you have a problem with your elbow and you cannot put on your sock, it may only be a minimal difference, that can be very inconvenient, and if it is your goal to be able to do that.* [Patient]

[a] HA: hemophilic arthropathy.

Stage 3: Design

The e-Exercise HA intervention was developed based on the existing e-Exercise OA intervention because of the findings generated from our focus groups, in which the physiotherapists stated that the basis of the treatment for persons with OA and HA is similar. The core components of e-Exercise OA are self-management information, a graded activity approach, and personalized exercises [11]. The need for information modules in e-Exercise HA intervention was expressed by the focus group with physiotherapists as the physiotherapists felt that they lacked the knowledge to educate persons with HA. Therefore, self-management information modules for patients and information modules for physiotherapists were included within e-Exercise HA. Furthermore, focus groups revealed the need for slowly increasing an activity and avoiding peak loads, goal-setting and performing meaningful daily activities. Those needs were met by the graded activity approach. Personalized exercises were suggested by persons with HA and have been reported in a previous study [6]. Feedback from the stakeholders on the drafts mainly consisted of changes to the content of the information modules and the script of the information videos. Since the web-based environment was already developed in cocreation with the end users and adjusted based on the experiences during the trial, the design of the web-based environment was not changed.

e-Exercise Hemophilic Arthropathy

This 12-week intervention integrates face-to-face physiotherapy with a smartphone app. Physiotherapists can log into the website, which offers the platform with the physiotherapist-specific information about HA. The physiotherapists can create an account for each patient. In this account, physiotherapists can create and personalize an exercise program for each patient and monitor the progress. The website allows physiotherapists to continuously adapt the treatment program according to the needs of the individual patient. Patients can log into their personal account in a smartphone app. In this app, the patients receive weekly modules with information and are able to review their personal physical activity program and their personalized exercises. They can give feedback on the performance of the prescribed program and receive tailored feedback messages. The components of e-Exercise HA have been further explained below. A screenshot of the e-Exercise HA app is shown in Multimedia Appendix 1.

Self-Management Information Modules

The information modules consist of text blocks supported by short videos [1,6,20-24]. For the physiotherapists, the following 5 information modules are available: (1) What is hemophilia? (2) Development of HA. (3) HA and physiotherapy. (4) Identifying a bleed. (5) Organization of care. The patients receive the following information modules on their smartphone app every week: (1) What is HA? (2) Pain and HA. (3) Joint bleed or HA? (4) Physical activity and HA. (5) Responsible exercise. (6) Arthropathy management. (7) A physical activity plan. (8) Maintaining an active life. (9) Maintaining healthy body weight. (10) Dealing with the surrounding people. (11) Fatigue. (12) What can you do? After every module, patients are invited to answer a reflective question in that particular theme. Physiotherapists are encouraged to further discuss the themes during the next face-to-face visit. When the patients feel that a specific theme does not suit their personal situation, they can choose to skip that specific information module.

Graded Activity

The behavioral graded activity approach is directed at increasing the amount of physical activity in a time-contingent way so that the activities are gradually increased by present quotas [25]. First, the persons with HA select their most problematic activity (eg, walking). The initial baseline measures, in which the patients perform the selected activity at home to the limit of tolerance (pain-contingent), are then performed for a week and will be registered in the app. Second, after these baseline measurements are recorded, the patients set their individual treatment goal for the selected activity. During this procedure of goal setting, the physiotherapist acts as a coach only, as it is essential that the goal is the patient's own internal goal. Throughout the program, this activity has to be performed 3 times a week for 11 weeks. The duration will be gradually increased in a time-contingent manner to reach the final goal at the end of the program. The weekly program will be automatically generated starting at 50% of the baseline assessment. On self-chosen moments (eg, every Monday at 8 PM), patients receive reminders on their smartphone to perform this activity. Patients can turn the timer on and off when they perform their activities so that the physiotherapist can monitor the progression. Third, tailored feedback messages are provided at the end of the activities with the aim of motivating or slowing down the patients with their program by using the principles of operant conditioning. The progression will be evaluated during the face-to-face visits.

Exercises

e-Exercise HA is linked to a database of over 1500 exercises, which are supported with texts and videos. In the face-to-face sessions, physiotherapists can start an exercise program by choosing personalized exercises and parameters. On their apps, patients can recall their exercises, including the parameters and the information about their performance. Similar to that in the graded activity approach, the physiotherapist is able to monitor the performance of the exercises. During the face-to-face visits, the performance of the exercises can be evaluated and adjusted when needed.

Face-to-Face Sessions

Face-to-face sessions are conducted to recall web-based self-management modules and to discuss how the themes affect the patient's personal situation by evaluating the answers on the reflective questions. The progress in the graded activity program and in the performance of the exercises can be visualized in the management portal of the website used by the physiotherapist. When needed, the graded activity program and the prescribed exercises can be adjusted. We propose 6 face-to-face visits during the 12-week program, with a decreasing frequency as the program progresses. The visits will be proposed to be scheduled on weeks 1, 2, 4, 6, 9, and 12. However, the number of visits and the timing of the visits depend on the personal needs of the patients, including the self-management skills and digital skills.

Discussion

Principal Findings

In this study, we developed a blended physiotherapy intervention for persons with HA, which meets the needs of the persons with HA and the physiotherapists in primary care. To enable successful implementation, the intervention was developed by cocreation with stakeholders such as persons with HA, physiotherapists, software developers, and researchers. Our focus group study with persons with HA and physiotherapists yielded the following findings: physiotherapy for persons with HA is similar to that for persons with OA, specific tailored information on rare diseases such as hemophilia and HA is required for patients and physiotherapists, patients prefer meaningful daily life activities and want to work toward achieving a goal, patients prefer choices and variability in exercises, and the exercise program needs to be personalized. Both physiotherapists and persons with HA agreed that integration of an e-Exercise app within physiotherapy treatment could be beneficial for the treatment of HA. The most important difference between providing treatment for OA and HA is that physiotherapists need to be aware of the disease symptoms that can be indicative of bleeding when treating a person with HA.

Comparison With Other Studies

Currently, several eHealth apps are being developed and used in hemophilia care [26]. However, these are mainly videoconferencing apps and apps the report bleeding and the use of clotting factor replacement therapy. No study has yet described smartphone apps that support physiotherapy in persons with hemophilia or related bleeding disorders [26]. Focus groups in this study showed that the Dutch physiotherapists and persons with HA showed a positive attitude toward the use of a blended physiotherapy intervention. This is in accordance with previous studies showing that blended eHealth intervention is feasible and effective in persons with OA, although some physiotherapists expected to face some barriers in this intervention mode [11,14,27]. An important barrier for physiotherapists to use e-Exercise OA was that it could be used for only 1 disorder. The current expanding of the platform with e-Exercise programs for several disorders is expected to facilitate the use of e-Exercise HA [28]. Another barrier was that some physiotherapists felt that the program interfered with their professional autonomy. However, given the limited knowledge of primary care physiotherapists about hemophilia, it is expected that this is less of a problem for e-Exercise HA. In accordance with previous studies, the requirement of e-Exercise determined in this study included a smartphone app with information for patients, goal-setting features, and a personalized exercise program [10]. The need for information modules for physiotherapists is specific for hemophilia, which is understandable, given the rare nature of the disease.

Strengths and Limitations of This Study

Hampered uptake and implementation of eHealth solutions in clinical practice is a common problem [29]. A strength of this study is that the intervention was developed in cocreation with the end users (ie, patients and physiotherapists) according to the CeHRes roadmap in order to accelerate implementation at a later stage. Adding information modules particularly for physiotherapists was a strong recommendation by the stakeholders and is expected to improve the quality of care. A limitation of this study is that only Dutch stakeholders were invited. We expect that different barriers and facilitators might be present in different countries, thereby limiting the generalizability of our findings in different countries. Moreover, only patients aged over 40 years participated in the process of cocreation. This limits the generalizability of the findings to adolescents and young adults. Furthermore, the feasibility and the effectiveness of this intervention have not yet been investigated and will be investigated at a later stage of this project. The intervention in this study was built upon an existing intervention for persons with OA and is part of a platform for blended physiotherapy interventions for several disorders. This has enabled us to learn from the results of these interventions and will lower the threshold for the implementation of our intervention for persons with a rare disease. The use of an existing platform also limited us to make major changes to the web-based environment. This intervention has been developed in cocreation with stakeholders as well and we expect that preferences regarding this topic will not be very different from those of our population. The cocreation process in this study focused mainly on the content of the intervention and less on the web-based interface.

Clinical Implications and Future Research

A possible use of e-Exercise HA is by physiotherapists who are associated with a hemophilia treatment center and who are able to treat patients who visit the clinic a few times, but not on a weekly basis. Moreover, e-Exercise HA can support physiotherapists in primary care, who have no experience with hemophilia but can treat persons with HA locally. We expect blended physiotherapy to lead to less face-to-face visits. This could increase the accessibility of physiotherapy for persons with HA, leading to lower costs and more flexibility for patients. Furthermore, we expect that e-Exercise HA will improve self-management with respect to the movement behavior because patients are provided with information modules and are stimulated to perform activities at home. Future research should be directed toward investigating the effectiveness of this intervention and the implementation of this intervention in the Netherlands. To enable the international implementation of this program, the barriers and the facilitators of the stakeholders in different countries need to be investigated.

Conclusion

We developed a 12-week blended physiotherapy intervention that integrates face-to-face physiotherapy sessions with a smartphone app for persons with HA. This personalized intervention consists of self-management information, a graded self-chosen activity program, and video-supported personalized exercises, which integrates face-to-face sessions and a smartphone app.

Acknowledgments

This study was supported by an unrestricted research grant from Pfizer (ID 35384245). The institutional review board of the University Medical Center Utrecht (reference number 18-081/c) provided ethical approval and the ethics protocol reference number.

Authors' Contributions

CJJK, CV, and MFP developed the previous e-Exercise programs and used their experience to advise on the development of e-Exercise HA. MAT performed the literature search and the focus group discussions. MAT and MFP created the draft versions of the intervention. MAT made adaptation to the intervention based on the iterative cocreation process. MAT, PdK, and IARK created the draft versions of the information modules (text and videos). All authors contributed to the critical reviewing and editing of the manuscript. All authors approved the final manuscript.

Conflicts of Interest

REGS reports grants from Bayer, NovoNordisk, Sobi, outside the submitted work.

Abstract

Background: Digital mental health interventions present a unique opportunity to address the lack of social connection and loneliness experienced by young people with first-episode psychosis (FEP). The first generation of digital interventions, however, is associated with high attrition rates. Social media presents an opportunity to target this issue. A new generation of digital intervention has harnessed the popularity of social media to both promote engagement and foster social connectedness in youth mental health interventions. Despite their potential, little is known about how young people engage with, and experience, social media–based interventions as well as the optimal design, implementation, and management needed to ensure young people with psychosis receive benefit.

Objective: This study aimed to explore how young people engage with, and experience, a long-term social media–based mental health intervention designed to address social functioning in individuals with FEP.

Methods: This qualitative study was based on 12 interviews with young people who used Horyzons, a long-term social media–based mental health intervention, as part of a previous randomized controlled trial. A semistructured phenomenological interview guide with open-ended questions was used to explore young people's subjective experience of the intervention. All interviews were recorded and transcribed verbatim. Data were analyzed using interpretative phenomenological analysis.

Results: A total of 4 superordinate themes emerged during the analysis including (1) shared experience as the catalyst for a cocreated social space, (2) the power of peer support, (3) an upbeat environment, and (4) experiences that interrupt being in Horyzons.

Conclusions: We found that Horyzon's therapeutic social network fostered a connection and an understanding among young people. It also aided in the creation of an embodied experience that afforded young people with FEP a sense of self-recognition and belonging over the long term. However, although we found that most young people had strong positive experiences of a social connection on Horyzons, we also found that they experienced significant barriers that could substantively interrupt their ability to use the platform. We found that social anxiety, paranoia, internalized stigma, lack of autonomy, and social protocol confusion interfered with young people's usage of the platform. From a design perspective, digital interventions are flexible and thus equipped to begin addressing these implications by providing customizable and personalized treatment options that account for varying levels of social connection and psychological need that could otherwise interrupt young people's usage of social media–based interventions.

Introduction

Background

The current treatment of psychosis focuses primarily on symptom reduction [1]. Psychological and pharmacological interventions are effective in treating symptoms and preventing relapse to a degree; however, many young people with first-episode psychosis (FEP) experience significant difficulties with regard to social functioning and report high levels of social isolation [2-4]. Despite these findings, very few studies have assessed interventions targeting social functioning as a primary outcome [2,3].

Even in the earliest stages of the disorder, young people with FEP experience reduced social opportunities, have limited social networks, report difficulty developing and maintaining social relationships, and experience high levels of loneliness [1,3,5]. These findings have led to an increased focus on effective interventions that target loneliness and social connection [6]. However, despite the recognized importance of including social connection within a broader recovery framework, there are limited evidence-based solutions available to address this need [3,7,8].

Digital mental health interventions present a unique opportunity to address a lack of social connection and loneliness in FEP [3,8-14]. However, the first generation of digital interventions is associated with high attrition rates [15,16]. Social media presents an opportunity to target this issue. A new generation of digital interventions has harnessed the popularity of social media to both promote engagement and foster social connectedness [8,9,12,13].

Objective

Despite their potential, little is known about how young people engage with, and experience, social media–based interventions as well as the optimal design, implementation, and management needed to ensure young people with psychosis receive benefit. In addition, little is known about how these interventions are experienced over the long term. This study will address this gap by exploring young people's experiences of a long-term social media–based intervention to inform the emerging generation of digital mental health interventions. Therefore, this study aimed to explore how young people engage with, and experience, a long-term social media–based intervention designed to address recovery in FEP.

Methods

Setting and Design

This phenomenological qualitative study was based on interviews conducted between October 2018 and March 2019. Young people interviewed in this study had previously participated in the Horyzons randomized controlled trial (RCT; ACTRN12614000009617). The Horyzons RCT evaluated whether a long-term 18-month moderated online social therapy (MOST) platform, known as Horyzons, was superior to 18 months of regular care, following discharge from 2 years of treatment at an FEP early intervention service [8]. The MOST platform was co-designed and developed by a multidisciplinary team of peer workers, clinical psychologists, computing and information systems researchers, software developers, illustrators, and writers [17]. Horyzons was underpinned by a strengths-based and positive psychology framework designed to generate long-term functional recovery and increase well-being in FEP. It was a closed digital platform with options to engage in web-based therapy pathways (Figure 1), speak with peer and clinical moderators (both privately via a web-based chat and publicly on the social network), and connect with other young people via the therapeutic social network, which was referred to as the *newsfeed* (Figure 2) [8]. The digital functions of the platform, such as the web-based therapy pathways, were reinforced by human support provided by the clinical moderators through a supportive accountability model [18]. This contact was primarily provided through web-based chats and phone calls. A key clinical moderator was also allocated to each participant and was responsible for overseeing their engagement and progress over the span of the intervention [18]. Young people could connect on the social network by posting and commenting, sharing experiences, and giving and receiving support. Conversation could occur between participants in a freeform way on the newsfeed and they could also take part in focused group discussions through a feature referred to as *Talk It Outs* [8]. These discussions were overseen by peer moderators. As described in the Horyzons protocol, the functions of the platform were "designed to reinforce each other, creating a flow for the young person between the social and therapy elements" [8]. For the Horyzons RCT, a total of 170 young people approaching or recently discharged from the Early Psychosis Prevention and Intervention Centre in Melbourne, Australia, were recruited. Of the 170 participants, 85 were randomly allocated to the specialist treatment group. This gave them access to the Horyzons platform for an intervention period of 18 months. The remaining 85 participants continued with treatment as usual.

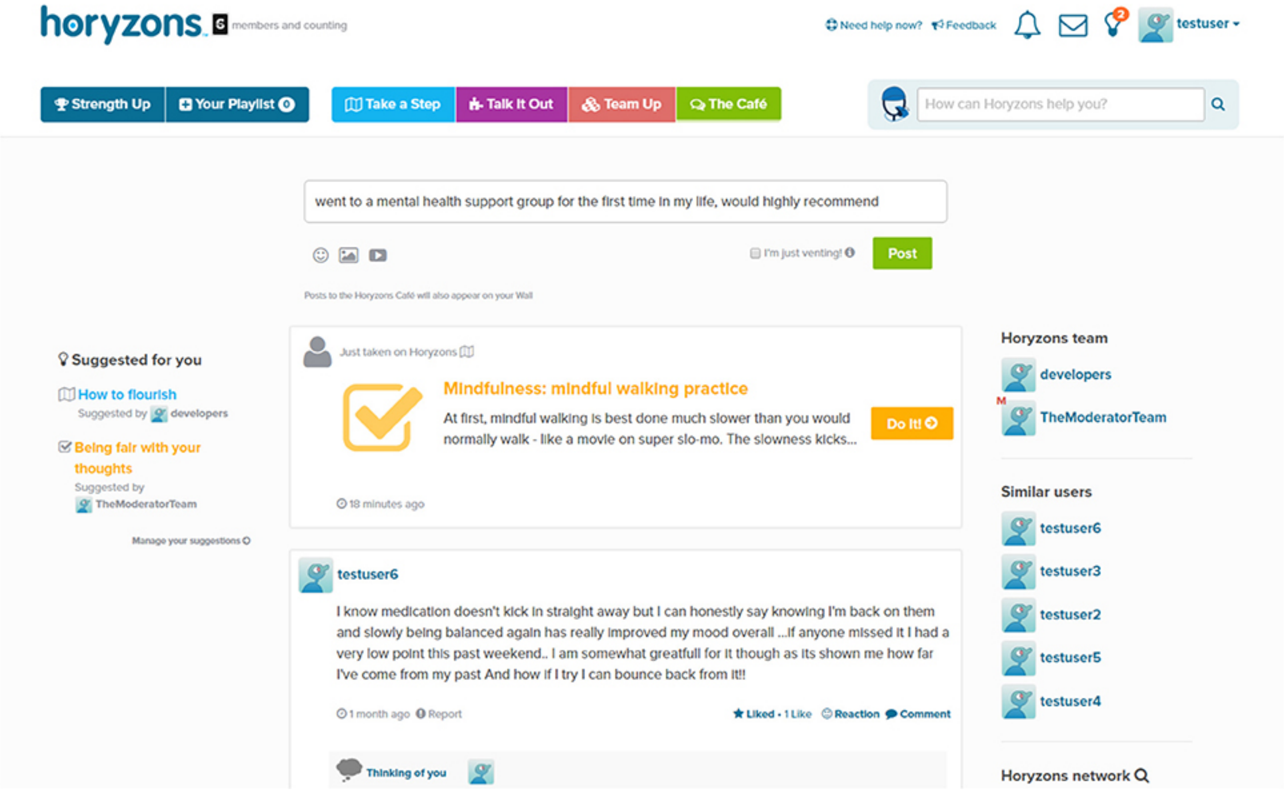
Figure 1. Everyday mindfulness therapy step.

Everyday mindfulness

In this Step

- Mindfulness is a kind of meditation that you don't need to be in one place or time for. It's great for everyday moments and can be done in a few seconds or a few minutes.
- Once you start practicing tuning in and anchoring yourself with your body, breath and senses, you can use those skills in everyday moments to help stay present, aware and alive to the world.

Figure 2. The Horyzons news feed.



went to a mental health support group for the first time in my life, would highly recommend

Mindfulness: mindful walking practice

At first, mindful walking is best done much slower than you would normally walk - like a movie on super slo-mo. The slowness kicks...

testuser6

I know medication doesn't kick in straight away but I can honestly say knowing I'm back on them and slowly being balanced again has really improved my mood overall ...if anyone missed it I had a very low point this past weekend.. I am somewhat greatfull for it though as its shown me how far I've come from my past And how if I try I can bounce back from it!!

Participants

The study inclusion criteria were as follows: (1) participation in the Horyzons RCT, (2) randomization to the treatment group of the Horyzons RCT, and (3) completing the Horyzons RCT. With the aim of sampling a range of young people with different levels of platform usage [19], a quantitative categorization of Horyzons participants was conducted. This categorization was based on each participant's overall number of log-ins to the Horyzons platform. Thus, all 85 participants randomized to the treatment group of the Horyzons RCT were divided into 4 quartiles based on the number of overall log-ins to the platform over the 18-month intervention period. Overall, log-ins ranged from 1 to 1568. The number of log-ins associated with each usage group is detailed in Table 1. The quartiles represented 4 usage groups: very low, low, moderate, and high usage. Young people from each usage group were then randomly contacted via phone call or text and invited to participate in a qualitative interview.

Table 1. Log-ins, mean, and standard deviation associated with each usage group.

Usage group	Total (N=84), n (%)	Log-ins	Mean (SD)
Very low	21 (25)	1-8	5 (2.2)
Low	21 (25)	9-23	15 (4.9)
Moderate	22 (26)	24-80	31 (19.3)
High	20 (24)	88-1569	366 (405.7)

Data Collection

All interviews were conducted using a phenomenological approach [20]. This interview method is concerned with the lived experience of a phenomenon, as experienced subjectively by the individual [21]. The interview schedule comprised 2 extremely broad, open-ended questions: (1) What was Horyzons? and (2) What was Horyzons like? These questions were designed to elicit young people's experiences of the Horyzons platform without leading them in a particular direction. Subsequent prompts were used if necessary; however, the method calls for the interviewer to follow the leads presented by the participant. Participants were given the option of completing the interview at the Orygen clinic, home, or in a public place (eg, library or café). Subsequently, interviews were conducted in a range of locations. Before beginning each interview, participants were required to complete a plain language consent form and given the opportunity to ask questions. Author LV conducted all interviews and had established relationships with all participants due to a previous position as a research assistant on the Horyzons RCT. LV is an early career researcher with extensive quantitative interviewing experience and is currently undertaking a research project using phenomenological methodological interviewing. Field notes were taken during the interviews, and a reflective log was maintained over the interview period. In accordance with the interpretative phenomenological analysis (IPA) approach, data collection, transcription, and preliminary analysis were conducted in parallel [22]. All interviews were audio-recorded and transcribed verbatim. All participants were reimbursed Aus $20 (US $12.63) for their participation in the study. All young people approached to participate in the study were interviewed with the exception of one young person who became distressed at the beginning of the interview due to acute psychotic symptoms, and the interview was quickly terminated. The recruitment of participants continued until a saturation of themes was reached at 11 participants [20]. The twelfth participant was then sampled to ensure that no additional themes emerged [20].

Data Analysis

Interviews were analyzed using IPA. In accordance with IPA, analysis for the study commenced once the first qualitative interview had been completed and transcribed [21]. Interviews were analyzed individually and in relation to all other interviews completed over the course of the study in a multilayered and overlapping IPA framework. Themes were derived directly from the data collected. Given that interpretation can be based on the context in which the phenomenon is viewed, member checking was not offered to participants because of the interpretative nature of the analysis used [22]. To begin, multiple close readings of each transcription were conducted. Initial responses to the data were noted and recorded. Codes or brief summaries describing the data were recorded. These codes formed the bases of emerging themes and patterns across the overall data set. The identification of reoccurring themes within and across interviews emerged and was noted. Some themes were distinct from one another, whereas others merged as superordinate themes. Strategies to maintain rigor, reliability, and validity throughout the analysis process included prolonged engagement with the data and thick and rich descriptions of results [23]. Author LV conducted the analysis and engaged in regular reflexive discussion regarding the codes and subsequent themes with the senior author (SB) [23]. Microsoft Excel was used in the data analysis process.

Results

A total of 12 participants aged 19 to 28 years (mean 23 years) were included in the study; 7 of the participants were female and 5 were male. All of the female participants were cisgender. Of the male participants, 4 were cisgender and 1 was transgender. Multiple participants from each of the 4 usage groups were interviewed. Interview times ranged from 30 to 86 min. The time period in which participants were interviewed for this study following the last date they were able to access the Horyzons platform ranged from 1 to 5 months. The mean follow-up time was 3 months. All participant names were replaced with an alias to ensure privacy. Table 2 gives a description of participant characteristics.

In total, 4 superordinate themes emerged during the analysis, with each theme divided into subthemes to comprehensively capture the phenomenon explored. The 4 superordinate themes were (1) shared experience as the catalyst for a cocreated social space, (2) the power of peer support, (3) an *upbeat* environment, and (4) interruptions to *being in* the Horyzons space.

Table 2. Descriptive summary of participant usage groups, alias, gender, age, follow-up time, length of interview, and overall log-ins to the Horyzons platform.

Usage group and alias	Gender	Age (years)	Time since last possible log-in (months)	Interview length (mins)	Overall log-ins, n
High

Shared Experiences as Catalysts for a Cocreated Social Space

Horyzons Was a Place and "I Felt at Home"

Young people used language commonly associated with the description of physical places when describing experiences of the Horyzons platform. That is to say that they spoke of Horyzons as a tangible or an embodied space that they could *arrive at* and *be in*. For instance, Audrey's description of sharing accomplishments with her peers on the therapeutic social network evokes imagery of *traveling to* and *being at* a physical destination:

> *So, I went there, and I would talk, talk about my achievements. I felt proud of myself for doing something. People would encourage me or commend me, yeah. So, it was a nice place to be.* [Audrey]

Audrey uses the spatial and social descriptors "went there," "talk about," "people would encourage me," and "a nice place to be" to describe moments that are technically confined to a computer, tablet, or phone. However, her phrasing of these experiences points toward a perception of Horyzons as a physical experience. Instead of detailing how she *uses* the platform, Audrey describes an experience of actually *going there* and *being in* the Horyzons social space.

"Don't Necessarily Know Each Other Personally" But a Connection Through Shared Experience

A number of participants described an experience of *knowing* other members of the platform. Interestingly, however, the *knowing* in most cases did not equate to a direct social relationship or connection, either physically or digitally, but was instead based on the participants' *common* history of mental health experiences:

> *It's like… war veterans… where you have all the gatherings of people who have been through wars and they don't necessarily know each other personally, but they've all got that common war experience. And they can relate to each other and they know what they've been through.* [Sam]

Sam's description builds upon commonplace social definitions of *knowing* and *connection.* It offers an alternative construct of what it might be to *know* other members in the particular place that is the *Horyzons space*. In this space, *knowing* each other may not be contingent on direct social contact but instead on the concept of *understanding* and *relating* to the *common* experience of being a young person with lived mental health experience.

"I Just Felt Like Relieved That I Wasn't The Only One"

Young people detailed a range of positive emotional responses at not being *the only one* with an experience of psychosis and other mental health experiences on the Horyzons platform.

Being in this space with others who shared this *common* history had a strong impact on participants. Many expressed that they could *relate* to others and both *understand* and feel *understood* in this environment. The sharing of experiences on the Horyzons platform by group members had a normalizing impact for some participants. For instance, Sam expressed:

> *It helped sort of reinforce that some of my experiences and feelings are normal… I'm not a weirdo.* [Sam]

Some members found it easier to share their own experiences with the group given they were in a shared social space with others who also had a lived experience of mental ill health:

> *My story is not as twisted as it is common, shit that happens. I could feel more comfortable sharing knowing that it's common...* [Jacob]

For some, sharing their personal stories with the group was a therapeutic activity in itself. The act of sharing supported the young person to unpack and reflect on their mental health experiences:

> *I wanted to support them, so I think I reflected on what I have been through…Actually gave them my experience, how I fought through it.* [Emily]

For Olivia, the shared experience of mental ill health sparked a sense of pride, pride that the group existed despite the adversity that its members face:

> *For me, it was just really important to see that there were other people that were kind of just saying like,' yeah, I'm proud.'… I think it's really important to be proud even though you've got fucking mental problems.* [Olivia]

Some participants identified the benefit of learning about other people's experiences, even if their stories were not directly relevant to the young person's own life. This information was a way to feel connected to others, receive encouragement, and access a diverse range of coping methods:

> *We didn't always have the same illness or anything. It was nice to hear people, people's experiences. It was encouraging to hear, yeah...Um, just how they dealt with the problem...And everyone approached them differently.* [Abigail]

One particular participant identified other members on the Horyzons platform that he knew from offline spaces. For him, this social overlap helped to reinforce that "mental health is a common thing."

For some participants, the opportunity to share a space with peers that they were able to relate to, and understand their experiences, reminded them of painful memories when their mental health struggles had been minimized, misunderstood, or mocked:

> *When I was with Orygen I told them the first time what had happened [family], and they're like "nah it's not true, it's just all in your head, it's all in your mind", and they didn't believe me, and it kinda just felt like I couldn't trust them.* [Emily]

"A Barrier That's Automatically Broken Down"

As described in the themes above, the cocreation of space and the concept of a *common* mental health history came together to create a social environment on Horyzons that participants described as *more intimate* than other spaces. Many participants described a greater sense of ease on the platform between peers than in other social spaces, both on the web and offline. This ease between young people acted to break down conventional social barriers and accelerated bonding:

> *Whereas I guess with traditional social media you don't just go up to random people and say "hey I've got this thing, do you want to talk about it?" whereas on Horyzons it was sort of specially crafted for that sort of thing, so it was a lot easier to approach people and sort of form bonds and stuff.* [Sam]

For participants, the awareness that they were among others with a shared experience meant they felt less judged and as a consequence of this, more relaxed to share and connect:

> *I connected to them a lot more easier than I would with others… I felt like I was in a more calm relaxed space connecting with them than other people that I meet at Uni… Like they were more open, non-judgemental... I felt relaxed…Yeah I felt really relaxed.* [Emily]

This dynamic appears to be somewhat cyclical in nature for participants. The recognition that their peers have a shared experience and a *more open* and *nonjudgmental* approach results in a more *relaxed* environment conducive to sharing. Once this process has occurred, several young people described an experience whereby they saw others sharing and this created a sense of positive responsibility to their peers in which they described wanting to "own up a bit more" to the group:

> *They were pretty much open with what they were going through…and I thought to myself 'I should open up at least and see where I would go'…Just like take a shot at it.* [Emily]

The Power of Peer Support

"Don't Really Know Unless You've Experienced It"

In the Horyzons context, the function of offering and receiving support was generally operationalized through public posts and replies on the social network. Participants expressed that offering and receiving advice and support from others with lived mental health experience, otherwise known as peer support, was a valuable practice that is unique to the peer-to-peer relationship. This dynamic is situated within the context of shared mental health history, a history that a clinician may not always have direct experience with. In the words of Abigail:

> *They don't really know unless [they've] experienced it.* [Abigail]
>
> *Like peer support really is helpful for me in particular, just cos like, I kinda find it more difficult to open up to someone that doesn't really fully get the picture, even if they're like a completely trained professional.* [Ruby]

Participants communicated that their life experiences should position them at the center of the Horyzons platform. They identified that their mental health journey can help to guide current day problem solving for themselves and others:

> *Apart from starting it and summarizing it at the end [group discussions], I feel like it was mostly handed over to the users, which is probably a good thing*

> *because it allows the people with the experiences to sort of come up with their own ideas and thoughts.* [Sam]

For some young people, the advice of a peer is elevated above that of a "completely trained professional" or "someone giving a TED Talk." Some young people expressed that support from a person with lived experience would be easier to implement in their own life because that individual would "fully get the picture" and be more likely to offer "practical" and "realistic" advice:

> *I want to know what real everyday people do. Not a social media presence person, just the person on the other side of the road. What do they do? ...It might not work for me…but it's probably most interesting because it's probably most um, uh, doable?* [Celeste]

"I Love Being a Massive Resource for That Sort of Thing"

Many participants described offering support and advice to others based on knowledge gained via their own mental health experiences as an empowering, validating, and, at times, joyful function of the Horyzons platform. Emily expressed, "I felt really calm, relaxed and over the moon because I was able to help someone."

"Responsibility to… Basically Just be Their Secondary Psychologist"

In total, 2 participants expressed strong reservations regarding what they experienced as an unwanted obligation to provide peer support to other members on the platform. Ruby stated, "just that fear if someone messages me, I have a responsibility to talk to them, to support them, to basically just be their secondary psychologist."

Ruby describes experiencing a lack of control over the peer support function of the platform, "I don't always like it when people open up to me when I don't ask for it." As well as anticipatory fear that denying a request for peer support from another member would result in a negative interaction, "I was scared that they'd like start cyber-stalking me or something."

An "Upbeat" Environment

As mentioned earlier, a positive psychology framework underpinned the Horyzons RCT. This framework informed how clinicians moderated the platform. For example, using a strengths-based reframing approach to young people's posts. Participants reported a spectrum of emotional responses to the environment that this clinical approach created on the Horyzons social network.

On one end of the spectrum, Celeste described feeling frustrated and patronized by this approach and described the social network as "mind-numbingly positive." She argued that this type of environment impedes the process of sharing the "bad stuff" that young people living with mental health problems can experience. To discuss difficult topics, which Celeste identified as an important process of mental health recovery, members would need to go against the grain of the established "upbeat" environment.

Celeste described feeling alienated by this approach and went so far as to describe a phenomenon akin to an uncanny valley experience. That is to say, the platform looked similar to other social networks, but that the environment did not feel like any other social spaces she was accustomed to. This irregularity led to a feeling of unease:

> *It was just odd, and it didn't feel like it could be genuine because it's not my experience of how people interact with each other in the everyday world, you know? [Celeste]*

In contrast to Celeste's experience, Audrey identified the "positive" environment on Horyzons as an important element of her high usage level. She did not want to spend time at a place where "the people are all negative."

Olivia's experience was similar to Celeste's in that she experienced the "upbeat" nature of the platform as different from that of commercial social network sites (SNS). However, she also identified that although it was positive for people with mental health difficulties to connect with others in certain mental health pockets of social media, such as "Instagram," certain relationships and dynamics that are borne from these unregulated digital spaces can have negative impacts on the young people who frequent them. For example:

> *You know, go on Instagram-... type in eating disorder, you got a whole world there. You know? You can type in depression; you've got a whole world of people struggling. And it's a good and a bad thing. So, it's good as in they can connect with other people. But, it's bad as in you get triggered constantly. Rather than that, Horyzons was, "Yeah, we're all struggling... but this is a place for improvement."* [Olivia]

For Eugene, the experience of being in an environment with a psychological lens tarnished his experience of the social network. He said:

> *…that's what my brain tells me, it's just like, super wanky. Like, I think psychology and… that sort of stuff is really wanky.* [Eugene]

He did, however, describe experiencing something of a psychological shift when the platform was able to support him during a time when he was experiencing "major issues." As a result, he identified that Horyzons "may have a point" and may not be "so wanky." A shift, such as a change in mind or need, was a phenomenon reported by other participants in reference to a range of issues on the platform.

Experiences That Interrupt Being in the Horyzons Space

Participants identified a lack of motivation to participate in the social network as well as a range of experiences that interrupted their ability to *be in* the Horyzons social space in an immersed or *relaxed* way. These interruptions gave way to a self-conscious or difficult moment, or a series of moments, which created tension between the young person and their ability to use the platform. Participants identified that these incidents could occur before, during, or after single sessions and throughout the overall intervention experience itself. Some participants identified multiple interruptions, or ruptures, throughout their Horyzons experience.

Absence of Motivation

A number of participants described an absence of motivation to participate in the social network, either before any initial engagement with the platform or at some point during the intervention period. This was due to the personal assessment that the social network was not relevant to them and their needs.

For instance, Tom identified that from the beginning of his intervention period, he intended to engage solely with the psychosocial content of the platform and expressed an active disinterest in the social network. He described experiencing ample levels of social media in his daily life and was not interested in getting "bogged down" in that aspect of the platform.

Jacob identified that although Horyzons was valuable during the first half of his intervention period, he went on to experience a "tipping point" in which he felt he had moved beyond what the platform was able to offer him. He explained, "that's not the stage of life that I'm at anymore."

Experiences That Interrupted Being in the Horyzons Space

A number of young people identified paranoia, social anxiety, and internalized stigma as experiences that interrupted them from *being in* the Horyzons space. These types of interruptions generally occurred *during* the young person's engagement with the platform. However, while they were attempting to engage, an emotional or psychological barrier arose that impeded that engagement. This ultimately took them out of the immersed or *relaxed* experience of *being in* Horyzons.

Paranoia in relation to Horyzons itself and paranoia in relation to social media use more broadly was a phenomenon described by 2 participants. Emily described experiencing paranoia in relation to social media use more generally, whereas Olivia expressed experiencing disruptive paranoia in regard to the Horyzons platform directly. For instance, she said, "I just get really paranoid about like who's behind this and stuff like that…like what are the motives behind this, and stuff like that." This experience of paranoia interrupted Olivia's capacity to share candid information and engage directly with other members on the platform. The act of even logging in to the site was difficult, as she explained, "They're watching me too closely. They know too much."

Participants also described experiencing social anxiety related to the complex psychological process of posting in the social network. This anxiety is generally related to how others might perceive them and prevented many young people from posting on the platform. For example, Ruby expressed fear of overwhelming others with the content of her posts and wrote and deleted "5 to 10" messages that she ultimately never shared with the group. Babak felt that his thoughts may not be important enough to share. A number of participants expressed uncertainty about Horyzon's general social protocol and speculated that they were concerned about breaking "weird, unwritten rules" that they were not aware of. Multiple participants described feeling nervous that if they were to post, then other members may not respond, or may not respond in a desired way. For instance:

> *It would just sit there, and no one would respond to it...and then I'd be like "ah ok" I'm just kind of in an echo chamber [laughs]...so embarrassing … [interviewer: how come?] cos like no one would really care. It would just kind of sit there and look weird. It's like having a spotlight on yourself and everyone just staring at you and it's completely silent.* [Ruby]

This idea of *sharing anxiety*—that is, the phenomenon of experiencing anxiety at the prospect of posting a message to the social network—interrupted young people's ability to act spontaneously in the social space. They reported feeling frozen in moments of rumination about possible negative consequences of posting that could go on for a short time, such as minutes, or could impede them from posting on the platform throughout their whole Horyzons experience, despite identifying that there was content they would like to share with other members. Interestingly, however, all but one participant who reported experiencing sharing anxiety about posting but went on to post did not go on to report any negative consequences of posting. On the contrary, Audrey reported that although replies to her posts in the Horyzons space were slower than she was accustom to on other social networks, she described feeling "patient" while waiting a "day or two" for a reply and felt "excited" when she received a response. Furthermore, she felt "happy" to receive fewer comments on Horyzons than compared with other social media because she considered the replies received on Horyzons to be genuine and "not just for attention."

However, one particular participant expressed that he continued to think about a post he shared on the network many months after he originally posted it. After initially sharing the post, Jacob became concerned that a moderator had potentially "hidden" it from the public feed because of the possibility that it was inappropriate:

> *I don't know if this is true or not, but I don't know if a moderator actually hid the post for a bit… I'm not sure… I didn't write again, because maybe then I started second thinking the post, maybe it wasn't appropriate.* [Jacob]

This confusion transformed into anxious rumination that interrupted Jacob's ability to post again during his intervention period. This may also be related to his decision that he had reached a "tipping point" and no longer needed the site.

Eugene experienced engaging with the Horyzons platform as incongruous with his sense of self. He considered himself older, more independent, and more advanced in his career than the other members of the platform and as a result, he felt an internalized pressure that he "shouldn't need this." Eugene's social struggle to engage with the platform was also closely tied to the judgments he was concerned his colleagues would make of him. He was concerned that they would not "trust" him professionally if they were aware of his mental health history. Eugene appeared to internalize this stigma and his ability to access support, even when identified as needed, was interrupted.

Discussion

Principal Findings

To the best of our knowledge, this is the first study to qualitatively explore young people's experiences of using a long-term social media–based intervention in FEP recovery. In relation to social connection, we found that experiences could be grouped into 4 superordinate themes, as detailed above. These themes have the potential to inform the development and implementation of social media–based interventions. We found that (1) peer support on a therapeutic social network could be beneficial and engaging for some, and burdensome for others; (2) the number of log-ins did not neatly reflect a young person's experience of the intervention, (3) unclear social protocol created an uncomfortable social environment in the digital space, and (4) social anxiety, paranoia, internalized stigma, and the perception of limited autonomy could interrupt a young person's ability to engage with the platform.

In line with previous findings, results from this study indicated that many participants lacked a confidant in their everyday life, a friend with whom they could confide in regarding their mental health experiences [1]. We found that the therapeutic social network offered participants a much-needed opportunity to feel heard, understood, and supported by their peers. For some, this was the first time they had felt connected to others in this way. These findings support previous research that has identified the value of peer support practice in mental health [24,25]. The supportive dynamic between peers on Horyzons aided in the creation of an embodied space in which young people experienced an ongoing sense of belonging. This study found that young people place great value on the advice and support offered by their peers, at times above that of a trained mental health professional. Some advised that they were more likely to activate behaviors suggested by their peers than those of a clinician. This example emphasizes the powerful role that peer support can, and does, play in shaping young people's mental health recovery. It also highlights the instrumental way peer support can create a digital environment that is (1) an engaging pathway to mental health treatment and to the web-based intervention itself and (2) a potentially therapeutic dynamic in itself.

In addition, this research also found that it was possible for young people to experience anxiety, to experience burden, and to perform avoidant behaviors at the perceived expectation to provide peer support to others on the web. This example illustrates the varied needs among young people (ie, what some find helpful, others may find burdensome), as well as the need to consider the autonomy of the user when designing and implementing interventions. This finding highlights the significance of recognizing young people as individuals with individual needs. Fortunately, the mode of digital intervention is well equipped to address this implication by providing customizable treatment options that are applicable to very large groups of diverse individuals.

We found that young people have varying levels of interest with regard to social connection on the web. Therefore, designing customizable interventions that allow young people to identify the importance of this function in regard to their own mental health treatment journey is recommended. For example, personalized onboarding options empower young people to determine the relevance of digital intervention functions, such as the level of peer support they wish to engage with. This places more power in the hands of the user and, in accordance with self-determination theory [26], has the potential to strengthen their engagement with the intervention overall. Furthermore, personalization should be temporally flexible, as this study also found that young people's mental health needs were dynamic in nature and could change over the course of a long-term intervention.

The knowledge that young people had internal experiences that interrupted their ability to be *in* the Horyzons space was a novel finding that has not been previously explored. By asking young people about their experiences of using the platform, we were able to elicit internal barriers to use. Social anxiety, level of paranoia, internalized stigma, and lack of perceived autonomy in providing peer support actively interrupted young people's ability to remain in the Horyzons social space. In line with previous findings that social anxiety is a significant health issue for young people experiencing FEP, this study found that many participants described experiencing social anxiety when using the Horyzons platform [11]. We suggest that anticipating and accounting for these experiences in the design and implementation phase of a digital platform could potentially enhance a young person's ability to use social media–based interventions. This study found that experiences of social anxiety in the digital therapeutic space may differ from that of offline social anxiety, or even anxiety in commercial social media spaces, such as Instagram and Twitter. For example, fear of overwhelming peers with the content of a mental health post may be unique to the therapeutic social network space. As such, young people may experience a new phenomenon of *therapeutic social media anxiety*. As such, anticipating and attempting to circumvent these experiences may increase young people's level of engagement and/or benefit from social media–based interventions. On the basis of these findings, we suggest 3 tangible approaches to addressing digital social anxiety in the therapeutic social network space: (1) As discussed above regarding the personalization of web-based peer support, offer young people the power to customize their level of engagement with others. (2) Pre-empt and creatively account for prevalent digital social anxieties in the design phase of an intervention. For instance, work to normalize the experience of posting anxiety by signposting this as a common fear through comics and quotes from previous users, this may work to normalize and reduce hesitations experienced by the user. (3) Future research should focus on the design of a tool that measures these types of engagement interruptions.

In line with previous findings [27], the results from this study indicate that the level of usage, in this case, the number of log-ins, does not neatly align with a young person's level of expressed connection with the platform. For instance, young people categorized as low or very low users still contributed to themes that characterized Horyzons as a supportive, connected, and embodied experience. The more limited use of the platform appeared to be driven less by indifference or dislike for the intervention itself and more by young people's complex and dynamic social and psychological experiences that interrupted their use of the platform. For example, social anxiety, internalized stigma, level of paranoia, and previous experiences providing peer support were some of the overarching themes that interrupted usage and were related to lower log-ins on the platform. Most young people had strong positive experiences of social connection on Horyzons. Importantly, however, the majority also experienced barriers to engaging with the platform. That is to say, the helpfulness of Horyzons was considered high, but so were the barriers.

This study found that designing a therapeutic social media–based intervention, such as Horyzons, in a similar way to existing commercial SNS archetypes, such as Facebook or Instagram, could create a sense of unease or discomfort for participants due to conflicting social protocols. For example, in many ways, Horyzons felt similar to commercial social media, but there were also distinct differences felt by participants with regard to the different social norms of the platform. For instance, Horyzons encouraged supportive engagement between members. By comparison, a similar act of responding to a personal post on a stranger's page on Facebook could be considered a social transgression. This highlights a nuanced misalignment between therapeutic and commercial social media protocols. In other words, Horyzons looked and functioned similarly to Facebook, which for participants evoked a Facebook-like behavioral framework. However, the social protocol encouraged by Horyzons did not exactly reflect Facebook's social protocol. As a result, young people reported feeling concerned or anxious about performing suggested tasks on Horyzons for fear of behaving inappropriately socially. This finding is in line with previously identified concerns [28] that digital mental health services are at risk of engaging in *psychological skeuomorphs* or the danger of designing derivative models of care and in doing so miss the opportunities that come with reimagining virtual models of care. In some ways, that Horyzons felt similar to commercial SNS may have led to higher user engagement because it is popular and compelling to young people. However, it may have also led to young people experiencing social anxiety or feeling socially exposed due to the nature of the content (ie, sharing mental health experiences in an arena that is not typically experienced in this way). Reimagining how social media–based interventions could still be compelling for young people due to their popularity but feel safer or more socially comfortable to participate in these spaces could be a possible way to reduce internal barriers to engagement. Thus, further research on both features and measures that can enhance engagement or reduce interruptions to a young person's experience of social media–based interventions over the long term would be of interest.

Strengths and Limitations

Recruiting a large sample for the original Horyzons RCT contributed to wide variation in platform usage. Thus, for this study, we were able to purposefully sample a diverse representation of young people from a variety of usage groups with the aim of exploring different user experiences that may have been associated with the level of usage. Although we found that low usage did not result from a blanket disinterest in the platform, this variety in sampling allowed for a better insight into the internal experiences that both drove and hindered usage on the platform from a variety of users. Additionally, this is the first study to explore an 18-month intervention period and as such afforded us the opportunity to explore adherence, experiences, and internal barriers to use over time, which had not yet been previously explored for this length of duration. With regard to limitations, recall bias could have impacted the participant's ability to discuss their experience with the intervention. It could be beneficial to interview participants closer to the completion of their intervention time or in accordance with user design theory, which may suggest interviewing in parallel with the intervention.

Conclusions

We found that Horyzon's therapeutic social network fostered connection and understanding between young people. It also aided in the creation of an embodied experience that afforded young people with FEP a sense of self-recognition and belonging over the longer-term. However, although we found that most young people had strong positive experiences of social connection on Horyzons, we also found that they experienced significant barriers that could substantively interrupt their ability to use the platform. We found that social anxiety, paranoia, internalized stigma, lack of autonomy, and social protocol confusion interfered with young people's usage of the platform. From a design perspective, digital interventions are flexible and thus equipped to begin addressing these implications by providing customizable and personalized treatment options that account for varying levels of social connection and psychological need that could otherwise interrupt young people's usage of social media–based interventions.

Acknowledgments

The authors would like to thank all of the young people who participated in this study and shared their time, experiences, and thoughts with us. LV was supported by the Mental Illness Research Fund from the State Government of Victoria. CM was supported by an Australian Government Research Training Program Scholarship. SO was supported by a rebound National Health and Medical Research Council (NHMRC) project grant. MA-J was supported by an NHMRC investigator grant APP1177235. SB was supported by a McCusker Charitable Foundation fellowship.

Authors' Contributions

LV conducted participant interviews and data analysis. The analysis was supervised by SB. The study was cosupervised by MA and SB. All authors have reviewed the final paper.

Abstract

Background: Early excess and inadequate gestational weight gain (GWG) have been associated with negative outcomes for mother and child. The use of digital media to deliver pregnancy lifestyle interventions is increasing, but there is little data on participant engagement. The Pregnancy Lifestyle Activity and Nutrition (PLAN) intervention pilot study was an electronic health and dietetic-delivered intervention program promoting healthy GWG in early pregnancy.

Objective: This study aims to explore the interactions of participants with the program and to assess its acceptability.

Methods: This study uses both quantitative and qualitative methods using data from parent randomized controlled trial (ACTRN12617000725369). Quantitative data from 22 participants in the intervention arm who completed the study provided measures of the interactions participants had with the digital components of the program and with dietetic consultations. A descriptive qualitative analysis employed semistructured interviews with 9 participants to elicit views on the acceptability of the intervention and its components.

Results: The electronic delivery of information and recording of weight from 8 to 20 weeks of gestation were universally accepted. Component (face-to-face dietitian, weight tracker, website information delivery, and SMS goal prompting) acceptability and engagement differed between individuals. A total of 4 key themes emerged from the qualitative analysis: supporting lifestyle change, component acceptability and value, delivery platforms, and engagement barriers.

Conclusions: The PLAN intervention and its delivery via a blend of personal dietetic consultations and digital program delivery was found to be acceptable and valuable to pregnant women. Individuals responded differently to various components, emphasizing the importance of including women in the development of lifestyle interventions and allowing participants to choose and tailor programs. Larger randomized controlled trials using these insights in a broader section of the community are needed to inform the iterative development of practical, time-efficient, and cost-effective ways of supporting optimal GWG with the potential to optimize outcomes for pregnant women and their child.

Introduction

Background

Gestational weight gain (GWG) has emerged as an important health variable contributing to the health of both mother and child. Weight gained outside the recommended Institute of Medicine guidelines [1] across all prepregnancy BMIs is associated with negative short- and long-term health outcomes [2,3]. For example, excess GWG increases the risk of antenatal hypertensive disorders, gestational diabetes, and atypical delivery outcomes [2,4-8], along with maternal, infant, and later life overweight or obesity [4,6]. Over the last two decades, women have increasingly failed to meet GWG recommendations, with more recently an estimated 30% to 65% of women in developed countries, across all prepregnancy BMI categories, exceeding the recommended guidelines for GWG [9,10]. These figures highlight the need for better education directed toward prevention.

Research interest in GWG has seen an increasing number of studies promoting healthy GWG through diet only, exercise only, and combined diet and exercise interventions, compared with standard care [11]. A limitation of many of these interventions is the reliance on support from research staff or health professionals, restricting the reach and scalability to larger sections of the community [12]. More recently, a small number of pilot studies have investigated the digital delivery of GWG interventions using internet and mobile phones (electronic health [eHealth] and mobile health [mHealth]), and the results from these studies show promise [13-15]. Digital delivery potentially offers an opportunity to augment health professional care and provide trusted source information across demographic groups through a low-cost, easy access method [16]. Although a 2017 meta-analysis of the effectiveness of eHealth technologies on GWG found a nonsignificant pooled result in only six studies, it emphasized that the engagement of participants was critical to the success of digitally delivered interventions [13].

Understanding how participants engage and the experiences they have with interventions is crucial to assist in their evaluation and to inform improvement [17,18]. According to O’Brien et al [19], *engagement* may be defined as “the ability to engage and sustain engagement in digital environments.” A number of papers have emphasized the importance of understanding and incorporating the views and engagement metrics of stakeholders into the evaluation of digital interventions [17,18]. For example, in a review of mobile technology in psychosocial and health behavior treatments by Heron and Smyth [17], the authors suggest that interventions need to be more sensitive to individual characteristics and needs of stakeholders. They argued that incorporating end-user feedback into evaluation will facilitate the feasibility and acceptability of interventions. There is a scarcity of literature evaluating participants' engagement with pregnancy and GWG interventions.

