Young adults had the highest self-efficacy score among the three age groups. Young adults are most receptive to completing the check-in process for their clinic visit using their phone and would opt for the convenience of Web-based audiovisual clinic visits, prefer smartphone access, and have a high use of the PHRs for convenience. Middle-aged adults had lower computer self-efficacy scores than young adults. Middle-aged adults are blenders of old and newer technologies. They prefer phone and email for provider communication and both electronic as well as paper calendars for appointment reminders. Similar to middle-aged adults, senior citizens had lower computer self-efficacy scores than young adults. Senior citizens in this study prefer phone communication and mention caregivers gaining access to their health information.

Comparison With Prior Work

Young adults grew up in the age when mobile devices exploded onto the market and are very familiar with these devices. Results from a 2015 survey conducted by Pew Research Center, determining technology device ownership, found that 86% of young adults (aged 18-29 years), 83% percent of adults (aged 30-49 years), 58% percent of middle-aged adults, and 30% of senior citizens owned a smartphone [63]. Similarly, a study by Zallman et al [64] found that being 40 years old and under was associated with a 50% to 90% increase in the odds of preferring text messaging over other modes of communication. Based on Dholakia’s framework [52], this explains young adults’ preference for mobile PHR access, text message, and electronic access to appointment reminders and their AVS. With a higher reported computer self-efficacy, future research should analyze the effects of a user-friendly mobile PHR interface on increasing adoption among young adults.

Middle-aged and senior patients’ tablet use can be explained by the simplified, less intimidating interface of tablets. A study by Jayroe and Wolfram [65] found that older adults had an overall positive experience when using a tablet to complete search tasks. Previous literature is rich with information on young adults and senior citizens’ as it relates to technology adoption. However, there is a lack of information on how to best present information and increase PHR adoption for middle-aged adults. Middle-aged adults and senior citizens share multiple similarities. Middle-aged adults and senior citizens may be content with their current modes of communication technology use and may be reluctant to attempt to keep up with the fast-changing technology environment.

Although senior citizens are usually behind when it concerns technology adoption, Pew’s report on Americans’ Internet Access found that senior citizens had the highest rate of change from 2000 to 2015, with more than half (58%) of all adults aged 65 years and older using the internet [66]. In addition, in a study by Gordon and Thornbrook [51], over 75% of senior citizens reported having access to a desktop or laptop and 25% owned a tablet. These results suggest a narrowing of the digital divide; therefore, it is crucial to support the senior citizens, who are open to eHealth, to adopt digital tools that enable better health care self-management. Senior citizens are also more likely to use technology that has been around longer and that are most familiar. A study by Olsen et al [67], surveying age-related differences in overall usage of technologies, found that older adults were more likely to use technologies, such as telephones, answering machines, credit cards, etc [67]. Senior citizens in this study also prefer phone communication for the sake of human interaction. Olsen et al [67] similarly discovered that older adults frequently made phone calls when the phone was an option. These results suggest that a combination of new and old technology is still imperative to satisfy the communication needs and preferences of all patients. Senior citizens are also more likely to be more concerned about their health and, maybe, feeling vulnerable because of their dependence on informal, family caregivers for their health management. This may be one motivation to providing caregivers with access to their patients’ health information [68-70]. Allowing caregivers improved access to manage senior patient’s health information is a useful feature to build into PHR redesign.

Patients search for health information on the internet using search engines without considering the links they are selecting from the search list. This is a patient safety issue because patients may be consuming misleading information. Providing patients with trusted links to websites and educating patients on how to determine if an information source is credible are two ways to reduce the potential of patient harm from misinformation.

Limitations

While this study recruited patients based on age, gender, race, ethnicity, and zip code, a continuing study is necessary to confirm, extend, and refine these results, as there may be other complex reasons that may affect results. The sample consists of patients from one health care system, using one patient portal, with similar chronic diseases. Our results need to be confirmed by a larger multisite study. However, patients receive care at institutions outside of Nebraska Medicine and have experience using PHRs from other manufactures. The purpose of this study is not to predict trends for the future, but to determine patients’ current practice, which can inform providers on the information patients seek and can improve the communication providers have with their patients during clinic visits. In addition, these results can inform vendors of patients’ desired functionality for the design and implementation of PHRs to improve the usability of PHRs.

Conclusions

This study demonstrates that as implemented, mandatory PHR use could increase the digital divide among vulnerable populations. Many patients, especially the elderly and those with low reported computer self-efficacy, find technology a barrier to use. PHR vendors should consider that young adults have a high affinity for electronics. Middle-aged adults are mixers of old and new technologies, and in our sample, many do not trust technology, preferring to interact with humans than with technology. Senior citizens also prefer human interaction but are willing to use technology that is familiar to them. The PHR does not suitably support the communication needs of elderly patients and their caregivers. Patient-centered care needs to support individual patient preferences, which includes nontechnology options.

Clinical Relevance Statement

To achieve substantial, meaningful use, HIT must adapt to the user, rather than forcing the user to adapt to the technology. Patients of different ages have different communication and technology preferences, information display differences, and preferences regarding how they wish to interact with their provider. The PHR does not correctly support caregiver access to health information. It is one approach to improving patient engagement, but to support all patients, sustaining nontechnological options are necessary.

Abstract

Background: Having patients self-manage their health conditions is a widely promoted concept, but many patients struggle to practice it effectively. Moreover, few studies have analyzed the nature of work required from patients and how such work fits into the context of their daily life.

Objective: This study aimed to review the characteristics of patient work in adult patients. Patient work refers to tasks that health conditions impose on patients (eg, taking medications) within a system of contextual factors.

Methods: A systematic scoping review was conducted using narrative synthesis. Data were extracted from PubMed, Excerpta Medica database (EMBASE), Cumulative Index to Nursing and Allied Health Literature (CINAHL), and PsycINFO, including studies from August 2013 to August 2018. The included studies focused on adult patients and assessed one or more of the following: (1) physical health–related tasks, (2) cognitive health–related tasks, or (3) contextual factors affecting these tasks. Tasks were categorized according to the themes that emerged: (1) if the task is always visible to others or can be cognitive, (2) if the task must be conducted collaboratively or can be conducted alone, and (3) if the task was done with the purpose of creating resources. Contextual factors were grouped according to the level at which they exert influence (micro, meso, or macro) and where they fit in the patient work system (the macroergonomic layer of physical, social, and organizational factors; the mesoergonomic layer of household and community; and the microergonomic triad of person-task-tools).

Results: In total, 67 publications were included, with 58 original research articles and 9 review articles. A variety of patient work tasks were observed, ranging from physical and tangible tasks (such as taking medications and visiting health care professionals) to psychological and social tasks (such as creating coping strategies). Patient work was affected by a range of contextual factors on the micro, meso, or macro levels. Our results indicate that most patient work was done alone, in private, and often imposing cognitive burden with low amounts of support.

Conclusions: This review sought to provide insight into the work burden of health management from a patient perspective and how patient context influences such work. For many patients, health-related work is ever present, invisible, and overwhelming. When researchers and clinicians design and implement patient-facing interventions, it is important to understand how the extra work impacts one’s internal state and coping strategy, how such work fits into daily routines, and if these changes could be maintained in the long term.

KEYWORDS

self-care; burden of illness; self-management

Introduction

Background

Chronic diseases are increasingly prevalent as the world's population ages, requiring millions of patients to adjust their lifestyle and manage their health [1]. However, patient work and patient ergonomics, defined, respectively, as the combination of all health-related tasks and the contextual factors influencing the tasks [2], are given little attention. Existing studies have investigated the influences of individual barriers for health management, such as time requirements [3], the burden of comorbidity [4,5], or complexities in specific diseases [6-8]. Few studies have analyzed the character of patient work and how such work fits into the context of an individual's life.

Patients conduct a variety of cognitive, visible, and collaborative work to accommodate health conditions and treatments, with such tasks changing throughout the *illness journey* as treatments are introduced or removed [9-13]. Using a work ergonomic system, Holden et al [2,14] posited that *patient work* is affected by a *patient work system*, which incorporates contextual factors affecting the performance of work [15-20]. A poor integration of patient work into the existing context and routine can generate excess stress, potentially contributing to noncompliance and suboptimal health outcomes [21,22]. The patient work system [2] groups all contextual factors into 3 levels: a microergonomic level (further separated into people, task, and tools), a mesoergonomic level including household and community, and a macroergonomic level (physical, social, and organizational), separating the influences that are inherent within the task or the patient from those that came from daily life.

Although health-related tasks are included in the umbrella terms of *self-management* (defined as actions and processes that people with a health problem intentionally perform to manage health in partnership with health care professionals [23]) and *self-care* (a more loose definition encompassing all things people do to manage and improve their health [24]), such tasks have not been reviewed to reflect how they relate to different aspects of the patient's life. Similarly, there have been few attempts to assess how patient work is influenced by different contextual factors. In particular, although these tasks and factors have been explored in specific conditions [2,25], a review across all health conditions remains lacking. Therefore, a scoping review was chosen to rapidly gain an understanding of this nascent field, following guidance from Arksey and O'Malley [26], who noted that the method was appropriate "especially where an area is complex or has not been reviewed comprehensively before."

Objectives

In this scoping review, we review the existing literature on patient work, examining what people do in self-management and why they do or do not undertake certain tasks [2]. We also examine the different levels of patient work contexts, where digital interventions could play a supporting role. Specifically, digital technologies can offer health advice based on the immediate tasks and contexts around the patient [27], making digital apps a viable solution to supporting patient work through one's life.

Methods

Search Strategy

The search was conducted using a modified participants, interventions, comparisons, and outcome strategy, which stated that the research question for a review must include the population, intervention, comparison, and outcome. Our research question was "What are the characteristics of patient work in adult patients?," with the population being adult patients, intervention being the presence of a health condition, comparison being daily life before diagnosis, and the outcome being the characteristics of patient work. A search was conducted on August 23, 2018, in PubMed, Excerpta Medica database (EMBASE), Cumulative Index to Nursing and Allied Health Literature (CINAHL), and PsycINFO, including all articles published from August 2013 onward. The search terms were designed to capture publications that depicted work conducted by patients to maintain their health and how such work was limited or facilitated by contextual factors. Only articles published in English were included in the search. Multimedia Appendix 1 provides the complete search strategy.

Inclusion and Exclusion Criteria

Articles were eligible if they focused on adult patients, included a qualitative component, and focused on assessing the impact of (1) physical tasks that patients undertake to manage their health, (2) cognitive tasks associated with managing health, *or* (3) contextual factors facilitating or restricting the physical or cognitive tasks.

Articles were excluded if they only focused on nonpatients (eg, caregivers); if they only presented biological or physiological data; if they only addressed health-related contextual factors that do not affect the work patients do (eg, computing systems in a hospital); were opinion articles or protocol papers; *or* if they focused on the design or evaluation of a measuring instrument, tool, or intervention.

Study Screening and Data Extraction

Multimedia Appendix 1 provides details on abstract and full-text screening as well as data extraction from full-text articles. Each abstract and full-text was screened independently by 2 researchers, and each full-text article was also screened independently by 2 researchers. The interrater score for abstract screening was 0.39 (fair agreement) [28] and for full-paper screening was 0.30 (fair agreement) [28]. Disagreements were resolved by having a third independent reviewer review the conflicting article and make a final decision. Data extraction was conducted by 3 researchers who met regularly to address concerns and to ensure that data extraction was conducted consistently.

Analysis Framework

We conducted a narrative synthesis on the patient work tasks and extracted contextual factors. The patient work tasks were assessed using the patient work model initially proposed by Corbin and Strauss [29,30], which indicates patient work as *illness work* that is influenced by *everyday life work* and *biographical work*. The work results in 3 types of tasks for self-management: medical management (eg, planning doctor appointments), emotional management (eg, dealing with anxiety and fear), and role management (eg, balancing one's role in the family with one's illness). We consulted a modified version of Corbin and Strauss's model by Dack et al [31], which encompassed the 3 types of tasks for self-management. For contexts, we used the patient work system proposed by Holden et al [2,14]. The patient work system encompasses a microergonomic aspect, which describes how contextual factors from the patient, task, and tools involved [14,32] affect the work done; a mesoergonomic layer of household and community; and a macroergonomic aspect where physical, social, and organizational influences [2,14] are outlined.

Work tasks were identified from the included articles, were clustered based on common themes that emerged, and were consulted against Dack et al's model [31]. Contextual factors were grouped according to where they fit within the dimensions outlined in the patient work framework (patient, tasks, tools, physical, social, and organizational) [2,14,32] and the level at which they exert influence (micro, meso, or macro) [33,34]. We identified microlevel contextual factors as aspects that only affected the patient's body or were psychological factors. Mesolevel contextual factors were the influences of people socially close to the patient or influences exerted by the immediate physical surroundings or social circumstances (eg, finances) of the patient [35]. We identified macrolevel contextual factors as aspects that arose from the society, culture, or geopolitical entity in which the patient lived. The micro-meso-macro framework has been used extensively in health care, ranging from describing the quality of life assessments at different levels of decision making [36], patient-reported outcome measures in hospital palliative care [34], enablers and barriers affecting nursing practices [37], policy implementation of health leadership [38], to health care priority setting across different countries [39].

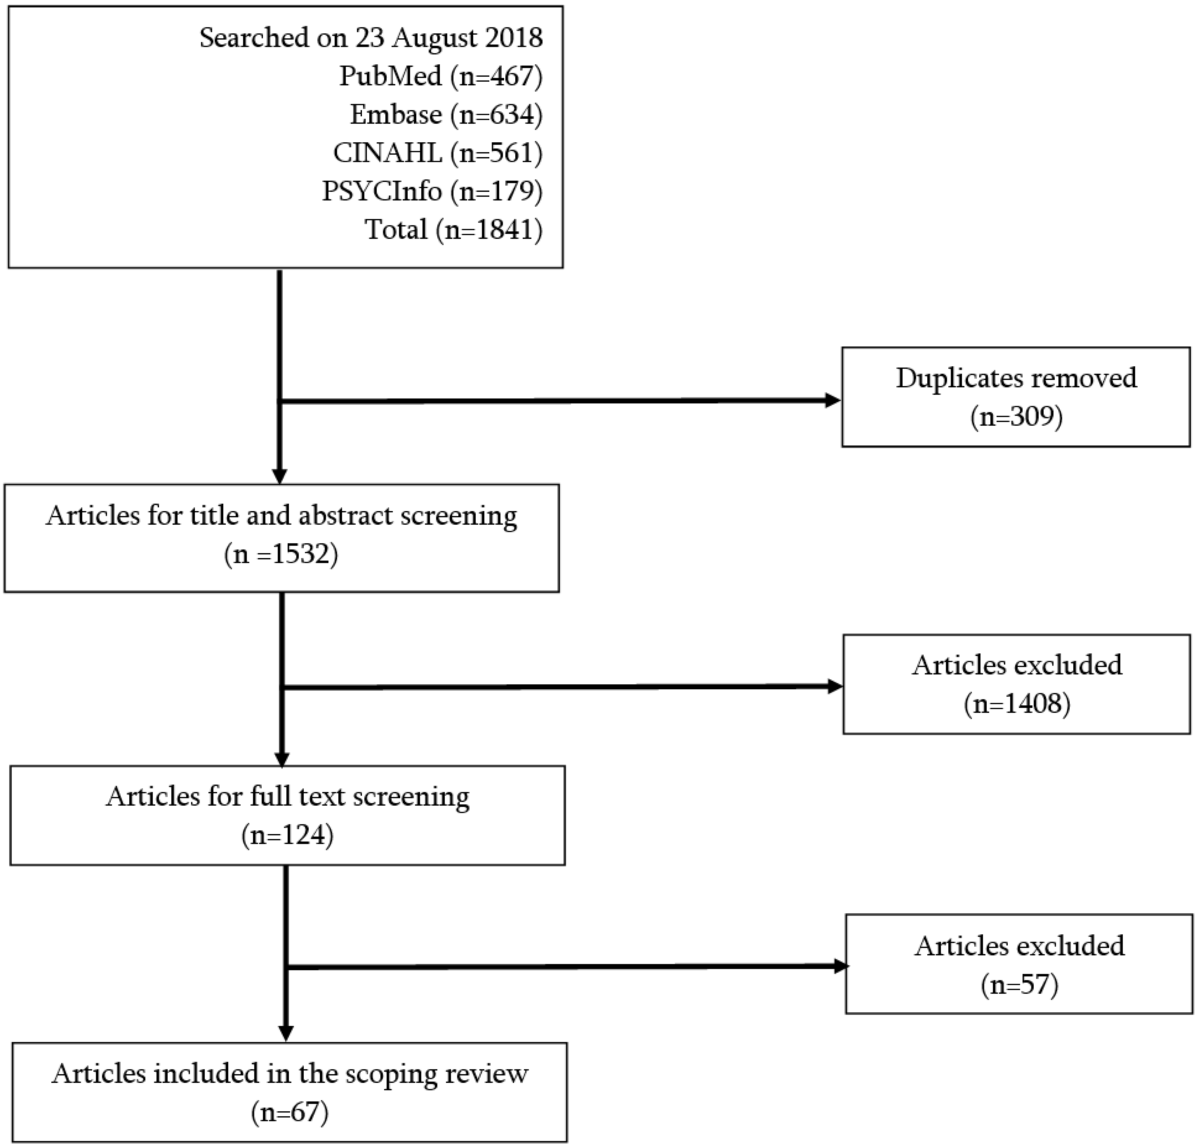
The articles were initially read by KY, JJ, and DP to extract passages that described patient work tasks or contextual influences on patient work. The 3 researchers then compiled our findings to reach a consensus and held frequent meetings over 1 month to sort all identified patient work tasks and contextual influences into themes. Reviewers decided by consensus to categorize the work tasks and the contextual factors based on the commonalities observed.

Results

Screening Process

Figure 1 outlines the screening process. Multimedia Appendix 2 gives more details about the screening process.

Figure 1. Number of articles included at each stage of the screening process.



Characteristics of Included Articles

Among the 67 articles included in the scoping review, 58 were original research and 9 were reviews. Semistructured interviews were the most common research strategy employed, and the articles studied 37 different health conditions. Multimedia Appendices 3 and 4 provide more information on the type and characteristics of the included articles.

Patient Work Tasks Conducted by Participants

Patient work occurs in 2 forms: visible and cognitive work. Visible work is performed within a physical space (such as driving to visit doctors). Such tangible tasks could be observed by other people and are easy for others to intervene. Cognitive work, on the other hand, is completely unseen by others (eg, mentally counting calories throughout the day). Such tasks would not be revealed unless the patient discussed the information directly, and the task could remain hidden even from family and close friends.

Patient work tasks can also be conducted collaboratively or alone. Some tasks must be conducted in collaboration with others (eg, visiting health professionals), whereas cognitive tasks are always conducted alone (eg, developing mental coping strategies). Most patient work tasks, however, existed between these 2 extremes and could be conducted collaboratively or alone, depending on the contextual influences.

All patient work tasks also consumed resources such as time [40,41], physical energy [42], or social support. However, although many patient work tasks consumed resources to maintain one’s state of health, some tasks had the precise purpose of creating more resources, such as learning about one’s health condition or attending patient support group meetings. The prevalence of resources available to a patient serves as a buffer to mitigate the effect of sudden changes (eg, having enough funds to undergo surgery), and tasks that increase resources can ultimately increase the patient’s capacity to cope [43].

In total, 6 different categories of patient work tasks emerged along the 3 aforementioned axes and are listed in Textbox 1. The categories were distinctive based on whether (1) the task was always visible or not, (2) the task must be conducted collaboratively or not, and (3) the purpose of the task was to create resources or not.

Tasks were further divided into 21 specific types of tasks according to the reviewers' consensus. Multimedia Appendix 5 provides a list of tasks identified in each included article, and Multimedia Appendix 6 provides a thorough description of each task type together with examples.

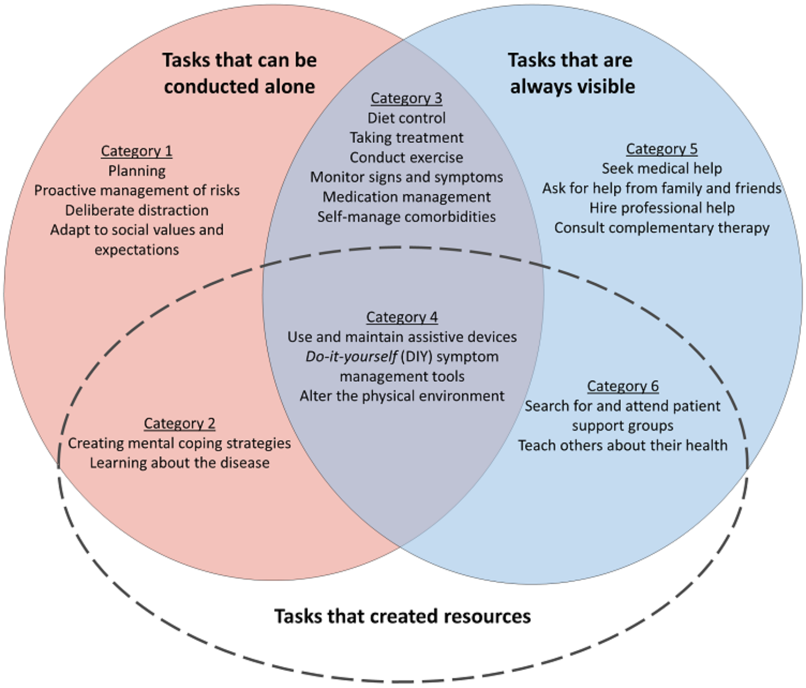
Figure 2 demonstrates how the tasks fit into the 6 identified categories and the relationship of the categories with each other.

Textbox 1. Classification of patient work tasks.

Category and description of the patient work tasks

- Category 1: Not always visible, can be conducted alone, and consumed resources
- Category 2: Not always visible, can be conducted alone, and purposefully created resources
- Category 3: Visible, can be conducted alone, and consumed resources
- Category 4: Visible, can be conducted alone, and purposefully created resources
- Category 5: Visible, must be conducted collaboratively, and consumed resources
- Category 6: Visible, must be conducted collaboratively, and purposefully created resources

Figure 2. Patient work tasks were categorized according to their alignment along the 3 axes of collaboration, visibility, and creating resources.



Category 1: Tasks That Are Not Always Visible, Can Be Conducted Alone, and Consumed Resources

Category 1 tasks made up a large portion of the instances of patient work tasks identified in the included studies, with the most prevalent tasks being *planning* [18,20,40,44-57] and *proactive management of risks* [20,40-42,45-47,49,50,52,57-78]. Tasks in category 1 are characterized by their pervasiveness and volume. Patients are constantly thinking about their prospective health-related plans and mitigating health risks, even when they are not currently experiencing symptoms or remaining in a health care setting. Significantly, health-related work in this category includes tasks that do not necessarily improve health outcomes (such as *adapt to social values and expectations* [19,20,48,55,57,58,61,64,70,79-82]). Despite the volume of work in this category, patients do not often discuss such tasks with others, making such work unacknowledged and sometimes taken for granted by the patient and their families, receiving very little organizational or psychological support.

Category 2: Tasks That Are Not Always Visible, Can Be Conducted Alone, and Purposefully Created Resources

Work tasks included in category 2 are not so much about managing one's symptoms, but work that enables patients to manage their symptoms better in the future. *Create mental coping strategies* [14,18,20,40,43,45,46,48-51,61,75-80,83-89] included overcoming emotional barriers [18], drawing upon spiritual beliefs [78], eventually coming to terms with a *new* *body* and a *new normal* [14,20,87,89] that enables patients to proactively engage with treatment. Patients also looked for relevant knowledge, either from written literature or by asking other people, in work tasks under *learning about the disease* [16,20,42,48,57,59,60,64,67,73,74,78,80,81,84,90]. Intellectual endeavors to understand the implications of symptoms [52] are also included here.

Category 3: Tasks That Are Visible, Can Be Conducted Alone, and Consumed Resources

Category 3 tasks included self-management tasks such as *diet control* [14,42,48,49,52,53,57,59,63-68,71,75,77-79,82,85,87,90,91], *conduct exercise* [19,20,25,40-42,45,49,56,59,63,66,67,73,77,79,82,87,90,91], *taking treatment* [2,18,42,47,49,57,63,64,66-69,71,73-75,78,82,84,85,90-94], *monitor signs and symptoms* [2,14,41,42,44,45,57,65,67-69,71,85,87,90,92,95], *medication management* [40,43,44,51,52,57,59,71,75,84,90,95,96], and *self-manage comorbidities* [14,41,44,59,75,79,82,97]. The effective carrying out of tasks in this category is underpinned by category 1 and 2 tasks, benefiting from good planning and attitude changes. Although patients recognize this category to be a significant drain on their resources (whether in terms of time [40,41], physical capacity [42], or appropriate knowledge [19,47,71]), they are aware of the importance of such tasks and noted that support for such tasks is already in place from public health initiatives and health professionals.

Category 4: Tasks That Are Visible, Can Be Conducted Alone, and Purposefully Created Resources

Category 4 was the only category that explicitly described how patients changed their physical environment and tools. Tasks in this category (eg, *use and maintain assistive devices* [16,20,42,50,56,58,59,62,67,69,72,74,89,90,95,97,98], *do-it-yourself symptom management tools* [18,19,47,59,62,66,74,77,95], and *alter the physical environment* [46,62,93]) had an immediate physical return in the form of better tools or a more comfortable physical environment, with the tools ranging from day-to-day items (eg, shoe insoles [97]) to specialized equipment (such as home oxygen tanks [59]). Patients are very aware of how this category is an investment to improve the quality of life as well as what kind of support (mainly financial) is available from health organizations.

Category 5: Tasks That Are Visible, Must Be Conducted Collaboratively, and Consumed Resources

This category included tasks where patients sought help from other people, including *seek medical help* [2,14,18,40,41,44,49-52,58,65,75,79,80,83,89,93,96,97], *ask for help from family and friends* [18,40,46,47,50,51,57,60,63,67,69,73,77,93,95,98], *hire professional help* [20,43,52,69,95,98], and *consult complementary therapy* [58,59,64,66,84]. This category also included unplanned interactions, such as visits to the emergency department [41,89]. The patient reported only initiating these tasks when issues have escalated beyond their individual control [41,52,89] and seeking help became a necessity. Being the most visible tasks observable by health professionals, health care systems have traditionally paid close attention to these interactions.

Category 6: Tasks That Are Visible, Must Be Conducted Collaboratively, and Purposefully Created Resources

The last category, category 6, included tasks that contributed specifically to building new social resources for the patient, *searching for and attending patient support groups* [57,59,67,73,99], and *teaching others about their health* [2,51,57,71,89]. Patients actively create new social circles and recruit other people into their lives, whether by joining patient support groups or educating family and friends about their health [2,51,57,71,89]. In these interactions, the patient acts as either a peer or an expert, instead of the party receiving help. They proactively share their own health information and self-care strategies with others and act to support other patients along the *illness journey*.

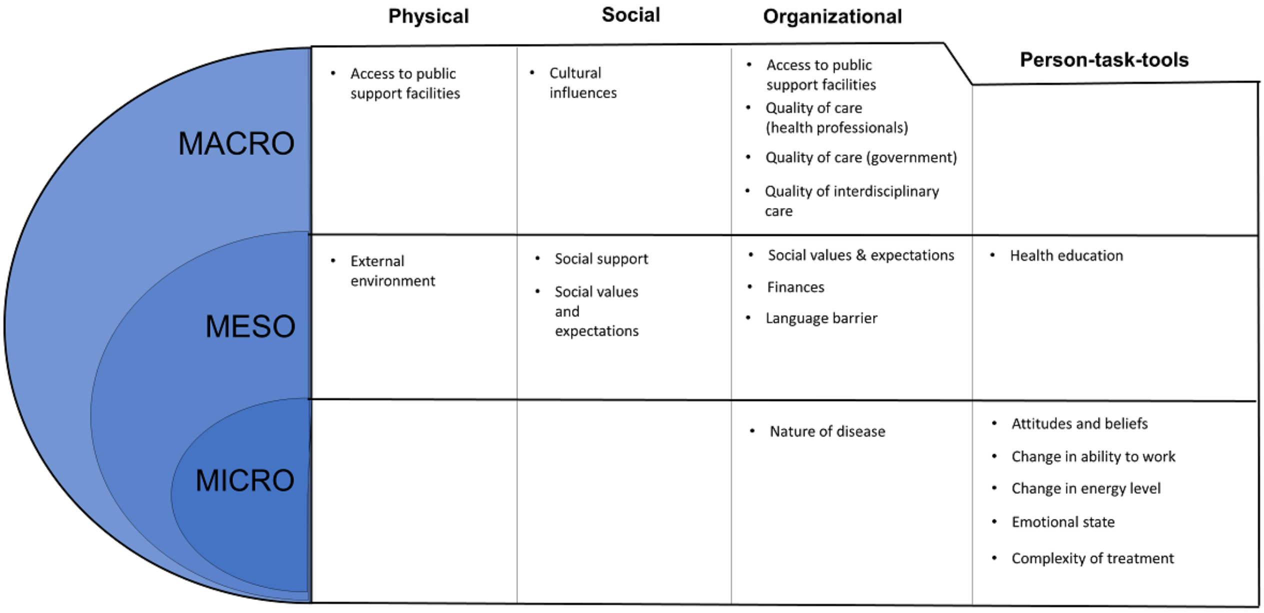
Contextual Factors Influencing Patient Work Tasks

We identified 17 types of contextual factors that influence patient work tasks. Multimedia Appendix 5 provides a list of contextual factors identified in each included article, and Multimedia Appendix 7 provides a thorough description of each contextual factor with examples. The contextual factors were grouped into how they fit within the patient work system (either in the macroergonomic triad of physical, social, and organizational factors or within the microergonomic triad of person-task-tools) [2,14,32]. As the patient work system has 3 layers, with households and communities comprising the mesoergonomic layer between the macro and microergonomic contexts, we also grouped contextual factors based on the level (macro, meso, or micro) at which they affected patient work tasks [33,34]. Although Holden et al [100] have identified *mesoergonomics* as the study of the relationship between variables in different layers of an ergonomics system, the *meso* contextual factors we identified here correspond to factors that sit between the micro- and macroergonomics levels.

Microlevel Contextual Factors

We identified microlevel contextual factors as aspects that only affected health management by influencing a patient’s body or were psychological factors that arose from the patient’s mindset. Such factors significantly influence patients on a personal level and are included in the microergonomic triad of person-task-tools within the patient work system by Holden et al [2], as indicated in Figure 3. Microlevel factors in the review were mostly psychological factors, not always noticeable to family members or health professionals [2,45,61,70]. Such factors echo the type of patient work tasks that were not always visible, indicating a concrete need for resources that assist with psychological coping and adopting self-care into one’s routine.

Figure 3. Contextual factors that influence patient work, separated on the basis of their allocation in the patient work system and whether they act on a macro, meso, or micro level.



Mesolevel Contextual Factors

Mesolevel contextual factors are aspects that affect self-management because of the influences of people socially close to the patient or influences exerted by the immediate surroundings or circumstances of the patient. These factors equally affected the physical, social, and organizational macroergonomic domains of the patient work system [2]. Contextual factors identified at this level, such as language barriers and social support, are widely recognized by health care systems, and supportive measures are often already in place [43,55,63,86]. Moreover, efforts to locally improve these contextual factors can significantly improve the patient’s health management, making such contextual factors an existing focus for intervention from health professionals.

Macrolevel Contextual Factors

Macrolevel contextual factors arise from the society, culture, or geopolitical entity in which the patient lived. These factors affected the organizational aspect of the patient work system [57,58,69,82]. Changing such contextual factors usually requires significant political or population health action, and individual patients and health care professionals often struggle to influence such factors on their own [47,57,63,69,82].

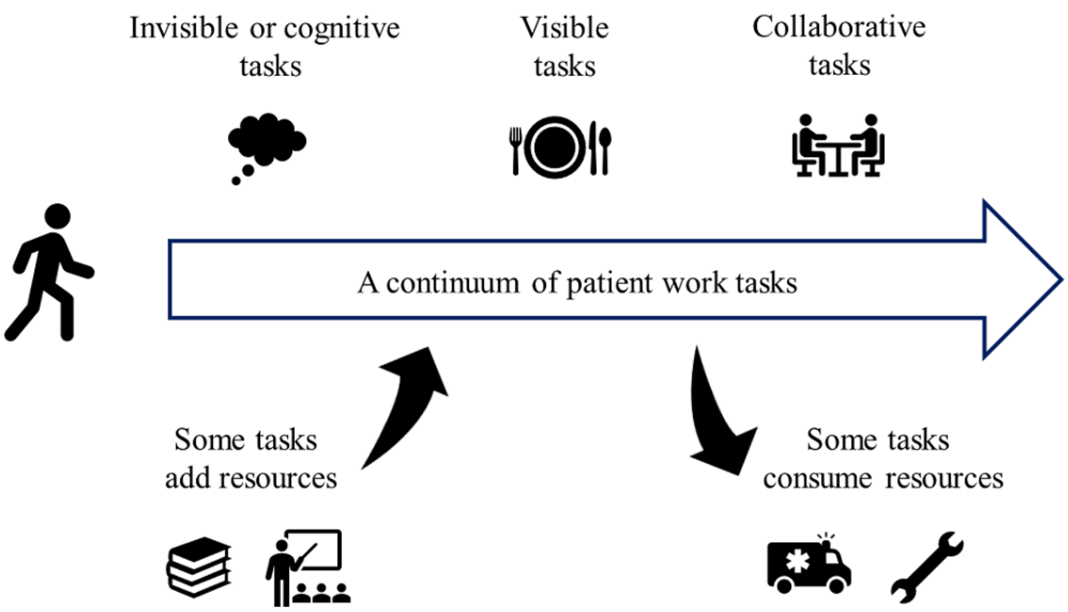
Discussion

Principal Findings

The purpose of this scoping review was to analyze the existing literature on the tasks that health conditions imposed on patients and the contextual factors affecting these tasks [2]. Our results indicate a continuum of patient work tasks, through which the patient moves from tasks that are cognitive only to tasks that are always visible and tasks that are always conducted collaboratively, while also experiencing how some tasks generated resources for the future, whereas others mainly consumed resources, as seen in Figure 4.

Contextual factors were mapped out by analyzing the factors according to their micro-, meso-, or macrolevel of influence and where they fitted along the patient work system, whether within the macroergonomic factors of physical, social, and organizational factors or the microergonomic triad of person-tasks-tool [14]. Although all contextual factors fit into the patient work system, there seems to be a *mesoergonomic* layer not specified in the patient work system that acted as a bridge between the macroergonomic influences and the more personal and psychological microergonomic contextual factors.

Figure 4. A continuum of patient work tasks that the patient moves through in their illness journey.



Limitations

Our review has some limitations. We only included articles published in English and did not have access to studies in other languages. The relationship between the different aspects of work tasks is propositional and has not been empirically tested. We also focused on articles that addressed work conducted by patients themselves, as opposed to work conducted by caregivers.

Our review also did not cover detailed physical ergonomic factors of the patient’s vicinity, such as the physical properties of the areas where patients placed their medications, as the included articles did not contain these details.

Comparison With Existing Literature

Corbin and Strauss [30] separated self-management into 3 different kinds of activities: emotional management, medical management, and role management. Category 1 (not always visible, can be conducted alone, and consumed resources) and category 2 (not always visible, can be conducted alone, and purposefully created resources) relate to cognitive workflow [101] and fit into emotional management within the Corbin and Strauss’s model. Within the cognitive workflow, which consists of sensemaking [102,103], planning, monitoring, decision making [9], and coordinating, the person makes the cognitive preparations necessary before conducting an action. This was reflected in activities such as planning and adjusting routines to *make space* for health-related work. Other cognitive tasks, such as finding information on the web and developing mental strategies, contribute to helping the patient to intellectually understand and psychologically accept their health condition.

Patients consider these tasks a part of life and rarely mention such tasks to health professionals despite its prevalence, reflecting a glaring need for more systematic support of these *invisible* tasks. Although this scoping review defined *not visible work* as work that is conducted primarily cognitively and thus *invisible* in the literal sense, tasks in categories 1 (not always visible, can be conducted alone, and consumed resources) and category 2 (not always visible, can be conducted alone, and purposefully created resources) can also fit into the definition of *invisible work* as it is used in ergonomics [104]—work that is taken for granted, underacknowledged, and undervalued. These tasks are only recognized as a burden when patients find them overwhelming.

A large body of literature exists on supporting patients with psychological distress, including psychotherapy [105] for patients with advanced cancer, cognitive behavioral therapy, and animal therapy [106], yet everyday tasks such as planning and establishing routines are much more nebulous to support. Patients reported using a variety of basic planning tools, such as notebooks and calendars with appointments written in them, and it is possible that a digital extension of such tools, such as integrated digital diaries, could better assist in this space.

Tasks in categories 3 (visible, can be conducted alone, and consumed resources) and category 4 (visible, can be conducted alone, and purposefully created resources) represent health-related work acted out by individual patients, corresponding to medical management [30]. The dimension of lifestyle changes [107] is incorporated in these tasks as patients carry out exercise, modify their diet, and sort their medications into doses, work that the clinician traditionally ascribes to self-management. It is well recognized that patients need to have sufficient resources such as time [40,41], access to affordable facilities, or physical capacities to perform tasks satisfactorily [42]. Health professionals and health organizations have focused on assisting with these tasks for many years, and many patients are aware of the presence of such support programs. Category 4 (visible, can be conducted alone, and purposefully created resources) present as a slightly different category that initially consumes time and money but ultimately results in a large increase in capacity, such as the purchase of assistive devices, which can significantly improve the efficacy of self-care in the future.

Tasks in categories 5 (visible, must be conducted collaboratively, and consumed resources) and category 6 (visible, must be conducted collaboratively, and purposefully created resources) are tasks that are inherently collaborative, bringing self-management out of the individual's personal lives and interacting with role and relationship management [30] regarding health professionals or family. These tasks also correspond to the self-care dimensions of communication [107,108] and obtaining help [109]. Some tasks in category 5 have the patient play a passive role (eg, visiting the emergency department), whereas activities in category 6 saw the patient interact with others as a peer or an expert (eg, attending patient support groups and teaching others about the disease and treatments). When a patient acts as an equal partner in a health-related relationship and feels the relationship to be a positive and empowering experience, the psychological and social benefits expand the patient's capacity [43] and social resilience [15,110]. However, although the health system noted the benefits of such tasks and encouraged collaborative and equal decision making between the patient and the clinician, category 6 tasks were the least prevalent in our review, indicating that such tasks may still be taken up by only a small section of more informed and proactive patients.

Contextual Factors in the Patient Work Framework

The patient work system [2] separates the patient's surroundings into macroergonomic and microergonomic categories, with a middle household and community levels. In the macroergonomics layer, physical contexts described influences of the physical world and social contexts described the influence of other people, whereas organizational contexts encompassed temporal organization (daily routines), societal organization (finances and family roles), and political organization (health system and legal issues). In the microergonomics layer, person described the characteristics of the people involved, task described the inherent challenges of the task, and tools described the method or tool used to perform the task.

This review further separated the contextual influences into 3 layers: macro, meso, and micro. At the macrolevel, the patient work system addressed many factors that affected patients on a governmental or cultural level. The mesolevel, which was not explicitly stated in the patient work system, appears to act as a bridge transporting macrolevel values and expectations down to the individual. For example, cultural values filtered down to social expectations, and the structure of the health care system emphasized the impact of financial problems. Although not addressed within the patient work system, the meso layer certainly exists and exerts its influence through the people and the environment closest to the patient.

On the microlevel, most of the identified contextual factors fit into the person-task-tools triad, and most of those factors were within *person*. Patients in our review reported a variety of emotional and mental influences that altered their actions, indicating their motivation and belief in their capacity was sometimes more important than the resources available to them. Patients experiencing different health conditions were affected by common emotional states, such as fear of medication side effects and dreading the future [67,69,71,75,80]. As an element of concern, patients in our scoping review rarely reported consulting mental health professionals about these fluctuating emotions, opting instead to *brave through* on their own [45,58,60,71,75,96]. Although there is literature indicating that different personality types respond differently to intervention styles [111-113], it is also probable that patients need to be aware of the available psychological help or be motivated to use such services to receive sufficient help through their psychological journey.

Conclusions

This review aimed to provide insight into the design and implementation of self-management interventions by understanding where the health-related work burden lies for community-based patients and how context influences such work. In our scoping review, we found a high prevalence of patient work tasks conducted in the privacy of the patient's own lives—often alone, cognitive or unacknowledged, and consuming resources. However, despite continuous efforts to improve community-based self-management, there are no definitive models of intervention addressing this need, and patients continue to struggle to incorporate self-management into their daily lives.

Innovative digital technologies, such as using digital devices to track and monitor one's health, may play a role in supporting individuals with these invisible and solitary health tasks. Similarly, more personalized and flexible treatment might be achieved by sociotechnical interventions, which carefully consider how interactions with the health care system could affect different facets of an individual's daily life.

Existing self-management literature, traditionally only focusing on the physical aspects of health-related work, has been enriched by unveiling the internal experiences of patients. As research increasingly considers health as an interplay between biology, psychology, and sociology, we are beginning to better assess the various layers of patient work and contexts that can influence the implementation of self-care.

Acknowledgments

The authors would like to thank Ms Yi-Jen Lu, Ms Natasha Hughes, and Mr Ivan Khizhnyak for their assistance with paper screening and data extraction. This research was supported by the National Health and Medical Research Council grant APP1134919 (Centre for Research Excellence in Digital Health). AL was supported by the New South Wales Health Early-Mid Career Fellowship.

Authors' Contributions

KY and JJ designed the study, developed the search strategy, conducted the searches, screened the retrieved papers, extracted relevant information, and drafted the paper as the first authors. EC conceptualized the study and helped with drafting the paper, and LL, AK, and WT contributed toward search strategy development, paper screening, and data extraction. AB helped with developing the search strategy and writing drafts of the paper, and DP assisted with data extraction. AL contributed throughout the project, starting from conceptualization, to study design, search strategy development, and editing subsequent drafts of the paper.

Conflicts of Interest

None declared.

Abstract

Background: Improvement of functional status with physiotherapy is an important goal for patients with postoperative complications and an increased length of hospital stay (LoS) after esophagectomy. Supervised physiotherapy with telerehabilitation instead of conventional face-to-face care could be an alternative to treat these patients in their home environment after hospital discharge (T0), but its feasibility has not yet been investigated in detail.

Objective: The aim of this study was to investigate the feasibility of a 12-week supervised postoperative physiotherapy intervention with telerehabilitation for patients with esophageal cancer who underwent esophagectomy and had postoperative complications or who had an increased LoS. The secondary objective was to investigate the preliminary effectiveness of telerehabilitation on functional recovery compared with usual care.

Methods: A prospective feasibility study with a matched historical comparison group was performed. Feasibility outcomes included willingness and adherence to participate, refusal rate, treatment duration, occurrence of adverse events, and patient satisfaction. Secondary outcome measures were measurements of musculoskeletal and cardiovascular functions and activities according to the domains of the International Classification of Functioning, Disability and Health.

Results: A total of 22 patients with esophageal cancer who underwent esophagectomy and had postoperative complications or an increased LoS were included. The mean age at surgery was 64.55 (SD 6.72) years, and 77% (17/22) of patients were male. Moreover, 15 patients completed the intervention. Patient adherence was 99.8% in the first 6 weeks and dropped to 75.6% in the following 6 weeks, with a mean difference of −24.3% (95% CI 1.3 to 47.2; *P*=.04). At 3 months post operation, no differences in functional status were found between the intervention group and the matched historical comparison group.

Conclusions: This study showed that a postoperative physiotherapeutic intervention with telerehabilitation is feasible for patients with postoperative complications or an increased LoS after esophageal cancer surgery up to 6 weeks after T0.

Introduction

Background

Surgical resection of the esophagus is the primary curative treatment for patients with esophageal cancer and is associated with a high risk of postoperative complications, varying from 25% to 60% [1,2]. This leads to an increased length of hospital stay (LoS) and a delayed postoperative recovery, with a significant decline in physical function in the first 3 months after surgery [2,3].

It has been demonstrated in many surgical populations that improving preoperative functional status by exercise training had a positive effect on long-term postoperative outcomes [4,5]. However, recent studies have shown that preoperative functional status was not associated with postoperative complications in patients treated with esophagectomy, justifying the need to focus on treating these patients in the postoperative phase [6,7].

Patients with postoperative complications after esophagectomy often have fatigue, decreased exercise capacity, and disability such as impaired walking capacity and their recovery could take up to one year and beyond [3,8]. These symptoms are explained by altered cardiopulmonary function, generalized muscle weakness, and malnutrition, and physiotherapists play an important role in improving these aspects of physical functioning [9].

Telerehabilitation as an Alternative to Face-to-Face Care

Instead of face-to-face care, postoperative physiotherapy can also be streamed by telerehabilitation. Telerehabilitation is a medium to provide physiotherapy with electronic health (eHealth), defined as *the delivery of rehabilitation services to patients at a distance using information and communication technologies* [10]. Telerehabilitation has shown to be a valuable tool in improving postoperative outcomes and functional recovery in surgical patients, where patients considered reduced barriers for travel, flexible exercise hours, and the ability to directly integrate exercises into daily life as positive [11,12].

Moreover, telerehabilitation interventions have been valuable to overcome discontinuities that may arise in communication between hospital and primary care, where physiotherapists may have a lack of knowledge about how to treat patients after a highly complex surgery [13].

There is evidence showing positive effects of physiotherapy with telerehabilitation on clinical outcomes in patients with cancer, patients with cardiac disease, and patients with musculoskeletal disorders, but information on the feasibility of this intervention in the postoperative phase of patients with esophageal cancer treated with esophagectomy is lacking [14,15].

Objectives

Therefore, the primary objective of this prospective feasibility study was to investigate the feasibility of a 12-week supervised postoperative telerehabilitation program for patients with esophageal cancer who underwent esophagectomy and had postoperative complications or who had an increased LoS. The secondary objective was to investigate the preliminary effectiveness of telerehabilitation on functional recovery compared with a matched historical comparison group receiving usual care.

Methods

Ethical Approval

The Medical Ethical Committee (METC) of the Amsterdam University Medical Centers provided ethical approval for this study (NL58388.018.16). All patients provided written informed consent. As this was a feasibility study, sample size calculations have not been performed, and the initial sample size of 30 participants was pragmatically chosen. Patients could leave the study at any time for any reason if they wished to do so without any consequences.

Study Design

A prospective feasibility study was performed in patients treated with esophagectomy. To assess preliminary effectiveness, the patients who underwent the complete treatment were matched with a historical comparison group of patients who underwent esophagectomy and had postoperative complications, receiving usual face-to-face care between March 2012 and October 2014. We decided to match one case to 2 patients from a historical comparison group to optimize statistical power. Data collected from this historical comparison group were part of a previous study performed by the same research group, from which the METC waived the need for informed consent [6]. Patients were matched for gender, age, American Society of Anesthesiologists Physical Status Classification, comorbidities, Body Mass Index, pulmonary function, surgical procedure, and severity of postoperative complications.

Participants

Patients were recruited from the surgical wards at the Gastrointestinal Oncologic Centre Amsterdam of the Amsterdam University Medical Centre, located in the Academic Medical Centre, just before discharge from the hospital by the supervising physiotherapist or the investigator. Patients who refused to participate were referred to face-to-face physiotherapy in primary care.

Inclusion Criteria

Participants were included if they were aged 18 years or older and the primary reason of hospital stay was status after esophagectomy, they had internet access at home, and they signed the informed consent form. Moreover, participants were included if they had a postoperative complication, grade 3a to 4 according to the Clavien-Dindo classification. This 5-scale classification reports surgical complications based on the type of therapy required to treat the complication [16]. Participants were also included if the postoperative LoS was longer than 9 days because they were physically too weak to be discharged earlier. There was an indication for face-to-face physiotherapy in primary care if a patient was not yet able to walk or transfer independently because of loss of muscle strength, mobility, or balance at discharge.

Exclusion Criteria

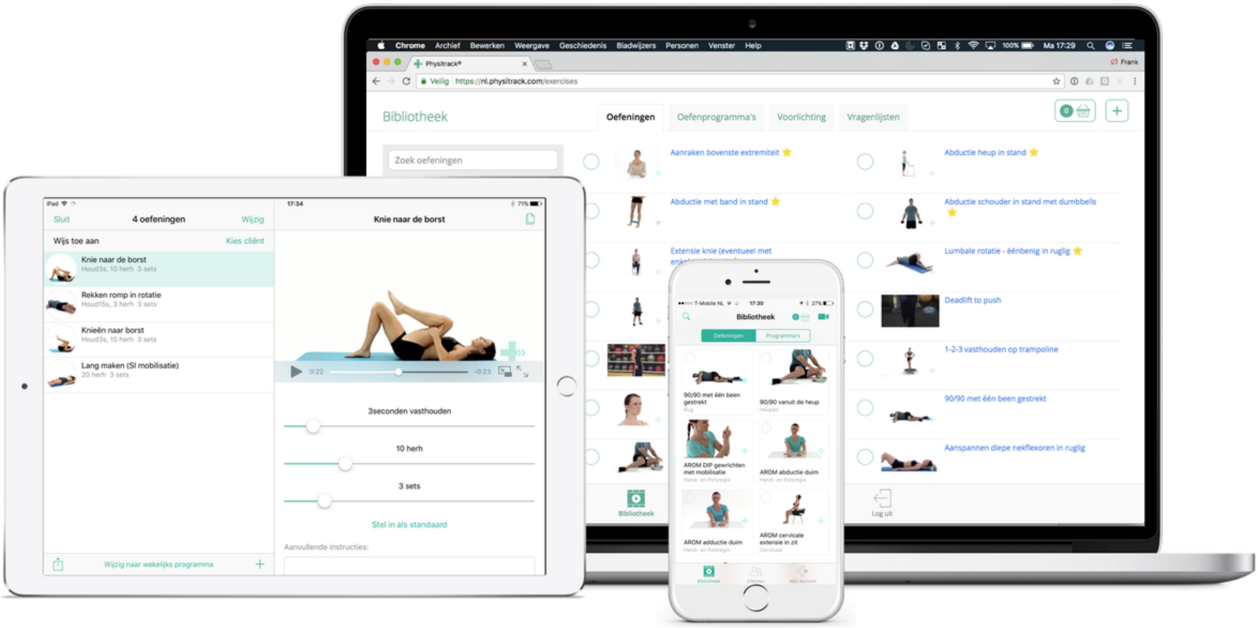
Patients were excluded if they were unable to complete self-reported questionnaires, insufficiently able to read or speak Dutch, had cognitive disorders, or had any other severe medical conditions that prevented them from doing unsupervised exercises at home.

Intervention

Participants received a 12-week supervised home-based telerehabilitation intervention after hospital discharge (T0) in their home environment. Before T0, a physiotherapist from the surgical ward instructed the patient on the telerehabilitation intervention.

The telerehabilitation intervention was provided with Physitrack (Physitrack Limited). Physitrack is an eHealth platform that enables physiotherapists to design home exercise programs and track patient adherence. Patients were provided with a goal-oriented exercise program created by the physiotherapist that could be accessed by a tablet, mobile phone, or computer (Figure 1). The physiotherapist accurately monitored the progress of the patient in weekly telephone, email, or video sessions, and exercises were adapted via the eHealth platform if needed. Physitrack had provided their services for this research project free of charge, and they will use the outcomes of this study to improve their services. They were not involved in the design, execution, analysis, and conclusions of this research. Physitrack will only have access to the published paper with its results, with no access to raw data.

Figure 1. Goal-oriented exercise program created by the physiotherapist, accessible by tablet, mobile phone, or computer (Used with permission from Physitrack).



The postoperative physiotherapeutic intervention with telerehabilitation was aimed at improving functional status. The intervention lasted 12 weeks with at least two sessions per week, depending on whether the treatment goals were achieved. The exercises were tailored to the patients' specific condition and needs, which were determined a day before T0. The physiotherapy goals were determined by using the patient-specific complaint list [17]. The exercises were aimed at improving the functional activity level of the patient, by increasing muscle strength, coordination, range of joint motion, and stamina. The intensity and frequency of the functional exercises were determined according to the guidelines of the American College of Sports Medicine [18]. Cardiorespiratory exercises to improve stamina were performed on a moderate-to-vigorous intensity level, measured using the Borg rating of perceived exertion scale (scores 6-20), for at least two sessions per week. Rating of perceived exertion with the Borg scale is a generally used and reliable scale to monitor and evaluate exercise intensity. A score from 13 to 16 relates to the moderate-to-vigorous intensity level, and this allowed us to monitor and adapt the appropriate intensity [19]. Exercises to improve muscle strength were performed 2 to 3 days per week on 60% to 70% of the 1 repetition maximum (moderate-to-hard intensity). We used the Holten curve that relates the percentage of the 1 repetition maximum to the estimated repetitions of that intensity. This allowed us to adapt the exercises without using fitness equipment to measure the 1 repetition maximum directly [18,20].

Feasibility Outcome Measures

Feasibility outcome measures were calculated for the 15 patients who completed the 12-week supervised home-based telerehabilitation intervention. Feasibility outcomes included refusal rate; adherence to the telerehabilitation intervention operationalized in the amount and duration of email, phone, and video calls conducted by patients and physiotherapists; treatment duration per session; adverse events; and patient satisfaction. Patient satisfaction was recorded with a modified telemedicine satisfaction and usefulness questionnaire (TSUQ), a 30-item Likert-type questionnaire including 3 subscales (usefulness, communication, and user friendliness) at 6 weeks post operation (T1) and at 3 months post operation (T2) [21]. Scores range from 30 to 150, with high scores indicating a higher satisfaction.

The telerehabilitation intervention was considered as feasible if at least an 80% adherence rate was achieved, if no adverse events took place, and if the average total patient satisfaction was higher than 75% (score >120).

Effectiveness Outcome Measures

Secondary outcome measures on preliminary effectiveness were musculoskeletal and cardiovascular functioning and level of activities according to the domains of the International Classification of Functioning, Disability and Health [22].

Handgrip strength was measured using the Jamar grip strength dynamometer (Lafayette Instrument Company) as a measure of generalized muscle strength [23,24]. Maximal inspiratory pressure was measured as an indicator of inspiratory muscle strength, with a Micro Respiratory Pressure Meter [2,4]. Functional lower extremity muscle function was measured with the 30-second chair stand test (30CST). This test measures extremity strength in relation to demanding functional daily activities such as stair climbing and getting out of a chair [25]. Walking capacity was measured using the 2-min walk test (2MWT) [26].

Fatigue was measured using the Multidimensional Fatigue Inventory [27].

Self-reported activities were measured using the Longitudinal Ageing Study Amsterdam Physical Activity Questionnaire (LAPAQ) in which patients reported the type, frequency, and duration of daily activities in the past 14 days. Health-related quality of life (HRQL) was measured using the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire C30, version 3.0 [28].

The effectiveness of outcome measures was recorded before the start of the intervention (T0) and at T1 and T2.

Standardized operating procedures of all measurements were used to guarantee uniformity and accuracy in operationalization. Trained and experienced physiotherapists performed the standardized measurements.

Statistical Analysis

Data were analyzed in the Statistical Package for the Social Sciences (version 25.0; IBM SPSS Statistics for Windows, IBM Corp). Statistical tests were analyzed two sided and considered significant with an alpha value ≤.05.

Baseline characteristics were summarized with descriptive statistics, where discrete variables were expressed as counts with percentages, ordinal variables as median and interquartile ranges (P25-75), and continuous variables as mean and standard deviation, and in case of a skewed distribution, they were expressed as median and interquartile range. Differences in outcomes before and after the intervention were determined by using a paired samples *t* test or a Wilcoxon matched-pairs signed rank test for skewed data. Differences between the intervention group and the historical comparison group were tested using a linear mixed model analysis to account for the dependency between observations.

Results

Baseline Characteristics

From January 2017 to October 2018, 22 patients with esophageal cancer who underwent esophagectomy were included in the study after obtaining informed consent. The study was terminated after the inclusion of the 22nd patient because we reached a point in data collection after which no new or relevant information emerged with respect to answering the primary research question.

The mean age at surgery was 64.6 (SD 6.7) years, and 77% (17/22) of patients were male. All patients received neoadjuvant chemoradiation therapy. At enrollment, mean pulmonary function expressed as a percent score of the predicted pulmonary function value was 116.1 (SD 18.7) for forced vital capacity, 109.0 (SD 19.3) for forced expiratory volume in 1 second, and 109.2 (SD 30.1) for inspiratory vital capacity. Except for 2 patients, all other patients were surgically treated with a minimally invasive transthoracic esophagectomy. In addition, 36% (8/22) of patients had a hospital stay of more than 9 days. Moreover, 91% (20/22) of patients had postoperative complications, of which 70% (14/22) required a surgical, an endoscopic, or a radiological intervention. Patient characteristics are presented in Table 1.

[a] ASA: American Society of Anesthesiologists.

[b] I: healthy person.

[c] II: mild systemic disease.

[d] III: severe systemic disease.

[e] BMI: body mass index is calculated as weight in kilograms divided by height in meters squared.

[f] COPD: chronic obstructive pulmonary disease.

[g] DM II: diabetes mellitus type 2.

[h] FVC: functional vital capacity.

[i] FEV1: forced expiratory volume in the first second of expiration.

[j] IVC: inspiratory vital capacity.

Feasibility

Of 22 patients, a total of 15 (68%) patients completed the 12-week program. Of the 7 patients who did not complete the study, 1 was discharged to a nursing home after inclusion, 2 quit the study intervention after 3 and 4 weeks because they preferred face-to-face physiotherapy, and 4 patients were withdrawn by the investigator because postoperative treatment required a multidisciplinary approach (n=3) or because of the presence of metastases (n=1). These patients did not systematically differ in baseline characteristics from the patients who completed the program.

The average duration of the treatment program was 11.1 (SD 5.2) weeks. Of the 4671 exercises provided to patients, 1337 (28.62%) were aimed at lower extremity muscle strength, 996 (21.32%) were aimed at respiration, and 1150 (24.62%) were aimed at walking.

Patient adherence, operationalized in the performance rate of exercises to the telerehabilitation intervention, was 99.8% in the first 6 weeks and dropped to 75.6% in the following 6 weeks, with a mean difference of −24.3% (95% CI 1.3 to 47.2; *P*=.04). The accomplishment of treatment goals was the main reason reported for being less or not adherent to the program anymore.

The physiotherapist and patients contacted each other 204 times in 243 weeks, with a minimum of 1 and a maximum of 3 times a week for coaching, for regular follow-ups, and for adjusting the treatment program, dependent on the patient's needs. Of these 204 direct patient contacts, 1 (0.5%) took place with a video connection, 26 (12.7%) with email, 122 (59.8%) with telephone, and 55 (27.0%) with live contact via home visits.

Total average patient satisfaction (range 30-150) measured at T1 was 135.0 (SD 19.5), with subscores on usefulness (range 10-50) being 44.66 (SD 7.4), communication (range 11-55) being 48.3 (SD 8.1), and user friendliness (range 9-45) being 42.8 (SD 3.2). Patients appreciated weekly follow-ups by telephone or email and especially appreciated the flexibility they had to perform the exercises at home. They rated the telerehabilitation app as user friendly, and they did not miss the physical presence of the physiotherapist to follow the exercise program. No adverse events took place during measurements or exercise sessions. Total average patient satisfaction at T2 was 139.6 (SD 15.4). Textbox 1 provides a selection of quotes provided by participants more than once about experiences with the program.

Textbox 1. Patient experiences.

Quotes:

- "It gave a lot of confidence to work at home on my recovery with supervision of a PT" [Mrs S, 70 years]
- "I could do the exercises whenever I wanted, that was very convenient" [Mr W, 54 years]
- "Without this program I would never have been that far" [Mr J, 66 years]
- "I should not have thought about going to the physiotherapist twice a week" [Mrs B, 60 years]
- "By practicing at home, I knew what I was doing it for. That was very motivating" [Mr B, 62 years]
- "I missed incentives in the program" [Mr B, 49 years]
- "I did not miss the physical presence of the physiotherapist, I felt that I could always reach him through the app" [Mrs B, 64 years]
- "Along the way, I found the exercise program less relevant, I could already do my daily activities again" [Mr S, 62 years]

Effectiveness

A total of 15 patients who completed the telerehabilitation program were matched with 30 patients from a historical comparison group for both pre- and postoperative characteristics (gender, age, preoperative pulmonary function, type of surgery, and postoperative complications classified according to Clavien-Dindo). Table 2 provides details about the matching characteristics.

At T0, patients in the intervention group had significantly lower functional capacity measures compared with reference values than patients in the matched historical comparison group (Table 3).

At 3 months post operation, no differences in functional status measures were found between the intervention group and the matched control group (Table 4).

Within the intervention group, 30CST, 2MWT, fatigue, and HRQL improved significantly between T0 and T1 and between T1 and T2, whereas activities of daily life (ADL) decreased significantly between T0 and T1 and improved again between T1 and T2 (Table 5).

Discussion

Principal Findings

To our knowledge, this is the first study demonstrating that postoperative physiotherapy with telerehabilitation is feasible in patients with postoperative complications after esophagectomy, primarily in the first 6 weeks after T0. This is in line with a study by Latham et al [11], who stated that telerehabilitation is a valuable tool to manage postoperative outcomes and functional progress directly after T0 in a patient's home environment.

The adherence rates were significantly higher in the first 6 weeks after T0 than in the following 6 weeks, where patients reported that they were generally more able to perform their ADL and were less dependent on the telerehabilitation intervention, which might explain the lower adherence rates despite a further incline in functional status. From a functional perspective, these lower adherence rates should be interpreted as a desired outcome, because it illustrates the patient's gradual independence of physiotherapeutic care.

The consistently high patient satisfaction rates of the telerehabilitation intervention in our study are confirmed in a systematic review by Mair et al [29], who stated that the greatest advantages experienced by patients were increased accessibility of specialist expertise, increased flexibility, less travel required, and reduced waiting times. This is also in agreement with the study by Moffet et al [30], who investigated patient satisfaction with in-home telerehabilitation after total knee arthroplasty and found similar results, concluding that patient satisfaction was at least equal to conventional health care delivery.

In this study, we compared patients who underwent the telerehabilitation program with a historical comparison group of patients receiving usual care and found equal functional status outcome measures at T2. This is in line with studies that found telerehabilitation interventions to be equally effective as usual care on at least one outcome measure; however, overall significant evidence in favor of telerehabilitation was still lacking [31,32].

Despite the similar functional outcomes at T2, it has to be noted that most of the functional status outcome measures of our intervention group at T0 were significantly lower than those of the matched historical comparison group. It could be argued that the intervention group gained more progress on functional status because of the physiotherapeutic treatment with telerehabilitation, in comparison with the matched historical comparison group, ultimately resulting in equal outcomes at T2.

Within the intervention group, most of the functional outcome measures significantly improved between T0-T1 and T1-T2, apart from ADL that significantly decreased during the first 6 weeks of the intervention and was restored in the following 6 weeks. A possible explanation could be that after T0, patients mostly stayed at home because they felt too weak to keep up with their ADL. Moreover, in the first 6 weeks, the telerehabilitation intervention primarily focused on increasing muscle strength of the lower extremities. After 6 weeks, the shift was gradually made toward implementing the exercises in daily life, finally resulting in a significant increase in ADL in the following 6 weeks.

Limitations

This study has intrinsic limitations. First, only 22 patients were included in this study, of which 15 patients completed the study. This might limit the generalizability of our findings. However, despite the small sample size, the included participants represented the population of interest in terms of baseline characteristics and postoperative complications. Moreover, inclusion was terminated after the inclusion of the 22nd participant because no new findings were to be expected with adding new participants to the study.

Second, this study was not a pilot feasibility trial, where patients were randomly assigned either to the intervention group or a control group to determine the effectiveness of investigational treatment. Instead, we compared the intervention group with a matched historical comparison group. Therefore, bias could not be ruled out completely.

We were not able to compare functional status outcome measures half way through the telerehabilitation intervention because the historical controls were not measured at T1.

Third, patient satisfaction was measured with a modified TSUQ that had not been validated in this specific population. Kairy et al [33] in their systematic review investigating clinical outcomes, clinical process, health care utilization, and costs associated with telerehabilitation concluded that patient satisfaction ratings were generally high, irrespective of the population. However, they also stated that operationalization and standardization of satisfaction were frequently lacking and too much focus was on the technology aspect instead of aspects of service delivery. The satisfaction questionnaire we used addressed both aspects, and therefore, we are confident that the satisfaction ratings were representative of the telerehabilitation intervention provided.

Conclusions

This study shows that patients are able to improve their functional status by doing functional exercises in their own meaningful environment supported by telerehabilitation and tablet use with distant guidance from an experienced physiotherapist. The feasibility of the physiotherapeutic intervention with telerehabilitation for this specific patient category has implications for (re)organizing postoperative physiotherapeutic care in the patient's home environment. Telerehabilitation cannot replace face-to-face physiotherapy as physical examination remains to be necessary, but taking into account positive adherence rates and satisfaction, we strongly suggest considering this way of treatment delivery for patients with esophageal cancer treated with surgery and having postoperative complications, especially in the first 6 weeks after T0. We also recommend investigating the potential cost-effectiveness of telerehabilitation compared with usual care. Although we found equal functional status outcomes in both the intervention group and the historical comparison group at T2, we suggest performing a randomized controlled trial to draw firm conclusions on its effectiveness.

Acknowledgments

The authors would like to acknowledge Sander Steenhuizen, PT, and Sven Geelen, PT, MSc, for recruiting participants and performing measurements. The authors would also like to acknowledge Physitrack, who provided their services for this research project free of charge without being involved in the design, execution, analysis, and conclusions of this research. Abstract

Background: The benefits of telemedicine include cost savings and decentralized care. Video consultation is one form that enables early detection of deteriorating patients and promotion of self-efficacy in patients who are well but anxious. Abdominal pain is a common symptom presented by patients in emergency departments. These patients could benefit from video consultation, as it enables remote follow-up of patients who do not require admission and facilitates early discharge of patients from overcrowded hospitals.

Objective: The study aimed to evaluate the safety and efficacy of the use of digital telereview in patients presenting with undifferentiated acute abdominal pain.

Methods: The SAVED study was a prospective randomized controlled trial in which follow-up using existing telephone-based telereview (control) was compared with digital telereview (intervention). Patients with undifferentiated acute abdominal pain discharged from the emergency department observation ward were studied based on intention-to-treat. The control arm received routine, provider-scheduled telereview with missed reviews actively coordinated and rescheduled by emergency department staff. The intervention arm received access to a platform for digital telereview (asynchronous and synchronous format) that enabled patient-led appointment rescheduling. Patients were followed-up for 2 weeks for outcomes of service utilization, efficacy (compliance with their disposition plan), and safety (re-presentation for the same condition).

Results: A total of 70 patients participated, with patients randomly assigned to each arm (1:1 ratio). Patients were a mean age of 40.0 (SD 13.8; range 22-71) years, predominantly female (47/70, 67%), and predominantly of Chinese ethnicity (39/70, 56%). The telereview service was used by 32 patients in the control arm (32/35, 91%) and 18 patients in the intervention arm (18/35, 51%). Most patients in control (33/35, 94%; 95% CI 79.5%-99.0%) and intervention (34/35, 97%; 95% CI 83.4%-99.9%) arms were compliant with their final disposition. There was a low rate of re-presentation at 72 hours and 2 weeks for both control (72 hours: 2/35, 6%; 95% CI 1.0%-20.5%; 2 weeks: 2/35, 6%, 95% CI 1.0%-20.5%) and intervention (72 hours: 2/35, 6%; 95% CI 1.0%-20.5%; 2 weeks: 3/35, 9%, 95% CI 2.2%-24.2%) arms. There were no significant differences in safety (P>.99) and efficacy (P>.99) between the two groups.

Conclusions: The application of digital telereview for the follow-up of patients with abdominal pain may be safe and effective. Future studies are needed to evaluate its cost-effectiveness and usefulness for broader clinical application.

KEYWORDS

digital health; teleconsultation; video consultation; telereview; abdominal pain; primary care; emergency department

Introduction

Existing literature on telemedicine suggests that it enables cost savings and improved health care access for patients with diverse illnesses [1,2]. These reports have fueled a rise in the adoption of telemedicine for these applications in various clinical settings [3], allowing new models for decentralized care that may help alleviate shortages in health care resources and help encourage self-management by patients where appropriate [4]. This need has been heightened with the coronavirus disease 2019 (COVID-19) pandemic which has been placing many health systems in dire straits. The application of video consultation to facilitate early discharge and subsequent remote follow-up of relatively well patients is a potential solution for increasingly oversubscribed emergency departments [5], given the detrimental effects of overcrowding on the timeliness and the quality of care [6].

Patient and provider acceptance of video consultation has grown in recent years, and over two-thirds of respondents to a survey of patient and caregiver acceptance conducted in the emergency department of Singapore General Hospital were comfortable using mobile technology to share information [7]. Prior studies in Singapore have reported benefits from telemedicine such as improved health care access in the form of remote consultation mediated by health professionals for acute illnesses such as poisoning [8] or maritime emergencies [9]; however, few international studies have reported controlled outcomes from the use of telemedicine for acute illnesses by patients directly. Furthermore, many studies had considerable limitations in terms of study design [10] and clarity in reporting which telemedicine interventions were used [11].

The use of video consultation for telereview has not been conclusively investigated in patients with acute gastrointestinal ailments [12,13]. The objective of this study was to evaluate the safety and efficacy of digital telereview for patients in the emergency department who present with undifferentiated acute abdominal pain. In this study, digital telereview was evaluated as a “pull-from-patient”, a patient-led form of service delivery, and was compared with existing telephone-based telereview evaluated as a “push-to-patient”, a provider-led form of service delivery. This was the first direct and pragmatic trial of these alternative forms of service delivery for the follow-up of patients with abdominal pain.

Methods

Study Design

The SAVED (Safety and Efficacy of Follow-up for Patients With Abdominal Pain Using Video Consultation) study was a prospective randomized controlled trial with a 1:1 allocation ratio. An existing telephone-based telereview service (control) was compared with digital telereview using DoctorBell—a novel, web-based telehealth platform (intervention). This study was approved by the Centralized Institutional Review Board of SingHealth Singapore General Hospital (protocol number 2017/2049) and conducted in accordance with the Declaration of Helsinki (2000).

Study Setting

The emergency department was selected as the location for this pilot study because 24-hour medical services were available to attend to any patients whose condition deteriorated [13]. Patients from the emergency department observation ward with severe undifferentiated illnesses that did not meet clinical criteria for hospital admission were recruited. This cohort represents a segment of the population of patients in the emergency department for whom the decision (final disposition) is delayed by clinical uncertainty [14,15]; therefore, the recruitment of patients discharged from the emergency department observation ward allowed investigators to stress-test the appropriateness of disposition assigned by digital telereview as well as patient adherence to recommendations, since telephone-based telereview is routinely conducted within 48 to 72 hours of discharge for patients with undifferentiated illness as a fail-safe measure that enables early detection of patients with deteriorating clinical condition. This practice improves care continuity while enabling safe discharge to address overcrowding.

Study Recruitment

Patients with undifferentiated acute abdominal pain who were discharged from a tertiary hospital in Singapore using detailed criteria (Abdominal Pain or Gastroenteritis Pathways in Multimedia Appendix 1) were considered for recruitment at the point of discharge by study team members after the patient had received routine treatment and a disposition plan which included counselling for self-efficacy and monitoring at home as well as education regarding clinical features that warrant a return to the emergency department (re-presentation).

From September 2017 to May 2018, consecutive patients who presented to the emergency department and who satisfied the study criteria were recruited. Inclusion criteria were the ability to read in English and the ability to operate smartphone messaging apps (such as WhatsApp). To exclude patients who may be considered vulnerable, exclusion criteria were defined as less than 21 years of age, pregnant, a prisoner, cognitively impaired, or requiring a legal representative for informed consent in Singapore. As a pilot, formal sample size calculation was not possible due to a lack of relevant data.

Randomization and Masking

After completion of informed consent, participants were randomly assigned by a study team member who withdrew lots from a box containing equal numbers of paper indicating either control or intervention. Lots in the box were replenished after each draw by a study team member (S.Y.) who was not involved in clinical care or the implementation of the randomization. At recruitment, study team members provided participants with links to web-based surveys about symptoms to be reported by patients at initial presentation and at follow-up, following recruitment and telereview, respectively. Blinding was not possible in this study.

Intervention

Follow-up after discharge by telereview is routinely conducted by triage nurses to facilitate early discharge from the observation ward, with follow-up review to ascertain right-siting through prompt identification of deteriorating patients as well as encouraging self-efficacy in well patients who are anxious but who do not need to re-visit the emergency department. During telereview, patients who are well are advised on self-management while patients with ominous symptomatology or deteriorating illness are advised to return to the emergency department for further evaluation. In this study, patients in the control arm received routine, provider-led telephone-based telereview after discharge. Telereview was conducted by the emergency department staff on-shift at the time of the patient's booked appointment. Any missed telereviews were actively and manually rescheduled by staff with three attempted phone calls within 48 to 72 hours following discharge. No further attempt was made to contact patients who were not reached in the 72-hour period or those who declined telereview.

Patients in the intervention arm had access to DoctorBell, a novel telehealth platform accessible on smartphone or desktop by web browsers. This was designed using a design-thinking process based on the context and workflows of an emergency department. It allowed patient-led booking, rescheduling, or cancellation of one digital telereview appointment based on the patient's own individual availability, restricted to 48- to 72-hour window following discharge from the emergency department. Digital telereview appointments through this platform were patient-led and were not actively rescheduled by emergency department staff if missed or cancelled. Before the digital telereview appointment (synchronous teleconsultation with video, voice, and text messaging), patients received an in-app form that allowed them to report important history or symptoms beforehand (asynchronous). This was sent to the emergency department staff on-duty before video consultation, providing them with the opportunity to clarify any uncertainties with the on-duty attending physician before synchronous consultation. Upon starting work, staff could view digital telereview bookings scheduled during their shift and received automated real-time push notifications of any changes made to appointments.

Study Outcomes and Statistical Analysis

Patients in both groups were followed up for 2 weeks to examine the study outcomes of service utilization (telereview appointments used), efficacy (patient compliance with their final disposition plan), and safety (re-presentation to the emergency department for the same medical problem within 72 hours or within 2 weeks). Initially, service utilization and safety were the only outcome measures planned for investigation; however, study team members observed that not all patients complied with instructions given during telereview to return to the emergency department. Therefore, efficacy was later added to the analysis as an outcome measure using existing data. No change to study procedures was required. For patients who did not receive telereview, the final disposition plan was that given at the point of discharge from the emergency department (ie, self-management and monitoring at home). For patients who received telereview, the final disposition plan was that given during telereview (ie, whether to continue self-management or return to the emergency department).

The study population was analyzed based on intention-to-treat. All hypotheses were two-sided with a $P<.05$ considered statistically significant. Descriptive statistical analysis was conducted using SPSS software (version 20.0; IBM Corp). Associations between categorical variables were analyzed using Fisher exact test. Where expected counts within all categories were greater than 5, chi-square test was used instead. Associations between continuous variables were analyzed using the two-tailed two-sample *t* test.

Results

From September 2017 to May 2018, patients (N=72) who were discharged from the emergency department observation ward and who satisfied inclusion criteria were recruited to participate in this study. One patient was under the age of 21 and was excluded. Another patient declined to participate in the study. The remaining patients (N=70) were enrolled with patients (n=35) randomized to each arm (CONSORT diagram, Figure 1). One patient crossed over from digital telereview to telephone-based telereview since, rather than booking a digital telereview appointment, the patient called the emergency department within 72 hours to report persistent symptoms and complied with instructions to return to the emergency department the next day (on the fourth day postdischarge). This patient was analyzed in the intervention arm in accordance with intention-to-treat.

There were no significant demographic differences between the study groups. Demographics of the study population are described in detail in Table 1. Patients were a mean of 40.0 (SD 13.8; range 22-71) years of age, mostly female (47/70, 67%) and mostly of Chinese ethnicity (39/70, 56%). Symptoms reported at initial presentation are detailed in Table 2 and those reported at follow-up are detailed in Table 3 demonstrating the usefulness of a structured web survey in gathering symptomatology during telereview.

Figure 1. A CONSORT diagram depicting the study. Patients in the control arm receive the push-to-patient form of telephone telereview while patients in the intervention arm receive the pull-from-patient form of digital telereview.

Giddiness	1 (2)	0 (0)	1 (3)	N/A	>.99

[a] This number is less than the group number because respondents did not submit their surveys (n=9, n=5, and n=4 missing in All, DoctorBell, and Telephone, respectively).

[b] N/A: not applicable as Fisher's exact test was used.

There was an overall 71% (50/70) utilization of the telereview service by 32 patients in the telephone-based telereview control arm (32/35, 91%) and 18 patients in the digital telereview intervention arm (18/35, 51%). Most patients in control (33/35, 94%; 95% CI 79.5%-99.0%) and intervention (34/35, 97%; 95% CI 83.4%-99.9%) arms were compliant with final disposition. There was a low rate of re-presentation at 72 hours for both arms (control: 2/35, 6%; 95% CI 1.0%-20.5%; intervention: 2/35, 6%; 95% CI 1.0%-20.5%) and at 2 weeks for both control (2/35, 6%; 95% CI 1.0%-20.5%) and intervention (3/35, 9%; 95% CI 2.2%-24.2%) arms. After the initial 72-hour period, no patients represented within the control arm crossed over whereas the single patient from the intervention arm who crossed over to telephone-based review re-presented at 4 days. Using the chi-square test, there were no significant differences between the control and intervention arms with regards to efficacy as well as safety in terms of re-presentation within 72 hours and within 2 weeks (*P*>.99).

Discussion

Principal Findings

Emergency department overcrowding is a persistent challenge despite increased human resource capacity and process innovations [16] including emergency department observation wards themselves [15]. This has been exacerbated by the COVID-19 pandemic with front-loaded emergency services. New technologies may help resolve overcrowding through automated solutions such as machine learning to optimize existing processes [17] or digital telemedicine to enable new processes that streamline the flow of patients [3]. This study is the first pragmatic randomized controlled trial that evaluated efficacy of digital telereview for the follow-up of patients with undifferentiated acute abdominal pain. This solution uses a hybrid of asynchronous and synchronous teleconsultation—the unique benefits of which have been outlined in a review and case study of their application in eye care [18]. This study is a timely contribution to ongoing debate surrounding the effective implementation of remote consultation in tertiary care. The results of this study suggest that digital telereview may be a safe and effective tool to optimize follow-up processes for right-siting patients in tertiary care.

Digital platforms may enable safe re-design of existing processes from a push-to-patient form of service delivery to a pull-from-patient form. Earlier studies have indicated that patients may not always have adequate insight about the severity of their illness [19]. Hildebrandt et al [19] surveyed primary care physicians regarding patient-directed afterhours telephone triage services. Calls from patients who considered their conditions to be non-emergent were reviewed by physicians who found that roughly half of these patients (range 22%-77%) required urgent review [19]. In this study, telereview following initial physician contact was selected instead of teletriage in order to ensure that all patients were first counselled by a health professional regarding their condition before intervention.

The use of telereview may not be appropriate in the presence of certain clinical factors. These include patient factors such as lack of insight regarding their health or lack of familiarity with the use of mobile phone technology [7,20]. Some researchers posit that dedicated staff should be rostered to respond to any urgent enquiries and actively follow-up all patients to ensure timely assessment [19]; however, the results from this study indicate that patient-led digital telereview following routine education and discharge advice can be as effective as provider-led active follow-up despite the finding of reduced resource utilization (patient-led digital telereview: 18/35, 51%; provider-led telephone-based telereview: 32/35, 91%; Figure 1).

This pull-from-patient service delivery reduces manpower utilization to coordinate unnecessary telereview in patients who are well. Findings from a retrospective study of 1522 video-conference teletriage interventions over 52 weeks support this notion that teleconsultation can improve clinical efficiency [21]. Similarly, Brennan et al [22] reported good outcomes and time saved from emergency department teleconsultations. In this study, the digital platform served as a filter to triage patients, saved time for emergency department staff by collecting fundamental patient-reported history asynchronously, and presented the information accessibly to emergency department staff for clarification with the attending physician at any suitable time before synchronous consultation (instead of traditionally having to place the patient on-hold and interrupt the attending for advice). The results from the current study will facilitate the necessary health economic assessments to guide the implementation of digital telereview, which need to be conducted based on relevant outcomes that have been identified in the literature such as reduced adverse events and reduced time requirement [23].

Limitations

Limitations of this study include a lack of pre-existing data for sample size calculation and possible selection bias since patients were only recruited when study team members were on shift—a common constraint of studies that are conducted in busy emergency departments [13]. Furthermore, these results may not be generalizable given that participants were relatively young and well-educated although, from a practical perspective, such patients are more likely to use digital consultation services [7,23]. Other limitations are consistent with intention-to-treat analysis such as conservative estimates for efficacy as a result of totals diluted by patients who did not receive the intervention (Figure 1). The strengths of intention-to-treat analysis are that it evaluates the actual performance compared objectively with existing practice by considering any deviations in protocol. Further strengths of this study are the use of the gold standard randomized controlled methodology and the comprehensive description of interventions, participants, and outcomes.

Existing reports caution that successful implementation of a telemedicine intervention may not necessarily be reproduced once the clinical application is even slightly modified. This has been observed with investigations of the WelTel telehealth intervention [2]. Lester et al [2] first reported successful implementation of WelTel for messaging that provides weekly automated notifications for patients with *Human immunodeficiency virus* (and promotes adherence to anti-retroviral therapy with messages based on patient-reported adherence. When van der Kop et al [24] evaluated use of WelTel to promote attendance to follow-up appointments, they found lower compliance in the patients who received the intervention and no significant difference between the groups. Therefore, the results from our study may not be generalizable to other undifferentiated acute presentations such as chest pain. Physicians, administrators, and researchers should be mindful of factors such as clinical context and the form of intervention in the consideration of existing evidence to guide telehealth implementation [20].

The benefits of applying design-thinking in this manner have been described for numerous telehealth applications including tele-ophthalmology enabled by artificial intelligence since contextual considerations such as lack of adequate infrastructure or stable internet access may have an impact on model implementation [25]. In the context of the COVID-19 pandemic, there is a heightened need for providers to evaluate models such as these to rapidly scale health system capacity to address clinical need and to decentralize services to reduce health care–associated transmission [26]. The concurrent use of asynchronous modalities as a filter before synchronous consultation may help ensure better allocation of healthcare manpower similar to the model in this study. Looking beyond the pandemic, when structured appropriately to address the clinical need, digital telereview developed using a design that is mindful of clinical context to guide telehealth implementation (as described above) may lead to considerable cost savings (as suggested by our results). This has already been definitively demonstrated at scale for other related technology applications such as synchronous artificial intelligence–enabled tele-ophthalmology [27] and asynchronous multicenter cloud-computing enabled registry-based research [28].

Conclusions

Digital telereview may safely facilitate a re-design from a push-to-patient to a pull-from-patient form of follow-up in select patients. This study suggests that there is potential to save cost and manpower-time with digital telereview and has laid the ground work for future investigations to examine the benefits of implementing digital telereview at scale for various clinical applications.

Acknowledgments

Patrick Poh Huan Yu, Ming Xiang Tham, and Nicholas Chew Yi Ming are acknowledged as clinical innovators and research collaborators for developing the novel DoctorBell telehealth platform used in this study. The DoctorBell platform was acquired by Mobile Health Pte Ltd on August 1, 2018 and integrated into the MaNaDr telehealth platform.

DVG received travel funding from the Mobile Health Education grant, Commonwealth Fellowship in Innovation award, and the National Youth Fund award for clinical research training and collaborations at Oxford University and Stanford University. The study was partially funded by the Singapore General Hospital in the form of the research hours contributed by study team members employed by the hospital. Funder(s) played no part in the design, conduct, or decision to publish for this study.

This manuscript is dedicated to the memory of our colleague and friend, the late SY, who succumbed to her illness in the months following the completion of this study. She was a dedicated researcher without whom this study among many others would not have been possible. Her passing is a profound loss and her contributions to medicine and clinical sciences will live on.

Conflicts of Interest

DVG reports investment in DoctorBell, VISRE, AskDr and Shyfts. He reports serving as lecturer and faculty advisor to the medical innovation program of the National University of Singapore, as well as Head of Health Informatics (Collaborative Ocular Tuberculosis Study group).

Abstract

Background: Web-based services for testing of sexually transmitted infections are widely available across the United Kingdom. Remote prescriptions with medications posted home may support prompt treatment; however, the absence of face-to-face contact with clinicians raises clinical safety issues as medical history may not be accurately provided.

Objective: This service evaluation aimed to capture the use and explore the safety of 3 remote communication strategies employed within a web-based service offering remote prescriptions of antibiotics, delivered via post, for uncomplicated genital *Chlamydia trachomatis*. User acceptability and time-from-diagnosis-to-treatment were also obtained.

Methods: Three iterations of the service were compared, where medical history was collected via SMS text message, telephone, or a secure web form before a prescription was issued. We contacted users after they were issued a prescription and completed the medical history a second time via telephone, asking when they took their medication and how they felt about the service. The primary safety measure was agreement in information supplied at 2 assessments (ie, clinical and evaluation assessment) on key elements of safe prescribing: allergies, current medications, or contraindicating clinical conditions or symptoms. Agreement in information between clinical and evaluation assessment was summarized as a binary variable. Factors associated with the assessment agreement variable were explored using univariate and multivariate analysis. The secondary evaluation measures were recall of and adherence to instructions for taking medication, time-from-diagnosis-to-treatment, and acceptability of the web-based service.

Results: All web-based service users, resident in the London Boroughs of Lambeth and Southwark with a positive chlamydia diagnosis, who were eligible for and chose postal treatment between February 15, 2017, and October 24, 2017, were invited to participate in this service evaluation. Of 321 eligible users, 62.0% (199) participated. A total of 27.6% (55/199) users completed the clinical assessment via SMS text message, 40.7% (81/199) users via telephone, and 31.7% (63/199) users via a secure web form. Those who were assessed for prescription via SMS text message were less likely to have an agreement in safe prescribing information than those assessed via telephone (adjusted odds ratio [aOR] 0.22, 95% CI 0.08-0.61; *P*=.004). We found no statistically significant difference in odds of agreement between the web form and telephone assessment (aOR 0.50, 95% CI 0.17-1.43; *P*=.20). Median time-to-treatment was 4 days (IQR 3-5.5). In addition, 99.0% (196/199) of users reported understanding remote communication, and 89.9% (178/198) would use the service again.

Conclusions: Postal treatment is an acceptable and rapid treatment option for uncomplicated genital chlamydia. Clinical assessment via SMS text message before remote prescription may not be accurate or sufficient. As health care is delivered via the web, strategies that support safe remote prescribing are increasingly important, as is their evaluation, which should be robust and carefully considered.

Introduction

Background

Web-based services for testing for sexually transmitted infections (STI) with test kits sent home are widely implemented in the United Kingdom [1,2]. In these services, users order a test kit from a web-based service, take the samples themselves, and post them to a laboratory with results given via SMS text message or telephone. There is evidence that they increase testing uptake in comparison with clinic-based services [3], but the clinical and public health impact of better access to testing requires prompt treatment of the diagnosed infections to prevent onward transmission. Remote prescriptions with medication posted home may facilitate prompt treatment.

Remote prescriptions without face-to-face health professional contact raise safety concerns [4]. The UK General Medical Council advises that clinicians should be satisfied in their ability to adequately assess the patient’s condition through satisfactory medical and drug history, including allergies before remote prescribing, and recommends consideration of the limitations of the medium of communication used to ascertain this information [5]. Health Care Improvement Scotland and the UK National Prescribing Centre have made similar recommendations [4,6,7], advocating a cautious approach to remote prescribing. This is particularly important when prescribing treatment for chlamydia within a web-based sexual health service because (1) there is no face-to-face contact throughout the process of testing, diagnosis, and treatment; (2) sexual health service records are not linked to the primary care record making it difficult to cross-check information, and (3) instructions for use and partner notification are provided remotely.

In this context, it is therefore, particularly important that there is effective remote communication to obtain accurate and sufficient medical history for prescribing, and to ensure correct use of medication and partner notification.

Research has documented poor practice in remote prescribing with medications available without a prescription or an appropriate medical history [8,9]; there are obvious health risks associated with this poor practice [10,11]. However, remote prescribing is also delivered by highly regulated providers where doctors obtain clinical histories through telephone, video, or email consultations [12,13]. There is good evidence that self-completed digital forms collect reliable data on past medical histories for diagnosis [14-17], but little evidence on their value before prescribing. As many health systems move toward a *digital first* approach (see, eg, the National Health Service, NHS long-term plan [18]) and increasingly use digital or web-based forms for clinical histories, we predict a need to understand their ability to generate accurate information for prescribing.

We developed and piloted remote prescribing and postal treatment of uncomplicated chlamydia infection within a web-based sexual health service. The process and outcomes of testing have been described elsewhere [3,19]. This service was evaluated during its implementation and development to monitor its clinical safety. As the service evolved, 3 remote communication strategies were used to take clinical histories before the prescribing and postal delivery of treatment of uncomplicated chlamydia. As the service evolved, the accuracy of the information obtained through each remote communication strategy was checked by telephoning users after they had received their prescriptions to recheck the information that they had provided. We sought to understand the safety issues highlighted by this service improvement activity. To do this, we described 3 cycles of service development to understand:

- How different media of assessment support accurate medical histories for prescribing
- To what extent service users understood remotely delivered instructions for use
- How different strategies for remote prescription and treatment impacted on time-to-treatment

The Service Evaluated

Sexual Health 24 hours a day (SH:24) is an NHS commissioned web-based service that specializes in system transformation in sexual health services through agile and design-led thinking, using an iterative process of build/test/learn for innovation. SH:24 offers postal self-sampling test kits for chlamydia, gonorrhea, HIV, and syphilis. Test kits are ordered through a website, with those reporting symptoms of infection referred to local clinics. Test kits are sent by post in discreet packaging that includes the materials for self-sampling—urine for men and vaginal samples for women—and a finger-prick blood sample for HIV and syphilis. The user posts the samples to a laboratory for testing. Chlamydia, gonorrhea, syphilis, and negative HIV test results are delivered via SMS text message. Reactive HIV test results are delivered via telephone with referral to local clinics for confirmatory testing.

Those with positive chlamydia results who are older than 18 years and asymptomatic are offered postal chlamydia treatment and complete a remote assessment to check their eligibility for the appropriate antibiotic. If eligible, an electronic prescription is issued by a clinician, and the medication is dispensed, packaged, and dispatched by a regulated pharmacy through the Royal Mail registered (but not signed for) postal service. If ineligible for the treatment offered by the web-based service, which at the time of evaluation was a single 1 g dose of

Azithromycin (SDA) users would be directed to local clinic services for treatment.

During and in response to the evaluation, the media of communication for assessment before the remote prescription changed 3 times.

1. During the first iteration of the service, eligibility was assessed via SMS text message. A single message rather than multiple messages was used as a break in communication during a process (eg, a loss of phone connection) would disrupt the assessment process. The message stated the following:

> *Your chlamydia result is positive. We would like to post you a single dose treatment. You would receive it the next working day. First, we need to know: Are you taking medicines or allergic to any medicines, soya or peanuts? (this is important because the medicine may trigger your allergy or interact with other medicines). Do you have liver, kidney, heart problems, or myasthenia gravis? (this is important because treatment may worsen your condition). Are you pregnant or breastfeeding? (this is important as the treatment may affect your baby). Do you have any symptoms: fever, joint pain, pelvic (lower abdominal) pain, or anal pain? (this is important as you may need a different treatment). If you answered no to ALL of these questions, reply NO. If you answered yes to ANY of these questions, reply YES. If you would like to go to a clinic for treatment instead, please reply CLINIC. Text back if you would like help. Thanks, SH:24.*

Those that responded no were then sent this message.

> *Thank you. Your treatment is now being prepared. You have told us that you are not taking any medicines, you do not have any medical problems (liver, kidney, heart, myasthenia gravis) and you do not have any symptoms of chlamydia. Text back if you have any queries or questions we always prefer to answer queries to prevent any future problems. Thanks, SH:24*

2. During the second iteration, the same questions were asked by a clinician over the telephone with responses recorded in the web-based clinical record.

3. During the third iteration, the same questions were asked via a secure web form, which was self-completed by service users.

Instructions for medication use, including abstinence from sexual intercourse for 7 days after commencing treatment and partner notification was provided in written form with the medication. The change from iteration 1 to iteration 2 occurred because a user reported an allergy in the evaluation that was not reported in the clinical assessment. The change from iteration 2 to iteration 3 occurred because it was felt to be time inefficient for the clinical team. Iteration 3 is the system currently implemented.

Methods

Design and Data Collection

All SH:24 users, resident in the London Boroughs of Lambeth and Southwark, with a positive chlamydia diagnosis who were eligible for and chose postal treatment between February 15, 2017, and October 24, 2017, were invited to take part in this service evaluation. Data were collected through a standardized telephone questionnaire delivered by a trained researcher after the medication had been prescribed and dispatched. This questionnaire documented relevant medical history, medication history (including allergies), time-to-treatment, and user experience. The full questionnaire can be found in Multimedia Appendix 1.

Each user, in effect, received the medical eligibility questions twice—once during their clinical assessment and once during the service evaluation. In iterations 1 and 3, there was a difference in the mode of communication between the clinical assessment and the evaluation assessment. During iteration 2, the mode of questioning before and after treatment delivery was the same. This is illustrated in Figure 1. As this was a service evaluation, there were no power calculations to determine the number of people in each arm. The service developed in response to real-time analysis of the evaluation rather than according to a research plan.

Measures

We refer to the preprescription assessment as the clinical assessment and the postprescription assessment as the evaluation assessment. The primary safety measure was agreement in information supplied at the 2 assessments on key elements of safe prescribing: allergies, current medications, or contraindicating clinical conditions or symptoms. The secondary evaluation measures were recall of and adherence to instructions for taking the medication, time-from-diagnosis-to-treatment, and acceptability of the postal treatment service.

Analysis

Descriptive statistics were used to summarize participant characteristics using parametric and, where appropriate, nonparametric tests. Agreement in key safe prescribing information supplied at the clinical assessment and the evaluation assessment was summarized as 1 binary variable, where matching information between assessments was given a value of 1, and conflicting or disparate information was given a value of 0. Logistic regression was then used to determine factors associated with agreement in key safe prescribing information. Univariate analysis was used to determine its relationship with demographic characteristics, previous clinic attendance, and method of clinical assessment, and variables significant at a 0.05 level were compiled to create a multivariable logistic model. A Kruskal-Wallis H test was conducted to determine the relationship between median time-to-treatment and method of clinical assessment.

Ethical Considerations

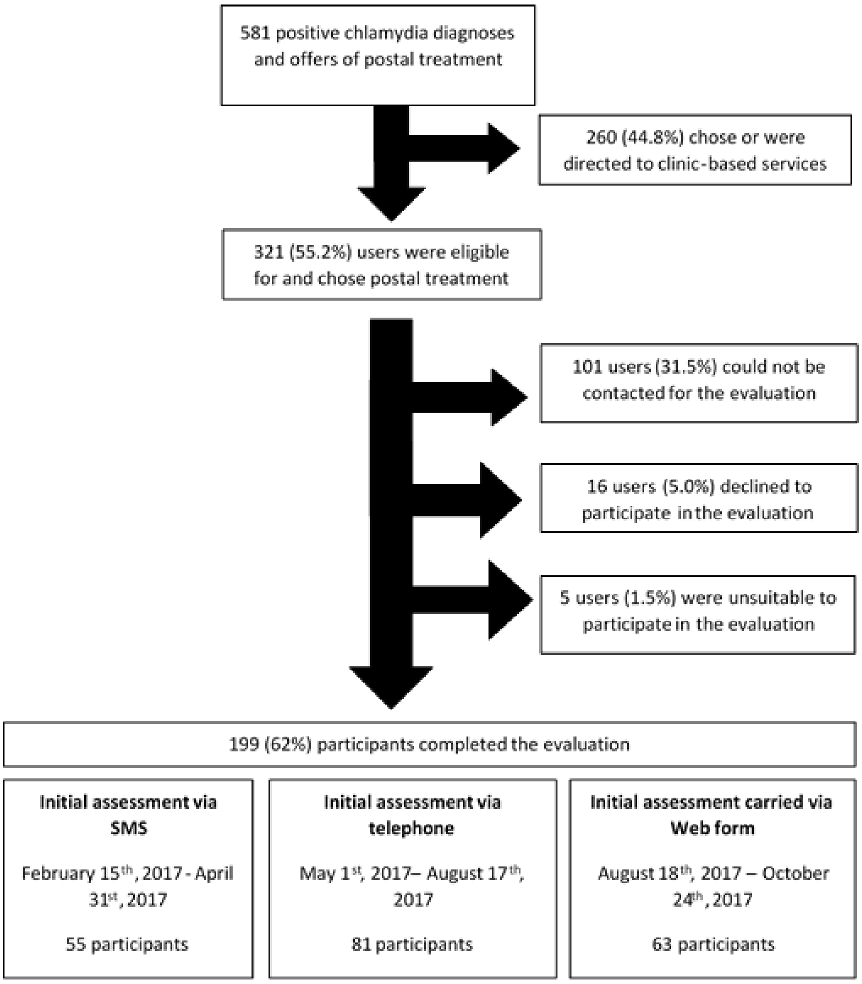
This work observed a build-test-learn cycle based on a human-centred design approach to service development carried out by a digital sexual health service, which adapted strategies that are already used by UK-registered web-based pharmacies. As a service evaluation, it focuses on auditable outcomes such as compliance with medical advice and processes, as well as time to treatment. For this service evaluation project, we did not request a formal ethics review; however, we conducted the evaluation in line with standard ethical procedures. To maintain confidentiality, users were asked to confirm the first line of their address before any information was disclosed about the nature of the telephone call. They were given full information about the evaluation and given the option to participate. Paper surveys, filled in by the researcher while on the phone, were marked with the user's unique identifier and stored in a locked filing cabinet. Unique identifiers could only be linked to identifiable data by accessing the web-based service.

Results

Evaluation Uptake

During the study period, there were 581 chlamydia diagnoses and offers of postal treatment, of which 260 (44.8%) chose to access or were directed to clinic-based services (mainly because they had symptoms). Of the 321 who chose postal treatment, 199 (62.0%) participated in the evaluation (101 could not be contacted, 16 declined to participate, and 5 were excluded—3 repeat users, 1 could not confirm their address, and 1 had decided to attend a clinic). Of the 199 participants, 55 (27.6%) completed the clinical assessment via SMS text message, 81 (40.7%) via telephone, and 63 (31.7%) via a secure web form (Figure 2). The median time between the clinical assessment and the evaluation assessment was 17 days (IQR 10-35).

Figure 2. Evaluation flowchart.



Participant Characteristics

The sociodemographic and clinic attendance characteristics of those who did and did not take part in the evaluation are described in Table 1.

Table 1. Sociodemographic characteristics of individuals who ordered postal treatment for chlamydia (N=321).

Sociodemographic characteristic	Sample (n=199), n (%)	Population (N=321), n (%)
Age group (years)		
18-19	21 (10.6)	37 (11.5)
20-24	83 (41.7)	126 (39.3)
25-29	54 (27.1)	95 (29.6)
30-34	26 (13.1)	39 (12.1)
35+	15 (7.5)	24 (7.5)
Gender		
Male	99 (49.7)	168 (52.3)
Female	100 (50.3)	153 (47.7)
Ethnicity		
White	76 (38.2)	143 (44.6)
Black British or Black Caribbean or Black African	73 (36.7)	103 (32.1)
Asian or Asian British	8 (4.0)	12 (3.7)
Mixed or multiple groups	24 (12.1)	38 (11.8)
Other or prefer not to say	18 (9.0)	25 (7.8)
Sexual orientation		
Heterosexual	176 (88.5)	288 (89.7)
Homosexual	5 (2.5)	7 (2.2)
Bisexual	14 (7.0)	17 (5.3)
Prefer not to say	4 (2.0)	9. (2.8)
Index of multiple deprivation quintile		
1 (most deprived)	66 (33.2)	108 (33.6)
2	83 (41.7)	127 (39.6)

No	94 (47.2)	150 (46.7)
Did not answer	28 (14.1)	62 (19.3)

[a] Was not answered by all participants.

Agreement in Key Safe Prescribing Information

We considered all discrepancies between the clinical and evaluation assessment. New clinical information reported at the evaluation assessment but not the clinical assessment was reported to the web-based service clinical team who managed it according to the clinical incident policy.

During the clinical assessment, 154 participants reported no contraindications, and all except 2 reported the same information at the evaluation assessment. The 2 exceptions were 2 women who were taking the contraceptive pill.

During the evaluation assessment, 45 individuals reported potential contraindications, and 31 of these omitted this from their clinical assessment (14 unreported medications, 6 allergies, 1 previous operation, and 10 genital symptoms). One of these contraindications, an allergy to peanuts, could have caused a serious interaction with the medication prescribed.

Of the 33 discrepancies between clinical and evaluation assessments, 15 (46%) occurred when the clinical assessment was completed via SMS text message, 8 (24%) via telephone, and 10 (30%) via the secure web form. Univariate analysis showed that method of clinical assessment, gender, and sexuality were independently associated with agreement between the clinical and evaluation assessment. When combined in a multivariable model, method of initial assessment, gender, and sexuality remained statistically significantly associated with agreement between the 2 assessments.

The adjusted odds of agreement between assessments were 78% less among participants who completed their clinical assessment via SMS text messaging compared with those who completed this via telephone. This result was statistically significant (see Table 2). We found no statistically significant difference between the odds of agreement between assessments completed via telephone and via the secure web form.

Of those who took their medication, 91.1% (175/192) correctly recalled advice to abstain from sex for 7 days after they and their partner had commenced treatment, 93.4% (184/197) recalled advice on partner notification, and 89.3% (176/197) had notified partners.

Table 2. Crude and adjusted odd ratios of agreement in reporting information.

Exposure variable	Crude odds ratio (95% CI)	*P* value	Adjusted odds ratio (95% CI)[a]	*P* value
Method of initial assessment				
Call	1 (reference[b])	—[b]	1 (reference)	—[b]

[a] Only variables where crude odds ratios were found to be significant ($P<.05$) were carried into the multivariable model.

[b] Reference group.

[c] Not applicable, as variable was not carried into the multivariable model.

[d] Not applicable, as no sample participants within these categories.

Time-From-Diagnosis-to-Treatment

From the 192 participants who took their treatment, median time-to-treatment was 4 days (IQR 3-5.5). A total of 91.7% (176/192) of those evaluated were treated within 7 days of receiving their positive diagnosis.

A Kruskal-Wallis H test was used to analyze the relationship between time-to-treatment and the medium of the clinical assessment as this variable was not normally distributed. Of the 192, 55 were assessed via SMS text message, 76 via telephone, and 61 via web form. There was a statistically significant difference between time-to-treatment by method of clinical assessment (H_2=24.169; P<.001), with a median time-to-treatment of 2.5 days for SMS text messaging, 4 days for web form, and 4.5 days for telephone call. Similarly, statistically significant differences were found between SMS text message and telephone call (H_2=21.990; P<.001) and SMS text message and web form (H_2=14.702; P<.001). There was no statistically significant difference in the median time-to-treatment between web form and telephone call.

User Acceptability

The majority of users (185/197, 93.9%) were happy with the information provided on treatment. Almost all users reported that they could both understand (196/199, 99.0%) and were comfortable (196/198, 98.5.0%) with the SMS text messages they received from the service. 19.4% (38/196) contacted SH:24 for support, and 89.9% (178/198) said they would use the web-based service again.

Discussion

Principal Findings

This service evaluation documented an iterative process of testing 3 methods of clinical assessment before remote prescribing. It showed that users are significantly more likely to report accurate clinical histories during a telephone consultation than through a single SMS text message. We did not find a statistically significant difference between the accuracy of clinical histories reported via telephone and via the secure web form. It showed that treatment via a web-based sexual health service in general, and SMS text message assessment in particular, supports rapid treatment that is well within the standards set in current guidance; the National Chlamydia Screening Programme (NCSP) audit standard aims for 95% of patients to have a time-to-treatment of 6 weeks or less [20,21]. An NCSP audit of chlamydia treatment services carried out in 2017 [22] found that 92.0% of the sample met this standard, whereas within this service evaluation, 91.7% (176/192) of those evaluated were treated within 7 days of receiving their positive diagnosis. This is comparable with findings from Estcourt et al’s [23] exploratory studies into an electronic sexual health clinic system for management, prevention, and control of STIs, where results were delivered via a secure web portal and treatment was collected from a local pharmacy.

Our findings are important as treatment is increasingly part of routine web-based sexual health services. This is reflected both in the use of the web-based service evaluated here and quality standards and guidelines recently released by relevant professional bodies.

Since the start of the service in 2017, 5130 chlamydia treatments have been delivered via SH:24 by post in 14 different areas of the country. Postal treatment is highly acceptable to service users, with 80% of those offered treatment by post taking up this offer. More information about the uptake and number of orders can be found in Multimedia Appendix 2. The service now uses the secure web form to assess eligibility, and SMS text messaging or telephone are no longer used, except to gain more detail on contraindications that have been reported in the form.

Since the development of the service, the Faculty of Sexual and Reproductive Healthcare and the British Association for Sexual Health and HIV (BASHH) have published the first quality standards for online and remote providers of sexual and reproductive health care [24]. These standards not only reiterate the General Medical Council’s (GMC’s) recommendations on safety and remote prescribing [5] but also highlight the *safety nets* services should have to navigate and mitigate risks that may come with remote consultations [24]. The service evaluated here has developed a *2-way process* around the secure web form that is now used as the clinical assessment for eligibility in the web-based remote chlamydia treatment service where free textboxes within the web form allow users to share, for example, any medication they may be taking. Furthermore, as per the GMC guidelines, they now ask patients for their consent to share treatment information with their general practitioner [25].

Other changes in the service since this evaluation reflect updated clinical guidelines; during the evaluation users were offered SDA as first-line treatment; however, in response to BASHH recommendations [21], the first-line treatment offer for uncomplicated urogenital, pharyngeal, and rectal chlamydia infections is now Doxycycline 100 mg bd for 7 days.

Interpretation

Higher risks associated with the SMS text message assessment provide important learning. New technologies such as cross-platform messaging services (eg, WhatsApp) are increasingly used by businesses for secure communication with their customers and strategies for assessment before medical prescribing may develop in this direction. We recommend further investigation into the risks and benefits of these approaches. The SMS text messaging strategy used here was limited to a single (rather long) message that included multiple questions and required a single answer. This is suboptimal and is a function of the limitations of SMS text messaging technology. It was not possible to break up the message into individual SMS text messages in case the connection was lost halfway through the interaction. SMS text messages remain undelivered when the connection breaks, unlike, for example, WhatsApp, where messages are delivered as soon as the connection is resumed. web forms are commonly used for history taking before prescriptions. This evaluation suggests that this is a promising approach, but our sample size was insufficient to provide significant results, and future research should explore their performance in comparison with telephone and face-to-face assessment.

Our analysis assumes that telephone assessment by an experienced clinician is safe as this is standard practice, but it also suggests that even this method is associated with inaccuracies. Even face-to-face consultations are associated with medication errors (usually prescribing errors) in hospitals varying between 2% and 14% [26]. It is likely that no method is consistently reliable in obtaining an accurate history. Situations where the clinical history can be checked against previous health records have obvious advantages, but this is not possible in sexual health where information traditionally is not linked to the rest of the medical record as a strategy to maintain confidentiality [27].

Limitations

A small evaluation of a rapidly evolving service, this service evaluation did not calculate sample size when conceived. Participants were not allocated to a method of clinical assessment; designed to judge current care provided, the service evaluation followed an evolving service, where 3 iterations of the service design allowed for retrospective exploration of factors associated with agreement in safe prescribing information, including method of clinical assessment. Although, even with a small sample, we did find a difference in odds of agreement between SMS text messaging and telephone call, a robust, considered piece of research, with a calculated sample size, would be needed to fully explore the relationship between method of clinical assessment and agreement in safe prescribing information. As methods were tested consecutively, users were not randomly allocated to a particular method. Hence, those carrying out the follow-up assessment may not have been blinded; a possible source of bias.

We recognize the role that reporting bias may have played in user evaluation assessments. Users asked to reflect on their symptoms, once they have been given a diagnosis, may recognize symptoms they previously may have been deemed unrelated. Several women reported abdominal pain in the evaluation assessment, that they had considered period pain before they received their positive diagnosis. Preexisting literature highlights poor knowledge of nature and symptoms of chlamydia infection [28-30]. In a study of 18- to 24-year olds, a third of respondents were unaware of the asymptomatic nature of chlamydia infection, and 80.2% of respondents failed to recognize lower abdominal pain as a potential symptom in women [30].

Although most participants of this service evaluation stated a preference for a remote treatment service, as the sample consists solely of those who self-identify as asymptomatic, this should not be generalized to everyone seeking treatment. Sexual health clinics remain an integral element of STI treatment and care, and web-based services should be well integrated with face-to-face services [31,32]. However, considering that at least 70% of women and 50% of men infected with chlamydia are asymptomatic [33,34], this shows acceptability in a large proportion of those who need treatment.

Conclusions and Recommendations

Postal treatment is an acceptable and rapid treatment option for uncomplicated genital chlamydia. Clinical assessment via SMS text message before remote prescription may not be accurate or sufficient. As health care is delivered, strategies that support safe remote prescribing are increasingly important, as is their evaluation, which should be robust and carefully considered.

Acknowledgments

This service evaluation was undertaken as part of a multidisciplinary evaluation of web-based sexual health services funded by Guys and St Thomas' Charity.

Authors' Contributions

PB, JS, GH, and CH contributed to the study conception. AS, JS, PW, and HM were responsible for data collection. HM contributed to the analysis. HM and PB contributed to the write-up.

Conflicts of Interest

PB, GH, and CH are directors of SH:24 (a not-for-profit community interest company). EA is also employed by SH:24. Since October 2019, HM has been working as a research associate at SH:24.

Abstract

Background: Many patients with mental disorders remain untreated. Video-based mental health care demonstrates comparable effectiveness to face-to-face treatments and is a promising mode for delivering specialized care within primary care. Nevertheless, professionals struggle with implementing video consultations in their daily practice. Specifically, little is known about mental health specialists' acceptance of mental health video consultations in routine practice. The PROVIDE (ImPROving cross-sectoral collaboration between primary and psychosocial care: An implementation study on VIDEo consultations) project aims to improve cross-sectoral collaboration between primary and psychosocial care through implementing video consultations in primary care. To increase the uptake of video consultations, it is crucial to account for necessary prerequisites and to tailor interventions to the needs of the target group prior to implementation.

Objective: The aim of this study was to explore the acceptance of video consultations embedded in primary care from the perspectives of mental health specialists in Germany.

Methods: We conducted a qualitative, exploratory, preimplementation study in urban and rural counties. We conducted three semistructured focus groups with 11 mental health specialists. We used qualitative content analysis combining an inductive-deductive approach, applying the Tailored Implementation in Chronic Diseases (TICD) framework to the text material, which comprises individual health professional factors; patient factors; professional interactions; incentives and resources; capacity for organizational change; social, political, and legal factors; and guideline factors.

Results: Against the background of long waiting times and a shortage of mental health specialists, especially in rural areas, participants valued video consultations as a potential means to improve access to mental health care. With respect to the TICD framework domains, the participants most often discussed individual health professional factors, followed by patient factors. All participants highlighted the importance of a trusting relationship between the patient and the therapist and doubted whether such a relationship could be established through video consultations (11/11, 100%). However, participants considered mental health specialist video consultations to be particularly suited for patients in rural areas, those with impaired mobility, and those who may otherwise remain untreated (6/11, 55%). Most participants expected video consultations to help the aforementioned patient groups avoid tedious searching for an available therapist and save on travel time and, therefore, improve access to specialized care for patients (7/11, 64%). Moreover, the participants expected video consultations to improve collaboration with the family physician (6/11, 55%). Finally, participants identified organizational aspects, such as reliable scheduling, the duration of the individual consultation (9/11, 82%), and reimbursement conditions (7/11, 67%), as key drivers for the acceptance and adoption of the model.

Conclusions: While mental health specialists expect video consultations to improve access to specialized care for some patients, they consistently wonder whether such consultations can establish a trusting patient-therapist relationship. When implementing video consultations, these concerns should be addressed by training providers in managing technology-based treatment settings, with extra consideration for fostering the patients' and therapists' engagement.

Introduction

Background

Many patients with common mental health conditions, such as depression, anxiety, or somatic symptom disorders, solely consult their family physicians. When seeking specialized mental health care, patients face the challenge of limited access, especially in rural areas. A significant number of these patients remain undiagnosed or receive psychiatric medication prescriptions, although most would prefer psychological treatment [1,2]. According to the American Psychiatric Association and the Academy of Psychosomatic Medicine, mental health care specialistss—namely, psychotherapists and psychiatrists—are required to provide patient-centered care and improve access of care (eg, by supporting integrated delivery and providing multiple points of access) [3]. Internet-based integrated care models such as video consultations are one way to address the demands for mental health care, provided that family physicians and mental health specialists can overcome system barriers and foster cross-sectoral communication. Several studies demonstrated acceptable feasibility and equal effectiveness of video consultations compared to face-to-face treatments in psychotherapy [4-10]. Additionally, video consultations can save costs and travel time [4,11]. Patients generally accept video consultations and are often satisfied with this mode of treatment delivery [6,8,12]. However, regarding the uptake of best evidence in practice, one consistent research finding is the gap between evidence-based interventions and their adoption in clinical practice. To bridge this gap, it is crucial to identify user acceptance of interventions and to explore prerequisites among the target group of intervention users to tailor the intervention to their needs and foster the adoption of best practice standards into routine care [13]. Several projects evaluated video-based integrated care models, but little is known regarding how mental health specialists, especially in Germany, perceive the acceptance of real-time video consultations between patients presenting to the primary care practice and off-site mental health specialists.

Mental Health Specialist Video Consultations Embedded in Primary Care

The PROVIDE (ImPROving cross-sectoral collaboration between primary and psychosocial care: An implementation study on VIDEo consultations) project aims to improve cross-sectoral collaboration between primary and psychosocial care through implementing video consultations in primary care. The intervention involves clinical diagnostics, care planning, and crisis management or brief psychotherapy and is limited to a maximum of five consultations. Specifically, mental health specialists will conduct video consultations with patients with depression and/or anxiety who are under the care of his or her primary care family physician. The PROVIDE project consists of three stages: first, we identified barriers and facilitators of stakeholders to determine their needs and tailor the model accordingly (preimplementation phase: PROVIDE-A). Supplementing our recently published work on the perceptions of family physicians regarding mental health specialist video consultations in primary care [14], this paper presents the results for psychotherapists and psychiatrists from the initial preimplementation phase of the PROVIDE project. Second, the video consultation model will be put into practice and evaluated regarding the acceptance and practicability within a pilot study (feasibility study: PROVIDE-B) [15]. Third, the model will be optimized where necessary and tested in a randomized controlled trial (RCT) with respect to the extent to which the burden of depression and anxiety of patients changes, as well as patient outcomes, as compared to patients who received usual care (implementation study, RCT: PROVIDE-C).

Purpose of the Study

This qualitative study from the preimplementation phase of PROVIDE-A aimed to (1) identify perceived acceptance of the intervention among mental health specialists and (2) shed light on prerequisites—namely, barriers and facilitators—for the implementation of mental health specialist video consultations.

Methods

Study Design

In order to assess the acceptance of mental health specialist video consultations, we conducted a cross-sectional, qualitative, exploratory preimplementation study with mental health specialists. The results of this study will be used to further tailor the intervention model to the practical needs of mental health specialists and will then be evaluated within a following feasibility study [15]. We conducted three focus groups with a total of 11 participants. By using focus groups, we were able to collect diverse perceptions and experiences, which focus group participants typically disclose to each other and on which they collectively reflect [16]. This study was approved by the Ethics Committee of Heidelberg Medical School (Reference S-197/2017) and was preregistered with the German Clinical Trials Register (DRKS00012487). We followed the COREQ

(COnsolidated criteria for REporting Qualitative research) guidelines for reporting study results (see Multimedia Appendix 1) [17]. The authors had full access to all the data in this study and take complete responsibility for the integrity of the data and the accuracy of the data analysis.

Participants and Recruitment

We used purposeful sampling to obtain a broad range of perceptions [18]. To be eligible, mental health specialists had to be registered with the Association of Statutory Health Insurance Physicians in one of the five counties covered in this study; the five counties were selected from a total of 35 counties in Baden-Wuerttemberg, one of 16 German federal states. Overall, 583 mental health specialists were eligible. We chose a stratified randomized sample of two waves—first wave in June 2017 (N=100); second wave in September 2017 (N=195)—in order to recruit at least 10 participants for the focus groups. Due to the shortage of mental health specialists, particularly in rural areas, we aimed to explore potential distinctions between *rural and suburban* areas and *urban* areas. Therefore, we used the Degree of Urbanisation (DEGURBA) classification from the European Commission to distinguish the urban and rural counties [19]. Overall, 275 mental health specialists from cities, 261 mental health specialists from suburbs, and 47 mental health specialists from rural areas were eligible. We sent a written questionnaire to a total of 295 stratified randomized mental health specialists regarding their perception of mental health specialist video consultations (results not presented here) and invited them to participate in a focus group. If no response had been received within 3 weeks, we reminded all nonresponders via follow-up telephone calls (up to three calls). To schedule the focus groups, we contacted all 27 eligible mental health specialists, by telephone, who had expressed interest in participating. A total of 15 mental health specialists subsequently declined study participation, mainly due to time restrictions (9/15, 60%). One participant agreed to participate in a telephonic interview but is not included in the analysis, as we focus on collective reflections on the intervention. Overall, we conducted three semistructured focus groups with a total of 11 participants. We stopped data collection and started data analysis when no new insights occurred in the data and the content began to repeat. We offered a nonadvertised, individual monetary compensation of €50 (US $55) to all participants.

Focus Groups

For the development of a questionnaire guide (see Multimedia Appendix 2), we followed established recommendations [20] and used a team-based approach—M Hoffmann, sociologist; MW, implementation science; M Hartmann, psychotherapist; and MWH, internal medicine specialist—advancing to specific open-ended, jargon-free questions from the initial formulation of key questions in a logical sequence. The interviews focused on (1) how mental health care providers perceive current mental health care, (2) the acceptance of and intent to adopt mental health specialist video consultations, and (3) factors that promote or inhibit the use of the model. Before conducting the focus groups, we piloted the guide on one mental health specialist and modified it accordingly. The question guide was also reviewed after the first focus group with mental health specialists. The first author (M Hoffmann: PhD student, master's degree in sociology, and expertise in qualitative research) and the last author (MWH: MD, internal medicine specialist, senior researcher, and content expert for mental health services), who had no contact or relationship with any participant prior to the study, conducted the focus groups. The focus groups, which ranged from 2 to 5 participants and lasted 80-110 minutes, were conducted at Heidelberg University Hospital between August and November 2017; participants were from one urban and four rural or suburban counties. We used the question guide to encourage discussion and to collect comparable data through introducing similar discussion topics. To stimulate the discussion, the moderators presented a video clip illustrating the model using an example of a fictional patient suffering from depression. We made the study objectives and data protection guidelines transparent to all participants, who provided written consent prior to data collection. We guaranteed the absence of nonparticipants during the focus groups. We audio recorded all focus groups and uploaded them to a secure server based at Heidelberg University Hospital, which was only accessible to the research team. Additionally, we made field notes.

Analysis

A professional transcription service completed verbatim audio transcriptions of all focus groups. We did not return transcripts to participants for comment. We pseudonymized all transcripts according to data protection guidelines. Two members of the research team (M Hoffmann and MWH) independently performed content analysis [21] using MAXQDA 2018, following a two-step, deductive-inductive, and data-driven development of a system of categories. First, we used the Tailored Implementation in Chronic Diseases (TICD) framework [22] as a coding framework to deductively identify relevant determinants, focusing on barriers and facilitators of the acceptance of mental health specialist video consultations. The TICD framework is regarded as particularly appropriate for processing data focusing on implementation factors in order to tailor an intervention to specific needs. Second, we inductively generated the subcodes based on the analysis of every transcript. Both researchers compared their analysis, and disagreements throughout the process were discussed and resolved among the research team. We analyzed the remaining transcripts based on the developed coding system. In order to ensure that all key aspects were represented in the coding system, codes were consequently modified when new aspects emerged. Table MA3-1 in Multimedia Appendix 3 provides a summary of the coding system. We did not ask participants to provide feedback on the findings.

Results

Overview

Table 1 shows the characteristics of the 11 participants. Specifically, we interviewed 4 licensed psychological psychotherapists (36%), 3 physicians with board certification in psychosomatic medicine and psychotherapy (27%), 3 board-certified psychiatrists (27%), and 1 medical doctor with an additional qualification in psychotherapy (psychotherapeutisch tätiger Arzt, in German) (9%).

Depiction of Current Practice

Three main topics related to the current practice of patients with mental disorders in outpatient care emerged. First, long waiting times and an insufficient number of available mental health specialists (10/11, 91%) were the most frequently discussed issue, particularly due to the urban-rural divide. Especially for more severely affected patients, participants perceived long travel distances as well as long waiting times as barriers for the uptake of psychotherapy.

> *Sometimes the patients must wait for a very long time and sometimes they are also very burdened. They are also not able to call five other psychotherapists and drive to all of them.* [Participant #3, focus group #2]

Second, mental health specialists identified another health care gap regarding some patient groups and their difficulties in finding a therapist (6/11, 55%), such as the elderly, patients with impaired mobility, as well as severely affected patients (eg, those with borderline personality disorders). Third, beyond patient-related factors, mental health specialists perceived a lack of collaboration with family physicians (6/11, 55%), for instance, the absence of comprehensive referral letters (4/11, 36%) and the lack of an opportunity to consult with specialists in cases of diagnostic uncertainty (5/11, 45%). This was often associated with limited time resources of the mental health specialist and the family physician.

Table 1. Characteristics of the sample participants.

Characteristic	Value (N=11)
Sex (male), n (%)	2 (18)
Age in years (n=10), mean (SD)	52.3 (12.8)
Years in office-based practice (n=8), mean (SD)	13.1 (11.8)
Areas of recruitment, n (%)	
Cities (ie, densely populated areas)	6 (55)
Towns and suburbs (ie, intermediate-density areas) and rural areas (ie, thinly populated areas)	5 (45)
Therapeutic approach, n (%)	
Psychodynamic psychotherapy	5 (45)
Psychoanalysis	3 (27)
Behavior therapy	3 (27)

Factors Determining the Acceptance of Mental Health Specialist Video Consultations

We present barriers and facilitators regarding the acceptance of mental health specialist video consultations in a descriptive manner alongside the seven TICD framework domains in descending order by code frequency. Two domains—namely, individual health professional factors and patient factors—were identified as highly relevant and most frequently discussed. Some domains—namely, social, political, and legal factors as well as guideline factors—were hardly discussed and are not reported.

Individual Health Professional Factors

Regarding the acceptance of the intervention model, mental health specialists most frequently discussed individual health professional factors (11/11, 100%). For instance, they perceived some organizational factors as potential challenges.

> *Of course, there are organizational issues which need to be addressed. Primarily, how can it be managed without any disadvantages for me...I still do not have more capacities this way.* [Participant #1, focus group #2]

According to most of the participants (9/11, 82%), time and duration of the individual video consultation may be one major challenge of implementing the intervention. For example, some participants perceived a video consultation to be more exhaustive compared to a face-to-face appointment and, therefore, considered 25 minutes to be an appropriate duration. Others emphasized that mental health specialist video consultations should last as long as face-to-face consultations, which usually run for 50 minutes. They argued that this would contribute to establishing a therapeutic setting of the video consultation and, therefore, 50 minutes would provide a sufficient duration to get a comprehensive understanding of the patients' situations. When asked about potential benefits or expected outcomes, participants commonly highlighted the collaboration with the family physician (6/11, 55%) and help for patients (7/11, 64%). Overall, mental health specialists expected fewer advantages for themselves than for patients, especially compared to their everyday practice in the face-to-face setting. As a major issue, which has been subject to every focus group, mental health specialists questioned whether video consultations can be an appropriate and suitable means to deliver specialized mental health care to patients in need (11/11, 100%).

> *So, the exclusive situation, precisely that you do not evade...this gets somewhat socially lost as a fundamental, therapeutic experience.* [Participant #3, focus group #3]

Mental health specialists most commonly highlighted the advantages of the traditional face-to-face setting, while emphasizing some disadvantages of mental health specialist video consultations. Specifically, they underscored a lack of personal interactions and nonverbal cues, which may impede the therapeutic relationship and engagement (8/11, 73%).

> *This may also entail several disadvantages for me. Because it is a different setting, sitting together in a room...I believe the ritual of doing therapy together in a room is too important.* [Participant #1, focus group #2]

Some participants considered the model to work better when the patients already had previous appointments with the therapist and when a sustainable patient-therapist relationship already existed (3/11, 27%). Others (4/11, 36%) expected the model not to work as therapy in the traditional sense. Moreover, they emphasized that mental health specialist video consultations might dehumanize the therapist-patient relationship and, consequently, should not replace face-to-face therapies. Against this background, mental health specialists considered it to be essential to clearly define the purpose of the intervention and how it can make a significant contribution to improve the patients' situations.

> *I believe it is important to define the framework. What is supposed to happen? Psychotherapeutic video consultation implies the message that something therapeutic happens. But we all shared to some extent the opinion that it is not likely that something psychotherapeutic can really happen.* [Participant #3, focus group #2]

From the perspective of the mental health specialists, the model may be particularly suited for an initial mental health consultation. Within this setting, mental health specialists could serve as experts to provide more rapid access to mental health care. Some participants stated that their professional and therapeutic habits, as well as their daily routines to work in a face-to-face setting, might lead to a more conservative attitude toward digital health interventions, in general, and mental health specialist video consultations, in particular (5/11, 45%). One mental health specialist stated the following:

> *And getting used to this, yes. That is certainly a difference. Now with the monitor and talking to the patient in this way. The familiarization. But I think it is also exciting.* [Participant #1, focus group #1]

Using the intervention in practice could reduce reservations and enable mental health specialists to become familiar with the video consultation.

Patient Factors

First, within this domain, mental health specialists most frequently discussed appropriate target groups for the intervention (10/11, 91%). They considered mental health specialist video consultations to be most suitable for patients with impaired mobility (6/11, 55%) who may otherwise remain untreated. The following statement by another participant emphasized that the model could serve as an alternative model to deliver mental health care, especially in rural areas.

> *...this is not supposed to replace conventional psychotherapy; rather, just for particular cases, right? For people who just live too far away, where the infrastructure is very, very poor.* [Participant #1, focus group #1]

In contrast, some participants mentioned patients with specific mental health conditions, such as anxiety disorders, or patients with posttraumatic stress disorders (3/11, 27%) as potentially less suitable for mental health specialist video consultations. Hence, they stated that it should be clearly specified which patients are the main target group to tailor the intervention to their needs. Furthermore, some mental health specialists indicated that in the event of an emergency, it should be clearly defined who is on site in general practice and responsible for the patient (3/11, 27%). Second, regarding patient barriers, participants anticipated that some patients might have concerns about the video technology, as such (5/11, 45%). This might lead to less interest or refusal to conduct mental health specialist video consultations, especially regarding the elderly. Therefore, it might take some extra effort to encourage the acceptance of mental health specialist video consultations. Considering potential benefits for patients, they valued quicker help, low-threshold access, and the initiation of psychotherapy as main facilitators.

> *I could very well imagine doing something like this. To offer a low-threshold service, to initiate psychotherapy, very carefully and sensitively.* [Participant #4, focus group #2]

As a potential result, long waiting times, a tedious search for an appointment, as well as long travel distances could be avoided.

Professional Interactions

Against the background of a lack of collaborative exchange with family physicians as outlined above, mental health specialists expected professional interactions with the family physician to be a potential benefit from, and facilitator for, mental health specialist video consultations (7/11, 64%). Some participants considered the model to foster collaboration with the family physician and highly valued the possibility to give feedback to the family physician and better involve him or her in the process of care (5/11, 45%). Specifically, they considered brief case discussions or the virtual handing over of the patient by the physician as advantageous.

> *For the initial contact, it would certainly be nice if the general practitioner would facilitate it by introducing it [the model] and state what he has thought of. To already sort of point me in the right direction...And then I could, I could go deeper with the patient. And maybe at the end, I could share the result, with him [family physician]...What, from my view, I believe could, should be done.* [Participant #1, focus group #2]

Some participants also discussed the possibility of a consultation not only between the patient and the mental health specialist but also with the family physician, who could attend the video consultation (3/11, 27%). In this setting, mental health specialists would want to discuss the patient's condition with the patient and the family physician. As a result, this could foster collaboration between the family physician and the mental health specialist, as well as the patient's involvement.

> *I think of a trialogue, for example, between the general practitioner, the patient, and psychotherapist and one asks the psychotherapist for his suggestion.* [Participant #4, focus group #3]
>
> *Yes, I also find the trialogue very exciting, because this way the patient and the general practitioner are on a triangulating level with me as a consultant. This also changes the relationship between them and adds something new.* [Participant #1, focus group #3]

Furthermore, within this domain, some mental health specialists discussed the distribution of roles and responsibilities (4/11, 36%). First, regarding family physicians' roles, referring patients would be an essential task. Also, as described above, participants considered as potentially helpful the introduction of the patient to the mental health specialist at the beginning of the video consultation. Second, mental health specialists regarded themselves as expert consultants, especially against the background of video consultations as a different model of delivery compared to traditional face-to-face psychotherapy.

> *And this would possibly also be the framework; for the patient, the psychotherapist would be the expert, so to say...Sort of, consulting someone and to get clarification in a particular, temporarily defined setting, and where the patient could possibly save trips.* [Participant #3, focus group #3]

Incentives and Resources

First, within this domain, the majority of participants extensively discussed costs and payment conditions related to the intervention (7/11, 64%). As outlined in the first domain, participants do see more disadvantages than benefits, especially compared to their daily face-to-face working practice. Therefore, mental health specialists regarded a prerequisite of a reasonable financial remuneration to be an incentive to conducting mental health specialist video consultations themselves.

> *I believe it is important to settle financial issues. Particularly, because therapists are not at all dependent on this [the model].* [Participant #1, focus group #1]

Some participants stated that the model should include remuneration of video consultations to be equal to face-to-face sessions (3/11, 27%) or higher (2/11, 18%), in order to enhance the mental health specialists' motivation to conduct video consultations. Also, considering financial compensation, 2 participants (18%) stated that the video consultation sessions should be remunerated even when patients were not able to keep the appointment. Otherwise, this might negatively affect mental health specialists' acceptance of the treatment model, as mental health specialists in Germany receive a payment in cases where the patient misses an appointment because most mental health specialists run an appointment-based practice. In addition to that, they underscored stable network connectivity, high visual definition, minimized speech delay, minimized interruptions, and the preinstallation of equipment as essential. Technical equipment should be provided and not be paid for by the mental health specialists themselves. Considering the coordination of appointments, participants stated that fixed time slots are a prerequisite as well as the duty of primary care practices to efficiently implement the intervention into their daily working practice. Overall, participants required organizational demands to be settled in order to commit themselves to mental health specialist video consultations, as illustrated by the following quote:

> *If we do not consider all organizational issues, as how is it practically possible...if I look at it from a completely IDEALISTIC perspective, then this would not be a bad idea. Let´s say as an initial contact.* [Participant #1, focus group #2]

Capacity for Organizational Change

Mental health specialists discussed aspects regarding the capacity for organizational change only when explicitly asked about their perceptions of the readiness for change of mental health specialists in general. Some participants expected heterogeneous attitudes among mental health specialists in general. Others expected younger mental health specialists to be more curious and open minded (2/11, 18%).

> *The people above 50 might be a little bit more reluctant; about the younger ones, I am not entirely sure. But I could imagine that they are more adventurous.* [Participant #2, focus group #1]

One participant suspected that either intrinsic motivation—namely, providing help for patients—or financial incentives would be a potential means to drive the capacity for organizational change.

> *I could imagine that those colleagues would agree to this [the model], who do this as additional benefit for the patient. Or one would have to compensate it in a way that it becomes financially profitable.* [Participant #5, focus group #2]

Differences in Views in Relation to Urbanization and Therapeutic Orientation

To account for potential distinctions, we compared data from cities (6/11, 55%) to that of suburbs and rural areas (5/11, 45%), as well as different therapeutic orientations—namely, psychodynamic psychotherapy and psychoanalysis psychotherapy (8/11, 73%) as well as cognitive behavioral therapy (3/10, 27%). First, a comparison of the degree of urbanization revealed that participants from cities (4/6, 67%) more frequently mentioned the appointment time and scheduling of the mental health specialist video consultations and technical requirements as prerequisites compared to participants from less-urbanized areas. Also, mental health specialists from cities (4/6, 67%) more often highlighted the possibility to collaborate with the family physician compared to specialists from suburbs or rural areas (2/5, 40%). Second, regarding different therapeutic approaches, we found that cognitive behavioral therapy–oriented participants considered clearly defined responsibilities in the event of an emergency (3/3, 100%), whereas participants with other therapeutic orientations did not discuss this issue. Also, cognitive behavioral therapy–oriented participants more frequently considered technical aspects and an impersonal setting within the mental health specialist video consultations model as potential barriers for some patients (3/3, 100%), compared to specialists practicing psychodynamic psychotherapy and psychoanalysis psychotherapy (4/8, 50%). Taking into consideration that all participants underscored the importance of physical presence for psychotherapy, mental health specialists with a background in psychodynamic psychotherapy and psychoanalysis psychotherapy particularly mentioned patients with impaired mobility as an appropriate target group for the model (5/8, 63%). Cognitive behavioral therapy–oriented participants (1/3, 33%) indicated these patients as a target group less frequently.

Discussion

Principal Findings

The aim of this study was to explore how mental health specialists perceive the acceptance of mental health specialist video consultation embedded into primary care practice against the background of their perception of current mental health care. Most mental health specialists described the latter as insufficient due to long waiting times and a lack of therapeutic capacities, especially in rural areas. We explored crucial barriers and facilitators of mental health specialist video consultations as a potential mode to deliver mental health care. First and foremost, mental health specialists questioned whether a stable therapeutic alliance can be established, especially with respect to the therapeutic alliance and engagement. Therefore, they considered mental health specialist video consultations to be particularly suited for an initial consultation and diagnosis, rather than a genuine alternative to face-to-face psychotherapy. Second, regarding mental health specialists' perceptions of the patient perspective, they highlighted fast access to mental health care, especially for patients with impaired mobility, as a major benefit of the model. Participants considered mental health treatment via video consultations not to be a barrier but to be rather predominantly advantageous for most patients. Third, apart from an intrinsic motivation—namely, to provide faster access to mental health care—mental health specialists considered financial incentives as instrumental. Fourth, participants underscored important organizational factors, such as stable network connectivity, high visual definition, and minimized interruptions. Therefore, training sessions in order to familiarize users with the video consultation in practice are key drivers for the intervention.

Strengths and Limitations

Our study has some limitations. First, due to the small sample size and only one mental health specialist from rural areas participating in our study, the results and distinctions between participants from different areas are reliable to a limited degree. Second, none of the participants had conducted mental health specialist video consultations before participating in the study, since we conducted the focus groups prior to implementation of the proposed intervention model. It is plausible that some mental health specialists would revise their initial perceptions regarding the intervention model after the actual implementation. However, by assessing the perceptions before the implementation, we explored necessary prerequisites for further tailoring mental health specialist video consultations to the mental health specialists' needs, which is key for the adoption of a new mode of delivering mental health care. Third, we did not apply a technology acceptance framework (eg, technology acceptance model [TAM] or unified theory of acceptance and use of technology [UTAUT]). Nevertheless, while such models support the explanation of the potential user's behavioral intention to engage with a technological innovation [23], our focus was on meso-level implementation in a broader sense. Thus, we employed the TICD framework for guiding both the analysis of our data and interpretation of our findings. Finally, not all barriers related to the proposed model may have been referred to by the study participants. For example, it is plausible that the distance between the patient's home and the general practice itself could be a problem for patients struggling with limited mobility. However, we would argue that patients usually need to see their general practitioner eventually for regular checkups and/or the monitoring and treatment of medical diseases. From a patient-centered perspective, the proposed video consultations could be included in these appointments. At the very least, patients would save time and avoid travel related to additional in-person visits with mental health specialists.