The Pregnancy Lifestyle Activity and Nutrition (PLAN) randomized controlled trial aimed to promote healthy GWG in early pregnancy via an eHealth and dietetic-delivered intervention [20]. Women were recruited between 8 and 11 weeks of gestation and randomized to the intervention or routine antenatal care. The 12-week intervention involved one dietetic one-on-one consultation, examining diet and physical activity, and a web-based and SMS program providing diet, physical activity, and well-being advice. The digital component of the program included tracking of GWG, lifestyle goal setting and feedback and diet, physical activity, and mental health information delivered weekly. Participants were then followed up to 3 months postpartum.

A total of 57 women, with a mean age of 33.3 (SD 2) years and a mean gestational age of 9.2 (SD 1.2) weeks, were recruited. The mean BMIs of women in the control and intervention groups at enrollment were 25.3 (SD 5.3) kg/m^2 and 26.0 (SD 1.3) kg/m^2, respectively. A total of 43/57 (75%) participants (control group: 19 and intervention group: 24) completed the study. Of the 24 participants in the intervention arm, 22 completed the 12-week intervention program. Although the pilot-sized numbers precluded the power to detect differences in GWG, as well as pregnancy and infant outcomes, infants weighed less in the intervention group (6193 g versus 5405 g; P=.01) at 3 months. Furthermore, participants in the intervention arm demonstrated a mean decrease in total fat consumption, increase in fruit serves per day, and score ranking perceived importance of dietary change, compared with participants in the control group. Although limited in number, these pilot results and learnings contribute to the literature on dietetic and digitally delivered antenatal interventions.

Objective

Consistent with the postevaluation phase of the development and evaluation processes for digitally delivered interventions [18], this study aimed to explore women’s engagement and perspectives on the PLAN eHealth and dietetic intervention [20].

Methods

This mixed methods study used quantitative assessment for the interaction with the PLAN intervention and qualitative assessment to investigate women’s engagement with and acceptance of the PLAN intervention.

The mHealth Development and Evaluation framework [18] and the Process-Evaluation Plan for Assessing Health Programme Implementation [21] informed the development of this study. The Consolidated Reporting Criteria for Qualitative Studies [22] informed the reporting of this study (Multimedia Appendix 1).

Ethics approval was obtained from the human research ethics committees of Joondalup Health Campus (October 17, 2015; ethics number 1525) and St John of God Health Care (May 26, 2016; ethics number 873). The trial was registered with the Australian New Zealand Clinical Trials Registry (ACTRN12617000725369).

Quantitative Assessment of Intervention Engagement

Intervention interaction was measured post hoc by program-generated data. The data were extracted from participants in the intervention arm who participated in the 12-week intervention (n=22).

Data Collection

The characteristics of the participants, including sociodemographic and GWG, were collected from the program data. Indicators of interaction were extracted from the program data files and included retention (numbers completing the trial), dose delivered (contacts delivered), and intervention engagement (contact with the program elements).

The contacts delivered included dietetic consultation, emails with links to lifestyle information and weight tracking prompting, and SMS for goal prompting. Contacts with the program elements included attendance at the dietetic consultation, accessing the web-based app, input into weight tracking, and replies to the goal accomplishments. Data on the frequency and depth of website access were not available.

Data Analysis

Quantitative interaction and participants' characteristics were analyzed with categorical variables reported as numbers and percentages and continuous variables reported as means and SDs.

Qualitative Assessment of Intervention Engagement and Acceptance

A qualitative descriptive research methodology [23,24] using semistructured interviews was employed to obtain in-depth data from consenting women.

Study Participants

Women who had completed the active 12-week phase of the PLAN intervention (n=22) were invited to participate in the qualitative review by the PLAN research coordinator.

Data Collection

Telephone interviews were conducted by an independent female interviewer trained in qualitative research methods and not involved in the PLAN study (JCW, a research fellow). The participants were informed that JCW was an independent researcher from a different university and had experience in this qualitative area of research. The content of the standard interview guide (Multimedia Appendix 2) was developed by R-CH. The semistructured and structured questions aimed to elicit women's views on the PLAN intervention, its components, and potential improvements. In addition, women were asked to rate the experience of the PLAN intervention on helping follow a healthier lifestyle during pregnancy (1=not good and 10=very good). The interviews were digitally recorded with the consent of the participants. Field notes were collected by JCW during and after the telephone interviews.

Data Analysis

Data immersion, coding, category creation, and thematic analysis were used to find repeated patterns of meaning across datasets [25,26]. The researchers (JCW and R-CH) used an inductive approach using raw data to derive themes through interpretations made from the raw data [27].

Results

Participants

The sociodemographic and GWG characteristics of the women in the total PLAN study are reported elsewhere [20]. The sociodemographic and GWG characteristics of the 22 participants in this substudy are provided in Table 1. The mean age of participants was 33.0 (SD 4.1) years, with a mean gestational age of 9.0 (SD 1.2) weeks at recruitment. The mean self-reported prepregnancy BMI was 25.4 (SD 4.7) kg/m^2, and one-fifth of the participants (21%) gained weight within the GWG guidelines. The majority of the participants (91%) had private antenatal care, and nearly two-thirds (64%) of those reported that their education held postsecondary qualifications.

Table 1. Characteristics of participants in the active Pregnancy Lifestyle Activity and Nutrition intervention arm and qualitative interviews.

Participant characteristic	Participants in the intervention arm who completed the study (n=22)	Qualitative interviews (n=9)
Maternal age (years), mean (SD)	33.0 (4.1)	33.0 (3.2)
Enrollment gestational age (weeks), mean (SD)	9.0 (1.2)	9.0 (1.3)
Reported prepregnancy BMI (kg/m^2), mean (SD)	25.4 (4.7)	26.7 (4.3)
Measured enrollment BMI (kg/m^2), mean (SD)	26.2 (4.9)	28.3 (4.5)
Enrollment BMI category (kg/m^2), n (%)		
Underweight (<18.5)	0 (0)	0 (0)
Normal weight (18.5-24.9)	10 (45)	3 (33)
Overweight (25.0-29.9)	8 (36)	3 (33)
Obese (≥30.0)	4 (18)	3 (33)
Ethnicity, n (%)		
White	22 (100)	9 (100)
Private health care, n (%)	20 (91)	9 (100)

Within	5 (21)	2 (22)
Exceed	12 (54)	6 (67)

[a] Intervention period.

Quantitative Assessment of Intervention Interactions: Intervention Interaction Data

All women accessed the website during the course of the program. Nearly all women (21/22, 96%) attended the dietetic visit and completed the accelerometer tracking (Table 2). Over the 12-week active intervention period, 31 emails were sent to each participant to notify them of a new release of nutrition, physical activity, and GWG information related to their pregnancy stage. In addition, over this period, a mean of 4.46 (SD 6.24) emails were sent to remind participants to input their weight on the website if this had not been completed. The total number of inputs for weight totaled 23.17 (SD 24.21), ranging from 1 to 92. One-fourth of participants (n=5/22, 23%) received emails notifying them of excessive weight gain (3 participants received 1 notification, 1 participant received 2 notifications, and 1 participant received 3 notifications).

Table 2. Intervention interaction data (n=22).

Components of the Intervention	Values	Range
Program component delivery, n (%)		
Dietetic visit with personalized nutrition and physical activity assessment and education	21 (96)	N/A[a]
Accelerometer wear and feedback	21 (96)	N/A
Website access[b]	22 (100)	N/A
Email engagement[c], mean (SD)		
Emails sent regarding new material on the web	31 (0)	31-31
Number of emails received reminding to input weight	4.46 (6.24)	0-23
Number of emails received warning of excess gestational weight gain	0.33 (0.75)	0-3
SMS messages sent prompting SMART[d] goal	8.5 (1.5)[e]	3-9
Reply to SMS message prompting SMART goal setting	2.96 (2.65)	0-8
Weight input: active self-monitoring	N/A	N/A
Number of weight inputs by participants	23.17 (24.21)	1-92

[a] Not applicable.

[b] Website access data only. Frequency of access not available.

[c] Value reflects the mean number of participants (SD).

[d] SMART: specific, measurable, attainable, realistic, and time-based.

[e] A total of 19 participants received all 9 reminders over the course of the active intervention, 3 opted out at weeks 4, 6, and 9, and hence, they received 3, 5, and 8 SMS messages, respectively.

Women were asked to set a specific, measurable, attainable, realistic, and time-based (SMART) goal [28] to assist them with lifestyle behavior change. SMS messages were sent prompting engagement with the SMART goals women set at the program commencement, with an invitation to reply via return SMS. Overall, 3 women opted out of receiving these messages partway through the intervention, receiving between 3 and 8 SMS messages prompting SMART goal engagement. The remaining participants received the full complement of 9 SMS messages prompting SMART goal engagement over the active 12-week period. Over the 12-week period, women replied on average 2.96 (SD 2.65, range 0-8) times to these messages, with 77% (n=17/22) of participants responding at least once with a range of 0 to 8. The SMS replies from the participants indicating if the SMART goal had been attained was positive on 86%, negative on 10%, and neutral on 4% of occasions.

Qualitative Assessment of the Intervention: Study Participants' Characteristics

In total, 11 women agreed to participate in the qualitative study (n=11/22, 50%), with 2 participants withdrawing before the interview. Of the 11 women, 9 were consented and interviewed, with 4 women having completed the total study, including the active and follow-up phases (range 38 weeks' gestation to 16 weeks postpartum). Of these 5 completed the active phase (range 22-28 weeks' gestation) and were yet to complete their pregnancy.

The mean age of women was 33.0 (SD 3.2) years, and enrollment BMI was 28.3 (SD 4.5) kg/m^2. One-third of women were of healthy weight, one-third were overweight, and one-third were obese. All women were identified as white, and 43% of the women had completed tertiary education. The interview length ranged from 22 to 36 min.

Emergent Themes

All participants spoke about their experiences with the PLAN intervention and the acceptability and usefulness of the intervention and its components and offered suggestions for improvement to support them in attaining a healthy GWG and pregnancy lifestyle. Saturation of themes appeared after 7 participants. In all, 4 key areas of focus for the women included the effectiveness of the PLAN intervention to encourage lifestyle change, individual component acceptability, delivery platforms, and barriers to engagement with the PLAN intervention.

Pregnancy Lifestyle Activity and Nutrition Intervention Supporting Lifestyle Change

In general, women reported a positive experience with the PLAN intervention. They were asked to rate their experience of the PLAN intervention with helping follow a healthier lifestyle during pregnancy with *one* (the lowest rating) and *ten* (the highest rating). A total of 2 participants rated the program a *ten*, 3 rated it an *eight*, 3 rated it a *seven*, and 1 rated it a *five*. A participant, who rated the program an *8*, qualified her answer by rating the active part of the program an *8* and by rating the nonactive part after 20 weeks a *two*.

When asked if they would recommend the program to a friend, all but 1 woman answered *yes* and 1 answered *maybe*. Again, 1 participant qualified the answer by saying *yes* if the program was fully active and *no* if it only involved data collection.

The most valuable aspect of PLAN cited by many women was the frequent contact and the level of support and encouragement provided. Overall, women conveyed valuing and liking “the extra support in the background”:

> *It was nice to feel supported and feel like you are on track. I really appreciated the ladies that worked with the study.* [Participant 9]
>
> *I felt cared for and nurtured through this [pregnancy] period.* [Participant 7]

Different Program Components Judged Acceptable and Valuable

Participants discussed the program components as mutually exclusive elements with different participants citing components that they found of value.

Dietitian Consultation

The dietetic consultation, which included assessment of food records, was highly valued by the majority of participants. A total of 4 participants expressed positive *surprise* with the extent of information and assistance that they received, particularly around the food groups that they were missing in their diets.

Another 2 participants suffered *morning sickness* and found the dietitian consultation ill-timed for their medical state. They reported finding it difficult to receive information that encouraged exercise and eating well and would have welcomed a later appointment or advice related to *morning sickness*. They expressed a desire to follow up on the recommended dietary changes or have a reassessment once their *morning sickness* had dissipated.

When asked, all women conveyed that they would find it helpful to have another consultation at around 16 to 20 weeks of gestation:

> *It would be great to get it again at 16-20 weeks. It is good to get the feedback.* [Participant 8]

Weight Tracker

Most women reported using the weight tracker at least once per week. Many women found value in prompting to weigh, recording their weight, and seeing a visual representation of the weight trajectory. A total of 4 women nominated the weight tracker as one of the most valuable aspects because of its help in “seeing how it progressed” and “reinforced the importance of eating well and being active”:

> *I looked forward to doing it. It was good to be prompted.* [Participant 7]
>
> *It was reassuring as a woman.* [Participant 9]

All but 2 women stated that they received reminders to weigh (once per week); 4 women described the frequency of weight input and reminder as acceptable, 1 as too infrequent, and 2 as too frequent.

In all, 3 women did not recall receiving feedback or comments from the weight tracker. One woman reported finding positive feedback but further commented that her weight stayed within the recommended quadrant. Moreover, 3 other women conveyed that they were not happy with the negative feedback, which they found “unhelpful.” They desired only constructive feedback and more of a sense of what to alter:

> *I would have liked more mindful about your lifestyle feedback.* [Participant 7]

Emails, Websites, and Health Information

All but 2 women reported receiving regular notifications for the release of nutrition, physical activity, and GWG information on the website/web-based app related to their pregnancy stage.

A total of 4 women reported reading all the information, 2 reading more than two-thirds, and 3 had not read any information. Many of the women who read the material found that it provided positive information for a lifestyle change and reinforced key health messages. One woman who read the information found the information did not meet her needs by being “too light”:

> *I liked the simple terms, not too complex. It made you think about your lifestyle.* [Participant 6]
>
> *[It] reinforced the importance of eating well and being active.* [Participant 1]

Although many participants found the quantity of information appropriate, 1 woman found the quantity of information overwhelming. This was partly because of not being able to exercise for medical reasons and found the information that did not relate to her difficulty:

> *It got a bit overwhelming. I felt bad that I couldn’t read and do things.* [Participant 8]

Most of the women who read the information indicated that they liked the information being “fed slowly.” The quantity of nutrition and exercise information each release was deemed “about right.”

All women expressed a desire for the information to continue beyond 20 weeks until pregnancy completion with information tailored to the issues relevant to pregnancy at that stage (eg, reflux). There were 2 women that stated preferences for the information to be provided at the start of the intervention, allowing them to access the correct information when required.

Participants suggested a range of opportunities for improvements to the information, with the most frequently suggested being more practical information about healthy eating, including meal plans and recipes. Additional structured guidance about physical activity was desired by 3 women with more information about the later stages of pregnancy. A few women desired more well-being information:

> *More information on well-being I think. I was neglectful of myself.* [Participant 7]

Moreover, 2 women suggested a more up-to-date “look and feel” and cited “Mind the Bump” and “Huggies” websites as having looks and functionality that they liked.

Goal Setting

Setting SMART goals was described as being “helpful” by some participants. The goals stopped them from becoming “complacent” and were good “external motivation.” The importance of the timing of text messages was mentioned by a few:

> *It was good to have a reminder.* [Participant 8]

> *The texts were frustrating when not in that space.* [Participant 4]

Another woman reported that she set a physical activity goal that she had already met for the sake of the program. She conveyed that she was not a "big goal setter."

Short-term goals that changed regularly were suggested by 4 women, and 2 women would find continuation of the goal setting beyond the active 12-week program.

Delivery Platform as a Positive and Familiar Source of Information and Contact

The electronic delivery of information and recording of weight was seen as positive, with women being familiar with this mode of delivery:

> *We are used to those sort of tools with Fitness Pals and others.* [Participant 9]

When prompted, women suggested multiple delivery platforms to meet different needs for different times:

> *Everyone loves an app now.* [Participant 9]
>
> *Texts with links to the information would be good as well as an app and a website.* [Participant 7]

Some women viewed that the addition of a private Facebook page or community forum would be positive, with its ability to allow interaction between women of different pregnancy stages:

> *It would be great to build rapport with other ladies going through the pregnancy journey.* [Participant 7]

Others were concerned about the intrusiveness of Facebook and not wanting to engage in a community where there was a burden of stress:

> *I have avoided it [Facebook] because of all the worriers on there. It depends on how it was structured.* [Participant 9]

Barriers to Engaging in a Pregnancy Lifestyle Program

Barriers to engaging with the PLAN program were mentioned by all participants in the context of barriers to program engagement and barriers to changing lifestyles.

Program-related difficulties included "glitches," "freezing," or "incorrect plotting" being reported by many participants. One participant recounted receiving a message telling her that she had gained excess weight when it did not plot that way on the graph. Another described weight being plotted on the graph in the incorrect section. Several women reported that the information was not accessible on mobile devices, which limited information access at convenient times.

Many women reported surprise in the cessation of the program, including the ability to track weight, beyond the active stage of the PLAN intervention at 20 weeks:

> *I was not mentally prepared for it [the weight tracker and program] to stop.* [Participant 6]

All but 1 woman wanted to be able to track weight and have the program continue till pregnancy completion to serve as a reminder to keep them on track with regard to lifestyle:

> *I would have liked to see it all the way through to after the baby was here. The numbers don't lie.* [Participant 7]

Women frequently cited barriers to maintaining a healthy lifestyle and following the guidelines set by the PLAN intervention. Morning sickness was a key reason given by 4 women, reflecting the early gestation commencement of the PLAN intervention. Work, family, and time constraints were the next most commonly discussed constraints:

> *I didn't use it all cause of working 52 hours a week.* [Participant 3]

Back pain and other pregnancy-related physical ailments were also cited, particularly as barriers to physical activity:

> *I had more pain in my second pregnancy.* [Participant 9]

A common barrier and concern expressed was the perceived inability to access ”pregnancy-safe” food when eating out. Therefore, some women concluded that it felt easier and safer to purchase unhealthy food that was more likely to be food safe and listeria free.

Discussion

This paper investigated both the quantitative and qualitative engagement of women in the PLAN intervention. The data contribute to the literature on the engagement and acceptability of digitally supported interventions in pregnancy. Of the women who completed the program, the majority accessed the dietetic consultation and the website. Most women read the health information provided and interacted and tracked GWG, whereas fewer women interacted with or replied to the SMART goal–monitoring SMS messages. A total of 4 key areas of focus were elucidated from the qualitative assessment, including the effectiveness of the PLAN intervention to encourage lifestyle change, individual component acceptability, delivery platform acceptability, and barriers to engagement with the PLAN intervention. Overall acceptance of the program was high, with the social support being offered identified as key. The components (dietitian consultation, weight tracker, health information, and goal setting) were identified as mutually exclusive elements of the intervention with variable acceptance. Although there was a consensus that the electronic delivery of information and recording of weight was positive and universally accepted, the cited barriers to adherence varied among the women. Suggestions for improvement of trial design, including an extension of the active program throughout pregnancy, will be incorporated into future program iterations.

The perceived support provided by the intervention program was a strong theme elicited from the women. This supports the findings of others who have found that health interventions, including digital support, can engender a continued sense of support and community [29-31]. Indeed, social support is an important technique [32] in lifestyle pregnancy interventions that have successfully altered GWG [15,21,33]. Digitally delivered interventions provide the opportunity for more frequent interactions delivered beyond the traditionally delivered environments [31].

This intervention mapped many of the key behavioral change variables required for behavior change [34], including providing information on the behavior-health link, goal setting, review of goals, and self-monitoring. The inclusion of behavior change techniques may be most effective when combined with dietary advice in GWG interventions [35]. Digital technologies capitalize on the ability to extend the reach of intervention delivery beyond a health professional appointment and expand the range of behavior change techniques that can be included [36]. Evidence for blended health professional and digitally delivered interventions is still limited to a small number of studies, and further research is needed to explore what types of blended interventions may be most effective and acceptable to both women and health professionals.

Individual participants identified greater affinity for different intervention components. Although some women identified the weight tracker as one of the most valuable components, others nominated the health information or dietitian visit as key. This highlights the importance of offering a suite of products and interactions that allows women to tailor their own programs and interactions according to their preferences, including personal physical and mental health and social support. This is consistent with a study by Willcox et al [37], where both health professionals and women articulated that the individual requirements of women would be best served by interventions that integrated multiple technology elements. This was seen to serve the individual acceptability and use of different technologies and also the needs of different learning styles. Women saw their ability to access different technologies and elements as a way to self-manage or control information acquisition that was unavailable in traditional care models and information sources. Heron and Smyth argue in their review of mobile technology in psychosocial and health behavior research that interventions need to be more sensitive to the individual characteristics and needs of stakeholders [17]. Further investigation with larger trials will be required to understand the underlying differences in characteristics that underpin this and understand how researchers may segment users and target them most appropriately.

One important finding of this study is that the recording of and education around weight was universally accepted by women. The weight tracker was consistently used by many women, and the qualitative interviews elicited positive views on the practice and prompting of weighing. Self-monitoring is known to be a powerful behavior change technique and is frequently adopted in technology interventions [38]. Feedback from all but 1 woman demonstrated the desire to be able to track weight though to pregnancy completion. Previous research has highlighted the need for women to understand their targeted GWG and allow tracking [39]. Although GWG is well understood to impact the health outcomes of both mother and child, concerns are often raised by health professionals as to the appropriateness of weight discussions with pregnant women [40,41]. Health professionals often cite concern for the physical and psychological health of pregnant women and worries about the perceived negative impacts of weight discussions. This study adds to the data supporting that the majority of women are accepting of GWG discussions and tracking. Further research could engage a wide range of health professionals in supporting digital health augmentation to their counseling to ensure that GWG messages are consistent and professionals are equipped with the necessary skills to address weight management in pregnancy.

Strengths and Limitations

A strength of this study was the use of a mixed methods design incorporating both quantitative engagement data and qualitative engagement and acceptability data. The pilot size of the original PLAN study, and hence the qualitative work, may be viewed as a limitation. Despite this, the application of qualitative research methods was able to define certain themes. Furthermore, the additional corroborating objective measures of engagement, such as frequency of weight entry and SMS response, correlated well with what was reported in the interviews, providing greater evidence for the integrity of the information obtained. Larger-scale studies with analysis of participant engagement and health outcomes will allow further exploration of engagement variables. Another limitation of the study was the recruitment of predominantly private patients from an upper socioeconomic stratum, with the complexity of recruiting early gestational age participants under public care. Recruiting more broadly and tailoring and testing the intervention on a broader section of the community is required. That only half of the women agreed to participate in the qualitative interviews may be viewed as a limitation. Although saturation was reached after 7 participants, the nonresponders may have held alternate views.

Conclusions

This study investigated the engagement with and acceptability of a combination of eHealth and dietetic intervention to promote healthy GWG in pregnant women. Women universally found the blended model of a dietitian consult and digital information and tracking acceptable and opportune. However, participants responded more favorably to different elements of the intervention and described a range of factors to enhance future interventions in preventing excess weight gain in pregnancy. This pilot study contributes to the literature on participant engagement and provides participant-related themes, including the importance of choice and tailoring, to inform future research.

Abstract

Background: A decreased capacity to self-manage medications results in nonadherence, medication errors, and drug-related problems in older adults. Previous research identified 80 electronic medication adherence products available to assist patients with self-management of medications. Unfortunately, the usability and workload of these products are unknown.

Objective: This study aimed to examine the usability and workload of a sample of electronic medication adherence products.

Methods: In a prospective, mixed methods study, a sample of older adults, health care professionals, and caregivers tested the usability and workload of 21 electronic medication adherence products. Each participant tested 5 products, one at a time, after which they completed the system usability scale (SUS) and NASA-task load index (NASA-TLX), instruments that measure the usability and workload involved in using a product. Higher SUS scores indicate more user-friendliness, whereas lower NASA-TLX raw scores indicate less workload when using a product.

Results: Electronic medication adherence products required a mean of 12.7 steps (range 5-20) for the appropriate use and took, on average, 15.19 min to complete the setup tasks (range 1-56). Participants were able to complete all steps without assistance 55.3% of the time (103 out of the 186 tests were completed by 39 participants; range 0%-100%). The mean SUS and NASA-TLX raw scores were 52.8 (SD 28.7; range 0-100) and 50.0 (SD 25.7; range 4.2-99.2), respectively, revealing significant variability among the electronic medication adherence products. The most user-friendly products were found to be TimerCap travel size (mean 78.67, SD 15.57; *P*=.03) and eNNOVEA Weekly Planner with Advanced Auto Reminder (mean 78.13, SD 14.13; *P*=.049) as compared with MedReady 1700 automated medication dispenser (mean 28.63, SD 21.24). Similarly, MedReady (72.92, SD 18.69) was found to be significantly more work intensive when compared with TimerCap (29.35, SD 20.35; *P*=.03), e-pill MedGlider home medication management system (28.43, SD 20.80; *P*=.02), and eNNOVEA (28.65, SD 14.97; *P*=.03). The e-pill MedTime Station automatic pill dispenser with tipper (71.77, SD 21.98) had significantly more workload than TimerCap (*P*=.04), MedGlider (*P*=.03), and eNNOVEA (*P*=.04).

Conclusions: This study demonstrated that variability exists in the usability and workload of different electronic medication adherence products among older adults, caregivers, and clinicians. With few studies having investigated the usability and workload of electronic medication adherence products, no benchmarks exist to compare the usability and workload of these products. However, our study highlights the need to assess the usability and workload of different products marketed to assist with medication taking and provides guidance to clinicians regarding electronic medication adherence product recommendations for their patients.

Future development of electronic medication adherence products should ensure that the target populations of patients are able to use these products adequately to improve medication management.

Introduction

Background

The global population is aging, and as a result, the proportion of older adults is growing rapidly. In 2017, there were 962 million individuals aged 60 years and older; by 2050, there will be 2.1 billion, accounting for 1 out of every 5 people [1]. With an increasing life expectancy, a greater proportion of the population is living well into their seventh and eighth decades, resulting in increases in the prevalence of chronic disease and comorbid medical conditions [2-4]. Indeed, in high-income countries, 86% of the burden of disease is due to noncommunicable chronic diseases; this is a phenomenon that is being replicated in middle- and low-income countries, as the ability to address infectious and parasitic diseases grows [2]. Chronic diseases such as heart disease, hypertension, diabetes, and cancer, among others, are typically managed with medications, in many cases, with multiple medications [5-7]. The use of multiple medications, commonly referred to as polypharmacy, for the treatment of comorbid conditions, brings its own set of complexities, including adverse effects, drug interactions, drug-induced disease, complex drug dosing regimens, and nonadherence, all of which increase the risk of hospitalization and mortality [5,8-10].

Medication nonadherence is a particularly problematic issue affecting older adults and results in suboptimal control of chronic conditions leading to poor health outcomes, hospitalizations, and significant health care costs [11,12]. For example, among patients aged 75 years and older, nonadherence to bisphosphonates resulted in an odds ratio of 1.49 for osteoporotic fractures and 13.4% higher medical costs than adherent patients [13]. Among older adults with epilepsy, the odds ratio of utilization of inpatient services was 0.66 among patients adherent to antiepileptic drugs compared with nonadherent patients and 13.2% less cost on the total direct health care costs [14]. Similarly, a population-level evaluation of the economic impact of nonadherence to medications used for the treatment of diabetes, heart failure, hyperlipidemia, and hypertension among Medicare beneficiaries in the United States demonstrated that improvement in adherence would result in an annual reduction of 117, 594 emergency department visits and over 7 million inpatient hospital days among patients with hypertension [15]. Likewise, reductions in these health care costs would also be realized in patients with hyperlipidemia, diabetes, and heart failure [15].

Adherence is defined as “the degree to which the person’s behavior corresponds with the agreed recommendations of a healthcare provider” [16]. Nonadherence to medications can arise from an intentional, active, and conscious decision to deviate, or result from passive, unintentional divergence from the prescribed dosing regimen [17,18]. Common causes of intentional nonadherence among older adults include beliefs related to the patient perception of illness and necessity for medications, experience of adverse events from medications, patient-prescriber relationship, and complexities related to dosing regimens of multiple medications [17]. Among older adults, nonadherence to medications can arise from several different factors, including patient-related, medication-related, health care provider–related, health care system–related, and socioeconomic-related factors [19]. Among the medication-related factors that can lead to inadvertent or unintentional nonadherence are dosing regimens, formulations, and packaging of medications [19]. Additionally, patient-related factors such as physical functioning (eg, vision limitations, impaired hearing, and poor dexterity) and cognitive impairment impact a patient’s ability to accurately administer medications, that is, the ability to take the right dose of the right medication at the right time [19-27]. These limitations are well recognized in both the clinical and research environments. As a result, several tools that measure the functional capacity of an older adult to manage medications have been developed to assist clinicians and patients in identifying different limitations in physical and cognitive capacities [28,29]. Several different strategies have been designed to address this need, including telephone reminders, memory aids and cues, pill boxes and dosettes, and compliance or blister-packaging, among others. However, systematic reviews indicate that the effectiveness of many of these strategies has produced mixed results in terms of the impact on adherence [30-32]. A systematic search for electronic products marketed to assist with medication management conducted in 2016 revealed that more than 80 such products were available for purchase to Canadians to address medication management needs [33]. These electronic medication adherence products may have audio and/or visual alarms, locking features, report-generating abilities, and real-time adherence monitoring, among others. These electronic medication adherence products are physical products that a patient can purchase and are not mobile or web-based apps. They may have a mobile or web-based app accessory to the product, but this is not the sole product. Very few of these commercially available electronic medication adherence products have been tested for usability and/or workload.

The usability of a product refers to the “facility with which users can use a technological artefact to achieve a particular goal” [34]. Before examining the effectiveness of these products on adherence and clinical outcomes, usability should be established. Products that are not user-friendly have the potential to worsen adherence in older adults. If a product is not practical, is socially unacceptable, has limited learnability, is inefficient and unpleasant to use, or results in increasing error rates, it may negatively affect adherence [35]. Usability is especially imperative to be established among older adults, given the higher prevalence of cognitive and physical impairments. A conceptual framework developed to address the usability of health technology among older adults highlights 4 different categories, including cognitive barriers, physical impairments, motivational issues, and perception barriers that impact usability and must be addressed [36]. However, usability of the majority of electronic medication adherence products has not been established. Of the products that have been tested, usability varies based on its features and limitations encountered in the participant population. In one study, 96 frail older adults used an electronic automated medication dispensing device for 1 year [37]. In this study, 94% (90/96) of the participants found the device to be easy to use, 95% (91/96) reported that it was reliable, and 95% (91/96) reported that the dispenser gave them peace of mind. However, only 84% (81/96) would consider using the dispenser in the future, and 5 participants indicated that they would require continued assistance from a nurse with pill setup. It is important to note that during this study, participants were not required to fill the dispenser with medications. In another study, 90% (18/20) of the 20 participants aged 55-75 years also indicated satisfaction with a personalized medication support system developed for Android platforms using quick response codes. However, users requested further improvements in printed characters, font sizes, and compatibility, and they noted financial constraints and the requirement of smartphones as limitations [38]. Similar limitations were identified in another study designed to investigate the usability of EMMA (R) among older adults [39]. Major challenges with usability were identified, including a narrow medication loading slot; difficulty in reading the font; and difficulty in identifying, retrieving, and opening delivered medications. In a separate study, usability of medication adherence technology was found to be limited in persons with cognitive impairment [40]. In this study, Mini-Mental Status Examination (MMSE) scores were significantly correlated with the percentage of task success; noncognitively impaired individuals completed 69% of the tasks required to use an integrated medication unit, whereas cognitively impaired individuals were only successful at completing 34.7% of the tasks [40]. Similar issues with navigation, poor visibility, and lack of transparency have been identified in medication management apps available for use in smartphones [41,42]. Usability scores of some of these apps ranged from 42 to 57 on the system usability score (SUS), a validated measure of usability where products are scored from 0 to 100, with higher scores indicating better usability [41,42].

Objectives

Given that these studies demonstrated significant variability and limitations in the usability of health technology addressing medication management capacity and adherence and that the usability of many commercially available electronic medication adherence products has not been tested, this study aimed to examine the usability and workload of a range of electronic medication adherence products among older adults, caregivers, and health care providers.

Methods

Study Design

This study was designed as a prospective, mixed methods study to investigate the usability and workload of 21 electronic medication adherence products. In an effort to measure usability in a multidomain approach, we used both quantitative measures, including validated tools, cognitive walkthroughs, observations, and qualitative one-on-one interviews [35,43]. The paper describes the quantitative findings of this study. We did not develop any of the products tested in our study.

Sample and Sample Size

We used purposive sampling techniques to recruit three types of participants for this study: older adults, caregivers of older adults, and health care providers. To be eligible, older adults had to be aged 65 years and older and taking one or more prescription or nonprescription medications regularly, whereas caregivers had to be assisting older adults with medication administration. Older adults and caregivers were recruited through advertising, professional networks, and from a participant pool of older adults who had previously indicated an interest in participating in research. All health care providers were eligible for the study and were recruited primarily through professional networks of researchers.

As 80% of the usability problems can be identified with 5 test-users [34], we aimed to test each product with at least five participants. Therefore, we targeted a recruitment sample of 25, composed of 15 older adults or caregivers and 10 health care providers.

Products Included

In total, 23 electronic medication adherence products were purchased for the purposes of this study; however, 1 product was nonfunctional and, as such, was not tested. One product was found to be nonelectronic; however, it was still tested, although the results are not included in this report. Products were chosen with the objective of representing different features such as automated dispensing, number and type of compartments, audio and vibration reminder alarms, cloud connectivity, and medication dispensing tracking. Products that cost over Can $1000 (US $710.84) to purchase were not selected based on funding constraints. The names and details of the electronic medication adherence products tested are described in Table 1.

[a] GMS: Group Medical Supply.

[b] Purchased from Amazon Canada or the United States.

[c] LLC: Limited Liability Company.

[d] e-pill: electronic pill.

[e] Purchased from Ebay Canada.

[f] LTD: Limited.

Outcome Measures

Usability: System Usability Scale

SUS is a popular end-of-test subjective assessment of the usability of a product [44,45]. It is a validated, quick, and easily administered tool that has been used to test products across a wide range of industries. It consists of 10 statements (5 positive and 5 negative), which are scored immediately after testing a product on a 5-point Likert scale. Scores range from 0 to 100, with higher scores indicating that a product is more usable.

Workload: NASA-Task Load Index

The NASA-task load index (NASA-TLX) measures the workload required to complete a task [46]. It consists of 6 subscales: mental, physical, demand, frustration, effort, and performance. Participants were asked to rate each of the above-mentioned variables on a 20-point scale that measures from high to low (scored from 0 to 100) [46]. The tool has been applied in various fields, such as measuring workload in persons working in critical care, performing surgery, commercial aviation, and daily activities (such as operating a medical device at home) [47]. There are 2 ways to calculate the score. For the purpose of this study, we calculated the average of the ratings of the 6 items for each participant [47]. Lower scores indicate less workload.

Task Completion Times, Task Completion Rates, and Error Rates: Cognitive Walkthrough Checklist, Thinking Aloud

A cognitive walkthrough checklist was used to portray the cognitive tasks an individual performs while completing a series of complex tasks [48]. Individual cognitive walkthrough checklists were developed for each tested electronic medication adherence product. Cognitive walkthroughs were designed as outlined by Kushrinuk and Patel [48] and included (1) identifying the end users of the medication adherence products (older adults, caregivers, and health care providers), (2) defining the tasks for the walkthrough based on instructions provided by the manufacturer and supplemental information available on the web, and (3) walking through the actions and critiquing the vital information and steps with several pilot runs by research team members. Any critical steps, defined as those that were necessary for the appropriate use of the product, were identified and noted. The cognitive walkthrough checklist for each product listed each task, the steps required to complete the task, space to note errors performed in completing the tasks as well as time to complete, and if the completion of all the tasks was unassisted or partially assisted. The tasks varied for each product, but generally included steps such as opening and filling a tray with medications by using a mock medication regimen with placebo tablets and capsules, setting an alarm, locking a device, and removing the placebo tablets or capsules. As participants tested each product, they were invited to *think aloud*, that is, verbalize their thoughts as they completed the tasks required to use a medication adherence product with the mock medication regimen [48]. The *think aloud* sessions were audio recorded using a digital recorder (Sony IC Recorder ICD-PX470), while also being observed by a research team member who recorded their observations on the cognitive walkthrough checklist. Having the patient verbalize their thoughts helped researchers gain insight into what the participant was thinking and why certain errors were occurring. Participants were timed from the point at which they started testing the adherence product up to the point at which they completed all the tasks required to use the product or the point at which the participant refused to continue because of frustration, confusion, or fatigue with completing the remaining tasks. Timing was measured using an Apple iPhone X (software version iOS 13.31, 2017) clock app with a built-in timer.

Mock Medication Regimen

A mock polypharmacy medication regimen was developed for the purpose of this study. Placebo tablets (national product number 00501190, Odan Laboratory, lot #188628A, 100 mg lactose tablets), candy (Tic Tac), and placebo capsules (manufactured in-house) were used to represent the following medications (with administration instructions as indicated here): warfarin 2 mg once daily on Monday, Wednesday, and Friday and 3 mg once daily on Tuesday, Thursday, Saturday, and Sunday; pantoprazole 20 mg twice daily; phenytoin 100 mg, 1 capsule in the morning and 2 capsules in the evening; and propranolol 20 mg, half a tablet once daily for 2 days, then 1 tablet daily. The dosing regimen was designed to reflect commonly prescribed regimens. Participants were required to use the mock medications and instructions provided on the prescription labels to fill the medication adherence products they were testing in an effort to reflect activities conducted in real-life scenarios. For each product participants tested, they were required to use the same mock regimen.

Testing Procedures

Each participant tested 5 electronic medication adherence products. No training was provided to participants as this option would not be available in the community setting, but participants were provided with manufacturer instructions. If manufacturer instructions were not enclosed with the product, researchers accessed web-based instructions and provided them to the participant. Each participant was required to perform a series of tasks while *thinking aloud*, covering all aspects of using the product. At the end of each product testing, participants were asked to complete both the SUS and NASA-TLX. Finally, each participant was invited to an optional one-to-one semistructured interview examining participant perceptions about the features of the products, if they would consider using the product for managing their medications or if they would recommend the product to friends or family members. The results of the qualitative analysis for the one-to-one interviews are not presented in this analysis.

Data Collection and Statistical Analysis

The SUS and NASA-TLX were provided to participants to complete in a paper format at the end of each product testing. The cognitive walkthrough checklist was completed by a research team member for each product. The audio recordings were then used to ensure the accuracy of the observations completed by a second team member. Data were entered in Microsoft Excel spreadsheets (Microsoft Excel version 16.16.14, 2016), Microsoft Word (Microsoft Word version 16.16.13, 2016), and Microsoft Access (Microsoft Access Version 16.0.4738.100, 2016).

SUS and NASA-TLX scores for the different electronic medication adherence products were analyzed using RStudio version 3.5.1 (2018-07-02). A repeated-measures analysis of variance (ANOVA) was used to compare both SUS and NASA-TLX scores of all the products, followed by Tukey posthoc analysis. The Pearson correlation was used to determine if there was a statistically significant relationship between SUS scores, that is, usability and NASA-TLX scores, that is, workload.

Error rate was calculated by dividing the number of total errors made (per person per product) by the total number of steps required to use the product (per product). Mean error rates are reported as percentages. Unassisted task completion rates were calculated by dividing the total number of tasks completed without assistance by each participant for each product by the total number of tasks required to use the particular product. The means of this measure are provided as percentages. Completion rates were calculated as the total number of tasks completed with or without assistance divided by the total number of tasks. Completion times reported are the mean time required to complete the setup and use of each product per participant. Error rates, completion times, and completion rates for each electronic medication adherence product tested are summarized.

Ethical Review and Location

This study was reviewed by and received approval from the University of Waterloo Office of Research Ethics. All participants were informed of the study and provided consent before enrolling. This study was conducted at the University of Waterloo School of Pharmacy in Kitchener, Ontario, Canada.

Results

Participant Demographics

A sample of 39 individuals were recruited to test the electronic medication adherence products in this study, of which 23 were older adults, 5 were caregivers, and 11 were health care professionals. The majority of the 23 older adults were taking more than 5 medications, including prescriptions, vitamin supplements, over the counter drugs, and/or natural health products concurrently (see Table 2).

Almost 70% (16/23) of older adults also reported using a medication aid to assist with medication management, with the most commonly utilized being pill boxes, followed by alarms on a phone/watch and blister pack. All 5 caregivers assisted older adults with their medication management. Of the 11 health care providers, all of them worked with older adults in some capacity, with more than 80% (9/11) assisting with medication taking activities, but all recommending some type of medication aid to older adults (see Table 3).

[a] One health care provider was a pharmacy student and thus had 0 years of practice as a registered pharmacist.

Usability

The overall mean SUS score for all 21 products tested was 52.28 (SD 28.52; range 0-100). The mean SUS score per product ranged from a low of 28.63 (SD 21.240) for the MedReady 1700 automated medication dispenser to a high of 78.67 (SD 15.572) for the TimerCap travel size (Table 4). The mean SUS scores were significantly different between MedReady 1700 automated medication dispenser and the TimerCap travel size (mean 28.63, SD 21.24 vs mean 78.67, SD 15.57; *P*=.03) and MedReady 1700 automated medication dispenser and the eNNOVEA Weekly Planner with Advanced Auto Reminder (mean 28.63, SD 21.24 vs mean 78.13, SD 14.13; *P*=.049).

Table 4. Mean system usability scale and NASA-task load index scores

Product name	System usability scale		NASA-task load index	
	Score, mean (SD)	Range	Score, mean (SD)	Range
Med-e-lert	40.75 (31.78)	7–85	67.08 (25.60)	33.33–97.50

Multi-Alarm	51.56 (24.59)	15–95	45.65 (25.79)	4.17–78.33
Pill Storage Case	34.75 (22.60)	0–62	65.10 (14.17)	41.67–80.83
Pocket Doctor	35.00 (33.19)	0–92	68.33 (27.37)	20.00–93.33

Workload

For the 21 products tested, the overall mean NASA-TLX score was 50.43 (SD 25.49; range 4.17-99.17). The mean NASA-TLX score per product ranged from 28.65 (SD 14.97) for the eNNOVEA Weekly Planner with Advanced Auto Reminder to 72.92 (SD 18.69) for the MedReady 1700 automated medication dispenser (Table 4). Similar to SUS scores, ANOVA analysis revealed significant differences in the NASA-TLX raw scores. The NASA-TLX raw scores for the MedReady 1700 automated medication dispenser (mean 72.92, SD 18.69) were significantly higher than those for the TimerCap travel size (mean 29.35, SD 20.35; *P*=.03), e-pill MedGlider home medication management system (mean 28.43, SD 20.80; *P*=.02), and eNNOVEA (mean 28.65, SD 14.97; *P*=.03). The e-pill MedTime Station automatic pill dispenser with tipper (mean 71.77, SD 21.98) demonstrated significantly higher workload than TimerCap (*P*=.04), MedGlider (*P*=.03), and eNNOVEA (*P*=.04).

Correlation Between System Usability Scale Scores and NASA-Task Load Index Scores

The SUS scores were highly correlated with NASA-TLX scores (Pearson $r=-0.877$; 95% CI −0.907 to 0.839; $df=184$; $P<.001$), such that an increase in usability of the product was inversely correlated with decreasing workload involved in using the product.

Mean Time to Task Completion, Task Completion, and Error Rates

The number of tasks and the number of steps within each task to use a product varied depending on the characteristics and features of the products. Products required an average of 12.7 steps (SD 4.1; range 5-20) for use and included steps such as inserting the key into the lock, rotating the key clockwise, and pinching the tab to open the product. These steps were grouped into tasks such as opening the product, loading the product with placebo pills or Tic Tac candy as per the standardized mock medication schedule provided, closing the product, setting an alarm, and removing the medications from the product after the alarm sounds (Table 5). On average, with assistance from a research team member, participants were able to complete 97% of the tasks required to use a product (SD 8.97%; range 16.7%-100%). However, without the assistance of a researcher, participants were only able to complete 100% of all steps required to use a product in 103 of 186 product tests (103/168, 55.3%; range: 0%-100%).

Table 5. Mean error rates, completion time, unassisted task completion, and completion rates of electronic medication adherence products tested.

Abbreviated product name	Total number of steps	Description of tasks					Mean time to task completion (min:sec)	Mean error rate (%)	Mean unassisted task completion (%)	Mean completion rate (%)
		Open and fill medication tray	Set alarm	Lock device	Remove medication from device	Other

[a] Task needed to be completed.

[b] N/A: not applicable.

[c] A total of 3 tasks (of the total 15) were only applicable for health care providers to complete. Thus, the total number of steps is 12 for an older adult or caregiver participant, and it is 15 for a health care provider participant.

Discussion

Principal Findings

To our knowledge, our study is the first and the largest study to examine and compare the usability and workload of electronic medication products in a population of older adults, caregivers, and health care providers. We tested a range of products, varying between products with few features to complex devices with multiple features, using a standardized mock medication regimen that mimicked polypharmacy and medication regimen complexity that is prevalent in an older adult population [5]. The electronic medication adherence products we purchased were discovered in a systematic search we conducted in a previous study and reflected a variety of characteristics and available features [33]. The results of our study demonstrate significant variability in both the usability and workload required to use electronic medication adherence products. Additionally, the task completion rates varied between electronic medication adherence products as well as the number of task errors.

We examined the usability of electronic medication adherence products by older adults, caregivers, and health care providers. The results of this study are of importance to both older adults and health care providers, especially when determining which electronic medication adherence product can be used to address medication management at home. Higher usability scores indicate that an older adult, caregiver, or health care provider is more likely to be able to use a product appropriately, potentially decrease medication error rates, and improve adherence. Products with lower usability scores may introduce dosing errors, reduce adherence, and, at worst, introduce medication errors. However, although the results of this study demonstrate that some products score well for usability, making them more user-friendly, and others score poorly demonstrating poor usability, there is no benchmark for SUS scores for electronic medication adherence products or for any adherence products for that matter. Therefore, an exact interpretation of this score is difficult. In comparison, the mean SUS scores for other everyday products are as follows: Excel, 56.5; iPhone, 78.5; and microwaves, 86.9 [45,46,48,49]. As a cutoff score above which a product could be deemed highly usable is not available, Bangor et al [45] described an emergence of scoring systems using adjectives such as *acceptable* for products that score above 70 on SUS, *marginal* for scores of 50-69, and *not acceptable* for scores of less than 50. It is easier to relate the product's usability with the use of these descriptive terms in clinical practice, especially when determining the potential usability of a product. In terms of the products we tested, we would then consider the TimerCap travel size, e-pill MedGlider home medication system, and the eNNOVEA Weekly Planner with Advanced Auto Reminder as products which have *acceptable* usability, whereas the TimerCap universal size, Jones medication adherence system, Reizen vibrating pill box, VitaCarry advanced pill case, MedGlider system 1 with talking reminder, Patterson medical TabTimer super 8, 100-Hour pill reminder, Med-Q smart pill box, MedCentre system, and e-pill multi-alarm pocket XL as *marginally acceptable*, and the remaining products as *unacceptable* for user-friendliness. This type of classification would allow clinicians to evaluate the potential problems with usability their older adult population would encounter. It also allows older adults and caregivers to evaluate products before making a financial investment.

Similar to SUS, the NASA-TLX has been applied in various fields. A meta-analysis of NASA-TLX scores in over 200 publications reported an overall range of scores from 6.21 to 88.5 for various activities (eg, air traffic control, cognitive activities, daily activities, and driving care) [47]. As with the SUS scores, no benchmark for the NASA-TLX regarding medication adherence products, electronic or not, is available. This limits the ability to generalize the scores to a level of workload, that is, to determine the cutoffs for scores that could be used to designate specific products as excellent, moderate, or poor, as has been recommended with SUS scores. Furthermore, adjectives such as those that exist with SUS are not available to allow us to easily apply the scoring in clinical practice. However, the NASA-TLX scores can be compared between the different products to gauge if the workload required to use a product in a population such as ours would be high or not, relative to other products tested. Additionally, by plotting the scores of SUS and NASA-TLX for each product, it became apparent that they were inversely related, that is, products that scored high for usability also scored low for workload. We were also able to demonstrate that the 2 variables are highly correlated (Pearson's $r=-0.877$; 95% CI −0.907 to 0.839; $df=184$; $P<.001$). Given this finding, it is reasonable to expect that a product that scores well on usability does not place an undue workload cost on the human user.

Strengths of the Study

Older adults rarely report the problems they have with medication management, and often, they develop their own strategies to address these problems, including the use of commercially available electronic medication adherence products. Our study is the first to compare a number of these products, and the results from our study indicate that usability, workload, time taken to complete tasks, and task completion rates vary between different products. The results of our study provide some evidence for factors to consider when choosing electronic medication adherence products in older adults at risk of medication nonadherence and can also help clinicians and caregivers to guide the choice of an electronic medication adherence product. Although much work needs to be done to investigate the impact of product choice on adherence and clinical outcomes, our study provides evidence to guide the first step in the process, that is, the choice of the product to use.

Limitations of the Study

This study has some limitations. The participants tested these products in an unfamiliar environment (the University of Waterloo School of Pharmacy) while being observed by research team members, which may have produced or increased anxiety in some of the participants and impacted their ability to use the products efficiently and effectively. Furthermore, participants were asked to test a product they had not been previously exposed to, and this may have impacted the scoring; gaining familiarity with products usually improves the ease of use. Participants were also asked to test 5 products, and frustration with one or more products may have filtered over to the other products they were asked to test thereafter.

Conclusions

As few studies have investigated the usability of electronic medication adherence products, benchmarks do not yet exist to compare the usability and workload of these products. Our study showed that some electronic medication adherence products may be easier to use than others. Furthermore, information such as usability and workload will provide older adults and clinicians with factors to consider when recommending or purchasing devices to address medication management among older adults.

Acknowledgments

This study was supported by the Spark Program at the Centre for Aging and Brain Health Innovation. The authors thank all the participants in the study for their time and input. The authors are grateful to Catherine Lee for assisting with copy editing and formatting the manuscript.

Abstract

Background: Clinical governance of medical mobile apps is challenging, and there is currently no standard method for assessing the quality of such apps. In 2018, the National Institute for Health and Care Excellence (NICE) developed a framework for assessing the required level of evidence for digital health technologies (DHTs), as determined by their clinical function. The framework can potentially be used to assess mobile apps, which are a subset of DHTs. To be used reliably in this context, the framework must allow unambiguous classification of an app's clinical function.

Objective: The objective of this study was to determine whether mobile health apps could be reliably classified using the NICE evidence standards framework for DHTs.

Methods: We manually extracted app titles, screenshots, and content descriptions for all apps listed on the National Health Service (NHS) Apps Library website on July 12, 2019; none of the apps were downloaded. Using this information, 2 mobile health (mHealth) researchers independently classified each app to one of the 4 functional tiers (ie, 1, 2, 3a, and 3b) described in the NICE digital technologies evaluation framework. Coders also answered contextual questions from the framework to identify whether apps were deemed to be higher risk. Agreement between coders was assessed using Cohen κ statistic.