Comparison With Prior Work

Previous work on video consultations, and telemedicine in general, has mainly focused on efficiency trials, satisfaction, and attitudes after the implementation of video consultations. A large body of research points to a comparable effectiveness of video consultations and face-to-face consultations [4,24-27]. Referring to the patients' perspective, many studies found high satisfaction rates with video consultations for addressing various health conditions [4,9,27,28]. In contrast, another study found higher satisfaction rates for patients than for clinical staff [27]. However, within this work (ie, focusing on chronic health conditions), reasons for the lower level of satisfaction among clinical staff remained unclear. Our results add that mental health specialists were most often concerned about a potential dehumanization of the therapeutic alliance caused by a lack of personal interactions and nonverbal cues. Another online survey study among stakeholders in eight European countries found that care providers had particular concerns regarding the therapeutic alliance [29], which is in line with our findings. However, we provide additional insights into the perspective of mental health specialists, as we also investigated necessary prerequisites and key drivers, such as the collaboration with the general practitioner, specific target groups, and the virtual handing over of the patient by the physician. A systematic review on the therapeutic alliance in videoconferencing found that therapists rated the therapeutic alliance as high, although not as high as their clients did, but often increasing over the course of therapy [30].

Our study, as well as other studies, point to the importance of training for mental health specialists regarding the use of video consultations [30-34]. Training sessions should impart knowledge regarding the preparation and technical conduct of video consultations as well as encourage the therapist's ability for reflection. This might potentially reduce some reservations.

Additionally, we found that training sessions should especially focus on establishing a therapeutic alliance via video, such as ways to greet the patient virtually and open the session, and on fostering therapeutic and patient engagement as crucial preconditions to adopt mental health specialist video consultations. We found that mental health specialists evaluated the acceptance of mental health specialist video consultations almost entirely in comparison to face-to-face consultations and particularly emphasized the benefits and qualities of the latter. Specifically, we found that participants in our study mainly did not consider mental health specialist video consultations as a favorable alternative mode to delivering mental health care, which some mental health specialists associated with their professional habits and daily routines. Exceptions were mental health specialist video consultations for otherwise untreated patients, especially in remote and rural areas, and mental health specialist video consultations as initial consultations. Besides training, previous studies also revealed that an existing relationship between the patient and the health care provider is crucial [35,36], which some mental health specialists in our study also indicated. When it comes to the acceptance and adoption of new innovations, such as mental health specialist video consultations, the perceived compatibility of innovation with the values and norms of the potential adopters are key elements [37]. Therefore, mental health care delivered via video consultations should focus on these target groups in order to increase the compatibility of mental health specialist video consultations with the norms of mental health specialists and their daily practices. Previous studies on this topic have been limited to perceptions after the treatment model has already been implemented. Regarding our previous work on family physicians' perceptions of mental health specialist video consultations in primary care [14], this study adds necessary insights from the perspective of mental health specialists on the proposed treatment model. Comparable to the main barrier perceived by mental health specialists, which is the therapeutic alliance, family physicians in our previous study underscored a lack of personal interactions and nonverbal cues that may impede therapeutic engagement. Also, they valued benefits not only for patients but also for the family physicians themselves—namely, that mental health specialist video consultations may free up resources for the primary care practice. However, in this study, we found that mental health specialists perceived more disadvantages for themselves and their therapeutic work, as described above.

Conclusions

To increase access to specialized care, emergent technologies like interactive video consultations, which are known to be highly accepted by patients, will probably complement traditional in-person consultations in future health care systems. However, we found that mental health specialists are still somewhat skeptical concerning the impact on the patient-therapist relationship. To foster the implementation and adoption of mental health specialist video consultations in primary care, it is essential to train providers in managing technology-based treatment settings with extra consideration for preserving therapeutic alliance and to familiarize mental health specialists with video consultations. Based on the findings from this study and our previous work, we started a feasibility study (trial registration number: DRKS00015812) to further tailor the intervention model to the participants' needs and to evaluate the acceptance and practicability of mental health specialist video consultation in primary care [15].

Abstract

Background: Due to demographic change and, more recently, coronavirus disease (COVID-19), the importance of modern intensive care units (ICU) is becoming apparent. One of the key components of an ICU is the continuous monitoring of patients' vital parameters. However, existing advances in informatics, signal processing, or engineering that could alleviate the burden on ICUs have not yet been applied. This could be due to the lack of user involvement in research and development.

Objective: This study focused on the satisfaction of ICU staff with current patient monitoring and their suggestions for future improvements. We aimed to identify aspects of monitoring that interrupt patient care, display devices for remote monitoring, use cases for artificial intelligence (AI), and whether ICU staff members are willing to improve their digital literacy or contribute to the improvement of patient monitoring. We further aimed to identify differences in the responses of different professional groups.

Methods: This survey study was performed with ICU staff from 4 ICUs of a German university hospital between November 2019 and January 2020. We developed a web-based 36-item survey questionnaire, by analyzing a preceding qualitative interview study with ICU staff, about the clinical requirements of future patient monitoring. Statistical analyses of questionnaire results included median values with their bootstrapped 95% confidence intervals, and chi-square tests to compare the distributions of item responses of the professional groups.

Results: In total, 86 of the 270 ICU physicians and nurses completed the survey questionnaire. The majority stated they felt confident using the patient monitoring equipment, but that high rates of false-positive alarms and the many sensor cables interrupted patient care. Regarding future improvements, respondents asked for wireless sensors, a reduction in the number of false-positive alarms, and hospital standard operating procedures for alarm management. Responses to the display devices proposed for remote patient monitoring were divided. Most respondents indicated it would be useful for earlier alerting or when they were responsible for multiple wards. AI for ICUs would be useful for early detection of complications and an increased risk of mortality; in addition, the AI could propose guidelines for therapy and diagnostics. Transparency, interoperability, usability, and staff training were essential to promote the use of AI. The majority wanted to learn more about new technologies for the ICU and required more time for learning. Physicians had fewer reservations than nurses about AI-based intelligent alarm management and using mobile phones for remote monitoring.

Conclusions: This survey study of ICU staff revealed key improvements for patient monitoring in intensive care medicine. Hospital providers and medical device manufacturers should focus on reducing false alarms, implementing hospital alarm standard operating procedures, introducing wireless sensors, preparing for the use of AI, and enhancing the digital literacy of ICU staff. Our results may contribute to the user-centered transfer of digital technologies into practice to alleviate challenges in intensive care medicine.

Introduction

Background

In the near future, continuous monitoring of patients' vital signs will play an increasingly important role in alleviating the burden on the health care system caused by demographic change and, more recently, coronavirus disease (COVID-19) [1]. Both lead to an increased number of critically ill patients requiring intensive medical care, including mechanical ventilation and patient monitoring. However, existing advances in informatics, signal processing, or engineering have not yet been applied to patient monitoring [2], making it primarily an alarm system notifying health care providers whenever a patient's parameter deviates from preset values that are considered safe. To accelerate technology transfer into clinical routine, it may be beneficial to include users' pain points and suggestions for research and development.

Patient monitoring can be applied across almost all health sectors, which underlines its importance and the potential offered by digitalization. First, patients can monitor themselves preventively (eg, for atrial fibrillation), even with a consumer product such as the Apple Watch [3]. Second, remote monitoring of patients over long distances is a crucial component of telemedicine, which is becoming increasingly widespread in most areas of medicine [4]. Third, patient monitoring might soon be mandatory in general wards due to a shift in inpatient clientele toward the more critically ill [5,6]. Finally, patient monitoring produces high-frequency data that are a valid and essential source for clinical decision support systems (CDSS) based on artificial intelligence (AI), opening up many possibilities for precision medicine [7].

In the intensive care unit (ICU), as one of the most technologically enhanced medical areas, staff have used monitoring technologies over decades. In a previous qualitative study from our research group, ICU staff demanded wireless, noninvasive, and interoperable monitoring sensors and improved alarm management for a future patient monitoring system [8]. Mobile phones were desired as displays for remote patient monitoring, and CDSS based on AI was considered useful. To validate these inclinations in a larger cohort, we designed this survey study of ICU staff.

Aim

This survey study focuses on ICU staff members’ satisfaction with the current patient monitoring system and their suggestions for future technological improvements. In particular, we aimed to identify the aspects of patient monitoring that disturb patient care, the display devices most appropriate for the ICU for remote patient monitoring on the hospital premises, the use cases for AI in the ICU, and whether ICU staff is willing to improve their digital literacy or contribute to product improvement. With regard to the multiprofessional structure of ICU teams, we further desired to uncover differences in perspectives between different health professions in the ICU.

Methods

Ethics Approval and Consent to Participate

The ethical approval for this study was granted by the Ethics Commission of the Charité – Universitätsmedizin Berlin (EA1/031/18). Participation in the survey was voluntary. Prior to the study, all participants provided their written consent.

Setting

This survey study was performed with ICU staff from 4 ICUs of a German university hospital, between November 2019 and January 2020 as a substudy for the implementation of the virtual patient monitoring platform Vital Sync 2.4 (Medtronic plc). This new system was implemented between May 2018 and June 2019 in one of the 4 ICUs as a secondary patient monitoring system to remotely monitor patients via tablet computers. As the primary patient monitoring system, the Philips IntelliVue patient monitoring system (Koninklijke Philips NV; MX800 software version M.00.03; MMS X2 software version H.15.41-M.00.04) was used in all 4 ICUs at the time of the study. COPRA 6 (COPRA System GmbH) was used as the patient data management system (PDMS).

Study Design

We chose a cross-sectional survey design, and developed a web-based questionnaire [9,10]. Survey item generation was initiated through the analysis of a preceding qualitative interview study with ICU staff about clinical requirements of future patient monitoring, and was saturated in focus group sessions within the research team [8]. Items were then grouped into topics, and 5 to 6 items per topic were anticipated. We chose a 5-point Likert-type scale as an ordinal response format, with the options “Strongly disagree” (score=1), “Disagree” (score=2), “Undecided” (score=3), “Agree” (score=4), and “Strongly agree” (score=5). In pretests with associated research colleagues, redundant items were eliminated without removing whole topics. Pilot testing was conducted face-to-face with experts from intensive care medicine, with a focus on the clarity, relevance, and arrangement of the items into topics as well as the usability of the web-based questionnaire. Experts also assessed content validity (ie, whether all aspects of the topic were accurately covered by the questionnaire) and clinical validity (ie, whether the questionnaire measured the intended research topic). The final questionnaire (Multimedia Appendix 1) contained 36 items grouped into 8 topics:

- ICU staff experience with the current patient monitoring system
- Aspects of patient monitoring that disturb patient care
- Improvements for future patient monitoring
- Suggestions for remote patient monitoring display devices
- Use cases for remote patient monitoring
- Use cases for CDSS based on AI
- Aspects that promote the usage of CDSS based on AI
- Attitude of ICU staff toward novel digital technology

Additionally, respondents indicated their age group, profession, and technical affinity. For the latter, we used the Affinity for Technology Interaction Short (ATI-S) scale [11] and reduced the options from a 6-point scale to a 5-point Likert-type scale due to usability issues. Other items in the questionnaire focused on alarm management, which was the subject of another study and is not reported here.

Data Collection

Data collection took place over a period of 2 months (November 2019 to January 2020) on an invitation basis. The sampling frame was defined as the 270 nurses and physicians working in the 4 ICUs the day before data collection began; in total, there were 177 nurses and 93 physicians. An email containing a detailed description of the study and the web address of the survey was sent to them. Study data were collected and managed using REDCap electronic data capture tools hosted at Charité – Universitätsmedizin Berlin [12,13].

To increase the survey response rate, participants were offered the opportunity to take part in a raffle to win a €50 (US $56.04) voucher for a train ticket after survey participation. Additionally, 2 reminder emails were sent to all participants 2 and 5 weeks after the initial email was sent. Finally, small handouts with a brief description of the study, the URL for the questionnaire, and a QR (quick response) code were given to ICU staff on site.

Data Analysis

We cleaned and analyzed the data with R (R Foundation for Statistical Computing) in combination with the packages tidyverse, psych, and sjPlots [14-17]. Inferential calculations were performed with the infer package [18]. For each of the 36 five-point items, we calculated the medians and their 95% bootstrap CIs by deploying a bootstrap resampling procedure as previously described [19,20]. For the bootstrap sampling distribution, we created 15,000 bootstrap samples per item. An item median was considered statistically significant when the 95% bootstrap confidence intervals of the median did not include 3, which indicates the response “Undecided.” To compare the distributions of item responses of physicians and nurses, we used chi-square tests. Here, a two-tailed *P* value <.05 was considered statistically significant.

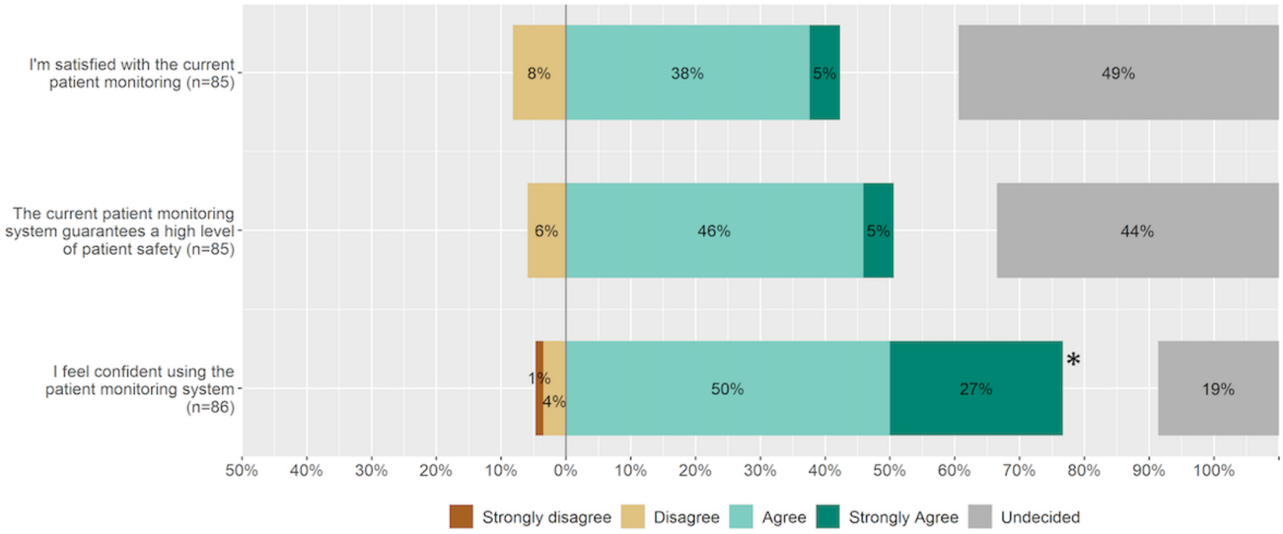
Results

Overview

This survey study is based on a questionnaire with 36 items regarding patient monitoring in the ICU, addressed to ICU staff. The actual response rate was 39.6% (107/270); however, only 86 responses from 62 nurses and 24 physicians were analyzable due to missing data. The ratio of male to female respondents was almost equal (42 men, 41 women, 3 not specified). The largest age categories were represented by participants aged 25 to 34 years (n=32, 37%) and those aged 35 to 44 years (n=28, 33%). Self-reported technical affinity (ATI-S) was rated with a mean of 3.4 (SD 0.88) and a median of 3.5 (range 2.9-4.1) on the 5-point Likert-type scale, with a Cronbach of 0.83 (95% CI 0.76-0.89).

The questionnaire results are presented as grouped Likert plots (Figures 1-8) [16], where one group represents one topic. An item median was considered statistically significant (items marked with an asterisk) when the 95% bootstrap CI of the median did not include 3, which indicates the response “Undecided” (Multimedia Appendix 2 shows item medians and bootstrap CIs). To improve readability, and in contrast to the questionnaire, the answer option “Undecided” is presented on the far right. Multimedia Appendix 3 contains the raw data, and Multimedia Appendix 4 shows the distribution of item responses of physicians and nurses.

Figure 1. ICU staff experience with current patient monitoring. An asterisk indicates statistical significance. ICU: intensive care unit.



Current Patient Monitoring

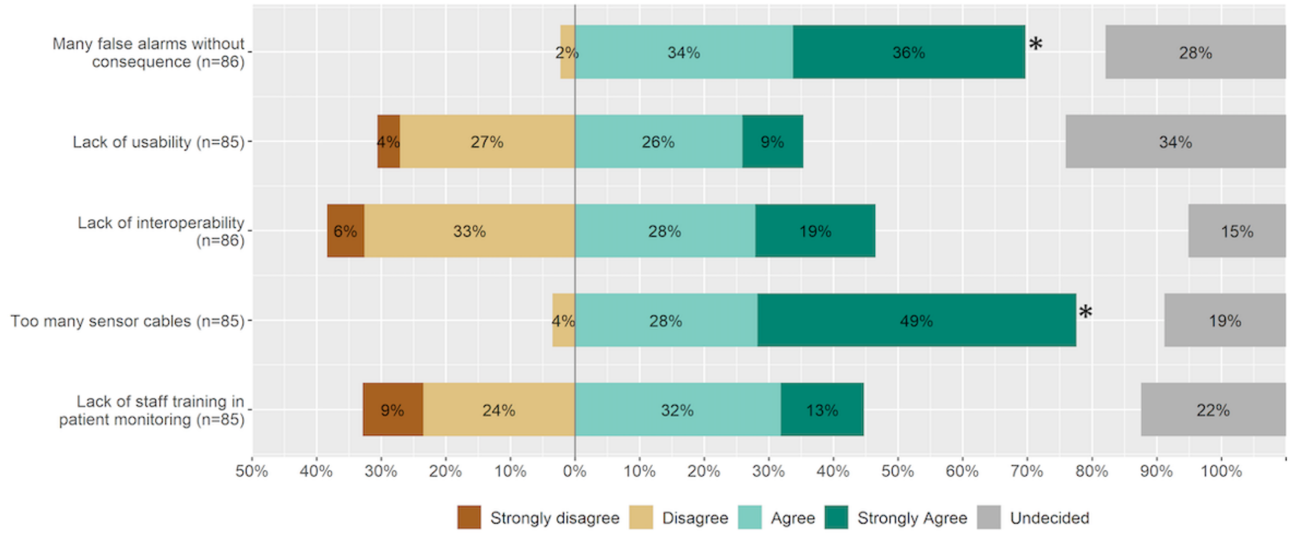
ICU Staff Experience

Most of the ICU staff who took part in the online survey were satisfied with the current patient monitoring system and felt that it ensured high patient safety, even though the median responses did not differ significantly from the option “Undecided” (Figure 1). The majority stated feeling confident in using the patient monitoring system (n=66, 77% chose “Strongly agree” or “Agree”).

Aspects Disturbing Patient Care

The majority of respondents indicated that the patient monitoring system’s high rate of false-positive alarms (n=60, 70% chose “Strongly agree” or “Agree”) and high number of sensor cables (n=66, 77% indicated “Strongly agree” or “Agree”) interrupted patient care. The opinions about detrimental effects elicited by a lack of interoperability, lack of staff training, and low usability of the patient monitoring system were split (Figure 2).

Figure 2. Aspects of patient monitoring disturbing patient care in the ICU. An asterisk indicates statistical significance. ICU: intensive care unit.

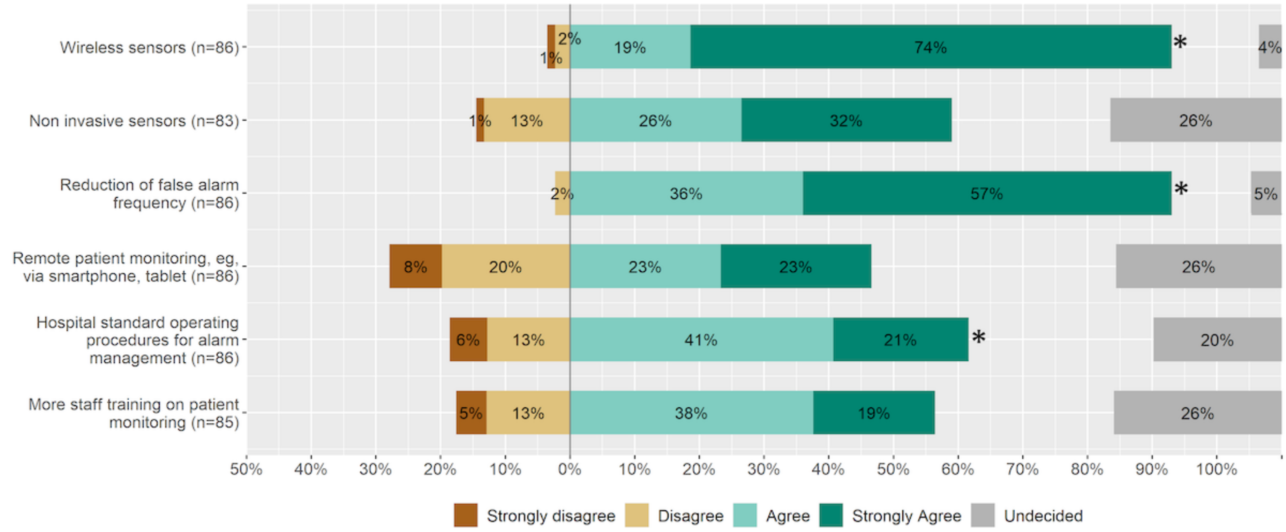


Suggestions for Future Patient Monitoring

Improvements for Future Patient Monitoring

For future patient monitoring, almost all of the ICU staff surveyed requested wireless sensors (n=80, 93% chose “Strongly agree” or “Agree”) and a reduction in false-positive alarms (n=80, 93% chose “Strongly agree” or “Agree”). False-positive alarms may occur due to measurement errors, artifacts, or incorrect settings (Figure 3). Furthermore, respondents wanted a hospital standard operating procedure (SOP) for alarm management (n=53, 62% chose “Strongly agree” or “Agree”). The median responses for the items “Noninvasive sensors,” “Remote patient monitoring,” and “More staff training on patient monitoring” did not significantly differ from the option “Undecided.”

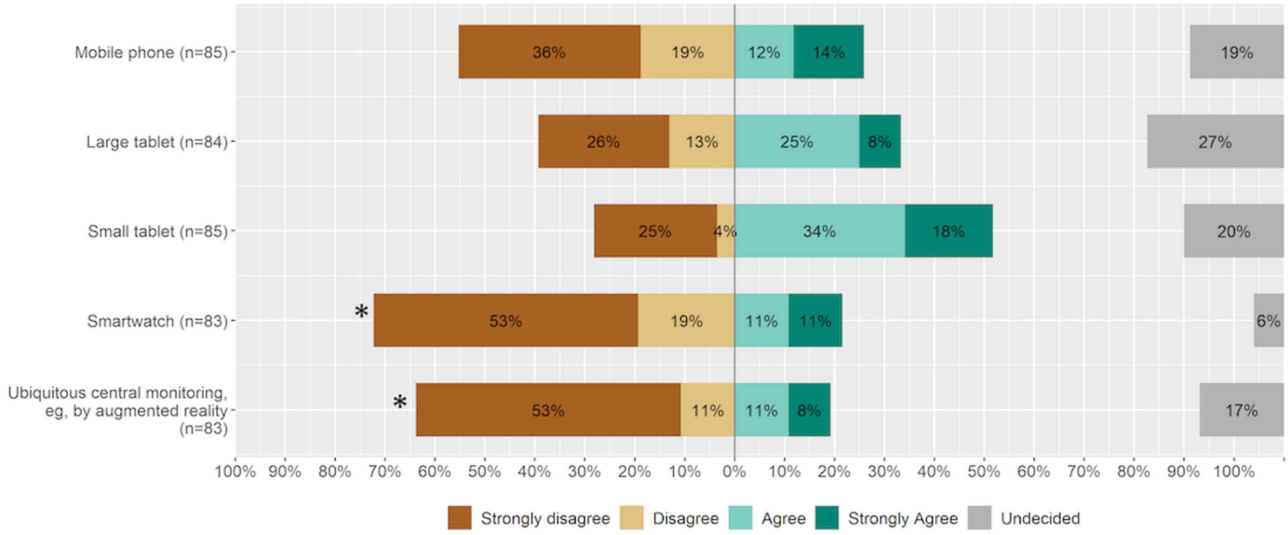
Figure 3. Improvements for future patient monitoring in the ICU. An asterisk indicates statistical significance. ICU: intensive care unit.



Display Devices and Use Cases for Remote Patient Monitoring

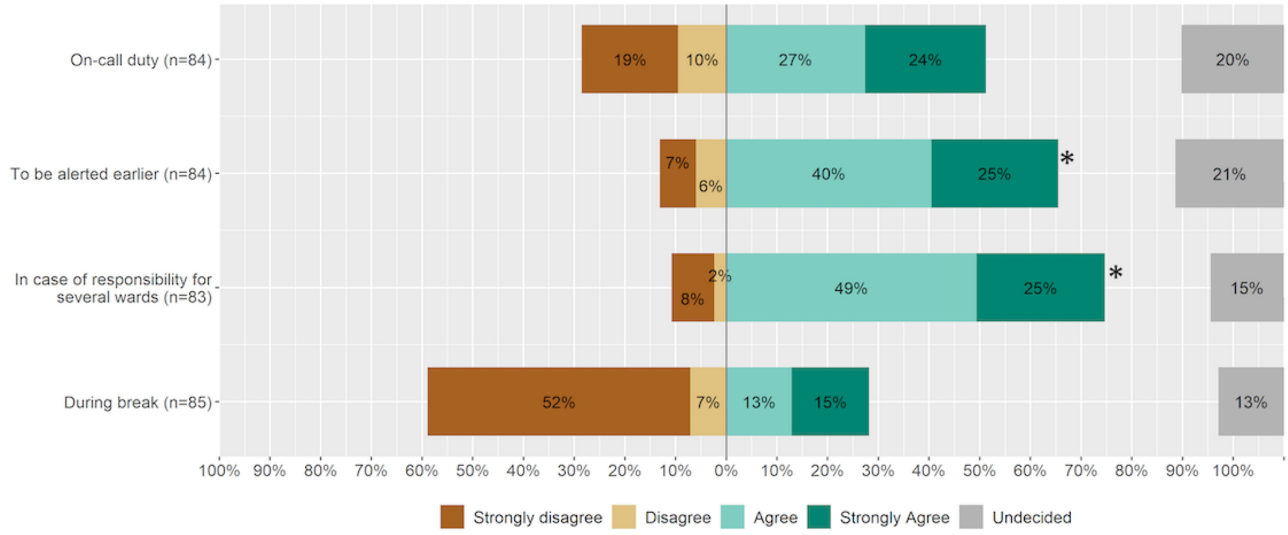
According to the survey results, none of the proposed display devices were desired by ICU staff (Figure 4). The use of smartwatches or augmented reality (AR) glasses in the ICU was rejected by 72% (n=60) and 64% (n=53) of respondents, respectively (those who chose "Strongly disagree" or "Disagree"). With regard to the use of mobile phones for remote patient monitoring, nurses strongly rejected it, while physicians had a neutral attitude toward it.

Figure 4. Suggestions for remote patient monitoring display devices in intensive care medicine for usage on hospital premises. An asterisk indicates statistical significance.



The majority of respondents would appreciate a remote patient monitoring system in an intensive care setting in case they wanted to be alerted earlier (n=55, 65% indicated "Strongly agree" or "Agree") or were responsible for multiple wards (n=62, 74% chose "Strongly agree" or "Agree"; Figure 5). Although not statistically significant, most respondents preferred a remote patient monitoring device for on-call duty, but did not find it useful while taking breaks.

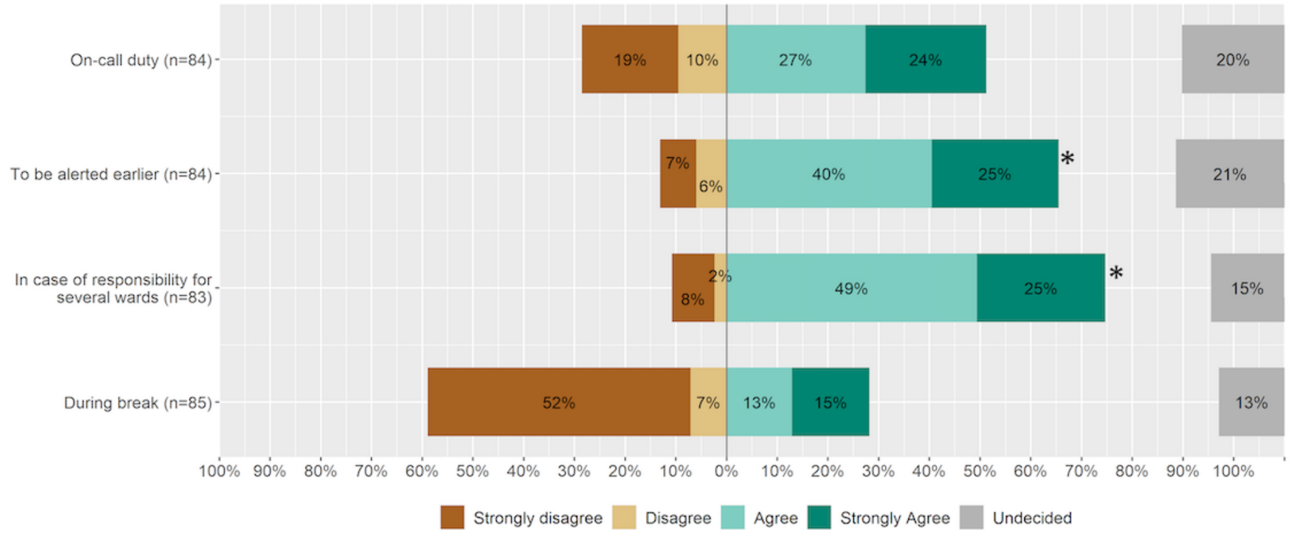
Figure 5. Use cases for remote patient monitoring on hospital premises for intensive care medicine. An asterisk indicates statistical significance.



CDSS

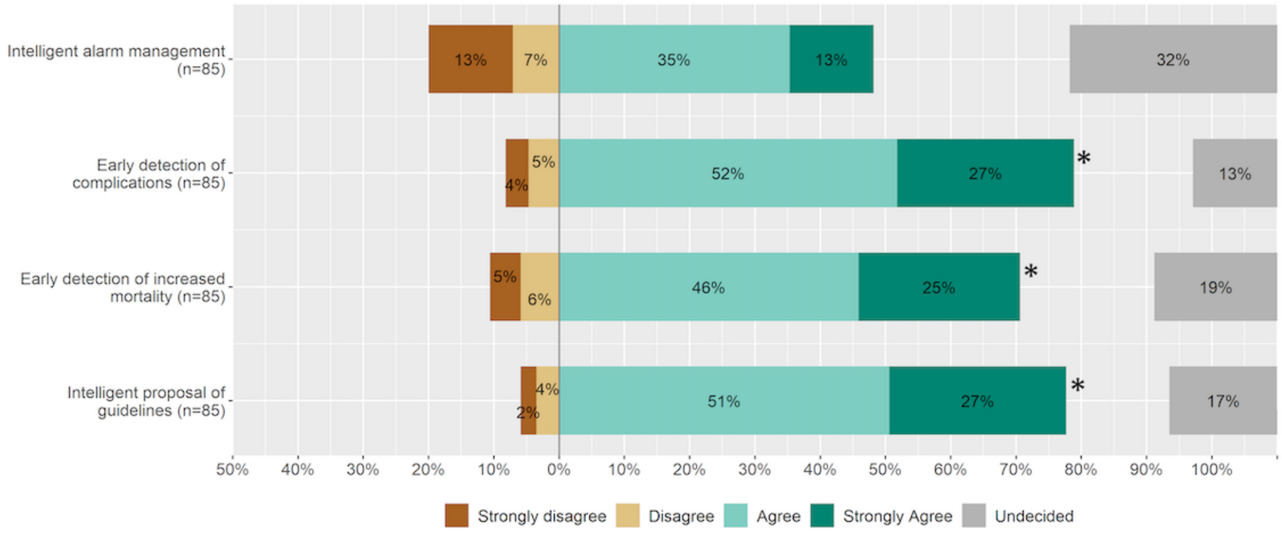
In the future, survey respondents would use a CDSS in the ICU that predicts complications (n=67, 79% chose "Strongly agree" or "Agree") or the risk of mortality of patients (n=60, 71% indicated "Strongly agree" or "Agree") as that intelligently proposes guidelines for therapy and diagnostics (n=66, 78% chose "Strongly agree" or "Agree"; Figure 6). Respondents were inclined to use it for alarm management. Physicians had fewer reservations in using a CDSS with intelligent alarm management than nurses.

Figure 6. Use cases for clinical decision support systems based on artificial intelligence in the ICU. An asterisk indicates statistical significance. ICU: intensive care unit.



Among the factors that users found essential for the use of CDSS, high interoperability (n=79, 93% chose "Strongly agree" or "Agree") and high usability (n=78, 93% indicated "Strongly agree" or "Agree") were deemed most essential. These were followed by the offer of regular staff training with the technology (n=75, 90% chose "Strongly agree" or "Agree") and high transparency of the system (n=66, 78% indicated "Strongly agree" or "Agree"; Figure 7). Most physicians and nurses agreed that regular support (eg, training and workshops) promotes the use of CDSS; more physicians chose "Strongly agree," while more nurses chose "Agree."

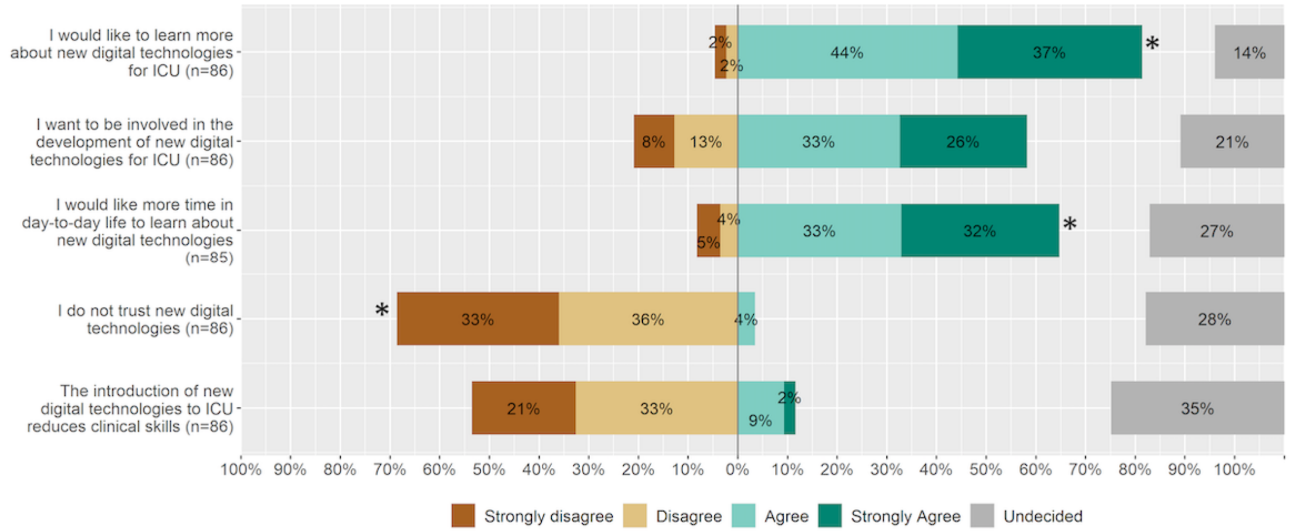
Figure 7. Aspects that promote the usage of clinical decision support systems based on artificial intelligence in the ICU. An asterisk indicates statistical significance. ICU: intensive care unit.



Attitude Toward Novel Technology

Overall, survey respondents were open-minded toward novel technology; among the respondents, 81% (n=70) wanted to know more and 65% (n=55) needed more time to learn about it ("Strongly agree" or "Agree"; Figure 8). The majority (n=59, 69%) disagreed or strongly disagreed on the item "I do not trust new digital technology." Although not statistically significant, 50 respondents (59%) wanted to be involved in the product development of novel digital technologies.

Figure 8. Attitude of ICU staff towards novel digital technology. An asterisk indicates statistical significance. ICU: intensive care unit.



Discussion

Principal Findings

This survey study of ICU staff provides a substantial understanding of the needs and expectations of patient monitoring systems in intensive care medicine from the user's perspective (Textbox 1). Although respondents were confident in using the current patient monitoring system, the high rate of false alarms and the numerous sensor cables were found to potentially interrupt patient care. ICU staff demanded wireless sensors, fewer false alarms, and a hospital SOP for alarm management. Notably, the median replies on display devices for remote patient monitoring did not differ significantly from the option "Undecided," except for the items "Smartwatch" and "Ubiquitous monitoring, eg, through AR," which were both declined. Remote patient monitoring was classified useful for earlier alerts or when responsible for several ICUs. Respondents would use a CDSS based on AI to predict complications, detect increased risk of mortality, and propose guidelines. High transparency, high interoperability, high usability, and regular staff training were all aspects that would promote its usage. Regarding digital literacy, ICU staff was eager to learn more about digital technology and spend more time with it.

Textbox 1. The five most anticipated improvements for patient monitoring by intensive care unit staff.

- Reduction of false alarms
- Implementation of hospital alarm standard operating procedures
- Introduction of wireless sensors
- Introduction of a clinical decision support system based on artificial intelligence
- Enhancement of staff members' digital literacy

Lessons Learned From Today's Patient Monitoring

Notably, we have not observed a proactive call to pioneer new technologies and integrate their respective digital gadgets (eg, smartwatch and AR) into clinical care. Rather, ICU staff looked forward to improvements in the functionality of existing technologies. In line with previous publications, respondents reported that the high rate of false alarms interrupted patient care and demanded a hospital SOP for alarm management [21]. In several studies, implementation of such an alarm management SOP reduced the alarm rate significantly [21,22]. Further temporal analysis of the alarm frequencies per sensor as previously described [23] may find causes for the high rate of false alarms.

It has been reported that cable entanglement is a problem in not only ICUs, but also other places where patients are monitored, such as in operating rooms [24]. Wireless sensors for monitoring vital signs have been tested and implemented several times on stepdown units [6,25]. In many cases, technical requirement analysis (eg, Bluetooth connectivity and interference with other medical devices) was conducted more than a decade ago [26,27]. However, implementation into intensive care routines is still in its infancy [28]. Reasons for this may be the costs associated with developing novel wireless sensors for a high-reliability environment such as the ICU, and technical challenges associated with the need to recharge sensors regularly. In the meantime, cord wraps may facilitate patient transfer with patient monitoring [29].

Remote Patient Monitoring in Intensive Care Medicine

Remote patient monitoring enables clinicians to collect health data via vital sign sensors from patients at location A and electronically transfer this information to location B, where specialists access the data and give health care providers at location A recommendations for managing their patients [4]. Although this is well established in the outpatient sector between the patient's home and the physician [30], the question remains whether this can be supportive to working conditions and patient care in the ICU without a telemedicine context.

Contrary to our preceding qualitative study results, opinions regarding the need for remote patient monitoring in the ICU were divided [8]. There are several industry providers that allow ICU patients to be monitored remotely from anywhere on the premises of the hospital [31-33]. However, scientific evidence of the utility of these devices (eg, for increasing patient safety) seems to be missing. For now, we can summarize that the advantages of on-premise remote patient monitoring for intensive care medicine have to be further quantified by measures such as the reduction of alarms, and improved patient outcomes such as a reduction in patient length of stay.

CDSS in Intensive Care Medicine

As the amount of data as well as the complexity of diseases and treatment of ICU patients are increasing, it seems reasonable to augment the abilities of ICU staff by implementing CDSS based on AI in the ICU. Our results indicate that most of the topics proposed (eg, prediction of mortality, prediction of complications, or proposal of guidelines) were seen as potential use cases for CDSS by ICU staff. For these and several other instances, algorithms already exist that could be adjusted for real-time data [34].

On the path toward implementing CDSS based on AI in intensive care medicine, several barriers have to be overcome [35]. With the introduction of the electronic health record and PDMS in the ICU, the first step has been taken to establish the technical infrastructure, but these systems need to be optimized in interoperability and data quality to act as the basis for complex machine learning processes. To utilize the power of AI as soon as possible, hospital providers should focus on developing data science departments, and introduce standards in implementing novel CDSS tools to rapidly address technical, legal, ethical, and privacy issues.

Transdisciplinary Research and Development

Clinical teams in ICUs are used to working closely together in multidisciplinary teams. This could be advantageous when adding further professions to the team for transdisciplinary research and the development of medical devices for intensive care medicine [36]. Our survey results show that ICU staff members are open to learning more about technology and are even willing to support product development in some cases. Thus, a clinical data scientist with formal medical training could be part of the ICU team as well as the product development team alongside engineers from a medical manufacturer [22,37]. This transdisciplinary approach should be piloted in further studies, to assess the effects on mutual exchange and innovation potential.

As much as the transdisciplinary approach is supported, blunt confidence in user feedback will mainly improve existing devices, as our study prominently indicates, which does not necessarily foster the discovery of disruptive technologies [38], such as avatar-based patient monitoring [39,40] or smart glasses [41]. More than cooperation, transdisciplinarity refers to the development of common theories, mutual observation, and search for challenges and needs [42]. Hackathons (weekend innovation events) are an excellent playground for transdisciplinary work, and participation should be encouraged and remunerated by medical manufacturers and hospital providers [43].

Limitations

With this survey study among ICU staff, we identified the most anticipated improvements for patient monitoring in the ICU from the user perspective. However, several limitations apply to this study. It is important to note that the developed questionnaire did not include questions of established reliability or validity; the data were collected at a single hospital in Germany; the number of participating physicians was small, making statements about group comparisons susceptible to coincidence; and the response rate was moderate. Due to the online collection of data, the participation of ICU staff with less technical affinity may have been reduced. Further studies including a sample size calculation and randomized sample collection would reduce the risk of bias.

Whether the findings (eg, introducing wireless patient monitoring sensors) actually lead to an improvement in working conditions and patients’ quality of life or quality of care in the ICU can only be ascertained by further studies. Finally, a bias due to the deployment of the Vital Sync virtual patient monitoring platform in 1 of the 4 ICUs cannot be ruled out with certainty.

Conclusion

This survey study among ICU staff revealed anticipated key improvements for patient monitoring in intensive care medicine from the user perspective. We did not observe a proactive call to pioneer new technologies and integrate their respective digital gadgets (eg, smartwatch and AR) into clinical routine. Instead, ICU staff looked forward to improvements in the functionality of existing technologies. Particularly, hospital providers and medical device manufacturers should focus on reducing false alarms, implementing hospital alarm SOPs, introducing wireless sensors, preparing for CDSS based on AI, and enhancing the digital literacy of ICU staff. In the medium term, our results may contribute to the user-centered transfer of digital technologies into practice to alleviate challenges in intensive care medicine, such as those recently caused by COVID-19.

Acknowledgments

We express our gratitude to the ICU staff for their participation in this study. We would further like to thank the German Research Foundation (DFG), the Open Access Publication Funds of the Charité – Universitätsmedizin Berlin, and the Einstein Center Digital Future as well as the Medtronic for providing the aforementioned devices free of charge.

Authors' Contributions

CS had the idea for shared decision allocation and initiated the implementation of remote patient monitoring in the intensive care unit. The study was conceived by ASP, CS, and FB. ASP conducted data acquisition, supported by LM and FS. ASP and MS analyzed the data, supported by HK, who provided expertise in statistics. ASP wrote the manuscript, supported by LM, MS, and FS. HK contributed to the study's design and interpretation of results from a psychologist's point of view. FB supervised all parts of the study. All authors critically reviewed and approved the manuscript.

Conflicts of Interest

CS and FB report funding from Medtronic. The other authors do not have conflicts to declare.

Abstract

Background: Comprehensive safety data for vaccines from post-licensure surveillance, especially active surveillance, could guide administrations and individuals to make reasonable decisions on vaccination. Therefore, we designed a pilot study to assess the capability of a regional health care information platform to actively monitor the safety of a newly licensed vaccine.

Objective: This study aimed to conduct active surveillance of human papillomavirus (HPV) vaccine safety based on this information platform.

Methods: In 2017, one of China's most mature information platforms with superior data linkage was selected. A structured questionnaire and open-ended interview guidelines were developed to investigate the feasibility of active surveillance following HPV vaccination using the regional health care information platform in Ningbo. The questionnaire was sent to participants via email, and a face-to-face interview was conducted to confirm details or resolve discrepancies.

Results: Five databases that could be considered essential to active surveillance of vaccine safety were integrated into the platform starting in 2015. Except for residents' health records, which had a coverage rate of 87%, the data sources covered more than 95% of the records that were documented in Ningbo. All the data could be inherently linked using the national identity card. There were 19,328 women who received the HPV vaccine, and 37,988 doses were administered in 2017 and 2018. Women aged 30-40 years accounted for the largest proportion. Quadrivalent vaccination accounted for 73.1% of total vaccination, a much higher proportion than that of bivalent vaccination. Of the first doses, 60 (60/19,328, 0.31%) occurred outside Ningbo. There were no missing data for vaccination-relevant variables, such as identity card, vaccine name, vaccination doses, vaccination date, and manufacturer. ICD-10 coding could be used to identify 9,180 cases using a predefined list of the outcomes of interest, and 1.88% of these cases were missing the identity card. During the 90 days following HPV vaccination, 4 incident cases were found through the linked vaccination history and electronic medical records. The combined incident rate of rheumatoid arthritis, optic neuritis, and Henoch-Schonlein purpura was 8.84/100,000 doses of bivalent HPV, and the incidence rate of rheumatoid arthritis was 3.75/100,000 doses of quadrivalent HPV.

Conclusions: This study presents an available approach to initiate an active surveillance system for adverse events following HPV vaccination, based on a regional health care information platform in China. An extended observation period or the inclusion of additional functional sites is warranted to conduct future hypothesis-generating and hypothesis-confirming studies for vaccine safety concerns.

Introduction

Vaccines, unlike drugs, are generally administered to healthy populations, so the target sample is much larger, especially for birth cohorts, children, or pregnant women. Concerns around vaccine safety, especially for rare adverse events, are increasing with the success of vaccines for the control of vaccine-preventable diseases [1,2]. These concerns can cause a lack of confidence in vaccines and further vaccine hesitancy, defined as a delay in the acceptance or refusal of vaccines despite the availability of vaccination services, that impede or undermine the efforts of an immunization program [3,4]. Although pre-licensure trials can assess the relationship between a vaccine and common adverse events, this type of trial does not have sufficient power to determine the general risk of rare diseases. Therefore, comprehensive safety data from post-licensure surveillance should be used to evaluate the benefit-risk ratio of vaccines, allowing evidence-based decisions by individuals and health organizations [5,6].

Surveillance of adverse events following immunization (AEFI), especially active surveillance for AEFI, should be an essential part of an immunization program to guarantee the safety of vaccines and help establish public confidence [7]. Worldwide, there are a variety of approaches for active AEFI surveillance. Of these approaches, two are the most recognized and replicated due to their robustness and continuity [7]: Vaccine Safety Datalink (VSD), consisting of population-based distributed datasets [8,9], and IMPACT, consisting of targeted hospital-based surveillance [10,11]. These systems were primarily created by developed countries, and limited such systems are available in developing countries [12]. Because of its large population, vast area, and different racial and cultural backgrounds, evidence of vaccine safety in China, especially from active surveillance, can contribute to global vaccine safety efforts.

In recent years, the number of electronic health data sources and interest in their applications have rapidly increased with the advances in medical information systems in China [13], and these electronic health databases could provide the potential for drug safety surveillance and pharmacoepidemiology [14]. Among the electronic health data sources, regional health data sources have been successfully used for drug safety evaluations and surveillance of chronic diseases [15,16]. However, very little is known about the capacity of this data source for active surveillance of adverse events following immunization, and increasing importance has been given to feasibility assessments as essential technical evaluations before starting any vaccine epidemiologic study. Here, we aimed to conduct a feasibility assessment for active surveillance of human papillomavirus (HPV) vaccine safety using the regional health data platform in the city of Ningbo, including a description of the database stakeholders and components, evaluation of the completeness of data relevant to HPV vaccine safety, and an examination of the linkage of data between different data sources.

Methods

Study Setting and Data Sources

Ningbo is a city in the Zhejiang province of China (28°51’ – 30°33’ N, 120°55’ – 122°16’ E). It is located in the south wing of the Yangtze River Delta and consists of 4 counties (Yuyao, Cixi, Ninghai, and Xiangshan) and 6 districts (Yinzhou, Haishu, Jiangbei, Zhenhai, Beilun, and Fenghua), with a total land area of 9365 km^2. In 2017, the city population was >8 million people, and nearly 6 million are part of the hukou (ie, registration of an individual) of Ningbo. The resident population is relatively stable, with a 4.1% out-migration rate and 11.1% in-migration rate.

The regional health care information platform in Ningbo was initially devised and launched in 2011 by the Health Commission of Ningbo to construct a united and standardized medical information network and facilitate health care services. By 2015, the database covered almost all health-related activities of residents within this area, and more than 87% of the residents were registered in the database with a valid health care identifier. In 2016, the database was approved and awarded a Four Grade Class A, which at the time was the top achievement level by the Standardization and Maturity Measurement of Regional Health Information Interconnection by the National Health Commission of China.

Questionnaire Design and Field Investigation

Based on information in previous studies, we developed the questionnaire and open-ended interview guidelines to evaluate the feasibility of active surveillance following HPV vaccination using the regional health care information platform in Ningbo. To finalize the questionnaire and guidelines, four experts from pharmacoepidemiology, vaccine safety, medical informatics, and database administration independently reviewed the documents and provided feedback. Then, a 2-step survey was conducted to collect database information from the data owners, management, and other staff. First, we sent the questionnaire, its instructions, a comprehensive description of the study purpose, and the completion deadline to the database staff via email. After receiving the questionnaire responses, we confirmed any potential discrepancies with Ningbo through telephone communication. Second, we conducted face-to-face interviews, using the open-ended interview guidelines, with relevant staff during field visits.

The questionnaire about the database consisted of 7 parts: (1) basic information in the database; (2) information in electronic medical records (EMR) in the database; (3) vaccination registration and information about maternal and child health care in the database; (4) method and possibility of linking data between different data sources; (5) age distribution of HPV vaccine–protected women in 2017; (6) completeness of core variables relevant to active surveillance of vaccine safety in 2017; and (7) crucial outcome information in EMR in 2017.

The interview guideline was mainly composed of 3 parts: (1) general characteristics of the database; (2) general characteristics of the essential information system for active surveillance, including vaccination registration, EMR, maternal and child health care information, cancer registration, death registration; and (3) other several specific questions.

The study was approved by the Peking University Institutional Review Board (IRB 00001052-18016). Moreover, all the tasks were performed by staff of the data owner, and investigators could not access the raw data throughout the study period.

Results

Stakeholders and Database Components in Ningbo

The Ningbo database was constructed and is owned by the Ningbo Health Commission (NHC), and the Ningbo Centers for Disease Control and Prevention (CDC) can operate and develop this database with permission from the NHC. There are two primary data sources in the database, including the digital CDC platform and digital hospital platform. The CDC controls the former, which mainly focuses on public health and provides a unified information system for the whole city, including integrated primary health care, chronic or infectious disease surveillance, vaccine registration (children and adults), and death registration. Data in the hospital digital platform are collected during regular clinical services provided in hospitals, such as from EMR, and the information system usually differs by hospital, but the NHC has developed harmonized standards to transform and upload these data, which are in a nearly structured format in the Ningbo database. Moreover, the NHC and CDC have endeavored to improve the data quality in the database through official regulations, upgrading of standards, and regular quality checks. The local CDC has also established an institutional review board to review ethical issues and guarantee privacy protection during the process of scientific research.

Characteristics of the Data Sources for Active Surveillance of HPV Vaccine Safety

Table 1 summarizes the characteristics of the five data sources related to active surveillance for HPV vaccine safety in the Ningbo database; data from these sources were updated and uploaded into the database daily. First, residents’ electronic health records were created primarily by general physicians when the residents visited medical and health institutions for services; these records currently cover >87% of the permanent residents in Ningbo. Second, all vaccination records, including free vaccines provided by the Expanded Programme on Immunization or vaccines paid for out-of-pocket, for infants and children aged <6 years are registered in the immunization program system. It was a compulsory requirement from the Ningbo CDC beginning in May 2017 that vaccination records for adults be registered. Third, starting in 2015, the platform integrated new and historical EMR data from all public hospitals and most of the large private hospitals in the city. Fourth, the maternal and child health care information system includes data recorded during health care services provided for prenatal examinations, maternal deliveries, and newborn follow-ups (until the infant was 1 year old), which resulted in an increase in the local pregnancy and maternal registration rate to 97% by 2016. Finally, the death surveillance information system primarily includes identity information and medical certificates of the dead and can trace death records outside of the city of Ningbo but inside Zhejiang province.

Table 1. Characteristics of the data sources related to HPV vaccine safety surveillance.

Data and population	Year surveillance began	Coverage	Main purpose
RHR[a]			
Residents	2010	>87% of permanent residents	Basic information, health checks, special population primary care
IP[b]			
Children	2005	100% for 167 vaccination clinics	Basic information, vaccination records, vaccine cold chain
Adults	2017		
EMR[c]			
Outpatients[d]	2015	All 221 public health hospitals and 28 large private hospitals	Diagnoses, prescriptions, medical examinations, lab tests
Inpatients	2015		
MCH[e]			
Maternal patients	2015	> 97% maternal registration rate	Prenatal examinations, birth deliveries, newborn follow-ups
Newborns	2015		
DS[f]			
Residents	2010	Permanent residents	Identity, death certificates

[a] RHR: residents' health records.

[b] IP: immunization program.

[c] EMR: electronic medical record.

[d] includes outpatient and emergency visits.

[e] MCH: maternal and child health care.

[f] DS: death surveillance.

Characteristics of HPV Vaccination in the Immunization Program

From 2017 to 2018, there were two types of HPV vaccines: bivalent and quadrivalent. Both were only available for women in this district. Table 2 describes the characteristics of the population who received the HPV vaccination in Ningbo. During this period, 19,328 women received at least one dose of the HPV vaccine. Women aged 30-40 years represented the largest proportion. Quadrivalent vaccination was administered more often than bivalent vaccination. Moreover, 60 (60/19,328, 0.31%) first doses seemingly occurred outside Ningbo, and these data were not traced back to the database.

The completeness of critical variables relevant to HPV vaccination (eg, recipient identity card [ID], name, gender, birth date, address, vaccine name, vaccination date, vaccination manufacturer, batch number) was also investigated, and for these variables, there were no missing data. The system did not have information for education, occupation, height, weight, smoking habits, and alcohol consumption.

Table 2. Characteristics of the women who underwent HPV vaccination.

Variables	Total (n=19,328), n (%)	First dose (n=19,268), n (%)	Second dose (n=13,404), n (%)	Third dose (n=5316), n (%)
Age group (years)				
9-15	1541 (7.97)	1532 (7.95)	1343 (10.02)	613 (11.53)
16-20	959 (4.96)	943 (4.89)	806 (6.01)	491 (9.24)
21-25	2735 (14.15)	2721 (14.12)	1961 (14.63)	1064 (20.02)
26-30	3221 (16.66)	3215 (16.69)	1966 (14.67)	634 (11.93)
31-35	4146 (21.45)	4138 (21.48)	2554 (19.05)	759 (14.28)
36-40	4117 (21.30)	4112 (21.34)	2753 (20.54)	902 (16.97)
41-45	2609 (13.50)	2607 (13.53)	2021 (15.08)	853 (16.05)
Vaccine				
Bivalent	5194 (26.87)	5147 (26.71)	4445 (33.16)	1721 (32.37)
Quadrivalent	14134 (73.13)	14121 (73.29)	8959 (66.84)	3595 (67.63)

Identification of the Outcome of Interest in EMR

Table 3 shows the ability of the 10th revision of the International Statistical Classification of Diseases and Related Health Problems (ICD-10) codes to identify the safety outcomes of interest in EMR as well as the incident cases of diseases 90 days after HPV vaccination. All visit records of the cases were retrieved from the EMR using standard query language and the ICD-10 code, and duplicate records were removed. As a result, for data from 2017 and 2018, ICD-10 codes can be used to identify all the outcomes of interest in women aged 9-45 years. Among these diseases, there were 1867 cases of systemic lupus erythematosus, which was the largest proportion of cases. In contrast, there were only 2 cases of acute disseminated encephalomyelitis, which was the smallest proportion of cases. Except for that of Henoch-Schonlein purpura (HSP; 118/1606, 7.35%), the rate of missing IDs for other diseases was near or <5%, and the total rate of missing IDs was 1.88% (173/9180). Moreover, we monitored the risk of specific adverse events during the 90 days after HPV vaccination. For all the doses, we found 4 incident cases with no history of the disease at least 1 year before HPV vaccination. Two new cases, one each of rheumatoid arthritis (RA) and optic neuritis (ON), were diagnosed within 30 days of bivalent HPV vaccination, and one new case of HSP was diagnosed within 90 days of bivalent HPV vaccination. One new case of RA emerged within 90 days after quadrivalent HPV vaccination.

Hospitals not included in the database could not diagnose nor treat the outcomes of interest. Regarding case validation, structured data from imaging examinations, laboratory tests, histological examinations, and other medical examinations could be found directly in the database, while nonstructured or free-text information, such as the chief complaint, may have needed to be retrieved from the hospital.

Table 3. Outcomes among women aged 9-45 years recorded in electronic medical records.

Disease	ICD-10[a]	n[b]	ID[c] missing, n (%)	New cases 30 days post-HPV[d] vaccination, n	New cases 90 days post-HPV vaccination, n
Rheumatologic/autoimmune diseases					
SLE[e]	M32	1867	39 (2.09)	0	0
RA[f]	M05, M06	2878	72 (2.50)	1	2

VTE[m]	I82.8|9	59	3 (5.08)	0	0
Raynaud’s disease	I73.0	131	1 (0.76)	0	0
Total	N/A[n]	9180	173 (1.88)	2	4

[a] ICD-10: 10th revision of the International Statistical Classification of Diseases and Related Health Problems.

[b] duplicate records were removed, and the number of patients was calculated using an encoded identifier consisting of the identity card or name, gender, birth date, and address.

[c] ID: identity card, which is unique for each individual in China.

[d] HPV: human papillomavirus.

[e] SLE: systemic lupus erythematosus.

[f] RA: rheumatoid arthritis.

[g] JRA: juvenile rheumatoid arthritis.

[h] ADEM: acute disseminated encephalomyelitis.

[i] GBS: Guillain-Barre syndrome.

[j] ON: optic neuritis.

[k] ITP: primary immune thrombocytopenia.

[l] HSP: Henoch-Schonlein purpura.

[m] VTE: venous thromboembolism.

[n] N/A: not applicable.

Discussion

Principal Findings

A feasibility assessment is the first step to improve the quality of study protocols and accelerate regulatory approvals and, in turn, the start of an actual study [17]. The regional health care information platform in Ningbo covers the entire city and has integrated the essential data sources for active surveillance of the HPV vaccine, including immunization program registration, EMR, resident health records, and death surveillance; these data can be linked using the unique national ID or encoded identifier. More importantly, this database can sensitively identify the outcome of interest through ICD-10 coding, so we can actively monitor risks following HPV vaccination by linking HPV vaccination records with adverse events from EMR, death, or other data sources. Therefore, this database could be available and feasible in research for active surveillance of adverse events following HPV vaccination.

Comparison With Prior Work

The Chinese CDC established the AEFI Surveillance System, which is a passive national surveillance system covering more than 29 provinces, in 2015 [18]. However, regarding active surveillance, the relevant studies have used traditional methods for timely collection of adverse events, such as by telephone or daily cards, that were designed and performed during the H1N1 pandemic [19]. Plus, we have not found a study that attempted to construct a sustained active surveillance system for AEFI despite the large population and vast geographical area in China [7]. Internationally, some countries have developed sustainable active surveillance systems for adverse events using population-based databases that link vaccine history with outcomes, such as the VSD [9] and Post-Licensure Rapid Immunization Safety Monitoring program [20]. In this study, considering that the crucial data components in the Ningbo database are similar to those in the VSD and Post-Licensure Rapid Immunization Safety Monitoring program, we consider this to be pioneering work in China – to construct a continuous method for actively monitoring AEFI during the post-marketing phase of vaccines. Moreover, we can also link vaccination history with death records in the Ningbo database, which might reduce potential bias from right-censored data.

In this study, of the specific list of outcomes, we identified 4 incident cases within the 90 days following HPV vaccination. The combined incident rate of RA, ON, and HSP was 8.84/100,000 doses of bivalent HPV, and the incident rate of RA was 3.75/100,000 doses of quadrivalent HPV. There was no cluster of these adverse events. Considering the prevalence of RA is 0.46% [21] and the lack of large epidemiology studies of ON [22] and HSP in Chinese women, the rate of adverse events was not high enough for a safety signal. Furthermore, an updated systematic review concluded that the risk of RA, ON, or HSP is not increased with any type of HPV vaccine [23]. However, due to the limited sample size and different backgrounds of Chinese women, a larger sample or longer observational period is required to comprehensively review the safety of HPV vaccines in China.

To monitor the long-term safety of HPV vaccines, a continuous, sustainable surveillance system is necessary. There are several ways of setting controls to promptly identify and alert of vaccine safety signals. First, comparing with historical controls, or background rates, is an approach to identify whether the incidence rate of adverse events following vaccination is higher than the background rate, which is not due to chance [24]. However, it may not be feasible to perform this comparison in the Ningbo database due to the short premarketing period of the HPV vaccine. Four study designs were recently recognized and have become widespread for vaccine safety surveillance, including the self-controlled case series (SCCS), self-controlled risk interval (SCRI), cohort, and case-control study designs [25], and SCRI and SCCS have been proven to be an efficient, rational alternative to the cohort in a simulation study [25,26]. In a real-world study, self-controlled analyses, such as those used in SCRI and SCCS, are used because each case acts as its own control within a short period, thereby inherently adjusting for all time-unvarying potential confounders, such as sex, nationality, and genetic predisposition [27,28]. In our study, given that the database can only capture the visit records of safety outcomes and HPV vaccines that occurred in the city, it is likely that we will misclassify these crucial variables in a subsequent study; for example, some local young women can be vaccinated while attending college outside the city. In addition, these records cannot currently be traced back to the Ningbo database unless the women return to Ningbo and utilize the relevant local services.

Therefore, using the SCRI as the primary design to evaluate the risk after vaccination seems most appropriate, minimizing misclassification bias due to incomplete vaccine exposure. A cohort study as the secondary design may improve statistical power [28]. Also, additional regional databases need to be incorporated to increase the robustness of risk estimation, especially for different subpopulations or districts.

Limitations

Some potential barriers need to be overcome in additional studies. First, because the HPV vaccination rate is so low in Ningbo, the observation period should be lengthened, or additional sites should be incorporated. Second, identification algorithms for safety outcomes should be developed to improve performance, with a positive predictive value >70% [29]. Third, migration may cause potential bias in the representative population or misclassification of exposure and outcomes, so we should consider its influence in future research. Finally, missing links between data should be addressed and balanced with privacy concerns [30].

Conclusions

The study presents an available approach to initiate an active surveillance system for adverse events after HPV vaccination, based on a regional health care information platform in China. Utilizing a longer observation period or including additional functional sites is warranted to conduct future hypothesis-generating and hypothesis-confirming studies to address vaccine safety concerns.

Acknowledgments

The study was funded by the Advanced Project of Beijing Natural Science Foundation (BMU2019GJJXK003) and sponsored by Merck Sharp & Dohme Corp (MSD; Beijing, China). The authors had full access to all data in the study and final responsibility for the decision to submit for publication. The authors' views are independent of the official views of the Beijing Natural Science Committee and MSD.

Authors' Contributions

At the time of the research, LZ led the development of the questionnaire and interview guidelines. YY, MR, and ZS were responsible for reviewing these documents. ZL and XG were responsible for data collection, and FT, DY, and LN assisted with the field investigation. This manuscript was written by LZ and reviewed by ZS. The two corresponding authors (ZS and XG) contributed equally to this work.

Abstract

Background: The most commonly used means to assess pain is by patient self-reported questionnaires. These questionnaires have traditionally been completed using paper-and-pencil, telephone, or in-person methods, which may limit the validity of the collected data. Electronic data capture methods represent a potential way to validly, reliably, and feasibly collect pain-related data from patients in both clinical and research settings.

Objective: The aim of this study was to conduct a systematic review and meta-analysis to compare electronic and conventional pain-related data collection methods with respect to pain score equivalence, data completeness, ease of use, efficiency, and acceptability between methods.

Methods: We searched the Medical Literature Analysis and Retrieval System Online (MEDLINE), Excerpta Medica Database (EMBASE), and Cochrane Central Register of Controlled Trials (CENTRAL) from database inception until November 2019. We included all peer-reviewed studies that compared electronic (any modality) and conventional (paper-, telephone-, or in-person–based) data capture methods for patient-reported pain data on one of the following outcomes: pain score equivalence, data completeness, ease of use, efficiency, and acceptability. We used random effects models to combine score equivalence data across studies that reported correlations or measures of agreement between electronic and conventional pain assessment methods.

Results: A total of 53 unique studies were included in this systematic review, of which 21 were included in the meta-analysis. Overall, the pain scores reported electronically were congruent with those reported using conventional modalities, with the majority of studies (36/44, 82%) that reported on pain scores demonstrating this relationship. The weighted summary correlation coefficient of pain score equivalence from our meta-analysis was 0.92 (95% CI 0.88-0.95). Studies on data completeness, patient- or provider-reported ease of use, and efficiency generally indicated that electronic data capture methods were equivalent or superior to conventional methods. Most (19/23, 83%) studies that directly surveyed patients reported that the electronic format was the preferred data collection method.

Conclusions: Electronic pain-related data capture methods are comparable with conventional methods in terms of score equivalence, data completeness, ease, efficiency, and acceptability and, if the appropriate psychometric evaluations are in place, are a feasible means to collect pain data in clinical and research settings.

Introduction

Background

Pain is an unpleasant sensory and emotional experience that is unique to the individual. It is also a dynamic process and fluctuates in a multidimensional manner across its sensory (eg, intensity, location, duration, etc), evaluative (ie, impact on functioning) and affective (ie, emotional effect) qualities within both the short and long term [1]. Pain is influenced by a variety of biopsychosocial factors, including genetics, mood, emotions, memory, and interpersonal relationships as well as external stimuli such as physical movement [1-3]. The accurate measurement of pain is of utmost importance to clinicians and researchers.

The most commonly used methods of measuring pain within a clinical and research context are self-reported questionnaires. Clinically, pain measurements are generally performed before and after an intervention to assess a patient's response to therapy. These assessments are typically performed using paper-based questionnaires or via face-to-face or telephone-based verbal surveys or interviews. Although widely used, these conventional data collection methods can introduce a number of biases in the collected pain data. In particular, these methods often rely heavily on a patient's recall of their pain symptoms (eg, pain intensity over the preceding week). Unfortunately, the recall of pain is problematic because memories of pain are vulnerable to distortion due to physical and psychological contextual factors and selective coding and retrieval of memories [4,5]. Additional issues with conventional data collection methods include limitations in conducting ecologically valid assessments of pain in the patient's natural environment and social context, logistical challenges for repeated measurements over time, potential burden to patients, clinicians, and researchers, and possibly reduced data quality due to incomplete or back-filled pain diaries [6-8].

The advent of mobile electronic devices has created novel opportunities to collect pain-related data in clinical and research settings. Electronic data collection methods have been used to assess variables related to a variety of conditions, including mood disorders, asthma, tobacco cessation, urinary incontinence, brain injury, diabetes, cancer, and pain [7,9-11]. Specialists in pain medicine have widely advocated for the use of electronic data capture over the past two decades [12,13], and mounting evidence suggests that data collected via electronic methods may be more accurate and contain fewer errors than conventional methods [14,15]. Although randomized controlled trials and observational studies comparing electronic and conventional data collection methods suggest benefits to the use of electronic devices in pain clinical trials, no review providing an overview of these benefits currently exists. Furthermore, with the advent of smartphone-style mobile phones and their nearly ubiquitous use in developed countries [16], electronic data collection methods are becoming more widely available. As such, a review of the literature is needed to understand the potential advantages and disadvantages of collecting pain data using electronic methods.

Objective

We aimed to identify and synthesize data from studies comparing electronic and conventional pain-related data collection methods to describe similarities and differences in pain scores, data completeness, ease of use, efficiency, and acceptability between methods.

Methods

Overview

We developed an internal protocol to guide the conduct of the review and meta-analysis. Reporting is guided by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses [17].

Eligibility Criteria

Criteria for Inclusion in the Systematic Review

To be included in this review, studies must have (1) been published in English, (2) enrolled participants in a clinical study examining an acute or chronic pain-related outcome as reported by participants, (3) used both an electronic data collection method and a conventional form of data collection (ie, paper-based, telephone, or in-person), and (4) collected data on pain score equivalence (including as part of a functional limitation or disease activity measure), data completeness, ease of use, efficiency, or acceptability between collection methods. There were no restrictions on the type of study design (randomized or observational), country of study, or year of publication. Only studies in which the full texts could be retrieved were included in the review.

Criteria for Inclusion in the Meta-Analysis

A subset of studies included in the systematic review was also included in the meta-analysis. These studies reported correlations or measures of agreement (ie, intraclass correlation coefficients [ICCs], Pearson correlations, Spearman rho, and weighted kappa) between patient-reported pain intensity or pain interference (including affect) scores assessed using an electronic and a conventional data capture method. Pain intensity and interference were the focus of the analysis as these constructs are commonly assessed, single-item aspects of both acute and chronic pain and are routinely used to determine treatment effectiveness and guide therapy [18,19]. As recalled pain reports may not be an accurate reflection of the momentary pain experience, we included only studies that compared momentary pain reports. No restrictions were placed on the type of data collection method (eg, mobile phone, computer-based, and tablet), pain assessment instrument (eg, numerical rating scale [NRS]), frequency of data collection, or other pain-related assessments (ie, studies that also assessed constructs such as quality of life or disease activity in addition to pain intensity or interference were included).

Study Selection

We developed a comprehensive search strategy in consultation with a tertiary hospital librarian with expertise in the scientific literature related to digital health. We customized the search strategy to conduct tailored searches of MEDLINE, EMBASE, and Cochrane Central Register of Controlled Trials (CENTRAL) from inception until November 19, 2019. Medical Subject Headings (MeSH) keywords in the search included: *pain*, *pain measurement*, *pain threshold*, *pain perception*, *electronics*, *cellular phone*, *computers*, *handheld*, *wireless technology*, *internet*, *computer communication networks*, *mobile applications*, *randomized controlled trial*, *multicenter study*, *observational study*, *humans*, and *prospective studies*. Additional keywords used in the search included: *pain*, *pain reporting*, *personal digital assistant*, *smartphone*, and *prospective study*. An example of the search strategy can be found in Multimedia Appendix 1. We supplemented our search with searches of the author’s own databases of electronic pain assessment studies.

Search results were initially electronically screened for intradatabase and interdatabase duplicates. After the electronic removal of duplicates, titles and abstracts were screened independently by 2 authors using piloted standardized screening forms (all authors involved). Subsequently, the full texts of the included citations were reviewed in duplicate to confirm study inclusion (all authors involved). The kappa statistic was calculated as a metric of screening agreement at the full-text stage. Following the literature-based precedent, we interpreted the kappa as follows: <0.00, poor; 0.00-0.20, slight; 0.21-0.40, fair; 0.41-0.60, moderate; 0.61-0.80, substantial; and 0.81-1.00, almost perfect [20]. Disagreements among reviewers about study eligibility were resolved by consensus through discussion by at least three authors.

Data Collection Process

A standard data collection form was created and piloted. Data abstraction occurred independently and in duplicate. Data extracted included study design, sample size, study population, electronic and conventional data collection method, duration of data collection, score equivalence between data capture methods (ie, correlations, score differences, and descriptive reports), data completeness, ease and efficiency of data collection, and patient or participant acceptability. An *a priori* decision was made to not formally assess study quality given the nature of the intervention (ie, data collection method) and the diverse study designs collected in the systematic search.

Data Synthesis

Descriptive statistics (ie, frequencies and percentages) were used to synthesize and present data across all included studies. Meta-analysis was performed to synthesize results related to score equivalence across data capture methods. For the analysis, reported correlation coefficients (or kappa in the case of 2 studies [21,22]) served as effect size indices. In all studies where more than one coefficient for a correlation or measure of agreement between electronic and conventional pain data collection methods was available, we used the average of the coefficients so that a single study did not disproportionately impact the summary effect size. Whenever available, the reported sample size used to produce the score equivalence coefficient was used in the model. In cases where the sample size for the score equivalence analysis was not explicitly mentioned, we used the sample size reported for the entire study. Random-effects models were used to combine data across studies, and the I^2 statistic was used to quantify heterogeneity. The criteria set out by Higgins et al [23] were used to interpret the I^2 statistic; namely, 25%, 50%, and 75% were considered low, moderate, and high heterogeneity, respectively. To further examine the impact of heterogeneity on the results, the standardized residual score (ie, the standardized difference between each study effect size and the weighted mean effect size) for each study was calculated and compared [9]. A conservative cutoff of ±2 was set to examine extreme effect sizes as determined by the standardized residuals. We performed a sensitivity analysis to evaluate any impact of the type of correlation or measure of agreement on the weighted summary correlation. Specifically, following previously used methods, separate meta-analyses were conducted with studies reporting ICC or weighted kappa, which account for covariance and score mean and variability, and studies reporting the more conventional Pearson or Spearman rho coefficients [9]. Possible publication bias was assessed by visual inspection of an asymmetrical funnel plot. To investigate the sources of heterogeneity, we conducted further subgroup analyses. Our subgroup analyses focused on elucidating the impact of (1) the similarity of pain assessment measure between electronic and conventional modalities (ie, same measure or different) and (2) the duration of data collection (ie, once or multiple times). Subgroup analyses by study participant age and pain condition were precluded by the structure of data reported in our included studies. Meta-analysis procedures were conducted using Microsoft Excel (Microsoft Corporation) and Distiller SR Forest Plot Generator (Evidence Partners Inc).

Results

Study Selection

The search strategy identified 4927 studies, of which 183 underwent full-text review and 129 were excluded (Figure 1). The kappa agreement score between appraisers at this stage was 0.69, which indicated substantial agreement. In all, 54 papers reporting on 53 unique studies were included in the qualitative synthesis. Stinson et al [5,24] reported different results from the same study, so were grouped presently for analyses purposes. In all, 21 studies were included in the quantitative synthesis. The number of published studies meeting our inclusion criteria increased steadily over time (Figure 2).

Figure 1. Study selection flowchart.

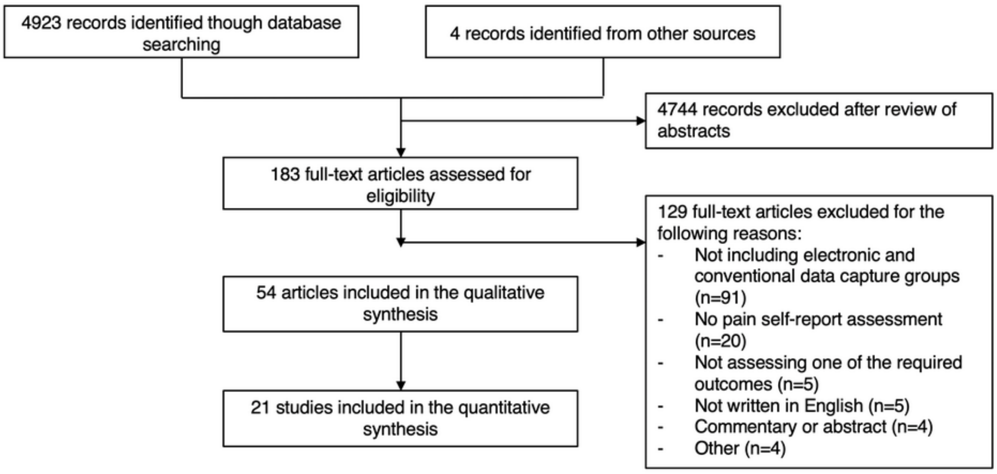

Figure 2. Number of studies meeting inclusion criteria overtime.

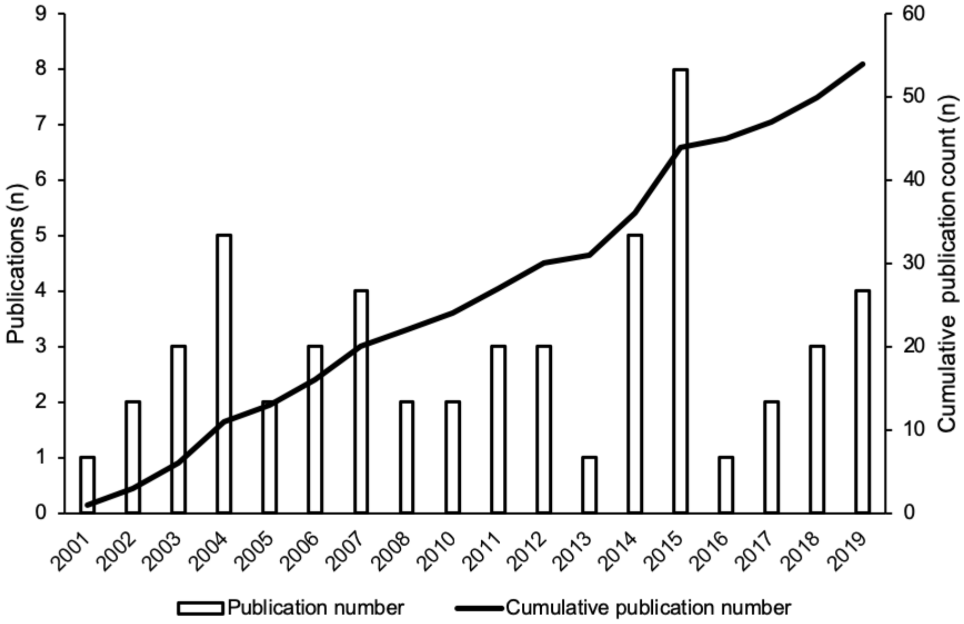

Study Characteristics

The study details are presented in Table 1. Data from a total of 7977 pain patients were included in this review. The mean number of participants across studies was 151 (range 15-2400). The average mean or median age of participants was 41.5 years (SD 17.5), and across studies, the average proportion of female participants was 63.1%; mean or median age data were missing from 9 studies and sex data were missing from 7 studies. Participants in the included studies had various painful conditions or diagnoses, including both acute and chronic pain. The most common pain conditions were nonspecific chronic pain (9/54, 17% studies), postoperative pain (8/53, 15% studies), and arthritis (8/53, 15% studies).

Table 1. Study characteristics.

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Allena et al (2012) [25]	Acceptability, data completeness, and ease	Not specified	85	Mean age 39.7 (SD 10.2) years, 68 females and 17 males, medication overuse headache	PDA[a] program collecting data on pain intensity (no indication of measure), pain sensory characteristics, associated symptoms, possible trigger factors and medication use	Paper-based tool (no indication if questions were the same across formats); prospective recording of attack characteristics, more accurate descriptions	Participants completed both formats daily for 7-10 days
Athale et al (2004) [26]	Acceptability, data completeness, ease, and score equivalence	Nonrandomized, crossover	43	Mean age not specified (range 18-75+ years), 36 females and 7 males, rheumatoid arthritis	Computer program collecting data on VAS[b]-rated pain intensity, pain sensory characteristics, and affective and functional impact of pain	Paper-based tool (different from electronic format only in that pain and swelling locations are indicated on separate body maps)	Participants completed each format once
Bandarian-Balooch et al (2017) [27]	Acceptability, data completeness, ease, and score equivalence	Randomized, controlled trial	181	Mean age 26.5 (range 18-55) years, 146 female and 35 males, headache and migraine	Mobile phone or computer program collecting NRS[c]-rated pain intensity, frequency, and duration data as well as triggers and medication use	Paper-based tool with one subgroup identical to electronic format and the other a long-form report representative of conventional paper diaries	Participants completed assigned format once per day for 30 days
Bedson et al (2019) [28]	Data completeness, ease, efficiency, and score equivalence	Nonrandomized, cohort	21	Median age 62 (IQR 50-70) years, 13 females and 8 males, musculoskeletal pain	Tablet program collecting data on NRS-rated pain intensity and pain interference, as well as sleep disturbance, analgesic use, mood, and side effects	Paper-based tool (same assessment as used in the electronic study)	Participants completed electronic assessment 2 times per day for 4 weeks and the paper-based tool once at baseline and once at study completion
Bishop et al (2010) [29]	Acceptability, data completeness, ease, efficiency, and score equivalence	Randomized, crossover	167	Complete age data not reported, (range 18-78), complete sex data not reported, back pain	Computer program collecting data on the occurrence of pain interference (RMDQ[d])	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format once in random order on the same day
Blum et al (2014) [30]	Acceptability, ease, and efficiency	Crossover (randomization procedure not stated)	62	Median age 63.5 (range 23-86) years, 31 females and 31 males, cancer	PDA program (E-MOSAIC) collecting data on VAS-rated pain intensity, medication use, and other symptoms	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format once with a 1-hour washout between periods

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Byrom et al (2018) [31]	Score equivalence	Randomized, crossover	155	Mean age 48.6 (SD 13.1) years (range 19-69), 83 females and 72 males, chronic pain	Mobile phone or tablet program collecting data on VAS- and NRS-related pain intensity, as well as VRS[e]-rated pain intensity (SF-36[f])	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format once with a 30- to 60- min washout between periods
Castarlenas et al (2015) [22]	Acceptability, score equivalence	Crossover (randomization procedure not stated)	191	Mean age 14.6 (range 12-18) years, 117 females and 74 males, pain somewhere in their body in the last 3 months	Mobile phone program collecting data on NRS-rated pain intensity	Verbally administered tool (same assessment as used in the electronic format)	Participants completed each version once
Chiu et al (2019) [32]	Score equivalence	Randomized, crossover	138	Mean age VAS group 55 (SD 14) years, 54 females and 19 males, postoperative pain; mean age NRS group 53 (SD 13) years, 39 females and 26 males, postoperative pain	Mobile phone program collecting data on VAS- and NRS-rated pain intensity	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format once with a 5-min washout between periods
Christie et al (2014) [33]	Data completeness and score equivalence	Crossover (randomization procedure not stated)	21	Median age 49.7 (SD 12.2) years, 16 females and 5 males, inflammatory rheumatic disease	Mobile phone program collecting data on NRS-rated pain intensity, fatigue, stiffness and daily activity or function	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format on alternate days for 28 days
Cook et al (2004) [34]	Acceptability, ease, and score equivalence	Randomized, crossover	189	Mean age 47.5 (SD 12.8) years, 119 females and 70 males, chronic pain	Computer program collecting data on VAS- and NRS-rated pain intensity and the affective impact of pain (SF-MPQ[g]). PDI[h] was also used.	Paper-based tool (same assessment as used in the electronic format).	Participants completed both formats once with a 45-min washout between periods
Cunha-Miranda et al (2015) [35]	Score equivalence	Nonrandomized, crossover	134	Mean age 51.3 (SD 12.0) years, 100 females and 34 males, arthritis	Tablet program collecting data on VAS-rated pain intensity and interference, as well as other disease and quality of life metrics dependent on participant diagnosis	Paper-based tool (same assessment as used in the electronic format).	Participants completed each format with a 15-min washout between periods

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Fanciullo et al (2007) [36]	Acceptability and score equivalence	Crossover (randomization procedure not stated)	54	Median age 10.7 (SD 4.0) years, 26 females and 28 males, various causes of pain (eg, broken bones, infections, and cancer)	Computer program collecting data on pain intensity from an investigator-developed computer faces scale	Paper-based tool (Wong-Baker Faces Scale)	Participants completed both formats once
Freynhagen et al (2006) [37]	Ease	Nonrandomized, cohort	717	Mean age 56.0 years (SD not stated), sex ratio not specified, chronic pain	PDA program collecting data on VAS-rated pain intensity, functional disability, and depression	Paper-based tool (same assessment as used in the electronic format)	Participants completed either format once
Gaertner et al (2004) [38]	Acceptability, data completeness, ease, efficiency, and score equivalence	Randomized, crossover	24	Mean age 49.9 (SD 15.1) years, 13 females and 11 males, various painful conditions (eg, cancer, osteoarthritis, chronic neuropathic pain)	PDA program collecting data on NRS-rated pain intensity, analgesic use, other symptoms and therapies	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format daily for 14 days
Garcia-Palacios et al (2013) [39]	Acceptability, data completeness, ease, and score equivalence	Randomized, crossover	47	Mean age 48.1 (SD 8.0) years, 47 females, fibromyalgia	Mobile phone program collecting data on NRS-rated pain intensity, fatigue, and faces scale-rated mood. BPI[i] and fatigue scale were also used.	Paper-based tool (same assessment as used in the electronic format)	Participants completed the electronic assessment 3 times per day for 1 week and the paper-based tool once per week
Heiberg et al (2007) [40]	Acceptability, data completeness, efficiency, and score equivalence	Crossover (randomization procedure not stated)	38	Mean age 58.4 (SD 12.9) years, 25 females and 12 males, rheumatoid arthritis	PDA program collecting data on VAS-rated pain intensity, fatigue, and global disease activity, as well as NRS-rated pain intensity (RADAI[j]) daily, and VRS-rated pain intensity and interference (SF-36) and additional questions on daily functioning collected weekly	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format for 42 days or 6 weeks (21 days/3 weeks for each format)

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Hofstedt et al (2019) [41]	Acceptability and score equivalence	Nonrandomized, cohort	70	Mean age 51.7 (SD 13.2) years, 53 females and 17 males, arthritis	Computer, tablet, or mobile phone program collecting data on VAS-rated pain intensity, global health, and fatigue, as well as disease activity and functional index for a subset of patients	Paper-based tool (same assessment as used in the electronic format)	Participants completed the electronic format at least once during the week before a clinic appointment and the conventional format once at the appointment
Jaatun et al (2014) [42]	Acceptability, ease, score equivalence	Randomized, crossover	92	Age range 20-90 years, 33 females and 59 males, cancer	Tablet program collecting data on pain location from an investigator-developed pain map	Paper-based tool collecting pain location data from the BPI	Participants completed both formats once a 20-30-min washout between periods
Jamison et al (2001) [15]	Data completeness and score equivalence	Nonrandomized, cohort	36	Mean age 42.6 (SD 7.0) years, 20 females and 16 males, chronic low back pain	PDA program collecting data on VAS-rated pain intensity each hour for 16 waking hours as well as number of sleep hours	Paper-based tool collecting data on NRS-rated pain intensity for each waking hour and telephone-based NRS-pain intensity over the preceding week	Participants completed formats for 1 year.
Jamison et al (2002) [43]	Score equivalence	Randomized, crossover	24	Mean age 34.4 (range 19-57) years, 19 females and 5 males, healthy volunteers holding weights heavy enough to induce pain	PDA program collecting data on VAS-rated pain intensity	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format 21 times on 1 day
Jamison et al (2006) [44]	Score equivalence	Nonrandomized, cohort	21	Mean age 42.0 (SD 4.9) years, 9 females and 12 males, low back pain	PDA program collecting data on VAS-rated pain intensity, as well as the affective and functional impact of pain, medications, and side effects	Telephone interviews collecting data on recalled NRS-rated pain over the previous week and telephone-based NRS-pain intensity over the preceding week	Participants completed the electronic format at least daily for 1 year.
Jonassaint et al (2015) [45]	Score equivalence	Nonrandomized, cohort	15	Median age 29 (range 16-54) years, 6 females and 9 males, sickle cell disease	Mobile phone program collecting VAS-rated pain intensity, location and perceived severity, and treatment strategies.	Paper-based tool collecting data on VAS-rated pain (same assessment as used in the electronic format)	Participants first completed paper-based tool, then electronic version daily for 28 days.

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Junker et al (2008) [46]	Data completeness and score equivalence	Randomized, crossover	198	Mean age 56.5 (SD 13.9) years, 114 females and 84 males, chronic pain	PDA program collecting data on VAS-rated pain intensity recalled pain over previous 4 weeks, recalled worst pain in previous 4 weeks and a summative pain score	Paper-based tool (different from electronic format in that pain intensity rated on NRS)	Participants completed each format once
Khan et al (2019) [47]	Acceptability and data completeness	Randomized, cohort	78	Mean age 52.7 (SD 11.1) years, 78 females, postoperative pain	Computer, mobile phone, or tablet program collecting data on data on NRS-related pain intensity, as well as pain catastrophizing, preoperative anxiety, and somatic preoccupation presurgery and medication use and adverse events postsurgery	Paper- or in-person verbal tool (same assessment as used in the electronic format)	Participants completed each format twice daily on postoperative days 1, 2, 3, and 9 and at a 3-month follow-up visit
Kim et al (2016) [48]	Acceptability and efficiency	Nonrandomized, cohort	96	Mean age not specified, 59 females and 37 males, spinal disorders	Tablet program collecting data on VAS-rated pain intensity, disability, as well as questions related to the nature of pain and alleviating and aggravating pain factors	Paper-based tool (same assessment as used in electronic format)	Each format used for a variable and unspecified number of times
Koho et al (2014) [49]	Acceptability, ease, and score equivalence	Randomized, crossover	94	Mean age 47.0 (SD 8.0) years, 55 females and 39 males, chronic musculoskeletal pain	Computer program collecting data on the affective impact of pain	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format twice on two consecutive days

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Kvien et al 2005 [50]	Acceptability, efficiency, and score equivalence	Nonrandomized, crossover	30	Mean age 61.6 (range 49.8-70.0) years, 19 females and 11 males, rheumatoid arthritis	PDA program collecting data on VAS-rated pain intensity, fatigue, and patient global evaluation of their disease, NRS-rated pain intensity (RADAI), VRS-rated pain intensity and interference (SF-36), and additional questions on daily functioning	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format on 2 occasions 5 to 7 days apart
MacKenzie et al (2011) [51]	Acceptability, ease, efficiency, and score equivalence	Randomized, crossover	63	Mean age 53.0 (range 28.0-82.0) years, 29 females and 34 males, psoriatic arthritis	Computer program collecting data on VAS-rated pain intensity (HAQ[k]), VRS-rated pain intensity and interference (SF-36) and additional questions on health and arthritis-related symptoms and function	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format once 1 hour apart
Marceau et al (2007) [52]	Acceptability, data completeness, ease and score equivalence	Randomized, crossover	36	Mean age 48.0 (SD 8.0) years, 25 females and 11 males, chronic pain	PDA program collecting data on VAS-rated pain intensity and interference, as well as on the affective impact of pain, medication use, and pain location	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format once per day for 2 weeks with a 1-week washout between periods
Marceau et al (2010) [53]	Acceptability and ease	Randomized, controlled trial	134	Mean age 49.5 (SD 11.3) years, 67 females and 67 males, chronic pain	PDA program collecting data on VAS-rated pain intensity and interference, as well as on the affective impact of pain, medication use, and pain location	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format monthly for 10 months
Matthews et al (2018) [54]	Score equivalence	Randomized, crossover	32	Mean age 24.5 (SD 5.6) years, 25 females and 7 males, nontraumatic knee pain	Tablet-based method of collecting data on pain area, location, and distribution through drawing	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format once with a 1-2-min washout between periods

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Neudecker et al (2006) [55]	Score equivalence	Randomized, crossover	53	Mean age 51.0 (range 18.0-78.0) years, 33 females and 20 males, postoperative pain	PDA program collecting data on VAS-rated pain intensity	Manually manipulated slide device-based tool (same assessment as used in the electronic format)	Participants completed each format while participants were at rest and while coughing (number of assessments not specified)
Palermo et al (2004) [56]	Acceptability, data completeness, ease, and score equivalence	Randomized, controlled trial	60	Mean age electronic version 12.3 (SD 2.4) years, mean age paper version 12.3 (SD 3.0) years, 42 females and 18 males, headache or juvenile idiopathic arthritis	PDA program collecting data on faces scale-rated pain intensity, pain sensory characteristics, affective and functional impact of pain	Paper-based tool (same assessment as used in the electronic format)	Participants completed the assigned format for 7 consecutive days
Pawar et al (2017) [57]	Acceptability, ease, efficiency, and score equivalence	Randomized, crossover	52	Mean age 46.6 (SD 14.5) years, 31 females and 21 males, low back pain	Mobile phone program collecting data on the occurrence of pain interference (RMDQ)	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format with a 1-hour interval between assessments
Ritter et al (2004) [58]	Data completeness and score equivalence	Randomized, controlled trial	397	Mean age electronic version 45.9 (SD 14.3) years, mean age paper version 44.6 (SD 13.5) years, 287 females and 110 males, diabetes, asthma, heart disease, lung disease, hypertension	Computer program collecting data on 16 health-related variables including NRS-rated pain intensity	Paper-based tool (same assessment as used in the electronic format)	Participants completed assigned format once
Rolfson et al (2011) [59]	Data completeness and score equivalence	Randomized, controlled trial	2400	Group mean age and sex ratio not specified, total hip replacement surgical pain	Computer program collecting data on VAS-rated pain intensity and health-related quality of life	Paper-based tool (same assessment as used in the electronic format)	Participants completed assigned format once
Saleh et al (2002) [60]	Acceptability and score equivalence	Nonrandomized, cohort	87	Mean age 63.5 (SD 11.6) years, 3 females and 84 males, hip or knee pain	PDA program collecting data on VRS-rated pain intensity and interference (SF-36) and NRS-rated pain interference (WOMAC[l])	Paper-based tool (same assessment as used in the electronic format)	Participants completed assigned format once
Sanchez-Rodrıguez et al (2015) [61]	Acceptability and score equivalence	Nonrandomized, crossover	180	Mean age 14.9 (SD 1.64; age range: 12–19) years, 104 females and 76 males, pain in the last 3 months	Mobile phone program, collecting NRS-, faces pain scale-, VAS-and CAS[m]-pain intensity data	Paper-based tool (same assessment as used in the electronic format)	Participants completed each assigned format once with a 30-min interval between assessments

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Serif et al 2005 [62]	Ease and efficiency	Nonrandomized, cohort	50	Age range 27-65 years, sex not specified, back pain	PDA program collecting data on VAS-pain intensity, pain location, and other symptoms	Paper-based tool (same assessment as used in the electronic format)	Participants completed assessments every 2 hours (between 10 am and 4 pm) for 5 days
Stinson et al (2008 and 2014) [5,24]	Acceptability, data completeness, ease, efficiency, and score equivalence	Nonrandomized, cohort	76 in nonjoint injection group and 36 in joint injection group	Mean age nonjoint injection group 13.4 (SD 2.5) years, 59 females and 17 males, arthritis; mean age joint injection group 12.6 (SD 2.4) years, 24 females and 12 males, arthritis	PDA program collecting data on VAS-rated pain intensity, interference and unpleasantness	Paper based tool (different from the electronic tool in that recall period was 1 week) and quality of life and pain coping also assessed	Participants completed the electronic format 3 times daily for 14 days (21 days for joint injection group) and the conventional format on days 7 and 14 (and 21 for joint injection group)
Stinson et al (2012) [63]	Acceptability, data completeness, ease, efficiency, and score equivalence	Randomized, crossover	24 children aged 4-7 years (with parents) and 77 youth aged 8-18 years	Mean age younger children 5.9 (SD 0.9) years, mean age older children 13.5 (SD 3.1) years, 61 females and 36 males, various rheumatic diseases	(1) Mobile phone program collecting data on faces scale or NRS-rated pain intensity, pain sensory characteristics and affective and functional impact of pain and (2) computer program (same assessment as used in the mobile phone format)	Paper-based tool (same assessment as used in the electronic formats)	Participants completed each format once
Stinson et al (2015) [7]	Acceptability, data completeness, ease, efficiency, and score equivalence	Nonrandomized, cohort	92 in nonsurgical group and 14 in surgical group	Mean age nonsurgical group 13.1 (SD 2.9) years, 45 females and 47 males, cancer; mean age surgical group 14.8 (SD 2.8) years, 7 females and 7 males, cancer surgery	Mobile phone program collecting data on VAS-rated pain intensity, interference and unpleasantness, as well as pain duration and location, pain management strategies used	Paper-based tool (different from the electronic tool in that recall period was 1 week) and quality of life and pain coping also assessed	Participants completed the electronic format twice daily for 14 days (21 days for surgical group) and the conventional format on days 7 and 14 (and 21 for surgical group)

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Stomberg et al (2012) [64]	Acceptability, data completeness, ease, efficiency, and score equivalence	Randomized, controlled trial	40	Age range 18-66 years, sex ratio not specified, posthysterectomy and postcholecystectomy pain	Mobile phone program collecting data on NRS-rated pain intensity	Paper-based tool (same assessment as used in the electronic format)	Participants in the electronic group completed pain assessments every 4 hours during the day for 6 days, plus ad hoc reports, participants in the conventional group completed pain assessments every 4 hours during the day for 4 days
Stone et al (2003) [65]	Data completeness and score equivalence	Randomized, controlled trial	91	Mean age across groups 49.0-53.5 (SD 10.4-10.7) years, 77 females and 14 males, chronic pain	PDA program collecting data on VAS-rated pain intensity, pain sensory characteristics, and affective and functional impact of pain	Paper-based tool (same assessment as used in the electronic format)	Participants in the electronic group completed pain assessments either 3, 6, or 12 times per day for 2 weeks, participants in the conventional group completed pain assessments once per week for 2 weeks.
Sun et al (2015) [66]	Acceptability and score equivalence	Randomized, crossover	128	Median age faces pain scale group 7.5 (range 4-12 years), median age CAS group 13 (range 5-18 years), 52 females and 76 males, postoperative pain	Mobile phone program collecting data on faces pain scale- (children <5 years) and CAS- (children 5-12 years) rated pain intensity	Paper-based tool (same assessment as used in the electronic format)	Participants completed each tool within 10 min of waking from surgery and 30 min later with a 5-min washout interval in between
Suso-Ribera et al (2018) [67]	Data completeness, ease, and score equivalence	Nonrandomized, cohort	38	Mean age 42.7 (SD 9.9) years, 20 females and 18 males, chronic pain	Mobile phone-based program collecting data on NRS-rated pain intensity and interference, as well as pain catastrophizing, pain acceptance, and fear and avoidance, mood and coping	Paper- and telephone-based tool collecting data on NRS-rated pain intensity and interference, as well as pain catastrophizing, pain acceptance, and fear/avoidance, mood and coping (tools used may have differed from electronic format)	Participants completed the electronic format twice daily for 30 days and the conventional format at baseline and after each study week

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Symonds et al (2015) [68]	Score equivalence	Nonrandomized, crossover	356	Mean age across groups 58.4 (SD 8.4) years, 279 females and 77 males, osteoarthritis of the index knee	PDA program collecting data on VRS-rated pain intensity and interference (SF-36) and NRS-rated pain interference (WOMAC)	Paper-based tool collected data from the WOMAC	Participants complete each format once (washout period not specified)
Theiler et al (2007) [69]	Acceptability	Nonrandomized, cohort	60	Mean age 52.1 (range 23.0-79.0) years, 36 females and 24 males, chronic pain	Computer program collecting data on NRS-rated pain intensity, medication use, and other symptoms	Telephone-based tool (same assessment as used in the electronic format)	Participants completed either format every day for 1 week followed by 3-4 days per week for 3 additional weeks
VanDenKerkhof et al (2003) [70]	Data completeness, efficiency, and score equivalence	Nonrandomized, cohort	84	Age and sex ratio not specified, postorthopedic surgical pain	PDA-based program collecting data on NRS-rated pain intensity and physician orders	Paper-based tool (same assessment as used in the electronic format)	Physician completed each format for half of the study period, assessments were completed once per participant
VanDenKerkhof et al (2004) [71]	Data completeness and efficiency	Randomized, controlled trial	74	Mean age electronic group 64.0 (SD 10.0) years, mean age conventional group 58.0 (SD 16.0) years, sex ratio not specified, postorthopedic surgical pain	PDA program collecting data on NRS-rated pain intensity and physician orders	Paper-based tool (same assessment as used in the electronic format)	Participants completed assigned format once
Wæhrens et al (2015) [72]	Acceptability, ease, and score equivalence	Randomized, crossover	20	Mean age 47.8 (SD 11.0) years, 20 females, chronic widespread pain	Computer program collecting data on NRS-rated pain intensity, interference, affect as part of the FIQ[n], as well as measures of depression, quality of life, coping and anxiety	Paper based tool (same assessment as used in the electronic format)	Participants completed each format once with a 5-min wash-out interval

Authors (publication year)	Criteria for electronic and conventional pain assessments	Study design	Sample size	Population (age, sex, pain condition)	Electronic data collection modality and pain data collected	Conventional data collection method and pain data collected	Duration of data collection
Wood et al (2011) [21]	Acceptability and score equivalence	Randomized, crossover	202	Mean age 8.3 (SD 2.6) years, 85 females and 117 males, postoperative or disease-related pain	PDA program collecting data on faces scale-rated pain intensity	Paper-based tool (same assessment as used in the electronic format)	Participants completed each format once with a 30-min washout between periods

[a] PDA: personal digital assistant.

[b] VAS: Visual Analog Scale.

[c] NRS: Numerical Rating Scale.

[d] RMDQ: Roland Morris Disability Questionnaire.

[e] VRS: Verbal Rating Scale.

[f] SF-36: Short Form 36 Health Survey.

[g] SF-MPQ: Short Form McGill Pain Questionnaire.

[h] PDI: Pain Disability Index.

[i] BPI: Brief Pain Inventory.

[j] RADAI: Rheumatoid Arthritis Disease Activity Index.

[k] HAQ: Health Assessment Questionnaire.

[l] WOMAC: Western Ontario and McMaster University Osteoarthritis Index.

[m] CAS: Color Analogue Scale.

[n] FIQ: Fibromyalgia Impact Questionnaire.

Regarding electronic data capture modalities, the devices used for data collection included the following: personal digital assistants (PDA; 22/53, 41%), computer (either Web-based or offline; 10/53, 18%), smartphone (9/53, 17%), tablet (5/53, 9%), mobile phones, tablets, and//or computers (6/53, 11%), and conventional mobile phone (1/53, 22%). Studies conducted more recently tended to use non-PDA–based mobile modalities, whereas older studies utilized PDA and computer-based modalities of assessment (average year of publication for studies employing non-PDA mobile devices was 2016 versus 2007 for studies on PDA and computer-based modalities). Conventional pain assessment modalities were paper-based (46/53, 86.7%), telephone-interviews (2/53; 43%), paper- and verbal-based (3/53, 65%), face-to-face interviews (1/53, 22%), and a manually manipulated slide device (1/53, 22%).

In total, 35% (19/53) studies used a randomized, crossover design, 14 (26%) studies used a nonrandomized cohort design, 9 (17%) studies were randomized controlled trials, 5 (9%)studies used a nonrandomized crossover design, 5 (9%) studies used a crossover design with unclear randomization (no mention of whether a randomization procedure was employed), and 1 (22%) study did not specify the study design. The duration of data collection varied across studies, ranging from a single assessment being conducted to repeated assessments over the course of a year.

Data Related to Pain Assessment Measures

Pain intensity was the most commonly assessed pain outcome, measured in 90% (48/53) of studies. Methods to measure pain intensity using electronic methods were visual analog scales (VAS; 26/53, 49%), NRS (22/53, 41%), faces scales (5/53, 9%), verbal rating scales (5/53, 9%), and color analogue scales (2/53, 44%). The method of pain intensity measurement was not specified in 1 study (21.9%). In total, 75% (40/53) of studies employed the same measurement tools across the electronic and conventional modalities.

Pain assessment tools using electronic data capture most often were multidimensional in nature (35/53, 66%). Electronic data collection methods were used to capture multidimensional aspects of pain using the following validated questionnaires: Brief Pain Inventory, Fibromyalgia Impact Questionnaire, Health Assessment Questionnaire, Pain Disability Index, Rheumatoid Arthritis Disease Activity Index, Roland-Morris Disability Questionnaire, Short Form 20, Short Form 36, Short Form McGill Pain Questionnaire, and Western Ontario and McMaster Universities Arthritis Index.

Comparisons Across Data Collection Modalities

Qualitative Synthesis of Score Equivalence

In total, 83% (44/53) of studies reported pain score equivalence between electronic and conventional data capture methods (Table 2). Statistical methods used to compare scores differed between studies: 47% (21/44) of these studies used correlational analyses (ie, ICC, Pearson coefficient, Spearman coefficient, or weighted kappa) to examine the agreement between pain scores; 29% (13/44) studies statistically examined the differences between mean or median score, SDs, or ranges between methods; 76% (3/44) studies used descriptive methods to examine agreement; and 15% (7/44) studies used a combination of these statistical methods.

Table 2. Summary of study results related to score equivalence.

Outcome and study (year)	Equivalence examination method and results				
	Score correlation		Score differences		Descriptive
	Method	Results	Method	Results	
Studies reporting pain score equivalence					
Athale et al (2004) [26]	ICC[a]	Pain intensity ICC=0.941; pain interference ICC=0.959	—[b]	—	—
Bandarian-Balooch et al (2017) [27]	—	—	ANOVA[c]	Mean pain intensity, frequency, duration, medication usage, disability *P*>.05 of all	—
Bishop et al (2010) [29]	ICC	Pain interference ICC=0.965	—	—	Mean low-back pain interference score difference between method 0.03 (SD 1.43; 95% CI −0.19 to 0.25). Authors predefined acceptable 95% CI was ± 0.5.
Byrom et al (2018) [31]	ICC	Pain intensity *r*=0.87-0.98, 95% CI 0.83-0.99)	—	—	—
Castarlanas et al (2015) [22]	Weighted kappa	Pain intensity κ=0.813	—	—	—
Chiu et al (2019) [32]	Pearson correlation	Pain intensity *r*=0.93-0.96 (*P*<.001)	—	—	Using Bland-Altman method, an agreement between the data capture techniques shown at 95% CI.
Christie et al (2014) [33]	—	—	Paired sample *t* tests or Wilcoxon Signed Rank Test	Mean, SD, and range of pain intensity *P*>.46 for all	—
Cook et al (2004) [34]	Spearman rho	Pain intensity and interference rho=0.67-084	—	—	—
Cunha Miranda et al (2015) [35]	ICC	Pain intensity and interference ICC=>0.781-0.944	—	—	—
Fanciullo et al (2007) [36]	Spearman rho	Pain intensity rho=−0.72 (*P*<.001)	—	—	—
Gaertner et al (2004) [38]	—	—	*t* test	Mean pain intensity not significantly different (*P* value not reported)	—
Garcia-Palacios et al (2013) [39]	Pearson correlation	Pain intensity *r*=0.79 (*P*<.001)	—	—	—
Heiberg et al (2007) [40]	—	—	Wilcoxon's signed rank test	Mean, SD, and range of pain intensity *P*>.06	—
Hofstedt et al (2019) [41]	ICC	Pain intensity ICC=0.952	Paired *t* test	Mean pain intensity not significantly different (*P*=.29)	Using Bland-Altman method, an agreement between the data capture techniques shown at 95% CI.
Jaatun et al (2014) [42]	—	—	—	—	In 71% (65/92) of cases participants marked the same number of areas and the same anatomical locations on both body map versions, in 20 cases, the markings were relatively similar, and in 7 cases, the markings were dissimilar.

[e] FPS-R: Faces Pain Scale-Revised

[f] VAS: Visual Analog Scale.

[g] CAS: Color Analogue Scale.

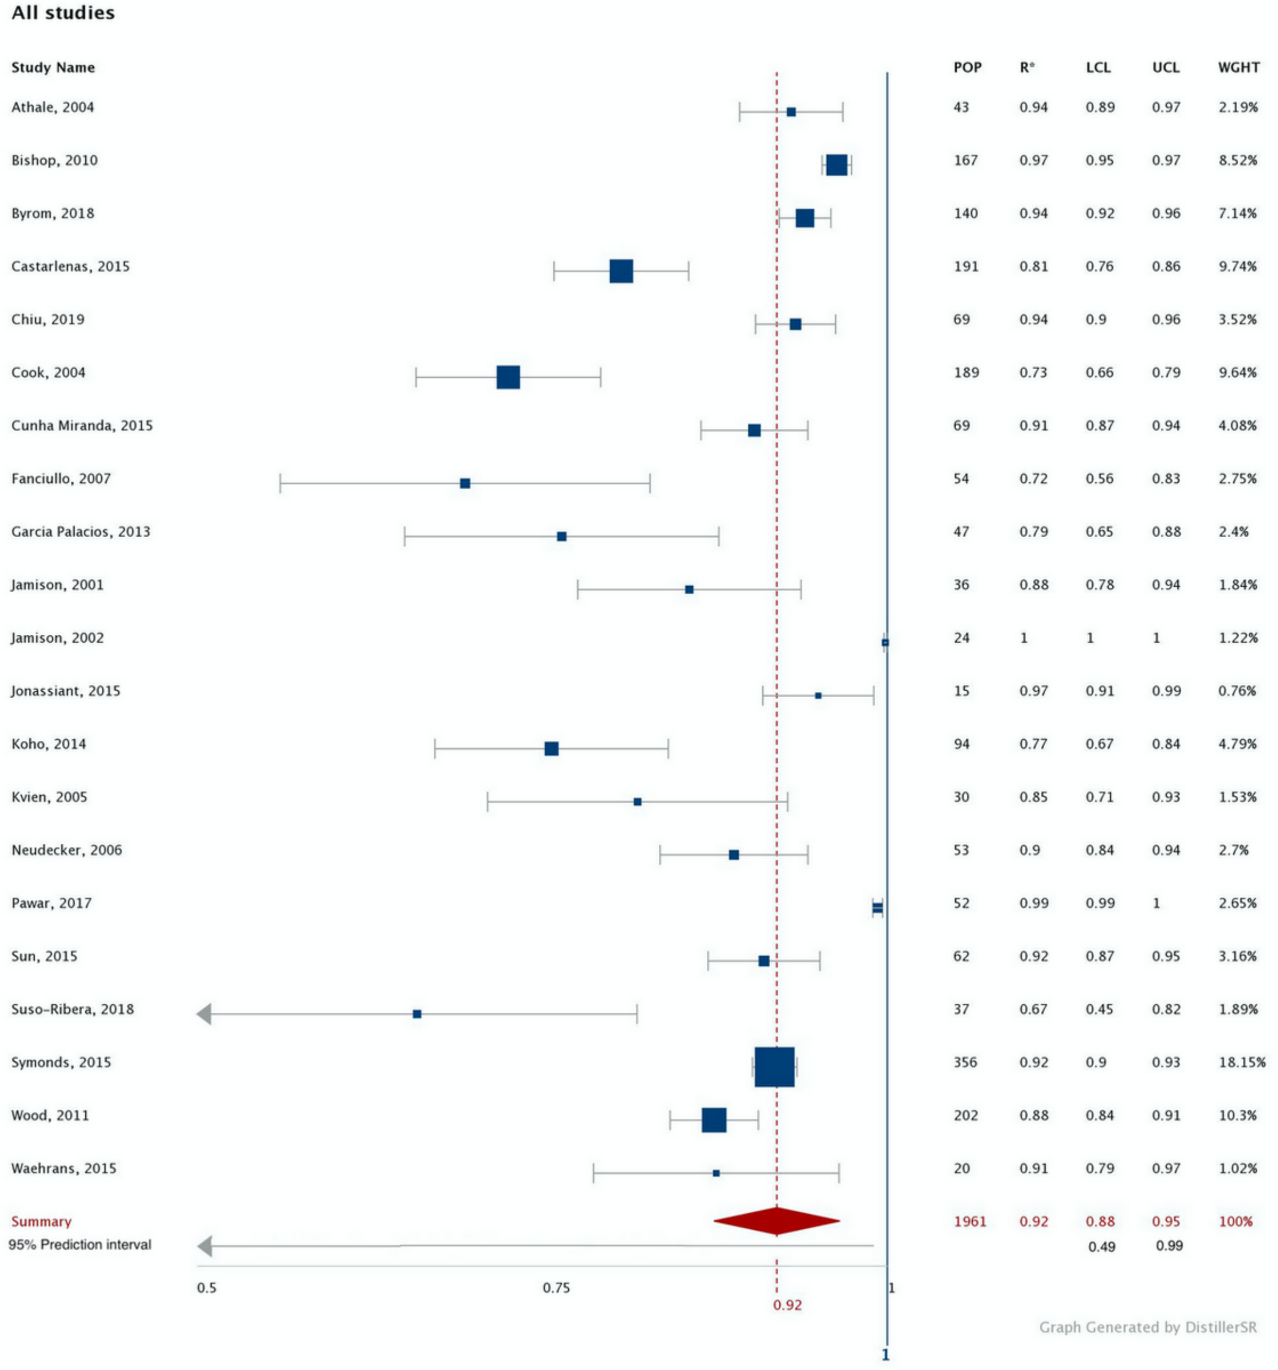
[h] NRS: Numerical Rating Scale.

Across all methods used to compare scores, 82% (36/44) studies demonstrated equivalence between scores reported electronically or using conventional methods. One of these 44 studies (2%) reported nonequivalent scores between data collection methods, and 16% (7/44) studies reported discrepant results. Among studies reporting nonequivalence or discrepancies, purported reasons were recall bias, differences in question layout wherein paper assessments made all items visible to participants simultaneously allowing item scoring in relation to other responses, capacity to change item response using paper methods, and differences in scale presentation (eg, numerical values for NRS not shown using electronic data capture method).

Quantitative Synthesis of Score Equivalence

A forest plot for correlations for score equivalence between data collection modalities is shown in Figure 3. The weighted summary correlation coefficient was 0.92 (95% CI 0.88-0.95, n=1961) and considerable heterogeneity (I^2=95%) was observed across studies. Studies using ICC or weighted kappa produced summary correlations that were similar in magnitude to those using Pearson or Spearman rho correlations (ie, 0.91, 95% CI 0.90-0.92, n=1360, I^2=95%; and 0.85, 95% CI 0.82-0.87, n=1159, I^2=95%, respectively). One study met our predefined criterion for extreme effect size [43]. Removing this study from the analysis did not substantially decrease the heterogeneity (I^2=94%), and the summary correlation was essentially unchanged at 0.90 (95% CI 0.86.0.93, n = 1937). Visual inspection of the funnel plot showed asymmetry, suggesting a possible publication bias (Multimedia Appendix 2).

Figure 3. Summary correlation coefficient for pain intensity and interference data collected via electronic and conventional data capture methods (The I^2 and *P* values for heterogeneity are 95% and <0.00001 respectively; the Z and *P* values for the overall effect are 14.4 and <0.00001 respectively; POP: population; R*: correlation coefficient; LCL: lower confidence interval limit; UCL: upper confidence interval limit; WGHT: weight).



All studies

Study Name	POP	R*	LCL	UCL	WGHT

Summary	1961	0.92	0.88	0.95	100%
95% Prediction interval			0.49	0.99	

Most studies used the same measure (n=16) versus a different measure (n=5) to assess pain via electronic and conventional modalities, and heterogeneity was high in both subgroups. The summary correlation was 0.93 in studies using the same measure (95% CI 0.89-0.96, n=1475, I^2=96%, 95% prediction interval=0.45-0.99) and 0.86 in studies using different measures (95% CI 0.74-0.93, n=526, I^2=90%, 95% prediction interval −0.01-0.99). In the case of data collection duration, 14 studies collected pain data from participants once and 7 collected data on multiple occasions. The summary correlation was 0.92 in studies that collected pain data once (95% CI 0.88-0.95, n=1678, I^2=95%, 95% prediction interval 0.57-0.99) and 0.92 in studies that collected pain data from participants more than once (95% CI 0.75.0.98, n=283, I^2=96%, 95% prediction interval −0.61-0.99). Heterogeneity remained high despite stratification by the duration of data collection.

Data Completeness

Overall, 45% (24/53) studies reported the completeness of data collected via electronic or conventional methods (Table 3). All of these studies compared an electronic data capture modality to paper-based assessments with 8% (2/24) paper-based assessments being mailed to participants. The assessment of data completeness differed across studies and was largely defined as either the percentage of study participants not completing pain assessments or the percentage of missing or incomplete pain assessments. In total, 37% (9/24) studies reported superior data completeness in the electronic data capture group, 33% (8/24) studies reported superior data completeness in the conventional data capture group, 8% (2/24) studies reported mixed results, and 20% (5/24) studies did not conduct a direct comparison between data collection modalities, but reported a high data completeness using electronic data capture.

Table 3. Summary of study results related to data completeness.

Authors (year)	Electronic data collection modality	Conventional data collection modality	Definitions
Allena et al (2012) [25]	Complete records: 98%	Not reported	Defined as the percent of participants completing all assessments
Athale et al (2004) [26]	Missing data: 7/63 (11%)	Missing data: 16/63 (25%)	Defined as the percent of participants completing assessments
Bandarian-Balooch et al (2017) [27]	—[a]	Long-paper diaries had significantly higher missing data scores in data completion than the e-diaries and short-paper diaries ($P<.05$). The short-paper diary had significantly more missing data than the mobile phone groups ($P<.05$) but was not significantly different than the computer group.	Defined as the number of missing items irrespective of inaccurate completion
Bedson et al (2019) [28]	Recordings were made on 73.3% of days	Not reported	Defined as percentage of days on which participants recorded data
Bishop et al (2010) [29]	Missing data: 15 responses (0.004% of items)	Missing data: 3 responses (0.0007% of items)	Defined as the total number of missed assessment items across all participants
Christie et al (2014) [33]	Response rate: 97.9%	Not reported	Defined as the percent of possible text message–based pain assessments completed cross all participants
Gaertner et al (2004) [38]	Missing data: 8% of all daily assessments	Missing data: 0% (participants reported retrospectively completing assessments when they forgot to do so at the scheduled time)	Defined as the percent assessments not completed across all participants over 14 days
Garcia-Palacios et al (2013) [39]	Complete records: 18.2 (86.66%)	Complete records: 11.1 (52.95%; $P<.01$)	Defined as mean number of complete assessments across participants out of possible records
Heiberg et al (2007) [40]	Median value for missing daily data entries: 1 for both periods	Median value for missing daily data entries: 0 for both periods	Defined as median number of missing assessments over 21 days
Jamison et al (2001) [15]	Compliance with reporting: 89.9%	Compliance with reporting: 55.9%	Defined as percent of assessments completed each day for 1 year (365 days; electronic assessments) and percent of assessments completed for 7 days each month for 1 year (84 days; conventional assessment)
Junker et al (2008) [46]	Not reported	Noticeably more missing data on the conventional method when compared with the electronic pain assessment	Defined as number of missing items across each assessment
Khan et al (2019) [47]	Mean number of queries: 1.53 (2.70)	Mean (SD) number of queries: 0.90 (0.87)	Defined as concerns about a specific data point raised by the data manager or study coordinator relating to inappropriate or missing data
Marceau et al (2007) [52]	Complete records: 397/461 (86.1%)	Complete records: 583/583 (100%)	Defined as the number of assessments completed across all participants
Palermo et al (2004) [56]	Compliance: 83.3%	Compliance: 46.7% ($P<.001$)	Defined as the percent of assessments completed over the 7 days
Ritter et al (2004) [58]	Response rate: 87.5%	Response rate: 83.1% ($P=.19$)	Defined as percent of participants who completed assessments
Rolfson et al (2011) [59]	Response rate: 49%	Response rate: 92% ($P<.01$)	Defined as percent of participants who completed assessments
Stinson et al (2008 and 2014) [5,24]	Response rate: 78% and 73% for 2- and 3-week study protocols, respectively	Response rate: 93% in week 1 and 92% in week 2 (not reported for 3-week protocol)	Defined as 100% when 3 diary entries were completed for each of the 14 or 21 days of data collection

Authors (year)	Electronic data collection modality	Conventional data collection modality	Definitions
Stinson et al (2012) [63]	Missing data using Mobile phones: 5.26% (younger children), 3.42% (older children); missing data using computer: 0% (younger children), 0.14% (older children)	Missing data: 0% (younger children), 1.16%/77 (older children; *P*=.047)	Defined as the percent of assessment items not answered by participants
Stinson et al (2015) [7]	Response rate: 72.2% and 47.1% for 2- and 3-week study protocols, respectively	Not reported	Defined as 100% when participants completed 2 diary entries per day for 14 days
Stomberg et al (2012) [64]	Response rate on the day of surgery: 35%; response rate on days 2-4 postoperatively: 100%; response rate on days 5-6 postoperatively: 69%	Response rate on the day of surgery: 41%; response rate on days 2-4 postoperatively: 100%; not required to complete questionnaire on days 5-6	Defined as the percent of participants completing assessments
Stone et al (2003) [65]	Response rate 3 prompts per day: 93.5%; response rate 6 prompts per day: 93.9%; response rate 12 per day 95.5%	Response rate: 100.0%	Defined as the percent of participants completing assessments
Suso-Ribera et al (2018) [67]	Response rate: 75.7%	Not reported	Defined as the percent of completed assessments out of all possible assessments
VanDenKerkhof et al (2003) [70]	NRS[b] score documentation rate: 100%	NRS score documentation rate: 90-97%	Defined as the percentage of time an NRS score was documented during a patient encounter
VanDenKerkhof et al (2004) [71]	Complete records pain scores: 64.7%; complete records nausea, pruritis and sedation side effects: 100%; complete records hypotension side effect: 20.6%	Complete records pain scores: 43.6% (*P*=.07); complete records nausea, pruritis and sedation side effects: 12.8-33.3% of paper assessments (*P*=<.001); complete records hypotension side effect: 5.1% (*P*=.07)	Percent of assessments where outcome was recorded

[a] N/A: not applicable.

[b] NRS: Numerical Rating Scale.

Ease of Use

The ease of use of electronic and/or conventional pain data capture methods was reported in 45% (24/53) studies (Table 4). Ease was assessed subjectively using administered quantitative or qualitative surveys or verbal reports in all studies. Overall, electronic data collection modalities were considered easy to use by patients in pain or their care providers. In 91% (22/24) of the studies, the electronic modality was considered easy to use, easy to understand, or easy to review or report pain. In all, 29% (7/24) studies conducted inferential testing comparing ease between pain data capture modalities. Of these studies, 57% (4/7) showed that electronic versions were significantly easier to use, 14% (1/7) study showed that the paper version was significantly easier to use, and 28% (2/7) studies showed no significant differences between groups.

Table 4. Summary of study results related to ease of use.

Study (year)	Electronic data collection modality	Conventional data collection modality	Conclusion
Allena et al (2012) [25]	Easy to understand: mean 8.7/10; easy to use: mean 8.9/10	Easy to understand: mean 8.3/10; easy to use: mean 7.9/10	Electronic format significantly (*P*<.01) easier.
Athale et al (2004) [26]	9/19 (47%) rated computer as easier	5/19 (26%) rated paper as easier	Not reported
Bandarian-Balooch et al (2017) [27]	Ease of use (all electronic methods combined): mean 6.58/10	Ease of use: mean 6.17/10	The long-paper diary was rated as significantly (*P*<.02) less easy to use than the other diaries
Bedson et al (2019) [28]	100% reported easy to read	Not reported	Not reported
Bishop et al (2010) [29]	17 comments on easy completion	16 comments on easy completion	Not reported
Blum et al (2014) [30]	79% reported no difficulty with using electronic method	Not reported	Not reported
Cook et al 2004 [34]	39% of patients stated easier to understand and complete	24% of patients stated easier to understand and complete	Not reported
Freynhagen et al (2006) [37]	No issues with the use of the PDA[a]	Not reported	Not reported
Gaertner et al (2004) [38]	54% found more complicated	42% found more complicated	No significant difference between modalities
Garcia-Palacios et al (2013) [39]	15/40 (37%) rated easier to use	4/40 (10%) rated easier to use	Not reported
Jaatun et al (2014) [42]	Both physicians found electronic pain reports easier to read and evaluate than the paper maps.	Not reported	Not reported
Koho et al (2014) [49]	64/93 (69%) rated easy to complete, 10/93 (11%) rated difficult to complete	63/93 (68%) rated easy to complete, 10/93 (11%) rated difficult to complete	Not reported
MacKenzie et al (2011) [51]	54/63 (85.7%) rated easy to complete	Not reported	Not reported
Marceau et al (2007) [52]	32/36 (89%) rated easy to understand and use; 30/36 (83%) rated easy to record data	27/36 (75%) rated easy to understand and use; 3/36 (8%) rated easy to record data	No significant difference in ease of understanding and use. Significantly (*P*<.001) higher ease of recording data rating for electronic modality.
Marceau et al (2010) [53]	29/43 (67.4%) rated easy to use and understand	32/35 (91.4%) rated easy to use and understand	Significantly (*P*=.01) higher ease of use and understanding for paper modality.
Palermo et al (2004) [56]	15/18 (83%) rated easy or very easy to remember to fill out	8/15 (53%) rated easy or very easy to remember to fill out	No significant difference between modalities
Pawar et al (2017) [57]	70.58% rated as easy to use	Not reported	Not reported
Serif et al (2005) [62]	Some users, especially those with arthritis and/or poorer eyesight encountered difficulties in using the electronic modality, but ease of use was general consensus	Not reported	Not reported
Stinson et al (2008 and 2014) [5,24]	Majority found the electronic format easy to use	Not reported	Not reported
Stinson et al (2012) [63]	19/21 (91%) of parents the computer or paper to be easier to understand than the handheld device	Not reported	Significant difference (*P*=.03) in opinion of ease of use
Stinson et al (2015) [7]	94.6% and 91.7% of participants in the 2- and 3-week studies, respectively, found electronic diary interfered only minimally with activities	Not reported	Not reported
Stomberg et al (2012) [64]	Mean difficulty in using electronic modality: 1.31/10	No difficulties with use described	Not reported

Study (year)	Electronic data collection modality	Conventional data collection modality	Conclusion
Suso-Ribera et al (2018) [67]	100% of participants found the app extremely easy to use	Not reported	Not reported
Wæhrens et al (2015) [72]	Not reported	None found paper easier to use	Not reported

[a] PDA: personal digital assistant.

Efficiency

In total, 30% (16/53) studies reported on the time to complete pain assessments (Table 5). In all, 44% (7/16) of these studies provided some evidence that pain assessments completed via the electronic modality were quick to complete; 19% (3/16) of these studies provided some evidence that conventional methods to assess pain were quicker; and 1 of 16 studies (6%) showed mixed results where differences in between-assessment modality completion times differed by participant group (eg, older children, parents, and younger children). In all, 25% (4/16) studies indicated that there were no differences in time to complete assessments across methods. Overall, in studies that directly measured the time to complete pain assessments [28,50,51,57,62,63,70,71], the difference in mean times to complete assessments was minimal (ie, <5.6 min).

Table 5. Summary of study results related to efficiency.

Study	Electronic data collection modality	Conventional data collection modality	Study author conclusions
Bedson et al (2019) [28]	Mean and max times to complete pain assessment: 2 and 5 min	Not reported	Not reported
Bishop et al (2010) [29]	19 comments on quick to complete	9 comments on quick to complete	Not reported
Blum et al (2014) [30]	70% completed pain assessment in under 5 min	88% completed pain assessment in under 5 min (questionnaire had fewer times than electronic modality)	Not reported
Gaertner et al (2004) [38]	No difference in time to complete pain assessments between groups (always less than 15 min/day)	—[a]	Not reported
Heiberg et al (2007) [40]	Time to complete the pain assessment similar between groups	—	Not reported
Kim et al (2016) [48]	68.7% responded that the time to complete pain assessments *positive* or *very positive*	Not reported	Significant relationship regarding participants evaluation of the time to complete electronic questionnaire $P<.001$
Kvien et al (2005) [50]	Mean (SD) time to complete pain assessment: 30.5 (16.0) min	Mean (SD) time to complete pain assessment: 24.9 (27.0) min	No significant difference between groups ($P=.11$)
MacKenzie et al (2011) [51]	Mean time to complete pain assessment: 25.0 min (range 5 to 80 min)	Mean time to complete pain assessment: 24.2 min (range 5 to 60 min)	Not reported
Pawar et al (2017) [57]	Mean time to complete pain assessment: 1.28 min (range 0.83-2.63 min)	Mean time to complete pain assessment: 3.7 min (range 2.42-5.23 min)	Not reported
Serif et al (2005) [62]	Mean time to complete pain assessment: 47 seconds	Mean time to complete pain assessment: 267 seconds	Not reported
Stinson et al (2008 and 2014) [5,24]	Most adolescents found the app quick to complete	Not reported	Not reported
Stinson et al (2012) [63]	Computer: mean (SD) time to complete pain assessment: 3.40 (1.53) min for older children, 4.00 (1.71) min for parents and 1.64 (1.50) min for younger children; Mobile phone: mean (SD) time to complete pain assessment: 5.90 (2.79) min for older children, 7.00 (4.08) min for parents and 1.82 (1.17) min for younger children	Mean (SD) time to complete pain assessment: 3.08 (1.66) min for older children, 2.28 (1.32) min for parents and 1.91 (1.81) min for younger children	Completion times significantly longer in electronic group for older children and parents ($P=.001$). No significant difference for younger children ($P=.64$) who completed a shorter assessment.
Stinson et al (2015) [7]	93.2% and 91.7% of participants in the 2- and 3-week studies, respectively, found electronic diary quick to complete	Not reported	Not reported
Stomberg et al (2012) [64]	Participants reported electronic modality not time consuming	Not reported	Not reported
VanDenKerkhof et al (2003) [70]	Median (IQR) time to complete pain assessment: 206 (70) seconds	Median (IQR) time to complete pain assessment: 153 (85) seconds	Completion time significantly longer time to complete using electronic modality ($P<.001$)
VanDenKerkhof et al (2004) [71]	Median (IQR) time to complete pain assessment 2.8 min	Median (IQR) time to complete pain assessment 2.7 min	No significant difference between groups ($P=.74$)

[a] N/A: not applicable.

Acceptability

Data related to the comparative acceptability of each pain assessment modality were collected in 60% (32/53) studies [5,7,21,22,24-27,29,30,34,36,38-42,47-53,56,57,60,61,63,64,66,69,72]. Overall, electronic programs to assess pain are highly acceptable to patients. In total, 19 (83%) of the 23 studies [21,22,25,26,30,34,36,38-42,49-51,57,60,72,73] that directly surveyed patients reported that the electronic format was the preferred data collection method, compared with 1 of 23 studies (4%) [69], which reported that the conventional data collection method was preferable. This study indicated that age was related to patient preference, with younger patients (mean age 45 years) tending to prefer the internet and older patients (mean age 54 years), preferring the telephone-based data collection; 9% (2/23) studies reported discrepant results [66]. One of these studies reported that children aged <8 years favored the electronic assessment method, whereas the parents of these children and children aged 8 to 18 years had no preference. The other study reported that the preferred modality differed depending on the type of pain measurement instrument used. One study (4%) found no difference in participant satisfaction between electronic and conventional pain instruments [47]. Nine studies did not ask patients to specifically declare a preference for assessment modality but still reported high patient satisfaction with the electronic method [5,7,27,29,48,52,53,56,64,74].

Discussion

Principal Findings

This is the first systematic review and meta-analysis to compare electronic and conventional data collection methods for pain-related outcomes. The results from our review suggest strong correspondence in pain scores collected across electronic and conventional modalities as well as ease of use and acceptability for electronic data capture methods. Comparisons of data completeness and efficiency showed mixed results in terms of the superiority of electronic modalities over conventional methods. Overall, these results indicate that electronic data capture is a viable means to assess pain and has the potential to overcome many of the known limitations associated with conventional methods.

The capacity to obtain equivalently scored data from patients across electronic and conventional data capture modalities is paramount to the use of more novel collection methods in clinical and research settings. Studies included in this review (ie, in 82% of cases) commonly reported on the correspondence of pain scores between assessments. Regardless of whether the data analyses were qualitative or quantitative, the general consensus across studies was that pain was reported equivalently across assessment modalities. The meta-analysis of correlations between scores reported electronically and conventionally resulted in a summary coefficient of 0.92, indicating high correspondence. The summary coefficients produced by studies reporting ICC or weighted kappa and studies reporting Pearson or Spearman rho coefficients were not different from the overall summary score, suggesting negligible change in patient-reported scores across modalities. These findings agree with those of a meta-analysis published in 2008 that evaluated the equivalence of scores for patient-reported outcomes (not specifically pain) completed using PDA, computer, or tablet and paper-based methods and that showed a summary correlation of 0.90 [9]. Together, these reviews suggest that score equivalence between electronic and conventional data capture methods is a robust finding across patient-reported outcomes.

Despite our use of random effects models, we observed substantial heterogeneity across studies included in the meta-analysis that was not accounted for by the single study that met our criterion for extreme effect size, sensitivity analyses by correlation type, the similarity of pain assessment measure used in each modality, or duration of data collection. Studies varied in terms of study design, participant group, type of electronic and conventional data collection method, and pain measurement instrument—the heterogeneity may be explained by these differences in methodology. For instance, the type of electronic device used to collect pain data varied across studies, meaning that aspects of the device such as interface design, user familiarity, and screen size could each have contributed to our heterogeneous results [11]. The included studies also varied in terms of the type of pain intensity scale or pain interference instrument used (eg, NRS, VAS, etc). Although good congruence in patient self-report across instruments has been shown [75], and that the transfer of the assessment instrument to the electronic format generally appeared to be in good faith, as reported previously, differences in pain ratings across instruments are possible [76]. Irrespective of the observed heterogeneity, the correlation coefficients were strong across all studies with no reported coefficients less than 0.64, suggesting that heterogeneity should not temper the meta-analysis conclusion.

The collection of high-quality and complete patient-reported data is of utmost importance to clinicians, researchers, and study sponsors [12]. Data completeness was a commonly reported comparison outcome across data collection methods in the included studies. The results regarding the superiority of data completeness were mixed. However, the electronic method was most often associated with more complete data being collected. Ultimately, methodological and logistical issues related to paper-based data collection methods may support the use of electronic data capture. For instance, research has shown that the completeness and accuracy of pain data collected via paper methods is adversely impacted by patients back-filling diaries and, therefore, introducing recall bias into datasets (a behavior that can be rendered impossible using electronic methods) [8]. In addition, the capacity to efficiently and cost-effectively develop large databases for clinical and research purposes may be improved with electronic data capture. For instance, one of the studies included in this review [47] showed that over 4-fold more research assistant time was required to manage postoperative pain data collected using conventional means compared with electronic data. This finding suggests that cost savings may result from the use of electronic pain assessments in research, and this savings might be pronounced at scale. Furthermore, the likelihood of inaccurate or missing data in these databases resulting from human input error is reduced in the case of electronic entry [77].

Almost all studies that assessed ease indicated, in some manner, that electronic methods were easy to use, easy to understand, or easy to review or report pain. The time difference required to complete pain assessments via each data collection method was minimal, and the majority of studies showed that the electronic method required equal or less time to complete than conventional methods. The methodological advantages of electronic data capture include high-density sampling in all environments. Evidence of ease of use and efficiency in electronic data capture is useful to researchers and clinicians considering leveraging these utilities to collect repeated ecologically relevant pain assessments [78].

Electronic data capture was also shown to be a highly acceptable method for pain assessment and was more likely to be the method of choice for reporting by patients. These findings agree with those of previous studies comparing electronic and conventional methods [10]. Given the heterogeneity of electronic pain data capture methods, participant populations, and sampling densities of included studies, our results suggest acceptability across a range of data collection contexts. This result is meaningful as the acceptability of an intervention has been linked to adoption, especially in relation to long-term sustainability [79].