Results: In total, we assessed 76 apps from the NHS Apps Library. There was classification agreement for 42 apps. Of these, 0 apps were unanimously classified into Tier 1; 24, into Tier 2; 15, into Tier 3a; and 3, into Tier 3b. There was disagreement between coders in 34/76 cases (45%); interrater agreement was poor (Cohen κ=0.32, 95% CI 0.16-0.47). Further investigation of disagreements highlighted 5 main explanatory themes: apps that did not correspond to any tier, apps that corresponded to multiple tiers, ambiguous tier descriptions, ambiguous app descriptions, and coder error.

Conclusions: The current iteration of the NICE evidence standards framework for DHTs did not allow mHealth researchers to consistently and unambiguously classify digital health mobile apps listed on the NHS app library according to their functional tier.

KEYWORDS

mHealth; telehealth; evaluation; evidence; interrater; NHS Apps Library; NICE

Introduction

Mobile apps for use in health care have been proposed in a variety of settings, including telehealth for disease management and monitoring, diagnosis and triage, and medication prescription and reminders [1-3]. To date, the evidence for their effectiveness is varied [4-6] and, in general, published evidence is extremely sparse [7].

Thorough governance of medical apps is challenging [8]. There is growing recognition that the required level of evidence for medical apps ought to differ depending on app function. For instance, Wyatt [9] suggested that apps be categorized as low, medium, or high risk for purposes of evaluation. The UK National Institute for Health and Care Excellence (NICE) further addressed this issue through their recent evidence standards framework for evaluating digital health technologies (DHTs) [10]. In this framework, digital technologies are categorized into one of 3 tier levels (with Tier 3 split into Tier 3a and 3b) according to their intended function. An additional set of questions assesses higher-risk technologies, complementing the tier levels.

The framework also provides minimum and best-practice recommendations on the associated standard of evidence required for each tier. For instance, Tier 3a technologies should be supported, at a minimum, by relevant *high-quality observational* or *quasi-experimental studies.* Best practice would include a *high-quality intervention study*. The recommended evidence standards are cumulative, such that Tier 3 digital technologies should also meet the criteria for Tier 2 and Tier 1 technologies. For Tier 2, this includes, for instance, having evidence to show that any health information provided is valid, accurate, up-to-date, regularly audited, and sufficiently comprehensive. At the time of writing, the framework is in its second iteration.

Although other frameworks exist and have been used for classifying mobile apps [11], we solely examine the NICE framework here. This framework is of particular importance as its development was commissioned by the National Health Service (NHS) England and is therefore likely to become an influential standard. In addition, its recency means that it has thus far received little external validation.

This study aims to evaluate the appropriateness and potential limitations of the functional classification guidance within the NICE framework as applied to trusted and safe mobile health (mHealth) apps. We will do this by assessing interrater agreement of functional tier classification for all apps curated on the NHS Apps Library. By examining cases in which reviewers disagreed, we will highlight ambiguities in the current classification guidance and discuss potential improvements.

Methods

Search Strategy and Data Extraction

All apps available on the NHS Apps Library [12] on July 12, 2019, were included in the analysis. For each app, the app title, screenshots, and description were extracted manually from the NHS Apps Library website; none of the apps were downloaded. No apps were excluded.

Classification

Two coders independently classified all apps according to functional classification. The coders were a clinician with formal postgraduate training in health informatics (KN) and an academic with research expertise in mHealth (MEL).

For each app, we recorded the main features as described on the NHS Apps Library, including any available screenshots. The coders assigned each app to a functional tier and noted whether the app should be considered for risk adjustment based on clinical context. Abridged information about each tier and criteria for determining risk-adjusted apps are shown in Tables 1 and 2. To guide our classification decisions, we used the (unabridged) evidence standards framework alongside the associated user guide [13]. If an app could be assigned into multiple tiers, it was assigned to the highest relevant tier, as per the framework guidance. If apps met the criteria for both Tier 3a and Tier 3b, they were assigned to 3b.

Table 1. Abridged definitions of digital health technology tiers from the National Institute for Health and Care Excellence (NICE) evidence standards evaluation framework [10].

Tier and functional classification	Description
1	
System service	Improves system efficiency. Unlikely to have direct and measurable individual patient outcomes.
2	
Information	Provides information and resources to patients or the public.
Simple monitoring	Allows users to record health parameters to create health diaries.
Communicate	Allows two-way communication between users and professionals, carers, third-party organizations, or peers.
3a	
Preventative behavior change	Designed to change user behavior related to health issues with, for example, smoking, eating, alcohol, sexual health, sleeping, and exercise.
Self-manage	Aims to help people with a diagnosed condition to manage their health.
3b	
Treat	Provides treatment for a diagnosed condition (such as cognitive behavioral therapy for anxiety), or guides treatment decisions.
Active monitoring	Automatically records information and transmits the data to a professional, carer, or third-party organization, without any input from the user, to inform clinical management decisions.
Calculate	Tools that perform clinical calculations that are likely to affect clinical care decisions.
Diagnose	Uses data to diagnose a condition in a patient, or to guide a diagnostic decision made by a health care professional.

Table 2. Abridged contextual questions to help identify higher-risk digital health technologies (DHTs), abridged from [10].

Question	Risk adjustment
1. Are the intended users of the DHT considered to be in a potentially vulnerable group such as children or at-risk adults?	The National Health Service (NHS) England defines an at-risk adult as an adult "who may be in need of community care services by reason of mental or other disability, age or illness; and who is or may be unable to take care of him or herself, or unable to protect him or herself against significant harm or exploitation." If the DHT is intended to be used by people considered to be in a potentially vulnerable group, then a higher level of evidence may be needed, or relevant expert opinion on whether the needs of the users are being appropriately addressed.
2. How serious could the consequences be to the user if the DHT failed to perform as described?	A higher level of potential harm may indicate that the best-practice evidence standards should be used.
3. Is the DHT intended to be used with regular support from a suitably qualified and experienced health or social care professional?	DHTs that are intended to be used with support (ie, with regular support or guidance from a suitably qualified and experienced health or social care professional) could be considered to have lower risk than DHTs that are intended to be used by the patients on their own. This contextual question may require careful interpretation depending on the individual DHT as the involvement of a clinician may in itself indicate that the DHT presents a specific risk.
4. Does the DHT include machine learning algorithms or artificial intelligence?	Refer to the code of conduct for data-driven health and care technology for additional considerations when assessing DHTs that use artificial intelligence or machine learning.
5. Is the financial or organizational risk of the DHT expected to be very high?	DHTs with very high financial risk should be assessed using the best-practice standards to provide surety that the DHT represents good value. High organizational risks may include situations in which implementing the DHT would need complex changes in working practice or care pathways.

Classification

We used descriptive statistics to summarize the membership of each tier and the differences in classification between reviewers. We reported Cohen κ as an overall measurement of interrater agreement [14]. In supplementary analysis, we reported interrater agreement for a subset of apps that had previously been classified by another independent team and published in the framework user guide. All analyses were conducted using MATLAB (version 18.1; MathWorks) [15].

We examined any apps with discrepancies in functional tier classification in greater detail. Using the publicly available descriptions of each app, we identified common themes that may have led to differences in classification.

Results

Interrater Agreement Results

In total, we assessed 76 apps from the NHS Apps Library. Overall, 0 apps were unanimously classified into Tier 1; 24/76 (32%), into Tier 2; 15/76 (20%), into Tier 3a; and 3/76 (4%), into Tier 3b. Full classification details for each app are presented in Multimedia Appendix 1.

Table 3 shows the interrater agreement for each tier of app. There was disagreement in 34/76 cases (45%) and Cohen κ was 0.32 (95% CI 0.16-0.47), which is commonly considered to correspond to poor agreement [12]. Of the 34 apps for which functional classification differed, 13 were due to discrepancies between apps classified in Tier 3a or 3b. The next largest group of discrepancies was with apps classified between Tiers 2 and 3a (n=11). Analysis of interrater agreement for a subset of apps previously reviewed by a third independent group is presented in Multimedia Appendix 2 (coder 1: κ=0.48, 95% CI 0.31-0.66; coder 2: κ=0.62, 95% CI 0.44-0.80). The apps for which the independent coders disagreed are also listed in Multimedia Appendices 1 and 2.

Coders also assessed on whether an app should be considered for *risk adjustment* or not based on a set on contextual questions (Table 2). Of these, Questions 2, 4, and 5 were not possible to answer without wider knowledge of the source code (for Question 4) or how the app interacted with the wider health care system. A total of 9 apps were unanimously considered to warrant risk adjustment, and 63 for no adjustment. There were discrepancies for 4 apps, and overall agreement may be considered good (κ=0.79; 95% CI 0.59-0.99).

Table 3. Number of apps coded into each functional tier classification, for both coders.

Classification: coder 1	Classification: coder 2			
	1	2	3a	3b
1	0	6	0	0
2	1	24	5	3
3a	0	6	15	1
3b	0	0	12	3

Analysis of Coder Discrepancies

On further collaborative review, differences in tier classification could be attributed to 5 causes: (1) app function not listed within framework, (2) app function corresponded to multiple tiers, (3) ambiguous tier description, (4) ambiguous app description, and (5) human error.

App Function Not Listed Within Framework

This occurred when the intended function of the app, as described on the NHS Apps Library, did not correspond to any of the functions listed within the NICE framework. One example of this was *MyChoicePad*, an app that is designed to assist nonverbal communication via symbols and signs from the Makaton language. Although one coder categorized the app and function as Tier 2: Communicate, the app does not facilitate two-way communication, so it does not strictly meet the associated criteria. Similarly, the other reviewers categorized the app into Tier 1: System service, but it is not entirely clear whether the app is designed to improve system efficiency, or even what the system is in this case.

App Function Corresponded to Multiple Tiers

This occurred when a single function of an app corresponded to more than 1 tier within the NICE framework. In particular, we noted ambiguity around mental health apps. For example, mindfulness or principles from cognitive behavioral therapy may be classified as a self-management strategy to reduce feelings of anxiety (3a), or as a treatment for anxiety disorders (3b). In this situation, the tier classification depended on the clinical use case, rather than the app function, which was the same in both cases. We also noted ambiguity between lifestyle/well-being versus diagnosed conditions. For example, an app that had a function to provide advice on stress or anxiety reduction might be classified into Tier 2 if it provides generic information, but into 3a if *stress* were part of a diagnosed condition.

Ambiguous Tier Description

Some terms used to describe the tiers within the NICE framework were not clearly defined. One specific instance of ambiguity between Tiers 3a and 3b occurred for the *engage warfarin self-care* app. The app allows warfarin test results to be *actively reviewed* by a clinician, but it is unclear whether this constitutes Tier 3b's *active monitoring* as results must be manually transmitted by the user, or *simple monitoring* which allows users to record their health parameters.

Ambiguous App Description

In some instances, the information provided on the NHS Apps Library was insufficient to definitively categorize an app. For example, screenshots on the NHS Apps Library for the *NHS App* show that users can *check symptoms*, but this functionality was not mentioned elsewhere. The main description for the app stated that users can "find reliable NHS information on hundreds of conditions and treatments, and get immediate advice." If the app merely catalogs searchable information on symptoms, it should be classed as Tier 2; however, if it provides a symptom checker algorithm that requires user input, and outputs relevant immediate advice, it is Tier 3b.

Human Error

This occurred when the reviewer failed to identify a relevant piece of information that would have influenced their tier categorization decision. This most commonly occurred when an app had multiple functions belonging to multiple functional tiers. Typically, the main stated function of the app belonged to the lower tier. For instance, the *Healthera* app is primarily designed to manage prescription management, a Tier 1 function. However, it also allows users to contact their pharmacist for clinical advice via the app, a Tier 2 function. Human errors accounted for 6 apps. In conjunction with the primary result, we can estimate an upper bound on the level of disagreement as 28/76 (37%; κ=0.44, 95% CI 0.30-0.60), when human error is removed.

Discussion

Principal Results

Our results show that, from their publicly available descriptions, only 42 of the 76 apps collated in the NHS Apps Library could be classified into a functional tier consistently by informed individuals. Interrater agreement between reviewers was poor (κ=0.32).

Of the 34 apps where there was disagreement, there was a subset (28/34) for which the tier could not be agreed, even after consultation (ie, excluding human error). In these cases, disagreement was attributed to four broad categories: *App function not listed within framework*, *App function corresponded to multiple tiers*, *Ambiguous tier description*, and *Ambiguous app description*.

There was good agreement in assessment of *higher risk* using the NICE framework's contextual questions (κ=0.79). Despite this, we noted ambiguity in the risk adjustment questions. One example of ambiguity occurs for the assessment question: "Does the DHT include machine learning algorithms or artificial intelligence?" If yes, framework users are advised to refer to the Code of Conduct for data-driven health and care technology [16].

Whilst the framework defines both artificial intelligence and machine learning, the provided definitions are ambiguous. For instance, it states that "Machine learning is an application of artificial intelligence that provides systems the ability to automatically learn and improve from experience without being explicitly programmed." This definition would include the vast majority of quantitative methods. For instance, linear regression is fully defined by the slope and offset parameters, as learned directly from a data set.

The Code of Conduct further provides an external link to the definition from the AHSN Network AI Initiative [17]. No definition is provided here, instead readers are informed that "there is no single, universally agreed definition of AI." The absence of any clear definition means that this risk adjustment question cannot be answered objectively.

Poor interrater agreement of tier classification may be attributed to two potential causes. First, the publicly available information on the NHS App Library may be insufficient to determine the functional tier. If true, this would motivate tighter regulation of how apps are described on the Library to ensure that the intended medical condition and patient or user group is clear. Second, the DHT framework is not specific enough to classify some types of apps. Based on our thematic analysis, in which we showed examples of misclassified apps due to ambiguity in the framework, we contend that this second reason contributes significantly to the overall level of disagreement.

A framework with inadequate specificity has implications for both developers and regulators. For developers wishing to bring products to market as soon as possible, opportunity for misclassification due to ambiguous tier criteria may result in more classifications to lower tiers, where the minimum standard of evidence is not as stringent. In particular, Tier 2 technologies require only information that would be commonly audited in standard software development, whereas Tier 3a and Tier 3b technologies specifically require formal studies that would likely require additional time and financial resource. This may lead to situations in which apps are regulated to a level of lower scrutiny than they ought to be, given their function.

In addition to the main result, we observed that some apps were categorized consistently by reviewers, but the minimum suggested level of evidence did not seem to align with the level of potential clinical risk. One example of this was *Cypher*, which was classified in Tier 2 as it facilitates communication. Whereas other Tier 2 apps allowed communication with health professionals, this app facilitates anonymous communication with other users to allow "anyone who want to share their thoughts". (We further note that as of October 17, 2019, Cypher App is not available for download on the either the Google Play store or Apple App Store and that the developer website is nonfunctional. Persistence of apps is a known problem in digital health [18].) The evidence framework directly addresses this use case by requiring peer-support apps to show evidence of appropriate safeguarding. However, internet communities, forums, and chat rooms [19,20] with similar peer-support functions have been shown to have potential for negative patient impact. Given that the potential harm aligns more closely with apps in Tier 3a or 3b, a higher standard of evidence may be appropriate for peer-support apps, despite the similarity in technical function to other communication apps.

Within mHealth more widely, we can select examples in which the dissonance between functional tier and required evidence is even greater. For instance, consider an app that calculates BMI by requiring the user to type height and weight. This may be categorized into Tier 3b, as a tool that performs a clinical calculation that can affect clinical care decisions. The associated minimum standard of evidence in the NICE framework requires a high-quality intervention study—a level of scrutiny that ought not to be required for simple and well-established calculations. This does not preclude the need for careful technical evaluation; indeed, Huckvale et al [21] have demonstrated how even simple clinical calculations in diabetes apps are often calculated or displayed incorrectly.

More broadly, this indicates that clinical risk and technical risk are not necessarily the same. One possible option to enable better classification and more specific evaluation guidance may be to categorize apps by technical complexity as well as clinical function. The idea of separating clinical and technical evaluation has been raised previously. Lewis and Wyatt [22] suggest evaluation could be based on the probability and severity of clinical harm, the complexity of the app, and additional contextual factors [22]. Others have commented that evidence of clinical effectiveness for software should include indication of safety, and that this must include formal technical evaluation [23].

Limitations

The NICE framework is designed for DHTs that are commissioned by the health system. In this case, we examined apps on the NHS Apps Library. According to the library's HTML description metadata, these are "digital tools that have been assessed by the NHS as clinically safe and secure to use" [12]. However, in most instances, the apps had not been specifically commissioned. Although the relevance of the framework for these apps may vary, multiple apps in the library (eg, GDm-Health, Health Help Now) have already been used as part of routine clinical care.

The primary limitation of work is that our classifications relied on the information presented by the NHS App Library; additionally, none of the apps were downloaded. As all products published in the Library met a set of internal standards, we believed, a priori, that written descriptions and screenshots should be sufficient to enable clear identification of all key functions (as this is key information for informing consumer app selection). Our results showed that this was not the case. Downloading each app would provide more comprehensive understanding of the key functions and may increase interrater agreement on app tier. We therefore recommend that future studies download and engage directly with the contents of mobile apps.

Our study compares only two sets of raters, so the results might be unduly influenced by the poor performance of a single individual. We partly addressed this by comparing interrater reliability with a third set of reviewers (see Multimedia Appendices 1 and 2), for which similar results were obtained. These were not included in the main manuscript as reviews were conducted under different conditions; we do not know if apps were downloaded, nor the time at which their review took place.

Finally, the NICE framework establishes a functional tier and provides guidance on required levels of evidence at each tier. In this work, we only examined the consistency of tier classification, and did not address whether apps within a tier met the evidence standards.

Conclusions

The NICE evidence standards framework for evaluating digital technologies is a significant and timely step toward establishing appropriate levels of evidence for DHTs. Despite this, we have demonstrated that the current iteration of the framework did not allow mHealth researchers to consistently and unambiguously group a set of digital health mobile apps according to their functional tier. In users with limited experience of mHealth evaluation (eg, app developers), we postulate that this ambiguity may lead to higher levels of misclassification. One potential improvement would be to classify DHTs by their technical complexity in addition to clinical function.

Abstract

Background: High-quality neuroimages can be viewed using a medical app installed on a smartphone. Although interdevice agreement between smartphone and desktop PC monitor was found to be favorable for evaluating computed tomography images, there are no interdevice agreement data for diffusion-weighted imaging (DWI).

Objective: The aim of our study was to compare DWI interpretation using the Join smartphone app with that using a desktop PC monitor, in terms of interdevice and interrater agreement and elapsed interpretation time.

Methods: The ischemic change in the DWI of consecutive patients with acute stroke in the middle cerebral artery territory was graded by 2 vascular neurologists using the Join smartphone app and a desktop PC monitor. The vascular neurologists were blinded to all patient information. Each image was categorized as either Diffusion-Weighted Imaging–Alberta Stroke Program Early Computed Tomography Scores (DWI-ASPECTS) ≥7 or DWI-ASPECTS <7 according to the Japanese Society for Neuroendovascular Therapy. We analyzed interdevice agreement and interrater agreement with respect to DWI-ASPECTS. Elapsed interpretation time was compared between DWI-ASPECTS evaluated by the Join smartphone app and a desktop PC monitor.

Results: We analyzed the images of 111 patients (66% male; median age=69 years; median National Institutes of Health Stroke Scale score on admission=4). Interdevice agreement regarding DWI-ASPECTS between the smartphone and the desktop PC monitor was favorable (vascular neurologist 1: κ=0.777, *P*<.001, vascular neurologist 2: κ=0.787, *P*<.001). Interrater agreement was also satisfactory for the smartphone (κ=0.710, *P*<.001) and the desktop PC monitor (κ=0.663, *P*<.001). Median elapsed interpretation time was similar between the smartphone and the desktop PC monitor (vascular neurologist 1: 1.7 min vs 1.6 min; *P*=.64); vascular neurologist 2: 2.4 min vs 2.0 min; *P*=.14).

Conclusions: The use of a smartphone app enables vascular neurologists to estimate DWI-ASPECTS accurately and rapidly. The Join medical smartphone app shows great promise in the management of acute stroke.

Introduction

In 1996, the first-line treatment for acute-onset ischemic stroke was intravenous thrombolysis using recombinant tissue plasminogen activator (IV rtPA) therapy, which was effective only within 3 hours after the onset of symptoms. Since then, the emergency medical systems for acute stroke patients have improved dramatically. The publication of the ECASS III (European Acute Stroke Study III) [1], DAWN (Clinical Mismatch in the Triage of Wake Up and Late Presenting Strokes Undergoing Neurointervention With Trevo) [2], and DEFUSE 3 (Diffusion and Perfusion Imaging Evaluation for Understanding Stroke Evolution) [3] trials and advances such as those reported from the WAKE-UP (Wake-Up Stroke) trial [4] and new thrombolytic agents [5] have expanded the therapeutic time window and increased the number of candidates suitable for IV rtPA and mechanical thrombectomy. Accordingly, the decision-making process for thrombolysis requires timelier, more accurate, and more professional neurological assessment (including neuroimaging) to be made by a stroke specialist. The sharing of clinical and neuroimaging information will become increasingly important in decision making for IV rtPA and mechanical thrombectomy, particularly at comprehensive stroke centers. There is an urgent need to build a more convenient and faster communication system for sharing this information among the stroke team, which comprises vascular neurologists, on-call physicians, residents, and emergency, operating room, and paramedical staff.

We used the Join medical smartphone app to build a seamless communication system for the stroke team. The app enables the team to share texts, neuroimaging, photos, and videos with high security (Figure 1A). Immediately after neuroimaging of a stroke patient, the images are sent from the hospital server to all smartphones that have the app installed and are signed in as members of the stroke team. The images can be enlarged and evaluations recorded with a simple touch sequence on the smartphone screen (Figure 1B). Before this communication system can be used in the newly extended therapeutic window in acute stroke, it is necessary to confirm interdevice agreement and interrater agreement with regard to assessment of the neuroimages.

At our stroke center, the initial imaging examination for patients with acute ischemic stroke is magnetic resonance imaging (MRI) rather than computed tomography (CT), for the following reasons: (1) hyperacute ischemic stroke is easily diagnosed on diffusion-weighted imaging (DWI) on MRI and (2) cerebral artery occlusion can be assessed on magnetic resonance angiography without the use of contrast agents. Although interdevice agreement between the smartphone and a desktop PC monitor was found to be favorable for evaluating CT images [6], there are no interdevice agreement data for DWI. The aim of our study was to compare DWI interpretation using the Join smartphone app with that using a desktop PC monitor, in terms of interdevice and interrater agreement and elapsed interpretation time.

Figure 1. A. The Join smartphone app utilizes the easy-to-use interface of the social networking communication environment. B. Communication with picture archiving and communication system and other intrahospital systems enable text and medical images hosted on a cloud server to be shared in a group chat. The Join smartphone app displays diagnostic medical images, such as MRI and CT, and enables app users to edit, comment on, and draw a shape. CT: computed tomography. MRI: magnetic resonance imaging.

Methods

Patient Characteristics

From January 2016 to September 2017, we enrolled 111 patients with acute ischemic stroke in the middle cerebral artery territory, diagnosed within 24 hours of onset. DWI on MRI was performed on all patients, and the following clinical information was recorded: cardiovascular risk factors (hypertension, diabetes mellitus, dyslipidemia, and smoking status) and atrial fibrillation. Stroke severity on admission was assessed using the National Institutes of Health Stroke Scale (NIHSS) score. Stroke subtype was categorized into four groups: small-vessel occlusion, large-artery atherosclerosis, cardioembolism, or other.

Join Smartphone App

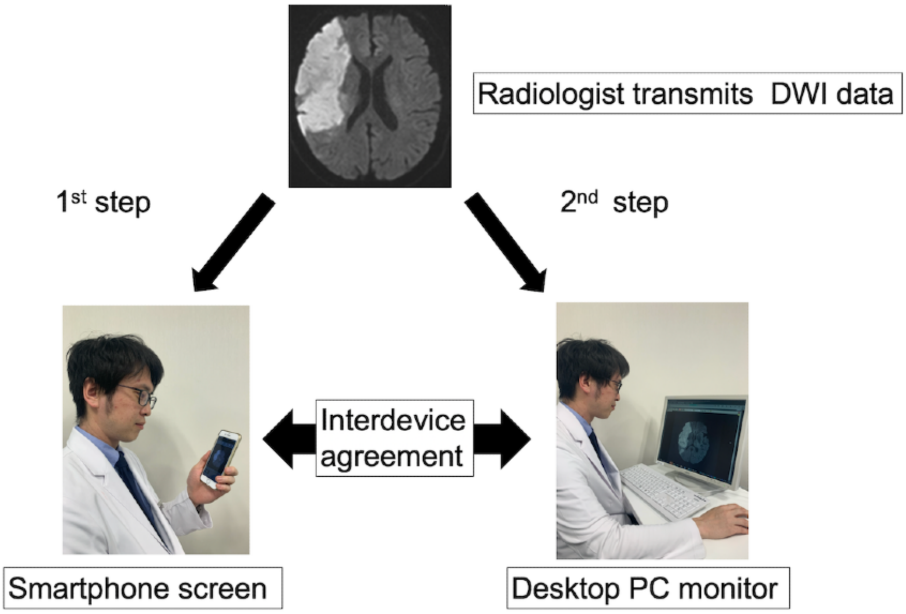
We evaluated the Join smartphone app (Allm Inc.), which was developed for use as a telemedicine app for health care professionals. The Join smartphone app leverages the easy-to-use interface of the social networking communication environment, such as SMS text messaging (Figure 1A) and, importantly, enables the stroke team to immediately share medical information such as diagnostic images (CT, MRI, and ultrasonography) and electrocardiograms as well as the results of blood tests (Figure 1B). Information sharing begins as soon as the emergency department is informed of an incoming potential stroke patient and continues as relevant personnel are called; the initial diagnostic and therapeutic orders are prepared, and senior staff are consulted if necessary. Following the acquisition of imaging studies, the images and radiological reports are shared. Additional details of the patient evaluation (including digital video recordings of clinical signs) can be requested and sent to the senior consulting staff. Following discussion among the team, the final management decisions are made before the patient is admitted to the stroke care unit. For purposes of security, no information is stored on any smartphone, and the app displays only the medical information and images that are streamed from the cloud server. On completion of the communication session, no discussion related to the patient remains on the smartphone.

Imaging

DWI was performed with a 1.5 T MRI unit (MAGNETOM Avanto/MAGNETOM Symphony, Siemens) using the following sequence: repetition time/echo time=2700/90 ms, section thickness=5 mm, section gap=1.5 mm, matrix=128x128, field of view=21 cm. Diffusion-Weighted Imaging–Alberta Stroke Program Early Computed Tomography Scores (DWI-ASPECTS) were defined using a scoring template comprising 2 axial DWI slices with markers for 10 anatomical regions [7,8]. We checked the entire sequence of DWI slices to calculate the score. Each patient was categorized as DWI-ASPECTS ≥7 or DWI-ASPECTS <7, according to the statement of the Japanese Society for Neuroendovascular Therapy for patients undergoing mechanical thrombectomy.

The study protocol was as follows (Figure 2). Two vascular neurologists (KS and TK) installed the Join smartphone app on their smartphones. After confirming operation of the app, a radiologist transmitted the DWI data of all patients to the vascular neurologists, in random order. As the first step, the vascular neurologists received the DWI data on their smartphones and independently scored DWI-ASPECTS for all patients using the Join smartphone app (JOIN-ASPECTS). The time for transfer of the DWI data was a few seconds. As the second step, vascular neurologists interpreted all DWI data on a desktop PC monitor and individually scored DWI-ASPECTS (PC-ASPECTS) a few days later. The vascular neurologists were blinded to the background and clinical information of all patients. We recorded the time taken for each vascular neurologist to complete DWI scoring for JOIN-ASPECTS and PC-ASPECTS**.** This study conformed to the ethical principles established in the Declaration of Helsinki, and the Institutional Review Board at the Jikei University School of Medicine approved the study protocol (no. 8813).

Figure 2. Study protocol. First, the vascular neurologists evaluated DWI-ASPECTS on a smartphone screen. Second, they evaluated DWI-ASPECTS on a desktop PC monitor. Interdevice agreement and interrater agreement were calculated for the same and for different devices. DWI-ASPECTS: Diffusion-Weighted Imaging–Alberta Stroke Program Early Computed Tomography Scores.



Statistical Analysis

To calculate interdevice (smartphone and desktop PC monitor) agreement, we prepared scatter diagrams for JOIN-ASPECTS and PC-ASPECTS. Scatter diagrams were created for all patients, including patients with major arterial occlusion and those without major arterial occlusion. Kappa statistics were used to calculate interdevice and interrater (vascular neurologists KS and TK) agreement.

We defined a component of interrater agreement among the vascular neurologists as the agreement rate of DWI-ASPECTS in each patient, for a DWI cutoff of ≥7 or <7. We evaluated interrater agreement between the vascular neurologists for the smartphone, the desktop PC monitor, and then for both the smartphone and the desktop PC monitor. Interrater agreement was assessed using 2x2 cross-tabulation.

Kappa scores were rated as follows: <0.20, poor agreement; 0.21-0.40, fair agreement; 0.41-0.60, moderate agreement; 0.61-0.80, favorable agreement; and 0.81-1.0, almost perfect agreement. *P*<.05 was considered significant. All statistical analyses were performed using SPSS for Windows, version 22.0 (IBM Corp.).

Results

We enrolled 111 patients (66% male; median age, 69 years; median NIHSS score on admission, 4). Table 1 lists the patients' clinical characteristics. Median DWI-ASPECTS was 9 (6-10), and 46 (41%) patients had major artery occlusion. The median elapsed time between symptom onset and DWI imaging was 270 min. Interdevice agreement between the smartphone and the desktop computer monitor was favorable (KS: κ=0.777, *P*<.001; TK: κ=0.787, *P*<.001) for all patients (Figures 3A and 3B). Interdevice agreement was also favorable for patients with and those without major arterial occlusion (Figures 4A, 4B, 5A, and 5B). The median elapsed interpretation times (from receiving the image to finishing interpretation) were similar for the Join smartphone app and the desktop PC monitor (KS: 1.7 min vs 1.6 min, *P*=.64; TK: 2.4 min vs 2.0 min, *P*=.14). Interrater agreement between the 2 vascular neurologists was favorable for the Join smartphone app (κ=0.710, *P*<.001; Multimedia Appendix 1) and the desktop PC monitor (κ=0.663, *P*<.001; Multimedia Appendix 2). Interrater agreement was also favorable between the 2 vascular neurologists for the different devices (KS using the Join smartphone app and TK using the desktop PC monitor: κ=0.663, *P*<.001; KS using the desktop PC monitor and TK using the Join smartphone app: κ=0.723, *P*<.001; Multimedia Appendices 3 and 4).

Discussion

Principal Findings

There were 3 major findings in this study. First, there was a high degree of interdevice and interrater agreement in terms of the vascular neurologists' neuroimaging findings between the smartphone and the desktop PC monitor among patients with acute stroke. Second, DWI-ASPECTS was favorable for smartphone–desktop PC monitor, desktop PC monitor–desktop PC monitor, and smartphone–smartphone. Third, the elapsed interpretation time for DWI-ASPECTS using the smartphone was similar to that for the desktop PC monitor. The smartphone was comparable to the desktop PC monitor concerning DWI in acute ischemic stroke patients.

Our study presents the following 2 original points. First, we evaluated neuroimaging using 2 different devices, a smartphone, and a desktop PC monitor. Telemedicine has been proposed for assessment and treatment of acute stroke patients, but few studies have investigated the reliability of telemedicine for neuroimaging assessment.

Previous reports of hub-and-spoke type telemedicine networks have shown the validity and reliability of a telestroke neuroimaging system (desktop PC monitor–desktop PC monitor) in differentiating between ischemic stroke and hemorrhage stroke [9-11]. To the best of our knowledge, this study was the first to confirm the diagnostic accuracy of neuroimaging accessed using a smartphone app. In addition, we investigated the agreement of DWI-ASPECTS for ischemic lesions. Measurement of ischemic core volume is essential for hyperacute stroke therapy [2]. According to the findings of the DAWN [2] and WAKE-UP [4] trials, DWI imaging should feature more prominently in assessment of the suitability of hyperacute ischemic stroke patients for treatments such as thrombolysis. Therefore, DWI-ASPECTS is a useful and important scale in hyperacute stroke care. The score and the specific DWI cutoff value should be determined and shared before thrombolysis and mechanical thrombectomy.

Our results were in line with those of previous studies that reported almost perfect interrater agreement [12-14]. According to the findings of the DAWN and WAKE-UP trials, the therapeutic time for thrombolysis can be extended if a mismatch in visibility of a lesion is found between DWI and fluid-attenuated inversion recovery. Thrombolysis with perfusion imaging using a contrast agent, as in the DEFUSE 3 trial [3], is limited to some special comprehensive stroke centers.

DWI-ASPECTS was carefully evaluated and shared among the physicians who participated in this study. We expect that in the near future, assessment by DWI-ASPECTS and sharing of this information using the smartphone app will become commonplace in the management of hyperacute stroke patients.

It is crucial in telemedicine to have a high degree of interdevice agreement for DWI-ASPECTS between the smartphone and PC monitor scores. Sharing information such as neuroimaging among vascular neurologists, emergency department staff, and paramedical staff enables the medical team to deliver IV rtPA and mechanical thrombectomy in the shortest possible time.

In this study, there was excellent physician acceptance and a high level of satisfaction with the smartphone app system. One difference in this study was that our proposed neuroimaging telemedicine service can be conducted smoothly using various devices rather than being limited to the conventional PC–PC system. The security of personal patient details in the Join smartphone app enables the stroke team to safely and rapidly share information that is important for acute stroke therapy. Thus, we consider that the use of a medical smartphone app would change the manner of communication among the members of the stroke team.

Many physicians currently use smartphones daily as a part of their clinical examinations [15]. The main requirements of a telestroke consultation are fast and accurate neurological assessment by a stroke specialist; a review of brain imaging; and formulation of the diagnosis and treatment plan, including assessment of eligibility for standard thrombolytic therapy and endovascular devices. Telemedicine carries a large burden regarding investment in equipment, which typically includes two or more PCs, a web camera, network system, and software. The Join smartphone app could be used in place of all of these components, as a standalone tool or as an adjunct to existing telemedicine technology. The widespread use of smartphones, coupled with widely available health care apps, could enable the affordable expansion of telestroke networks. In addition to the Join smartphone app, numerous other videoconferencing and teleradiology apps are available in the smartphone app marketplace, many of which could facilitate telestroke consultation in the manner described here.

Our results revealed no significant difference in the time required for neuroimaging interpretation between the smartphone and desktop PC monitor systems. The main requirements of a telestroke consultation are rapid and accurate neurological assessment; review of neuroimaging; and formulation of the diagnosis and treatment plan, including IV rtPA and mechanical thrombectomy. We estimated that using a smartphone could take time for a neuroimaging evaluation, because this is a possibility due to a time lag resulting from connection issues. However, we found no delay in the time required for a neuroimaging review between the wireless connection by smartphone app and the wired connection by desktop PC monitor.

Smartphones are in common use by many physicians and already contribute to decisions made in medical treatment. We believe that the advantages of using a smartphone app are its portability and faster time to access to target neuroimages. Usually, stroke neurologists are not necessarily in front of a desktop or laptop computer. If an evaluation were requested, a stroke neurologist would need a certain amount of time to reach the computer, boot up the computer, log in to a network with a tight security system, and finally start browsing the images using a picture archiving and communication system. Using a smartphone app can solve the problem of the amount of time it takes a neurologist to evaluate neuroimaging by skipping these processes. Supplementation of the app with neuroimaging software has the potential to transform the smartphone into a complete tool for acute stroke evaluation. The Join smartphone app can play an important role in teleconsultation even when the stroke team comprises members who are located outside the hospital and who cannot access a desktop PC monitor.

There are several limitations in this study. First, the 2 vascular neurologists who evaluated the neuroimages have extensive clinical experience. It would be necessary to evaluate the interpretations of those physicians who have less experience. Second, we restricted our evaluation to neuroimaging of an anterior circulation stroke. It may be more difficult for vascular neurologists to detect a small infarction in the brain stem [16,17]. If applicable, axial and sagittal DWI should be routinely examined. Finally, our relatively high DWI-ASPECTS values compared with those of previous investigations [12-14] suggest the influence of high interdevice and interrater agreement in our results.

Conclusion

The Join smartphone app enabled stroke neurologists to estimate DWI-ASPECTS accurately and rapidly. We demonstrated the usefulness of the app in facilitating management of acute stroke using a system that offers sharing of images and discussion across different devices, in the manner of a social networking service.

Abstract

Background: There is increasing information characterizing menstrual cycle length in women, but less information is available on the potential differences across lifestyle variables.

Objective: This study aimed to describe differences in menstrual cycle length, variability, and menstrual phase across women of different ages and BMI among a global cohort of Flo app users. We have also reported on demographic and lifestyle characteristics across median cycle lengths.

Methods: The analysis was run based on the aggregated anonymized dataset from a menstrual cycle tracker and ovulation calendar that covers all phases of the reproductive cycle. Self-reported information is documented, including demographics, menstrual flow and cycle length, ovulation information, and reproductive health and diseases. Data from women aged ≥18 years and who had logged at least three cycles (ie, 2 completed cycles and 1 current cycle) in the Flo app were included (1,579,819 women).

Results: Of the 1.5 million users, approximately half (638,683/1,579,819, 40.42%) were aged between 18 and 24 years. Just over half of those reporting BMIs were in the normal range (18.5-24.9 kg/m^2; 202,420/356,598, 56.76%) and one-third were overweight or obese (>25 kg/m^2; 120,983/356,598, 33.93%). A total of 16.32% (257,889/1,579,819) of women had a 28-day median cycle length. There was a higher percentage of women aged ≥40 years who had a 27-day median cycle length than those aged between 18 and 24 years (22,294/120,612, 18.48% vs 60,870/637,601, 9.55%), but a lower percentage with a 29-day median cycle length (10,572/120,612, 8.77% vs 79,626/637,601, 12.49%). There were a higher number of cycles with short luteal phases in younger women, whereas women aged ≥40 years had a higher number of cycles with longer luteal phases. Median menstrual cycle length and the length of the follicular and luteal phases were not remarkably different with increasing BMI, except for the heaviest women at a BMI of ≥50 kg/m^2.

Conclusions: On a global scale, we have provided extensive evidence on the characteristics of women and their menstrual cycle length and patterns across different age and BMI groups. This information is necessary to support updates of current clinical guidelines around menstrual cycle length and patterns for clinical use in fertility programs.

Introduction

Background

For more than 30 years, the notion has been that the average woman is potentially fertile between days 10 and 17 of her 28-day menstrual cycle. However, this assumes that ovulation occurs exactly 14 days before the onset of the next menstrual period and that the fertile window extends before and after ovulation [1]. Data on aggregated cycles show mean cycle lengths of 28 to 29 days [2,3] and 29 to 30 days [4-7]. Other studies reporting on the number of women and their cycle length have demonstrated that 77% of women in the United States and Canada have a cycle length of 25 to 31 days [5]; 65% of rural Chinese women have a cycle length of 27 to 29 days [8]; and 84% of Australian women have a cycle length of 26 to 34 days [9]. Few studies also reported on the estimated day of ovulation, demonstrating an estimated day of ovulation at day 14 in only 3% to 10% of cycles [10] and at day 15 in 12% to 16% cycles [10].

Landmark longitudinal [7,11] and cross-sectional [5] studies on menstrual cycle variability in the late 1960s and 1970s demonstrated that the majority of women had a cycle length between 15 and 45 days [5,7,11], with mean cycle lengths decreasing with increasing age. Subsequent studies have reported similar findings with a shorter cycle length and less variability with increasing age [3,12,13]. Studies among Western populations have shown that longer menstrual cycles were associated with a higher BMI [14], increased parity [14], and recent use of oral contraceptives [15], whereas shorter menstrual cycles were associated with smoking [14,16], heavy caffeine intake [17], and alcohol consumption [18]. There is much less information on other lifestyle and behavioral factors; however, women reporting depression, higher perceived stress levels, and high levels of physical activity were associated with having irregular periods, anovulation, and heavier menstrual bleeding [19-22], highlighting the impact that a range of modifiable factors may have on future fertility. Additionally, although early studies with small sample sizes show measures of obesity and body composition associated with menstrual cycle irregularities [23-26], the specific impact of BMI has not been clearly determined. This is important given the global increase in BMI, of which the rise in obesity prevalence has been most prominent in women of reproductive age [27].

For the past 10 years, hundreds of smartphone apps have been developed for women to track their menstrual cycles, ovulation and fertile days, and health information [4,28-32]. A calendar-based method app used with 949 women indicated a mean 28-day cycle (range 17-35 days), with the most likely day of ovulation being day 16 [33], and in 45,360 women using the *Ovia Fertility* app, the mean cycle length was 30.4 (SD 4.6) days [34]. In over 600,000 cycles collected using the *Natural Cycles* app, the mean cycle length was 29.3 (SD 5.2) days [4], and in 225,596 cycles, the mean cycle length was 29.6 (SD 5.4) days [35]. Despite this surge in population data of menstrual cycle length, information on *individual women* is lacking rather than aggregates of cycle length, and it remains unclear how many women actually have an *average* 28-day cycle. Furthermore, the characteristics of women according to cycle length and lifestyle are limited.

Objectives

This study aimed to describe differences in menstrual cycle length, variability, and menstrual phase across women of different ages and BMIs. We also reported on demographic and lifestyle characteristics across the median cycle length. The study analyses will provide extensive worldwide evidence on the characteristics of menstrual cycle length and patterns among a global cohort of Flo app users. This information is necessary to support recommendations within current obstetric clinical guidelines around menstrual cycle length and patterns for clinical use in fertility programs.

Methods

Data Collection

The data were collected through the mobile period tracking and ovulation calendar called Flo, which was launched in October 2015. Users of the Flo app are found in over 200 countries, but the vast majority of them are located in Europe and North America. Flo’s privacy policy and terms of use permit the use of aggregated and anonymized data for research purposes. Data collection for this study started in December 2018 and extracted from 2 million users aged ≥18 years. Women were not included if they had logged a pregnancy, oral contraceptive reminders, and had recorded less than 3 menstrual cycles, which was the minimum number needed to obtain median cycle data. This resulted in a cohort of 1,579,819 women.

App Content

The participants' ages were collected through the mandatory sign-up questionnaire, and BMI was calculated for women who reported their weight (the latest input was used) and height. Additional information was collected from the user in 2 ways: (1) by tracking the symptoms that users log themselves and (2) by survey answer questions. For example, the user can log information on cycle length, period length and intensity, and days of the luteal phase. The survey information that users can report includes a range of questions regarding diet, lifestyle (general well-being, sleep, sexual activity, physical activity, stress, alcohol), menstrual cycle symptoms, and reproductive health information. Manually logged information reported in the current analyses included information on weight (in kilogram, logged manually), menstrual flow (light, medium, heavy), smoking status (regularly, sometimes, do not smoke), alcohol consumption (≥3 times a week, 1-2 times a week, <2-3 times a month, none), frequency of high stress (≥3 times a week, 1-2 times a week, <3 times a month, none), frequency of physical activity (≥3 times a week, 1-2 times a week, <3 times a month, none), relationship status (married or stable partner, single, no partner), months trying to conceive (<1 month, 1-3 months, 3-6 months, >6 months to 1 year, >1 year), number of children (0, 1, or 2, ≥3), and any reproductive disorders (yes, no, I don't know).

Menstrual Cycle Characteristics

Women manually logged information about their menstrual cycles (days of menstruation), including the intensity of menstrual flow (light, medium, heavy). The start and end dates of menstrual cycles were defined by the logged first day of menstruation. To estimate mean and median cycle lengths, we computed intrawomen inputs and then calculated the mean and median for population groups.

Menstruation flow calculation was completed for every cycle for each woman. If the length of a period was 1 or 2 days, it was calculated as low, but for a length of ≥3 days with more than half of the days logged with the intensity, it was calculated as light (L)=1, medium (M)=2, heavy (H)=3, none=no data. These numbers were arbitrary, as there is no measure of the volume of blood loss during menstruation. The average was computed for all bleeding days per cycle (eg, bleeding days: LMHHML=1+2+3+3+2+1=12 divided by 6=2=M). If the average was <1.5, it was recorded as light. If the average was ≥1.5 to <2.4, it was recorded as medium, and if the average was ≥2.4, it was recorded as heavy flow. In the case of ≥3 days logged and <50% days with reported intensities, it was considered as not tracked. Calculations were performed for all cycles that were logged by each woman.

Ovulation was recorded in women who reported a positive luteinizing hormone (LH) test, signifying the end of the follicular phase, and the next day estimated ovulation. In the case of multiple results logged, the last one was used. The length of the follicular phase was estimated from the first day of the menstrual cycle up to and excluding the day of ovulation. The length of the luteal phase was defined as the period from the day of ovulation up to and excluding the first day of menstruation.

The cycle length variation was calculated as the expected value of the mean square deviation, that is, var(x)=E[(x-mu)2], where E[.] is expectation and mu=E[x].

Results

Participant Characteristics

The data from over 1.5 million nonpregnant women who were not using oral contraceptives and who had logged at least 3 cycles (N=1,579,819) were included in the study (Table 1). The number of women with 2 completed and 1 current cycle was 123,245, with 3 to 10 cycles (n=819,933), 11 to 20 cycles (n=450,096), 21 to 30 cycles (n=154,536), and ≥31 cycles (n=32,009). Overall, the women were young, did not smoke, and rarely consumed alcohol but were mostly sedentary. That is, approximately half (638,683/1,579,819, 40.42%) of the users were aged 18 to 24 years. Only 22.57% (356,598/1,579,819) of the women reported their height and weight (to determine BMI); over half had a BMI in the normal range of 18.5 to 24.9 kg/m^2 (202,420/356,598, 56.76%) and one-third (120,983/356,598, 33.93%) were overweight or obese. About half of the total population reported their smoking, alcohol, and physical activity habits, of which 25.73% (192,118/746,396) smoked, 25.10% (186,378/742,615) consumed alcohol ≥1 time per week, and 45.36% (363,314/800,870) did not engage in physical activity.

Menstrual Cycle Length and Characteristics

In all, 91.13% (1,439,613/1,579,819) of women had a median cycle length of 21 to 35 days, whereas 89.04% (1,406,643/1,579,819) had an average cycle length of 21 to 35 days. A total of 0.17% (2614/1,579,819) had a short cycle length (<21 days), and 8.60% (135,824/1,579,819) had a long cycle length (>35 days). The percentage of women with a median 27-day, 28-day, and 29-day cycle length was 12.05% (190,373/1,579,819), 16.32% (257,889/1,579,819), and 12.11% (191,351/1,579,819), respectively. Table 2 describes the demographic and lifestyle characteristics of the women, split by median cycle length. A higher percentage of women with short cycles reported having high stress ≥3 times/week (448/1117, 40.10%) and performing no physical activity (622/1158, 53.71%) compared with women with normal and long cycles. A higher percentage of women with short cycles had a lighter menstrual flow (240/476, 50.4%) compared with women with normal (37,469/172,025, 21.78%) and long cycles (6462/25,078, 25.77%). Consumption of alcohol or smoking status did not appear to influence menstrual cycle length (Table 2).

Figures 1 and 2 show the median cycle length distribution by age and BMI, respectively. In women aged 35 to 39 years and ≥40 years, more than 16% had a median cycle length of 27 days, compared with 9.6% of women aged 18 to 24 years. Comparatively, <8% of women aged 35 to 39 years and ≥40 years had a median 30-day cycle length compared with 10.8% of women aged 18 to 24 years. For BMI <50 kg/m^2, the highest percentage of women had a 28-day median cycle (15%-18%) and tended to track similarly across BMIs for shorter and longer day cycles (Figure 2). There were 592 women (0.17% of all women) with a BMI of ≥50 kg/m^2; the highest percentage had a median 29-day cycle (n=80, 13.6%). A higher percentage of women with a BMI of 35 to 50 kg/m^2 (11.6%) and >50 kg/m^2 (11.7%) had a median cycle of 36 days or more, compared with between 7.5% and 9.6% for the lower BMI categories.

Table 2. Demographic and lifestyle characteristics across median cycle length.

Characteristics	Short cycle (≤20 days), n (%)	Normal cycle (21-35 days), n (%)	Long cycle (≥36 days), n (%)
Age (years)[a]			
18-24	1255 (48.01)	556,541 (39.57)	80,887 (47.42)
25-29	634 (24.25)	334,817 (23.80)	47,728 (27.98)

Cycle Length Variability

Figure 3 illustrates the variation in cycle length for all women and for each age group. Among all women, 25.37% (275,715/1,086,923) had a cycle length variation of 0 to 1.5 days and 69% (753,831/1,086,923) of women had a <6-day variation. Variation in cycle length of 1.5 to 4.5 days was more common for women aged ≥35 years than for women aged <29 years, and this was particularly prominent at 1.5 days variation. That is, in women aged 35 to 39 years, and ≥40 years, a 1.5-day variation in cycle length was found in 25.17% (27,754/110,252) and 26.64% (14,255/53,502) of women, respectively, compared with 18.08% (63,314/350,021) and 20.12% (45,683/227,109) of women aged between 18 and 24 years and 25 and 29 years, respectively. Normal cycle variation between 3 and 4.5 days was also higher in women aged between 35 and 39 years (16.11%; 17,761/110,252) and ≥40 years (16.85%; 9015/53,502) compared with women aged between 18 and 24 years (13.38%; 46,817/350,021) and 25 and 29 years (14.17%; 32,185/227,109). Comparatively, a variation of ≥6 days was more prominent in the younger women and tracked similarly with increasing age. Across BMI groups, women with a higher BMI tended to have less variation in their cycle. This was particularly evident with a cycle variation of ≥4.5 days, where there were fewer women with a higher BMI and more women with a low BMI (<18 kg/m^2; Figure 4).

Figure 3. Variation in cycle length across age group.

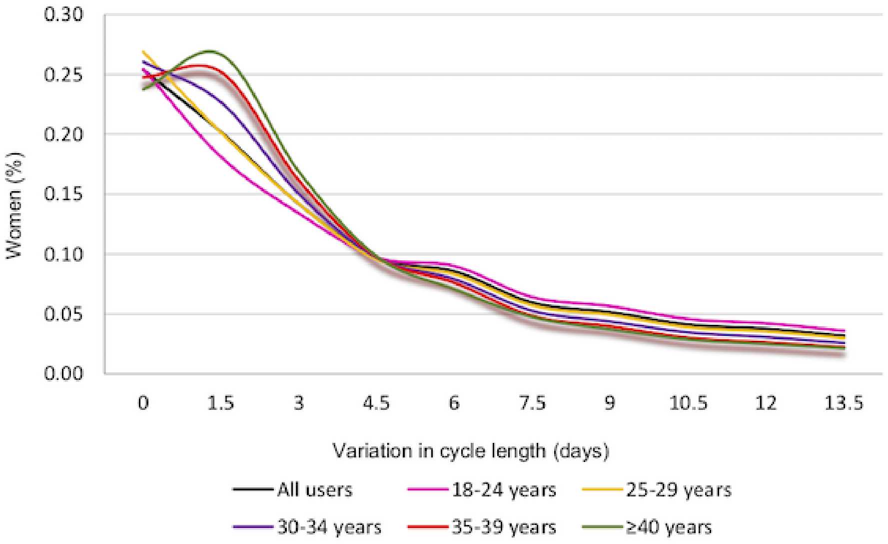

Figure 4. Variation in cycle length across BMI categories.

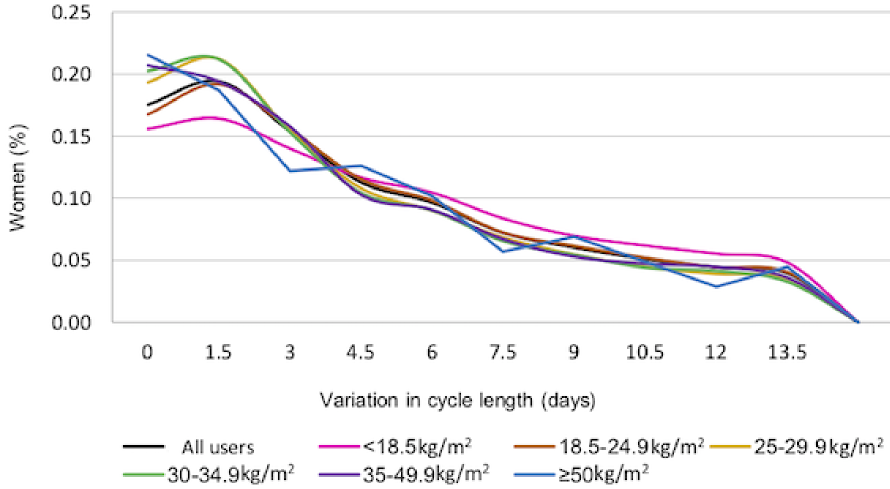

Ovulation and Phases of the Menstrual Cycle

There were 18,761 cycles with positive LH ovulation tests, signifying the end of the follicular phase, and the following day to be the day of estimated ovulation. The highest percentage of cycles was at an estimated ovulation day 14 (13.08%, 2509 cycles; Table 3), indicating a 13-day follicular phase (Multimedia Appendix 1). There was a similar percentage of cycles with estimated ovulation at day 13 (2248 cycles, 12.13%) and day 15 (2267 cycles, 11.96%). The number of cycles with estimated ovulation continued to reduce outside these days. Across age groups (Multimedia Appendix 2), the highest percentage of cycles was at an estimated ovulation day 15 for women aged between 18 and 24 years (187/1687 cycles, 11.08%), day 14 for women aged between 25 and 39 years (2108 cycles, 12%-15%), but at day 12 for women aged 40 years (237/1594 cycles, 14.9%). Across BMI categories (Multimedia Appendix 3), more frequent positive ovulation tests occurred at day 14, indicating a 13-day follicular length, except for a BMI of 35 to 49.9 kg/m^2, which was highest at day 13 (80 cycles).

The length of the luteal phase was highest at day 15, with 16.96% (3696/21,788) of the cycles, followed by a 14-day luteal phase, with 16.17% (3523/21,788) of the cycles (Table 4). The number of cycles reduced to around 12% at a 13-day and 16-day luteal phase length and dropped to 6% to 7% at a 12-day and 17-day luteal phase length. The luteal phase length across age and BMI are reported in Multimedia Appendices 4 and 5, respectively. For all age groups, the number of cycles was highest for a 15-day luteal phase length, followed by a 14-day luteal phase length. There was a higher percentage of cycles with shorter (5 to 10 day) luteal phases among the youngest compared with the higher age groups, but for a luteal phase of 13 to 16 days, more cycles were present in the age group of 25 years. Comparatively, there was a higher percentage of cycles from women aged ≥40 years that had longer luteal phases (≥15 days; Multimedia Appendix 4). A luteal phase length of 15 days was most common across all BMI categories except for the 30.0 to 34.9 kg/m^2 category, which was at a length of 14 days. Overall, the percentage of cycles tended to track similarly across BMI categories; however, there tended to be a higher percentage of cycles with a luteal phase of 11 to 13 days from overweight (25.0 to 29.9 kg/m^2) and obese (30.0 to 50.0 kg/m^2) women compared with the other BMI categories (Multimedia Appendix 5).

Discussion

Principal Findings

We have reported recent and comprehensive data characterizing over 1.5 million women and their menstrual cycle patterns. Approximately two-thirds of women using the app were aged <30 years and one-third were overweight or obese based on their BMI. The majority of women (1,439,613/1,579,819, 1.13%) had a usual median cycle length of 21 to 35 days, of whom 16.32% (257,889/1,579,819) had a median cycle length of 28 days. Shorter cycles with less variation were more common for women ≥40 years. Among women who reported short cycles, a higher percentage reported higher stress levels, no physical activity, and a lighter menstrual flow in comparison with women with normal or long cycles. There were only subtle differences in length and variability across BMIs; however, women with the lowest BMI tended to have the highest variation in cycle length and more women with a BMI >35 kg/m^2 had a median cycle of 36 days and longer.

Strengths and Limitations

The reporting of menstrual cycle length and patterns was estimated from mobile phone data collected from women using the app. Although this app has a global reach of 100 million women using the app, and 30 million active users monthly, not all women reported on their BMI or other lifestyle characteristics. This means these findings cannot be generalized to all women using the app. Recently, a review of pregnancy apps and their use in culturally and linguistically diverse women found that engagement with apps may be lower in areas of higher social disadvantage, cultural and language barriers, and health literacy [36]. This study did not ask about reasons for using the app (except if it was to become pregnant); thus, it is unclear whether women who provided more demographic and fertility details have a different level of knowledge or interest in reproductive health. We did not have data to assess cultural disparities across menstrual cycle characteristics, which would be valuable in future research. Information on cycle intensity was self-reported based on subjective feelings of *light*, *medium*, and *heavy* flow; objective measures of menstrual flow would improve the accuracy of cycle intensity. We used the data on women to assess menstrual cycle characteristics, but also used the number of cycles to assess ovulation. Understanding the characteristics of women that contribute to anovulatory cycles would provide important information on other potential issues with fertility. Among women who have reproductive health issues, including polycystic ovary syndrome or endometriosis, the ability to become pregnant may already be reduced. An app estimating ovulation or suggesting the most fertile period for those women may be limited in its effectiveness.

The strengths of this study include the very large cohort of women providing fertility information, along with data on a high number of ovulatory cycles. The Flo app uses artificial intelligence–based algorithms, and when additional data, such as basal body temperature and ovulation data, are entered, the predictive ability improves. Comparatively, calendar-based apps may only use simulated 28-day cycles to estimate ovulation, or predictive methods may be used; for example, the standard days method, where users avoid unprotected intercourse during cycle days 8 through 19 [37] or the rhythm method, which predicts fertile days using a formula and is based on data from the menstrual records of the past 6 cycles [6]. They do not provide information on how the predictions are calculated or the accuracy of predictions.

Comparison With Prior Work

Imperative to our study is that we assessed *individual* women, and we report on the number and percentage of women and median menstrual cycle length. Our results are useful in the clinic setting and provide information on the actual occurrence of cycle data in women but also differences in cycle patterns across age groups, BMI, and some lifestyle characteristics. Importantly, we show that a cycle length of 28 days is not common for many women, which is usually the reference length for a typical woman. Comparatively, previous analyses among women using fertility apps or cohort studies have reported that the mean or median cycle length for all women ranged between 28 and 30 days [8,11,33,34], and studies reporting on actual cycles reported means between 27.7 and 29.6 days [2,4,5,7,35]. These results cannot be extrapolated to an individual woman, and clinically, it is not helpful, as we have clearly demonstrated that the percentage of women with an average cycle length of 28 days is uncommon. Our results provoke a potential paradigm shift, changing our thinking from the current concept of mean cycle length to frequencies of cycle length in individual women.

Our results are consistent with previous studies reporting on shorter cycle lengths with increasing age [3-5,11], but also less variation with older age [5,13]. Additionally, there is a dependence between age and length of the luteal phase. Only a small number of cycles were assessed in our luteal phase data, but our results are partly consistent with the study by Lenton et al [12] showing a higher incidence of shorter cycles in the youngest women (18-24 years) but also the oldest women aged between 45 and 50 years. A recent study by Bull et al [4] using a fertility app did not show any difference in the luteal phase across age groups. Such differences are likely because of the assessment of this phase, and when using an app, one that includes thermal changes, but also objective markers of ovulation are more likely to provide accurate information.

Epidemiological evidence has demonstrated the adverse effects of obesity on female reproduction, including anovulation and menstrual cycle irregularities [24,25,38], impaired pregnancy success using assisted reproductive technology, and infertility [39]. Furthermore, mechanistic studies have confirmed alterations in reproductive hormones associated with obesity [40]. Small studies demonstrated body composition measures associated with menstrual cycle irregularities [23-26], and an Australian study of 726 women was the first to show that obese women were twice as likely to have greater cycle variation (>15 days) compared with women with a normal weight [9]. In a recent app study using >600,000 cycles, there were no differences in the percentage of cycles across BMI categories, except morbidly obese women had higher cycle length variation by 0.4 days and longer follicular phase length by 0.9 days, than women with a normal BMI [4]. The current analysis revealed that median menstrual cycle length and length of follicular and luteal phases were not remarkably different with increasing BMI, except for the heaviest women at a BMI of ≥50 kg/m^2. It is interesting to note that of the over 1.5 million women in the study, only 22.57% (356,598/1,579,819) reported height and weight to calculate BMI. Although this might demonstrate some information bias such that our findings may systematically underestimate the relationship between BMI and menstrual cycle, the proportion of women who were overweight or obese (33.93%) in this study is similar to the current prevalence rates in the general and reproductive population of women [27,41]. Thus, the effect of BMI on menstrual cycle length may be mediated by other factors that we did not assess in our descriptive study. Given the inconsistent findings and lack of clear association between BMI and menstrual cycle characteristics in large cohorts of women (rather than data on cycles), further investigation into this area is needed.

This is the largest analysis to report on physical activity, stress, and menstrual flow across short, normal, and long menstrual cycle lengths. Interestingly, shorter cycles were associated with a higher frequency of high stress, no physical activity, and lighter menstrual flow. There is limited information on stress and physical activity, but research to date suggests that professional and high-frequency training impairs ovarian activity, which may manifest as luteal phase defects, irregular menstruation, or amenorrhea [42-44]. In nontrained women aged 18 to 44 years, total recreational physical activity and vigorous recreational activity were positively associated with cycle length, but not cycle variability [45]. Regarding sedentary behavior, among 2613 nulliparous Danish women, those who were sedentary (ie, <5 metabolic equivalents [METs] per week of physical activity), had a higher prevalence of irregular cycles than women who engaged in moderate levels of activity (20 to 39 METs per week; probability ratio 1.54; 95% CI 1.16-2.04) [46]. Small cross-sectional studies have shown that higher stress is a significant predictor of irregular menstrual cycles [47] and dysmenorrhea [48]. Although these findings support the benefits of moderate physical activity and minimizing stress, further investigation into the impact of lifestyle factors on menstrual cycle characteristics is necessary.

The current findings have clinical implications for women who are trying to conceive but also for women with different lifestyle characteristics. First, current estimations for conceiving are based on the premise of a 28-day cycle with ovulation on day 14. We demonstrated that only 16% of women had a median 28-day cycle. Our results invoke a fundamental change in the assessment of cycle lengths of individual women and that the population mean cycle length may no longer be an applicable form of its measurement. Second, few menstrual cycle differences were seen in women with different BMIs. Finally, lifestyle factors such as physical activity and stress may relate to cycle length and therefore the potential day of ovulation. Prediction models, including menstrual cycle data as well as age and lifestyle factors, could be developed to predict the likelihood of pregnancy success. The use of such models would be helpful in the clinic setting to optimize conception, particularly in those who do not have regular cycles.

Conclusions

On a global scale, we have provided extensive evidence on the characteristics of women and their menstrual cycle length and patterns. We demonstrate that the typical average 28-day cycle length is not common for a high percentage of women, and only 13.08% of cycles had an estimated ovulation on day 14. Age appeared to be a more important factor than BMI in terms of menstrual cycle length and variability. Our data provide important information on the necessity for an individualized approach to support reproductive health and fertility, and modifiable factors such as physical activity and stress should additionally be considered when planning a pregnancy. Future work could extend these findings by addressing cultural and ethnic diversities in relation to menstrual cycle patterns.

Acknowledgments

The authors gratefully acknowledge the members of the Flo team, Anna Targonskaya, Natalia Kukharchyk, Anna Klepchukova, and Andrei Zhabinsk, who generated the results and allowed the authors to make use of the data. Without them, this paper would not have been possible. The authors appreciate their guidance and assistance with the results and the overall paper.

Authors' Contributions

JG and RN contributed substantially to the conception and design of the study. JG wrote the first draft of the manuscript. All authors read the final draft of the manuscript and revised it critically for its intellectual content. All authors read and approved the final manuscript.

Abstract

Background: Discontinuation of contact lens use is mainly caused by contact lens–associated dry eye. It is crucial to delineate contact lens–associated dry eye's multifaceted nature to tailor treatment to each patient's individual needs for future personalized medicine.

Objective: This paper aims to quantify and stratify individual subjective symptoms of contact lens–associated dry eye and clarify its risk factors for future personalized medicine using the smartphone app DryEyeRhythm (Juntendo University).

Methods: This cross-sectional study included iPhone (Apple Inc) users in Japan who downloaded DryEyeRhythm. DryEyeRhythm was used to collect medical big data related to contact lens–associated dry eye between November 2016 and January 2018. The main outcome measure was the incidence of contact lens–associated dry eye. Univariate and multivariate adjusted odds ratios of risk factors for contact lens–associated dry eye were determined by logistic regression analyses. The t-distributed Stochastic Neighbor Embedding algorithm was used to depict the stratification of subjective symptoms of contact lens–associated dry eye.

Results: The records of 4454 individuals (median age 27.9 years, SD 12.6), including 2972 female participants (66.73%), who completed all surveys were included in this study. Among the included participants, 1844 (41.40%) were using contact lenses, and among those who used contact lenses, 1447 (78.47%) had contact lens–associated dry eye. Multivariate adjusted odds ratios of risk factors for contact lens–associated dry eye were as follows: younger age, 0.98 (95% CI 0.96-0.99); female sex, 1.53 (95% CI 1.05-2.24); hay fever, 1.38 (95% CI 1.10-1.74); mental illness other than depression or schizophrenia, 2.51 (95% CI 1.13-5.57); past diagnosis of dry eye, 2.21 (95% CI 1.63-2.99); extended screen exposure time >8 hours, 1.61 (95% CI 1.13-2.28); and smoking, 2.07 (95% CI 1.49-2.88). The t-distributed Stochastic Neighbor Embedding analysis visualized and stratified 14 groups based on the subjective symptoms of contact lens–associated dry eye.

Conclusions: This study identified and stratified individuals with contact lens–associated dry eye and its risk factors. Data on subjective symptoms of contact lens–associated dry eye could be used for prospective prevention of contact lens–associated dry eye progression.

Introduction

Contact lens (CL) wear is an established and efficient method for improving vision quality by correcting refractive errors. More than 140 million estimated CL users exist worldwide [1]. However, despite available CL products on the market, studies show that 12% to 58% of CL users discontinue CL use due to CL discomfort (CLD) [1-6]. Additionally, many continue using CLs while feeling CLD.

Dry eye disease (DED) is characterized by a tear film disorder, potentially causing ocular surface damage and ocular discomfort [7,8]. DED is becoming more prevalent due to aging society and increased digital device usage [9-13]. Accumulating studies indicate that dryness is one of the main reasons for CLD [2,3,8]; 68% to 79% of CL users have reported feeling dryness [14-16], and CL use especially is a risk factor for severe DED [17,18]. CL-associated dry eye (CLADE) may be caused by changes of tear film stability on the CL surface, decrease in the tear exchange rate, decrease in reflex secretion due to perception decline, oxygen deprivation, lens deposits, and adverse reactions to CL solutions [5]. Suggested CLADE risk factors, including environmental and host factors, and lifestyle habits are related [1,19-21]; thus, a comprehensive, multidisciplinary mass customization is needed in individual CLADE treatments. Accordingly, it is crucial to understand CLADE's multifaceted nature by monitoring various symptoms and visualizing patient lifestyle practices to improve the CL users' quality of vision through personalized treatment [22,23]. Notably, a smartphone app could effectively monitor subjective symptoms and lifestyle habits, check changes in each factor's contribution, and visualize each individual’s lifestyle [22]. The collected medical data could help lay the foundation for understanding how individual factors contribute to the aggravation of CLADE.

To reveal and simplify how multiple factors intertwine to affect CLADE's progression, we conducted this large-scale crowdsourced study using the DryEyeRhythm app (Juntendo University) to quantify and stratify the symptoms of CLADE and collect evidence for prospective prevention of CLADE progression.

Methods

Study Enrollment and Participants

The DryEyeRhythm app's development and the study's enrollment process have been previously described [18,24,25]. Briefly, DryEyeRhythm was developed using Apple Inc’s open-source framework, ResearchKit. DryEyeRhythm was released on Apple’s App Store in Japan on November 2, 2016, and in the United States in April 2018 [18]. Prospective participants can download the app using their own App Store credentials. This large-scale, crowdsourced, prospective, cross-sectional observational study was conducted between November 2, 2016, and January 12, 2018. All users provided electronic informed consent for participation following explanation of the study's nature and possible consequences. Duplicate users, foreign participants (outside of Japan), and users who did not complete all surveys were excluded. This study was approved by the Independent Ethics Committee of Juntendo University Faculty of Medicine (approval number 19-226) and adhered to the tenets of the Declaration of Helsinki. The methodology and results of this survey are reported according to the checklist for reporting results of internet e-surveys [26].

User Data Collection

Using DryEyeRhythm, data on participant demographics, medical history, lifestyle habits, daily subjective symptoms, Ocular Surface Disease Index (OSDI) scores (Allergan), and Zung Self-Rating Depression Scale (SDS) scores were collected [27-29]. Multimedia Appendices 1 and 2 show specific questions and parameters used for data collection. Data that were recorded included basic demographic characteristics, including age, sex, height, body weight, race, and geographic location; medical history of hypertension, diabetes, systemic disease, mental illness, past diagnosis of DED, hay fever, and ophthalmic surgeries; and lifestyle habits, including daily coffee intake, CL information (such as the type of CL, period of CL use, and daily duration of CL use), eye drop use, screen exposure time, periodic exercise, sleep duration, smoking, and hydration. Daily subjective symptoms included eye itching, asthenopia, headache, mental fatigue, stiffness, and stress.

Classification of CLADE

Participants were divided into the following 2 groups: non-CLADE and CLADE. Those who reported current use of CL and had an OSDI total score <13 were included in the non-CLADE group. Those who reported current use of CL and had an OSDI total score ≥13 were included in the CLADE group.

The OSDI questionnaire is a 12-item questionnaire used to assess DED severity based on ocular symptoms, impact on visual functioning, and environmental triggers [27,29]. The overall OSDI total score was determined based on a 100-point scale correlated with the severity of symptoms [30]. We previously demonstrated that the Japanese version of OSDI with DryEyeRhythm had good validity compared with that with the paper-based questionnaire [18,29,31].

Depressive symptoms were evaluated using SDS [28]. The SDS is an internationally used 20-item self-administered depression scale and has been validated in Japan. Each item is rated on a 4-point Likert scale, with a total score ranging from 20 to 80. An SDS score of ≥40 is possibly suggestive of depression [32,33].

Statistical Analysis

Continuous variables (not normally distributed based on Shapiro-Wilk tests) are presented as medians (with interquartile ranges), and categorical variables are presented as percentages. We conducted Mann-Whitney U tests for continuous variables not normally distributed and chi-square tests for categorical variables. A comparison between negative, current, and past CL use groups was performed by one-way analysis of variance using a Bonferroni post hoc test. The odds ratio of each risk factor for CLADE was determined by multivariate adjusted logistic regression analysis, which included factors significantly associated with CLADE, as indicated by the univariable logistic regression analyses with a threshold 2-tailed, unpaired *P* value of .05. Pearson’s rank correlation coefficients were calculated to determine the correlation between each subjective symptom and CLADE. A heatmap was then made using the heatmap function of the seaborn module (version 0.9.0; Python 3). A t-distributed Stochastic Neighbor Embedding (t-SNE) was performed with a scikit-learn Python package (version 0.21.3; Python 3) [34]. *P* values were considered statistically significant at *P*<.05, *P*<.01, or *P*<.001. All data were analyzed with Stata (version 15; Stata Corp) software.

Results

Application Downloads and Clinical Study Enrollment

As seen in Figure 1, DryEyeRhythm was cumulatively downloaded 18,991 times between November 2, 2016, and January 12, 2018. As Figure 2 shows, a total of 21,394 records were identified in our crowd database; 11,485 and 5455 records were excluded from the study because of duplicate user data and incomplete survey responses, respectively. Finally, 4454 out of 9909 participants (44.95%) completed the survey and were included in the final analysis. Multimedia Appendix 3 shows the sensitivity analysis between included and excluded participants.

Figure 1. Trends in the number of downloads.

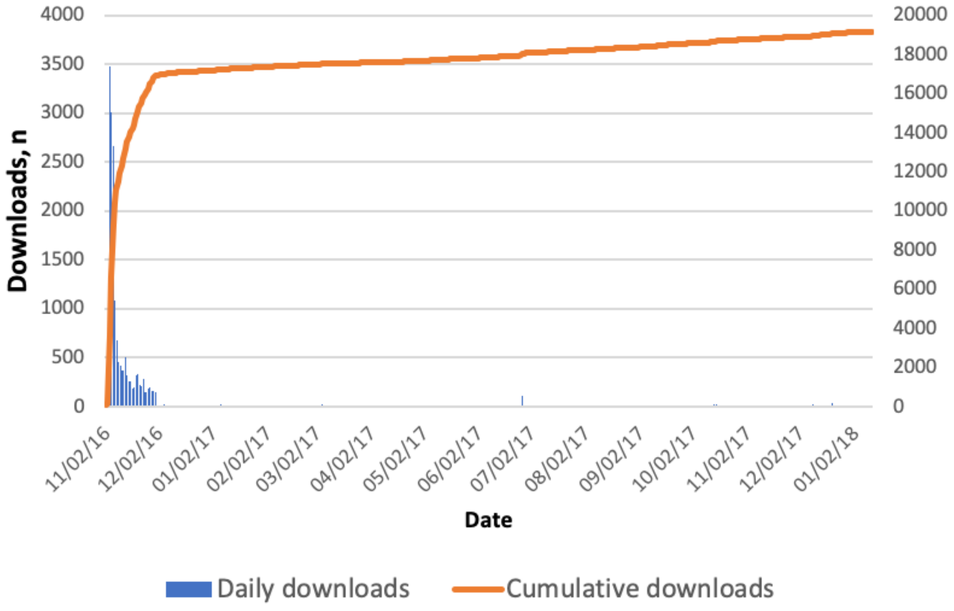

Figure 2. Flow chart of the enrollment process used in this study. CL: contact lens.

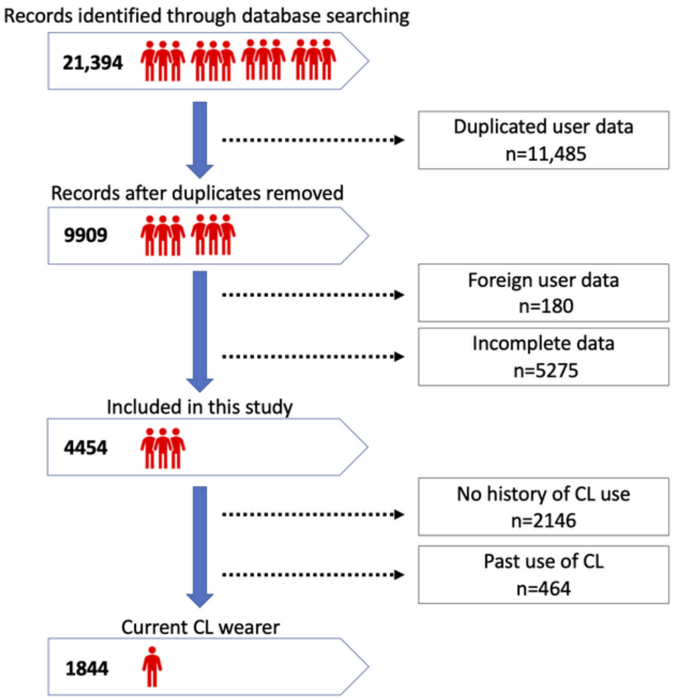


Participant Characteristics

Multimedia Appendix 4 summarizes participants' demographics, medical history, and lifestyle habits according to CL usage. The included participants' median age was 23 years (IQR 18-35), and women accounted for 66.73% (2972/4454) of the participants. Most participants were in the age group of 18 to 34 years (2362/4454 participants, 53.03%), followed by the age group of 35 to 64 years (1133/4454 participants, 25.44%). CL users were divided into the following subgroups: negative (2146/4454 participants, 48.18%), past use (464/4454 participants, 10.42%), and current use (1844/4454 participants, 41.40%). Most of the current CL users were younger than 65 years.

Regarding the medical history survey, the majority of the participants (2747/4454, 61.67%) did not present medicated hypertension, diabetes, systemic diseases, or mental illness history. Hay fever was present in about half of the participants (2249/4454, 50.49%). Previous DED diagnoses were reported in 26.08% of past (178/464) and current (481/1844) CL users, while 17.99% (386/2146 out of participants) of negative contact lens users had previous DED diagnoses. The history of laser-assisted in situ keratomileusis surgery was significantly increased in past CL users (*P*<.001).

Regarding lifestyle habits, eye drop use was reported in 23.49% (109/464) of past CL users and 26.03% (480/1844) of current CL users, while 13.42% (288/2146) of negative contact lens users did not use eye drops. Median screen exposure time was 6 hours (IQR 4-10). About two-thirds of participants (2919/4454, 65.54%) showed periodic exercise habits, with an average exercise time of 1 hour (IQR 0-3) per week. The median sleeping time was 7 hours (6-8.5) per night; however, more than half of participants (2355/4454, 52.87%) slept fewer than 6 hours per night. About a quarter (1058/4454, 23.75%) of participants smoked.

Characteristics of Non-CLADE and CLADE Groups

Multimedia Appendix 5 shows the characteristics of non-CLADE and CLADE groups. Most participants in both non-CLADE and CLADE groups were in the 18 to 34 years age group. There were significantly more female participants in the CLADE group (*P*<.001). Height and body weight were higher in the non-CLADE group. The median CL term was 6 hours (IQR 3-10) per day in both the non-CLADE and CLADE groups, and approximately half of the participants used CL for 12 to 18 hours per day. More than 90% (1725/1844, 93.55%) of the participants in both non-CLADE and CLADE groups used soft contact lenses (SCL). The majority of the SCL types were the daily disposable type (823/1844 participants, 44.63%), followed by the biweekly (every 2 weeks) type (741/1844 participants, 40.18%). Regarding the medical history survey, the prevalence of hay fever (*P*=.002), past diagnosis of DED (*P*<.001), and mental illnesses other than depression or schizophrenia (*P*=.003) were significantly higher in the CLADE group than in the non-CLADE group. Regarding lifestyle habits, eye drop use (*P*<.001), screen exposure time (*P*<.001), and smoking habits (*P*=.001) were significantly higher in the CLADE group than in the non-CLADE group.

Subjective Symptoms

Table 1 shows daily subjective symptoms and OSDI and SDS data. Eye itching was significantly higher in the CLADE group than in the non-CLADE group (*P*<.001). Other subjective symptoms, including asthenopia, headache, mental fatigue, and stiffness, were higher in the CLADE group compared with the non-CLADE group. The median OSDI total scores were 8.3 (IQR 6.3-10.4) in the non-CLADE group and 30 (IQR 20.8-43.8) in the CLADE group. Subscale scores of OSDI were higher in the CLADE group than in the non-CLADE group. The SDS score was also higher in the CLADE group, and 80.10% (1159/1447) of participants in this group experienced depressive symptoms (SDS score ≥40).

Table 1. Subjective symptoms of contact lens–associated dry eye.

Daily subjective symptoms	Non-CLADE[a] (n=397)	CLADE (n=1447)	*P* value
Eye itching (0-10), median (IQR)	0 (0-2)	2 (0-5)	<.001
Asthenopia (yes), n (%)	147 (37.0)	899 (62.1)	<.001
Headache (0-10), median (IQR)	0 (0-2)	1 (0-4)	<.001
Mental fatigue (yes), n (%)	57 (14.4)	446 (30.8)	<.001
Stiffness and pain of body axis muscle (yes), n (%)	151 (38.0)	816 (56.4)	<.001
Stress (1-10), median (IQR)	4 (2-6)	5 (3-7)	<.001
J-OSDI[b] total score (1-100), median (IQR)	8.3 (6.3-10.4)	30 (20.8-43.8)	<.001
Ocular symptoms (0-100), median (IQR)	15 (5-20)	35 (25-45)	<.001
(1) Eyes that are sensitive to light (0-4), median (IQR)	1 (0-1)	1 (1-3)	<.001
(2) Eyes that feel gritty (0-4), median (IQR)	1 (0-1)	1 (1-2)	<.001
(3)Painful or sore eyes (0-4), median (IQR)	0 (0-1)	1 (1-2)	<.001
(4) Blurred vision (0-4), median (IQR)	0 (0-1)	1 (1-2)	<.001
(5) Poor vision (0-4), median (IQR)	0 (0-1)	1 (1-2)	<.001
Vision-related function (0-100), median (IQR)	0 (0)	12.5 (6.3-25)	<.001
(6) Reading (0-4), median (IQR)	0 (0)	1 (0-1)	<.001
(7) Driving at night (0-4), median (IQR)	0 (0)	0 (0-1)	<.001
(8) Working with a computer or bank machine (0-4), median (IQR)	0 (0)	0 (0-1)	<.001
(9) Watching TV (0-4), median (IQR)	0 (0)	1 (0-1)	<.001
Environmental triggers (0-100), median (IQR)	8.3 (8.3-16.7)	41.7 (25-66.7)	<.001
(10) Windy conditions (0-4), median (IQR)	0 (0)	1 (1-3)	<.001
(11) Places or areas with low humidity (0-4), median (IQR)	0 (0-1)	2 (1-3)	<.001
(12) Areas that are air conditioned (0-4), median (IQR)	0 (0-1)	2 (1-3)	<.001
SDS[c] score (20-80), median (IQR)	42 (36-49)	48 (41-55)	<.001
SDS score >40, n (%)	234 (58.9)	1159 (80.1)	<.001

[a] CLADE: contact lens–associated dry eye.

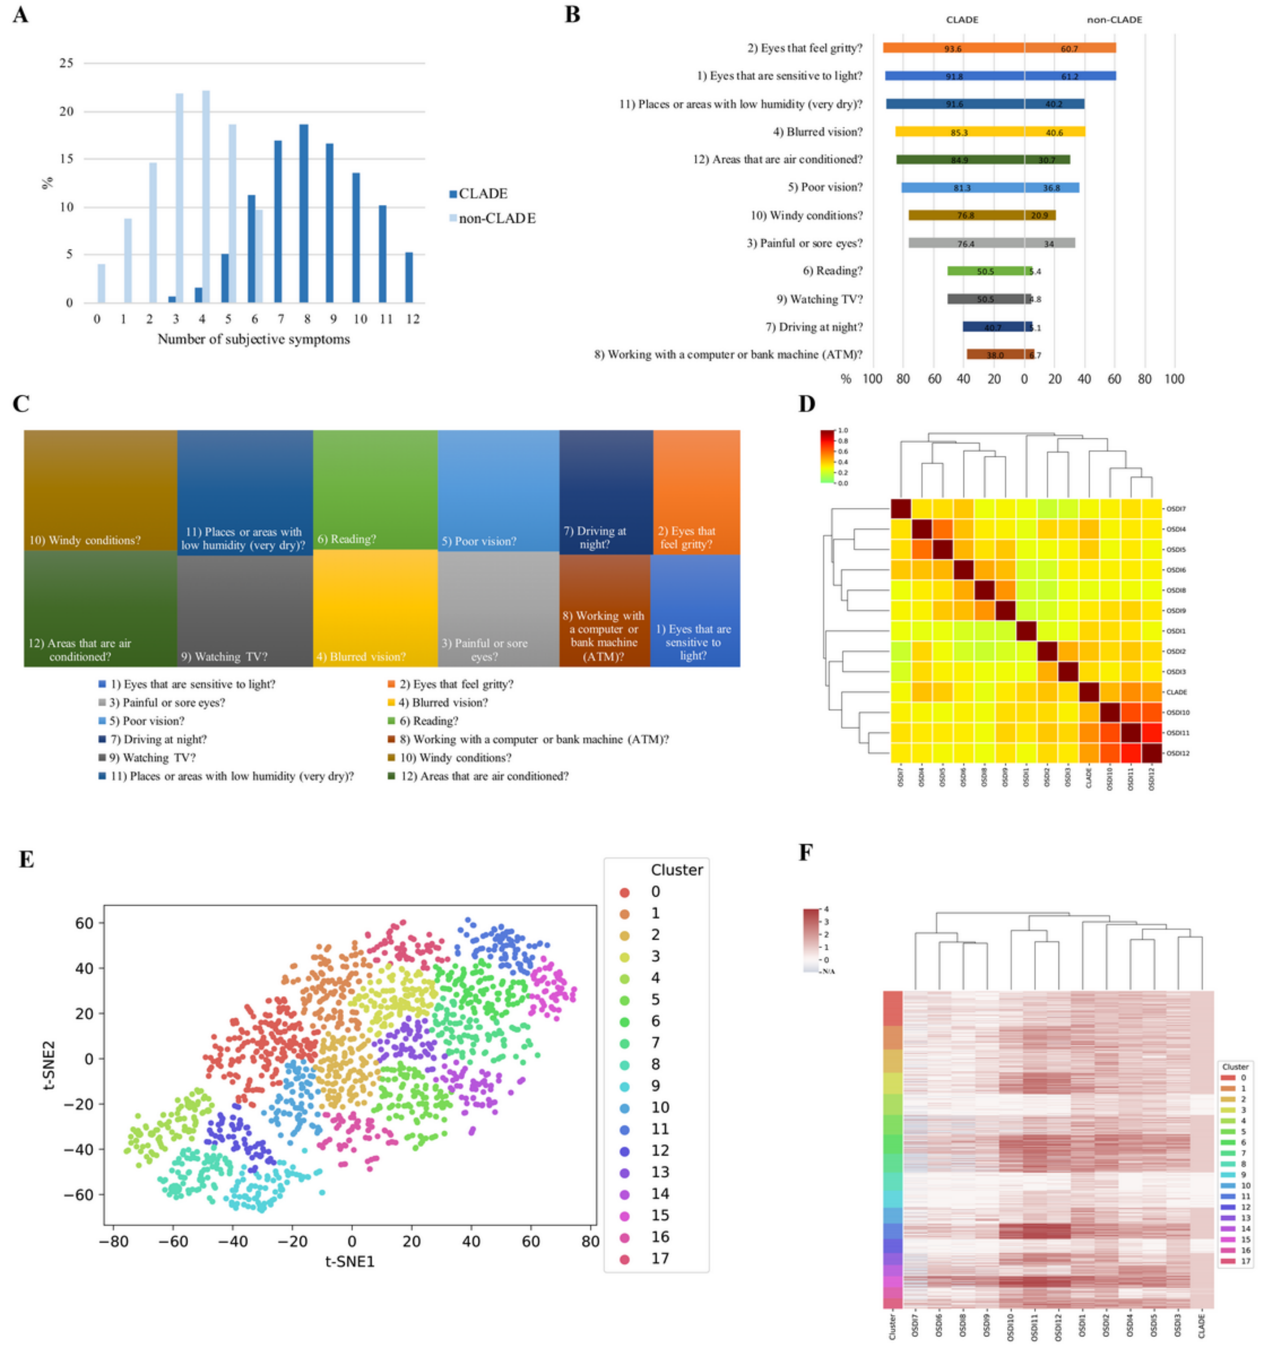
[b] J-OSDI: Japanese Ocular Surface Disease Index.

[c] SDS: Zung Self-Rating Depression Scale.

Stratification of Subjective Symptoms of CLADE

Figure 3 shows various representations of the stratification of the subjective symptoms of CLADE. The number of subjective symptoms for both CLADE and non-CLADE groups is based on OSDI questionnaires, and the number of subjective symptoms was higher in the CLADE group. The rate of positive signs in each OSDI item between the CLADE and non-CLADE groups shows that over 90% of CLADE participants felt gritty eyes, were sensitive to light, and felt uncomfortable in low-humidity places. The treemap consists of the differences between the CLADE and non-CLADE groups in the frequency of subjective symptoms of DED triggered by environmental factors (OSDI questions 10-12). The environmental factors are characterized as subjective symptoms of CLADE. The heatmap that visualizes the correlation between each subjective symptom and CLADE demonstrates that the subjective symptoms triggered by environmental factors (OSDI questions 10-12) were highly positively correlated with CLADE. The t-SNE projection of CLADE and non-CLADE groups according to the subjective symptoms shows that the CLADE group had a variety of subjective symptoms compared with the non-CLADE group (14 groups vs 4 groups, respectively). Finally, we created a heatmap in which the patterns in the 18 groups based on each subjective symptom were stratified by the t-SNE projection. Those 18 groups were subgrouped based on the OSDI as follows: ocular symptoms (OSDI questions 1-5), vision-related function (questions 6-9), and environmental triggers (questions 10-12).

Figure 3. Stratification of subjective symptoms of CLADE. (A) The number of subjective symptoms in the non-CLADE and CLADE groups. (B) The frequency of subjective symptoms of DED based on each OSDI questionnaire. (C) The treemap shows the difference in the frequency of subjective symptoms of DED (the percentage of subjective symptoms in the CLADE group minus the percentage of subjective symptoms in the non-CLADE group) based on each OSDI question. (D) The Pearson correlation coefficients between subjective symptoms and CLADE are shown in the heatmap as a color gradient. (E) t-SNE projection shows the groups of CLADE based on the subjective symptoms. (F) The heatmap shows the correlation between the groups made by t-SNE projection and each OSDI item. CLADE: contact lens–associated dry eye. DED: dry eye disease. OSDI: Ocular Surface Disease Index. t-SNE: t-distributed Stochastic Neighbor Embedding.



Risk Factors for CLADE

Table 2 shows univariate odds ratios of each risk factor for CLADE, determined by logistic regression analysis. The univariate odds ratios were 0.99 (95% CI 0.975-0.998) for age, 1.75 (95% CI 1.33-2.23) for female sex, 0.98 (95% CI 0.97-0.99) for height, 1.41 (95% CI 1.13-1.77) for hay fever, 3.13 (95% CI 1.43-6.84) for mental illness other than depression or schizophrenia, 2.11 (95% CI 1.58-2.82) for past diagnosis of DED, 1.56 (95% CI 1.11-2.19) for more than 8 hours of screen exposure per day, and 1.69 (95% CI 1.26-2.28) for smoking. Relevant risk factors for CLADE were identified by the analyses of univariate odds ratios and were further analyzed by multivariate analyses. Table 2 also shows the multivariate odds ratios of each risk factor for CLADE. The multivariate odds ratios were 0.98 (95% CI 0.96-0.99) for age, 1.53 (95% CI 1.05-2.24) for female sex, 1.38 (95% CI 1.10-1.74) for hay fever, 2.51 (95% CI 1.13-5.57) for mental disease other than depression or schizophrenia, 2.21 (95% CI 1.63-2.99) for past diagnosis of DED, 1.61 (95% CI 1.13-2.28) for more than 8 hours of screen exposure per day, and 2.07 (95% CI 1.49-2.88) for smoking. Number of years of CL use, duration worn per day, and CL type had no significant association with CLADE.

Table 2. Univariate and multivariate adjusted odds ratios of risk factors for contact lens–associated dry eye.

Risk factors	Univariate odds ratio (95% CI)	Multivariate odds ratio (95% CI)
Demographic characteristics		
Age (per year)	0.99 (0.975-0.998)	0.98 (0.96-0.99)
Sex (female vs male)	1.75 (1.33-2.23)	1.53 (1.05-2.24)
Height (cm)	0.98 (0.97-0.99)	1.00 (0.98-1.02)
Weight (kg)	0.99 (0.98-1.00)	N/A[a]
CL[b] use (0-10 years)	0.98 (0.95-1.02)	0.99 (0.95-1.03)
CL duration (hours per day)		
0-6	1 (N/A)	1 (N/A)

[a] N/A: not applicable.

[b] CL: contact lens.

[c] Biweekly: every 2 weeks.

[d] LASIK: laser-assisted in situ keratomileusis.

Discussion

CL use significantly contributes to the quality of vision by correcting refractive errors. However, many CL users discontinue CL wear because of CLD [1-6]. This study analyzed individuals' medical data obtained from the DryEyeRhythm app and clarified the characteristics of subjective symptoms of CLADE and its risk factors. We found that CLADE remained undiagnosed in many individuals who experienced dry eye symptoms and had not been treated with eye drops. Since CLADE is a risk factor for CL discontinuation, evaluating individual subjective symptoms of CLADE and identifying personalized and preemptive medical care will contribute to more comfortable CL use. This study found that younger age, female sex, hay fever, mental illness other than depression or schizophrenia, extended screen exposure time, and smoking were CLADE risk factors. Our findings might help develop individual preemptive strategies for CLADE.

New medical big data collected from mobile health apps and the Internet of Medical Things have been used in recent years [18,22,35-37]. Because CL users are relatively young [38,39], using innovative methods such as smartphone apps is crucial in investigating individual subjective symptoms. This app recruitment model is more inclusive of younger people because they are relatively healthy and seldom visit hospitals. Indeed, many younger individuals (median age of 23 years) participated in this crowdsourced study due to DryEyeRhythm. Previous studies presented challenges regarding information collection for individuals who previously wore CL [1]; however, this crowdsourced study allowed an easier collection of the information compared with the conventional hospital-based study. This study found that 41.40% (1844/4454) of current CL users and 10.42% (464/4454) of past CL users discontinued CL use for various reasons, as Multimedia Appendix 4 showed. Moreover, as demonstrated in previous studies [40], the proportion of current CL users tended to decrease with increasing age, as seen in Multimedia Media Appendix 4. Our findings are consistent with those of previous studies using hospital-based, mail-based, email-based, and Facebook-based methods, which found that between 12% and 51% of CL users discontinued use [2,3,6]. Therefore, this mobile-based health study can be used to supplement traditional hospital-based studies.

Because 23% of the symptomatic participants did not exhibit typical clinical signs of dryness [41], investigating subjective symptoms of CLADE is likely to have more diagnostic value than conducting clinical tests. In this study, 78.47% (1447/1844) of current CL users had CLADE with an OSDI score ≥13. Given that only 28.82% (417/1447) of participants with CLADE had been diagnosed with DED in the past and only 27.92% (404/1447) of participants with CLADE had used eye drops, this study could assess the proportion of individuals who were undiagnosed with DED and did not undergo treatment intervention while experiencing CLADE symptoms. However, since CLADE presents various subjective symptoms, it is possible that those CL users might already have been experiencing CLADE symptoms but were not diagnosed. This study found that individuals with CLADE had multiple subjective symptoms, and more than 90% of participants with CLADE reported that their eyes felt gritty (1355/1447 participants, 93.64%) and were sensitive to light (1328/1447 participants, 91.78%). In particular, items related to environmental triggers were more frequent in CLADE patients than in non-CLADE patients (Figure 3), indicating that CLADE may be strongly influenced by environmental factors. Therefore, improvement of environmental triggers may be a potential intervention method to prevent CL discontinuation due to CLADE. Furthermore, this study stratified various individual subjective symptoms of CLADE using a multidimensional analysis with t-SNE (Figure 3), and the subjective symptoms of CLADE were divided into 14 subgroups. Some CLADE subgroups were strongly related to environmental factors and others were not. The findings indicate that it is important to conduct personalized medicine based on individual CLADE symptoms.

Our study aimed to identify risk factors that contribute to CLADE in a large-scale prospective clinical study using real-world data. The resulting data are shown as odds ratios of risk factors for CLADE (Table 2), including younger age, female sex, hay fever, mental illness other than depression or schizophrenia, past diagnosis of DED, extended screen exposure time, and smoking. Among these risk factors, female sex, mental illness other than depression or schizophrenia, extended screen exposure time, and smoking are associated with DED [17]. Young age is also a risk factor for CLADE, probably because of the higher sensitivity to CLADE symptoms among CL users in the younger cohort and the cessation of CL use in the older cohort due to DED [11,24]. Our study revealed that CLADE was recognized by many young CL users, suggesting the importance of the prevention and treatment of CLADE among young CL users. It should be noted that many CL users were women (1471/1844, 79.77%), and although our results do not directly associate the physiology of female sex with the pathology of CLADE, we believe that the significantly higher prevalence of CL use in the female cohort warrants the recognition of the female population as a relative risk factor for CLADE and DED. This study showed that the median wearing time per day of CL was 14 hours (IQR 12-16), indicating that CL are worn almost all day. We also demonstrated that over 8 hours of screen exposure time was a risk factor for CLADE, and many of the individuals in this study had more than 8 hours of screen exposure time. Therefore, to improve CLADE symptoms, it is necessary to propose a limit on screen time while wearing CL. Additionally, recent studies have demonstrated that hay fever and DED are pathologically related [42,43], thereby positing a synergistic effect of hay fever and DED on exacerbating CLADE symptoms. Moreover, our previous study demonstrated that hay fever, extended screen exposure time, and smoking are risk factors for severe dry eye symptoms [18]. Notably, these risk factors are modifiable and can be improved by lifestyle management [17]. Our findings would help identify individuals who are not yet diagnosed with CLADE and prevent deterioration of CLADE in routine clinical service and life.

Additionally, the types of CL were also identified using real-world data. Most of the CL users wore SCL and disposable lenses (Multimedia Appendix 5). However, the CL type and the daily CL duration did not correlate with CLADE (Table 2), as demonstrated in previous studies [44-46]. This study is a cross-sectional observational study; the causal relationship between CL type or daily duration of CL use and CLADE or CL discontinuation cannot be determined. Therefore, further study is needed to elucidate the associations between them.

Our study has several limitations associated with crowdsourced research, as presented in our previous studies [18,24,25]. First, this crowdsourced clinical study was characterized by selection bias for age, socioeconomic factors, and user characteristics because this app was released only for iOS (Apple Inc) devices. Furthermore, participants who were more interested in CLADE and had experienced CLADE symptoms might have completed all surveys and were subsequently included (Multimedia Appendix 3). Therefore, the prevalence of CLADE might have been overestimated. Second, this study might have recall bias because this study employed many self-administered questionnaires. We demonstrated the internal validity of the study [18]; however, considering the health-seeking behavior and cultural factors in Japan, the external validity or generalizability of the findings remains unknown. Additionally, socioeconomic status, education level, cultural background, and some important unmeasured factors related to CLADE were not investigated. In particular, this study found that one of the risk factors for CLADE was mental illness other than depression and schizophrenia, indicating that further precise classification for mental illness is needed. Further updates and development of an Android version of DryEyeRhythm and recruitment of individuals from other countries will reduce these biases. Third, this was a cross-sectional study; therefore, temporal relationships and causality between CLADE and the risk factors cannot be inferred. Additionally, this mobile health app study identified symptomatic dry eye based only on the OSDI questionnaire and might contain false-positives because dry eye examinations, including the Schirmer's test and measurement of tear film break-up time, were not performed. However, this crowdsourced clinical study using DryEyeRhythm overcame several common participant recruitment–related issues, including diverse cohort and geographic restrictions, thus leading to the collection of real-world medical big data. Notably, it would be difficult to identify non-CLADE without our mobile app. Moreover, DryEyeRhythm also presents a unique opportunity for preventive care by identifying individuals at risk for CLADE earlier than currently possible. The app can be used to supplement traditional hospital-based research, thereby encompassing a broader population.

In conclusion, we identified individuals with CLADE and the associated risk factors using DryEyeRhythm. The various subjective symptoms of CLADE collected and stratified in this study could be used for the future prevention of CLADE.

Acknowledgments

Special thanks to Ohako Inc for developing the DryEyeRhythm app, and Tina Shiang, Yosuke Yoshimura, Yoshimune Hiratsuka, and Miki Uchino for the initial development of the app. This study was supported by Seed Co, Ltd; Alcon Japan, Ltd; Rohto Pharmaceutical Co, Ltd; Hoya Corporation; and Wakamoto Co, Ltd. The sponsors had no role in the design or conduct of this research.

Abstract

Background: Self-management of type 1 diabetes (T1D) requires numerous decisions and actions by people with T1D and their caregivers and poses many daily challenges. For those with T1D and a developmental disorder such as autism spectrum disorder (ASD), more complex challenges arise, though these remain largely unstudied.

Objective: This study aimed to better understand the barriers and facilitators of raising a child with T1D and ASD. Secondary analysis of web-based content (phase 1) and telephone interviews (phase 2) were conducted to further expand the existing knowledge on the challenges and successes faced by these families.

Methods: Phase 1 involved a qualitative analysis of publicly available online forums and blog posts by caregivers of children with both T1D and ASD. Themes from phase 1 were used to create an interview guide for further in-depth exploration via interviews. In phase 2, caregivers of children with both T1D and ASD were recruited from Penn State Health endocrinology clinics and through the web from social media posts to T1D-focused groups and sites. Interested respondents were directed to a secure web-based eligibility assessment. Information related to T1D and ASD diagnosis, contact information, and demographics were collected. On the basis of survey responses, participants were selected for a follow-up telephone interview and were asked to complete the adaptive behavior assessment system, third edition parent form to assess autism severity and upload a copy of their child’s most recent hemoglobin A_{1c} (HbA_{1c}) result. Interviews were transcribed, imported into NVivo qualitative data management software, and analyzed to determine common themes related to barriers and facilitators of raising a child with both ASD and T1D.

Results: For phase 1, 398 forum posts and blog posts between 2009 and 2016 were analyzed. Common themes related to a lack of understanding by the separate ASD and T1D caregiver communities, advice on coping techniques, rules and routines, and descriptions of the health care experience. For phase 2, 12 eligible respondents were interviewed. For interviewees, the average age of the child at diagnosis with T1D and ASD was 7.92 years and 5.55 years, respectively. Average self-reported and documented HbA_{1c} levels for children with T1D and ASD were 8.6% (70 mmol/mol) and 8.7% (72 mmol/mol), respectively. Common themes from the interviews related to increased emotional burden, frustration surrounding the amount of information they are expected to learn, and challenges in the school setting.

Conclusions: Caregivers of children with both T1D and ASD face unique challenges, distinct from those faced by caregivers of individuals who have either disorder alone. Understanding these challenges may help health care providers in caring for this unique population. Referral to the diabetes online community may be a potential resource to supplement the care received by the medical community.

Introduction

Background

Individuals with type 1 diabetes (T1D) spend over 8000 hours per year self-managing diabetes outside of the medical setting [1]. Optimal management includes numerous daily behaviors and decisions such as checking blood glucose levels, counting carbohydrates, calculating doses of and administering insulin, and changing dietary habits. Following this regimen is challenging for anyone, but for people with developmental disorders, such as autism spectrum disorder (ASD), this complex care can be even more demanding. Individuals with ASD can have impairments in social communication and interaction as well as repetitive or restrictive behaviors and preferences [2]. Behaviors and activities that individuals with ASD perceive as unimportant or do not understand, such as self-care, health and safety awareness, and activities of daily living, can be very difficult for them to manage independently, which can make the complexity of self-managing diabetes even more challenging. In addition, over 30% of people with ASD also have an intellectual disability (ID), which can add additional challenges in the self-management of T1D [3].