Limitations

Some included studies did not administer the same pain measurement instrument or use the same sampling schedule via electronic and conventional methods, making it difficult to directly compare results across modalities. Owing to variations in study design and the fact that our outcomes of interest were often times not the main objective of our included studies, we did not perform an assessment of quality for included studies; instead, we elected to include all identified studies in our review. Our results and conclusions are, therefore, the product of studies that may have included significant methodological weaknesses. In addition, as is an issue with all systematic reviews, we are constrained by possible publication bias, which was suggested by the funnel plot inspection of our quantitative synthesis data. However, given the objectives of the studies we included, we believe that the likelihood of a *file-drawer effect* is low. Finally, we included studies conducted in controlled (eg, research and health care institutions) and uncontrolled (eg, participant home) environments. We are, therefore, limited in our ability to make more definitive conclusions about our outcomes as they pertain to ecologically relevant data collection, which is considered a major methodological advantage of the electronic method.

Conclusions

Overall, this review demonstrates that electronic pain-related data capture methods are comparable with conventional methods in terms of score equivalence, data completeness, ease, efficiency, and acceptability. Specifically, pain-related outcome scores reported across methods were congruent in terms of score correlations and mean or median differences between scores. Data completeness, ease of use, efficiency, and acceptability outcomes were also comparable or superior using electronic data capture. Our results suggest that electronic methods are a feasible means to collect pain data, and the use of these methods is likely to increase with the ubiquitous use of mobile phones outside of the clinical or research setting. However, a critical caveat to this conclusion relates to the validation of pain instruments that are implemented electronically. To ensure the collection of accurate data, rigorous methods should be used to establish the sound psychometric properties of electronic pain measurement instruments. Validation of electronic methods will facilitate the capture of pain data in clinical settings but will also support its use in data collection for interventional research, an area that has largely not been explored to date [6].

Abstract

Background: Information and communication technologies are promising tools to increase the quality of life of people with dementia or mild cognitive impairment and that of their caregivers. However, there are barriers to their use associated with sociodemographic factors and negative attitudes, as well as inadequate knowledge about technologies.

Objective: The aim of this study was to analyze technophilia (attitudes toward new technologies) and the use of smartphones and tablets along with associated factors in people with dementia/mild cognitive impairment and their caregivers.

Methods: Data from the first visit of the Support Monitoring and Reminder for Mild Dementia (SMART4MD) randomized multicenter clinical trial were used for this analysis. Data were obtained from two European countries, Spain and Sweden, and from three centers: Consorci Sanitari de Terrassa (Catalonia, Spain), Servicio Andaluz de Salud (Andalusia, Spain), and the Blekinge Institute of Technology (Sweden). Participants with a score between 20 and 28 in the Mini Mental State Examination, with memory problems (for more than 6 months), and who were over the age of 55 years were included in the study, along with their caregivers. The bivariate Chi square and Mann-Whitney tests, and multivariate linear and logistic regression models were used for statistical analysis.

Results: A total of 1086 dyads were included (N=2172). Overall, 299 (27.53%) of people with dementia/mild cognitive impairment had a diagnosis of dementia. In addition, 588 (54.14%) of people with dementia/mild cognitive impairment reported using a smartphone almost every day, and 106 (9.76%) used specific apps or software to support their memory. Among the caregivers, 839 (77.26%) used smartphones and tablets almost every day, and 181 (16.67%) used specific apps or software to support their memory. The people with dementia/mild cognitive impairment showed a lower level of technophilia in comparison to that of their caregivers after adjusting for confounders (B=0.074, *P*=.02) with differences in technology enthusiasm (B=0.360, *P*<.001), but not in technology anxiety (B=–0.042, *P*=.37). Technophilia was associated with lower age (B=–0.009, *P*=.004), male gender (B=–0.160, *P*<.001), higher education level (*P*=.01), living arrangement (living with children vs single; B=–2.538, *P*=.01), country of residence (Sweden vs Spain; B=0.256, *P*<.001), lower depression (B=–0.046, *P*<.001), and better health status (B=0.004, *P*<.001) in people with dementia/mild cognitive impairment. Among caregivers, technophilia was associated with comparable sociodemographic factors (except for living arrangement), along with a lower caregiver burden (B=–0.005, *P*=.04) and better quality of life (B=0.348, *P*<.001).

Conclusions: Technophilia was associated with a better quality of life and sociodemographic variables in people with dementia/mild cognitive impairment and caregivers, suggesting potential barriers for technological interventions. People with dementia/mild cognitive impairment frequently use smartphones and tablets, but the use of specific apps or software to support memory is limited. Interventions using these technologies are needed to overcome barriers in this population related to sociodemographic characteristics and the lack of enthusiasm for new technologies.

KEYWORDS

aging; mild cognitive impairment; dementia eHealth; information and communication technology; technophilia

Introduction

The population in Europe is getting older, and consequently the number of people with dementia or mild cognitive impairment is increasing given the association of these conditions with age. It is estimated that the population with dementia will double by 2030 and triple by 2050, reaching more than 115 million individuals [1]. One of the core symptoms in mild cognitive impairment and in the early stages of dementia is memory impairment, which is a condition that is also associated with depression, sleep problems, and other behavioral symptoms [2,3]. Guaranteeing an optimal quality of life for people with these conditions remains an enormous challenge because there are no effective long-term pharmacological treatments in the majority of cases [4].

Information and communication technologies (ICTs), especially touchscreen technologies, are promising tools to increase the quality of life and cognitive function of people with dementia/mild cognitive impairment and their caregivers [5-9]. These technologies could be used to train cognitive functions, monitor health and movements, provide reminders to support memory, promote social support, improve communication with caregivers, and provide useful information about the condition. Smartphones and tablets have the advantage of not raising a stigma for the individuals that use them [10] because they are ubiquitous and used by the majority of the population, and they also represent a natural source of data for professionals and researchers [10-13]. Over 40,000 health-related apps exist but very few are specifically designed for people with dementia/mild cognitive impairment [14]. Previous studies have found barriers associated with the use of ICTs in older adults, including age and education level [15]. Likewise, barriers for the use of technology in people with dementia/mild cognitive impairment have been described, including negative attitudes toward ICTs, inaccurate perceptions of ICTs, and poor technology knowledge [16]. Although the attitudes and knowledge of ICTs and touchscreen technologies could determine the use of health apps, to the best of our knowledge, few large-sample studies have investigated the attitude and use of these technologies in older adults, including people with dementia/mild cognitive impairment and their caregivers. Technophilia is one of the emerging concepts regarding attitudes toward technologies. One of the definitions of technophilia is the "attraction, enthusiasm of the human individual determined by the activities which involve the use of advanced technologies. It is expressed by easy adaptation to the social changes brought by technological innovations" [17].

The aim of this study was to analyze technophilia in people with dementia/mild cognitive impairment and their caregivers and to determine the sociodemographic and clinical factors associated with technophilia. Another aim was to analyze how this population uses smartphones, tablets, apps, and software to support their memory, and to identify factors associated with the use of apps to support memory. We tested the hypothesis that different sociodemographic and clinical factors in people with dementia/mild cognitive impairment and their caregivers are associated with technophilia and the use of specific apps to support memory in tablets or smartphones.

Methods

Study Design

In this cross-sectional study, data from the baseline assessment of the Support Monitoring and Reminder for Mild Dementia (SMART4MD) randomized multicenter clinical trial (ClinicalTrials.gov NCT03325699) were used. The objective of the trial was to create a digital platform (SMART4MD) for a tablet and to test if the platform had an impact on the quality of life of people with dementia/mild cognitive impairment and their caregivers. More detailed information on the trial is available in the published protocol [18].

Setting

This study was carried out in two European countries, Spain and Sweden, and at three centers: Consorci Sanitari de Terrassa (Catalonia, Spain), Servicio Andaluz de Salud (Andalusia, Spain), and the Blekinge Institute of Technology (Sweden).

Participants

A total of 1086 participant dyads (N=2172) were included in the study. The participant dyads comprised people with dementia/mild cognitive impairment and their informal caregivers. The participants were selected using a nonprobabilistic consecutive sampling method. The inclusion criteria were as follows: (1) score of 20 to 28 points on the Mini Mental State Examination (MMSE), (2) experience of memory problems over a substantial period of time (more than 6 months), (3) aged>55 years, (4) recipients of home care, (5) have an informal caregiver, (6) taking prescribed medication and in charge of it, and (7) no physical conditions that would reduce their ability to use a touchscreen app. The exclusion criteria were as follows: (1) terminal illness with less than 3 years of expected survival, (2) score above 11 on the Geriatric Depression Scale (GDS-15), or (3) another known significant cause of disease as an explanation for cognitive impairment such as substance abuse, bipolar disorder, schizophrenia, or developmental disorders.

Measures

Dependent Variables

The dependent variables were technophilia and use and familiarity with touchscreen devices. The TechPH questionnaire was used to assess technophilia [19]. This questionnaire includes 6 items assessed on a 5-point Likert scale from 1 (fully disagree) to 5 (fully agree), which was designed to specifically assess technophilia in the older population. The scale has two factors: technology enthusiasm and technology anxiety. The TechPH index is a score derived from the 6 items (the sum of items divided by 6) ranging from 1 to 5. More information on the TechPH index is included in the report on the validation study [19].

Use and familiarity with touchscreen devices was assessed with a questionnaire tailored to this study covering the following aspects: (1) use of a smartphone and tablets ("On average how often would you say you have been using a smartphone or tablet during the last 3 months?"), (2) use of the internet ("How often do you use the internet on your smartphone or tablet?"), (3) knowledge ("How knowledgeable do you consider yourself when it comes to using a smartphone or a tablet?"), (4) use of technology to support memory ("Are you using your mobile phone or tablet as a way to support your memory today?"), (5) use of specific apps for memory ("Do you have any special app or software on your mobile phone or tablet that you use to support your memory?"), and (6) perspective on the helpfulness of the technology for their memory ("Do you think that using your mobile phone or tablet to support your memory helps you to remember things?").

Independent Variables in People With Dementia/Mild Cognitive Impairment

Health-related quality of life was measured using the total score of the Quality of Life in Alzheimer's Disease (QoL-AD) questionnaire [20], which is a 13-item measure with a 4-point Likert scale. The EuroQoL-5D-3L [21] (EQ5D) questionnaire was also administered, which is a self-completion questionnaire that consists of 5 questions along with a scale for the participant to rate their health state on a scale thermometer of 0 to 100 (EQ-VAS). The European value set of Köning et al [22] was used for calculation of the EQ5D score.

Functional decline was assessed with the Lawton Instrumental Activities of Daily Living (IADL) [23] scale in people with dementia/mild cognitive impairment. The IADL uses 8 items for women and 5 items for men. The score was rescaled to range between 0 and 1.

The severity of cognitive impairment was assessed with the MMSE [24]. Depression was scored with the GDS-15 [25], which is a widely used scale to assess geriatric depression with 15 items and a range of 0-4 (normal), 5-8 (mildly depressed), 9-11 (moderately depressed), and 12-15 (severely depressed). Since an inclusion criterion for study participation was a GDS-15 score<11, the range in this study was 0–11.

Sociodemographic data included age, gender, education, living arrangement, marital status, and country of residence. Medical history included a diagnosis of dementia and comorbidity based on the International Classification of Diseases-10 [26].

Independent Variables for Caregivers

The independent variables for caregivers included the caregiver burden, which was assessed using the Zarit Caregiver Burden Interview (ZBI-12) [27,28], a 12-item 5-point Likert scale questionnaire. This is the short version of the original scale and was designed specifically for caregivers of people with dementia/mild cognitive impairment. Health-related quality of life was measured using the EQ5D as described above. The sociodemographic data included age, gender, education, living arrangements, marital status, country of residence, and relationship with the patient.

Statistical Analysis

The mean (SD) and frequency and percentages are used to describe continuous and categorical variables, respectively. To compare groups with high and low technophilia, we used the median TechPh Index (2.83 in people with dementia/mild cognitive impairment and 3.00 in caregivers) as the cut-off point. To compare groups, we used the Chi square test for categorical variables and the Mann-Whitney test for continuous variables. A multivariate linear regression analysis was conducted to analyze the factors associated with technophilia. To check the assumptions of the linear model, the Breusch-Pagan test (homoscedasticity), Shapiro-Wilk normality test of the residuals, variance inflation factor (VIF; multicollinearity), and a scatter plot for the linearity of the variables were used. We also analyzed the factors associated with the use of specific apps or software to support memory using multivariate logistic regression. To check the goodness of fit, we used the Hosmer-Lemeshow test and the VIF for multicollinearity. If the VIF was higher than 2, the variable was taken out of the model. A 95% level of significance was used for assessment. R program version 3.6.1 (R Foundation for Statistical Computing, Vienna, Austria) and the R Commander package were used for these analyses.

Results

The basic characteristics of the sample of people with dementia/mild cognitive impairment are summarized in Table 1. Nearly a third of the sample were diagnosed with dementia. A total of 588 of the 1086 people with dementia/mild cognitive impairment (54.14%) used smartphones and tablets almost every day and 284 (26.15%) had never used these technologies. Only 381/1086 (35.08%) used the internet on smartphones and tablets almost every day and 470/1086 (43.28%) never used the internet on these gadgets. More than half (706/1086, 65.01%) considered themselves not at all or quite knowledgeable when it comes to using a smartphone or a tablet. A total of 106 (9.76%) had a special app or software on their mobile phone or tablet to support memory, and 669/1086 (61.60%) believed that using a mobile phone or tablet to support their memory helps them remember things. Additional information about the use of smartphones and tablets by the people with dementia/mild cognitive impairment is provided in Multimedia Appendix 1. Information about groups with high and low technophilia and groups that use or do not use specific apps or software on their mobile phone or tablet to support memory is shown in Table 1.

Table 1. Characteristics of participants with dementia or mild cognitive impairment.

Variables	All participants (N=1086)[a]	High technophilia (N=591)[b]	Low technophilia (N=493)[c]	*P* value	Use apps to support memory (N=106)[d]	Do not use apps to support memory (N=877)[e]	*P* value

The basic characteristics of the caregivers are summarized in Table 2. Among the 1086 caregivers, 839 (77.26%) used touchscreen technologies almost every day, and 123 (11.33%) had never used smartphones or tablets. A total of 721 (66.39%) used the internet on smartphones and tablets almost every day, and 191 (17.59%) never used the internet on touchscreen gadgets. A total of 433 (39.87%) considered themselves not at all or quite knowledgeable when it comes to using a smartphone or a tablet. A total of 181 (16.67%) had a special app or software on their mobile phone or tablet to support their memory, and 773 (71.18%) believed that using a mobile phone or tablet to support their memory helps them to remember things. Additional information about the use of smartphones and tablets by the caregivers is provided in Multimedia Appendix 1. Information about the caregivers overall, groups with high and low technophilia, and groups that use or do not use specific apps or software on their tablet or mobile phone to support memory is shown in Table 2.

Table 2. Characteristics of caregivers.

[g] EQ5D: EuroQoL-5D-3L.

The people with dementia/mild cognitive impairment had a mean TechPH index of 2.84 (SD 0.69). The TechEnthusiasm score was 2.95 (SD 1.07) and the TechAnxiety score was 3.30 (SD 0.95). The caregivers had a TechPH index score of 3.07 (SD 0.68); the TechEnthusiasm score was 3.31 (SD 1.00) and the TechAnxiety score was 3.19 (SD 0.95). There were differences in the TechPH index between patients and caregivers (B=0.223, SE 0.030, *P*<.001), which remained significant after adjusting by age, gender, education level, and health status (B=0.074, SE 0.032, *P*=.02). There were significant differences in TechAnxiety between patients and caregivers (B=–0.120, SE 0.041, *P*=0.004); however, these differences were not significant after adjusting for age, gender, education level, and health status (B=–0.042, SE 0.047, *P*=.37). There was a significant difference in TechEnthusiasm between patients and caregivers (B=0.360, SE 0.045, *P*<.001), and this difference was still significant after adjusting for confounders (B=0.128, SE 0.050, *P*=.01). There were significant differences in the use of specifics apps or software to support memory between patients and caregivers (odds ratio [OR]=1.783, SE 0.131, *P*<.001); however, these differences were not significant after adjusting for confounders (OR=0.818, SE 0.167, *P*=.23).

In the multivariate analysis, the TechPH index in people with dementia/mild cognitive impairment was related to lower age, male gender, higher education level, living arrangement (living with children vs single), country of residence (Sweden vs Spain), depression, and health status (Table 3). In caregivers, the TechPH index was associated with lower age, male gender, higher education level, country of residence (Sweden vs Spain), lower caregiver burden, and better quality of life (Table 4). The use of specific apps or software on tablets or mobile phones to support memory was only associated with age in people with dementia/mild cognitive impairment (Table 5) and was associated with age, education level, and caregiver burden in caregivers (Table 6).

Discussion

In people with dementia/mild cognitive impairment, technophilia was associated with less depression, better health status, as well as with sociodemographic variables. In caregivers, technophilia was associated with a better quality of life, less care burden, and other sociodemographic variables. The results of this study indicate that people with dementia/mild cognitive impairment have less technophilia than their caregivers, specifically less TechEnthusiasm, but no differences were found in TechAnxiety. The people with dementia/mild cognitive impairment used smartphones and tablets with specific apps or software to support their memory less than their caregivers, despite being a population who would benefit most from these apps. These differences are likely due to age barriers.

The use of smartphones and tablets in our study was lower than that reported in a recent study in Australia in which 91.4% of people with dementia/mild cognitive impairment reported routinely using smartphones [29]. Likewise, in other studies that included older adults and populations with cognitive impairment and dementia, attitudes toward technology were associated with factors such as age [30-32], male gender [33], higher education level [29,30,33,34], depression and negative cognitions [35], and health status [30], and variability was found between countries [36]. A correlation between the use of health apps and age has also been reported [32,37]. However, some results in other studies have not been replicated. For example, one study reported an association between cognitive functioning and the use of technologies in a cognitively impaired population [38], and another study found that women used more health apps than men [39].

The differences in technophilia between people with dementia/mild cognitive impairment and caregivers, mainly due to the lack of technology enthusiasm, could be related to dementia or mild cognitive impairment itself. In fact, other studies have found that dementia and mild cognitive impairment were related to more perceived difficulties in everyday technology use [40]. In addition, this lack of enthusiasm for technology could be related to the apathy associated with dementia and mild cognitive impairment, which is a persistent behavioral symptom [41,42]. This apathy could affect the enthusiasm toward new technologies and may be a barrier for interventions that demand learning and adaptation to the use of these technologies.

Other studies have also found that barriers to the use of ICTs and assistive technologies in older adults are due to the lack of "interest or relevance to life" and the perception of "no need" [15,43]. Indeed, these ICTs are often not designed specifically to cover the real needs of this population and they do not arouse interest. Other studies have also found that a lack of knowledge in older adults is a barrier to the use of technologies [11,16]. In addition, age was identified as one of the most critical determinants of the use of apps to support memory after adjusting for health status. This result coincides with other studies [15,30] in the general population.

Interestingly, technophilia was also strongly associated with health status and depression after adjusting for possible confounders such as gender, age, education level, and cognitive function. One longitudinal study conducted by Cotten et al [44] and other studies [45,46] have found that use of the internet and ICTs in older individuals is associated with less depression and a better quality of life, and there is some evidence that this association is mediated by loneliness and social isolation [44,45]. In conclusion, these results highlight the potential barriers of interventions for the use of ICTs, including smartphones and tablets, to improve the quality of life of people with dementia/mild cognitive impairment. The nature of the relation between use and technophilia and quality of life and mood needs to be clarified with longitudinal and experimental studies.

The use of specific apps or software to support memory was not associated with better cognitive function, better quality of life, or less depression. However, some positive results have emerged from several meta-analyses reporting that computerized cognitive training and electronic health apps are effective in improving cognition and quality of life in people with dementia/mild cognitive impairment [47,48]. This result comes from formal interventions, and the results of the present study could be due to possible confounders not assessed in the study or because the participants were not using the apps or software adequately (eg, insufficient training time or not using well-designed apps). Other studies have also indicated inconsistencies and lack evidence regarding the effectiveness of ICT interventions to improve cognition and other health-related variables [49,50].

The results of this study need to be considered in the context of several limitations. This was a cross-sectional study, and therefore the causal relation of the variables could not be established. More longitudinal and interventional studies are necessary to determine the effects of ICT use and the attitudes toward technology in people with dementia/mild cognitive impairment and their caregivers and to identify the factors that influence these variables in the other direction. In addition, this was a secondary analysis from a clinical trial, and the sample may not be representative of all people with dementia/mild cognitive impairment and caregivers. Individuals with severe depression were excluded and more than half of the sample was from only one country. There was no established cut-off point for the definition of high or low technophilia, which limits the use of the mean as the cutoff. Another limitation is that only a small set of variables was assessed. However, the strength of the study is the large sample used with more than 2000 individuals.

In conclusion, the factors associated with technophilia suggest potential barriers to technological interventions in people with dementia/mild cognitive impairment and their caregivers. These results have implications on the possible usefulness of considering technophilia and enthusiasm toward ICTs as determinants and moderator elements in digital interventions in the elderly population. The results suggest that designers of apps for older adults with cognitive impairment should create apps that engage users and are designed specifically for their needs as this population frequently lacks enthusiasm for technology. The use of touchscreen technologies was also frequent among people with dementia/mild cognitive impairment, whereas the use of specific apps or software to support memory was reduced in people with dementia/mild cognitive impairment and caregivers, and they face age barriers for the use of these apps. However, the majority of this population considers that use of smartphones or tablets is helpful for memory, which highlights the presence of a gap between the perceived potential and actual use of these technologies.

Acknowledgments

The study is supported by a grant from European Commission, Horizon 2020 (code 643399). This work is a collaboration among several members of the SMART4MD consortium. The consortium acknowledges the contributions of members not reaching full ICMJE standards for authorship in this manuscript: Karen Hayden, Tony Fenton, Jufen Zhang, Selim Cellek, Claire Preston, Tomer Regev, and Stephen Moore (Anglia Ruskin University, UK); Dominique Manhaeve and Jessie Schrijvers (University Colleges Leuven-Limburg, Belgium); Professor María Teresa Arredondo Waldmeyer (Universidad Politécnica de Madrid, UPM, Spain); Ifty Ahmed (Healthbit Ltd, UK); Michal Stefan, Karel Huk, and Jan Kubalik (DEX innovation Center, Czech Republic); Lisa Seeman (Athena ICT, Israel); and Carmen Sanmartin, Line Christensson, Eric Picullel, Joakim Frögren, and Doris Bohman (Blekinge Institute of Technology, Sweden).

Abstract

Background: Disparities in access to specific technologies within gender groups have not been investigated. Slum settings provide an ideal population to investigate the contributing factors to these disparities.

Objective: This study aimed to examine gender differences in mobile phone ownership, internet access, and knowledge of SMS text messaging among males and females living in urban slum settings.

Methods: A convenience sampling approach was used in sample selection from 675 unnotified slums. A total of 38 slum sites were then selected across four geographic zones. Of these, 10% of the households in each slum site was selected from each zone. One household member was interviewed based on their availability and fulfillment of the eligibility criteria. Eligible individuals included those aged 18 years and above, residing in these slums, and who provided voluntary consent to participate in the study. Individuals with mental or physical challenges were excluded from the study.

Results: Our results showed that females were half as likely to own mobile phones compared with males (odds ratio [OR] 0.53, 95% CI 0.37-0.76), less likely to have internet access (OR 0.79, 95% CI 0.56-1.11), or know how to send text messages (OR 0.93, 95% CI 0.66-1.31). The predictors of mobile phone ownership, internet access, and text messaging *between* males and females included age, individual education, housing type, and the number of earning members in a household in the adjusted analysis. Among males, the number of earning members was a predictor of both mobile phone ownership and text messaging, whereas household education was a predictor of both internet access and text messaging. Age and individual education only predicted internet access, whereas housing type only predicted text messaging. Among females, household education was a predictor of all the technology outcomes. Age and type of toilet facility only predicted mobile phone ownership; housing type only predicted internet access whereas television ownership with satellite service and smoking behavior only predicted text messaging.

Conclusions: Our study findings showing disparate access to technology *within* gender groups lend support for further research to examine the causal mechanisms promoting these differences to proffer significant solutions. Specifically, our study findings suggest that improving household education is crucial to address the disparate access and usage of mobile phones, the internet, and text messaging among women in slum settings. This suggestion is due to the consistency in household educational level as a predictor across all these technology indicators. In addition, the mechanisms by which the number of household earning members influences the disparate access to technology among men call for further exploration.

Introduction

Digital Divide

Information and Communication Technology (ICT) plays a major role in fostering access to knowledge and key services across various sectors. ICT proliferation has been associated with increasing economic benefits, including new economic opportunities, increased trade, higher productivity, and lower costs. ICT is in a continuous state of advancement, evolution, and rapid diffusion at record-setting rates. For instance, global internet penetration rose from around 6% to almost 50% between 2000 and 2016, with penetration rates exceeding 90% in developed countries [1]. The term *digital divide* was coined in the 1990s by Lloyd Morriset (President of the Markle Foundation) to describe these inequalities, which depict a divide between the *information-haves and have-nots* [2]. The digital divide connotes disparate access to information across individuals with and without access to the internet, and more broadly, ICT as well as the general media [2]. However, the digital divide is most commonly used for indicating the availability of internet access at an affordable cost and quality [3,4]. Disparate patterns in technology access are frequently measured by internet access, penetration, the number of internet users, household ownership of computers, and mobile phone usage [5].

Background

The factors impacting the digital divide were conceptualized using the resources and appropriation theory developed by Van Dijk [5]. This theoretical framework depicts a causal model of the interplay between 1) individual and societal inequalities, 2) distribution of resources, 3) access to ICTs, and 4) societal participation. Specifically, the differential growth in ICT access and usage across countries in varied settings has been attributed to gross inequalities at the individual and societal levels. These are observed across age distributions, gender, race or ethnicity, income, literacy, personality, health, household conditions, and socioeconomic status (SES) [5]. The inequalities subsequently produce an unequal distribution of resources that promote unequal access to technology. Unequal access to technology is also dependent on the type of technology (ie, basic phone with limited functionality such as the absence of cameras, smartphone, computer, and other advanced systems). Unequal access to technology contributes to unequal societal participation, which, in turn, reinforces the existing inequalities [5]. Such inequalities tend to be more pronounced in marginalized settings, notably in urban slum settings in developing countries, which constitute a hub of economic disadvantage.

Although a variety of individual-level determinants of ICT inequalities exist, gender remains one that is of primary importance, as reflected in the United Nations (UN) Sustainable Development Goal 5: Gender Equality. The Sustainable Development Goal 5B target is to enhance the use of enabling technology, in particular ICT technology, to promote the empowerment of women [6]. Unequal access to technology among men and women constitutes one of the most striking aspects of the digital divide. The impact of the digital divide on gender has been widely studied in various developing and developed economies [7]. According to the International Telecommunication Union (ITU), on average, women are 16 percentage points less likely to use the internet compared with their male counterparts. This gender-gap is consistent globally, varying between 11% and 19% in Nigeria, Tanzania, India, Pakistan, and Japan, with differences as high as 31% in the least developed settings [7]. Gender gaps in these settings have been attributed to a variety of determinants, including disproportionate access to education among young women, which impairs their literacy levels. Further determinants include limited institutional opportunities for ICTs, personal safety issues with access to ICTs, and the *leaky pipe phenomenon*, which describes female preference to advance their family’s welfare over their personal development [6]. These barriers are perpetuated by structural factors such as extreme poverty and highly patriarchal societies, as well as psychological barriers such as limited confidence among women in their capacity to learn ICT skills, and the belief that technology is reserved for their male counterparts [7].

Objectives

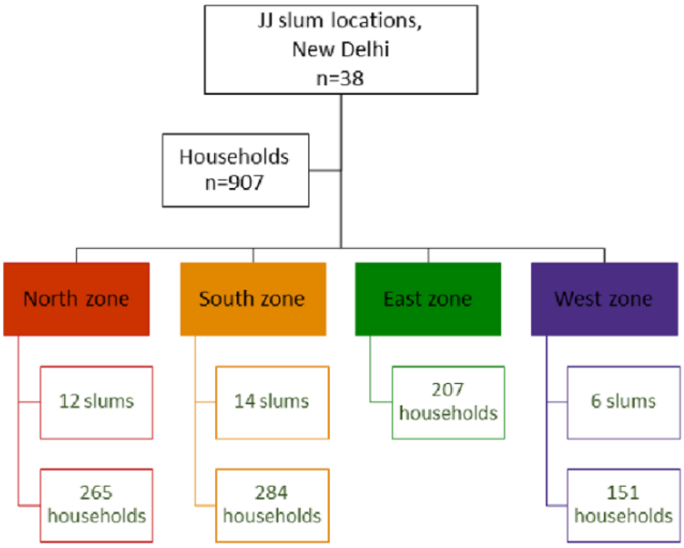
Although prior research has established the existence of a digital divide between gender categories, findings of these studies suggest that variations within individual gender categories may be significantly contributing to the existing digital divide [8]. Slum settings provide a unique population to investigate the contributing factors to the disparity in technology access and usage within gender categories. This is because slums represent a hub of staggering economic disparities, which tend to be more diverse than the nonslum populations. In particular, a UN habitat report indicated that slums suffer from higher disease incidence and mortality, which exceed nonslum populations, and these disparities are rarely reflected in the national statistics, thereby masking the extent of the deprivation in slum settings [9]. Essentially, the state of slums constitutes an indicator of prosperous cities [9]. The objective of this study was to examine gender differences in mobile phone ownership, internet access, and knowledge of SMS among males and females living in urban slum settings.

Methods

Overview

A cross-sectional study was conducted between June 2016 and January 2017 to assess the impact of the digital divide among women and men residing in urban slums of Delhi, India. The sampling frame used was the *Delhi Urban Shelter Improvement Board Jhuggi-Jhopadi Cluster List of 2015*, which enumerated a total of 675 unnotified urban slums across the four geographic zones (North, South, East, and West) of New Delhi, India. Unnotified slums are slum settlements that are not federally recognized and do not benefit from government subsidies and interventions across slums [10]. A convenience sampling approach was used in identifying 675 unnotified slums, and selecting 38 slum sites across four zones (north zone, n=12; south zone, n=14; east zone, n=6; and west zone, n=6; Figure 1). From each zone, 10% of the households were selected based on proximity to the researcher, ease of access to the slums, and the presence of local collaborators in these slums who could help in navigating them. Of these, 1 member from each household was selected and interviewed based on availability for the interview and fulfillment of the eligibility criteria. Eligible individuals included those who were aged 18 years and above, resident in these slums, and provided voluntary consent to participate in the study. Individuals who did not provide consent and had any mental challenges were excluded from the study. This resulted in a total sample of 907 study participants across all the slums. The Institutional Review Board (IRB) of the Foundation of Healthcare Technologies Society, New Delhi, India, approved the study protocol (IRB number: FHTS/041/2016).

Figure 1. Study participant recruitment.



Variables Assessed

The following variables were assessed:

- Sociodemographic characteristics: age, gender, education, household education, type of family, earning members in the household, housing type, type of toilet facility, television ownership, and healthy behaviors, including smoking and alcohol consumption.
- Living index: information was collected about housing type (concrete, semiconcrete, or not concrete), access to toilet facility (in-house, public place, or open defecation), television ownership, and use of satellite television service.
- High-risk behaviors: information was collected on the reporting of high-risk behaviors, including smoking and alcohol consumption.
- Mobile ownership, internet access, and knowledge of SMS: information was collected about individual or household mobile phone ownership, internet service (mobile phone), and knowledge of SMS text messaging.

Statistical Analysis

Descriptive analysis was conducted to report means with SDs and frequencies for all continuous and categorical variables, respectively. Association was performed between sociodemographic characteristics, living index, and health behaviors and technology outcomes, including mobile phone ownership, access to the internet, and knowledge of text messaging. Stratified analysis by gender was performed to determine the between sociodemographic characteristics, living index, and health behaviors and technology outcomes, including mobile phone ownership, access to the internet, and knowledge of text messaging. Variables having significant relationship were included in multivariable logistic regression. Multivariate analyses, stratified by gender, were performed to examine variables that were associated with mobile phone ownership, internet access, and knowledge of SMS after adjusting for potential confounders including sociodemographics, healthy behaviors, and living index conditions. The analyses were performed using SAS, AS, Version 9.4 (SAS Software Limited).

Results

Study Participant Characteristics

The average age of the study participants was 36 years (SD 13). Almost half of them were between the ages of 18 and 30 years (398/904, 44.0%). More than half of them were females (599/904, 66.3%), and 46.2% (418/904) had not completed high school. Half of them lived in households where the highest level of education was less than a high school diploma (453/904, 50.1%). More than half of the study participants lived in nuclear families (578/904, 64%) and had 1 earning member per household (534/904, 59.1%).

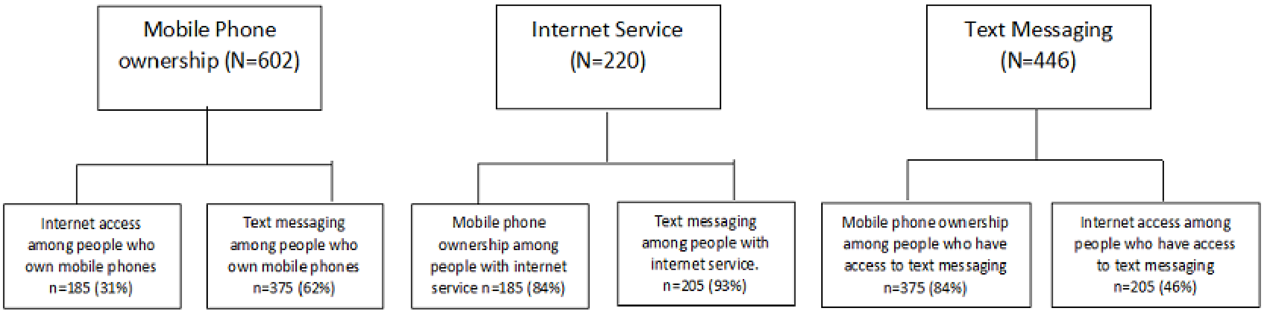
More than half of the study participants resided in houses that had concrete finishing (496/904, 54.9%). Of which, 45.2% (409/904) of the study participants utilized public toilet facilities as their primary source of sanitation. More than two-thirds of the study participants owned a television set (705/904, 77.9%) and had satellite television service (592/904, 65.5%). Then, 22.0% (199/904) of the participants reported smoking and 11.6% (105/904) reported alcohol consumption. The characteristics of the study participants have been previously published [11]. Less than 1% of responses were missing across the technology outcomes assessed (34/85000, 0.04%).

Mobile Phone Ownership, Internet Service, and Text Messaging Among Study Participants

More than half of the study participants owned a mobile phone (602/904, 66.5%). Only 24.3% (220/904) of the study participants had internet service on their mobile phones. Less than half of the study participants had knowledge of sending text messages (446/904, 49.3%; Figure 2).

More than half of the study participants who owned mobile phones had knowledge of sending text messages (375/602, 62.2%). However, less than half of them had internet service on their mobile phones (185/602, 30.7%; Figure 2 and Multimedia Appendix 1). More than two-thirds of the study participants who had internet service owned a mobile phone (185/220, 84.1%), and 93.2% (205/220) of them had knowledge of sending text messages. In all, 84.1% (375/446) of the study participants who knew how to send text messages owned a mobile phone, and less than half of them had access to the internet (205/446, 45.9%; Figure 2).

Figure 2. Phone ownership, internet service, and text messaging among the study participants (N=904).



Mobile Phone Ownership and Technology Access and Familiarity

Variables Associated With Mobile Phone Ownership, Internet Access, and Knowledge of Text Messaging Among the Study Participants

Mobile Phone Ownership

More than half of the study participants owned a mobile phone (602/904, 66.3%). A total of 61.7% (365/904) of them were females, 43.8% (264/602) of them were between 18 and 30 years old, and 54.3% (327/602) had not obtained a high school diploma (Multimedia Appendix 1). More than half of them lived in nuclear families having 1 earning member (351/602, 58.3%), and with a household educational level of less than high school (312/602, 51.8%). College education at the individual and household levels were significantly higher among study participants who owned a mobile phone compared with those that did not (*P*<.001).

A total of 61.7% (372/602) of the study participants that owned a mobile phone resided in households with concrete finishing compared with 41.1% (124/302) of those who did not own a mobile phone (*P*<.001). Less than 10% of the participants that owned a mobile phone practiced open defecation (40/602, 6.6%) compared with 25.8% (78/302) of those that did not own a mobile phone (*P*<.001). The majority of mobile phone owners also owned a television (515/602, 85.5%) and had access to a satellite television service (437/602, 72.5%). Smoking (*P*=.50) and alcohol consumption (*P*=.40) were not significantly associated with those owning a mobile phone (Multimedia Appendix 1). Age of the study participant, gender, individual and household education, type of family, number of earning members, housing type, type of toilet facility, and television ownership with satellite service were significantly associated with mobile phone ownership.

Internet Access

Less than one-third of the study participants had internet service on their mobile phones or had a household member with internet service (220/904, 24.3%). percent of these, 51.4% (113/220) of those with internet service on their phones were between the ages of 18 and 30 years (*P*=.02; Multimedia Appendix 1). More than half of them were females (127/220, 57.7%) and had not completed high school (116/220, 52.7%). In all, 52.7% (116/220) of them lived in nuclear family settings and had 1 earning family member (110/220, 50.0%). More than two-thirds of them resided in houses with concrete finishing (153/220, 69.5%), and 50.0% (111/220) of them utilized in-house toilet facilities. Then, 78.6% (173/220) of them owned a television with satellite television service (*P*<.001)

The study participants age (*P*=.02), gender (*P*=.002), individual and household education, type of family, number of earning members, housing type (*P*=.02), type of toilet facility, and television ownership with satellite service were significantly associated with internet access on a mobile phone (*P*<.001). Smoking (*P*=.50) and alcohol consumption (*P*=.40) were not significantly associated with having internet service on their mobile phones.

Text Messaging

Less than half of the study participants knew how to send text messages (446/904, 49.3%; Multimedia Appendix 1). More than half of them were females (276/446, 61.9%) and had not completed high school (252/446, 56.5%). Almost one-third of the study participants who were knowledgeable about texting had obtained some college education (123/446, 27.5%) compared with 7.0% (31/446) of those who did not know how to send text messages. The majority of them had 1 to 2 earning members in the household. More than two-thirds of them resided in houses with concrete finishing (299/446, 67.0%). Less than half of them utilized public places (205/446, 45.9%) or in-house toilet facilities (212/446, 47.5%) as their primary mode of sanitation. Of these, 6.5% (29/446) practiced open defecation. The majority of them owned a television (402/446, 90.1%) and had satellite television service (347/446, 77.8%). Smoking and alcohol consumption were not significantly associated with the knowledge of text messaging. Age of the study participant, gender, individual and household education, type of family, number of earning members, housing type, type of toilet facility, television ownership with satellite service, and technology usage were significantly associated with the knowledge of text messaging.

Predictors of Mobile Phone Ownership, Internet Access, and Text Messaging Among the Study Participants

Predictors of Mobile Phone Ownership

Age, household educational level, number of earning members, housing type, and type of toilet facility remained significantly associated with mobile phone ownership (Multimedia Appendix 2). Females had lower odds of mobile phone ownership compared with males (odds ratio [OR] 0.51, 95% CI 0.35-0.75). Study participants in the age group of 41-50 years had the highest odds of mobile phone ownership as compared with those in the 50+ age (OR 1.99, 95% CI 1.07-3.69). Individuals living in households where the highest educational level was less than a high school diploma was associated with lower odds of mobile phone ownership (OR 0.51, 95% CI 0.28-0.94). Similarly, no earning member in a household was associated with lower odds of mobile phone ownership (OR 0.27, 95% CI 0.08-0.91). Living in houses made of concrete was associated with higher odds of mobile phone ownership (OR 1.99, 95% CI 1.13-3.49). In addition, living in households that utilized public places as their primary mode of sanitation was associated with a higher odds of mobile phone ownership (OR 1.56, 95% CI 1.07-2.25), whereas open defecation was associated with a lower odds of mobile phone ownership (OR 0.49, 95% CI 0.29-0.84).

Predictors of Internet Access

Age and household education remained significantly associated with internet access (Multimedia Appendix 2). Females had lower odds of internet access compared with males (OR 0.65, 95% CI 0.44-0.96). Study participants aged between 18 and 30 years had the highest odds of internet access across age groups (OR 2.19, 95% CI 1.15-4.19). Households in which the highest level of education attained was high school were associated with a lower odds of internet access (OR 0.49, 95% CI 0.28-0.87).

Predictors of Text Messaging

Age, individual education, household education, number of earning members in the household, housing type, and satellite television service remained significantly associated with text messaging (Multimedia Appendix 2). Study participants between the ages of 41 and 50 had the highest odds of text messaging (OR 2.12, 95% CI 1.13-3.97). Households in which no member had obtained any schooling was associated with lower odds of text messaging (0.22, 95% CI 0.05-0.93). Living in houses made of concrete (OR 2.05, 95% CI 1.13-3.72) and having a satellite television service were associated with higher odds of text messaging (OR 1.94, 95% CI 1.12-3.33).

Stratified Analysis of Mobile Phone Ownership, Internet Access, and Text Messaging Across Gender Categories (Bivariable Analysis)

Mobile Phone Ownership Stratified by Gender

A total of 39.4% (237/602) of males and 60.1% (365/602) of females owned mobile phones. Gender differences in mobile phone ownership were significant across age groups (*P*=.002), educational status of the participant (*P*<.001), housing type (*P*=.02), smoking (*P*=.001), and alcohol consumption (*P*=.02; Multimedia Appendix 3). Of which, 60.1% (365/602) of the females owned mobile phones compared with 39.3% (237/602) males; 8.4% (20/237) of the males who owned a mobile phone had obtained some college education compared with 5.2% (19/365) of the females (*P*<.001); 8.5% (31/365) of the females who owned a mobile phone resided in houses with nonconcrete finishing compared with 5.1% (12/237) of the males (*P*=.02). One-third of the males who owned a mobile phone reported smoking (n=73), compared with 17.3% (63/365) of the females. And 16.9% (40/237) of the males reported alcohol consumption compared with 10.4% (38/365) of the females. Gender differences were not significant by household education (*P*=.74), family type (*P*=.97), total earning members (*P*=.19), type of toilet facility (*P*=.91), and television ownership (*P*=.29)

Access to Internet Services Stratified by Gender

A total of 42% (93/220) of the males had access to internet services as compared with 57.7% (127/220) of females. Gender differences in internet access were significant across educational levels (*P*<.001) and housing type (*P*=.01; Multimedia Appendix 4). Almost one-quarter of the males had obtained some college education (21/93, 23%) compared with 9% (11/127) of females (*P*<.001) More than two-thirds of the females (94/127, 74%) resided in houses made of concrete compared with 64% (59/93) of the males. Gender differences in access to the internet were not significant by age (*P*=.09), household education (*P*=.25), family type (*P*=.78), toilet facility (*P*=.73), television ownership (*P*=.09), smoking (*P*=.05), and alcohol consumption (*P*=.92) .

Text Messaging Stratified by Gender

A total of 38.1% (170/446) of males were familiar with sending text messaging as compared with 61.8% (276/446) of females. Gender differences were significant across educational groups (*P*<.001), total earning members in the household (*P*=.03), housing type (*P*<.001), smoking behaviors (*P*<.001), and alcohol consumption (*P*<.04; Multimedia Appendix 5). Almost half of the study participants capable of texting were aged 18 to 30 years. Of which 47.1% (130/276) of them were females compared with 45.9% (78/170) of them that were males; 14.2% (24/170) of the males were 50 years or older compared with 7.9% (22/276; *P*=.03) of females; and 12.3% (21/170) of the males had obtained some college education compared with 7.6% (21/276) of the females (*P*<.001). Less than half of the males had 1 earning member (83/170, 48.8%) compared with 58.7% (162/276) of the females. More than two-thirds of the females (201/276, 72.8%) resided in houses made of concrete compared with 57.6% (98/170) of the males, 30.6% (52/170) of the males reported smoking (*P*<.001), and 15.9% (27/170) of the males reported drinking (*P*=.04).

Factors Associated With Mobile Phone Ownership, Internet Access, and Text Messaging Stratified by Gender (Multivariable Analysis)

Age (*P*=.002), educational status (*P*=.003), and type of housing (*P*=.004) remained predictors of mobile phone ownership between males and females (Multimedia Appendix 6). Being older than 30 years (OR 2.19, 95% CI 1.35-3.58) and living in houses made of concrete (OR 2.49, 95% CI 1.50-4.14) were also significant predictors of mobile phone ownership. Educational status was the only significant predictor of internet access between males and females (*P*<.001). Older age (*P*=.004), less than high school education (*P*<.001), 1 household earning member, or less (*P*=.02) were associated with a lesser odds of text messaging between males and females. Living in houses made of concrete was associated with greater odds of text messaging (OR 2.69, 95% CI 1.55-4.69) (Multimedia Appendix 6).

Within-Gender Variation Related to Mobile Phone Ownership, Internet Access, and Text Messaging

Within-Gender Variation Related to Mobile Phone Ownership

Educational status of the individual (*P*<.001), household educational attainment (*P*<.001), total earning members in the household (*P*<.001), housing type (*P*<.001), type of toilet facility (*P*<.001), television ownership (*P*<.001), having a satellite television service (*P*<.001), and smoking (*P*=.02) were significantly associated with mobile phone ownership among males (Multimedia Appendix 7). More than half of the males who owned mobile phones had not obtained a high school education (154/237, 64.9%); resided in households where the highest level of education was less than high school (127/237, 53.6%), and had 1 earning member (129/237, 54.4%). More than half of them resided in houses with concrete finishing (137/237, 57.8%), and half of them utilized public places as the main source of sanitation (n=119). More than two-thirds of them owned a television and had satellite television service. One-third of the male participants who owned a mobile phone were smokers (n=73/237). Age (*P*=.30), type of family (*P*=.31), and alcohol consumption (*P*=.89) were not significantly associated with mobile phone ownership among men (Multimedia Appendix 7).

Age of the study participants, individual and household educational attainment, type of family, housing type, type of toilet facility, television ownership, and having a satellite television service were significantly associated with mobile phone ownership among female study participants (*P*<.001; Multimedia Appendix 6). Almost half of the females who owned a mobile phone were between 18 and 30 years old (167/365, 45.2%) and had not obtained a high school diploma (173/365, 47.4%; *P*<.001). More than half of them resided in households where the highest level of education attained was less than a high school diploma (185/365, 50.7%), and 64% (234/365) of them lived in nuclear families and in houses with concrete finishing (n=235). Less than half of them utilized public places as their main source of sanitation (177/365, 48.5%); 84.9% (310/365) of them owned a television, and 70.1% (256/365) of them had satellite television service. The number of earning members in the household (*P*=.52), smoking (*P*=.24), and alcohol consumption (*P*=.14) were not significantly associated with mobile phone ownership among women (Multimedia Appendix 7).

Within-Gender Variation Related to Internet Access

Age of the study participant (*P*=.002), educational level (*P*<.001), household education (*P*<.001), total earning members in the household (*P*=.003), and housing type (*P*=.01) were significantly associated with mobile phone internet access among men (Multimedia Appendix 8). More than half of the males who had internet access on their mobile phones were aged 18 to 30 years (*P*=.002). Almost a quarter of them had obtained some college education (21/93, 23%). Almost half of them lived in households where the highest level of education attained was college (40/93, 43%), and 41% (38/93) of them had 1 earning member in the household.

The educational level of the study participant, household education, type of family, housing type, type of toilet facility, television ownership, and satellite television service were significantly associated with mobile phone internet access among the females (*P*<.05). Of these, 9.0% (11/122) of females who had internet access had obtained some college education (*P*<.001). More than one-third of the females with internet access lived in households where a college degree had been attained (45/127, 35.4%; *P*<.001). Half of them came from nuclear families (64/127, 50.4%). More than two-thirds resided in houses made of concrete (94/127, 74.0%) and primarily used in-house toilet facilities (67/127, 52.8%). Almost all of them owned a television (117/127, 92.1%) and had satellite television service (103/127, 81.1%). Age (*P*=.22), total earning members in the household (*P*=.33), smoking (*P*=.29), and alcohol consumption (*P*=.05) were not significantly associated with internet access among females (Multimedia Appendix 8).

Within-Gender Variation Related to Text Messaging

The study participant's education (*P*<.001), household education (*P*<.001), total earning members (*P*=.001), housing type (*P*<.001), toilet facility (*P*<.001), television ownership (*P*<.001), and satellite television service (*P*<.001) were significantly associated with the knowledge of text messaging among males (Multimedia Appendix 9). More than half of the males who were familiar with text messages had not completed high school (112/170, 65.9%; *P*<.001). Half of them lived in households where the highest level of education attained was less than a high school diploma (85/170, 50.0%; *P*<.001). Less than half of them had 1 earning member (83/170, 48.8%), 57.6% (98/170) of them lived in houses made of concrete, and 50.0% (85/170) of them utilized public places as their primary source of sanitation. The majority of them owned a television (153/170, 90.0%) and had satellite television service (134/170, 78.8%; *P*<.001). High-risk behaviors, including smoking (*P*=.15) and alcohol consumption (*P*=.66) were not significantly associated with text messaging among males.

Age of the study participant (*P*=.02), education (*P*<.001), household education (*P*<.001), type of family (*P*=.002), housing type (*P*<.001), toilet facility (*P*<.001), television ownership

(*P*<.001), satellite television service (*P*<.001), and smoking (*P*=.03) were significantly associated with the knowledge of text messaging among females (Multimedia Appendix 9). Almost half of the females who were familiar with sending text messages were between the ages of 18 and 30 years (130/276, 47.1%; *P*=.02). More than half of them had not completed high school (140/276, 50.7%), and less than half of them resided in households where the highest level of education was less than a high school diploma (121/276, 43.8%; *P*<.001). More than half of them resided in nuclear families (158/276, 57.2%) with 1 earning member (162/276, 59%). Half of them lived in houses with in-house toilet facilities; 72.8% (201/276) of the females who were familiar with sending text messaging resided in houses made of concrete compared with 43.0% (139/323) who were not capable of texting (*P*<.001). The majority of them owned a television (249/276, 90.2%) and had satellite television service (213/276, 77.1%); 12.3% (34/276) of females who were capable of texting reported smoking behaviors compared with 18.9% (61/323) who were not capable of texting (*P*=.03).

Multivariable Analysis of Factors Associated With Mobile Phone Ownership Within Males and Females

The number of household-earning members and the type of toilet facility in a household remained significantly associated with mobile phone ownership among males (*P*=.01; Table 1). Males who had no earning members in the household had a lesser odds of mobile phone ownership (OR 0.06, 95% CI 0.01-0.54; *P*=.01), and a higher odds of practicing open defecation as their primary source of sanitation (OR 2.88, 95% CI 1.09-7.63; *P*=.03).

Age of the study participant (*P*=.01), household education (*P*=.001), and type of toilet facility (*P*=.03) remained significantly associated with mobile phone ownership among females. Females between the ages of 31 and 40 years had the highest odds of mobile phone ownership among all the age groups (OR 2.418, 95% CI 1.243-4.703; *P*=.009). Females in households where no one had obtained any schooling had the lowest odds of mobile phone ownership (OR 0.27, 95% CI 0.12-0.59). In addition, females living in households that utilized public places as their primary mode of sanitation had a higher odds of mobile phone ownership (OR 1.59, 95% CI 1.04-2.43; *P*=.03), whereas those practicing open defecation had a lower odds of mobile phone ownership (OR 0.47, 95% CI 0.26-0.87).

Table 1. Multivariable analysis showing predictors of mobile phone ownership within the male and female study participants (N=904).

Multivariable Analysis of Factors Associated With Internet Access Within Males and Females

Age of the study participant (*P*=.04), education (*P*=.01), and household education (*P*<.001) remained significantly associated with mobile phone internet access among males (Table 2). Males between the ages of 18 and 30 years had higher odds of internet access (OR 2.60, 95% CI 1.02-6.67; *P*=.04). The odds of internet access were lower among males with no schooling (OR 0.09, 95% CI 0.02-0.57; *P*=.01) or incomplete schooling (OR 0.16, 95% CI 0.03-0.83; *P*=.03). Living in households where the highest educational level was at most a high school diploma was associated with a lower odds of internet access (OR 0.29, 95% CI 0.09-0.89; *P*=.03).

Household educational level (*P*<.001) and housing type (*P*=.03) remained significantly associated with mobile phone internet access among females. Living in households where the highest educational level was less than a high school diploma was associated with a lower odds of internet access (OR 0.16, 95% CI: 0.09-0.31; *P*<.001). In addition, the odds of internet access were lower among females living in houses made of semiconcrete (OR 0.38, 95% CI 0.16-0.92).

Multivariable Analysis of Factors Associated With Knowledge of SMS Text Messaging Within Males and Females

Household educational level (*P*<.001), number of earning members (*P*=.01), and housing type (*P*=.02) remained significantly associated with the knowledge of text messaging among males (Table 3). Males from households who had no schooling (OR 0.05, 95% CI 0.02-0.18) or less than high schooling (OR 0.23, 95% CI 0.09-0.54) had a lower odds of text messaging. Having no earning member in the household was also associated with a lower odds of text messaging among males (OR 0.04, 95% CI 0.004-0.43). Males who lived in houses made of semiconcrete had higher odds of text messaging (OR 3.94, 95% CI 1.28-12.09).

Individual education (*P*=.04), household education (*P*<.001), satellite television service (*P*=.03), and smoking (*P*=.01) remained significantly associated with text messaging. Females who had no schooling (OR 0.24, 95% CI 0.06-0.97) or incomplete schooling (OR 0.23, 95% CI 0.12-0.46) had a lower odds of text messaging. Females who owned a television with satellite service had higher odds of text messaging (OR 2.06, 95% CI 1.08-3.93). Smoking behavior was associated with lower odds of text messaging (OR 0.45, 95% CI 0.26, 0.79).

Table 3. Multivariable analysis showing predictors of text messaging within the male and female study participants (N=904).

Discussion

Principal Findings

The results of this study showed that more than half of the study participants owned a mobile phone (602/904, 66.3%), 49.3% (446/904) of them were familiar with sending text messages, and 24.3% (220/904) of them had internet service on their mobile phones. Variables associated with mobile phone ownership included gender, age, household educational level, number of earning members, housing type, and type of toilet facility. Variables associated with text messaging included the age of the study participant, individual education, household education, number of earning members in the household, housing type, and satellite television service. Variables significantly associated with internet access included gender, age, and household education. High-risk behaviors, including smoking and alcohol consumption were not significantly associated with mobile phone ownership, internet access, or text messaging.

This study identified important differences in the demographic and behavioral correlates of mobile phone ownership, access to the internet, and text messaging between males and females. Females were half as likely to own mobile phones compared with males (OR 0.53, 95% CI 0.37-0.76), less likely to have internet access (OR 0.79, 95% CI 0.56-1.11), or knew how to send text messages (OR 0.93, 95% CI 0.66-1.31). This finding is consistent with several similar studies in the literature [12]. Prior studies have shown that women in low- and middle-income countries (LMICs) are 14% less likely to own mobile phones compared with men. In addition, internet access is 12% lower among women compared with men [13].

Variables associated with mobile phone ownership between males and females included age, individual education, and housing type, in the adjusted analysis ($P<.05$). Being older than 30 years of age (OR 2.19, 95% CI 1.35-3.58), having no education (OR 0.31, 95% CI 0.14-0.66), and living in houses made of concrete (OR 2.49, 95% CI 1.50-4.14) were associated with mobile phone ownership. Some of these findings were not consistent with prior literature [3]. A prior study assessing determinants of household phone ownership in rural Bangladesh showed higher odds of mobile phone ownership among younger participants between the ages of 20 and 24 (OR 1.22, 95% CI 1.03-1.44), with lesser odds among participants aged 30 years or more (OR 0.95, 95% CI 0.77-1.18) [3]. A consistent finding of the highlighted literature with this study was the significance of wealth index measures (such as living in houses made of concrete) as a predictor of mobile phone ownership ($P<.001$). In particular, the highest quartile of wealth index was a key predictor of mobile phone ownership in rural Bangladesh [3].

In addition to age and individual education, the number of earning members in a household and housing type were predictors of text messaging between males and females in the adjusted analysis. Having 1 earning member or less was associated with reduced odds of text messaging (OR 0.547, 95% CI 0.329-0.909). This finding is consistent with prior literature in similar settings [14]. Such findings indicate that a high financial debt (especially in the absence of male family members), coupled with family responsibilities that affect finances (such as having several dependent family members), are possible mechanisms that explain the lower technology utilization among females [14].

Individual education was the sole predictor of internet access between males and females in the adjusted analysis. Having less than a high school education was significantly associated with reduced odds of internet access between males and females (OR 0.34, 95% CI 0.15-0.75). This finding was consistent with prior studies highlighting the role of literacy in internet utilization across LMICs. According to a qualitative analysis of socioeconomic correlates of the gender digital divide in Rwanda, a male participant stated as follows [15]:

> *For most Rwandan women, particular barriers are illiteracy, lack of familiarity with the main languages of computer technology and the internet, lack of operational training in computers, heavy household tasks, and lack of self-confidence* [male, 50 years]

The relevance of individual education as a key predictor of all three measures of technology used between males and females in this study is consistent with prior literature [12,14]. These findings have been attributed to patriarchal norms, which are arguably more prevalent in the South Asian context [12]. One of such patriarchal norms is the dedication of funds for educating male children, but rather preparing for the wedding of female children [14]. Such norms largely promote mobile phone ownership and technology usage among male family members, although limiting their use among women, who would often require permission to use mobile phones [16].

Our study findings comparing the differences in technology outcomes between gender groups highlighted disparate predictors of mobile phone ownership, internet access, and text messaging between males and females. For instance, individual education was a predominant factor associated with all three technology outcomes. Age and housing type were only predictive of mobile phone ownership and text messaging, and the number of earning members was only predictive of text messaging. These disparate findings across these predictors suggested that individual differences within gender groups may also be evident across the technology outcomes.

Subsequent investigations indicated that predictors of the technology outcomes differed significantly within males and females. These findings are suggestive of disparate levels of social class that are predominant even with slum settings, consistent with prior literature [17]. For instance, slum studies conducted in the Indian states of Chennai showed that individuals residing on the outskirts or margins of slums that adjoin wealthy neighborhoods are likely to absorb the culture of these wealthy Chennai neighborhoods. Owing to this, they were found to have higher levels of technology awareness and utilization [17]. It is also likely that such slum residences that are situated closer to wealthy neighborhoods may have lower crime and poverty rates, which are major predictors of the disparate access to technology by gender [16]. These findings can be extrapolated to this study in explaining the individual differences within gender categories with respect to the technology outcomes studied, as discussed below.

Our results showed that the type of toilet facility in households was significantly associated with mobile phone ownership. However, this association was different among males and females. Using a public toilet facility was not significantly associated with mobile phone ownership among males but was significant for females. In addition, open defecation was significantly associated with mobile phone ownership among females and males. These findings can be explained by prior literature indicating that open defecation is a marker of reduced SES [18]. In comparison to public places where slum residents have to pay around US $0.03 to US $0.04 to use a community public toilet, individuals practicing open defecation do not have to pay for this practice. The finding of open defecation being protective among females could be attributed to a higher sense of insecurity among females with using shared public latrines [19]. In addition, prior literature has indicated that although policies have been enacted to foster the provision of gender-specific toilets and infrastructure, females remain disproportionately affected by a lack of female-specific sanitation facilities compared with their male counterparts. In particular, findings have recorded a 66% disparity between toilets for men and women as of April 2019 [19]. Taken together, open defecation as a marker of reduced socio-economic status ultimately impacts female ownership of household assets and technologies [19].

Our study also showed that among females, household education was a predictor of all the technology outcomes, in the adjusted analysis. The finding that household education (and not individual education) was a key predictor of all the technology outcomes within females is consistent with the dominance of patriarchal norms within slum settings, which serve to marginalize women. In particular, gender inequities have been attributed to norms such as lack of prioritization of women's education from the childhood stage, women being forced to get married before they can attain financial independence, family responsibilities preventing women from working outside their homes, or in-laws forcing women to work in low-profit family businesses rather than letting them earn independently, and much more [14]. These combined factors serve to increase women's financial dependence on the men within their households; thus, the educational level of these women become less significant, as that of the household earning member takes precedence [14].

This in turn lends support to our study finding that having 1 earning member or less was a key predictor of both internet access and text messaging (corresponding to higher levels of technology usage) among men. Our study findings showed that among males, the number of earning members was a predictor of both mobile phone ownership and text messaging. This situation may be explained by the likelihood for women to depend more on the men in the households for financial sustenance; hence, the lack of a household earning member may significantly impair the financial status of the households. This phenomenon may then translate into a reduced ownership of household infrastructure and assets such as housing type (concrete vs semiconcrete vs nonconcrete) and television ownership, which are essentially markers of wealth, with higher values indicating better SES.

Strengths and Limitations

A limitation of this study is the convenience approach employed in the identification of slums and, ultimately, the households that were interviewed. This approach may have introduced selection bias and affected the generalizability of the results to the entire population across Indian slums. This study is, however, generalizable to individuals residing in the unnotified slums included in this study. This study had several strengths. Our study findings provide an in-depth exploration of individual gender differences in the digital divide and highlight relevant measures of these differences. Although our study does not demonstrate any causal or quasi-causal claims, it highlights the possible areas of intervention that are in line with the identified predictors.

Conclusions

Our study findings show disparate access to the technology outcomes *within* males and females in slum settings and lend support for further research to examine the causal mechanisms promoting these differences. Such mechanisms may proffer significant solutions to address the technology divide within gender groups and ultimately between gender groups. Specifically, our study findings suggest that improving household education is crucial to address the disparate access and utilization of mobile phones, internet, and text messaging among women in slum settings, owing to the consistency in household educational level as a predictor across all these technology indicators. In addition, the mechanisms by which the number of household earning members influences the disparate access to technology among men, call for further exploration. Finally, although our chosen study focus was on gender disparities in access to specific technology outcomes, future studies could explore the impact of the gender digital divide on access to health care and other health-related behaviors beyond those covered in this study. Internet and mobile phone usage are required for electronic health and mobile health technologies to promote the utilization of health care services.

Abstract

Background: The number of older adults with vision impairment (VI) is growing. As health care services increasingly call for patients to use technology, it is important to examine internet/health information technology (HIT) use among older adults with VI.

Objective: This study aimed to examine (1) the rates of internet/HIT use among older adults with VI compared with a matched sample of their peers without VI, (2) associations of VI with internet/HIT use, and (3) association of HIT use with psychological distress, assessed with the Kessler-6 screen.

Methods: Data were obtained from the 2013 to 2018 US National Health Interview Survey. Older adults (aged ≥65 years) with self-reported VI were matched with older adults without VI, in a 1:1 ratio, based on age, sex, number of chronic medical conditions, and functional limitations (N=2866). Descriptive statistics and multivariable logistic regression models, with sociodemographic factors, health conditions, health insurance type, and health care service use as covariates, were used to examine the research questions.

Results: In total, 3.28% of older adults (compared with 0.84% of those aged 18-64 years) reported VI, and 25.7% of them were aged ≥85 years. Those with VI were significantly more socioeconomically disadvantaged than those without VI and less likely to use the internet (adjusted odds ratio [aOR] 0.64, 95% CI0.49-0.83) and HIT (aOR 0.74, 95% CI 0.56-0.97). However, among internet users, VI was not associated with HIT use. HIT use was associated with lower odds of mild/moderate or serious psychological distress (aOR 0.62, 95% CI 0.43-0.90), whereas VI was associated with greater odds of mild/moderate or serious distress (aOR 1.84, 95% CI 1.36-2.49). Health care provider contacts were also associated with higher odds of internet or HIT use.

Conclusions: Compared with their matched age peers without VI, older adults with VI are less likely to use HIT because they are less likely to use the internet. Socioeconomically disadvantaged older adults experiencing a digital divide need help to access information and communication technologies through a fee waiver or subsidy to cover internet equipment and subscription and ensure continuous connectivity. Older adults with VI who do not know how to use the internet/HIT but want to learn should be provided instruction, with special attention to accessibility features and adaptive devices. Older adults with a low income also need better access to preventive eye care and treatment of VI as well as other health care services.

KEYWORDS

older adults; vision impairment; HIT; psychological distress; digital divide; mobile phone

Introduction

Background

A significant portion of older adults in the United States have vision impairment (VI) and associated disability. According to the 2014 American Community Survey, 4.3% (1.1 million) of the civilian, noninstitutionalized population of adults aged 65 to 74 years and 10% (1.9 million) of those aged ≥75 years reported blindness or serious trouble seeing, even when wearing glasses [1]. In the 2014 National Health Interview Survey (NHIS), 13.5% (6.1 million noninstitutionalized adult participants aged ≥65 years, including 350,000 who were blind) reported “any trouble seeing, even when wearing glasses or contact lenses” [1]. VI increases with advancing age, and the rate for the ≥85 age group in the 2014 NHIS was 22.3% [1]. The Centers for Disease Control and Prevention’s (CDC) analysis of the 2016 Behavioral Risk Factor Surveillance System (BRFSS) data also found that 6.6% of noninstitutionalized older adults reported having a vision-related disability, compared with 2.7% in the 18 to 44 age group and 6.1% in the 45 to 64 age group [2]. The BRFSS data showed that regardless of age group, VI (similar to other types of disability) is more prevalent among women than men, racial/ethnic minorities than non-Hispanic whites, and among those with lower income.

VI in older adults is attributable to refractive error (correctable with glasses) and eye disease (often not correctable or requiring surgical/medical interventions: age-related macular degeneration, ocular complications of diabetes mellitus, glaucoma, and age-related cataracts) [3,4]. According to Swenor et al [3], in the United States, uncorrected refractive error accounts for approximately 79% of VI, and cataracts are the most common correctable eye disease, accounting for approximately 50% of VI from eye disease. There are also effective strategies to prevent or delay late-life vision loss and blindness resulting from other defined diseases [4].

VI has a variety of functional consequences, as it can restrict certain activities that require good vision. One such activity may be technology use, including internet and health information technology (HIT) use. The rate of internet use in older adults has steadily risen over the past decade, with 67% using the internet and 51% having a home broadband connection in 2017 [5]. According to the Health Information National Trends Survey data, seeking health information and communicating with physicians on the web were the most significant areas of increase in internet use among older adults between 2003 and 2011/2012 [6]. However, although the digital health technology divide between genders, racial/ethnic groups, rural/urban residents, and those of various health statuses has narrowed over the years, HIT use has remained lower among those in advanced age, racial/ethnic minorities, and those with less education and lower income [6-8]. Lower levels of internet use among disabled older adults with a low income are largely attributable to the lack of financial resources to obtain computers and technology or medical conditions, disabilities, and associated pain that restrict use [9]. Keränen et al [10] also found that physical frailty was associated with lower information and communications technology (ICT) use independent of age, education, and opinions of technology use among older adults. However, studies on the internet and HIT use among older adults in the United States with VI compared with those without VI are not available, indicating a major gap in knowledge regarding VI’s impact on the digital divide.

As health care services, including provider-patient communications, increasingly rely on technology, the use of HIT by older adults has significant implications for the health care system and older adults themselves. HIT may reduce health care spending by providing preventive health promotion information, facilitating communication with health care providers, and improving health care quality and outcomes for older adults [8,11]. Longitudinal data show that HIT use may be associated with fewer physician visits among older adults with certain chronic health conditions (eg, diabetes). However, cross-sectional data show that HIT use is associated with higher health service use (eg, general practitioners, medical specialists, eye doctors, physical therapists/occupational therapists [PT/OT]) [7,12]. The latter may also be positive, as health information seeking and other HIT use behaviors, either encouraged by providers or initiated by the patient, can contribute to increased disease-related knowledge and better adherence to prevention and treatment regimens. Increased HIT use thus has significant potential for health care cost savings and improved health care quality and outcomes, especially among socioeconomically disadvantaged older adults and those with chronic medical conditions and disability.

ICT use may also impact how older adults perceive social support, loneliness, depression, psychological well-being, and quality of life, but findings vary. Some studies show that internet use results in higher levels of social support, life satisfaction and well-being, and reduced loneliness and depression [13-16]. Other studies indicate that variables such as living arrangements, ethnicity, and contact with family mediate these positive relationships and that more frequent use of ICT was associated with more psychological distress and less sense of community among older adults who were lonelier [17-19]. Elliot et al [20] found that although ICT use was not directly related to depressive symptoms or well-being, it acted as a moderator. In essence, functional limitation was a stronger predictor of depressive symptoms for high users, and ill health was a stronger predictor for nonusers or limited users. However, to our knowledge, there is no published study on the association of internet/HIT use with psychological well-being among older adults with VI.

Study Aims

Given the increasing number of older adults with VI, this case-control study examined (1) rates of internet and HIT use among a nationally representative sample of older adults with VI, compared with a matched sample of their peers without VI, (2) associations between VI and internet and HIT use, and (3) association of HIT use with psychological distress. The study hypotheses were that VI will be associated with lower odds of internet/HIT use (H1), and HIT use will be associated with lower odds of mild/moderate or serious psychological distress, controlling for VI (H2). Other covariates for the multivariable hypotheses testing were sociodemographic factors, health conditions, health insurance type, and health care service use. These findings may help identify VI as a barrier to internet/HIT use among older adults and suggest ways to improve access to technology for older adults with VI.

Methods

Data and Sample

Data from the 2013 to 2018 NHIS public-use data files were downloaded from the CDC's National Center for Health Statistics website. The NHIS is an annual, cross-sectional household survey that is the principal source of information on the health and health care access of the civilian, noninstitutionalized US population [21]. For each sampled household, interviews are conducted (mostly face-to-face) with an adult family member who answers questions about each family member's demographic and health status characteristics. The NHIS also collects more detailed health and other data from 1 sample adult from each household, which is the primary data source for this study. Combining 6 consecutive years of annual NHIS data resulted in 190,113 sample adult respondents aged 18 to ≥85 years (NHIS public-use data sets do not provide the chronological age of those aged >85 years). Of the 190,113 sample adults, 19.4% (n=48,287) were aged ≥65 years. In this study, we focused on those aged ≥65 years with VI and their matched peers without VI (n=2866).

Measures

Vision Impairment

In the NHIS, respondents were asked about vision ("any trouble seeing, even when wearing glasses or contact lenses" and "blind or unable to see at all"). They were also asked a series of questions about the levels of difficulty (not at all to cannot do it at all) performing physical functions (eg, walking, climbing) and social activities (eg, going out to social events, participating in social activities) without special equipment. Those who reported any difficulty in any of these activities/functions were then asked a series of follow-up questions about whether the difficulty was caused by specific conditions (eg, vision problems, illnesses, injuries). In this study, we refer to older adults who reported that "vision/problem seeing causes difficulty with activities" as those with VI.

Internet Use

Respondents were asked if they had used the internet in the past 12 months (yes=1 and no=0).

Health Information Technology Use

Respondents were asked if they had (1) looked up health information on the internet, (2) filled a prescription on the internet, (3) scheduled a medical appointment on the internet, and (4) communicated with a health care provider by email in the past 12 months. In this study, HIT use refers to any of these 4 activities.

Psychological Distress

This was assessed using the Kessler-6 screen (K6), a global measure of distress that includes depressive- and anxiety-related symptomology over the 4-week period before test administration [22]. The 6 items were how often you felt nervous, restless/fidgety, so depressed that nothing cheered you up, hopeless, worthless, and that everything was an effort (0=none of the time, 1=little of the time, 2=some of the time, 3=most of the time, and 4=all of the time). K6 has reported a sensitivity of 0.36, a specificity of 0.96, and a total classification accuracy of 0.92 in predicting severe mental illness, defined as any Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition (DSM-IV) disorder, other than a substance use disorder, with a Global Assessment of Functioning score less than 60 occurring in the past 12 months [22]. K6 scores of 13 to 24 (ie, serious distress) indicate a probable DSM-IV disorder and significant impairment in functioning, and K6 scores of 8 to 12 (mild/moderate distress) indicate a probable diagnosable mental illness but with less severe impairment in functioning [23]. Cronbach α for the 6 items among the study sample was 0.86.

Sociodemographic Factors

Sociodemographic factors are as follows: (1) age (65-74, 75-84, and ≥85 years), (2) gender, (3) race/ethnicity (non-Hispanic white, non-Hispanic black, Hispanic, Asian, and other), (4) marital status (not married vs married), (5) education (bachelor's degree vs no degree), and (6) ratio of family income to the official US poverty threshold (<200%, 200%-399%, ≥400%, and missing).

Health Status

Indicators of health status are as follows: (1) number (0-10) of diagnosed chronic medical conditions (eg, arthritis, asthma, diabetes, hypertension, heart disease, stroke, chronic kidney disease, liver disease, lung disease, and cancer) with which the respondent had ever been diagnosed, and (2) hearing impairment ("hearing problem causes difficulty with activity," yes=1 and no=0).

Health Insurance

Respondents were asked if they had Medicare, Medicaid, private health insurance, and veterans/military insurance coverage (yes=1 and no=0 for each) in the past 12 months.

Health Care Use

Respondents were asked if they had in the past 12 months (1) had an overnight hospitalization, (2) received health care 10 or more times, and (3) saw/talked to a general practitioner, eye doctor, medical specialist, PT/OT, or mental health professional (yes=1 and no=0 for each).

Data Analysis

All analyses were conducted with Stata 15 (Stata Corp)/MP's svy function to account for the NHIS's stratified, multistage probability sampling design and to ensure that variance estimates incorporate the full sampling design. All statistics were weighted except for sample sizes. First, using the ccmatch function [24] in Stata, we matched older adults with VI with those without VI in a 1:1 ratio, based on age, sex, number of chronic medical conditions, any other functional limitation than VI, and self-response vs proxy response status. Second, we used chi-square and 2-tailed t tests to describe and compare older adults with and without VI on sociodemographic and health statuses, K6 scores, health insurance, and health care use. For

K6 scores, we excluded 57 respondents with missing data on 4 or more items but included 6 respondents who had missing data on 1 item and 3 respondents who had missing data on 2 or 3 items after replacing the missing data with the mean of their nonmissing items on the scale for the summed score. Third, we used chi-square tests and 95% CIs to compare older adults with and without VI on their internet and HIT use. Fourth, we tested H1 (association of VI with internet/HIT use) with the study sample using 2 logistic regression models with VI (vs no VI) as the independent variable and internet use (vs nonuse) and any HIT use (vs nonuse) as the dependent variables. We also used logistic regression to examine the association of VI with any HIT use among internet users. Finally, we tested H2 (association of HIT use with psychological distress) using a logistic regression model with any HIT use (vs nonuse) as the independent variable and mild/moderate or severe distress versus no distress (ie, K6 scores 8-24 vs K6 scores 0-7) as the dependent variable. Variance inflation factor diagnostics, using a cutoff of 2.50 [25], showed that multicollinearity among covariates was not a concern. Logistic regression results are presented as adjusted odds ratios (aORs) with 95% CI. Statistical significance was set at a *P*<.05.

Results

Study Sample Selection

Of the 48,287 sample adult respondents aged ≥65 years in the 2013 to 2018 NHIS, 16.07% (n=7896, including 398 blind respondents) reported that they had “any trouble seeing, even when wearing glasses or contact lenses.” However, only 18.73% of those who were not blind but had vision problems and 53.15% of blind older adults reported vision-caused difficulty with activities. As a result, 1630 older adults, including 210 blind persons or 3.28% of all NHIS sample adults aged ≥65 years, were deemed to have VI. The 3.28% rate of VI was significantly higher than the 0.84% rate of VI among the NHIS sample adults aged 18 to 64 years. Annual rates of “any trouble seeing” among the age group ≥65 years showed an overall increasing trend over the study period; however, annual VI rates among the age group ≥65 years were not significantly different over the study period.

Of the 1630 older adults with VI, 1598 were matched in a 1:1 ratio with 1598 older adults without VI. After excluding 165 from each group whose interviews were done by proxy (as some questions were not asked of the proxy respondents), the study sample was 2866 older adults (1433 with and 1433 without VI), representing 2.67 million older adults in the United States.

Sample Characteristics

As Table 1 shows, of the study sample, 39.94%, 34.37%, and 25.68% of the VI group were in the 65-74, 75-84, and ≥85 age groups, respectively. The proportion of those aged ≥85 years in the VI group was much higher than the proportion of the same age group among all NHIS sample adults (11.38%). As the VI and no VI groups were matched for age, sex, and number of medical conditions, these variables were not significantly different between the 2 groups. However, even after matching, compared with the no VI group, the VI group had significantly higher proportions of racial/ethnic minorities, nonmarried individuals, and those with an income less than 200% of the poverty threshold and Medicaid and lower proportions of those with a college degree and private health insurance.

Of the VI group, 88.15% reported that they had VI for more than a year, and 96.99% reported that VI was a chronic condition. The VI group also included more blind and hearing-impaired individuals, with 31.01% (compared with 2.87% in the no VI group) reporting hearing-caused difficulty with activities. Psychological distress was significantly higher among the VI group, with approximately one-fourth of participants reporting mild/moderate or serious psychological distress in the preceding month. The VI and no VI groups did not differ in rates of hospitalization and visits/consultations with health care professionals other than eye doctors. Although the data did not show the exact number of times these older adults saw/talked with health care providers, a higher proportion of the VI group reported receiving health care services ≥10 times, indicating that they were more frequent health care service users than those without VI.

Table 1. Sociodemographic, health insurance, and health care use characteristics of the matched sample

Variables	No VI[a] (n=1433)	VI (n=1433)	*P* value[b]
Age (years), %			.67

Hospitalized	23.08	23.49	.83
Received care 10 or more times	27.97	33.47	.02
Saw/talked to a general practitioner	89.38	87.77	.30
Saw/talked to an eye doctor	63.09	71.99	<.001
Saw/talked to a medical specialist	52.58	47.51	.05
Saw/talked to a physical/occupational therapist	20.36	23.25	.16
Saw/talked to a mental health professional	5.97	7.88	.14

[a] VI: vision impairment.

[b] Probability values for differences between the no VI and VI groups were calculated using Pearson chi-square tests for categorical variables and, two-tailed, independent sample *t* tests for continuous variables (number of medical conditions and K6 scores).

[c] N/A: not applicable.

[d] K-6: Kessler-6 screen.

[e] Sample size is 2809 (1413 without VI and 1396 with VI) because of missing data.

Internet and Health Information Technology Use

Table 2 shows that compared with 42.61% and 30.87% of the no VI group, 29.63% and 22.37% of the VI group used the internet and any HIT, respectively. More specifically, the VI group was significantly less likely to have sought health information on the web or communicated with health care providers via email; however, the 2 groups did not differ with respect to filling a prescription and scheduling a medical appointment on the web. In addition to health information seeking, only a small proportion (3.69%-7.96%) of these older adults with or without VI used HIT for other medical/health purposes. Table 2 also shows that of those who used the internet, the VI group and the no VI group did not differ on the rates of HIT use: 67.04% of the no VI group and 69.58% of the VI group used any HIT. Although internet users' most common HIT use was for health information seeking, between 10.80% and 18.31% also engaged in the other 3 types of HIT use.

Table 2. Internet and health information technology use in the past 12 months among the matched sample

Variable	No VI[a] (n=1433), % (95% CI)	VI (n=1433), % (95% CI)	*P* value[b]
Internet use	42.61 (39.37-45.93)	29.63 (26.50-32.96)	<.001
HIT[c] use	30.87 (27.95-33.94)	22.37 (19.53-25.48)	<.001
Looked up health information on the internet	28.59 (25.74-31.63)	20.54 (17.83-23.54)	<.001
Filled a prescription on the internet	6.71 (5.24-8.55)	4.91 (3.67-6.55)	.11
Scheduled medical appointment on the internet	5.66 (4.18-7.62)	3.69 (2.52-5.38)	.07
Communicated with health care provider by email	7.96 (6.21-10.13)	5. 45 (4.14-7.13)	.04
HIT use among internet users[d]	67.04 (62.32-71.43)	69.58 (63.42-75.11)	.50
Looked up health information on the internet	61.81 (56.82-66.56)	65.62 (59.44-71.32)	.33
Filled a prescription on the internet	15.72 (12.37-19.78)	15.54 (11.60-20.51)	.95
Scheduled medical appointment on the internet	12.86 (9.56-17.08)	10.80 (7.38-15.56)	.46
Communicated with health care provider by email	18.31 (14.47-22.89)	16.42 (12.43-21.39)	.55

[a] VI: vision impairment.

[b] Probability values for differences between the no VI and VI groups were calculated using Pearson chi-square tests.

[c] HIT: health information technology.

[d] Sample size is 963 (582 without VI and 381 with VI).

Association of Vision Impairment With Internet and Health Information Technology Use Multivariable Analyses

Table 3 shows that controlling for sociodemographic characteristics, health status, health insurance, and health care service use, VI was still significantly associated with lower odds of internet (aOR 0.64, 95% CI 0.49-0.83) and HIT (aOR 0.74, 95% CI 0.56-0.97) use, although being blind by itself was not a significant factor. In terms of other significant covariates, being in the 2 older age groups, non-Hispanic black or Hispanic, and nonmarried and receiving health care ≥10 times were associated with lower odds of both internet and HIT use, whereas having a college degree, family income ≥200% of the poverty threshold (compared with <200% of the poverty threshold), and veterans/military insurance and seen/talked to a medical specialist and a PT/OT were associated with greater odds of both internet and HIT use. In addition, receiving Medicaid and having seen/talked to a mental health provider were associated with lower odds, and having seen/talked to a general practitioner and an eye doctor was associated with higher odds of internet use but not HIT use.

Table 3 also shows that among internet users, VI was not a significant factor for HIT use. Age group, marital status, education, and health insurance type were not significant. Compared with non-Hispanic white internet users, only Hispanic internet users had lower odds of HIT use. With respect to family income, only those in the *missing* income category had significantly greater odds than those with income <200% of poverty to have used any HIT. Having seen/talked to a medical specialist and a PT/OT was also associated with greater odds of HIT use among internet users.

Table 3. Association of vision impairment with internet use and any health information technology use: logistic regression results.

Variable[a]	Internet use vs nonuse, aOR[b] (95% CI)	Any HIT[c] use vs nonuse, aOR[b] (95% CI)	Any HIT use vs nonuse among internet users, aOR[b] (95% CI)
Vision impairment vs no impairment	0.64 (0.49-0.83)[d]	0.74 (0.56-0.97)[e]	1.15 (0.77-1.74)
Blindness vs no blindness	0.83 (0.44-1.57)	1.08 (0.54-2.17)	2.32 (0.72-7.43)
Age group (years; vs 65-74 years)			
75-84	0.39 (0.29-0.52)[f]	0.45 (0.34-0.59)[f]	0.92 (0.61-1.37)
≥85	0.20 (0.15-0.27)[f]	0.17 (0.11-0.25)[f]	0.36 (0.20-0.63)
Female vs male	1.31 (1.00-1.71)	1.25 (0.96-1.64)	1.02 (0.69-1.49
Race/ethnicity (vs non-Hispanic white)			
Non-Hispanic black	0.35 (0.23-0.54)[f]	0.44 (0.28-0.71)[d]	0.87 (0.40-1.86)
Hispanic	0.23 (0.14-0.40)[f]	0.23 (0.12-0.45)[f]	0.37 (0.16-0.83)[e]
Non-Hispanic Asian	0.53 (0.31-0.91)[e]	0.86 (0.41-1.77)	1.81 (0.50-6.54)
Other	1.07 (0.53-2.15)	0.89 (0.41-1.94)	0.69 (0.22-2.19)
Not married vs married	0.70 (0.55-0.89)[d]	0.76 (0.59-0.99)[e]	1.00 (0.70-1.43)
College degree vs no degree	4.17 (3.09-5.62)[f]	3.04 (2.23-4.12)[f]	1.27 (0.86-1.87)

Association of Health Information Technology Use With Psychological Distress: Multivariable Analyses

Table 4 shows that controlling for sociodemographic characteristics, health status, health insurance, and health care service use, HIT use was significantly associated with lower odds of mild/moderate or serious psychological distress (aOR 0.62, 95% CI 0.43-0.90). As expected, VI was associated with greater odds of mild/moderate or serious psychological distress (aOR 1.84, 95% CI 1.36-2.49), but blindness by itself was not. Of the other covariates, being in the 2 older age groups and black, and having a college degree and private health insurance were associated with lower odds of mild/moderate or serious distress; however, being female and nonmarried, having a higher number of medical conditions and hearing impairment, and being seen/having talked to a mental health provider were associated with greater odds of mild/moderate or serious distress. The interaction terms between HIT use and VI were not significant. The findings from the logistic regression model with internet use as the dependent variable were similar, showing lower odds of mild/moderate or serious distress among internet users but higher odds of such distress among those with VI.

Table 4. Association of any health information technology use with psychological distress: logistic regression results.

Variable[a]	Mild/moderate or serious vs no distress, aOR[b] (95% CI)
Any health information technology use	0.62 (0.43-0.90)[c]
Vision impairment vs no impairment	1.84 (1.36-2.49)[d]
Blindness vs no blindness	1.44 (0.83-2.51)
Age group (vs 65-74 years)	
75-84	0.53 (0.38-0.74)[d]
≥85	0.46 (0.31-0.70)[d]
Female vs male	1.40 (1.02-1.91)[c]
Race/ethnicity (vs non-Hispanic white)	
Non-Hispanic black	0.61 (0.39-0.93)[c]
Hispanic	1.10 (0.68-1.76)
Non-Hispanic Asian	1.18 (0.61-2.28)
Other	0.76 (0.37-1.56)
Not married vs married	1.40 (1.04-190)[c]
College degree vs no degree	0.60 (0.39-0.92)[c]
Family income (vs <200% of the poverty threshold)	
200-399	1.09 (0.76-1.55)

Discussion

Principal Findings

This study shows that 3.28% of older adults in the United States (compared with 0.84% of those aged 18-64 years) reported that their VI caused difficulty with activities. As expected, the ≥85 age group was overrepresented among those with VI as common age-related eye disorders (eg, macular degeneration, glaucoma, and cataract) tend to be associated with a gradual decline in vision [26]. Although these older adults with VI were matched in a 1:1 ratio with their peers without VI based on age, gender, and health/other disability status, those with VI were still significantly more socioeconomically disadvantaged in terms of education and income, included more racial/ethnic minorities, and had higher proportions of those with blindness and hearing impairment. They also used more health care in the past year.

The first key finding is that older adults with VI are less likely to engage in internet and HIT use than their matched age peers, even after controlling for other sociodemographic, health status, health insurance, and health care use variables, which supports H1. However, among those who used the internet, VI was not associated with the odds of HIT use. This indicates that among older adults with VI, their lower likelihood of internet use is the main reason for their overall lower rate of HIT use compared with their matched age peers. Internet users with VI are likely to navigate the internet using screen magnification and reading software and other accessibility features for vision [27] and are as likely to use HIT as their peers without VI. The second key finding is that HIT use is associated with a lower likelihood of having experienced mild/moderate or serious psychological distress in the past month, controlling for VI, which supports H2. VI is associated with greater odds of having experienced mild/moderate or severe psychological distress, suggesting that VI (and hearing impairment) negatively impacts overall well-being.

The lower odds of internet use among older adults with VI may be because of their lower socioeconomic status and higher levels of health problems and disability that previous studies identified as major contributors to the digital divide [7,8]. Costs of an internet subscription and equipment (eg, computer, tablet) are not likely to be priority items, especially among older adults with a low income who have to contend with the financial strains of managing their health and disability (eg, costs of prescription medications and transportation to health care appointments). Given that almost one-third of older adults with VI also had hearing impairment, these double disabilities were likely barriers to internet and HIT use. A survey of individuals aged 50 to 74 years in the United Kingdom found that those with moderate/serious hearing difficulties were less likely to use computers than those with no hearing difficulty [28].

Our findings also show that internet use was higher if older adults saw/talked to a general practitioner, eye doctor, medical specialist, or PT/OT, and HIT use was higher if they saw/talked to a medical specialist or PT/OT. Those who had visits with an eye doctor may be more socioeconomically advantaged than those who did not. Ehrlich et al [29] found that unmarried, older adults with a low income were less likely than their more advantaged peers to report a recent eye examination, and common reasons for not having an eye examination included cost and lack of insurance coverage. Thus, the relationship between health care provider contact and internet use may reflect the digital divide because of socioeconomic status. The association of HIT use with specialist and PT/OT consultations is also consistent with a previous study [7], suggesting that patients with complex medical conditions that lead to specialist care may be more likely to use HIT to better understand their conditions and treatments. Physical and occupational therapists also tend to spend more time with patients than physician providers do, which allows them more opportunities for patient education. Thus, patient education may have extended the use of web-based resources and encouragement for older adult patients to use these resources as part of promoting specific condition- and treatment-related knowledge as well as overall health to prevent disease, disability, and injury. The importance of integrating health promotion and wellness in PT/OT practice has also been underscored [30].

The finding that internet/HIT use was higher if older adults had veterans/military health insurance regardless of VI is likely because of the fact that the Veterans Administration (VA) health care systems are the most digitalized and telehealth-oriented of all health care systems [31]. VA patients may receive greater encouragement to use HIT to seek health information and navigate the VA health care systems. More research is needed on specific health care service/system use and HIT use among older adults.

Along with the costs of technology adoption and continued connectivity, lack of interest in and distrust of the internet as a source of health information and means of health management may be barriers to the use of HIT by older adults. A survey done in the United Kingdom on the use/nonuse of consumer electronic devices (eg, smartphones, tablet computers, and electronic book [ebook] readers) among people with VI found that cost and lack of interest were among the most frequently cited reasons for nonuse [32]. An earlier study also found that older adults were less likely than middle-aged adults to trust the internet as a source of health information; however, the association between age and distrust was no longer significant after adjusting for potential contributors to distrust, such as confusion in using the internet and providing too much information [33]. Lack of interest may also be caused by a lack of knowledge and skills for adopting technology.

Given the divergent findings discussed earlier on the relationship between ICT use and psychological well-being among older adults, more research is needed to examine moderators and mediators of the association between HIT use and lower likelihood of mild/moderate or serious psychological distress found in the study sample. Among those with VI, ICT use may facilitate social connections (eg, participation in online support and interest groups) and informational/instrumental activities (eg, reading/listening to ebooks, watching/listening to live-streamed religious services). Studies show that ICT use among older adults is associated with increased engagement/participation in social, instrumental, and leisure activities, with some ICT use compensating for aging-related and other challenging circumstances [34,35].

Limitations

This study has limitations because of data constraints. First, VI was self-reported, and data on age of onset and change over time were not available. Thus, we do not know if some older adults with VI had stopped using the internet because of progressing VI. Second, because the NHIS reports HIT use as a dichotomous variable (use vs nonuse), we could not study the effects of HIT use frequency. More detailed data on HIT use frequency and context can help in better understanding their effects on the well-being of older adults. Third, additional data on the type of activities negatively affected by VI (and other disabilities) would also have been helpful in better understanding their impacts and recommending strategies that can help people with disabilities use the internet and HIT to their advantage. Fourth, because the NHIS data are cross-sectional, we can report associations (correlations) but not causal relationships.

Conclusions

As more health care services and instrumental daily living activities (eg, banking, paying bills, applying for social services) require ICT use, the digital divide among older adults with VI must be closed. Given the potential of ICT to help older adults with VI remain active and enrich their lives, closing the digital divide may also improve their psychological well-being. First, we recommend that socioeconomically disadvantaged older adults experiencing the digital divide should be provided help to access ICT through a fee waiver or subsidy to cover internet equipment (eg, computer, tablet) and subscription services. The movement for equitable internet access as a public utility has gained momentum in state and local governments [36]. Older adults should be included as targets as they are the largest group of consumers of health care services and services that increasingly rely on ICT use. Second, older adults with VI who do not know how to use the internet and HIT but want to learn should be provided instruction and technology support services. Attention must be paid to accessibility features and adaptive devices that will facilitate technology use among those with VI. Third, in addition to improved ICT access, older adults with a low income need better access to preventive eye care and treatment of VI and other health care services. As refractive errors and some age-related eye diseases can be effectively treated to improve vision, more concerted efforts are needed to reduce VI in late life. Improved access to other health care services and providers is also important for patient education, prevention, treatment, and alleviation of health problems and functional impairment. As our study shows, certain health care provider contacts are associated with higher HIT use among older adults, suggesting attempts to better understand their health problems and treatments using technology.

Abstract

Background: Web-based self-care interventions have the potential to reduce health inequalities by removing barriers to access to health care. However, there is a lack of evidence about the equalizing effects of these interventions on chronic conditions.

Objective: This study investigated the differences in the effectiveness of web-based behavioral change interventions for the self-care of high burden chronic health conditions (eg, asthma, chronic obstructive pulmonary disease [COPD], diabetes, and osteoarthritis) across socioeconomic and cultural groups.

Methods: A systematic review was conducted, following Cochrane review guidelines. We conducted searches in Ovid Medical Literature Analysis and Retrieval System Online and Cumulative Index to Nursing and Allied Health Literature databases. Studies with any quantitative design were included (published between January 1, 2006, and February 20, 2019) if they investigated web-based self-care interventions targeting asthma, COPD, diabetes, and osteoarthritis; were conducted in any high-income country; and reported variations in health, behavior, or psychosocial outcomes across social groups. Study outcomes were investigated for heterogeneity, and the possibility of a meta-analysis was explored. A narrative synthesis was provided together with a novel figure that was developed for this review, displaying heterogeneous outcomes.

Results: Overall, 7346 records were screened and 18 studies were included, most of which had a high or critical risk of bias. Important study features and essential data were often not reported. The meta-analysis was not possible due to the heterogeneity of outcomes. There was evidence that intervention effectiveness was modified by participants' social characteristics. Minority ethnic groups were found to benefit more from interventions than majority ethnic groups. Single studies with variable quality showed that those with higher education, who were employed, and adolescents with divorced parents benefited more from interventions. The evidence for differences by age, gender, and health literacy was conflicting (eg, in some instances, older people benefited more, and in others, younger people benefited more). There was no evidence of differences in income, numeracy, or household size.

Conclusions: There was evidence that web-based self-care interventions for chronic conditions can be advantageous for some social groups (ie, minority ethnic groups, adolescents with divorced parents) and disadvantageous for other (ie, low education, unemployed) social groups who have historically experienced health inequity. However, these findings should be treated with caution as most of the evidence came from a small number of low-quality studies. The findings for gender and health literacy were mixed across studies on diabetes, and the findings for age were mixed across studies on asthma, COPD, and diabetes. There was no evidence that income, numeracy, or the number of people living in the household modified intervention effectiveness.

We conclude that there appear to be interaction effects, which warrant exploration in future research, and recommend a priori consideration of the predicted interaction effects.

Introduction

Chronic Illness and Health Inequalities

Chronic or long-term conditions such as diabetes have a significant impact on the individual's quality of life and are the major cause of disability and premature death worldwide [1,2]. In high-income countries, chronic conditions are estimated to account for 87% of all deaths [3]. Due to their nature, they cause illness over long periods and their management is complex and costly [2]. In countries where health care is universally provided (such as the National Health Service [NHS] in the United Kingdom), services are struggling with the increasing demand, partly driven by the increasing number of people with chronic conditions [4-7]. Even in high-income countries, people living in constrained conditions and with a lower socioeconomic status (SES) experience chronic illness more commonly and severity is greater than average [2,8]. For example, 52% of those from unskilled occupations suffer from chronic conditions in comparison with 33% of those in professional occupations [9]. These inequalities in health have been attributed to social determinants of health (SDH) and inequity in access to health care [10]. SDH are the complex interacting elements in the physical and social environment that contribute toward disparities in health status. Inequalities in the distribution of good quality health care mean that people do not have equal access to treatments that can improve health outcomes. Taken together, SDH mean disadvantaged groups suffer more illness and more severe illness, but are least likely to receive effective treatment, which together result in disparities in health outcomes [11].

Proposed Solutions to Increase Access to Health Care for People With Chronic Conditions

Both self-care and web-based interventions have been proposed as methods for increasing access to health care while relieving pressure on health care services. The underlying assumption with self-care interventions is that they provide health care where there was none, by encouraging people to be their own health resource [12]. Web-based interventions have the potential to increase access to good quality health care by providing support to an almost unlimited number of people from the same digital platform at the same time, and the interventions can be tailored to individual needs [13-16]. More recently, combinations of the 2 approaches, in the form of web-based self-care interventions, have become more prevalent for a range of health conditions, particularly for chronic conditions [17,18]. These digital self-care interventions are viewed as playing a vital role in the prevention and treatment of long-term illnesses such as chronic lung disease, cancer, cardiovascular disease, and diabetes [18,19].

The Impact of Electronic Health and Self-Care Interventions on Health Inequalities

Evidence of the impact of these approaches on health inequalities has been mixed. Nondigital self-care interventions in the form of community-based training courses have been found to improve health status, health behaviors, and the quality of life of patients with chronic conditions [20-24]. However, there is evidence that disadvantaged groups face barriers to accessing these interventions, such as the high levels of health literacy that are often required to understand the training materials as well as language barriers where the training is only conducted in English [8]. Web-based interventions designed specifically for those from underserved and disadvantaged groups have been found to benefit these populations [14,25,26]. However, there is also evidence that access and usability for disadvantaged groups remain to be barriers [27-30]. People from lower socioeconomic groups and older adults are less likely to seek health information on the web and have problems using the web-based information available [31-38]. There is an absence of systematic review evidence investigating whether web-based self-care interventions designed for people with chronic conditions are equally effective for people with different social characteristics.

Methods

A systematic review was conducted following the Cochrane review guidelines [39] and was reported using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses-Equity 2012 extension checklist [40]. The protocol was registered in advance on the PROSPERO international prospective register of systematic reviews (registration number CRD42017056163).

Objective

This study aimed to synthesize evidence investigating whether web-based self-care interventions designed for people with chronic conditions are equally effective for people with different social characteristics.

Inclusion Criteria

Population

A total of 4 high burden physical health conditions were included: asthma, diabetes mellitus (type 1 and type 2), osteoarthritis, and chronic obstructive pulmonary disease (COPD). The health conditions were identified using the World Health Organization's disease burden data and were selected from the top 10 conditions that cause the greatest number of years lost to disease [2,41-44]. All included conditions cause considerable burden and disability to patients [41] and health services [42,43] and have been shown to have social patterning in severity and incidence [2,44]. Furthermore, all 4 have the potential for symptoms, severity, and prognosis to be improved through changes to behavior, such as diet or physical activity.

Intervention

We included interventions that were aimed at improving symptoms or prognosis and had a web-based component or were delivered exclusively on the web. This included mobile apps with web connectivity. Interventions were included if they were predominantly reliant on the individual changing their self-care behavior without intensive contact with a therapist or clinician.

Study Types

Studies with a quantitative design were included, such as randomized controlled trials (RCTs), observational studies, quasi-experimental designs, feasibility and pilot studies, and mixed methods studies that included a quantitative element. Abstracts were not included where no full publication or report was available [45].

Systematic Review Outcomes

Studies reporting health, behavior, knowledge, and psychosocial outcomes were included.

Available Data

Studies were included if the study teams had explored whether the social or cultural groups had modified intervention effectiveness and whether the independent contribution of the group on the outcome could be determined. The authors were contacted for models where the independent contribution of the social group could not be determined in the text.

Exclusion Criteria

There were no language restrictions. The publication dates were limited from January 1, 2006, to February 20, 2019, to ensure that the review included interventions with recent technology.

Search Strategy

We conducted searches in Ovid Medical Literature Analysis and Retrieval System Online (MEDLINE; Allied and Complimentary Medicine [AMED], Excerpta Medica dataBASE [EMBASE], and PsycINFO) and Cumulative Index to Nursing and Allied Health Literature (CINAHL) databases. The final search strategy included terms for web, health conditions, self-care, or behavior change. The final search strategies are available in the Multimedia Appendix 1. Corresponding authors were contacted for additional publications, including where only abstracts were located in the search. References of the included papers were screened for inclusion.

Study Selection

After deduplication, screening was performed in 2 stages. In stage 1, abstracts and titles were screened. In line with previous practice where a large number of studies were located, partial double screening with checks for accuracy were used [46]. A random 10% sample of the abstracts and titles were independently double screened for inclusion by ST and a single second researcher [47]. Agreement between reviewers of the 10% of titles and abstracts was good (87.5%, where the prevalence-adjusted and bias-adjusted kappa=0.75 indicates good agreement) [48]. Disagreement was resolved by discussion, and consensus and screening tools were refined in light of these. The remainder of the title and abstracts were reviewed by ST only. At stage 2, full texts were obtained and screened for inclusion by ST [49,50].

Data Extraction

One author (ST) extracted the data from the included studies. Where more than one outcome was reported in each category, the primary outcome was included. Quality of life (QoL) was categorized as a health or psychosocial outcome depending on whether there was a greater balance of health or disability or psychosocial questions in the QoL tool.

The PROGRESS Plus (PP) framework was used to identify the SDH that could contribute toward health inequalities in the included health conditions and in the context of web-based interventions [51]. The analyses that had explored the modification of intervention effectiveness by social characteristics in the PP framework were extracted.

Risk of Bias (Quality) Assessment

Methodological quality was assessed independently by ST and either PL, CC, or AH. Disagreement was resolved by discussion, and consensus was reached for all of the risk of bias (RoB) domains. The Cochrane collaboration RoB tool 1.0 was used to assess the quality of RCT studies [52]. The newly updated version 2.0 was not used as it does not allow for assessment of *other bias* and would therefore not allow us to capture issues with selective recruitment. The Risk Of Bias In Non-randomized Studies-of Interventions (ROBINS-I) tool was used to assess the quality of non-RCT studies [53]. These tools were used to produce an overall RoB rating for each study.

Much of the Cochrane RoB assessment is focused on ensuring that there is balance in the samples in the two arms of the study. However, the potential for selective recruitment is also important to ensure that the sample is representative of the population with the condition. Here, selection bias was assessed under the *other* category. Inclusion and exclusion criteria were examined to determine whether they potentially excluded people who experienced greater health inequity (eg, no access to the internet, not having the skills to use it, language barriers) and whether there was a discussion of the study population being representative of those with the condition.

Data Analysis and Synthesis

Descriptive tables were populated using the data from the included papers, accompanied by a narrative synthesis. A meta-analysis was not possible due to the heterogeneity of outcomes. A novel summary figure was developed for this systematic review, which was based on an adapted version of the Harvest plot, referred to here as the *Adapted Harvest plot* [54]. The Adapted Harvest plot allows for a direct comparison of the sample size of the studies where the effect was found (or not found) across outcomes, and an impression of the quality of the study through RoB. This gives an indication of the strength and validity of the findings in relation to each outcome. A key explanation of the features and representation of the Adapted Harvest plot is shown in Multimedia Appendix 2, and information is provided in each plot. To be inclusive, all reported trends (*P*<.10) were included as evidence regardless of whether they fell under the standard *P*<.05 probability cut off and were reported in the text.

Analysis of Subgroups or Subsets

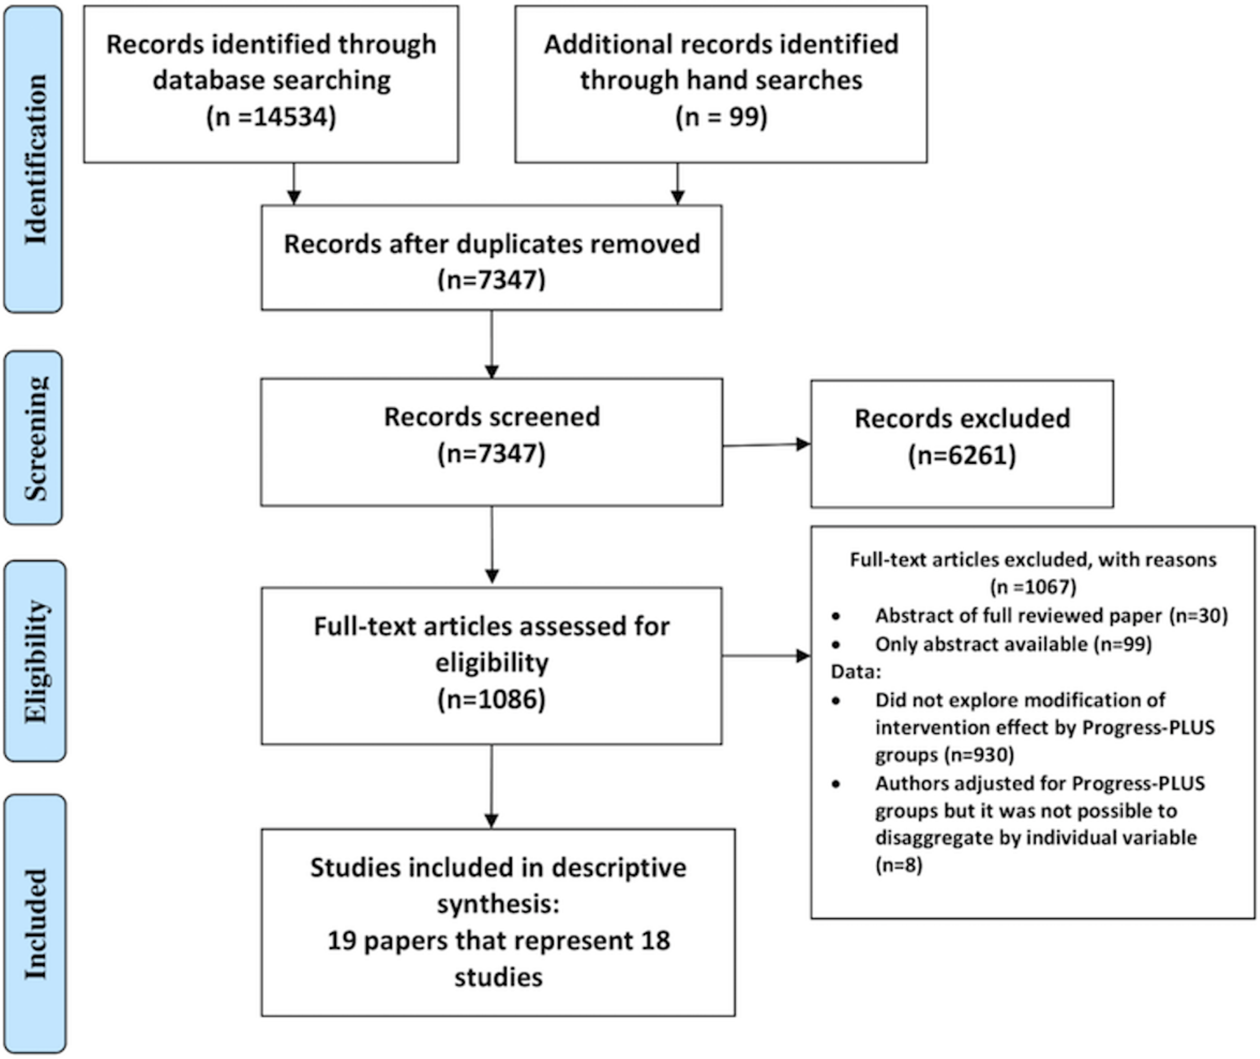
We intended to conduct subgroup analysis of differences in the application of behavioral change techniques and theory in intervention development and differences in use as potential mechanisms for modification of intervention effect by the PP group. However, these were inconsistently reported, making it challenging to analyze and draw any conclusions. Only 7 of the studies reported modification of use by PP characteristics, and 11 described the use of theory in intervention development. The selection and application of behavioral change techniques have largely not been described. Therefore, the exploration of mechanisms for modification of the intervention effect did not progress to a full analysis.

Results

Selection of Studies

After the removal of duplicates, 7346 records were obtained (Figure 1). A total of 18 studies (reported across 19 papers) were eligible for inclusion in the review (Figure 1).

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analysis flow chart.



Description of Studies

Of the 18 included studies, 1 focused on asthma [55], 2 on COPD [56,57], 13 on diabetes (5 on type 1 [58-62], 6 on type 2 [63-68], and 2 on both [69,70]), and 2 studies included participants with osteoarthritis [71,72]. The study characteristics are described in Multimedia Appendix 2. In total, 9 of the studies were conducted in the United States, 3 in the Netherlands, 2 in Canada, and 1 in the United Kingdom, Australia, France, and Israel; 13 of the studies were RCTs and 5 were non-RCTs. In total, 6003 participants were included, and the study size ranged from 38 to 1799. The reported characteristics of the study participants are presented in Multimedia Appendix 3. Studies of both children and adults were included, with an age range of

12 to 75 years across the studies. Half of the participants were female (50.1%).

Only 1 study reported that the patients enrolled in the study were representative of the population with diabetes [69]. In total, 4 studies purposely recruited a highly diverse sample in terms of ethnicity [62,67,69,73]. Follow-up times varied from 2 weeks to 12 months, and the follow-up time point was not clear for 1 study [69]. Study attrition ranged from 0% [67,70] to 31% [65], and attrition was not clearly stated in 2 studies [69,71].

Intervention Content and Outcomes Targeted by the Intervention

In total, 4 of the studies explored the effectiveness of smartphone apps and the remaining 14 explored interventions delivered through websites. Descriptions of the intervention content are provided in Multimedia Appendix 4 and summarized below. In addition to the website or app, 3 interventions provided remote support by phone or video call [55,63,65,72], 1 provided a workbook [67], 1 provided a blood glucose monitor with wireless transfer [69], and 1 provided motivational interviewing before use of the website [61]. In 3 studies, there were 2 versions of the intervention, 1 with and 1 without external support (eg, email or phone support) [60,64,67].

Modification of Intervention Design for the Needs of Disadvantaged Social Groups

A total of 2 studies designed the intervention so it had an accessible format: one was designed to maximize usability for people with lower health literacy [65] and the other study used a serious-game intervention designed to be appealing to a range of ages (11-18 years) and a range of baseline knowledge levels in boys and girls [59]. Studies also designed interventions so they were appealing or accessible to ethnic minority groups. TEENCOPE was developed specifically for young people and used a graphic novel format and a cast of ethnically diverse characters with type 1 diabetes (T1D) who present challenging social situations, approaches to solving problems, and consequences of decisions [62]. Another study that targeted Latinos for a type 2 diabetes (T2D) self-management program was provided in Spanish and English [64,67,73].

Overall Duration of Intervention

Intervention duration varied from 4 weeks to 12 months, and 5 studies did not provide clear information on the duration [60,64,68,69,71].

Potential for Meta-Analysis

It was not possible to conduct meta-analysis due to differences in the outcomes and PP categories included in the modification of intervention effect analysis, resulting in a high level of heterogeneity. Narrative synthesis was used to present findings in relation to the research questions for each of the 4 health conditions.

Methodological Quality

Randomized Controlled Trial

Using the Cochrane RoB assessment, 4 of the 13 RCTs were considered to be low-risk RoB [56,62,63,72], 6 had high RoB [55,57,60,61,64,69], and 3 did not have enough information to assess RoB [58,66,67]. Methodological assessments for each of the domains in the Cochrane RoB assessment are provided in Figure 2. Overall, the lowest RoB came from the random sequence generation (low RoB in 10 studies, high in 1, and insufficient information was provided in 2 studies) and the highest came from blinding of participants and personnel (10 studies had high RoB, 2 had low, and 1 was unclear). However, given the nature of the digital interventions, it was often not possible to blind the participants and personnel. Selection bias was assessed under the *other* category, with 8 studies classified as unclear RoB, 3 as high, and 2 as low RoB.

Figure 2. Risk of bias table for randomized controlled trials.

Nonrandomized Controlled Trial Studies

Using ROBINS-I, all 5 of the non-RCT studies were considered to have critical RoB (Figure 3) [59,65,68,70,71]. Across the studies, the lowest RoB came from the measurement of outcomes, and the highest RoB came from the classification of the intervention, and bias due to missing data.

Figure 3. Risk of bias assessment for the nonrandomized controlled trial (RCT) studies. [a]Overall risk of bias: equal to the most severe level of bias found in any domain.

?	Unclear risk of bias
NA	Intervention group not differentiated so questions did not apply

Modification of Intervention Effectiveness by PROGRESS Plus Groups

A total of 15 of the 18 studies that explored the modification of intervention effectiveness by PP categories reported effect modifiers. There was evidence that people were more likely to benefit from the intervention if they were from a minority ethnic group, were employed, had a higher level of education, and had divorced parents (study of adolescents). The findings for age, gender, and health literacy were mixed. There was no evidence of an interaction income, numeracy, or the number of people living in the household. The full key to the Adapted Harvest plot is shown in Table 1. Further details including outcomes and estimates (where provided) where interactions were found are presented in Multimedia Appendix 5 and a matrix table containing an overview of interactions across the conditions and PP groups is provided in in the Multimedia Appendix 6.

Table 1. Key to the Adapted Harvest plot.

Feature	Representation
Direction of effect category	- Positive: favors the PROGRESS Plus group ($P<.10$) - No effect: study found no evidence of an effect ($P\geq.10$) - Negative: favors the comparator group ($P>.10$)
Stack height	- Study size
Stack color	- Risk of bias assessment - RCT[a] studies: Low risk—blue, high risk—purple, unclear—gray - Non-RCT studies: low risk—blue, moderate risk—yellow, serious—orange, critical—purple, not enough information—gray
Stack pattern	- RCT studies: solid colors - Non-RCTs: patterned with dots
Number within the stack	- Study ID
Bar size	- Total number of participants in the studies finding evidence of a positive association, no effect, or a negative association with the outcome

[a] RCT: randomized controlled trial.

Age

A total of 14 studies (1 asthma, 2 COPD, 9 diabetes, and 2 osteoarthritis) examined the modifying effect of age on at least one outcome, with evidence of mixed effects (younger and older benefited more) across asthma, COPD, and diabetes studies.

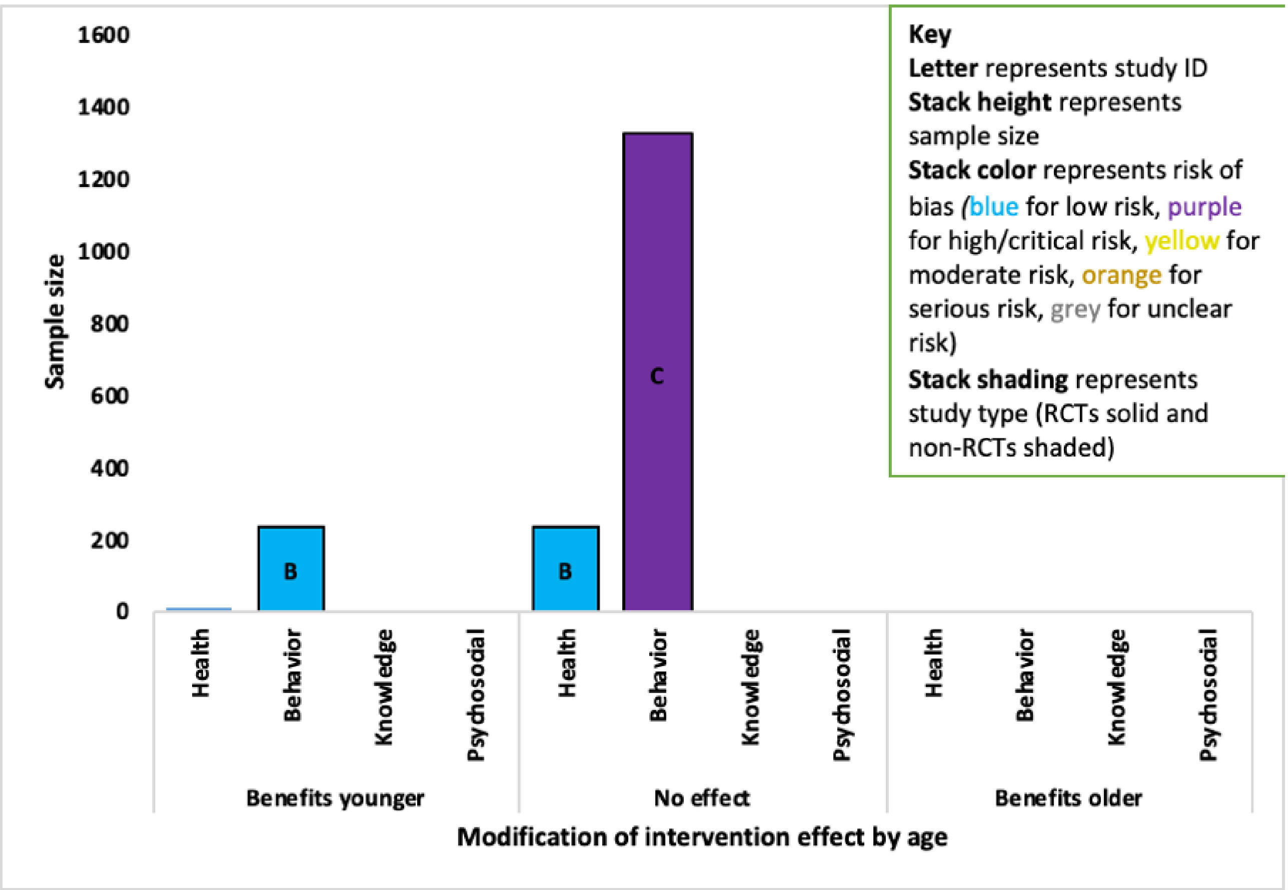
Asthma

The one asthma study (ID A; n=234; high RoB) found that increasing age was associated with increased medication adherence among adolescents aged 12 to 18 years [55]. Those scoring in the higher range in the Medication Adherence Report Scale (>19) were on average aged 0.7 years ($P=.02$) than those who scored in the lower range.

Chronic Obstructive Pulmonary Disease

One of the 2 COPD studies found evidence that older participants benefited less from the intervention than younger people on the behavioral outcome (Figure 4). The higher quality evidence came from an RCT (ID B; n=239; low RoB) that indicated that a 1-year increase in age was associated with a 33-point decrease in change in daily step count ($P=.03$) but found no association with the health-related QoL outcome [56]. The evidence for no effect on the behavioral outcome came from an RCT (ID C) with a high RoB but a larger sample (n=1325) [57].

Figure 4. Adapted Harvest plot with evidence for the modification of intervention effect by increasing age for chronic obstructive pulmonary disorder studies. RCT: randomized controlled trial.

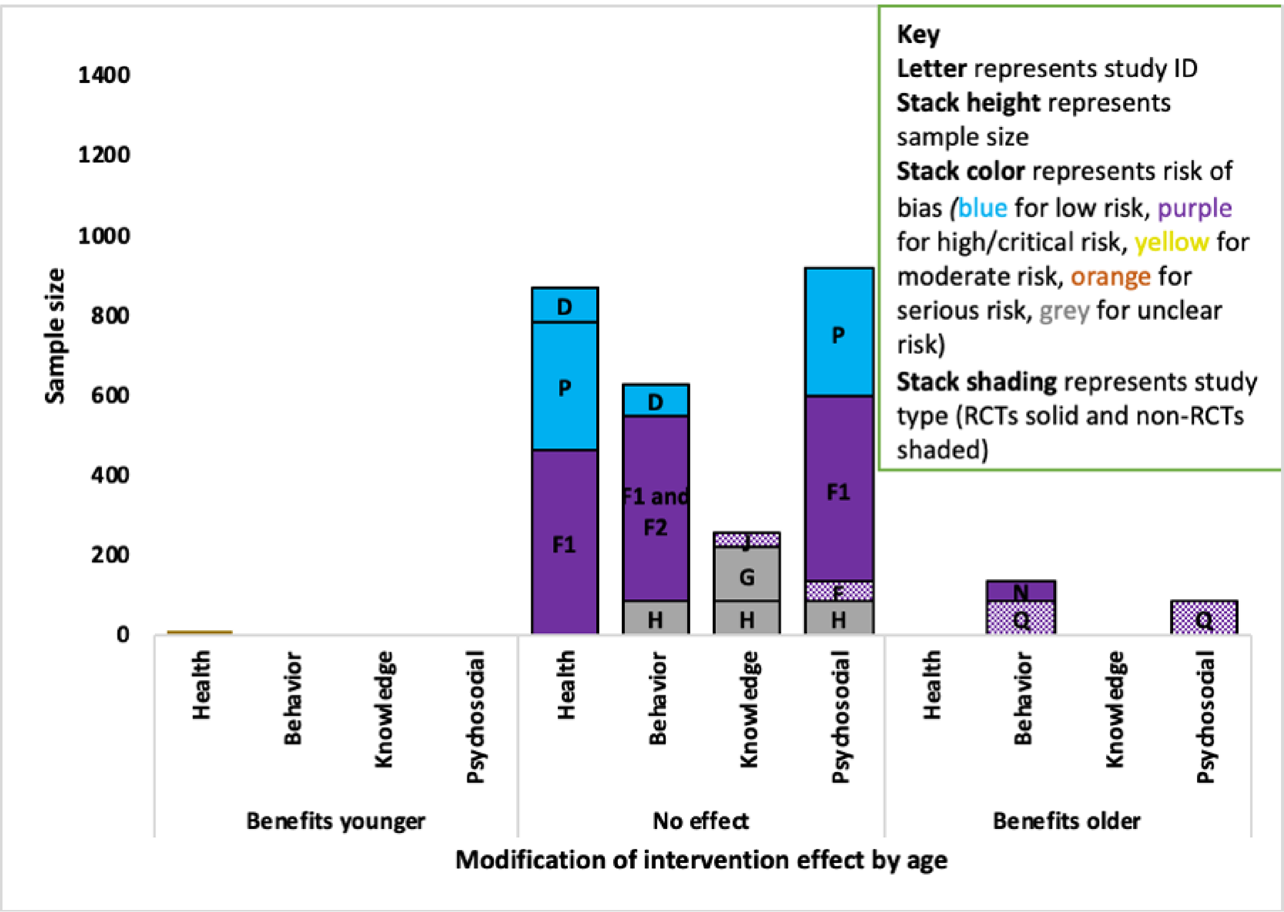


Diabetes

Of the 9 diabetes studies that reported the modification of intervention effectiveness by age, 2 studies indicated that older participants benefited more from using the intervention (Figure 5).

For the behavioral outcome, the strongest evidence indicated that there was no modification of intervention effect by age, which came from 3 studies (IDs D, F, and H) with an overall sample of 628 patients and a low, high, and unclear RoB [58,63,64,73]. There was evidence that older participants benefited more in 2 small studies (combined n=133) with a high and critical RoB: a non-RCT (ID Q; n=81; critical RoB) found that older participants benefited more (*P*<.001) in adults aged ≥25 years with T2D [68], and an RCT (ID N; n=52; high RoB) found older adolescents (aged 16-18 years) improved more (*P*<.01) than younger adolescents with T1D (aged 13-18 years) [61].Regarding psychosocial outcomes, the strongest evidence indicated that there was no modification of effect by age and it came from 4 studies (IDs P, F, E, and H, combined sample n=915) with low, unclear, high, and critical RoB [58,62,64,65]. Whereas evidence for modification for intervention effect on the behavioral outcome (*P*=.01) in adults aged ≥25 years with T2D came from a small non-RCT (ID Q; n=81; critical RoB) [68]. There was no evidence of an interaction effect with age across the health outcomes in 3 studies (IDs D, P, and F) [62-64] or with diabetes knowledge in 3 studies (IDs J, G, and H) [58,59,66].

Figure 5. Adapted Harvest plot with evidence for increasing age-modifying intervention effects across outcomes in diabetes studies. RCT: randomized controlled trial.



Osteoarthritis

There was no evidence of a difference in effectiveness by age for health outcomes in the 2 studies [71,72].

Gender

A total of 12 studies (8 diabetes, 1 asthma, 1 COPD, 2 osteoarthritis) examined the modifying effect of sex on at least one outcome, with mixed findings in diabetes studies.

Asthma, Chronic Obstructive Pulmonary Disease, and Osteoarthritis

There was no evidence of a difference in effectiveness by gender on a behavioral outcome (medication adherence) in the asthma study (ID A) [55], a behavioral outcome in the COPD study (ID C) [57], or on health outcomes in either of the osteoarthritis studies (IDs R and S) [71,72].

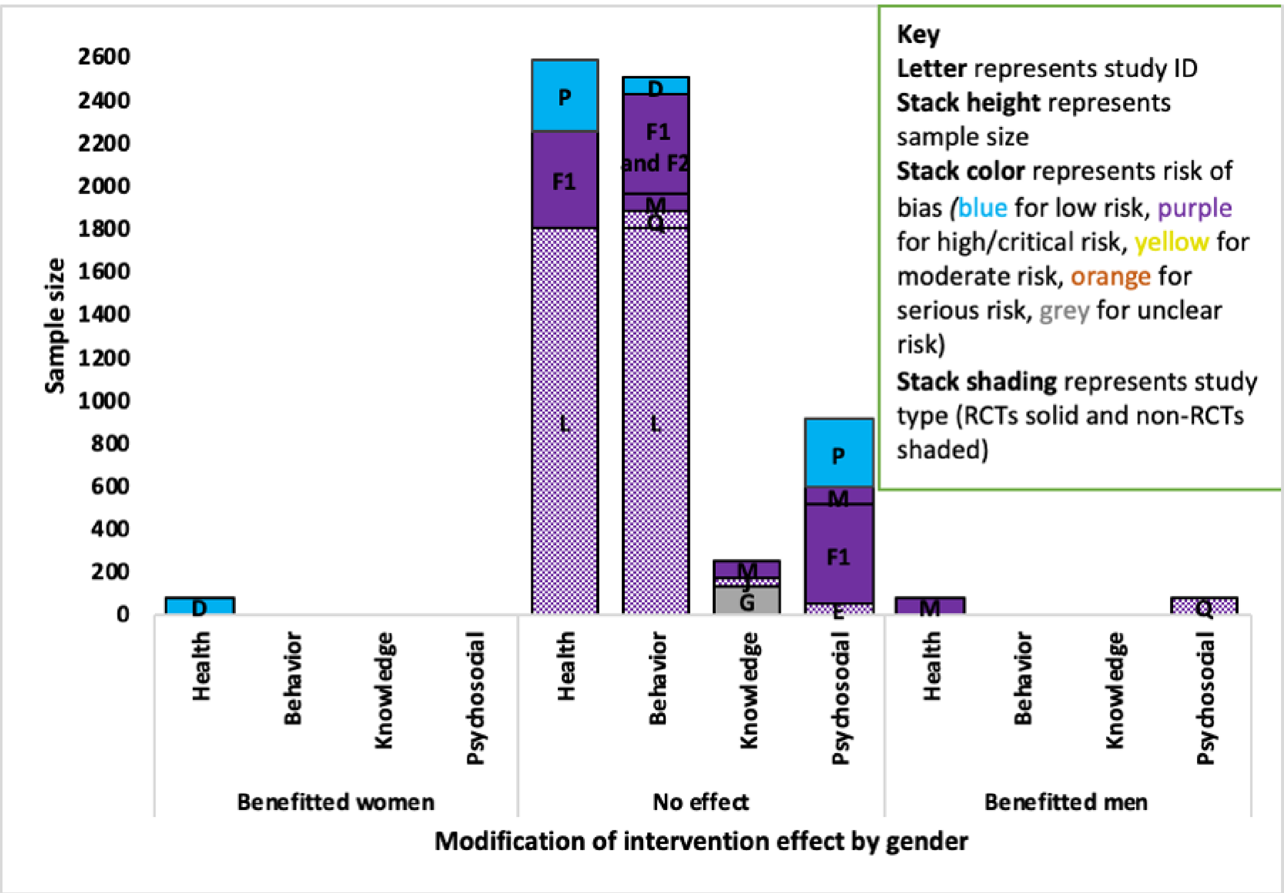
Diabetes

Of the 9 diabetes studies that explored the modification of intervention effect by gender, 3 small studies (IDs D, M, and Q) found evidence of a difference. Two studies (IDs M and Q) indicated that male participants benefited more, and one study (ID D) indicated that female participants benefited more (Figure 6).

The evidence that gender modified the health outcome was mixed. The strongest evidence indicated that gender did not modify the intervention effect and it came from 3 studies (IDs P, F1, and L; combined n=2582) with low, high, and critical RoB [62,64,70]. Of the studies that indicated gender-modified intervention effectiveness, one small RCT (ID D; n=84) with a low RoB indicated female participants benefited more (P=.03) [63] and a small RCT (ID M; n=79) with a high RoB indicated male participants benefited more (P=.06) [60].

For psychosocial outcomes, all of the evidence came from studies of high and critical RoB. The evidence that male participants benefited more (P=.01) on psychosocial outcomes came from one small non-RCT (ID Q; n=81) with a high RoB [68], in comparison with 4 studies (IDs P, M, F1, and E) that found no evidence of an effect with a combined sample of 862 and low, high, critical, or unclear RoB (Figure 6) [60,64,65]. There was no evidence of the intervention effect being modified by gender for the behavioral outcomes in 5 studies (IDs D, F, M, Q, and L) or knowledge outcomes in 3 studies (IDs M, J, and G) [60,64,66,68,73].

Figure 6. Adapted Harvest plot for gender-modifying intervention effect across outcomes in diabetes studies. RCT: randomized controlled trial.



Education

A total of 7 studies (5 diabetes, 1 COPD, and 1 osteoarthritis) examined the modifying effect of education as an outcome, with evidence that higher education benefited more in 1 diabetes study.

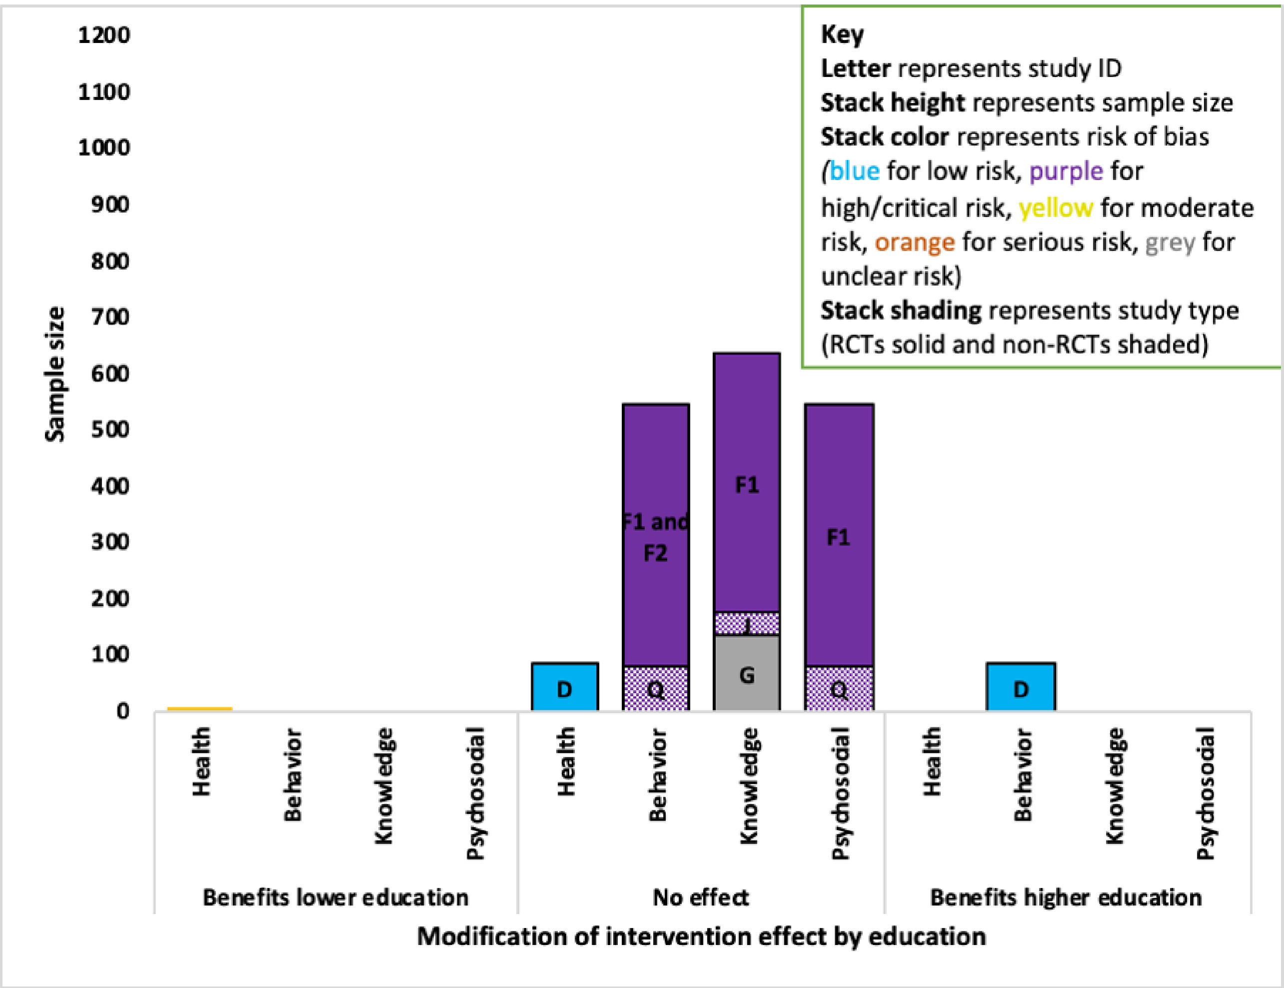
Chronic Obstructive Pulmonary Disease and Osteoarthritis

There was no evidence that the levels of education-modified intervention effectiveness in one COPD (ID C) study on a behavioral outcome [57], or an osteoarthritis study (ID R) on health outcomes [72].

Diabetes

There was evidence that those with higher education benefited more in one study, and no evidence of a difference in 4 diabetes studies (Figure 7). The strongest evidence came from a small RCT (ID D; n=84) with low RoB, which indicated that those with higher education benefited more from the intervention on a behavioral outcome (*P*=.03) but did not find an effect on a heath outcome [63]. The combined sample of the 2 studies where there was no effect on the behavioral outcome was 544, with a high (ID F1 and F2; n=463) [64,73] and critical RoB (ID Q; n=81) [68]. There was no evidence that education-modified intervention effect on knowledge outcomes in 3 studies (IDs F1, J, and G) [59,64,66] or psychosocial outcomes in 2 studies (IDs F1 and Q) [64,68].

Figure 7. Adapted Harvest plot for higher education modifying intervention effects across outcomes in diabetes studies. RCT: randomized controlled trial.



Ethnicity

A total of 8 studies (7 diabetes and 1 osteoarthritis) examined the modifying effect of ethnicity on study outcomes, with evidence that ethnic minority groups benefited more from the interventions in diabetes studies.

Diabetes

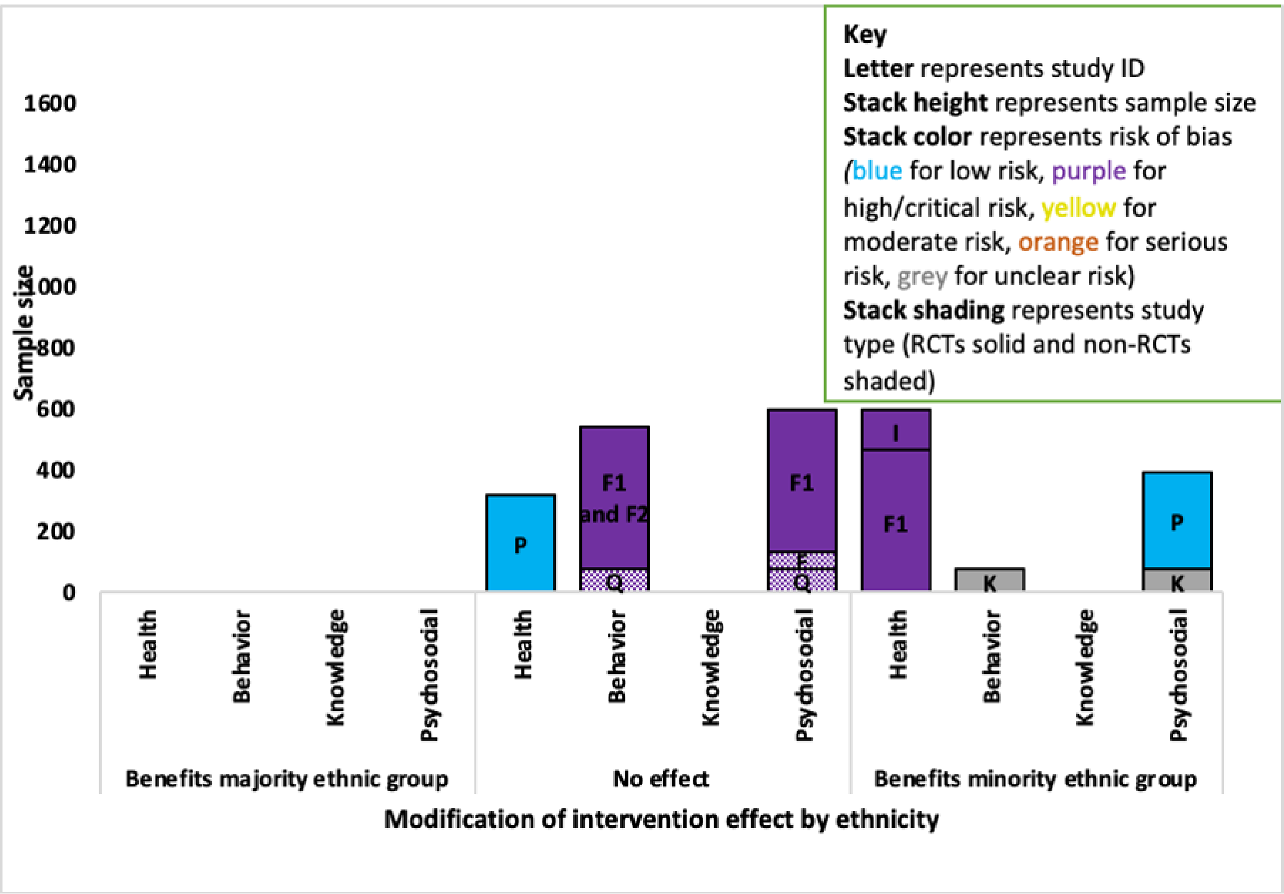
There was evidence that minority ethnic groups benefited more from the intervention than majority ethnic groups in 4 of the 7 diabetes studies that explored this interaction (Figure 8).

For the health outcomes, an RCT study with a low RoB (ID P; n=320) found no evidence that the intervention effect was modified by ethnicity [62], while 2 RCTs (ID F1 and I; combined sample n=597) both with a high RoB indicated that people from minority ethnic groups benefited more on the health outcome (ID F1; *P*=.006; for study ID I no estimates were provided) [64,69].

Regarding the behavioral outcome, a small RCT (ID K; n=73) with an unclear RoB found that minority ethnic groups benefited more (*P*=.01) [67], and the evidence of no effect came from one non-RCT (ID Q; critical RoB) and an RCT (ID F; high RoB) with a combined sample of 544 [64,68,73].

For the psychosocial outcomes, evidence indicating that minority groups benefited more from the intervention came from 2 RCTs (combined sample n=393): ID P with a low RoB (n=320; *P*=.07) [62] and ID K (n=73; *P*=.003) with an unclear RoB [67]. The evidence of no effect on the psychosocial outcome came from 3 studies (IDs F1, E, and Q; combined sample n=595): an RCT with a high RoB and 2 non-RCTs with critical RoB [64,65,68]. No studies reported the modification of a knowledge outcome by ethnicity.

Figure 8. Adapted Harvest plot for minority ethnic group modifying intervention effects across outcomes in diabetes studies. RCT: randomized controlled trial.



Osteoarthritis

There was no evidence that ethnicity-modified intervention effect on a health outcome in adults with osteoarthritis in a non-RCT (ID S) [71].

Employment

A total of 3 studies (1 COPD, 1 diabetes, and 1 osteoarthritis) examined the modifying effect of employment on at least one outcome, with evidence that employed participants benefited more in an osteoarthritis study.

Chronic Obstructive Pulmonary Disease and Diabetes

There was no evidence that employment was a moderator of intervention effectiveness in one RCT COPD study (ID C) [57] or one non-RCT diabetes study (ID Q) [68].

Osteoarthritis

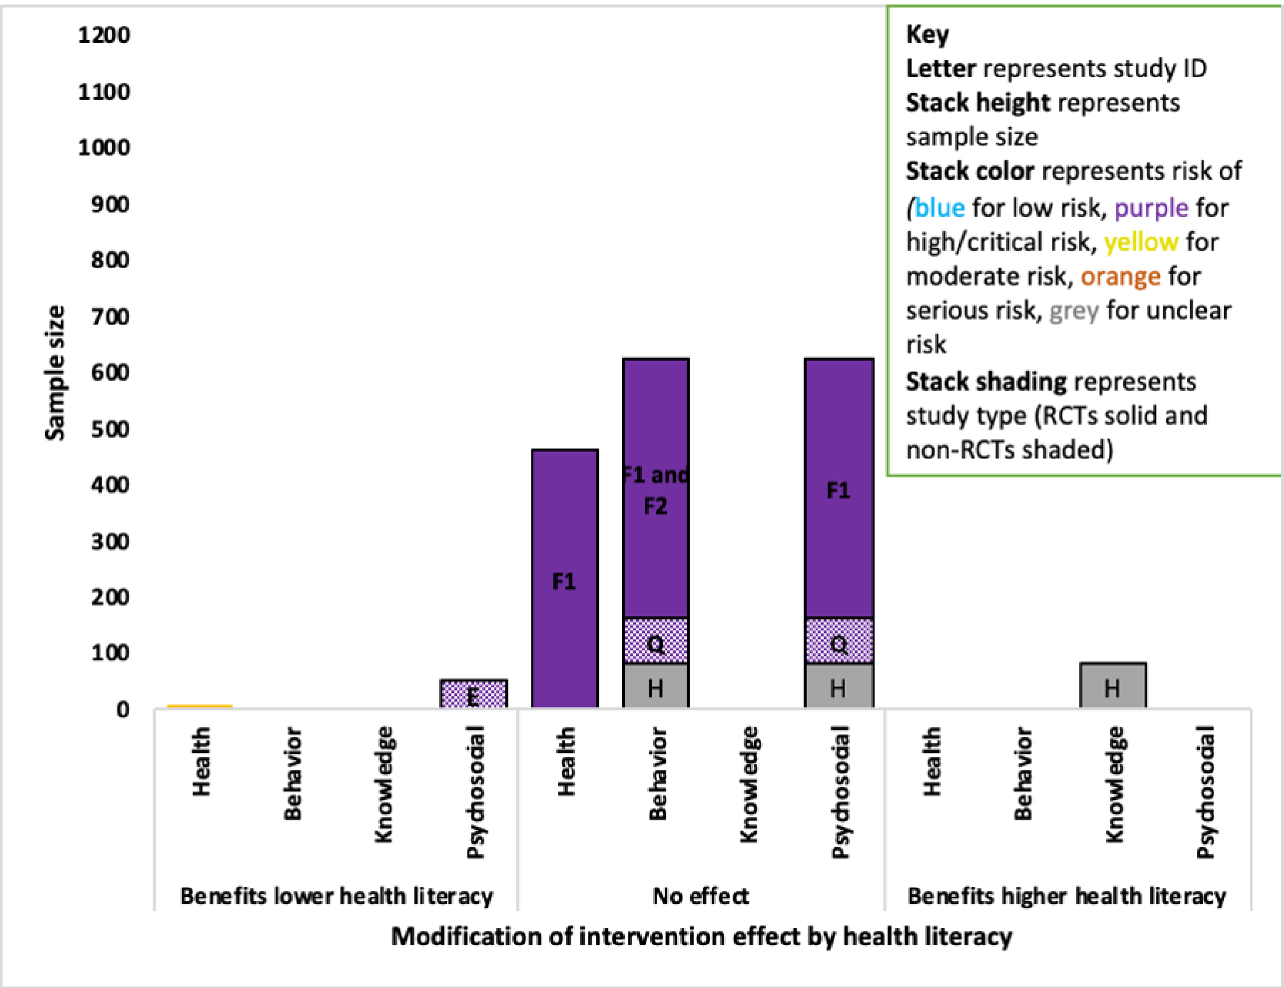
An osteoarthritis RCT with a low RoB (ID R; n=148) found that participants who were employed showed greater improvements in health outcomes (walking pain) than unemployed participants 3 months after using the intervention (interaction: *P*=.02) [72].

Health Literacy

A total of 4 diabetes studies examined the modifying effect of health literacy on study outcomes, with 2 of the 4 diabetes studies reporting evidence of a difference. However, the 2 studies provided evidence in different directions for different outcomes (Figure 9). The evidence from both studies was weak: a small RCT (ID H; n=81) with an unclear RoB found evidence that people with higher health literacy benefited more from the intervention on a knowledge outcome (no estimates provided) [58].

For psychosocial outcomes, 3 studies (combined sample: n=625) indicated that health literacy did not modify the intervention effect; these were 2 RCTs with an unclear (ID H) and high RoB (ID F1) and a non-RCT with a critical RoB (ID Q) [58,64,68]. A small single-arm pilot non-RCT (ID E; n=51) with a critical RoB found that those with lower health literacy benefited more on psychosocial outcomes (*P*=.02) [65]. There was no evidence that health literacy modified the intervention effect on a health outcome in 1 study (ID F1) [64] or behavior change outcomes in 3 studies (IDs F, Q, and H) [58,64,68,73].

Figure 9. Adapted Harvest plot for higher health literacy modifying intervention effects across outcomes in diabetes studies. RCT: randomized controlled trial.



Family Structure

One small non-RCT (ID J; n=38) diabetes study with a critical RoB examined the modifying effect of family structure on study outcomes, finding children of divorced parents benefited more from the intervention. A higher proportion of children (aged 11-18 years) with T1D who were in the high-effect subgroup for change in diabetes knowledge (benefited more from the intervention) had divorced parents (35%) compared with the low-effect subgroup (6%; *P*=.03) [59].

Income, Numeracy, Number of People Living in the Household

There was no evidence that income modified effectiveness on 2 diabetes studies (1 non-RCT: ID Q and 1 RCT: ID P) [62,68] or numeracy in 1 RCT (ID F) [64]. There was no evidence that the number of people living in the household modified the effectiveness of an intervention on health outcomes in a non-RCT osteoarthritis study (ID S) [71].

Discussion

Principal Findings

This review examined the modifying effects of participant characteristics on the effectiveness of web-based interventions for chronic health conditions. We found evidence that intervention effectiveness was modified by participants' social characteristics. In the diabetes literature, there was evidence that people from minority ethnic groups gained greater benefits from interventions than majority ethnic groups. There was evidence from single studies with variable quality that those with higher education, divorced parents (adolescent), and who were employed benefited more from interventions. A small high-quality diabetes study indicated that those with a higher level of education benefited more from the intervention. A small low-quality diabetes study found that a higher proportion of adolescents with divorced parents (adolescents) were in the high-effect intervention group compared with the low-effect group. A high-quality osteoarthritis study indicated that employed participants were more likely to benefit from the intervention than unemployed participants. The findings for modification of the effect by participant age were mixed. Older people were found to benefit less from the intervention in high-quality COPD studies, and they were found to benefit more from the intervention in 2 low-quality diabetes studies and a low-quality asthma study. Gender and health literacy were only considered in studies on diabetes and showed mixed effects. A total of 2 small low-quality studies indicated that male participants benefited more from diabetes interventions, and 1 small high-quality study indicated that female participants benefited more. Two studies had contradicting findings for health literacy: a small study with an unclear RoB indicated that those with higher health literacy benefited more, while a small low-quality study found that those with lower health literacy benefited more. There was no evidence of a modification to intervention effectiveness by income, numeracy, or the number of people living in the household.

The strength of evidence across the studies could not be assessed through a meta-analysis as not all studies provided estimates, and the outcomes were heterogeneous. Therefore, the strength of the evidence was explored through study size, RoB, and estimates, where possible. The majority of the evidence was drawn from studies with high and uncertain RoBs.

Strengths and Limitations of the Methods Used

To our knowledge, this is the only systematic review that has investigated whether there are equal benefits of web-based self-care interventions for people with different characteristics. The breadth of the studies reviewed here is both a strength and a weakness. The inclusion of 4 different physical health conditions meant that it was not possible to combine the evidence in cases where the outcomes targeted were heterogeneous, which limits what can be inferred from the results. However, we summarized the available evidence, providing the first systematic exploration of how PP characteristics modify intervention effectiveness. Simple vote counting was not judged appropriate for the synthesis of findings that could not be meta-analyzed. Instead, we created a novel summary figure based on the Harvest plot referred to here as the *Adapted Harvest plot*. The Adapted Harvest plot provided an indication of the strength of the evidence for narrative synthesis by including study size and RoB.

The majority of the screening was conducted by one person, and only 10% of the abstracts and titles were double screened. This is in line with previous practice where a large number of studies were located [46,74-77]. Every effort was made to locate all relevant literature; however, it is possible that some relevant studies may have been missed.

Limitations of the Evidence Base

There were several limitations in the methodology and data reported by the studies included in the review. It was not possible to conduct a meta-analysis because the outcomes were heterogeneous, and essential data were not reported. A high proportion of the included studies found that the intervention effect was modified by at least one participant characteristic on at least one outcome. This suggests that teams may be more likely to publish these analyses when they find evidence of a difference in effect [78].

There was a high risk of selection bias across the included studies, which may have excluded people from lower SES groups. The few studies that did comment on the representativeness of the study population indicated that the samples tended to be more white people, with higher levels of education. This not only limits the generalizability of the study findings but also potentially masks differences in effectiveness that may have been present between more and less advantaged groups because the sample is underpowered to detect differences in these subgroups.

The complex relationship between social characteristics and potential effectiveness or engagement with online interventions was not considered carefully in the included studies. The range of different PP characteristics explored and the comparisons within the PP characteristic appeared to be decided post hoc and did not appear to be guided by theory. Therefore, the evidence on the influence of PP on effectiveness was limited.

The Cochrane RoB 1.0 tool was limited in evaluating bias in the data that were important for this systematic review. Although the tool is very effective at identifying bias that can arise from the arms of a study with an unbalanced sample, it does not provide a category that evaluates the risk of the sample not being representative of the general population with the condition. RoB 2.0 was not used in this study because it does not allow for *other* RoBs and would therefore not allow us to capture issues with selective recruitment.

Comparison With Prior Work

There is no previous systematic evidence comparing the health equity effects of web-based self-care interventions for people with different social characteristics. This review agrees with previous evidence from single studies that have found that web-based self-care interventions can benefit underserved and disadvantaged groups when the intervention has been designed specifically for such groups [14,25,26]. Some of the included studies that found evidence that underserved groups benefited more from the intervention had modified their interventions to be more accessible, useable, or engaging for these groups. Two studies designed the intervention, so it was in an accessible format for those with different educational abilities. A study found that those with lower health literacy benefited more and designed interventions to maximize usability for people with lower literacy [65]. A study found that those with divorced parents and lower baseline knowledge benefited more from the intervention and opted for a serious-game intervention that was designed to be appealing to a range of ages (11-18 years) and therefore a range of baseline knowledge in boys and girls [59].

Of the 4 studies that found that ethnic minority groups benefited more, 2 studies had adapted the intervention to be appealing to the study population targeted. One study targeting Latinos with T2D provided the intervention in Spanish and English [64,73]. Another study that found that ethnic minority youth with T1D benefited more from using the intervention than majority ethnic groups used an intervention with a graphic novel format and a cast of ethnically diverse characters with T1D [62]. However, there are no specific design features that suggest why ethnic minority groups may benefit more than majority ethnic groups in these studies. Indeed, the other 2 studies that found ethnic minority groups benefited more did not adapt the interventions to make it more accessible to ethnic minority groups. It is possible that in these studies, ethnic minority groups may have benefited more from the intervention because they had less exposure to health care support before using the digital intervention. There has been previous evidence that those from ethnic minority groups and those with lower SES face greater challenges accessing health care services and support [79-81]. Therefore, interventions that reduce barriers to access and use may be more effective for populations currently underserved by health care services.

Common to the 4 studies that found minority ethnic groups benefited more from the intervention was their sampling strategy aimed at maximizing the recruitment of minority ethnic groups [62,67,69,73]. Subsequently, all 4 studies had a high representation of people from ethnic minority groups in the sample, resulting in the sample being powered to detect differences in effectiveness by ethnicity. Webb et al [82] similarly found that recruitment sampling was an important predictor of the effectiveness of an intervention. They found that when theory or predictors were used to select recipients for the intervention, the intervention had the greatest improvements in behaviors [82]. The 4 studies in this review cited the potential for digital interventions to increase access to health care in these minority groups, as motivation for their study design, and target the recruitment of minority groups [62,67,69,73]. Therefore, consideration of the sample where the intervention was evaluated appears to be important in addition to considering the needs of the target population.

Interventions designed without considering the needs of the users can exclude social groups, and this is the likely cause of the difference in effectiveness found by education and employment. Van Dijk's theory of the digital divide proposed that if the content of the technology only fulfils the needs of the dominant group (eg, high education, employed) or is challenging to use, those users from the less dominant group will benefit less from the use of the technology [83]. This supposition has been supported by findings that the design of web-based health information can limit the usability of digital interventions for people of lower SES [36,37,84,85].

The mixed findings for age, gender, and health literacy may be associated with whether the interventions were designed considering the needs of people with those characteristics. This was illustrated by the findings for health literacy in this review. Davis et al [65] designed their intervention with the needs of low literacy individuals in mind and found that those with lower literacy levels benefited more from the intervention. Huang et al [58] found that those with higher literacy benefited more and acknowledged that they would need to provide additional support for users with lower health literacy levels at baseline. Alternatively, mixed findings may be related to the participant's other social characteristics. For example, in studies where older people were found to benefit more from the intervention, they may have had a higher level of education and consequently higher digital skills relative to their younger counterparts. There is growing evidence that individual social characteristics do not work in isolation but interact in complex ways that influence health outcomes [86]. As such, conducting an analysis involving the comparison of individual groups may not be sufficient to establish how digital self-care interventions may impact health inequities.

Conclusions

There was evidence that web-based self-care interventions for chronic conditions can benefit some (minority ethnic groups, divorced parents) and disadvantage other (low education, unemployed) social groups who have historically experienced health inequity. However, these findings should be treated with caution as most of the evidence came from a small number of low-quality studies. The findings for gender and health literacy were mixed across diabetes studies, and the findings for age were mixed across asthma, COPD, and diabetes studies. There was no evidence that income, numeracy, or the number of people living in the household modified intervention effectiveness. We conclude that there appear to be interaction effects that warrant exploration in future research, and a priori consideration of predicted interaction effects is recommended.

Acknowledgments

This project was funded by the National Institute for Health Research (NIHR) School for Primary Care Research (SPCR; project reference 2019-5007) at the University of Bristol. Abstract

Background: As a result of demographic changes, the number of people aged 60 years and older has been increasing steadily. Therefore, older adults have become more important as a target group for health communication efforts. Various studies show that online health information sources have gained importance among younger adults, but we know little about the health-related internet use of senior citizens in general and in particular about the variables explaining their online health-related information–seeking behavior. Media use studies indicate that in addition to sociodemographic variables, lifestyle factors might play a role in this context.

Objective: The aim of this study was to examine older people's health-related internet use. Our study focused on the explanatory potential of lifestyle types over and above sociodemographic variables to predict older adults' internet use for health information.

Methods: A telephone survey was conducted with a random sample of German adults aged 60 years and older (n=701) that was quota-allocated by gender, age, educational status, and degree of urbanity of their place of residence.

Results: The results revealed that participants used the internet infrequently (mean 1.82 [SD 1.07]), and medical personnel (mean 2.89 [SD 1.11]), family and friends (mean 2.86 [SD 1.21]), and health brochures (mean 2.85 [SD 1.21]) were their main sources of health information. A hierarchical cluster analysis based on values, interests, and leisure time activities revealed three different lifestyle types for adults aged over 60 years: the Sociable Adventurer, the Average Family Person, and the Uninterested Inactive. After adding these types as second-step predictors in a hierarchical regression model with sociodemographic variables (step 1), the explained variance increased significantly (R^2=.02, P=.001), indicating that the Average Family Person and the Sociable Adventurer use the internet more often for health information than the Uninterested Inactive, over and above their sociodemographic attributes.

Conclusions: Our findings indicate that the internet still plays only a minor role in the health information–seeking behavior of older German adults. Nevertheless, there are subgroups including younger, more active, down-to-earth and family-oriented males that may be reached with online health information. Our findings suggest that lifestyle types should be taken into account when predicting health-related internet use behavior.

older adults; online health information seeking; lifestyle; segmentation; cluster analysis

Introduction

Background

The world population is aging; in 2017, at least 962 million people worldwide were 60 years old and older. Researchers expect a doubling of this number by 2050 [1]. The reasons for this tendency are an increase in life expectancy and a decline in birthrates. This demographic change implies multiple challenges for society, especially for the health care system and health care communicators because aging is linked with several health-related restrictions: research predicts a sharp increase in age-related diseases [2,3], which will lead to a greater need for medical care [4]. For this reason, it is important to effectively inform older adults about health issues, help them manage (chronic) diseases, and promote a healthy lifestyle and, in doing so, relieve the health care system in the long run. In order to guarantee successful communication, it is important to understand what sources of health information seniors use and which predictors best explain their health information–seeking behavior.

In general, the internet has become increasingly important as a source of health information. Research indicates that there has been a great increase in internet use for health information among several target groups [5-8]. Several studies even proclaim the internet to be the most important source of health information nowadays [7,8]. However, other studies show that sources such as interpersonal communication with health care providers or traditional media channels are still more important than the internet [9]. Among older adults, both data on general internet use [10] and data on online health information seeking [9,11] indicate that the internet does not play a major role as a source of health information among older adults.

Given the rapid evolution in this area and the contradictory view on the role of the internet for older adults, we sought to examine the role of the internet as a source of health information for older adults in Germany and, in particular, identify which attributes best explain their online health information–seeking behavior. Research findings indicate that sociodemographic variables are strong predictors of online health information behavior [11], but they do not explain all of it. Thus, explaining the use of the internet for health information using only sociodemographic variables reflects only a part of the picture. Studies in the context of consumer research have considered lifestyle attributes in order to better understand and explain user behavior [12]. Accordingly, online health information–seeking behavior might be influenced by lifestyle factors and values.

Thus, our study focused on the role of lifestyle variables to explain older adults' online health information behavior. In our article, we focus on adults aged 60 years and older because in the field of gerontology and consumer research it is a common practice to subdivide old age into those aged under 60 years and those aged 60 years or older [13-15]. Because there has been no research showing the impact of lifestyles as predictors of older adults' online health information behavior, we investigated in a representative survey (1) the role of the internet for health information–seeking behavior among German adults ages 60 years or older and (2) to what extent lifestyle types contribute to the model over and above sociodemographic variables.

Health Information–Seeking Behavior of Older Adults

According to the Health Information National Trends Survey, in 2014 at least 45% of Americans stated that the internet was their primary source of health information, followed by health care professionals, traditional media, and family and friends [7]. In Germany, representative data showed a similar picture—for instance, in 2013 40% of Germans used the internet for health information [16,17].

However, for adults aged 60 years and above, findings present a different picture. People in this age group predominantly consult health care professionals to obtain health-related information [18,19]. Moreover, they typically use traditional media such as print media, radio, TV, and material from health insurance funds or pharmacies for health-related information [17,20,21]. Although internet use for health-related information among older adults has been steadily increasing over the past years, it still seems to play a minor role. In 2013, just 16% of German adults 60 years and older indicated the use of the internet for health purposes [17]. In America, the number is slightly higher, with 29% of people 65 years and older using the internet to obtain health information [5]. Due to increasing internet use in general during the past several years and a lack of data about the current status quo, we asked:

- RQ1: Which sources of health information do older adults use in Germany and what role does the internet play in this context?

Factors Explaining Online Health Information–Seeking Behavior of Older Adults

Online health information seeking can be determined by many different factors. A representative study in Europe examined age as one of the strongest predictors of online health information behavior [11]. With increasing age, the number of people who use the internet to seek health-related information decreases [9,18]. Those differences between younger and older people might be a result of psychological and social aging processes. Thus, research found that older people have less technological control and self-efficacy in addition to fewer skills for adapting to new technologies [22]. This lack of confidence can reduce the intention to use online health information [23]. Additionally, adults do not trust the internet as a source of health information [9] and have difficulties in coping with the information overload they find when seeking information online [24]. Other age-related factors that determine internet use are people's cognitive capability (such as memory loss) and physical conditions (such as sight loss) [25]. Furthermore, people who are generally curious about life in particular search more actively for health information online [26].

In addition to age, research findings indicate that well-educated people who live in an urban area are more likely to use the internet for health-related purposes than those who are less educated and live in a rural area [11,16,27]. Research focusing on the influence of gender-specific online health information–seeking behavior demonstrates heterogeneous findings: while men generally use the internet more often, women are more interested in health information [28]. Accordingly, some researchers found more frequent health-related use of the internet for females [29,30], while others indicate that the typical online health information seeker is male [31].

Another discrepancy in research findings can be found with respect to individuals’ health status. On the one hand, studies indicate that people with poorer health are more likely to search for health information online than people with a good health status [11,26]. On the other hand, studies suggest that adults with a good health status use online health information sources more frequently than those with a poorer self-reported health status [32]. Given the inconclusive picture, we ask the following question:

- RQ2: Which factors (age, education, gender, place of residence, health status) explain older adults’ online health information–seeking behavior?

Lifestyle Segmentation to Explain Online Health Information–Seeking Behavior

Differences in (consumer) behavior cannot only be explained by demographic variables but rather are influenced by people’s general lifestyles as well [33]. Lifestyles can be defined as “patterns of action that differentiate people.... Lifestyles therefore help to make sense of...what people do, and why they do it, and what doing means to others” [34]. Lifestyle segmentation is a concept derived from market or audience research [12] that aims to cluster people with similar characteristics or values. It has been used primarily in the marketing sector [35] but also in the context of health campaign planning [12]. In marketing and consumer research literature, the term lifestyle is often used synonymously with psychographics [36]. However, psychographics mainly focus on personality traits whereas lifestyles mainly focus on needs and values closely associated with behavior [37]. Because of this, we decided to refer to the lifestyle concept instead of psychographics in this study.

In the context of lifestyles, audience segmentation can be seen as “classification schemes...[that] are based in overarching models and assumptions about...lifestyles and values and not on variables that predict a specific behavior” [38]. Lifestyle is primarily defined by activities, interests, and opinions [33,39-41]. Accordingly, activities (such as work or hobbies), interests (such as family, home, media), and beliefs (such as social issues, politics, culture) are typically measured in order to identify lifestyle types [42]. In addition, researchers often relate lifestyles to values [43] because they are a part of individuals’ views of the world and thus form a major factor in people’s character and behavior [33,44].

In the context of consumer research and audience segmentation, previous studies have already addressed lifestyle attributes to explain consumer behavior [33]. In the specific case of media use, lifestyle segmentation has been used to understand habits such as daily newspaper use [45], adolescents’ media use [46], adoption and use of pagers and mobile phones [41], older adults’ participation in online communities [47], and attitudes toward internet advertisements [48]. While these studies found differences in the behavior between the examined lifestyle types, another study investigated whether lifestyles have the potential to explain online news usage [49]. The authors found that lifestyles did not predict the adoption of online news in general. However, the enjoyment of interactive capability of online news was predicted most strongly by lifestyles in the group of adopters [49].

Most of the aforementioned studies included internet use either as a cluster-forming variable rather than a dependent variable [50,51] or studied differences within the clusters and not the explanatory potential of lifestyles [41,45-48]. Additionally, there is an ongoing debate about whether lifestyles, compared with demographics, are suitable to explain media use patterns. Skeptical researchers suggest that lifestyles are already included in demographic variables [52]. Hence, one study compared the influence of demographics and psychographics to explain the consumption of different forms of media use [53]. It found that the contribution of demographics and psychographics varied across the different behaviors: while psychographics played no role beyond the demographic explanation in outcomes such as genre preferences, the prediction of TV consumption benefited from adding lifestyle variables. Therefore, the authors of this study recommend integrating both approaches to explain and understand behavior [53].

The role of lifestyle variables becomes particularly important when focusing on older adults: several studies show that age itself is not the main predictor for behavior among older people [47,54,55]. A reason might be that aging is a very individualistic process: rather than aging chronologically, people age very differentially [54,56]. How old someone feels is directly associated with their mindset (eg, values) and activity—thus, lifestyle variables play a major role in explaining behavior [54]. For instance, a 65-year-old person can have a very inactive lifestyle and may wish to stay at home most of the time, while a 75-year-old person can be still very sporty and interested in discovering new things. This example might make clear why older people are often described as the most heterogeneous audience [47]. Lifestyle types have already been successfully used to segment this heterogeneous target group into homogenous subgroups to get a better understanding of the so-called gray market [50,51,57-59], but there is no research examining the impact of lifestyle segmentation on the online health information–seeking behavior older adults.

In sum, demographic variables such as age, education, gender, and health status have an influence on online health information–seeking behavior. However, in many cases lifestyle types can go beyond demographics in explaining behaviors. Nevertheless, there has been no research examining the impact of lifestyle segmentation on the online health information–seeking behavior in general and especially of older adults. This led us to ask the following:

- RQ3: Which lifestyle types can be identified in the age group 60 years and older based on general values, leisure values, leisure activities, and interests?
- RQ4: Do lifestyle types offer added value to explain older adults’ online health information–seeking behavior beyond demographics?

Methods

Recruitment

To answer our research questions, we conducted a telephone survey with 701 adults aged 60 years and older recruited by the Institute for Applied Marketing and Communication Research GmbH. As the study involved human participants, an institutional review board approval was obtained by the advisory board on ethical issues of the University of Erfurt (No. 17/05/29). All participants gave their informed consent to use and share their data for scientific purposes without disclosure of their identity. The respondents were selected randomly and quota-allocated by age (60-64 years, 65-74 years, and >75 years), rural/urban living areas (<10,000 residents, >10,000 residents), gender (male, female), and education (low, high). The survey was conducted as part of the formative research for the strategic development of a vaccination campaign and therefore also included health-related questions not relevant here. For this reason, the interview duration was about 30 minutes.

About half (15,967/31,419, 50.82%) of the total sample did not fit into the quota or were not reached. In addition, 46.57% (14,633/31,419) of the respondents refused to participate. Since the response rate was low (701/31,419 [2.23% of the gross sample]), the telephone survey did not fully reach the targeted quotas. Because of this, a weighting factor was applied in the following analyses, except in the factor analysis and cluster analysis—SPSS Statistics (IBM Corporation) does not allow the use of weighting in those data analytic procedures.

Measurement

Dependent Variables

Participants' health information–seeking behavior was measured using sources of health information with 11 items—internet use, health personnel, brochures, family and friends, conventional media (TV, radio, newspapers), apps, pharmacy, books, other patients, health insurance, and health workshops—on a 5-point scale (How often do you use the following sources of health information in general? 1 = never to 5 = very often) [60,61].

Lifestyle Variables

As a central determinant of lifestyle types, we measured general values and life goals with 11 items on a 5-point scale (1 = not at all important to 5 = very important): law and order, safety, success, creativity, political commitment, amusement, conformity, friends, environment, peace and harmony, and religion.

In addition, we assessed participants' leisure values with 3 items (experience adventures, meet interesting people, and do something new/crazy) on a 5-point scale (1 = not at all important to 5 = very important).

To examine the recreational activity of our participants, we asked how often they engage in the following leisure time activities during their free time (eg, at weekends, in the afternoon): using a computer, participating in sports, going to the theater/opera, visiting a museum, eating out in a restaurant, having guests visit them at home, reading books, watching TV, gardening, doing handicraft work, going for a walk, baking/cooking, listening to music, and spending time with their family. The frequency was measured on a 5-point scale (1 = never to 5 = very often).

Participants' personal interests were assessed on a 5-point scale (1 = not interested in to 5 = very interested in) via 11 items: politics, economics/law, sports, health, arts/literature, science, children/upbringing, partnership/family, traveling/vacation, work, and house/garden.

Further Predictor Variables

Participants' subjective health status was measured on a 5-point scale (1 = very bad to 5 = very good) with the question: How would you describe your actual state of health? (mean 3.06 [SD 0.80]) [62].

Finally, we assessed age, gender (0 = male, 1 = female), educational level (0 = low, including no educational qualifications, secondary modern school until class 9, or junior high; 1 = high, including university-entrance diploma, university degree, or higher), and the urbanity of place of residence (0 = under 10,000 residents, 1 = more than 10,000 residents).

Power Analysis

A power analysis determined the sample size for inferential statistics (independent *t* test: power=.80, α=.05, effect size *d*=0.2) and was rounded up to the nearest hundred [63].

Results

User Statistics

After weighting, the average age of participants was 71.6 (SD 7.3) years and 55.3% (388/701) were female. Most subjects had lower education levels (590/693, 86.0%) and came from cities with a population of more than 10,000 residents (518/701, 73.9%). Regarding their technical equipment, nearly two-thirds of our sample owned a computer (464/698, 66.2%) and nearly half of them had a smartphone (289/699, 41.4%). Furthermore, 60.7% of the participants (425/697) used the internet at least occasionally with an average duration of 85.2 (SD 109.9) minutes per day. See Multimedia Appendix 1 for descriptive analyses of all variables included in the following main analyses.

Evaluation Outcomes

Health Information Behavior of Older Adults

For our first research question (RQ1), we wanted to know what health information sources older adults use and if the internet plays a role in this context. A descriptive analysis (Table 1) showed that the most commonly used sources of health information were free brochures and pharmacy magazines, followed by interpersonal communication with medical staff, family, and friends, and traditional media sources. The internet was only infrequently used as a source of health information (mean 1.82 [SD 1.08]). Only other patients, health insurances, health workshops, and apps are used less often than the internet to get health information.

Table 1. Frequency of older adults' use of health information sources (n=681-689).

Source	Mean (SD)	95% CI
Health personnel	2.89 (0.04)	2.81-2.98
Family/friends	2.87 (0.40)	2.80-2.95
Brochures	2.85 (0.05)	2.76-2.94
Conventional media	2.70 (0.04)	2.61-2.78
Books	2.01 (0.04)	1.93-2.09
Pharmacy	1.97 (0.04)	1.90-2.04
Internet	1.83 (0.04)	1.78-1.91
Other patients	1.80 (0.04)	1.73-1.87
Health insurance	1.42 (0.03)	1.34-1.47
Health workshops	1.29 (0.03)	1.23-1.34
Apps	1.12 (0.02)	1.08-1.15

Lifestyle Types of Older Adults

In order to identify lifestyle types among adults aged 60 years and above (RQ3), we combined factor analyses with a cluster analysis. Because all lifestyle constructs were assessed via numerous items, in a first step we conducted exploratory factor analyses (rotation method: varimax; missing data: listwise deletion) with principal axis factoring in order to group similar variables into dimensions. Items that could not be summed up to one of the factors were treated separately in the cluster analysis.

Four of the 11 general values items could be combined into 2 factors (Kaiser-Meyer-Olkin [KMO]=.539; Multimedia Appendix 2), including the dimensions harmony (high loadings on importance of friends, peace/harmony) and regularity (high loadings on importance of law and order, safety).

The leisure activities were assessed with 14 items, of which 6 could be summed to 3 factors (KMO=.501; Multimedia Appendix 3), including culture (high loadings on going to a theater/opera, visiting museums), home and garden (high loadings on handicraft work, gardening), and technology (high loadings on using a computer, anti-baking/cooking). The leisure values (3 items) were treated separately (in accordance with the underlying scale).

The participants' personal interests were measured with 11 items that were combined into 2 factors (KMO=.580; Multimedia Appendix 4), including news (high loadings on interest in politics, economics/law) and family (high loadings on interest in children/upbringing, partnership/family, work/education).

In order to identify homogenous groups of cases based on the above-mentioned lifestyle variables, a hierarchical cluster analysis was computed. Ward minimum-variance clustering was performed using the squared Euclidean distance. Prior to the hierarchical cluster analysis, the relevant assumptions of this statistical analysis were tested [64,65]: (1) sample size of n=701 was deemed adequate, (2) statistical outliers were eliminated, (3) there were no missing data, (4) all analyzed variables were z-standardized, and (5) cluster variables were tested for normal distribution (the latter assumption was violated, but the hierarchical cluster analysis is robust to this violation) [66]. At each step, samples were merged into larger clusters to maximize the between-cluster sum of squares. Using this approach, three clusters were identified. They differed significantly in all cluster variables except for the leisure activity domestic work (Table 2).

Table 2. Differences in general values and life goals, leisure values, leisure activities, and interests between the identified clusters (n=595).

[a-c]Cells in a row with different letter superscripts differ with $P<.05$ (Duncan post hoc test).

Cluster 1 consisted of 28.5% (169/595) of the total subjects. This cluster was characterized by participants who were interested in almost all questioned activities. They stated an appreciation for meeting interesting people, doing something crazy, and experiencing adventures. In addition, they liked to have guests, read books, and spend time actively (eg, doing sports, visiting a museum). Furthermore, they attached great importance to a life full of creativity, amusement, and political engagement. Hence, cluster 1 was called the Sociable Adventurer.

The second cluster was the largest group, with 51.7% (308/595) of the total subjects. This group included older adults who put less value on experiencing adventures or doing something crazy. Instead, they appreciated doing domestic work and gardening or spending time with their families. In general, they did not focus on a life full of success or amusement. Therefore, we called this type the Average Family Person.

Cluster 3 was the smallest group (118/595, 19.8%) and significantly different from the others, characterized by participants who had no real interests and did not like to leave their comfort zones (such as having no interest in experiencing adventures or trying something new). These subjects had a great sense for regularity. Cluster 3 was called the Uninterested Inactive. For a more comprehensive overview of the three lifestyle types, we look at their demographics in the next step (Table 3).

Table 3. Characteristics of clusters by demographic variables.

Demographics	Sociable Adventurer, n (%)	Average Family Person, n (%)	Uninterested Inactive, n (%)
Age in years			
60-64	48 (28.4)	76 (24.8)	25 (21.2)
65-69	45 (26.6)	65 (21.2)	13 (11.0)
70-74	25 (14.8)	55 (17.9)	18 (15.3)
75+	51 (30.2)	111 (36.2)	62 (52.2)
Gender[a]			
Female	81 (47.9)	126 (41.0)	66 (55.9)
Male	88 (52.1)	181 (59.0)	52 (44.1)
Education[a]			
Low	67 (40.1)	172 (56.0)	87 (74.4)
High	100 (59.9)	135 (44.0)	30 (25.6)
Place of residence[a]			
Smaller city	23 (13.5)	94 (30.5)	39 (33.1)
Middle sized or larger city	147 (86.5)	214 (69.5)	79 (66.9)

[a] Demographic factors differ with $P<.05$ (χ^2 difference test).

Corresponding to the degree of activity, the oldest participants belonged to cluster 3. This cluster was also characterized by individuals with lower educational status. With regard to the place of residence, it becomes obvious that cluster 1 mainly consisted of people who lived in middle sized or larger cities. Last, cluster 2 can be characterized by a high proportion of men as compared with the other lifestyle types.

Factors Influencing Online Health Information–Seeking Behavior

In order to analyze which factors influence online health information seeking among older adults (RQ2 and RQ4), we conducted a 2-step hierarchical regression analysis with internet use for health information as the dependent variable (for an overview of distribution of the outcome variable, see Multimedia Appendices 1 and 5). The independent variables age, gender, educational status, health status, and place of residence were entered in step 1 and the lifestyle types in step 2. Because of the significantly different characterization of cluster 3, the Uninterested Inactive (dummy) served as reference group for the variables the Sociable Adventurer (dummy) and the Average Family Person (dummy). Prior to the hierarchical regression, the relevant assumptions of this statistical analysis were tested. First, the sample size was deemed adequate for the 7 independent variables to be included in the analysis [67]. The assumption of singularity was also met, as the independent variables were not a combination of other independent variables. An examination of correlations revealed that no independent variables were highly correlated. Also, there was no multicollinearity as indicated below (tolerance >0.10, variance inflation factor <10) [68]. Residual and scatter plots indicating the assumptions of normality, linearity, and homoscedasticity were all satisfied [69,70].

Hierarchical regression revealed that at step 1, demographic variables contributed significantly to the regression model (R^2=.114, $F_{5,582}$=14.92, P<.001). As can be seen in Table 3, age correlated negatively with the frequency of online health information seeking (β=–.236, P<.001). Accordingly, younger elderly used the internet more often than older ones as a source of health information. Another significant predictor was participant gender. Specifically, men showed greater online heath information–seeking behavior than woman (β=–.131, *P*=.001). Moreover, educational status (β=.126, *P*=.002) and health status (β=.081, *P*=.04) correlated positively and significantly with online health information use, indicating that highly educated and healthy seniors tend to use online health information more often than less well-educated subjects and those with poorer self-reported health. The place of residence was not significantly associated with health-related use of the internet.

Introducing the lifestyle types in step 2 explained another 2 percentage points of variance (R^2=.132). This change in R^2 was significant ($F_{7,580}$=12.57, *P*<.001). Again, the demographic variables age (β=–.208, *P*<.001), gender (β=–.151, *P*<.001), and education (β=.093, *P*=.03) correlated significantly with internet use, whereas the influence of subjects' health status disappeared. Both lifestyle types influenced online health information significantly; that is, the Sociable Adventurer (β=.186, *P*<.001) and the Average Family Person (β=.160, *P*=.003) used online health information more often than the Uninterested Inactive (Table 4). To examine differences between the Sociable Adventurer and the Average Family Person, we repeated the analysis with changed reference group (Multimedia Appendix 6). We found no significant influence of the Adventurer type when comparing it with the Average Family Person. Therefore, while both the Sociable Adventurer and the Average Family Person use the internet for health information more often than the Uninterested Inactive, there is no significant difference between them.

Table 4. Summary of hierarchical multiple regression analysis for variables predicting older adults' online health information–seeking behavior (n=587).

Predictors	Step 1				Step 2			
	B[a]	SE B[b]	β[c]	*P* value	B	SE B	β	*P* value
Step 1								
Age	–0.033	0.005	–0.236	<.001	–0.029	0.006	–0.208	<.001
Gender	–0.281	0.085	–0.131	.001	–0.323	0.085	–0.151	<.001
Education	0.270	0.087	0.126	.002	0.199	0.088	0.093	.03
Place of residence	0.184	0.096	0.076	.05	0.155	0.096	0.064	.11
Health status	0.102	0.050	0.081	.04	0.068	0.051	0.054	.18
Step 2								
Sociable Adventurer (dummy)	N/A[d]	N/A	N/A	N/A	0.439	0.132	0.186	.001
Average Family Person (dummy)	N/A	N/A	N/A	N/A	0.341	0.114	0.16	.003

[a] B: unstandardized regression coefficient.

[b] SE B: standard error for unstandardized regression coefficient.

[c] β: standardized regression coefficient.

[d] N/A: not applicable.

Due to the fact that internet use for health information did not show wide variance in our sample, we verified our results by testing a logistic regression model recoding internet use as a dummy variable (0 = never, 1 = at least infrequently). The tested model was significant (χ^2_2=9.853, *P*=.007). Findings indicate the same tendencies as the linear regression model (Multimedia Appendix 7).

Discussion

Principal Results and Comparison With Prior Work

Our study examined the relevance of the internet as a source of health information for older adults in Germany and the explanatory potential of lifestyle types over and above sociodemographic variables. Our findings highlight the fact that the internet still has a minor role compared with other sources in the health information–seeking behavior of older adults. Traditional health information sources such as brochures or medical consultations still are their major sources of health information. These findings are in line with current research showing that traditional media and health care workers are the most important health information sources for older adults [19,20].

A hierarchical cluster analysis based on values, interests, and leisure time activities revealed three different lifestyle types: (1) the first type was the Sociable Adventurer; these subjects were the most active with many interests and free time activities; (2) around 50% of the total participants were assigned to the Average Family Person; they preferred to do domestic work and gardening or spend time with their families; and (3) the smallest number of participants belonged to the Uninterested Inactive type; they were characterized by a lack of interests and an increased need for security.

There were several factors that abet the online information–seeking behavior of older adults. In line with current research, participants' age, education, and gender were, in particular, defining factors [11,27]: younger, highly educated participants used the internet more often for health information seeking than older participants with lower education. Regarding the heterogeneous evidence of the influencing role of gender on online health information–seeking behavior, our study suggests that the over 60-year-old male segment used the internet more often than women. This finding may be explained by the higher internet use of men in general [28] and in the age group of older adults in particular [71]. Furthermore, it seems reasonable that the age differences in internet use arose from cohort effects within the different age segments. A representative study showed that in 2017, Germans aged 50 to 69 years used the internet 98 minutes per day, while older adults (>70 years) used it much less (36 minutes per day) [72]. These numbers suggest that the internet will become an increasingly important health information source for the next generation of older people.

In addition, our study showed that beyond demographic variables, lifestyle types contributed significantly to our model and were relevant factors in predicting online health information–seeking behavior. Specifically, we found active and open-minded older adults (the Sociable Adventurer) as well as down-to-earth and family-oriented participants (the Average Family Person) to be more likely to seek online health information than uninterested, inactive ones (the Uninterested Inactive). This finding is in line with the results of another study indicating that people who are particularly curious and interested in many things use the internet more often for seeking health information [26]. Interestingly, by introducing the lifestyle types to the regression model, the influence of health status on the dependent variable disappeared. An explanation for this finding might be the fact that health status is associated with a person's lifestyle; lifestyle, in turn, includes many more dimensions (eg, interests, values) and seems to be more appropriate to predict the online health information–seeking behavior of older adults than health status alone.

The results indicate that demographics alone are not adequate to explain the use of internet sources for health information and lifestyles play an important role as well. Although the additional explained variance was rather small at 2%, lifestyle variables do explain significantly more than demographics alone. However, this small effect is in line with other studies that have either found no effect beyond sociodemographic variables (online news usage [49]) or only a very small effect (consuming various forms of media [53]). However, these studies also found that the explanatory potential of lifestyles varies between different behaviors [53] or may become more important if they are used to explain not only general media use but specific patterns within a behavior [49]. In addition, it should be noted that there are currently no other comparative studies, as most studies in this context rely on variance analyses to show differences in media use between different types of lifestyles [41,45-48]. Due to the ongoing debate about the suitability of lifestyles in comparison with demographics to explain media use patterns, our article provides new insight into this issue. Nevertheless, further studies are necessary to examine the influence of lifestyles beyond sociodemographic variables for different media use behaviors, especially among older people.

As a central part of health campaign planning, an adequate characterization of the addressees of a health message and a target group–specific implementation of the material often determines the success or failure of an intervention [73]. Our results showed that innovative digital health campaigns do not reach older adults as well as traditional media sources do. However, our study has shown that certain groups of older people can also be reached online; therefore, health information campaign planners should not only address sociodemographic variables but also general lifestyle types. Until now, only little was known about lifestyles in the age group 60 years and above except for a few studies such as one about preferences and perception of marketing communication of Poles aged 55 years and older [57] and a general lifestyle typology in the older American market [58]. Our study gives detailed insight into the lifestyles of older adults. This becomes relevant for health care communicators even outside older adults' online health information–seeking behavior. Therefore, addressing the Sociable Adventurer with images of active older people may work better than images of inactive testimonials. Another conclusion could be drawn for the implementation of health campaign material: in order to address the Average Family Person, gardening or living magazines could be used for distribution. These potential differences should be tested in another study.

Additionally, studies have shown that older people prefer a wide range of content when using the internet, depending on their lifestyle [74,75]. It can be assumed that not only the general internet use differs between lifestyle types but also the way the internet is used: Sociable Adventurers are the most active and open-minded among the examined lifestyle types, which is why they may be more likely to use blogs or interactive offerings. Many people aged 60 years and older, however, are more family oriented. Therefore, they may use the internet primarily for interpersonal communication with their loved ones. If so, social media or mailings have the potential to reach this specific group. We recommend that future studies should investigate the explanatory potential of lifestyle types for the use of specific health services in the internet rather than just general internet use for health information.

Limitations

This study has several limitations. First, we decided to focus on demographics and lifestyle types as defining factors of internet use for health information since other predictors such as trust, limited skills, or technophobia are defined as age-related [9,22]. However, the observed variables only explained 13% of the variance of older peoples' online health information–seeking behavior. Future research should include other variables such as trust in the internet or technical skills to better explain older adults' online health information–seeking behavior.

Further, the response rate was only 2.4%. Low response rates in telephone surveys can lead to biased data under the assumption that people who consistently participate in surveys are different than those who do not. This nonresponse bias occurs for civic and social engagement as well as volunteering [76]. Nevertheless, telephone polls show only minimal bias from nonresponses on lifestyle, health, and demographic questions, which leads us to the assumption that the nonresponse bias in our sample was low [76].

Last, the analyses are based on cross-sectional survey data. Therefore, we cannot make clear statements regarding causality and the sequence of relationships. Future research should focus on longitudinal data to investigate more support for the order of events.

Conclusions

Our study focused on understanding the use of the internet for health information by adults 60 years and older and how lifestyle types can contribute to explain this behavior. Our study showed that older adults still use the internet very infrequently when seeking health information. However, a subgroup of older adults may be reached with online health information; this group includes the subset of younger, male senior citizens who like to spend their free time actively or with their family and enjoy working in their house and garden. Taking into account a predicted increase in internet use by the next generation of older adults, these individuals should be adequate recipients of online health information, while older inactive people should still be addressed with traditional media like health information brochures.

Acknowledgments

This work was supported by the German Federal Ministry of Education and Research (Bundesministerium für Bildung und Forschung) under grant number 03ZZ0819A, the Robert Koch Institute, the University Hospital of Jena, and Lindgrün GmbH. The total volume of the grant is 2,136,463 €. The Federal Ministry for Education and Research did not influence the design of the study; the collection, analysis, and interpretation of data; or the writing of the manuscript. The authors would like to thank the members of the vaccination60+ study group and its advisory board.

Authors' Contributions

All authors contributed to the conceptualization of the study and the writing and review of this manuscript.

Abstract

Background: Swedish municipalities are facing demographic challenges due to the growing number of older people and the resulting increased need for health care services. Welfare technologies are being launched as possible solutions for meeting some of these challenges.

Objective: The aim of this study was to explore the perception, experimentation, evaluation, and procurement of welfare technology practices among professionals working in municipal elder care in relation to their gender, age, and profession.

Methods: Data for this explorative cross-sectional study were collected from 393 responses to a web-based survey on municipal elder care in Sweden. Chi square tests were performed to determine the associations.

Results: The results revealed gender, age, and professional differences in perspectives of municipal elder care workers. Differences were particularly evident in attitudes toward technology, both the use of technology in general and in the workplace, and involvement and participation in decision making regarding the procurement of new welfare technologies. Men (37/53, 70%) expressed a more positive attitude toward and curiosity regarding new technologies than women (157/336, 46.7%) (*P*=.03). Regarding age, the younger respondents (18-24 years old) perceived the digital transformation in the workplace as “too slow” (4/4, 100%), whereas the majority of older respondents (65-74 years old) perceived it as happening at the “right pace” (4/7, 57%). The elder care personnel felt encouraged by management to explore and experiment with new welfare technologies, but never did so either for management or with patients. Even though the majority of the respondents were women, more men (4/7, 57%) were involved in the procurement process for welfare technology devices and solutions than women (98/336, 29.2%) (*P*<.001).

Conclusions: Personnel working within municipal elder care were generally very positive toward new technologies. However, both gender and age differences may influence these perspectives such as the personnel’s resistance to welfare technology and patients’ participation in welfare technology usage and deployment. Different levels of participation in the decision-making process regarding new technology deployment may negatively affect the overall digital transformation within municipal elder care.

Introduction

Background

Due to demographic changes, developed countries have growing concerns about the future challenges aging populations will present to their welfare systems [1-3]. In the Nordic countries, welfare technologies have been introduced as an important means of meeting these challenges [1]. In Sweden, the welfare system was developed to promote universal rights and social equality. Despite the increasing demand on the limited resources of welfare services, it is believed that welfare technology can help to sustain these rights through the digital transformation of care for all Swedish citizens, including older people in need [4]. The Swedish National Board of Health and Welfare believes that digital technology can help older individuals and people with disabilities to feel safe and to participate in society [5].

The expectation is that welfare technology will "gain time" for health care personnel to engage in human contact and that it will increase patients' self-management and independence [6-8]. Societal changes and scarce resources are constant challenges to both welfare technology practitioners and policy makers whose aim is to reap the benefits of technological change for individuals and for society as a whole [9-12]. Municipalities and county councils or regions in Sweden provide welfare technology as aids and housing adaptations. Examples of welfare technologies provided at the municipal level are social security alarms that can be used to call for emergency help, electronic home services that replace or supplement physical visits with digital contacts, advanced toilets with flush and drying functions, key-free home services that replace physical keys with digital key management systems, individual rehabilitation training through game consoles in the home, camera surveillance during the night, and medicine reminders of when to take prescriptions, which may be linked to an alarm system [13]. Welfare technology designed to support daily living must be understood and assessed in their context and from a social perspective [1,13,14]. The provision of a good lifestyle through welfare technology is affected by decisions made at the municipal level; it is therefore important to understand how the decisions are made at the municipal level when new welfare technologies are purchased.

Exploring the role of welfare technology in municipal elder care is important because the use of technology in home care and in health care is constantly increasing [12,14-21]. However, research on the use of welfare technology in elder care has often focused on the attributes of leadership and management. A review of welfare technology use in elder care highlighted that the success factors in integrating welfare technology into elder care are having clear goals, incentives, and strong leadership; an infrastructure with proper capacity; a well-functioning organizational structure; collaboration with others; and awareness of resources [14]. However, the review did not identify success factors relating to gender, age, or work experience among the various care professionals involved in welfare technology work and in decision making regarding welfare technology.

Aim

The aim of this study was to explore the perceptions of professionals involved in municipal elder care regarding the use of welfare technology and to assess the influence of gender, age, and profession on their perceptions, experimentation, evaluation, and procurement of these technologies.

Methods

Survey Design

This explorative cross-sectional study involved a web survey and a descriptive data analysis. In May 2018, the authors sent a hyperlink to a web-based survey to all municipal registrars in Sweden (N=290). The registrars were asked to distribute the link to those working with and involved in welfare technology work in elder care organizations. In the information letter, the researchers stated that that the respondents' answers would be confidential and not linked to any individual. Participation was voluntary. Anonymity was assured and participants were informed of the survey aim.

To explore the aim of the study, in the absence of any previous research addressing this topic, a new questionnaire was designed, and its psychometric properties were tested for both validity and reliability [22]. The survey covered five question areas with a fixed number of options (3-6 possible answers) for the respondent to choose from. The areas included questions on perceptions of the speed of technological change, participation in decision making in relation to welfare technology, experimentation and exploration of welfare technology at work, involvement in procurement, and "about you." The survey also included four areas of open-ended questions addressing the concept, advantages and potential, barriers to use, and evaluation methods for welfare technology. The results of the open-ended questions have been published in a separate article [23]. The questionnaire was pilot-tested with three potential users, and its content, face validity, and test-retest reliability were examined prior to distribution [24]. Four established and experienced researchers rated the content validity of the items using a 4-point scale (4=very relevant, 3=quite relevant, 2=somewhat relevant, 1=not relevant). The same experts were asked to determine the face validity by answering the following question: "Please write your reflections and comments about the questionnaire concerning readability, clarity, and layout." After 3 weeks, their comments on the content and face validity were reviewed by the authors and discussed [24], and some changes were made to the questionnaire. The test-retest reliability tests, conducted at 2-week intervals with three potential users, showed that the questionnaire was easy to understand and answer and took 10-15 minutes to complete [25]. The focus of the present study is to analyze the quantitative data from the fixed-option questions (see Multimedia Appendix 1) in the questionnaire.

Sample

In this explorative cross-sectional study [22], the respondents were personnel who worked with welfare technology in municipal elder care. Table 1 summarizes the respondents' professional affiliations.

Table 1. Characteristics of the study population (N=393).

Characteristic	n (%)
Sex	
Male	53 (13.5)
Female	336 (85.5)
Missing	4 (1.0)
Age (years)	
18-24	4 (1.0)
25-34	43 (10.9)
35-44	75 (19.1)
45-54	146 (37.2)
55-64	118 (30.0)
65-74	7 (1.8)
Working experience	
Less than 1 year	18 (4.6)
1-4 years	52 (13.2)
5-9 years	58 (14.8)
10-19 years	125 (31.8)
More than 20 years	140 (35.6)
Profession/Roles	
Information technology staff	29 (7.4)
Chief medical nurse responsible	78 (19.8)
Chief rehabilitation office responsible	28 (7.1)
Occupational therapist/physiotherapist	103 (26.2)
Specialist dementia nurse	51 (13.0)
Other (manager/electronic health strategist)	104 (26.5)

Statistical Analysis

Descriptive statistics were used to summarize the characteristics of the sample and its subgroups. Crosstabulation with chi square computation was used for analysis of categorical variables, which is a nonparametric test recommended when analyzing ordered categorical data [22].

The associations between the variables are summarized in Multimedia Appendix 2. The occupational therapist (OT) and physiotherapist (PT) respondents who have direct contact with patients in their everyday work were grouped into the category "OT/PT." Managers and electronic health (eHealth) strategists who work at the strategic level in elder care organizations and do not have daily contact with patients were grouped as "other." The survey data were imported into and analyzed with IBM SPSS version 24.

Ethics

This study did not include any personal or sensitive information that required ethical approval under the standards of the Swedish Research Council [26]. The study followed the guidelines for research ethics issued by the Swedish Research Council [26].

Results

Respondents' Characteristics

The online survey elicited 393 responses. Table 1 presents the respondents' demographic data.

Perceptions of the Speed of Change

The perceptions of personnel in elder care regarding the speed of digital transformation in their organizations was investigated through a question asking the participants to "grade the speed of the digital transformation in your workplace" (see questionnaire, Multimedia Appendix 1). The majority of both women (245/336, 72.9%) and men (46/53, 87%) answered that it was "too slow," and the chi square test showed a significant association of gender (*P*=.05). Regarding age, all of the younger respondents (18-24 years old) perceived the speed of digital transformation as "too slow" (4/4, 100%), whereas the majority of older respondents (65-74 years) perceived the digital transformation in the workplace as happening at the "right pace" (4/7, 57%).

The perceptions of surveyed personnel regarding the overall speed of technological change in health care was also examined

(Multimedia Appendix 1: question 2), demonstrating an association between gender and attitudes toward technology and digitalization within health care organizations (*P*=.03). Although 157/336 (46.7%) of the women disagreed with the statement that the change in health care organizations was too rapid, 37/53 (70%) of the men also disagreed with the statement. The results also showed an association between the respondents' profession/role in the organization and their perception as to whether technology and digitalization have made health care organizations change too quickly (*P*=.04). Specifically, 21/29 (72%) of the information technology (IT) staff, 20/28 (71%) of the chief rehabilitation officers responsible, and 42/78 (54%) of the chief medical nurses responsible disagreed with the statement that technology and digitalization have made health care organizations change too quickly. These results indicate that in their experience, technological developments in elder care have not been occurring fast enough.

The questionnaire also addressed whether the personnel perceived their workplaces as using welfare technology optimally (Multimedia Appendix 1, question 3). The chi square test showed no effect of gender but a strong association with profession/role (*P*<.001). Approximately half of the IT staff (13/29, 45%), chief medical nurses responsible (35/78, 45%), and OT/PTs (53/103, 51.4%) completely disagreed with the statement that their workplace optimized welfare technology.

To learn more about the respondents' attitudes and perceptions of technology (Multimedia Appendix 1, question 4), the respondents indicated their level of interest in technology. Here, some gender and age differences emerged. Overall, 191/336 (49.1%) of the women responded that "they use technology when most people do," whereas 30/53 (57%) of the men answered that they "like new technology and use technological solutions before most people."

The distribution of responses showed that most 18-24-year-old respondents (3/4, 75%) answered "I like new technology and use technological solutions before most people," whereas none of the 65-74-year-old respondents answered that they "love new technology." Considering profession/role, 16/29 (55%) of IT personnel, 33/78 (42%) of chief responsible rehabilitation specialists, and 49/103 (47.5%) of those in the "others" category responded that they "like new technology and use technological solutions before most people." In the groups of specialist dementia nurses (36/51, 71%), OT/PTs (53/103, 51.4%), and chief responsible rehabilitation specialists (15/28, 54%), the majority answered that "they use new technology when most people do."

Encouragement, Exploration, and Experimentation With Welfare Technology

The next question examined how the personnel perceived the importance to their management or closest superior of their working with welfare technology (Multimedia Appendix 1, question 5). The chi square test results showed no effect of gender and age but a strong association between profession/role and encouragement from management to use welfare technology (*P*=.01). Most respondents working in IT (26/29, 90%) reported that they were encouraged by their managers to test and use welfare technology, as did the "other" group of professionals such as eHealth strategists and unit managers (82/103, 79.6%). The results showed almost the same pattern among the other professionals, including the chief medical nurses (yes: 57/78, 73%; no: 21/78, 27%) and chief responsible rehabilitation specialists (yes: 22/28, 79%; no: 6/28, 21%).

The questionnaire then asked how much the respondents experimented with and explored welfare technology in their everyday work (Multimedia Appendix 1, question 6). The chi square test results showed an association between gender and experimentation with new welfare technology (*P*<.001). Over half of the women (186/335, 55.5%) answered that they do "not very often" experiment with welfare technology, whereas among the male respondents, only 19/53 (36%) answered that they "do not very often" experiment. The chi square test showed an independence between age and experimentation of welfare technology in daily work. There were associations between experimentation with welfare technology and the respondents' profession/role (*P*=.02). The majority of the personnel responded that they never explored or experimented with new welfare technology solutions (IT staff: 12/29, 41%; chief responsible medical nurses: 46/78, 59%; chief responsible rehabilitation specialists: 14/28, 50%; OT/PTs: 31/102, 30.3%; specialist dementia nurses: 36/51, 71%; "others": 45/103, 43.7%).

Two questions assessed whether the respondents explored and experimented with new welfare technology solutions with management and clients/patients in their everyday work (see Multimedia Appendix 1, questions 7 and 8). The results showed that more men than women experimented and explored welfare technology with management. Neither age nor work experience had any association with opportunities to experiment and explore welfare technology with management.

The chi square test also showed an association of profession/role with experimentation and exploring welfare technology with management. The IT staff reported that they occasionally (10/29, 35 %) or never (11/29, 38%) experimented and explored welfare technology with management. Among the chief responsible medical nurses, 35/78 (45%) chose the "never" option. The majority of OT/PTs and specialist dementia nurses gave almost the same answer. In response to a question concerning whether the respondents experimented and explored welfare technology solutions in collaboration with potential end users such as clients/patients, the majority (184/336, 54.8%) of the female participants responded "never," whereas 71 (21.1%) responded "yes, sometimes." Among the male participants, 23/53 (43%) answered "never." Respondents in patient-related professions, including the specialist dementia nurses and the chief responsible medical nurses, answered that they never experimented. The results also showed that professionals with longer work experience (more than 20 years) largely did not experiment and explore welfare technology with patients (91/140, 65.0%).

The next question examined whether the respondents experienced any problems in purchasing and exploring welfare technology in their profession/role (Multimedia Appendix 1, question 9). Both women (53%) and men (53%) reported experiencing such difficulties. The chi square test showed independence (*P*=.95) from gender; however, more than half the respondents indicated that they experienced problems. A clear association emerged with profession/role (*P*=.07). The majority of the IT personnel (19/29, 66%) answered that they had no such problems, whereas the majority of chief responsible medical nurses (41/78, 53%), OT/PTs (67/103, 65.0%), and specialist nurses in dementia care (26/51, 51%) did encounter such difficulties (see Table 2).

The next question asked whether the respondents regularly evaluated potential new welfare technology for their elder care organizations (Multimedia Appendix 1, question 10). These results showed independence of gender, age, and work experience. However, the majority of both the men (55%) and the women (62%) answered that they never evaluated new welfare technology. The results showed an association between profession/role and regular evaluation of new welfare technology (*P*=.02), with the majority reporting that they did not evaluate and test the suitability of new welfare technology (Table 3).

Responses to the question "Do you evaluate and follow up the welfare technology that is implemented?" were independent of gender. However, the association between profession/role and continuous evaluation of existing welfare technology was strong (*P*=.02), with the majority of participants answering that they do evaluate the welfare technology devices and solutions implemented in their organizations (Table 4).

Table 2. Distribution of responses regarding experimentation with and purchase of new welfare technology in relation to profession/role (N=393).

Profession/role	N	Yes, n (%)	No, n (%)
Information technology staff	29	10 (34.5)	19 (65.5)
Chief medical nurse responsible	78	41 (52.3)	37 (47.4)
Chief rehabilitation officer responsible	28	14 (50.0)	14 (50.0)
Occupational therapist/physiotherapist	103	67 (65.0)	36 (35.0)
Specialist dementia nurse	51	26 (51.0)	25 (49.1)
Other (manager/electronic health strategist)	103	52 (50.5)	51 (50.1)

Table 3. Distribution of responses regarding continuous evaluation of potential welfare technology for future deployment in elder care in relation to profession/role (N=393).

Profession/role	N	Yes, n (%)	No, n (%)
Information technology staff	29	13 (44.8)	16 (55.2)
Chief medical nurse responsible	78	39 (50.0)	39 (50.0)
Chief rehabilitation officer responsible	28	11 (39.1)	17 (60.7)
Occupational therapist/physiotherapist	103	27 (26.2)	76 (73.8)
Specialist dementia nurse	51	17 (33.3)	34 (66.7)
Other (manager/electronic health strategist)	103	45 (43.7)	58 (56.3)

Table 4. Distribution of responses regarding continuous evaluation of implemented welfare technology in relation to profession/role (N=393).

Profession/role	N	Yes, n (%)	No, n (%)
Information technology staff	29	23 (79.3)	6 (20.7)
Chief medical nurse responsible	78	57 (73.1)	21 (26.9)
Chief rehabilitation officer responsible	28	22 (78.6)	6 (21.4)
Occupational therapist/physiotherapist	103	57 (55.3)	46 (44.7)
Specialist dementia nurse	51	38 (74.5)	13 (25.5)
Other (manager/electronic health strategist)	103	75 (72.8)	28 (27.1)

Procurement

The respondents' involvement in the decision making related to buying and procuring welfare technology was also investigated (Multimedia Appendix 1, question 12). The chi square analysis showed that even though the majority of the participants were women, more men (30/53, 57%) were involved in the procurement process for welfare technology devices and solutions than women (98/336, 29.2%) (*P*<.001).

More than half of the chief responsible medical nurses (41/78, 53%) were involved in decision making related to buying and procurement, whereas the chief responsible rehabilitation officers (4/28, 14%), OT/PTs (7/103, 6.8%), and specialist nurses in dementia (5/51, 10%) reported little involvement. Most of the IT staff (27/29, 93%) were involved in welfare technology procurement decisions, but those who worked closely with the patients, such as the OTs (who prescribe most of the welfare technology), specialist dementia nurses, and chief rehabilitation officers responsible, had no such involvement.

Discussion

Principal Findings

The aim of this study was to explore and describe experiences of working with welfare technology in municipal elder care across gender, age, and profession. Some of the most interesting results are highlighted as follows. There was an overall positive attitude among the respondents toward digital transformation but the process was also perceived as too slow. Respondents are encouraged by management but never explore welfare technology with their managers. Moreover, elder care organizations are perceived to neither optimize nor experiment with new welfare technology. A significant decision-making and gender aspect was revealed, demonstrating issues with emancipation and welfare technology implementation. Finally, one of the key results from this study is that young personnel want to speed up the digital transformation.

Most of the respondents in this cross-sectional, explorative study were women, reflecting the nature of health care as a female-dominated occupation. In the gender distribution, the majority of IT staff and the group of “others” (eg, eHealth strategists and managers) were men. Women constituted the majority in the professions working closely with patients. The IT staff had less work experience (less than 4 years), whereas the other groups, especially the specialist dementia nurses, had far longer work experience. These demographic features of the sample are important to bear in mind to contextualize the discussion below.

Positive But Slow Digital Transformation

In general, municipal elder care personnel viewed the deployment of new technology in their work positively. Society, media, and political discourse all express the expectation that welfare technologies offer potential solutions to the demographic challenges and shortages in health care staff, and that they could have positive effects on the personnel implementing the welfare technology [4,27]. In terms of the participants’ perceptions of the speed of digital transformation, the results showed that both men and women perceive the technological developments in elder care as being “too slow.” These results confirm the high expectations for welfare technology in society and demonstrate the reality that progress is very slow in everyday elder care practices.

Personnel Are Encouraged to Explore and Experiment With Welfare Technology But Never Do

Other interesting results that emerged from the questionnaire concerned encouragement, experimentation, and exploration with welfare technology. The high level of encouragement from management that the different professional groups in municipal elder care experienced would seem to reflect the Swedish government’s positive views on the use of welfare technology [4]. This study shows that most management encouraged personnel to experiment with and explore welfare technology. However, most of the participants had never explored welfare technology with their managers. Based on these findings, it can be concluded that personnel (eg, eHealth strategist) make decisions on new technology purchases without management’s involvement in experimentation with the new welfare technology. Alternatively, it can be assumed that some welfare technology is procured and purchased without being tested. Further studies are needed to explore these aspects.

Elder Care Personnel Neither Optimize Nor Experiment With New Welfare Technology

Participants gave negative responses as to whether they perceived their workplace as optimizing the use of welfare technology. Those working closely with patients, including OT/PTs and specialist dementia nurses, perceived that the elder care organizations could optimize the use of welfare technology to a greater extent. However, some of the participants also responded that technology had changed health care organizations in negative ways. These findings might indicate a negative reaction to the rapid technological change in society or the overburdening of these professions/roles with responsibilities in their everyday work.

The association of profession/role and experimentation with new welfare technology was strong, with a majority of the respondents answering that they never experimented. Interestingly, the participants felt encouraged to experiment with and explore welfare technology but never did so with either management or patients. These findings could indicate that patients in need of elder care have little influence on the kinds of welfare technology recommended and implemented. Substantial research has shown the importance of patient participation in the procurement process for assistive and welfare technologies [28,29-33]. Evidence supports the conclusion that patients use assistive technology and welfare technology more if they are involved in the entire process of its procurement [34].

Decision Making and Gender

More than half the female participants reported that they “use technology when most people do,” whereas the majority of men responded that they “like new technology and use technology before most people.” These findings support earlier research showing that men have greater confidence in using new technologies than women [35]. Studies on gender and technology have shown that the introduction of new technologies tends to degrade women’s work and separate it from men’s work [36], while women tend to be replaced by men during technological change in the workplace [37]. As welfare technology enters the generally female domain of elder care, men seem to carry the professional role (IT strategist) of introducing the welfare technology into municipal elder care. The present results showed that men have a more positive attitude toward and curiosity regarding new technologies than women. This may result from their role in the organization and may not be due to a gender effect itself. However, this finding raises the question as to whether the introduction of technology into municipal elder care will lead to an increase in male care professionals.

Considering welfare technology procurement, the results showed that although most of the participants were women, more male respondents were involved in the decision making than women.

These results confirm that technology is often constructed as a male domain [38,39], and that it is not neutral but is rather shaped by social values and norms [40,41]. These results indicate that the male respondents had more power than the female respondents in the decision-making process regarding the deployment and use of technological innovations in the elder care sector.

Historically, women have experienced the negative effects of hierarchical structures of power and technology deployment [37,38,41-43]. The digital transformation has, and will continue to have, major impacts on many aspects of everyday and professional life, including gender equality. Digital transformation will affect political participation, the nature of the labor market, and interactions with friends and colleagues, opening opportunities for dealing with gender differences that affect both women and men, albeit often differently [43]. Digital transformation has the potential to either reproduce and maintain gender expectations and power structures or to advance a more equal society. Digitization and technological innovations take place not in a vacuum but in interactions with social, cultural, economic, and political factors [44].

Personnel in municipal elder care are shaped by their working conditions, and, unfortunately, our results indicate that welfare technology maintains and reproduces gender expectations and power structures in municipal elder care. For example, the male participants had much higher levels of power in the decision-making process by which new technological solutions were selected for implementation in municipal elder care.

Emancipation and Welfare Technology Implementation

Almost all of the IT staff and the chief rehabilitation officers responsible were involved in procurement decisions, but among those working closely with patients, OT/PTs and specialist dementia nurses did not participate in these decisions. These results suggest that those with strong power in the procurement process do not work closely with patients or even regularly meet them, while those who work directly with patients daily and implement the new technological solutions have little power and do not control what solutions or devices are procured. The consequence might be a resistance to technology among frontline care personnel and patients in municipal elder care [10,15,45,46]. Recent studies have analyzed aspects of participation among different care professionals when welfare technologies have been implemented [12,17,19,20,45-49]. These studies have shown that the work of the individual care personnel is crucial in technology deployment in elder care and that technology innovation also changes the dynamics within practices [21]. However, this research has generally failed to acknowledge the participation or lack of participation by care professionals in the initial exploration and experimentation with welfare technology before procurement and implementation, which requires further study. Research on well-being in the workplace has shown that having control and a voice in the workplace are key factors for well-being and satisfaction at work [50-53]. A lack of a voice on which welfare technology solutions are implemented may therefore negatively affect those working closely with patients, consequently increasing their work-related stress and administrative load [54].

Young Personnel Want to Speed Up the Digital Transformation

Our findings indicate that not only gender but also age affect the perception of welfare technology. The association between age and perceptions of the speed of digital transformation shows the importance of age as a variable. All of the 18 to 24-year-old participants thought that the speed was "too slow," whereas more than half of the 65 to 74-year-old participants thought that it was moving at the "right pace." These findings indicate that the perception that digital transformation is proceeding at the right pace increases with age. Prensky [52] defines "digital natives" as those who have used and been surrounded by technology their whole lives and "digital immigrants" as those who learn and adopt to technology and have had experience of doing similar tasks without technology. Prensky [52] proposed that digital natives have significant advantages when using technology. This was confirmed by our study results in which the younger respondents declared that they "like new technology and use it before most people do."

Limitations

One limitation of this study was that the questionnaire was sent to municipal registrars who passed it on to potential participants working with welfare technology, resulting in the participants occupying different levels and roles in organizations, and included registered nurses, OT/PTs, managers, and IT strategists. It would have been interesting to determine the level at which the individual participants worked in terms of how much decision-making power they had for buying and implementing welfare technology; however, this was not the aim of the study. Another limitation was that the questionnaire was anonymous, and therefore the geographic spread of the participants in Sweden was unclear. However, a total of 393 responses were received and Sweden has 290 municipalities, suggesting a good geographic spread.

Conclusion

The findings show that various professions working in municipal elder care hold very positive views on new technologies. However, there are both gender and age differences in attitudes toward technology (for the use of technology in general and in the workplace) and in participation in decision making for the procurement of new welfare technologies. The consequences of this might include personnel's resistance to welfare technology in municipal health care [46], which would affect clients and their potential participation in welfare technology. Therefore, the people working closely with patients who are expected to implement the new technologies need to be more involved in the procurement process.

Among other findings, a majority of the IT staff were men who had worked in municipal elder care for less than 4 years, and most of these participants were involved in welfare technology procurement decisions. These findings imply that men with little work experience or knowledge of elder care carry high levels of power and responsibility for decisions that will be executed by the female-dominated groups of elder care personnel. The decisions of these few could have a major influence on future elder care as digital transformation changes how work is carried out in municipal elder care.

Acknowledgments

The research presented in this paper was funded by National Network of Assistive Technology Managers (Nationella Hjälpmedelschefsnätverket) and the School of Health, Care and Social Welfare, Mälardalen University, Sweden. We thank Professor Britt Östlund who secured the funding for this research. We are also truly grateful to Sylvia Olsson, Emmie Wahlström, and Carina Loeb for their perceptive statistical input and discussions, and to all of the respondents who volunteered to participate in the study. We also want to thank Natasha Layton for her skillful input.

Abstract

Background: Digital health stations offer an affordable and accessible platform for people to monitor their health; however, there is limited information regarding the demographic profile of users and the health benefits of this technology.

Objective: This study aimed to assess the demographic representativeness of health station users, identify the factors associated with repeat utilization of stations, and determine if the health status of repeat users changed between baseline and final health check.

Methods: Data from 180,442 health station users in Australia, including 8441 repeat users, were compared with 2014-2015 Australian National Health Survey (NHS) participants on key demographic and health characteristics. Binary logistic regression analyses were used to compare demographic and health characteristics of repeat and one-time users. Baseline and final health checks of repeat users were compared using McNemar tests and Wilcoxon signed rank tests. The relationship between the number of checks and final health scores was investigated using generalized linear models.

Results: The demographic profile of SiSU health station users differs from that of the general population. A larger proportion of SiSU users were female (100,814/180,442, 55.87% vs 7807/15,393, 50.72%), younger (86,387/180,442, 47.88% vs 5309/15,393, 34.49% aged less than 35 years), and socioeconomically advantaged (64,388/180,442, 35.68% vs 3117/15,393, 20.25%). Compared with NHS participants, a smaller proportion of SiSU health station users were overweight or obese, were smokers, had high blood pressure (BP), or had diabetes. When data were weighted for demographic differences, only rates of high BP were found to be lower for SiSU users compared with the NHS participants (odds ratio [OR] 1.26; *P*<.001). Repeat users were more likely to be female (OR 1.37; *P*<.001), younger (OR 0.99; *P*<.001), and from high socioeconomic status areas—those residing in socioeconomic index for areas quintiles 4 and 5 were significantly more likely to be repeat users compared with those residing in quintile 1 (OR 1.243; *P*<.001 and OR 1.151; *P*<.001, respectively). Repeat users were more likely to have a higher BMI (OR 1.02; *P*<.001), high BP (OR 1.15; *P*<.001), and less likely to be smokers (OR 0.77; *P*<.001). Significant improvements in health status were observed for repeat users. Mean BMI decreased by 0.97 kg/m2 from baseline to final check (z=−14.24; *P*<.001), whereas the proportion of people with high BP decreased from 15.77% (1080/6848) to 12.90% (885/6860; χ^2_1=38.2; *P*<.001). The proportion of smokers decreased from 11.91% (1005/8438) to 10.13% (853/8421; χ^2_1=48.4; *P*<.001). Number of repeat health checks was significantly associated with smoking status (OR 0.96; *P*<.048) but not with higher BP (*P*=.14) or BMI (*P*=.23).

Conclusions: These findings provide valuable insight into the benefits of health stations for self-monitoring and partially support previous research regarding the effect of demographics and health status on self-management of health.

Introduction

Background

Technological advances in recent years have changed the way consumers access health care and enabled the use of a range of digital mechanisms for self-monitoring of health, including mobile phone apps, wearable trackers, and web-based monitoring systems [1,2]. Although self-monitoring in general has been shown to be effective in the management of health risk factors and chronic disease and in increasing self-efficacy in disease management [3-5], limited research has been conducted to date regarding the long-term benefits of using digital technologies to self-monitor health [6,7]. Some benefits have been identified in terms of supporting behavior change [7,8], promoting weight loss [7,9,10], increasing physical activity [7,8,10,11], assisting with smoking cessation [7,10], and improving self-management of chronic disease [7,12], particularly in those with more serious chronic illness [6]; however, findings to date have been inconsistent.

The increased utility of digital self-monitoring technology over traditional paper-based tracking, in terms of it enabling the easy collection and exchange of health-related information between consumers and health care providers, has also been supported by a number of authors [13-15]. There is some evidence that data collected through such technologies is more reliable than data collected via other means such as manual measurement, self-report, and in some cases medical professionals [16-18]. The mechanisms behind these findings are varied and include the competence of the general public in using and interpreting medical instrumentation such as sphygmomanometers [19], social desirability associated with self-reports of disease and risk factors [16,20], and a phenomenon known as *white coat syndrome*, in which blood pressure (BP) and heart rate are artificially elevated in a clinical setting [21,22].

The uptake and utilization of health monitoring devices and apps appear to be influenced by a range of social, health-related, and demographic factors, including age [23-25], health status [25-27], and socioeconomic status (SES) [23,25,28]. However, it is possible that the influences of such characteristics may be dependent on the type of technology in question [23].

Given the potential benefits to both consumers and health professionals, and the rapid increase in the use of technology in the health arena, there is some concern surrounding the influence of sociodemographic characteristics on access to digital technologies [23,29]. Such influences may result in the potential for certain disadvantaged subgroups to be *left behind* in the digital health age and unable to benefit from the potential of such technologies [23]. Older age and socioeconomic disadvantage, in particular, are often associated with barriers to the utilization of digital health apps, due to poor levels of electronic health literacy, prohibitive costs, and limited access to the internet [23,30].

The SiSU Health Group is a health and wellness company that aims to ease the effects of lifestyle-related diseases on global health care systems through the use of technology. Their health check stations, installed in a number of locations across Australia, offer an affordable and accessible platform to help people live a healthier life. SiSU health stations are free of charge for all Australians aged 16 years and older, providing an alternative method of enabling the general population to monitor their health and access relevant health information. These stations have the potential to reach consumers who face barriers to the utilization of digital health technologies [29-31], particularly those facing economic barriers to such technologies. Although several studies have been published that investigate the determinants of health kiosk utilization, findings are varied. Socioeconomic factors including income, employment status, country of birth, gender, and age have all been found to influence the utilization of health kiosks to varying degrees [29-33]; however, the results are inconsistent.

There is some evidence to demonstrate that the utilization of health kiosks to access health information can lead to increased screening rates, improved health literacy, and a reduction in the burden on medical services [33]. The majority of these studies, however, investigated the utilization of kiosks that provide health information only, with very few including kiosks that enable health measurement and self-monitoring [29-32] such as the SiSU health station. Limited information is available regarding the potential benefits of health kiosk utilization for self-monitoring in terms of improved health status and a reduction in health risk behaviors. For this reason, this study aimed to provide insight into the demographic and health-related characteristics that are associated with the utilization of health kiosks for self-monitoring and identify any observed improvements in the health status of users over time, using data obtained from SiSU health stations. These stations are installed in a number of pharmacies, retail outlets, and workplaces throughout Australia and the United Kingdom. In Australia, the majority are currently located in Priceline Pharmacies.

Objectives

The SiSU wellness health check station collects data on a range of self-reported and machine-measured health indicators, including diabetes status, physical activity levels, waist circumference, dietary practices, heart rate, BP, weight, BMI, and body fat percentage. The SiSU station is designed to be a vertical space with mobile 3G connection or access to a private Wi-Fi network. Users engage with the station for approximately 7 min to answer a series of questions and to provide various health-related measures, before they receive immediate feedback about their health status on the screen of the station. Users of the health stations are able to monitor their progress and health changes over time by connecting their health check station profile to a free app developed by SiSU Health Group and downloadable from Google Play or the iTunes store. The stations and associated apps are intended to assist consumers by allowing them to monitor their health status over time and providing alerts to consumers when follow-up with a general practitioner is recommended [34].

There is a lack of evidence regarding the health benefits of kiosks that allow self-monitoring of health outcomes and inconsistent evidence regarding the demographic of users. This study, therefore, aimed to determine if the users of SiSU health stations in Australia differ from the general population in terms of demographics and health status by comparing SiSU health station users with participants of the 2015 National Health Survey (NHS); investigate the demographic and health-related characteristics that are associated with repeated utilization of the SiSU health stations in Australia; and identify if the health status of repeat users of SiSU health stations in Australia improved from baseline (at their first check) to their final health check.

Methods

Study Sample

This study uses data collected from 192 SiSU health check stations installed across Australia, for the period October 28, 2017, to June 27, 2018. Due to resource limitations, data for health check stations in the United Kingdom were not considered in this study. This resulted in a total of 271,151 records pertaining to males and females aged 16 years and above in Australia. Users reporting a pregnancy at one or more of their health station checks were removed from the dataset (n=3315). The majority (266,813/271,151, 98.40%) of data were obtained from health check stations installed in Priceline Pharmacies across Australia.

For research question 1—analysis of the demographics and health status of SiSU users—and 2—investigate the demographic and health-related characteristics that are associated with repeated utilization of the SiSU health stations in Australia—only the first health checks of users were included to avoid bias in measurements introduced through potential improvements in health status as a result of self-monitoring. Therefore, records that were identified as repeat checks were excluded from the analysis, as were any users who had undertaken their first health check in the time before the study period. Invalid measurements were also identified and removed, resulting in a sample size of 180,442 records.

The demographics and health status of the users were compared with those of the participants in the 2014-2015 Australian NHS, a nationally representative survey of 19,000 people in approximately 15,000 households. NHS data are weighted to reflect sampling fractions for each respondent, ensuring that the results are representative of the general population [35]. Only NHS participants aged 16 years and above were included in this analysis, resulting in a total of 15,393 records.

For research question 3—analysis of changes in health status from baseline—only users who had undertaken 2 or more health checks were included. Users were classified as repeat users if their unique user ID appeared more than once in the dataset. Suspected shared accounts were also identified by comparing the age and gender recorded at each health check. User IDs with inconsistent entries for these variables were considered to be shared accounts and were removed from the analysis, resulting in a total of 27,522 health checks pertaining to 8441 users.

Measures

Data on the following variables were used in this study: gender, age, SES, state, BP, BMI, diabetes status, smoking status, and repeat user status.

The health station questions regarding fruit and vegetable consumption and physical activity are only asked of nondiabetic health station users, resulting in a large amount of missing data for each of these variables (64,959/180,442, 36.00% missing). Therefore, these variables were excluded from this analysis.

The format of the age variable in the NHS data, which was grouped into 5 year categories, necessitated the grouping of the SiSU health station age variable into categories for the purposes of research question 1. To reduce the number of categories, 10 year age groups were selected. For the remaining research questions, age was treated as a continuous variable.

SES was defined using the 2016 version of the index of relative advantage and disadvantage (IRSAD) under the Australian Bureau of Statistics’(ABS) socioeconomic indexes for areas (SEIFA), which summarizes a range of variables that are considered to represent relative socioeconomic advantage and disadvantage. The IRSAD ranks geographical areas on a continuum from most disadvantaged to least disadvantaged based on this summary. Areas are ranked into quintiles, where quintile 1 contains the lowest 20% of areas (most disadvantaged), quintile 2 contains the next lowest 20% of areas, and so forth, resulting in 5 equal-sized groups. SEIFA scores were allocated to SiSU health station users by matching their residential postcode to the SEIFA index. State was recorded as the state in which the person resided at the time of their health check.

BP was grouped into categories based on measured systolic and diastolic readings: a reading of ≥140/90 mm Hg was categorized as high. Similarly, BMI was calculated using a person’s measured height (m) and weight (kg), and values of ≥30.0 kg/m^2 were categorized as overweight or obese. Binary categories were chosen for these variables to enable a direct comparison of the proportion of participants with or without the respective health conditions (prevalence rates).

Diabetes status and smoking status were recorded as *yes* if a person had an affirmative response to the questions: “Do you have a current diagnosis of type 1 or type 2 diabetes?” and “Are you a current smoker?,” respectively.

Missing Data

Analysis of missing values was performed on the SiSU wellness data to determine the volume of missing data and identify factors associated with missingness. The total proportion of missing values in the dataset was 5.40% (9744/180,442), with BMI and BP having the highest proportion of missing values at 19.00% (34,284/180,442) and 18.79% (33,923/180,442), respectively. Due to the high rate of missing data, inverse probability weighting (IPW) was used to weight records according to their probability of being a complete record, according to the methodology detailed in the study by Seaman and White [36]. A binary logistic regression was conducted to calculate the IPW, with the variables gender, age, state of residence, and SES included in the model. Separate weights were calculated for each missing variable. All statistical analyses were conducted with these weights applied, using only records with complete data for the variables in each model.

Missing data for physical measurements was higher in the NHS compared with the SiSU wellness data. In the 2014-2015 NHS, physical measurements were taken for height, weight, and BP. A total of 24.29% (3740/15,393) of respondents did not have their BP measured, whereas 26.80% (4125/15,393) did not have their height, weight, or both measured. The NHS utilized imputation to estimate physical measurements for these participants.

Statistical Analysis

To assess if the users of SiSU health stations are representative of the general population, selected demographic and health characteristics of the sample were compared with the those of the Australian population using data from the 2014-2015 NHS.

Characteristics that were directly comparable between the SiSU health station users and the NHS dataset were age group, sex, SES, state of residence, BP, BMI, diabetes status, and smoking status. Demographic characteristics of the 2 groups were compared, and SiSU health station data were then weighted to account for demographic differences between the SiSU health station users and NHS participants. Using these weighted data, logistic regression was used to obtain odds ratios (ORs) to determine the magnitude of any differences between the health-related measures for SiSU health station users compared with NHS participants. In total, 4 models were created, 1 for each of the health characteristic variables—BMI, BP, diabetes status, and smoking status—with the health characteristic as the dependent variable and *group* (SiSU user or NHS participant) as the independent variable. The demographic variables age, gender, SES, and state were included as controls in these models.

Comparisons were also made between repeat and nonrepeat users of the SiSU health stations. Users were classified as repeat if they had undertaken 2 or more health checks within the time period, whereas users were considered nonrepeat if they had only undertaken 1 health check during the period or had no recorded user ID number. Binary logistic regression was performed to identify the demographic and health-related factors that predict the probability of being a repeat user. With repeat status as the dependent variable, demographic and health predictors included in the model were age, gender, SES, state, BMI, BP category, diabetes status, and smoking status. Binary logistic regression was chosen because of the binary nature of the dependent variable and the ability to introduce covariates for analysis and quantify the relationship between the dependent and independent variables in terms of ORs [37,38].

To establish if the health status of repeat users changed between their first and final health checks, the baseline (first health check) and final (last check identified in the period under study) health measurements of repeat users were compared. McNemar tests were performed for the categorical variables BP category and smoking status to identify any change in proportions between baseline and final checks, and a Wilcoxon signed rank test was performed for baseline and final BMI measurements to identify any change in mean BMI scores from baseline to final check. Both methods were chosen because of their ability to allow the comparison of related or paired samples, and both the methods are often used in research comparing pre and posttreatment measurements [39,40].

Finally, to determine if the number of health checks completed by a user affects health outcomes at their final check, binary logistic regression models were constructed for each of the health outcomes BP category and smoking status, again because of their ability to include covariates and produce ORs for the quantification of relationships. A generalized linear model was used for BMI, assuming a gamma distribution due to the skewness of the data. This is a method suggested by some authors to overcome the issue of right-skewed data while avoiding issues associated with log-retransformation [41]. Baseline measurements were included in these models to control for differences in baseline health scores, and the demographic variables gender, age, and SES were included as covariates.

A *P* value of less than .05 (2-tailed) was deemed to be statistically significant. All analyses were performed using International Business Machines SPSS version 21.

Results

Comparison of Demographic and Health Characteristics of SiSU Health Station Users and National Health Survey Participants

The demographic characteristics of SiSU health station users compared with NHS users are presented in Table 1, revealing large differences in proportions across all demographic variables under consideration. SiSU health stations users were found to be younger (86,387/180,442, 47.87% vs 5309/15,393, 34.49% aged less than 35 years; *P*<.001) and living in higher SES areas (64,388/180,442, 35.68% vs 3117/15,393, 20.25% in quintile 5; *P*<.001) compared with NHS participants. A higher proportion of SiSU health station users were female (100,814/180,442, 55.87% vs 7807/15,393, 50.72%; *P*<.001), and the proportion of SiSU users living in each state varied from that of NHS participants, with a larger proportion of SiSU health station users residing in New South Wales compared with the NHS participants (92,636/180,442, 51.34% vs 4982/15,393, 32.37%; *P*<.001).

Although detailed data are not available for Priceline Pharmacy customers, according to Priceline Pharmacies, 97.00% of their customer base is female [42]. This gender distribution varies greatly compared with that of NHS participants and SiSU health station users.

Table 1. Comparison of the demographic characteristics of SiSU health station users and National Health Survey participants.

Variable	SiSU health station users (n=180,442), n (%)	NHS[a] participants (n=15,393), n (%)	*P* value

[a] NHS: National Health Survey.

[b] SEIFA: socioeconomic indexes for areas.

Table 2 provides a comparison of the unweighted and weighted health characteristics of SiSU health station users and NHS participants. Before weighting, SiSU health station users were generally healthier than NHS participants on the variables measured. There was a lower proportion of people with high BP (22,556/140,100, 16.10% compared with 3386/14,690, 23.05%), a lower prevalence of diabetes (9339/180,290, 5.18% compared with 11,909/180,988, 6.58%), and a smaller proportion of people who smoked (22,470/180,481, 12.45% compared with 2149/15,394, 13.96%) in the SiSU health station group. There was also a lower proportion of people with BMI in the overweight to obese range (83,055/149,676, 55.49% compared with 92,651/149,727, 61.88%), with the average BMI almost 2 kg/m^2 lower for SiSU health station users (25.56 kg/m^2, SD 5.88 kg/m^2) compared with NHS participants (27.29 kg/m^2, SD 5.61 kg/m^2). Interestingly, however, Figures 1 and 2 demonstrate that the shape of the distribution of BMI for SiSU health station users and NHS participants is almost identical, with both distributions demonstrating right skewness and similar variability.

Table 2. Comparison of the health characteristics of SiSU health station users and National Health Survey participants.

Variables	SiSU health station users (unweighted), n (%)	SiSU health station users (weighted), n (%)	NHS[a] participants, n (%)	NHS participants vs weighted SiSU health station users, OR[b] (95% CI)[c]	*P* value[d]
High BP[e](mm Hg)

[d] *P* value was obtained from binary logistic regression.

[e] BP: blood pressure.

[f] N/A: not applicable.

Figure 1. BMI distribution (kg/m2) of SiSU Health Station users, unweighted.

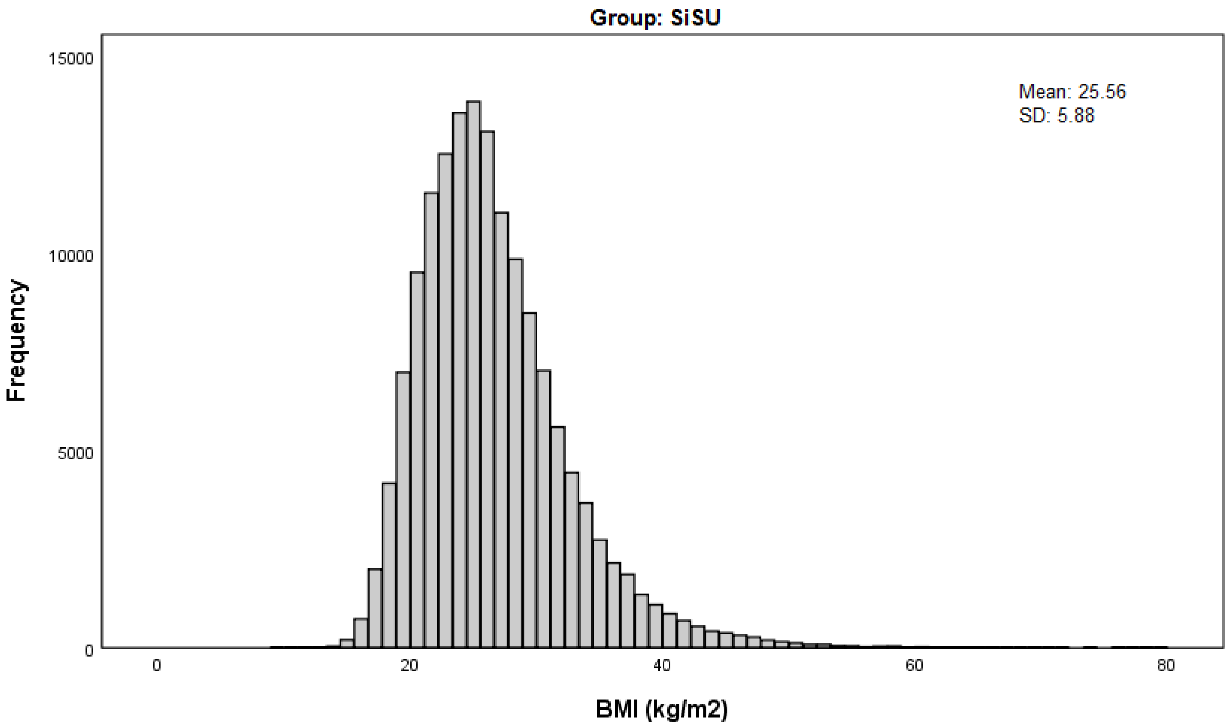

Figure 2. BMI distribution (kg/m2) of National Health Survey participants.

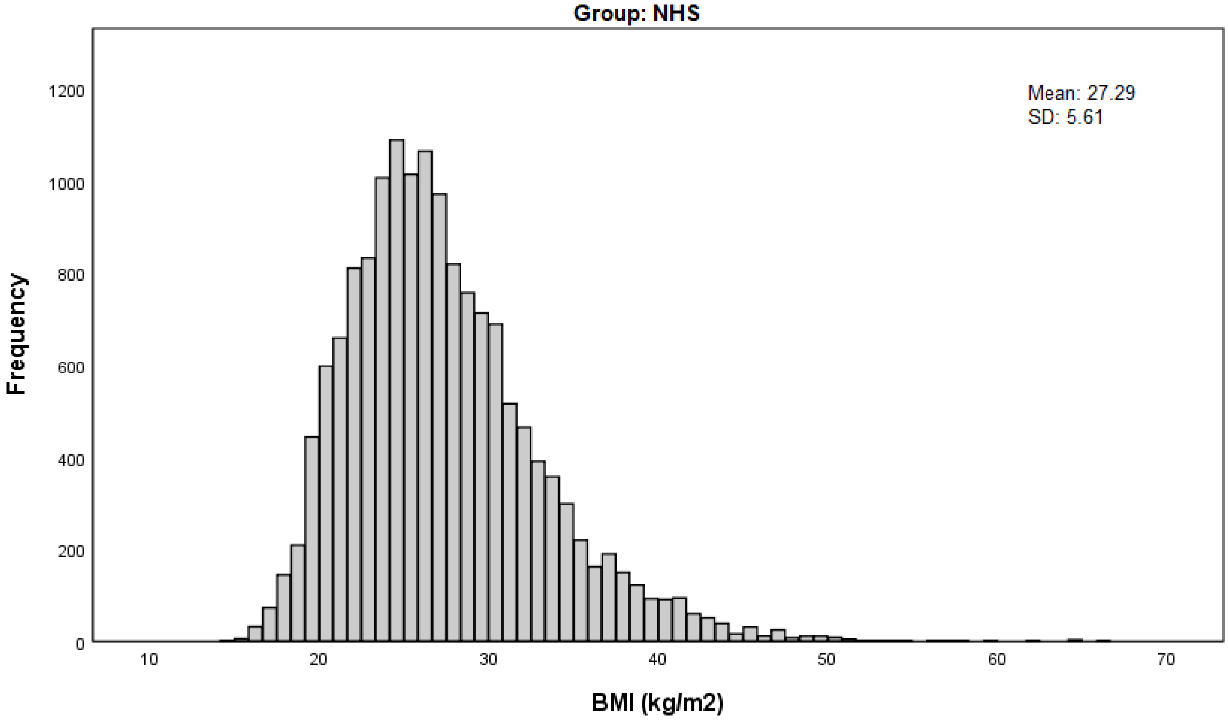

Given the demonstrated difference in demographics between the 2 groups, weights were applied to the SiSU health station data to account for these disparities, using the demographic variables age, gender, SES, and state to calculate the weights. The comparison of health characteristics was repeated using these weighted data to determine if SiSU health station users are healthier than the general population when these demographic differences are taken into consideration. ORs were calculated for each health characteristic to assess the magnitude of the difference between the weighted health characteristics of SiSU participants and those of the NHS participants.

Following the weighting of the SiSU health station data, the high BP and smoking variable distributions both demonstrated a significant difference with NHS participants. The proportion of SiSU health station users with high BP remained smaller compared with that of NHS participants (26,905/140,423, 19.16% compared with 3386/14,690, 23.05%), with NHS participants 1.26 times more likely to have high BP compared with SiSU users (*P*<.001). With regard to smoking status, the weighting of the SiSU data did result in a slight increase in the proportion of smokers; however, a smaller proportion of smokers remained in the SiSU group (23,999/180,444, 13.30% compared with 2149/15,394, 13.96%). Although this difference in the proportions was significant, the OR for this relationship was close to 1 (OR 1.06; *P*=.02), indicating that the difference is negligible.

Comparison of the BMI and diabetes status of SiSU health station users and NHS participants demonstrated no significant difference between proportions or an OR close to 1. The difference in the proportion of people with BMI in the overweight to obese range was not significant (92,651/149,727, 61.88% compared with 9455/15,233, 62.07%; OR 1.01; *P*=.66); although there was now a larger proportion of SiSU users with diabetes compared with the NHS participants (11,909/180,988, 6.58% compared with 969/15,381, 6.30%), this relationship was not significant (OR 0.95; *P*=.17).

Investigation of the Factors That Predict the Repeat Utilization of SiSU Wellness Health Check Stations

Binary logistic regression was used to identify demographic and health-related factors that are associated with repeat utilization of the SiSU health stations. Suspected shared accounts were removed from the analysis, resulting in a sample size of 179,467. Repeat users comprised 4.68% (8441/179,467) of all SiSU health station users in the sample, accounting for a total of 27,522 health checks, with a mean of 3.26 (SD 3.44) checks per person. The average time between baseline and final check for the users in this cohort was 77.60 days, with a minimum of 1 day and a maximum of 283 days between baseline and final check. Overall, 50.84% of users undertook their final check less than 90 days after their baseline check.

Overall, the model was found to be statistically significant (χ^2_{17}=483.5; *P*<.001), but only accounted for 1.00% of the total variance in the dependent variable, repeat user status (Nagelkerke R Square=0.011). Age was found to be significantly associated with being a repeat user, with the odds of being a repeat user decreasing with age; however, this effect size was small (OR 0.992; *P*<.001). Females were 1.371 times more likely to be repeat users (OR 1.371; *P*<.001), whereas those who resided in SEIFA quintiles 4 and 5 were significantly more likely to be repeat users compared with those residing in quintile 1 (OR 1.243; *P*<.001 and OR 1.151; *P*<.001, respectively). Only those residing in the Australian Capital Territory, Victoria, and South Australia had significantly lower odds of being repeat users compared with those residing in New South Wales (Table 3).

In terms of health characteristics, BMI, high BP, and smoking status were all significantly associated with being a repeat user. As BMI increased, the odds of being a repeat user increased; however, the effect size was small (OR 1.020; *P*<.001). Those with high BP were significantly more likely to be repeat users (OR 1.151; *P*<.001), whereas smokers were significantly less likely to be repeat users (OR 0.773; *P*<.001). There was no significant association between diabetes status and being a repeat user (Table 3).

Identify If the Health Status of Repeat Users of SiSU Health Stations in Australia Improved From Baseline to Final Check

A Wilcoxon signed rank test and McNemar tests were performed on the baseline and final health scores for the continuous and binary health characteristic variables, respectively. At baseline, the mean BMI was 26.37 kg/m^2 (SD 7.43 kg/m^2), decreasing to 25.40 kg/m^2 (SD 8.06 kg/m^2) at the final check. Results of the Wilcoxon signed rank test indicated that this change in mean BMI scores was significant (Z=−14.24; *P*<.001; Table 4).

The proportion of people with high BP decreased from baseline (5768/6848, 15.77%) to final check (885/6850, 12.92%). The results of the McNemar test confirmed that this change in proportions was significant (χ^2_1=38.2; *P*<.001). Of the 1080 users with high BP at baseline, 590 (54.63%) did not have high BP at their final check. Conversely, of the 5768 users who did not have high BP at baseline, 395 (6.85%) had high BP at their final check (Table 5).

The proportion of smokers was also found to decrease from baseline (1005/8438, 11.91%) to final check (854/8430, 10.13%). This decrease was found to be significant (χ^2_1=48.4; *P*<.001). Of the 1005 smokers at baseline, 308 (30.65%) were not smokers at their final check, whereas 2.11% (157/7436) of the nonsmokers at baseline reported smoking at their final check (Table 5).

Table 4. BMI of repeat SiSU users at baseline compared with final check.

Variable	Baseline, mean (SD)	Final check, mean (SD)	Test statistic (Z)	*P* value
BMI (kg/m^2)	26.37 (7.43)	25.40 (8.06)	−14.24	<.001

Table 5. Blood pressure and smoking status of SiSU users at baseline compared with final check

Variables	Baseline, n (%)	Final check, n (%)	Chi-square value (*df*=1)	*P* value
High blood pressure (mm Hg)				
No	5768 (84.23)	5963 (87.08)	38.2	<.001
Yes	1080 (15.77)	885 (12.92)	N/A[a]	N/A
Smoking status				
Nonsmoker	7436 (88.09)	7578 (89.87)	48.4	<.001
Smoker	1005 (11.91)	854 (10.13)	N/A	N/A

[a] N/A: not applicable.

Finally, linear models were used to determine if the number of health checks a user undertakes was significantly related to their final health scores. The baseline scores were controlled in these models.

Due to the skewed distribution of BMI in the final check variables, a generalized linear model with gamma distribution and log link was used to assess the relationship between final BMI measurements and number of health checks. When controlling for baseline measures, the exponentiated coefficient (Exp[b]=0.999; *P*=.23) indicates that BMI at the final check was not significantly associated with the number of health checks (Table 6).

Binary logistic regression demonstrated that an increasing number of health checks were significantly associated with a decreasing likelihood of being a smoker at the final check, although this effect was small (OR 0.959; *P*<.048). There was no significant relationship between the number of health checks and high BP at the final check (OR 0.985; *P*=.14; Table 7).

Table 6. Generalized linear model explaining the effect of number of health checks on BMI at final check.

Parameter	Exp (b)[b] (SE)	*P* value
Number of health checks	0.999 (1.001)	.23

Discussion

Principal Findings

At 180,000 health checks, the SiSU wellness dataset is one of the largest datasets ever provided for research, which has been generated by interactive health stations that measure biometric indicators. The scale of this dataset is clearly significant, and this study and the SiSU wellness dataset provide a valuable foundation for extensive investigation into the benefits of health stations in terms of their health monitoring and health promotion capabilities.

This study builds on previous research in the health technology field by providing further insight into the factors that are associated with health kiosk utilization and the potential health benefits of using health kiosks to self-monitor health. Findings indicate that demographics, including gender, age, and SES, were associated with both utilization and repeat utilization of the SiSU health stations, with females, younger people, and those of higher SES using the SiSU health stations at higher rates and more likely to be repeat users. A relationship between health characteristics and repeat utilization of the health stations has also been demonstrated; both higher BMI and high BP at baseline increased the odds of being a repeat user, and smokers were less likely to be repeat users.

The results are consistent with findings regarding the influence of age on the utilization of health technologies, which suggest that younger people use these technologies at higher rates [23-25]. Despite the suggestion by some authors that health kiosks may play a role in reducing this age bias in the use of technology by reducing age-related barriers [29-31], this does not appear to be supported by the results of our study.

Previous studies investigating the influence of gender on health kiosk utilization have demonstrated mixed results. Consistent with our findings, 1 study found that females access health kiosks at higher rates [29], whereas another study found that the relationship between gender and kiosk use is dependent on other demographic variables such as country of birth and SES [32], and other studies have found no relationship between gender and kiosk use [30,33]. The inconsistency of these results is potentially due to differences in the location of the health kiosks (eg, retail environment and hospital setting), which has been found to influence utilization rates [31]; further research could aim to investigate these effects. It is worth noting, however, that although a smaller proportion of SiSU health station users are males, the sheer volume of males undertaking health checks using the SiSU health stations provides a unique opportunity for engaging this demographic, who have been found to access traditional preventative health services at lower rates than females [43,44].

When considering the gender distribution of Priceline Pharmacies' customer base in conjunction with that of SiSU health stations users, evidence emerges that suggests that the SiSU health stations are highly effective in engaging the male demographic, with 44.13% (79,628/180,442) of SiSU health station users being males. Evidence to support the hypothesis that the SiSU health station is particularly attractive to males in retail environments is further supported by unpublished data from a 6-store retail health station pilot that SiSU wellness undertook with a major Australian Supermarket chain, where males accounted for 54.29% (50,143/92,345) of the checks recorded. In 5 of the 6 supermarkets, males contributed the clear majority of checks, and in the only store where females were the majority, the spread between genders was just 1.40% (Personal Communication by Patrick J Hannebery, May 29, 2019).

The findings regarding the SES of SiSU health station users support previous research that demonstrate that higher SES levels are associated with higher utilization rates of health kiosks [30,31] and health technologies in general [23,25,28]. The poorer rates of utilization in lower SES populations may be the result of a combination of factors, including lower health literacy [45,46]; access barriers such as cost, time, and transport [46,47]; and attitudes toward health care and health care providers [47,48]. Again, location of the health kiosks may play a role in the lower rate of utilization by those from low SES areas.

Our initial descriptive analysis of the health characteristics of SiSU health station users found that SiSU users are generally healthier than the NHS participants on the 4 health characteristics investigated in this study. This supports the findings of previous research, which found that people with chronic disease are less likely to engage in self-monitoring. Such research suggests that poor health is associated with decreased self-efficacy and confidence in health monitoring and improvement, sometimes leading to decreased utilization and adoption of monitoring and prevention [26], which may in part explain these findings. The results of the weighted analysis, however, indicate that age, gender, SES, and place of residence (state) play a large role in the difference in the disease status between SiSU users and the general population, with BP being the only indicator with a substantially large difference between SiSU users and the NHS participants once data were weighted to address the disparity in demographics.

Our investigation of the factors associated with repeat utilization, however, demonstrated that people with high BP are more likely to be repeat users of the health stations and that as BMI increases, the odds of being a repeat user increases. This is an interesting finding in that SiSU users were found to have more favorable outcomes on the 4 health indicators under investigation, whereas repeat users were more likely to have high BP, diabetes, and higher BMIs. These findings provide insight into the differences between once-off utilization of health technologies as opposed to sustained use. The placement of the majority of SiSU health stations in pharmacies may play a role in this relationship, given that those with health issues may be more likely to go to pharmacies on a regular basis.

Regarding repeat utilization of SiSU health stations, our results are somewhat consistent with previous research that demonstrate that people with chronic disease are more likely to use technology to self-monitor their health in a sustained manner [24-27]. For example, higher BMI has been found to be associated with higher frequency of use of mobile health apps [25], whereas those with hypertension have previously demonstrated a higher willingness to consistently self-monitor their health [26]. The difference in the health characteristics of repeat users compared with one-time users is interesting. It has been suggested by some authors that sustained use of self-monitoring may be driven by health-related goals such as weight loss [24,49], which may partially explain these findings.

This study has also provided an initial analysis of the health outcomes of health kiosk users, which to date, have not been established. In doing so, it has paved the way for further investigation into the benefits of such technologies for health monitoring by identifying potential areas for further research.

The findings of our study demonstrate positive initial results in terms of the change in health status between baseline and final health checks for repeat users, although the number of health checks a person undertakes does not appear to influence outcomes at the final check. In terms of the comparison of baseline and final checks, these results are somewhat consistent with much of the research that has been conducted regarding the benefits of various self-monitoring health technologies [6,50,51]; however, they are somewhat inconsistent with the finding that the number of health checks does not impact health outcomes at the final check. For example, previous research has found that the adherent use of digital trackers is associated with weight loss and increased physical activity [6], whereas other studies have found that regular monitoring of BP leads to reductions in BP when combined with other interventions [50,51].

Although the suggestion that self-monitoring is effective when combined with other health interventions is interesting, unfortunately it is difficult from the SiSU data to determine the method through which improvements were achieved (eg, counseling, medication, and physical activity) and, if so, whether the use of SiSU health stations influenced the uptake of these methods. Due to the dearth of research regarding the benefits of technology for self-monitoring, there is also limited information available regarding the possible mechanisms behind the behavior changes that result in the health improvements observed in our study and other studies. Research into the effect of self-monitoring in general on health status suggests that mechanisms may include empowerment or self-efficacy [8,13], self-actualization and self-esteem, as well as greater sensitivity and awareness [6]. With regard to health technologies, there is also some evidence that the aggregation of health data in 1 place provides a more complete picture of health status, enabling more holistic behavior change [14]. Again, these findings present further research opportunities with regard to SiSU health station users.

Finally, there is also some evidence that the benefits of digital health monitoring are more pronounced for people with more serious health problems [6], again demonstrating the potential for further investigation of the SiSU data with regard to this finding.

It is worth noting that the results of all analyses undertaken have the potential to be influenced by the location of the SiSU health stations, that is, pharmacy, retail shopping center, gym, or corporate setting, rural versus metropolitan area, and other location variables. There is potential that the differences in demographics and health status between the SiSU wellness users and NHS participants may be partially explained by the placement of stations across the country, with more health check stations in New South Wales than other states. Repeat utilization and frequency of use of the SiSU health stations are also likely to be influenced by these factors. Future research should aim to investigate the effect of location on the demographic representatives and health characteristics of all users, the factors associated with repeat utilization, and the changes in the health characteristics of repeat users.

Overall, the results of this study are promising in terms of the potential for utilization of SiSU health stations as an effective catalyst for change and a means of empowering consumers to take ownership and achieve improvements in their health status. The considerably large sample size, digitization, and representativeness of health status measures in the data demonstrate the unique value of the SiSU health station data as a cost-effective method of monitoring population health data over time and provides a valuable data source for health workers, population health professionals, policy makers, and researchers alike.

Limitations

A number of potential limitations of this study have been identified. First, the range of demographic data available in both the SiSU wellness and ABS datasets limit the investigation of the representativeness of the SiSU data. It is possible that there may be underlying differences between the SiSU wellness sample and the general population that cannot be identified through this study. The limited number of demographic variables available for analysis and comparison also mean that the weighting of the SiSU wellness data is restricted to variables available in both the SiSU wellness dataset and the NHS dataset. Furthermore, only a small percentage of the variance in the repeat status of users could be explained by the available variables; additional variables would allow more robust models to be developed to investigate the relationship between demographics, health status, and repeat users more thoroughly.

It must also be acknowledged that the SiSU wellness data and the ABS census/NHS data are not mutually exclusive; in that it is possible that subjects in the SiSU wellness dataset could also be participants in the NHS. Due to this, and as there is no sampling frame to directly compare users and nonusers of the SiSU health stations, interpretation of the results of the comparison of SiSU users and NHS participants should be treated with caution. There are also limitations associated with comparing data from different sources. Although every effort has been made to ensure that the variables from the SiSU health station and NHS data are directly comparable, by collapsing response categories where necessary and using actual measurements to compute categories for variables such as BMI and BP, we were unable to control for potential differences in measurement techniques.

A further limitation is associated with the study design, as it is difficult to determine from the results if the utilization of SiSU health stations has led, directly or indirectly, to the improvements in health characteristics observed in this study. Data available through the SiSU health stations include Prochaska and DiClemente’s *Stages of Change* assessment data, and it is recommended that further studies investigating the relationship between SiSU health station utilization and health outcomes incorporate the relationship between these responses, repeat utilization of health stations, and health outcomes. Additional considerations for further investigation include the presence or absence of other potential drivers of change, including contact with health practitioners and healthy lifestyle programs, and potentially the inclusion of a control group to identify if these improvements are only observed in SiSU users. It must also be noted that the statistical methodology used for this particular research question did not allow for the inclusion of covariates; future research should aim to develop more complex models that involve a wider range of explanatory variables. Finally, the time elapsed between baseline and final check was not considered in these models and could be included in future to identify if changes to health status are more pronounced and/or sustained over time.

For these reasons, although contributing to the small body of research regarding the factors associated with and benefits of health kiosks for self-monitoring health, care should be taken in generalizing these results. Further research should build upon these initial investigations to address some of the identified limitations.

Conclusions

The findings of this study support much of the previous research regarding the relationship between demographics, health status, and uptake of self-monitoring for health, and, in particular, provide valuable insights regarding the health benefits of health kiosks for the self-monitoring of health. In general, users of SiSU health stations differ from the general population in terms of demographics and are likely to be healthier than the general population. However, this difference in health status appears to be minimal when differences in demographics are taken into account. The results of the study are promising in terms of the potential benefits of using SiSU wellness stations to monitor health; however, there are opportunities for further research into the factors relating to and mechanisms behind these benefits.

Acknowledgments

The authors would like to acknowledge Dr Noel Duncan, PhD and founder of SiSU Health Group, for providing the data to enable this research.

Abstract

Background: Wearable devices can be used for continuous patient monitoring in the general ward, increasing patient safety. Little is known about the experiences and expectations of patients and health care professionals regarding continuous monitoring with these devices.

Objective: This study aimed to identify positive and negative effects as well as barriers and facilitators for the use of two wearable devices: ViSi Mobile (VM) and HealthPatch (HP).

Methods: In this randomized controlled trial, 90 patients admitted to the internal medicine and surgical wards of a university hospital in the Netherlands were randomly assigned to continuous vital sign monitoring using VM or HP and a control group. Users' experiences and expectations were addressed using semistructured interviews. Nurses, physician assistants, and medical doctors were also interviewed. Interviews were analyzed using thematic content analysis. Psychological distress was assessed using the State Trait Anxiety Inventory and the Pain Catastrophizing Scale. The System Usability Scale was used to assess the usability of both devices.

Results: A total of 60 patients, 20 nurses, 3 physician assistants, and 6 medical doctors were interviewed. We identified 47 positive and 30 negative effects and 19 facilitators and 36 barriers for the use of VM and HP. Frequently mentioned topics included earlier identification of clinical deterioration, increased feelings of safety, and VM lines and electrodes. No differences related to psychological distress and usability were found between randomization groups or devices.

Conclusions: Both devices were well received by most patients and health care professionals, and the majority of them encouraged the idea of monitoring vital signs continuously in the general ward. This comprehensive overview of barriers and facilitators of using wireless devices may serve as a guide for future researchers, developers, and health care institutions that consider implementing continuous monitoring in the ward.

Trial Registration: Clinicaltrials.gov NCT02933307; http://clinicaltrials.gov/ct2/show/NCT02933307.

Introduction

Background

Today's technology is increasingly influencing health care [1]. Numerous wearable devices such as patches, smart watches, and even tattoos exist that can register vital signs such as heart rate (HR), respiratory rate, oxygen saturation (SpO_2), and blood pressure (BP) [2-5]. These devices are increasingly accurate and reliable [2,6], smaller, and more user friendly than current hospital monitoring devices. This could facilitate patients' mobility and recovery during admission [7,8]. Moreover, the devices can result in improved health outcomes and can be used as a diagnostic tool in the identification of several diseases or clinical deterioration during admission [2,9-11].

Clinical Deterioration

Vital signs of patients in general wards are usually monitored periodically by nurses, primarily during daytime [12]. As a result, clinical deterioration in between two subsequent measurements may not always be detected and can result in unplanned admission to the intensive care unit (ICU), which is associated with longer hospital stay, increased mortality rate [13-15], and higher costs [16]. During night hours, when less medical personnel are available, clinical deterioration may remain undetected until the next morning [17]. With wearable devices, patients can be monitored more frequently or continuously. This results in additional information about a patient's health status, particularly during out of office hours when patients are less frequently seen by nurses [4]. By implementing continuous monitoring, clinical deterioration can be detected in an earlier phase, particularly as changes in vital signs are often present 8 to 24 hours before a life-threatening event occurs [18-22]. Additional benefits of wearable device–based continuous monitoring are a reduced workload in nurses [23], improved patient comfort because of fewer vital sign measurements [8,24], and safe patient transport between wards [25]. Besides positive effects of wearable devices, continuous monitoring can lead to false alarms that result in unnecessary additional diagnostic procedures and possible alarm fatigue in health care professionals [26,27].

Wearable Devices

Recently, ViSi Mobile (VM) and the HealthPatch (HP) were introduced to hospital care. These two wearable devices are approved by the Food and Drug Association for continuous vital sign monitoring and have shown to be as accurate as nurse measurements in admitted patients [6]. Several studies describing the opportunities of wearable devices including VM and HP were primarily focused on the accuracy of data [11]. For successful implementation in hospital wards, wearable devices for continuous monitoring of vital signs should be comfortable and user friendly for both patients and health care professionals. Besides, patients and health care professionals should be willing to use them and see the benefit of these wearable devices and of being monitored continuously. A complete overview of experiences and expectations of patients regarding continuous monitoring with wearable devices is lacking. Therefore, this study aimed to identify experiences of patients, relatives, nurses, physician assistants, and medical doctors about the use of VM and HP in daily practice for continuous monitoring of vital signs in the general ward.

Methods

Setting, Participants, and Sampling

This randomized controlled trial was conducted in a university hospital between April 2015 and August 2016. The objective of this study was to give an overview of the experiences and expectations regarding continuous monitoring with wearable devices by most important stakeholders. This design was chosen as a control group would give an insight into the current experiences of patients who were not yet influenced by the use of wearable devices. Besides patients, the target population consisted of nurses, physician assistants, and medical doctors who were involved in the care of the included patients. Surgical patients were included when they were scheduled for an elective abdominal surgical procedure. Patients were excluded and replaced when they were monitored for less than 24 hours. A sample size of 90 patients (45 surgical patients and 45 internal medicine patients) was estimated to be sufficient to obtain data saturation regarding interviews, based on our pilot study [6]. As there are no standards to calculate sample size for qualitative research [28], we focused on data saturation. This was defined as the moment when additional interviews would not result in new information or themes, which was discussed and decided by two experienced qualitative researchers (MW and TB). Patients' relatives were involved if they attended the interview. We aimed to interview all nurses, physician assistants, and medical doctors who were involved in the care of the included patients to obtain a complete overview of users' experiences and expectations. The institutional review board decided that formal approval was not required after they reviewed the study protocol extensively (Local Ethical Committee number 2015-1717). The study was conducted in accordance with The Code of Ethics of the World Medical Association (Declaration of Helsinki).

Wearable Devices

VM (Sotera Wireless) is a patient monitoring system developed to enhance patient safety and early detection of clinical deterioration in a general ward. VM continuously measures 5-lead electrocardiography (ECG), HR, respiratory rate, SpO_2, BP, and skin temperature. It transmits all data wirelessly to a platform with Sotera's analytic software such as desktop PCs or tablet PCs from where health care professionals have a real-time insight into patients' vital sign data. VM consists of a wrist device with a touch screen display that shows vital signs and a thumb sensor that measures SpO_2 and BP. Five ECG cables and a chest sensor that measures skin temperature and respiratory rate are attached to the patient's chest. The battery in the wrist device has to be changed every 12 to 16 hours.

The HP (Vital Connect) is a small and lightweight disposable adhesive patch that consists of two ECG electrodes and a reusable module, which contains a sensor and a Bluetooth transmitter. It contains a battery that has a wear cycle of approximately 3 to 4 days. The patch continuously measures 1-lead ECG, HR, respiratory rate, HR variability, skin temperature, steps, and body posture [29]. The patch is attached to the patient's chest, from where it sends data via Bluetooth to a mobile device where patients can see their own vital signs. Data are transmitted to a secured Vital Connect cloud on the internet via Wi-Fi.

Study Procedures and Data Collection

Interviews

Patients in the surgical and internal medicine wards provided written informed consent after being informed about the study protocol. All interviewed nurses, physician assistants, and medical doctors also signed the informed consent form. Patients were randomly assigned to (1) VM, (2) HP, or (3) control group (no device; 1:1:1). This was done to equalize individual factors between groups and minimize bias. The control group only received the regular nurse measurements. They were interviewed about their current experiences and their expectations of continuous monitoring, without being influenced by wearing a device. In the internal medicine ward, patients were randomized immediately after signing the informed consent form. Surgical patients signed the informed consent form before an elective surgical procedure and were randomized after surgery on arrival in the ward. Vital signs were continuously measured for 2 to 3 days in the VM and HP groups. Regular vital sign measurements (three times a day) by nurses continued according to the hospital protocol for all patients.

At the end of the study, patients and their relatives were interviewed face-to-face for approximately 45 min by one trained investigator. Nurses, physician assistants, and medical doctors who were involved in the care of the included patients were also interviewed. For each semistructured interview, an interview guide was used that consisted of predetermined themes based on the model for implementation by Grol and Wensing [30]. We added themes identified in a recent pilot study about monitoring with similar wearable devices [6]. Themes concerned attitude toward continuous monitoring and the wearable devices, experiences with both wearables in clinical practice, future expectations of the devices, and perception on changes in clinical care using the devices. Questions focused on, for example, feelings of safety, users' experiences with the devices, expected effect of continuous monitoring on patient safety and quality of care, and effect on nurse-patient interaction. The interview guide is available on request. The interviews were conducted by two researchers with a biomedical and medical background and who were trained in interviewing.

Questionnaires

To determine psychological distress, all patients completed the short version of the State Trait Anxiety Inventory (STAI) [31,32] at baseline and on each day of the study period. On day 3, they completed the Pain Catastrophizing Scale (PCS), which provided a valid index about the extent to which people catastrophize [33]. STAI and PCS scores were compared between randomization groups as psychological distress can be a confounding factor. Furthermore, this allowed us to assess whether the devices affected psychological distress. In addition, nurses who took care of the participating patients and who were involved in, for example, attachment of the devices and changing batteries completed the System Usability Scale (SUS) [34], which is a reliable tool for assessing usability.

Analysis

Interviews

All interviews were audio-recorded and transcribed verbatim. Subsequently, two researchers (MW and TB) individually performed a thematic content analysis on all data (double coding) to determine facilitators, barriers, and positive and negative effects [35,36]. The researchers discussed the results until consensus was reached. The Donabedian framework for the quality of health care was used to present all positive and negative effects [37]. This framework distinguishes structure (context in which the care is delivered), process (all actions that make up health care), and outcome (all effects on patients' health). Facilitators and barriers were categorized according to an existing framework concerning determinants of adoption of mobile health [38,39]. New determinants regarding the use of VM and HP were added to the framework. Interviews were consecutively analyzed during the study, and saturation was assessed using histograms, in which all new factors per interview were presented. Quotes and striking issues were also documented. Once data saturation was reached, no further interviews were analyzed as it was expected that no new factors would be identified.

Questionnaires

STAI, PCS, and SUS scores were analyzed using SPSS package version 20.0 (SPSS Inc). STAI scores ranged from 6 to 24, and a higher score indicated more psychological distress. SUS scores ranged from 0 to 100, and a score above 68 was considered above average [34].

Descriptive statistics were presented as mean (SD). Statistical significance between patient groups regarding demographics and PCS was calculated using the analysis of variance (ANOVA) or Pearson chi-square test. ANOVA for repeated measures was used to assess differences in the STAI score between days and randomization groups. An independent samples *t* test was used to calculate the difference between HP and VM regarding SUS. STAI and SUS results were not correlated with the interview results. A *P* value less than .05 was considered significant.

Results

Demographics

A total of 165 patients were invited to participate: 89 patients from the surgical ward and 76 patients from the internal medicine ward. In each ward, 58 patients signed the informed consent form; 45 patients eventually participated in the study. Reasons for refusal were expectation of a large mental (n=37) or physical burden (n=10) and expected discharge within 24 hours (n=2). In the surgical ward, 13 patients were excluded because of rescheduling of the surgery (n=5), withdrawal of informed consent (n=4), early death (n=2), prolonged ICU stay (n=1), and a delirium (n=1). Reasons to exclude patients in the internal medicine ward were monitoring for less than 24 hours because of unexpected discharge (n=11) or physical burden by VM (n=2). No differences were found between randomization groups regarding age (*P*=.74) and gender (*P*=.55). Demographics are shown in Table 1. Relatives of 6 patients attended the interview. Six medical doctors (2 surgeons, 2 internists, and 2 intensivists), 3 physician assistants, and 20 nurses were interviewed.

Table 1. Patient demographics.

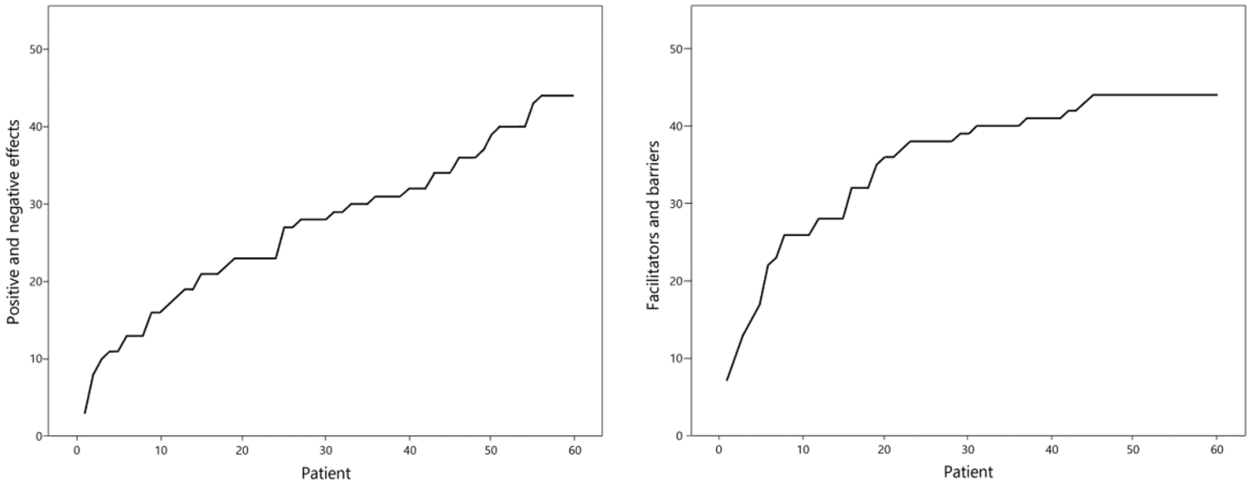
Interview Data

After analyzing 60 interviews (19 VM group, 21 HP group, and 20 control group) with patients, data saturation occurred, indicating that it was considered unlikely that new factors would be identified in additional interviews (Figure 1). We interviewed 29 health care professionals: 6 medical doctors, 3 physician assistants, and 20 nurses. After interviewing and analyzing professionals, we concluded that data saturation may not have been reached. Interviews with patients lasted for a median of 16 min (range 37 min). Generally, interviews with study participants from the control group lasted for a shorter duration as these people had no experience with the device. For professionals, interviews lasted for a median of 33 min (range 33 min). A total of 33 unique positive effects by patients and 56 positive effects by health care professionals and 14 negative effects by patients and 31 negative effects by health care professionals were identified. Patients reported 13 facilitators and 22 barriers, and health care professionals reported 13 facilitators and 36 barriers.

Figure 1. Saturation of positive and negative effects and facilitators and barriers. X-axis represents number of patients interviewed; Y-axis represents the accumulated number of new items mentioned by patients.



Positive Effects

In the structure, process, and outcome domains, 1, 23, and 23 positive effects were identified, respectively, (Multimedia Appendix 1) by patients, their relatives, and health care professionals. Moreover, 6 patients and 2 nurses mentioned alarms as a positive effect of continuous monitoring using wearable devices. A nurse stated:

> *We should all receive a mini-Ipad. It can show us patients' vital signs during our shift and will send us an alert in case the vital signs drop outside the normal ranges.* [NurseID4]

A total of 17 patients, 2 relatives, and 17 health care professionals expected to be able to detect clinical deterioration in an earlier phase using continuous monitoring. Moreover, 5 patients, 3 nurses, and 1 medical doctor mentioned that earlier detection can result in earlier interventions. Furthermore, 6 patients, 1 relative, and 5 nurses thought that the implementation of continuous monitoring can lead to less patient disturbances. In addition, 7 patients and 11 health care professionals thought that continuous monitoring can save time. We asked all nurses how to spend the saved time. A nurse mentioned:

> *Just talking to the patient. To have more time for the story of the patient.* [NurseID7]

Other positive effects regarding efficiency in health care were a reduced workload, shorter hospital stay, prevention of ICU admission, reduced costs, and lower amount of nursing staff required. A patient described:

> *You can stay shorter in the hospital and can go home with a wearable device. They can inspect your data in the hospital while you are at home. I would like that, it would feel more safe.* [PatientID40]

A total of 17 patients, 1 relative, and 9 health care professionals expected increased feelings of safety in patients in the general ward. In addition, patients' relatives and nurses mentioned feeling safer. A nurse explained:

> *Postoperative patients have been monitored continuously at the ICU. Some do feel unsafe after return at the general ward because of a lower number of vital sign measurements.* [NurseID1]

All nurses and most patients encouraged the implementation of wearable devices for continuous monitoring of patients. A nurse and a patient mentioned:

> *This is the future. We have to deal with it and the sooner we start working with those wearable devices, the more profit we will have.* [NurseID16]
>
> *The future...I think only 30% of the patients will be hospitalized by then. Patients will be monitored from home with this kind of smart devices.* [PatientID50]

Negative Effects

A total of 12 and 18 negative effects were identified in the process and outcome domains, respectively, by patients, their relatives, and health care professionals (Multimedia Appendix 2). Moreover, 1 patient and 5 health care professionals thought that continuous monitoring can generate an overload of information. An internist mentioned:

> *Sometimes you just do not want to know, making yourself crazy with too much data. Particularly when data does not influence your decision in patient's treatment.* [MedicaldoctorID5]

Particularly, nurses in the surgical ward were afraid that their ward would become like an ICU; 3 nurses and 1 medical doctor thought that this can lead to reluctance in transfer to the ICU. The alarm system was mentioned as a negative effect by 3 nurses and 3 medical doctors, leading to false-positive alarms, irrelevant alarms, and alarm fatigue. Moreover, 9 patients, 1 relative, and 5 nurses were afraid that interaction between patient and health care professionals would be reduced. A patient mentioned:

> *You need the confidence from the nurses, I would miss that. However, quantity time might become quality time.* [PatientID58]

In addition, 7 nurses and 1 medical doctor mentioned that continuous monitoring would cost more time, and 1 nurse, 1 physician assistant, and 1 medical doctor thought that it would increase workload. A nurse said:

> *Maybe it will increase work load. What if you receive an alarm every time a patient falls asleep and the oxygen saturation decreases a little bit?* [NurseID6]

A total of 12 patients, 2 relatives, and 2 health care professionals mentioned that patients can become worried by being able to see their own vital signs. A patient explained:

> *Some people are very anxious. Like my wife...like she already said: she would overreact. I would like to know my vital signs, but she would panic.* [PatientID54]

Facilitators

Eight facilitators were found in the domain Factors related to devices (Multimedia Appendix 3). In addition, 1 nurse and 1 medical doctor mentioned that by using continuous monitoring, health care professionals are able to see trends in vital signs. A surgeon stated:

> *Last night we saw a patient with an Early Warning Score of 3 and in the morning it suddenly was 13. Using continuous monitoring, we would have been able to see the Early Warning Score slowly increasing during the night.* [MedicaldoctorID6]

Moreover, 2 patients, 2 nurses, and 1 medical doctor mentioned the small size of the HP. Three patients said that they thought it was easy to view all vital signs on the VM wrist device or the mobile device of the HP. In addition, 2 patients and 1 nurse said that they think both the devices are reliable.

Three facilitators were found in the domain Individual factors. In addition, 2 patients, 2 nurses, and 2 medical doctors thought that continuous monitoring will lead to earlier detection of clinical deterioration, and 2 patients mentioned that they think that patient safety will be improved. In the Human environment domain, 8 facilitators were identified. Five patients mentioned that the devices were invisible under their clothes, and 7 patients said that they were not aware of the device. Moreover, 1 patient, 2 nurses, and 1 medical doctor mentioned fewer actions during vital sign measurements as a facilitator, such as putting on the upper arm cuff for BP measurements.