T1D prevalence is increasing, affecting 1.25 million people in the United States in 2014, and 5 million people are expected to be affected by 2050 [4-6]. Up to 1 in 59 children in the United States have been identified with ASD [7], and the reported prevalence of ASD is also increasing [3,7]. There is little research regarding the prevalence of individuals with both ASD and T1D in the United States [3,6-8], although a recent study found the prevalence of ASD in the pediatric T1D population in 1 clinic to be 1.16% (95% CI 0.96-1.26) [9]. An additional study reported that among 10,032 participants from the T1D Exchange Clinic Network, 159 (1.58%) had T1D and ASD [10]. These studies suggest that there is no increased prevalence of ASD in children with diabetes. However, research has documented that people with ID alone may be more likely to develop T1D as a result of having genetic conditions such as Down syndrome [11,12]. In addition, 31% of children with ASD also have an ID [3]. Although ASD alone may not lead to increased diabetic ketoacidosis, severe hypoglycemia, or worsening glycemic control [10], T1D patients with both ASD and comorbid ID are more likely to have very poor glycemic control, higher emergency room utilization, and lower rates of achieving national standards of diabetes management, including lower rates of lipid screening and retinopathy screening [11-13]. With this comes greater risk for negative outcomes, and indeed diabetes-related morbidity and mortality have been identified as a particular concern for people with ID [14,15]. As people with ASD and ID live longer, it has become even more important that they achieve better long-term disease management, including glycemic control and control of other modifiable risk factors, to decrease the occurrence of potentially preventable complications as they age. The interplay between ASD with or without ID and impacts on clinical, behavioral, and psychosocial outcomes related to T1D continue to be areas where little has been explored. Many factors may be involved in such interplay and outcomes, including access to social support and social networks [16], which may be valuable resources in raising a child with both T1D and autism.

Although there have been great advances over the last decades in health care delivered to children with chronic conditions, not all children have benefited equally [17]. Although there is a well-developed evidence base regarding diabetes care and education for populations without ASD or ID, very little research has been done to better understand optimal ways to deliver education and behavioral interventions and to align clinical care with the needs of families raising a child with both T1D and ASD, with or without an ID.

Objectives

This study sought to better understand self-management challenges and successes experienced by families with experience in raising a child with both T1D and ASD to lay the groundwork for future studies. This will enable the exploration of interventions to improve diabetes outcomes and reduce health disparities in this special population and other unique populations of children living with diabetes and other chronic medical conditions. To the best of our knowledge, this is the first study that utilizes a qualitative component to allow further exploration of the lived experience of raising a child with both T1D and ASD. We also sought to gather some exploratory information on glycemic control related to the degree of adaptive function in light of the coexisting ASD, hypothesizing that adaptive impairment may be associated with hemoglobin A_{1c} (HbA_{1c}).

Methods

Design and Ethics

This study involved an innovative approach consisting of 2 phases and included the use of social media as well as traditional interviews to capitalize on the strengths of each. In the first phase, secondary data analysis of web-based content was conducted to understand the challenges and successes families raising a child with T1D and ASD experience, similar to our other studies using web-based content to evaluate barriers and facilitators of living with or raising a child with T1D [18,19]. The themes generated from this study were used to create an interview guide that was used in phase 2 to interview caregivers of children with varying degrees of glycemic control and ASD severity to provide richer exploration of the lived experience in raising a child with both T1D and ASD. This 2-step approach allowed further exploration of initial themes identified from the secondary data analysis of web-based content, with the advantage of being able to ask follow-up questions.

This study was approved by the Penn State College of Medicine institutional review board through expedited review and was considered to be *no greater than minimal risk.* No procedures or participant interactions took place before receiving this approval.

Phase 1

Recruitment

No individuals were actively recruited for the first phase of the study, as it consisted of a secondary data analysis of publicly available data. Content from a publicly available forum and 2 blogs were identified through an internet search using the search terms *type 1 diabetes and autism* and *diabetes and autism*, which would capture both *autism* and *autism spectrum disorder*.

Analysis

Qualitative methods are appropriate for generating new knowledge and hypotheses, especially when little is known about the area of investigation [20]. This type of analysis allows the emergence of themes from the data when there are no existing hypotheses to test, such as in this understudied population of children living with both T1D and ASD.

A total of 2 experienced qualitative researchers (TO and SO) undertook data analysis. Content from online forums and blogs were imported into NVivo version 12 qualitative software (QSR International Pty Ltd) post by post. After reviewing blogs and forum posts and noting initial impressions, a codebook was developed and revised through ongoing discussions among the study team. To establish Cohen κ (a measure of interrater reliability in qualitative coding) [21], the primary coders (TO and SO) each coded 20% of the dataset ($\kappa=0.996$). With the established interrater reliability, the remaining posts and blog comments in the full dataset were coded. The research team employed an exploratory inductive thematic approach to construct emergent themes [22]. Themes from the analysis of web-based content were used to create an interview guide for use in the second phase of the study.

Phase 2

Recruitment

For the second phase of the study, participants were recruited on the web, through physician referral, and with flyers posted in the waiting room of an academic pediatric endocrinology practice. Participants were considered eligible if they were a caregiver (parent, grandparent, adult sibling, or guardian) to a child aged 5-18 years with both T1D and ASD; able to read, write, and communicate effectively in English; and had telephone and internet access. A summary explanation of the research was provided, including implied consent upon reading the summary of explanation and agreeing to participate.

Instrument

The eligibility survey was hosted in Research Electronic Data Capture (REDCap), a secure electronic data collection system [23]. The survey was tested for technological function before distribution, and questions were answered on 1 page. REDCap automatically captures the date of survey completion and completeness of the survey and assigns each participant a unique study code number. Participants were unable to go back in the survey and change their answers. The survey could only be completed once per Internet Protocol address. Participants reported demographics and information related to their child’s conditions and diabetes provider.

Interview

Survey participants were also asked if they would consent to a subsequent 30-min telephone interview. The interview guide was developed based on the thematic qualitative analysis of web-based content in phase 1. This included themes that seemed fully or nearly fully contextualized by the web-based data as well as themes that may not have been as fully developed, as the phase 2 interviews were used to assess the potential completeness of the phase 1 themes as well as to elicit deeper and more nuanced exploration of the phase 1 themes. To do this, a random sample of interview participants from online recruitment sources was selected for interviews based on consent and responses to the survey questions. As certain demographic groups (eg, clinic patients) were underrepresented in this sample, we also purposively chose to interview the few clinic patients who completed the survey (n=2). Such a targeted, purposive approach to adding participants is standard in qualitative research, as it is 1 of the distinct features that increases efficiency and yield, thereby minimizing overrepresentation and unneeded effort from participants in groups adequately represented [24]. This strategy enabled an interview sample large enough to reach saturation in the interviews, as is also typical of such qualitative research [24].

Telephone interviews were scheduled based on the earliest convenience of the participant. The interviews lasted approximately 30 min and were conducted by 3 authors (PH, SO, and TO). Interviews were audio recorded on a hand-held device and then transferred to a secure web-based storage location with access limited to the study team and an approved Health Insurance Portability and Accountability Act (HIPAA)-compliant transcriptionist.

After scheduling the interview, participants received a link to the adaptive behavior assessment system, third edition (ABAS-3) parent form [25], also hosted in REDCap, and were instructed to complete it either before or after the telephone interview. The ABAS-3 parent form assesses the functional skills of children and adolescents who display various types of limitations, disabilities, or disorders, much like those subjectively displayed by children with ASD and ID. The items included *assess everyday activities required, eg, to function adaptively, respond to environmental demands, care for oneself, and interact with others*. The results of the ABAS-3 identify, among other things, strengths and limitations as well as the need for services and support [25,26]. The general adaptive composite (GAC) scores were derived from all of the adaptive skills areas in the assessment and ranged from 40 to 120. Higher scores indicate a greater level of daily functioning, whereas lower scores suggest impairments in any of a variety of adaptive areas that are assessed by the ABAS-3. The further the GAC score deviates downward from what is considered typical of an individual's age, the greater the impairment in function. For example, a GAC score of 65 would suggest a greater level of impairment in adaptive behavior than a GAC score of 95.

Participants were also asked to upload a copy of the child's most recent HbA_{1c} result (within the past 4 months) into the REDCap survey. After completing all procedures, participants were compensated for their time and effort with a gift card.

Analysis

In all, 12 respondents were interviewed. Interviews were transcribed using HIPAA-compliant Penn State transcription services. Interview transcripts were imported into NVivo 12 (QSR International) for analysis and analyzed as detailed above through an exploratory inductive thematic qualitative approach (Cohen κ after 20%=0.942). Attempts were made to include caregivers of children with varying degrees of glycemic control and varying degrees of function related to their ASD.

Descriptive statistics were calculated for ABAS-3 parent form data and for HbA_{1c} results were also calculated by subgroups based on HbA_{1c} being <7.5% (<58 mmol/mol) or ≥7.5% (≥58 mmol/mol) according to then-current American Diabetes Association glycemic target recommendations [27].

Results

Phase 1

There were 398 posts between 2009 and 2016 from a publicly available forum for caregivers raising a child with both T1D and ASD (117 unique members) and 25 individual blog posts from 2 blogs authored by a caregiver to a child with T1D and ASD. In all, 4 themes emerged from phase 1 (Table 1).

Table 1. Phase 1 themes and representative quotes from analysis of online forums and blogs.

Themes	Representative web-based quotes
Parents of children with T1D[a] and autism yearned for support and did not feel understood by the autism community or the T1D community; social media provided much needed peer support from families that understood the unique experience of raising a child with both conditions.	• "I feel left out of the T1D groups because Aspergers brings a whole new set of concerns. But the Aspie groups are completely afraid of T1D." • "Like you said—the autism community is not equipped for our extra needs and the diabetes community just doesn't get the autism side of it." • "I found this group less than a week ago, and WEPT tears of joy that there are other parents out there who know what this is like." • "I am so thrilled to have found this group! I knew there were other families like ours but I didn't know how/where to access them. I am in tears right now because I feel so overwhelmed knowing that there are other people who understand the everyday trials (and victories!) both autism and diabetes bring to your life 24/7."
Numerous coping techniques were discussed, including focusing on T1D management first, as glucose levels could affect behavior.	• "What has worked is focusing on diabetes management first. When his blood sugars are high he is so irritable and easily set off." • "We chose to focus on T1D first because I do believe that has a huge effect on his behavior."
Descriptions of the health care experience, including the helpfulness of multidisciplinary teams with endocrinologists and autism specialists jointly developing treatment plans.	• "But the Endocrinologists I've encountered don't seem to see it that way. Ours acts like autism and diabetes are as related as a sprained ankle + appendicitis. To them, diabetes is about numbers and autism doesn't affect those. (Ha!)" • "Psychiatrists have only a passing familiarity with insulin dependence from an hour or two during med school, and they are mostly only interested in how it intersects with the meds they prescribe. So again, you as the advocate have to navigate the separate systems, trying to educate whoever is willing to listen along the way." • "My suggestion would be that the Endo consult with your regular doctor. A treatment and medical management plan should be put into place between the two offices. You may also ask for nutritionist, OT and behavior consults to help your child learn more about his diabetes and how his anger issues play into his blood glucose levels."
Sensory issues precluding the use of technology such as insulin pumps and the utility of tubeless pumps in overcoming some of these challenges.	• "My son is on shots, BTW. We tried a pump for a brief time but he wouldn't tolerate it. He pulled it off up to three times a day." • "We went with the tubeless pump for the reasons that have come up...we were concerned about our son messing with the controls and we also knew that for a kid with sensory issues, the external tubing would be a real problem." • "There was NO WAY my son could have dealt with tubing, but he's not having problems with the tubeless pump, we've been very pleased." • "There is just no way my sensory son would have tolerated tubing so I am glad we pursued the tubeless pump option." • "The one thing that helped with sensory issues for things attached [insulin pump, CGM] was I started putting bandaids on for everything-- every shot, bump, bruise, etc. After a few years he hardly noticed them...and as long as the tubing is tucked in he won't use that as something to self-stimulate with."

[a] T1D: type 1 diabetes.

Phase 2

In phase 2, 12 participants were selected for a telephone interview from among 29 respondents who completed the eligibility survey. Information related to participant demographics and study variables such as HbA_{1c} and ABAS-3 parent form scores were obtained (Table 2). On average, both interview participants and the broader group of survey respondents were similar in current age, age of child's diagnosis with T1D, age of child's diagnosis with ASD, and self-reported HbA_{1c}. For both interview participants and survey respondents, the majority reported that they were white, not Hispanic or Latino, lived in a suburban setting, and visited their child's provider every 3-6 months. The majority of both groups reported using continuous glucose monitoring (CGM). The majority of survey respondents reported using an insulin pump, whereas interview participants were evenly split.

In the study sample, 8 individuals had the most recent HbA_{1c} >7.5%, with an average of 9.7% (SD 1.89), or 82.5 mmol/mol (SD 20.5); 4 individuals had the most recent HbA_{1c} <7.5%, averaging 6.9% (SD 0.29), or 52.8 mmol/mol (SD 2.9). There was no statistically significant difference in GAC scores between those with HbA_{1c} >7.5% (mean 68.6, SD 14.22) and those with HbA_{1c} <7.5% (mean 76.3, SD 11.73; t_{10}=0.92; *P*=.38).

Overall, 3 themes emerged from an inductive thematic analysis of content obtained from interviews during phase 2 (Table 3).

Table 2. Phase 2 participant characteristics.

Variable	Interview participants (n=12)	Survey respondents (not interviewed; n=17)
Child's current age (years), mean (SD)	12.3 (3.1)	12.6 (3.7)
Child's age at diagnosis with T1D[a] (years), mean (SD)	7.9 (2.8)	7.3 (3.4)
Child's age at diagnosis with ASD[b] (years), mean (SD)	5.6 (3.5)	5.6 (3.8)

[g] GAC: general adaptive composite.

Table 3. Phase 2 themes and representative quotes from analysis of interviews.

Theme	Representative interview quotes
Caregivers of children with T1D[a] and autism face emotional burdens that may be more than additive compared with raising a child with only T1D or autism, and they describe the constant monitoring and work required to care for their children.	• “Autism doesn’t go away because of a diabetes diagnosis.” • “How are we going to do this forever?” • “I am a nervous wreck every day.” • “She doesn’t show any signs of being low until she is on the brink of losing consciousness and then all of a sudden she is almost passing out.” • “There is a different kind of fear when it comes to diabetes than with autism.” • “Things are very overwhelming---I cried myself to sleep a couple of nights last week.” • “We are working harder than any other parent in the diabetes clinic and no matter what we do or how much monitoring, or how much insulin we give, it’s like nothing seems to help.” • “We try so hard and it seems like it’s not doing anything.” • “He cannot tell me if his blood sugar is low or high so I always have to be right there, constantly monitoring.”
Caregivers of children with T1D and autism express frustration surrounding the amount of T1D information they are expected to learn and the manner in which it is presented.	• “Sometimes people should understand that the best learning is from somebody teaching you and not from reading it.” • One caregiver describes a nurse educator who told her “you should know how to do this already. Just change the insulin. You should know how to do that already,” and her concern “that’s a really dangerous statement to make to a parent who’s new, who you never taught to change those doses.” • “They showed me how to put it [the CGM] in and sent me on my merry way, which was the hardest thing ever to learn. I had to then put it in on my own and it took me three tries and I ruined two sensors. I felt so bad because I didn’t know how to do it.” • Another caregiver described how a health care provider “handed me the Pink Panther [reference book regarding type 1 diabetes] and thought I had read it all.” • “I feel like especially with the hurdles we deal with, a lot more education from the onset would be very helpful.” • Caregivers offered solutions such as “make step by step videos like the ‘how to’ videos seen on YouTube” and offering “extra appointments and longer appointments.”
Caregivers describe numerous challenges surrounding their child’s experience in the school setting.	• “I am literally on call even when she’s at school. Even though she has an aide and there’s a nurse, they will still call me to come help take care of her on a daily basis.” • “They’ve dealt with her eloping from the classroom for years and they know she’s a good hider. They knew about the diabetes. I mean, I know they’re only human, but my goodness. If you lose a diabetic autistic child, that’s kind of a big deal.” • “I stepped down from my position as a paralegal to take care of my child and I now work at my daughter’s school, just to make sure that she is ok.” • Multiple caregivers described how they had to take “time off”, “reduce to part-time,” or even “take jobs at the school to be available to assist with [their] child’s care”. • “Schools are not doing the best they can to help these kids. Sometimes they think the kids can do it on their own where you know they have more challenges and they need more help.” • “No one can work together to get us what we need.”

[a] T1D: type 1 diabetes.

Discussion

Principal Findings

Caregivers raising a child with comorbid T1D and ASD face unique challenges that are not well understood by families with a child with only 1 of the individual conditions or by health care providers, as evident by the themes that emerged from phase 1. Themes were generally related to the combination of T1D and ASD and focused on coping techniques, advice on needles and technology, health care experience, and sensory issues related to technology (eg, insulin pumps). Themes from phase 2 are complementary. Although some could be interpreted as applying to nearly anyone performing T1D management (with or without coexisting ASD), many of the diabetes-specific challenges were influenced (and generally amplified) by the coexistence of ASD.

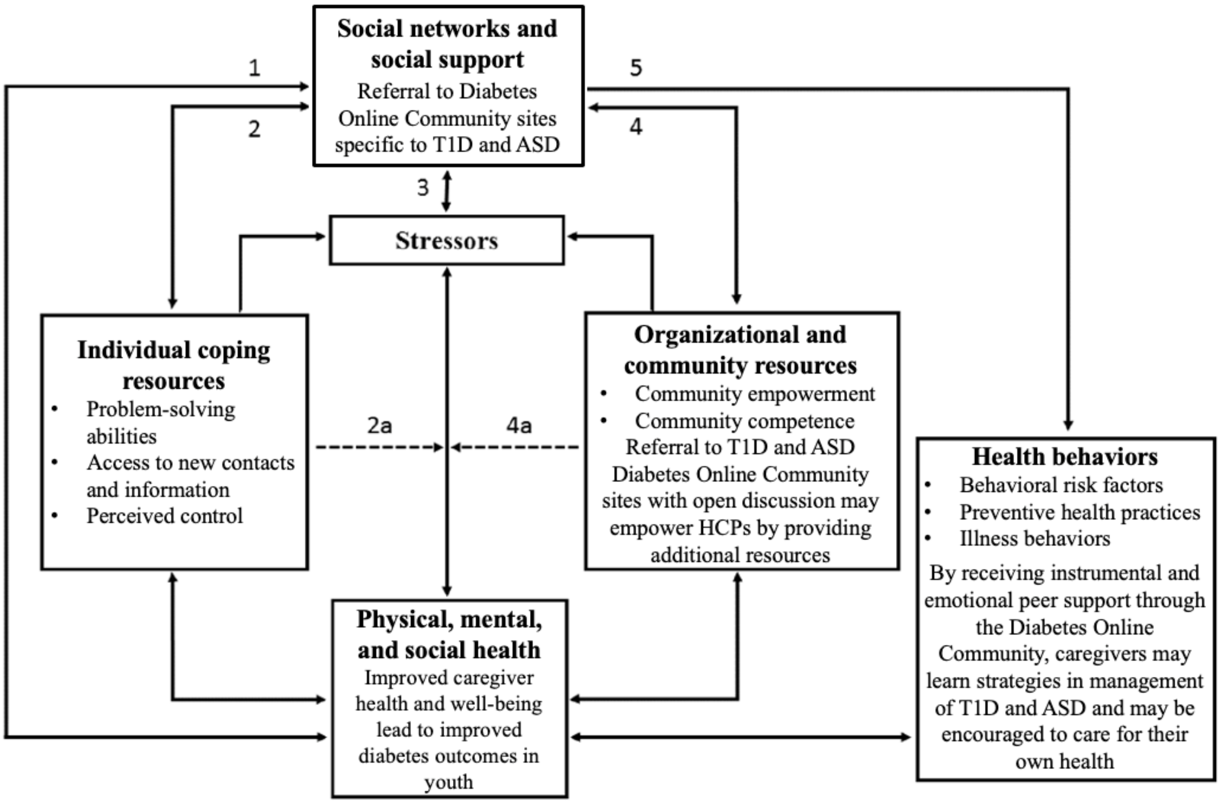
To the best of our knowledge, this is the first study with a large qualitative component to better understand the experience of raising a child with both T1D and ASD. The use of both social media and interviews as qualitative data sources in this special population provided a deeper understanding than using either type of data source alone, much like we found in another study using social media and interviews in a sample of adults with T1D [18].

Overall, our study results show that children who have greater impairment in function based on adaptive skills areas do not achieve target HbA_{1c} values. On the basis of the themes that emerged from our interviews (phase 2), this may be due to the additional barriers that come with the comorbidity, overwhelming amount of information to learn, and challenges in the school setting. More detailed comparisons around our exploratory aim were not conclusive due to the small sample size, not surprisingly.

Caregivers who shared the many challenges they face in raising a child with T1D and ASD might benefit from expanded social networks to provide social support, including emotional, instrumental, informational, and appraisal support. Both in-person support and referral to components of the online caregiver community specific to comorbid T1D and ASD could be valuable resources, as supportive ties may enhance well-being and health of the caregivers, which has been shown to lead to positive outcomes in children with T1D [28-34]. Social networks can provide much needed emotional support, exemplified by 1 participant who, upon finding such a web-based resource, “WEPT tears of joy that there are other parents out there who know what this is like.” Instrumental support might result if caregivers to a child with comorbid T1D and ASD find they are geographically able to provide assistance such as babysitting services, because finding caregivers for any child with T1D presents challenges, and these challenges may be significantly increased in a child with both T1D and ASD [19]. This study shows that caregivers identified numerous coping techniques, including focusing on T1D management first, establishing concrete rules and routines, advice on types of needles and technology, and suggestions for health care appointments. Prioritizing disease-specific tasks when diabetes coexists with other health conditions has been reported elsewhere [35]. Referral to social networks where this kind of informational support can be shared may be highly valuable. Appraisal support in the form of feedback may be especially useful to caregivers with a child newly diagnosed with either T1D or ASD in the setting of having previously been diagnosed with the other condition, as receiving feedback that the challenges they are facing are real and being handled to the best of the caregiver’s ability may help the caregiver in coping with the added new diagnosis.

A modified conceptual model for the relationship of social networks and social support to health can be applied to this unique population (Figure 1, adapted from Glanz et al [16]). Pathway 1 shows that through the expansion of social networks, the supportive ties developed may enhance caregiver health and well-being, which is linked in multiple studies to improved diabetes outcomes in their youth. Pathway 2 represents the hypothesized effect of social networks and social support on individuals’ coping resources. By being able to access new contacts and information to help solve the unique challenges faced by families raising a child with T1D and ASD, there may be a sense or perception of increased control that may also improve the physical and mental health of caregivers. The community of health care providers caring for these children should consider referral to web-based caregiver sites specific for families raising children with both T1D and ASD. By providing resources to these families to strengthen their social networks, the community of health care providers caring for these children may also feel more empowered in caring for this challenging population, as shown in pathway 4. Pathways 2a and 4a demonstrate the *buffering effect*, whereby the negative effects of the stressful experience of raising a child with T1D and ASD described in this study may be diminished through an expanded social network and having health care providers who understand the potential role of peer support in coping. Pathway 3 illustrates how receiving information through an expanded social network may reduce the amount of stress experienced, which, in turn, can lead to improved mental and physical health in caregivers of children with T1D and ASD. Finally, pathway 5 describes the potential effects of social networks and support on health behaviors. By exchanging information and support, caregivers to a child with T1D and ASD may be more supported in health behaviors that improve the care of their child and themselves as well.

Figure 1. A modified conceptual model for the relationship of social networks and social support to health, specific to type 1 diabetes and autism spectrum disorder. ASD: autism spectrum disorder; HCP: health care practitioner; T1D: type 1 diabetes.



Comparison With Previous Work

Our study demonstrated that the majority of survey respondents (8/12, 67%) and interview participants (13/17, 77%) had a child who used CGM technology. However, 82% (14/17) of the survey respondents reported their child using an insulin pump, compared with only 50% (6/12) of interview participants. Among those using insulin pumps, the majority use tubeless pumps (12/20, 60% overall, 5/6, 83% of interviewees and 7/14, 50% of survey respondents).

These findings complement the work of Stanek et al [9] and Bethin et al [10], who found that CGM use was the same among children with T1D and ASD as it was among those with T1D but without ASD, whereas insulin pump use was lower for those with both T1D and ASD. This qualitative work adds some explanatory context, as caregivers identified that sensory issues can preclude the successful use of insulin pumps and that successful solutions for some have included the use of tubeless pumps and desensitization techniques, such as the routine use of band-aids before attempting to use diabetes technology.

HbA_{1c} among study participants was not statistically correlated with the degree of function related to ASD, but it was limited by sample size. However, the trends of 2 comparisons (mean GAC scores of those achieving target HbA_{1c} vs those not achieving target HbA_{1c} and correlation of GAC scores with HbA_{1c}) were both in the direction that one would expect: children who scored higher in skills of daily living had improved HbA_{1c} values (<7.5%). It is not surprising that this study did not achieve statistical significance, as it was not powered to do so and the sample size was chosen for the greater qualitative focus here. This also echoes comments by Bethin et al [10] and Stanek et al [9] that further work is needed to be able to better support these children and their families. From this study specifically, we propose that further research with larger sample sizes is needed to continue to explore the potential relationships between the degree of functioning related to ASD and glycemic control.

Limitations

Limitations of this study include the lack of representation of caregivers from diverse ethnic backgrounds and rural areas. In addition, although attempts were made to recruit both from an endocrinology clinic and the diabetes online community (DOC), a minority of participants were recruited through the clinic. An additional limitation is that the search strategy included *autism* to capture ASDs but did not specifically include *Asperger* and may, therefore, have limited the scope of search returns. However, this would not fully exclude representation of Asperger's-related content as it is an ASD, and it would also tend to skew the sample toward more severe levels of impairment, increasing the ability to identify challenges within the sample. This study aligns with previous work involving the DOC that demonstrates a larger web presence of white individuals living in suburban or urban areas, which is not likely representative of the greater population with comorbid T1D and ASD [36]. This may represent a health disparity whereby those in rural areas or from diverse ethnic backgrounds may not be aware of the DOC, may not have access, or may not feel welcome or included in that space.

Conclusions

Raising a child with both ASD and T1D presents significant self-management challenges. However, caregivers of this population identify various coping techniques and strategies and find support in social media sites specific to this unique population. Further research is needed to develop new ways for the health care community to partner with this population.

Acknowledgments

This research was funded by the Penn State College of Medicine Qualitative Research Initiative. The authors would like to thank the caregivers of children with T1D and ASD for their participation in this study. The authors would also like to thank Dr Cheryl Tierney for reviewing the interview guide and Jessica Wright for contributing to study start-up and project management.

Abstract

Background: Social media are an increasingly commonly used platform for delivering health promotion interventions. Although recent research has focused on the effectiveness of social media interventions for health promotion, very little is known about the optimal content within such interventions, and the active ingredients to promote health behavior change using social media are not clear. Identifying which behavior change techniques (BCTs) are reported may help to clarify the content of interventions using a generalizable terminology that may facilitate future intervention development.

Objective: This study aimed to identify which BCTs are reported in social media interventions for promoting health behavior change in adults.

Methods: We included 71 studies conducted with adult participants (aged ≥18 years) and for which social media intervention was considered interactive in a Cochrane review of the effectiveness of such interventions. We developed a coding manual informed by the Behavior Change Technique Taxonomy version 1 (BCTTv1) to identify BCTs in the included studies. We identified BCTs in all study arms (including control) and described BCTs in the group and self-directed components of studies. We characterized the dose of delivery for each BCT by low and high intensity. We used descriptive analyses to characterize the reported BCTs.

Results: Our data consisted of 71 studies published from 2001 to 2017, mainly conducted in high-income countries (n=65). Most studies (n=31) used tailored, interactive websites to deliver the intervention; Facebook was the most used mainstream platform. In developing our coding manual, we adapted some BCTTv1 instructions to better capture unique nuances of how BCTs were operationalized in social media with respect to likes, retweets, smiles, congratulations, and badges. Social support (unspecified), instruction on how to perform the behavior, and credible source were most frequently identified BCTs in intervention arms of studies and group-delivery settings, whereas instruction on how to perform the behavior was most commonly applied in self-directed components of studies, control arms, and individual participant settings. Instruction on how to perform the behavior was also the most frequently reported BCT in both intervention and control arms simultaneously. Instruction on how to perform the behavior, social support (unspecified), self-monitoring of behavior, information about health consequences, and credible source were identified in the top 5 BCTs delivered with the highest intensity.

Conclusions: This study within a review provides a detailed description of the BCTs and their dose to promote behavior change in web-based, interactive social media interventions. Clarifying active ingredients in social media interventions and the intensity of their delivery may help to develop future interventions that can more clearly build upon the existing evidence.

Introduction

Background

With more than 4 billion users worldwide and a projected yearly growth of 7% [1], the internet has become a central means of delivering health promotion interventions [2,3]. In particular, the advent and widespread use of social media have fostered a novel setting in which to deliver public health and health equity–oriented interventions [2,3]. These interventions greatly differ in their health aims, including HIV testing [4], mental health [5], physical activity [6], smoking cessation [7], and vaccination [8]. Social media can be characterized as consisting of “activities, practices, and behaviors among communities of people who gather online to share information, knowledge, and opinions using conversational media...that make it possible to create and easily transmit content in the form of words, pictures, videos, and audios” [9]. A primary goal of these social media interactions in health promotion is to change health behavior.

Interactions among participants in web-enabled interventions can lead to better health outcomes [10,11]. The past decade of research suggests that social media interventions may be effective in promoting health behavior change [12,13]. Earlier research has highlighted the need to improve the assessment of the design, implementation, and effectiveness of health promotion interventions delivered through social network technologies [14]. The findings from a recent review have revealed the diversity of social media features used in health-focused interventions delivered through the internet [15]. These features support several functions, including identity representation, peer grouping, and web-based social networking [15]. However, it is currently unclear which specific techniques are delivered within social media interventions, that is, which *active ingredients* are leveraged to promote behavior change in this new medium [11,12]. The active ingredient of an intervention that aims to change behavior can be defined as a behavior change technique (BCT), which consists of “an observable, replicable, and irreducible component of an intervention designed to alter or redirect causal processes that regulate behaviour” [16]. It is, therefore, important to describe the content of interventions delivered in social media and unpack their *active ingredients* to determine (1) what is actually being delivered in both intervention and control groups, (2) gaps and opportunities to consider integrating underrepresented BCTs, and (3) if this delivery mode of social media presents new BCTs or novel ways of operationalizing BCTs. Using a shared language to describe the intervention content, including which BCTs are used and how they are employed within an intervention, can help elucidate the development of future effective interventions.

Identification of BCTs using an agreed taxonomy ensures consistent comparison of techniques across studies, building toward a cumulative evidence base for informing terminology and for chartering the active ingredients of social media interventions. The Behavior Change Technique Taxonomy version 1 (BCTTv1) was developed to identify such active ingredients and to characterize the components of strategies that aim to change behavior [16-18]. The BCTTv1 with its 93 individual BCTs grouped into 16 categories [16] provides a standardized approach to classifying the content of health promotion interventions that involve behavior change. The taxonomy has been used extensively to clarify the active ingredients of health behavior change interventions in systematic reviews across several settings [19-21]. In addition, the effectiveness of health behavior change interventions in other areas has been shown to be associated with the inclusion of particular BCTs [22-24]. The findings from a systematic review that assessed the behavioral mechanisms of social media interventions on adolescent diet suggested that BCTs such as goal setting and self-monitoring of behavior may have a positive impact on changing dietary habits in adolescents [25]. However, the authors highlight the need to improve the description of BCTs delivered in social media interventions [25].

Objectives

In this study within a review (SWAR) [26], we aimed to gain a better understanding of the active ingredients of social media interventions by identifying and describing BCTs and assessing the applicability of the BCT framework to studies considered for a Cochrane review of the effectiveness of interactive social media interventions [27].

Methods

Identification of Studies

The details of the systematic review methods, including the search strategy, are available in our published protocol [27]. We searched the following major electronic databases: Cochrane Central Register of Controlled Trials (CENTRAL), Medical Literature Analysis and Retrieval System Online, or MEDLARS Online (MEDLINE), EMBASE, Cumulative Index to Nursing and Allied Health Literature (CINAHL), and PsycINFO. We also conducted a focused search for unpublished studies or reports within Google Scholar and Web of Science. The search was also extended to websites of public health governmental and nongovernmental organizations, such as the Public Health Agency of Canada, the World Health Organization (WHO), and international development agencies such as the Asian Development Bank and the Inter‐American Development Bank. Clinical trial registries and the WHO International Clinical Trials Registry Platform were also searched for relevant studies. We also searched the reference lists of the included studies. Multimedia Appendix 1 provides a sample of the search strategy and results from MEDLINE. In brief, we included studies focused on individuals from the general population who were aged ≥18 years with no limitations on their health status. We only included social media interventions that allowed two-way communication and interaction between and among participants. Some examples consisted of interventions supported through major (as of 2019) social media outlets, such as Facebook, Instagram, Twitter, and YouTube. However, interventions implemented through these platforms had to allow peer interaction to be considered in this review.

Study comparators included usual care, no intervention, or an active comparison (eg, one type of social media compared with another). The primary outcomes included validated measures of health-related behaviors, physical health, well-being, and psychological health. Studies were not excluded based on the outcome. The literature search was limited to studies that were published between January 2001 and March 2017 as most of the commonly used social media platforms were developed in 2001 or later (eg, Facebook and Twitter), and our overview showed no earlier studies using these (currently) widely used social media platforms [3]. The types of included studies consisted of randomized controlled trials (RCTs), controlled before-and-after studies, interrupted time series, and RCTs with stepped-wedge designs.

We excluded interventions that used one-way communication or one-to-one communication between a user and practitioner. For example, we excluded studies that assessed mobile health apps (eg, apps that track clinical information with contact between an individual and their health care provider) and studies with content that is transmitted unidirectionally (eg, text message reminder interventions in which the recipient is unable to reply and podcasts in which health information is provided with no opportunity for two-way communication) or which only allows for comments without sharing functionality, such as blogs. We also excluded studies that assessed web-based interventions that are based on the exchange between a single care provider and an individual participant, such as web-based cognitive behavioral therapy. Advertisements on social media (eg, Facebook) without interactive functionality and virtual gaming interventions were also excluded.

Coding and Analysis Strategies

For each eligible study, 2 trained coders (JT and RS) used BCTTv1 as a basis for coding BCTs. Coders completed BCTTv1 training and met the requirements for accurate and reliable coding. Following training, coders calibrated their coding by independently coding 3 included studies to resolve any initial discrepancies and to inform the development of a contextualized coding manual to supplement the BCTTv1. This was an iterative process to adapt the instructions if needed, which were applied to previously coded and future studies for testing. We developed a coding manual and identified any BCTs that were unique to social media. Multimedia Appendix 2 provides more details on the coding and analysis strategies related to this review.

We also distinguished between low- and high-intensity use to allow a balanced characterization of BCTs in interventions. In this review, we defined low-intensity BCT delivery as a given BCT delivered using one modality at one time. We coded high-intensity BCT delivery as a given BCT delivered more than once using the same or different modalities. Multimedia Appendix 2 provides examples of BCT statements coded as high or low intensity.

The titles of the included studies were entered in an Excel sheet, which contained all 93 BCTs organized under their respective categories. Our coding process captured the distribution of BCTs in interactive social media and self-directed components of the included studies. Interactive social media were defined as two-way communication and interaction between and among participants. Self-directed activities consisted of those carried out by participants outside of social media, such as tracking steps in a diary or using a pedometer. BCTs were extracted in both intervention and control arms in reported papers, appendices, websites, and other references indicated by the authors. We also recorded BCTs applied to participants in a group and individual participants. An interrater reliability score of kappa value 0.60 was used before starting to code [25]. Reviewers convened weekly to reconcile coding discrepancies. A third researcher (J Presseau) was consulted when discrepancies could not be resolved. Frequency counts were performed separately to quantify the categories of BCTs recorded and the intensity with which these were applied. A descriptive analysis was conducted on the identification and application of BCTs in interactive social media interventions.

Results

Characteristics of the Included Studies

Studies were identified using the search strategy specified in the systematic review protocol [27]. Our team screened more than 25,000 records and assessed 282 full-text studies for eligibility criteria. After applying the eligibility criteria, 71 studies were retained eligible for analysis. The majority of the studies consisted of RCTs (60 studies). As shown in Table 1, the studies reviewed were mainly conducted in high-income countries, which hosted 92% (65/71) of the interventions. Only 5 interventions were conducted in upper–middle-income countries. There was only 1 study identified in lower–middle-income countries.

Table 1. Summary of characteristics of included studies (N=71).

Study characteristics	Value, n (%)
Country	
High-income countries	65 (92)
Upper–middle-income countries	5 (7)
Lower–middle-income countries	1 (1)
Study design	
RCT[a]	60 (85)
Non-RCT	11 (15)
Types of social media	
Tailored interactive website only	31 (44)
Facebook only	23 (32)
Tailored interactive website and other social media components (Facebook and interactive apps)	13 (18)
Twitter or WhatsApp or WeChat	3 (4)
Twitter and other social media components	1 (1)
Types of outcomes[b]	
Health-related behaviors	40 (56)
Physical health	25 (35)
Well-being	11 (15)
Psychological health	8 (11)

[a] RCT: randomized controlled trial.

[b] More than one outcome per study.

Interactive social media attributes were identified in both the experimental and control arms of the included studies. In studies with active comparators, study arms were distinguished by changing the intensity of BCTs delivered [28,29], varying web-based social interactivity [6,30], or applying different BCTs in each arm [31,32]. The authors used a variety of interactive platforms to deliver interventions. The types of social media reported were distributed as follows: tailored, interactive websites (31 studies); Facebook only (23 studies); and a combination of tailored websites and other social media components (13 studies). Although not the focus of this review, self-directed strategies used in the intervention arms of the studies were noted. These included sharing informational and educational materials through means such as email [33-35] and video recordings [36,37]. Participants also had access to noninteractive aids such as pedometers [38,39] and used text messages [40,41] and personal diaries [42] to support their offline activities.

The included studies cover a variety of population groups, including college students [43], men who have sex with men [44], parents [45], patients with chronic diseases [46,47], and pregnant women [42,48].

We classified the outcomes of interest for the systematic review into 4 main categories: (1) health-related behaviors, (2) physical health, (3) well-being, and (4) psychological health. Health-related behaviors and physical health were the most reported outcomes and were identified in 40 and 25 studies, respectively. Health-related behaviors referred to the activities or practices taken by an individual, which either enhanced or deteriorated their health. It included measures such as physical activity [6,30,32,33,38,39,41,43,46,47,49-67], diet/nutrition [47,49,52,54,56,58,59,66,68,69], screening/testing [35,44,70-72], smoking [7,73-77], and medication adherence [45,78,79]. Physical health was used to describe any physiological measure such as BMI [32,41,56,58,63,67] and weight [38,40,48-50,52,59,65-67,69,80-84] but not biochemical markers of physiological health.

Well-being and psychological health were reported in 11 and 8 studies, respectively. Well-being was used to classify measures of quality of life [46,50,57,59,61,68,85], whereas psychological health was used to classify measures of psychological functioning, including depression [47,49,57,86,87], stress/distress [49,68,88], and anxiety [49,86].

Capturing Behavior Change Techniques Unique to Social Media

As shown in the examples in Table 2, in identifying BCTs across studies, 3 nuanced operationalizations of existing BCTs emerged that did not fit neatly within the existing taxonomy specifications without losing content. Our new instructions allowed us to capture overt endorsement and virtual rewards noted in specific interventions [67,89]. Overt endorsement consists of open approval of a message by participants, and it can be observed in behaviors such as forwarding emails and comments, likes, and *retweets* on Facebook and Twitter [47,48]. Virtual rewards consist of a system that allows collecting prizes in the form of *smiles*, *congratulations*, *badges*, *virtual gifts*, *or stars* to encourage participants in their progress toward achieving their goals [47,48].

Virtual rewards (by design), although in principle consistent with the *rewards (behavior)* BCT, have a level of nuance within the web-based environment that we decided it was worth making an explicit distinction in coding instructions for that BCT. Namely, we coded all statements that described overt endorsement such as *likes*, *smiles*, *virtual gifts*, *Twitter posts*, and *public post on profile page wall* as *social support (unspecified)* when these statements came from participants themselves in a natural manner. However, we coded these same statements as *nonspecific reward* or *social reward* when they were embedded in the design of the intervention to acknowledge the achievement of participants.

Table 2. Application of newly created rules for capturing virtual rewards.

New instructions	Representative example of coded statements	Behavior change technique taxonomy version 1 code
Overt endorsement (from participants)	"Participants in this intervention were free to post their own relevant messages through videos, text, pictures and so on. They could engage in relevant discussions via commenting." [90]	Social support (unspecified)
Virtual rewards (by design)	"It included gamification features, such as awards for individual and team step-logging and step-count achievements and the ability to send virtual gifts to teammates." [61]	Social reward
Virtual rewards (by design)	"Engagement was rewarded in the intervention group with points, badges and gradual revealing of graphic-level images and other virtual elements." [89]	Nonspecific reward

Identification of Behavior Change Techniques in the Studies

We identified 46 out of 93 techniques from the BCTTv1 across the 71 included studies, which are displayed in Multimedia Appendix 3. BCTs were mainly reported in the Methods section of the studies (68 studies). We also identified BCTs from additional sources, such as protocols (11 studies), study appendices (4 studies), and author-identified companion papers (4 studies).

Behavior Change Techniques Applied in Interactive Social Media and Self-Directed Components

More than 55% (26/46) of the BCTs identified were applied in the interactive social media component of interventions (two-way communication and interaction between and among participants). The top 15 BCTs applied across interactive social media and self-directed components of studies (one-way communication or no social interaction) are displayed in Table 3. As expected, *social support (unspecified)* was the most common BCT identified in interactive social media components (51 studies) [6-8,28,30,32,35,36,38,39,41,44-47,50-55,57,59,61, 63-66,69-73,75,77-80,82,83,85,87-95], followed by *instruction onhow to perform the behavior* (21 studies) [28,36,37, 46-49,52,61,64,68,72,76,77,82,84,85,91,95-97], *credible source* (16 studies) [7,28,30,35,36,39,47,55,64,69,72,76,79,94,95,97], *social comparison* (8 studies) [36,43,48,54,61,65,80,82], and *information about health consequences* (8 studies) [28,43,64,68,72,83,90,95]. On the other hand, *instruction on how to perform the behavior* was the most commonly identified BCT in the self-directed component of interventions (39 studies) [6-8,30,32,34,38-41,43-45,50,51,53,55-60,62,65-67,69,71,74,75,79-81, 83,86,87,89,93,94], followed by *self-monitoring of behavior* (32 studies) [6,30,32,33,38-41,45,46,48,50,51,54-58,60,63-66, 69,76,79,81-84,92,98], *credible source* (29 studies) [8,32,34,38,41,44,45,48,50,53,56,58,59,62,65,66,68, 74,75,77,80-82,85,88,90,92,93,96], *goal-setting behavior* (25 studies) [6,30,32,38,39,41,48,50,51,54,55,57-60,65-67,74,75, 81-84,98], and *adding objects to the environment* (24 studies) [30,32,38-41,46,48-51,56-61,66,70,80,81,83,93,98].

Behavior Change Techniques Applied in the Intervention and Control Arms

The top 5 BCTs applied in intervention arms of the included studies: *social support (unspecified*; 56 studies) [6-8,28,30,32-36,38-41,44-47,52-62,64-66,69,70,72,73,75,77-83,85-95,97], *instruction on how to perform the behavior* (37 studies) [8,28,36,37,40,44-48,52,53,56-58,61,64,67,68,72,75,77,79,81-87,89,91,93-97], *credible source* (35 studies) [7,8,28,34-36,39,41,44,45,47,48,53,56,58,59,62,64,65,68,69,72,75,77,79,81,82,85,88,92-97], *self-monitoring of behavior* (25 studies) [6,32,39,40,45-48,56-58,61,64,65,69,76,78-84,88,92], and *prompts/cues* (24 studies) [33,39-41,43,47,48,52,55,56,58,61,64,65,69,73,78,79,81,82,89,92,93,97]. The content of the control arms was generally reported as *usual care*. Only 9 different BCTs were uniquely applied in the control arms of the studies. *Instruction on how to perform the behavior*, *social support (unspecified)*, and *information about health consequences* constituted the most commonly applied BCTs in control arms only and were identified in 8 [7,29,34,38,39,41,59,66], 3 [50,51,63], and 2 [38,63] studies, respectively. The top 15 BCTs applied to the intervention and control arms of the included studies are displayed in Table 4.

Across the included studies, 14 of the top 15 BCTs applied in intervention arms only were also used in studies with BCTs applied in both arms. The exception was *social comparison*, which was solely identified in the intervention arms of 11 studies [32,33,36,43,48,54,58,61,65,80,82]. As shown in Table 4, the ranking of BCTs also changed with the simultaneous application of BCTs in both study arms in comparison with application in intervention arms only.

Behavior Change Techniques Applied to Group and Individual Participants

Social support (unspecified) was the most commonly applied BCTs to a group of participants (50 studies) [6-8,30,32,33,36,38,39,41,44-46,50-61,63-66,69-73,75-78,80,82,83,85-87,90-95]. It was then followed by *instruction on how to perform the behavior* (24 studies) [36,37,44,45,48,52,53,55-58,62,64,67,72,76,82,84,85,87,93,95-97], *credible source* (23 studies) [7,30,35,36,39,44,45,47,53,55,56,58,64,69,72,75,77,79,85,90,94,95,97], *demonstration of the behavior* (12 studies) [6,36,52,53,55,56,58,62,64,76,93,94], and *social support practical* (11 studies) [7,32,33,39,48,52,53,58,68,72,76]. When BCTs were applied to individuals, *instruction on how to perform the behavior* was the most frequent (36 studies) [6-8,28,30,32,34,38-41,43,46,47,49-51,59-61,65,66,68,69,71,74,75,77,79-81,83,86,89,91,94], followed by *self-monitoring of behavior* (34 studies) [6,30,32,33,38-41,46-48,50,51,54-58,60,61,63,65,66,69,76,78-83,88,92,98], *goal-setting behavior* (30 studies) [6,30,32,38,39,41,46-48,50,51,54,55,57-60,65-67,74-77,81-84,86,98], *adding objects to the environment* (24 studies) [30,32,38-41,46,48-51,56-61,66,70,80,81,83,93,98], *and credible source* (22 studies) [8,28,32,34,38,41,48,50,59,62,65,66,68,74,77,80-82,88,92,93,96]. Table 5 shows the most frequent BCTs applied to group and individual participants.

[a] Behavior change techniques applied to individuals in the group setting and individual participants.

Low- and High-Intensity Use of Behavior Change Techniques

We characterized the intensity of delivering BCTs by identifying the modalities used to expose participants to a BCT. BCTs that were delivered using at least two modalities were coded as high intensity. Participants were exposed to BCTs through interactive social media and self-directed components in intervention or control arms of the studies and in a group or individually. The top 5 BCTs that were delivered with high intensity included *instruction on how to perform the behavior* (35 studies) [7,28,32,34,36-38,40,45,48,49,52,53,55-59,62,65-69,72,74,75,77,79,80,83,85,93,95,96], social *support (unspecified*; 28 studies) [7,8,28,32-35,37,40,41,45,50,51,56,61-67,71,73-75,77,81,86], *self-monitoring of behavior* (16 studies) [32,50,51,54,57,58,60,63,64,66,67,69,78,82,92,96], *information about health consequences* (13 studies) [7,32,34,36,38,48,50,56,59,80,81,95,96], and *credible source* (13 studies) [7,32,34,36,38,48,50,56,59,80,81,95,96]. The top 15 most frequent BCTs coded for high-intensity delivery are displayed in Table 6.

Discussion

Principal Findings

We found that the BCTTv1 was applicable to studies promoting health behaviors using social media in a web-based environment. Given that all these studies focused on interactive web-based platforms, it is surprising that relatively few studies have reported leveraging the full spectrum of social comparison and social support BCTs. Furthermore, few studies have reported using BCTs that have been associated with effective behavior change in other settings (eg, goal setting and action planning) [99,100].

We made 3 adaptations to the coding structure to accurately and specifically code overt endorsement and virtual rewards, which we decided to be a type of social support when provided by peers through the internet and a type of social reward when provided by intervention designers. We also developed a method for coding the intensity of BCTs, which allowed us to identify studies with more intense use of BCTs. We added to the description of some BCTs to capture these nuances of interactive social media. Kadushin [101] and Southwell [102] highlighted the potential of overt endorsement and virtual rewards in influencing individual attitudes and health-related behaviors. We also noted that these techniques were reported in other studies as a measurement of engagement with participants and reach of interventions [67,90].

The interventions were mainly delivered through tailored, interactive platforms (ie, platforms developed by the research team). At the time of conducting this research, Facebook remained the most commonly used platform among the mainstream social media outlets for intervention studies and was used either alone or in combination with other social media components. Nonetheless, this does not dismiss the popularity of other social media platforms implemented in other countries. Social media platforms usually allow social interactions beyond geographical boundaries. We noted that none of the included studies had a global focus, that is, all were conducted within a specific country or region. In addition, with the widespread digital technologies, we expected to see more than one study from low- and middle-income countries. Resource settings [103] and research capacity [104,105] might be explored when assessing possible reasons for limited implementation internationally.

Almost all the studies used a variety of BCTs to deliver interventions through social media. The identified BCTs were applied in both the intervention and control arms of the studies. For this reason, it is essential to identify the intensity with which BCTs are applied. Identifying the intensity can help to determine if the extent of exposure makes a difference in the impact of changing behavior. Even after considering intensity, caution should still be applied when assessing the role of BCTs in changing the behavior of participants because some BCTs were applied with almost equal intensity in the control and intervention arms. This was observed for the BCT *instruction on how to perform the behavior.*

In addition, the content of control arms was mainly reported as *usual care*, with often no accompanying details on the features of such conditions. This situation makes it difficult to adequately characterize the content of control arms and warrants more analysis in attributing effectiveness to BCTs applied in intervention arms [52]. The types of BCTs applied to individuals in a group setting and those applied to individual participants varied greatly. This provides opportunities to explore which BCTs are optimal in a group setting and to identify which ones are inherently appropriate for individual activity only. Additional research can help elucidate the mechanisms of action of BCTs in interventions and further contribute to their optimal use to foster behavior change.

Limitations

One limitation of this research is that we relied on what was reported in the source studies. We attempted to check the web-based sites, but a lot had changed since the publication of the studies in the review. Therefore, the relative paucity of some BCTs (eg, social comparison and goal setting) may be related to insufficient detail in the published papers to code these aspects of the intervention. We encourage future reports of interventions to provide screenshots or access to the version of the platform used at the time of the intervention as additional files or links. In addition, the use of validated tools such as the Consolidated Standards of Reporting Trials eHealth can help improve the description and reporting of web-based interventions, thereby facilitating their implementation and replication to improve health outcomes [106].

Future research can also contribute to better characterize BCTs applied to foster social support in interactive social media interventions. *Social support (unspecified)* was the most commonly applied BCT in the studies analyzed. The definition of this BCT is comprehensive enough to allow the identification of social assistance with no specific descriptors, whereas BCTs such as *social support (practical)* and *social support (emotional)* allow capturing what social assistance entails. A better characterization of *social support* in interventions could help to distill in what ways this particular social interaction makes a difference in the behavior of participants.