Barriers

In the domain Factors related to the devices, 22 barriers were identified (Multimedia Appendix 3). In addition, 2 patients, 3 nurses, and 1 medical doctor mentioned the VM battery change as a barrier. VM wrist device was thought to be too big or heavy by 5 patients, 3 nurses, and 1 medical doctor. Furthermore, VM cables and the patches and electrodes were also mentioned as barriers. A patient said:

> *Yesterday I felt very ill. I noticed that when you do not feel very well, every line, every device is just too much.* [PatientID40]

Three patients mentioned that devices are not able to measure patient experiences, such as pain. A patient described:

> *The devices are not able to register pain. When the nurse does not visit me, I cannot tell her I am having a headache. The device will not register that.* [PatientID55]

Moreover, 2 patients and 5 nurses said that it is a barrier that the HP is not able to measure all vital signs. Furthermore, it was also mentioned that VM and HP both are not able to measure core temperature.

Four barriers were identified in the Individual factors domain. One medical doctor mentioned the risk of overtreatment by identifying abnormalities in vital signs that cannot be ignored. Moreover, 1 medical doctor and 1 patient said that the VM wrist device is stigmatizing. In the domain Human environment, six barriers were identified. Three patients thought that it was a burden to carry the HP mobile device. One medical doctor feared that there will be too much attention for the vital signs and less attention for the individual patient. One nurse mentioned that patients were worried that the patches would come off. Four barriers were identified in the Organizational environment domain. Two medical doctors mentioned that nurses do not have adequate training to interpret continuous data. In addition, 4 nurses and 1 medical doctor thought that there would not be enough personnel to monitor all data:

> *At this moment it is not feasible to monitor all patients 24 hours a day and to anticipate adequately to clinical deterioration with the amount of nursing staff we have.* [NurseID6]

Questionnaires

Psychological Distress

No significant effect between the three randomization groups was found on STAI score (*P*=.33), and no significant within-subject effect was found in STAI score between days (*P*=.78; Table 2). Data of surgical and internal medicine patients were calculated separately; no significant effect between the randomization groups was found on STAI score (*P*=.86 and *P*=.17, respectively). No significant differences were found between the three randomization groups regarding PCS (*P*=.57; Table 2).

Table 2. State Trait Anxiety Inventory and Pain Catastrophizing Scale.

Group	STAI[a] baseline, mean (SD)	STAI day 1, mean (SD)	STAI day 2, mean (SD)	STAI day 3, mean (SD)	Pain Catastrophizing Scale, mean (SD)
ViSi Mobile	11.8 (2.7)	11.3 (2.9)	10.6 (2.6)	10.6 (3.0)	14.2 (11.2)
HealthPatch	11.4 (2.7)	11.2 (2.8)	11.5 (2.8)	11.2 (3.3)	15.7 (11.6)
Control	11.0 (3.1)	11.1 (3.1)	11.2 (3.3)	11.7 (3.5)	17.4 (10.9)

[a] STAI: State Trait Anxiety Inventory.

Usability

The SUS was filled in by 6 nurses (3 internal medicine nurses and 3 surgical nurses), 1 for each device. Both devices scored above average, indicating good usability. No significant difference was found between VM and HP (mean 77.9, SD 18.5 and mean 82.5, SD 18.6, respectively; *P*=.68).

Discussion

Principal Findings

In this study, we used two wearable devices for continuous monitoring of vital signs in non-ICU patients with a wide spectrum of clinical conditions in two different wards. Our study resulted in a broad overview of experiences and expectations with the devices of both patients and health care professionals. We showed that continuous monitoring in the ward was not only well received by most patients and their relatives but also by their health care professionals. We also identified relevant barriers of continuous monitoring with wearable devices and that using wearable devices did not affect stress levels. Both patients and health care professionals expected that continuous monitoring of vital signs would lead to an earlier identification of clinical deterioration and to an improvement of quality, safety, and efficiency in health care. We also identified relevant barriers of continuous monitoring with wearable devices.

Our semistructured interviews revealed a primarily positive attitude toward continuous monitoring. A recent study by Abelson et al [40] also confirmed that surgical patients have a positive attitude toward wearable devices and mobile apps and that they are willing to use them. Earlier detection of clinical deterioration was frequently mentioned by patients and health care professionals corresponding with the findings from a recent review by Cardona-Morrell et al [10]. They showed that continuous monitoring of vital signs in the general ward leads to an earlier detection of clinical deterioration [10]. Respondents mentioned that continuous monitoring could lead to saved time and reduced workload for nurses, which is also found in other studies [10]. All nurses mentioned that they would use this time for the patient, such as mobilization, washing or showering patients, providing information, and providing a listening ear for the patient. This might solve the problem for less nurse-patient interaction, which was frequently mentioned by patients. Future research should shed light on changes in nurses' workload after the implementation of continuous monitoring. A frequently reported barrier was the wrist device and cables of VM. Particularly, surgical patients mentioned that the VM cables were a burden in combination with other lines, such as abdominal drains and urinary catheters. However, patients did not feel restricted during daily activities. This is important as early appropriate mobilization improves recovery and reduces the risk of complications [41,42]. STAI and PCS scores revealed no differences in psychological distress between patients in the intervention and control groups, indicating that neither the VM nor the HP caused additional stress or reduced stress. According to SUS scores, the larger VM wrist device and cables did not influence the overall usability of the VM in comparison with the much smaller HP. It is expected that future devices will become even smaller while being able to wirelessly monitor an increasing number of vital signs continuously. The amount of data that will become available by continuous monitoring was mentioned as a negative effect by health care professionals, as it was expected that they would never be able to review all data. Big data analytics are available for effective storage and processing of large amounts of data [43,44]. Alarms can alert the nurse when patient's vital signs drop out of normal ranges, resulting in a high number of false-positive or irrelevant alarms or even alarm fatigue [27,45]. Machine learning algorithms can prevent unnecessary diagnostic procedures and overtreatment because of a reduced number of irrelevant and false-positive alarms [46-48].

Other Research

Few studies regarding continuous monitoring in the general ward exist. Brown et al [49] compared continuous monitoring using the EarlySense system with intermittent monitoring in a medical-surgical ward. This system includes a flat sensor that is placed under the patient's bed and monitors HR and respiratory rate continuously. They found a reduced number of days in the ICU and shorter overall hospital stay because of earlier interventions in patients who were monitored continuously. However, the system is not able to monitor other vital signs such as BP, SpO_2, and temperature when patients are out of bed. Other researchers used patches to monitor several vital signs such as the HP in this study, with promising results [50]. Using HP and VM, patients are able to mobilize throughout the hospital while being monitored continuously for relevant vital signs. VM measures almost all vital signs, which are required to calculate the Modified Early Warning Score and judge the clinical situation of the patient. More recent work found that patient monitoring systems should be tailored to users' needs [51].

Strengths and Limitations

An important strength of this study is that we were able to monitor patients admitted for various reasons for a longer period in a clinical setting in two different departments. We conducted a large number of semistructured interviews with both patients and health care professionals and were able to reach data saturation in patients about all predefined categories. This resulted in a comprehensive overview of the positive and negative effects of continuous monitoring and facilitators and barriers regarding VM and HP. The control group allowed us to collect current experiences from patients that were not yet influenced by using wearable devices. Regarding interviews with health care providers, data may not have saturated, although this is difficult to assess [28]. Selection bias could have occurred as not all invited patients participated in the study, particularly in the surgical ward. However, we randomized all patients to VM, HP, or a control group, and no significant differences were found between randomization groups, for example, gender, which minimized bias. Patients who refused to participate reported that they feared the mental or physical burden, particularly severely ill patients or patients with psychological distress. No differences were found in stress experienced between different randomization groups. Although the STAI questionnaire is validated for measuring psychological distress, many other stressful factors may have an impact on patients and may potentially influence the outcomes (stress before surgical procedures or complications during hospitalization).

Future Perspectives

Implementation of wearable devices for continuous monitoring is expected to influence health care in several ways. Patient safety can be improved as trained and experienced personnel can be warned during an earlier phase of deterioration and perform early interventions. This can prevent unnecessary ICU admissions and shorten hospitality stay. Nurses will have to be trained in using wearable devices and continuous vital sign data in the general ward. It is expected that nurses will have more time for other needs of a patient during admission. Data transmission via Wi-Fi between the device and the electronic health record should be safe and accurate. Potential alarms in vital signs can be processed using predictive analytics and machine learning techniques to prevent false-positive alarming. Furthermore, patients can benefit from continuation of monitoring using the same or comparable wearable devices. Vital signs data collected at home can be shared with trained nurses or physicians. With continuous monitoring, patients can be more actively involved in their own treatment. To stimulate this, the facilitators and barriers reported in this study are of great value when planning to implement wearable devices in the general ward.

Conclusions

According to patients and health care professionals, VM and HP have potential for continuous monitoring of vital signs in the general ward, and almost all of them encouraged the idea of monitoring vital signs continuously in the general ward. The comprehensive overview of barriers and facilitators of using wireless devices should be taken into consideration when choosing the device for implementing continuous monitoring. Continuous monitoring may facilitate the use of predictive analytics for clinical deterioration and early interventions. Further studies should explore the effect of continuous monitoring on clinical outcomes of patients in the general ward.

Abstract

Background: The prevalence of infertility in China is high, but the advent of assisted reproduction technology (ART) has greatly eased this situation. Social media, such as WeChat official accounts, have become the preferred tool for ART centers to communicate with patients, but their attention and operational status differ, and the Internet influence of WeChat official accounts is insufficient. In addition, questions about whether Internet influence is consistent with academic influence and whether the Internet can influence patients' choice of medical treatment to a certain extent have not been explored.

Objective: This study aimed to examine the operational status and Internet influence of WeChat official accounts for ART centers and to explore the degree of Internet influence on patients' choices of medical treatment.

Methods: We collected information from the WeChat official accounts for ART centers approved by the National Health Commission of the People's Republic of China and used the technique for order of preference by similarity to ideal solution to build an Internet influence model of the ART centers and obtained a Ranking of Internet Influence on Reproductive Centers (RIIRC) for each center.

Results: We found there were 451 ART centers throughout the country by the end of 2016 and 498 by the end of 2018. The number of medical institutions is quite large, but their distribution is uneven, and their level of medical technical ability is very different. Analysis of the text data of posts of WeChat official accounts showed the ART centers have insufficient awareness of network exposure and publicity, and the RIIRC of some medical institutions was inconsistent with their medical level and academic status.

Conclusions: ART institutions have varying degrees of emphasis and use of WeChat official accounts in China. They fail to realize that the Internet influence of WeChat may bring them potential patient resources and that Internet influence may affect the future market structure of ART and may also potentially affect academic rankings.

KEYWORDS

ART center; WeChat official account; Internet influence

Introduction

Severe Infertility and the Increased Requirements of Assisted Reproduction Technology Service

The prevalence of infertility in China, which has increased from 6.7% in 1988 to 15% to 20% now [1,2], has been influenced by a number of factors, including marital status, educational level, delayed age of child-bearing, the two-child policy, repeatedly induced abortions, poor lifestyle, and environmental pollution. Infertility has brought a heavy burden on countless families and has had a number of important effects on both personal and public health [3-6], including damage to social reputation [7], increased psychological pressure [8], long-term infertility [9,10], and constraints on economic development [11].Infertility is not only a physical condition but also a complicated sociological problem in China. However, it is possible to achieve pregnancy through assisted reproductive technology (ART) in cases that cannot be successfully addressed by conventional drugs or surgery.

The National Health Commission of the People’s Republic of China (NHCPRC) approved the implementation of human ART licenses in medical institutions more than 30 years ago. However, it was not until 2007 that the State Council delegated approval authority to the provincial health commissions. Before then, there were only 95 ART centers in China [12], and the number of these centers was initially limited, and their growth was slow because of the technical barriers to ART. Since the decentralization of approval authority and the development of the second and third generations of ART, these centers grew rapidly, and by the end of 2018, there were 498 such centers in China [13]. However, this rapid growth has led to uneven development in terms of the geographical distribution and the level of medical technology.

Competition in Assisted Reproduction Technology Market Approaches into the Qualitative Stage

In 2015, the NHCPRC proposed there should be *one institution for every 3 million people* to plan the development of ART centers [14]. The total number of ART centers in China under this policy was set at about 550, and the number of ART centers is approaching this limit, which is expected to result in a new stage of qualitative growth rather than quantitative growth. As it is extremely unlikely that there will be new public medical institutions, private capital investment is making competition in the ART market increasingly fierce. Many private investors have entered into the 100 billion market, such as Chengdu Xi’nan Gynecology Hospital and China IVF Medical Group Medical Group. Therefore, the focus of the ART centers in this next stage should be not only to upgrade their medical technology but to expand their public presence to attract the attention of potential patients.

Ignorance of Internet Images Influencing Patients’ Choice by Assisted Reproduction Technology Centers

Recent statistics indicate that the number of mobile internet users in China has reached 847 million, of which 48.3% are between 20 and 40 years of age [15]—the so-called generation of “Cyberspace natives.” They are accustomed to searching for information on the internet and forming their own opinions, which guides their decision in selecting medical institutions, but they may not pay much attention to the academic standing of medical institutions. This age group is also the main population that is interested in pregnancy preparation, and many of them are currently undergoing ART.

In contrast, most hospitals, including their ART centers, have ignored the impact of the internet, focusing instead on feedback from patients. In the highly competitive medical market, the technology and equipment of ART centers are increasingly easy to imitate and replace, and it is difficult for their hospitals to create their own unique identity. As the costs of infertility diagnosis and treatment are not covered by essential national medicare and the role of Cyberspace natives, internet influence on ART centers cannot be ignored. Is the influence of the internet on the ART center consistent with the influence of academic standing? What is the gap between them? Whether the internet influences patients' choices, and whether it can attract the attention of the capital market and alter the nature of hospitals in the future have not been examined.

The Aim of This Study

This study investigated the operation and popularization of the WeChat internet connection by ART centers. We used the technique for order of preference by similarity to ideal solution (TOPSIS) to construct an internet influence measure of ART centers and obtain a Ranking of Internet Influence on Reproductive Centers (RIIRC), which provides guidance for encouraging patients to seek reproductive help at ART centers by enhancing public awareness of them and their public image.

Methods

Sample Selection

The initial study sample consisted of 451 ART centers that had been approved by the NHCPRC by the end of 2016. A total of 498 medical institutions were approved by the NHCPRC as of December 31, 2018 [13]. The 47 new medical institutions approved between December 31, 2016, and December 31, 2018, were not included in the study because of their short history.

We began by browsing the official website of each ART center, including its main page and subpages, searching for the WeChat icon, QR codes, and opening announcements. If no WeChat official account was found, we proceeded to the next step, which was to search for sites that contained words or phrases such as “Weixin” or “WeChat.” If the website of the ART center did not have a “search” function, we used Google or Baidu to search within the medical institution’s website.

We also searched directly in the WeChat App using the keywords “name of medical institution,” “reproductive medicine,” “ART center,” or “reproductive medicine department.” Finally, we consulted with the person in charge by emails, messages on the website of ART center, etc. If we confirmed that WeChat account have been applied, they will not be consulted.

These procedures revealed that 200 of the 451 ART centers had opened WeChat official accounts, as of December 31, 2018.

Afterwards, Webpage parsing techniques and other technical means were used to obtain basic information for the 200 centers.

The WeChat accounts of the 200 ART centers were screened again, and unqualified accounts were excluded. We examined the text data of the official account posts to see if they met the first exclusion criterion: that is, having multiple values (five or more values) on the 19 indicators described in the section on Index of Internet Influence. A total of 41 accounts that had multiple missing values were excluded. The second criterion was that there was no record value; that is, the account had not been continuously maintained and updated. We found that nine accounts had not pushed tweets or only had a few tweets in the past year, so they were excluded. This left a total of 150 official accounts included in the analysis. All NULL values in the text of tweets of the 150 accounts were replaced with zero for the convenience of subsequent processing.

Collection of Basic Data

The basic data of the 150 centers were collected manually to evaluate the influence of the internet through the WeChat accounts. We hired 4 assistant researchers to inspect and collect the data after they received professional training. The account data from each center were randomly divided into four equal parts, and the 4 assistant researchers randomly selected one of them to inspect and collect the data. After one round of collection, they exchanged the list for a second round, and finally inspected the two rounds of data. If a discrepancy was found, it was discussed and consensus was reached.

Basic information included an assessment index for the access to technology, an official account menu bar score, geographical location, date of formation on the department, date of approval by the NHCPRC, date of creating the WeChat official account, and whether there was an official website and official hospital certification (service account and subscription account).

The assessment index for access to technology refers to the type of ART approved by the NHCPRC (Table 1).The official account menu bar score refers to the functions contained in the menu bar of the official account, which generally included a department introduction, appointment registration, navigation, medical examination reports, popular scientific articles, etc. One point was assigned for each function and the sum of the points was the score.

Table 1. Types and scores of assisted reproduction technology in medical institutions.

Access to technology	Score
Artificial insemination with husband (AIH)	0.5
Artificial insemination by donor (AID)	0.5
In vitro fertilization and embryo transfer (IVF-VT)	2
Intracytoplasmic sperm injection (ICSI)	3
Preimplantation genetic diagnosis (PGD)	4

Acquisition, Conversion, and Cleaning of Data

Data mining of WeChat accounts generally requires using appropriate methods and tools, according to the characteristics of the dataset. This study mainly adopted the Webpage parsing technique, using Python 3.7 as the development language, PyChram as the development platform, and MongoDB for data storage. The data had to be further processed and structured for later analysis and mining, mainly involving data deduplication, integration, and transformation.

The data from the eligible centers were from November 1, 2018 to October 31, 2019.

Index of Internet Influence

In light of the existing research literature and the purpose of this study [16-18], we developed an index to measure the internet influence for ART centers through their WeChat accounts. The 19 indices shown in Table 2 were selected for use in the study.

It was necessary to clarify the concepts and definitions of indices selected in this study. WeChat service account and subscription account can setup to eight tweets at a time. The heading of the main title was called the “headline,” and the seven subtitles were collectively referred to as “subheadlines.” “Posting frequency” (x_1, number of posts per month) equals to the number of articles WeChat account posts in the past year divided by 12. “Number of articles of each post” (x_5, number of articles per post) equals to the total number of articles WeChat accounts posts divided by the number of posts in the past year. “Average number of views of the headlines” (x_6, number of views per article) equals to the total number of views of headline articles divided by the number of headlines in the past year. “Average number of likes of headlines” (x_7, number of likes per article) equals to the total number of likes of the headline articles divided by the number of headlines in the past year. The number of views and likes of posts of the other indicators used a calculation method similar to that of the “Average number of views of the headlines” and “Average number of likes of headlines.”

Table 2. The index of internet influence for assisted reproductive technology centers.

Category and index	Symbol
Basic index	
Posting Frequency	x_1
Number of articles of each post	x_5
Menu bar score	x_{18}
Headline index	
Average number of views of headlines	x_6
Average number of likes of headlines	x_7
Average number of views of original headlines	x_8
Average number of likes of original headlines	x_9
Average number of views of unoriginal headlines	x_{10}
Average number of likes of unoriginal headlines	x_{11}
Academic index	
Assessment Index for Access Technology	x_{19}
Articles type	
Number of headlines	x_2
Number of subheadlines	x_3
Number with original content	x_4
Subheadline index	
Average number of views of subheadlines	x_{12}
Average number of likes of subheadlines	x_{13}
Original content	
Average number of views of original content	x_{14}
Average number of likes of original content	x_{15}
Average number of views of unoriginal content	x_{16}
Average number of likes of unoriginal content	x_{17}

Construction of the Internet Influence Measure

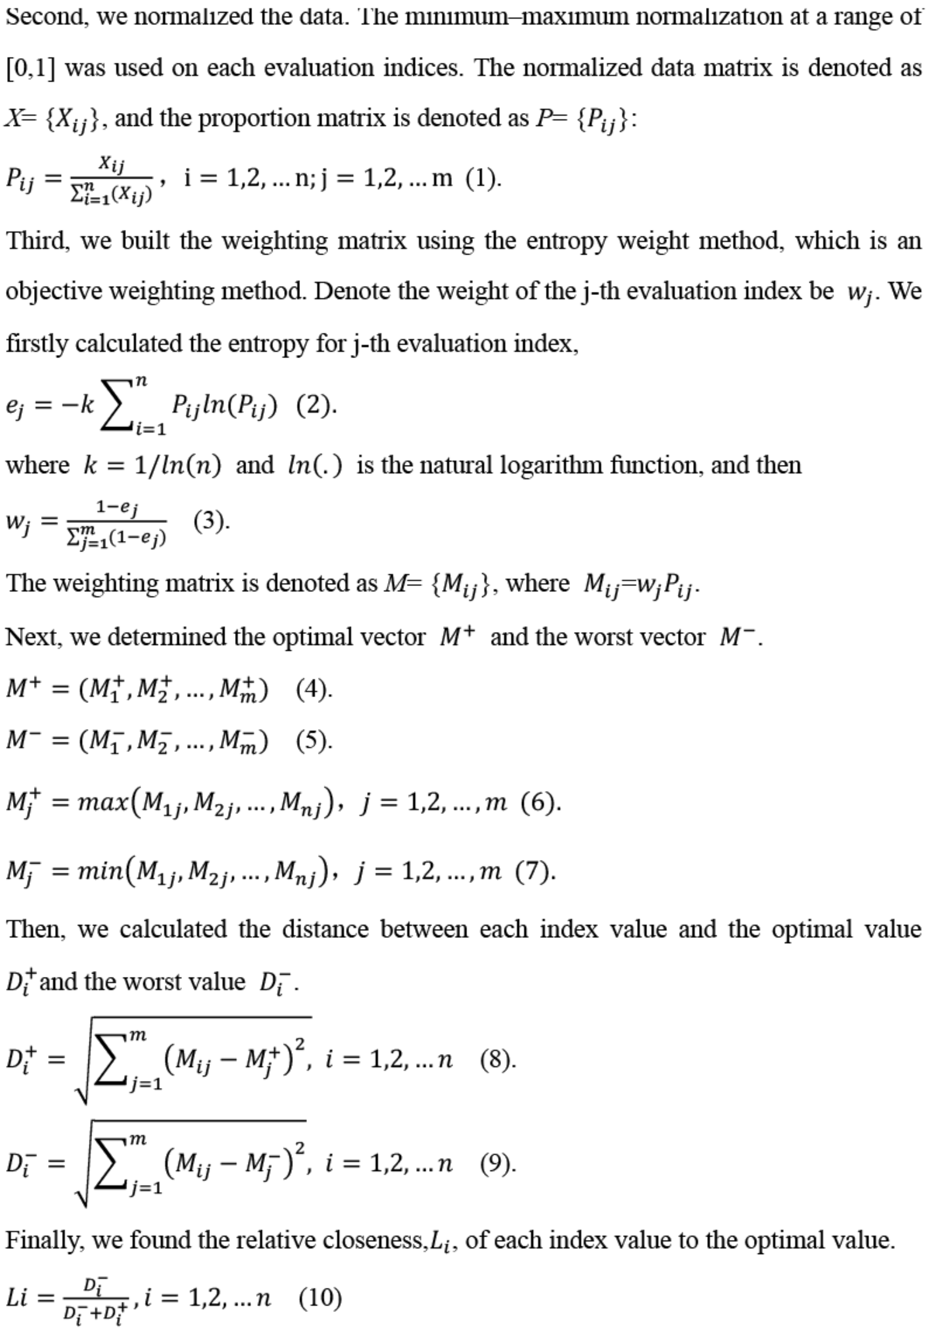
The construction of the measure of internet influence and the output of the figures were based on R Programming Language (The R Foundation Conference Committee, version 3.6.1, 2019-07-05).

The determination of the weight of the index and measurement model were based on TOPSIS.

First, we created an index matrix; there were n evaluation objects, and each evaluation object had m evaluation indices. It is usually necessary to convert low-quality indices with lower values and better evaluation results to high-quality indices to make the objectives have the same trend. In this study, however, all of the indices were high-quality indices, so conversion did not have to be performed.

The proportion matrix P_{ij}, weighting matrix M_{ij}, and relative closeness Li were computed by equations (1), (4), (5), (6), (7), and (10) as shown in Figure 1.

Figure 1. Mathematical equations.



Second, we normalized the data. The minimum–maximum normalization at a range of [0,1] was used on each evaluation indices. The normalized data matrix is denoted as $X = \{X_{ij}\}$, and the proportion matrix is denoted as $P = \{P_{ij}\}$:

$$P_{ij} = \frac{X_{ij}}{\sum_{i=1}^{n}(X_{ij})}, \quad \mathrm{i} = 1,2, \ldots \mathrm{n}; \mathrm{j} = 1,2, \ldots \mathrm{m} \quad (1).$$

Third, we built the weighting matrix using the entropy weight method, which is an objective weighting method. Denote the weight of the j-th evaluation index be w_j. We firstly calculated the entropy for j-th evaluation index,

$$e_j = -k \sum_{i=1}^{n} P_{ij} ln(P_{ij}) \quad (2).$$

where $k = 1/ln(n)$ and $ln(.)$ is the natural logarithm function, and then

$$w_j = \frac{1-e_j}{\sum_{j=1}^{m}(1-e_j)} \quad (3).$$

The weighting matrix is denoted as $M = \{M_{ij}\}$, where $M_{ij} = w_j P_{ij}$.

Next, we determined the optimal vector M^+ and the worst vector M^-.

$$M^+ = (M_1^+, M_2^+, \ldots, M_m^+) \quad (4).$$

$$M^- = (M_1^-, M_2^-, \ldots, M_m^-) \quad (5).$$

$$M_j^+ = max(M_{1j}, M_{2j}, \ldots, M_{nj}), \quad j = 1,2, \ldots, m \quad (6).$$

$$M_j^- = min(M_{1j}, M_{2j}, \ldots, M_{nj}), \quad j = 1,2, \ldots, m \quad (7).$$

Then, we calculated the distance between each index value and the optimal value D_i^+ and the worst value D_i^-.

$$D_i^+ = \sqrt{\sum_{j=1}^{m} (M_{ij} - M_j^+)^2}, \quad i = 1,2, \ldots n \quad (8).$$

$$D_i^- = \sqrt{\sum_{j=1}^{m} (M_{ij} - M_j^-)^2}, \quad i = 1,2, \ldots n \quad (9).$$

Finally, we found the relative closeness, L_i, of each index value to the optimal value.

$$Li = \frac{D_i^-}{D_i^- + D_i^+}, i = 1,2, \ldots n \quad (10)$$

Results

Distribution and Technical Ability of the Centers Is Uneven

The 451 ART centers were located in 31 provincial administrative regions of China, including 22 provinces, five autonomous regions, and four municipalities directly under the central government. However, they were mainly in the southeast coast, the middle and lower reaches of the Yangtze River, and the Bohai Rim (Figure 2).

Nearly three-quarters (327/451, 72.5%) of the ART centers in Chinese performed in vitro fertilization-embryo transfer and intracytoplasmic sperm injection, whereas only 8.9% (40/451) could perform preimplantation genetic diagnosis (Table 3).

The Third Hospital of Beijing Medical University (now known as Peking University Third Hospital) and the Second Clinical Medical College of Hunan Medical University (now known as Xiangya Hospital Central South University) were the earliest medical institutions to conduct ART in China. The number of ART centers increased dramatically from 2007 to 2016, during which time a total of 403 ART centers were approved (Table 4).

Figure 2. Distribution of 451 assisted reproduction technology center across Mainland China.

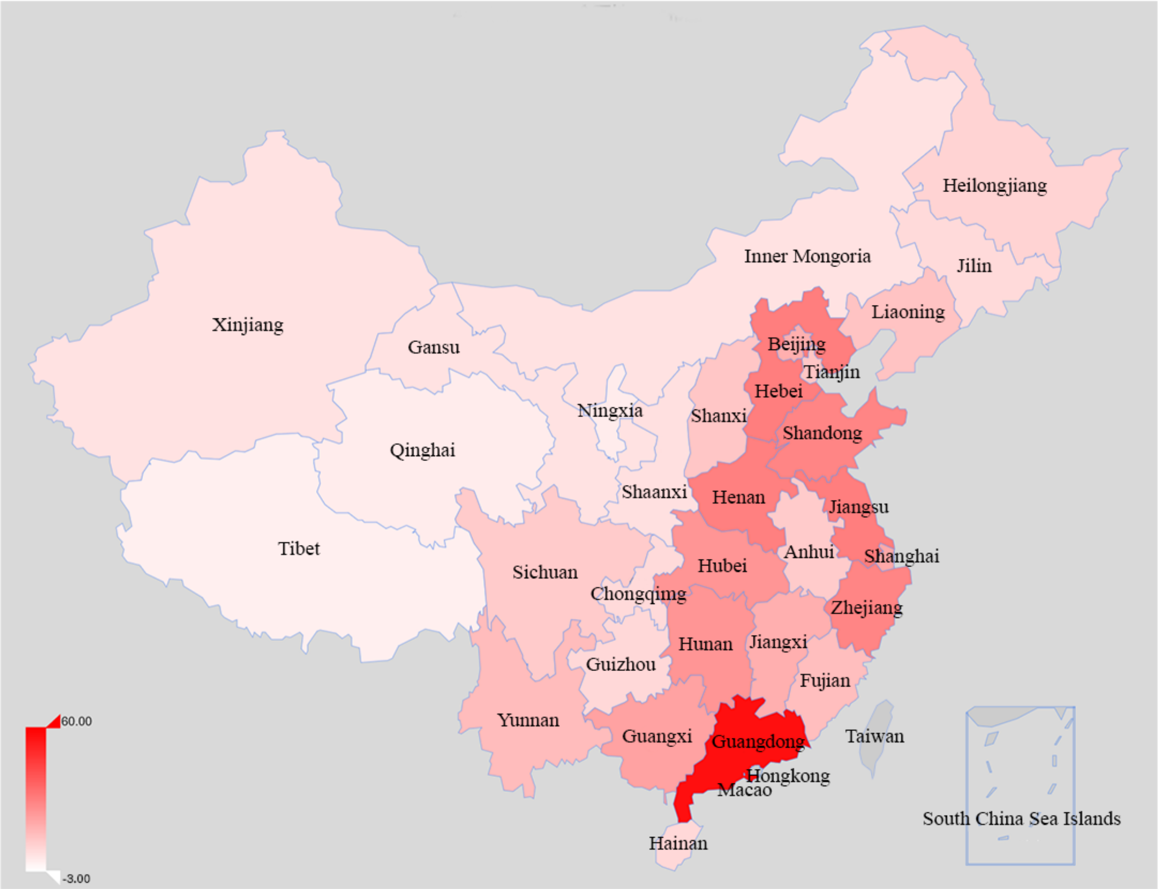


Table 3. The number of accessible technologies (total is the sum of all access technology).

Access to technology	Value, n (%)
Artificial insemination with husband (AIH)	449 (37.02)
Artificial insemination by donor (AID)	60 (5.00)
In vitro fertilization and embryo transfer (IVF-VT)	327 (26.96)
Intracytoplasmic sperm injection (ICSI)	327 (26.96)
Preimplantation genetic diagnosis (PGD)	40 (3.30)

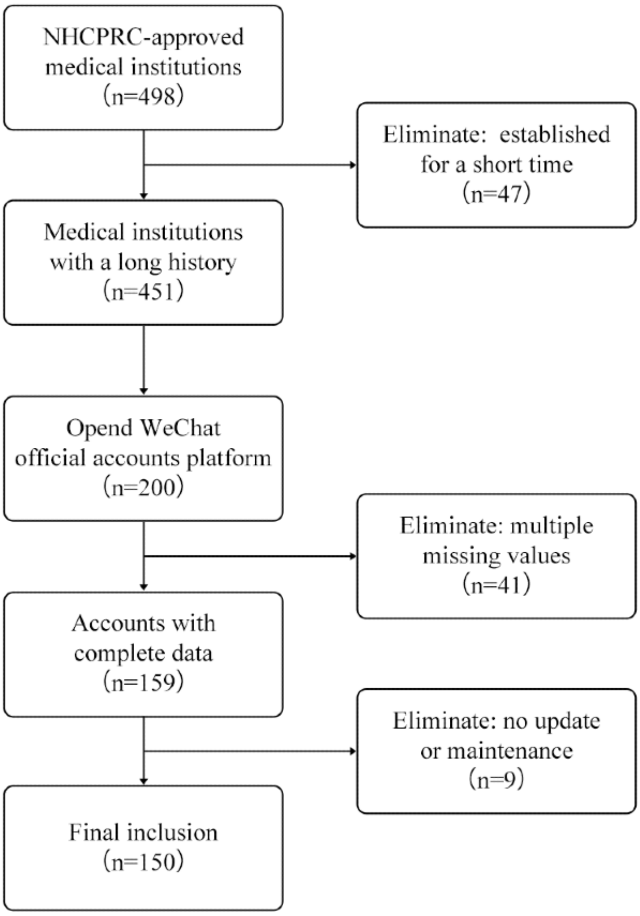
2016	451
2018	489

WeChat Accounts Are Uncommon and Their Operation Is Inadequate

We found only 200 ART centers had opened WeChat official accounts, and the operation of these media accounts differed. Of these 200 accounts, 41 had multiple missing values related to their posts, and another nine accounts had not been continuously maintained, updated, or pushed, or only had a few tweets in the past year. Therefore, only 150 accounts ultimately met the criteria for inclusion in the study (Figure 3).

Figure 3. Flowchart of the selection process for WeChat official accounts of assisted reproduction technology centers. NHCPRC: National Health Commission of the People’s Republic of China.



Low Usage and Quality of WeChat Accounts

The main page of a WeChat official account displays posts, including text, graphics, audio, and video. And there is an area at the bottom is called *menu bar*, through which patients can quickly find what they want (Figure 4). On November 14, 2012, Beijing Baodao Healthcare was the first ART institution to open a WeChat official account. However, the emergence of centers using WeChat official accounts did not attract people’s attention, according to our measures (Table 5). The index of the functionality of the WeChat account menu bar showed that the menu bar scores of most accounts were between 5 and 10 points (Table 6).The first wave of ART centers began in 2013 and reached its peak in 2014, indicating that the awareness and utilization of WeChat official accounts by ART centers needs to be further improved in China. The official website and certification of the WeChat official account is an important indicator of patients’ trust. As shown in Tables 7 and 8, there were 127 (63.5%) and 166 (83.0%) accounts with an official website and certification, respectively.

Extremely Uneven Quantity of Posted Article

As already mentioned, NHCPRC approved 451 medical institutions to conduct human ART, but less than half (200/451, 44.4%) of the ART centers have opened WeChat official accounts, of which 28.4% (128/451) have a subscription account and 16.0% (72/451) have a service account. The overall number of ART centers without an official account is 55.6% (251/451; Multimedia Appendix 1).

In roughly the past year, the cumulative number of posts of these official accounts varied greatly. In ascending order, the medical institutions below the third quartile (Q3) had not posted more than 100 times (Multimedia Appendix 1). Similarly, posting frequency and the number of articles of each post showed the same trend; the Q3 was 5.7 posts per month and 2.9 articles per post (Multimedia Appendix 1).

Afterward, we focused on the number of views of posts. In general, the average number of views of the headlines of the 150 official accounts was 1344.20, whereas the average number of views of the subheadline was only 5.20.

Further analysis of these accounts found that the greatest number of views of the headlines of accounts falling into Q1, Q2, Q3, and Q4 were 375.4, 795.3, 1791.2, and 18445.0, respectively, and the number of views of the subheadline was 128.6, 323.8, 710.0, and 9421.5, respectively (Multimedia Appendix 1). The number of likes was another evaluation index, which measures readers' recognition and approval of tweets. The number of likes for the headline and subheadlines showed trends similar to the number of views (Multimedia Appendix 1).

Ranking of Internet Influence

As mentioned earlier, TOPSIS was used to evaluate the internet's influence for ART centers through their WeChat accounts. To do this, we adopted the objective method to determine the weight of the index (Table 9).

Multimedia Appendix 2 shows the results of the TOPSIS analysis. Among the top 10 medical institutions in the RIIRC are the Reproductive and Genetic Hospital of CITIC-XIANGYA, the Guangdong Institute of Family Planning Science and Technology, The First Affiliated Hospital of Anhui Medical University, the Jiangsu Province Hospital Affiliated with Nanjing Medical University of Medicine, the Peking University Third Hospital, the Kunming IVF Hospital, the Third Affiliated Hospital of Guangzhou Medical University, the Sun Yat-Sen Memorial Hospital of Sun Yat-Sen University, the Northwest Women' and Children's Hospital, and the Reproductive Hospital Affiliated with Shandong University.

Table 9. The index weight of WeChat official accounts for assisted reproduction technology centers.

Index	Weight
x_1	0.029225
x_2	0.027547
x_3	0.067134
x_4	0.090053
x_5	0.027628

x_{18}	0.008801
x_{19}	0.006303

Discussion

Principal Findings

Taking WeChat official accounts as the breakthrough point, this study analyzed the information about ART centers from the perspective of a semiprofessional patients, using basic information and the number of views and likes to construct a mathematical model and obtained the RIIRC. The major findings involve the geographic distribution of the ART centers, their technical ability, their use of WeChat, and the internet influence for the centers.

Although the 451 ART centers in the sample are distributed throughout the country, their geographic distribution is uneven, and they vary in terms of types of ART they provide. Analysis of the text of posts in their official accounts found the ART centers have insufficient awareness of network exposure and publicity, and some of the centers' internet influence rankings are inconsistent with their medical level and academic status. We also found evidence that internet influence may affect the ART market structure in the future and affect the academic rankings of the medical institutions.

WeChat Official Account Is an Excellent Tool to Popularize Assisted Reproduction Technology Centers

WeChat is an internet instant-messaging social software that was launched by Tencent in January 2011 and launched its official account in July 2012 [19]. As of June 2019, WeChat had 1.08925 billion users who were active every month, and the total number of registered official accounts exceeded 20 million, forming a new type of vast social network, which has increasingly attracted the attention of researchers [20]. In the first half of 2019, the average daily use time of WeChat was 89.8 min, which is 5.1% higher than it was in 2018, making it become one of the apps with the longest daily use time per capita in China [21]. In addition, WeChat has a function that other social software does not have. It is called "Moments (Pengyouquan)," which refers to a circle formed by friends who know each other through WeChat; it is a niche and private circle constructed by an acquaintance relationship chain. This attribute of the "Moments" makes information posted by individuals more likely to be followed and trusted by friends. Given the characteristics of WeChat and WeChat official accounts, we have reasons to believe that WeChat platforms can provide ART centers with a convenient and low-cost opportunity to attract local customers and increase exposure.

The Selected Indices Are Reasonable to Reflect Ranking of Internet Influence on Reproductive Centers

We chose 19 indices as model parameters based on the framework of the WeChat official account, used an objective method to determine the weight of each index, and used TOPSIS to construct a measurement model of internet influence for ART centers (the RIIRC).Some WeChat official account rankings have recently appeared in China, including the WeChat Communication Index and the New Rank Index [16-18]. These rankings and evaluation methods are based on data available from WeChat official accounts, which reasonably reflect the comprehensive internet influence of official accounts to a certain extent and are generally consistent with our methods.

Although the focus of our research was the WeChat official account for ART centers, we also included an index of access to technology. The weight of the access to technology index in our study was 0.006303, which is very low. The reason is that this index assesses the medical level and academic ability of the ART center; it is not a conventional index of internet influence.

The number of views and likes have been used in capacity research as indices to measure the internet influence. We found that the weights for the number of articles of each post (x_5) and posting frequency (x_1) were 0.027628 and 0.029225, respectively, accounting for a relatively low proportion of influence. There was no obvious correlation between these two indices and propagation, indicating that they affect a small portion of the internet influence on the WeChat official accounts, which is consistent with previous results [22].One possible reason is that posting articles too frequently does not increase the average number of views, nor enhance a good reputation. Indeed, frequent posting may even distract patients' attention. The majority of the content posted by the WeChat official accounts of the ART centers was popular scientific articles. The number of views of such articles was acceptable, but the number of likes was not high. Psychological research shows that likes are a way for the public to express their approval of content and ideas [23]. The possible reasons why such articles fail to motivate patients' likes include their scientific nature, the preciseness of posts, and the fitness of the health hotspots. Among the many indices, originality was one of the most important ones for measuring the quality of official accounts and the authors' writing level, and its weight was relatively high (30% of the total weight). Some studies have shown that the average number of views of original articles is 6.54 times greater that of nonoriginal [24], which is consistent with our results. In addition, the data used in our analyses were the average number of views and likes of posts of official accounts during the past year, which avoids the problem of variations in the number of views and likes over shorter time periods. Moreover, the selected indices are data that can be viewed directly by general patients. Assessing the internet behavior of hospitals from the perspective of users can better and more objectively reflect the internet influence of WeChat official accounts for ART centers. In summary, no matter what type, quantity, or weight of an index is used, it can represent the internet influence of the official account for the ART center to a certain extent.

Most Assisted Reproduction Technology Centers' Ranking of Internet Influence on Reproductive Centers Are Inconsistent With Their Medical Level and Academic Status

WeChat launched its official accounts in July 2012, but this tool has not received the attention of ART institutions. By the end of 2018, only 200 ART centers had opened official accounts, and only 150 had operated and maintained them normally. The RIIRC showed that the Reproductive and Genetic Hospital of CITIC-XIANGYA is at the top of the list with 100 points. The Guangdong Institute of Family Planning Science and Technology (66.08), the First Affiliated Hospital of Anhui Medical University (65.86), the Jiangsu Province Hospital Affiliated with Nanjing Medical University of Medicine (50.22), and the Peking University Third Hospital (46.86) are among the top five. At present, the most authoritative list of medical institutions in China is the "Fudan University Hospital Ranking," released in November 2019, which includes rankings of the reproductive medicine specialty [25]. Those rankings focus on discipline structure, clinical technique and medical quality, and the level of scientific research of each hospital. The ART hospitals at the top of these two lists are mainly distributed in the coastal areas of Southeast China and the Bohai Rim region. The ART centers in these areas are rated significantly higher than those of other regions in terms of their opening proportion and internet influence. This may be because of the superior resources, such as open policies, sufficient techniques, and financial support [26,27].

Ranking of Internet Influence on Reproductive Centers May Indicate the Future Market Position of Assisted Reproduction Technology Centers

The Peking University Third Hospital and the Reproductive and Genetic Hospital of CITIC-XIANGYA were the earliest medical institutions to provide ART in China. The first two test-tube babies in mainland China were born in 1988, and these two hospitals were the domestic leaders of ART [28,29]. The ART center of the Peking University Third Hospital has published more than 100 scientific articles in internationally renowned magazines, such as *Nature*, *The Lancet*, *Cell*, and *Proceedings of the National Academy of Sciences*, and it is the most powerful ART center in China [30-33]. The ART cycle of the Reproductive and Genetic Hospital of CITIC-XIANGYA reached 49,000 cases in 2018. In the first quarter of 2019, this increased by 14.84% compared with the same period of last year, making it ART center with the most comprehensive medical technology and the largest number of patients at home and abroad [29]. The Peking University Third Hospital and Reproductive and Genetic Hospital of CITIC-XIANGYA are both at the forefront of the two rankings. They not only lead in terms of scientific research and clinical technique but also attach great importance to internet influence. We have reason to believe that such ART centers can maintain and further enhance their level of medical care, academic status, and internet reputation, so as to expand market advantages and become leaders in ART in China.

The Guangdong Institute of Family Planning Science and Technology, the Third Affiliated Hospital of Guangzhou Medical University, and Sun Yat-Sen Memorial Hospital Sun Yat-Sen University are all located in Guangdong Province of China, ranking 2nd, 7th, and 8th in RIIRC, respectively. The Third Affiliated Hospital of Guangzhou Medical University was ranked 20th in the Fudan University Hospital Ranking, and the other two hospitals were not nominated. There are two possible reasons for the above phenomenon: (1) Guangdong, as the province with the largest gross domestic product in China, has a developed economy and a strong business sense, and it recognizes the importance of public praise and (2) Guangdong Province has a large number of ART centers (as many as 56), and the intensively competitive situation made the ART centers aware of the importance of survival, so they paid attention to their image and reputation on the internet. Jiangsu Province Hospital Affiliated with Nanjing Medical University and The First Affiliated Hospital of Anhui Medical University are ranked 4th and 3rd in RIIRC, respectively, while they rank 9th and 13th in the Fudan University Hospital Rankings, respectively. Both of these ART centers have been established for a long time, have a high level of medical care, and a strong sense of subjective development. With the continuous increase of internet exposure opportunities, the number of patients will definitely increase, which will also improve the clinical technique and medical quality of ART centers. We have reason to believe that the aforementioned ART centers will continue to be important players and the front runners in the ART market in the region by focusing on academic development and online exposure.

We also found another interesting phenomenon, which is that some hospitals are at the top of Fudan University Hospital rankings but in the middle and lower range of the RIIRC. These ART centers are at the forefront in terms of clinical technique and scientific research, but their WeChat official accounts are not well operated, and the number of views is lower. For some public hospitals, though there are still many patients who can help them maintain their market position in the region, the long-term adoption of this approach will lead to the loss of patients, which will lead to their annexation by other public medical institutions or private hospitals

Although the NHCPRC has approved 498 ART centers, the existing medical institutions are far from meeting the needs of the market, and private hospitals and private capital have targeted this market.

Listed company Jinxin Fertility and internet medical platform WeDoctor conducted ART technology services to provide patients with high-quality and personalized treatment programs; its Chengdu Xinan Gynecology Hospital and Kunming IVF Hospital are among the top 10 in China. These private hospitals joined the top 10 in a short period of time; one important reason is that they pay attention to network publicity. Once they have more technology, talent, and capital, they are likely to become leaders in the field of ART, and even surpass the top public medical institutions in the region, because the general public does not know much about the academic standing.

Summary and Limitation

In addition, this study found that in the media era, WeChat can provide hospitals with a convenient and low-cost opportunity to attract customers, as well as provide an easy and efficient way to promote their brand and market. Generally speaking, the following three problems exist.

First, the earliest ART centers using WeChat official accounts were newly established hospitals, rather than older ones, probably because the new hospitals were more open to new technologies. Medical institutions with a long history prefer to focus on patient safety, such as reducing medical malpractice, rather than increasing opportunities to communicate with patients.

Second, in the information age, users have more opportunities to obtain various types of information and less patience for reading. For the WeChat account of an ART center, it is necessary to grasp the frequency, time and user needs of the post, and cultivate the user's website "stickiness" and reading habits through a fixed post mode.

Third, opening and verifying an official account of an ART center on the WeChat app is only the first step for a medical institution to take action. In fact, some hospitals stop updating their accounts after only a few tweets. Although some scholars have proposed detailed guidelines for the use of social media in medical institutions and answering patients' difficult questions, most ART centers do not follow these recommendations [34,35].

The sample size of the ART centers included in this study's sample was limited by two factors. First, although the NHCPRC had approved 498 ART centers by July 4, 2019, 47 new medical institutions were not included in the study because they only had a short history. Other centers had to be excluded because they had incomplete data. Future research should include more ART centers and compare their use of WeChat official accounts and changes over time. Second, all the information used in this study was based on public data, and the cycle number of each ART center has not been reported. The reason for this is that the reporting system of the Chinese Society of reproductive medicine is for internal use only. In addition, the WeChat official accounts of some ART centers were registered in the names of individuals rather than the hospitals or departments, so these official accounts did not fall within the scope of this study.

Although this study has some limitations, we analyzed and compared the operation of WeChat official accounts for ART centers and considered the combined academic influence, which offers guidance for promoting patients' access to these hospitals by strengthening their public image and exposure and a reference point for patients to choose suitable ART medical services. It also analyzed the market situation and future competitive advantage of domestic ART centers and indicated ways in which potential investment institutions can enter the field.

Abstract

Background: Conventional approaches to improve the quality of clinical patient imaging studies focus predominantly on updating or replacing imaging equipment; however, it is often not considered that patients can also highly influence the diagnostic quality of clinical imaging studies. Patient-specific artifacts can limit the diagnostic image quality, especially when patients are uncomfortable, anxious, or agitated. Imaging facility or environmental conditions can also influence the patient's comfort and willingness to participate in diagnostic imaging studies, especially when performed in visually unesthetic, anxiety-inducing, and technology-intensive imaging centers. When given the opportunity to change a single aspect of the environmental or imaging facility experience, patients feel much more in control of the otherwise unfamiliar and uncomfortable setting. Incorporating commercial, easily adaptable, ambient lighting products within clinical imaging environments allows patients to individually customize their environment for a more personalized and comfortable experience.

Objective: The aim of this pilot study was to use a customizable colored light-emitting diode (LED) lighting system within a clinical imaging environment and demonstrate the feasibility and initial findings of enabling healthy subjects to customize the ambient lighting and color. Improving the patient experience within clinical imaging environments with patient-preferred ambient lighting and color may improve overall patient comfort, compliance, and participation in the imaging study and indirectly contribute to improving diagnostic image quality.

Methods: We installed consumer-based internet protocol addressable LED lights using the ZigBee standard in different imaging rooms within a clinical imaging environment. We recruited healthy volunteers (n=35) to generate pilot data in order to develop a subsequent clinical trial. The visual perception assessment procedure utilized questionnaires with preprogrammed light/color settings and further assessed how subjects preferred ambient light and color within a clinical imaging setting.

Results: Technical implementation using programmable LED lights was performed without any hardware or electrical modifications to the existing clinical imaging environment. Subject testing revealed substantial variabilities in color perception; however, clear trends in subject color preference were noted. In terms of the color hue of the imaging environment, 43% (15/35) found blue and 31% (11/35) found yellow to be the most relaxing. Conversely, 69% (24/35) found red, 17% (6/35) found yellow, and 11% (4/35) found green to be the least relaxing.

Conclusions: With the majority of subjects indicating that colored lighting within a clinical imaging environment would contribute to an improved patient experience, we predict that enabling patients to customize environmental factors like lighting and color to individual preferences will improve patient comfort and patient satisfaction. Improved patient comfort in clinical imaging environments may also help to minimize patient-specific imaging artifacts that can otherwise limit diagnostic image quality.

ambient lighting; patient comfort; medical imaging; color perception; health care environment; internet protocol–based light-emitting diode lighting

Introduction

To improve the quality of clinical patient imaging studies, imaging environments predominantly consider updating the equipment, and they do not sufficiently appreciate that the quality of an imaging examination is highly influenced by the patient. When there is an unmet need to improve the overall quality of clinical imaging studies, hospitals and imaging centers predominantly focus on updating or replacing the imaging system hardware and rarely consider that patient-specific factors within the imaging environment can also influence overall quality.

When a patient is uncomfortable, anxious, or agitated, any patient motion during the image acquisition can contribute to artifacts that limit the diagnostic quality of the imaging study. This can result in inconclusive results and potentially the need to repeat the imaging study, readminister imaging pharmaceuticals, and re-expose patients to ionizing radiation (eg, radiography, computed tomography [CT], and positron-emission tomography [PET]/CT). Imaging facility or environmental conditions can greatly influence the patient's experience, comfort, and satisfaction with an imaging study.

By providing patients with the ability to choose aspects of their environmental experience, they feel much more in control of an unfamiliar and uncomfortable setting [1]. Researchers used an experimental audio-visual installation in a PET uptake room and reported reduced patient anxiety during the uptake phase prior to ^{18}Fluorine-fluorodeoxyglucose PET imaging [2]. Additionally, studies have reported the use of video goggles as a distraction approach in pediatric patients [3]. The distress experienced in a waiting room was studied, and it set the stage for a more comprehensive approach to address patient comfort and related psychological influences [4]. This study was initiated to enable an in-depth analysis of the perception of light and its psychological influences in order to help develop use case scenarios within imaging environments and provide pilot data for a future prospective clinical trial.

Empirical research indicates that color has a large influence on cognition, affect, and behavior of individuals [5]. Color stimuli consist of multiple dimensions including hue, lightness, and chroma. Hue is defined as the comparability to one of the perceived colors (red, yellow, green, and blue) and is often reported with a hue circle [5]. Lightness is comparable to brightness and is inherently the white to black quality of a color [5]. Chroma resembles saturation and is fundamentally considered the intensity or vividness of the color [6]. Since color is entirely dependent on both photoreceptors and neural processing, it is not a physical quantity, but rather a psychophysical one [7].

In a study associating color and mood, researchers confirmed that color schemes in interior design alone could impact an individual's mood [8]. Another study suggested that generally warm color schemes increase an individual's stimulation and muscle tension, whereas cool color schemes tend to relax and decrease tension [9,10]. However, creating one ideal ambiance applicable to all individuals within an environment may be impractical owing to differing individual characteristics and preferences, suggesting that those environments capable of individually modifying color schemes would be most effective [8].

One way to allow for this flexibility in an environment is to use commercial, easily adaptable, ambient lighting products so that patients can personalize their facility environment experience. With such lighting products available, we embarked upon this feasibility demonstration to explore how consumer products in an imaging environment could be used to achieve better patient comfort. The aim of this pilot study was to use a customizable white/colored light-emitting diode (LED) lighting system within a clinical imaging environment and demonstrate the technical feasibility and initial findings of enabling healthy subjects to individualize the ambient lighting and color.

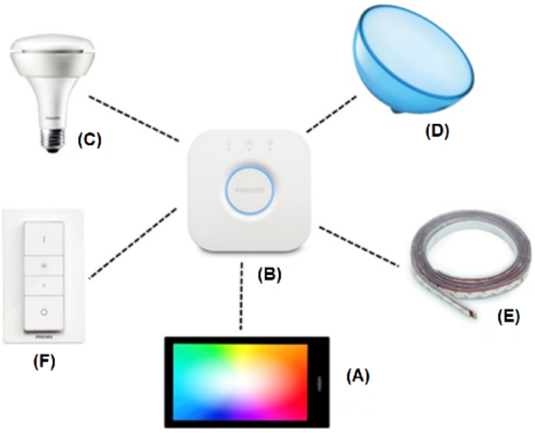
Methods

Internet Protocol Addressable Digital Light-Emitting Diode Lighting

Currently, there are different approaches within the consumer LED lighting market. We chose the ZigBee Alliance standard [11] that supports internet protocol (IP) addressable LED lights and interface devices from different manufacturers. Most of these devices provide dedicated software development tools to support broadly utilizable smart devices. Although various manufacturers have such products, we chose the Philips Hue Personal Wireless Lighting system (Signify, Eindhoven, Netherlands) [12]. This system supports uniquely addressable LED lights that can be remotely controlled and individually programmed to different settings of light hue, chroma, and lightness, making such lights fully interoperable and capable of individualized real-time setting adjustments in imaging environments.

With the lighting system hub in place, we installed BR30 bulbs (Figure 1) [13]. The wirelessly controllable bulbs can be installed in a specific room and then collectively grouped using the unique bulb serial numbers via the Hue smart device app (available on the Apple App Store and Google Play Store). It is also possible to operate multiple hubs on the same network, enabling a well-defined environmental layout with sufficient speed for real-time responsiveness.

Figure 1. A ZigBee internet protocol (IP)-based lighting system and setup with different styles of Philips Hue white and colored lighting bulbs. (A) A smart device via a Wi-Fi router has access to the hub allowing the Philips Hue app to control light settings in various rooms. The screen of the device shows a Hue circle. Figure adapted [13]. (B) The hub (or bridge) is IP connected and communicates with the lights using the ZigBee 2.4 GHz radiofrequency spectrum multihop mesh network to control light (on/off), intensity, and hue. All lights are powered from normal bulb outlets. Each light functions in the multihop setup in both receive and transmit mode. (C) Light-emitting diode (LED) ZigBee bulbs that can be placed in standard light fixtures. (D) Portable LED wireless Philips Hue Go light. (E) Philips Hue Lightstrips can also be added to enhance the room lighting and ambiance. (F) Philips Hue Dimmer Switch can be used to select from preprogramed light color settings. After the color scene is chosen, this device allows the user to both increase and decrease the dim.



Imaging Facilities

We implemented this IP addressable lighting system in three patient preparation rooms, one PET/CT scan room, and one PET/CT control room (Figure 2). Although specialized app designs can be readily achieved using the software development kit (SDK), we focused on the commercially available product app for ease of adoption by others. With the commercially available product app, different ambiences and scenes can be created by individually or collectively setting the hue, chroma, and lightness for each addressable light in the various rooms. In our experiments, each room was individually addressed, but all lights within each room were collectively setup so that each light in the room produced the same hue, chroma, and lightness within the room.

Figure 2. Different color settings in three rooms within an imaging environment. (A) Patient injection/preparation room; (B) scan room of the digital positron-emission tomography/computed tomography (PET/CT) system; and (C) PET/CT control room. In each of these rooms, different color settings are demonstrated as follows: standard bright white light, red light, green light, blue light, and yellow light.

Feasibility Trial Population

For this feasibility phase I trial (ClinicalTrials.gov NCT03456895), we enrolled 35 subjects to participate in the patient injection/preparation room experience only. These subjects did not participate in the PET/CT scan room or PET/CT control room experiences. Each subject was coded with a subject ID number and was evaluated inside a patient injection/preparation room while sitting in a standard patient injection chair with the room door closed. There were several steps.

First, a hardcopy questionnaire covering visual impairment, current mood, favorite color, least favorite color, lighting preferences, and preferred color schemes was completed.

Second, an investigator, who was sitting behind the subjects, set the room's lighting to a full intensity red, identified to the subject as color A. The subjects were exposed to the color A ambience for 30 seconds before being asked to complete another Likert-type scale questionnaire involving five (n=5) or seven (n=30) questions. Upon completion of the color A questionnaire, this procedure was repeated for green light (color B), blue light (color C), and yellow light (color D). The investigator did not name the color but instead used letters to allow the subjects to label the perceived color.

Third, after the four predefined ambient lighting exposures, the subjects completed another survey asking whether they felt that their ability to be productive is influenced by light, which color (A-D) made them feel most relaxed, and which color (A-D) made them feel most anxious.

Fourth, the subjects selected their preferential lighting scheme. The subjects were asked to create their most relaxing light ambience for the room while being able to individually set the hue, chroma, and lightness of the room lights using an app (iOS "Huemote") within a 3-minute timeframe. After the subjects selected their most relaxing light ambience settings, they completed a final questionnaire asking how calm, uncomfortable, and energetic they felt with the individualized relaxing light ambience. The investigator used the "Color Grab" app to identify the subjects' chosen color (specifically, the name of the color and its corresponding red, green, blue [RGB] color codes). The entire testing procedure for the subjects was on average 20 minutes.

For this phase I study, only descriptive statistics are reported. A 5-point Likert-type scale was used to assess subjects' perception with the general layout (1, *strongly disagree*; 2, *disagree*; 3, *neutral*; 4, *agree*; and 5, *strongly agree*). For the charts and overall categorization, we combined in this pilot population all scores of preference involving strong preference and kept the "neutral" answers separate.

Results

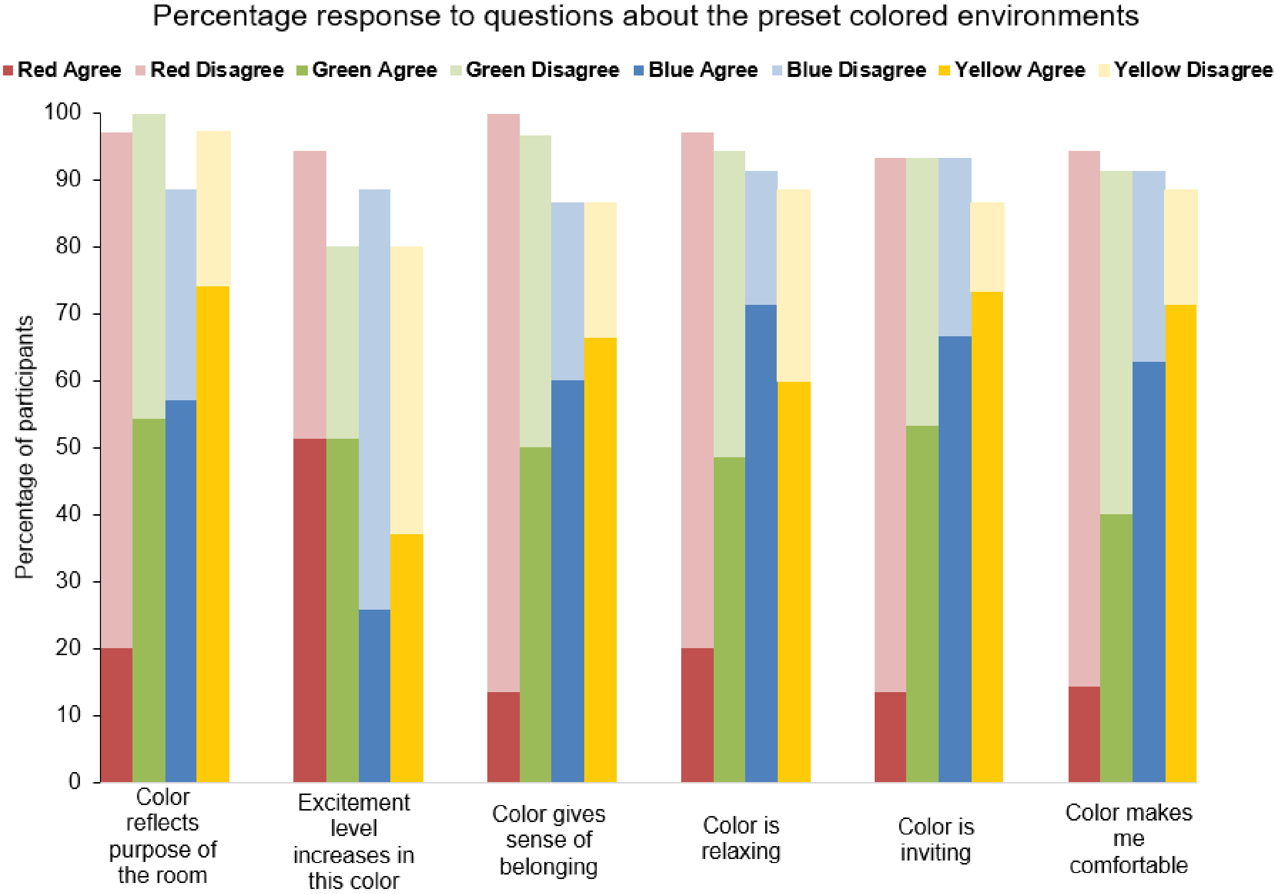
Characterization of the Subjects

Of the 35 subjects, 17 were male and 18 were female. The average age was 33 years (SD 14 years). Among the 35 subjects, 17 wore prescription glasses and seven used contact lenses. The initial questionnaire data revealed substantial variability in perceptions among subjects, with 71% (25/35) choosing natural light as their preferred lighting preference, followed by 17% (6/35) choosing a warm yellow, 6% (2/35) choosing bright white light, and 6% (2/35) choosing very dim light. It should be noted that bright white light is the most common lighting used in health care environments.

Red Lighting (Color A)

Red was the preferred color for 17% (6/35) of subjects and the least preferred for 3% (1/35). In a subset of 30 subjects, red was classified as a warm color by 80% (24/30) of subjects, but was also associated with an increased excitement level, with less favorable ratings for a sense of belonging, being relaxing, being inviting, and being comforting. Only 20% (7/35) of subjects agreed that red was ideal for the patient preparation room, whereas 77% (27/35) disagreed (Figure 3).

Figure 3. Perceptions related to each color. After experiencing each of the four preset colored environments (red, green, blue, and yellow), subjects completed questionnaires on perceptions related to each color. Bars represent the percentage response distributions for the Likert-type preference questions.



Green Lighting (Color B)

Green was the preferred color for 14% (5/35) of subjects and the least preferred for 6% (2/35). In a subset of 30 subjects, green was classified as a warm color by 13% of subjects (4/30), with an almost even split between those who perceived green as relaxing, inviting, comforting, and belonging and those who did not. More than half of the subjects (19/35, 54%) indicated that green was ideal for the patient preparation room (Figure 3).

Blue Lighting (Color C)

Blue was the preferred color for 46% (16/35) of subjects and the least preferred for 6% (2/35). The majority of subjects (22/35, 63%) indicated that blue decreased the excitement level, while increasing the sense of belonging (18/30, 60%), being relaxing (25/35, 71%), being inviting (20/30, 67%), and being comforting (22/35, 63%), despite blue being classified as a warm color by only 13% (4/30). More than half of the subjects (20/35, 57%) reported that blue was ideal for the patient preparation room (Figure 3).

Yellow Lighting (Color D)

Yellow was never the preferred color among subjects and was the least preferred for 20% (7/35) of subjects. In a subset of 30 subjects, yellow was classified as a warm color by 60% (18/30) of subjects and was associated with a decreased excitement level and other favorable ratings for a sense of belonging, being relaxing, being inviting, and being comforting. A high proportion (26/35, 74%) of subjects indicated that yellow was ideal for the patient preparation room (Figure 3).

Combined Color Lighting

The most relaxing color for the patient preparation room was blue in 43% (15/35) of subjects, followed by yellow in 31% (11/35), green in 14% (5/35), and red in 11% (4/35). The most anxiety-inducing color was red in 69% (24/35) of subjects, followed by yellow in 17% (6/35), green in 11% (4/35), and blue in 3% (1/35).

Preferred Lighting

When the subjects individualized their preferred lighting scheme for the patient preparation room and could manually adjust hue, chroma, and lightness, 43% (15/35) preferred blue lighting and 26% (9/35) preferred yellow lighting. The remaining 31% (11/35) of subjects selected a variety of other colors including orange (1/35, 3%), purple (2/35, 6%), red (4/35, 11%), pink (1/35, 3%), and white (3/35, 9%).

Hardware Costs

A large component of implementing this concept is the organizational setup, as the equipment cost is marginal. A starter kit including a hub and three LED IP addressable A19 bulbs costs approximately US $180/€164. An additional hub costs approximately US $60/€55. Extension bulbs, including BR30 bulbs used in this experiment, cost approximately US $50/€45 each. An additional dimmer switch costs approximately US $25/€23.

This feasibility study established the methodology and demonstrated the technical feasibility to test how individual subjects perceive different colored lighting. The technical implementation using consumer-based commercially available LED lights was realized without any hardware or electrical modifications to the existing imaging environment/facility. The installed IP programmable lights were readily controllable using smartphone or tablet-based apps.

Discussion

Principal Findings

This feasibility study demonstrated that a clinical imaging environment can be readily modified to enable an individualized lighting experience with adjustable color schemes using commercially available consumer-based products without specific facility or hardware changes and within manageable costs. The hardware and software used for this study can readily be replaced with alternative technology, making our findings vendor neutral. We have also pilot tested the replacement of hardcopy questionnaires with smartphone or tablet-based surveys that would be even more convenient and efficient for subjects as well as investigators. The subject assessment methodology used in this study can be easily implemented for other clinical applications within health care environments.

Our phase I data indicated that blue lighting was perceived as the most relaxing and was most preferred for the patient preparation room. In contrast, red lighting was perceived as the most anxiety inducing in the patient preparation room. No subject preferred the standard bright white lighting of health care environments, and only 9% (3/35) of subjects preferred a more neutral white lighting for patient preparation rooms when given the opportunity to individualize room lighting.

Available smart device apps can provide patients with individual control of the room’s lighting, allowing them to set their personal preference, which can thereby reduce the stress and anxiety of imaging environments.

Future Studies

Future clinical studies may further examine the impact of ambient light settings on patient experience, mood, perception, and resting physiology. Color psychology is an essential aspect that may explain the variability among subjects’ perception of different lighting schemes. Color has been proven to have a psychological and physical effect on humans, as explained by the Wright theory of color psychology (Table 1) [14]. It was shown that each hue influences particular psychological modes and can therefore affect the mood and behavior of the individual [15].

The psychological properties of the 11 basic colors are described in Table 2. When the human eye sees light, the different wavelengths lead to different perceptions of light. In the retina, these light waves are transformed into electrical impulses that are processed in the thalamus. According to Angela Wright, these psychological colors relate to body, mind, and emotion [16]. The properties further highlight that individuals perceive color differently. Therefore, to maximize comfort levels, lighting systems need to be versatile and readily adaptable to individual user preferences. Our study confirmed that this is achievable using existing consumer LED IP addressable lighting systems.

Given the small number of subjects in this feasibility trial, we are developing future larger clinical trials that will further assess individualized lighting preferences in clinical imaging environments (ie, patient injection/preparation room, PET/CT scan room, and PET/CT control room) and the impact on clinical patients and healthy subjects. Some aspects of future clinical trials will be the randomized assignment of clinical patients and healthy subjects to rooms with standard bright white lighting versus individualized white/colored lighting and the impact on existing institutional patient satisfaction survey scores, as well as net promoter scores. In addition, these trials in clinical patients will evaluate the rates of patient motion artifacts in PET and CT imaging datasets among PET/CT patients imaged under standard lighting versus individualized white/colored lighting in PET/CT scan rooms to address whether individualized ambient lighting reduces patient motion artifacts in diagnostic imaging studies.

Table 1. Seven principal tenants of the Wright theory of color psychology and color harmony [15].

Tenant	Description
1	Each hue affects distinct psychological modes.
2	The psychological effects of color are universal.
3	Every shade, tone, or tint can be classified into one of the four color groups.
4	Every color will harmonize with every other color in the same group.
5	All humanity can be classified into one of four personality types.
6	Each personality type has a natural affinity with one color group.
7	Response to color schemes is influenced by personality type.

Table 2. Current psychological interpretation and association of the 11 basic colors [16].

Color	Psychological aspect	Positive effects	Negative effects
Red	Physical	Physical courage, strength, warmth, energy, basic survival, "fight or flight" stimulation, masculinity, and excitement	Defiance, aggression, visual impact, and strain
Blue	Intellectual	Intelligence, communication, trust, efficiency, serenity, duty, logic, coolness, reflection, and calm	Coldness, aloofness, lack of emotion, and unfriendliness
Yellow	Emotional	Optimism, confidence, self-esteem, extraversion, emotional strength, friendliness, and creativity	Irrationality, fear, emotional fragility, depression, anxiety, and suicide
Green	Balance	Harmony, balance, refreshment, universal love, rest, restoration, reassurance, environmental awareness, equilibrium, and peace	Boredom, stagnation, blandness, and enervation
Violet	Spiritual	Spiritual awareness, containment, vision, luxury, authenticity, truth, and quality	Introversion, decadence, suppression, and inferiority
Orange	N/A[a]	Physical comfort, food, warmth, security, sensuality, passion, abundance, and fun	Deprivation, frustration, frivolity, and immaturity
Pink	N/A	Physical tranquility, nurture, warmth, femininity, love, sexuality, and survival of the species	Inhibition, emotional claustrophobia, emasculation, and physical weakness
Grey	N/A	Psychological neutrality	Lack of confidence, dampness, depression, hibernation, and lack of energy
Black	N/A	Sophistication, glamour, security, emotional safety, efficiency, and substance	Oppression, coldness, menace, and heaviness
White	N/A	Hygiene, sterility, clarity, purity, cleanness, simplicity, sophistication, and efficiency	Sterility, coldness, barriers, unfriendliness, and elitism
Brown	N/A	Seriousness, warmth, nature, earthiness, reliability, and support	Lack of humor, heaviness, and lack of sophistication

[a] N/A: not applicable.

Limitations

A limitation of this phase I trial is that it demonstrates feasibility and findings in healthy subjects with no known diseases in an imaging environment as opposed to patients undergoing imaging procedures for the evaluation of clinical signs or symptoms concerning underlying diseases. Specifically, the healthy subjects in this trial were only tested in the patient preparation rooms, which are used clinically for PET/CT patients, but were not tested in the PET/CT scan room or PET/CT control room. These PET/CT scan room and PET/CT control room evaluations in healthy subjects or clinical patients will be the focus of future studies.

Given that adaptable ambient lighting systems are being incorporated and integrated into many aspects of daily life, we are confident that this work will encourage other researchers to investigate the ambient lighting experience within health care environments in the future.

Comparison With Prior Work

To date, no prior studies have been reported on this topic and the potential utility within clinical imaging environments.

Conclusion

This feasibility study demonstrated that individualizing the ambient lighting experience within a clinical imaging environment can be achieved and implemented using commercially available, consumer-grade, IP addressable lighting products. We found variability among the subjects' perceptions of the various lighting schemes used in this trial, which suggests that an individualized approach to modify the ambient lighting of patient-specific rooms could create more comforting health care environments. This pilot trial found that most subjects (>90%) preferred colored ambient lighting as opposed to standard bright white lighting for patient-specific rooms within the clinical imaging environment.

Abstract

Background: Web-based outpatient portals help patients engage in the management of their health by allowing them to access their medical information, schedule appointments, track their medications, and communicate with their physicians and care team members. Initial studies have shown that portal adoption positively affects health outcomes; however, early studies typically relied on survey data. Using data from health portal applications, we conducted systematic assessments of patients' use of an outpatient portal to examine how patients engage with the tool.

Objective: This study aimed to document the functionality of an outpatient portal in the context of outpatient care by mining portal usage data and to provide insights into how patients use this tool.

Methods: Using audit log files from the outpatient portal associated with the electronic health record system implemented at a large multihospital academic medical center, we investigated the behavioral traces of a study population of 2607 patients who used the portal between July 2015 and February 2019. Patient portal use was defined as having an active account and having accessed any portal function more than once during the study time frame.

Results: Through our analysis of audit log file data of the number and type of user interactions, we developed a taxonomy of functions and actions and computed analytic metrics, including frequency and comprehensiveness of use. We additionally documented the computational steps required to diagnose artifactual data and arrive at valid usage metrics. Of the 2607 patients in our sample, 2511 were active users of the patients portal where the median number of sessions was 94 (IQR 207). Function use was comprehensive at the patient level, while each session was instead limited to the use of one specific function. Only 17.45% (78,787/451,762) of the sessions were linked to activities involving more than one portal function.

Conclusions: In discussing the full methodological choices made in our analysis, we hope to promote the replicability of our study at other institutions and contribute to the establishment of best practices that can facilitate the adoption of behavioral metrics that enable the measurement of patient engagement based on the outpatient portal use.

patient portals; health records, personal; health information technology; electronic health record

Introduction

Background

Patient portals are Web-based platforms administered by health care service providers that enable patients to access data held in their personal health record. Meaningful Use (MU), the US federal program that sought the promulgation of electronic health records (EHRs), and its associated incentives resulted in the widespread adoption of patient portals [1].

A notable component of MU required health care organizations to focus on improving patient engagement, specifically through the use of patient portals. This requirement came with the challenge of providing access to vulnerable members of the population (eg, ethnic and racial minorities, persons with disabilities, and those with lower health literacy skills), who are part of groups with higher medical needs in addition to facing technology access issues [2-4]. At the same time research has shown that investments in Web-based portals by health care organizations are increasing in order to meet demands from the general population, as patients want to use these tools at rates faster than they are made available [5]. As a result, many organizations now use outpatient portals that allow patients to access and view their prescriptions and medical information, schedule appointments, and communicate with their doctors [6].

Much of the research assessing the benefits of patient portals has focused on outpatient portals [7]. Studies have shown, for example, that outpatient portal users experience improvements in areas such as reducing risk factors for chronic diseases [8-12] and improving health outcomes [13,14]. However, what characterizes these prior studies is the generalized use of survey data for analysis as opposed to considering direct measures of online actions as a measure of engagement.

One approach to measuring engagement is based on the mining of EHR metadata. Modern EHR systems log every action taken by individuals signed into their systems. These actions create transactional traces on the EHR server in the form of log files, which can be leveraged as the foundation for analysis. Recent studies have made use of log file analysis as a means of assessing and understanding how and why patients engage in their care [7,15,16].

However, barriers remain to using this approach, including difficulty in tracking and accessing the data, the need to process a large volume of information, and the challenge of establishing use metrics. To lower such barriers to adopting this methodology, we add to the existing literature by documenting and describing the data wrangling process and its implications to enable future researchers to apply and validate our approach. To that end, together with our analysis, we publish the Stata code (StataCorp, 2017. Stata Statistical Software: Release 15, StataCorp LLC) required to replicate our analysis to contribute to the creation of shared data models that could enable the quantification of patient portal use behavior across portal types.

Objectives

This methods-focused paper consequently addresses two aims. First, the study aimed to significantly expand the knowledge base of the methodological choices and challenges faced when processing log files. We provide documentation of our approach to process log files using data from our academic health system at the Ohio State University Wexner Medical Center (OSUWMC). This health system offers its patients electronic access to their health care information through the MyChart outpatient portal (Epic Systems Corporation) and has been in use since 2011. We intend to promote a standardized approach to this type of research by including our statistical program files as Multimedia Appendices 1-8 that can be used to analyze log files from Epic Systems. We do so by providing guidance to ensure that future studies adhere to the highest quality of data analysis when using audit log files of outpatient portal use. This approach is similar to the approach undertaken by Huerta et al [17], where a data model and procedure for processing log files from an inpatient portal were provided. However, given the differences between the outpatient portal and the inpatient portal log files, these data are idiosyncratic, affecting how they can be parsed; we note many of these differences in our Discussion section. We address this first study aim below in our Methods section.

The second aim of our study was to provide prescriptive data about outpatient portal usage to demonstrate the implications of our methodological approach and the assumptions about the decisions we made. Our results provide a glimpse into the outpatient portal usage in the context of the care provided at our institution. MyChart portal features include messaging with providers, prescription renewals, appointment information and scheduling, clinical updates, and billing. This approach could be replicated at other institutions that also desire to quantify outpatient portal use for different purposes such as quality improvement (eg, investigate tool performance), increasing patient engagement (eg, identifying the types of users), or for research (eg, summative evaluations of tool uptake). We address this secondary study aim in our Results section, in which we use descriptive statistics to present the portal use data.

Methods

Data Model

This section describes the data model used to examine outpatient portal use. It also documents the data sources required to produce the final data model and lists the recommended computational steps to clean and process the information extracted from the audit log files. The log files audited belong to a sample of 2607 OSUWMC patients, whose patient portal metadata from July 2015 to February 2019 were mined for the purpose of developing the methods to enable the study of patient engagement with Web-based portals.

The analysis of outpatient portal use started with the categorization of all the individual actions performed on the portal by the patients. Actions were then aggregated across functions and over time to quantify user engagement with the technology. The resulting data model is represented in Table 1 and comprises four levels, with each subsequent level comprising the elements of the preceding level.

Table 1. Data model for outpatient portal use.

Data aggregation level	Definition
Action type	Single action performed by the user on the outpatient portal
Portal function	Category grouping user actions under the different functionalities offered through the outpatient portal
Session	Coherent, limited, and uninterrupted use of one or more of the outpatient portal functions via a sequence of user actions
Patient	Use of the outpatient portal, or one of its functions, across the entirety of a patient's recorded sessions

Outpatient portal usage metrics were defined along the following two dimensions:

- Frequency of use: number of times an outpatient portal function has been accessed by a patient
- Comprehensiveness of use: number of unique outpatient portal functions accessed by a patient

Both dimensions were studied at the session and the patient levels of our data model.

Data Sources

We audited the log files from MyChart's instance at our institution to assess portal use. Data from these files included the date and time of the specific actions patients made using the outpatient portal (eg, appointment scheduling and viewing test results).

To support reproducibility of results, we document in Table 2 the sources for the data pertaining to the users' MyChart actions and the status of their accounts by listing the exact variables and tables queried from Epic's Clarity database.

Outpatient portal logs are recorded by Epic in the form of time-stamped sequences of user actions, and an example of this log is reproduced in Table 3. This table contains a sample from the MYC_PT_USER_ACCSS Clarity table, with personal identifiable information redacted. The first three columns present identifiers for a patient's action, which include the medical record number (MRN), a time stamp, and a categorical variable indicating the type of action performed by the patient.

Table 2. Variables queried on the Epic's Clarity database tables, to retrieve data about the users' access to MyChart and their account status history, identified by their master table number by Epic System.

Variable name	Variable description	Master table number
Patient information[a]		
PAT_MRN_ID	Patient identifier	EPT 2061
Account status history log variables[b]		
MYC_STATUS_HX	Update to account status	EPT 28100
MYC_STATUS_TMSTP	Status update time stamp	EPT 28110
MYC_STATUS_MTHD	Technology implementing the update	EPT 28140
MYC_STATUS_CMT	Additional status update description	EPT 28130
User access log variables[c]		
UA_TIME	Action time stamp	WPR 520
MYC_UA_TYPE_C	Action type	WPR 530
UA_EXTENDED_INFO	Additional action type information	WPR 550
UA_SESSION_NUM	Unique session identifier	WPR 561
UA_USER_AGENT	Client user agent information	WPR 566

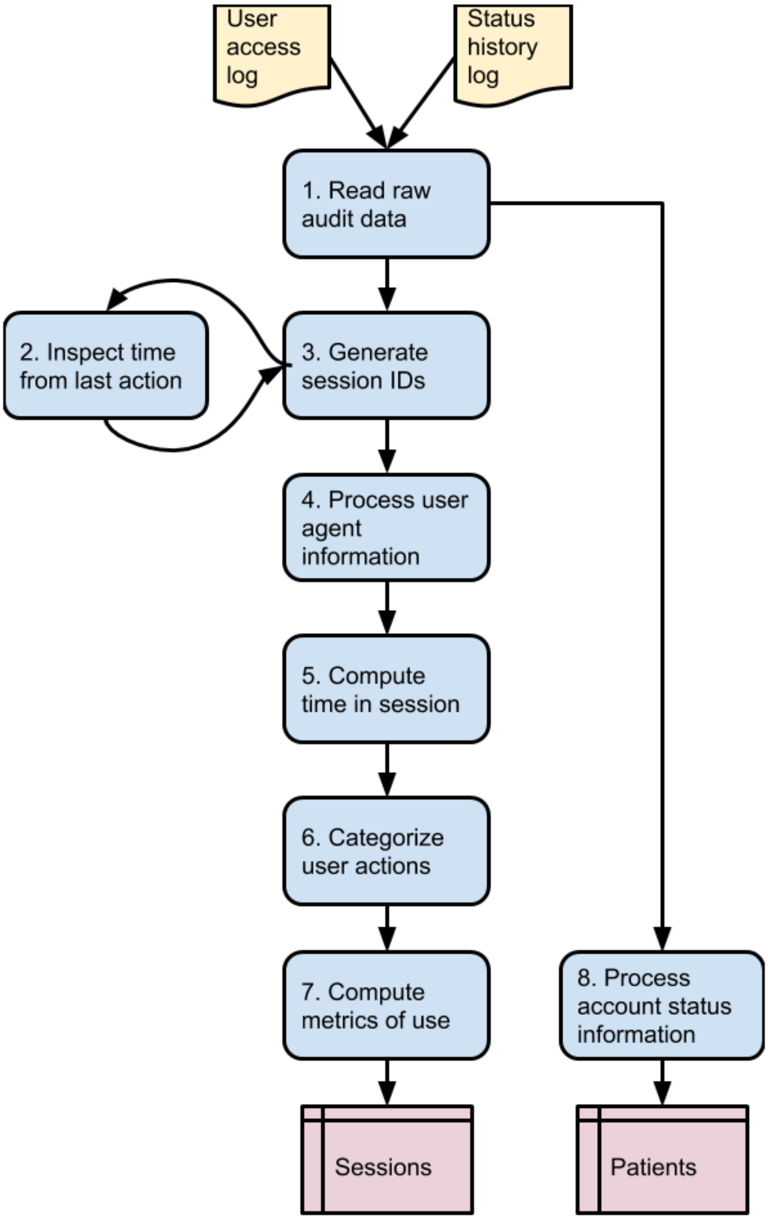
For every recorded user action, Epic's MyChart also reports metadata that can be used to reconstruct the patient's online behavior (ie, what was their activity and how long did it take them to accomplish that action). The variables *UA_EXTENDED_INFO* and *UA_USER_AGENT*, for example, provide important details for the categorization of user actions, necessary for quantifying the use of the different functionalities offered by the outpatient portal. The session number variable *UA_SESSION_NUM*, is instead a unique marker assigned by the server to sequences of user actions that presents patterns of consistent and continuous use.

Data Processing

We next documented the steps taken to process the audit log file data. The result of this data processing is a dataset where each row represents a session and contains information about the time it started, its length, the device type used, and a set of frequency counts for all the activities available to the patient via the outpatient portal.

The steps for processing the raw data were broken down into modules, and these modules are presented in Figure 1 as a flowchart. The assumptions and specific goals of each module are described next. We have included the Stata programming code used to convert the raw data into the final data model as Multimedia Appendices 1-8.

Figure 1. Data processing flowchart.



Module 1: Read Raw Audit Data

In module 1, raw data are imported, and preliminary computations of secondary analytical variables are completed (see Multimedia Appendix 1). In addition to standardizing variables that contain free text or time values, this step generates a categorical variable based on the list of user actions contained in the user access log. This process both establishes MYC_UA_TYPE_C as a sorting variable and controls the ordering of concurrent user actions. For example, when multiple actions are recorded as cooccurrent, log-in attempts are listed first so as to establish a logical order of events.

Module 2: Inspect Time From Last Action

Module 2 quantifies and analyzes the time difference between user actions (see Multimedia Appendix 2). The intent of this step is to control and limit the time gap that identifies a coherent session.

MyChart assigns a *session number* (variable UA_SESSION_NUM) to user actions that signify continuous engagement with the outpatient portal functions; however, this variable can be unreliable. This step enables resolution of issues encountered when working with data from MyChart's Clarity tables. The following are examples of these issues:

- Tracking of the variable might be unavailable: Institutions might deploy a patient portal but postpone tracking of the session number variable. This can result in old audit logs—even for the same patient—that have no server-assigned session information. This is true at our institution for all MyChart data older than May 15, 2016.
- The variable might be tracked intermittently: A session number might fail to be assigned to a subset of user activities, although being recorded correctly for the other activities in the enclosing sequence.
- The variable might be recorded correctly but might indicate implausible sequences of user activities: In some instances, the raw server data can indicate sessions spanning multiple

days (see example in Table 3 above); this is deemed inconsistent with normal user behavior and can be resolved by enforcing a limit to the time gap between consecutive user actions.

Quantifying the time gap between consecutive actions is important as it allows the identification of implausibly long sessions and helps to correct issues with data reliability. This process occurs by calculating a parameter to limit the time gap between user actions, and it has the effect of splitting unusually long sequences into shorter ones, ensuring that the time spans recorded by the audit data measure the actual user engagement with the outpatient portal.

The exact value of the parameter marking the maximum period of inactive time allowed is determined by generating a new variable, *time gap*, which stores the number of seconds separating a user action from the preceding one in the same session and analyzing its density estimation. As shown in Figure 2, this variable appears to have a wide range, with the majority of values at the lower interval, and a long right tail that is approximately log-normal, except for the spike at approximately 20 min. Upon closer inspection, this spike is explained by the time gaps associated with user actions that are recognized as *log-outs* by the MYC_UA_TYPE_C variable. The dotted line reflects the density distribution after this artifact in the data is removed.

Figure 3 shows that establishing a time limit of 1256 seconds (approximately 20 min) allowed us to preserve 99.80% (3,248,044/3,254,561) of the data (excluding the *log-outs*) in their original form.

Figure 2. Density distribution of the time gaps between user actions.

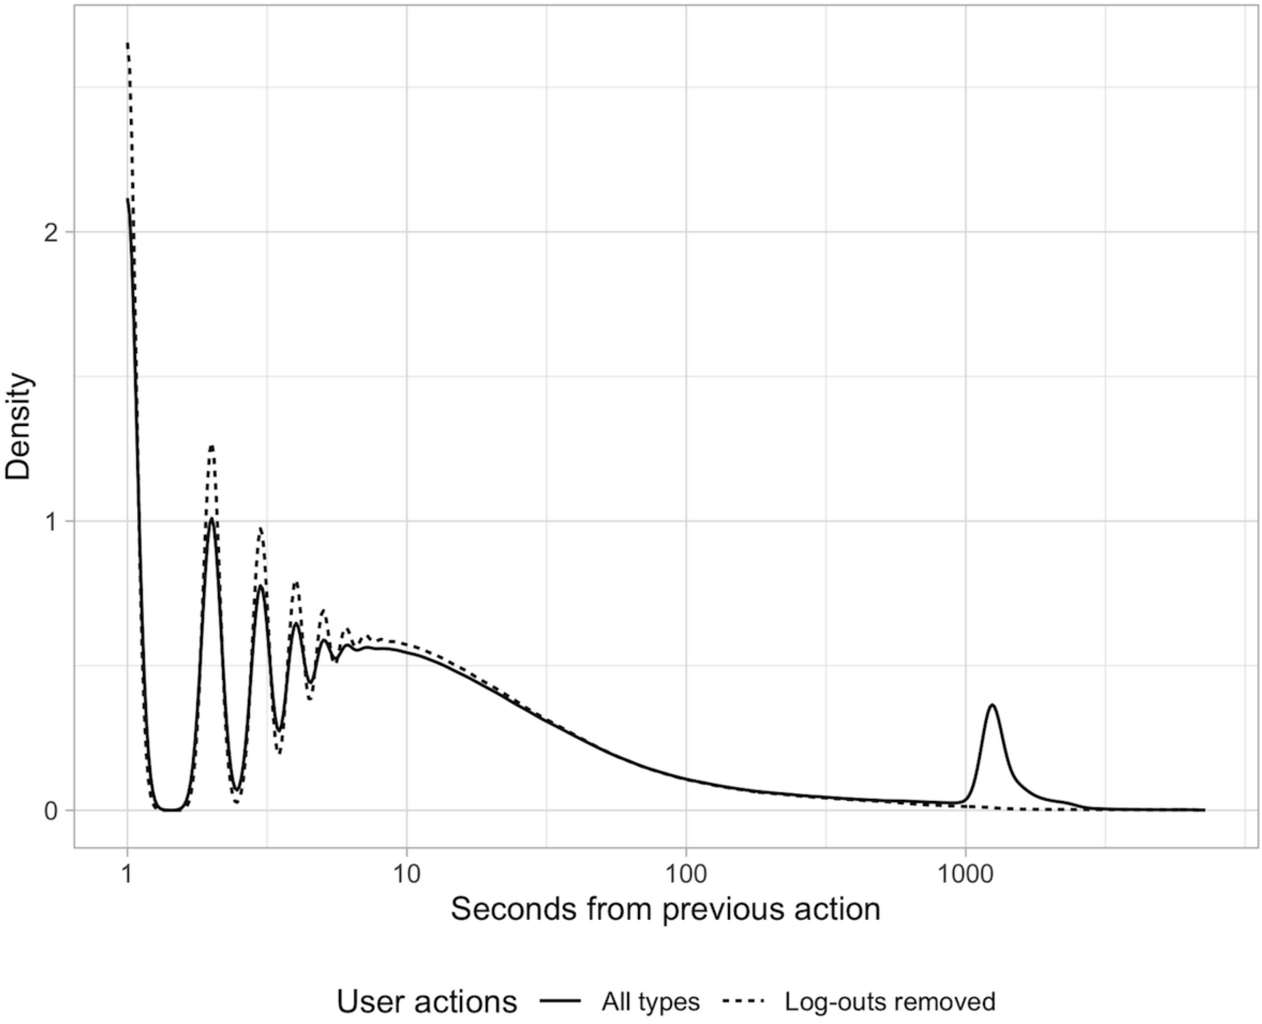


Figure 3. Possible thresholds for inactive time in session. Log-outs action type is removed from the dataset.

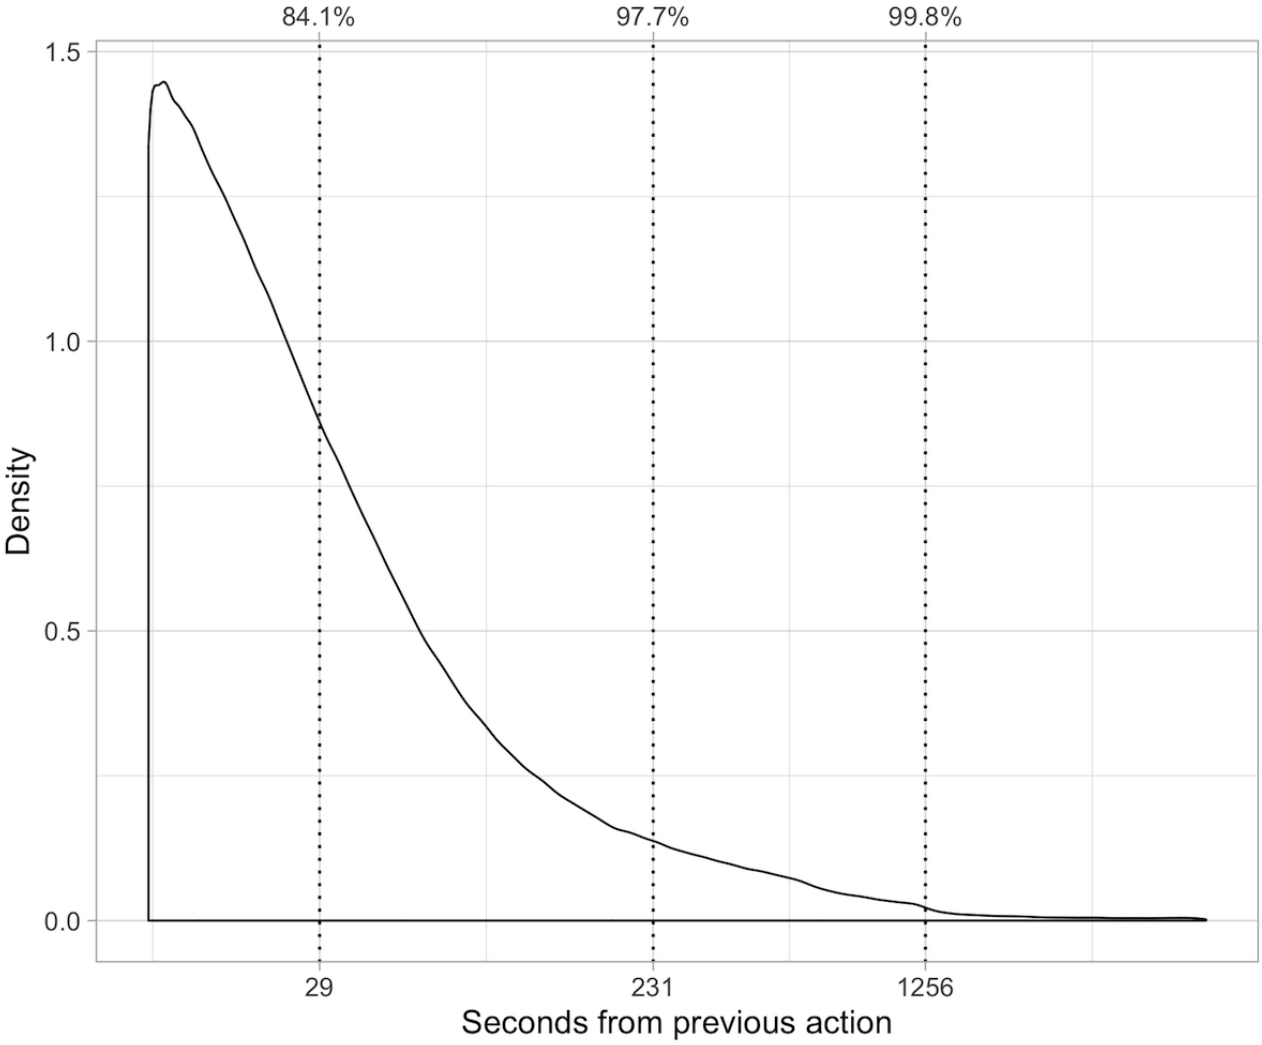

Module 3: Generate Session IDs

Module 3 (see Multimedia Appendix 3) creates a session ID that groups together patient activities separated by either a patient's manual log-out or his or her failure to engage with the outpatient portal for what is deemed a significant period of time (defined in module 2). This step supersedes the system-generated UA_SESSION_NUM and groups user activities into sequences of consistent continuous use. By identifying the start and end points of the user sessions, which in most cases would match the user actions marked as *log-in*—for the start point—and as *log-out*—for the end point, an identification label is generated for every user log-in. This label is then extended to all subsequent user-recorded actions, usually up to a recorded log-out. In the event of unusual cases (ie, missing end point, start point, or both), a limit to the time gap between two consecutive user actions is enforced (calculated at approximately 20 min, as described above for module 2). Consequently, all sequences of user actions that are recorded after an inactive time greater than the calculated threshold are regrouped, and a newly created session identification label is generated.

Module 4: Process User Agent Information

User agent information is used in this module to infer the type of device the patient uses to access the outpatient portal (see Mutimedia Appendix 4). Metadata associated with the log-in attempts in the UA_USER_AGENT and UA_EXTENDED_INFO variables can consistently indicate whether access is originating from a desktop or mobile platform. As part of this step, the device type information is stored in a newly created variable, *se_device*, that marks all the actions belonging to the same session.

Module 5: Compute Time in Session

Module 5 calculates the time taken in seconds for each sequence of actions marked with the same session ID (see Multimedia Appendix 5). The algorithm excludes all the *log-outs* from the computation to return an effective time in session. As shown in Figure 3, log-outs consistently overestimate the time a patient remains engaged with the outpatient portal; therefore, we filter out log-outs to avoid artifactual results (see Results section).

Module 6: Categorize User Actions

This module classifies user actions under the categories of the outpatient portal's functions (see Multimedia Appendix 6). The list of labels used to classify user action types, together with their associated grouping functions, are reported in Table 4. This list has been compiled after extensive testing involving the following:

- Controlled interaction with the functionalities of the outpatient portal in a test environment using quality assurance automation tools to verify the traces left by user actions on the server side: As a single user action can be instantiated via multiple system calls—some essential and others ancillary to many other calls, with each one independently leaving traces of its own activation in the audit log—there is no one-to-one correspondence between the user behavior on the client side and the logged portal functions on the server side. We, therefore, undertook a systematic and exhaustive exploration of the functionalities made available to patients via MyChart in a test environment. This test environment mirrored the production portal and included the availability of Clarity tables and automation tools such as Selenium [18], a tool common in quality assurance testing that allows for the reproducibility of workflows and fine-grained control over the timing of actions. This test environment allowed us to generate reproducible patterns in the log data and required the extraction of the signals associated with specific user activities.
- Investigation of more complex cases with information technology (IT) specialists at OSUWMC: In cases where the sole user behavior was not enough to produce unambiguous logs, the help of an IT specialist was enlisted to produce the intended response from the server or to observe in real time if and when fields in the Clarity tables were populated, as a means to verify that the correct data were being collected.
- Clarification of the implementation details with technical support from Epic: In rare cases, information related to implementation details and other clarifications were obtained directly from Epic through their technical support services.

The labels of the action types and portal functions offer a 2-level taxonomy for the categorization of user actions that employ terms from the MyChart user interface. At the higher level, the portal functions are named as follows:

- Messaging: Contains links to the message center, letters to the patient, and an option to request prescription refills
- Visits: List of past and upcoming visits and the ability to schedule and cancel appointments
- My record: List of medications, allergies, medical history and immunization status, health summary and test results, preventive care, and a summary table of the plan of care
- Medical tools: Sharing medical records with others or with other services (Lucy and MyChart Central), participate in research studies, and connect tracking devices (eg, Fitbit)
- Billing: Bills, insurance information, and estimates for common procedures
- Resources: Frequently asked questions, terms and conditions, and patient education
- Proxy: Request proxy status or renew proxy requests
- Preferences: Personal settings, security settings, and notification preferences

Auxiliary action types, such as log-ins, log-outs, and 2-factor authentication, were flagged with a *Miscellaneous* label, but were otherwise excluded from the calculation of portal use metrics. Frequency counts associated with the *Resources* portal function are absent because this set of action types contains links to patient educational information that are all pointers to resources hosted outside MyChart; interaction with these elements, if present, is not captured before the patients navigate away from MyChart.

Table 4. Labels for action types and portal functions used to categorize raw audit log data from Epic's MyChart. For each label, we report the count of sessions in which the action was performed and the percentage represented by the session count over the total number of sessions (N=451,762).

Action type	Portal function	Sessions, n (%)
Letters	Messaging	5318 (1.18)
Message center	Messaging	146,394 (32.41)
Send new message	Messaging	45,391 (10.05)

[a] eCheck-in: Electronic check-in.

[b] EMR: electronic medical record.

Module 7: Compute Metrics of Use

The goal of this module is to calculate count values for the portal usage metrics and merge them with the other session-level variables (see Multimedia Appendix 7). The output at the end of this step is a dataset ready for data analysis, organized at the session level. For each constructed session, information about the device used and the time spent in sessions are reported along with frequency counters for the MyChart activities of the taxonomy developed during the previous step. In addition, a reference to the MRN enables the computation of statistics at the patient level as well as the merging of demographic information, when it is available.

Before computing usage metrics, the module filters out redundant records of the same user action from the log file data. Owing to the implementation details affecting users accessing MyChart from a mobile platform, the audit reports can contain many duplicate rows as the same user action can be logged at intervals of 2 seconds until the patient navigates away from the page that is triggering the behavior. Although this does not affect the time in session, it results in inflated action counts for patients accessing the outpatient portal via a mobile phone.

The first part of the code for module 7 controls for the presence of a series of identical user actions, with matching values in both the MYC_UA_TYPE_C and UA_EXTENDED_INFO variables, and deletes all but the first occurrence in each series.

Module 8: Process Account Status Information

The account status information is processed in this module to create a dataset organized at the patient level (see Multimedia Appendix 8). The module accepts as input the list of status changes recorded for each patient's account and processes it to determine the time the patient's account was activated and the current account status. The status of a MyChart account can vary over time, marking, among other things, the sign-up phase (status: *pending activation*), a phase of regular use (status: *active*), and potentially the termination of online use (status: *inactivated*). The resulting dataset, with one row per patient, is suitable to be merged with demographic data to support more detailed analysis of the outpatient portal use.

Results

Session Counts and Activation Status

Using this protocol, we applied the processing steps outlined above to the log files of MyChart activity for the patients in our sample. The following sections present and summarize the results of our analysis of metrics pertaining to the frequency and comprehensiveness of outpatient portal use.

All descriptive statistics were calculated using data from sessions with nonzero duration and from patients who had at least two valid sessions on record. As a result, we discarded all the log-in attempts that did not result in actual user navigation of the outpatient portal; we further refined the dataset to exclude patients who never engaged with MyChart beyond the time required to register an account.

Overall, the dataset contained 451,762 valid sessions (total number of sessions=482,443) for 2511 active patients (total number of patients=2607). On average, each patient had 180 sessions on record; the median number of sessions per patient was 94 sessions, with an IQR of 207 and a maximum recorded count of 6012 (Figure 4).

MyChart account status of the patients included in the final dataset is reported in Table 5, together with the account status of the general hospital population. Not all patient accounts were flagged as *activated*. The majority of *inactivated* accounts were accounts that had been previously active but had been closed because of the death of their owner (*patient deceased*, n=125). The remaining cases represented individuals who never formally concluded the sign-up process or inadvertently invalidated their status after activating their account, but nonetheless engaged with the outpatient portal; as a result, their audit data had been consistently recorded.

The distribution of patients with activated MyChart accounts across age groups (Table 6), although inversely related to the ages of patients, shows that activated accounts remain the largest category across our sample population.

Figure 4. Distribution of session counts per patient.

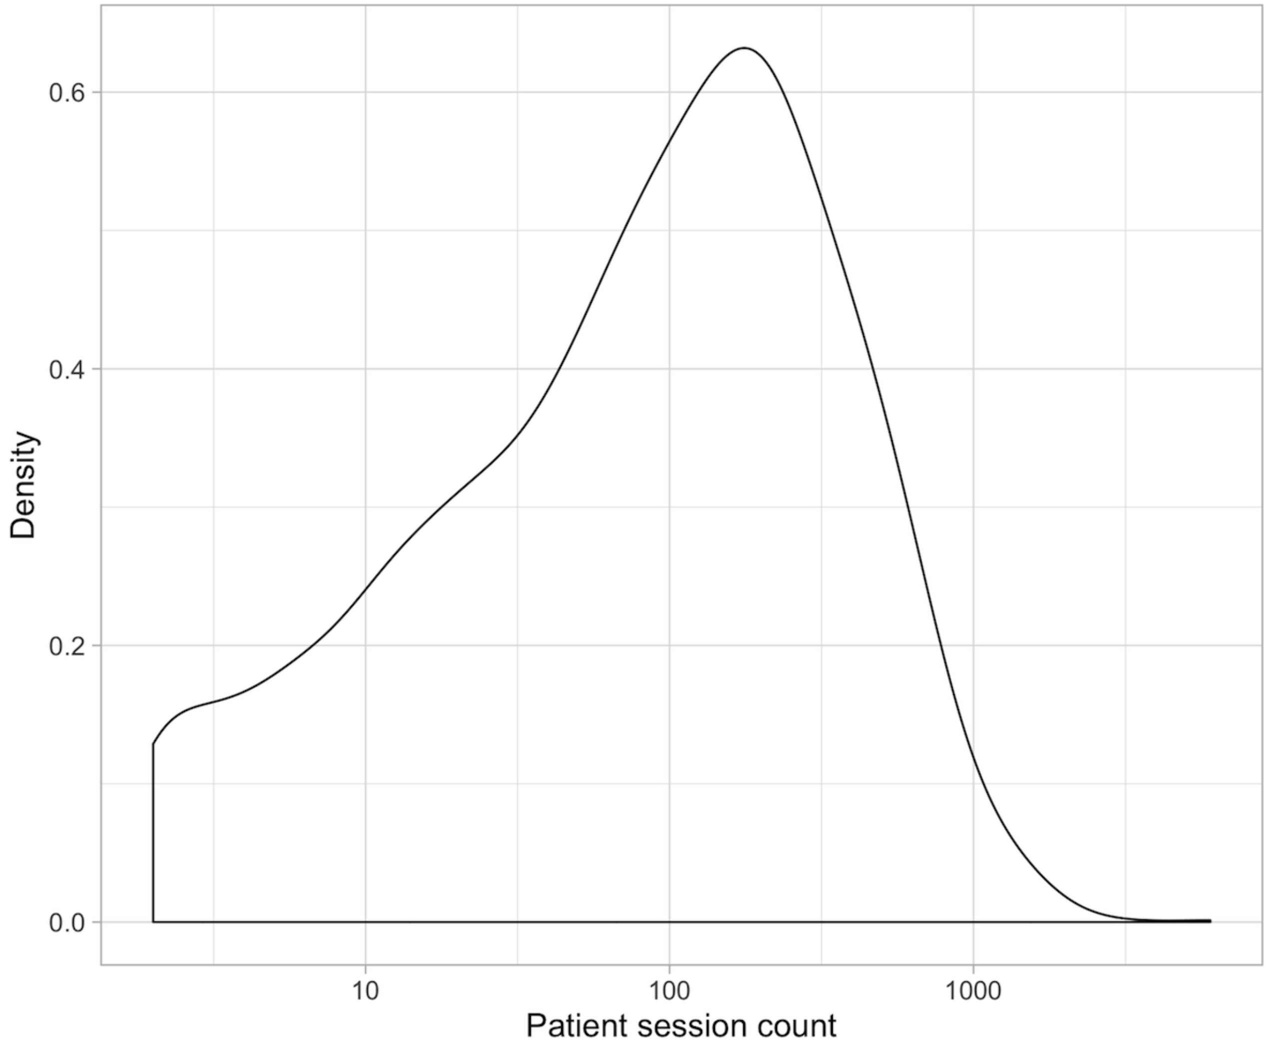

Table 5. Patients' MyChart account status for sampled and overall hospital population.

Account status	Sample population (N=2511), n (%)	Hospital population (N=70,076), n (%)
Activated	2360 (93.99)	39,373 (56.18)
Inactivated	134 (5.34)	12,678 (18.09)
Patient declined	4 (0.16)	6433 (9.18)
Pending activation	13 (0.52)	11,592 (16.54)

Table 6. MyChart account status as a function of patient age group.

Age group (years)	Account status (N=2511), n (%)				
	Activated	Inactivated	Patient declined	Pending activation	Total
18-29	357 (15.13)	7 (5.22)	0 (0.00)	4 (30.77)	368 (14.66)
30-39	468 (19.83)	14 (10.45)	0 (0.00)	2 (15.38)	484 (19.28)
40-49	456 (19.32)	21 (15.67)	1 (25.00)	0 (0.00)	478 (19.04)
50-59	500 (21.19)	36 (26.87)	1 (25.00)	1 (7.69)	538 (21.43)
60-69	429 (18.18)	38 (28.36)	1 (25.00)	3 (23.08)	471 (18.76)
70+	150 (6.36)	18 (13.43)	1 (25.00)	3 (23.08)	172 (6.85)

Frequency of Use

The results in Table 7 show descriptive statistics for the frequency counts associated with each MyChart portal function as defined by the taxonomy of user actions (see also Figures 5 and 6). Of note, at the session level, the median frequency count for the use of all MyChart functions is 0. Although in most cases the ranges are quite broad, the 0 medians suggest that the values are concentrated at lower intervals.

Table 7. Frequency of use at session and patient levels for each of the MyChart portal functions.

Portal function[a]	Session level (N=451,762)				Patient level (N=2511)			
	Minimum value	Median	Maximum value	IQR	Minimum value	Median	Maximum value	IQR
Messaging	0	0	84	1	0	51	2087	134
Visits	0	0	113	0	0	38	1670	108
My record	0	0	227	1	0	87	3503	171
Medical tools	0	0	12	0	0	1	223	3
Billing	0	0	81	0	0	10	659	31
Proxy	0	0	9	0	0	0	498	3
Preferences	0	0	15	0	0	3	228	7

[a] Frequency counts associated with the *Resources* function on the outpatient portal are absent because of technical reasons (see module 6 in the Methods section).

Figure 5. Frequency distribution of the use of the different portal functions across all the sessions in the dataset.

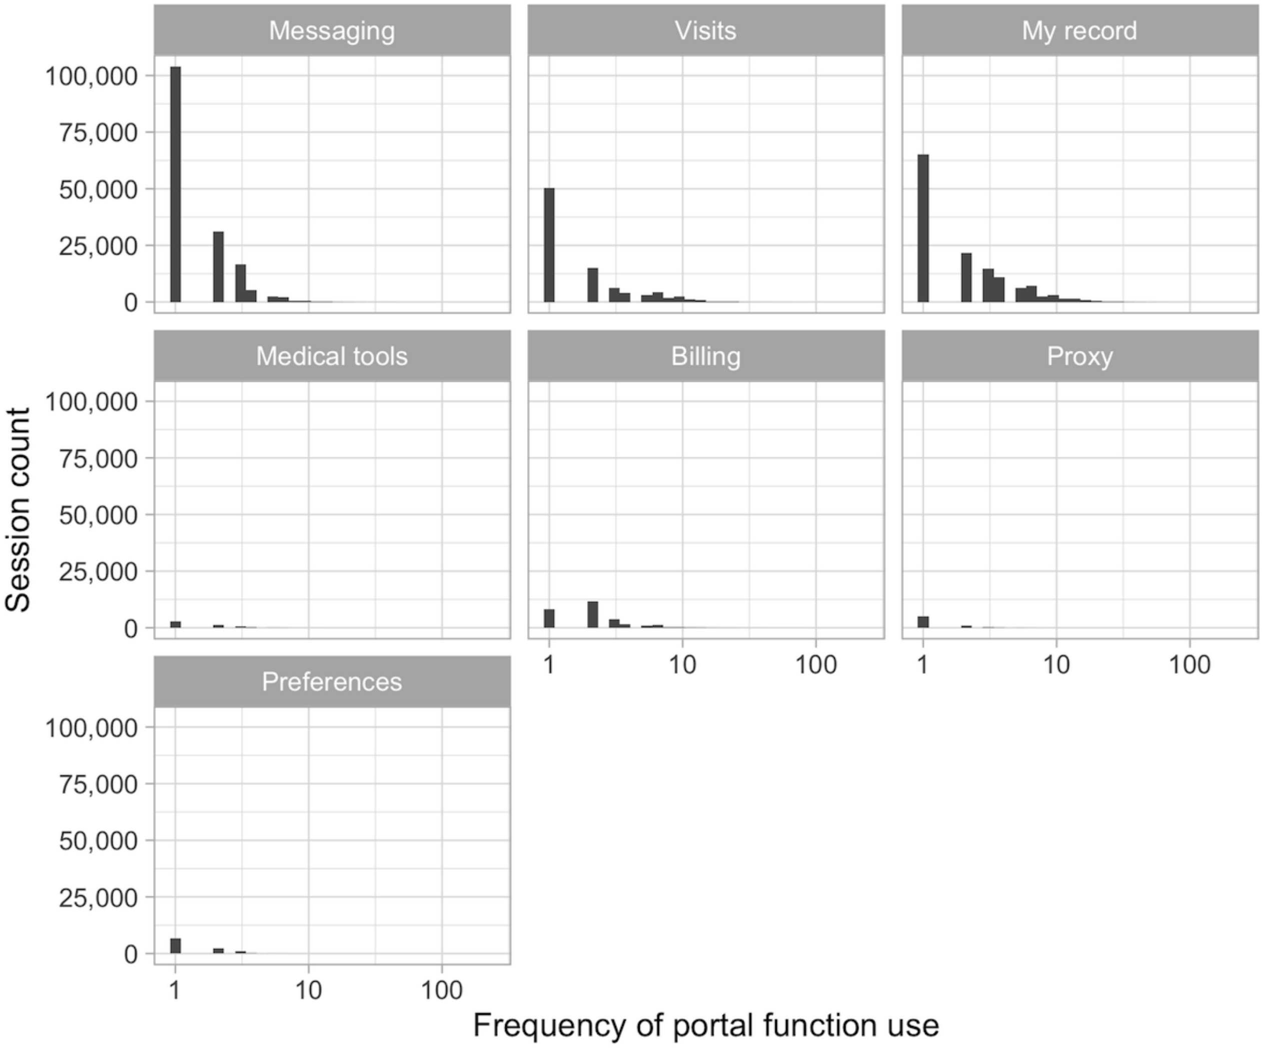

Figure 6. Frequency distribution of the use of the different portal functions across the patient population.

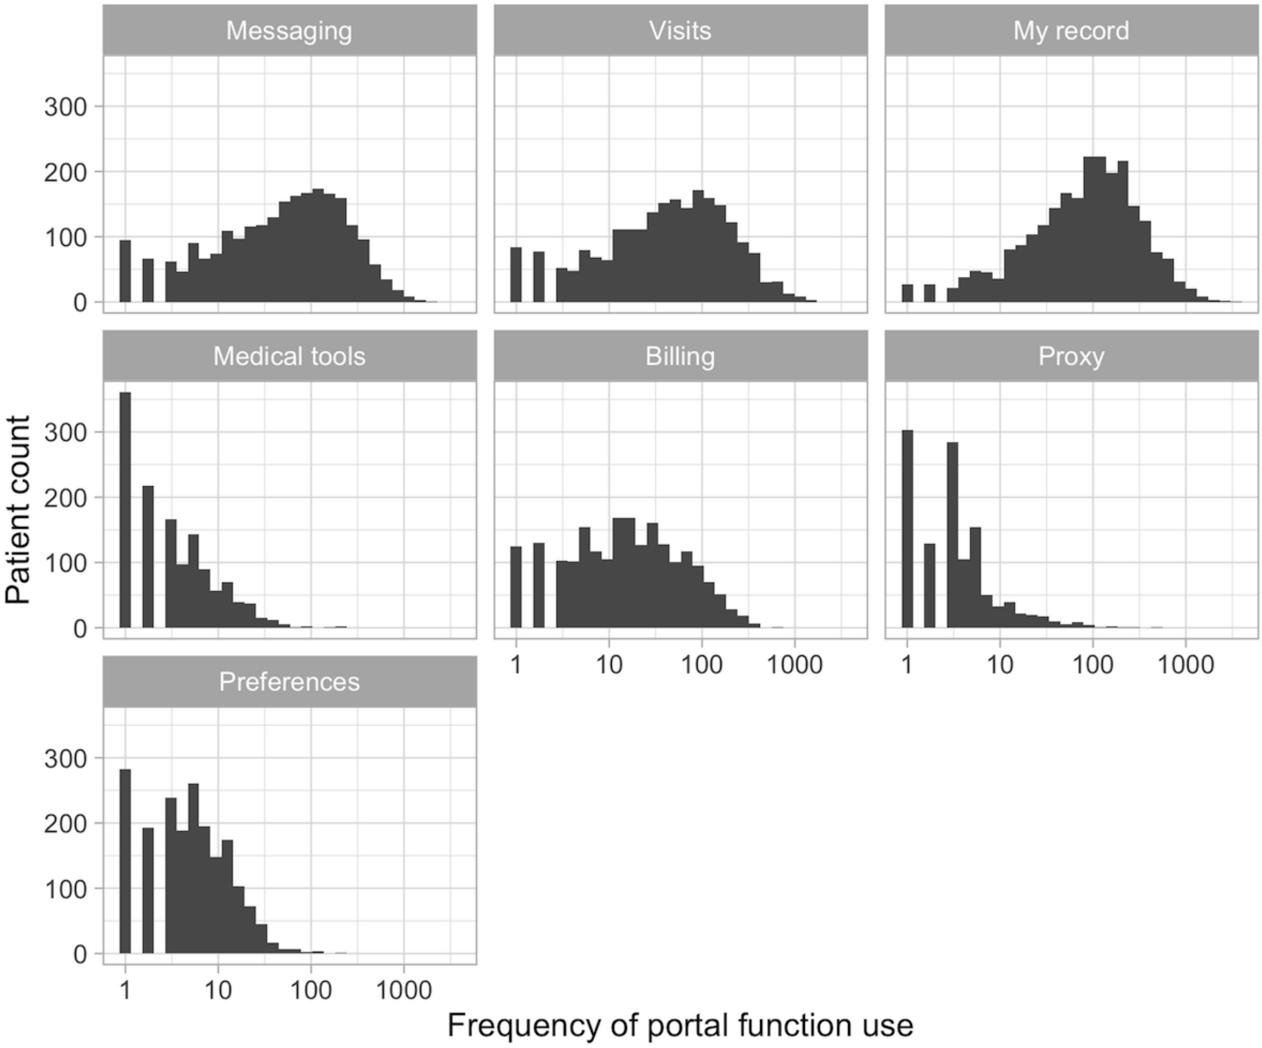


Comprehensiveness of Use

Comprehensiveness of portal function use, defined according to our proposed data model as the number of distinct functions accessed by the patient, provides a summary of how the patient engaged with the outpatient portal.

Comprehensiveness of use results are presented in Table 8. At the session level, in most cases, patients were found to engage with the portal for one specific function; only 17.45% (78,787/451,762) of the sessions were linked to activities involving more than one portal function. At the patient level, most individuals used 3 to 4 of the portal's functions over the course of the study.

Table 8. Comprehensiveness of use.

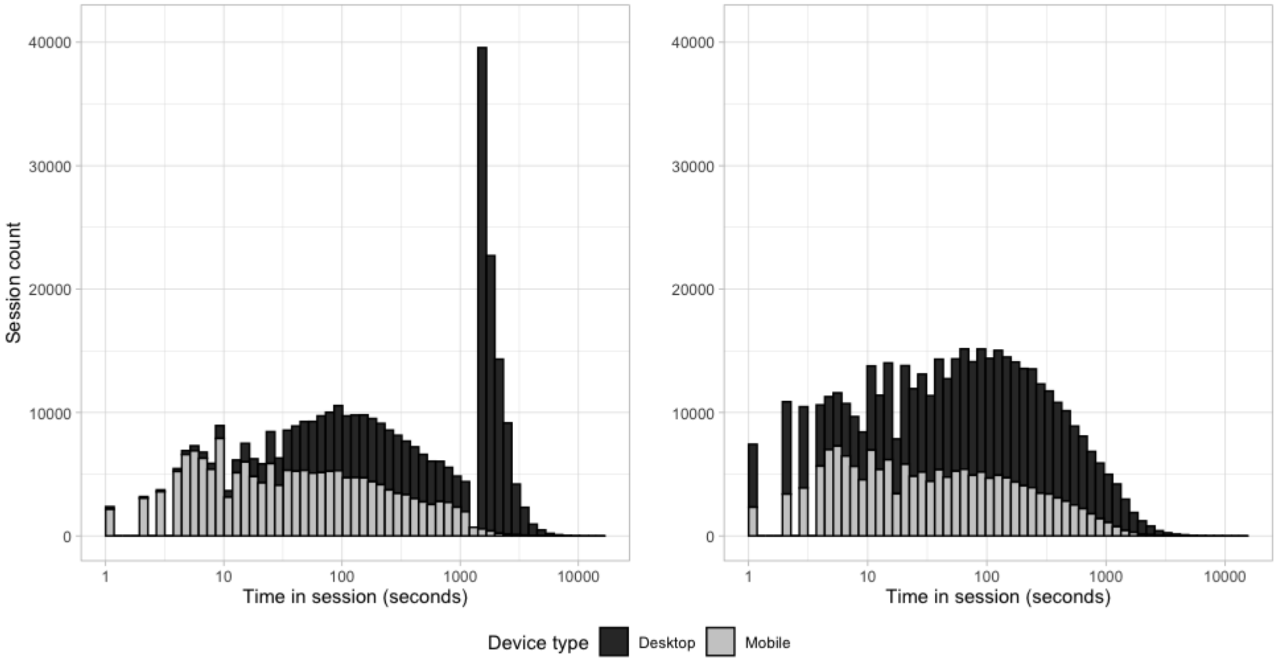
Counts of portal function used	Session (N=451,762), n (%)	Patient (N=2511), n (%)
0	117,819 (26.08)	14 (0.56)
1	255,156 (56.48)	64 (2.55)
2	57,761 (12.79)	274 (10.91)
3	16,215 (3.59)	696 (27.72)
4	4271 (0.95)	1066 (42.45)
5	491 (0.11)	349 (13.90)
6	47 (0.01)	46 (1.83)
7	2 (0.00)	2 (0.08)

Artifacts in the Data

Of note, our data processing methodology also uncovered a series of artifacts in the data, which we were able to correct. The first artifact affected the measurement of the time patients actively engaged with the portal. The distribution of the time spent in sessions calculated on raw server logs showed a bimodal distribution, with most sessions registering a length of a few minutes and a sizable group of longer sessions of approximately 20 min to 22 min (see graph of the left in Figure 7). This second group exclusively comprised patients connecting via a desktop computer (as opposed to a mobile phone), whose connections were kept alive by the server despite the patient being idle on the portal (see description of module 2 in the Methods section). The same analysis performed on audit logs processed with our proposed methodology showed how the distribution of the length of the sessions is instead approximately log-normal (see the graph on the right in Figure 7) and, by getting rid of idle time, better approximated the actual engagement duration of the patient with the portal.

A second type of artifact involved the audit logs mined from the mobile client. As documented in module 7 of the Methods section, duplicate data for MyChart activities recorded during mobile sessions can affect the frequency of use metrics if not properly identified and filtered.

Figure 7. Distribution of time in session by device type. On the left, time in session is calculated on raw server data. On the right, time in session is calculated after processing user access logs, removing log-outs action type, and enforcing a limit of 1256 seconds to the time patients can be idle on the portal.



Discussion

Principal Findings

Patient portals have the potential to improve patient engagement and health outcomes. Our intention with this preliminary study was to uncover the main artifacts in the data and to build a model that starts a conversation on how to use outpatient portal log files for research purposes. As previously noted, evaluations of portal use have, to date, mainly been conducted through the analysis of self-reported behaviors [8]. Furthermore, a review conducted by Irizarry et al [19] about patient portals and patient engagement highlighted the lack of objective measures for usability testing and attributed this gap to the high costs of this type of analysis in terms of time and effort. Our analysis of log files to develop metrics responds to this problem and presents the opportunity to augment self-reports of portal use with the new behavioral measure for portal function use we have described.

Data analytics research has additionally proven effective in describing portal adoption for targeted subpopulations [20]. Our methodology demonstrates how to incorporate information about the status of patient portal accounts in the final dataset (see script for module 8 in the Multimedia Appendix 8). This approach provides information grounded in longitudinal changes to patient accounts that can provide the basis for evaluating portal adoption and use and inform targeted strategies for implementation, improvement, and optimization of use.

Following the recommendations of Sieverink et al [16], our approach highlights the importance of examining outpatient portal use based on how the tool was actually used by patients (ie, including the different functions or elements within it) as opposed to simply reporting the number of log-ins and the frequency of use of the tool. Our results also demonstrate that, based on the level of analysis (ie, patient or session), the patterns of outpatient portal use by function show variability. Interestingly, this variability is more pronounced at the patient level as opposed to the session level. In contrast, at the session level, the usage pattern showed frequent but highly specialized interactions: patients visit the outpatient portal to achieve a single goal and navigate away from it as soon as the goal is achieved. Considering use metrics at the patient level instead, we found that although the portal use spread across all functions, many patients engaged only with a subset of those—a phenomenon that was also detected by Huerta et al [17] in their log file assessment of inpatient portal use.

Although the scope of this descriptive study is limited to the presentation of usage metrics constructed from data elements presently available in our institution's outpatient portal database, the integration of these data with other data sources will present additional opportunities for analysis. Future research on outpatient portal use can explore potential confounders that may influence use, such as demographics, diagnoses, treatments, and patients' communications with care team members. In addition, further work will permit the identification and characterization of user clusters, similar to the work of Jones et al [15] on outpatient portal use among chronic patients and of Fareed et al [21] on inpatient portal use; this approach will improve our understanding of the observed differences in usage patterns at the patient level.

Limitations

We acknowledge two main limitations to this study. First, although we have attempted to generalize our methodology and note procedures that are relevant to log file analysis independent of the institutional context, our study was limited to the analysis of log files from a single outpatient portal system that had retained many of the vendor's technical specifications. For instance, we were unable to obtain log files for functions connected to health educational resources because of the decisions by the EHR vendor and/or our institution to not track such actions. As such information is valuable in measuring patient engagement with their health, additional study is warranted in contexts where these data are collected. Our choice to document the processing steps for our data analysis in the form of Stata do files was motivated by the consideration that enabling reproducible research might bridge the institutional gap and mitigate this limitation. However, applying our methodology in other contexts or with other portal systems will require accounting for the institutional idiosyncrasies and contingencies that influence how the log files are parsed.

Second, with regard to identifying a level of analysis for portal use, as we were working with outpatient records, our data did not have a well-defined cutoff period. This is different from the case of inpatient portal data, where the hospital admission period provides a discrete time frame and level of analysis. We believe that with outpatient portal use, linking portal use to patients' medical history (eg, outpatient portal use during a specific index event such as major surgery) could guide researchers toward more meaningful ways to aggregate log file data and we aim to pursue such an approach in the future.

Conclusions

Although there has been rapid adoption of patient portals across health care organizations, traditional approaches to assessing their impact have not leveraged the potential of detailed audit log file analysis as we have presented. We aimed to model an approach to the outpatient log file analysis by presenting our methodology and describing the challenges associated with accessing and analyzing this type of data. Improving understanding of this process should enable researchers and practitioners to consider this methodology in future studies of outpatient portal use and impact.

Abstract

Background: Health services in many countries are promoting digital-first models of access to general practice based on offering online, video, or telephone consultations before a face-to-face consultation. It is claimed that this will improve access for patients and moderate the workload of doctors. However, improved access could also potentially increase doctors' workload.

Objective: The aim of this study was to explore whether and under what circumstances digital-first access to general practice is likely to decrease or increase general practice workload.

Methods: A process map to delineate primary care access pathways was developed and a model to estimate general practice workload constructed in Microsoft Excel (Microsoft Corp). The model was populated using estimates of key variables obtained from a systematic review of published studies. A MEDLINE search was conducted for studies published in English between January 1, 2000, and September 30, 2019. Included papers provided quantitative data about online, telephone, or video consultations for unselected patients requesting a general practice in-hours consultation for any problem. We excluded studies of general practitioners consulting specialists, consultations not conducted by doctors, and consultations conducted after hours, in secondary care, in specialist services, or for a specific health care problem. Data about the following variables were extracted from the included papers to form the model inputs: the proportion of consultations managed digitally, the proportion of digital consultations completed without a subsequent consultation, the proportion of subsequent consultations conducted by telephone rather than face-to-face, consultation duration, and the proportion of digital consultations that represent new demand. The outcome was general practice workload. The model was used to test the likely impact of different digital-first scenarios, based on the best available evidence and the plausible range of estimates from the published studies. The model allows others to test the impact on workload of varying assumptions about model inputs.

Results: Digital-first approaches are likely to increase general practice workload unless they are shorter, and a higher proportion of patients are managed without a subsequent consultation than observed in most published studies. In our base-case scenarios (based on the best available evidence), digital-first access models using online, telephone, or video consultations are likely to increase general practitioner workload by 25%, 3%, and 31%, respectively. An important determinant of workload is whether the availability of digital-first approaches changes the demand for general practice consultations, but there is little robust evidence to answer this question.

Conclusions: Digital-first approaches to primary care could increase general practice workload unless stringent conditions are met. Justification for these approaches should be based on evidence about the benefits in relation to the costs, rather than assumptions about reductions in workload. Given the potential increase in workload, which in due course could worsen problems of access, these initiatives should be implemented in a staged way alongside careful evaluation.

general practice; family practice; electronic consultations; remote consultation; telemedicine; telephone consultation; video; access to health care; health care quality, access, and evaluation

Introduction

An increasing number of primary care consultations are being provided under a digital-first model, in which consultations are conducted by telephone, video, email, or online "e-consultation" systems, before offering patients a face-to-face consultation only when necessary. Examples include Doctor On Demand in the United States, Curon in Japan, Ping An Good Doctor in China, and KRY, which operates in several European countries. In England, National Health Service (NHS) policy strongly promotes the use of online consultations [1] and companies such as Babylon GP at Hand, LIVI, and Push Doctor, which offer video consultations free of charge to NHS patients, are expanding rapidly [2]. The introduction of these new access pathways in England will be accelerated by a contract reform framework that will require all general practices to offer online and video consultations by April 2021 and to allow NHS 111 (a national telephone helpline) to directly book face-to-face appointments in local practices [3]. NHS England has recently issued detailed guidance to support the introduction of online consultations [4].

These changes are justified by two main arguments [1-5]. First, they are designed to facilitate quick and convenient access to care by patients, in line with similar changes in how consumers access almost all other services apart from health care. Second, it is argued that the introduction of "online-first" or "telephone-first" models of access will help to manage workload pressures on general practitioners (GPs). However, the twin aims to improve patient access and to manage workload pressures on GPs are likely to be in tension. Whether digital-first models of care decrease or increase general practice workload depends on factors such as the duration of the initial digital consultation and the proportion of these consultations that result in the patient needing a subsequent face-to-face consultation. The impact on general practice workload also depends on whether the demand for consultations is fixed or related to accessibility [6]. At present, many people have difficulty obtaining GP consultations and some may therefore seek help elsewhere or not obtain any professional advice [7]. If quicker and easier access to care means more people contact general practices, this supply-related demand needs to be considered alongside any efficiency gains.

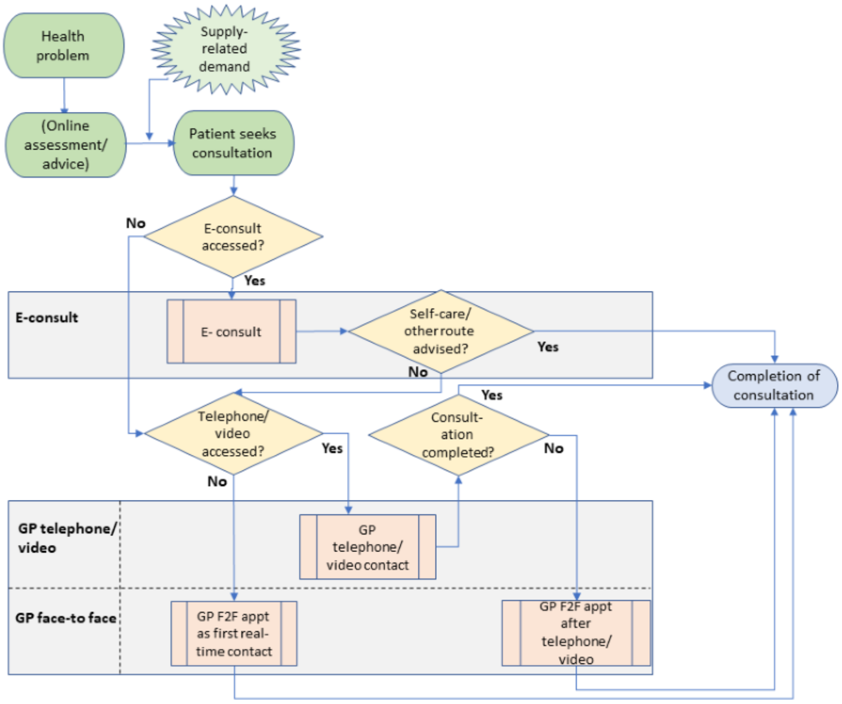
The overall impact on workload in general practice therefore depends on the relationship between several variables. We developed a model to estimate the impact of alternative access pathways on general practice workload and populated the model using a systematic review of studies of digital consultations in primary care. The aim of this study was to inform debate about to what extent, and under what circumstances, digital-first primary care consultations are likely to decrease or increase general practice workload.

Methods

Overview

We developed a process map to delineate the access pathway from when patients first seek a general practice consultation through to obtaining definitive assessment and care (Figure 1). Given the interconnectedness of health care systems, any such model is a simplification and must have a defined scope. Our process map begins with a patient having a health problem and considering requesting a GP consultation. They will often seek advice, which may be from family, a pharmacist, or online through an internet search, an automated symptom-checker app, or a patient forum [7]. Our model begins at the point following this, when a patient actively contacts a general practice requesting a consultation. It therefore excludes administrative issues conventionally dealt with by receptionists (for example, repeat prescriptions), consultations usually managed by nurses (for example, vaccinations), and patients who complete an online application but do not seek contact with a GP. The model includes consultations directly necessitated by a previous step (for example, a face-to-face consultation resulting from an online consultation) but ignores follow-up consultations. The model is limited to the impact on GPs, although we recognize that changes in access to GPs can have consequences for administrative and nursing staff and for demand on other parts of the health service.

Figure 1. Process map: impact of digital first access pathways on general practitioner (GP) workload. E-consult: online consultation. F2F: face-to-face.



We populated the workload model using data from a systematic review for 3 scenarios, representing the following 3 access pathways:

- In an online (or e-consultation) first model, patients describe their problem using an electronic form that may involve an automated algorithm or a less structured form. Administrative requests are dealt with by receptionists (excluded by our model). Requests for medical advice are reviewed by a GP who responds with a message or prescription, or a telephone, video, or face-to-face appointment.
- In a telephone-first model, the GP attempts to resolve the problem by telephone if possible, but if not, invites the patient to a face-to-face consultation.
- A video-first model follows a similar pattern, but there may be differences in variables such as the length of the consultation and the proportion of contacts that require a subsequent face-to-face consultation.

Model

The outcome for the model is percentage change in GP workload using the digital approach compared with GP workload using a conventional approach, in which most patients have face-to-face consultations, but a small proportion have telephone consultations. We created a dynamic spreadsheet model that allowed us to calculate how GP workload changes depending on the values of the key variables in the process map (such as the duration of digital consultations, or supply-related changes in demand). The results from our model are expressed as a percentage, so a result of 10% would mean 10% more hours of work than under conventional care.

The estimates for the conventional approach came from a large and rigorous study of GP consultations in England [8]. The study showed that 86% of consultations were conducted face-to-face and 14% were conducted by telephone, with a mean duration of 9 minutes and 5 minutes, respectively. The estimates for the new digital approaches came from a systematic review, described below. The results from the model illustrate the impact of a central base-case estimate, based on the best available evidence from our systematic review. For each variable in the model, we also considered plausible upper and lower limit estimates based on outlier studies from the review or on our own informed opinion in the absence of evidence. We have made the dynamic model available online, so that readers can test the effect of their own assumptions and estimates [9].

Systematic Review

To include evidence-based estimates in the model, we conducted a systematic review to identify studies of any design that provided quantitative data about digital consultations in primary care, including consultations by telephone, email, e-consultation systems, or video. The quantitative variables of interest were the proportion of consultations managed digitally, completion rate (digital consultations completed without needing a subsequent GP consultation), the proportion of subsequent consultations managed by telephone rather than face-to-face following an online consultation, the duration of different types of consultation, and any indicators of changes in demand or workload after the introduction of a digital-first model.

A change in the number of requests for health care following improved access is commonly referred to as supply-induced demand [6], which implies that a change in services has caused increased demand. However, in this study we used the more neutral term “supply-related demand” because it could equally represent underlying demand, which becomes visible only once access is improved. We sought to estimate the proportion of digital consultations that represented new supply-related demand based on (per month) the number of contacts of all types after introducing digital consultations, minus the number of contacts before introducing digital consultations, minus the number of duplicate consultations where patients had a face-to-face consultation directly resulting from a digital consultation, divided by the number of digital consultations.

Our focus was on consultations for undifferentiated problems between a patient and a GP; therefore, we excluded studies of communication between health professionals (for example, GPs consulting specialists), after-hours consultations, specialist or secondary care consultations, consultations not conducted by GPs, studies limited to a specific type of health problem, qualitative studies, studies of patient or GP opinion, and systematic reviews that did not provide any new quantitative analyses beyond the already-included papers. Our search strategy included terms for general practice, family practice, or primary care, or papers published in leading primary care journals, combined with a wide range of terms relating to telephone, online, digital, or video consultations. We included papers identified through the bibliographies of other papers. Multimedia Appendix 1 shows the search strategy, which was conducted in MEDLINE. We restricted searches to papers published since January 1, 2000, in English, and in developed countries to focus on papers of current relevance to the United Kingdom and other similar health care systems. We did not attempt to grade the quality of the studies or assess the risk of bias. The searches were updated to September 30, 2019. CS and PD reviewed the titles and abstracts of papers independently, retaining any papers that were potentially relevant. They then independently reviewed the full text of these papers to identify those that met the inclusion criteria. CS extracted quantitative data about the variables of interest, and this was checked by PD. Disagreements between reviewers were resolved by discussion involving the third author, MM.

Results

The systematic review identified 1246 papers, of which 90 were judged to be potentially relevant based on their titles and abstracts (Multimedia Appendix 2). Of these, 29 papers provided data of relevance to this study (Multimedia Appendix 3) [8,10-37]. Table 1 shows the estimates for the variables included in the workload model.

Based on our workload model, the final row in Table 1 shows workload in general practice using our central estimates for each scenario, compared with a conventional pathway based predominantly on face-to-face consultations.

The dynamic model makes it possible to test the sensitivity of the model to different assumptions by graphically showing the impact on workload (y-axis) of changing any 2 variables simultaneously (x-axis and legend). In Figures 2 and 3, we show 2 different scenarios as examples; readers can use the model to test their own scenarios [9]. Figure 2 shows that if the average duration of a telephone call is 5 minutes, a telephone-first approach has the potential to reduce workload if at least 55% of telephone consultations are completed without needing a subsequent face-to-face consultation, assuming no supply-related increase in demand. Figure 3 demonstrates that an online-first approach could reduce GP workload only if there is minimal increased demand (<4% of online contacts represent new demand) and about 50% of all requests are resolved in one online contact, but it has the potential to substantially increase workload if there is any supply-related increase in demand. However, 2 recent UK studies suggest that only about 30% of online consultation requests are resolved entirely online [13,17], and several studies suggest that there could be a substantial inflation in demand [14,16,26,31].

Table 1. Alternatives to face-to-face consultation: default values for variables in workload model. All values can be altered in the interactive model to test different scenarios and assumptions. Values without citations are authors' estimates.

Variable	E-consultation[a]			Telephone			Video		
	Base case	Lower value	Upper value	Base case	Lower value	Upper value	Base case	Lower value	Upper value
Access rate: Consultations initially requested in this way[b] (%)	90[b]	0.01 [17]	100	93 [12]	10 [20]	100	90[b]	50	100
Completion rate									
Digital consultations completed without needing a subsequent consultation (%)	30 [17]	28 [13]	70 [33][c]	52 [25,29]	40	90 [20]	65	50	83 [10]
Of those having a real-time consultation after e-consultation, consultations having phone rather than face-to-face consultation (%)	46 [17]	20	90	N/A[d]	N/A	N/A	N/A	N/A	N/A
Average time: Average time spent by GP[e] on this type of consultation (minutes)	4	3	5 [17]	5 [8]	4 [11,15]	6 [29]	9[f]	6 [21]	15 [34]
Supply-related demand: Alternative form consultations that are new demand (%)	10	–10	30	0 [29]	–10	30	0	–10	30
Total workload resource compared with conventional care, using base case assumptions (%)	25	N/A	N/A	3	N/A	N/A	31	N/A	N/A

[a] E-consultation: online consultation.

[b] At present, usage of e-consultation and video consultation in the United Kingdom is generally very low, so the impact is minimal. For the base cases, we have modeled a scenario in which the use of these alternatives is usual.

[c] Penza et al report a 66% completion rate [33]. Completion rates of 70% are claimed by eConsult, cited by Marshall et al [2]. Longman reports similar experiences in practices using askmyGP [38].

[d] N/A: Not applicable.

[e] GP: general practitioner.

[f] Assumed to be similar to conventional face-to-face care.

Figure 2. Impact of telephone consultations on general practitioner workload: varying telephone completion rate and call duration.

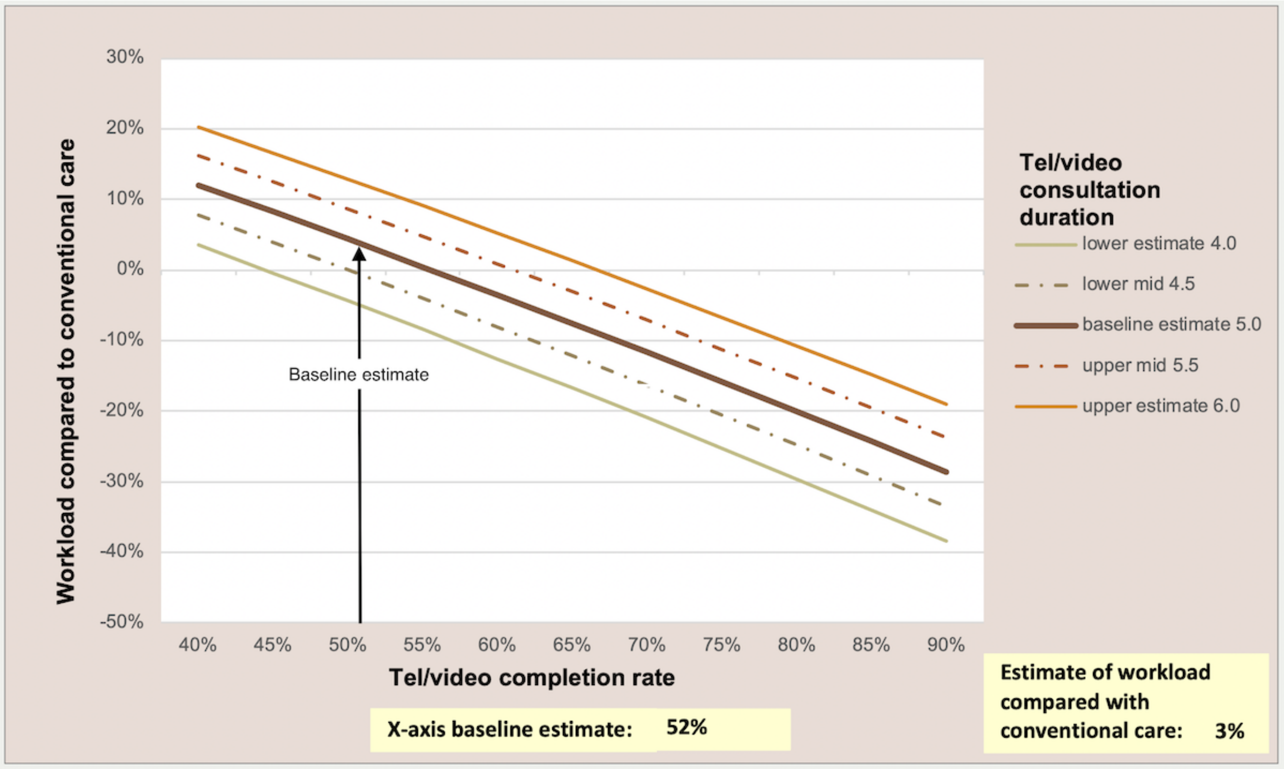


Figure 3. Impact of e-consultations on general practitioner workload: varying supply-related demand and e-consultation completion rate. E-consult: online consultation.

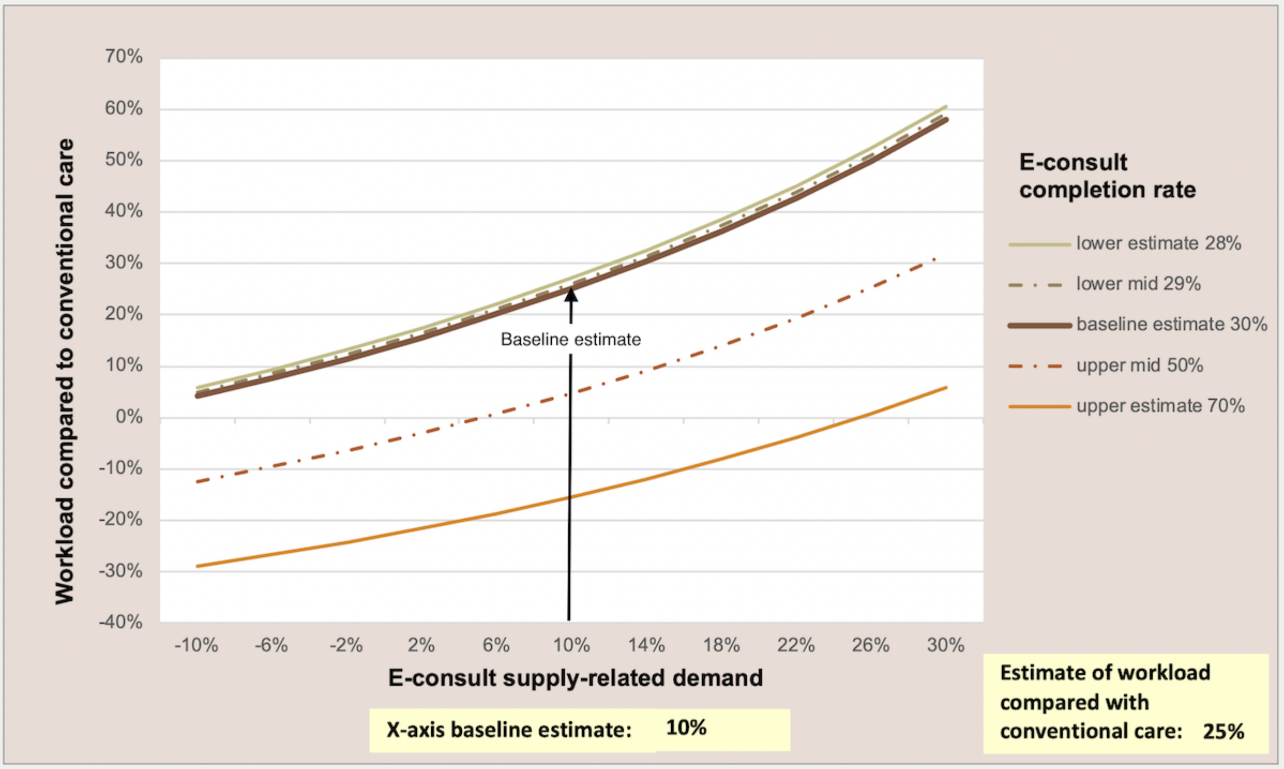

Discussion

Principal Results

Current initiatives to improve access and reduce GP workload through digital-first approaches could have benefits for patients and GPs or could have entirely the opposite effect to that intended. Based on current evidence, these approaches are at least as likely to increase as to decrease workload pressure on general practice. There is potential to reduce general practice workload, but only under stringent conditions, whereby the initial assessment is short and a high proportion of contacts are managed without needing a subsequent face-to-face review. Under almost all scenarios, even modest increases in demand related to improved accessibility would lead to increases in workload.

Comparison With Prior Work

The estimates used to populate this model are based on the best available published evidence. Companies providing digital-first consultation systems claim that general practices using their systems achieve impressive improvements in access and reductions in workload [38,39], and anecdotal reports from some early adopter practices suggest that these benefits can be achieved [4,40]. However, research studies involving larger numbers of practices show that this is not necessarily generalizable [12,29], and UK health services that have introduced digital-first approaches have reported that they do not appear to save GP time [13,41-43]. Furthermore, 2 studies have suggested that telephone-first approaches that lead to reductions in consultations on the same day are compensated for by increased consultations over the next 28 days [11,28]. Evidence from other countries relates to consultation rates or costs rather than workload and provides conflicting findings, with some studies reporting that offering digital consultations leads to increases (including the online consultations themselves) [14,16,26,30,31], while other studies report reductions [18,22,37]. This implies that it is important to understand how and why digital-first approaches are successful in some circumstances but not others. This study helps to inform this debate.

Strengths and Limitations

To ensure comparability between different access pathways, the denominator for our model was patients who decide to seek a consultation with a GP, rather than all patients who use an automated symptom-checker or triage app. About one-third of people look for information online about their symptoms in a conventional consultation system [7], so the use of symptom-checker apps may be partly substituting for this use rather than replacing consultations. The possibility that the availability of an online symptom-checker or triage app could decrease or increase the number of requests for contact with a GP is taken into account using the supply-related demand parameter in our model. Although some providers of online consultation services report that a high proportion of contacts can be managed entirely online [38,39], it is important to consider the denominator, since some of these contacts might not have been made at all or would not have led to a consultation under conventional care. These effects can be considered by comparing the total number of online, telephone, and face-to-face contacts with the number of consultations under a previous conventional approach (see formula in "Systematic Review" in the Methods section).

Some of the estimates used in this model could be challenged because they depend on the context in which the access pathway is introduced. For example, some of the estimates in the model come from the ESTEEM trial of telephone triage of requests for same-day consultations rather than all consultations [11,12]. Second, some clinicians suggest that the duration of a face-to-face consultation might be shorter after a prior online or telephone assessment than under conventional care [19] (although the evidence suggests this is not the case) [23,29]. Third, the proportion of consultations that can be successfully completed online or by telephone might be higher when patients are given the choice to consult in this way, rather than in systems where all patients have to go through this step before accessing a face-to-face consultation. A strength of this study is that by making our model freely available, anyone can explore how workload varies under different assumptions.

The need to limit the scope of the workload model means that it does not consider the effect on other services. The availability of digital consultations could be efficient if it reduces consultations in hospital emergency departments, but the evidence so far provides little support for this hypothesis [12,29,34,44]. The use of digital-first approaches could reduce GP workload by directing patients needing face-to-face care to other primary care professionals, such as nurses and pharmacists. However, we were unable to include this in the model because of a lack of evidence about how much this delegation occurs (compared with the extent to which receptionists direct patients to these professionals under conventional appointment systems) and the proportion of patients that would need to be transferred back to a GP after a nurse or pharmacist consultation. It will be increasingly important to consider the impact on nonmedical workloads in general practice as roles and responsibilities evolve. It is important to note that although delegation to other staff may reduce GP workload, it is not necessarily more efficient for the health care service overall [45].

Finally, we recognize that this study was designed from the perspective of the NHS in the United Kingdom, and usual care is different in other countries. However, by making the workload model freely available, including allowing changes to estimates such as the duration of face-to-face consultations under usual care, we hope that our model will be useful in various settings.

Implications for Clinicians and Policy Makers

If initiatives to improve access to care do lead to increased GP workload, this is not necessarily an argument against them. Ensuring good access to health care is a core purpose of primary care, and additional consultations might represent a response to previously unmet need. However, these initiatives should be justified on the grounds of benefits to patients rather than claims about reductions in GP workload [46]. As with most medical interventions, the key issue is whether the additional benefits are justified in relation to any extra costs. Furthermore, our analysis shows that assumptions about efficiency savings may be misplaced and general practice may need more resources to implement digital-first pathways.

It is important to consider how the benefits of different access pathways are felt by different segments of the population. Digital consultations are predominantly used by patients in the 20-44 age group [17,34], which is a group with generally fewer health care needs. If improving access for them requires more GP time, this will decrease rather than increase the time available for patients with more complex problems, as well as decreasing access for those without internet access. To reduce the potential for worsening health inequalities, it is important to prioritize the use of technology to improve access for the groups of patients with the greatest health care needs, such as older adults, carers, and people with disabilities.

Digital-first access models may have other potential advantages and disadvantages. Improved access could help reverse the decline in public satisfaction with NHS general practice [47] and help avoid inappropriate use of expensive hospital care [3]. Triage systems may offer GPs a greater sense of control over their working day [4]. Technologies to allow GPs to work from home could expand the workforce by unlocking the potential contribution of doctors who cannot work fixed hours in conventional settings [34]. On the other hand, a shift in working patterns toward significant amounts of time spent consulting online or by telephone could lead more GPs to leave the workforce than to join it.

Apart from the impact on workload, there are very important unknowns about the quality and safety of alternatives to face-to-face consultations, as well as the acceptability of these access pathways to different patient groups [2]. These questions should be a priority for research.

Conclusions

This study has highlighted that efficiency gains or losses from the use of digital-first access pathways are finely balanced, and the main impact on workload will be determined by whether these pathways change demand. Digital-first services could increase demand through improved supply or surfacing previously unmet need, or could reduce demand by encouraging patients to self-care or use other services. This is, therefore, an issue of critical importance, but about which we currently have the least evidence. It may take several years for these effects to become manifest. Given that it will be difficult to lower expectations and demand after these have been raised, this suggests the need for careful and staged implementation alongside evaluation rather than universal implementation of digital-first access pathways as soon as possible, as advocated by current UK policy [3].

Acknowledgments

CS is a senior investigator at the National Institute for Health Research. The views expressed in this article are those of the authors, not necessarily those of the National Institute for Health Research or the Department of Health and Social Care.

CS had the idea for the paper, reviewed papers, extracted data, developed the first draft of the workload calculator, and wrote the first draft of this paper. MM devised the first draft of the process map for the access pathway and contributed to development of the interactive workload calculator. PD reviewed papers and extracted data for the systematic review. All authors provided critical intellectual input and approved the final paper. CS is guarantor and affirms that the manuscript is an honest, accurate, and transparent account of the study being reported; that no important aspects of the study have been omitted; and that any discrepancies from the study as originally planned have been explained.

Abstract

Background: Tinnitus is often described as the phantom perception of a sound and is experienced by 5.1% to 42.7% of the population worldwide, at least once during their lifetime. The symptoms often reduce the patient's quality of life. The TrackYourTinnitus (TYT) mobile health (mHealth) crowdsensing platform was developed for two operating systems (OS)—Android and iOS—to help patients demystify the daily moment-to-moment variations of their tinnitus symptoms. In all platforms developed for more than one OS, it is important to investigate whether the crowdsensed data predicts the OS that was used in order to understand the degree to which the OS is a confounder that is necessary to consider.

Objective: In this study, we explored whether the mobile OS—Android and iOS—used during user assessments can be predicted by the dynamic daily-life TYT data.

Methods: TYT mainly applies the paradigms ecological momentary assessment (EMA) and mobile crowdsensing to collect dynamic EMA (EMA-D) daily-life data. The dynamic daily-life TYT data that were analyzed included eight questions as part of the EMA-D questionnaire. In this study, 518 TYT users were analyzed, who each completed at least 11 EMA-D questionnaires. Out of these, 221 were iOS users and 297 were Android users. The iOS users completed, in total, 14,708 EMA-D questionnaires; the number of EMA-D questionnaires completed by the Android users was randomly reduced to the same number to properly address the research question of the study. Machine learning methods—a feedforward neural network, a decision tree, a random forest classifier, and a support vector machine—were applied to address the research question.

Results: Machine learning was able to predict the mobile OS used with an accuracy up to 78.94% based on the provided EMA-D questionnaires on the assessment level. In this context, the daily measurements regarding how users concentrate on the actual activity were particularly suitable for the prediction of the mobile OS used.

Conclusions: In the work at hand, two particular aspects have been revealed. First, machine learning can contribute to EMA-D data in the medical context. Second, based on the EMA-D data of TYT, we found that the accuracy in predicting the mobile OS used has several implications. Particularly, in clinical studies using mobile devices, the OS should be assessed as a covariate, as it might be a confounder.

Introduction

Background

Mobile health (mHealth) uses smart mobile devices to address various questions in the context of neuroscience, psychology, and medicine. New paradigms, such as ecological momentary assessment (EMA), mobile crowdsourcing, and mobile crowdsensing, as well as mHealth apps, in general, have enabled data collection procedures that surpass many existing methods in gathering valuable medical data by several orders of magnitude [1]. Among others, by using smart mobile devices, data can be gathered in everyday life, on a cost-effective basis, and by adding contextual information sources, such as Twitter or Facebook. As many medical phenomena pose daily variations [2], mHealth technology is predestined to be utilized in this context. Along these trends, many insights have been presented by researchers that show that smart mobile devices can help to establish new data sources in many scenarios [3].

In these data collection scenarios, which are built on the usage of mobile devices and their sensors, one dimension has been less considered so far. It refers to the question of whether the operating system (OS) of the mobile technology being used (eg, iOS or Android) constitutes a valuable information source or confounder for medical data analyses. Or, as another example, is it possible to derive insights if a patient changes the OS during a study when using mHealth apps? As Android and iOS dominate the mobile OS market [4]—with a market share of 99.32% in May 2020 (72.52% Android and 26.80% iOS)—any insights gained based on differences from users regarding these OS types could provide a representative picture for the OS market. Following this, data that were gathered with the TrackYourTinnitus (TYT) mHealth crowdsensing platform for tinnitus patients over 5 years of age are analyzed in this paper. TYT is an mHealth crowdsensing platform that offers iOS and Android apps that can empower patients to learn more about their tinnitus symptoms over time. Tinnitus is the phantom perception of a sound and it is experienced by 5.1% to 42.7% of the population worldwide at least once during their lifetime [5]. The symptoms often reduce the patient's quality of life. As tinnitus constitutes a chronic condition for which currently no cure or general treatment exists, patients suffering from it crave for new treatment procedures or at least new medical insights. With the idea of EMA, also known as ambulatory assessment or experience sampling, and mobile crowdsensing techniques in mind, TYT was developed by an interdisciplinary team of medical experts, psychologists, and computer scientists.

The development of TYT was motivated by the clinical experience that among many tinnitus patients, tinnitus loudness and tinnitus annoyance vary over time and that patients' experiences differ in the pattern of these fluctuations. Therefore, the variations are considered to provide new valuable insights in the pathophysiological mechanisms of this chronic condition [6]. To learn more about these fluctuations, TYT applies EMA and mobile crowdsensing to capture them. In EMA, the variable in question (eg, a symptom) is assessed repeatedly in daily life [7]. In mobile crowdsensing, only mobile devices are used for the data collection procedure, while their sensors are used to capture, for example, the GPS position or the external sound level [8]. In contrast, in mobile crowdsourcing, tasks are proposed by a crowdsourcer to a group of individuals, who voluntarily undertake tasks. The undertaking of the task always entails mutual benefit. The user will receive the satisfaction of a given type of need, while the crowdsourcer will obtain and utilize to their advantage what the user has brought to the venture [9]. In contrast to mobile crowdsourcing, mobile crowdsensing relies solely on mobile technology and integrates sensors to collect data. Two recent works that discuss mobile crowdsensing in the context of health care can be found in Kraft et al [1] and Pryss [10]. In TYT, the users fill in a registration questionnaire (ie, static data) and can provide repeated assessments in daily life (ie, dynamic data) afterward [11].

Objectives

Compared to the existing studies on TYT, this work investigates repeatedly provided EMA datasets from TYT users (ie, dynamic data) and their relation to the mobile OS used. While this study analyzes this dynamic data, a previous study focused on differences between Android and iOS users in the static data given at registration [12]. Contrary to the Android versus iOS comparison of the SmokeFree28 (SF28) smoking cessation app [13], in our study we found no differences in gender, but we did find differences in age for TYT users. However, in Pryss et al [12], we found differences that might be of interest for medical purposes. More specifically, we revealed that Android users reported a significantly longer tinnitus duration than did iOS users, cross-sectionally. Future longitudinal research is necessary to address the question of whether users with longer tinnitus duration prefer Android to iOS or whether users of Android tend to develop longer tinnitus durations than iOS users. In another recent work [14], we investigated differences in Android and iOS users of the TrackYourHearing (TYH) mHealth crowdsensing platform. This platform aims to measure fluctuations in hearing of users with hearing loss. In the TYH study, we found no differences in gender or age, but significant differences were revealed in three questions of the dynamic data that were repeatedly provided. This shows that the dynamic data in combination with the OS are worth being investigated more deeply.

As another current trend, the application of machine learning techniques in different fields is promising. In the medical field, there is a remarkable discrepancy between huge expectations in the potential of machine learning on one side and the current application of this technique on the other [15-19]. Importantly, there is an increasing consensus about its potential in the context of mobile technology [20-23]. However, the application of machine learning to a large group of users of an mHealth crowdsensing platform that gathers EMA datasets is still rare [19,24-27]. As we already found relevant differences between Android and iOS pertaining to the TYT users' static characteristics at registration [12], this work investigates the following research question: *Is it possible to predict the mobile OS used based on dynamic TYT data with high accuracy using machine learning methods? More specifically, is it possible to predict the mobile OS used based on the repeatedly given daily data provided by the TYT users with high accuracy using machine learning methods?* To the best of our knowledge, thus far, no other work has considered this research question in the given context.

Methods

Overview

TYT was developed to track the individual tinnitus perception of users in their daily lives [28]. In this context, the procedure shown in Figure 1 is applied to all TYT users. In general, TYT pursues three major goals.

First, dynamic EMA (EMA-D) data shall be collected during the continuous mobile crowdsensing procedure (see Figure 1, box #4). Importantly, a crowdsensing user shall not foresee the times he or she is asked to provide the data (see Figure 1, box #3). This is ensured by asking the crowdsensing users for data in various daily-life situations by the use of smartphone notifications. When a user clicks on such a notification, the tinnitus-tracking questionnaire is presented to a user, consisting of eight EMA-D questions. Table 1 lists the eight questions of the EMA-D questionnaire.

Note that the questionnaire appears visually on both mobile OS types in the same way. For more information on the questionnaire shown in Table 1 and how it appears on the mobile devices, see Pryss et al [11].

Second, the collected data shall enable innovative data analyses, such as juxtaposing the prospectively assessed EMA-D and retrospectively assessed static EMA (EMA-S) at registration (see Figure 1, box #2; [11]). Third, gathered data shall be used to provide feedback to the mobile crowdsensing users [29].

When initially designing the user procedure of TYT, we had not yet considered comparing users based on the mobile OS they used. The initial intention to collect information about the mobile OS used (see Figure 1, box #1) when filling out a questionnaire had been to quickly identify technical issues that could emerge with the large variety of mobile OS versions and mobile devices used. However, it turned out that the information can be also used for innovative analyses. For interested readers, more technical information of the platform can be found in Pryss et al [28,29].

A further note is provided to distinguish between static and dynamic data in the procedure shown in Figure 1. Usually, existing works distinguish between questionnaire, sensor, and behavioral data when utilizing mHealth crowdsensing approaches [30-32]. However, our distinction between static *trait* (ie, EMA-S) or dynamic *state* EMA data (ie, EMA-D) is done less frequently by other works. This is remarkable, as the distinction between trait (ie, static) and state (ie, dynamic) variables is fundamental in clinical and psychological research. As an example, trait data are expected to have a closer association with genetic information as compared to state data, which depend more strongly on environmental factors.

The experimental protocols were approved by the Ethics Committee of the University Clinic of Regensburg, Germany. All methods were carried out in accordance with the relevant guidelines and regulations. The users of the app were informed that their gathered data will be used for scientific analyses; informed consent was given.

Figure 1. TrackYourTinnitus (TYT) mobile crowdsensing collection procedure. EMA: ecological momentary assessment.

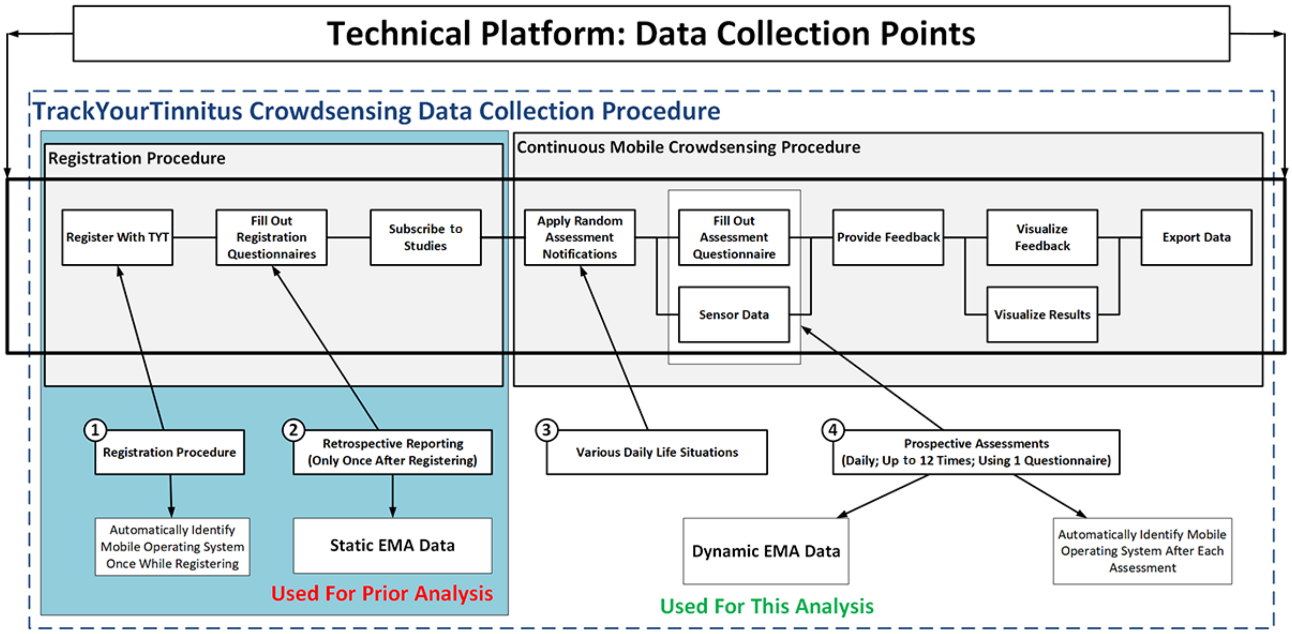

Table 1. Questions from the dynamic ecological momentary assessment (EMA-D) questionnaire.

Number	Question (Q)	Answer type
Q1	Did you perceive the tinnitus right now?	Yes or no
Q2	How loud is the tinnitus right now?	Slider[a]
Q3	How stressful is the tinnitus right now?	Slider
Q4	How is your mood right now?	Manikins[b]
Q5	How is your arousal right now?	Manikins
Q6	Do you feel stressed right now?	Slider
Q7	How much did you concentrate on the things you are doing right now?	Slider
Q8	Do you feel irritable right now?	Yes or no

[a] Each slider has a different range; the slider for Q2, for example, ranges from *not audible* to *maximal loudness*.

[b] We made use of the Self-Assessment Manikin (SAM) scales, which are a pictorial rating system to obtain self-assessments of experienced emotions on the dimensions affective valence, dominance, and arousal.

Data Source

The TYT platform includes a website, uses a relational database, and includes an iOS and Android app. The latter are implemented as native apps. Users can register with the platform by using the website or the mobile apps. After that, three registration questionnaires must be completed—EMA-S questionnaires, which can be filled out using the website or the mobile apps—before users can provide the EMA-D data repeatedly in daily life—this is denoted as the EMA-D questionnaire, which can only be filled out using the mobile apps. After completing the registration questionnaires, users must decide whether they want to use the default notification schema for the EMA-D questionnaire. The default setting means users would receive random notifications up to eight times per day. This setting can be changed by a user in many ways. The user can reduce the notification number to a minimum value of three or a maximum value of 12 notifications per day. In addition, a user can select specific days of the week when no notifications shall appear. Finally, a user can switch to the fixed notification mode, in which he or she specifies exact notification points. Note that in this analysis, it is not distinguished which mode has been selected by a user. Finally, if the user clicks on a notification, the EMA-D questionnaire appears. A detailed description can be found in Pryss et al [11]. Finally, note that users can fill out the EMA-D questionnaire in a user-initiated manner as well (ie, without getting a notification to fill out a questionnaire).

Another feature is offered to the TYT users. They can obtain their results of all answered EMA-D questionnaires through the apps or the website. For this purpose, two options are provided: first, they can visualize the results via the website or the mobile apps; or second, they can download a CSV (comma-separated values) file, only via the website, for further personal evaluations.

Participants

The analysis was conducted in March 2020. At this time, the TYT platform had 4835 registered users. From them, 2584 users completed the EMA-D questionnaire at least once and, in total, 75,278 EMA-D questionnaires were available. To get an impression of how TYT is used worldwide, the country distribution was determined; it shows the number of completed EMA-D questionnaires (ie, all eight items filled in) from 2065 users from the 12 countries with the most completed EMA-D questionnaires out of the 2584 users who completed the questionnaires. This resulted in 67,789 EMA-D questionnaires from 2065 users. The worldwide distribution is shown in Table 2.

The OS distribution of the 2584 users who completed the EMA-D questionnaire at least once is as follows: 40.02% (1034/2584) of the data were provided by iOS users, while 59.98% (1550/2584) were provided by Android users. The OS distribution of all completed EMA-D questionnaires in TYT is as follows: 32.00% (24,089/75,278) of the data were provided by iOS users, while 68.00% (51,189/75,278) were provided by Android users.

The data preparation steps for the machine learning analysis, including use of a scikit-learn function [33] to compare the same number of EMA-D questionnaires from Android and iOS users, can be seen in Figure 2.

For the final study sample of 297 Android users and 221 iOS users, Table 3 shows statistical comparisons between the Android and iOS users in terms of gender, age, and numbers of completed EMA-D questionnaires (chi-square test and *t* tests for independent samples, two-sided). Age was set to *missing* if users provided invalid entries.

Finally, Figure 3 shows the histogram for the number of completed EMA-D questionnaires for the 518 investigated TYT users (see Figure 2).

Table 2. Country distribution of TrackYourTinnitus (TYT) users (n=2065) in ascending order.

Number	Country	Completed dynamic ecological momentary assessment (EMA-D) questionnaires (n=67,789), n (%)
1	Australia	535 (0.79)
2	Belgium	819 (1.21)
3	Italy	1026 (1.51)
4	Russia	1076 (1.59)
5	Austria	1110 (1.64)
6	Norway	1159 (1.71)
7	Canada	2113 (3.12)
8	Great Britain	3202 (4.72)
9	Switzerland	5229 (7.71)
10	Netherlands	6917 (10.20)
11	United States	9117 (13.45)
12	Germany	35,486 (52.35)

Figure 2. Data preparation steps for the machine learning analysis. [a]Information about the scikit-learn function can be found on the scikit-learn website [33]. EMA-D: dynamic ecological momentary assessment; Q: question; TYT: TrackYourTinnitus.

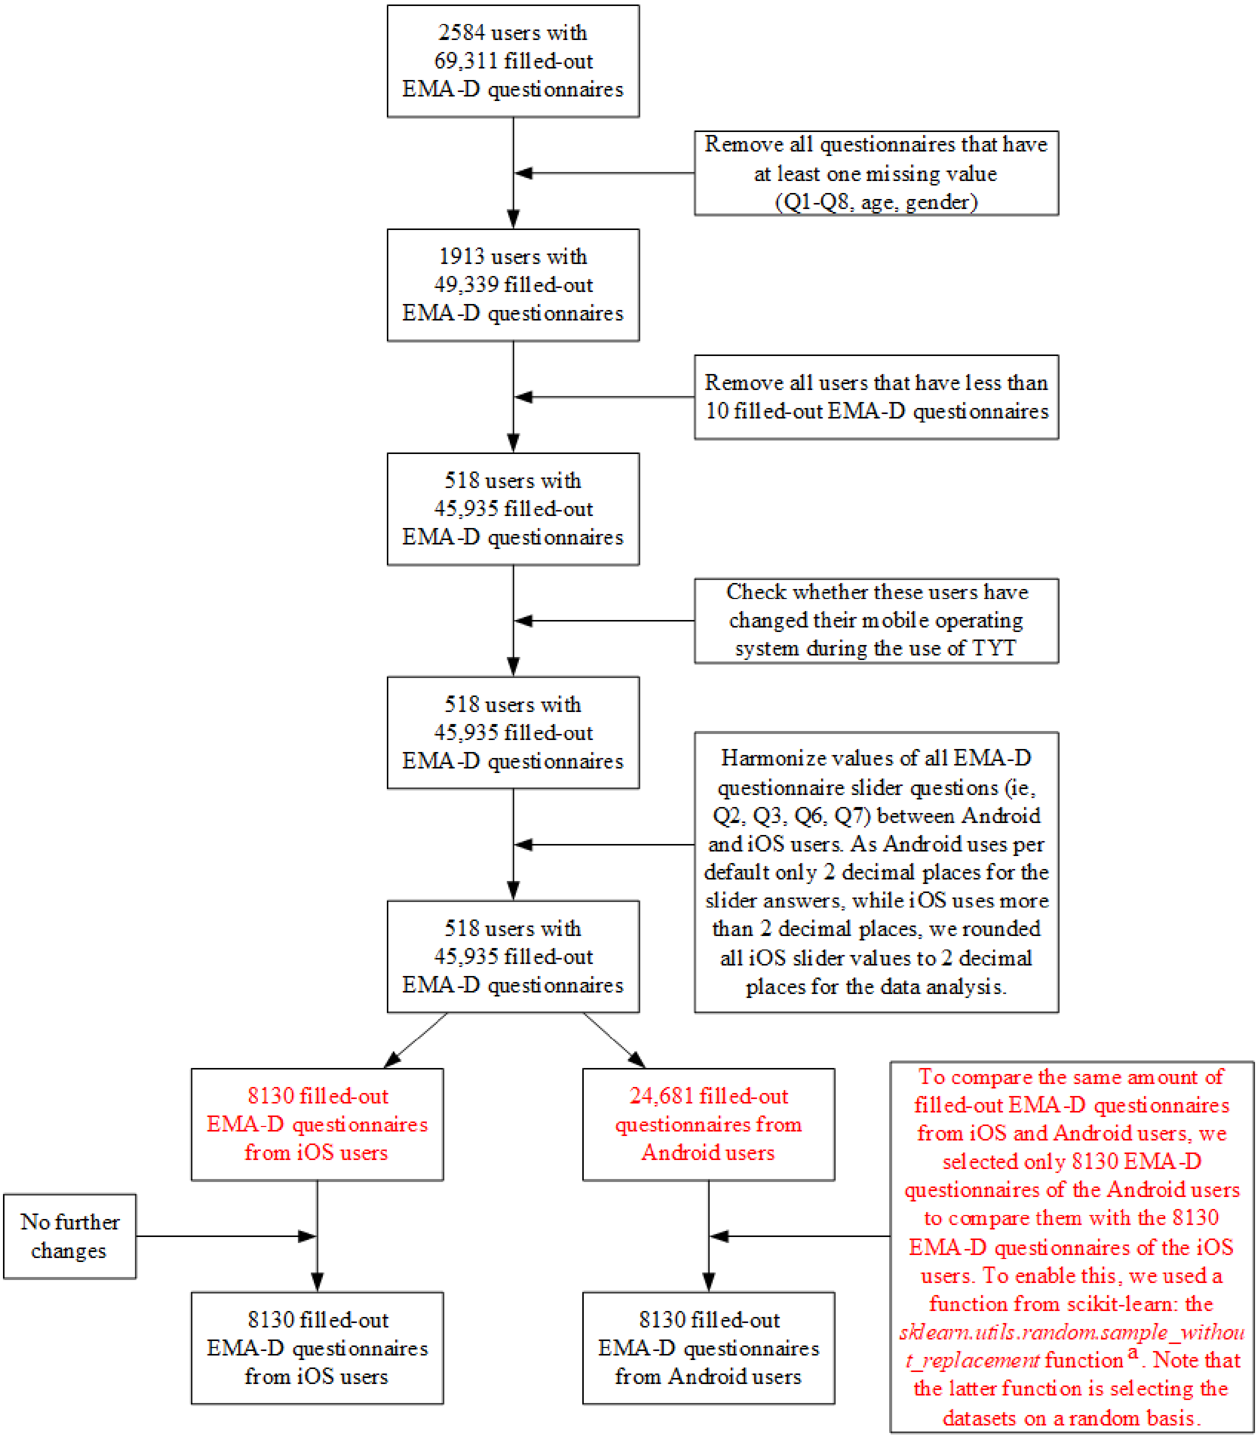

Table 3. Comparisons between iOS and Android users regarding gender, age, and number of completed dynamic ecological momentary assessment (EMA-D) questionnaires.

Variable	Android	iOS	Chi-square (*df*)	Two-tailed *t* test (*df*)	*P* value
Gender[a] (male), n (%)	221 (74.4)	147 (66.5)	1.2 (1)	N/A[b]	.27
Age[c] (years), mean (SD)	49.76 (12.29)	50.57 (13.09)	N/A	–0.71 (497)	.48
Number of completed EMA-D questionnaires[d] (ie, all eight questions completed), mean (SD)	49.52 (80.32)	66.55 (125.92)	N/A	–1.87 (516)	.06

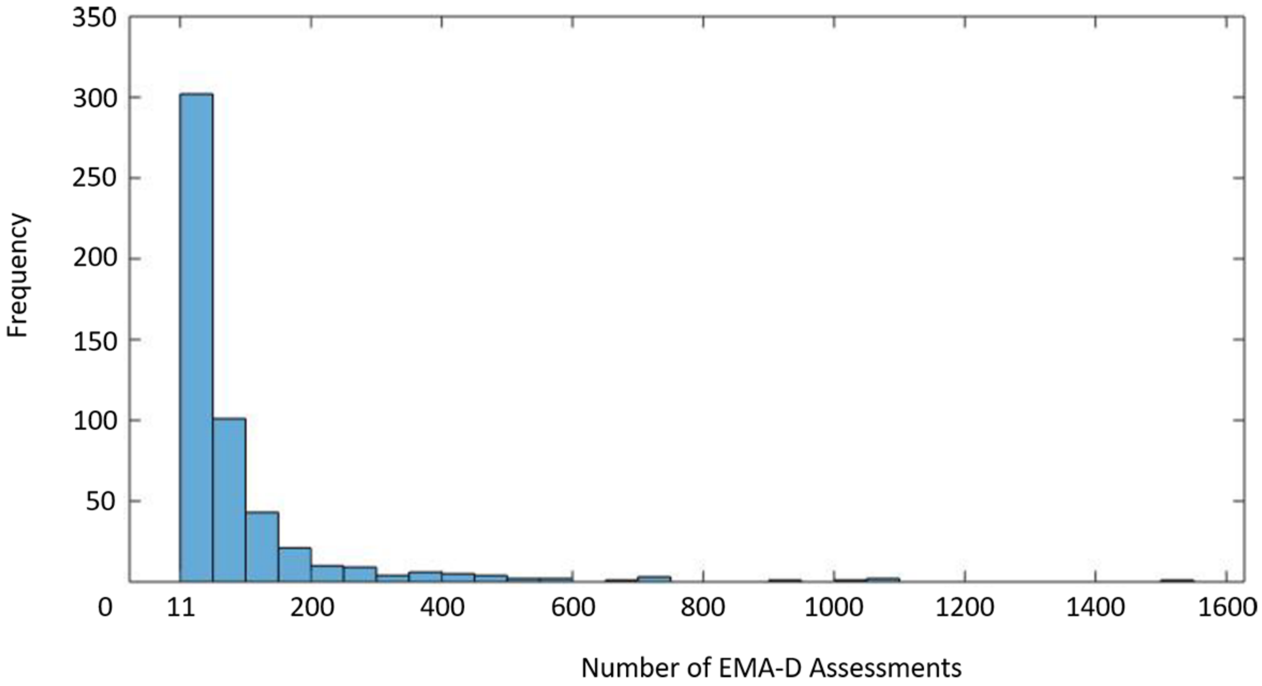
[a] Sample sizes for gender are n=297 for Android and n=221 for iOS.

[b] N/A: not applicable.

[c] Sample sizes for age are n=295 for Android and n=204 for iOS.

[d] Sample sizes for number of completed EMA-D questionnaires are n=297 for Android and n=221 for iOS.

Figure 3. Frequencies of completed questionnaires of the investigated TrackYourTinnitus (TYT) users (n=518). EMA-D: dynamic ecological momentary assessment.



Machine Learning Analysis

We applied machine learning approaches with the goal to predict the OS—Android or iOS—of a provided assessment of the EMA-D data. For this purpose, four machine learning approaches were applied to the dataset: a feedforward neural network (FNN), a decision tree (DT), a support vector machine (SVM), and a random forest classifier (RFC). All approaches were chosen because they are appropriate for high-dimensional datasets, which is the case for the given EMA-D questionnaires of the TYT users. This is supported by similar works [34,35].

Concerning the dataset in general, it is noteworthy that the machine learning approaches were applied on the assessment level of the EMA-D questionnaires. This means that assessments from one user can be in both the training and the validation datasets. Performing a separation on assessment level has advantages and disadvantages. As the main disadvantage, it can be argued that if a participant is in both datasets, then there might be a bias. On the other hand, if users of the training phase are separated from the validation phase users, then it must be ensured that the user characteristics between the training and validation phases generate no bias. In an EMA-driven approach, where daily assessments on a random and voluntary basis are the main goal, it is difficult to be able to evaluate a large group of users with similar assessment characteristics. However, in future work, it will be a further goal to also separate the dataset on the user level in a reasonable manner. That individual users play an important role in health care studies is emphasized by the emerging paradigm of N-of-1 studies [36].

Concerning the validation procedure, the following has been accomplished: in a first step, the validation was based on a *10-fold cross-validation* approach [34,35] (ie, for the SVM, the DT, and the RFC). Here, the entire dataset was distributed into 10 equal parts. Nine of these parts were used for the training phase, while the remaining one part was used for the testing phase. The whole procedure was repeated 10 times and the average values were then calculated over all 10 runs. To foster our results, another validation was performed for the SVM, the

DT, and the FNN. We conducted a leave-one-out approach on the user level, for all of the 518 included users, combined with a majority vote for the EMA-D questionnaires from the user that was left out, to see whether the prediction differs if the EMA-D questionnaires from the user who was left out are excluded. In conclusion, there was no obvious difference observed.

For all analyses, the following technical environment was used: a laptop with an i7 core (2.60 GHz); MATLAB, version R2017a (MathWorks); the Statistics and Machine Learning Toolbox (MathWorks); and scikit-learn, open source machine learning library, for Python (Python Software Foundation). For all applied methods, we used the default parameters of the technical environment. In MATLAB, the FNN, the SVM, and the DT were calculated, while in Python scikit-learn, the RFC was calculated.

Results

Overview

The four applied machine learning approaches showed different results for the research question. In general, the prediction accuracies were unexpectedly high.

Feedforward Neural Network

The FNN was the worst-performing candidate. Here, for 72.67% of the EMA-D questionnaires, the mobile OS could be correctly predicted. In the MATLAB toolbox that was used, the essential parameter for the calculation was *feedforwardnet(10)*.

Decision Tree

The DT, in turn, performed as the third-best candidate. It was applied with a 10-fold cross-validation and it predicted the correct mobile OS for 76.36% of the EMA-D questionnaires. Importantly, the resulting DT has a depth of 379, showing that the prediction can be categorized into a high-dimensional calculation. In the MATLAB toolbox that was used, the essential parameter for the calculation was *fitctree(X,Y,'CrossVal','on')*.

Random Forest Classifier

The RFC performed as the best candidate; the mobile OS could be predicted correctly for 78.94% of the EMA-D questionnaires. In the Python scikit-learn method that was used, the essential parameter for the calculation was as follows: *RandomForestClassifier(n_estimators=100, bootstrap=True, max_features='sqrt', random_state=42)*. In addition to the prediction results, Table 4 shows the importance of the eight EMA-D questions for the overall prediction result of 78.94%; here, we used the *model.feature_importances_* feature of Python scikit-learn. Importantly, question 7 and then question 2 are the most important questions for the prediction result of 78.94%.

Table 4. Importance of the eight dynamic ecological momentary assessment (EMA-D) questions for the random forest classifier prediction. Question 1 (Q1): Did you perceive the tinnitus right now? (yes or no); Q2: How loud is the tinnitus right now? (slider); Q3: How stressful is the tinnitus right now? (slider); Q4: How is your mood right now? (manikins); Q5: How is your arousal right now? (manikins); Q6: Do you feel stressed right now? (slider); Q7: How much did you concentrate on the things you are doing right now? (slider); and Q8: Do you feel irritable right now? (yes or no).

Question Number	Q1	Q8	Q5	Q4	Q3	Q6	Q2	Q7
Percentage of Importance	0.03043	0.03985	0.08728	0.0913	0.17246	0.17425	0.19247	0.21194

Support Vector Machine

The SVM performed as the second-best candidate. Overall, using all eight questions, the mobile OS could be predicted correctly for 78.65% of the EMA-D questionnaires. For the SVM, detailed results for single questions and question combinations are discussed in more detail. This will show that all eight questions are needed to get a prediction result with an accuracy that shows that the OS might be a confounder that should be further considered. The same detailed discussion could be accomplished for the other approaches, such as the RFC. We opted for the SVM for a more detailed discussion and to compare the results to other approaches to see if they deviate significantly from each other. More specifically, prediction results for combinations of two questions as well as single questions are shown in Table 5. Seven results will be further discussed. The discussion will show that the accuracies vary among the eight EMA-D questions on one hand. One the other hand, it will show that despite the observed variances, the overall achieved accuracy is high for different questions and their combinations.

First, we consider question 7—How much did you concentrate on the things you are doing right now? (slider)—and question 8—Do you feel irritable right now? (yes or no). They performed as the two best single questions for the prediction. Each of them has an accuracy of 58.80%. This result is only partly confirmed by the RFC. For the RFC, question 7 is also very important, but question 8 is less important for the RFC.

Second, question 5—How is your arousal right now? (manikins)—performed with the third-best result for a single question; here, an accuracy of 57.14% was attained. This question is like question 8, in that it is less important in the case of the RFC.

Third, the combination of question 7—How much did you concentrate on the things you are doing right now? (slider)—and question 8—Do you feel irritable right now? (yes or no)—performed as the best candidate for two-question combinations; in this case, an accuracy of 63.95% was achieved. This result is again only partly supported by the RFC (ie, for the RFC, question 8 was less important; see Table 4).

Fourth, the worst result was achieved when only using question 4—How is your mood right now? (manikins)—as the predictor. For question 4, an accuracy of 54.07% was achieved. Again, this deviates from the result of the RFC, where question 1 was the worst candidate.

Fifth, when solely combining *yes or no* questions (ie, question 1—Did you perceive the tinnitus right now?—and question 8—Do you feel irritable right now?), the mobile OS could be predicted correctly for 63.37% of the user assessments. This result also shows that without slider questions, a meaningful accuracy can be achieved.

Sixth, when looking at question-question combinations that include only sliders as answer types, the highest accuracies were achieved by the combination of question 2—How loud is the tinnitus right now? (slider)—and question 7—How much did you concentrate on the things you are doing right now? (slider). Here, an accuracy of 59.86% was achieved. This, in turn, is supported by the result of the RFC.

Seventh, it is remarkable that the overall prediction result with all eight questions is considerably higher than with single questions or combinations of two questions.

Finally, Table 6 represents the confusion table for the SVM calculations. Note that the values are for all eight EMA-D questions of the considered 14,708 Android questionnaires as well as 14,708 iOS EMA-D questionnaires.

Table 5. Prediction accuracies of the support vector machine (SVM) based on the eight dynamic ecological momentary assessment (EMA-D) questions and their combinations.

Question[a] (Q)	Accuracy for each question (Q) combination, %							
	Q1	Q2	Q3	Q4	Q5	Q6	Q7	Q8
Q1	55.69	—	—	—	—	—	—	—
Q2	59.18	55.90	—	—	—	—	—	—
Q3	58.53	56.80	56.61	—	—	—	—	—
Q4	56.37	57.89	58.28	54.07	—	—	—	—
Q5	59.55	61.08	61.31	60.10	57.14	—	—	—
Q6	58.59	57.27	56.35	58.69	62.83	56.28	—	—
Q7	61.24	59.86	59.40	60.19	62.38	59.33	58.80	—
Q8	63.37	62.32	63.57	60.18	61.57	62.67	63.95	58.80

[a] Q1: Did you perceive the tinnitus right now? (yes or no); Q2: How loud is the tinnitus right now? (slider); Q3: How stressful is the tinnitus right now? (slider); Q4: How is your mood right now? (manikins); Q5: How is your arousal right now? (manikins); Q6: Do you feel stressed right now? (slider); Q7: How much did you concentrate on the things you are doing right now? (slider); and Q8: Do you feel irritable right now? (yes or no).

Table 6. Confusion table for the support vector machine (SVM) calculations over all eight dynamic ecological momentary assessment (EMA-D) questions.

Predicted class	Actual class			
	iOS		Android	
	True positives, n	False negatives, n	False positives, n	True negatives, n
iOS	13,002	N/A[a]	1967	N/A
Android	N/A	1706	N/A	12,741

[a] N/A: not applicable.

Importance of Questions

In general, the question emerges as to why some of the eight EMA-D questions are better suited than others to correctly predict the mobile OS. One possible explanation refers to the answering behavior of the users of the two mobile OS types. To illustrate this, Figures 4 and 5 show, as examples, histograms of question 3—How stressful is the tinnitus right now? (slider)—and question 5—How is your arousal right now? (manikins). It is obvious that Android and iOS users answer differently.

Figure 4. Answers to question 3—How stressful is the tinnitus right now? (slider)—and the difference vector of Android and iOS users.

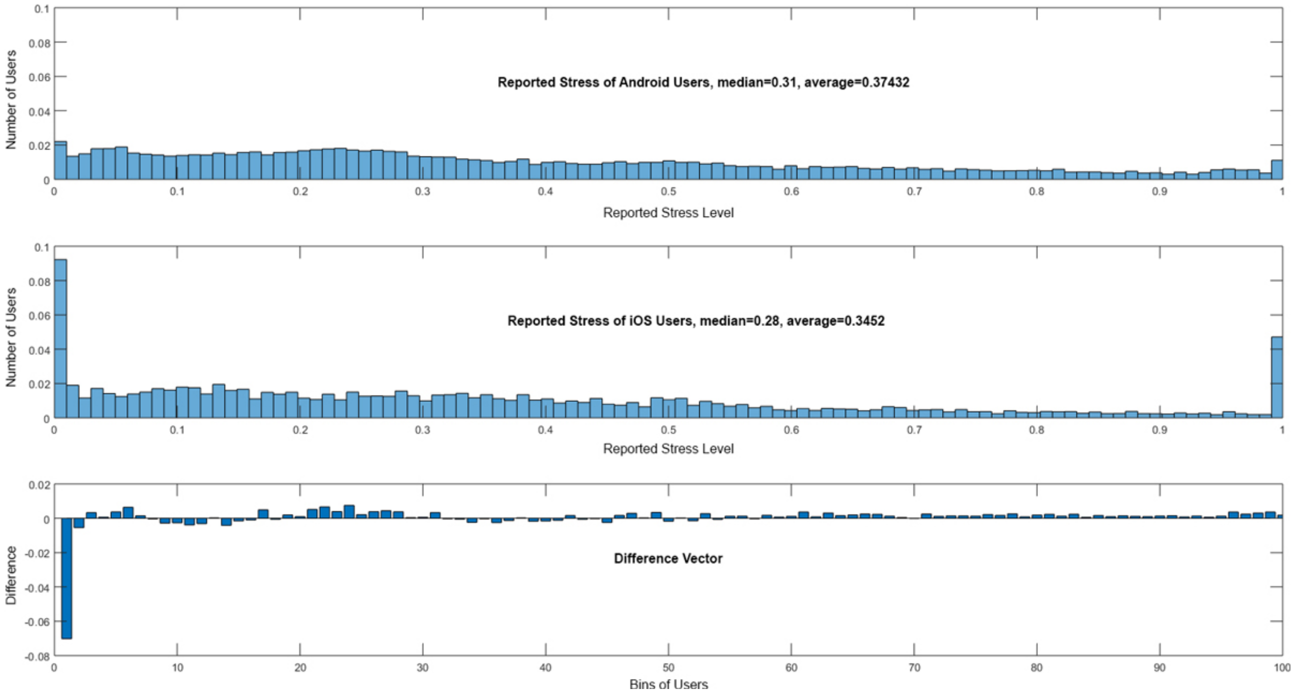


Figure 5. Answers to question 5 "How is your arousal right now? (manikins)" and the difference vector of Android and iOS users.

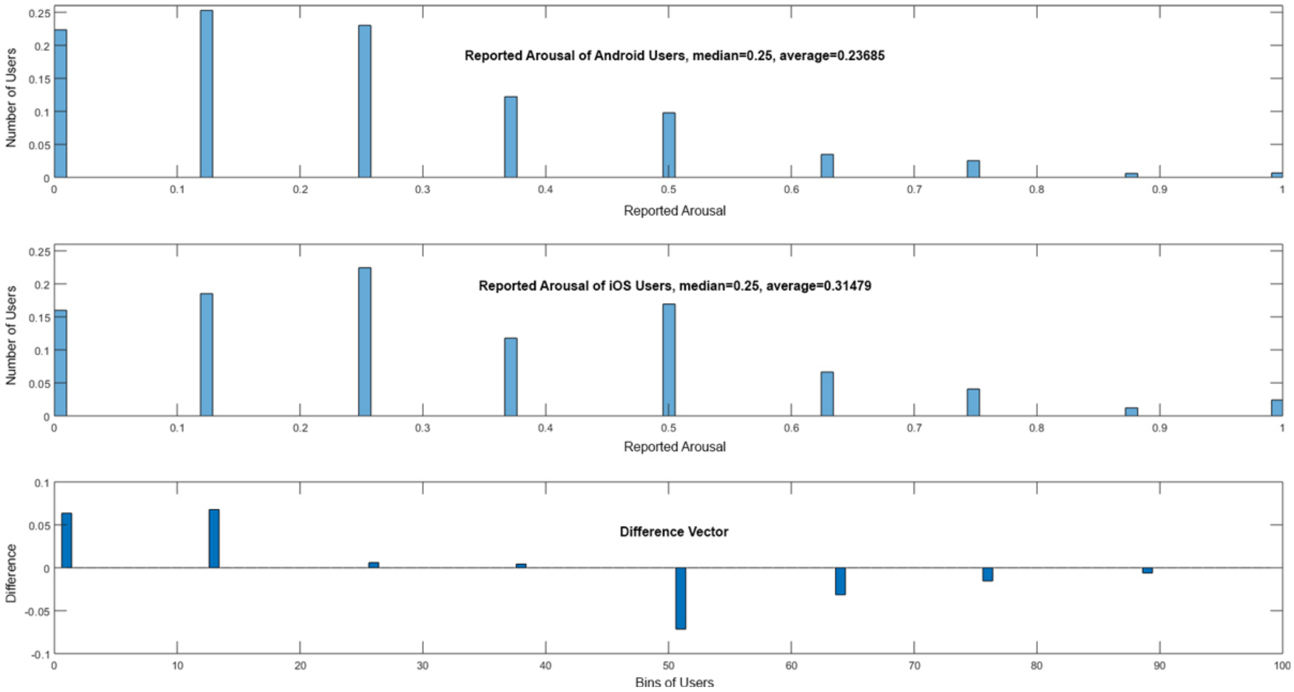

Question 3 and question 5 have been chosen as examples, as they differ in their importance between the machine learning approaches: question 3 is the fourth-most important in SVM versus the third-most important in RFC, while question 5 is the third-most important in SVM versus the sixth-most important in RFC. In addition, other questions are more suitable for the overall prediction. Although they differ and other questions are better, they still show striking differences between assessments from Android and iOS users. To support this result, further consider Figures 6 and 7; they each show data for 100 users in total, distributed among Android and iOS. The data were randomly selected out of the entire dataset. This subset was chosen for the sake of clarity; if all data points were shown, less could be visually observed. In Figure 6, for question 2—How loud is the tinnitus right now? (slider)—in combination with question 3—How stressful is the tinnitus right now? (slider)—shown on the left-hand side of the figure, or question 6—Do you feel stressed right now? (slider)—shown on the right-hand side of the figure, the blue dots show the answers from the Android users, while the red dots show answers from the iOS users. It is striking that Android and iOS users answer differently. Furthermore, in Figure 7, for question 4—How is your mood right now? (manikins)—in combination with question 3—How stressful is the tinnitus right now?

(slider)—shown on the left-hand side of the figure, or question 5—How is your arousal right now? (manikins)—shown on the right-hand side of the figure, the same can be observed. Importantly, Figures 6 and 7 are not representative of the entire dataset, but it is nevertheless notable that Android and iOS users answer differently. Further note that in Figures 6 and 7, we do not illustrate the achieved predictions. Instead, the attained loss is shown (ie, *1-loss* denotes the achieved accuracy). Furthermore, these combinations have been selected as they also show clear differences between Android and iOS assessments, although other questions have higher prediction accuracies.

Figure 6. Support vector machine (SVM) results for question 2 (Q2), combined with question 3 (Q3) and question 6 (Q6), from 100 data entries. Q2: How loud is the tinnitus right now? (slider); Q3: How stressful is the tinnitus right now? (slider); and Q6: Do you feel stressed right now? (slider).

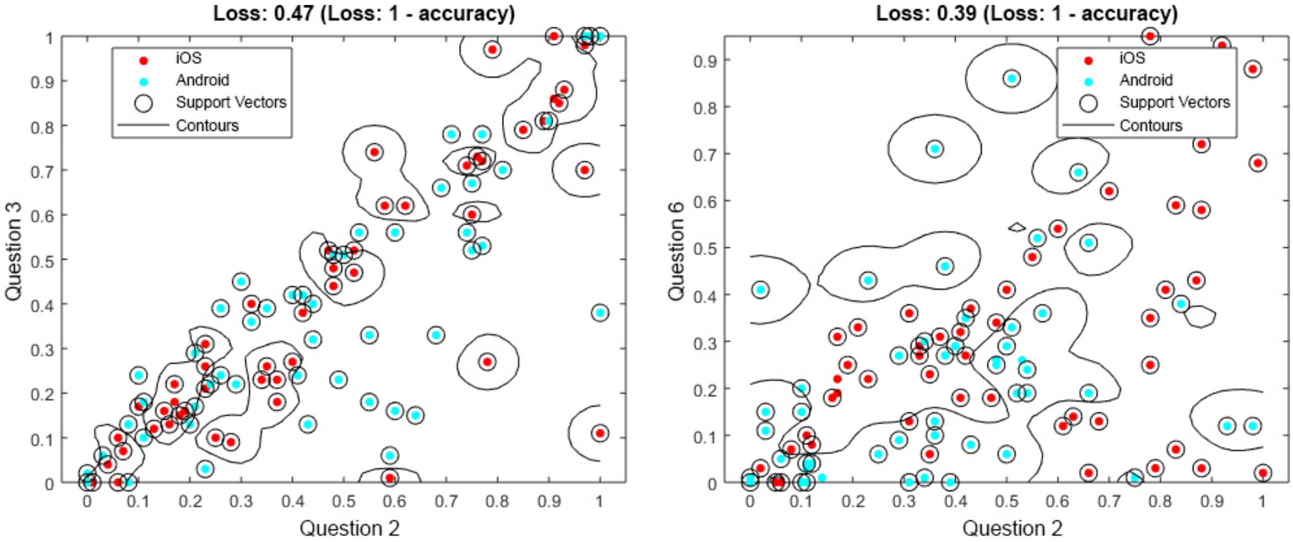

Figure 7. Support vector machine (SVM) results for question 4 (Q4), combined with question 3 (Q3) and question 5 (Q5), from 100 data entries. Q3: How stressful is the tinnitus right now? (slider); Q4: How is your mood right now? (manikins); and Q5: How is your arousal right now? (manikins).

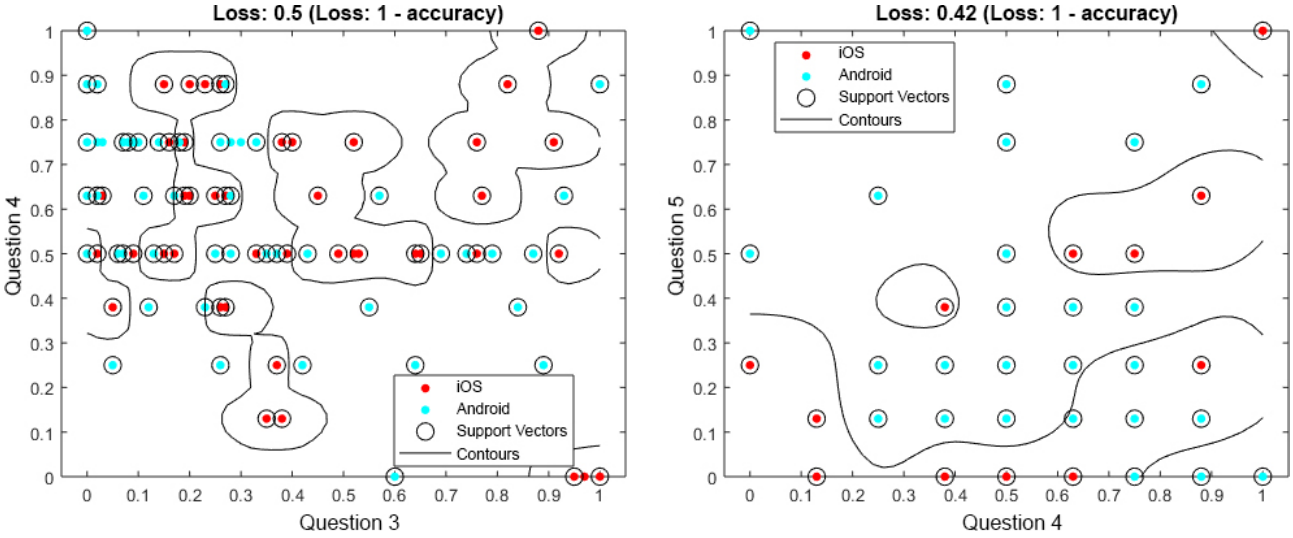

Discussion

Principal Findings

This study evaluated whether it is possible to predict the mobile OS used by respondents for a provided EMA-D questionnaire based on the eight daily tinnitus questions included in the questionnaire, which was administered via TYT. Although the applied machine learning approaches showed different prediction results, in general, the achieved accuracies indicate that the mobile OS is a confounder that must be further considered. This confirms the investigated research question. We are able to predict the mobile OS used with high accuracy based on the dynamic daily assessment data. Compared to Pryss et al [12], the users' ages were no longer different between Android and iOS users, which might be explained by the selection of the sample for this study: only users with more than 10 completed EMA-D questionnaires were selected. In addition to our prior works [12,14], this study shows that the mobile OS not only reveals insights into the tinnitus characteristics of the users, but it is possible to predict the mobile OS based on the provided daily TYT data. On top of this, widely used machine learning approaches with commonly used frameworks and without parameter tuning are able to predict the mobile OS with high accuracy. Note that the RFC achieved the highest prediction result of 78.94%, with default parameter settings using Python scikit-learn. In this context, question 7—How much did you concentrate on the things you are doing right now? (slider)—of the EMA-D questionnaire, which measures the concentration level of a TYT user at the moment, has especially revealed a high accuracy for the RFC prediction. In summary, four important results were found. First, the research question can be answered positively. We are able to predict the mobile OS used for a given EMA-D questionnaire with high accuracy using machine learning methods. Second, the prediction is possible with well-known machine learning methods and frameworks without parameter tuning. Third, machine learning indicates promising results on the EMA-D from TYT users. Therefore, this result should be exploited for further analyses. Fourth, when using mobile devices to collect clinically relevant data, the mobile OS used might be a confounder. Therefore, this information should be collected for each measurement and could be a relevant covariate in data analyses.

Strengths and Limitations

In general, as a strength of this work, it could be shown that the technical peculiarities of different mobile OS types must be considered for the collection of clinically relevant data. As another positive aspect of this work, it could be shown that the types of answers for the questions do not necessarily indicate that a particular answer type, such as a slider, is used a priori with a bias. Otherwise, sliders or any other answer type would be more important than others. In general, we aimed at technically implementing TYT in a way that made sure the questionnaires looked identical on Android and iOS devices as well as having no default setting [11,28,29]. Despite this way of implementing the questionnaires visually, a potential bias cannot be excluded. Therefore, further investigations are required. For example, the sliders on Android and iOS have different numbers of decimal places. On Android, only 2 decimal places are stored, while on iOS, more than 2 decimal places are stored. For the investigation in this paper, the scales of all sliders were harmonized, but such differences must also be further investigated.

For the aspect of whether EMA-D can be used to predict not only the TYT assessments but the TYT users in general, we are conducting another study, in which we investigate whether we are able to predict the mobile OS used on the user level instead of on the assessment level. However, such investigation requires many more considerations. For example, how can we ensure that the training dataset users have similar characteristics as the users for which we apply the trained classifier? Note that such an investigation requires efforts regarding the frameworks used and their provided features.

Conclusions

This work has shown opportunities on one hand and limitations on the other. A particular strength of this study is that TYT has a unique dataset, which is able to comprehensively compare Android and iOS OS types in a medical context. However, the different results between different machine learning approaches showed that it is difficult to predict which questions and answer types are, in general, appropriate for predictions. If a new platform shall be realized and one goal of the platform constitutes using machine learning methods for a prediction, this analysis has not revealed general guidelines that can be followed. Thus, these results can only be seen as a particular outcome for TYT. In addition, when gathering additional contextual information from the TYT users, such as geospatial data, new investigations become possible. In a recent work [27], for example, we investigated geospatial data of mobile crowdsensing users and whether their movement behavior could be a predictor for their current stress situation. As this work also revealed promising results, in the next version of TYT, GPS data can be gathered while filling out the EMA-D questionnaire, if a user allows this measurement.

In future work, we will further address the following three aspects. First, more studies must confirm the results of this work. Second, the results of TYT must be compared to other similar EMA datasets in order to confirm the results between different scenarios. Third, we need to conduct this study again based on the user level instead of on the assessment level.

However, if future work can confirm the presented results, then the combination of EMA, mobile crowdsensing, and machine learning seems to be a worthwhile research endeavor. Nevertheless, we are far from using the results of this work in clinical practice. On the other hand, together with already-revealed medical insights on TYT [6,37-40], the results of this work show that new opportunities are possible in the broader EMA and mobile crowdsensing contexts. In particular, EMA data that were gathered by mobile devices, as well as the crowdsensing paradigm, seem to be promising targets for the application of machine learning algorithms.

Abstract

Background: As user modification can alter the addictiveness and toxicity of electronic nicotine delivery systems (ENDS), more research is needed to understand the types, motivations, risks, and information sources that lead to these product alterations. YouTube has been identified as a major platform where ENDS users obtain and share information about ENDS products and modifications. However, a comprehensive study of ENDS modification videos on YouTube is lacking.

Objective: This study aimed to analyze the content of YouTube videos depicting modifications of ENDS.

Methods: YouTube was searched in March 2019 to identify videos depicting ENDS modifications. Search terms were derived from interviews with ENDS users and current literature. We used 28 search phrases that combined the words vape and vaping with modification-related key terms (eg, custom build, modification, and dripping). The final sample included 168 videos.

Results: Videos were 1 to 108 min long (median 9.55). Presenters were largely male (117/168, 69.6%), white (94/168, 56.0%), and older than 25 years (94/168, 56.0%). Most videos gave *how to* instructions (148/168, 88.1%), but few offered warnings (30/168, 17.9%) or mentioned commercial alternatives to modifications they presented (16/168, 9.5%). The ENDS devices most often featured were drippers (63/168, 37.5%) and refillable tanks (37/168, 22.0%). The most often modified ENDS components were coils (82/168, 48.8%) and e-liquids (34/168, 20.2%), which included adding other substances, such as cannabis, to the e-liquids (6/168, 3.6%). Most videos portrayed ENDS modifications positively (106/168, 63.1% positive; 60/168, 35.7% neutral; and 2/168, 1.2% negative) and were either neutral or positive in their overall portrayal of ENDS devices (78/168, 46.4% positive; 89/168, 53.0% neutral; and 1/168, 0.6% negative).

Conclusions: This study identified several concerning trends in popular YouTube videos on ENDS modifications, including lack of warnings, the addition of marijuana derivatives to e-liquids, and the positive portrayal of ENDS devices and modifications. By identifying the types of modifications (coil and e-liquid being the most prevalent), this study sets an agenda for research on the effects of modifications.

(J Med Internet Res 2020;22(6):e17104) doi:10.2196/17104

KEYWORDS

ENDS modifications; YouTube; coils; e-liquid; vaping

Introduction

Background

Since the mid-2000s, electronic nicotine delivery systems (ENDS) have become an increasingly popular method for inhaling nicotine from tobacco in the United States [1]. As a category, ENDS include a wide variety of products consisting of a battery, a heater (coil), a mouthpiece, and a chamber containing e-liquid (a solution of propylene glycol [PG] or vegetable glycerine [VG] and other chemicals, usually nicotine and flavors). The heater vaporizes the e-liquid, producing an aerosol that is inhaled. ENDS can also be called vapes, e-hookahs, and e-cigarettes. Since June 2019, an outbreak of lung disease linked to vaping and the use of ENDS has sickened 2506 and killed 54 people [2]. Although this outbreak is ongoing, the US Centers for Disease Control and Prevention urges ENDS users not to modify the products or add substances not intended by the manufacturer, highlighting the potential role ENDS modifications might play in this outbreak [3]. For this study, we define *modification* as both product misuse and tampering unintended by the manufacturers as well as alteration, customization, adjustment, and user choice of e-liquid or accessories made within manufacturer specifications. Examples of ENDS modifications include coil replacement, mixing of e-liquids, or increasing battery voltage. Although some users view the modifiability of ENDS devices as a positive attribute [4,5], research has found that modifications can have harmful effects, such as creating higher levels of toxic emissions when users increase power to the coil [6-8]. Given the popularity of ENDS and health risks from modification, research is needed to understand the primary ways ENDS are modified by users.

To date, little research has described the methods of ENDS modifications. YouTube is the most popular video-sharing site in the world [9], and there are a large number of ENDS videos on YouTube [10], including videos about ENDS modifications [11]. YouTube has been identified as a major platform where ENDS users obtain and share information about ENDS products and modifications [12-14]. However, a comprehensive study of ENDS modification videos on YouTube is lacking. One recent study examined YouTube videos depicting orthodox (intended by manufacturer) and unorthodox (unintended by the manufacturer) ENDS modifications [11]. Results showed that videos depicting unorthodox use were three times more prevalent than videos depicting orthodox use, although the analysis only focused on open devices and e-liquids and not on closed devices [11]. Furthermore, the sample was collected in 2016 and may not account for recent trends in ENDS modification. A more in-depth study is needed to update and assess the breadth of ENDS modifications on YouTube.

Objectives

In this paper, we examined YouTube videos posted between 2013 and 2019 showing modifications of ENDS devices pertaining to hardware (eg, coil, battery, pods, and other modifications) and e-liquids. Our objective was to understand the video features (including presenter characteristics, if applicable) as well as the types, motivations, communication of risks, and information sources of ENDS modifications. Although other studies have examined the social acceptability of ENDS on YouTube [15], unorthodox use of ENDS on YouTube [11], and promotion of vape tricks on YouTube [16], this study, to the best of our knowledge, is the first to analyze modifications to the full spectrum of ENDS devices on YouTube.

Methods

Identifying Electronic Nicotine Delivery Systems Modification Videos

YouTube was searched on March 15, 2019, to identify videos depicting ENDS modifications. An account was created on an incognito (private) browser to ensure browsing history did not influence the results. Search terms were derived from interviews with ENDS users [14] and the current literature [10] indicating that “vape” and “vaping” are common and inclusive terms used by ENDS enthusiasts to describe a number of different ENDS devices. Search phrases included the following: “vape DIY (ie, do it yourself),” “vape build DIY,” “vape custom build,” “vape modification,” “vape rebuild DIY,” “vape coil rebuild,” “vape coil DIY,” “vape ohm rebuild,” “vape ohm DIY,” “vape e-juice DIY,” “vape e-juice custom build,” “vape voltage DIY,” “vape voltage custom build,” “vape RBA (ie, rebuildable atomizer) custom build,” “vape RBA DIY,” “vape dripping custom build,” “vape dripping DIY,” “vape refill custom build,” “vape refill DIY,” “vaping custom build,” “vaping DIY,” “vaping modif* custom build,” “vaping rebuild DIY,” “mods rebuild DIY,” “vape chang* DIY,” “vape chang* custom build,” “vape wattage DIY,” and “vape wattage custom build.” Search terms were entered into the YouTube search engine, and the top 10 results for each phrase were included (N=280). After removing duplicates, non-English videos, and those not presenting ENDS modifications, 207 videos remained. Each video was reviewed by trained coders to ensure that the content included ENDS modifications. This verification process excluded 39 videos, resulting in a final sample of 168 videos. This study was approved by the Georgia State University Institutional Review Board (H19055).

Coding Scheme

We developed a codebook based on interviews with ENDS users [14], previous literature [10,15], and expert consensus. By expert consensus, we refer to review by our interdisciplinary team of collaborators with substantial expertise in ENDS use behavior and ENDS product research. We collected information on the attributes of the videos (eg, length, number of views, number of likes and dislikes, and date of posting). We coded the video source as individual, retailer, manufacturer, or group or organization. We noted whether the videos included links to vendors, whether the videos were followed by other modification videos via YouTube’s auto-play feature (ie, showing content based on user search history), gave *how to* instructions, included a warning (a warning statement about the health risks of smoking or a formal, legal, or conflict of interest disclaimer), or offered information about commercially available alternatives to modifications. If a person appeared in the video, we recorded if it was a single presenter or multiple presenters and their sex (male or female), race (white, black, other, or cannot be determined), and estimated age range (youth: younger than 18 years, young adult: approximately 18-25 years, or adult: older than 25 years). We classified the device(s) featured in the video as dripper, refillable tank, closed pod, refillable pod, home-built refillable tank, cig-a-like, squonk, 2-pod systems, and stem/salt hybrid [17]. Definitions for ENDS devices are provided in Table 1. If multiple devices were shown in a single video, all devices, regardless of their prominence, were included in the coding.

Table 1. Content codes for electronic nicotine delivery systems devices (N=168) and the percentage and number of videos in the final sample that featured each device type.

Device type	Definition	Value, n (%)
Dripper	These devices do not include a tank but do include a tip, coil, wicks, battery housing, battery, and fire button. There is no e-liquid reservoir—e-liquid is squirted directly on to the coil housing or *deck* and heated up as soon as the fire button is pressed. They are intended to be taken apart and put back together, which makes them an open system. Some or most of the device has been hand-built, with some parts being retrofitted from existing commercially produced devices.	63 (37.5)
Refillable tank	A commercially produced refillable tank system, which features, at minimum, a tip, a glass tank, a coil, a battery unit, and a fire button. The tip, tank, coil, and batteries can be removed, and the tip, tank, coil, and battery unit can be easily separated from each other and reconnected, which makes it an open device. For commercially produced devices, the battery unit is shaped either like a rectangular box (box mod) or like a cylinder (vape pen).	37 (22.0)
Closed pod	A commercially produced closed pod system with a single pod that cannot be refilled, such as a Juul. These are typically small, thin, rectangular boxes about the shape of a 4-inch long USB drive. However, some may also be parallelogram, square, or teardrop shaped.	7 (4.2)
Refillable pod	A commercially produced closed pod system with a single pod that can be refilled. These are similar to closed pod systems, except that the pods include a small port that allows the e-liquid reservoir to be refilled. Refillable pod devices with only 1 pod usually use salt nicotine (higher concentration and lower wattage).	5 (3.0)
Home-built refillable tank	A home-built device featuring a refillable tank that is not commercially produced. They are intended to be taken apart and put back together, which makes them an open system. Some or most of the device has been hand-built, with some parts being retrofitted from existing commercially produced devices. Home-built parts may include a tip, battery housing, and fire button. Retrofitted parts may include a tip, tank, coil, electronics, and batteries.	4 (2.4)
Cig-a-like	A commercially produced device designed to look like a combustible cigarette in size, shape, and color (sometimes including a brown/tan filter tip). However, it is entirely electronic and includes a battery, a small e-liquid reservoir, and an atomizer. Some are not rechargeable, nor can they be taken apart but are intended to be disposed of once the e-liquid has been used up. Others are rechargeable and have replaceable pods.	4 (2.4)
Squonk	A squonker, also known as squonk mod, is a type of dripper. Like drippers, they include a tip, coil, wicks, battery housing, battery, and fire button. There is, however, a small e-liquid reservoir made out of a pliable material such as silicone, which can be refilled. The e-liquid reservoir is accessible through a hole or window in the device, which allows the reservoir to be compressed. Compressing the reservoir squirts e-liquid directly on the coil, which heats it up as soon as the fire button is pressed. Squonks are only commercially produced and typically look like small box mods without the tank on top of the mod, but with the e-liquid reservoir visible and accessible through a small window on the side.	4 (2.4)
2 pod systems	Devices that include 2 pods of the same type and 2 receptors that can be swapped. This allows the device to provide vapor with 2 distinct flavors as well as vapor that blends the 2 flavors.	0 (0.0)
Stem/salt hybrid	A hybrid that includes 2 refillable pods each with its own receptor on the device. One is intended for salt nicotine e-liquid (higher concentration/lower wattage) and the other is for *stem* nicotine, that is, typical e-liquid (lower concentration of nicotine, if at all/higher wattage). Each pod can only fit into 1 receptor on the device, and they cannot be swapped with the other receptor.	0 (0.0)
Multiple devices	Several devices are featured.	7 (4.2)
Other	Device featured is another product not listed or unsure of the product type.	15 (8.9)

We developed a coding scheme to capture ENDS modifications to the coil, e-liquid, battery, pods, and other modifications. For each type of modification, we developed codes for common reasons for this modification, including an *other* option with text descriptions. Each modification was coded as 1 (present) or 0 (absent). The detailed codes with descriptions for modifications and reasons are presented in Table 2.

Finally, we coded the video's tone toward the featured ENDS modification and ENDS devices in general as positive, neutral, or negative.

Table 2. Codes and definitions of modifications and reasons for modifications (N=168).

Code	Definition	Value[a], n (%)
Coil modification		
Coil build	Building the coil	60 (35.7)
Replacing coil	Replacing existing coil with a different coil from the manufacturer	9 (5.4)
Coil voltage	Altering the voltage of the existing coil through controls built into the device by the manufacturer	8 (4.8)
Number of coils	Altering the number of coils in the device	1 (0.6)
Coil gauge	Explicitly replacing an existing coil with a coil that is a different gauge wire	3 (1.8)
Pod coil	Cleaning the coils built into the pods/closed systems	2 (1.2)
Other coil modification	Other type of coil modification	35 (20.8)
Reasons for coil modification		
Increased voltage	To increase the voltage of the heating coil	9 (5.4)
Other	Other reasons for coil modification	31 (18.5)
E-liquid modification		
E-liquid mixing	Mixing e-liquid includes making your own e-liquid from standard components (any of PG[b], VG[c], nicotine, flavors, etc) or altering bought e-liquid with any of these components (adding flavors and changing PG/VG ratio)	20 (11.9)
E-liquid concentration	Replacing e-liquids with different levels of nicotine concentrations	3 (1.8)
Adding substances	Adding other substance (eg, cannabis oil) or replacing e-liquids with other substances	6 (3.6)
Other e-liquid modification	Other type of e-liquid modification	13 (7.7)
Reasons for e-liquid modification		
Flavor	To enhance flavors in e-liquid	16 (9.5)
Cost	To save money/reduce the cost of manufactured liquid	10 (6.0)
Other	Other reasons for e-liquid modification	15 (8.9)
Battery modification		
Replace battery	Replacing a battery with a battery with different properties	0 (0.0)
Battery configuration	Changing battery configuration, either in series or in parallel	0 (0.0)
Additional battery	Attaching additional batteries	0 (0.0)
Other battery modification	Other modification to battery	13 (7.7)
Reasons for battery modification		
Increased power	To increase the power of the existing tank device	0 (0.0)
Other	Other reasons for battery modification	4 (2.4)
Pod modification		
Pod refilling	Refilling pods with e-liquids	9 (5.4)
Reasons for pod modification		
Extend life	To extend the life of a pod/cartridge	4 (2.4)
Other	Other reasons of modifications to closed pod	7 (4.2)
Other modification		
Modifying controls	Modifying software regulating controls	2 (1.2)
Improved features	Replacing existing device with another device with improved features	1 (0.6)
Additional features	Replacing existing device with another device with additional features	3 (1.8)
Other	Other types of modification that are not listed above	22 (13.1)

[a] The number of videos and the percentage in the final sample with each code present.

[b] PG: propylene glycol.

[c] VG: vegetable glycerin.

Video Coding

The coding team consisted of 5 members, who received a minimum of four 2-hour training sessions. The coders coded 5 to 10 videos for each training session, and discrepancies were discussed and resolved. Training videos were not included in the final data analysis because the code book was further revised during the training. To establish intercoder reliability, approximately 15% of videos (25/168, 14.9%) were randomly selected from the final sample. Due to the large amount of time spent to code each video, sequential-overlapping coding was used for reliability testing [18]. Specifically, each of the 25 videos was coded by 2 coders, and each coder coded 10 videos in total. Using Randolph's free-marginal kappa [19,20], the intercoder reliability of each variable was high, ranging from 0.74 to 1.0. The remaining videos were then divided and independently coded by 4 coders.

Data Analysis

Data were analyzed using IBM SPSS 25. Descriptive statistics were performed to assess the frequency of each coding variable.

Results

Characteristics of Videos, Presenters, and Device Types

Videos (N=168) ranged from 1 to 108 min in length (median 9.55) and accounted for a total of 112,043,718 views (median 168,234) as of March 15, 2019. Videos had more *likes* than *dislikes* (12 to 1 ratio). Examining videos by year showed an increase from 2013 (2/168, 1.2%) to 2014 (19/168, 11.3%), to 2015 (27/168, 16.1%), to 2016 (34/168, 20.2%), peaking in 2017 (51/168, 30.4%), and decreasing from 2018 (29/168, 17.3%) to 2019 (6/168, 3.6%). The most common source for videos were individuals (135/168, 80.4%), followed by retailers (18/168, 10.7%), manufacturers (8/168, 4.8%), and groups/organizations (7/168, 4.2%). A majority of videos (120/168, 71.4%) provided a link to a vendor's site, and most videos (136/168, 81.0%) were followed by another modification video via auto-play. Most videos gave *how to* instructions (148/168, 88.1%); few videos offered warnings (30/168, 17.9%) or mentioned commercially available alternatives (16/168, 9.5%).

Most videos showed 1 or more persons (125/168, 74.5%), and presenters were largely male (117/168, 69.6%), white (94/168, 56.0%), and appeared to be adults older than 25 years (94/168, 56.0%). Modifications were most frequently performed on drippers (63/168, 37.5%) and refillable tanks (37/168, 22.0%; Table 3).

Table 3. Modification by device type.

Device type	Coil[a], n	E-liquid[a], n	Battery[a], n	Pods[a], n	Other[a], n
Dripper	38	7	6	0	3
Refillable tank	28	3	2	0	3
Home-built refillable tank	0	0	2	0	1
Closed pod	0	4	0	6	0
Refillable pod	0	2	0	1	0
Cig-a-like	0	4	0	2	0
Squonk	2	0	0	0	3
Stem/salt hybrid	0	0	0	0	0
Two-pod system	0	0	0	0	0
Multiple devices	3	1	1	0	3
Other	5	1	2	0	9
Total	76	22	13	9	22

[a] Each cell shows the number of videos with each modification. If a video showed a specific modification, the video was coded as 1. Videos coded as 1 include single modifications (eg, building a coil from scratch) or multiple modifications (eg, removing coil, cleaning coil, and rewrapping coil).

Coil Modifications

Modifications to the coil were the most frequently portrayed; building coils from scratch was featured in 35.7% (60/168) of the videos. Coil replacement with a manufactured alternative was depicted in 5.4% (9/168) of videos, and 4.8% (8/168) of the videos showed how to alter coil voltage through controls in the device. Less than 0.6% (1/168) of the videos gave instructions on how to alter the number of coils in the device, and 1.8% (3/168) showed how to replace coils with a wire of different gauge. Only 1.2% (2/168) of the videos showed how to clean the coils in a nonmodifiable pod.

Reasons for modifying in many of the coil videos (31/168, 18.5%) were not in the prespecified list. Among these reasons, building coils from scratch (17/168, 10.1%) and enhancing flavor (6/168, 3.6%) were the most commonly described.

Building coils from scratch included home builds (necessitating a new coil) and adding coils in store-bought devices. According to the presenters, enhancing flavor can be achieved by changing the wire gauge (eg, 28 vs 24 gauge), wire composition (eg, nickel vs stainless steel), or number of wire wraps. Increasing voltage was also listed as a reason for modifying coils (9/168, 5.4%).

The most viewed coil modification video (3,017,588 views) shows a presenter instructing the audience on how to build a sleeper coil (ie, double-wrapped coil made from a single wire). The tutorial includes instructions on how to wrap the coil and attach it to the battery posts. The *how to* portion is book-ended by discussion and demonstration of the modification. Before the tutorial, the presenter describes how the sleeper coil heats e-liquid efficiently, producing a greater cloud and better flavor. After the tutorial, the presenter vapes to demonstrate the size of his aerosol cloud, presumably the result of the sleeper coil.

Modifications of E-Liquids

Modifications of e-liquids were depicted in 20.2% (34/168) of videos. Many of the e-liquid modification videos showed mixing (20/168, 11.9%; eg, mixing store-bought glycol). Separately, 1.8% (3/168) of videos included mixing liquids to increase nicotine levels. Adding other substances (eg, cannabis oil) was found in 3.6% (6/168) of videos.

Enhancing flavor (16/168, 9.5%) and saving money (10/168, 6.0%) were reasons given for e-liquid modifications, as were *other* reasons (15/168, 8.9%). Descriptions of other reasons included creating better clouds, making nicotine-free liquid, and creating marijuana e-liquid. Overall, e-liquid modifications centered on allowing users to control the flavor, price, and composition of e-liquids.

The most viewed e-liquid mixing video (1,769,171 views) shows how to make e-liquids with store-bought materials. The presenter's face is not shown, although the video is narrated. The presenter describes 4 components necessary to make e-liquid: VG, PG, premixed liquid nicotine (75% VG and 25% PG), and store-bought flavoring (eg, strawberry and banana). Before mixing the components, the presenter uses a web-based e-liquid calculator. The calculator uses batch size, nicotine strength (mg/ml), and VG/PG ratio to calculate the mixing recipe. However, the calculator does not account for the addition of flavor. Therefore, the presenter explains the conversion necessary to add these liquids. At the completion of the conversion, the presenter combines the liquids in a cylinder and then attaches a clamp to a power drill, wraps the clamp fingers around the cylinder, and engages the drill, spinning the cylinder and mixing the liquids within. The liquid is then *steeped* in warm water to allow the ingredients to blend together. The video closes by encouraging viewers to document mixes in a spreadsheet.

The most viewed *adding substances video* (717,781 views) gives a tutorial on how to make *weed e-cig juice*. The presenter bakes marijuana on a cooking sheet, breaks it apart by hand, and mixes it with VG. After 3 months of iteratively adding glycerin and remixing the solution, the presenter strains marijuana-infused glycerin through a mesh and then injects the liquid into an ENDS tank. The video closes with the presenter blowing vapor clouds over an advertisement for marijuana accessories. Among the *adding substances* videos, most (5 of 6) focused on adding marijuana derivatives to e-liquids.

Battery Modifications

No videos showed modifications to increase battery power, change configurations, or add additional batteries. The only videos coded for battery modifications were those in the *other battery modification* category (13/168, 7.7%), which showed variations of adding batteries to home-built devices. Examining descriptions for the *other* category showed that all entries were home builds, either adapting household items (eg, a flashlight) or using commercially made parts. Adapting household items to create a vape involved a premade battery, whereas building from scratch sometimes required wiring batteries. This distinction could indicate differences in battery modification hazards.

The most viewed (1,645,630 views) battery modification video transforms a flashlight into an ENDS device. The presenter does not address the audience, but text is displayed to highlight important steps. In the video, the presenter disassembles a flashlight and uses the parts as well as household materials to create a small vape. The body of the flashlight is retrofitted to hold a battery and the head with an atomizer (ie, a coil and wick attached to battery posts housed on a deck). The flashlight button engages the battery, heating the coil and producing a stream of vapor from the atomizer. The battery does not require wiring and appears to be a standard battery consistent with those used in any flashlight.

Other battery videos, however, depict more advanced constructions. One example (763,291 views) shows how to build a *box mod*, which is a highly modifiable ENDS device characterized by a removable atomizer, open tank, and accessible battery housing. The presenter walks the audience through the build, which includes wiring of 2 lithium polymer batteries (ie, LiPo) into the device. LiPos are lightweight batteries that can explode if they are overcharged. Such explosions have been linked to injury of ENDS users [21]. The presenter warns viewers not to let battery wires touch during construction. However, the breadth of the hazard is not disclosed, and the video contains no warnings about the danger of explosions.

Modifications of Pods and Cartridges

A pod is a cartridge containing e-liquids to be inserted in an ENDS device. When the liquid is gone, many manufacturers intend that the cartridge is discarded and not reused (although there are some refillable pods on the market). Refilling nonreusable pods with e-liquid was found in 5.4% (9/168) of videos. The primary reasons for pod modifications (7/168, 4.2%) were not in the specified list, and thus, they were coded as other. Descriptions of *other* reasons included customizing the look of devices, increasing vapor production, and enhancing flavor. Extending the life of a pod was listed as a reason for 2.4% (4/168) of videos.

An example of pod modification (182,621 views) depicts a presenter changing the liquid in a nonreusable pod. In the video, the presenter uses scissors to open the cartridge. The presenter pours the liquid into another container, cleans the pod, and then refills it with an e-liquid called *Heisenberg* (fruit-flavored menthol). After the refill, the presenter takes several drags until the tobacco flavor is gone, and only Heisenberg remains. In this case, the pod modification is motivated by the choice of the flavor.

Other Modifications

Only 1.2% (2/168) of videos showed modifications to the software regulating built-in controls. Replacement of an existing device with another with improved features was found in 0.6% (1/168) of videos, whereas replacing an existing device with another device with additional features was featured in 1.8% (3/168) of videos. Although drippers were the most featured devices (63/168, 37.5%), our analyses did not show any instances of converting nondripping devices to drippers.

Finally, 13.1% (22/168) of videos did not fit within our specified coding categories and were coded as *other* modifications. These videos showed building ENDS as the primary activity. Several videos depicted unusual builds, such as creating a vape from an empty mint box or adapting a soda can into an e-liquid tank. One unique example (66,573 views) showed how to build an ENDS in the dashboard of a car. Other videos showed how to make *drip tips* to replace lost mouthpieces for drippers. In one example (85,006 views), the mouthpiece was made from a copper plumbing fitting. Together, videos coded as *other* showed unique modification behaviors mostly related to building from scratch.

Tone

Most videos used a positive tone to portray ENDS modifications (106/168, 63.1% positive; 60/168, 35.7% neutral; and 2/168, 1.2% negative) but were either neutral or positive in their portrayal of ENDS devices (78/168, 46.4% positive; 89/168, 53.0% neutral; and 1/168, 0.6% negative).

Discussion

Principal Findings

This study provides information about the ways in which users modify ENDS devices on YouTube. Results identified several concerning trends, including lack of warnings, addition of marijuana derivatives to e-liquids, and the positive portrayal of ENDS devices and modifications. Regarding specific modifications, the most often modified components were coils and e-liquids. Modifications to the wick and battery were less often discussed. The sample of modification videos did not depict potentially harmful practices identified in past literature, such as modifying a device for *dripping* or increasing battery power. Together, these results help inform public health researchers by identifying trends in ENDS modifications on YouTube, the most popular video-sharing website in the world [9] and a primary source of information on ENDS devices and modifications [11,15,16].

Our findings identified several concerning trends in modification videos. Specifically, the majority of videos gave *how to* instructions without warning viewers about potential dangers (eg, exploding batteries or lung exposure to harmful constituents). The majority also failed to mention commercially available alternatives, which could be less dangerous than home-grown modifications. ENDS devices and modifications were also depicted in a favorable light, and a majority of videos were followed by another modification video, likely the result of YouTube's default auto-play feature, which queues similar content based on search history. In a situation where YouTube users search for ENDS modifications, favorable portrayals and lack of warnings, coupled with auto-play features, could potentially create a self-reinforcing loop where users search for modification videos. The dangers of modifications are underemphasized to viewers, and these videos are followed by additional videos portraying ENDS in a favorable light, further underemphasizing the dangers of modification. Repeated, user-driven exposure to videos underemphasizing risks could normalize ENDS modifications, which is of particular concern given YouTube's primary audience.

YouTube is the most popular video-sharing site in the world [9], and YouTube has been identified as a major platform where ENDS users obtain and share information about ENDS products and modifications [12-14]. Many YouTube users are young, with 81% of those aged 15 to 25 years in the United States using YouTube [22]. This demographic is often targeted by tobacco companies [23,24] and is a group that often experiments with cigarettes and ENDS [25]. Positive portrayals of modifications without safety warnings, which are algorithmically linked and shown in sequence to impressionable audiences, bear serious consideration from tobacco control experts. Future research may explore how YouTube modification videos could potentially detract from nicotine cessation campaigns aimed at youth and young adults.

Altering the coil was the most prevalent type of modification in our study. Little research has investigated the effects of exposure to the components of coils on user health. One notable study tested e-liquids for neurotoxicants before and after contact with ENDS devices [26]. Results showed higher levels of toxic metals in the aerosol, suggesting that the contamination resulted from the contact of e-liquids with the metals in ENDS devices, including coils. As coil modifications were most prevalent in our analysis, we suggest future research investigating possible health effects of coil modifications.

E-liquid was the second most often modified characteristic in our sample. E-liquid modifications included mixing from scratch and adding other substances. In terms of mixing, most videos cited a desire to control the flavor as a reason for the modification. This finding is informative given the recent interest among policy makers to ban flavored e-liquids from the market [27]. Regulatory policy should consider how regulating ENDS flavors might influence the likelihood that these actions will impact the frequency at which consumers mix their own flavored e-liquids.

Marijuana derivatives were used in most videos depicting substances added to e-liquids. This finding is significant given the recent outbreak of vaping-related lung disease [28]. Early investigation revealed that the majority of patients had a history of vaping tetrahydrocannabinol (THC) products, suggesting that the outbreak may be related to the source of THC or vaping THC in a device intended to be used with nicotine [29]. Given the deadly nature of the new vaping lung disease, this particular modification may demand greater scrutiny from public health experts.

Tampering with devices to expose heating coils for dripping has been cited as a modification trend in past research [30]. Yet, none of the videos in our sample showed how to adapt a nondripping device into a dripper. This finding resonates with recent interviews of ENDS enthusiasts, indicating that dripping modifications may be less frequent due to increased availability of commercially produced drippers and other devices that were previously only available via users' modifications [14]. However, it should be noted that drippers were the most featured devices in YouTube videos. Thus, although dripping conversions were absent in our sample, modifications to drippers were frequent.

Although exploding batteries are a risk [6], we found only a few videos on battery modifications. They were generally associated with building ENDS mods from scratch and showed some dangerous practices (eg, wiring LiPo batteries) that have not been widely discussed previously.

Limitations

As this sample was collected in early 2019, it is unclear if the decline in videos on ENDS modifications we observed since 2017 will continue. Although this decrease corroborates our findings from interviews with ENDS enthusiasts [14], more research is needed to determine if this decrease continues. As this study was conducted before the first cases of e-cigarette– and vaping-associated lung injury were reported, we do not know what impact this outbreak may have had on ENDS modification activities. Our search keywords were not exhaustive and may not capture all ENDS modification videos on YouTube. Due to the variation of ENDS modification videos, our results are descriptive. More research is needed to isolate and identify causal mechanisms that motivate modification behaviors. This work informs future population-level surveillance research aimed at identifying motivations for modifying ENDS devices.

Conclusions

Our content analysis of the full spectrum of ENDS devices and modifications in YouTube videos identified several concerning trends, including lack of warning to viewers, addition of marijuana derivatives to e-liquids, and the positive portrayal of ENDS devices and modifications. At the same time, our analysis did not find certain modifications (eg, dripper conversions or battery tampering), which have been identified previously as a public health concern. By identifying the types of modifications (with modifications to coil and e-liquid being the most prevalent), this study provides a foundation for assessing the prevalence of ENDS modifications in the population and informs the agenda for research assessing the health effects resulting from ENDS modifications.

Acknowledgments

Research reported in this publication was supported by the National Institute of Drug Abuse of the National Institutes of Health and Food and Drug Administration Center for Tobacco Products (R01DA047397). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health or the Food and Drug Administration.

Authors' Contributions

ZBM wrote the first draft. YL and J Holli conducted the data analysis. DLA and LP conceptualized the study and wrote the implications. YL, J Holli, BY, KH, and VC coded videos. All authors contributed to the writing and revision and approved the final version of the manuscript.

Conflicts of Interest

DLA has received funds for work done for the World Health Organization Tobacco Free Initiative, has worked as a consultant for Pfizer and McKing Consulting, Inc, and has worked as a Special Government Employee of the US Food and Drug Administration.

Abstract

Background: The effectiveness of personal health records (PHRs) in diabetes management has already been verified in several clinical trials; however, evidence of their effectiveness in real-world scenarios is also necessary. To provide solid real-world evidence, an analysis that is more accurate than the analyses solely based on patient-generated health data should be conducted.

Objective: This study aimed to conduct a more accurate analysis of the effectiveness of using PHRs within electronic medical records (EMRs). The results of this study will provide precise real-world evidence of PHRs as a feasible diabetes management tool.

Methods: We collected log data of the *sugar* function in the My Chart in My Hand version 2.0 (MCMH 2.0) app from Asan Medical Center (AMC), Seoul, Republic of Korea, between December 2015 and April 2018. The EMR data of MCMH 2.0 users from AMC were collected and integrated with the PHR data. We classified users according to whether they were continuous app users. We analyzed and compared their characteristics, patterns of hemoglobin A_{1c} (HbA_{1c}) levels, and the proportion of successful HbA_{1c} control. The following confounders were adjusted for HbA_{1c} pattern analysis and HbA_{1c} regulation proportion comparison: age, sex, first HbA_{1c} measurement, diabetes complications severity index score, sugar function data generation weeks, HbA_{1c} measurement weeks before MCMH 2.0 start, and generated sugar function data count.

Results: The total number of MCMH 2.0 users was 64,932, with 7453 users having appropriate PHRs and diabetes criteria. The number of continuous and noncontinuous users was 133 and 7320, respectively. Compared with noncontinuous users, continuous users were younger (*P*<.001) and had a higher male proportion (*P*<.001). Furthermore, continuous users had more frequent HbA_{1c} measurements (*P*=.007), shorter HbA_{1c} measurement days (*P*=.04), and a shorter period between the first HbA_{1c} measurement and MCMH 2.0 start (*P*<.001). Diabetes severity–related factors were not statistically significantly different between the two groups. Continuous users had a higher decrease in HbA_{1c} (*P*=.02) and a higher proportion of regulation of HbA_{1c} levels to the target level (*P*=.01). After adjusting the confounders, continuous users had more decline in HbA_{1c} levels than noncontinuous users (*P*=.047). Of the users who had a first HbA_{1c} measurement higher than 6.5% (111 continuous users and 5716 noncontinuous users), continuous users had better regulation of HbA_{1c} levels with regard to the target level, 6.5%, which was statistically significant (*P*=.04).

Conclusions: By integrating and analyzing patient- and clinically generated data, we demonstrated that the continuous use of PHRs improved diabetes management outcomes. In addition, the HbA_{1c} reduction pattern was prominent in the PHR continuous user group. Although the continued use of PHRs has proven to be effective in managing diabetes, further evaluation of its effectiveness for various diseases and a study on PHR adherence are also required.

KEYWORDS

personal health record; mobile health; electronic medical record; diabetes mellitus; glycated hemoglobin A

Introduction

Background

Diabetes mellitus is a global issue, and its contribution to numerous complications and increased mortality is well known. Moreover, diabetes prevalence is constantly growing, a trend that might continue until 2030 or longer [1,2]. According to the American Diabetes Association (ADA), diabetes care is mainly based on insulin delivery [3]. According to the Korean Diabetes Association (KDA), the target value of hemoglobin A_{1c} (HbA_{1c}) is recommended to be 6.5% for patients with type 2 diabetes, and antihyperglycemic therapy is mainly considered in Korea. Metformin is considered to be the first-line therapy. However, these traditional drug therapies result in inevitable hypoglycemic events and body weight change. An unachieved glycemic target can only be solved by increasing drugs in mono, dual, or triple therapy [4]. Traditional methods are expensive, and this is becoming a national health care problem [5,6]. To overcome several limitations of traditional diabetes management, mobile health (mHealth) technology and personal health record (PHR) implementation have been suggested as innovative solutions.

In the diabetes management market, new treatments with new devices and apps are being introduced. Most functions of diabetes apps focus on maintaining a blood glucose diary. Some are also connected with blood glucose sensors and treatment devices. Among diabetes apps, *OneTouch Reveal* had the best validation [7]. This app is wirelessly connected to the *OneTouch Verio Flex meter*, making users self-monitor their blood glucose. Blood glucose data are delivered to health care professionals, and users receive text message feedback [8]. Technologies using automatic alarm systems have also been introduced. The Dexcom G6 Continuous Glucose Monitoring system effectively reduced hyperglycemia and also hypoglycemic events with the *Urgent Low Soon* automatic alert system [9]. Monitoring insulin delivery became possible with internet-based connections. *NovoPen 6* and *NovoPen Echo Plus* are called *smart insulin pens*, which can monitor the insulin injection amount and provide both health providers and patients treatment accuracy [10,11].

Previous studies have shown the health improvement of PHR users, thus suggesting that a digital health care system is feasible for improving health behavior and chronic conditions. According to a systematic review, users experienced a positive effect on their health-related behavior and clinical results when using health apps on their mobile devices [12]. Another systematic review in South Korea showed that mHealth interventions were effective in improving self-management behaviors, biomarkers, or patient-reported outcome measures [13]. However, the positive effect of mHealth and PHR interventions is not always ensured.

In diabetes care, PHR and mHealth interventions are expected to be effective treatments. WellDoc, a remote blood glucose monitoring system, was effective in lowering HbA_{1c} levels, thereby improving clinical, behavioral, and diabetes knowledge outcomes [14]. A phone-based treatment and behavioral coaching intervention also improved HbA_{1c} levels [15]. A similar improvement in HbA_{1c} control for type 2 diabetes was seen with another mobile-based intervention [16]. The addition of a tailored mobile coaching system for patients with diabetes showed reduced HbA_{1c} levels and improved diabetes self-management; the results were reproducible and durable [17].

Along with the expectations of the clinical implications of PHRs, some concerns and slightly controversial results have been reported. Despite its advantages, studies have reported the barriers in PHR implementation. Patients are concerned about the security of their health information. Health care providers are concerned about patients altering their own PHR information. Other issues are that there is no practical difference in health outcomes, the use of stand-alone PHRs with electronic medical records (EMRs) and electronic health records, and a low health care literacy rate, which can diminish the benefits of PHRs [18]. Moreover, the barriers associated with patients' age, sex, socioeconomic status, education level, internet and computer access, and health have been reviewed [19]. Contrasting results of the relation between PHR use and diabetes management have been reported. A study using a regression model claimed that there was no association between the increasing number of days of PHR use and better diabetes quality measure profiles [20].

Objectives

In this study, we used a 4-year mobile PHR (mPHR) log and users' EMR data to analyze the effects of diabetes management on the continuous use of the PHR system distributed by a tertiary hospital in South Korea. A study with the earlier version of the mPHR app was conducted to verify characteristics of continuous users [21], and patient-generated health data (PGHD) of continuous users had a higher proportion of a chronic disease diagnosis, such as diabetes, than noncontinuous users [22]. With the new version, we will verify its effect in glycemic control on patients with diabetes. To the best of our knowledge, this is the first study to verify the effectiveness of disease management by integrating a long-term mPHR log and EMR data.

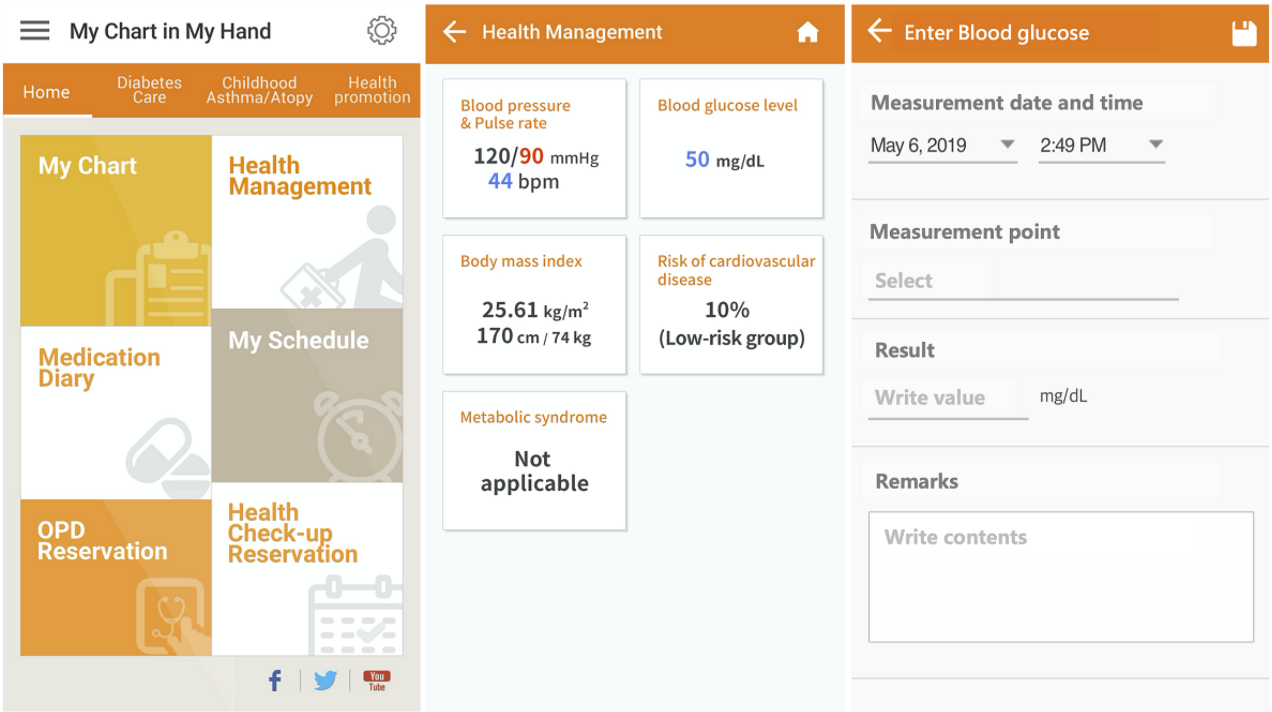
Methods

Data and Mobile Personal Health Record Description

We collected log data from an mPHR app called My Chart in My Hand (MCMH) and their EMR data at the Asan Medical Center (AMC), which is the largest general hospital in South Korea. Launched in January 2011, MCMH is the first mPHR in South Korea; it enables patients to view and manage their own health records [21]. We used the MCMH version 1.0 log to identify patterns of continuous generation of PGHD in specific populations [22]. This study performed a diabetes management analysis using the MCMH version 2.0 log and EMR data. For patients with diabetes, MCMH version 2.0 provides *sugar*, *diabetes calendar*, *insulintreatment*, *food intake*, and *exercise* input functions. Among these functions, we only used the log data of the *sugar* and *diabetes calendar* function; the remaining functions had very few records. The items in Figure 1 show the details of the *sugar* function. Users enter the date, time, situation, and result of their blood glucose measurement in these PGHD functions.

We also gathered demographic and medical record information of patients, such as age, sex, residence, and health information, including hospital visits, HbA_{1c} level, diagnosis, and medication data, using our clinical research data warehouse.

Figure 1. Screenshots of My Chart in My Hand version 2.0. Inputting data in the sugar function follows from the home page to Enter Blood Glucose.



Blood pressure & Pulse rate 120/90 mmHg 44 bpm

Blood glucose level 50 mg/dL

Body mass index 25.61 kg/m² 170 cm / 74 kg

Risk of cardiovascular disease 10% (Low-risk group)

Metabolic syndrome Not applicable

Measurement date and time May 6, 2019 2:49 PM

Result Write value mg/dL

Study Design

MCMH version 2.0 replaced MCMH version 1.0 on December 31, 2015, but some patients had already created their accounts in December 2015 before the replacement. For each user, the records generated in MCMH version 2.0 functions were analyzed, but only records generated after account creation were used.

The user log of the *sugar* function contained user access ID and time stamps of data input. We gathered the HbA_{1c} measurement results of MCMH version 2.0 users from January 2014 to November 2018.

For user selection, we used the criteria of diabetes for diagnosis. First, the criterion of Glasheen et al [23] was adopted: a user should have one or more International Classification of Diseases 10th Revision (ICD-10) diabetes codes in the diagnosis record, which are E08, E09, E10, E11, and E13. Second, the HbA_{1c} cutoff value of 6.5% for diagnosing diabetes was used [24]. For the complication classification and diabetes complications severity index (DCSI) scoring, the selected complication fields from the diagnosis record were retinopathy, nephropathy, neuropathy, cerebrovascular, cardiovascular, peripheral vascular disease, and metabolic complications. DCSI scoring used the criteria of the study by Glasheen et al [23]. However, urine laboratory data were not included in DCSI scoring because of its unavailability. Above all, we classified all diseases according to ICD-10.

The criterion for whether a user was a continuous user was adopted from the PGHD pattern analysis study of MCMH version 1.0: a user entering data in the *sugar* function at least once per week and doing so for at least four weeks (28 days) [22].

We analyzed the pattern of HbA_{1c} levels with the trend line slope of HbA_{1c} levels. The fluctuation of HbA_{1c} levels was compared with the *r*-squared value of the trend line and the standard deviation of the patient's HbA_{1c} level.

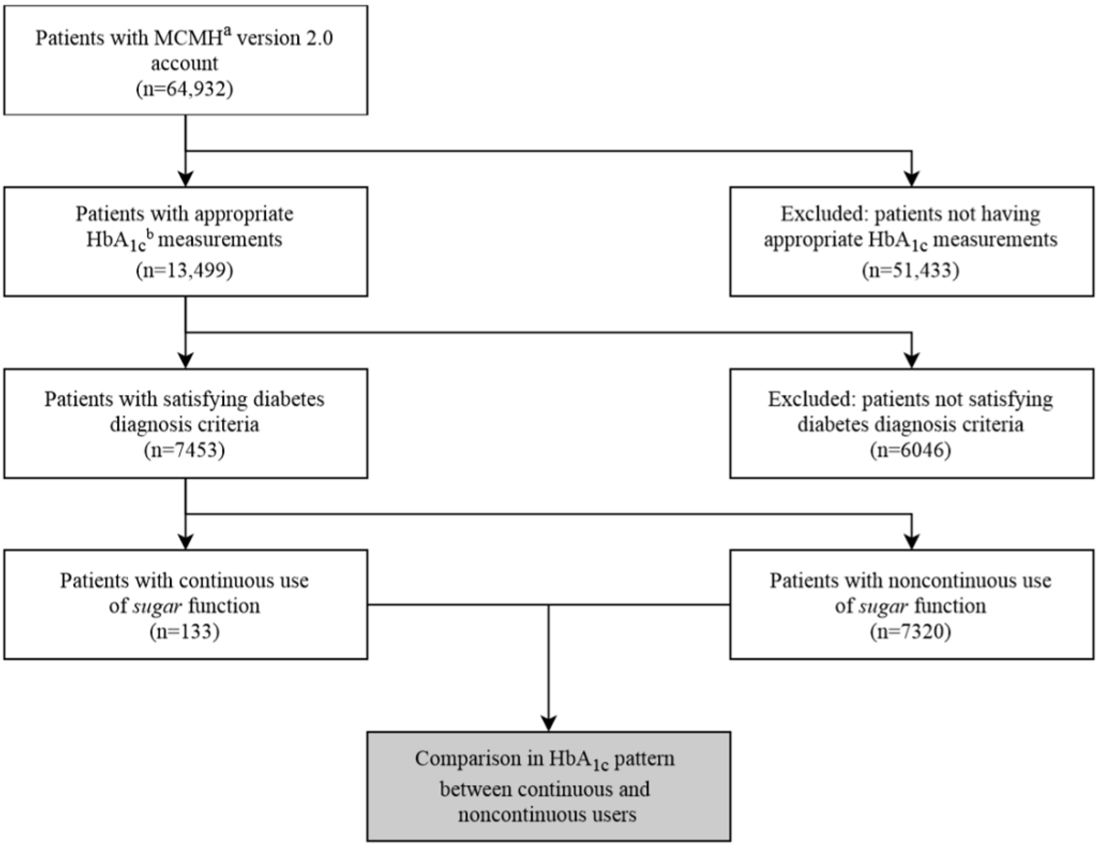
In this study, the trend line slope considerably depended on the measurement days between the first and last HbA_{1c} measurement. Therefore, we created a patient filter called *appropriate* HbA_{1c} *measurement*. This criterion excluded patients with short periods between measures because a short period will lead to an exaggeratedly steep slope, which is inappropriate for the analysis. The criterion for an appropriate HbA_{1c} measurement is patients should have at least two HbA_{1c} measurements and the period between the first and last HbA_{1c} measurement should be over 100 days. To normalize the effect of measurement days between the first and last HbA_{1c} measurement, we defined a variable called *decline*. *Decline* is defined as a trend line slope times the period (in days) divided by 100. This normalization is represented in the equation in Multimedia Appendix 1.

This study was approved by the Institutional Review Board (IRB) of the AMC (IRB number: 2018-0321). The need for informed consent was waived by the ethics committee because this study utilized routinely collected log data that were anonymously managed at all stages, including during data cleaning and statistical analyses.

Study Participants

Figure 2 shows the patient selection flow in this study. Among 64,932 users who downloaded and created an MCMH version 2.0 account, we first excluded 51,433 users with inappropriate HbA_{1c} measurements. We considered 13,499 users with the appropriate HbA_{1c} measurements, excluded 6046 users without diabetes, and selected 7453 users with diabetes.

Figure 2. Patient inclusion and exclusion criteria (white boxes) and flow through the study. The gray box shows user hemoglobin A_{1c} (HbA_{1c}) analyses. Criteria for appropriate HbA_{1c} measurement: two or more HbA_{1c} measurements, duration of the first and last measurement over 100 days, and creating My Chart in My Hand version 2.0 account during HbA_{1c} measurement. Criteria for diabetes diagnosis: having International Classification of Diseases 10th Revision code E08, E09, E10, E11, or E13 or first HbA_{1c} measurement ≥6.5%. Criteria for continuous use of sugar function: patient-generated health data entered in the sugar function at least once per week and used for at least 28 days. [a]HbA_{1c}: hemoglobin A_{1c}; [b]MCMH: My Chart in My Hand.



Data Analysis

We first compared the general characteristics of continuous (n=133) and noncontinuous users (n=7320). The following characteristics were compared: age, gender proportion, *sugar* and *diabetes calendar* function use pattern, HbA_{1c} measurement pattern, HbA_{1c} value, DCSI score, and complication proportion. A Student *t* test was conducted for the comparison of age, the number of HbA_{1c} measurements, measurement days, and measurement days before MCMH version 2.0 start. A Wilcoxon rank-sum test was used for individual *sugar* and *diabetes calendar* function data generation, HbA_{1c} measure frequency, first HbA_{1c} measurement, and DCSI score comparison. The median test was used for the individual *sugar* and *diabetescalendar* function data generation comparison. The Z test was conducted for *sugar* and *diabetes* function generation user proportion, first HbA_{1c} measurement over 6.5% proportion, and complications proportion comparisons. For gender proportion comparison and DCSI score distribution, a chi-square test was used.

Next, comparative analyses of HbA_{1c}*decline*, *r*-squared value, and standard deviation between continuous and noncontinuous users were performed. We used the Shapiro-Wilk test and D'Agostino K-squared test to determine if these data followed a normal distribution. HbA_{1c}*decline*, *r*-squared value, and standard deviation were compared using the Wilcoxon rank-sum test. For confounder adjustment, we used an analysis of covariance (ANCOVA) with some variables: continuous use, age, sex, first HbA_{1c} measurement, DCSI, *sugar* function data generation weeks, HbA_{1c} measurement in weeks before MCMH version 2.0 start, and *sugar* function data generation count.

Finally, the Z test was conducted for comparing the proportions of 4 groups between continuous and noncontinuous users. The 4 groups were divided by whether the first HbA_{1c} measurement was higher or lower than 6.5% and whether the last HbA_{1c} measurement was higher or lower than 6.5%. For confounder adjustment, multivariable logistic regression was used for users with the first HbA_{1c} measurement over 6.5%. The same variables, as used in ANCOVA, were used for logistic regression. Data analyses were conducted using *Python* 3.6.7, with *Jupyter Notebook*.

Results

Overall Characteristics

Within 29 months of operation of MCMH version 2.0, 64,932 users created an account and logged in at least once. Among these users, 7453 users were selected on the basis of the inclusion criteria of this study. Approximately 1.78% (133/7453) of these users were continuous users, and 98.22% (7320/7453) were noncontinuous users. Continuous and noncontinuous users had no statistically significant difference in the number of HbA_{1c} measurements and the period between the first and last HbA_{1c} measurements.

Table 1 summarizes the results of a basic characteristic analysis between continuous and noncontinuous users. In Table 1, measure frequency refers to the number of measurements per day, measurement days refers to days between the first and last HbA_{1c} measurement, and measurement days before MCMH version 2.0 start refers to days between the first HbA_{1c} measurement and MCMH version 2.0 account generation period. Compared with noncontinuous users, continuous users were younger (mean 53.59, SD 9.89 years vs mean 57.58, SD 11.95 years, respectively) and had a higher male proportion (110/133, 82.7% vs 4859/7320, 66.38%, respectively), which was statistically significant (both *P*<.001). The number of HbA_{1c} measurements was not significantly different. The frequency and period between the first and last measurements exhibited a significant difference between continuous and noncontinuous users (*P*=.007 and *P*=.04, respectively). The proportion of patients with the first HbA_{1c} measurement below 6.5% had no significant difference (*P*=.14), but continuous users had a higher first HbA_{1c} measurement, and this was statistically significant (*P*=.01). Furthermore, among continuous users, there were a higher proportion of users who generated data in the sugar function and diabetes calendar function (both *P*<.001). Continuous users also entered more sugar and diabetes calendar data (both *P*<.001). The DCSI score had no significant difference (*P*=.99). The proportion of complications, defined by the DCSI criteria, also showed no significant difference between continuous and noncontinuous users. Although the difference was statistically insignificant, retinopathy and cardiovascular complications had a proportional difference.

The DCSI score proportion of continuous and noncontinuous users had no significant difference in the chi-square test. This can be found in Multimedia Appendix 2. Among the 14 DCSI scores, those with zero proportion in both patient groups (scores 10, 12, and 13) were excluded in the analysis using the chi-square test, because calculation with the chi-square test is only possible when each score does not have zero proportion in any group.

Table 1. General characteristics of continuous and noncontinuous users.

Variables	Users		Total (N=7453)	*P* value[a]
	Continuous (n=133)	Noncontinuous (n=7320)

Hemoglobin A_{1c} Pattern Analysis According to Continuous Use

Figure 3 shows the trend of the HbA_{1c} pattern for continuous and noncontinuous users. The HbA_{1c} *decline* of continuous and noncontinuous users was also compared. The HbA_{1c} *decline* (mean −0.00533, SD 0.0144) in continuous users was significantly steeper than that of noncontinuous users (mean −0.00278, SD 0.0137; *P*=.02). The SD of continuous users (mean 0.832, SD 0.574) was significantly higher than that of noncontinuous users (mean 0.719, SD 0.541; *P*=.005). However, the *r*-squared value had no statistically significant difference between continuous and noncontinuous users (*P*=.40).

When adjusting confounders that can contribute to the *decline*, continuous use had a statistically significant effect (*P*=.047) on making *decline* steeper, as seen in Table 2. In addition, age, first HbA_{1c} measurement, DCSI, weeks of *sugar* function data generation, and HbA_{1c} measurement in weeks before MCMH version 2.0 start showed statistically significant effects (*P*=.004; *P*<.001; *P*=.01; *P*=.003; *P*<.001, respectively).

Figure 3. Hemoglobin A_{1c} (HbA_{1c}) patterns (decline, r-squared value, and SD) of continuous and noncontinuous users. The x-axis is the percentage of days past from the first HbA_{1c} measurement compared with the period between the first and last HbA_{1c} measurements. The dashed lines are the HbA_{1c} decline of each patient. The slope and y-axis intercept of the continuous lines indicates the mean of slope and y-axis of patients, respectively.

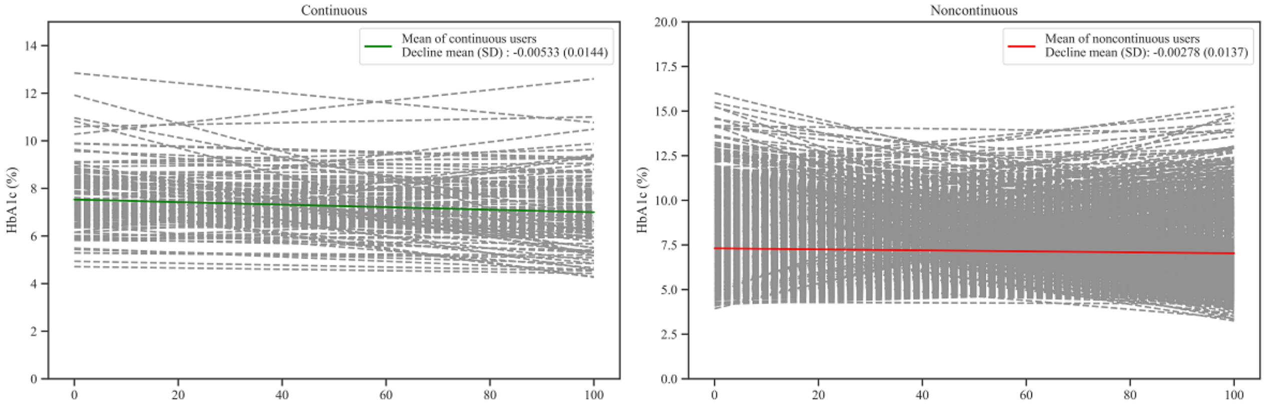

Table 2. Results of adjusting confounders with the analysis of covariance in decline comparison.

Variables	*F* test (*df*=1)	*P* value
Continuous users	3.94	.047
Age (years)	8.07	.004
Sex	0.17	.68
First HbA_{1c}[a] measurement	3054.90	<.001
DCSI[b]	6.45	.01
Sugar function data generation (weeks)	8.68	.003
HbA_{1c} measurement weeks before MCMH version 2.0 start	154.25	<.001
Generated *sugar* function data count	0.03	.86

[b] DCSI: diabetes complications severity index.

Comparison of Hemoglobin A_{1c} Regulation With Target Level in Continuous Use

Table 3 lists the proportion with regard to HbA_{1c} patterns. The proportion of users with the first HbA_{1c} measurement higher than 6.5% and the last HbA_{1c} measurement lower than 6.5% had a statistical difference (*P*=.01). Among users with the first HbA_{1c} measurement lower than 6.5%, the proportion of patients with the last HbA_{1c} measurement lower than 6.5% and the last HbA_{1c} measurement higher than 6.5% had no significant difference (*P*=.34 and *P*=.29, respectively). No significant difference was found between proportions of patients with the first HbA_{1c} measurement of 6.5% or higher and the last HbA_{1c} measurement higher than 6.5% (*P*=.41).

Similar to the *decline* analysis, the result of confounder adjustment by logistic regression for users with a high first HbA_{1c} measurement is summarized in Table 4. The continuous use of MCMH version 2.0 had a statistically significant effect in helping users move from an HbA_{1c} measurement above 6.5% to an HbA_{1c} measurement below 6.5% (*P*=.04). In addition, age, first HbA_{1c} measurement, and HbA_{1c} measurement in weeks before MCMH version 2.0 start showed statistically significant effects (all: *P*<.001).

Table 3. Pre– and post–hemoglobin A_{1c} management comparison by continuous use.

HbA_{1c}[a] pattern	Users		*P* value
	Continuous (n=133)	Noncontinuous (n=7320)	
First measurement <6.5%			
Last measurement			
<6.5%, n (%)	15 (11.3)	1040 (14.21)	.34
≥6.5%, n (%)	7 (5.3)	564 (7.70)	.29
First measurement ≥ 6.5%			
Last measurement			
<6.5%, n (%)	38 (28.6)	564 (7.70)	.01
≥6.5%, n (%)	73 (54.9)	4278 (58.44)	.41

Discussion

Principal Findings

For the following reasons, this study supports the use of mPHRs as an effective platform for diabetes management by integrating patient-generated health and clinical data from PHRs and EMRs, respectively. First, analyzing the characteristics of continuous users of MCMH version 2.0, male patients with a high HbA_{1c} level seemed to use MCMH version 2.0 more continuously. Second, the continuous use of PHRs resulted in a higher decrease of HbA_{1c} levels and enhanced the regulation of high HbA_{1c} levels of patients to the target range. Therefore, male users with high HbA_{1c} levels had a higher decrease in HbA_{1c} levels and improved HbA_{1c} regulation to the target level. By analyzing the characteristics of continuous users and their HbA_{1c} patterns, we also suggest the use of mPHR as a diabetes care support tool enabling personalized management.

This study is unique when compared with previous studies on the basis of the following characteristics. First, we suggested the health improvement effect of mPHRs on the basis of the integration of PHRs and EMRs. In this study, we expected two benefits of integrating PHRs and EMRs. One is suggesting a different methodology for real-world data analysis and presenting additional real-world evidence, which supports previous studies. Another is ensuring a high-quality data analysis is conducted. There are many previous studies implying the advantages of PHRs and PGHD with positive conclusions of the use of mPHRs [14-17]. The results of these studies were collected on the basis of clinical trials such as nonblinded, open-label randomized controlled trials (RCTs) and cluster-randomized trial designs. As a real-world data analysis covers bias limitations in RCTs and can handle unknown factors of PHRs, the results of a real-world data analysis provide strong and necessary support to previous RCTs [25]. Moreover, the integration of EMRs gave high-quality HbA_{1c} data and diagnosis data, which made the analysis more precise.

Second, previous studies mainly discussed about the decrease in HbA_{1c} levels as an advantage of using PHRs. However, as the main goal of glycemic control is regulating a patient's HbA_{1c} level to the recommended range, we compared both HbA_{1c} decrease and proportions of patients who initially had a high HbA_{1c} level but their HbA_{1c} level decreased to a low value. According to the 2015 and 2019 diabetes management guidelines from the KDA, the recommended target HbA_{1c} level is 6.5% in patients with type 2 diabetes, and this differs from the guideline by the ADA [4,26,27]. As this study was conducted in AMC, South Korea, we used the guidelines from KDA and defined the cutoff value of the HbA_{1c} level as 6.5%. Recent studies recommend that patients with severe diabetes mellitus should be controlled to lower than 7%, depending on the severity and complications of diabetes [28-30]. Moreover, a stable decrease in blood glucose levels is also an important task in glycemic control. We also focused on the *r*-squared value of the trend line and SD as an indicator of stabilized HbA_{1c} decrease, but we could not achieve any outstanding results.

Overall User Characteristics

Analyzing users who had access to MCMH version 1.0 indicated that these users visited hospitals more with chronic diseases [21]. Continuous users were younger than noncontinuous users ($P<.001$), and there was a significant difference in sex proportion; the continuous user group had a higher male ratio ($P<.001$). In previous research, groups that used a PHR system had young users and a high proportion of males or generated more PGHD, especially those related to diabetes [21,22]. This is because male users aged between 51 and 70 years tend to adopt the PHR system [31]. In addition, in this study, the HbA_{1c} level in continuous users was measured for a shorter period ($P=.04$) and more frequently ($P=.007$) than noncontinuous users. However, the number of HbA_{1c} measurements had no significant difference between continuous and noncontinuous user groups. In South Korea, the social health insurance program was introduced with the 1977 National Health Insurance Act. This program was thereafter progressively rolled out to the general public, and it finally achieved universal coverage in 1989. According to the National Health Insurance Act, the criteria for the method, procedure, scope, and upper limit of health care shall be prescribed by the Ministry of Health and Welfare [17].

National insurance only supports up to 6 HbA_{1c} tests per year, in accordance with the National Health Insurance Act. First, we considered the number of HbA_{1c} measurements as another indicator of diabetes severity. This is because well-controlled patients typically undergo HbA_{1c} tests twice a year, whereas poorly controlled individuals undergo testing 4 times a year [32]. However, the number of measurements seems to be similar because of the policy in South Korea. Although continuous users had shorter periods (approximately 80 days) between the first and last measurements, this group took HbA_{1c} tests more frequently. This may be because of the increase in hospital visits, along with more satisfaction and loyalty to the hospital [33]. To compare diabetes severity, the proportion of patients with an HbA_{1c} level of 6.5% or above, a first HbA_{1c} level measurement, and a DCSI score distribution were compared between continuous and noncontinuous groups. The two groups had no significant difference in the proportion of high HbA_{1c} levels and DCSI distribution; however, continuous users had a higher HbA_{1c} level ($P=.01$). Retinopathy patients tended to use MCMH version 2.0 more continuously, but the complication proportion also had an insignificant difference between the two groups. Except for the first HbA_{1c} level measurement, most diabetic-related baseline characteristics appeared to have no significant difference, and the first HbA_{1c} measurement can be adjusted as confounders in an additional analysis. By using PHR and EMR integration, the general characteristics and severity of diabetes were compared.

As the period of HbA_{1c} measurement before MCMH version 2.0 use was shorter in the continuous group ($P<.001$), continuous users seemed to have an earlier MCMH version 2.0 start compared with noncontinuous users. In addition, continuous users tended to use the *sugar* and *diabetes calendar* functions more and generate more data. This was because continuous users tended to use MCMH version 2.0 functions with fewer burdens.

Verifying the Effect of Personal Health Record Use in Hemoglobin A_{1c} Control

The main advantage of PHRs and PGHD is health improvement, especially in diabetes. Among the types of diabetes management, determining the change in HbA_{1c} levels was the most effective method to verify the effectiveness of PHRs in the real world. The results of this study indicate that continuous users had a larger *decline*; a greater increase in HbA_{1c} levels was observed in users who continuously used the diabetes management–related *sugar* function in MCMH version 2.0. As *decline* is the result of the trend line slope normalized to 100 days, the value itself also refers to the change in the HbA_{1c} level. For example, HbA_{1c} was 6.9% on January 1, 2014, and HbA_{1c} was 6.4% on October 19, 2018, in one particular continuous user; therefore, the decline value was −0.0044, which means that this patient's change in HbA_{1c} level was approximately −0.44% (100 times the value of decline). Thus, the decrease in HbA_{1c} levels in continuous users was approximately 1.9 times that in noncontinuous users. The result of ANCOVA shows that along with continuous use, other factors were also important: age, first HbA_{1c} measurement, DCSI, duration of using the *sugar* function, and HbA_{1c} measurement period before using MCMH version 2.0. Glycemic control is important for reducing both microvascular risk and emergent risk for myocardial infarction and death [34]. This indicates that the group that continuously used PHRs had health improvement with a decreasing trend of HbA_{1c} levels.