Comparisons With Prior Work

A recent review that focused on social media features in web-based interventions reported that communication in the form of forums is the most common social media feature for sustaining behavior change [15]. These results are aligned with those of this SWAR, which shows that generic social support is the most common BCT used in interactive social media interventions, which was mainly captured in interventions that use discussion forums, group activities, and other exchanges to foster mutual support among participants.

Future Work

In this study, we provide an overview of the most commonly reported BCTs applied in social media intervention studies. As social media interventions continue to increase in popularity, it may be useful in future work to assess how the presence of particular BCTs or a combination of BCTs is associated with effects on health behavior change.

Conclusions

Our newly developed coding instructions along with BCTTv1 were useful in characterizing behavior change content in social media interventions and evaluating its effectiveness. This assessment of BCTs identified nuances in the operationalization of the BCTTv1 to characterize the unique features of interactive social media interventions for health promotion. These characteristics may be considered when designing social media platforms aimed at promoting public health. Our coding could further help deconstruct the complexity of interventions that use digital technologies and provide further understanding of the role of specific BCTs on behavior change. Although other studies highlighted the effectiveness of BCTs, such as goal setting and action planning, very few of the included studies used them. Increasing the use of BCTs is known to be effective in improving social media interventions.

Acknowledgments

The authors would like to thank Tamara Rader who developed the search strategy for the systematic review with the assistance of Jordi Pardo and Manosila Yoganathan. The authors acknowledge the assistance of Alexandra Sokolovski in testing the data extraction form. RS received funding from the Bruyère Research Institute Studentship Program. PT is the Canada Research Chair of Health Equity. VW is a recipient of the Ontario Early Research Award.

Authors' Contributions

RS, VW, J Presseau, JT, and OD drafted the review. Input on the review draft was provided by HM, SD, JR, J Petkovic, MY, J Presseau, and PT. VW and J Presseau are joint senior authors.

Conflicts of Interest

None declared.

Abstract

Background: In recent years, flavored electronic cigarettes (e-cigarettes) have become popular among teenagers and young adults. Discussions about e-cigarettes and e-cigarette use (vaping) experiences are prevalent online, making social media an ideal resource for understanding the health risks associated with e-cigarette flavors from the users' perspective.

Objective: This study aimed to investigate the potential associations between electronic cigarette liquid (e-liquid) flavors and the reporting of health symptoms using social media data.

Methods: A dataset consisting of 2.8 million e-cigarette–related posts was collected using keyword filtering from Reddit, a social media platform, from January 2013 to April 2019. Temporal analysis for nine major health symptom categories was used to understand the trend of public concerns related to e-cigarettes. Sentiment analysis was conducted to obtain the proportions of positive and negative sentiment scores for all reported health symptom categories. Topic modeling was applied to reveal the topics related to e-cigarettes and health symptoms. Furthermore, generalized estimating equation (GEE) models were used to quantitatively measure potential associations between e-liquid flavors and the reporting of health symptoms.

Results: Temporal analysis showed that the Respiratory category was consistently the most discussed health symptom category among all categories related to e-cigarettes on Reddit, followed by the Throat category. Sentiment analysis showed higher proportions of positive sentiment scores for all reported health symptom categories, except for the Cancer category. Topic modeling conducted on all health-related posts showed that 17 of the top 100 topics were flavor related. GEE models showed different associations between the reporting of health symptoms and e-liquid flavor categories, for example, lower association of the Beverage flavors with Respiratory compared with other flavors and higher association of the Fruit flavors with Cardiovascular than other flavors.

Conclusions: This study identified different potential associations between e-liquid flavors and the reporting of health symptoms using social media data. The results of this study provide valuable information for further investigation of the health effects associated with different e-liquid flavors.

Introduction

Background

Electronic cigarette (e-cigarette) is an electronic nicotine delivery system (ENDS) that vaporizes electronic cigarette liquid (e-liquid), a solution that contains a number of substances [1]. E-cigarette is promoted as a tobacco substitute, which usually delivers nicotine, flavorings, and other additives via an inhaled aerosol. Since the first device publicly marketed in 2003, the e-cigarette market has experienced a significant growth in prevalence among all age groups [2].

The flavored e-cigarette market has grown extremely rapidly and has become increasingly popular among teenagers and young adults. A recent study identified 7764 distinct e-liquid flavors in 2014, and the number doubled to 15,586 in 2017 [3]. Adolescents and young adults prefer electronic cigarettes (e-cigarettes) over conventional tobacco because they are more affordable, accessible, convenient, and, especially, come with a variety of flavors [1]. A recent examination of the Population Assessment of Tobacco and Health (PATH) Wave 2 data found that more than 75% of youth e-cigarette users used a flavored e-cigarette with Fruit being the most popular e-cigarette flavor category, followed by the Candy/Sweet flavor category [4]. Nearly two-thirds of the adult e-cigarette users vape (ie, the behavior of inhaling vaporized aerosol) a flavored e-cigarette with Menthol or Mint as the most popular flavor category, followed by the Fruit flavor category [4]. The 2019 National Youth Tobacco Survey showed that current e-cigarette consumption among high school students increased from 1.5% in 2011 to 27.5% in 2019, with an estimated 72% of high school e-cigarette users using a flavored e-cigarette [5]. In addition, the number of e-cigarette users in middle school (grades 6-8) increased from 3.3% in 2017 to 10.5% in 2019, with nearly 60% of the middle school e-cigarette users using a flavored e-cigarette [5].

With the increasing popularity of e-cigarettes, it becomes important to understand the health symptoms associated with e-cigarettes and flavored e-cigarette consumption. There were claims that e-cigarettes are 95% safer than conventional tobacco, and nicotine released into the environment, if the e-cigarette liquid contains any, is negligible [6]. A previous study has shown that nonsmokers, such as children and pregnant women, had cardiovascular and other diseases due to passive vaping [7]. E-cigarette flavorings could damage human blood vessel cells in a laboratory environment, even in the absence of nicotine [8]. A number of studies have shown the association of vaping with some respiratory diseases or symptoms, including wheezing and asthma [9-12]. The cinnamon-flavored vaping products had the most potent cytotoxicity, leading to significantly decreased cell viability, increased reactive oxygen species levels, and other health symptoms [8]. Exposure to ENDS aerosol resulted in decreased metabolic activity and cell viability, whereas flavors significantly affected the toxicity of ENDS aerosol, with menthol, coffee, and strawberry flavors having the most significant impact on the overall cytotoxicity of e-cigarette products [13].

Objectives

E-cigarettes and e-cigarette use experiences are widely discussed on social media. Thus, the association of user-reported health risks with e-cigarette flavorings could be explored from social media posts. A recent review on e-liquid flavors using the JuiceDB data from 2013 to 2017 found that Fruity and Sweet were the two most popular e-liquid flavors and have more positive sentiments from users [14]. However, possible associations of e-liquid flavors with health risks have not been well investigated using social media data. Therefore, we aimed to examine probable associations between e-liquid flavors and the reporting of health symptoms using social media data through a data-driven approach.

Reddit was chosen as our main online data source. Reddit is a platform for any user (older than 13 years) to discuss, connect, and share their experiences and opinions online [15]. Besides not allowing the unwelcome content (eg, illegal, sexual, and confidential information), Reddit prohibit users from asking for votes or engaging in vote manipulation. As one of the biggest social media platforms in the United States, Reddit operates like a forum with divided communities called *subreddit*s, such that each one focuses on a specific topic such as sports and politics. Empirically, Reddit contains fewer advertisements and promotions but more self-reporting discussions from vapers (ie, people who vape), making it a desired source to reflect users' experiences and opinions [16]. In addition, discussions about e-liquid flavors have been shown to be one of the most prevalent topics about e-cigarettes on Reddit [17], with Fruit, Sweet, and Cream being the most prevalent flavors discussed among Reddit users [18]. A keyword list was generated by combining the keywords used in a previous e-cigarette–related social media study [19] and was used to filter out non-e-cigarette posts. To analyze the textual contents and users' opinions, topic modeling (Latent Dirichlet Analysis [LDA]) and sentiment analysis were conducted. We applied generalized estimating equation (GEE) models to quantify the potential associations between e-liquid flavors and major related health symptoms based on the e-cigarette–related discussions from Reddit users. Our study provides valuable information about the potential health effects of different e-liquid flavors, which could guide future research on flavored e-cigarettes.

Methods

Data Collection

We obtained the Reddit posts between January 01, 2013, and April 30, 2019, from pushshift.io [20]. We curated a list of e-cigarette–related terminologies (eg, vape, e-cig, e-liquid, and e-juice) from a prior study [19] on related topics as a preliminary list for keyword matching to generate an e-cigarette–related dataset. To account for typos and abbreviations, we applied Frequent Itemset Mining (FIM) based on the first iteration of the keyword-filtered dataset. FIM accepts all posts as input, and it outputs the combinations of most frequently appearing words in the dataset. We then manually selected high-frequency keywords to enrich the initial keyword list.

To investigate the e-cigarette–related health concerns discussed by Reddit users, we further generated a health-related subset (referred to as the health subset) from the e-cigarette dataset. A preliminary health keyword list was curated from a related prior study [21]. The list mostly comprised medical terminologies; thus, we applied FIM after filtering the preliminary list to include relevant conversational terms that frequently appear in our dataset. Similarly, a flavor-related subset (referred to as the flavor subset) was generated by using a flavor-related keyword list. The flavor keywords were generated by crawling the top e-cigarette manufacturers' websites to collect brand names, e-cigarette products' marketing names, and key ingredients.

All datasets were validated and denoised. We manually examined the noisy keywords (eg, blue, hard, and life can be flavor names or have other semantic meanings) from the keyword lists and removed the related posts if such keywords result in low precision during the filtering process. For keywords that were less semantically generic and noisy, we applied an additional filter to clean the data. For example, the flavor keyword "tobacco" contributes to a noisy flavor subset, which contains posts only about conventional tobacco products. We discovered a filter rule that filters out most of the undesired data while maintaining a decent level of recall to ensure the completeness of the dataset, by selecting 10 flavor-related keywords such as "flavor" and "e-liquid," which were found to frequently appear when users talk about tobacco-flavored e-cigarettes rather than conventional tobacco products. As a result, posts were classified as tobacco flavor-related when at least one sentence of the post contains both tobacco and one of the 10 flavor-related keywords. To examine the accuracy of our filter, we selected our top 10 flavor-related keywords, randomly picking 100 posts for each keyword. We then highlighted the sentences that contained the flavor-related keyword and manually examined whether the sentences were about discussions on e-cigarette–related topics. The accuracy of filtering was then calculated and is shown in Multimedia Appendix 1. Most flavor-related keywords have an accuracy between 0.8 and 0.9, which can be considered as clean.

Finally, we curated an e-cigarette keyword list of 20 terms ("e-cig," "e-cigs," "ecig," "ecigs," "electroniccigarette," "ecigarette," "ecigarettes," "vape," "vapers," "vaping," "vapes," "e-liquid," "ejuice," "eliquid," "e-juice," "vapercon," "vapeon," "vapefam," "vapenation," and "juul") and constructed the e-cigarette dataset consisting of 2,865,467 posts from 623,258 unique users. For data preprocessing, all URLs, email addresses, and non-English posts were removed to form a cleaner dataset. We created the health subset by applying 144 health keywords from nine health categories (Multimedia Appendix 1) and obtained 337,482 health-related posts from 138,448 unique users after filtering. Similarly, the flavor subset was generated with a flavor list of 1229 flavors (Multimedia Appendix 1) from 123 e-cigarette brands under 7 flavor categories including Fruit, Menthol or Mint, Tobacco, Sweet, Beverage, Mixed, and Other, containing 446,440 posts from 111,869 unique users.

Temporal Analysis

A temporal analysis was conducted to investigate longitudinal changes in the discussions about e-cigarettes on Reddit from January 2013 to April 2019. In addition, discussions about e-liquid flavors and health symptoms associated with e-cigarettes were examined using temporal analysis. A temporal trend for the percentage of Reddit posts for each reported health symptom was calculated as the number of Reddit posts mentioning each reported health symptom divided by the total number of e-cigarette related Reddit posts in each month.

Sentiment Analysis of Posts With Health Symptom Category Mentions

Sentiment analysis is a contextual analysis of sentences and paragraphs, which can extract subjective attitudes and opinions from the source documents. The Valence Aware Dictionary and sEntiment Reasoner (VADER) was used as the sentiment analyzer to extract users' opinions when discussing about health symptoms in each category on Reddit [22]. We calculated the sentiment score for each Reddit post and the average sentiment score for each health category. As some health-related keywords have negative sentiments (eg, headache), such keywords were replaced by a sentiment-neutral word "X." Such a process better reflects users' opinions about e-cigarettes. Sentiment propensity was then computed for each post with the suggested threshold from VADER. We classified posts with sentiment scores between +0.05 to +1.00 as positive posts, posts with sentiment scores between −0.05 to +0.05 (not including −0.05 and +0.05) as neutral, and posts with sentiment scores between −1.00 to −0.05 as negative. We normalized the numbers of positive, neutral, and negative posts by the total number of posts in each category to reflect the distribution of sentiment results. In addition, we compared the proportions of positive and negative posts within each health category using two proportion Z-tests in statistical analysis software R to determine the significant differences between the proportion of positive sentiments and the proportion of negative sentiments for each health category. We set the significance level for all tests at 5% and adjusted the original *P* values using the Bonferroni method to control for multiple testing error rate.

Topic Modeling

Topic modeling, specifically the LDA model, was applied to identify e-cigarette–related topics that were most frequently discussed [23]. LDA is a generative model for unsupervised topic modeling that can be regarded as a three-layer Bayesian distribution of words (or terms), topics, and documents such that each word in a document is expected to be allocated to a specific topic, where words in each topic are given a certain weight representing the possibility of appearance.

We applied topic modeling to the health subset. After data cleaning, all uppercase characters were converted to lowercase to ensure consistency, and words were lemmatized using spaCy to its stem form because different tenses will not be considered in the model. In addition, we removed stop-words (eg, you, I, and) using the Natural Language ToolKit.

As the LDA model considers each word's possibility of occurrence in a topic, we converted frequent phrases into one word so that a phrase can be considered as an *element* of a document, rather than a combination of separated words. For example, "throat" and "hit" are often mentioned together; thus, topics that contains both words as a "term" could be regarded as one element. We processed the dataset to find frequent bigrams (eg, panic attack, blood pressure, and lipid pneumonia) and trigrams (eg, food drug administration) using the Gensim package and then converted them into a single term.

Associations Between E-Liquid Flavors and Health Symptoms

To determine possible associations between e-liquid flavors and the reporting of health symptoms, we applied GEE models based on binomial distributions with logistic link functions. The within-user correlations were considered through the compound symmetry variance-covariance matrices under the GEE model framework. The GEE models were conducted using the statistical analysis software SAS v9.4 (SAS Institute Inc).

From the e-cigarette dataset, we selected posts with only one flavor-related keyword and at least one health-related keyword. If one selected post contained more than one health keyword, each health-flavor keyword pair was regarded as one unique entry. In total, 3336 entries were included in the dataset. From the GEE models, the probability of comentioning each flavor category with each health category was estimated, and the Tukey method [24] was used to adjust for multiplicity in pairwise comparisons between flavors.

The estimated probabilities of associations represent the probabilities that one flavor category and one health symptom category were comentioned by the same user. By performing pairwise comparisons, significant differences in the probabilities of association were identified within each health category. A heatmap was created to highlight the probabilities of associations between e-cigarette flavors and the reporting of health symptoms. All tests were two-sided with a significance level of 5%.

Results

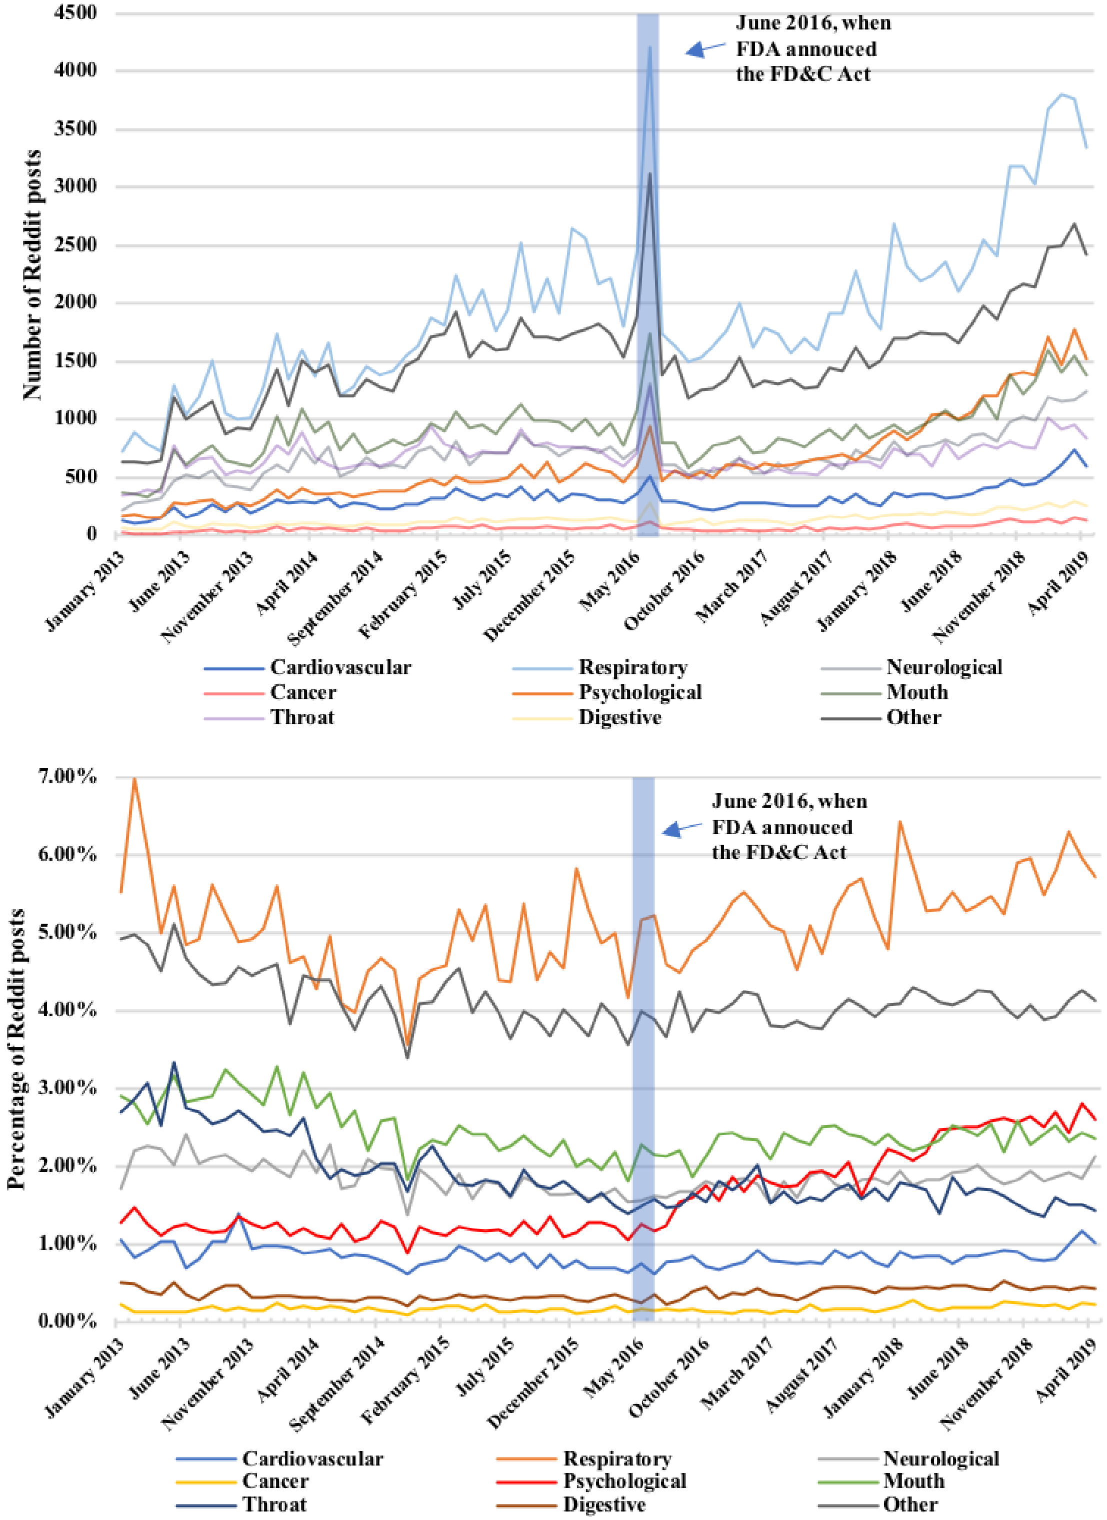
Classification of Health Symptoms

To better understand the potential association of e-liquid flavors with the reporting of health symptoms, we grouped 144 health keywords collected from Reddit into nine health categories, such as Respiratory, Neurological, and Cardiovascular (Multimedia Appendix 1). By counting the number of times mentioned in 337,482 Reddit posts, we found that Respiratory was the most mentioned health category (94,691/337,482, 28.06%), followed by Other (75,102/337,482, 22.25%), Mouth (44,212/337,482, 13.10%), Neurological (33,650/337,482, 9.97%), Throat (33,151/337,482, 9.82%), Psychological (31,041/337,482, 9.20%), Cardiovascular (15,460/337,482, 4.58%), and Digestive (6876/337,482, 2.04%) categories. Cancer was the least mentioned health category on our Reddit dataset at only 0.97% (3299/337,482).

Temporal Analysis of Health Symptom Category Mentioned on Reddit

To determine whether the frequency of each health symptom category mentioned on Reddit changes over time, we examined their longitudinal trend. Our results showed that the number of e-cigarette–related Reddit posts were steadily increasing over time since 2013 (Multimedia Appendix 2). We observed a spike in the temporal trend in June 2016 due to an increase in community discussion around the release of the Federal Food, Drug and Cosmetic (FD&C) Act on tobacco products and its substitutes, which prohibited e-cigarette and peripheral products to be sold to people aged under 18 years [7]. By examining the frequency of each health symptom category mentioned on Reddit over time, we observed that each health symptom category has a similar uptrend (Figure 1), which is similar to all e-cigarette–related posts. We observed that the Respiratory category mentions were consistently the highest among all health categories, whereas the Cancer category was the lowest. Spikes were also observed in the unnormalized temporal trend in June 2016 for all health categories due to the increased discussion on the FD&C Act. After normalization to the number of e-cigarette–related posts in each month, the percentage of health-related keywords mentions was relatively consistent over time, with one exception that the Psychological category had a noticeable growth from June 2016 to April 2019 (Figure 1).

Figure 1. Monthly health-related posts count and proportion of health-related posts (normalized to electronic cigarette–related posts) from January 2013 to April 2019. The blue, shaded region indicates the period where the US Food & Drug Administration (FDA) released the 2016 Federal Food, Drug and Cosmetic Act (FD&C Act).



Sentiment Analysis of Posts With Mentions of Health Categories

Sentiment analysis was conducted applied to the health-related subset posts to understand users' opinions regarding health symptoms in the discussion of e-cigarettes. Most health categories have a positive average sentiment score, whereas the Cancer category yields a negative average sentiment score (Table 1). For most health categories, the proportions of positive sentiment posts were significantly higher than the proportions of negative sentiment posts (*P*<.001), except for the Cancer category (Multimedia Appendix 3). Posts in the Cancer category had mostly negative sentiments, with over 70% of the posts identified with negative sentiment scores (*P*<.001). Example posters used in sentiment analysis are shown in Multimedia Appendix 1. For all categories, significantly more positive and negative sentiment posts were identified in comparison with neutral posts, suggesting that posts on Reddit usually had polarized opinions.

Table 1. Total post count and average sentiment score of posts in health categories.

Health category	Total post count	Average sentiment score
Respiratory	93,259	0.197
Cardiovascular	20,111	0.1889
Neurological	49,351	0.2862
Psychological	41,454	0.2104
Digestive	9123	0.1296
Mouth	62,011	0.2186
Throat	36,250	0.3062
Cancer	4983	−0.333

Potential Associations Between E-liquid Flavors and Health Categories

The LDA topic model was applied to the health-related subset posts to reveal content-wise insights from the discussions on e-cigarette–related health symptoms. As we used the health subset, the majority of the contents were health related. Noticeably, 17 out of 100 topics were mostly related to e-liquid flavors (Textbox 1). A number of representative posts are also provided for positive and negative sentiment posts in each health category to show the topics of discussions on Reddit using a qualitative approach (Multimedia Appendix 1).

Textbox 1. Examples of top 100 topics observed from health-related posts on Reddit.

Health related (n=7)

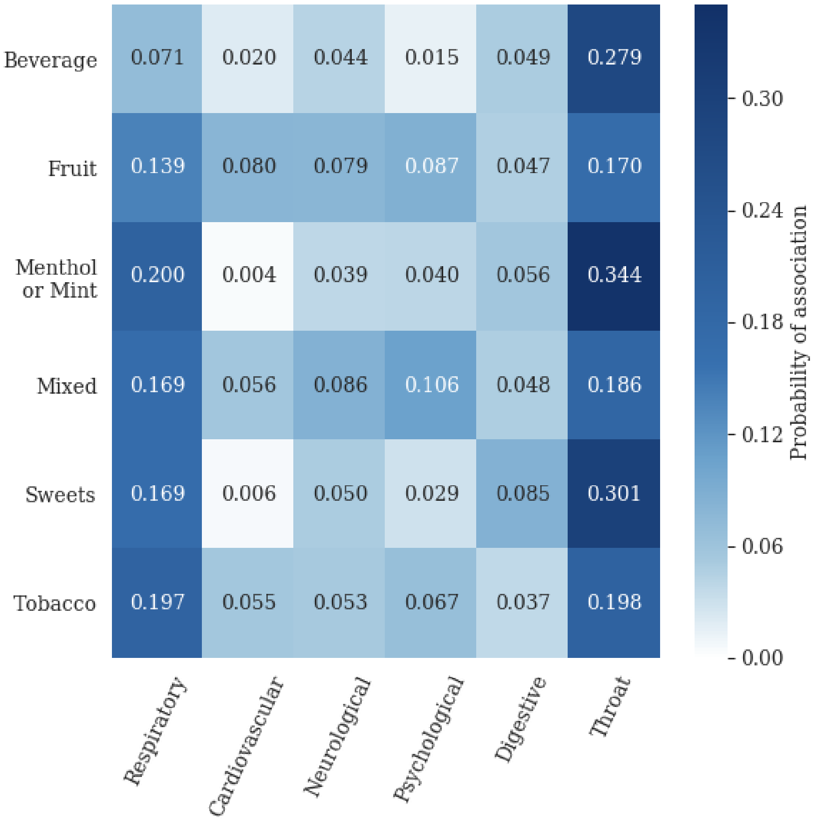
- Pain, symptom, relief, work, migraine, chronic, doctor, nausea, pill, and stomach
- Throat, vape, cold, allergy, irritate, sore, sensitive, sick, reaction, and irritation
- Smoking, vape, healthy, lung, alternative, bad, vaping, smoke, compare, and unhealthy
- Anxiety, depression, medication, attention-deficit/hyperactivity disorder, med, calm, panic attack, mental, symptom, and anxious
- Lung, cancer, die, kill, vape, death, tar, smoking, year, and chronic obstructive pulmonary disease
- Feel, vape, headache, sick, give, head, buzz, make, stomach, and feeling
- Cough, lung, asthma, breath, breathe, breathing, inhaler, clear, phlegm, and smoke

Flavor related (n=10)

- Juice, flavor, menthol, vendor, taste, order, vapor, bottle, sample, and Mt Baker Vapor, a major flavor concentrate wholesale for e-liquid DIY (MBV)
- Flavor, taste, strawberry, sweet, candy, favorite, fruit, juice, milk, and custard
- Vape, “flavour,” “vapour,” liquid, find, bit, UK, good, give, and taste
- Hit, throat, harsh, smooth, propylene glycol (PG), ratio, high, burn, vegetable glycerin, strong
- Flavor, taste, tongue, vaper, juice, strong, sweet, tasting, sense, and burn
- High, tetrahydrocannabinol, strain, cannabidiol, effect, anxiety, edible, cannabis, indica, and sativa
- Lung, popcorn, diacetyl, chemical, case, cigarette, inhale, amount, juice, and find
- Liquid, ingredient, propylene glycol, flavoring, safe, chemical, nicotine, e-liquid, PG, and flavor
- Flavor, taste, strawberry, sweet, candy, favorite, fruit, juice, milk, and custard
- Flavor, sweet, recipe, mix, taste, note, The Flavor Apprentice, a major flavor concentrate wholesale for e-liquid DIY (TFA), cream, cap, and candy

The probability of each health category being simultaneously mentioned with e-liquid flavors was calculated from GEE models to examine the potential associations of e-liquid flavors with the reporting of health symptoms. The associations between some e-liquid flavors and some health symptoms were not investigated due to small sample sizes, which left us with the associations between six e-liquid flavors and six health symptoms (Figure 2). As shown in Figure 2, the Respiratory category had high probabilities of association with most flavors, including Menthol or Mint (0.200), Tobacco (0.197), Sweet (0.169), and Mixed (0.169). The Fruit flavor category (0.080) had a relatively higher probability of association with the Cardiovascular category than the other flavor categories. Both the Fruit (0.079) and Mixed (0.086) flavor categories had a relatively higher probability of association with the Neurological category than other flavor categories. The Mixed flavor (0.106) category had a relatively higher probability of association with the Psychological category than other flavors. The Sweet flavor (0.085) category had a relatively higher probability of association with the Digestive category than other flavors. The Throat category had relatively high probabilities of association with all flavor categories, with Menthol or Mint (0.344), Sweet (0.301), and Beverage (0.279) being the highest.

Figure 2. Heatmap of the estimated probabilities of associations between e-liquid flavors and health symptoms on Reddit.



To test whether any e-liquid flavors have significantly higher probabilities of association with a certain health category than other flavors, we performed pairwise comparisons among e-liquid flavor categories on their associations within each health category (Multimedia Appendix 4). The Tobacco flavor category had a significantly higher probability of association with Respiratory than both Fruit and Beverage flavors. Both the Menthol or Mint and Mixed flavor categories had significantly higher probabilities of association with the Respiratory category than Beverage. Fruit flavor had higher probabilities of association with the Cardiovascular category than Menthol or Mint and Sweet. In the Neurological category, Mixed flavor had a significantly higher probability of association than the Tobacco flavor. For the Psychological category, Mixed flavor had a significantly higher probability of association than other flavor categories, except for Fruit flavor. Sweet flavor had higher probabilities of association than tobacco in the Digestive category. In the Throat category, a number of flavor categories had significantly higher probabilities of association than other categories (Menthol or Mint over Fruit, Mixed, and Tobacco; Sweet over Mixed and Tobacco; and Beverage over Fruit). No significant pairwise comparisons were observed between e-liquid flavors for the Cancer or Mouth category.

Discussion

Principal Findings

By examining the frequency of health keywords mentioned on Reddit, we showed that Respiratory was the most dominant health category, followed by Mouth, Throat, and Neurological categories. A previous social media study showed that the Mouth and Throat (combined), Respiratory, and Neurological health categories were the most frequently mentioned health symptoms on Reddit [25]. These frequency differences could be a result of different health-related keywords used, as our study included more keywords (n=23) in the Respiratory category than the mentioned previous study (n=4). E-cigarette consumption could lead to decreased exhaled nitric oxide, increased respiratory impedance, and increased flow respiratory resistance after short-term e-cigarette use, all of which are indications of immediate adverse physiological effects [26]. Adolescent e-cigarette users have increased rates of chronic bronchitis symptoms [9]. Using the PATH Wave 2 national survey data, e-cigarette use has been shown to be associated with wheezing and other related respiratory symptoms [10]. A recent cross-sectional study using the combined Behavioral Risk Factor

Surveillance System 2016 and 2017 national survey data showed a significant association between e-cigarette use and asthma in US adults who never smoked combustible cigarettes [11]. The dominant temporal trend of the Respiratory category shown in our results, along with the previously reported effects of e-cigarettes on respiratory symptoms, suggests that respiratory diseases are highly related to e-cigarette use.

Our study analyzed users' opinions on e-cigarettes from posts containing mentions of health keywords using sentiment analysis. Most health categories were dominated by positive sentiment posts, except that the Cancer category was dominated by negative sentiment posts. These results indicated a generally positive opinion toward e-cigarettes when Reddit users mentioned health-related keywords during discussion. As a forum consists of mostly teenagers and young adults, most users seem to advocate novel products such as e-cigarettes. This demographic characteristic could contribute to the average positive sentiments. In terms of the average negative sentiment on the Cancer category, we found that most posts discussed about the anecdotes of relatives or friends contracting cancer in the past with consumption of conventional tobacco products. This is reasonable considering the relatively young age of majority of the Reddit users, as cancer is not a prevalent disease in this age group (age: 13 to 32 years) [27]. We also noticed that a great proportion of posters were comparing e-cigarettes with conventional tobacco products, most of whom argued about the benefits of the former over the latter, thus contributing to the rather positive sentiment of most health keyword categories. A previous investigation on health-related effects reported by e-cigarette users in online forums also identified positive effects on the respiratory system, which is consistent with our study [21]. The sentiment analyses from this study are consistent with the sentiment analyses from a previous study using Reddit posts, which found a 60.7% provaping rating using textual analysis [17]. A recent investigation on online forum posts related to the health effects associated with e-cigarettes from 2008 to 2015, however, found that negative sentiment posts were dominant in almost all health categories [28]. This discrepancy might be due to the differences in the time frame, sentiment analysis methods, and data sources. Overall, the average positive sentiment scores across most categories reflect the provaping attitude of teenagers and young adults.

This study investigated the potential associations between e-liquid flavors and the reporting of health symptoms. Other than the Mouth and Cancer categories, some e-liquid flavor categories were identified to have significantly higher association with some health symptom categories compared with other flavor categories. For example, the Mixed flavors had a higher association with the Psychological category than other flavors except Fruit, suggesting that the Mixed e-liquid flavors might lead to a higher risk of psychological symptoms than other flavors. Using monocytes, one previous study showed that mixed flavors had greater cytotoxicity and higher levels of reactive oxygen species than individual flavors, which suggests that mixed flavors might be more harmful to e-cigarette users in psychological symptoms [29]. For the Throat category, Menthol or Mint had higher associations than other flavors, which is consistent with the previous finding that Menthol or Mint flavors lead to strong throat hit. For the Respiratory category, Menthol or Mint and Tobacco flavors had higher associations than other flavors, but this needs further exploration through both epidemiological and experimental studies. Previous studies have shown that some flavoring chemicals such as acetoin (in buttery flavor) and maltol (in candy flavor) can induce inflammatory responses and impair epithelial barrier function in human bronchial epithelial cells [30]. It has been shown that diacetyl, contained in buttery or creamy e-liquid [31,32], might be associated with respiratory disorders [33,34]. Cinnamaldehyde in cinnamon-flavored e-liquid has been shown to correlate with respiratory diseases and lung irritations [35-37]. In addition, benzaldehyde in cherry flavor and furfural in sweet flavor might lead to the irritation of respiratory airways [38]. Our results also showed a high probability of association (0.14-0.17) between Fruit, Mixed, and Sweet flavors and respiratory symptoms, which is consistent with previous studies. Although these associations between e-liquid flavors and health categories require further clinical validation, our results provided a systematic investigation on the association of e-liquid flavors and health symptoms using social media data and some valuable guidance for further studies.

Limitations

Due to the characteristics of social media platforms, the user demographic information (including age, gender, etc.) as well as other factors associated with e-cigarettes such as Propylene Glycol/Vegetable Glycerin ratio and nicotine concentrations were not included in our data analysis. In addition, the Reddit data provide information from users' perspectives, not from controlled laboratory experiments or clinical trials. Although such data provide us with the first-hand experience of e-cigarette users, they need to be further validated by well-designed laboratory or clinical studies. The measures including e-liquid flavors and health symptoms in this study were just mentions by Reddit users, which did not necessarily mean that the users were using these e-liquid flavors or having these health symptoms. In addition, as e-cigarettes have become increasingly popular in recent years, the research field in e-cigarettes has rapidly evolved. More health effects related to e-cigarettes have been identified. The new research findings might affect people's opinions on e-cigarettes and their association with health symptoms. Meanwhile, a scare story related to e-cigarettes might also cause a flurry of health posts. This analysis did not consider the effects of this evolvement, which we will explore in our future studies.

Conclusions

Using social media data from Reddit, our study quantitatively measured potentially different associations between e-liquid flavors and health symptoms. Temporal analysis revealed that mentions of keywords in most health categories were increasing, as the Psychological category had the most significant increase. Sentiment analysis showed that most health categories have a positive average sentiment score, whereas the Cancer category yields a negative average sentiment score. This study also investigated the potential associations between the reporting of health symptoms and e-liquid flavors. Other than the Mouth and Cancer categories, some e-liquid flavor categories were identified to have a significantly higher association with some health symptom categories compared with other flavor categories. With e-cigarette being prevalent worldwide and more e-liquid flavors being available, the health risks associated with e-cigarettes with different flavors should be further investigated. The results from this study could provide guidelines for future clinical and social media studies on the potential associations between e-liquid flavors and health symptoms as well as valuable guidance in future research on flavored e-cigarettes.

Acknowledgments

Abstract

Background: Adolescents and young adults in the age range of 13-24 years are at the highest risk of developing HIV infections. As social media platforms are extremely popular among youths, researchers can utilize these platforms to curb the HIV epidemic by investigating the associations between the discourses on HIV infections and the epidemiological data of HIV infections.

Objective: The goal of this study was to examine how Twitter activity among young men is related to the incidence of HIV infection in the population.

Methods: We used integrated human-computer techniques to characterize the HIV-related tweets by male adolescents and young male adults (age range: 13-24 years). We identified tweets related to HIV risk and prevention by using natural language processing (NLP). Our NLP algorithm identified 89.1% (2243/2517) relevant tweets, which were manually coded by expert coders. We coded 1577 HIV-prevention tweets and 17.5% (940/5372) of general sex-related tweets (including emojis, gifs, and images), and we achieved reliability with intraclass correlation at 0.80 or higher on key constructs. Bivariate and multivariate analyses were performed to identify the spatial patterns in posting HIV-related tweets as well as the relationships between the tweets and local HIV infection rates.

Results: We analyzed 2517 tweets that were identified as relevant to HIV risk and prevention tags; these tweets were geolocated in 109 counties throughout the United States. After adjusting for region, HIV prevalence, and social disadvantage index, our findings indicated that every 100-tweet increase in HIV-specific tweets per capita from noninstitutional accounts was associated with a multiplicative effect of 0.97 (95% CI [0.94-1.00]; P=.04) on the incidence of HIV infections in the following year in a given county.

Conclusions: Twitter may serve as a proxy of public behavior related to HIV infections, and the association between the number of HIV-related tweets and HIV infection rates further supports the use of social media for HIV disease prevention.

HIV/AIDS; social media; youth; natural language processing; surveillance

Introduction

The highest burden of new HIV infections has been reported in adolescents and young adults between the ages of 13 and 24 years, with 37.1% of the new HIV infections occurring in this age group in the United States [1]. Among the youths in this age group, 87% of the individuals diagnosed with HIV infection were reported to be young men, and 51% of these young men were identified as African American, while 25% of these young men were identified as Hispanic/Latino [1]. With the rapid increase in the usage of social media over the last 15 years, Twitter has emerged as a popular social networking platform. Studies have shown that Twitter is used by 32% of the adolescents and 44% of the young adults, with Black youths reporting higher levels of use than their white and Latino peers [2,3]. Since Twitter is used to discuss health-related and risk-related topics [4-6], this platform offers a distinct opportunity to investigate the attitudes, beliefs, and behaviors of the youths via their publicly shared posts that they have created or to which they have responded. This unique content may provide additional insights into the sentiments and discourses of youths [7] beyond what can be identified in traditional formative research methods, particularly at the national level. Analysis of Twitter, for example, might offer insight into the HIV-related beliefs and attitudes of youths of different races/ethnicities and help inform interventions that are designed to curb the HIV epidemic among youths.

The popularity of Twitter and the high volume of public tweets provide unprecedented access to discourses about sexual health and HIV by youths across a country. Although youths use social media platforms such as Twitter to share and seek sexual health information and to communicate with romantic and sexual partners [8], research on tweets related to alcohol, marijuana, cancer, and vaccines has shown that Twitter is also used to promote risky behaviors, spread misinformation, and reinforce HIV- and sexually transmitted infection (STI)-related stigmas [4,5,9,10]. Several studies have also considered social media messages as surveillance data to monitor the incidence of influenza, depression, Zika virus infections, and substance use [11-13]. Similar techniques have been used to assess the associations between social media messages on sex and HIV and the risk behavior and HIV incidence [14].

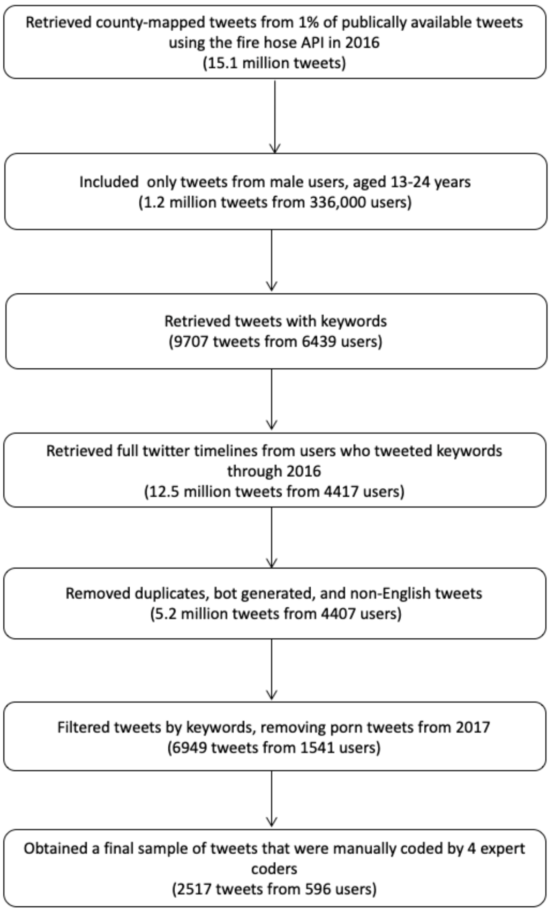
Several studies have shown evidence of a correlation between HIV-related tweets and HIV prevalence in a population [8,14,15]. Two studies [14,15] showed that future-oriented and action-based tweets regarding HIV were associated with decreased incidence of HIV infections at the county level in the United States. In contrast, Young et al [8] found that there was a statistically significant positive association between HIV-related tweets and HIV prevalence. However, these studies [8,14,15] did not distinguish between the source of the tweet; instead, they combined tweets from individual users and institutions such as public health agencies in their analyses. Importantly, studies on HIV and social media focus on certain keywords such as “sex,” “HIV testing,” and “discrimination.” Although the use of these keywords is useful for examining the associations between HIV-related tweets and HIV prevalence, studies often have reduced sensitivity to retrieve relevant tweets for analysis and intervention [16]. Since the abovementioned studies have provided promising evidence that tweets may be associated with HIV risk, there is a need for in-depth contextualized analysis of Twitter messages on risky sexual behavior and health, including analyses of message source variations. Therefore, the goal of our study was to explore how Twitter activity is related to HIV incidence and whether message characteristics such as content and source can reveal the incidence of HIV infection in a population and the future risks associated with HIV. Twitter messages may serve as a signal of the real-time dynamics in HIV epidemiology. In this study, we combined in-depth content analysis of HIV-related tweets with automated machine learning techniques to analyze the county-level associations between HIV-related tweets and new HIV infections in the United States.

Methods

Sample

Using the Twitter “fire hose” application programming interface, which provides broad access to public Twitter data, we drew a random sample of 1% of publicly available tweets posted between January 1, 2016 and December 31, 2016. We sampled tweets from users who tweeted at least 500 words in 2016 and who were geolocated in a county in the United States. To determine the geolocation, we used two types of data: tweet-specific latitude/longitude coordinates and the self-reported location information in Twitter user profiles. The distribution of the geolocated tweets by county approximate the US population density [17]. Duplicate tweets, bots, and non-English tweets were removed [18,19]. After we produced age and gender affiliation estimates for each user with HIV-related tweets, based on our tested algorithms [20,21], we limited our sample to users with predicted age (range, 13-24 years) and predicted gender (males only). Using previous literature [22] and input from our young researchers, we developed a keyword list of HIV-related terms such as HIV, AIDS, HIV testing, condoms, multiple sexual partners, STI, risky sexual behavior, and pre-exposure prophylaxis (PrEP). PrEP is an effective HIV prevention medication taken prior to exposure to the virus. This keyword list was used to identify relevant tweets, and we extracted 9707 HIV-related tweets from 6439 users from the age/gender stratified sample. We also removed pornographic tweets by developing a classifier to identify pornography and excluded those tweets from our data set. Our final data set included 6949 tweets by 1541 young male adults and male adolescents in the United States, and these tweets contained at least one relevant keyword. Figure 1 shows the number of messages and users retained at each step of the above described process.

Figure 1. Twitter sample retrieval flowchart. API: application programming interface.



Content Analysis

Data analysis was conducted with a sample of HIV-related tweets posted on Twitter. We manually coded a sample of HIV-related tweets by oversampling tweets with HIV-specific keywords. To accomplish this, we grouped our keywords into 2 broad categories: HIV prevention-specific tweets (n=1577) and general sex-related tweets (n=5372). We initially included a third category, namely, risk-related, which included risk behavior-promoting (n=6) tweets. However, we excluded this category from our analysis owing to the small number of tweets in this category. From the final data set, we took the full sample of 1577 prevention-related and a 17.5% (940/5372) random sample of general sex-related tweets, yielding 940 general sex-related tweets for manual content analysis.

The final data set (2517 tweets by 596 users) was coded by 4 expert coders for 19 nonexclusive categories. To capture the context, we expanded the coding unit beyond the initial tweet. The coders read the 5 tweets that proceeded from the tweet and the 5 tweets that followed the tweet. They also reviewed the images or webpages linked to the tweet. The coders achieved reliability by using a separate training data set of tweets, which was created through the same procedure used for the sample data set. We used a training set to train the coders without depleting the main data set. During training, the coders reconciled the differences in the code interpretations and coding approaches as a team. After the coding schema was finalized, the 4 coders achieved intercoder reliability on key constructs assessed with an intraclass correlation at 0.80 or higher. Approximately 20% (500/2517) of the final data set was coded by at least two coders.

Measures

The HIV incidence—the outcome variable—was assessed as the number of new cases of HIV infections in a given county in 2017. These data were sourced from the Centers for Disease Control and Prevention AtlasPlus data platform [23]. Counties with suppressed data owing to low case counts were assigned a value of 2, which represented the midpoint between the lowest possible suppressed value of 1 and the highest possible suppressed value of 4.

Twitter messages were classified into the following 3 categories in 2016: risk-specific Twitter activity, prevention-specific Twitter activity, and HIV-specific Twitter activity. Risk-specific Twitter activity is the sum of all the tweets categorized with a risk-related code (eg, multiple partners, pro risk-taking, substance use, transactional sex, and unprotected sex) in a given county, per 100,000 residents. Prevention-specific Twitter activity is the sum of all the tweets categorized as prevention-related (eg, antirisk taking, condoms, HIV testing, HIV/AIDS, PrEP, research, education, and news) in a given county, per 100,000 residents. HIV-specific Twitter activity is the sum of the risk-specific and prevention-specific Twitter activities, in addition to the tweets that were tagged as related to LGBTQ content. All users in our data set were identified as either an individual or an institution based on the manual review of the user profile and recent posting activity. Institutions included public health agencies, social service organizations, and advocacy groups, and typically included the organization name in the username or user description. Our final measures of the tweets consisted of 3 Twitter activity categories (risk, prevention, or HIV-specific) from individuals or institutions, resulting in 6 Twitter variables.

We accounted for 3 geographic control variables: HIV prevalence, social disadvantage, and census region. HIV prevalence in a geographic area is the key epidemiological factor linked to the number of new cases in that area [24]. We used county-level HIV prevalence rates in 2015 to account for the existing patterns of HIV infection. Counties with suppressed data owing to low case counts were assigned case counts of 6, which represented the midpoint between the lowest possible suppressed value of 1 and the highest possible suppressed value of 11. Studies have also shown that socioeconomic factors measured at the city-wide level are the key drivers of new HIV infections [25]. To capture the combined effect of multiple dimensions of socioeconomic disadvantage, we calculated the social disadvantage index at the county level for the counties in our study (Cronbach α=.82) [26]. This index was calculated by summing the z-scores for the percentage of the population living in poverty, the percentage of the population with a high school degree or equivalent, the median household income, and the percentage of the population lacking health insurance. These measures were obtained from the US Census Bureau Small Area Income and Poverty Estimates and the American Community Survey [27]. Negative weights were applied to high school education and median income, yielding an index that reflected greater social disadvantage for high values of the index and lesser social disadvantage for low values of the index. Census region was included to account for the regional variations in the HIV epidemic. The four regions, that is, northeast, south, Midwest, and west regions of the United States, were treated as the control variables in the models.

Statistical Analysis

General sex-related tweets were given sample weights of 6.25 for all the analyses to reflect the random samplings performed to reduce the data for coding. We used the Wilcoxon rank sum test with continuity correction for large samples to compare county tweet outputs based on the message source (ie, tweets from individuals vs institutions). We used negative binomial regression to estimate the effects of Twitter activity on HIV incidence at the county level. Our outcome of interest for this analysis was the rate of new diagnoses of HIV infections per capita at the county level. To model this rate variable, we included an offset term for the county population in 2017 in our regression analysis [28]. Negative binomial regression was chosen because our county outcome variables showed significant overdispersion from the Poisson distribution. Unadjusted models were run first for each of the 6 Twitter variables and the 3 control variables. Separate multivariate models were run for each of the Twitter variables, thereby adjusting for all the control variables. Variance inflation factors were examined for all final models, and none showed evidence of multicollinearity. Analyses were performed in R-3.5.1 [29] using the MASS package [30] glm.nb() function for negative binomial regression.

Results

Descriptive and Geospatial Data

Our data included 2517 tweets that were identified as potentially relevant to HIV risk (eg, unprotected sex) and prevention tags (eg, condom use, HIV testing, research, education), and these tweets originated in 109 counties across the United States. Of these, 940 were general sex-related tweets (including emojis, gifs, and images) and were given a sample weight to reflect our random sampling procedure. Each tweet in our data set represents 100 tweets in the real world as our data was drawn from 1% of publicly available tweets. However, we have reported all our results in units of true tweets, which were calculated by multiplying our results by 100. In 2016, 321 HIV-specific tweets, on an average, originated from individuals in each county. Counties had an average of 143 prevention-related and 118 risk-related tweets from individuals. An average of 944 HIV-specific tweets, 843 prevention-related tweets, and 31 risk-related tweets originating from institutions were sourced to each county. Institutions tweeted significantly more HIV-related (U=67,812; P<.001) and prevention-related messages (U=62,711; P<.001) and significantly less risk-related messages as compared to individuals (U=63,879; P<.001). Within counties that had at least one potentially relevant tweet, the median number of new HIV cases diagnosed in 2017 was 70 per county (range: 0-1530). HIV prevalence in these counties ranged from 6.02 to 2590 per 100,000 residents, with a median prevalence rate of 306 per 100,000 residents. The social disadvantage index ranged from –6.52 to 7.53 (Table 1).