In glycemic control, it is important to reduce not only blood glucose levels but also hypoglycemic events [35]. Traditional diabetes care includes insulin delivery using syringes, pens, or pumps [3]. Although hypoglycemic side effects can occur with multiple daily injections and continuous subcutaneous insulin injection, the invasive characteristic of such forms of care is an inevitable disadvantage [36-39]. In this study, we tried to minimize the risk of hypoglycemic events in PHR-implemented diabetes management by using stability indicators, *r*-squared value and *SD*. However, stability was not ensured. In fact, a previous study showed increased glucose stability with the use of an internet-based glucose monitoring system [40]. This indicates that patients can improve hyperglycemia and hypoglycemia management by using PHRs with a blood glucose meter through continuous glucose monitoring diabetic care.

The goal of decreasing the HbA_{1c} level is to prevent the occurrence and aggravation of diabetic complications. Although the criterion for HbA_{1c} in a diagnostic test for diabetes has been recommended by the American Association of Clinical Endocrinologists and ADA, it is an "acceptable complementary diagnostic test for diabetes in Korean patients" [28,41]. Among the many glycemic controls, the tight regulation of HbA_{1c} levels is essential for health improvement and for lowering complication risks such as diabetic retinopathy [42]. In addition, the tight glycemic control of HbA_{1c} levels to 7.0% induces a lower risk of fracture in elderly patients with diabetes [43]. When comparing the ratio of patients with HbA_{1c} levels above and below 6.5% before and after the use of MCMH version 2.0, the group that continuously used MCMH version 2.0 had a higher proportion of regulated patients; initially, the first HbA_{1c} level measurement was over 6.5%, and then it reduced to lower than 6.5%. In addition, among users with the first HbA_{1c} level measurement over 6.5%, the logistic regression results showed that regulation was associated not only with continuous use but also with age, first HbA_{1c} level measurement, and how fast MCMH version 2.0 was adapted. The data generation amount was thought to be important too, but it was statistically insignificant. Therefore, we can claim that the improvement of HbA_{1c} levels by PHR use can eventually affect diabetes management by controlling HbA_{1c} levels to 6.5% in practice.

Limitations of This Research

The main limitation of this study is the concern of general biases in real-world studies: selection bias, information bias, recall bias, and detection bias [44]. As this study mainly focused on analyzing real-world data, strict criteria and inevitable exclusion are necessary, leading to concerns in selection bias and detection bias. However, the criteria for the comparison group were the same, and despite including and excluding many patient criteria and comparing with the MCMH 1.0 user analysis, the study scale is almost similar [22]. The size of the continuous user groups is sometimes larger than that used in other RCT studies and had little baseline differences in diabetic severity [17]. As MCMH version 2.0 data are PGHD, continuous use can only be analyzed by its log data, which does not represent adherence to the app and can lead to information bias. On the contrary, we note that information bias that can occur in HbA_{1c} level scaling can be controlled with the integration of EMRs. This integration helped in reducing recall bias in diabetes and complication diagnosis.

Time scale is also another limitation. In RCTs, the HbA_{1c} measurement point, the app account creation point, and app use frequency can be controlled and optimized for convenient data analysis. However, in real-world data, patients have diverse points of HbA_{1c} measurement and MCMH version 2.0 starting points. Even though there were limitations with regard to missing data, inappropriate data, and ambiguous time scale standards, we used patient selection criteria to choose patients who can be analyzed and used the *decline* factor to monitor the HbA_{1c} level for minimizing the effect of irregular time points. The *decline* factor is a variable that has been coined for the purpose of this study and has an uncertain clinical rationale. However, as the *decline* variable also implies a decrease in HbA_{1c} levels, and the decreasing trend is being maintained, the quantitative comparison of *decline* between groups is meaningful. In diabetes care, lowering HbA_{1c} levels to the target level and maintaining the decreased HbA_{1c} level is the primary goal. Thus, the *decline* is a reasonable variable for analysis in studies with data having unspecific HbA_{1c} measurement points.

An additional limitation is that AMC is a territorial hospital, and almost all the study patients are residing in South Korea. The small size of the study population and short duration are other limitations. The low frequency of PHR data generation and short-term MCMH version 2.0 operation is not an ideal database for analyzing chronic diseases such as diabetes. A larger study size and longer study duration will provide stronger real-world evidence of the clinical meaning of PHRs.

On the basis of the proportion of continuous and noncontinuous users, further research for encouraging patients to use PHRs more continuously is essential. In this study, continuous users had better diabetes management outcomes than noncontinuous users. However, continuous users were only 1.78% (133/7453) of the study population and were only 0.20% (133/64,932) of users who started using MCMH version 2.0. Thus, studies for maintaining active PGHD-generating users and turning noncontinuous users into continuous users are necessary. Finding out whether giving health-related advice on the basis of MCMH version 2.0 encourages patients to use a PHR app for changing app use patterns needs to be studied to prevent usability issues [45]. Furthermore, for personalized PHR advice, if larger and better quality of data is provided, the glycemic control outcome analysis by treatment is important. Further studies in diverse territories and a deeper analysis of MCMH version 2.0 should be performed to prove the effectiveness of PHRs as a diabetes management tool in decreasing HbA_{1c} levels.

Conclusions

By integrating and analyzing patient- and clinically generated data, the continuous use of PHRs improves diabetes management outcomes. A greater decrease in HbA_{1c} levels was observed in continuous users, and HbA_{1c} levels were regulated to the target level in continuous users compared with noncontinuous users. Previous clinical trials and the results of this study proved that PHRs are effective in managing diabetes. However, further evaluation of the effectiveness of PHRs in various diseases and studies for adherence to PHRs are needed. A larger study population and longer duration will be necessary for the accurate analysis of the clinical rationale of PHRs on chronic diseases.

Acknowledgments

The authors would like to thank the Medical Information Office of AMC for providing log data of the mobile EMR and supporting data analysis and interpretation. This study was supported by a grant of the Research and Development Project, Ministry of Trade, Industry and Energy, Republic of Korea (no. 20004503) and a grant of the National Research Foundation of Korea funded by the Korean government (Ministry of Science and ICT; no NRF-2019M3E5D4064682).

Authors' Contributions

DS, YP, and JL conceived and designed the study; DS, YL, and JK reviewed records and collected the data; DS analyzed the data; DS and YP wrote the manuscript; and YP, JP, and JL reviewed the manuscript.

Abstract

Background: Using big data and the theory of cumulative deficits to develop the multimorbidity frailty index (mFI) has become a widely accepted approach in public health and health care services. However, constructing the mFI using the most critical determinants and stratifying different risk groups with dose-response relationships remain major challenges in clinical practice.

Objective: This study aimed to develop the mFI by using machine learning methods that select variables based on the optimal fitness of the model. In addition, we aimed to further establish 4 entities of risk using a machine learning approach that would achieve the best distinction between groups and demonstrate the dose-response relationship.

Methods: In this study, we used Taiwan's National Health Insurance Research Database to develop a machine learning multimorbidity frailty index (ML-mFI) using the theory of cumulative diseases/deficits of an individual older person. Compared to the conventional mFI, in which the selection of diseases/deficits is based on expert opinion, we adopted the random forest method to select the most influential diseases/deficits that predict adverse outcomes for older people. To ensure that the survival curves showed a dose-response relationship with overlap during the follow-up, we developed the distance index and coverage index, which can be used at any time point to classify the ML-mFI of all subjects into the categories of fit, mild frailty, moderate frailty, and severe frailty. Survival analysis was conducted to evaluate the ability of the ML-mFI to predict adverse outcomes, such as unplanned hospitalizations, intensive care unit (ICU) admissions, and mortality.

Results: The final ML-mFI model contained 38 diseases/deficits. Compared with conventional mFI, both indices had similar distribution patterns by age and sex; however, among people aged 65 to 69 years, the mean mFI and ML-mFI were 0.037 (SD 0.048) and 0.0070 (SD 0.0254), respectively. The difference may result from discrepancies in the diseases/deficits selected in the mFI and the ML-mFI. A total of 86,133 subjects aged 65 to 100 years were included in this study and were categorized into 4 groups according to the ML-mFI. Both the Kaplan-Meier survival curves and Cox models showed that the ML-mFI significantly predicted all outcomes of interest, including all-cause mortality, unplanned hospitalizations, and all-cause ICU admissions at 1, 5, and 8 years of follow-up (*P*<.01). In particular, a dose-response relationship was revealed between the 4 ML-mFI groups and adverse outcomes.

Conclusions: The ML-mFI consists of 38 diseases/deficits that can successfully stratify risk groups associated with all-cause mortality, unplanned hospitalizations, and all-cause ICU admissions in older people, which indicates that precise, patient-centered medical care can be a reality in an aging society.

Introduction

Population aging is a global phenomenon that poses various challenges to societies [1]. The health characteristics of older people and their health care service utilization differ greatly from those of younger adults [2], and frailty plays a pivotal role in the health of older people [3-5]. Frailty has been widely accepted as a geriatric syndrome that substantially increases the complexity of diseases and the burden of care [3-5]. In addition, frailty is recognized as an intermediate state between healthy and unhealthy states, and the potential reversibility of its nature highlights the importance of considering frailty when aiming to maintain the health of older people [6]. Moreover, frailty involves the coexistence of multiple comorbid conditions, such as polypharmacy, depression, cognitive impairment, falls, and malnutrition [7]. Therefore, the early identification of frailty and appropriate intervention remain the core of health care services for older people.

Despite the clinical significance of frailty, conceptual and operational definitions of frailty are inconsistent across studies [8]. Currently, the two most widely accepted approaches include the phenotypic approach for physical frailty and the frailty index based on the theory of cumulative deficits [9]. Although the definitions of frailty provided by the two approaches overlapped to some extent, the major discrepancy is in the prefrail group, such that physically prefrail subjects demonstrated a wide range on the frailty index. Nevertheless, both definitions remain the most widely accepted [10]. The theory of cumulative deficits proposed that aging may be characterized by the presence of cumulative deficits in various domains of health (eg, multimorbidity, functional assessment, and psychosocial perspectives) [9]. With a sufficient number of variables, the individual component of the frailty index was considered the same weight to constitute the frailty index. Researchers applied the theory of cumulative deficits to various data sets and validated the ability of the frailty index (FI) to predict adverse clinical outcomes [4,9]. Internationally, documented health care services data sets have been widely used to develop the FI for the prediction of health outcomes, and studies from different countries have all shown optimal results [5,11,12]. In the United Kingdom, researchers developed the electronic FI (eFI) using electronic medical records, which significantly predicted the mortality of older people [13,14]. Using similar principles, we developed the multimorbidity FI (mFI) using Taiwan’s National Health Insurance data set and significantly predicted mortality, hospitalizations, and admissions to critical care units [4]. However, it is always challenging to use data sets with large study samples and many variables to select appropriate variables to construct an FI and to optimally categorize the FI into risk classes. Both eFI and mFI adopted expert recommendations in the selection of variables, and the eFI and mFI were then categorized into quartiles for group comparisons, which is a widely accepted approach. Nonetheless, selecting variables based on expert recommendations may result in a failure to recognize previously unidentified associations. In addition, the quartile approach for risk group categorization may successfully be used to construct the prediction model, but the intergroup comparisons in survival analysis may overlap and fail to establish a clear distinction.

Therefore, this study aimed to develop the mFI by using machine learning methods that select variables based on the best fitness of the model. Furthermore, we aim to further establish 4 entities of risk using a machine learning approach and ensure the dose-response relationship and the best distinction between groups.

Methods

Study Design and Participants

This is a retrospective cohort study using data from Taiwan's National Health Insurance Research Database (NHIRD). Details about the NHIRD have been published [15]. Briefly, the NHIRD is a nationwide database composed of outpatient and inpatient claims, and it covers more than 99% of Taiwan's population. The data are checked for quality and maintained by the Data Science Centre of the Ministry of Health and Welfare of Taiwan. We used a subset of the NHIRD, which contains claims data for one million randomly selected beneficiaries from the Registry of Beneficiaries of the NHIRD in 2005. The study cohort consisted of 86,133 older adults aged 65 to 100 years who had full National Health Insurance (NHI) coverage from January 1, 2005, to December 31, 2005. Claims data from 2005 to 2013 for the one million beneficiaries was extracted to compose a 9-year (2005-2013) panel of claims for analysis. The study protocol was approved by the Research Ethics Committee of the National Taiwan University Hospital (NTUH-REC-201403069W).

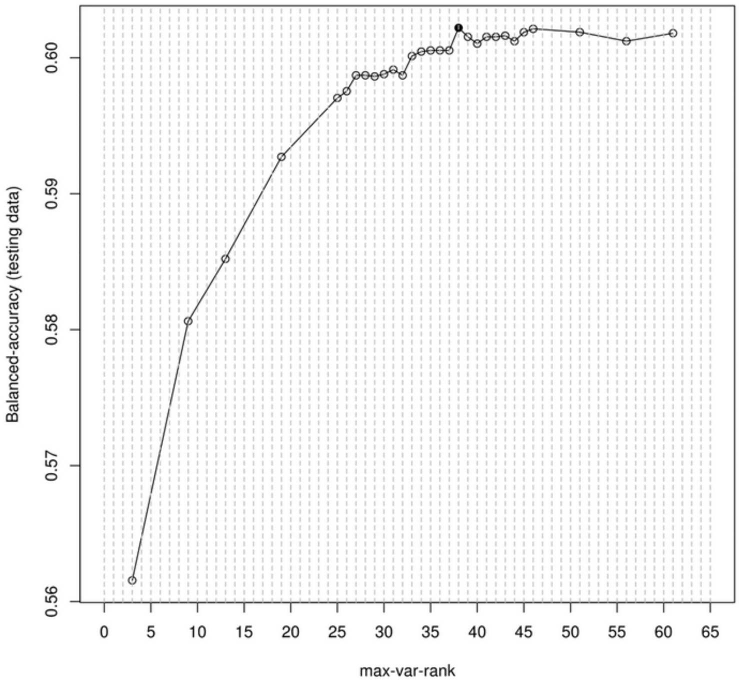
Construction of the Machine Learning–Based Multimorbidity Frailty Index

The mFI was constructed following standard procedures [16], and this method has been validated in the Taiwanese population [4,5]. Disease diagnoses (International Classification of Diseases, Ninth Revision, Clinical Modification [ICD-9-CM]) from outpatient and inpatient claims of the NHIRD between January 1 and December 31, 2005, were used to identify accumulated deficits to construct mFI. We adopted an algorithm widely used in studies using NHIRD as the data source to validate the diagnostic codes of the specified deficits within

NHIRD; that is, only those who had at least 3 outpatient claim records or 1 inpatient claim record for that specified diagnosis code were considered to have the specified deficit. For example, an older adult must have at least 3 outpatient claim records or 1 inpatient claim record of diabetes mellitus [ICD-9-CM: 250] to be defined as having a deficit based on our definition.

A random forest method, with significant improvements in classification accuracy that resulted from growing an ensemble of trees and letting them vote for the most popular class, was adopted [17]. The variable importance of the random forest uses mean decrease accuracy to determine the specific conditions of machine learning–based multimorbidity frailty index (ML-mFI). The adequate constructive number of ML-mFI was 38 conditions, when the model accuracy reached the highest level, 0.602 (Figure 1 and Multimedia Appendix 1). The ML-mFI was calculated as the number of conditions a person encountered in a year out of the 38 selected ones.

Figure 1. Numbers of diseases versus random forest model accuracy to determine an adequate number of frailty indexes.



Determination of Frailty Status by ML-mFI

All subjects were further categorized into 4 entities (fit, mild frailty, moderate frailty, and severe frailty) based on their risk status; this categorization was used by a previous study [4]. The fundamental rules for risk stratification included the following: (1) the individual risk groups were significantly different from each other, and (2) the health risk of these groups showed a dose-response relationship (ie, those in the severe frailty group had a higher risk than those in the moderate frailty group, who had a higher risk than those in the mild frailty group, and so on, at any follow-up time point after the first year). To achieve this purpose, we developed two indices, the distance index and the coverage index, which ensured the distinction and dose-response relationship of all survival curves.

The distance index measured the distance between each survival curve and the stability of those distances within groups. At any time point, the distance index was defined as . Therefore, the distances within groups are wider and more stable when the distance index is larger (Multimedia Appendix 2). Conversely, the coverage index aimed to evaluate the length of the confidence interval for each survival curve. The total length of the confidence intervals indicated the overall estimated error in the grouping method. In Multimedia Appendix 3, the coverage index was defined as at any individual time point, where L_total measured the difference in the estimated survival probability between the fit group and the severe frailty group, and L_error measured the total estimated errors within the 4 groups. When the coverage index is smaller, the estimated error within groups is smaller. With the application of both the distance index and the coverage index, the levels of frailty were successfully categorized into 4 groups by values of ML-mFI: fit was indicated by 0≤ML-mFI<0.026; mild frailty was 0.026≤ML-mFI<0.105; moderate frailty was 0.105≤ML-mFI<0.157; and severe frailty was 0.157≤ML-mFI. In the survival analysis, the grouping strategy successfully categorized all subjects into 4 groups with significant distinction during the follow-up period. In other words, there were no overlaps between the survival curves and the dose-response relationship between groups was clearly shown.

Outcomes of Interest

The outcomes of interest in this study include all-cause mortality, unplanned hospitalizations, and intensive care unit (ICU) admissions. The date of mortality was identified as the date of disenrollment from the NHIRD, which has been validated in a previous study [4]. Unplanned hospitalizations were any unexpected hospitalizations after an emergency department visit. ICU admissions were any hospital admissions with the use of ICU services. All study subjects were continuously followed from January 1, 2006, to the occurrence of each outcome or the end of 2013, whichever came first. For the outcomes of unplanned hospitalizations and ICU admissions, subjects were censored at death if it occurred first. Preplanned analyses were conducted to evaluate the effectiveness of ML-mFI in predicting outcomes at 1, 5, and 8 years.

Statistical Analysis

Numerical variables were expressed as the mean (SD), and categorical variables were expressed as a number or percentage. A random forest method not only determined the number of disease items comprising ML-mFI but also identified potential conditions of ML-mFI with prediction accuracy and variable importance. The distance index and coverage index with min-max and max-min criteria were used to determine cut points and categorize the frailty group by ML-mFI automatically. The Kaplan-Meier survival curve with the log-rank test was used to examine the association between categories of ML-mFI (fit, mild frailty, moderate frailty, and severe frailty) and 8-year mortality and hospitalizations. Cox proportional hazard models were used to estimate the hazard ratios (HRs) and 95% CIs for mortality and hospitalizations at 1, 5, and 8 years after the ML-mFI and mFI were estimated (based on a previous study [4]), considering both to be the independent variable. We further included age and gender as covariates in all adjusted models. Sex-specific analysis was conducted.

All of the analyses were performed using R Version 3.4.4 (R Foundation for Statistical Computing). A two-sided *P* value of <.05 was considered statistically significant. The coxph function in the survival package showed nonviolation of the proportional hazards assumption and a linear relationship between the log hazard and each covariate. The random forest and importance functions in the randomForest package showed the model building and variable importance to predict the outcome occurrence and comprise ML-mFI, respectively.

Results

Construction of ML-mFI

The final ML-mFI with the highest model accuracy (0.6022061) contained 38 conditions (Multimedia Appendix 1). Details of convergences and divergences of composing conditions among ML-mFI and mFI are shown in Multimedia Appendix 4. Table 1 compares the ML-mFI group and traditional mFI by age and sex. There were two similar distribution patterns on mFI and ML-mFI. ML-mFI increased with age, but reached a plateau at age 80 years and older. Both indices were higher in males, which is compatible with the shorter life expectancy of men in Taiwan. However, the mFI was calculated based on 32 selected conditions a person may have in a year, while the ML-mFI was calculated based on 38 selected conditions a person may have in a year; thus, the actual numbers on the mFI and ML-mFI were very different. Among people aged 65 to 69 years, the mean mFI and ML-mFI were 0.037 (SD 0.048) and 0.0070 (SD 0.0254), respectively. The difference may result from discrepancies in the conditions selected on the mFI and the ML-mFI. For example, some conditions were selected only on the ML-mFI but not on the mFI (eg, ICD-9-CM: 250 [diabetes mellitus] and, vice versa, ICD-9-CM: 374 [entropion]). These discrepancies have been shown in Multimedia Appendix 1.

Table 1. Comparisons of mFI and ML-mFI by age and sex.[a,b]

Age (years)	All subjects (N=86,133)		Male (n=42,914)		Female (n=43,219)

Survival Analysis

Overall, 86,133 subjects aged 65 to 100 years were included in this study. With a mean follow-up of 6.57 (SD 2.37) years, 30,136 deaths (34.99%) occurred among the study cohort during the study period. Figure 2 summarizes the results of the Kaplan-Meier survival curves estimating 4 levels of ML-mFI on all-cause mortality, unplanned hospitalization, and ICU admission, and shows that ML-mFI significantly predicted all these outcomes of interest.

Table 2 shows the hazard ratios of all-cause mortality, unplanned admissions, and ICU admissions for the ML-mFI and the mFI at the 1-, 5- and 8-year follow-up periods. Among all three outcomes of interest, ML-mFI posed higher hazards than did mFI. For example, those who were categorized as severely frail by the mFI or the ML-mFI were associated with 4.97-fold (adjusted HR 4.97, 95% CI 4.49-5.50) and 11.4-fold (adjusted HR 11.40, 95% CI 10.32-12.59) increases in 1-year all-cause mortality, respectively. Similar patterns were observed for 5-year and 8-year all-cause mortality.

Figure 2. The 8-year Kaplan-Meier survival curve for the outcome of (A) all-cause mortality, (B) unplanned hospitalizations, and (C) intensive care unit admissions for different frailty categories.

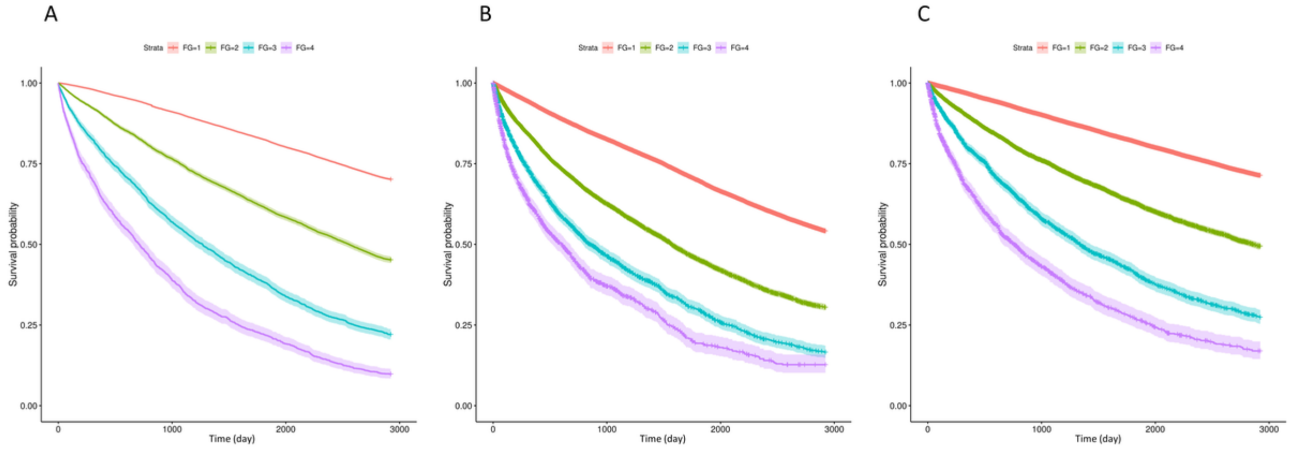

Table 2. Hazard ratios of all-cause mortality, unplanned hospitalizations, and intensive care unit admissions for the ML-mFI and the mFI at the 1-, 5- and 8-year follow-up periods.[a,b,c] All values are given as hazard ratio (95% CI).

[a] For all outcomes, the comparator is the study subjects in the fit categories (n=64,650). All data were adjusted for age and gender.

[b] ML-mFI: machine learning multimorbidity frailty index.

[c] mFI: multimorbidity frailty index.

[d] HR: hazard ratio.

For unplanned hospitalizations, those who were categorized as severely frail by the mFI or the ML-mFI were associated with 4.28-fold (adjusted HR 4.28, 95% CI 3.94-4.64) and 6.20-fold (adjusted HR 6.20, 95% CI 5.66-6.80) increases in 1-year unplanned hospitalizations, respectively. Similar patterns were observed for 5-year and 8-year all-cause unplanned hospitalizations.

For ICU admissions, those who were categorized as severely frail by the mFI or the ML-mFI were associated with 4.28-fold (adjusted HR 5.35, 95% CI 4.84-5.91) and 9.41-fold (adjusted HR 9.41, 95% CI 8.49-10.44) increases in 1-year ICU admissions, respectively. Similar patterns were observed for 5-year and 8-year all-cause ICU admissions.

Sex-specific analysis showed that both indices were higher in men than in women for various outcomes and follow-up periods (Tables 3 and 4 for males and females, respectively). For example, men in the severe frailty group (as defined by the ML-mFI) were associated with a 12.64-fold increased risk of 1-year mortality, while women in the severe frailty group (as defined by the mFI) were associated with a 10.37-fold increased risk of 1-year mortality.

Table 3. Male hazard ratios of all-cause mortality, unplanned hospitalization, and intensive care unit admission for ML-mFI and mFI among 1-, 5-, and 8-year follow-up periods.[a,b,c]

Discussion

In this study, we successfully used a machine learning approach to define ML-mFI. Specifically, we selected disease/deficit items by the random forest method and ranked the importance of each individual disease accordingly. The selection of these diseases/deficits items to construct ML-mFI was driven solely by data, while the conventional mFI included disease/deficit items based on expert recommendations. Moreover, the combined use of the distance index and coverage index successfully distinguished 4 groups with dose-response risks of adverse outcomes. In epidemiological studies, researchers have often encountered similar challenges in selecting appropriate variables for analysis and optimally categorizing continuous variables into categorical variables for further comparisons. Traditionally, researchers need to search for literature support or adopt a generic approach to develop an optimal statistical model for data interpretation [18-20]. The hypothesis-driven approach for a research question is of great importance in scientific development; however, previously unknown or unidentified factors may be overlooked in the analysis, which may lower the statistical power in the interpretation of the phenomenon. Compared to our previous work where we used a hypothesis-driven approach to construct the mFI [4], the machine learning model selected significantly different disease/deficit items for ML-mFI construction. The traditional approach selected the diseases/deficits of older adults based on the selection criteria, and the machine learning approach identified more disease/deficit items, including chronic diseases, infectious diseases, and even some cancers, but these items did not comprise the majority of disease/deficit items.

The FI developed by Rockwood et al [18] hypothesized that cumulative deficits in various health domains may represent the process of biological aging, and this FI has been widely validated to predict adverse health events and mortality in different countries [5,11,12]. In theory, an FI may consist of as many variables as possible, so there are no issues regarding variable selection. However, to meet the needs of the busy clinical environment, the mFI is derived from the concept of the FI; a selection of age-related chronic conditions were the key variables used to construct the prediction model. Existing studies have shown that these previously developed mFIs can significantly predict the mortality of older adults [13.14]. However, to maximize the effectiveness of the prediction model, using a data-driven approach to construct the ML-mFI may provide better prediction accuracy. Moreover, in the survival analysis, the dose-response relationship is usually expected when grouping continuous measurements into distinct risk groups in association with outcomes. However, the distinction between individual groups from the continuous measurements is not always statistically significant even though the whole model reached statistical significance. For example, in one Taiwanese study, the developed FI was found to predict the adverse outcomes of older adults, which was in line with most related studies [5]. However, in that study, different risk groups that were categorized based on FI tertiles resulted in overlapping survival curves of the intermediate- and high-risk groups; it failed to achieve the stratification of risk groups. The combined use of the distance index and coverage index developed in this study engenders the ability to address the overlapping phenomenon of survival curves.

Although the mFI we developed adequately predicted adverse outcomes for older adults, the ML-mFI showed relatively higher hazard ratios than did the mFI for all health outcomes. Overall, the data-driven ML-mFI may identify different at-risk populations than the hypothesis-driven mFI. The data-driven approach may disclose the phenomenon of the whole data set [21-23], but the hypothesis-driven approach may provide a better explanation for the observations [24,25]. The data-driven approach may not be superior to the hypothesis-driven approach, since the study purpose and research questions may vary greatly. Although a data-driven approach may usually establish a prediction model with better accuracy, it is difficult to implement intervention programs for the observed phenomenon. Applying the theory of cumulative deficits, a large number of variables may be used to construct the prediction model, but it becomes challenging to further utilize the prediction model with a large number of variables. Therefore, researchers have attempted to reduce the number of variables while maintaining optimal prediction accuracy. Our previous study used factor analysis to reduce the 125 selected variables into 35 factors to improve the clinical application [5]. However, the machine learning approach in this study may play a similar role in reducing the selected number of variables and optimizing prediction accuracy. The main strength of this study was to demonstrate the methodological advance of processing a large data set to select appropriate variables to construct a prediction model and to ensure the distinction of different risk groups with dose-response relationships. This methodological advance may facilitate public health or social sciences research, or interdisciplinary research that uses a large data set with a wide array of data characteristics. In particular, the distance index and coverage index would be of great importance for future research to categorize the results of continuous variables into distinct entities with different health risks. Avoiding the overlap of the survival curves of different risk groups by using the distance index and coverage index is important to strengthen the observed phenomenon and the risk group classification.

Therefore, this ML-mFI demonstrated an automatic approach to predict adverse outcomes in older people, and it can be applied to different populations in different countries. Using the same approach, different diseases can be selected to construct the new ML-mFI in another population to predict adverse outcomes in the corresponding population. For example, we further stratified our study population into 3 subcohorts, including those aged 65 to 75 years, 76 to 85 years, and 85 years and older, and we constructed three kinds of ML-mFI for each age group according to the same automatic machine learning approach and model selection criteria. We found that the total deficit number and composing deficits on the ML-mFI, as well the cut-off points of different frailty statuses, are quite different in distinct age groups. For example, the total deficit numbers on the ML-mFI were 59, 47, and 39 for those who were aged 65 to 75 years, 76 to 85 years, and 85 years and older, respectively. In addition, the composing deficits were different, as displayed in Multimedia Appendix 5. Although the composing deficits of the ML-mFI are different in distinct age groups, all of these ML-mFI can successfully predict all-cause mortality (C index>0.6). These findings are inspiring because they indicate that the same machine learning approach can be used to construct one’s own ML-mFI to fulfill this purpose. Individual diseases may have different clinical impacts in different countries due to diagnosis, treatment, and quality of care. Therefore, the results of this study can be applied to different countries and populations using the same approach to construct their own ML-mFI to meet their needs.

Therefore, our ML-mFI could have clinical implications in public health or in health care administration. For example, in large long-term care facilities management, the administration needs to optimize the admission waiting list through the estimation of the mortality of all residents. On the other hand, in public health settings, the government is able to accurately estimate the health risk of residents in a certain geographic area and to provide optimal health care or palliative care services. Traditionally, these decisions were made based on existing medical knowledge, but a data-driven approach may better predict outcomes and optimize the government's public health policy. In clinical practice, the ML-mFI may enable physicians and families to quantify health risks for optimal care planning. Hence, using available electronic medical records, the ML-mFI can be automatically generated and integrated as part of the medical record to facilitate certain forms of decision-making in care planning.

Despite all the effort that went into this study, there are still some limitations. First, like all data-driven studies, the results of this study could not provide or validate a well-established hypothetical framework due to the nature of machine learning. Second, it remained difficult to develop further intervention programs based on the diagnostic entities identified by machine learning. Third, another data set is needed to examine whether overfitting exists in the machine learning model. Finally, as in most of the previous frailty index studies, although we adjusted for age and sex as covariates in the Cox model, we were unable to access some residual confounders not routinely captured in a claims database, such as disease severity or lifestyle factors (eg, physical activity and diet).

In conclusion, the ML-mFI significantly predicted adverse health outcomes for older adults, and the risk groups defined by the combination of the distance index and coverage index distinguished the different risk groups with dose-response relationships and clear distinctions. The methodological advance of this study also had further research implications for studies with similar data and research questions. The data-driven approach may provide better prediction accuracy than the hypothesis-driven approach, but the superiority of the data-driven approach requires further study for confirmation.

Acknowledgments

Abstract

Background: Social network sites (SNSs) are widely exploited in health education and communication by the general public, including patients with various conditions. Nevertheless, there is an absence of evidence evaluating SNSs in connecting health professionals for professional purposes.

Objective: This pilot randomized controlled trial was designed to evaluate the feasibility of an intervention aiming to investigate the effects of a continuous professional education program utilizing Facebook to obtain knowledge on dementia and care for patients with dementia.

Methods: Eighty health professionals from Hong Kong were recruited for participation in the study and randomized at a 1:1 ratio by a block randomization method to the intervention group (n=40) and control group (n=40). The intervention was an 8-week educational program developed to deliver updated knowledge on dementia care from a multidisciplinary perspective, either by Facebook (intervention group) or by email (control group) from October 2018 to January 2019. The primary outcomes were the effects of the intervention, measured by differences in the means of changes in pre- and postintervention scores of knowledge assessments from the 25-item Dementia Knowledge Assessment Scale (DKAS) and formative evaluation of 20 multiple choice questions. Other outcome measurements included participant compliance, participant engagement in Facebook, satisfaction, and self-perceived uses of Facebook for continuing professional education programs.

Results: Significantly more intervention group participants (n=35) completed the study than the control group (n=25) (*P*<.001). The overall retention rate was 75% (60/80). The mean of changes in scores in the intervention group were significant in all assessments (*P*<.001). A significant difference in the mean of changes in scores between the two groups was identified in the DKAS subscale Communication and Behavior (95% CI 0.4-3.3, *P*=.02). There was no significant difference in the total DKAS scores, scores of other DKAS subscales, and multiple choice questions. Participant compliance was significantly higher in the intervention group than in the control group (*P*<.001). The mean numbers of participants accessing the learning materials were 31.5 (SD 3.9) and 17.6 (SD 5.2) in the intervention and control group, respectively. Polls attracted the highest level of participant engagement, followed by videos. Intervention group participants scored significantly higher in favoring the use of Facebook for the continuing education program (*P*=.03). Overall, participants were satisfied with the interventions (mean score 4 of a total of 5, SD 0.6).

Conclusions: The significantly higher retention rate, together with the high levels of participant compliance and engagement, demonstrate that Facebook is a promising tool for professional education. Education delivered through Facebook was significantly more effective at improving participants' knowledge of how people with dementia communicate and behave. Participants demonstrated positive attitudes toward utilizing Facebook for professional learning. These findings provide evidence for the feasibility of using Facebook as an intervention delivery tool in a manner that can be rolled out into practical settings.

KEYWORDS

dementia; Facebook; social network sites; continuous professional education

Introduction

Background

Social network sites (SNSs) have become an essential part of the daily lives of billions of users globally. Facebook currently represents the largest social network in the world, which engages more than 2.45 billion users globally [1]. SNSs are widely exploited in research on health behavior-related outcomes and health communication by both the general public and patients [2,3]. A systematic review showed that health professionals have also extensively adopted SNSs for professional purposes [4]. SNSs are used to support the delivery of clinical services, make referrals, and share information [5-7], demonstrating benefits in network building and professional collaboration [8-10]. Facebook is a novel tool for enhancing educational interactions [4,11], sharing domain knowledge through developing professional communities [12,13], and staying abreast of news and information pertaining to professional needs and interests [14-16]. With increased adoption of SNSs, it is critical to evaluate the effectiveness of such utilization for professional purposes by health professionals. This pilot study is the first to evaluate the effects SNSs in continuous professional education (CPE) programs by utilizing Facebook in the delivery of education on dementia care to a cohort of health professionals.

Need for CPE on Dementia

Dementia has been acknowledged as a significant global public health issue [17,18]. In 2015, it was estimated that 46.8 million people were living with dementia worldwide, with those numbers expected to almost double every 20 years, reaching up to 131.5 million by 2050 [19]. Timely detection and proper management of dementia are critical to allow patients to plan for their future care while they still have the capacity to make important decisions [20]. However, inadequate effort has been made to address the continuous educational needs of the health care workforce on the topic of dementia [21]. Low levels of dementia knowledge among health care personnel remain common [21], representing a major barrier to providing appropriate end-of-life care to people with dementia [22]. The limited teaching hours in preregistration programs was identified as one of the main factors associated with the lack of knowledge of dementia [23]. Postregistration training on dementia care has been offered in some programs, but the most common approach was traditional small to large group face-to-face delivery [21], which has limitations in terms of resources, time, and geographical factors. Electronic learning (eLearning) options for CPE programs offer flexibility with respect to both the time and place of learning. Nevertheless, these types of programs can be accompanied by inadequate levels of participant interaction, reflection, practice, and application to practice [24,25]. With the evolving utilization of SNSs by health professionals, there is potential to make the most of SNSs to meet professional education requirements and promote interaction while avoiding a significant resource burden.

Although some research has been conducted to investigate the uses of SNSs in health communication and education among the general public and patients, there is a general lack of literature on the topic, with a notable sparsity of evidence from intervention trials on evaluating SNSs in connecting health professionals for professional communication [4]. The findings obtained to date are in line with reviews on professional dementia education, in which most of the included studies used weak research designs that were unable to identify the direct effects of the interventions [26,27].

Aim and Objectives

This pilot trial was designed to fill the gaps in the current literature, representing the first pilot randomized controlled trial (RCT) examining the effects of an SNS on professional education by health professionals. The aim of the study was to evaluate the feasibility of an interventional trial designed to investigate the effects of a CPE program utilizing Facebook on dementia knowledge and care. The objectives to achieve the research aim were to: (1) quantitatively evaluate the effects of a Facebook intervention by measuring the change in knowledge pre and postintervention, (2) quantitatively evaluate the feasibility and acceptability of the intervention, and (3) qualitatively assess participant perceptions of the intervention related to recruitment, delivery, and usability.

Methods

Overview

The study was a pilot randomized, unblinded, controlled trial with mixed-research methods (quantitative and qualitative). The intervention was an 8-week CPE program on dementia delivered to participants either by Facebook (intervention group) or by email communications (control group) from October 2018 to January 2019. Ethical approvals were obtained from the Hong Kong Polytechnic University (reference number: HSEARS20180307007) and the Caritas Institute of Higher Education (IRG180100). Trial reporting follows the CONsolidated Standards of Reporting Trials (CONSORT) 2010 statement: extension to randomized pilot and feasibility trials [28].

Subject Recruitment and Randomization

Health professionals were recruited via promotion of the trial at professional conferences, and by invitations disseminated through professional bodies and health institutes. Inclusion criteria were being a health professional, having access to the internet, in addition to having an email account and Facebook account or willing to create one otherwise. Individuals were excluded if they were working at institutes specializing in the delivery of dementia or geriatric care or had prior training in dementia care that was completed in the past 6 months.

Before randomization, participants were required to complete baseline assessments, knowledge tests, and consent forms. In addition to collecting background information such as age, gender, occupation, and years of working experience, the baseline assessment also surveyed the participants' habits with respect to the use of SNSs, including SNS choices and frequency of use.

Consenting participants were randomized to two groups at a 1:1 ratio by a block randomization method in view of the small sample size [29]. The randomization was performed by an independent researcher who had no involvement in the trial. The block size was blinded from the investigator performing this study.

Intervention

The learning materials (ie, the educational intervention) were developed by a team of experts from the relevant disciplines, including medicine, nursing, pharmacy, occupational therapy, speech therapy, and social sciences, to provide updated interdisciplinary knowledge on dementia care. Upon completion, participants would be able to (1) describe the prevalence, pathophysiology, and recognition of dementia; (2) apply the key screening and assessment tools for diagnosing dementia; (3) explain management and support to both elderly patients with dementia and their caregivers; and (4) appraise their roles in the provision of dementia care.

Along with the textual content, a collection of multimedia materials was selected to supplement participant learning, including websites, educational videos, pictures, diagrams, and interactive online games.

Participants in both groups received the same content and were expected to spend approximately 15 minutes daily reading the materials. Together with the time spent in assessments, the total learning hours amounted to approximately 12 hours throughout the 8-week intervention period.

In the intervention group, a Facebook Social Learning Group was created to deliver the CPE program. A Social Learning Group has additional features to an ordinary Facebook group, which facilitate the retrieval of learning materials and tracking participant engagement. The learning materials were uploaded every 1 to 3 days in the form of Facebook posts, photos, videos, text, files, or polls (Figure 1). A variety of components and post lengths were utilized, with the aim of maximizing participant engagement and interest [30,31]. There were typically 14 posts per week, including a post containing the notes (learning materials) of the week in PDF format. Participants were encouraged to comment, react, and interact with the other group members but were not allowed to create a new post.

In the control group, before the beginning of each study week, participants received emails containing their individual Bitly links to the PDF notes of that week. Bitly is a link management platform that enables analysis of the activity of each link [32]. Contents of notes were identical to those received by the intervention group participants, including the revision questions, photos, videos, games, and websites. Control group participants could access the multimedia content using the Bitly links inserted in the PDF notes, but could not take part in the polls or view the previews of links generated by Facebook. During the intervention period, control group participants received a total of 8 sets of notes.

Comorbidity with other diseases

Comorbidity with other diseases:
(a) Diabetes mellitus: The incidence of AD is 50 - 100% higher in people with type 2 diabetes mellitus (T2DM) than those without the disease. A higher blood glucose level has been shown to associate with an increased risk of dementia, even among people without T2DM.
(b) Depression: Meta-analysis revealed that late-life depression was associated with an increased risk of AD with OR of 1.65. People with MCI were also more often depressed than normal controls. Reciprocally, patients with depression had higher deficiency in executive function, memory and attention.

Poll

Which is True?

Which is TRUE?

☑ Alzheimer's disease is the most common form of dementia. +29
☐ Most forms of dementia do not generally shorten a person's life.
☐ Blood vessel disease (vascular dementia) is the most common form of dementia.
☐ People can recover from the most common forms of dementia.
☐ Dementia is a normal part of the ageing process.

2 Comments Seen by 36

Windy Chan Although treatment can help,dementia (including AD & vascular dementia) can significantly shorten life expectancy. But this is variable and many people live for a number of years with the condition or die from some other cause.

Prevalence and incidence

The global prevalence of dementia for people aged >60 years is 5% to 7%. In 2010, approximately 35.6 million people lived with dementia, and the number is expected to double every 20 years.
There is a regional difference in the disease prevalence, with estimates of 6.9% in Western Europe, 6.5% in North America, and 4.6% among the Chinese population including Hong Kong. The prevalence of dementia increases exponentially with age. For the age group of 60 – 64, the p... See more

Outcome Measures

Primary Outcome: Quantitative Evaluation of the Effects of a Facebook Intervention

The effectiveness of using Facebook to deliver the CPE program was measured by the knowledge gain between the pre and postintervention knowledge tests, calculated as the difference in scores. The knowledge gain in the two groups was also compared.

The knowledge tests consisted of formative evaluation, 20 multiple choice questions, and the 25-item Dementia Knowledge Assessment Scale (DKAS). Content for the multiple choice questions was drawn directly from the learning materials throughout the 8 learning weeks. The DKAS has been validated as a reliable measure of dementia knowledge for a wide spectrum of populations, including health professionals. The DKAS elucidates respondents' knowledge characteristics across four coherent domains: Causes and Characteristics, Communication and Behavior, Care Considerations, and Risks and Health Promotion [33]. A pilot assessment of the knowledge tests was performed to determine the coverage of questions, level of difficulty, and potential ceiling effects.

Quantitative Evaluation of Participant Compliance

Participant compliance was quantified by the number of week(s) (out of 8) the material was accessed by the participants, recorded by the "Seen by" feature of Facebook in the intervention group and by the Bitly link in the control group.

In Facebook, the "Seen by" feature of a post automatically records the individual group members that had seen the post (Figure 1). In the control group, each participant had their own 8 unique Bitly links to access the corresponding 8 weeks of materials. A participant clicking on the Bitly link was counted as having accessed the materials for that week. Bitly links were also created to track participant compliance in accessing the recommended external learning resources such as videos and websites.

Quantitative Evaluation of Intervention Group Participant Engagement

In studying the communication artifacts occurring in Facebook, engagement was defined as the metric of actions that participants took in the group during the intervention period. In addition to ordinary actions such as comment and reactions, a unique feature of the Facebook Social Learning Group is the "Done" button (Table 1). Participants were encouraged to click the "Done" button to share their learning progress. A set of descriptive data was also extracted from analyzing participant engagement in the intervention group, considering features that have been generally used in previous Facebook-based studies [30,31].

Table 1. Participant engagement actions on Facebook.

Engagement Action	Definition
Comment	A participant commented on a post or a comment made by another member in the group
React	A participant clicked the reaction button on a post to share different reactions: Like, Love, Haha, Wow, Sad, or Angry
Done	A participant clicked the "Done" button of a post. The "Done" button will turn green after being clicked.

Quantitative Evaluation of Participant Satisfaction

All participants were invited to complete a satisfaction evaluation form developed for the effective appraisal of training delivery for health professionals [34]. The form contained 10 5-point Likert-style positively phrased statements focusing on the achievement of program objectives, impact on learning, learning experiences, and application to clinical practice. There were 3 questions that evaluated the program length, information quantity, and difficulty level. A pilot assessment of the evaluation form was performed to determine the coverage of questions.

Quantitative Evaluation of Participants' Attitudes Toward Using Facebook for the CPE Program

Participants' attitudes on the professional use of Facebook were evaluated in a questionnaire modified from the Continuous Medical Education App Attitudes Survey Instrument, a validated measure of participant attitudes toward mobile app use in a continuous medical education program [35]. There were 10 5-point Likert-style positively phrased statements evaluating the educational value, acceptability, usability, and future feasibility of using Facebook to deliver the program. A pilot assessment of the survey was performed to determine the question coverage.

Qualitative Assessment of Feasibility and Acceptability

To investigate the pilot study's feasibility and acceptability, all participants were invited to complete a feedback form on their learning experiences and to take part in short semistructured interviews. To encourage participation of interviews, reminders were sent twice by Facebook messages (intervention group) and emails (control group).

In the feedback form, qualitative data were obtained via two free-form questions that asked the participants about their perceptions of the most valuable sections as well as suggestions for improvement.

The semistructured interviews were conducted following a flexible interview guide to explore a wider range of respondents' perceptions and comments. Participants were invited to share their views on (1) promotion, recruitment, and randomization arrangement; (2) delivery of the educational intervention; (3) usability of the learning materials; (4) feasibility and acceptability of the study; and (5) comments for further improvement. Respondents could refuse to answer any question or ask questions. Interviews were audio-recorded and transcribed manually. Data were organized using a Microsoft Excel 2016 spreadsheet.

Thematic analyses of the contents of feedback forms and semistructured interviews were conducted independently by the authors. Discrepancies on data analyses, coding, and themes generated were resolved by discussion until consensus was reached [36].

Statistical Analysis

A literature search did not identify any RCTs conducted on the effects of an educational intervention utilizing SNSs that could be used as a basis for calculating sample size. This study conservatively assumed a small effect size of 0.2. For a full RCT designed with 90% power and a two-sided 5% significance threshold, the recommended sample size for a pilot trial is 30 per group [37]. Assuming a dropout rate of 10%, the total target number of participants was 66. Slightly more participants (N=80) were recruited for this study due to positive responses from professional bodies.

Participant demographics and SNS usage characteristics were treated as categorical variables. The Chi square test and Fisher exact test were used to analyze dichotomous and categorical variables. Participant performance on the knowledge test is presented descriptively. To compare the knowledge gains of the two groups (primary outcome), an independent sample *t* test was used. The effect size of the outcome measure between the two groups was estimated according to the formula proposed by Morris [38] for mean pre-post changes between the intervention and control groups. An intention-to-treat approach was adopted in this study. Scores in the evaluation and survey on the use of Facebook (secondary outcome) are presented as descriptive statistics and were analyzed by a two-sample *t* test or Fisher exact test. *P*≤.05 was considered significant. Statistical analyses were conducted using R v. 3.1.2 (R Foundation for Statistical Computing, Vienna, Austria) and IBM SPSS Statistics version 23 (IBM Corp, Armonk, NY, USA).

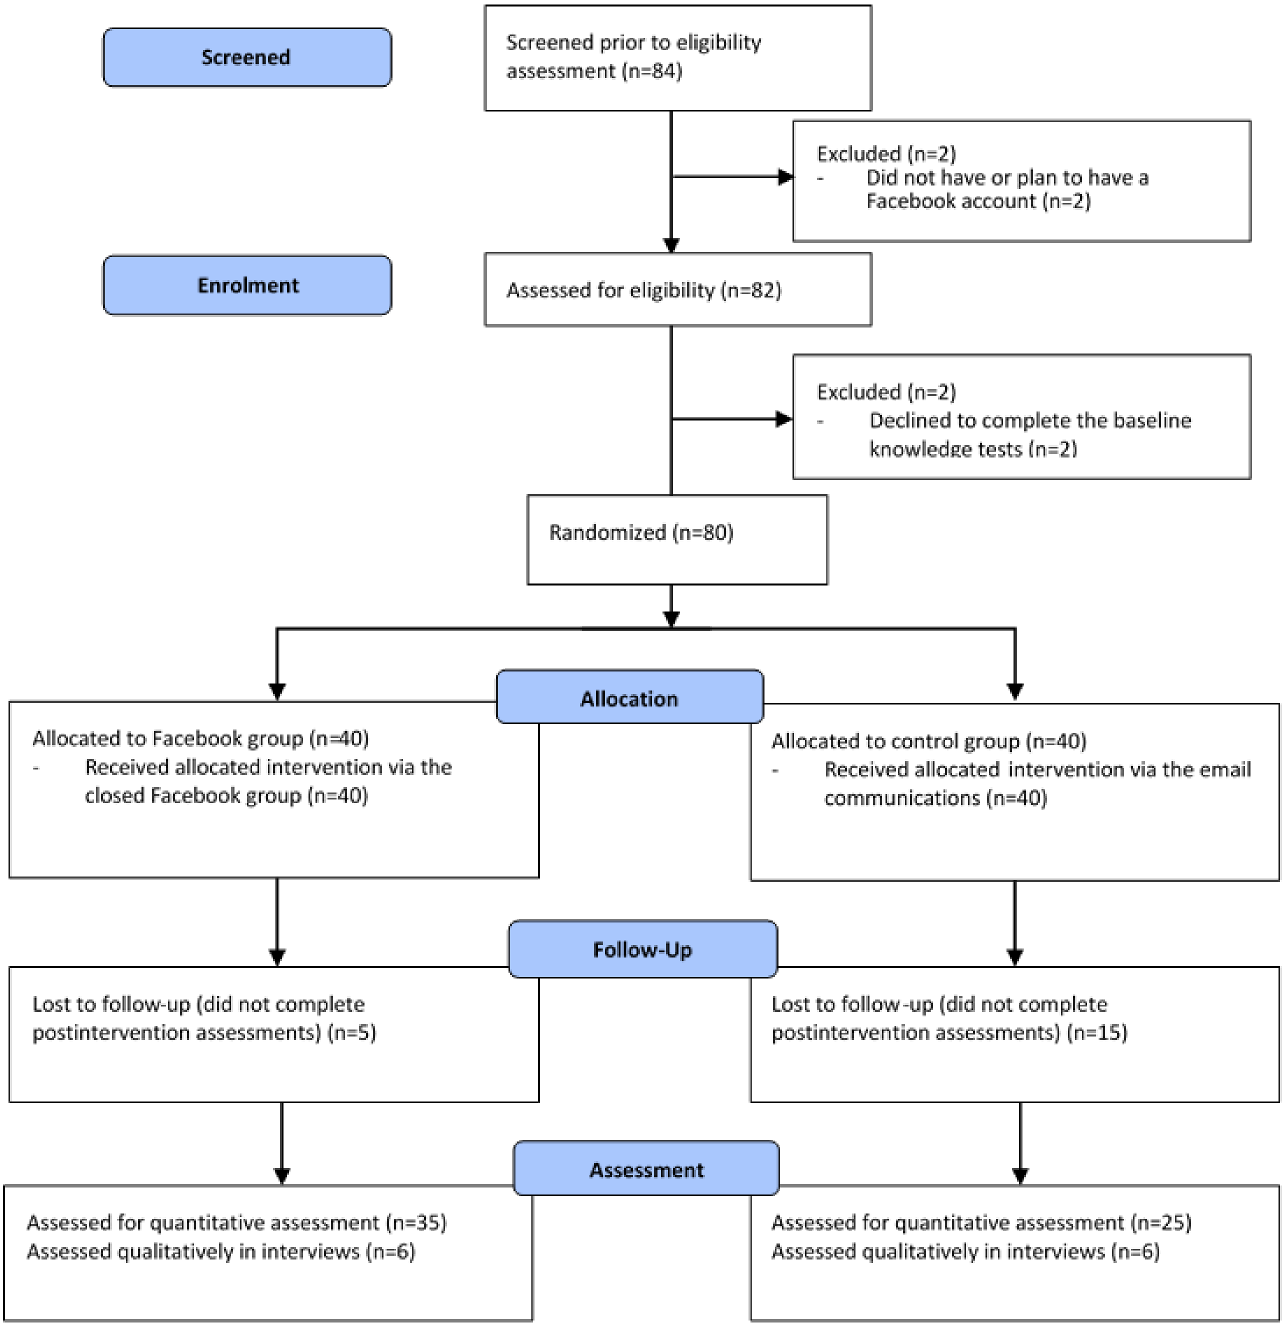
Results

Participants

Figure 2 shows the flow of study subject recruitment and randomization according to the CONSORT guidelines. Eighty participants underwent randomization with 40 allocated to the intervention group and 40 allocated to the control group.

The overall retention rate was 75% (60/80). Significantly more intervention group participants (35/40, 88%) completed the study compared to those in the control group (25/40, 63%; *P*<.001). Twelve participants, six from each group, attended postintervention interviews.

Figure 2. Study CONsolidated Standards of Reporting Trials (CONSORT) flowchart.



At baseline, participant characteristics and habits when using SNSs were comparable in the two groups (Table 2 and Multimedia Appendix 1). The majority (64%, 51/80) of participants ranged in age from 20-39 years. The participants, who worked in various health disciplines, included pharmacists, nurses, optometrists, and physiotherapists.

Among all participants, 95% were daily SNS users. WhatsApp Messenger and Facebook were the most frequently used SNSs, followed by Instagram, WeChat, and Line. SNSs were mainly used for personal use and communication as well as for general knowledge. Less than half of the participants had used SNSs for professional communication. Only two participants had previously participated in a CPE program delivered via SNSs (Multimedia Appendix 1).

At baseline, the knowledge test overall mean scores were similar in the two groups (Multimedia Appendix 2). In both groups, the lowest mean correct responses in the DKAS were found in the subscale Communication and Behavior.

Table 2. Baseline characteristics of the study participants.

Characteristic	All participants (N=80)	Intervention group (n=40)	Control group (n=40)	*P* value
Age (years), n (%)				**.80**[a]
20-29	28 (35)	14 (35)	14 (35)	
30-39	23 (29)	13 (33)	10 (25)	
40-49	15 (19)	6 (15)	9 (23)

[b] Fisher exact test.

Quantitative Evaluation of the Effects of a Facebook Intervention

At the postintervention assessment, intervention group participants demonstrated significant knowledge gains, reflected by significant increases in the total DKAS scores, each of the DKAS subscale scores, and multiple choice questions (Table 3). In the control group, significant knowledge gains were not identified in the DKAS subscales Communication and Behavior and Care Considerations.

A significant difference in changes in the mean knowledge gain scores between the two groups was identified in the DKAS subscale Communication and Behavior, with a medium effect size (Table 3). The CPE program delivered by Facebook was more effective than the control (email provision) at increasing participants' understanding and knowledge of the communication and behavior of people with dementia. There was no significant difference between the two groups in the total DKAS, multiple choice questions, and other DKAS subscale scores.

The effect size in the change in the overall DKAS score was small. For a full-scale two-armed RCT, assuming a standard error of 5% with 95% power, a total of 272 participants would be required (ie, 136 per group). With attrition rates of 10%, 20%, or 30%, the total number of participants required is 304, 340, and 390, respectively.

Table 3. Scores and the comparison of changes in scores at postintervention knowledge assessment.

Assessment	Intervention group (n=40)			Control group (n=40)			95% CI	*P* value	Effect size
	Postintervention score, mean (SD)	Change in score, mean (SD)	*P* value	Postintervention score, mean (SD)	Change in score, mean (SD)	*P* value			
Total DKAS[a] score (maximum score 50)	36.9 (8.0)	8.3 (8.6)	<.001	35.1 (8.0)	4.9 (8.4)	.007	–1.1-7.8	.13	0.44 (small)
DKAS subscale Causes and Characteristics (maximum score 14)	11.3 (3.0)	2.5 (3.4)	<.001	10.8 (2.5)	1.8 (3.4)	.01	–1.1-2.5	.44	0.20 (small)
DKAS subscale Communication and Behavior (maximum score 12)	7.5 (3.1)	2.1 (3.6)	.001	6.2 (2.6)	0.3 (2.1)	.51	0.4-3.3	.02	0.77 (medium)
DKAS subscale Care Considerations (maximum score 12)	9.5 (2.6)	1.4 (2.8)	.007	9.9 (2.6)	1.1 (2.9)	.07	–1.2-1.8	.70	0.23 (small)

[a] DKAS: Dementia Knowledge Assessment Scale.

Quantitative Evaluation of Participant Compliance

Participant compliance with the educational intervention was significantly higher in the intervention group (mean 6.30, SD 2.28 weeks) than in the control group (mean 3.53, SD 3.21 weeks) (*P*<.001). Overall, 75% of the intervention group participants completed at least 6 weeks or more of the intervention compared to only 35% of the control group participants (Table 4). The mean number of participants accessing the materials was 31.5 (SD 3.9) and 17.6 (SD 5.2) in the intervention and control group, respectively.

Participant compliance was significantly higher in the intervention group (mean 14.9, SD 14.1) than in the control group (mean 2.1, SD 1.8) (*P*<.001) with respect to accessing the 18 external learning resources (9 videos and 9 website links) (Multimedia Appendix 3). Participants who learned via Facebook were significantly more compliant in viewing multimedia content.

Table 4. Participant compliance.

Total number of weeks accessed	Intervention group (N=40), n (%)	Control group (N=40), n (%)
0	1 (3)	9 (23)
1	2 (5)	9 (23)
2	1 (3)	1 (3)
3	2 (5)	4 (10)
4	1 (3)	2 (5)
5	3 (8)	1 (3)
6	5 (13)	1 (3)
7	7 (18)	5 (13)
8	18 (45)	8 (20)

Quantitative Evaluation of Participant Engagement on Facebook

A total of 97 Facebook posts were created for the intervention group. All posts received a considerable number of participant engagement actions (mean 19.03, range 11-33). Polls, which were question-related posts designed to encourage member interaction, attracted the highest degree of participant engagement (mean 20.17), followed by videos (mean 19.56). Links (mean 17.33) generated the lowest number of engagement actions during the intervention period.

Quantitative Evaluation of Participant Satisfaction With the Educational Intervention

As illustrated by item 10 in the satisfaction evaluation (Table 5), participants were satisfied with the training overall. There was no significant difference between the two groups. Evaluating achievement in each of the four course objectives (items 1-4), the overall mean scores ranged from 3.8 to 3.9 (SD 0.6-0.7). More than 80% of participants regarded the program length, quality, and difficulty level as appropriate.

Table 5. Participant satisfaction with the educational intervention.

Item	All (N=60)	Intervention group (n=35)	Control group (n=25)	*P* value
Achievement of objectives, mean (SD)				
1. Describe the prevalence, pathophysiology and recognition of dementia	3.9 (0.6)	3.8 (0.6)	4.0 (0.6)	.28[a]
2. Apply the key screening and assessment tools for diagnosing dementia	3.8 (0.7)	3.7 (0.7)	3.9 (0.8)	.30[a]
3. Explain the management and support to both elderly people with dementia and their caregivers	3.9 (0.6)	3.9 (0.6)	4.0 (0.6)	.26[a]
4. Appraise your role in the delivery of dementia care	3.8 (0.7)	3.7 (0.7)	3.9 (0.7)	.22[a]
Overall (sum of items 1 to 4)/20	15.4 (2.3)	15.1 (2.3)	15.8 (2.2)	.19[a]
Learning experiences, mean (SD)				
5. The training enhanced my knowledge of dementia care	4.2 (0.6)	4.2 (0.6)	4.1 (0.6)	.75[a]
6. The learning material was well organized	4.1 (0.7)	3.9 (0.8)	4.2 (0.6)	.18[a]
7. The learning material was easy to use	3.9 (0.9)	3.8 (1.0)	4.1 (0.8)	.21[a]
8. I will be able to apply the training information to my professional practice	3.8 (0.8)	3.8 (0.8)	3.8 (0.7)	.89[a]
9. I would recommend this training to others	4.0 (0.7)	3.9 (0.7)	4.0 (0.7)	.49[a]
10. Overall, I am satisfied with this training	4.0 (0.6)	4.0 (0.6)	4.0 (0.6)	.81[a]
Overall (sum of items 1 to 6)/30	23.9 (3.8)	23.6 (4.0)	24.3 (3.5)	.49[a]
Length of training, n (%)				**.71[b]**
About right	49 (82)	27 (77)	22 (88)	
Too long	10 (17)	7 (20)	3 (12)	
Too short	1 (2)	1 (3)	0 (0)	
Quality of information, n (%)				**.34[b]**
About right	51 (85)	30 (86)	21 (84)	
Not enough	4 (7)	1 (3)	3 (12)	
Too much	5 (8)	4 (11)	1 (4)	
Level of difficulty, n (%)				**.45[b]**
About right	52 (87)	29 (83)	23 (92)	
Too difficult	8 (13)	6 (17)	2 (8)	
Too easy	0 (0)	0 (0)	0 (0)

[b] Chi square test.

Quantitative Evaluation of Participant Attitudes Toward Using Facebook for the CPE Program

Overall, the respondents were positive about using Facebook for a CPE program. Intervention group participants rated the use of Facebook significantly higher (*P*=.03) (Table 6).

Significant differences between the two groups were identified in responses to the survey questions "I would recommend Facebook for other CPE courses" (*P*=.01), "Using Facebook improved my learning experience" (*P*=.02), and "I would be more likely to attend a CPE/CNE course if it used Facebook" (*P*=.02).

At completion of this pilot trial, participants who had learned via Facebook were more willing to use Facebook in future CPE programs.

Table 6. Attitudes toward the use of Facebook for continuous professional education programs.

Item	All (N=60), mean (SD)	Intervention group (n=35), mean (SD)	Control group (n=25), mean (SD)	*P* value[a]
1. Using Facebook improved my learning experience	3.6 (0.8)	3.7 (0.9)	3.3 (0.7)	.02
2. Using Facebook helped me stay more engaged	3.5 (0.9)	3.6 (0.9)	3.2 (0.7)	.09
3. Using Facebook enabled me to gain more knowledge	3.4 (0.8)	3.5 (0.9)	3.3 (0.7)	.26
4. Using Facebook will help me apply what I have learned to clinical practice	3.2 (0.9)	3.4 (1.0)	3.0 (0.8)	.09
5. Using Facebook enhanced my education	3.4 (0.9)	3.5 (0.9)	3.2 (0.8)	.28
6. I would be more likely to attend a CPE[b]/CNE[c] course if it uses Facebook	3.4 (0.9)	3.6 (0.8)	3.1 (0.9)	.02
7. I am likely to use Facebook after the course is over	3.4 (0.9)	3.6 (0.9)	3.1 (1.0)	.05
8. Facebook is easy to use	3.6 (0.8)	3.8 (0.7)	3.4 (0.8)	.05
9. Facebook is intuitive to use	3.5 (0.8)	3.6 (0.8)	3.2 (0.8)	.05
10. I would recommend Facebook for other CPE courses	3.4 (1.0)	3.7 (0.9)	3.0 (0.9)	.01
Overall (sum of items 1 to 10)/50	34.3 (7.5)	36.0 (7.4)	31.8 (6.9)	.03

[a] Independent sample *t* test.

[b] CPE: continuing professional education.

[c] CNE: continuing nursing education.

Qualitative Assessment of Feasibility and Acceptability

Twenty-nine responses were collected from the feedback forms. Twelve participants, six from the intervention group and six from the control group, attended the semistructured interviews. A wide range of inputs were collected, including comments on current models of dementia care and CPE frameworks. We here focus on the findings that helped in evaluating the design of the study and the feasibility and acceptability of interventions. The qualitative data analyses led to the generation of the following themes.

Flexible and Effective Learning via Facebook

Learning through Facebook is highly mobile and flexible, without geographic or time constraints. Most of our participants easily accessed Facebook via the Facebook app installed on their mobile phones. Many stated that they seldom set aside a particular time to study, but rather tended to read posts whenever they had a chance. This was exemplified in the following participant comments: "I am glad that I can learn new knowledge during my daily commute," and "I appreciate the flexibility provided by Facebook, so I can learn whenever and wherever I want."

Furthermore, participants appreciated the conciseness and effectiveness of the education. One participant stated, "It's nice the Facebook posts are kept short, because I can complete them easily." Facebook provides a user-friendly platform that facilitates information retrieval, particularly during revision. This advantage was exemplified in participant comments such as "I hadn't expected that posts in Facebook could be organized in such a systematic way," and "I like the tracking feature in the Facebook group that clearly shows which posts I haven't read."

A majority of respondents, including a few from the control group, commented that "More CPE programs should be delivered by Facebook." A few participants concluded, "The flexibility in learning and attractiveness of the content on Facebook could not be replaced by other platforms."

Motivated and Engaged Participation on Facebook

All respondents from the intervention group appreciated the feeling of being encouraged to learn, which could be attributed to the Facebook automatic notification function. One participants stated "It's nice to receive notifications of new posts. That reminds me to study." A few participants liked to finish the new posts promptly after reading the Facebook notifications because it was similar to their usual Facebook habits.

Respondents also valued the sense of community that exists in a CPE course delivered using Facebook. In addition to the learning curriculum designed with a multidisciplinary approach, Facebook participants were also aware of their peers from different health disciplines and they appreciated the opportunity to know how others work in delivering dementia care.

The motivating interactions in the Facebook group also enhanced self-learning. Facebook participants claimed that they did notice how other members react to the posts. Some of them stated, “The polls remind me to take action, particularly when many members have voted.”

Enriched Learning With Multimedia Components

The multimedia components in the learning curriculum, such as videos and photos, were well accepted by all respondents, particularly those in the intervention group. They considered that the use of multimedia helped to more comprehensively explain concepts, which increased their motivation to learn. Some participants particularly prefer watching videos over other multimedia sources and considered videos as a good source for deepening their understanding on topics. This was exemplified in the following participant comments: “There should be more videos,” and “Some videos are quite interesting and informative, so I shared them with my friends.”

Participants found that Facebook highly facilitated the viewing of multimedia, which encouraged them to access the materials. Some of them claimed, “I watched most of the videos because they were easily played on the Facebook app.” However, the control group participants might not have utilized the multimedia to the same extent as their intervention group counterparts as described in the following section.

Low Compliance in the Control Group

In this study, control group participants generally experienced a less satisfactory learning experience and compliance. Although they might have accessed the materials, the majority did not read them all the way through. All control group respondents agreed that it was straightforward to access the learning materials, and felt that the topics and length were appropriate. Nevertheless, a majority claimed that they were not motivated to study in this one-way eLearning mode. One of the perceived obstacles was time. Control group participants typically felt that they ought to set aside a particular period of time to read through the learning materials. However, in their busy lives they usually failed to do so, and then gave up. This was exemplified by participant comments such as “The topics are interesting, but I feel that I need to set aside a particular time to read the notes. Then, I am too occupied to do so,” and “It seems too heavy and boring to read through all the notes.” Moreover, control group participants tended not to view the multimedia components, as they perceived it to be an inconvenience.

Other than receiving emails from the course administrator, control group participants did not have the chance to interact with other participants. A majority of control group respondents claimed they were not engaged in the course until the moment they were asked to complete the postintervention assessments. A few respondents commented, “I did not feel that I had been enrolled in a course until I was reminded to do the tests.”

Technical Issues Encountered in Online Learning

All respondents denied that any particular technical issues hindered their learning.

In both groups, several participants stated a concern that viewing videos on mobile phones would consume too much data. Consequently, they tended to study only when they had a Wi-Fi connection. There were suggestions to enlarge some diagrams and photos to enhance reading on a mobile phone. A few intervention group participants commented that the posts were not easy to read (the font size was quite small) on their mobile phone, and therefore they needed to use a computer.

Discussion

Principal Findings

This pilot RCT, as the first to evaluate the effects of using an SNS to deliver a CPE program, demonstrates how a novel educational intervention can result in significant knowledge gains in dementia care to health professionals. The high participant compliance and engagement, together with high satisfaction and acceptability, indicate that Facebook can be an effective and feasible learning tool that could easily be rolled out in practical settings.

Effectiveness of Facebook in Improving Knowledge

The Facebook intervention succeeded in offering the participants significant knowledge gains in all aspects of the knowledge assessments.

Comparing the means of changes in scores between the two groups, the Facebook intervention excelled at producing significant knowledge gains according to the DKAS subscale Communication and Behavior with a medium effect size. The six items included in this subscale assess how respondents interpret the behavioral symptoms of people with dementia and the proper way to communicate efficiently. Communication is a crucial skill in dementia care, but has been difficult for health personnel to learn [39]. For effective learning, rather than using plain text, all participants were instructed to view a collection of videos, websites, and online resources illustrating actual patient behaviors and communication. Although participants in both groups could access the same resources, significantly more intervention group participants accessed the materials. In addition to attracting participants by showing previews of multimedia contents, Facebook’s mobile app enables users to browse external links within the interface. In contrast, the control group participants tended to skip the links, because opening a separate browser appeared to disrupt their reading. Likewise, respondents in previous studies appraised the key benefit of SNSs as being efficient channels for a complex stream of information and multimedia files with no restriction in terms of location or office hours [40,41].

Facebook includes important features affecting participant performance in an online course, improving instructor effectiveness in facilitating learning [42]. On Facebook, posts were formatted in a concise and appealing way to reduce readers’ cognitive loads. With the Facebook tracking function, participants could review the contents nonsequentially and refer back to materials based on their study preferences. By contrast, in the control group, participants usually perceived reading the learning materials as a heavy workload that hindered their learning. Therefore, Facebook is a more effective learning platform by facilitating the integration of learning into routine habits of daily life.

Motivated Compliance and Engagement on Facebook

Learning through Facebook encouraged participant engagement and compliance. Indeed, participant retention in the intervention group (88%) was remarkably higher than that in the control group (63%) at study completion. Compared to other Facebook interventions for patients or the public, similarly high retention rates have been noted in studies promoting health-related behavioral changes such as running (78%) [43], physical activity (86%) [44], and weight loss (96%) [45]. The sense of presence and interactions with members in the Facebook group were appreciated by respondents in the evaluation and interviews. A higher degree of engagement could contribute to higher attendance [46], explaining the promise of learning through Facebook. However, the control group participants lacked a sense of belonging and involvement, which may explain the high dropout rate in this group.

Facebook is superior to email communication in providing a learner-centered, instructor-facilitated, more interactive platform for participants, which are demonstrated influencing factors of successful CPE programs [47]. Of note, in many jurisdictions, CPE schemes are voluntary, making it a challenge to motivate health professionals to complete learning programs [48,49]. The main deterrents to participation in a CPE include cost, resources, inability to get time off from work, household responsibilities, and lack of time [48,49]. Facebook features good usability to be an attractive CPE program by providing a learning platform unrestricted by time and geographical factors.

Analyses of intervention group activities were conducted to determine the post type generating the highest participant engagement. Polls attracted the most engagement, followed by videos. Links generated the lowest engagement rates, because they were perceived to lead to an external site, disrupting participants' reading on Facebook. These findings are consistent with previous studies in the marketing field investigating brand engagement [30,31].

Participants' Attitudes Toward Facebook for Professional Education

Participants in this study were found to have positive views toward utilizing Facebook for a CPE program.

Intervention group participants rated their learning experience as significantly improved when using Facebook. They were significantly more supportive of recommending the use of Facebook for other CPE courses. Participants appreciated the convenience, flexibility, and usability offered by Facebook that enables ready participation for health professionals living in different regions, negating geographical boundaries. Likewise, respondents in previous studies appraised the key benefit of SNSs as being efficient channels with no restrictions in terms of location or office hours [40,41].

With the extensive use of SNSs in our daily lives, these positive attitudes toward Facebook highlight the feasibility of conducting further research on SNS use by health professionals.

Study Strengths

This pilot RCT has several strengths, including the randomized controlled design, learning curriculum developed from a multidisciplinary approach, and evaluation of a novel educational intervention utilizing Facebook with both quantitative and qualitative research approaches. The utilization of validated tools allowed for reliable quantitative measures. The qualitative data analyses enabled gaining deeper understanding of experiences on the educational interventions and identification of factors that were important to the participating health professionals.

Limitations

There are limitations of this study that warrant mention. Health professionals who had been frequent SNS users were more willing to join this study, which introduced bias in evaluating users' perceptions of Facebook. A majority of participants were aged between 20 and 39 years. These factors would affect the generalizability of the results to the overall workforce.

Many control group participants dropped out of the study, which made the overall dropout rate (25%) larger than the assumption in estimating the sample size (10%). This may have introduced bias and reduced power, affecting the generalizability, validity, and reliability of the results [50]. This issue is slightly mitigated by the increase in sample size from 60 to 80 and the intention-to-treat approach. However, it is understood that the estimate of effect becomes conservative due to dilution as a result of dropouts [51]. Very few participants took part in the semistructured interviews. Therefore, these responses might not adequately reflect the experiences of all those who completed the study, and response bias was likely.

For practicality, the knowledge tests were self-administered, which reduces the ability to standardize test conditions. Although participants were reminded not to check other resources, it was unfeasible to prevent participants from seeking help from others or checking references.

Implications

This pilot RCT brings forward several implications for further research and practice.

Facebook was found to offer substantial advantages over conventional online CPE programs, being beneficial to those who prefer distance learning, while maintaining interactions with classmates. Leadership by the administrator and member engagement were identified as crucial factors in SNSs [52]. A larger trial is required to thoroughly examine the potential effectiveness of an SNS-based educational intervention as compared to traditional learning approaches. Given the effect size of 0.44 of this study, the total number of participants required would be 272 for a full-scale two-armed RCT.

The benefits of utilizing multimedia components on Facebook highlight strategies for designing suitable educational content delivered by SNSs. Facebook can be an effective training tool for understanding patients or caregiver communication and behavior. Not restricted to dementia care, Facebook may also be used to deliver training on other mental health conditions such as depression and schizophrenia, or behavioral conditions, including speech and movement disorders.

In future research, in addition to measuring changes in knowledge, the impacts on practical implementation and even patient care would be important to investigate. However, the complexity of behavioral change increases as evaluation of an intervention ascends the hierarchy [53]. For dementia, there are some feasible, validated measurement tools available for this purpose, including attitudes toward dementia and self-confidence in caring for people with dementia [54].

Further research would consider including an economic analysis to investigate the cost of delivering CPE through Facebook compared to other channels such as face-to-face meetings and email communication. One of Facebook's economic advantages is that the post content can easily be reused. Owing to Facebook's user-friendly features such as post scheduling, the resources required for program administration are minimal.

Conclusion

Significantly more intervention group participants completed the study than control group participants (*P*<.001). The high levels of participant compliance and engagement make Facebook a promising method for delivering professional educational programs. Attending a CPE program through Facebook significantly improved participants' knowledge of dementia (*P*<.001). Compared to the control group, although a significant difference was not observed in the mean of changes in total scores, the Facebook intervention was significantly more effective at improving participants' knowledge of communication and behavior in dementia patients (*P*=.02). Participants demonstrated positive attitudes toward utilizing Facebook for professional learning. As the first pilot RCT examining the effectiveness of an SNS for professional education for health professionals, the findings of this study provide evidence for the feasibility of using Facebook for intervention delivery in a practical setting.

Acknowledgments

This project was funded by the Internal Research Grant of the Caritas Institute of Higher Education (IRG180100).

Authors' Contributions

All authors made significant contributions to the planning, recruitment, execution, analysis, and publication of this study.

Conflicts of Interest

None declared.

This randomized study was not registered as it is an educational intervention involving health care professionals only. The editor granted an exception as ICMJE does not require a registration if the purpose of the study is to examine the effect only on health care providers rather than patients. However, readers are advised to carefully assess the validity of any potential explicit or implicit claims related to primary outcomes or effectiveness, as retrospective registration does not prevent authors from changing their outcome measures retrospectively.

Abstract

Background: Prompt and accurate identification of stroke victims is essential to reduce time from symptom onset to adequate treatment and to improve neurological outcomes. Most neurologists evaluate the extent of neurological deficit according to the National Institutes of Health Stroke Scale (NIHSS), but the use of this scale by paramedics, the first healthcare providers to usually take care of stroke victims, has proven unreliable. This might be, at least in part, due to the teaching method. The video used to teach NIHSS lacks interactivity, while more engaging electronic learning (e-learning) methods might improve knowledge acquisition.

Objective: This study was designed to evaluate whether a highly interactive e-learning module could enhance NIHSS knowledge acquisition in paramedics.

Methods: A randomized controlled trial comparing a specially designed e-learning module with the original NIHSS video was performed with paramedics working in Geneva, Switzerland. A registration number was not required as our study does not come into the scope of the Swiss federal law on human research. The protocol was nevertheless submitted to the local ethics committee (Project ID 2017-00847), which issued a “Declaration of no objection.” Paramedics were excluded if they had prior knowledge of or previous training in the NIHSS, or if they had worked in a neurology or neurosurgery ward. The primary outcome was overall performance in the study quiz, which contained 50 questions. Secondary outcomes were performance by NIHSS item, time to course and quiz completion, user satisfaction regarding the learning method, user perception of the course duration, and probability the user would recommend the course to a colleague.

Results: The study was completed by 39 paramedics. There was a better overall median score (36/50 vs 33/50, *P*=.04) and a higher degree of satisfaction regarding the learning method in the e-learning group (90% vs 37%, *P*=.002). Users who had followed the e-learning module were more likely to recommend the course to a colleague (95% vs 63%, *P*=.02). Paramedics in the e-learning group took more time to complete the course (93 vs 59 minutes, *P*<.001), but considered the duration to be more adequate (75% vs 32%, *P*=.01). Time to quiz completion was similar between groups (25 vs 38 minutes, *P*=.12).

Conclusions: Use of an e-learning module shows promising results in teaching the NIHSS to paramedics.

Introduction

Background and Importance

Prompt and accurate identification of stroke victims is essential to reduce time from symptom onset to adequate treatment and to improve neurological outcomes [1]. Evaluation of the extent of the neurological deficit is generally performed according to the National Institutes of Health Stroke Scale (NIHSS), which was first described in 1989 [2,3]. Although the NIHSS has been extensively studied and validated in the hospital setting for many different types of provider, data regarding its application in the prehospital setting is limited [4]. Moreover, in contrast to other stroke scales, use of the NIHSS by Helicopter Emergency Medical Services crews has proved unreliable [5-8]. Nevertheless, the NIHSS enables identification of neurological deficits often missed when using other scales, particularly in cases of cerebellar stroke [9]. Accurate and reliable use of the same scale as that used by hospital neurologists might enable paramedics to improve the prehospital triage of stroke patients, and could help decrease door-to-needle time in patients for whom thrombolysis can be considered [10].

Many different factors might contribute to the difficulty of using the NIHSS in acute stroke, including the method used to teach this scale to paramedics. The video developed by Patrick Lyden et al is the most studied method used to teach NIHSS to in-hospital providers [11]. This media has many advantages, as it does not require the presence of a teacher or of a patient, and can be used at any time, even during night shifts. Lack of interactivity, however, has also been noted as a potential shortcoming [4].

Electronic-learning (e-learning) in its various forms is increasingly used in health professional education. Highly interactive self-paced modules are part of current e-learning models and often elicit higher satisfaction in the learning population [12,13]. Greater satisfaction with the learning method is usually associated with better understanding and performance [14].

Goal of This Investigation

The aim of our study was to evaluate the performance of an e-learning module in teaching the NIHSS to paramedics. Our hypothesis was that an e-learning module should, through its higher degree of interactivity, increase the paramedics' performance.

Methods

Study Design and Setting

This was a randomized (1:1), controlled, outcome assessor and data analysts blinded superiority study compliant with the CONSORT-EHEALTH guidelines [15]. The study took place in July 2019 in Geneva, Switzerland. In this state, paramedics need to follow a 3-year curriculum before certification, during which they are taught to assess potential stroke patients using simplified scales such as the Cincinnati and G-FAST, but not the NIHSS. Geneva emergency dispatchers send an ambulance staffed with two certified paramedics whenever they identify a possible stroke. Medical reinforcement by a physician-staffed mobile unit (Service Mobile d'Urgence et de Réanimation – SMUR) is only sent if an immediate vital threat is identified by the dispatchers or ambulance crew [16].

The study protocol (Project ID 2017-00847) was submitted to the local ethics committee, which issued a "Declaration of no objection" as this project does not come into the scope of the Swiss federal law on human research. A registration number was therefore not required.

Subjects and Enrollment

All paramedics working for any of the 7 ambulance services in Geneva and/or in the SMUR unit were invited to join the study on a voluntary basis. Four training sessions were organized on two different days to ensure maximum participation despite the shift work pattern. Paramedics were excluded if they had prior knowledge of or previous training in the NIHSS, or if they had worked in a neurology or neurosurgery ward. Consent was obtained through the online platform.

Learning Material and Online Platform

An e-learning module containing 184 highly interactive slides was created by 4 of the authors (MS, LSt, LSu, and AK) under Storyline 3 (Articulate Global). The entire module is available online at https://e-learning.nihss-study.ch. To make navigation easier and to allow the end user to easily review the learning material, this module is divided into chapters, each representing one item on the NIHSS. Each chapter is composed of 3 parts: an initial description explaining the scoring of the item, an illustration of how to test the patient, and a summary of the scoring and key pitfalls to look out for. To increase interactivity and user involvement, challenging questions are presented to the participants at the beginning of each chapter prior to displaying key learning material to stimulate curiosity [17]. Each wrong answer leads to a cue or to a detailed explanation before the user can either retry or move forward. Completion of all the chapters enables access to a practice quiz covering all scoring items.

Parts of the original video by Lyden et al are embedded in the e-learning module to illustrate clinical testing, with permission of the author. The original video had to be subtitled as English language skills vary widely among the paramedics working in Geneva. It was therefore fully translated by one author (MS), who also created the required subtitles. Three of the other authors (AK, LSt, LSu) reviewed the subtitled video to ensure the quality and accuracy of the translation. The subtitled video is available at https://video.nihss-study.ch.

The learning material was uploaded to an online platform developed under the Joomla! 3.9 Content Management System (Open Source Matters).

Study Sequence

Once paramedics had registered for the study, one investigator (LSt) sent the total number of registered participants to a second investigator (MS). This second investigator, thus blinded to the participants' information, performed randomization with a 1:1 allocation using a computer-generated table (https://www.randomizer.org/), and created unique identifiers (usernames and passwords). These identifiers, that would allow paramedics to log into the e-learning platform, were printed and placed in identical, opaque, sealed envelopes. These envelopes were shuffled and randomly scattered on a table by one of the co-authors (LSt or LSu) before each study session. Paramedics were asked to randomly choose one of the envelopes upon entering the study room, and to sit in front of a computer. Paramedics discovered their allocated group (e-learning vs video) only after logging into the online platform. They were then asked a set of questions designed to gather demographic data and to screen for exclusion criteria before being able to access the learning material.

The control group watched the subtitled video with unrestricted access to the controls, allowing them to pause, rewind, or move forward as they wished. The experiment group was given access to the e-learning module and could freely review and navigate the e-learning chapters at will. Each group only had access to their learning media, and no time constraints were imposed.

All participants could take notes while consulting the learning material and use them during the study quiz but were not provided with a NIHSS form. For both groups, access to the study quiz was enabled only after completion of the learning material. The study quiz was identical for all participants and contained 50 questions. The first 5 questions were related to key NIHSS concepts and were followed by full NIHSS evaluations of three patients. These evaluations were taken from the Lyden certification videos and were displayed according to the regular NIHSS scoring logic. To allow the candidates to immediately score the item they had viewed, each evaluation was divided into 15 subtitled video extracts, which could be paused, forwarded, or rewound at will. None of these extracts were shown to the paramedics either in the control video or in the e-learning module.

Once the quiz was completed, a last set of questions, based on a 5-point Likert scale, was displayed in order to assess the paramedics' feelings and thoughts regarding the length of the course, their satisfaction regarding the teaching method, the perceived difficulty, and the probability they would recommend the course to a colleague.

Data Collection

Data was electronically and automatically recorded in a MariaDB database version 5.5.5 (MariaDB Foundation) before being extracted to an Excel spreadsheet (Microsoft Corporation). Group-related data was coded before the spreadsheet was sent for data analysis to the same investigator who performed the randomization (MS) in order to ensure the blinding.

The original data have been deposited to Mendeley Data [18].

Outcomes

The primary outcome was overall performance in the study quiz. Secondary outcomes were performance by NIHSS item, time to course and to quiz completion, user satisfaction with the learning method, user perception of the duration of the course, and probability that the user would recommend the training to a colleague.

Statistical Analysis

Based on prior teaching experience and clinical assumption, we determined that a sample size of 34 (17 per group) was required to have an 80% chance of detecting a difference of 10% in the overall performance at the 5% level of significance.

Given the low sample size, we decided to use only non-parametric statistical tests. The Fisher exact test was used for categorical variables and the Mann-Whitney U test for continuous variables. A two-sided *P*-value <.05 was considered significant.

Data analysis was performed using STATA 16.0 (Stata Corporation).

Results

Characteristics of Study Subjects

Of the 40 paramedics who registered to one of the four study sessions, 39 (98%) completed the study, none of whom met any of the exclusion criteria. One paramedic who was expected to participate did not appear for the study session. Gender distribution was the only statistically significant variable between groups (2/19 women in the e-learning group vs 10/20 in the video group, *P*=.01) (Table 1).

Table 1. Participant characteristics.

Characteristic	Video (n=19)	E-learning (n=20)	*P* value
Age range (years), n			.46
18-25	2	1	
26-30	3	7	
31-35	6	6	
36-40	4	3	
≥41	4	3	
Years since diploma, median (Q1;Q3)	5 (2;8)	6.5 (2.5;9)	.68
Gender, female, n (%)	2 (11)	10 (50)	.01

Main Results

Participants who followed the e-learning module performed better than those who followed the video—36 (34;37) vs 33 (31;38), *P*=.04. Paramedics who had followed the e-learning module had better scores regarding key NIHSS concepts (*P*=.01), the consciousness—commands item (*P*=.03), and the ataxia item (*P*=.02). Paramedics in the video group evaluated dysarthria better than those in the e-learning group (*P*=.02). Detailed results are shown in Table 2.

The e-learning module took more time to complete than the video with a median time of 93 (81.5;107.5) vs 59 (55;80) minutes, *P*<.001, though time to quiz completion was not significantly different between groups (*P*=.12) (Table 2). Duration of the course was considered adequate by 75% of the paramedics who had followed the e-learning module, but only by 32% of those who had followed the video (*P*=.01). Satisfaction regarding the learning method was also higher in the e-learning group compared to the video group (90% vs 37%, *P*=.002) (Figure 1). The paramedics who had followed the e-learning module were more likely to recommend the course than those who had followed the subtitled video (95% vs 63%, *P*=.02).

Table 2. Quiz results. Data are expressed as median (Q1;Q3).

Variable	Video (n=19)	E-learning (n=20)	*P* value
Overall score	33 (31;38)	36 (34;37)	.04
Time to course completion (min)	59 (55;80)	93 (81.5;107.5)	<.001
Time to quiz completion (min)	38 (33;41)	35 (31;39)	.12
Detailed results by item			
Key NIHSS[a] concepts	5 (3;5)	5 (5;5)	.01
Consciousness–Global	2 (2;2)	2 (2;3)	.30
Consciousness–Questions	3 (2;3)	3 (2;3)	.40
Consciousness–Commands	2 (2;2)	3 (2;3)	.03
Gaze	3 (2;3)	3 (2;3)	.85
Visual	2 (2;2)	2 (2;2)	1
Facial Palsy	1 (0;2)	1 (0;2)	.71
Motor arm	4 (3;5)	4 (4;5)	.75

Discussion

Main Results

The participants who followed the e-learning module performed slightly better than those who watched the subtitled version of the original NIHSS video. Our results show that paramedics who followed the e-learning module had a better understanding of the NIHSS key concepts. This difference might prove useful for the application of the NIHSS in the field.

While some specific NIHSS items, such as ataxia, were scored more accurately by the paramedics who followed the e-learning module, participants in the video group evaluated the dysarthria item significantly better. After careful review of the module, it appears that we did not include extracts from the original video for all 15 items. Indeed, the e-learning module used in this study did not contain any video extract demonstrating how to assess dysarthria. This shortcoming might, at least in part, explain why the paramedics who followed the e-learning module did not perform as well as those who had seen the video. The e-learning module should therefore be updated to include video extracts of each specific item before being tested again to assess whether our hypothesis holds true. The difference observed regarding dysarthria evaluation might also be explained by the fact that this item has been shown to have a low interrater reliability [19].

The e-learning module took longer than the video to complete, with a median difference of 34 minutes. Nevertheless, 75% of the paramedics who had followed the e-learning module judged its length adequate, whereas less than a third of those who had followed the video were of the same opinion. Three main factors might contribute to this finding. First, while the video does not allow for interactions other than pausing, forwarding, or rewinding, the e-learning module stimulates and engages the learners. Second, the possibility of quickly going back to the learning chapter one wishes to review is facilitated by the e-learning interface, as the learner loses less time looking for the right sequence. Last, the introductory chapter in the e-learning module seems to lead to an enhanced understanding of key NIHSS concepts, and might therefore help the learner better understand the goals of the course, therefore acting as a primer by increasing both the learner’s commitment and attention.

The higher level of satisfaction with the learning method is probably most strongly linked to the high interactivity of the e-learning module. Previous studies have indeed shown that a greater level of interactivity increases learner engagement while decreasing the attrition rate [20]. Though other factors such as quality of content, convenience of the technology, and quality of the support received have also been found to increase learner satisfaction [21], they probably had little influence on this outcome given our study design as these elements were almost identical for both groups.

The term e-learning is generic and is used to describe any kind of educational material made available through technological means. It therefore covers many different formats (video, podcast, interactive module, serious game, etc), which have been increasingly used in the last decades because of their many advantages such as flexibility, mobility, and avoidance of both time and space constraints [22]. Advanced models of e-learning can mimic real-life situations and are often considered preferable to classical models of education thanks to their interactivity. Systematic reviews have however failed to demonstrate a superiority of e-learning compared to traditional learning in improving patient outcomes or health professionals’ behaviors, skills, or knowledge [23,24]. This might be because e-learning materials are so different in conception and philosophy that they cannot be directly comparable.

Even if it cannot entirely substitute for face-to-face learning, e-learning seems to be particularly well adapted to the field of emergency medicine where shift work is common [25]. It is indeed often difficult to provide recurrent practical hands-on sessions for paramedics once they have completed their training, though they must still acquire new knowledge and skills on a regular basis. Studies have shown that e-learning is the preferred learning method for paramedics when practical training is not possible due to diverse constraints [26,27].

Stroke is the second leading cause of death worldwide and a major cause of long-term disability [28]. One of the best ways to limit stroke sequelae is to reduce the time between symptom onset and administration of the appropriate treatment. Swift and accurate identification of stroke symptoms is therefore of paramount importance to enable prompt transport to a stroke center. Some studies suggest that the use of e-learning material enhanced both neurological assessment by nurses and quality of care in stroke teams [29,30]. Different e-learning tools aiming to improve symptoms recognition and global care of stroke patients are currently being developed and implemented [31,32].

Strengths and Limitations

Though this study has several strengths, it also has limitations. First, given our initial power calculation and the small number of paramedics working in Geneva, the sample size is limited. Moreover, as there can be considerable differences between prehospital emergency medical systems or paramedic certifications, even across different Swiss regions, the results of this study might not be entirely applicable to other systems [16]. As this study only assessed learning material, it also might not adequately predict the performance of the paramedics in the field. Finally, as the video had a fixed duration of about 59 minutes, the main investigator might have been only incompletely blinded as to group allocation. Nevertheless, randomization, concealment, and blinding were performed according to the strictest standards. Comparison of this innovative highly interactive e-learning module with a well-established teaching standard is another strength of this study.

Implications for Future Research

After an update and improvement of the e-learning module used in this study, a new assessment of this teaching method should be performed. The performance of healthcare providers trained with this new method and its impact on the global care of stroke patients should also now be assessed in the field.

Conclusion

Use of an e-learning module shows promising results in teaching the NIHSS to paramedics. The module should be improved according to the study results and user feedback, and performance of healthcare providers who have followed this module should be tested in the field.

Acknowledgments

The authors would like to thank Professor Patrick Lyden for allowing the use of his original NIHSS material in this study.

Conflicts of Interest

None declared.

Editorial notice: This randomized study was not prospectively registered. The editor granted an exception of ICMJE rules for prospective registration of randomized trials because the risk of bias appears low. The authors' argument for non-registration is that registration was not required as the study does not come into the scope of the Swiss federal law on human research. The protocol was, however, submitted to the local ethics committee.

Abstract

Background: Although gamification continues to be a popular approach to increase engagement, motivation, and adherence to behavioral interventions, empirical studies have rarely focused on this topic. There is a need to empirically evaluate gamification models to increase the understanding of how to integrate gamification into interventions.

Objective: The model of gamification principles for digital health interventions proposes a set of five independent yet interrelated gamification principles. This study aimed to examine the validity and reliability of this model to inform its use in Web- and mobile-based apps.

Methods: A total of 17 digital health interventions were selected from a curated website of mobile- and Web-based apps (PsyberGuide), which makes independent and unbiased ratings on various metrics. A total of 133 independent raters trained in gamification evaluation techniques were instructed to evaluate the apps and rate the degree to which gamification principles are present. Multiple ratings ($n \geq 20$) were collected for each of the five gamification principles within each app. Existing measures, including the PsyberGuide credibility score, mobile app rating scale (MARS), and the app store rating of each app were collected, and their relationship with the gamification principle scores was investigated.

Results: Apps varied widely in the degree of gamification implemented (ie, the mean gamification rating ranged from $0.17 \leq m \leq 4.65$ out of 5). Inter-rater reliability of gamification scores for each app was acceptable ($\kappa \geq 0.5$). There was no significant correlation between any of the five gamification principles and the PsyberGuide credibility score ($P \geq .49$ in all cases). Three gamification principles (supporting player archetypes, feedback, and visibility) were significantly correlated with the MARS score, whereas three principles (meaningful purpose, meaningful choice, and supporting player archetypes) were significantly correlated with the app store rating. One gamification principle was statistically significant with both the MARS and the app store rating (supporting player archetypes).

Conclusions: Overall, the results support the validity and potential utility of the model of gamification principles for digital health interventions. As expected, there was some overlap between several gamification principles and existing app measures (eg, MARS). However, the results indicate that the gamification principles are not redundant with existing measures and highlight the potential utility of a 5-factor gamification model structure in digital behavioral health interventions. These gamification principles may be used to improve user experience and enhance engagement with digital health programs.

KEYWORDS

gamification; internet interventions; eHealth; mHealth; digital health

Introduction

There is substantial interest in understanding how gamification can improve electronic health (eHealth) and mobile health (mHealth) interventions [1-3], yet significant gaps in the literature remain. Metareviews of gamification strategies within behavioral interventions summarize the work in this area [4,5] but often focus on the mechanics employed (eg, badges, leaderboards, etc) and neglect other potentially important factors (ie, the context of the app). In addition, individual studies of gamification of digital health interventions typically present results as general game vs control studies [6,7] or focus more on the qualitative and subjective aspects of gamification [8]. As gamification techniques are intertwined with other intervention components, their validity and incremental impact are relatively unknown.

The model of gamification principles for internet interventions [9] was developed to present a unifying, theory-driven set of five gamification principles (Textbox 1) that can be used in the building and testing of digital health interventions. There is no widespread agreement on how the principles of gamification should be applied to eHealth/mHealth interventions. Although the detailed justification for the development of these principles is beyond the scope of this paper, additional information can be found in the prior study on which this one is based [9]. These principles, which were extracted from several well-known gamification models, represent independent and actionable items regarding the application of gamification (see the study by Floryan et al [9] for details). The model is composed of five separate yet interrelated constructs: meaningful purpose, meaningful choice, supporting player archetypes, feedback, and visibility. Textbox 1 summarizes the five gamification principles and provides a short description of each principle. The principles provide concrete and measurable descriptions of gamification while focusing on the context, goals, and attitudes of users of the program. These principles provide a descriptive framework for measuring both the presence and quality of gamification implementation. Although these have been well defined, empirical validation is a necessary next step.

Textbox 1. Summary of principles of gamification.

Gamification principle and description:

- Meaningful purpose: The app presents goals that align with the user’s motivations and interests
- Meaningful choice: The app gives users agency over how they achieve their goals
- Supporting player archetypes: Mechanics in the app leverage individual user and player characteristics
- Feedback: The app communicates how user actions affect progress
- Visibility: The app makes clear to users the amount of progress made and how much more is needed

The proposed gamification principles encourage developers to separate the idea of typically considered gamification mechanics (eg, points, badges, and leaderboards) from the purpose of those mechanics (eg, motivating the purpose, increasing user choice, supporting player archetypes, etc). In this way, the model encourages researchers to consider the mechanics of gamification and how those relate to the underlying motivational affordances of the user. It also provides researchers with a framework for implementing these mechanics within the technology-based interventions they create. In behavioral science, several attempts have been made to specify various behavior change strategies [10] and call for increased use of evidence-based behavior change techniques within research and commercially developed products and interventions [11]. However, there have been few efforts to map behavior change principles to design features that could be implemented by researchers. The principles of gamification attempt to address this mapping by providing actionable principles contextualized by known behavior change principles for internet interventions (details regarding this mapping can be found in the study by Floryan et al [9]). The specification of these principles can facilitate research and lead to a better understanding of these mechanisms and how they can best be used. The goals of this study were to understand the validity and reliability of this 5-factor gamification model.

Methods

Overview

Mobile- and Web-based interventions were selected from PsyberGuide, a nonprofit endeavor that aims to provide consumers with information to aid in selecting different types of mental health apps. PsyberGuide conducts independent and unbiased reviews of mental health apps and evaluates products on three dimensions: credibility, user experience, and privacy and data security. PsyberGuide has evaluated over 200 mental health apps and is viewed as a useful standard for determining the quality of apps on these various metrics [12-14]. Given the variety of apps reviewed on PsyberGuide and the variance in scores of credibility and user experience of these apps, it provided a useful point of comparison to evaluate the gamification assessment. Specifically, the credibility and user experience scores (see the *Measures* section for more detail) for each app were useful to compare the presence of gamification with these other metrics. Apps were selected (Table 1) in February 2018 and evaluated for the presence and implementation of the five internet intervention gamification principles (Textbox 1). They were selected using the following criteria: (1) presence on the PsyberGuide listing, (2) free to use or provided core content free of charge, (3) broadly applicable to the general population in the domain of behavioral and mental health, and (4) available through at least one of the Apple App Store, Android Store, or a Web browser (eg, website based). A total of 133 trained independent raters and undergraduates enrolled in a college-level human-computer interaction (HCI) course served as judges. The raters were all aged between 18 and 22 years and majoring in computer science or a related field (eg, systems engineering, computer engineering). Many of the raters were double majoring in a related field (eg, cognitive science, psychology, etc). To obtain adequate interrater reliability, Saito et al [15] recommend a higher number of ratings when the potential variance between ratings is high, 20 to 25 ratings were desired for each app. Therefore, with each judge providing up to 3 ratings, 17 apps were selected.

Table 1. List of apps and their modality or purpose.

App name	Modality or purpose
Headspace	Mindfulness and meditation
Lumosity	Cognitive training
iSleep Easy	Meditation and restful sleep
FitBrains	Cognitive training
Happify: For Stress & Worry	Well-being and happiness
Serenita	Stress and anxiety
SuperBetter	Goal setting, resilience, motivation
Flowy	Breathing and relaxation
The Mxindfulness App	Mindfulness and meditation
HAPPYneuron	Cognitive training
Smiling Mind	Mindfulness and meditation
Pacifica (now Sanvello)	Anxiety and depression
Virtual Hope Box	Anxiety and depression
Peak	Cognitive training
Personal Zen	Stress and anxiety
BrainHQ	Cognitive training
Wildflowers	Mindfulness and meditation

Measures

Gamification Principles

A novel self-report measure was developed based on the gamification principles for internet interventions model. The measure is composed of five items, with each item assessing the principle of gamification. Items include a description of the gamification principle (eg, meaningful purpose) in question and instruct the rater to judge the presence of that principle within the intervention. Embedded within the descriptions are probing questions to help determine the extent the principle is present (eg, “Does the application allow the user to make decisions about how they reach their goal?”). One item was used to assess each gamification principle to increase the efficiency of raters and limit the response burden. Single-item scales have been used and validated to assess complex constructs such as self-esteem, job satisfaction, and personality traits [16-18]. The items were assessed on a 6-point Likert scale (0=complete absence of the gamification principle and 1-5=weak to strong presence of the principle in question; Multimedia Appendix 1).

App Quality (Mobile App Rating Scale)

The Mobile App Rating Scale (MARS; Stoyanov et al [19]) is a widely used measure of app quality that focuses on aspects of engagement, functionality, aesthetics, and information quality. MARS scores for each program included in this study were obtained from the PsyberGuide website. MARS scores are averaged from multiple independent raters who either have expertise in health interventions or psychology, technology development or design, or lived experience with intended clinical issues. Each MARS score was calculated using a combination of at least three raters. MARS scores are represented as *user experience* ratings (with a maximum score of 5.0) on the PsyberGuide website.

App Credibility (PsyberGuide Credibility)

PsyberGuide credibility ratings are meant to determine the likelihood that a given product will produce the proposed benefits. It is based on an assessment of the strength of research evidence, source of research evidence, specificity of the app, expertise of the development team, number of app store ratings, and recency of updates. PsyberGuide credibility rating scores are made by a team of trained reviewers consisting of undergraduate or masters-level students using an approval and consensus process (maximum score of 5.0). PsyberGuide credibility rating scores were obtained from the PsyberGuide website.

App Store Rating

The app store rating (Apple or Android) for each intervention was obtained. App store ratings are based on a system of stars

(0-5), with a higher number of stars indicating a greater degree of liking the app.

Procedure

Each of the 133 raters was randomly assigned to evaluate three apps. Raters were trained using a 2-part approach. The first was a 75-min training session that reviewed the theory of heuristic evaluations, a core concept in HCI. Heuristic evaluations occur when trained raters use a system and rate how well the design conforms to a set of described heuristics [20]. The heuristics used for this study were the five principles of gamification [9]. The training also involved teaching the raters about the principles of gamification, as these were the heuristics to be used for comparison when rating. Although this is not the prototypical use of a heuristic evaluation (a company, eg, would typically rate a user interface against a set of design principles), the training focused on how the process of rating gamification in apps was analogous to a classical heuristic evaluation. The apps were rated against a different set of heuristics (gamification principles), and these principles were enumerated and discussed in detail during the training. The training also provided a broad overview of digital health interventions (definition and brief examples) but did not include any detailed training in this area. To increase our confidence that the ratings were done thoughtfully and consistent with the training guidelines, raters were required to provide a written justification for their ratings.

Raters were given 2 weeks to evaluate their apps and were instructed to use each app for at least 15 min every day. Specifically, raters were asked to use the app as a normal user and to examine the presence of each of the gamification principles. Although rater usage was not tracked, the raters were encouraged to maintain lists of specific examples of each gamification principle they encountered and to list them in their written justifications. After 2 weeks, raters were given 1 week to complete a 10-question survey. For each gamification principle, raters were asked whether the principle was present in the app (binary), and, if so, to what degree that principle was present (1-5 scale). These pairs of questions were later combined to create single 6-point (0-5 scale) responses. For the presence questions (1-5 scale), a description was provided for scores 1, 3, and 5. This was done to allow raters some flexibility in interpreting the score between these endpoints and middle points. To ensure that raters had provided thoughtful responses, they were asked to provide a justification for each of their scores by writing a supporting paragraph. The raters were assigned a grade to complete this assignment and to provide reasonable and thoughtful justifications for the provided scores. Raters provided reasonable justifications, earning an average of 9.4 out of 10 on this assignment. The university institutional review board (IRB) was contacted with the details of this endeavor, and it was determined that no IRB protocol was necessary.

Statistical Analysis Outliers

Statistical analysis outliers (ratings more than two SDs from the mean) were identified. However, on review of the justifications provided by these raters, no data were removed. For each program and survey question combination, the mean scores and SDs were calculated. Interrater reliability scores for each app were calculated to determine the degree of agreement among the independent raters. Interrater reliability was obtained by using the weighted Fleiss kappa [21,22] for each app, across all questions and raters. Fleiss kappa is recommended when there are more than two raters.

Correlations and *P* values were calculated between the average ratings of each gamification principle and each of the three dependent measures (ie, app quality, app credibility, app store rating). Correlations between the gamification principles were examined to detect the presence of collinearity among the ratings. A custom program, written in Python, was used for outlier identification, coalescing the raw data into mean (SD), and for computing the interrater reliability (ie, all results from Tables 2 and 3). The statistics program R was used to compute all correlation coefficients and related statistics (ie, all results from Multimedia Appendix 2 and Table 4).

Table 2. Mean and SD ratings for each gamification principle across raters.

App name	Meaningful purpose, mean (SD)	Meaningful choice, mean (SD)	Supporting player archetypes, mean (SD)	Feedback, mean (SD)	Visibility, mean (SD)
Headspace	4.29 (0.84)	3.92 (1.04)	3.50 (1.47)	3.33 (1.49)	4.08 (1.08)

Results

Overview

The means and SDs for each gamification principle across the 17 apps are shown in Table 2. There was a wide degree of variation in gamification present in the apps. The average gamification score (ie, the mean of all five gamification principle ratings) ranged from 1.64 to 4.16 out of 5. Among the principles, supporting player archetypes was judged as being the least present (average 2.57 out of 5), whereas meaningful purpose was judged as being most present (average 3.75 out of 5).

Table 3 lists the interrater reliability scores for each app studied. Interrater reliability scores range from 0.51 to 0.67, indicating acceptable levels of agreement across raters for each app [23].

Criterion Validity and Associations Between Gamification Principles and Other Measures

Table 5 lists the app credibility score (ie, PsyberGuide Credibility Score), the MARS score, and the app store ratings for each app. One app (HAPPYNueron) did not have an app store rating. In general, the three scores were not strongly associated with one another ($r=-0.09$ for PsyberGuide Credibility vs MARS; $r=0.32$ for MARS vs app store rating; $r=0.04$ for PsyberGuide Credibility vs app store rating), suggesting that each of these three measures likely represent different aspects of app quality.

Table 5. Various metrics scoring each studied app (1-5 scale).

App	PsyberGuide Credibility Score	Mobile App Rating Scale	App store rating
Headspace	4.64	4.74	4.9
Lumosity	3.21	4.34	4.7
iSleep Easy	3.55	3.01	4.6
FitBrains	2.85	4.67	3.7
Happify: For Stress & Worry	3.92	3.34	4.5
Serenita	3.2	3.2	3

Wildflowers	2.85	4.08	4.33

[a] N/A: not applicable.

Multimedia Appendix 1 lists the correlation coefficients as well as t test statistics (2-tailed) and P values among gamification principles ratings and the PsyberGuide Credibility Score, the MARS rating, and the app store rating. There were generally weak correlations between the gamification principle ratings and the PsyberGuide Credibility Score, indicating a low degree of overlap. Supporting player archetypes ($P=.001$), feedback ($P=.01$), and visibility ($P=.008$) correlated strongly with the

MARS rating, whereas meaningful purpose (*P*=.04), meaningful choice (*P*=.002), and supporting layer archetypes (*P*=.04) correlated strongly with the app store ratings. A closer examination of the significant associations between the gamification principles and the MARS and app store ratings revealed between 25% and 52% shared variance (r-squared) among these variables, indicating that they are related yet measure different constructs.

Inter-Relationships Between Gamification Principles

Table 4 contains a correlation matrix of the relationships among gamification principles. The strength of associations varied widely (*r*=0.11 to 0.92), with visibility and feedback as the most strongly associated and overlapping principles. On average, the correlations were *r*=0.50, indicating that principles were related yet separate from one another.

Discussion

Principal Findings

This study provides empirical support for the model of the five gamification principles for internet interventions. We believe this model will help researchers develop new interventions and evaluate existing interventions that better engage users through the proper implementation and integration of gamification techniques. By evaluating the gamification principles in 17 health apps, the findings from this study indicate that the gamification principles are not redundant with existing app measures.

A weak relationship was found between the gamification principle ratings and the PsyberGuide credibility score. The PsyberGuide credibility score is based on several factors, some of which have no intuitive relationship to the gamification principles evaluated in this study. For example, one aspect of the PsyberGuide credibility score involves the amount of research funding the app had garnered, which has no direct connection with gamification. Other aspects of the PsyberGuide credibility score focus on the degree to which research is available on the efficacy of that app or the frequency of the updates to the app. Although some of these aspects, such as the frequency of updates, have been found to be useful predictors of some evaluations of apps such as expert-rated quality or user ratings [24], they would not be expected to categorize the features into the app. In sum, the lack of relationship between the credibility score and the gamification principle ratings suggests that the credibility of an app (which includes efficacy as well as other issues such as software support, input from experts, etc) is largely independent of its level of gamification.

There were significant relationships between 3 of the 5 gamification principles (supporting player archetypes, feedback, and visibility) and the MARS score. Theoretically, one would imagine some overlap between our gamification model and user experience aspects such as engagement. The MARS (collected from PsyberGuide) [19] explicitly mentions qualities that overlap with feedback and visibility, namely, items such as *quality or quantity of information* or *visual information*. However, the gamification principles go beyond the MARS by providing specific guidelines for presenting this information and contextualizing it within a user's broader goals and understanding. Thus, even with some conceptual overlap, the gamification principles still have added value. Engagement and attrition have long been identified as an issue within eHealth [25-27], and this can be helped by having patients play a more active role in their own care [28]. Gamification principles may therefore facilitate the execution of game mechanics by providing researchers another avenue to explore and measure engaging features that involve the patient. Similarly, the gamification principle of *supporting player archetypes* has an intuitive overlap with MARS items involving engagement and subjective quality. However, the gamification principle of supporting player archetypes presents specific mechanisms through which these qualities can be achieved and are commonly done in games and game-like systems. Thus, we believe that our gamification principles are not in direct conflict with the MARS; rather, they provide a roadmap for ways to increase app quality.

Three different gamification principles (meaningful purpose, meaningful choice, and supporting layer archetypes) were significantly associated with the app store ratings. In contrast to the MARS, the app store ratings are single overall ratings provided by end users. By directly sampling from end users, the app store rating may be viewed as largely a reflection of user choice. There was a strong association between app store ratings and the gamification principle of meaningful choice (*r*=0.71), suggesting that users may value having agency in how they use and navigate through an app. App store ratings are subjective, personal, and nonstandardized and have been shown to be an indication of app popularity, but not clinical outcomes [29]. Thus, it is notable that the strongest related principles of meaningful purpose (the user has a goal in using the app), meaningful choice (the user has agency over their progress), and supporting player archetypes (the app leverages individual user characteristics) all directly involve the user, whereas the other two gamification principles, feedback and visibility, relate more specifically to the app design, its presentation, and organization of information.

This study extends the existing literature that aims to understand technology-based behavioral interventions by identifying and coding their features [24,30,31]. Although past work has used different conceptual models, this study evaluates features based on gamification principles. Our findings that gamification principles overlap with some, but not all, other assessments of app quality and popularity indicate both convergent and discriminant validity of the gamification principles assessment. Future work may wish to apply this assessment to other behavioral change interventions and examine if gamification principles in apps correlate with real-world engagement or effectiveness. In addition, researchers and developers would be well served with a streamlined evaluation method for incorporating gamification (or measuring the presence of gamification) in their apps. Future work should focus on providing such artifacts and continuing to study their utility.

Strengths and Limitations

Several potential limitations exist for this study. Most notably, although the raters were trained with several modes of material, they were undergraduate students and not experts; however, several results from the study help limit this concern. The interrater reliability scores (weighted kappa) were all within the acceptable range (κ>0.50), which suggests that although there was variance in the scores, the raters generally gave similar ratings to apps. In addition, raters provided written justifications for each of their scores. An expert read through these justifications with the intention of removing ratings that included clear evidence of a poor rating. In the end, no ratings were deemed to lack sufficient justification, and all ratings were included in the analysis presented here.

Owing to the difficulty in calculating internal consistencies and establishing construct validity for single-item measures (to assess each gamification principle), future work should examine ways to assess gamification using more items. Although our decision was influenced by a desire to reduce the burden on raters and increase the efficiency with which ratings could be completed, there are many ways to assess gamification that should be explored in future work. However, because the results show evidence of both convergent and discriminant validity, there is some evidence that construct validity does exist.

Potential bias also exists with the app selection methodology. Although the PsyberGuide listing likely contained more than 17 apps that fit the inclusion criteria, this was deemed a sufficient number, given the quantity of raters and associated ratings to be obtained. An attempt was made to include a heterogeneous sample of apps that covered a variety of areas of focus and population types. However, a more systematic approach could have been used to select the apps, or, with sufficient resources, to include all apps.

There were some strong associations among gamification principles. Most notably, the principles of feedback and visibility had a strong relationship (r=0.92), potentially suggesting that these principles may measure the same underlying construct. It is possible that although these principle definitions are indeed mutually exclusive (ie, feedback involves the effects of user actions on the future, whereas visibility shows the results of accomplishments from the past), perhaps apps tend to use them in unison as they complement one another. It is also possible that the raters did not fully understand the distinction between these principles and may have conflated them.

Strong correlations occurred among other gamification principle ratings as well, most of which are less easily explainable. For example, the principles of meaningful choice and meaningful purpose correlate strongly (r=0.71), suggesting raters may have interpreted the meaningful qualifier as being shared across the ratings (ie, to make a meaningful choice, there must be a meaningful purpose toward which the user is progressing). More research is necessary to determine the nature of these correlations. In addition, no analysis was done to compare apps of similar purpose (eg, comparisons within mindfulness apps). Other studies have focused on comparing MARS scores or other measures among similar apps [32-35]. There might exist patterns that are stronger or weaker within apps of a specific purpose that could provide additional insight into the role of gamification and other measures (credibility rating, MARS, and app store rating), and this might be an avenue for future research.

Conclusions

In short, this paper is the first evaluation of a method determined to assess previously proposed gamification principles [9]. Our findings suggest that gamification principles relate to some, but not all, previously proposed methods of assessing app quality and popularity, which blend ratings made by experts (such as the PsyberGuide credibility scores), ratings made by consumers (app store ratings), and ratings made by both (in this case, the MARS scores). The pattern of relationships has considerable face validity, including those with the MARS scores and user ratings, and the lack of relationship with PsyberGuide credibility scores. This lack of rating does not indicate that either scale is invalid, but instead that the rating of gamification principles and credibility might offer unique perspectives in terms of understanding apps. The demonstration of a process of rating these products through collaborative assessments of a team of lightly trained raters also demonstrates a potential way to easily and scalably understand the growing number of technology-based behavioral interventions that are being developed. We also believe the demonstration that gamification principles have value helps support the application of these principles to the design of novel technology-based behavioral interventions and might help developers incorporate evidence-based behavior change strategies into their products. As such, both the methodological and conceptual contributions of this work can move forward the research and practice of gamification principles being thoughtfully applied to behavior change digital interventions.

Acknowledgments

The authors would like to acknowledge Jodie Ryu, who managed the curating of the apps, assignments of raters to apps, and other logistical matters.

Conflicts of Interest

SS receives funding from One Mind, of which PsyberGuide is a proprietary project. SS is the executive director of the PsyberGuide.

Abstract

Background: Over the past few years, the development of technologies supporting active aging has been increasing. Among the activities that promote physical exercise by using technologies is geocaching—a treasure hunt of sorts in which participants use a receiver GPS to hide or find real or virtual objects. Although this activity is particularly suited to the promotion of healthy lifestyles in older people, geocaching remains to be unexplored in this area.

Objective: This study aimed to investigate the effectiveness of activities combining geocaching and self-tracking technologies to promote active aging, evaluate the usability of technologies, and explore the ways in which technologies have been integrated in the organizational context under examination to determine the user experience of participants.

Methods: A group of individuals aged 65 years and older (N=14) attending a senior center managed by a social cooperative was involved in the study. Some of them created the geocaching contents, and others, split into 2 teams, participated in the game. Each participant was given a pedometer bracelet and the geocaching app. The steps taken by individual participants along with the number of caches found by each group translated into team scores.

Results: The main results of the study were as follows: (1) activities in favor of active aging that involve the use of new technologies can foster the participation of elderly people; in particular, adding gamification to self-tracking can be a valid strategy to promote physical exercise among the elderly; (2) for this to happen, involvement of older people firsthand is crucial, and there must be a focus on their active involvement and empowerment in every phase of the project; and (3) the mediation of conflicts and competition that arise from the gamification could only take place because of the strong support of the organization in the form of social workers.

Conclusions: The results show that promoting active aging through technologies requires more effort than simply using these tools; it requires a wider process that involves an articulated organizational network with heterogeneous actors, technologies, and relations.

geocaching; active ageing; elderly empowerment; qualitative methods

Introduction

Challenging Aging Through Technology

Population aging involves an increase in the demand for care and an overload of the pension and welfare system. For this reason, aging can be considered a challenge for society [1]. To overcome this challenge, the promotion of active aging is essential, and one key strategy is the promotion of physical exercise. Regular physical activity delays functional decline, reduces the risk of chronic diseases and falls, improves the quality of life, and helps elderly people remain independent for as long as possible [1,2]. Over the past few years, the development of technologies supporting physical activity has been increasing, and the effectiveness of these tools in the promotion of active aging has also been demonstrated. Several studies have underlined the beneficial impact of technologies on the daily lives of this segment of the population. Technologies allow for an increase in physical activity [3,4] and combat loneliness by increasing sociality, self-esteem, and cognitive functions in the elderly [5]. With regard to the type of technologies used, the literature is divided into 2 main strands: on the one hand, studies that deal with devices for self-tracking of physical exercise, such as pedometer apps and wristbands [6,7], and, on the other hand, a recent trend has revealed virtual physical training through exergames [8,9] and serious games [10,11], making gamification an effective tool to motivate older people to exercise.

From Self-Tracking to Gamification

The most recommended physical activity for the elderly is walking. Independence in a person's life is strongly based on the ability to walk, an activity that allows one to carry out most daily tasks [12]. Emerging persuasive technology and ubiquitous wearable sensors offer much promise for improving health and fitness practices. These technologies can persuade the individual user to change his/her lifestyle and integrate a greater amount of physical activity into their daily life. Persuasive technologies use varied strategies for influencing behavior and activities, most notably self-tracking. Research has made great strides in understanding several aspects of these technologies, such as how their design affects activity and behavior, how to use visualization to motivate activities and provide awareness, and how feedback is understood and used [13,14]. A variety of monitoring devices have been studied and analyzed for their persuasive influence on practices and behavior. One of the most common devices is the pedometer, which is used to measure and motivate physical activity and also to set personal step goals [15]. With regard to elderly people, the literature highlights how technologies allow for an increase in physical activity levels and an improvement in self-esteem and cognitive functions [4,16]. However, some studies have reported that only 26% of these tools are used twice and that 33% of owners abandon the use of sensors after 6 months [17]. To enhance self-tracking mechanisms, gamification strategies have therefore become widespread. These include using rewards and incentives to support users' motivation and involving users in identifying and establishing their own goals [18-20]. Some studies have reported how the use of motivational elements such as rewards, feedback and progress bars, and competition can encourage older people to use technology and slow down cognitive aging. This highlights the reasons why they adopt, continue, or abandon such practices [21-23]. The literature on how the context of sport helps the elderly negotiate the aging process shows how competition in physical activity helps in redefining aging in terms of physical competency, social engagement, and mental stimulation [24].

Other studies have highlighted the relationship between user motivations and social behavior in the social context of self-tracking technologies [25-27]. For example, a study by Spillers and Asimakopoulos [27] explores how self-tracking is not just meaningful in a rational or an instrumental utilitarian sense but also in the sense of being a source of joy and pleasure for the individual. To account for the meaning of self-tracking, Spillers and Asimakopoulos [27] proposed conceptualizing self-tracking as a social and cultural practice that is fundamentally communicative. The combination of competition, communication, and cooperation consistently led to higher levels of intrinsic motivation [28,29].

Geocaching for Active Aging

Among the activities that promote physical exercise by using technologies, geocaching, a treasure hunt of sorts in which participants, called *geocachers*, use a receiver GPS to hide or find real or virtual objects (called caches), is one of them. Several studies have highlighted the benefits of this activity for the elderly. Studies that have addressed geocaching from an active aging perspective report the positive effects of spending time outdoors on health, well-being, and sleep [30,31]. Geocaching also stimulates group physical exercise, emphasizing the dimensions of social relations and interactions. It can therefore become a means of communication with family and friends, thus reducing the effects of social isolation that are often involved in aging [31,32]. Other studies have reported how geocaching allows older people to stay informed in an ever-changing environment and share an interest in a city's historical and artistic heritage [33]. It also provides the opportunity to learn and apply new knowledge in the field of Information and Communications Technology such as the use of digital devices and geolocation [30,34-36]. Geocaching is particularly suited for the promotion of healthy lifestyles in older people, because it combines outdoor activity with new technologies. However, the literature tends to emphasize the social, relational, and recreational aspects of the game, and how geocaching could effectively motivate elderly people to stay active is still unexplored.

Objectives of the Study

The Impronte project was created in 2017 as part of a series of initiatives aimed at promoting healthy lifestyles by the TrentinoSalute 4.0 Competence Center, which includes the Department of Health and Social Solidarity of the Province of Trento, the Provincial Health Services, and the Bruno Kessler Foundation. This study, which involved the senior center *Contrada Larga* of Trento, Italy, managed by the Kaleidoscopio social cooperative, aimed to show the results of a geocaching activity combined with the use of pedometer bracelets aimed to promote active aging. There were 3 main objectives of the study: first, to investigate how geocaching could effectively motivate elderly people to stay active, in addition with combining a game with the use of self-tracking technologies to quantify physical activity; second, to evaluate the usability of technologies; and third, to explore the ways in which technologies have been integrated into the organizational context under examination to determine the user experience of participants.

Methods

Context

To involve participants aged 65 years and older, the service center for elderly people, *Contrada Larga* of Trento city, was contacted. The center is managed by the *Kaleidoscopio* social cooperative that has encouraged activities concerning active aging for years. The service center is considered to be a meeting point for self-sufficient elderly people who use the spaces to meet, find and exchange useful information, have discussions with operators and other people, read newspapers, and use computers. The project activities were therefore fitted into a context that was particularly attentive: care was taken to promote the active participation of the elderly through their involvement in the ideation and realization of the activities. Thanks to the intervention of the center operators, 14 people aged between 65 and 82 years, 13 women and 1 man, were involved (Table 1).

Table 1. Demographics of study participants.

Demographics	Number of participants

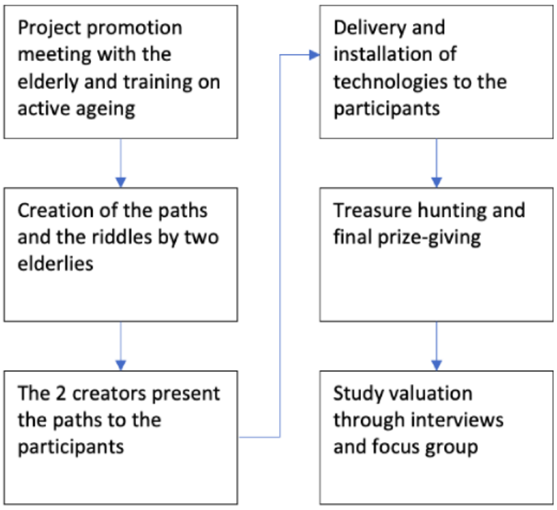
[a] N/A: not applicable.

Study Design

The project took place between April and May 2017 and was divided into 6 main phases (Figure 1):

1. First meeting: project activities, methods, and roadmap were presented to the participants. The meeting was an opportunity to offer a training introduction on active aging and on the importance of adopting a healthy lifestyle.
2. Ideation of the treasure hunt by two of the participants who collaborated in the creation of the contents of the game, identifying culturally or historically significant places in the local area.
3. Peer-to-peer presentation of the treasure hunt. A description, by researchers, of the functionalities of the technologies and the score collection mechanism.
4. The delivery of pedometer bracelets to participants, installation of the geocaching app on the participants' smartphones, team formation, and designation of team captains.
5. Treasure hunt and final distribution of prizes.
6. Study evaluation through interviews and focus groups.

Figure 1. Flowchart of project phases.



The System

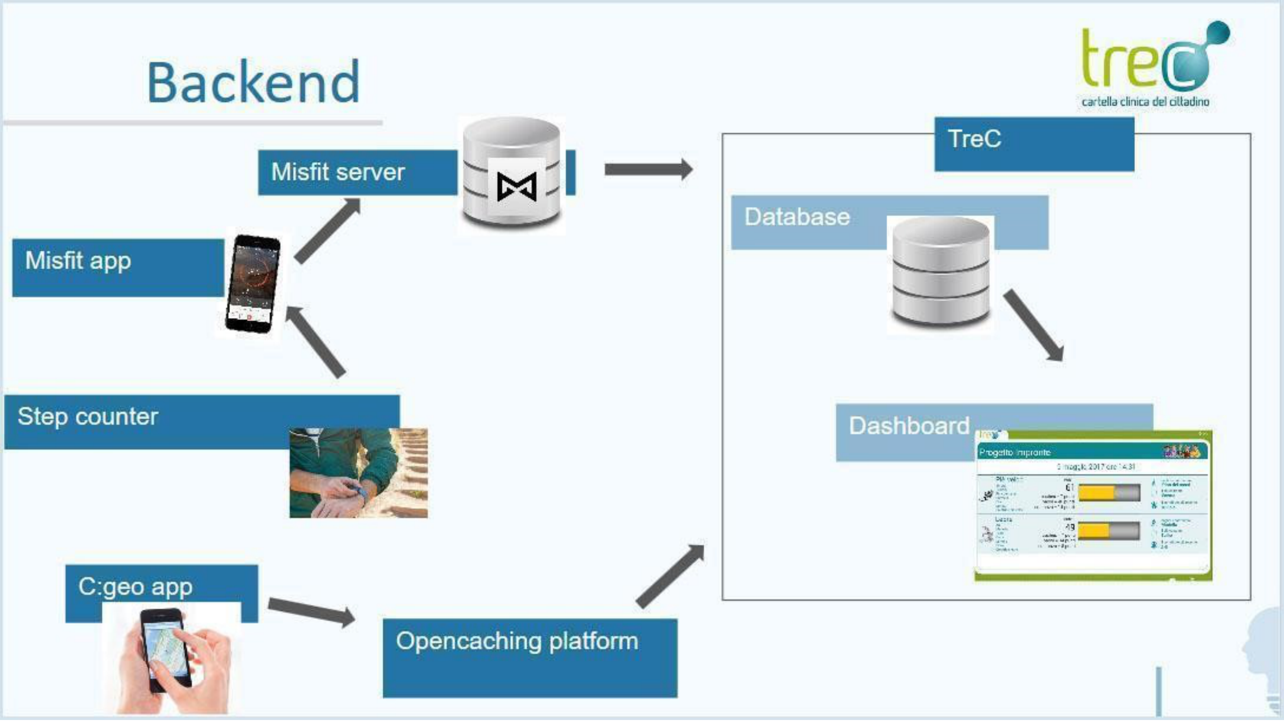
The idea behind the project was to combine the geocaching activity, accompanied by some gamification elements, with the use of fitness tracking technology in the form of a pedometer bracelet. The steps taken by individual participants along with the number of caches found by each group translated into team scores. Each participant had an activity goal of 10,000 steps a day, as advised by the World Health Organization [2]. The project therefore entailed the creation of a system that would connect the technological devices required for geocaching with those necessary for gamification: the opencaching.de website; the C: geo app; and the pedometer bracelet, a digital dashboard for step tracking and reporting of the caches found (Figure 2).

The *opencaching.de* website was selected as we preferred an open-access platform. Unlike other geocaching platforms, it is created by users, allowing anyone to register and play. It also provides the application programming interfaces (APIs) needed to access the data (number of finds, position, comments, etc). The APIs were critical to load the score on the dashboard and keep it updated daily during the challenge. To keep the score of each team, the total number of caches found was included, which we accessed from the opencaching.de website in the caches_found attribute.

The *C: geo app*, available for Android, was selected for the cache search. The app is free and is among the most complete in terms of functionality and compatibility with geocaching services. Being fully compatible with the open caching platform, it was the tool that allowed the teams to read the riddles from the open caching platform, find the caches, log them, and leave comments.

With regard to self-tracking technologies, we chose to give to each participant a pedometer bracelet. The score of each participant as well as that of the team was visible on the digital monitoring dashboard and was automatically calculated based on the number of steps taken, the number of caches found during the outings, and the number of days in which users walked more than 10,000 steps. For both teams, the scores ranged from 0 to 100, calculated according to the following proportions: cache score, 40%; step score, 40%; and constancy score, 20%. The cache score was given by the number of caches found, and the step score was 100 for the team with the highest number of total steps and a proportionally lower number for the other team. The last component of the score, *constancy*, was determined as a proportion between the number of days elapsed since the start of the race and the number of days in which the team members exceeded 10,000 steps. The data were made available periodically to the participants at the senior center or on the dedicated website.

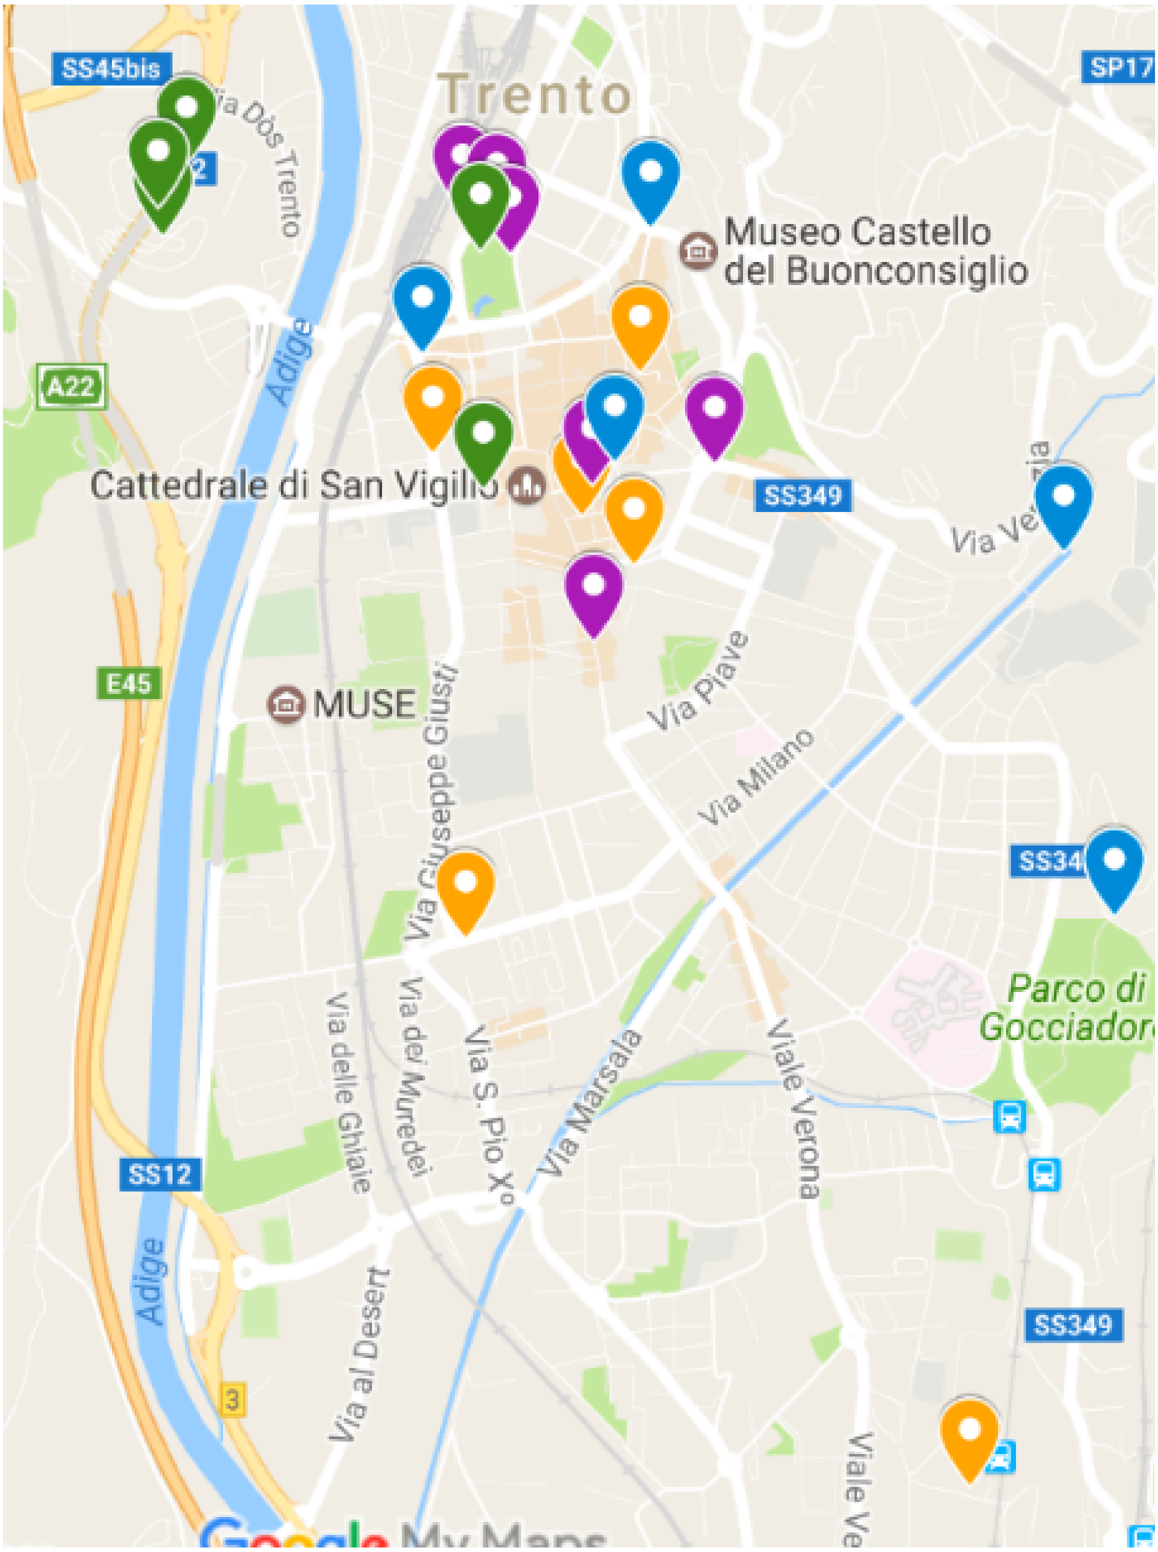
Figure 2. The backend system to collect the steps and the data from the C:Geo app and to show them in the dashboard.