The crude incidence rate ratios (IRRs) for each variable of interest of HIV incidence in 2017 were calculated using negative binomial regression with an offset for the county population (Table 2).

HIV prevalence in 2017 was positively associated with HIV prevalence in 2015 and social disadvantage index in 2015 (IRR 1.104, 95% CI 1.075-1.134; P<.001). Compared to that in the Midwest region, significantly higher HIV incidence was observed in the northeast (IRR 1.286, 95% CI 0.985-1.683; P<.001) and south (IRR 2.126, 95% CI 1.711-2.630; P<.001) regions of the United States. We did not observe a significant difference (IRR 0.967, 95% CI 0.749-1.250; P>.99) in the counties in the west region of the United States. The large number of prevention tweets from individuals in 2016 was significantly associated with the high incidence of HIV in the following year (IRR 1.082, 95% CI 1.003-1.183; P=.048). No other significant bivariate associations were found between HIV-related tweets and HIV incidence for combinations of tweet category and user type.

Table 1. Descriptive statistics at the county level (n=109).

Descriptive statistics	Values	
	Mean (SD)	Median (Min, Max)
HIV prevalence case count, 2017	173 (260)	70 (0.00, 1530)
HIV prevalence case count, 2015	484 (500)	306 (6.02, 2590)
County population, 2017	832,000 (1,090,000)	535,000 (13,900, 8,580,000)
Social disadvantage index, 2015	0.251 (3.06)	0.463 (–6.52, 7.53)

Table 2. Crude incidence rate ratios (bivariate models).[a]

[b] Ref: reference.

Multivariate Analyses

Multivariate models were used to test the adjusted effects for each of the 3 categories of tweets, for individuals and institutions separately, on HIV incidence in the following year. These models are summarized in Tables 3 and 4.

In all 6 models, HIV prevalence in 2017 was positively associated with HIV prevalence in 2015 and social disadvantage index. Additionally, all 6 models showed a significant difference in HIV incidence between the south and Midwest regions. Only one model, Model 1, showed statistically significant effect for a tweet variable on HIV incidence. In Model 1, HIV-specific tweets originating from individuals were negatively associated with HIV incidence at the county level in the following year, after adjusting for region, HIV prevalence, and social disadvantage index. Each additional 100 HIV-specific tweets per capita that originated from an individual in a given county was associated with a 3% decrease in the incidence rate of HIV in the following year, after adjusting for covariates.

Discussion

Principal Findings

In this study, we analyzed the association between geolocated HIV-related tweets within the United States and the future incidence of HIV infection. HIV-specific tweets were more likely to emerge in those locations in the United States that had a high incidence of HIV. The number of HIV-specific tweets made by institution-associated accounts was higher than that of individual tweets. Interestingly, risk-related information in institution-associated tweets was lesser than that in tweets made by individual users. However, we did not observe significant associations between the number of HIV-specific tweets made by institutions and county-level HIV incidence. In contrast, increased numbers of HIV-specific tweets made by individual users were significantly associated with the decreased number of HIV cases in the following year at the county level, even when controlling for the geographic location. These findings suggest that the source of the tweet plays an important role, with individuals tweeting less about prevention, and these individual tweets showed a strong association with the future outcomes of HIV infections.

Geolocated conversations regarding HIV infections were negatively associated with county-level HIV incidence. These findings suggest that locations with few HIV-related Twitter posts and conversations by individuals may indicate those that require targeted interventions. Thus, counties with high incidence of HIV infections and few tweets may indicate an opportunity for increased investigation and potential intervention.

There are several possible reasons for our observation of low incidence of HIV infections in counties with large numbers of HIV-related tweets in the previous year. Increased numbers of HIV-related tweets at the county level could indicate increased community involvement, policy initiatives, and resource utilization in a given county [31]. Additionally, increased numbers of HIV-related tweets by individuals could reflect increased activities in addressing various determinants of HIV risks, including limited institutional support and reduced access to health care [32]. Although studies have sought to incorporate real-time analysis of Twitter data in association with localized HIV incidence, up-to-date HIV epidemiological data is limited or inaccessible to researchers. It is critical that public health professionals and computer scientists collaborate to develop novel approaches in analyzing Twitter data in accordance with the available HIV epidemiological data.

Our findings corroborate those of Ireland et al [15] but they are in contrast to those reported by Young et al [8] who found a positive association between HIV-related tweets and HIV prevalence. Although our study was similar in concept to that conducted by Young et al [8], we used a more specific definition of HIV-related tweets by excluding keywords that were less sensitive in our training sample (eg, “fuck”) and including a variety of slang terms that were compiled by our young researchers. Moreover, our study may have some slight differences from that of Young et al [8] because of the time period in our study—we may have identified a more recent phenomena in the prevalence of HIV infections. Two previous studies [14,15] analyzed the association between the HIV-related tweets and the corresponding epidemiological data in the same time period as considered in our study, whereas Young et al [8] analyzed the Twitter data with the epidemiological data of the previous year. The analyses in this study mirror those reported by Young et al [8] because we also analyzed the epidemiological data from the year after obtaining our specified frame of tweets in 2016.

Our findings suggest that discourses on HIV and risky sexual behavior on Twitter may serve as a signal of sexual health outcomes at the aggregate level. However, the low effect size and nonsignificant results of some of the models make it difficult to state this fact conclusively. It is clear that HIV-related discourse is geographically concentrated, and in coordination with epidemiological surveillance efforts, it may be used to inform intervention efforts. Despite the relative rarity of direct discussion of HIV on Twitter, this social media platform is still an important medium for conversations regarding HIV and health behaviors. Given its wide user base, Twitter can serve as a platform for discussing useful HIV prevention strategies, and such platforms deserve further investment as tools to end the HIV epidemic.

This study has several strengths. Our analysis combined NLP and manual coding, thereby allowing for coding of a large number of tweets for in-depth meaning, while preserving context. Our use of geolocated tweets allowed for location-based analysis with epidemiological and census data. These aspects of our study allowed for contextualized analysis of Twitter data, which may be useful for targeted interventions across the United States.

Limitations

This study has several limitations. First, we did not evaluate model significance by using multiple correction comparisons. Our study only used a set of geolocated tweets from 2016, which greatly reduced the available sample. This analysis included 10.8% (339/3141) of all the counties and there may have been different Twitter discourses in other regions that were not included in this analysis. It is possible that tweets that were not geolocated in that year could have revealed additional information about the nature of HIV-specific tweets relative to HIV incidence. Second, we excluded Spanish tweets, which limited our ability to capture the web-based discourse among Latino men. Third, since we focused on deidentified Twitter data, our study does not contain information on individual characteristics or behaviors.

Conclusion

With the increase of public discourse through Twitter, public health efforts leveraging this social medium are needed. Social media platforms such as Twitter offer an opportunity for health professionals to monitor population health and promote HIV disease prevention. We observed a negative association between HIV-specific tweets made by individual users and HIV incidence in the following calendar year at the county level. Our study underscores the importance of social media as a crucial aspect in the lives of individuals, as these discourses might unearth the youths' knowledge, attitudes, and beliefs related to HIV. Public health efforts seeking to use social media as a tool for HIV surveillance and intervention are warranted.

Acknowledgments

This work was supported by the National Institute of Health CFAR administrative supplement and the University of Pennsylvania Center of AIDS HIV Disparities Scientific Working Group. The authors would like to acknowledge Genevieve Afrifa, Obumneke Obi, Chinanuekpere Emma Ezeala, and Rashaan Galloway for their brilliant coding assistance.

Abstract

Background: The number of electronic cigarette (e-cigarette) users has been increasing rapidly in recent years, especially among youth and young adults. More e-cigarette products have become available, including e-liquids with various brands and flavors. Various e-liquid flavors have been frequently discussed by e-cigarette users on social media.

Objective: This study aimed to examine the longitudinal prevalence of mentions of electronic cigarette liquid (e-liquid) flavors and user perceptions on social media.

Methods: We applied a data-driven approach to analyze the trends and macro-level user sentiments of different e-cigarette flavors on social media. With data collected from web-based stores, e-liquid flavors were classified into categories in a flavor hierarchy based on their ingredients. The e-cigarette–related posts were collected from social media platforms, including Reddit and Twitter, using e-cigarette–related keywords. The temporal trend of mentions of e-liquid flavor categories was compiled using Reddit data from January 2013 to April 2019. Twitter data were analyzed using a sentiment analysis from May to August 2019 to explore the opinions of e-cigarette users toward each flavor category.

Results: More than 1000 e-liquid flavors were classified into 7 major flavor categories. The fruit and sweets categories were the 2 most frequently discussed e-liquid flavors on Reddit, contributing to approximately 58% and 15%, respectively, of all flavor-related posts. We showed that mentions of the fruit flavor category had a steady overall upward trend compared with other flavor categories that did not show much change over time. Results from the sentiment analysis demonstrated that most e-liquid flavor categories had significant positive sentiments, except for the beverage and tobacco categories.

Conclusions: The most updated information about the popular e-liquid flavors mentioned on social media was investigated, which showed that the prevalence of mentions of e-liquid flavors and user perceptions on social media were different. Fruit was the most frequently discussed flavor category on social media. Our study provides valuable information for future regulation of flavored e-cigarettes.

KEYWORDS

e-cigarette; flavor; social media

Introduction

Background

An electronic cigarette (e-cigarette) is a product for users to consume nicotine-related aerosols by heating a solution comprising propylene glycol or glycerol, nicotine, and flavoring chemicals [1]. The first e-cigarette product appeared in the market in 2003 and became popular in the United States in 2006-2007 [2]. E-cigarette products are commonly used as substitutes for conventional cigarettes. Consequently, conventional cigarette consumption in the United States has been decreasing in recent years [3]. The number of adult smokers declined from 20.9% in 2005 to 15.5% in 2016 [4]. Recently, people have tended to use e-cigarette products over conventional tobacco products, especially among adolescents and young adults [5]. According to the 2019 National Youth Tobacco Survey, among middle school students, the prevalence of e-cigarette use increased from 4.9% in 2018 to 10.5% in 2019, and for high school students, the number increased from 20.8% in 2018 to 27.5% in 2019 [6]. Approximately 72.2% of high school and 59.2% of middle school exclusive e-cigarette users used flavored e-cigarettes [6]. Flavored e-cigarette use among current young adult users (aged between 18 and 24 years) exceeds that of current older adult users (aged 25 years), and 81.5% of students aged between 12 and 17 years, used e-cigarettes because they came with attractive flavors [7]. Fruit, menthol or mint, candy, desserts, or other sweets were the most popular flavors among high school and middle school students [8].

Although perceived as safe to be ingested, flavorings in e-cigarettes remain to be a health concern, especially for adolescents, as they might not be safe to inhale. Different electronic cigarette liquid (e-liquid) flavors contain different flavoring chemicals [9]. Exposure to e-cigarette aerosols with flavorings could cause DNA damage, increased oxidative stress, inflammatory cytokine release, and epithelial barrier dysfunction [10,11]. A recent study showed that treating monocytic cells with different flavoring chemicals and flavored e-liquids without nicotine could cause different cytotoxicities [11]. E-cigarette flavorings could damage endothelial cells that line the interior of human blood vessels and may increase the risk of heart disease [12]. In particular, cinnamon and menthol flavors were more harmful than other flavors [11]. Diacetyl and 2,3-pentanedione, 2 of the most common flavoring ingredients in e-cigarettes, were found to have adverse effects on lung cells, which can impair lung function and cause a *popcorn lung* [9]. Another study suggested that the complexity of e-cigarettes on human health goes beyond respiratory and cardiac systems and may have significant implications on oral health [13].

Objective

Although most studies focus on the health effects of different e-liquid flavors, it has become very important to understand the relative proportions of mentions of different e-liquid flavors and user perceptions to reduce their potential health effects. Krüsemann et al [14] constructed an e-liquid flavor wheel based on flavor classifications using terms associated with e-cigarettes and flavors in research articles. Wang et al [15] investigated the e-cigarette content on Reddit without analyzing preferences and sentiments. A Twitter-related study focused on analyzing sentiments of general e-cigarette posts among different groups of users without considering e-cigarette flavors [16]. Currently, there have been few discussions about the e-liquid flavor classification, sentiment analysis, and trend analysis from the perspective of e-cigarette users on social media, which we explored in this study using Reddit and Twitter data.

With the emergence of new e-liquid flavors, the prevalence of mentions of e-liquid flavors might evolve over time, which needs to be monitored in a timely manner. In addition, it is important to understand how the perception of e-liquid flavors correlates with their prevalence. In this study, we employed a data-driven approach to characterize the dynamic changes in mentions of e-liquid flavors over time and to correlate them with the users' perceptions of each flavor category on social media. With the development of technology, social media have become popular in our daily lives. The number of American adults using social networking sites increased from 7% in 2005 to almost 65% in 2015 and is still increasing [17]. We collected data from Reddit, which is one of the most popular social media platforms [18]. Reddit posts usually contain more information because they have a much higher character limit compared with other social media platforms such as Twitter, thus allowing the discussions on Reddit to focus more on the opinions and experiences of users. Twitter posts have a lower character limit than Reddit posts. This advantage makes it easier to locate flavor-related sentences, which can lead to a more accurate sentiment analysis compared with using Reddit data. Therefore, we downloaded Twitter data using the public Twitter app programming interface to explore people's attitudes toward each flavor category. This study investigated the trends of mentions of e-liquid flavors and their perception on social media and provided some guidance for future research on the associations between the prevalence of e-cigarette flavors and user perceptions.

Methods

Electronic Cigarette Liquid Flavor Data Collection and Preprocessing

To obtain a full list of e-liquid flavor names, we searched the 3 major e-cigarette web-based stores, including *electrictobacconist.com*, *myvaporstore.com*, and *ecig-city.com*. The information on e-liquid flavors, including e-liquid brands, flavor names, and flavor ingredients, was manually recorded and curated. In addition to the unique flavor names (brand flavor names) from e-cigarette companies (eg, *Lava Flow* from *Naked 100* and *Green Goblin Salt* from *Oh My Gush*), specific flavor names (eg, mango, cotton candy, coffee) were also added to the list as people tend to mention specific flavor names more frequently on social media instead of using specific brand names. A total of 129 e-liquid brands and 1198 e-liquid flavors were collected.

Electronic Cigarette Liquid Flavor Classification

We applied a data-driven approach to construct a hierarchical e-liquid flavor classification, including 3 levels: major flavor categories (column 1 in Table 1), subcategories (column 2 in Table 1), and specific flavors (column 3 in Table 1). Specific flavor names were first standardized based on the flavor components and key ingredients because different brands or websites may use different names for the same flavor. As some specific e-cigarette flavor names mentioned in Reddit posts were sparse, the specific flavors were classified into several major categories. Similar to categories mentioned in the study by Krüsemann et al [14], 7 major flavor categories were generated: fruit, tobacco, menthol or mint, sweets, beverage, mixed, and others (Multimedia Appendix 1). Within each major flavor category, specific flavors were merged into several subcategories (middle level). For example, in the *fruit* flavor category, there are *tropical*, *berry*, *melon*, *mixed fruit*, and *others* flavor subcategories. In each subcategory, specific fruit flavors were listed. E-liquid flavors that contain more than one flavor ingredient in multiple categories were classified into the *mixed* category. All other flavors that could not be classified into previous categories were classified into the *others* flavor category.

Table 1. Classification of electronic cigarette liquid flavors.

Flavor categories and subcategories	List of specific flavors
Fruit	
Berry	Wildberry, currant, blackcurrant, blackberry, grape, raspberry, blueberry, strawberry, etc
Tropical	Mango, lychee, guava, passion fruit, pineapple, etc
Citrus	Grapefruit, lime, orange, lemon, etc
Melon	Cantaloupe, honeydew, melon, watermelon, etc
Mixed fruits	Mango apricot, apple melon, nana berry, etc
Others	Pomelo, papaya, apricot, dragon fruit, pomegranate, cucumber, kiwi, pear, cherry, peach, coconut, banana, apple, etc
Sweets	
Dessert	Mochi, pie, waffle, donut, mixed, cake, s'more, muffin, ice cream, cream, custard, macaron, granola, pastry, meringue, bread, cheesecake, cookie, etc
Candy	Lollypop, mixed, jelly bean, gummy bear, cotton candy, marshmallow, bubble gum, chocolate, etc
Others	Cereal, honey, caramel, etc
Beverage	
Coffee	Latte, mocha, cappuccino, espresso, coffee
Tea	Chai, tea, etc
Juice	Limeade, lemonade, apple juice, etc
Milk	Yogurt, milkshake, milk
Soft drinks	Cola, coke, soda, etc
Others	Energy drink, smoothie, etc
Tobacco	
Tobacco	Classic tobacco, Virginia tobacco, cigar, etc
Menthol or mint	
Menthol	Menthol
Mint	Mint, peppermint, spearmint
Mixed	
Mixed	Fruit + mint, fruit + sweets, fruit + beverage, fruit + beverage, sweets + other, sweets + mint, sweets + tobacco, fruit + tobacco, etc
Others	
Alcohol	Margarita, whiskey, rum, bourbon, cocktail, etc.
Nuts	Walnut, pecan, pistachio, hazelnut, almond, peanut butter, etc
Spice	Vanilla, cinnamon, etc
Others	Pure VG[a], pure PG[b], PG/VG, etc

[a] VG: vegetable glycerin.

[b] PG: propylene glycol.

Reddit

Reddit Data Collection and Preprocessing

Reddit posts from January 2013 to April 2019 were downloaded from *pushshift.io* (a website that publishes archive Reddit data) [19]. E-cigarette–related Reddit posts were obtained using keyword matching based on a list of e-cigarette–related keywords, including *e-cig*, *e-cigs*, *ecig*, *ecigs*, *electroniccigarette*, *ecigarette*, *ecigarettes*, *vape*, *vapers*, *vaping*, *vapes*, *e-liquid*, *ejuice*, *eliquid*, *e-juice*, *vapercon*, *vapeon*, *vapefam*, *vapenation*, and *juul* [20]. As a result, 2,865,467 e-cigarette–related Reddit posts were collected.

We further extracted e-liquid flavor–related Reddit posts from the e-cigarette dataset we collected. We applied the constructed flavor classification scheme and used the flavors and flavor names as the keywords to obtain posts that discuss e-liquid flavors. We observed that some flavor names were very likely to cause confusion and introduce noises such as *contact* and *punched*; thus, a denoise procedure was performed to filter out noisy flavor keywords [21]. For each confusing flavor name, sample posts were generated and manually labeled. The goal of the denoise procedure was to optimize the precision to 90% while maintaining an acceptable recall of ≥75%. If flavor names did not achieve the goal, they were excluded from further data analysis. After filtering out noisy flavor keywords, the final flavor subset contained 904,045 posts (Multimedia Appendix 2).

Temporal Analysis of Reddit

A temporal analysis was conducted to investigate the longitudinal trend of the intensity of discussion about each e-cigarette flavor category using the monthly post counts from January 2013 to April 2019. To further investigate competitions and substitutions between flavors, data were further normalized by the total number of flavor subset post counts in each month.

Twitter

Twitter Data Collection and Preprocessing

Using the same e-cigarette–related keywords, Twitter streaming data were downloaded from May 31 to August 22, 2019, leading to a collection of 2,757,860 e-cigarette–related Twitter posts.

To obtain e-cigarette flavor–related feedback from e-cigarette users instead of e-cigarette promotions from official accounts, promotion-related Twitter posts were filtered out in 2 steps. First, Twitter IDs that contain promotion-related keywords were eliminated, including *dealer*, *deal*, *store*, *supply*, *e-cig*, *e-cigs*, *ecig*, *ecigs*, *electroniccigarette*, *ecigarette*, *ecigarettes*, *vape*, *vapers*, *vaping*, *vapes*, *e-liquid*, *ejuice*, *eliquid*, *e-juice*, *vapercon*, *vapeon*, *vapefam*, *vapenation*, and *juul*. Second, Twitter posts that contain promotion-like keywords (eg, customer, promotion, discount, sale, and free shipping) were eliminated. After these 2 filtering procedures, a subset of 2,530,048 e-cigarette–related posts remained. To obtain an accurate result on the Twitter sentiment analysis of each flavor category, another flavor-related filtering was conducted by using keywords from the previous e-liquid flavor list Multimedia Appendix 1). As a result, we obtained an e-liquid flavor–related Twitter subset that contains 21,389 posts, and each post contains only 1 flavor keyword. The complete procedures of Twitter data preprocessing are shown in Multimedia Appendix 2.

Sentiment Analysis of Electronic Cigarette Liquid Flavors on Twitter

A sentiment analysis is a contextual analysis of sentences and paragraphs, which can extract subjective attitudes and opinions from the source material. The Valence Aware Dictionary and sEntiment Reasoner was used as the sentiment analyzer to extract the thoughts and opinions of e-cigarette users on each flavor category from Twitter posts [22]. We obtained a sentiment score for each tweet, and the average sentiment score was calculated for each flavor category. On the basis of the suggested threshold for determining the sentiment (positive, neutral, and negative), tweets with sentiment scores in the range of −1.00 to −0.05 were classified as negative posts, tweets with sentiment scores in the range of −0.05 to +0.05 (not include −0.05 and +0.05) were classified as neutral posts, and tweets with sentiment scores in the range of +0.05 to +1.00 were classified as positive posts [22]. The number of posts for each flavor category with positive, neutral, and negative sentiments was normalized by the total number of posts for each flavor category to explore the distribution of the sentiment results for each flavor category. In addition, comparisons between the proportions of positive and negative Twitter posts within each flavor category were conducted using 2 proportion z tests in SAS version 9.4 (SAS Institute Inc) to determine the significant differences between the proportion of positive sentiments and the proportion of negative sentiments. All tests were two sided, with a significance level of 5%. The original *P* values were adjusted using the Bonferroni method to account for multiplicity.

Results

Prevalence of Electronic Cigarette Flavors Mentioned on Reddit

E-liquid flavors were classified into different flavor categories. Table 1 provides an overview of the multiple levels of classifications, including major flavor categories, subcategories, and specific flavors. The proportions of hierarchical 3-layer flavor classifications are shown in Multimedia Appendix 1. Using the filtered Reddit data, Table 2 shows the percentage distribution of major flavor categories as well as detailed percentage distributions of 4 major flavor subcategories. As shown in Table 2, the *fruit* and *sweets* categories were the most mentioned and popular flavor categories on Reddit, followed by *beverage*, *menthol or mint*, *tobacco*, *others*, and *mixed*. In addition, *berry* was the dominant subcategory with a percentage of 45.84% (7,27,404/15,86,926) over all fruit-related subcategories; *dessert* was dominant in the *sweets* subcategory with a percentage of 47.43% (1,89,946/400,500). *Coffee* (118,129/2,77,005, 42.65%) and *tea* (1,07,449/2,77,005, 38.79%) were the most popular subcategories in the *beverage* flavor category. In the *menthol or mint* flavor category, the *menthol* (1,73,641/2,29,817, 75.56%) subcategory was more popular than the *mint* (56,176/2,29,817, 24.44%) subcategory. The percentage of post count for specific flavors in Multimedia Appendix 1 showed that the *strawberry* flavor was the most mentioned in the *fruit* category, and the *vanilla* flavor had the most mentions in the *sweets* category.

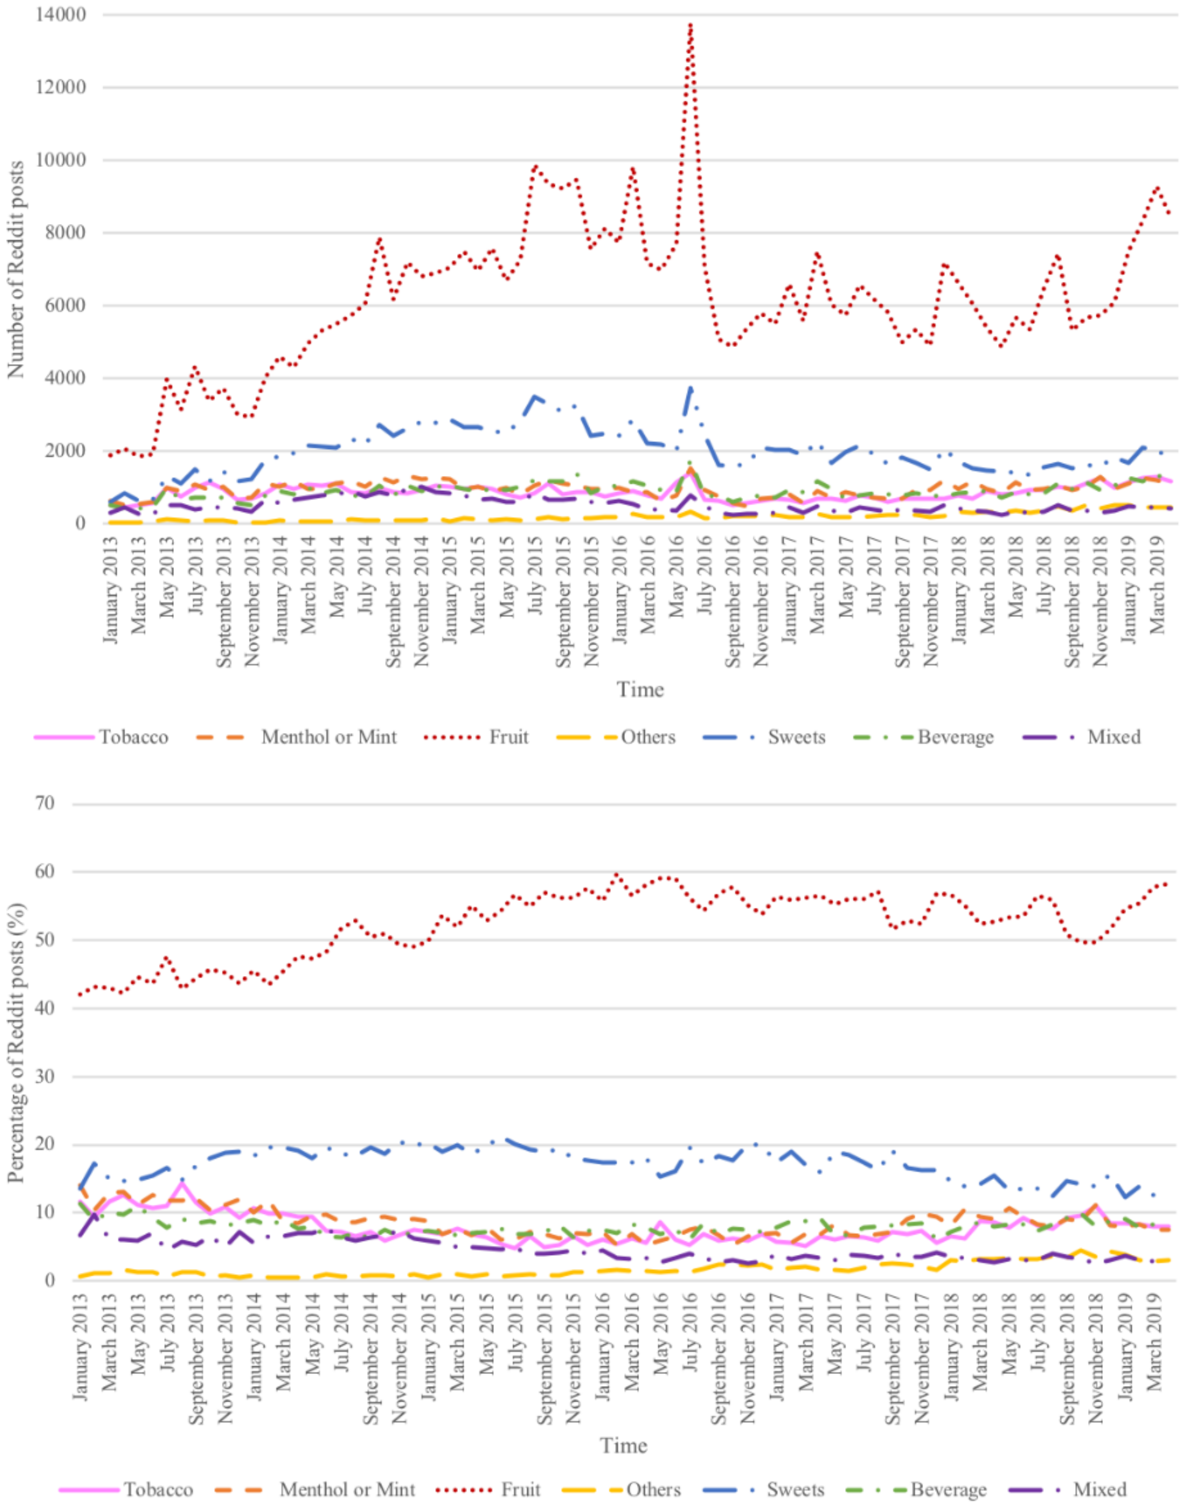
Table 2. Percentage distribution of e-liquid flavors mentioned on Reddit.

Flavor categories and subcategories	Count, n (%)
Fruit	1,586,926 (58.15)
Berry	727,404 (45.84)
Others	374,886 (23.62)
Tropical	190,639 (12.01)
Melon	138,876 (8.75)
Mixed fruit	102,618 (6.47)
Citrus	52,503 (3.31)
Sweets	400,500 (14.67)
Dessert	189,946 (47.43)
Others	113,688 (28.39)
Candy	96,866 (24.18)
Beverage	277,005 (10.15)
Coffee	118,129 (42.64)
Tea	107,449 (38.80)
Milk	21,764 (7.85)
Juice	21,117 (7.62)
Soft drink	5377 (1.94)
Others	3169 (1.14)
Menthol or mint	229,817 (8.42)
Menthol	173,641 (75.56)
Mint	56,176 (24.44)
Tobacco	163,377 (5.99)
Others	43,922 (1.61)
Mixed	24,769 (0.91)

Temporal Analysis of Mentions of Electronic Cigarette Liquid Flavors on Reddit

With the availability of new e-liquid flavors and the changes in the perception of users on e-liquid flavors over time, it is important to examine the temporal changes of e-liquid flavors mentioned on social media, so that the appropriate regulation of e-liquid flavors could be applied. To address this, we used the Reddit data collected from January 2013 to April 2019. By examining the number of Reddit posts on each e-liquid flavor, we observed a relatively increasing trend on the *fruit* category, whereas it remained relatively constant for the other flavor categories (Figure 1). The temporal analysis also showed a significant spike for each flavor category in June 2016 (Figure 1). This spike coincided with the US Food and Drug Administration (FDA), extending its regulatory authority to all tobacco products, including e-cigarettes and pipe tobacco on June 16, 2016. The number of posts mentioning e-liquid flavors on Reddit after June 2016 was much less than that before June 2016 but still showed an upward trend. After normalization to all posts mentioning flavors, the *fruit* flavor category had a steady upward trend from January 2013 to June 2016 and then showed some fluctuation. Most of the other flavor categories did not show significant trends, with *sweets* and *mixed* categories having a relatively noticeable decreasing trend.

Figure 1. The longitudinal trend of e-liquid flavors mentioned on Reddit, including the number of Reddit posts and the proportion of Reddit posts of each flavor category from January 2013 to April 2019. The proportion is normalized by the monthly total flavor-related post count. e-liquid: electronic cigarette liquid.



Sentiment Analysis of Electronic Cigarette Liquid Flavors Mentioned on Twitter

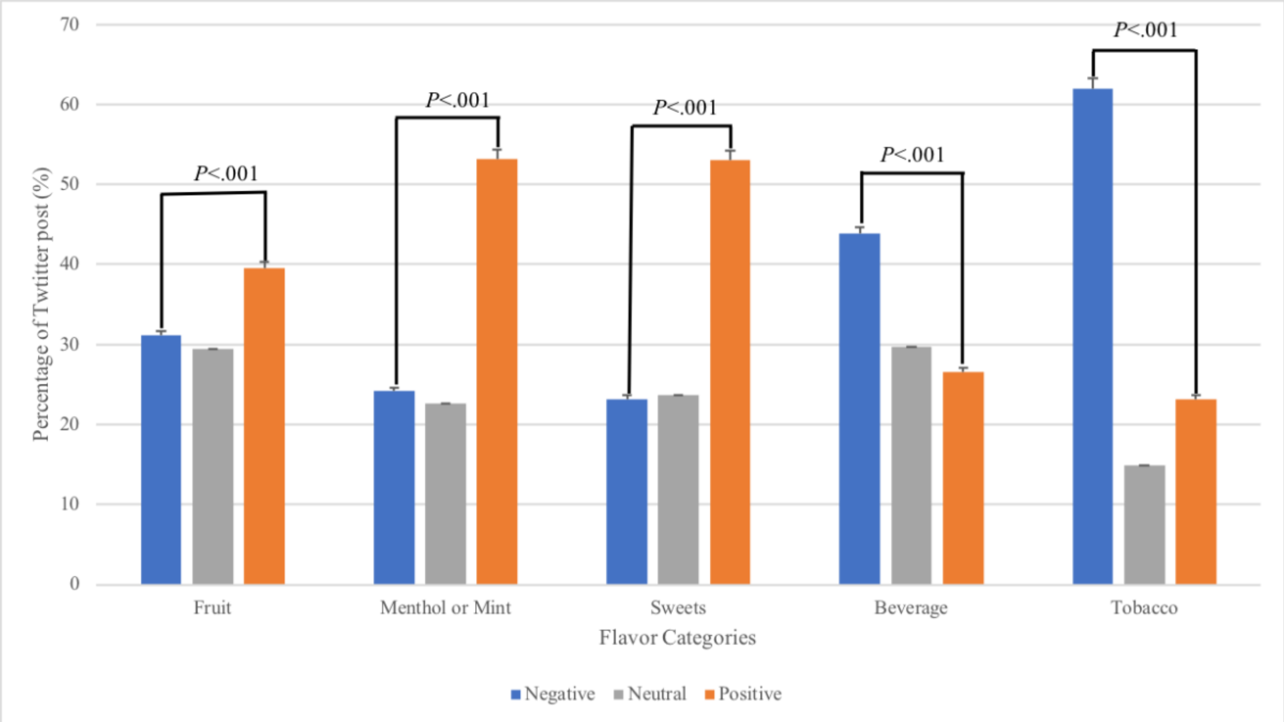
Although there are more than 7000 e-liquid flavors available on the market, it is important to examine the perception of public users to different e-liquid flavors, which will help us understand their prevalence on social media. As the character limit of Reddit subreddits is 40,000, it was difficult to locate the sentences only about e-liquid flavors in long Reddit messages. In this case, sentiment analysis precision for e-liquid flavors on Reddit cannot be ensured. Thus, Twitter data with a character limit of 280 were used instead for the sentiment analysis for more precise results. To obtain the most recent sentiments toward e-liquid flavors, we decided to use Twitter data from May 31 to August 22, 2019. As the total post counts in the *others* (276 posts) and the *mixed* (126 posts) flavor categories are much lower than other flavor categories and because e-cigarette flavors in these 2 categories were miscellaneous and diverse, we excluded these 2 categories in the sentiment analysis. The sentiment analysis on each e-liquid flavor category using Twitter data showed that, on average, the posts with the *sweets*, *menthol or mint*, and *fruit* flavor categories had positive sentiments, whereas the posts with the *tobacco* and *beverage* flavor categories showed negative sentiments (Table 3).

On the basis of thresholds of +/- 0.05 for positive and negative sentiments, each post was classified into positive, negative, or neutral sentiments. Within each flavor category, the proportion of posts with different sentiments was calculated (Figure 2). The *fruit*, *menthol or mint*, and *sweets* flavor categories had a significantly higher proportion of positive posts than negative posts (*P*<.001). In contrast, the *beverage* and *tobacco* flavor categories had a significantly higher proportion of negative posts than positive posts (*P*<.001).

Table 3. Sentiment analysis of flavor categories on Twitter.

Flavor category	Total post count, N	Average sentiment score, mean (SD)
Fruit	9852	0.074 (0.453)
Menthol or mint	4582	0.128 (0.379)
Sweets	3190	0.156 (0.442)
Beverage	1805	−0.090 (0.451)
Tobacco	1555	−0.134 (0.440)

Figure 2. Sentiment analysis of the flavor categories mentioned on Twitter. Error bars represent the estimated SDs.



Discussion

Principal Findings

In this study, by mining e-cigarette–related posts on social media (Reddit and Twitter), we showed that *fruit* and *sweets* flavors were the most popular flavors mentioned on social media, which remained to be the top popular flavors mentioned on social media over time. In addition, the sentiment analysis result showed significant positive attitudes toward *fruit* and *sweets* flavor categories. Although there were significant negative attitudes toward *tobacco* and *beverage* flavor categories, these 2 flavors were less mentioned on social media. Therefore, the perception of e-cigarette flavors on social media positively correlates with their popularity, that is, a positive sentiment correlates with high popularity on social media.

Our temporal studies showed that *fruit* and *sweets* have constantly been the most frequently mentioned e-liquid flavors on social media from 2013 to 2019, suggesting that the prevalence of e-liquid flavors mentioned on social media has not changed much over time. However, with the implementation of the e-cigarette flavor enforcement policy by the FDA on February 6, 2020, which bans all cartridge-based–flavored e-cigarettes except tobacco and menthol flavors, the popularity of e-liquid flavors will change accordingly. In addition, with the availability of other flavored e-cigarette products (such as disposable e-cigarette devices) on the market after the FDA flavor enforcement policy, it is hard to predict which flavors will become popular, which warrants further investigation.

In this study, we provided a way to timely monitor the prevalence of e-liquid flavors mentioned on social media as well as to identify the positive correlation between the perception of e-liquid flavors and their prevalence. With the power of this surveillance system, current regulation on flavored e-cigarettes could be modified or updated in a timely manner, and more importantly, the epidemic of e-cigarette use, especially among the youth, could be ameliorated to protect public health.

Comparison With Prior Work

Compared with the previous flavor wheel that was based on manually reviewed papers, the proposed e-liquid flavor classification in this study has better coverage of the up-to-date e-cigarette flavors with practical frequency distributions because it was constructed based on products on the web and discussions on social media [14]. As a result, we revised the flavor classification in several ways. First, the major flavor categories were merged from 13 into 7 categories [14]. For example, we combined the *candy*, *dessert*, and *other sweets* categories into the other sweets category of *sweets* as most of these flavors have sweetener ingredients. In addition, subcategories were created to form a more detailed flavor classification. For example, within the *fruit* flavor category, besides the existing second-level subcategories *tropical*, *berry*, *citrus*, and *others*, a *melon* subcategory was added because of the frequent mentions of melon-related flavors on social media. Together, the revised flavor classification contains more complete and the most up-to-date e-cigarette flavors.

A previous study showed the prevalence of the mentions of e-liquid flavor use on Reddit [15]. Instead of showing the yearly nominal post counts of each flavor category, our temporal analysis used the total flavor-related Reddit post counts to normalize the monthly data to see the trend of mentions of e-liquid flavors. Similar to previous findings [15], our results showed that the *fruit* flavor category was the dominant flavor on Reddit, followed by *sweets*. Another study showed that the *fruit* flavor category was mentioned most frequently on Facebook, followed by *sweet* and *cream* (classified as the *sweets* flavor category in our study) [23]. Compared with the findings from the previous study [15], the *beverage* flavor had a slightly larger portion of mentions recently. The percentage distribution of the *beverage* flavor increased from 7% to 10% from 2015 to 2019. Although this increase is small, which could be because of random error, there might be 2 other reasons. First, it could be caused by increased discussions about the *beverage* flavors on Reddit. Second, our *beverage* flavor-filtering keyword list contains more flavors. Besides the *coffee* and *tea* flavors, we added the *juice*, *soft drinks*, and *energy drinks* flavor subcategories in the *beverage* category, which might cause the *beverage* flavor category to have a larger percentage of mentions on Reddit [15].

On June 16, 2016, the FDA finalized a rule that extended its regulatory authority to all tobacco products, including e-cigarettes and pipe tobacco, as part of its goal to improve public health. This new rule also restricted youth access to newly regulated tobacco products [24]. Due to this new rule released by the FDA, more flavor-related e-cigarette Reddit posts were mentioned during that month, causing a significant spike in Figure 1. These data also demonstrated that social media data could accurately and timely reflect what happens in real life. There was a slightly increasing trend in the *fruit* category in Figure 1, which suggests that people tend to talk about fruit-related e-liquid flavors more frequently on Reddit compared with other flavor categories. A recent study using the Population Assessment of Tobacco and Health Wave 3 data showed that 52.8% of youths used fruit-flavored electronic nicotine delivery systems, which is consistent with our findings on the prevalence of fruit flavors (58%) mentioned using Reddit data [25]. Our sentiment analysis showed positive attitudes toward the fruit flavor category. Thus, our data suggest that the regulation of e-cigarette use should focus on the restriction of e-cigarette use with fruit flavors.

There have been few studies on flavor sentiment analysis on social media [16,26]. One study focused on e-cigarette–related Twitter post sentiments among users with respect to different genders and age ranges [16]. However, flavor-related sentiments were not discussed. Another study showed the sentiments on e-liquid flavors mentioned on JuiceDB, but only focusing on the 2 most popular flavors, *fruit* and *sweet* flavors [26]. Our results were similar to the sentiment analysis from JuiceDB, showing that the overall sentiments for those 2 flavors were positive. More importantly, our results performed a sentiment analysis on other flavor categories, thus providing a more comprehensive picture of the perception of e-liquid flavors on social media.

Limitations

In this study, Reddit and Twitter data were used to answer different questions considering their characteristics. A Reddit post has a relatively large character limit, which makes it an ideal data source to examine the experience users have with e-cigarettes. In addition, Reddit posts were available from January 2013 to April 2019, which made it possible to examine the temporal changes in popular e-liquid flavors. However, as Reddit posts have a 40,000-character limit, it is difficult to obtain accurate sentiment results for specific e-liquid flavors. Twitter posts have a much smaller character limit (280 characters) compared with Reddit, which makes it ideal for a sentiment analysis. Switching social media platforms from Reddit to Twitter in the process of a sentiment analysis may create some bias. The attitudes of users toward e-cigarette flavors on Twitter might be slightly different from those on Reddit.

Although there are more than 7000 e-liquid flavors on the market [27], just over 1000 specific e-liquid flavors were included in our dataset. In the future, more e-liquid brands and flavors will be collected for a more complete dataset, which can generate more detailed flavor classification. More analyses could be conducted by using additional social media platforms, such as Facebook and Instagram.

User demographic information, including gender, age, and ethnicity, is not available from social media data, which might limit further analysis of the prevalence of e-liquid flavors mentions among different demographic groups.

In general, the information from social media data is noisy, which could bias the results. However, our results are consistent with the results from the national survey data, which indicate the reliability of our conclusions.

With the announcement of the e-cigarette flavor enforcement policy by the FDA at the beginning of 2020, the prevalence of e-cigarette flavors will likely evolve as most flavors (such as fruit and sweets) are banned and as disposable e-cigarette devices with different flavors become available on the market. Understanding which flavors are the most popular after the flavor enforcement policy will be very important, which awaits further investigation.

Conclusions

Although the popularity of e-liquid flavors has been reported in previous studies, this study showed the longitudinal changes in the prevalence of mentions of e-liquid flavors as well as the perceptions users have of different e-liquid flavors. The findings from this study will provide the most updated information about the popular e-liquid flavors mentioned on social media and how the perceptions of different e-liquid flavors are correlated with their prevalence on social media, which could guide further regulation of e-cigarette flavors. Our results showed that the prevalence and perceptions of different flavors on social media were different. The findings of this study have several valuable applications. Social media data can be used to inform researchers or policymakers about the prevalence of mentions of different e-liquid flavors in a timely manner and provide some guidance on the regulation of flavored e-cigarettes. Although the FDA has restricted the sale of unauthorized flavored cartridge-based e-cigarettes, flavored e-cigarettes in other formats still exist in the market, such as disposable e-cigarette devices. Here, we provided a cost-effective surveillance system to monitor the prevalence of e-liquid flavors over time.

Abstract

Background: To improve working conditions and prevent illness and deaths related to overwork, the Taiwanese government in 2015, 2016, and 2018 amended regulations regarding working time, overtime, shifts, and rest days. Such policy changes may lead to a rising public awareness of overwork-related issues, which may in turn reinforce policy development.

Objective: This study aimed to investigate to what extent public awareness of overwork-related issues correlated with policy changes.

Methods: Policies, laws, and regulations promulgated or amended in Taiwan between January 2004 and November 2019 were identified. We defined 3 working conditions (overwork, long working hours, and high job stress) related to overwork prevention, generated a keyword for each condition, and extracted the search volumes for each keyword on the Google search engine as proxy indicators of public awareness. We then calculated the monthly percentage change in the search volumes using the Joinpoint Regression Program.

Results: Apparent peaks in search volumes were observed immediately after policy changes. Especially, policy changes in 2010 were followed by a remarkable peak in search volumes for both overwork and working hours, with the search volumes for overwork increased by 29% per month from June 2010 to March 2011. This increase was preceded by the implementation of new overwork recognition guidelines and media reports of several suspected overwork-related events. The search volumes for working hours also steadily increased, by 2% per month in September 2013 and afterward, reaching a peak in January 2017. The peak was likely due to the amendment to the Labor Standards Act, which called for “1 fixed and 1 flexible day off per week,” in 2016. The search volumes for job stress significantly increased (P=.026) but only by 0.4% per month since March 2013.

Conclusions: Over the past 15 years, Taiwanese authorities have revised and implemented several policies to prevent overwork-related health problems. Our study suggests a relationship between the implementation of policies that clearly defined the criteria for overwork and working hours and the rising public awareness of the importance of overwork prevention and shorter working hours.

KEYWORDS

overwork; working hours; policy; big data

Introduction

Overwork—including long hours or high physical or psychological effort or strain—may lead to the occurrence of cerebrovascular and cardiovascular diseases, mental disorders, and even *karoshi* (occupational sudden death) [1-3]. The first *karoshi* case was reported in Japan in 1969: the death of a 29-year-old male worker in a shipping department due to a stroke [4]. An increasing number of overwork-related events have been reported ever since in Japan, South Korea, and

Taiwan, where the culture of long working hours is prevalent and even valued [5].

In Taiwan, several apparent overwork-related cases were reported in the period between 2009 and 2011 but their workers' compensation claims were disapproved by the Bureau of Labor Insurance. The ways the labor insurance authorities handled such disputes ignited public criticisms. Finally, these workers' family members turned to legislators for help, pushing the governments to revise their policies and regulations concerning overwork [6]. In response to societal concerns, the Taiwanese government has modified both the policies for workers' compensation benefits and the prevention policies for overwork [6]. With regard to workers' compensation, the government has loosened the recognition guidelines since the late 2010 to allow more cases to be compensated by the labor insurance system. With regard to prevention of overwork problems, the government adopted new prevention measures in the Occupational Safety and Health Act in 2013; revised legal regular working hour limit stipulated in the Labor Standards Act in 2015 from 84 hours over 2 weeks to 40 hours per week; and twice—in 2016 and again in 2018—amended regulations pertaining to regular working time, overtime, annual leave, shifts, and rest days. Through these actions, the government has demonstrated its commitment to preventing overwork by shortening working hours and improving working conditions.

In addition to regulatory reforms, for the prevention of overwork problems, it is important to enhance public awareness of health risks associated with overwork and other adverse working conditions, such as long working hours and high job stress [7,8]. On the one hand, policy changes may be the results of increased social concerns. On the other hand, the development of policies could further enhance social awareness. According to the knowledge, attitude, and practice theory [9], it can be expected that higher social awareness will lead to the acquisition of information and knowledge and the cultivation of better attitudes toward preventative practices. For example, clear regulation of a company's working hours could facilitate better understanding of how to prevent overwork among its employees. However, public awareness levels are not easily assessed.

The use of internet and online search engines such as Google, Yahoo!, and Bing has become one of the most popular means to obtain knowledge on specific topics, which further enhance people's attitudes, behaviors, and decisions [10]. A previous study has identified that in 2012, around 55% of internet users in the United States used search engines to obtain health-related information [11]. Among all search engines, Google is the most popular in many countries, and in Taiwan about 94% of internet users use Google as their primary search engine [12]. The Google Trends website reports on recorded Google search volumes, and has been widely used to measure public awareness and interest in specific issues, such as cancer screening and crude oil prices [13,14], to assess the impact of celebrity on public behavior [15], and to conduct health assessment studies [16]. Thus, Google search volumes extracted from the Google Trends platform can be a proxy indicator of public awareness of overwork-related issues.

Previous studies in Japan and South Korea have mentioned that public awareness of overwork is likely to be enhanced both by reports of the occurrence of overwork-related diseases and by recent changes in overwork-related policy [7,17]. While this assumption has been proposed, no study has yet demonstrated whether or not public awareness has been influenced by policy changes and reported overwork incidents. We hypothesized that public awareness increased following changes in policies which clearly address overwork-related risk factors. We therefore aimed to use Google search volumes to investigate whether and to what extent the public's awareness of overwork prevention has been influenced by policy changes and the occurrence of overwork-related events.

Methods

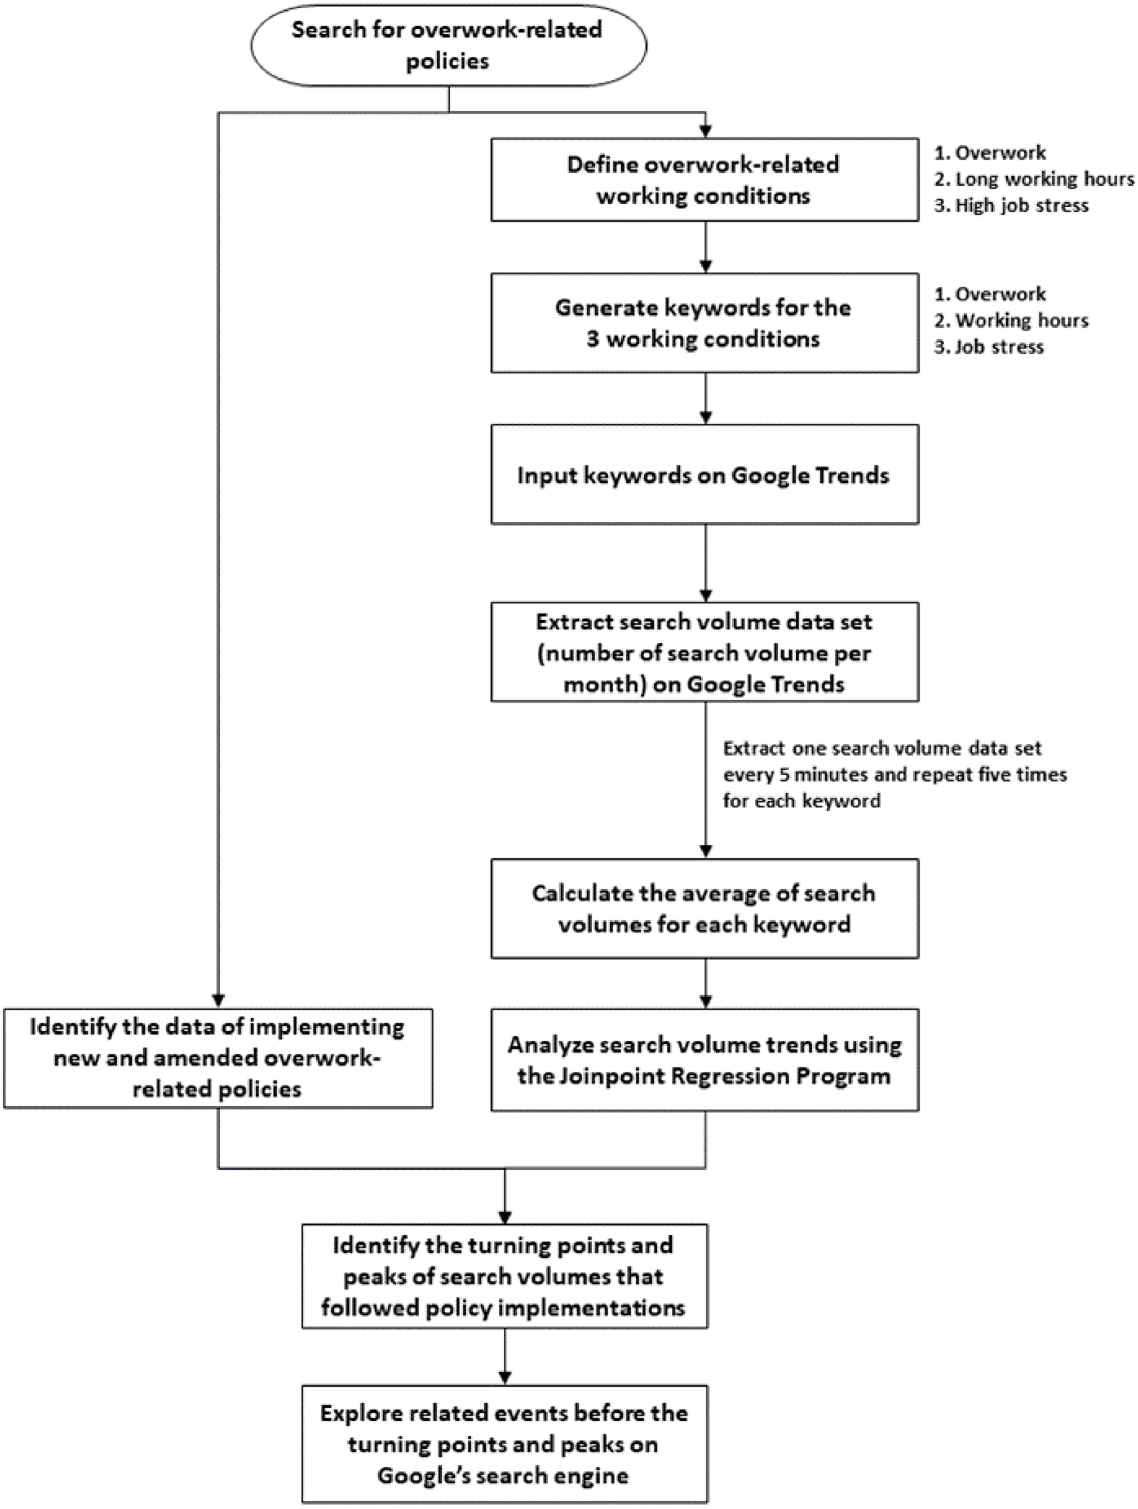
Study Process

Figure 1 shows our study process. We searched for policies, laws, and regulations promulgated or amended in Taiwan during the period between January 2004 and November 2019. We then identified 2 working conditions related to the aforementioned policy changes: (1) overwork, which has no official definition in Taiwan but is understood to describe both working too long (too many hours) and as working too hard (physically or psychologically); and (2) long working hours, which are regulated through both regular working time and overtime policies. We further identified a third working condition related to the 2004–2019 policy changes but had no direct quantitative measure: (3) high job stress. We treated overwork and long working hours as the main topics of interest, and high job stress as a reference topic (relevant to overwork but not addressed in the amendments of Labor Standards Act). To measure these 3 working conditions, we identified a keyword for each condition.

We used the keywords to extract search volumes from the Google Trends platform [18], which is used to record big data related to search volumes. The data on search volumes were scaled on a range of 0-100, with the scaled number shown as relative proportional to all searches. The website has 4 filter options: region, time, category, and search type; for these filter options, we selected Taiwan, January 2004–November 2019, all categories, and web search, respectively.

We noticed the variability of search volumes while we repeatedly searched on the Google Trends platform. The Google Trends sampled data on searches correspond to billions of Google searches per day. However, the algorithms behind the platform were not available to the general public [19]. We, therefore, developed our search strategy, repeated data extraction, and smoothed data by taking averages. We extracted one search volume data set every 5 minutes and repeated five times for each keyword. We then calculated the average of search volumes for each keyword and analyzed search volume trends using the Joinpoint Regression Program [20]. Next, we identified the turning points and peaks of search volumes that followed policy implementations. For points or peaks that did not follow policy changes, we used Google's search engine to explore related events before the turning points and peaks.

Figure 1. The study process.



Study Period

Our study period was from January 2004 to November 2019. January 2004 was the earliest data we could access from the Google Trends platform, and 2004 was also the year when Taiwan's Recognition Guidelines for Overwork-Related Diseases were first amended.

Data Analysis

First, we calculated the average monthly search volume for each keyword. Second, we used the Joinpoint Regression Program to estimate the web search volume trends over time [20]. The Joinpoint Regression Program allows us to analyze trend data and test joinpoints (or apparent changes or peaks) across the whole study period. Data captured as 0 were adjusted to 0.5 to fit all data on a log-linear Poisson regression model. Bayesian information criterion was used to identify turning points and select the best model. The monthly percentage change of search volumes of each segment during the study period was estimated by the following equation:

$$\log(V_t) = \beta_0 + \beta_1 \times t \ (1)$$

where $\log(V_t)$ is the natural log of the average number of relative search volumes at time t; β_0 indicates the intercept of the model; β_1 is the slope of the model, which was later used to estimate the monthly percentage change of search volumes of each segment [20]; and t is the time variable, indicating the month (from January 2004 to November 2019, indicated as 1 to 191).

Results

Figure 2 shows the policy changes and the search volume trends for the keywords of the 3 working conditions. The red line shows overwork trends, the blue line shows working hours trends, and the gray line shows job stress trends. A higher search volume represents relatively higher public awareness of the topic.

Comparing the relative average search volumes of the 3 working conditions between January 2004 and November 2019, we found the highest volume was for working hours (average volumes=37), followed by overwork (average volumes=13) and job stress (average volumes=11). Most of the observed peaks occurred in 2 periods: the first from the middle of 2010 to early 2011, and the second from the middle of 2015 to early 2018. The first period included peaks in search volumes for both overwork and working hours. The first overwork peak—indicated as the filled circle on the red line—appeared in September 2010, following a death of an engineer in January 2010 that was suspected to be an overwork-related event. Then, a dramatic increase and peak for overwork appeared in March 2011—indicated as the inverted triangle on the red line, following media reports on an increase in suspected overwork-related events and the second revision of Taiwan's Recognition Guidelines for Overwork-Related Diseases in December 2010 (dashed line R2). This phenomenon also urged the government to include more occupations (preschool educator, medical personnel, and hotel and motel bedmaker) among those covered by the Labor Standards Act Articles 30 and 32 in order to regulate their normal working hours and overtime hours. This is indicated as the filled square on the blue line in November 2011.

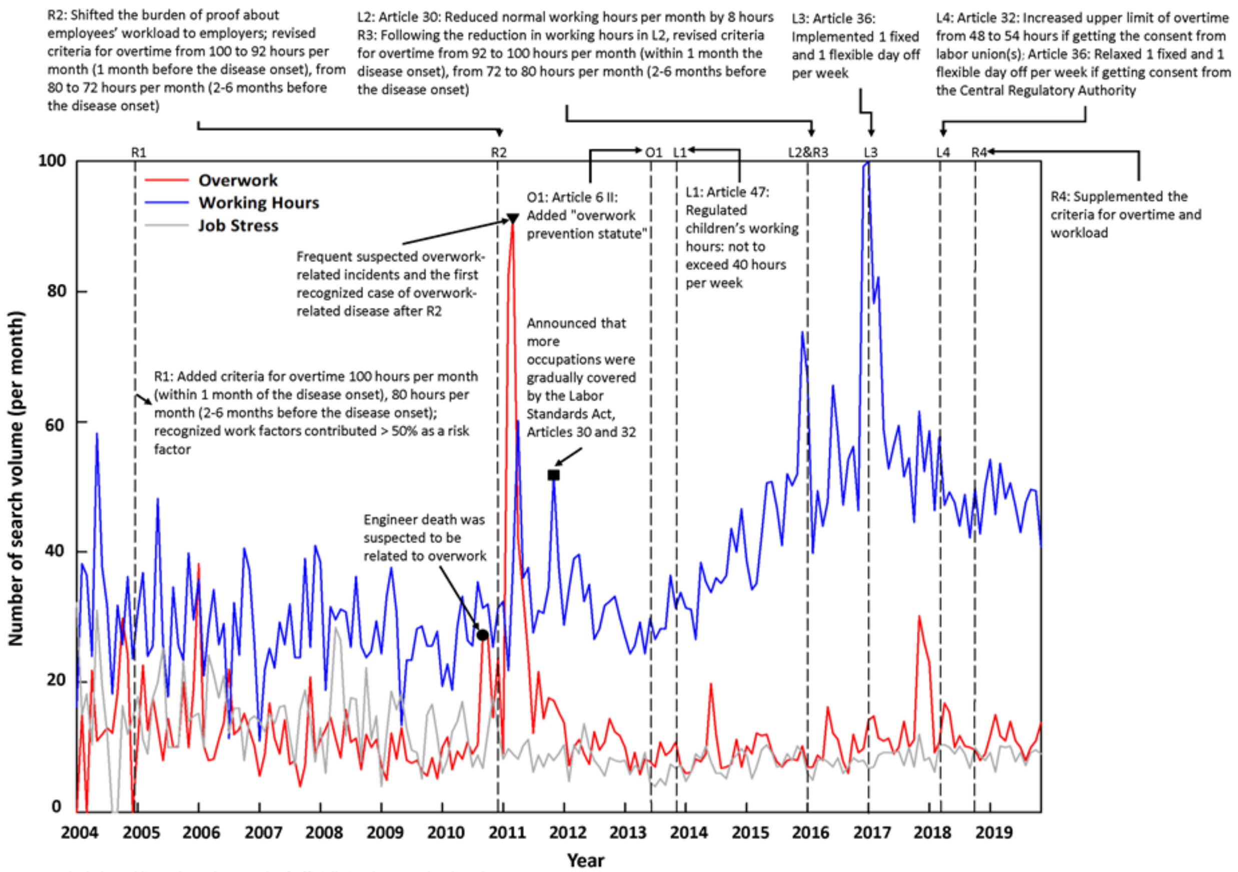
The second peak period appeared to be attributed mainly to policy changes related to working hours: most peaks on working hours searches matched the policy changes, such as the 12th revision of the Labor Standards Act in May 2015, and its implementation in January 2016 (dashed line L2); the 16th amendment of the Labor Standards Act, stipulating 1 fixed and 1 flexible day off per week, in December 2016, and its implementation in January 2017 (dash line L3); and the 18th amendment of the Labor Standards Act, which was implemented in March 2018 (dashed line L4). Over the entire period, the search volume for job stress remained relatively lower and more stable than those for overwork and working hours.

Table 1 presents the monthly percentage change of search volumes for the 3 working conditions, with obvious and significantly increasing trends for both overwork and working hours. From June 2010 to March 2011, the monthly percentage change of search volumes for overwork significantly increased by 28.97% per month (95% CI 19.25-39.49; $P<.001$), following (1) the frequent reports of suspected overwork-related events, especially among engineers and security personnel (Figure 2, inverted triangle), and (2) the second amendment of Recognition Guidelines for Overwork-Related Diseases in 2010 (Figure 2, line R2).

For working hours, the monthly percentage change of search volumes significantly increased from September 2013 to October 2016 by 1.78% per month (95% CI 1.14-2.43; $P<.001$). This trend occurs after the 12th amendment of the Labor Standards Act (ie, reduce 2 hours for normal working hours per week) and the disputes for 16th Labor Standards Act revision (regarding 1 fixed and 1 flexible day off per week); the search volumes peaked in concert with the implementation of the 16th amendment in January 2017.

Slightly increasing trends appeared for job stress from the middle of 2013 to the end of 2019, by 0.39% per month (95% CI 0.05-0.73; $P=.026$), but 84% of the number of search volumes per month was still lower than 10. This trend occurs after the new revision of Occupational Safety and Health Act in July 2013, which added the "overwork prevention statute."

Figure 2. Policy changes and search volume trends for working hours, overwork, and job stress from January 2004 to November 2019.



R2: Shifted the burden of proof about employees' workload to employers; revised criteria for overtime from 100 to 92 hours per month (1 month before the disease onset), from 80 to 72 hours per month (2-6 months before the disease onset)

L2: Article 30: Reduced normal working hours per month by 8 hours
R3: Following the reduction in working hours in L2, revised criteria for overtime from 92 to 100 hours per month (within 1 month the disease onset), from 72 to 80 hours per month (2-6 months before the disease onset)

L3: Article 36: Implemented 1 fixed and 1 flexible day off per week

L4: Article 32: Increased upper limit of overtime from 48 to 54 hours if getting the consent from labor union(s); Article 36: Relaxed 1 fixed and 1 flexible day off per week if getting consent from the Central Regulatory Authority

O1: Article 6 II: Added "overwork prevention statute"

L1: Article 47: Regulated children's working hours: not to exceed 40 hours per week

R4: Supplemented the criteria for overtime and workload

Frequent suspected overwork-related incidents and the first recognized case of overwork-related disease after R2

Announced that more occupations were gradually covered by the Labor Standards Act, Articles 30 and 32

R1: Added criteria for overtime 100 hours per month (within 1 month of the disease onset), 80 hours per month (2-6 months before the disease onset); recognized work factors contributed > 50% as a risk factor

Engineer death was suspected to be related to overwork

Black dotted lines show the month of officially implemented policy changes
(R: revisions of Recognition Guidelines for Overwork-Related Diseases, O: revisions of the Occupational Safety and Health Act, L: revisions of the Labor Standards Act)

Table 1. Trends and monthly percentage change of search volumes for the 3 working conditions.

Working conditions and their periods studied	Trend (*P* value)	Monthly percentage change of search volumes (95% CI)
Overwork		
January 2004 to June 2010	↓ (*P*<.001)	–1.08 (–1.45 to –0.71)
June 2010 to March 2011	↑ (*P*<.001)	28.97 (19.25 to 39.49)
March 2011 to July 2011	↓ (*P*=.014)	–36.06 (–55.14 to –8.87)
July 2011 to November 2015	↓ (*P*=.004)	–0.99 (–1.66 to –0.32)
November 2015 to December 2017	↑ (*P*=.006)	2.99 (0.86 to 5.16)
December 2017 to November 2019	↓ (*P*=.020)	–2.50 (–4.55 to –0.41)
Working hours		
January 2004 to September 2013	↔ (*P*=.768)	0.02 (–0.11 to 0.15)
September 2013 to October 2016	↑ (*P*<.001)	1.78 (1.14 to 2.43)
October 2016 to January 2017	↔ (*P*<.470)	19.07 (–26.00 to 91.59)
January 2017 to May 2017	↔ (*P*=.194)	–14.22 (–32.00 to 8.22)
May 2017 to November 2019	↔ (*P*=.121)	–0.59 (–1.34 to 0.16)
Job stress		
January 2004 to January 2008	↓ (*P*<.001)	–0.93 (–1.45 to –0.41)
January 2008 to April 2008	↔ (*P*=.810)	12.49 (–57.19 to 195.55)
April 2008 to March 2013	↓ (*P*<.001)	–1.64 (–2.10 to –1.18)
March 2013 November 2019	↑ (*P*=.026)	0.39 (0.05 to 0.73)

Discussion

Principal Findings

Over the past 15 years, Taiwanese authorities have revised and implemented several policies to prevent overwork-related health problems. By treating search volumes for overwork-related keywords as proxy indicators of public awareness, our findings suggest that increasing public awareness of the importance of overwork prevention and shorter working hours was observed after Taiwan's recent policy changes related to overwork prevention. Such increased awareness is expected to contribute to better attitudes and practices regarding overwork prevention among the general public [9].

Public awareness of overwork significantly increased ($P<.001$) following the 2010 revision and implementation of the Recognition Guidelines for Overwork-Related Diseases, as well as the frequent media reports in 2009–2011 of suspected overwork-related incidents. Public awareness of working hours increased from 2013 and peaked twice, in the end of 2015 and early 2017, along with the two amendments (12th and 16th) of the Labor Standards Act.

Overwork

The search volumes for overwork increased from June 2010 to March 2011, a period which saw frequent reports of suspected overwork-related incidents prompt public realization of the seriousness of the problem. During the same period, more overwork cases were recognized by the 2010 Recognition Guidelines for Overwork-Related Diseases, which encouraged public confidence in overwork-related policy. After the revised recognition policy was implemented in 2010, the average number of working hours per month of those employed in the industry and service sectors in Taiwan decreased by 9.1 hours from 178.7 hours in 2011 to 169.6 hours in 2016 [21]. The amendment to the recognition guidelines followed the sudden death, in January 2010, of an engineer in Taiwan by cardiogenic shock and hypertrophic cardiomyopathy. Although some of the disease cases could not be officially recognized as related to overwork right out, they exerted influences because a nongovernmental organization (Taiwan Labour Front) and a legislator (Ms Sue‐Ying Huang) organized several press conferences on behalf of families of deceased to promote social awareness via social media, and finally intervene in the decision making of the Ministry of Labor in Taiwan [6]. These activities had aroused public awareness about the strenuous working conditions of elite image engineers. When the 2010 Recognition Guidelines for Overwork-Related Diseases were implemented, cerebrovascular and cardiovascular diseases related to working conditions with long-term excessive overtime became the first recognized overwork disease [6]. Social media together with efforts of Legislator Huang and nongovernmental organizations appeared to have a strong influence on the policy changes in Taiwan [6,22]. Based on this understanding, one way to significantly enhance public awareness of overwork is to cooperate with legislators and nongovernmental organizations and to encourage more media reports on policy changes via social media.

Working Hours

Public awareness about working hours significantly increased ($P<.001$) from September 2013 and reached a peak in January 2017, which included 2 relevant policy amendments to the Labor Standards Act. Among all search volume peaks in this period, the highest were observed in January 2017, aligned with the start of implementation of the 16th amendment, which called for "1 fixed and 1 flexible day off per week." That this policy change would call forth such a high search volume might be due to presidential influence. The theme of overwork was a hot issue during Taiwan's 2016 presidential election. Among all presidential candidates, one candidate (Dr Ing-Wen Tsai, who later won the election) was most committed to preventing overwork problem in Taiwan and even claimed to have prepared related policies that would improve working conditions. This candidate went on to get most of the labor unions' support. Along with their candidate's victory in the presidential election, union workers now look forward to the corresponding policy changes [23], which they expect to provide better working conditions. Since President Tsai was inaugurated in May 2016, the Labor Standards Act has been revised seven more times between November 2016 and May 2019 [24].

Policies and Public Awareness

In our study, we observed higher search volumes around the months when policies were revised and implemented. Revision and implementation are the 2 phases wherein the public can participate in the policy change process (comprised from invention, estimation, selection [revision], implementation, evaluation, to termination) [25]. High search volume observed during policy revision and implementation periods may be attributable to the healthy democracy in Taiwan, which allows for public participation in the policy change process, promotes mutual understanding among stakeholders, and emphasizes the legitimacy of governance [26].

Public awareness on both overwork and working hours was enhanced along with the related policy changes and frequent reports of suspected overwork-related events. However, the search volume trends on overwork and working hours differ. The trend of increasing search volumes on overwork (June 2010 to March 2011) lasted for only 10 months, following the reporting of suspected overwork-related events. By contrast, the trend of increasing search volumes on working hours (September 2013 to October 2016) lasted for 38 months, following the amendments of the Labor Standards Act. Our results suggest that public awareness caused by events is short lived, whereas public awareness induced by policy exists for a longer time, likely because social media continues to provide new information and discussion on the topic [27,28]. Therefore, we suggest that developing overwork-related policies that clearly address risk factors contributes to increasing the public awareness of overwork prevention.

As a reference outcome, public awareness of job stress was lower than public awareness of overwork and working hours over the past 15 years. Given the fact that high job stress is one of the major reasons for overwork [29], we suggest that policies should also target overwork caused by job stress, similar to

European policies for psychosocial risk management in the workplace [30].

Limitations

There are some limitations to our study. First, we identified one keyword with the highest search volume as the representative keyword for each working condition. The general public might use other unpopular keywords (synonyms) to search for more knowledge on each working condition. That is, each working condition could be described using different keywords. Thus, our choice of high-volume keywords might underestimate the effect of policy changes on public awareness.

Second, we could not get an absolute value for search volume on Google Trends. Data obtained from Google Trends are a relative search volume (search volume range from 0 to 100). For cross-keyword and overtime comparisons, we could only compare search volumes for up to 5 keywords at once. Our choice of 3 keywords ensured the comparability of search volumes in our results. Future studies that attempt to expand the number of keywords compared will warrant the development of advanced adjustment methods.

Third, search volumes on Google Trends have been used to explore and predict behaviors on the outpatient visits and people's awareness of health care [16,31-33], but have been shown to be less predictive of public opinions on elections and referendums in low-internet-use or low-freedom-of-speech regions [34]. Our study focuses on searches in Taiwan, where over 80% of the population uses the internet and people have a high degree of freedom to speak their personal opinions [35,36]. The advantages of using Google Trends should also be highlighted, including reducing the time and cost associated with the traditional measures of public awareness and acting as a supplement and complement to traditional polls or surveillance systems [37], especially in countries with high internet penetration and freedom of speech. Although Google is the most commonly used search engine in Taiwan, there are other types of search engines that may be used by different sectors of population, thus may generate different search patterns. Yet, comparative analyses of search patterns across different search engines are beyond the scope of this study. A separate study involving the collection and comparison of data from different search engines can help explore the diverse patterns.

As described in a 2014 review about big data's features [38], the 4V concept—related to the high volume, velocity, variety, and veracity of information—was developed, along with the understanding that transforming data into value requires specific technology and analytical methods. Search volumes obtained from Google Trends are relative, and some might doubt if these search volumes should be considered big data. However, Google Trends data fit the aforesaid 4 features, and some earlier studies have set precedents for considering Google Trends data as online big data [39]. Moreover, the novel way in which Google Trends presents data largely reduces equipment requirements for big data analysis and can be used in many fields. Google Trends can in fact help government officials quickly clarify fast-changing events that raise public concern [40,41] and collect large volumes and a variety of past data in a short period, which is hard to achieve through traditional public polls.

What our study contributes to the global society, particularly labor policymakers, is that a clear policy will lead to rising public awareness, and such an increase in public awareness will reinforce policy change—leading to a virtuous circle. In addition, study findings from Taiwan, a democratic society, highlight the importance of communication capacity in informing and engaging citizens. We believe that our approach enabled a reasonable representation of countries with similar internet access, freedom of participation in political and public affairs, and government responsiveness; by contrast, countries with different political environments warrant separate analyses. We encourage the country's citizens to have more access and freedom to engage in public affairs, particularly labor and public health issues.

Conclusions

Overwork-related health problems due to long working hours, heavy workloads, hectic work pace, and insufficient rest time are major occupational health concerns in many East Asian countries, and in certain occupational groups of Western societies. Regulations concerning working hours, overtime pay, paid leave, and rest time have long been central issues in labor and health protection policies. While in Taiwan, the labor and health authorities have made efforts by revising laws and implementing new policies to improve work quality and to reduce overwork-related health risks, there are still controversies and debates with respect to their regulatory designs and enforcement. Analyses of substantive policies are beyond the scope of this study.

Yet, this study demonstrates rising public awareness of overwork prevention, particularly as it relates to overwork and working hours, following recent overwork-related policy changes. Public awareness of policy contents and citizens' supports are essential for effective policy implementation. Our findings suggested that in Taiwan, certain components of overwork prevention policies were conveyed to the public more effectively while the others were conveyed less effectively. Because our findings indicate that the public are less aware of the role of job stress in overwork prevention, we suggest implementing interventions to address this phenomenon. Ultimately, to enhance public awareness of overwork prevention, national overwork-related policies that clearly address risk factors are necessary.

Abstract

Background: Identifying effective means of communication between patients and their health care providers has a positive impact on patients' satisfaction, adherence, and health-related outcomes.

Objective: This study aimed to identify the impact of patients' age on their communication and technology preferences when managing their health. We hypothesize that a patient's age affects their communication and technology preferences when interacting with clinicians and managing their health.

Methods: A mixed methods study was conducted to identify the preferences of patients with cardiovascular diseases. Results were analyzed based on the patients' age. Grounded theory was used to analyze the qualitative data. Patients were recruited based on age, gender, ethnicity, and zip code.

Results: A total of 104 patients were recruited: 34 young adults (19-39 years), 33 middle aged (40-64), and 37 senior citizens (>65). Young adults (mean 8.29, SD 1.66) reported higher computer self-efficacy than middle-aged participants (mean 5.56, SD 3.43; $P<.05$) and senior citizens (mean 47.55, SD 31.23; $P<.05$). Qualitative analysis identified the following three themes: (1) patient engagement (young adults favored mobile technologies and text messaging, middle-aged patients preferred phone calls, and senior citizens preferred direct interactions with the health care provider); (2) patient safety (young adults preferred electronic after-visit summaries [AVS] and medication reconciliation over the internet; middle-aged patients preferred paper-based or emailed AVS and medication reconciliation in person; senior citizens preferred paper-based summaries and in-person medication reconciliation); (3) technology (young adults preferred smartphones and middle-aged patients and senior citizens preferred tablets or PCs). Middle-aged patients were more concerned about computer security than any other group. A unique finding among senior citizens was the desire for caregivers to have access to their personal health record (PHR).

Conclusions: Patients of different ages have different communication and technology preferences and different preferences with respect to how they would like information presented to them and how they wish to interact with their provider. The PHR is one approach to improving patient engagement, but nontechnological options need to be sustained to support all patients.

Introduction

Background

The purpose of the Health Information Technology for Economic and Clinical Health Act was to promote the adoption and meaningful use of health information technology (HIT) [1]. Meaningful use is an endeavor initiated by the Centers for Medicare and Medicaid Services (CMS) and the Office of the National Coordinator for Health IT. It involves the use of certified electronic health records (EHR) fundamentally to improve the quality, safety, and efficiency of care [2]. One of the meaningful use requirements is to engage patients and families in their health by offering secure, Web-based access to patients' health information and provide tools that support electronic communication between patients and providers [3]. A more robust understanding of patient communication and technology preferences is essential for ensuring that patients have access to relevant information needed to make informed health care decisions [4-7]. Providing patients access to personal health information has the potential to enhance the delivery of health care services and encourage patient engagement [8]. Patient experience is an integral component of health care quality and focuses on aspects of health care delivery, such as getting timely appointments, easy information access, and effective communication with health care providers. Accurate perception of the patient experience is an essential step in moving toward patient-centered care [4,9]. Patient-centered care is 1 of the 6 major domains of health care quality and is defined as "providing care that is respectful of and responsive to individual patient preferences, needs, and values and ensuring that patients' values guide all clinical decisions [10]." Identifying effective means of communication between patients and their health care providers have a positive impact on patients' satisfaction, adherence, and health-related outcomes [11-13]. This allows for critical and necessary communication to enable the highest level of patient-centered care possible.

Electronic health (eHealth) is an effective medium for bringing HIT to patients in ways that are easily accessible [14]. eHealth is "*health services and informational resources delivered or enhanced through the Internet and related information and communication technologies* [15]." eHealth supports communication between health care providers and their patients and promotes patients' self-management of chronic diseases [16-19]. As the use of eHealth increases, it is crucial to examine sociodemographic characteristics, such as age, that may affect patients' ability to use eHealth [20-26]. Younger adults are historically more open to using eHealth than older adults [25,27-35]. Not all older adults own internet-connected devices to access eHealth tools or have the necessary skills needed to use it, increasing the digital divide gap [27,32,33,35].

With increased access to the internet, digital divide research has shifted from internet connectivity barriers (level one of the digital divide) to barriers related to internet skills and usage (level two of the digital divide) [36]. The third level of the digital divide focuses on individuals' capacity to translate their internet access and use into favorable tangible outcomes [37-39]. The digital divide has the potential to intensify health disparities among vulnerable populations; previous research provides evidence of the digital divide being a barrier to eHealth adoption [24,26,40-49]. Providing effective eHealth interventions is an opportunity to provide patients with the necessary communication tools for self-management [25,50,51]. This opportunity could be easily missed if patients' needs, preferences, and abilities are neglected [14].

Objectives

This study's objective was to identify the impact of patients' age on their communication and technology preferences when managing their health. Communication and trust are at the core of the patient-clinician interaction. In addition, technology adoption outside of health care is heavily influenced by a user's age [52]. Thus, we investigated the communication and technology preferences of patients with cardiovascular diseases in the age of CMS' Promoting Interoperability Program. Dholakia [52] presents a general framework that an individual's age is a critical determinant of a person's attitude, use, and perceived benefits of many technologies. Age is influential in technology use and adoption because the periods of a person's life, notably during years as a youth, shape the skills, orientations, and environments of particular technologies [52]. Therefore, we hypothesized that communication and technology preferences are determined, in part, by the age of the patient. The study aimed to test this hypothesis with the following research question: How does age impact patients' preferences when managing their health?

Methods

Study Design

A mixed methods approach was applied to examine communication and technology preferences by conducting interviews with 104 cardiovascular medicine patients at the University of Nebraska Medical Center (UNMC) in the United States of America. UNMC's Institutional Review Board approved the study.

Organizational Setting

UNMC is a Midwest academic medical center whose clinical partner is Nebraska Medicine. The Division of Cardiovascular Medicine operates three clinics with over 28,000 annual patient visits. The Health care Information and Management Systems Society, a nonprofit organization that examines hospitals' advancement toward implementing HIT, has honored UNMC with Stage 7 of the Electronic Medical Record Adoption Model [53]. Stage 7 means UNMC's hospitals and clinics have a fully integrated EHR, employ Continuity of Care Documents to transport data, use data warehousing to assess clinical data, and demonstrate summary data continuity for all hospital services [54]. The personal health record (PHR) offered at UNMC's is Epic MyChart, a tethered PHR.

Participants

Patients with heart disease were chosen for this study because cardiovascular disease is a complex, chronic disease and is one of the leading causes of death in the United States. Heart disease and stroke account for over 800,000 deaths annually, costing

US $316 billion in health care expenditures and lost productivity yearly [55]. Although patients were recruited from the cardiovascular clinic, patients in this sample had comorbidities. A cardiovascular medicine research nurse coordinator recruited patients after their clinic visit based on age, gender, race, ethnicity, and zip code. Zip codes were used to determine urban versus rural environments and establish average household income. Rural areas were defined as a population less than 10,000 and nonadjacent to a metropolitan area. Income was based on census data of median household income for that zip code. Participants were grouped according to their age. Younger participants were categorized as *young adults* (19-39), senior citizens in the US begin at age 65 and were categorized as *senior citizens* in this study, and middle aged were categorized as adults in between the age ranges of the young adults and senior citizens (40-64). Data collection sessions were scheduled and conducted in a clinic or adjacent conference room. Whenever possible, the research interview was linked to their scheduled appointment. Participants were not compensated for their participation.

Data Collection

Each data collection session lasted 30 to 60 min. After the consent was obtained, sociodemographic data were obtained, and instruments to measure health literacy, confidence using technology, and patient activation were administered followed by the interview. Health literacy was measured using three health literacy screening questions for detecting patients with inadequate or marginal health literacy using a 5-point Likert scale [56]. Confidence using technology was measured using the Computer Self-Efficacy Survey, which is a 10-item survey using a 10-point Likert scale to measure a person’s ability to use a computer [57]. Patient activation was measured using the Patient Activation Measure (Insignia Health), which is a 13-question survey using a 4-point Likert scale to measure the level of patients’ engagement in their health [58].

Participants were interviewed using a semistructured interview guide as a part of the grounded theory approach. The session intended to have an open dialog with patients to understand how they currently receive their clinical care. The moderator discussed with the participants a typical clinic visit asking exploratory questions about their care, communication preferences, use of technology, and patient portal, use if any. Members of the research team asked relevant follow-up questions based on participants’ responses. Sampling continued until saturation was reached and no new information was gained during interviews. Study timeframe was from July 2015 to November 2018.

Data Analysis

A mixed methods approach was used to collect and analyze data. Survey data were recorded in a secure database and analyzed in conjunction with a biostatistician using SAS 9.4. Descriptive statistics, which included counts and percentages, means, standard deviations, medians, minimums, and maximums were used to summarize the data. Patient demographics were compared between age categories using the Fisher exact test for categorical data. Comparisons of scores between age groups were done using the Kruskal-Wallis test. Pairwise comparisons were adjusted using Bonferroni method if the overall P value from the Kruskal-Wallis test was significant. All tests were two-sided and a $P<.05$ was considered statistically significant.

The audio-recorded interviews were stored on a secure server. Grounded theory approach was used to analyze the qualitative data. Concurrent data collection and analysis were conducted through various stages of coding. Audio files were transcribed, and two independent, qualitative coders analyzed the transcribed interviews. A codebook was created, and themes were revised until coders came to a consensus. A third independent reviewer settled any disagreements between the two coders. Qualitative data were analyzed using NVivo 11, a qualitative data analysis software (QSR International, Doncaster, Australia).

Results

Participant Characteristics

Table 1 shows the demographics of patients with cardiovascular diseases who participated in the study and whose ages ranged from 19 to 95 years. Responses are classified according to age groups: young adults: 19-39 years of age (34 participants), middle aged: ages 40-64 (33 participants), and senior citizens’ age >65 (37 participants). A difference was found among race across the three age groups.

There is no significant difference among the three age groups’ health literacy ($P=.10$) and activation level ($P=.09$). There is a significant difference between at least 2 of the 3 age groups in computer self-efficacy (Table 2). Young adults report higher computer self-efficacy than middle-aged participants ($P<.05$) and senior citizens ($P<.05$).

Table 1. Demographics of 104 patients with cardiovascular diseases who participated in interviews presented as percentages. Examined demographics include gender, race, age, location, income, and personal health record use.

Demographics	Aged 19-39 years, n (%)	Aged 40-64 years, n (%)	Aged >65 years, n (%)	*P* value
Age (mean 55 years)	34 (33)	33 (32)	37 (36)	
Gender				.49
Male	14 (41)	19 (56)	18 (53)	
Female	20 (59)	14 (41)	19 (56)	
Race and ethnicity				.02
African American	3 (9)	10 (29)	4 (12)	
Hispanic	6 (18)	1 (3)	1 (3)	
White	24 (71)	22 (65)	30 (88)	
Asian	1 (3)	0 (0)	0 (0)	
American Indian	0 (0)	0 (0)	2 (6)	
Location by zip codes				.14
Rural (population<10,000)	11 (32)	7 (21)	12 (35)	
Urban (population>10,000)	23 (68)	26 (76)	25 (74)	
Income by zip codes				.69
Average household income <US $45,000	5 (15)	12 (35)	10 (29)	
Average household income >US $45,000	29 (85)	21 (62)	27 (79)	
Personal health record user				.55
Yes	26 (76)	17 (50)	19 (56)	
No	8 (24)	16 (47)	18 (53)	

Table 2. Comparison of composite scores of surveys between age groups.

Survey	Count, n	Mean (SD)	Median (min-max)	*P* value[a]
Computer self-efficacy				<.001
Young adult	34	8.29 (1.66)	9 (3.6-10)	
Middle aged	30	5.56 (3.43)	5.85 (0-10)	
Senior	31	4.78 (3.13)	4.6 (0-9.9)	
Patient activation measure				.09
Young adult	34	72.18 (14.43)	71.34 (51-100)	
Middle aged	30	63.4 (15.7)	59.38 (44-100)	
Senior	31	65.24 (20.13)	65.47 (44-100)	
Health literacy				.16
Young adult	34	2.6 (0.42)	2.33 (2-3.7)	
Middle aged	30	2.84 (0.5)	2.67 (2-4)	
Senior	32	2.82 (0.74)	2.67 (1.3-5)	

[a] Pairwise comparisons: young vs middle aged, *P*<.05; young vs senior, *P*<.05.

Impact of Age on Patients' Preferences When Managing Their Health

In total, three themes emerged by analyzing and combining findings to form overarching concepts: Patient Engagement, Patient Safety, and Technology.

Patient Engagement

Patient Engagement is based on the foundations of trust and communication, which are two common and important sub-themes identified by patients across all demographics. Trust and communication in patient-provider relationships can influence patients' communication preferences [59].

Similarities Among Age Groups

Patients view care as continuous rather than episodic (ie, a clinic visit) and expect communication to occur both before and after appointments. Calendar reminders are preferred (paper and electronic) with the option to add appointments directly to their calendar.

> *When she comes to give me my paper, I will go and start putting it in my calendar. I will put it in my calendar on my phone which also pops up in my tablet because it is through google. I will put it on my calendar at work…* [Participant 394-082, age 37]

Between visits, patients who use a PHR prefer to communicate electronically with their physicians via their PHR or email. PHR nonusers prefer to communicate in person or over the phone. Irrespective of age, trust is a common subtheme and is vital to all age groups with one exception; middle-aged patients are less likely to trust technology than young adults or senior citizens. Irrespective of age, most patients prefer to complete questionnaires before their clinic visit either over the phone or electronically.

> *I like it when they send them to you before. I have had that done here, and that is nice. It saves me some time because I don't live in Omaha. I drive like 45 minutes in. So that is nice.* [Participant 394-087, age 35]

Patients have strong negative feelings about redundant questioning during their clinic visits. All patients understand the importance of knowing their diagnosis, lab results, and medications and prefer their physician's impressions, in lay terms, rather than a table of results.

> *Instead of the big words and I have no idea what it is. That would be great.* [Participant 394-030, age 67]

Differences Among Age Groups

Differences in preferences are found between groups (Table 3). Young adults have an interest in communicating with other patients with similar conditions via social groups but strongly prefer those sessions to be moderated by professionals. Young adults also request the ability to update information through the PHR and to communicate with providers through text, email, and secure messaging. Of note, social media is not a priority for middle-aged adults. They prefer to contact their physician by phone or email rather than texting. Senior citizens prefer communication with their providers through phone calls, email, and in person and are not interested in participating through social media.

Table 3. Preferences between age groups (young adults, middle-aged adults, and senior citizens) regarding the theme of patient engagement.

Patient engagement[a]	Differences in preferences between age groups
Phone reminder issues	• Young adults: Ineffective because they rarely check their voicemail. • *Sometimes I get a voicemail, and sometimes I don't check my voicemail until a week after. I've never missed an appointment, but just that I read my texts all the time, so that would be nice.* [Participant 394-017, age 24] • Middle-aged adults: Did not mention issues with phone reminders. • Messages begin too abruptly, so they miss the beginning. • *We older people can't just run and jump to the phone. By the time I pick up the phone, the message is done, and I heard it say 3 o'clock. I heard the 13th. I think that the message that they leave on the phone should wait until somebody picks it up.* [Participant 394-036, age 64] • Senior citizens: Miss reminders because of low ringtones. • *All I have to do is answer. My problem is that a lot of times I don't hear because the ring isn't so loud, and by the time I get to it, the caller has already hung up.* [Participant 394-018, age 84]
Provider communication	• Young adults: Text, secure messaging, email • Middle-aged adults: Phone, email • Senior citizens: In-person, phone, email
Scheduling appointments	• Young adults: In-person after a visit, phone, PHR[b] • Middle-aged adults: Phone, open to using PHR • Senior citizens: Phone
Appointment reminders	• Young adults: Electronic calendar, text messages • Middle-aged adults: Electronic and paper calendar, email • Senior citizens: Phone calls, handwritten notes
Repetition	• Young adults: Dislike repetitive questions during current check-in • Middle-aged adults: Do not mind repetitive questions during check-in • Senior citizens: Approve of repetitive questions during the current check-in process because they believe it confirms that the right patient is being treated. • *I don't mind. Sometimes you will see five or six different people, and they will all ask the same thing. I think that's good. That way if they have to give you something, they are not giving it to the wrong person.* [Participant 394-002, age 80]
Caregivers	• Young adults: Did not mention caregiver access. • Middle-aged adults: Some do not want to share information with children because they want to be in control of their health care. • Senior citizens: Wants caregivers to have Web access to health information. • *M: I have a list of medications I carry with me all the time. She comes to the appointments, and she is my secretary.* • *F[spouse]: That way, I know what is going on. I ask, are there any surprises?* [Participant 394-011, age 73]
Lab results	• Young adults: Did not mention a preference • Middle-aged adults: Phone call, letter • Senior citizens: Letters, email
Social engagement	• Young adults: Had an interest in social groups with patients with similar diseases. • Middle-aged adults and senior citizens: Did not mention an interest in social engagement.

[a] The three age groups categorize the findings. Text in *italics* represents participants' quotes.

[b] PHR: personal health record.

Patient Safety

The quality of health care can be improved by focusing on improving patient safety and is an excellent standard of measure for high-quality health care. Patient safety is the effective prevention and amelioration of the risk of medical-error related adverse events [60].

Similarities Among Age Groups

Medication reconciliation is critical in ensuring proper medication adherence and avoiding patient harm from inaccurate information [61,62]. All patient groups are frustrated that their home medications often are not reflected in the EHR despite attempts at reconciliation.

> *Mine [home medication list] is correct, but for some reason, whenever I go in, they have some that are like from 12 years ago. I don't understand why the doctor's list is so wrong compared to mine.* [Participant 394-017, age 24]

The after-visit summary (AVS) reflects a summary of activities that occurred during the clinic visit including lab results, medications and changes, and treatment plans, as well as patient education. All age groups focus on and prefer changes in treatment plans and medications to be highlighted in their AVS.

Age impacts internet use for health information. Patients commonly identify the Google search engine as their health information source. Patients enter their search and select a link from the populated list. They can occasionally name the websites they access for health information. They also request links to credible sources about their diseases.

> *No, I just kinda Google it and go through anything I can get into. I do not belong to any medical thing. Doctors have told us that is probably not a good idea to do all that but I always do.* [Participant 394-011, age 73]

Age also impacts travel with health information. Participants carry some part of their health information with them while traveling. They are also open to alternative ways of travelling with their health information when out of town in case of an emergency, such as, on their phones or on a card the size of a debit card.

> *Not like I should. I mean, I have the thing on my iPhone that is the emergency alert. I put my conditions on that. I guess I kind of, maybe, but it does not have like a list of your medicines or things like that.* [Participant 394-084, age 35]
>
> *…I got a cut deep in my ear from something, and it bled like crazy forever, all of the ways home. It happened in Hawaii, and all of the ways home, we were changing cotton soaked and I came in, and they put me with the ENT out at Oakview [UNMC clinic]. When I went to the hospital, of course, they wanted to know about me before they do anything and so I had to fill out a bunch of paperwork. It would be nice to be able just to hand them the flash drive. They could then plug it in their computer and sync it up.* [Participant 394-007, age 77]

Differences Among Age Groups

There are differences between preferences for the AVS and medication reconciliation at clinic visits (Table 4). Young adults expressed little interest in the paper version of the AVS, preferring an electronic version. Middle-aged and senior citizens prefer a paper-based AVS.

Young adults and senior citizens are most likely to look up health information on the internet than middle-aged adults. Young adults usually search for information about their condition and the meaning of their lab results. Middle-aged adults search for information about their condition and information on nutrition and weight loss. Senior citizens search for information concerning their medications and the meaning of their lab results.

Young and middle-aged adults report visiting trusted, well-known websites for their health information, citing WebMD and hospital websites, such as Mayo Clinic. Young adults verify the information they receive on the internet by comparing the information provided by multiple sites. Senior citizens determine if the information gathered from the internet is accurate by verifying the information with their physician or pharmacist.

Regarding travelling with health information, some young adults do not want to travel with their health information but are open to doing so in the future when their chronic disease is less controlled. Middle-aged adults and senior citizens travel with their current medication list. Senior citizens also carry other pertinent health information, such as medical device information. Young adults and senior citizens are open to traveling with their health information on their phones. Young and middle-aged adults are less enthusiastic about the option of a health information card because the card is another item they would have to keep track of.

Table 4. Preferences between age groups (young adults, middle-aged adults, and senior citizens) regarding the theme of patient safety.

Patient safety	Differences in preferences between age groups
AVS[a]	- Young adults: Did not find AVS very useful - Preferred an electronic copy - Middle-aged adults: Focused on highlighted sections in AVS. - Preferred paper copies for record-keeping. - Senior citizens: Focused on highlighted sections in AVS. - Preferred paper copies for record-keeping.
Medication reconciliation[b]	- Young adults: Did not mention issues with the medication reconciliation process - Middle-aged adults: Carry medication list to clinic visits. - Senior citizens: Prefer to complete before clinic visit electronically or over the phone - Carry medication list to clinic visits.
Navigation	- Young adults: Did not mention navigational functionality within the hospital. - Middle-aged adults: Did not mention navigational functionality within the hospital. - Senior citizens: Desire navigational functionality within the hospital, reporting getting lost more than once in hospitals.
Traveling with health information	- Young adults: Rarely travel with health information but open to doing so on the smartphones - *When I used to go out in Colorado Springs to visit my boyfriend's family, I would tell his mom everything and give her paperwork. So, that way then, in case something happens to me for all I know, I'll get run over by a bull, you know, eaten by a mountain lion.* [Participant 394-089, age 36] - Middle-aged adults: Travel with their current medication list - Senior citizens: Travel with their current medication list and medical device information
Health information source	- Young adults: Trusts well-known health websites (eg, WebMD) and hospital websites (eg, Mayo Clinic) for their health information - Middle-aged adults: Trusts well-known health websites (eg, WebMD) and hospital websites (eg, Mayo Clinic) for their health information - Senior citizens: Identifies mainly Google as their health information source - *No, I am just on Google and I just type in the medicine's name and look it up and see what the side effects are and stuff like that. They show pictures of what they used to look like, the different brands, and get information on them.* [Participant 394-046, age 72]
Information search topics	- Young adults: Search for information about their condition and the meaning of their lab results - *Vagal tone, yes! So like that word, just, I have got to remember all those things, so it's nice to be able to go on there and you know, read things like that.* [Participant 394-034, age 28] - Middle-aged adults: Search for information about their condition and information on nutrition and weight loss. - Senior citizens: Search for information concerning their medications and the meaning of their lab results.

Technology

The technology theme focuses on attitudes, device preferences, and password management.

Similarities Among Age Groups

All age groups are open to using a swipe card similar in size to a debit card for checking into their clinic visit. Participants in all age groups find the tables and graphs in the PHR hard to understand. They also prefer a phone call when receiving abnormal test results to allow a dialog concerning the results.

> *…when sometimes things could be abnormal and need to be discussed, the phone call would be better.* [Participant 394-003, age 65]

They also desire medication information in the PHR.

> *What I don't find useful, when he takes his meds, it usually just has your dosage you take and what it is, the name of it, but it doesn't tell you, and I think it should tell you, because he takes so many meds, why, what is this for. Like today, this is for your cholesterol. That is why you are taking it. Because for him, when he goes from doctor to doctor, he has so many, he forgets, and I'll even forget because he just takes so much, so I do think it should say something like that.* [[Participant 394-037, age 57]

Patients find passwords cumbersome to recall and are open to alternative authentication methods for accessing their PHR. Participants attempt to recall their passwords from memory, but to assist with recall, they keep a notebook with a list of their passwords, or they use the same passwords for all the sites they access. They also confess to sharing their passwords with others.

> *I have basically one password for everything I do, and then every six months, I change it…* [Participant 394-001, age 57]

> *I have a book of passwords at home that if she [spouse] needed to get to it, she could get to it.* [Participant 394-004, age 67]

All age groups desire the ability to have electronic access to laboratory and test results with normal values and their trends in the PHR.

> *The synopsis from the doctor looking at it would be my guess. The option of looking at it just for curiosity, but that wouldn't make as much difference as what the doctor would have to say because unless I'm trained in the field, I wouldn't know what I was looking at anyway.* [Participant 394-013, age 65]

Differences Among Age Groups

Young adults prefer to access their PHR through an app on their smartphones (Table 5). Young adults are willing to complete the check-in process for their clinic visits using their phones and are open to Web-based audiovisual clinic visits. Middle-aged participants prefer a PC or tablet to smartphones. Senior citizens are similar; they prefer a PC or tablet because of the need for a larger font. Middle-aged participants express difficulties navigating the PHR. A unique feature request by senior citizens is the ability to delegate PHR access to caregivers.

Young adults maintain their passwords from memory for fear of misplacing a written list. To mitigate this fear, young adults write their passwords in an encrypted format or keep a list in a notes app on their phone or a computer file. Senior citizens' main frustration with passwords is that they cannot remember them because of the differing password criteria that websites require. Some senior citizens keep their password list in a computer file. Misplacing paper versions of their password list is rarely a concern and even have passwords written on Post-It notes taped to their desks at home.

Table 5. Preferences between age groups (young adults, middle-aged adults, and senior citizens) regarding the theme technology.

Technology[a]	Differences in preferences between age groups
Electronic check-in	• Young adult: Very receptive to complete the check-in process for their clinic visit using their phone. • Middle-aged adults: Not open to complete the check-in process for their clinic visit using their phone. • Senior citizens: Preferred human interaction but were open to complete the check-in process for their clinic visit using their phone. • *I would not do FaceTime. I prefer human to human contact.* [Participant 394-015, age 86] • *I do not think it would be necessary. It might add to it for some people. I think there are some people that work better in that kind of environment, but that is not necessary for me.* [Participant 394-007, age 77]
Web-based clinic visit	• Young adult: Very receptive to the convenience of Web-based audiovisual clinic visits. • *If I were master of the universe, I would have FaceTime appointments. I would have it where I can get the lab done, you know, at my local lab link at the local hospital.* [Participant 394-020, age 35] • Middle-aged adults: Split when it came to Web-based and audiovisual clinic visit option. • Senior citizens: Not receptive to the convenience of Web-based audiovisual clinic visits.
Preference: PHR[b] access device	• Young adult: Smartphone • Middle-aged adults: Tablet, computer • Senior citizens: Tablet, computer
Preference: internet access device	• Young adult: Smartphone • Middle-aged adults: Tablet, computer • Senior citizens: Tablet, computer
Accessibility	• Young adult: No issues • Middle-aged adults: Larger font • Senior citizens: Larger font
Password management	• Young adult: Use the same password, alternate between a few passwords, keep a computer file, Post-it • Middle-aged adults: Notebook, use, the same password, spouse • Senior citizens: Use the same password, notebook, Post-it, saved in the browser, computer file.
Message received receipt	• Young adult: No issues • Middle-aged adults: Do not electronically communicate because they don't know if their provider receives messages • Senior citizens: Confirmation receipt to know that their message is received

[b] PHR: personal health record.

Discussion

Summary of Findings

This study demonstrates the importance of the role that age plays in determining communication preferences and technology use, with age having a significant impact on patient preferences in clinical care. There was a difference between race across the three age groups. This difference was because our sample was representative of the population studied. The US Census Bureau estimates Nebraska's population to be 78.6% (1,520,445/1,934,408) White, 11.2% (216,654/1,934,408) Hispanic, 5.1% (98,655/1,934,408) Black or African American, 2.6% (52,229/1,934,408) Asian, and 1.4% (29,016/1,934,408) American Indian.

Principal Findings