Building Active Aging in a Participatory Perspective

One of the main characteristics of the project was an approach that would allow the elderly to participate actively in most of the project phases. For this reason, the treasure hunt was created by two of the participants who identified the stages of the hunt and the riddles to be solved without the help of the researchers. The 2 *creators*, after taking a tour of the city center and its surroundings, decided to design a treasure hunt divided into 4 thematic routes: "The city over the centuries," "The Italian hallmarks of the city," "Water," and "Buildings and monuments." For each route, the 2 creators identified 5 or 6 historically, artistically, and culturally relevant points (Figure 3). For each point, they created a card with its description, some curiosities, and a riddle, which could only be solved by visiting the place. In total, 24 points of interest were designed. The cards were then shared and discussed with the researchers, who uploaded them to the opencaching.de website, thus creating the actual virtual caches. The 2 creators had the task of describing the characteristics of the routes to the group of participants during a meeting that preceded the treasure hunt. During this meeting, the duration, modalities, and characteristics of the routes were presented to the group of seniors, without excessively disclosing the details to keep the curiosity alive. Under the supervision of the center operators, the participants split into 2 teams and appointed 2 team leaders with the task of using the C: geo app during the geocaching activity.

Figure 3. The points of the treasure hunter in the city of Trento.



The Treasure Hunt and Final Awarding

A total of 4 treasure hunts were created, 1 per week. The 2 teams would meet at the senior center half an hour before each hunt to prepare and organize the search, following which the teams would set out on the search to reach the greatest number of stages in the set time. We had to decide whether to encourage learning about technology by giving each participant a smartphone with the app and risk-isolated participation or whether to encourage the social aspect of the game by stimulating communication between participants. We chose the second option, and each team was accompanied by an operator. The senior center was the departure and arrival point for the participants. Both team leaders had a smartphone equipped with the C: geo app and were tasked with guiding the team's search for the stops.

Before each hunt, we recommended that participants try to leave comments and photographs in the app at each stage. This was done because one of the recreational and relational aspects of geocaching is the possibility to contribute to the contents of the game firsthand. We decided to try to focus the activity also on this aspect because the literature on elderly competition in physical activity shows that the combination of competition and cooperation consistently led to higher levels of motivation. By commenting on the cache and taking pictures, participants would have the opportunity to collaborate more. The 2 creators of the hunt, knowing the solutions to the riddles, were not able to participate in the outings, but they contributed nonetheless to the score of their team—they did not know to which team they had been assigned until the end—by accumulating steps. The final event was an opportunity to sum up the outcomes of the experience as well as to award the prize to the winning team. Each participant was given a certificate of participation.

The Evaluation

The evaluation of the study was aimed at investigating the effectiveness of the activity, the usability of the system, and the relevance of the organizational context in which the activity was organized. The first evaluation of the effectiveness of the activity was based on quantitative data: the average daily steps and the constancy (Figure 4) in doing 10,000 steps daily (x-axis: data and y-axis: number of steps). These data show a good level of engagement: the average daily steps per participant was 9660; the constancy oscillated between 4562 steps and 15,854 steps, as shown in the figure.

The second evaluation was based on qualitative data. The small number of participants involved in this first pilot study and the exploratory nature of the project led to the use of semistructured interviews and focus groups to collect the data. A total of 3 semistructured interviews were conducted with the operators and the coordinator of the center to examine in depth the characteristics of the context being studied and the perceptions of the stakeholders with regard to the project. The interviews had a duration of about an hour each. They were recorded and later transcribed. A total of 2 focus groups were used to involve the participants. The focus group is a particular type of focused meeting or interaction [37] that occurs when people recruited by a research group cooperate to turn their attention to a topic of discussion presented by a facilitator [38]. The reduced number of participants ensures and facilitates interaction [39]. Some authors [40] suggest the use of this technique to collect the opinions of older people on technology by stimulating a conversation about ideas or themes, bringing out important data that are difficult to investigate through face-to-face interviews [41]. The 2 focus groups involved 7 and 5 seniors. The first group discussion was attended by 3 members of a team and 4 members of the other team, a creator, and no team leader. The second group discussion saw the presence of 3 people from one team and 2 people from the other team, including the 2 team leaders. Both focus groups, which took place at the senior center, were led by a facilitator. The questions were asked to the whole group, and participants were encouraged to respond freely. The facilitator prepared a discussion guide with the questions (Table 2), which were considered "moments of an interaction ritual" [38] and therefore used flexibly and adapted to the conversation flow. Following an opening speech that described the plan for the meeting to the participants, they were asked questions about the organizational context of the project, the reasons that led them to participate, the usability of the technology, and the critical aspects of the gamification and finally some suggestions to improve the activity.

Figure 4. Daily steps constancy.

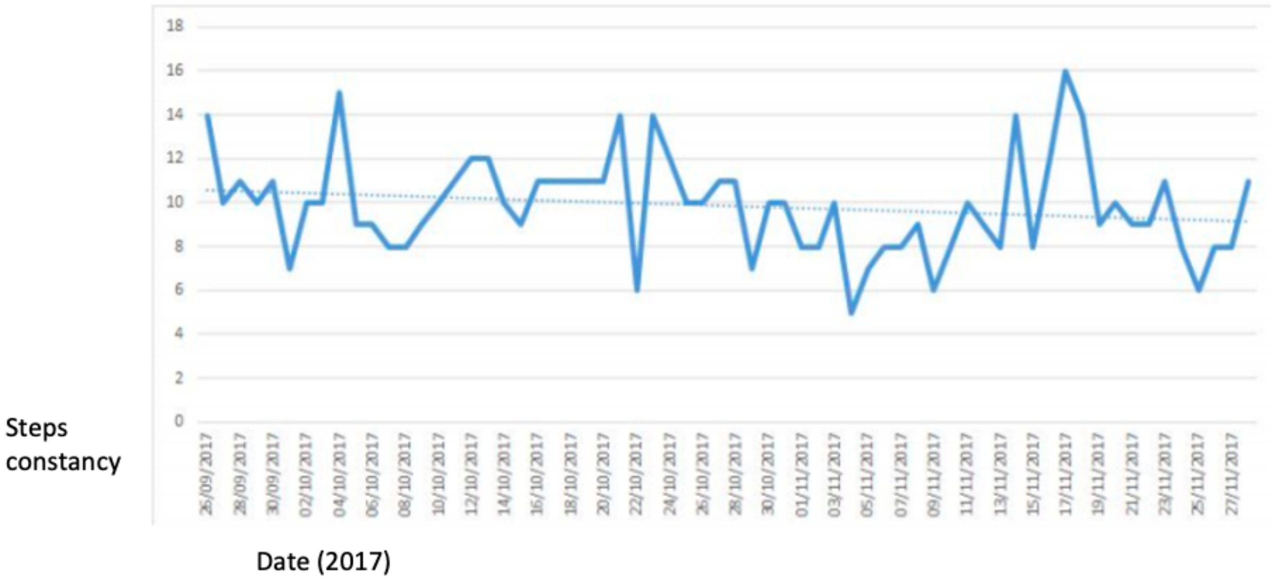


Table 2. Focus group discussion guide.

Stage	Question
Opening question	• As you know, you have been asked to participate in a research project that looks at active ageing through games and the use of new technologies: today, I would like to discuss with you how the project went.
Introductory questions	• How did you come across this project? (eg, flyer, word of mouth, operators' invitation). • What do you think about this project compared to other initiatives offered by the centre? • Do you deem it appropriate for a centre to offer a larger number of initiatives involving physical exercise and technology?
Transitional questions	• What were the reasons that led you to participate in the project? (eg, curiosity about technology, desire to take more exercise, company) • Were there people who did not participate? Why?
Key questions	• Since I was present only at some stages of the project, would you please tell me how the hunts worked? • What suggestions would you give me in order to create interesting paths? (this question was made by the participant who created the path) • Would you check your progress on the step counting app often? (eg, during the hunt, during day-to-day activities) • What are, in your opinion, the reasons why you did not take pictures or make comments? • Would you find yourselves checking on the progress of the other team on the website? And on the screenshot posted at the centre? • Would you talk about it during the week? (Was there anyone who motivated the others? Would you talk about it only at the meetings at the centre?) • What were the pros and cons of playing in a team? What suggestions would you give me in order to form teams that work well together?
Final question	• Should we propose these activities in other contexts, and do you have any suggestions to improve it?

Qualitative Data Analysis

With regard to the phase of transcription and analysis of the material collected during the focus groups, we adopted the *content analysis* or *template analysis* technique [4], a dynamic form of analysis oriented to summarizing the information content of data collected [42,43]. In particular, we opted for an *inductive* analysis of content, a "research method for the subjective interpretation of the content of text through the systematic classification process of coding and identifying themes or patterns" [44]. In the inductive analysis of the contents, categories derive directly from raw data: the use of prebuilt categories was therefore avoided [44-46]. The validity of the inference is ensured by a systematic codification process, which begins with the isolation of fragments of text by grouping them into common themes. For each topic, the different opinions of the participants were then identified, focusing on the ways in which they emerged and on the interactions with each other. In addition to the analysis of the verbal data content, the situational factors of the focus groups were considered [47], in particular, the interaction between the participants and the forms of social influence that occur in the group [38].

Results

The inductive analysis of contents and interactions revealed 3 main categories: *gamifying self-tracking: motivation vs competition*, *gamifying geocaching: cooperation vs conflict*, and *gamifying active aging: empowerment vs assistance*. The categories have been illustrated in the following sections. For privacy reasons, we used fictitious names to report participant quotes.

Gamifying Self-Tracking: From Motivation to Competition

A total of 3 factors motivated the elderly to participate in the project: curiosity about technology, the possibility of doing physical exercise with others, and an interest in cultural and historical aspects. From the analysis of the focus group conversations, the first aspect stands out: most of the participants stated that they were stimulated and intrigued by "using technology to support physical activity." The pedometer was found to be the most motivating element for the entire duration of the project, among the technologies proposed (ie, smartphones with the C: geo app and a pedometer bracelet):

> *I kept checking how many steps I had taken and tried to increase them...when you can check and you realise that at some point you are almost there, then you go for a walk* [Anna, participant]
>
> *After having exercised regularly for a month, activity becomes a physical need* [Gina, participant]
>
> *Normally when you walk you don't have the perception of taking so many steps* [Sara, participant]
>
> *You think you take so many steps at home...I never sit down...I take steps, but taking ten thousand...that's a long way!* [Diana, participant]

The use of the pedometer and thus the possibility of keeping track of the steps taken were, therefore, critical to motivating the participants to carry out physical activity and to making them aware of their physical activity level. Between the lines, we could also read the *coercive* aspect of the pedometer, which for some has become an almost necessary control tool. This trend was confirmed by the fact that, although the project was finished, most of the focus group participants continued to wear and use the bracelets. It was apparent that this coercive aspect had positive effects on both physical well-being and personal satisfaction:

> *When you see that you have walked that much, you are happy* [Gina, participant]

...and you have a result, because I feel better [Sara, participant]

The possibility of keeping track of the steps had positive effects on the motivation of the individual participants to obtain results. In addition, the awareness that their steps would influence the score of their team transformed the pedometer into an instrument of competition and comparison with other participants:

> *Initially it was like a game, but then came the rivalry...when I saw that we were below the score, I started to do some serious walking...at ten o'clock in the evening I was around increasing our step levels...I had a share of score that I could not fail to achieve...I had to stay on that level...so it was challenging* [Marina, participant]

The expectations regarding the team scores were high. The meetings before the hunts turned into opportunities for scores to be compared, and taking steps was seen almost as an obligation: a participant who missed a day's worth of walking to be present at a tournament of burraco (a card game) was (somewhat jokingly) accused of making their team lose. The creators of the hunt, despite not knowing which team they were assigned to, experienced this sense of challenge:

> *We didn't even know which team we were helping, so it was a matter of constancy...then it almost became an obsession...I would check and say to myself "I have to reach ten thousand, otherwise they'll hang me"* [Rita, creator]

The collective contribution to the group's score led to a strong team spirit, which heightened the competition during the hunts, as can be seen from the following discussion:

> *For example, when we were solving a riddle, the others would come and we looked in the other direction to give them wrong clues...We didn't even say goodbye! That's how much we felt we were enemies* [Fiona, participant]
>
> *I think the other team envied us...There was also some tipping off* [Sara, participant]

This strong sense of competition also emerged from the interaction between the focus group participants: opportunities for jokes, tensions, and even controversy between the members of the 2 teams were frequent.

Gamifying Geocaching: From Cooperation to Conflict

As mentioned earlier, the possibility of counting the steps and contributing to the team's score led to a strong sense of competition among the participants in the project. This sense of competition influenced the relations between individual participants and between the 2 teams and also involved other aspects of the gaming experience. All the focus group participants said that they were in a hurry to find all the caches:

> *We were mad...so we said "no comment"* [Alda, participant]
>
> *Also because often the riddle was not clear, but it needed to be understood* [Fiona, participant]
>
> *Did you focus on riddles or on the steps? Were we supposed to focus on taking many steps? As far as that is concerned, we succeeded...For the rest, I remember the hurry, but less hurry would have been nice for me since I don't know Trento...when the two teams met, people who knew each other didn't even say goodbye* [Marina, participant]
>
> *Also, about entering our observations...how were we supposed to write something?...it would have been nice to be able to write down some nice comments* [Margherita, participant]

Owing to the rush to reach the points of interest before the opposing team, some peculiar features of the geocaching game slipped into the background, such as carefully reading the cache description, leaving a comment after finding the cache, or adding photographs. Interviews with operators during outings confirm this trend: "Due to the rush to move on fast, we did not focus on other smartphone features such as selfies or writing sentences" (Mario, social operator). The sense of competition led to the rush to participate in the game, to solve the riddles, and to comment below the found caches, and this led to a deviation from the initial motivation that was the interest in historical and cultural aspects. However, this did not happen in the case of the creators, who, having not experienced the sense of team competition, maintained their enthusiasm for these aspects:

> *Even now when I walk around the city I look up...it is actually by looking up that you discover things...I discovered, on a building, a coat of arms that I didn't even know existed* [Gina, creator]

The lack of interest in some features of the game should not be attributed solely to the sense of competition. In fact, some features of the technologies contributed to this situation: first, the decision to entrust the team leader with the map with the smartphone led to a series of difficulties:

> *It was backlit, too shiny, and it was sunny...it was difficult to mark the riddles solved...if there were a bigger screen, everyone would see it...if you could see the whole journey perfectly...if you zoom in, you lose the other piece* [Alda, participant]
>
> *One of the important points was to read the description of the hunt stop...I read it aloud during the journey because there was no time...but of course there was the one with the stick behind you who couldn't hear* [Margherita, participant]

Hurdles were caused by the intrinsic features of the technology: the glare on the smartphone screen in the bright sun and a screen too small to display the whole map discouraged participants from using the tools necessary for carrying out the activity.

The comments reported so far have pointed out the ways in which some features of geocaching and aspects of gamification came into conflict, leading to hurdles that can become important when it comes to involving people of a certain age, as a participant stated in a very appropriate fashion:

> *If you want more people to have this chance, you should allow for much more time, including the chance to use the restroom, the chance to rest for those who walk with a stick...and to rest twice for those who feel they have walked too much...if instead you want to focus only on the treasure, then it is no longer for us* [Margherita, participant]

Gamifying Active Aging: From Empowerment to Assistance

The development of the project saw the constant presence of the center operators, from the first presentations to the hunt coplanning with the creators, the treasure hunt, and the final awarding. During all these phases, their experiential contribution to the user experience proved critical, both in terms of organization and support with the use of technologies as well as the management of conflicts among participants. The organizational context proved essential for the involvement of the participants. On the one hand, the fact that the senior center operators were already accustomed to proposing activities of this kind and paying attention to technology and active aging translated into having a pool of people already interested in the subject and, above all, people who trusted the operators:

> *Ease of involvement: we know who comes here for technology-related concerns, about eighty people* [Mario, social operator]
>
> *Gina, who hadn't been to the centre for a long time, was invited by Agnese, and came because she believed in it, trusted her* [Cristina, social operator]

On the other hand, the peculiarity of the center, owing to its recreational activities, allows the development of a strong network of relationships that, in turn, helps spread the word among people and facilitates chain involvement, thus allowing people to overcome the possible distrust of technologies:

> *The first time I didn't know what it was, then you told me, "do you want to participate?"* [Anna, participant]
>
> *Many, when they saw that I was enthusiastic, wanted to participate* [Rosa, participant]

The intervention of the operators was critical to the success of the project, particularly when it came to supporting the elderly in the use of technologies:

> *The first hunt was chaotic...we struggled because even the two team leaders felt awkward...we [operators] also had to help a lot with the phones...but in the end we learned by doing.* [Cristina, social operator]
>
> *We were always supported by Mario and Cristina, because if it happened they would jam.* [Marina, participant]
>
> *The team members who didn't have a smartphone weren't interested in using it. Maybe this fact may have taken the responsibility off the others with the risk that they would just follow...So I would say: "Come on, come here, let's look together where the points are" and there my role was that of regrouping them.* [Cristina, social operator]

The operators were able to support the participants in the use of the app, and their intervention proved to be decisive in directing the group's attention to the technology. This curbed an issue caused by the intrinsic characteristics of the technology and the spirit of competition among the participants.

Finally, the intervention of the operators allowed them to mediate some relational issues that emerged during the course of the project, such as the strong spirit of competition:

> *We had to work a lot on the team: we would encourage them to come closer, listen, help find the solution, look carefully...team members were granted a good level of autonomy but we had to provide assistance anyway as finding an agreement was not so simple.* [Mario, social operator]

As pointed out by Mario, the operator, although his main role was to support independent action on the part of the participants, in some cases, his presence was considered almost an excuse to delegate some activities: "No, we didn't take pictures, we were in a hurry...there was either Mario or Cristina [social operators] to do that" (Rosa, participant).

Discussion

Principal Findings

To the best of our knowledge, this is the first study on active aging that has combined elements of self-tracking and gamification with a geocaching activity. The success of the project, backed by the data on daily walk constancy of the participants and their satisfaction, is in line with the results of the studies that show how adding gamification to self-tracking can be a valid strategy to promote physical exercise among the elderly. However, through our study, we wanted to describe how the introduction of gamification elements required the inclusion of heterogeneous contextual and organizational elements that proved to be critical in determining the success of the project. Therefore, the study aimed to highlight how promoting active aging through technologies does not happen solely with the use of these tools but instead requires a wider process that involves a complex, articulated network.

Technologies as Responses to the Limits?

A study by Vartiainen and Tuunanen [48] pointed out the importance of the *hedonistic* value of geocaching: instead of stimulating the participants' sense of competition, the primary value remains to be the stronger sense of community that is aroused in geocachers. Our study aimed to propose a geocaching activity to promote active aging, integrated with elements of quantification (step counting) and gamification (team challenge). These elements—the pedometer bracelet, the team scoring mechanism, and the counting of the caches—proved to be highly motivating for the participants; however, they also led to a strong sense of competition, altering the nature of the activity and coming into conflict with some of the intrinsic characteristics of the game. For instance, in an endeavor to only come first, the participants did not use some features of the geocaching app, such as the ability to read cache descriptions, leave comments, and take photos. The haste and competition also led to some moments of tension and conflict among the participants. The correct use of the app and the mediation of conflicts could only take place thanks to the support of the center operators who mediated the conflicts and introduced older people to the use of technology. The technological tools were therefore integrated into a context that determined the methods of use: the familiarity of the social center with the technologies and the support of the social operators contributed to recreating an experience that was tailored to the skills and difficulties of the participants.

One of the most positive aspects of the project turned out to be the successful involvement and motivation of the participants. Although the involvement of users has become necessary for many technological innovations in different sectors [49], it has so far received little attention as an epistemic process itself. In most studies on active aging, there is an “accommodationist view” [50], which sees technologies designed as mere solutions to age-related needs and limitations. In our study, we wanted to go beyond this vision, focusing on the active involvement of the participants in every planning phase, from the conception of the paths to the presentation of the project to their peers. We wished to create a protagonism of elderly people, who do not feel abandoned but are accompanied by the caregivers on their journey toward autonomy and independence. This path is not exempt from contradictions, as is evident from the fact that the intervention of operators can also become an excuse to delegate the use of technology. However, this confirms that these limits derive from the interactions among players, institutions, and material objects [51]. As we highlighted in this paper, the introduction of technologies for active aging inevitably involves an interactive and evolving commitment with the social and cultural spheres of the users with all their difficulties, abilities, and constant reinventions.

Study Limitations and Future Developments

Our study had some limitations and some lessons learned. The first limitation of the study concerned the limited nature of the sample examined. Although this was the first pilot study in which the qualitative methodologies proved to be most appropriate in achieving the research objectives, the project nevertheless took the first step toward the expansion to other organizations in the local area (such as senior centers, clubs, and schools), which would provide a larger sample. To this end, in the year following the pilot study described in this paper, the Impronte project saw 2 further additions: the first involved a school, in addition to the senior center, with a view to intergenerational exchange, and the second saw the inclusion of a natural park, with the objective of local seniors devising routes for tourists. The idea was to continue on this track, owing to the development of a geocaching platform designed by and for the elderly, which would allow heterogeneous and, in some cases, isolated contexts to be reached. A second limitation—and a lesson learned—of the study was the lack of a collection of pre- and postactivity data: analyzing the amount of steps taken by older people before and after participating in the project could provide interesting statistics on the motivation to maintain healthy lifestyles. Another lesson learned is with regard to encouraging participants to learn to use technology through geocaching. Our study provided that only 1 team component managed the phone during the game. This is because we had to decide whether, on the one hand, to encourage participants to learn to use technology, but with the risk that each participant would have to participate on his or her own and be isolated from the rest of the group, or whether, on the other hand, to encourage the social aspect of the game, stimulating the communication between participants. We chose the second option, but at the expense of encouragement to learn to use technology. It would be interesting to investigate if providing all participants with the opportunity to manage a phone would encourage them to learn to use technology.

Conclusions

Activities in favor of active aging that involve the use of new technologies can foster the participation of elderly people, as was evident in the success of this project: an activity that allows outdoor exercise through a playful activity such as geocaching and the use of self-tracking tools can encourage and motivate older people to perform physical activity, as shown by the quantitative data. However, this paper aimed to show how technology use of older people was reshaped and contextualized during the project, with some aspects of the activity prioritized and others sent to the background.

It is important to go beyond the fact that users simply have to be involved and that the involvement of multiple users automatically leads to better knowledge. We propose that it is essential to develop a detailed understanding of how, when, and why they should be involved and also when and how they should not. Above all, users should actively participate in the creation of project contents from a peer-to-peer perspective, as was the case for the project described in this paper.

This approach can enable stakeholders, policy makers, and innovators to better understand the future of aging and address the challenges of innovation for older users more completely. Going beyond an *accommodating* vision that sees science and technology as mere solutions is critical to designing technologies that are functional for seniors (and their caregivers) and allow them to embrace the challenge of active aging.

Acknowledgments

The Impronte project is a part of a series of initiatives aimed at promoting healthy lifestyles by the TrentinoSalute 4.0 Competence Center, which includes the Department of Health and Social Solidarity of the Province of Trento, Italy; the Provincial Health Services; and the Bruno Kessler Foundation. The study involved the *Contrada Larga* senior center of Trento, managed by the Kaleidoscopio social cooperative. The authors would like to thank the social operators and all the elderly involved in this study.

Abstract

Background: Maintaining a healthy weight can reduce the risk of developing many diseases, including type 2 diabetes, hypertension, and certain types of cancers. Online social media platforms are popular among people seeking social support regarding weight loss and sharing their weight loss experiences, which provides opportunities for learning about weight loss behaviors.

Objective: This study aimed to investigate the extent to which the content posted by users in the *r/loseit* subreddit, an online community for discussing weight loss, and online interactions were associated with their weight loss in terms of the number of replies and votes that these users received.

Methods: All posts that were published before January 2018 in r/loseit were collected. We focused on users who revealed their start weight, current weight, and goal weight and were active in this online community for at least 30 days. A topic modeling technique and a hierarchical clustering algorithm were used to obtain both global topics and local word semantic clusters. Finally, we used a regression model to learn the association between weight loss and topics, word semantic clusters, and online interactions.

Results: Our data comprised 477,904 posts that were published by 7660 users within a span of 7 years. We identified 25 topics, including food and drinks, calories, exercises, family members and friends, and communication. Our results showed that the start weight (β=.823; $P<.001$), active days (β=.017; P=.009), and median number of votes (β=.263; P=.02), mentions of exercises (β=.145; $P<.001$), and nutrition (β=.120; $P<.001$) were associated with higher weight loss. Users who lost more weight might be motivated by the negative emotions (β=−.098; $P<.001$) that they experienced before starting the journey of weight loss. In contrast, users who mentioned vacations (β=−.108; P=.005) and payments (β=−.112; P=.001) tended to experience relatively less weight loss. Mentions of family members (β=−.031; P=.03) and employment status (β=−.041; P=.03) were associated with less weight loss as well.

Conclusions: Our study showed that both online interactions and offline activities were associated with weight loss, suggesting that future interventions based on existing online platforms should focus on both aspects. Our findings suggest that online personal health data can be used to learn about health-related behaviors effectively.

Introduction

Background

Maintaining a healthy weight can reduce the risk of developing many diseases, including type 2 diabetes, hypertension, heart disease and strokes, kidney diseases, and certain types of cancers [1-6]. Unfortunately, overweight or obesity has nowadays become a public health crisis that impacts many Americans. For example, it was reported that nearly 94 million US adults were affected by obesity in 2015 and the annual medical cost was approximately US $150 billion [7]. To promote public health and help control overweight and obesity, it is critical to understand what factors are associated with weight loss and design effective weight loss interventions.

Over the past decade, people have been increasingly leveraging online social media platforms to share personal experiences and seek social support regarding weight loss, understand the impact of obesity, and learn their interpretation as contributing factors to a healthy life [8]. This huge amount of online information enables health care providers and researchers to gain insights into both public and personal health. For example, studies showed that what people shared on Instagram and Twitter could be used to effectively assess obesity prevalence in the United States [9,10]. While a content analysis showed that Twitter users were more likely to discuss weight loss during and after holidays [11], a survey-based study suggested that the interactions on Twitter were too brief and shallow [12], which might constrain its users to gain deep social support. This is, however, a major motivation for people to engage in other online weight loss forums or communities [13].

As such, recent studies, which aimed to prevent obesity and promote healthy weight loss, tended to incorporate online social media platforms into their intervention design, but the effects were found to be mixed. While some investigations showed that these online platforms had the potential for an innovative weight loss intervention [14,15], others found their effects were limited because of a low retention and engagement rate [16,17]. Moreover, a meta-analysis of over 2000 studies concluded that the effects of the interventions incorporating online social networks were very modest in improving health-promoting behaviors [18]. This suggested that before designing interventions based on qualitative evidence that online support and engagement are helpful [19], a quantitative analysis is necessary in determining how online interactions with other users (as a potential external influential factor), and a user's offline activities recorded in online discussions (as a potential internal driving factor), are associated with their weight loss.

Current Research and Its Limitation

It should be noted that there were studies showing that consistent online activities (eg, updating progress in weight loss and interacting with others) in online weight loss programs or training were associated with higher weight loss [20-22]. Particularly, a study using data from *r/loseit* showed that higher BMI levels and higher online activities were associated with more weight loss [23]. Similarly, another study based on causal inference found that, on average, users who received comments in *r/loseit* lost 9 lb more than users who did not receive any comments [24]. Although online interactions were shown to have a significant impact on weight loss [25], existing studies focused less on the content of posts. While both the aforementioned studies used topic modeling to extract topics, they merely focused on the most popular ones. This method, however, was too general to identify detailed offline activities that were disclosed in such a large number of posts. Moreover, these studies used the data that were generated during 2010 and 2014, which, as we showed later, consisted of only a small fraction of the posts published in *r/loseit*.

In fact, highlighting both online interactions and personal offline activities aligns with social cognitive theory (SCT) [26]. The theory emphasizes that external and internal social reinforcement together lead to behavior change in a dynamic fashion and is often applied to guild the design of effective intervention strategies [27]. This suggests that focusing on either online interactions or personal offline activities but not both might lead to an incomplete view of the roles of online communities in the process of weight loss, but this needs to be examined and confirmed with evidence.

Objective

Therefore, considering the limitation of previous studies and inspired by SCT, we aimed to investigate the extent to which the offline activities communicated by users in the *r/loseit* subreddit, an online community for discussing weight loss, and online interactions were associated with their weight loss. Specially, we focused on a data set consisting of 477,904 posts that were published by 7660 users before January 2018 in *r/loseit*. We used the self-reported weight change to measure weight loss and the average number of comments and votes that they received from other users to characterize online interactions. We applied both topic modeling and word clustering to obtain detailed and interpretable contributing factors from online posts. Finally, we used a linear regression model to quantitively examine the association between online interactions, factors described in online discussions, and the amount of weight loss.

Our work provided evidence that an online social media platform can serve as an effective data source to understand weight loss, and our findings implied that in future weight loss analyses or interventions, online interactions should be considered as a factor that influences long-term self-efficacy.

Methods

Data

Our data were collected from *r/loseit*, a subreddit focusing on weight loss in Reddit, an online discussion platform. Within the subreddit, users can either publish a *submission* to start a new discussion thread or make comments on either a submission or another comment to an existing discussion thread. For simplicity, we used the word *post* to denote either a submission or a comment when we did not differentiate them. In addition, Reddit users can upvote or downvote a comment but can only upvote a submission. Furthermore, users in many subreddits are allowed to enter text or symbols into a *flare*, which appears next to their usernames in a post, to show some basic information of themselves. For example, in *r/loseit*, users can show their *start weight*, *current weight*, and *goal weight* and even their *gender*, *age*, and *height* information in flairs. However, as creating a *flare* is not required, users can ignore it when publishing a post.

In this study, we used the Python Reddit API Wrapper python package (version 5.3.0) to extract data from the Reddit application programming interface. Specifically, we collected all the posts in *r/loseit* that were published before January 13, 2018. We used the flares tagged with usernames to confine our study cohorts to those users who disclosed their start, current, and goal weights and were active for at least 30 days in this subreddit [23]. It should be noted that we did not ask for permission to use the data from the Reddit community because the data are publicly accessible. However, we never tried to identify any Reddit user by linking their Reddit data with additional data sets. All the results, and post samples presented in this paper, were carefully examined and revised such that no personally identifiable information was disclosed.

Topic Modeling and Word Semantic Clustering

Owing to high dimensionality, noise, and ambiguity of natural language text, processing and analyzing raw post content are often challenging, and the analyzed results are difficult to interpret. In this study, we used 2 types of methods to mitigate this problem: topic modeling and word semantic clustering based on low dimensional representation (eg, word2vec) [28]. While topic modeling can help identify themes in a global context, word semantic clusters can provide more detailed concepts in a local context [29].

Specifically, we used the implementation of latent Dirichlet allocation (LDA) in Mallet (version 2.0.8) to identify the main topics of online discussions in *r/loseit* [30]. Since LDA is an unsupervised algorithm, we relied on a coherence score to determine the optimal number of topics [31]. In this study, we trained LDA models for 5 to 75 topics (with a step size of 5) on all of the posts and chose the number of topics that was corresponding to the highest coherence score. To mitigate word sparsity, we only kept nouns, verbs, adjectives, and adverbs.

To obtain word semantic clusters, we relied on the Google pretrained word2vec model because our data set was not large enough to train an accurate word2vec model. We relied on the standard deviation of cluster size to determine the optimal number of clusters [29]. Specifically, we used a hierarchical clustering algorithm with 25 to 1000 clusters (with a step size of 25) and used the elbow rule to the standard deviation of the number of words in clusters. Intuitively, a large word cluster is more likely to contain multiple concepts, while a small word cluster is more likely to have little contribution to reducing hundreds of thousands of word dimensions [29].

Regression Analysis

In this study, we investigated the association between weight loss and online discussions by using a linear regression model. Specifically, we characterized a user's online discussion by using the following predictors:

- The days that the user was active in the subreddit.
- The number of posts that the user published.
- The topics conveyed in the posts, measured by topic distribution.
- The word semantic clusters, measured by term frequency–inverse document frequency values.
- The median karma score or votes that the user received for each post, measured by subtracting the number of upvotes from the number of downvotes [32].
- The median number of comments for each post that the user published.

We used weight loss, measured by subtracting the start weight from the current weight, as the outcome variable of the regression model. As the distribution of the weight loss variable is right-skewed, we log-transformed it before feeding it into the regression model. All the predictors were normalized and scaled into a range of (0, 1). It should be noted that the active days and the number of comments were also log-transformed because of their right-skewed distributions.

Considering that a person who had higher weight at the beginning is more likely to lose more weight, we also introduced *start weight* as a control variable in the model. Before applying the regression analysis, we used the *findCorrelation* function, as implemented in the caret R package (version 6.0-81), with a cutoff of 0.3 to remove correlated predictors. We reported predictors with a statistical significance level of .05.

Results

Data Statistics

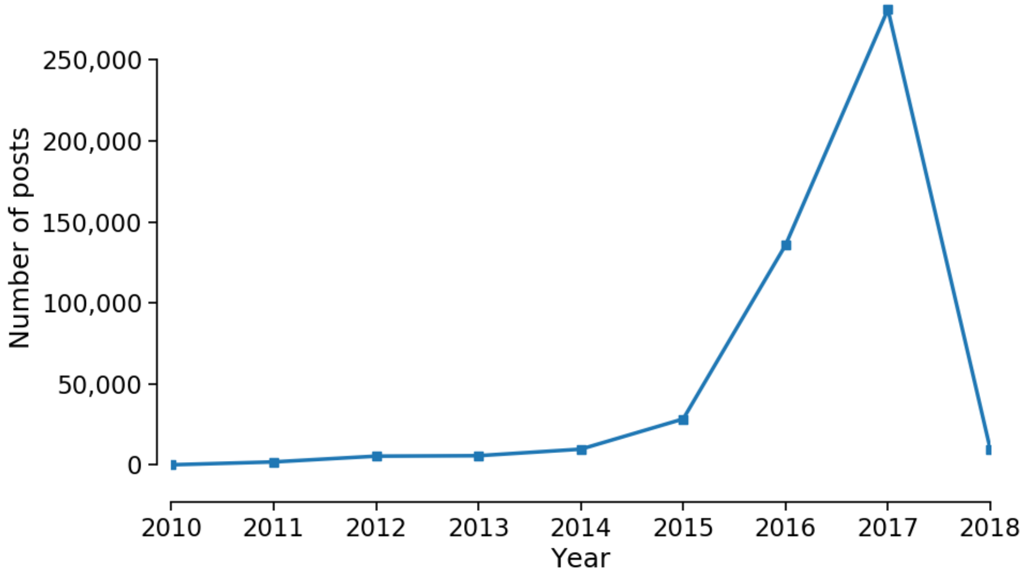
We collected 2,526,277 posts published by 205,722 users during the period between July 30, 2010, and January 13, 2018. Focusing on the users who disclosed their start, current, and goal weights in flairs, we finally obtained 7660 users with a total of 477,904 posts. These posts included 16,332 submissions and 461,572 comments. Table 1 summarizes the basic statistics of key factors regarding this study cohort. From the table, we observed that most posts received a small number of comments and karma scores.

Figure 1 shows the number of posts for each year during 2010 and 2018. From the figure, we can see that the number of posts surged after 2014. It should be noted that the number of posts in 2018 was small because there were only 2-week data before we stopped data collection.

Table 1. Basic statistics of the study cohort.

Statistics	25th percentile	Median	75th percentile
The number of posts per user, n	8	19	52
The number of words per post, n	18	39	78
The start weight (lb)	183.0	220.0	265.0
Weight loss (lb)	16.0	30.0	52.0
Active days, n	21	89	281
The number of comments for each post, n	1	1	1
The karma score for each post, n	1	2	3

Figure 1. The number of posts published in this subreddit in each year (from July 30, 2010, to January 13, 2018).



Topics Discovered in Online Discussions

We identified 25 topics that were corresponding to the highest coherence score (Multimedia Appendix 1). Table 2 shows the inferred topics, their marginal distribution, and the most relevant terms. The marginal distribution of a topic was measured by the probability that the topic was sampled from online discussions, while the relevance of a term was measured by the probability that it was sampled from a topic. The identifier of each topic was named based on the descending order of their topic distribution. For example, topic T1, talking about drinks, had the highest distribution, while topic T25, one of the weight change–related topics, had the lowest topic distribution.

We also manually summarized the 25 topics into 11 categories and provided the associated labels in Table 2. The table shows that people in this subreddit often talked about food and drinks, exercise, calorie, clothes, time, health issues, weight change, feelings, plans, and communication.

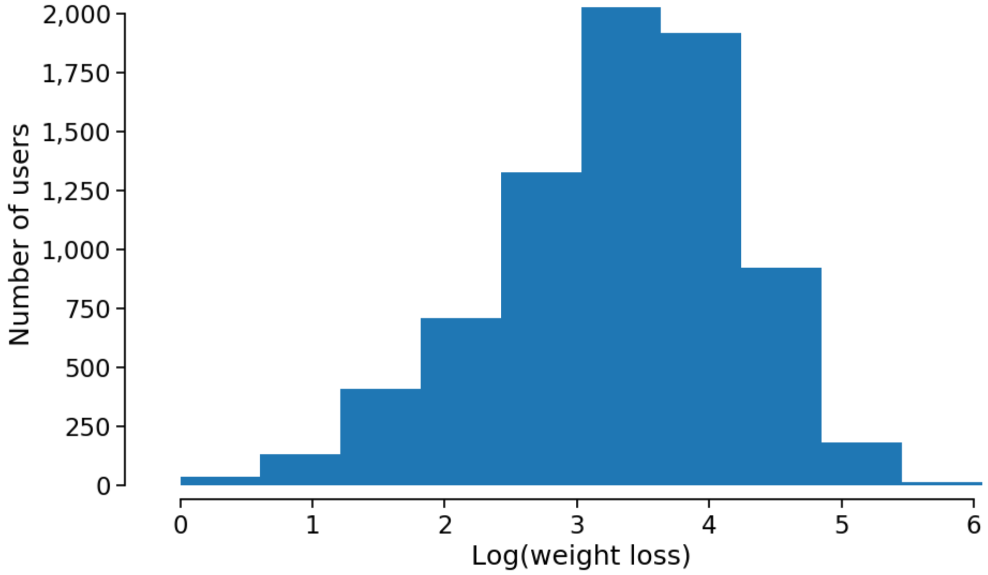
Table 2. The 25 topics that were identified from r/loseit. The sample terms were ordered based on their relevance to the topic. The distribution of each topic is calculated on all the posts published by these users.

Label and ID	Most relevant terms	Distribution (probability)
Food or drinks		
T2	water, drink, lot, drinking, make, soda, cut, diet, beer, bit, thing, alcohol	.053
T11	eat, food, meal, eating, lunch, dinner, hungry, calorie, breakfast, pizza	.051
T21	food, diet, eating, eat, low, protein, fat, calorie, lot, high, carbs, cico	.049
T22	veggie, chicken, salad, cheese, add, recipe, make, cook, egg, rice, meat	.048
Health issues		
T5	doctor, body, issue, problem, health, level, pain, energy, effect, surgery	.052
Family or friends		
T6	friend, family, guy, kid, mom, school, husband, life, live, told, girl	.052
Calorie		
T7	calorie, deficit, exercise, tdee, eat, counting, count, eating, daily, mfp	.052
T8	calorie, chocolate, sugar, sweet, snack, coffee, craving, bar, fruit, cal, cup	.051
Exercise		
T9	run, running, walk, minute, time, walking, mile, step, hour, half, long	.051
T16	gym, exercise, muscle, workout, start, working, work, body, cardio	.049
Weight change		
T3	lb, year, lost, month, started, pound, back, ago, gained, weight, starting	.052
T17	weight, lose, loss, fat, body, gain, healthy, bmi, height, normal, range	.049
T25	week, scale, weight, pound, number, plateau, drop, weighing, daily	.043
Feelings		
T12	thing, work, make, find, lot, time, hard, put, give, won, easy, worry	.051
T13	goal, hit, progress, end, picture, feel, close, happy, set, time, challenge	.050
T14	feel, feeling, eating, binge, bad, stop, time, control, hard, stress, struggle	.050
Communication or encouragement		
T1	good, pretty, yeah, luck, lol, idea, feel, kind, sound, guess, bit, haha, stuff	.053
T10	people, person, health, comment, understand, talk, mental, life, care	.051
T23	post, read, check, https_www, question, loseit, app, mfp, reddit, http	.048
T24	great, love, awesome, job, amazing, congrats, hope, sound, glad, similar	.046
Plan or decision		
T4	day, week, back, track, maintenance, couple, plan, log, logging, cheat	.052
T18	change, time, make, start, long, life, habit, making, thing, choice, healthy	.049
T20	time, thought, made, felt, wanted, started, back, needed, decided, found	.049
Clothes		
T19	fit, size, clothes, big, wear, buy, pant, bought, short, shirt, dress, store	.049
Time		
T15	today, morning, night, yesterday, work, tomorrow, weekend, day, home	.050

Regression Analysis

We chose 425 as the optimal number of word clusters based on the elbow rule (Multimedia Appendix 1). The word semantic clusters, together with other proposed predictors, were applied to fitting a linear regression model. After examining the feature correlation, we included 6 topics and 402 word semantic clusters into the regression model. Figure 2 shows the distribution of the log-transformed weight loss, which matches the loose constraint of applying a linear regression model.

Figure 2. Histogram of log-transformed weight loss.



Goodness of Fit and Non–content Predictors

The fitted linear regression model had an adjusted R^2=0.315, $F_{7,191}$=9.553, and P<.001, suggesting that the model with proposed predictors predicted weight loss better than the basic intercept-only model. Among the non–content-related predictors, the *start weight* (β=.823; *P*<.001), the *active days* in the subreddit (β=.02; *P*=.009), and the *median karma score* (β=.263; *P*=.02) were associated with higher weight loss. However, the *median number of comments* was not significantly associated with weight loss in our analysis (β=.001; *P*=.95).

Topic-Related Predictors

There were 3 topics that were found to be significantly associated with weight loss. Topics T16 (exercise in the gym) and T19 (purchase of clothes) were associated with higher weight loss (β=.072; *P*=.007 and β=.080; *P*<.001, respectively), while topic T7 (counting calorie) was associated with lower weight loss (β=−.074; *P*=.007).

Word Semantic Cluster–Related Predictors

Table 3 shows word semantic clusters that were significantly associated with higher weight loss, which are summarized below.

Table 3. Word semantic clusters that were statistically significant with respect to weight loss. Sample words are presented based on their distances to the center of a cluster in ascending order.

ID	Sample words	Beta	z score	SD	*P* value
C258	jacket, sweater, socks, sweaters, shirt, shirts, scarf, plaid, sweatshirts, jackets, coats, sandals, sweatshirt	.145	6.126	0.024	<.001
C383	emulate, replicate, magic, magical, superhuman, miraculous, recreate, miracle, feats, imitate, miracles	.130	4.699	0.028	<.001
C46	zelda, kinect, newb, wii, noob, mod, addons, nintendo, mmo, mario, xbox, mods, gamers, sims, addon, gamer	.129	1.988	0.065	.047
C93	cardio, aerobic, yoga, boxercise, gymming, pilates, plyometrics, treadmill, stairmaster, calisthenics	.128	4.567	0.028	<.001
C301	protein, metabolism, metabolic, leptin, lipids, proteins, serotonin, enzyme, enzymes, hormone, ghrelin	.120	5.143	0.023	<.001
C334	angst, frustration, anguish, anxiety, unhappiness, despair, bitterness, anger, loathing, resentment	.098	3.826	0.025	<.001
C304	musical, orchestra, opera, rehearsal, rehearsals, singers, performances, theater, choir, audition, artistic	.093	3.163	0.029	.002
C203	coach, powerlifting, teammates, captain, coached, squad, powerlifter, weightlifting, players, coaches	.085	2.027	0.042	.04
C110	younger, age, youngest, older, aged, ages, novice, old, beginners, beginner, oldest, lifelong, intermediate	.081	4.643	0.017	<.001
C24	straightforward, efficient, economical, adaptable, intuitive, inexpensive, sophisticated, expensive, easy	.081	4.405	0.018	<.001
C143	copper, zinc, moly, gold, ore, metals, tungsten, mineral, nickel, minerals, lithium, silver, metal, mines	.073	2.860	0.025	.004
C193	flower, flowers, bulb, dandelion, fragrant, roses, twigs, leaf, daffodils, buds, hibiscus, tree, crocus, trees, moss	.073	2.520	0.029	.01
C291	restaurant, restaurants, diner, deli, resturant, café, diners, bistro, cafe, pizzeria, steakhouse, resturants	.065	2.153	0.03	.03
C368	fitted, styled, proportioned, equipped, smooth, positioned, engineered, designed, smoother, molded	.059	2.584	0.023	.01
C293	discarded, trash, garbage, trashcan, bins, dumpster, recycle, dump, rubbish, scraps, leftovers, recycled, bin	.057	2.243	0.025	.03
C108	socialize, invite, catered, inviting, socializing, catering, cater, hosting, caters, hosted, invited, accommodating	.055	2.982	0.018	.003
C233	driveway, pavement, sidewalk, sidewalks, road, roads, highway, street, freeway, streets, alley, intersection	.054	2.062	0.026	.04
C66	cookouts, picnics, barbecues, cookout, feasts, picnic, potluck, togethers, barbeque, barbecue, potlucks, feast	.052	2.280	0.023	.02
C285	gerd, brussel, havn, ddp, utrecht, stephan, scandinavia, bulgarian, cico, sicilian	.045	2.797	0.016	.005
C25	gluttony, indulgence, vices, gluttonous, sinful, stupidity, hedonistic, sin, decadent, indulgent, excesses, sloth	.044	2.563	0.017	.01
C200	walkable, downtown, waterfront, neighborhoods, neighborhood, park, city, touristy, parks, suburbs	.041	1.967	0.021	.049

Exercise-Related Clusters

Exercise-related clusters included C258 (clothes), C46 (Xbox games), C93 (cardio), C203 (coaching), C233 (roads), C285 (city-related food, exercise), and C200 (hangouts places). The following are some examples that were composed by users with higher weight loss:

> *6 shirts, 2 sweaters, 6 jeans and my belts are on the last hole! I was so surprised when I read a post about new cloths and the belt was mentioned...I never knew I was already on the last hole D: I don’t need to use it, but I certainly can!*
>
> *You forget that with muscles, you'll burn more fat. 80% of my training consists of strength and I do some small amount of cardio on the side.*
>
> *I liked the suggestions and coaching from the jawbone app, but the overestimation is why I got a Fitbit with a heart rate monitor.*

Diet- or Dining-Related Clusters

Diet- or dining-related clusters included C301 (nutrition), C143 (minerals), C291 (restaurant), C293 (leftover), C108 (hosting), C66 (cookout), C25 (evil gluttony), and C285 (city-related food, exercise). The following are some examples that were communicated in related posts:

> *today I eat a pancake with plain greek yoghurt as a pre-workout in-work snack, after gym I will inhale two greek yoghurts with two spoons of protein powder, which catapults me to 170g of protein today.*
>
> *I think I've spent more time replacing bad items (like I have asparagus and Brussel sprouts instead of freezer fries now, for example) with better options than I have really giving things up.*
>
> *I learned the same thing with pizza. I love pizza, but nowadays I would much rather enjoy a slice of pizza from a good local restaurant, than an entire pizza from Domino's or Papa John's.*

> *And knowing myself before I started losing weight, if I can do it so can everyone else. I was the embodiment of laziness, gluttony and excuses.*

Other Clusters

Other clusters included C304 (performances), C334 (negative emotions), C24 (simple, straightforward, economic), C193 (flowers), C110 (beginner), and C383 (replicate). The following are some examples of these clusters:

> *I ended up just drinking water at the theater because everything was either full of calories or full of sugar. ended up having some leftover chicken and a banana when I got home.*
>
> *About the anxiety, yea same boat. I struggle with social anxiety since I'm 13 years old but it did get a lot better over the last few months.*
>
> *Look into a Hot Pot—they are relatively inexpensive (< $15) and at least allow you to do some basics like cook rice/pasta/soup/sauces.*
>
> *Finished the 13-week beginner program on DDP Yoga. Hit every workout on the schedule, didn't lag behind the schedule by even a single day once...Feels great to have stuck with it so well.*
>
> *I got flowers at work! And a sweet little card that said "I'm proud of you" from my mom because of how much effort and progress I've made in the last two months.*

Table 4 shows word semantic clusters that were significantly associated with lower weight loss, which are summarized below.

Table 4. Word semantic clusters that were statistically significant with respect to weight loss. Sample words are presented based on their distances to the center of a cluster in ascending order.

ID	Sample words	Beta	z score	SD	*P* value
C153	rising, dwindle, skyrocket, soar, rise, skyrockets, fluctuating, rises, fluctuates, spiking, spike, fluctuate	−.148	−2.782	0.053	.005
C359	purple, blue, colored, pink, brown, orange, burgundy, red, teal, gray, yellow, russet, tangerine, shades, amber	−.125	−3.464	0.036	.001
C120	request, permission, allotted, permit, requesting, requested, requests, alloted, permits, allotment, orders	−.114	−2.283	0.05	.02
C266	payments, payment, allowances, reimbursement, deduct, refund, deduction, benefits, premiums, payout	−.112	−3.282	0.034	.001
C184	vacation, vacations, getaway, vacay, resort, vacationing, resorts, honeymoon, hassle, hotels, hotel, disneyworld	−.108	−2.821	0.038	.005
C262	measurements, measurement, measuring, correlate, tracking, analysis, quantifying, monitoring, mapping	−.108	−3.627	0.030	<.001
C80	downstairs, sofa, upstairs, hallway, doorway, drawers, room, couch, cupboards, stairwell, bookshelf, fireplace	−.107	−2.022	0.053	.04
C418	hotline, contacting, contact, dialing, dialed, emailing, dial, calling, information, calls, info, referrals, referral	−.105	−5.653	0.019	<.001
C263	convince, persuade, entice, woo, coax, appease, tempt, lure, excite, inspire, convey, enlighten, quell, quench	−.101	−4.830	0.021	<.001
C421	production, producers, manufacturers, producing, output, prices, price, produce, pricing, manufacturer	−.091	−2.618	0.035	.009
C375	skinny, chubby, endomorph, lithe, pudgy, muscly, muscley, beefy, chunky, muscular, scrawny, lanky	−.084	−2.552	0.033	.01
C395	alternative, viable, workable, safe, safer, safest, alternatives, foolproof, alternate, bulletproof, inclusive	−.083	−3.455	0.024	.001
C103	tools, design, recommendations, recommended, designing, advice, recommend, materials, designs, kits	−.082	−3.075	0.027	.002
C20	split, dividing, separate, separating, splitting, divides, separated, divided, splits, divide, seperate, separation	−.070	−3.867	0.018	<.001
C227	league, scouts, rookie, leagues, teams, club, clubs, scout, seasons, season, veteran, rounder, draft	−.069	−2.911	0.024	.004
C142	budge, averse, succeeded, budging, budged, backslid, waver, incapable, qualms, bother, regressed, headway	−.062	−2.756	0.023	.006
C51	asda, morrisons, waitrose, sainsbury, sainsburys, weightwatchers, lidl, quorn, crisps, weetabix, twinings	−.060	−2.642	0.023	.008
C363	tonsils, cavities, tooth, pimples, molar, redness, toenails, teeth, sinuses, jaw, bone, zits, sinus, pimple	−.058	−2.232	0.026	.03
C18	varying, variety, varied, various, differing, different, multiple, individual, diverse, longevity, effectiveness	−.056	−3.412	0.016	.001
C124	undergraduate, college, undergrad, graduate, university, semester, graduates, semesters, academic, colleges	−.055	−2.117	0.026	.03
C92	maintenance, maintanence, maintence, maintenace, repairs, maintenence, maintainance, maintainence	−.050	−2.207	0.023	.03
C229	tweak, tweaking, tweaked, adjust, revising, updating, modifying, tweaks, modify, adjusting, readjust	−.046	−2.228	0.021	.03
C17	employed, working, work, volunteer, volunteering, volunteered, engaged, worked, engage, hire, hired	−.041	−2.127	0.019	.03
C333	moisturizer, lotion, creams, moisturizers, moisturizing, lotions, shampoo, cleanser, exfoliating, moisturising	−.034	−2.228	0.015	.03
C239	mother, daughter, aunt, niece, son, dad, grandmother, father, cousin, uncle, husband, wife, brother, sister	−.031	−2.133	0.014	.03

Activity-Related Clusters

Activity-related clusters included C184 (vacation), C227 (clubs, scouts), C124 (college, graduation), C92 (maintenance), and C17 (employment, volunteer). The following are some examples that were posted by users with lower weight loss:

> *I was fortunate enough to go on 2 European vacations this year (Italy in April, France and London 2 weeks ago) and I've gained 10lbs on top of the 15 I was already planning on losing.*
>
> *At my thinnest after college I was 5'6“ 165 lbs, and after I put 20 or 30 lbs back on my mom said she was relieved because I was starting to look ”too thin.“*
>
> *I'm actively seeking employment, so it depends what time I wake up if I have breakfast or not, but my usual day consists of...*

> *My weekend was okay. Had a big unhealthy meal yesterday but stayed 200 cal. under maintenance.*

Verb and Adjective Clusters

Verb and adjective clusters included C153 (skyrocket), C120 (request), C418 (contact hotline), C263 (entice related words), C20 (separate), C142 (backtrack), C229 (readjust), C359 (color), C375 (chunky), and C18 (various). The following are some examples:

> *I'm already exercising an hour 6 days a week. I really can't push it any more than that because my appetite skyrockets.*
>
> *I have three diagnosed illnesses and have been hospitalized twice. Users who exhibit suicidal behavior should be pointed to suicide prevention hotlines...*
>
> *I've backtracked by a couple weeks, which is partially water weight, and partially actual weight gain. It sucks.*
>
> *However, I'm over my 1200 for the day, not by much but I made a silly calorie budgeting decision earlier in the day. I readjusted dinner to try to make up for it, but I was too far in the hole.*
>
> *I was a chubby child, a chubby adult, and I've NEVER been in an acceptable BMI zone.*

Expense-Related Clusters

Expense-related clusters included C226 (payment, refund), C80 (home design), C51 (supermarket), C363 (otolaryngology related issues), C421 (production, price), C333 (moisturizer), and C239 (family members). The following are some examples that were related to these clusters:

> *I haven't been to the gym in over a week, and honestly don't think I will unless I can come up with $350 for the remainder of my Personal Training payments...oh, and more money for actual membership dues.*
>
> *I have enough motivation to get myself to the gym and am actually starting to have fun, but today I went after 4 weeks of not going, because I had my tonsils removed.*
>
> *Guilty of this! I tend to drink more frequently than my husband. I was going to try to stop drinking on weekdays. However last week, for whatever reason, he had a beer 4/7 nights.*

Discussion

Principal Findings

We used topic modeling to identify 25 general topics from the *r/loseit* subreddit. These topics covered a broad range of weight loss–related themes, including food and drinks, exercises, calorie, health issues, family members and friends, feelings, and communication. Among these topics, topics regarding food and drinks, health issues, family members and friends, calorie, and exercise were most discussed. These topics were aligned with the findings from another study [23].

Our regression analysis showed that the start weight and active days were associated with higher weight loss, which was aligned with our common sense. Furthermore, our results showed that receiving a higher karma score was associated with higher weight loss, but the median number of comments received was not significantly associated with weight loss. Our findings were a little different from the two studies, where both the karma score and comments were associated with higher weight loss [24,25]. We suspected that this might be because (1) we included far more users in our study and most of the posts received a very limited number of comments (Table 1) and (2) the previous studies did not control the model with more detailed content.

After adjusting for active days, start weight, karma score, and the median number of comments received, our analysis suggested that exercises, including coaching and nutrition, were the most effective content factors that were associated with higher weight loss, which were confirmed by previous investigations [33,34]. In addition, users with higher weight loss mentioned negative emotions that they experienced before they started to make efforts for weight loss. Our findings also suggested that mentioning food-related topics (eg, not eating too much, eating healthy food) were associated with higher weight loss, which was also found in a previous study [35]. Interestingly, we found that the mention of Xbox games was associated with higher weight loss as well. Evidence suggested that incorporating active video games had a positive effect on increasing physical activity and promoting healthy weight for both overweight adults and children [36,37].

In addition, we found that many content factors were associated with lower weight loss. For example, we found that people who mentioned vacations and clubs were more likely to have lower weight loss [38]. Furthermore, users in this subreddit mentioned that they gained weight after college graduation. Those users who had lower weight loss often mentioned supermarkets, payment or refund to exercise programs, and employment [39,40]. We also found that users who experienced health issues related to otolaryngology tended to have less weight loss. This might be due to the fact that the related treatment disturbed the weight loss plan. However, a study found that otorhinolaryngologic diseases themselves were associated with patients with obesity [41].

Another interesting finding was that users who used *skyrocket* to describe their weight loss experience (eg, feeling of eating) were less likely to have significant weight loss. This suggested that controlling the diet extensively during this process might not be an effective, healthy strategy [42]. In addition, users who often mentioned maintenance (eg, maintaining the intake of calories) were less likely to lose weight as expected. After a close examination of the related posts, we found that some of these users struggled with weight loss activities. We also found that expense-related content was associated with lower weight loss. This could be explained by a recent finding that low socioeconomic status was associated with lower weight loss outcomes [43]. Finally, users who mentioned family members were found less likely to lose more weight, suggesting that family members may not always have a positive impact on weight loss as found by other studies [44].

It should be noted that after examining feature correlation, only 6 topic predictors were included in the regression model, suggesting that word semantic clusters can capture more detailed offline activities. It was interesting that we found a calorie-related topic (T7) associated with lower weight loss, which could be partially supported by a previous finding that reducing calorie intake alone may not help in weight loss [45].

Implications

In this study, we acknowledged that while some associations were statistically significant, the value of the coefficients was very low, indicating a weak correlation between predictors and the dependent variable. However, we did not directly interpret the predictor importance from the values of their coefficients. This is because it is practically meaningless to say that *more weight can be reduced by increasing the distribution of a certain topic discussed in an online community* [46]. Rather, we believe that it is the actual offline activities described in online discussions (or self-efficacy) that actually matter in weight loss. By using word clusters, we obtained more detailed, concrete offline activities that were often ignored by other social media–based studies but were significantly associated with the amount of weight loss. While karma scores (votes) from other users were associated with higher weight loss, considering the right-skewed distribution of karma scores (Table 1 and Multimedia Appendix 1), a majority of posts in this online community received very small karma scores.

These were somewhat aligned with the findings in an offline, SCT-based weight loss intervention program [47], where self-efficacy and intention, instead of online interaction, were found to be significant factors leading to weight loss. While self-efficacy performed well in weight loss interventions [48-50], there was evidence that self-efficacy may face the challenge of decreasing over time [51]. This is very interesting because it implied that interactions, either in online or offline environments, may serve as an indirect factor that affects weight loss through maintaining a participant’s long-term self-efficacy.

From this perspective, future weight loss analyses or interventions should consider online interaction as a key factor to improve self-efficacy, instead of directly being linked to weight loss. Our study also implied that an aggressive weight loss plan may not work in the long run.

Limitations and Future Work

There are several limitations that we want to highlight here. First, our findings were based on merely the *r/loseit* subreddit, which constrained the generality of findings. Future work may consider extending the research to other online platforms. Second, we did not incorporate gender into the analysis. It might be possible to first infer such information from online discussions [52] and then investigate how the association between posting content and weight loss changes after controlling for this information. Third, we relied on self-reported weight loss in this study, which limited our investigation, and findings were applicable to only a small fraction of Reddit users who disclosed weight change. It will be interesting to investigate the specific characteristics that are related to the majority of Reddit users who did not report such information. Furthermore, self-reported weight changes might not be accurate because Reddit users might not update their weights in a timely manner. Our study only investigated what was presented in the online discussions, instead of examining the real-world events. Finally, it would be interesting to investigate the extent to which online interaction, not merely responses and votes but the detailed categories, and offline activities that were recorded in online discussions can lead to weight loss change in a dynamic setting.

Conclusions

In this study, we analyzed online discussions regarding weight loss in *r/loseit*. We used topic modeling and the hierarchical clustering algorithm to extract topics and word clusters that were discussed in this subreddit. We used a regression analysis to determine the association between weight loss change and the factors that were conveyed in these online discussions. We found that the start weight and median karma scores were associated with higher weight loss. Users who had higher weight loss might be motivated by negative emotions experienced before starting weight loss. By contrast, users who mentioned vacations and payments were less likely to lose more weight. Furthermore, mentions of family members and employment were also found to be associated with lower weight loss. Our findings suggest that future interventions based on online social media platforms should focus on both online interaction and offline activities and that online personal health data can be effectively used to learn about users’ health-related behaviors.

Acknowledgments

The authors thank the colleagues in Changchun Normal University and Vanderbilt University for the positive feedback on this project. Special thanks go to Na Liu from Georgia Institute of Technology for the constructive discussion on the work implication.

Authors' Contributions

ZY proposed the research question and designed the experiments. YL collected data and conducted the experiments. ZY and YL wrote the manuscript. ZY reviewed the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Superusers, defined as the 1% of users who write a large number of posts, play critical roles in online health communities (OHCs), catalyzing engagement and influencing other users’ self-care. Their unique online behavior is key to sustaining activity in OHCs and making them flourish. Our previous work showed the presence of 20 to 30 superusers active on a weekly basis among 3345 users in the nationwide Asthma UK OHC and that the community would disintegrate if superusers were removed. Recruiting these highly skilled individuals for research purposes can be challenging, and little is known about superusers.

Objective: This study aimed to explore superusers’ motivation to actively engage in OHCs, the difficulties they may face, and their interactions with health care professionals (HCPs).

Methods: An asynchronous web-based structured interview study was conducted. Superusers of the Asthma UK OHC and Facebook groups were recruited through Asthma UK staff to pilot and subsequently complete the questionnaire. Open-ended questions were analyzed using content analysis.

Results: There were 17 superusers recruited for the study (14 patients with asthma and 3 carers); the majority were female (15/17). The age range of participants was 18 to 75 years. They were active in OHCs for 1 to 6 years and spent between 1 and 20 hours per week reading and 1 and 3 hours per week writing posts. Superusers’ participation in OHCs was prompted by curiosity about asthma and its medical treatment and by the availability of spare time when they were off work due to asthma exacerbations or retired. Their engagement increased over time as participants furthered their familiarity with the OHCs and their knowledge of asthma and its self-management. Financial or social recognition of the superuser role was not important; their reward came from helping and interacting with others. According to the replies provided, they showed careful judgment to distinguish what can be dealt with through peer advice and what needs input from HCPs. Difficulties were encountered when dealing with misunderstandings about asthma and its treatment, patients not seeking advice from HCPs when needed, and *miracle cures* or dangerous ideas. Out of 17 participants, only 3 stated that their HCPs were aware of their engagement with OHCs. All superusers thought that HCPs should direct patients to OHCs, provided they are trusted and moderated. In addition, 9 users felt that HCPs themselves should take part in OHCs.

Conclusions: Superusers from a UK-wide online community are highly motivated, altruistic, and mostly female individuals who exhibit judgment about the complexity of coping with asthma and the limits of their advice. Engagement with OHCs satisfies their psychosocial needs. Future research should explore how to address their unmet needs, their interactions with HCPs, and the potential integration of OHCs in traditional healthcare.

Introduction

Background

Recent work has suggested that taking part in online communities for people with long-term conditions (LTCs) improves illness self-management [1] and adherence to treatment [2], produces positive health-related outcomes [3-5], facilitates shared decision making with health care professionals (HCPs) [6-8], and may even reduce mortality [9]. There is also evidence that self-management support interventions can reduce health service utilization [10,11]. Participation in online health communities (OHCs) for patients with LTCs can take up part of the health care service demand and indirectly improve access to health care [12]. However, much of this evidence comes from qualitative and observational studies [6,13,14]. Despite a lack of definitive evidence, policymakers are starting to see the potential of OHCs, for example, the Big White Wall, an OHC commissioned by some mental health services in the United Kingdom, Canada, and New Zealand [15]. The Irish health system is piloting closed Facebook groups for smoking cessation [16], whereas the Public Health England Stoptober smoking cessation campaign includes a Facebook group [17] among other initiatives. In the United Kingdom, Facebook is also being piloted by the National Health System Digital (NHS Digital) to improve cancer screening rates, with promising results [18]. This increasing attention to health social media calls for elucidating the mechanisms that make OHC engagement successful in terms of improving self-management [12,19]. Indeed, although some OHCs flourish, many suffer from little or no traffic [20]. The emerging literature investigating mechanisms of effective OHC engagement shows that superusers (ie, users who are in the top 1%-5% in terms of messages posted to the OHC) are key to success. They generate the majority of traffic and create value, so their recruitment and retention are imperative for the long-term success of OHCs [21]. A previous analysis of an online community for people with drinking problems found that common themes for superusers' engagement included introductions, greetings, general supportive statements, suggested strategies, success stories, and discussion of difficulties [22], showing that superusers reassuringly offer peer support toward behavioral and emotional self-management tasks [23], appropriately leaving to HCPs medical self-management tasks.

To fully understand the unique mechanisms of behavior change through internet-based interventions, collaboration and knowledge transfer between researchers, nonprofit organizations, and private organizations have been recommended [24]. Our network study of peer support in the Asthma UK and British Lung Foundation (BLF) OHCs [25] in collaboration with the platform provider HealthUnlocked has highlighted the key role of superusers. Superusers are distinct from community moderators formally appointed by the platform provider; the number of moderators among the highly active users was negligible [25]. Superusers are a naturally available resource and are responsible for holding successful OHCs together, engage with users with low posting activity, and indirectly contribute to the formation of ties between users. As users become more active within the community, they become more likely to reply to posts than to ask questions. This suggests that superusers gradually become *experts*, providing others with advice and support [2,7,26].

Online superusers could be considered allies of the health care workforce [27,28]. Our work has inspired the development of a new network-based theory of social medical capital, broadly defined in terms of the advantages that any user (patient or caregiver) can gain from participation in OHCs [29].

In this context, strategies to increase superusers' participation can improve engagement with OHCs [30]. This is attracting growing interest from academics, HCPs, and policymakers. Despite the evidence of superusers' key role in successful OHCs, little is known about this small but critical population, what motivates them to contribute to the community and stay active over time [22,25], whether they encounter any challenges, how their contribution could be supported in any way, and what would make OHCs safer and more effective. This study set out to understand what motivates superusers to adopt this role and the reciprocal value it offers them. Although the research was pragmatically driven, our interpretation draws on self-determination theory [31], a framework for differentiating intrinsic and extrinsic forms of motivation, to help link the insights to recommendations for health organizations seeking to engage with and utilize the value offered by superusers in their online communities.

Objectives

Here, we undertook an asynchronous web-based structured interview study of UK superusers previously quantitatively characterized [25], in collaboration with the charity Asthma UK. We additionally aimed to explore superusers' interfaces with HCPs and their views on HCPs' potential role in promoting engagement with OHCs and on HCPs' engagement as OHC participants themselves.

Methods

Interview Schedule Development

The interview schedule was developed with questions based on the extant literature, recent work on OHCs [25,32], and informal discussion dated from 2015 to 2018 with 2 superusers, 1 from a stroke OHC previously studied [33] and 1 from Asthma UK OHC.

Piloting Phase

Piloting was undertaken with 6 superusers recruited through the Asthma UK research operating officer (JP) and OHC moderator. JP emailed the weblink to the study questions and attached to the same email a Microsoft Word document with the interview questions in November 2018. Comments and suggestions were received by JP between November 2018 and February 2019. Superusers' suggestions improved the clarity of the introductory text and the queries asked. Some questions initially part of the same query were split to make replying easier (ie, questions 3-5 and 7-8), whereas new questions were suggested (ie, questions 10, 13-15, 21, and 24). This process resulted in 10 additional questions. The wording of some questions was also adjusted to make it more neutral to participants.

Inclusion Criteria

The inclusion criteria were as follows:

- Living with asthma or caring for somebody with asthma
- Having posted to an online asthma community at least one message per week for at least four weeks.

As there is no evidence yet about whether superusers' posting activity over time is regular or occurring in bursts (eg, when off work due to illness), we opted to be nonspecific about the 4-week period. Therefore, posting activity over any 4 weeks, consecutive or not, at any point in time would qualify participants as superusers.

In this asynchronous web-based structured interview, the definition of superusers is different from the *retrospective* one used in the study by Joglekar et al [25] (ie, top 1% of users characterized by the largest number of posts posted in the community *over the entire observation period of 10 years).* This previous study showed that only about 20 to 30 superusers were active on a weekly basis since 2015. The inclusion criteria for superusers were agreed upon by coauthors and the superusers who took part in the pilot phase. Due to the hypothesized small sample of potential participants available to recruitment [25], no saturation criteria were used to determine the study sample size.

Participant Recruitment

Of the 17 participants, 16 were recruited by the Asthma UK research operating officer (JP) by email and through an Asthma UK monthly email bulletin to take part anonymously through a SurveyMonkey link [34]. Responses were collected between March and April 2019. A superuser (OF) who is a member of the Asthma UK Centre for Applied Research Patient and Public Involvement (PPI) group [35] was invited and recruited by AD.

Ethical Approval

The study was approved by the Queen Mary University Research Ethics Committee (ref QMREC2205a). To address the issue of confidentiality around patient information and to avoid this information being known to the research team, superusers were approached only by the Asthma UK staff (JP) and invited to participate. The research team did not have access to personally identifiable information apart from the AUKAR PPI member and coauthor (OF).

Analysis

We analyzed the text from open questions using inductive content analysis as described by Elo and Kyngas [36]. Two authors (AS and AD) read all responses to familiarize themselves with the data. An initial coding framework with themes and subthemes was developed, which was adjusted as new data were added. This was done for the first 10 individuals and, subsequently, for the additional 7 individuals. Coding was then performed independently by 2 authors (AS and AD) on all data. Coding was discussed until agreement was reached, and the themes were revised as well.

Results

Characteristics of the Participants

A total of 17 participants were included in the study (Table 1): 14 were people living with asthma, whereas 3 were mothers of children with asthma. The majority were female (15/17), with an age range of 18 to 75 years (3 out of 17 participants were aged 66-75 years).

Of the 17 users, 10 participated in 2 or more OHCs: 15 out of 17 in Asthma UK HealthUnlocked community and 10 out of 15 in Facebook groups. HealthUnlocked is the platform provider of the Asthma UK online community.

With respect to education, 65% (11/17) had at least an undergraduate degree and 18% (3/17) had a postgraduate degree.

Before taking part in the study, they had been active in OHCs for 1 to 6 years and spent between 1 and 20 hours/week (11 out 17 participants spent ≥2 hour/week) reading and between 1 and 3 hours/week (7 out of 17 participants spent ≥1 hour/week) writing posts.

Self-reported participation increased over time for 14 out of 17 superusers and was linked to wanting to know more about asthma and its treatment in the context of deterioration of asthma or change in medical treatment. Other factors contributing to participation were increased familiarity and interest toward OHC members and improved awareness and knowledge of asthma.

Table 1. Participants' characteristics.

Participant number	Gender	Age range (years)	OHCs[a] joined	Duration as OHC member (years)	Time spent reading posts[b] (hours)	Time spent writing posts[b] (hours)	Number of posts written[b]	Highest level of education
1[c]	Female	36-45	Facebook group (UK Parents of Children with Asthma)	2	5	<1	4-5	Undergraduate degree or similar
2	Female	46-55	Asthma UK	1	1	N/A[d]	0	Postgraduate degree or similar (eg, PhD)
3	Female	66-75	Asthma UK	>1	5	NS[e]	4-10	Undergraduate degree or similar
4	Female	66-75	Asthma UK	2.5	>0.5[f]	NS[e]	Variable[f]	Postgraduate degree or similar (eg, PhD)
5	Female	66-75	British Lung Foundation, Asthma UK	>3	10	2	4	Undergraduate degree or similar
6	Female	46-55	Asthma UK, British Lung Foundation	5	5	<0.5	1	O-levels/ General Certificate of Secondary Education or similar
7	Female	46-55	Asthma UK	5	20	1	5	Prefer not to say
8	Male	46-55	Asthma UK, Facebook	6	1	NS	1	A-level or similar
9	Male	46-55	Asthma UK	0.5	1	0.3	2	Undergraduate degree or similar
10	Female	18-25	Facebook groups, Asthma UK	0.5	1-2	0	0-1	Undergraduate degree or similar
11	Female	46-55	Asthma UK	>3	1-2	1	0-1	A-level or similar
12[c]	Female	36-45	Asthma UK, Facebook group (UK Parents of Children with Asthma)	2.5	2	0.3	4	Undergraduate degree or similar
13	Female	26-35	Asthma UK, HealthUnlocked communities	2.5	6	2-3	15	Postgraduate degree or similar (eg, PhD)
14	N/A	N/A	Facebook group (Bronchiectasis)	<1	0.5	NS	0-5	NS
15	Female	26-35	Asthma UK, Facebook groups	>5	3	1-2	3	Undergraduate degree or similar
16[c]	Female	36-45	Facebook group (UK Parents of Children with Asthma), Asthma UK	2-3	2	0.2	5	Undergraduate degree or similar
17	Female	18-25	Asthma UK, Facebook groups	0.5	3-4	0-1	0-1	A-level or similar

[a] OHCs: online health communities.

[b] Hours of engagement and number of posts refer here to the average week. Some superusers' engagement may be concentrated over certain time periods.

[c] Superuser is a carer (mother of a child with asthma).

[d] N/A: not applicable.

[e] NS: not stated.

[f] Higher contribution when not well with asthma.

Themes

Themes and subthemes were generated through content analysis of open-ended questions and are shown in Table 2. Our findings will be articulated into 4 themes:

1. Motivation to engage: Motivation to active participation in OHCs included personal advantage and the desire to help others/being altruistic. Engagement with OHC promoted superusers' sense of personal control, agency (ie, the actual ability to deal with a task or situation), and self-efficacy (ie, the perceived ability to deal with a task or situation) over their illness, particularly when they adopted the informal role of *wise mentors* wise mentors or supporters to other users. An important reason for people taking part in asthma OHCs was the reward felt by being helpful to other members.
2. Awareness of the limits of peer self-management support: Superusers showed a sense of awareness of what can be dealt with through peer support/advice (ie, behavioral and emotional self-management tasks) and of what instead would require input from HCPs (ie, medical self-management tasks).
3. Challenges: Superusers encounter several challenges, such as dealing with misunderstanding about asthma and treatment and a general sense of responsibility toward other OHC users. Superusers could find themselves under moral pressure to respond to risk-indicating or inappropriate posts and reporting posts to moderators, which could cause at times cognitive stress.
4. Interface with HCPs: Most HCPs were not aware of OHC engagement. Superusers generally felt that HCPs should direct patients to well-trusted and moderated OHCs. Some felt that HCPs themselves should take part in OHCs.

Table 2. Themes.

Themes	Subthemes
Motivation	
Seeking information and support	• Gaining knowledge about asthma illness and its treatment • Validation of own experiences in the context of asthma • Feeling less isolated • Talking with fellow sufferers • Enjoying reading conversations of users one got to know
Helping others	• Giving advice that could potentially save a life • Supporting others with asthma and their carers • Making people with asthma and their carers feeling less isolated • Show others that living with chronic conditions is not always negative • Making sure people with asthma take their disease seriously • Disseminating of scientific information
Feeling rewarded through helping	• Positive feeling when helping others • Replacement of role
Financial or social recognition not important	• Not important: reward is helping others, enjoying interactions • Not important: all users shall be equal with equal voice importance • Not important: voluntary nature—financial incentives potentially causing misuse • Unsure/yes important: recognition of sensible/knowledgeable users
Awareness of the limits of peer self-management support	
Decisions on posts to reply to	• Drawing from personal experience • Providing a different point of view
Types of support offered	• Behavioral and emotional peer self-management support • Empowering patients and carers through own experience • Signposting to source information and support
Medical self-management needs HCPs’[a] input	• Showing appropriate insight of potentially serious medical issues • Advising to seek medical help with appropriate urgency
Challenges	
Top 3 problems and difficulties encountered	• Worrying about users struggling with asthma and not seeking medical help as appropriate • Misunderstanding, spam, miracle cures, or dangerous ideas • Negative tone of some conversations
Posts causing superusers’ worries	• Religion-based advocacies; derogatory, emotionally challenging posts • Offering bad advice or indicating that users have little knowledge about asthma and its gravity
Need of additional policies and guidance	• Improve awareness of existing policies and guidance for safe engagement with asthma OHCs[b] • Policies and guidance about buying asthma medications on the web • Quicker removal of bad posts/advice
HCPs and asthma OHCs	
HCPs’ awareness of engagement with asthma OHCs	• Engagement with asthma OHCs is not discussed during consultations with HCPs • Engagement with asthma OHCs is not discouraged by HCPs • HCPs’ belief that engagement with asthma OHCs focuses patients on illness and potentially increases their anxiety

Themes	Subthemes
HCPs' promotion of engagement with OHCs	HCPs should direct patients with LTCs[c] to moderated/trusted OHCs Advantage is obtaining behavioral and emotional self-management support that HCPs may not be able to offer Ways of promotion: posters up in the waiting rooms of relevant hospital departments and General Practice (GP) surgeries and face-to-face discussion of OHC information by nurses during asthma clinics
Suggestions to reassure HCPs about OHC engagement	Clearer statements about contacting HCPs for medical self-management Improving HCPs' awareness of benefits of online peer support; robust evaluation of the effects of OHC engagement Readily accessible guidance about keeping safe in social media Clear rules about posting activity; regular, nonintrusive participation of moderators
HCPs' participation in OHCs	Benefits: for the opportunity to get worries and questions addressed, as long as HCPs' identity is stated Difficulties: potential scrutiny of all posts, limitation of expression of different points of view, lack of sufficient clinical details, and issues with code of conduct of HCP registering bodies

[a] HCP: health care professional.

[b] OHC: online health community.

[c] LTC: long-term condition.

Motivation of Engagement

Seeking Information/Support

Motivation to engage with OHCs was linked to personal advantage through gaining knowledge and support for asthma and its treatment:

> *To learn from others who actually know what it can be like and to learn from their experiences.* [N.4]

Validation of own experiences in the context of asthma and the feeling of being less isolated were also important factors:

> *To get validation from others with the same symptoms.* [N.17]

Having the opportunity to talk with people who live with asthma was considered important:

> *...many people find comfort and support in such communities that cannot be offered by family members and/or friends that have not experienced the day-to-day living of conditions.* [N.14]

Reading other users' conversation was described as a positive experience that increased engagement:

> *I enjoy the chats with others and reading the dialogue between others, many of whom I've got to know.* [N.5]

Helping Others

Altruisms and the benefit of feeling in a position to help others were a significant factor sustaining the motivation to regularly take part in OHCs.

Some even mentioned the potential to save lives:

> *If my own message or experience could help save a child's life.* [N.1]

Most participants talked about the motivation to support others with asthma and their carers to mitigate their sense of social isolation:

> *…especially when you are supporting parents who are new to dealing with asthma in their child.* [N.1]
>
> *I remember how lost and frustrated and alone I felt. I don't want other mums who are new to asthma to have those same feelings and struggles.* [N.16]
>
> *...being there to give emotional support when needed.* [N.17]

Part of the motivation was to show others that living with chronic conditions is not always negative and to offer hope to others:

> *I wish to show that I can live a normal life with chronic condition.* [N.2]

Using their knowledge to clear up any confusion about asthma and medications was relevant, as well as making sure people with asthma took their disease seriously and did not rely on social media for queries that needed HCPs' input:

> *Trying to make people take their asthma more seriously and not rely on social media for the answers which often don't come and then they end up in hospital.* [N.15]

Interestingly, a participant mentioned that part of the motivation was to disseminate proper scientific information:

> *To be helpful and disseminate information, especially scientific information.* [N.8]

Rewards for Online Health Communities Engagement

Participants found helping others a positive experience for themselves. By providing replies to other users' queries, superusers increasingly acquired confidence and were recognized for their role as community *experts*, which in turn boosted their motivation to further engage in OHCs. For some participants, who were unable to work due to ill health or were retired, taking part in OHCs could work as a replacement of role:

> *I feel that I can still use the knowledge and skills from my previous work along with my personal experience of asthma.* [N.3]
>
> *I use it far more when I am unwell with asthma.* [N.4]

Financial or Social Recognition Not Important

A question addressed whether the contribution superusers make could be recognized in any way (socially or financially), considering it might help other patients to manage their illness better. Of the 17 participants, 13 replied negatively, 3 were unsure, and only 1 replied positively.

The main reason behind the *no* answer was that reward should come from the awareness of helping others and the fact that social interaction is actually enjoyable.

The motivation to ensure that all users felt equally important to the whole community also played a role:

> *There is no guarantee that a superuser is any better informed than any other user. Superuser status might make others feel their contributions were not worth making. In my view, the forum should be one where every voice has equal status.* [N.9]

Other factors against social and financial recognition were the voluntary nature of contributions and the potential misuse of financial incentives:

> *I do it because I can, if I didn’t want to I wouldn't.* [N.16]

Some positively saw the social recognition as sensible/knowledgeable users:

> *Those who are particularly helpful could be recognised with titles, so users know who to contact for issues. Monetary incentives could also be considered, but most people who help online are doing it just to be helpful rather than for any other purposes.* [N.10]

Awareness of the Limits of Peer Self-Management Support

Decisions on Posts to Respond to

When asked about what determines their decision to reply to certain posts, participants showed a reassuring awareness of the type of self-management support they were able to offer (ie, emotional and behavioral but not medical tasks):

> *By drawing in on your own experiences. You soon recognise familiarities with symptoms.* [N.1]
>
> *I choose the ones which I have some relevant knowledge or experience to reply to.* [N.3]

Some mentioned that they posted replies when they felt they were able to provide a different/unrepresented point of view with respect to the ones already given, which in turn could help others make decisions:

> *...there may not be another voice in that comment section giving the view I feel, so I may choose to add it.* [N.16]

Participants’ aim was to empower patients and carers through their own experiences:

> *I will post a reply from my own experience of asthma gained over 50 years.* [N.11]

Types of Support

The type of support most frequently provided by our respondents was mainly behavioral and emotional. In addition, most participants also mentioned their role in signposting users to source of information and support:

> *Reassurance, information, sharing my experience of a particular health issue, information about where to go for further advice and information.* [N.3]

Medical Self-Management Needing Health Care Professionals’ Input

Medical self-management was unanimously agreed upon as something that required consultation with HCPs, and all superusers had prior experience of referring other community members to their HCPs:

> *I never give specific medical advice though.* [N.10]
>
> *Almost every time, the default answer is always to contact your own medical help for guidance.* [N.16]

Challenges

Problems and Difficulties

Of the 17 superusers, 9 described problems and difficulties associated with their role in the OHCs (2 were unsure about it, 4 replied no, and 2 did not reply).

The main difficulty described by superusers was the worry they felt regarding other community members who were not successfully managing their asthma and not seeking appropriate medical help:

> *Members who put their health at risk by not realising how dangerous a situation they are in.* [N.17]

Other problems described included dealing with misunderstandings, spam, or posts promoting miracle cures or dangerous ideas (eg, buying medicine over the internet). Of the 17 participants, 9 had experience of reporting such posts to moderators:

> *Spam e mails, folks responding who’ve not understood my posts, prolonged communication.* [N.2]
>
> *People offering “miracle” cures; people not being supportive; going off topic of the original post.* [N.14]

Some users found it difficult to deal with the negative tone of some conversations, when the underlying aim was to complain:

> *Some people don't want to take advice and will just complain constantly no matter what you suggest.* [N.15]

Only 1 user mentioned being trolled once in the past and this being a negative experience. Asthma UK HealthUnlocked community was described as a *good forum*.

Posts Causing Superusers Worries/Stress

Posts causing superusers worry were about religion-based advocacies and derogatory or emotionally challenging stories. Posts offering bad advice, indicating that users had little knowledge of asthma and its gravity, and revealing a sense of responsibility of superusers to reply to posts and moral pressure toward other OHC users also caused worry and stress.

Moreover, superusers worried about posts from users who were struggling or acutely unwell and subsequently stopped posting or from users who had been chronically struggling with their asthma without seeking professional help:

> *Those that encourage people with less knowledge to take actions that could put their child in danger/people who are disparaging someone else's intelligence or understanding of the illness.* [N.16]
>
> *[Posts suggesting that] children can be in respiratory distress.* [N.16]

Suggestions for Policies and Guidance

Of the 17 participants, 8 believed that more policies and guidance should be available for asthma OHCs (2 did not, 4 were unsure, and 3 did not answer the question). In particular, they felt that additional policies and guidance should be introduced on the rules for safe engagement with asthma OHCs and for clarifying when emergency medical advice is needed. Some participants did acknowledge that such policies were already in place, though not all users seemed to be aware of them. A suggestion was made for new users to be encouraged to passively engage and read posts before active engagement:

> *New members should be encouraged to read without contributing at first. I think all members do this instinctively anyway...joining a social group is rarely instant. Good sites include few risks, made safe by the site rules, moderators and experienced users.* [N.5]

One participant recommended having policies and guidance about buying medications over the internet.

A number of participants highlighted the importance of quick removal of clearly bad advice so as to develop patient confidence in participation:

> *Quick removal or "bad" posts (including spam). [Moderators to] Respond to occasional posts (especially if there's an argument going on in the feed).* [N.13]

Interface With Health Care Professionals

Health Care Professionals' Awareness of Engagement With Asthma Online Health Communities

Most participants' HCPs (10 out of 17) were not aware of superusers' engagement with asthma OHCs. Only 3 out 17 participants reported that their OHCs' involvement was known by their HCPs, whereas 4 out of 17 participants were unsure. Even when the HCPs were aware, this was because superusers mentioned their engagement with OHCs, though they did not discuss it any further:

> *The only person who knows is my husband.* [N.3]

Of the 17 participants, 15 stated that they did not believe that HCPs would discourage participation in asthma OHCs:

> *I think the quality of the BLF and Asthma UK sites is generally accepted. Medics know I'm am open minded and analytical about any information.* [N.5]

Only 1 participant reported being discouraged by their HCP from engaging with OHCs, and this was linked to concerns about patients becoming focused on illness rather than health and well-being:

> *They seemed to feel that by engaging with other people in online health forums it focused people on the illness rather than on getting on with life. They seemed to feel that it made people more anxious about their illness rather than provide reassurance, information and support. It seems to me that they were worried that it reinforced an 'illness' mentality. However, my experience is that generally it empowers people to take control of their own lives and make decisions in partnership with their medical carers rather than feel disempowered and uncertain.* [N.3]

Health Care Professionals Promote Engagement With Asthma Online Health Communities

The majority of participants (11 out 17) thought that HCPs should direct patients with LTCs to OHCs, provided they were appropriately moderated and trusted platforms. The remaining 6 out of 17 participants were unsure, though no one felt that HCPs should not promote engagement with OHCs:

> *Any recommended communities would need to be appropriately vetted/ endorsed by medical professional to ensure their accuracy in terms of medical advice and to keep people safe.* [N.10]

Respondents offered several specific suggestions about how to promote engagement with OHCs:

> *There could be posters up in the waiting rooms of relevant hospital departments and GP surgeries. Asthma nurses could inform patients. Ask people how they feel they have benefited from online communities.* [N.9]

Indeed, a range of advantages arising from the promotion of OHCs by HCPs included obtaining behavioral and emotional self-management support that HCPs may not be able to offer as easily:

> *For support for people when they get diagnosed, have a really difficult time with their asthma and recovering.* [N.11]

Suggestions to Reassure Health Care Professionals About Online Health Community Engagement

To reassure HCPs about the safety of OHCs, participants felt OHC providers should have clearer statements about contacting HCPs for medical self-management, place more emphasis on the fact that posts from peers come from not medically qualified people, and have a readily accessible guidance about keeping safe in social media. Comments from moderators should be regular and nonintrusive, with strict rules regarding posts:

> *Healthcare professionals may need to be reassured that any group they signpost is a medically sound one. However, they cannot dictate. It is about mutual respect for the role of the medical professional and the role of an on-line health community.* [N.3]

Participants felt improving HCPs' knowledge and awareness of why patients engage with OHCs and the benefits of peer support on LTCs would make them keener to promote OHCs. Evaluation of the impact of engagement in OHCs on patients was also suggested:

> *[HCPs' awareness that] online communities are primarily useful for feeling more "normal" with your condition - connecting with others in the same situation.* [N.10]

Health Care Professionals' Participation in Online Health Communities

When exploring whether HCPs should themselves take part in OHCs, 9 out of 17 participants replied positively, 5 were unsure, 2 were against it, and 1 did not answer the question.

The reasons behind perceiving HCPs' participation beneficial were the opportunity to get worries and questions addressed. However, as this respondent notes, their participation may be mutually beneficial through learning more about the patient experience of their illness:

> *Not only could a lot of peoples' worries and questions be easily answered authoritatively healthcare professionals could gain much knowledge from forums.* [N.8]

There was a mention of engagement in OHCs as an additional remunerated duty for HCPs:

> *I think they [HCPs] should be paid to set aside time to monitor forums.* [N.8]

Most participants felt that HCPs' participation in OHCs was important as long as their identity was stated:

> *They should include their medical specialisms in their profiles and understand that there are many viewpoints on some issues.* [N.5]

Difficulties making participants unsure about HCPs' participation were potential scrutiny of all posts, limitation of expression from different points of view, and the problem of not knowing the clinical details of users well enough before an appropriate answer could be given:

> *I feel the community is for those who don't otherwise have a voice and that it would seem too "preachy" to have a medic commenting on every post.* [N.9]
>
> *...it might get difficult (difficult/awkward for medics when dealing with people they know little about).* [N.13]

Issues with HCPs' code of conduct and difficulties with HCPs being patients themselves were also expressed:

> *Difficult. There is a place for it but I think it blurs the lines a little and their code of conduct with their registering body...I think as a healthcare professional who is also a patient they need to be aware of the blurred line between patient and healthcare worker.* [N.15]

Discussion

Principal Findings

This is the first study to provide evidence of superusers' motivations for engagement in a large nationwide OHC, the challenges they face when interacting with other users, and their interface with HCPs. As the use of social media in health care is increasing, taken together with our previous network study [25], these results provide unprecedented insight on superusers who are key to creating value, driving and sustaining user engagement and contributing to the success of an OHC.

Superusers are both patients with asthma and carers of a wide age range, tend to take part in more than one OHC, and spend considerable time in a role sometimes similar to that of moderators [37]. Reassuringly, they showed awareness of the complexity of coping with asthma and the limits of their advice, provided emotional and behavioral self-management support, and had at times to direct users to HCPs for medical queries. This is an important point as much of the work exploring HCPs' views of OHCs suggests that they are concerned that inappropriate advice is commonly shared and that community members may not be skilled/reflective enough to realize it.

The superuser role appears to be acquired by users as they deepen their asthma-related knowledge and become accustomed to web-based communication and the dynamics of group-based anonymous interaction [26], turning into *expert patients*, acquiring some of the characteristics of the *second generation of e-patients* [8].

Although the superuser role could be stressful at times, most HCPs were unaware of superusers' engagement with OHCs and therefore unable to provide support. This is also in contrast with the general agreement among superusers that patient engagement with trusted and thriving OHCs should be promoted within health care. For some, being a superuser could work as a *replacement* of role, as in the case of a retired HCP participant or a participant in working age who is identified as an HCP off work due to asthma.

Superusers who were themselves HCPs raised the issue of the need to develop a code of conduct within their registering bodies to engage with users in OHCs.

It has been suggested that HCPs' engagement with OHCs could be remunerated as part of HCP duties.

Superusers' perspectives on what would make OHCs safer and more effective are of interest not only to OHC platform providers but also to policymakers who are increasingly considering leveraging OHCs for health care delivery.

Strengths and Limitations

There are a number of strengths and limitations to our work, which merit comment. The data we collected from superusers in this study came from an existing and thriving asthma OHC [25,27]. In our previous study, we uncovered the emergence of superusers (or hubs) as the OHC network grew larger. Our findings suggest that users with a disproportionate number of contacts started to emerge only when many users had already joined the network (about 1000). This has important implications for the size of our sample of superusers. Although the absolute number of superusers in this study may appear to be small, it takes a very large-scale network for these superusers to emerge. Thus, our sample size must be gauged jointly with the (large) size of the underlying network to which the superusers belong. Although no saturation criteria were used to determine the study sample size, our qualitative analysis revealed that saturation of emerging themes was reached.

The currently limited literature about superusers in OHCs, the lack of a formal identification of *superuser status* in OHCs, and the a posteriori definition of superusers (ie, superusers as the top 1% active users over a 10-year period [25]) make it difficult to judge the response rate in this study. Our previous work [25] showed the presence of 20 to 30 superusers active on a weekly basis. Although for obvious reasons we could not use the same definition to identify superusers in this study, based on our previous results, the superuser response rate would support the validity of the data presented here.

The study benefited from a superuser piloting phase that face-validated the questions and improved their focus, resulting in additional questions. The study was not designed to test the self-determination theory, which was used as an interpretive lens.

The Asthma UK and Facebook communities are established OHCs (Asthma UK OHC has been operational since 2006) and are moderated and trusted; thus, the results may not extend to other OHCs. Although we cannot confirm superuser sharing of scientific information being always appropriate, in such circumstances, it is likely moderators and other superusers, as seen in this study, would intervene in providing rectification.

Moreover, the self-selective nature of recruitment may have introduced a subjective bias, as less altruistic superusers with different characteristics may not have responded to the invitation.

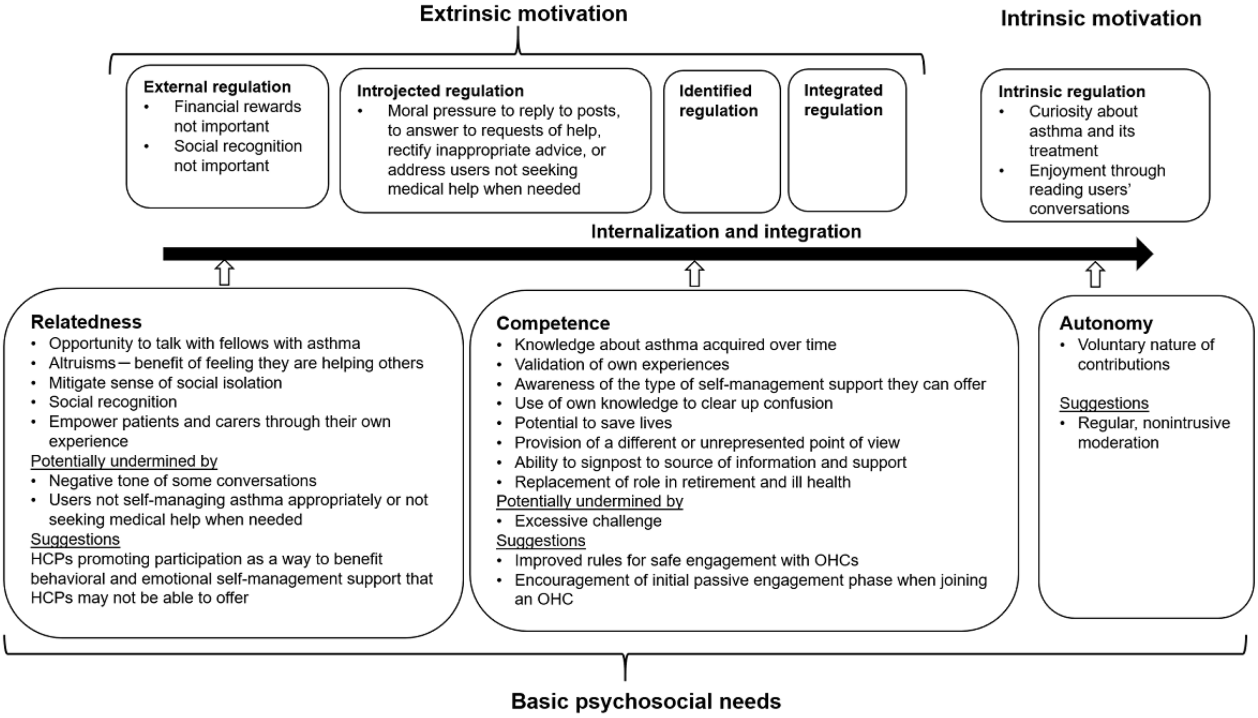
Comparison With Existing Literature

Only a handful of studies characterizing superusers in OHCs are present in the literature, and to our knowledge, this is the first direct account of superusers' motivation to engage in OHCs. Previous work focused on quantifying superusers [21] and their posting behavior [24] using a passive approach. Superusers have been described as mostly female [24], at times, assuming a role similar to moderators [37]. The desire for agency and mastery in asthma patients has been previously described [38]. Engagement with OHCs promoted superusers' sense of personal control/agency/self-efficacy over their illness, particularly when adopting the informal role of wise mentors or supporters to other users. Interestingly, a recent study indicated that patients gained empowerment through OHCs, which was positively related to patient commitment to the physician and to patient compliance with the proposed treatment [2]. Moreover, there is evidence that users who are high engagers (such as superusers who are themselves patients) exhibit the greatest improvement in patient activation measure (PAM; a measure that captures the extent to which people feel engaged and confident in taking care of their condition) in HealthUnlocked OHCs, even if the average change in PAM across all levels of engagement is not clinically meaningful [39].

Interpretation of Findings Through the Lens of Self-Determination Theory

Superusers display high intrinsic motivation to engage with OHCs (Figure 1) [31]. Intrinsically motivated behaviors are carried out for the sake of sheer interest or satisfaction derived from the task. Intrinsic motivation constitutes the most autonomous form of motivation and is highly evident in the participants of this study [31]. Through OHCs' engagement, they exhibited fulfillment of the 3 basic psychosocial needs: relatedness, competence, and autonomy. With respect to relatedness, superusers described a sense of belonging to the community and a feeling that they mattered to other users. Participants also expressed a sense of mastery (competence), believing in the effectiveness of their ongoing interactions with users within the OHCs. Their behavior is self-endorsed, reflecting autonomy. Superusers are autonomous and wholeheartedly behind their engagement with OHCs. With such strong intrinsic motivation, extrinsic motivation, that is, behaviors that are carried out to obtain outcomes unrelated to the activity itself, such as financial rewards, unsurprisingly, is not particularly relevant. Nevertheless, moral pressure to monitor OHCs, answer to requests of help, rectify any inappropriate advice, or address users not seeking medical help when appropriate were extrinsic motivation factors that at times felt difficult and stressful, needing to be internalized and integrated in their role of superusers.

Figure 1. Superusers' self-determination theory, freely adapted from Ryan and Deci's theory. Intrinsic motivation constitutes the most autonomous form of motivation and is highly evident in superusers. Such motivation emerges from pure personal interest, curiosity, or enjoyment through engagement with online health communities. The transition from external to intrinsic regulation is promoted by superusers' fulfillment of the 3 basic psychosocial needs: relatedness, competence, and autonomy. Within the basic psychosocial needs, factors potentially undermining fulfillment and suggestions for improvement are listed. HCP: health care professional; OHC: online health community.



Clinical and Research Implications

There is a need to improve clinicians,' researchers,' and policymakers' awareness of superusers. Clinicians could inquire about OHCs' engagement during consultations with patients with LTCs and offer support to any potential superusers. The first step is establishing a definitive trial to determine whether a primary care intervention specifically aimed at promoting engagement with trusted and thriving OHCs improves the health and well-being of patients with LTCs.

If integration of OHCs proves to be beneficial, given superusers' potential (ie, 10 superusers can sustain a community of 1000 people) [25,27], campaigns to promote patients with LTCs actively engaging with disease-specific and trusted OHCs may be a way to tackle the demand for behavioral and emotional self-management support in LTCs. Through participation in OHCs, patients who were unable to work due to ill health or retired naturally acquire over time the role of superusers and become a resource to the community, as shown in this study.

Further research should investigate the possible role of HCPs in OHCs based on their monitoring activity and contributions to web-based conversations. Indeed, the Big White Wall [15] and Health Service Executive Facebook [16] are already including HCPs in the delivery of health care.

Further studies of OHC superusers are needed, aimed at addressing their unmet needs and understanding their role as mentors, their learning potential, and how other users within the community learn from them. Using more explicitly self-determination theory approaches can inform the design of new theoretically informed strategies for planning, managing, and sustaining OHCs.

As with the UK NHS face-to-face peer supporters in mental health, the usefulness and development of potential training packages for superusers could be explored.

Superusers expressed the need to improve OHC moderation through quicker removal of harmful posts. This could be achieved by taking advantage of advances in artificial intelligence, which increasingly allow real-time monitoring of OHCs and identifying and *quarantining* posts until review by moderators.

HCPs' registering bodies may need to develop a code of conduct for HCPs' participation in OHCs, especially when they take on a superuser role.

These results should be considered in the current increasingly wider uptake of digital skills across populations, with 95% of UK adults being on the internet [40]. In this context, OHCs assume growing potential as vehicles of health and social interventions [41], with the presence of superusers playing a key role in guaranteeing OHC success or failure. The roll out of the NHS app through the National Health Service [42] and initiatives such as the Online Centres Network [43] are working to tackle digital and social exclusion by providing people with the skills and confidence they need to access digital technology. Indeed, 70% of homeless people use social media [44], and the estimated penetration of broadband connection ownership and the tendency to be influenced by web-based content are wider in ethnic minorities [45].

This study offers a novel and fresh perspective on motivation, difficulties, and interaction with HCPs of superusers, a group of patients likely to be key players in the digital health social media landscape.

Acknowledgments

AD was funded through the Barts Charity *real health* grant. The study is based on a previous work funded by a Queen Mary University of London Life Science Initiative grant (supported by the Wellcome Trust Institutional Strategic Support Fund). AS received support from Asthma UK for the Asthma UK Centre for Applied Research and from the Medical Research Council and other funders for the Health Data Research UK.

Conflicts of Interest

JP works as the Research Operations Officer at Asthma UK. AS acknowledged research grants from Asthma UK and Health Data Research UK. OF is a Patient Partner in the Patient Centricity Platform at Astra Zeneca. She is also a writer for the TEVA Life Effects web platform. Abstract

Background: The use of peer-to-peer online support groups and communities has grown into a social phenomenon. Many people use online support groups and communities to seek and provide social support. It is essential to examine how users' participation behaviors may contribute to different outcomes.

Objective: This study aimed to (1) use the structural positions of online depression forum users in their reply network to predict received support and (2) examine their language use reflecting their health conditions.

Methods: A total of 2061 users and their 62,274 replies posted on a depression forum from July 2004 to July 2014 were extracted using a web crawler written in Python. The content of the forum users' posts and replies and their reply patterns were examined. A social network analysis method was used to build the reply networks of users. The computerized text analysis method was used to measure features of the forum users' language styles.

Results: Forum users' bridging social capital (operationalized as network betweenness) was positively associated with the level of communication accommodation in their received replies (*P*=.04). Forum users' bonding social capital (operationalized as network constraint) was negatively associated with the level of communication accommodation in their received replies (*P*<.001). The forum users' change in their use of self-referent words and words expressing negative emotions were examined as linguistic proxies for their health conditions and mental states. The results revealed a general negative association between the number of received replies and the degree of decrease in the use of words expressing negative emotion (*P*=.007).

Conclusions: The structural positions of online depression forum users in the reply network are associated with different participation outcomes in the users. Thus, receiving replies can be beneficial to online depression forum users.

Introduction

Background

Social capital, broadly defined as the potential benefits one receives from relationships with others, is a well-researched concept in many social science disciplines. Social capital has been associated with various positive outcomes at both the individual level (such as an increased sense of trust and belonging and improved mental and physical health) [1] and societal level (such as improved public health, promoted social integration, and decreased crime rate) [2]. With the popularity of internet technologies and social networking sites, a growing number of people are turning to web-based venues to seek social support. Many studies have documented that social media and online support groups generate social capital [3].

Social support is a concept closely related to the concept of social capital. Social support encompasses the comfort, assistance, and reassurance that people experience as a function of social relationships [4]. Social support can be viewed as a product resulting from the interpersonal relationships that constitute a support network. A unique feature of seeking and providing social support online is that individuals have more opportunities to communicate with others who share similar experiences and greater access to weak-tie networks [5]. The social capital and weak-tie network theories have also been adopted to explain why and how individuals may benefit differently from participating in online support groups [6,7].

Objectives

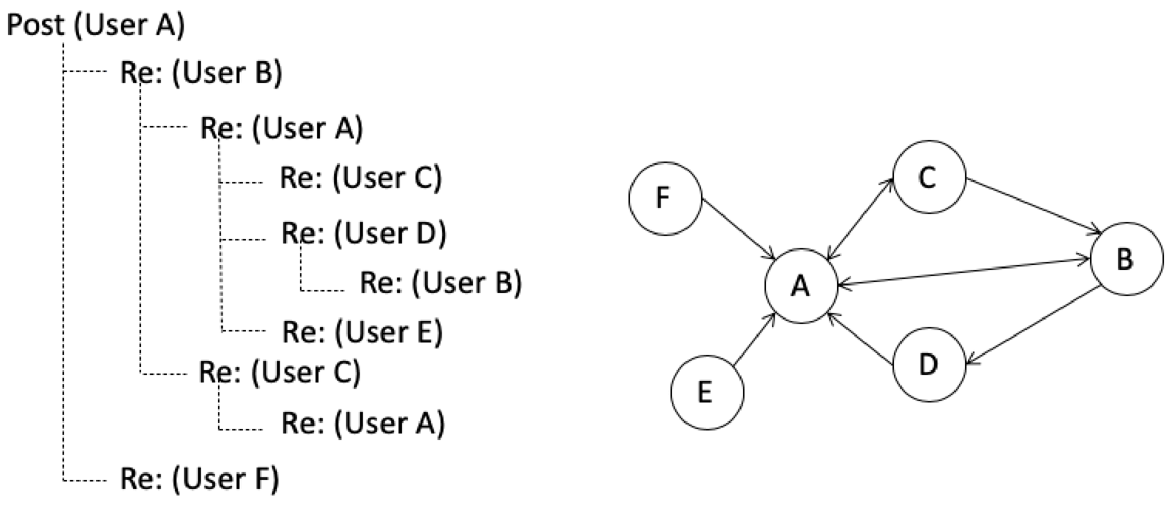
Previous studies investigating the network features of support seeking and provision in online support groups rarely measured the actual tie strength or examined the structural features of the support network. Furthermore, studies focusing on the content and qualities of support-seeking and support-provision messages are rare. Without examining the content of the exchanged messages, we cannot tell how support-seeking and support-provision messages are qualitatively different from each other. Utilizing big data–powered techniques such as web scraping and computerized text analysis, this study aimed to analyze the reply patterns and language styles of online depression forum users. The social capital and communication accommodation theories were adopted to make and test predictions about the association between social capital and social support of online support forum users. Drawing on the buffering effect model and self-awareness theory of depression, this study also examines the health benefits resulting from receiving social support by monitoring the changes in depression forum users' language use over time.

Theories and Hypotheses

Social Capital in Online Support Forums

Active participation in an online support forum generally takes one or both of the following 2 forms: contributing an original post and responding to posts by other users. Original posts typically reflect support-seeking efforts, whereas replying to the posts of other users can be seen as support-provision efforts [7]. Replies to an original post indicate attention, engagement, and responsiveness to the posts [8,9]. Therefore, an online support forum can be conceptualized as a network of users connected by their reply-based relationships (Figure 1). An online support forum provides social capital in that it is an embedded community activated for purposeful action [10]. Social support can be viewed as an outcome of social capital because the latter provides individuals with connections or relations to receive social support from network members when needed [11].

Figure 1. Illustration of a hypothetical user discussion network.



Bridging and Bonding Social Capital

Social capital can be categorized into two types: bridging and bonding social capital [12]. Bridging social capital is linked to weak ties, which are loose connections between individuals and are better for linkage to external assets and information diffusion [13]. Research has shown that bridging social capital may translate to job-related information [13], higher salaries and promotion opportunities [14], and better task performance in virtual worlds [15]. Bonding social capital is inward looking and tends to reinforce exclusive identities and homogeneous groups [12]. Bonding social capital has been shown to be associated with greater emotional support, better general health and well-being, and a greater level of social trust [16].

Communication Accommodation Reflecting Social Support

As human beings, we consciously and unconsciously match each other's communication acts (both verbally and nonverbally) [17]. From the message production end, communication accommodation is a socially motivated process where people engage in more or less accommodation based on their social assessment and social status of themselves and others [18]. From the message reception end, communication accommodation tends to be positively evaluated and can result in positive future intentions toward interactions with another person [18].

Individuals go to online support forums to seek and provide informational, emotional, and esteem support to each other. As these online forums are text based, various forms of support are sought and provided through text form. Communication accommodation reflected in the form of linguistic accommodation conveys a sense of caring and engagement. Linguistic accommodation can be captured through language style matching (LSM). LSM measures linguistic accommodation by taking into account the production of identical words and grammatical structures between the interactants and encompasses conversation level and synchrony on a turn-by-turn level [17]. Past research also shows that LSM among health bloggers and their readers contributes to the bloggers' perceptions of the availability of support from the readers [19]. In this study, the level of linguistic accommodation in the received replies was employed as a proxy for social support.

Social Capital and Communication Accommodation

The concept of social capital can be understood structurally in that social capital refers to the "extent or the intensity of associational links or activity" [16]. The structural perspective represents an objective view of the concept of social capital, and the tie strength or the structural positions can be assessed accurately using the social network analysis method. The nature of social capital entails that, social capital, as a form of capital, can be viewed as an investment in social relations with expected returns. Bridging and bonding social capital represents two unique ways individuals choose to invest in their social relations. The different positions forum users have in the reply network represent their structural aspects of social capital. Users who possess more bridging or bonding social capital are those who (1) occupy important positions in the users' reply social network and (2) share distinctive interaction patterns with other users. In online support forums, by investing their limited time and resources to manage their social relations, forum users expect returns in the form of social support. On the basis of the previous discussion, communication accommodation reflected in forum users' replies can serve as an indicator of social support. In online support forums, the bridging and bonding capital of users should be positively associated with received social support. The accumulated interaction patterns among users should be associated with social support reflected in other users' communication accommodation toward them. Therefore, based on discussion regarding the association between social capital, social support, and communication accommodation, the following hypotheses were proposed:

Hypothesis 1: Forum users' bridging social capital will be positively associated with the communication accommodation of others in their replies.

Hypothesis 2: Forum users' bonding social capital will be positively associated with the communication accommodation of others in their replies.

Owing to the weak nature of ties where bridging capital is accumulated, substantial emotional support or tangible support is less frequently observed compared with informational support [20]. As bonding social capital facilitates the exchange of emotional support, whereas bridging social capital facilitates the exchange of informational support, users will be more engaged in communicating with others whom they share strong ties with. The increased engagement between two communication partners also increases their degree of communication accommodation [21]. The association between users' bridging social capital and the degree of communication accommodation in received replies should be weaker compared with the association between users' bonding social capital and the degree of communication accommodation in received replies. Therefore, the following hypothesis was proposed:

Hypothesis 3: The association between forum users' bridging social capital and the level of communication accommodation in their received replies will be weaker compared with the association between forum users' bonding social capital and the level of communication accommodation in their received replies.

Health Outcomes of Receiving Replies

One of the most important benefits related to participation in online support groups is the improvement of the individuals' psychological and physical health [22]. The buffering effect model maintains that social support helps individuals buffer the negative impacts caused by stressful events [23]. Drawing on the buffering effect model, studies have found that receiving social support in an online support community was negatively associated with perceived stress [24] and positively associated with online network size and perceived social support [25]. Social support exchanged in online support groups also facilitates the management of health-related uncertainty [26] and promotes positive health outcomes [27].

However, previous studies examining health outcomes mostly adopted self-reported measures [25,28]. Self-reported data are usually accompanied by the inaccuracy of memory or recall. Examining the changes in the language use of online support forum users can avoid (1) sampling error by web scraping and analyzing all messages exchanged in online depression forums and (2) other limitations usually associated with survey methodologies, including interviewing effect and inaccuracy of memory or recall. Several linguistic features can serve as indicators of people's mental states [29]. Depressed individuals are more self-focused, express more negative emotions, and sometimes use more death-related words [30,31]. Research has shown that depressed patients tend to use more first-person singular pronouns and words expressing negative emotions than people who have never been depressed [32].

On the basis of previous theories regarding the buffering effect model and health benefit, it can be predicted that there should be a positive association between forum users' number of received replies and their health improvement as reflected in their language use. Therefore, we predict the following two hypotheses:

Hypothesis 4: Forum users’ number of received replies will be negatively associated with the change in their use of first-person singular pronouns.

Hypothesis 5: Forum users’ number of received replies will be negatively associated with the change in their use of words expressing negative emotion.

Methods

Data Collection

The depression forum examined in this study [33] is one of the largest peer-to-peer mental health community and support group in North America (see Figures 2 and 3 for screenshots). The forum is administered and moderated by volunteers rather than health professionals. Anyone who registers as a user of the forum can make a post or reply to others to participate in forum discussion.

Figure 2. Screenshot of the depression forum’s threads. The virtual identities of the forum users are masked.

I am really close to giving up for good and I've been trying for years to get help, I called the crisis team, my doctors who decided they wouldn't offer me an appointment after I said that I have PTSD they decided I was to complicated after speaking to them and they palmed me off on to the crisis team who also palmed me off and I just get passed around like I am somebody else's problem that nobody wants. My wife is ill, I'm ill and i don't see a way out of this mess with no support, I don't think I can be saved in this life or in the next. I can't afford to pay to get help if I could I would pay someone to do the chores and help prepare food, I would pay for therapy and maybe check myself in somewhere until I feel safe again. All I feel able to say is sit or lay down and wait to feel okay again. I believe I have some kind of mood disorder which makes my mood change rapidly and little things can trigger me

I wish there was a way to guarantee that even after I leave this world I would cease to exist because I fear even more suffering. My mind is broken so is my body and I feel I am waiting for something to further break in it so I can leave this place

I ruined my life and other people's and I've made no difference in this world.

Hey, my friend, I know that life can be extremely difficult at times but you can always

try to do whatever little bit you can and try to add to it each day. Don't give upon on

yourself and life just keep trying to get better a little bit at a time. Be blessed my friend

[redacted] - I'm sorry you're in so much emotional pain, and that you haven't gotten the help you want and need. I see you've been trying to take responsibility for your life (in that you want to get better and have a life with your wife) but you have been disappointed at every turn.

I have this problem with my physical health; I've been in pain for years and no one has been willing or able to help me heal. It's far too easy for medical/emotional professionals (ha!) to turn away from you, and trust me, it's probably because they know they're Impostors and, as you guessed, are afraid they'll be found out! So, consider it lucky that you've been rejected by these people and can move on to find someone who WILL help you. I have not stopped looking for concrete help, and it's slow going. After two back surgeries and knee replacements, the pain in my back is sometimes excruciating. Doctors in my State are real chickens and will not prescribe pain medication; so I live on Ibuprofen (a joke drug, to be sure) and turmeric with little result and just have to function feeling like (many times) I'd rather be dead. So, I do things to take my mind off my pain. I visit here at DF, I write, and watch a t.v. show called "Ridiculousness," my go-to program for a sure way to lighten my mood, and listen to music.

I know this probably is not helpful to you, but I want you to know that I empathize and hope you will find the patience and the will to keep going until your problems are addressed.

Thinking of you --

I remember when I was at my lowest from ptsd in the military. I was in the military psych ward and I felt like I was getting attacked by a pack of wolves and I fought them with my bare hands. I remember that night, I started to force myself to smile and I kept laughing like the joker and I kept my hands raised all night.

I did not care what people thought, I knew that my vessel was sick, there were chemical imbalances in my brain so I forced myself to produce endorphins to heal my amygdala.

From there I started bodybuilding to train my body and emotions. I became the master and decided.

It is profoundly difficult to crawl out of a hole alone. I would have died and not made it but I remembered the things mental health experts talked about and applied the principles.

If you are losing the fight then ask for help in the fight. What works for me may not work for others but it is always good to ask for help. I would fight your wolves if I knew how, life is complex though sometimes its not an enemy just yourself.

Sometimes when I look deep into my heart, I see myself when I was a child and I think what would I say to this child? Would I dash their dreams or would I inspire them to fight?

Hi [redacted] just wanted to add my support to a fellow sufferer. Hope you can get the help you need soon. Meanwhile try to add something small to your day, however little that at the moment you can manage, a few wise people have given that advice to me in the past (here) and I have to re read it to remind myself. Thinking of you, hang on in there fella.

Web-scraped data from the depression forum were used for this study [6]. The original forum was written in hypertext markup language in a structured format. The web crawler was written in the computer programing language, Python. Forum data including the title of the subforums, the title of the thread, post ID, reply ID, time stamps, full texts of the posts, and replies were extracted. The web-scraped data were then converted into JavaScript Object Notation (JSON) files. To perform a social network analysis, the adjacency matrix in comma separated value (csv) was constructed from the JSON file using the Python code. The Python code for the web crawler and network data extraction can be found in Multimedia Appendices 1 and 2.

The complete data set included 34,554 users and their 63,514 posts and 592,649 replies from July 2004 to July 2014. Users who never made any posts or replies (n=17,572) were removed from the analysis. The mean number of sent-out replies was 10 (SD 74.23), and the mean for the number of received replies was also 10 (SD 36.05). Furthermore, more than 94.04%

(32,493/34,553) of users had <10 sent-out and received replies combined over 10 years. Therefore, following a procedure similar to that of previous studies to capture users' active participation, only users who contributed ≥10 sent-out and received replies in total were included in the final data set [34,35]. The final data set included 2061 users and their 62,274 replies".

Data Analysis

On the basis of the final data set, an adjacency matrix was created to represent the users' reply patterns, with rows and columns representing each user and the number in each cell representing the number of replies between any given 2 users. Packages *sna* [36] and *network* [37] in the R programing language were used to calculate network-related variables such as the number of received replies, number of sent-out replies, betweenness, and constraint.

To calculate the forum users' language use styles, a computerized text analysis program, linguistic inquiry and word count (LIWC; Pennebaker, Booth, and Francis), was used [38]. LIWC is a dictionary-based software that compares and matches textual messages with predefined word categories. LIWC has been widely adopted and validated to examine the content and style features of various texts [30]. IBM's SPSS version 26 was used to perform linear regression analyses.

Measures

Bridging Social Capital

Following similar studies of online social capital [39], bridging social capital was structurally measured by each node's network betweenness. Betweenness measures the extent to which the actor falls on the geodesic (shortest) paths between other pairs of actors in the network [40]. Definitions of the key variables, operationalization, and measurements are included in Table 1.

Table 1. Definitions, operationalizations, and measurements of the key theoretical constructs.

Concepts	Definitions	Operationalizations	Measure
Bridging social capital	Bridging social capital is linked to weak ties, which are loose connections between individuals and are better for linkage to external assets and information diffusion	Network structural representation of structural hole or brokerage	Betweenness: Suppose that $g_i^{(st)}$ is the number of geodesic paths from actor *s* to actor *t* that pass through *I*, and that n_{st} is the total number of geodesic paths from *s* to *t*. The betweenness of the actor *i* can be given in the following formula [41]:
Bonding social capital	Bonding social capital is inward looking and tend to reinforce exclusive identities and homogeneous groups	Network structural representation of closely connected components	Constraint [42]: where p_{ij} is the proportion of ego *i*'s resource invested in connection with *j* and p_{qj} is the strength of *q*'s tie to *j*.
Social support	Social support encompasses the comfort, assistance, and reassurance that people experience as a function of social relationships	Communication accommodation reflected in forum users' posts and replies	Language style matching (LSM): For example, for personal pronouns (pp) between a given post of user A and the first received replies, the calculation would be:
Health conditions	Language use can reflect individuals' psychological states and health conditions	(1) Use of self-referent words (2) Use of words expressing negative emotion	(1) Change in the use of self-referent words=the number of self-referent words in last 10 replies−the number of self-referent words in the first 10 replies (2) Change in the use of words expressing negative emotion=the number of words expressing negative emotion in last 10 replies−the number of words expressing negative emotion in the first 10 replies

Bonding Social Capital

Bonding social capital was measured structurally as a network constraint. Constraint is "a concentration measure that varies from zero to 100 with the extent to which all of a person's network time and energy is concentrated in one contact" [42]. A large number of constraints suggest that the ego invests most resources within a small and connected group of nodes.

Language Style Matching

LSM scores were calculated for each user to measure the extent to which others have used similar language styles [19,43,44]. LSM was operationalized as the degree to which a user's post and received replies from others used a similar proportion of 9 classes of function words. Each forum user's use of 9 types of function words in each of their posts was calculated. The 9 types include auxiliary verbs (eg, to be, to have), articles (eg, an, the), common adverbs (eg, hardly, often), personal pronouns (eg, I, they, we), indefinite pronouns (eg, it, those), prepositions (eg, for, after, with), negations (eg, not, never), conjunctions (eg, and, but), and quantifiers (eg, many, few). To capture the nuance of language use similarity within each thread, the percentage of total words for each of the 9 types of function words was then calculated for each post and subsequent replies. On the dyadic level, between each user's original posts and each of his or her received replies, the absolute value of the difference was divided by the total for each category. The LSM score can only range from 0 to 1, with scores closest to 1 reflecting high degrees of style matching [43]. The formula used to calculate the LSM is shown in Table 1.

For example, user A made a post and received 3 replies. The personal pronoun LSM for user A's first post was calculated for each of the 3 replies, AR1ppLSM, AR2ppLSM, and AR3ppLSM. Then, the overall personal pronouns LSM score for user A's first thread was calculated by taking the average of the personal pronouns LSM between user A and all of the received replies under the same thread. In the case of user A receiving 3 replies, the overall personal pronoun LSM score for user A is calculated as the mean of the 3 personal pronoun LSM scores.

As there are 9 separate dimensions of function words that make up the overall LSM score, similar calculations were conducted for each user's thread for each function word category. For each user's thread, the 9 separate mean LSM scores for each category were averaged to yield a total LSM score. The same process was applied to each user's thread. The final LSM score for a given user was calculated by taking the average of all threads.

Number of Received Replies

The number of received replies of the forum users were operationalized as the total number of replies one user received from others.

Change in Language Use

In this study, linguistic markers including first-person singular pronouns and words expressing negative emotion were examined. First-person singular pronouns include pronouns such as *I*, *me*, *mine*, and *my* and negative emotions words include words regarding anxiety, anger, and sadness (eg, *hate*, *worthless*, *afraid*, *cry*). For change in first-person singular pronouns, the percentage of first-person singular pronouns in their first 10 messages was subtracted from the percentage of first-person singular pronouns in their last 10 messages. The same process was applied to the calculation of the change in words expressing negative emotion.

Results

Preliminary Analysis Results

The final forum user reply network included 2061 users, and 62,274 replies. On average, each user received 29.23 (SD 44.09) replies and sent out 29.22 (SD 58.20) replies to others. Each user, on average, engaged in interaction with 11 other users (SD 5.00). The average length of their received replies was 155.85 (SD 144.00) words. Descriptive statistics of the key variables are included in Table 2. Theoretical models and results of the hypotheses testing are shown in Figures 4 and 5.

Table 2. Descriptive statistics and zero-order correlation among variables.

Hypotheses Testing Results

H1 predicted a positive association between users' bridging social capital (betweenness) and their overall LSM. As the LSM score is likely to be affected by the number of users one receives replies from, it was then included in the regression model as a control variable. The analysis revealed that, after controlling for the number of users one received replies from, betweenness (mean 0.77, SD 7.57) was positively associated with the overall LSM (mean 0.21, SD 0.10; β=.06; t_{2059}=2.05; *P*=.04). Bridging social capital explained a small but significant portion of the variance in users' overall LSM (R^2=0.03; $F_{1,2059}$=43.84; *P*=.001). Therefore, H1 was supported.

H2 predicted a positive association between users' bonding social capital (constraint) and their overall LSM. After controlling for the number of users, one received replies from constraint (mean 0.05, SD 0.03) was negatively associated with the overall LSM (mean 0.21, SD 0.10; β=−.17, t_{2059}=−6.72; *P*<.001). Bonding social capital explained a significant portion of the variance in users' overall LSM (R^2=0.04; $F_{1,2059}$=63.24; *P*<.001). This finding was not consistent with the hypothesis. Therefore, H2 was not supported.

H3 predicted that the association between forum users' bonding social capital and LSM would be stronger compared with the association between forum users' bridging social capital and LSM. Standardized *z* scores for LSM were entered as dependent variables, whereas standardized betweenness and constraint scores were entered as independent variables [45]. The corresponding 95% CIs were estimated via bias-corrected bootstrapping (1000 resampled). The CI for betweenness was 0.04 to 0.38, whereas the CI for constraint was −0.19 to −0.05. Therefore, the proportion overlap between the 2 CIs was negative (*P*<.001). This result showed that the association between bonding social capital and LSM was stronger than the association between bridging social capital and LSM. However, the direction of the association between bonding social capital and LSM was the opposite of the prediction. Therefore, H3 was not supported.

H4 predicted a positive association between the users' received replies and their use of first-person singular pronouns change. As the users' language use change is likely to be affected by the number of replies they sent out, it was then included in the regression model as a control variable. Considering that the change in each user's use of first-person singular pronouns was calculated based on the differences between their first and last 10 messages, each user's length of forum use on the forum could also affect their change in language style. Therefore, each user's length of forum use was included in the regression model as a control variable. After controlling for the number of sent-out replies and length of forum use, regression analyses showed that the number of received replies (mean 29.23, SD 44.09) was not significantly associated with the change in their use of first-person singular pronouns (mean 0.01, SD 2.29; β=.01; t_{2059}=0.07; *P*=.94). Therefore, H4 was not supported.

H5 predicted a negative association between the users' number of received replies and their use of words expressing negative emotions changed over time. Similar to the analysis of H4, each user's number of sent-out replies and length of forum use were also included in the regression model as control variables. After controlling for the number of sent-out replies and length of forum use, regression analyses showed that users' number of received replies (mean 29.23, SD 44.09) was negatively associated with the change in their use of words expressing negative emotions changed over time (mean 0.17, SD 1.38; β=−.06; t_{2059}=−2.69; *P*=.007). The users' number of received replies explained a significant portion of the variance in users' use of words expressing negative emotions changed over time (R^2=0.004; $F_{1,2059}$=4.39; *P*=.01). H5 was supported.

Discussion

Principal Findings

Depression, as a common mental disorder, has been estimated to affect more than 264 million people worldwide [46]. Owing to its detrimental effects on the individual's psychological and physical health, scholars and practitioners are dedicated to the prevention, diagnosis, and treatment of depression. Other than seeking help from professionals, individuals with depressive symptoms sometimes turn to online support groups and forums to seek, provide, and exchange social support. Online support groups and forums provide them with access to others who share similar experiences at a low cost. Therefore, studying peer-to-peer support exchanged in these online support groups and forums posits both practical and theoretical importance.

Adopting conceptualizations of social capital and its 2 forms, this study differentiated between 2 distinctive patterns (bridging reflected in betweenness and bonding reflected in constraint) of participation behaviors of online forum users. This study also investigated the associations between online support forum users' social capital and social support in the form of linguistic accommodation. Furthermore, this study also examined the association between receiving replies and health conditions as reflected in forum users' language use. The findings and their implications are discussed in the following paragraphs.

First, the associations between forum users' social capital and their received support were examined. Using social network structural measurement of social capital based on the users' reply patterns, this study found that forum users' bridging social capital was positively associated with the received support, as reflected in the level of linguistic accommodation. This result is in line with previous research examining the association between the positions of online network members and their influences on other networks [9] as well as the association between network positions and their perceived or received support from the network [6]. Network members who possess more central positions tend to stay active in health communities and are more likely to share informational support with less central members [47]. When online forum users engage in interactions with other members, they invest their limited time and attention. From the cost-benefit perspective of social capital, this invested social capital in the form of attending to the support-seeking efforts of others can bring them benefits. For example, the users' bridging capital has been positively associated with the diversity of received replies, whereas users' bonding capital has been positively associated with the length of received replies [6]. Similarly, this study also found that users serve as bridges that connect otherwise unconnected others together may also receive a higher level of linguistic accommodation from others.

However, in terms of the association between users' bonding social capital and received replies, the result indicated an opposite pattern. Forum users' bonding social capital was negatively associated with the level of linguistic accommodation in the received replies. Communication accommodation is a complex phenomenon that can be promoted by various perceptions and social processes. One line of research sees communication accommodation as a reflection of mutual trust, liking, or rapport [48], whereas another line of research treats communication accommodation as being promoted by social perceptions reflecting engagement as well as expertise judgment [49]. Predictions rooted in the rapport perspective would support a positive association between LSM and bonding social capital because the latter facilitates the building of trust and emotional bonds among members, whereas researchers focusing on the engagement perspective see LSM as a reflection of communication partners' involvement and engagement. For example, the use of words expressing emotion from posters can elicit a higher level of engagement and involvement from others [44].

Additional analysis showed that the bonding capital of the forum users was negatively associated with their use of words expressing emotion ($\beta=-.05$; $t_{2059}=-2.34$; $P=.02$). In other words, the more users possessed bonding social capital, the less they will use emotional words in their posts. The less they used emotional words in their posts; the less others were mimicking their language style when replying. The findings on the negative association between bonding social capital and LSM suggest that the underlying mechanism of LSM could be multifaceted, and accommodation could be a function of many social processes such as engagement rather than building rapport or liking.

Expertise judgment, as outlined in expectation states theory (EST), can also shed light on unexpected findings in which a negative association between bonding social capital and LSM was observed [50]. According to EST, individuals use characteristics indicating pre-existing status (eg, gender, race) and behavioral interchange patterns within-group processes to judge the competence of others. Characteristics indicating pre-existing status can be directly communicated or inferred through speech and nonverbal cues, whereas interchange patterns can be observed during interactions with others [49]. In this study, the language used by a given user and the linguistic accommodation of others can serve as characteristics indicating pre-existing status and behavioral interchange patterns, respectively. For users who possess more bonding social capital, their language style is less affective and less accommodated by others. They can both serve as grounds for others to form expert judgments. Therefore, users who possess more bonding capital are likely to be viewed as possessing less expertise and a low social status. Thus, others are less likely to accommodate their language style. Although without further examination of the users' motives or subjective experience of their interactions with other forum users, it remains an empirical question as to what cues forum users utilize to form judgments or perceptions about other users. However, in text-based online support forums with a limited number of cue systems, the language use of forum users can nonetheless serve as an important ground for users to form perceptions about each other.

One caveat regarding the association between the users' social capital and LSM in their received replies lies in the direction of the association. Social capital and social support theories may evaluate LSM as an outcome or reflection of interpersonal and social processes, whereas virtual team dynamics and related computer-mediated communication (CMC) theories may see network positions and formations as outcomes of LSM because of the text-based nature of CMC. For example, language features of the user him or herself and the perceived LSM of the user can both be associated with the user's network position. As the LSM was calculated between a user's original post and the received replies to the same post, language features of the poster could affect the level of linguistic adaptation from others. The forum user's own language features can also be affected by their network positions or the composition of their social networks. For example, the heterogeneity of the social networks of Facebook users is negatively associated with language style variability, as reflected in their status updates [34]. The lowest common denominator approach to online self-presentation posits that individuals will choose to share information that is considered appropriate for all audience segments [51]. The proposed pattern has been observed in the status updates of Facebook users: users tend to vary little in their language style when the audience segments are disconnected with each other [34]. Online support forum users who possess more bridging social capital (higher network betweenness) share ties with heterogeneous groups of others. On the basis of the lowest common denominator approach, these users are assumed to have less variability in their language style. Therefore, the replies they received from others share more similarities with their own language style, given that a user's LSM is calculated between each post contributed by the same user and each reply addressing the same post.

The results of this study showed a positive association between the number of received replies and a decrease in the use of words expressing negative emotion. These results are in line with the self-awareness theory of depression [52] and previous literature on language features of depressed people. As discussed earlier, words expressing negative emotion are important linguistic markers for identifying depression. Depressed individuals are more self-focused and express more negative emotions [30]. Previous studies have established that language features can be markers of mental health [32]. The results suggested that for depression forum users, after controlling for their length of forum use, receiving replies was associated with improvement in their psychological states, although causality could not be established because of the nature of the data. Further mediation analysis showed that the level of communication accommodation exemplified in the users' received replies did not mediate the effects of bridging and bonding social capital on the users' change in their use of self-referent words or words expressing negative emotion (Multimedia Appendix 3 shows mediation results).

Limitations

Several limitations of the study are worth noting. The first limitation lies in the lack of causality in the findings. As the users' bridging and bonding social capital, as well as the LSM, was treated cross-sectional as individual attributes, causal relations cannot be established. Although the changes in the language features of forum users can serve as longitudinal indicators of their language use tendency, the data were treated as cross-sectional. Although the benefit of web-scraped forum users' participation patterns is to offer an unobtrusive way to collect the users' actual behavioral data, future studies could split data into different periods and observe the trend in the users' social capital and language use to establish causal relations between forum participation and related outcome measurements.

The second limitation lies in the lack of content measures for exchanged messages. Although computerized text analyses offer powerful and effective ways to investigate the forum users' language features, the context is largely ignored. Due to the exclusive reliance on words recorded in the analytical software's dictionaries, the assessment of the outcomes of interest can be somewhat rigid. Future research could use human coders to cross-validate computerized text analysis results.

Conclusions

This study contributes to our understanding of how people interact with each other in online support forums. In particular, we extend the research focus of online supportive communication to the network positions of users and the communication accommodation of their received support. Using a social network analysis method to analyze web-scraped data from an online support forum, this study offers an objective and nuanced way to examine the structural aspect of social capital. Analyzing the linguistic features of messaged exchanged in online support forums, this study also offers an unobtrusive way to analyze the actual messages created and used by online support forum users.

Abstract

Background: Mobile health (mHealth) apps have the potential to be effective tools for encouraging patients with chronic diseases to self-manage their health. The success of mHealth apps is related to technology acceptance and its subsequent use by intended consumers. Therefore, it is essential to gain insights from consumers' perspectives about their use of mHealth apps in daily life.

Objective: The purpose of this work was to understand consumers' perspectives on use of a self-management app following completion of a clinical trial that tested the efficacy of the app for improving health outcomes.

Methods: We conducted five focus groups with paricipants of a clinical trial (NCT03182738) who were randomized to use the video information provider (VIP) for HIV-associated nonAIDS (HANA) conditions app (VIP-HANA) or an attention control app. Thematic analysis was conducted, and the themes were organized according to the two key constructs of the technology acceptance model framework: perceived usefulness and perceived ease of use.

Results: Thirty-nine people living with HIV (20 from the intervention group and 19 from the control group) participated in the focus group sessions. Of the eight themes identified from focus group data, the five themes related to perceived usefulness were: (1) self-monitoring HIV-related symptoms of HANA conditions, (2) enhanced relationship with clinical providers, (3) improvement in physical and emotional health, (4) long-term impact of self-care strategies on improvement in symptoms of HANA conditions, and (5) inspired lifestyle changes to manage symptoms. The three themes related to perceived ease of use were: (1) easy to navigate, (2) avatar personalization, and (3) privacy/confidentiality maintained even when changing the location of app use.

Conclusions: Perceived ease of use was similar in both study groups but perceived usefulness differed between study groups. Participants in both study groups found the VIP-HANA app to be useful in monitoring their symptoms and enhancing communication with their clinical care providers. However, only intervention group participants perceived the app to be useful in improving overall health and long-term symptom management. Findings from this study highlight factors that are essential to ensure the usefulness of self-management apps and facilitate sustained use of mHealth apps for people living with chronic illnesses.

consumer health informatics tool; mobile Health; mobile apps; clinical trial; symptom care; self-management; HIV-associated nonAIDS (HANA); HANA conditions; HIV/AIDS

Introduction

With the widespread proliferation of smartphones, the use of mobile technology has rapidly increased in health care [1,2]. Consumer health informatics tools such as mobile health (mHealth) apps have the potential to be effective tools to encourage patients with chronic diseases to self-manage their health [3-7]. The video information provider (VIP) for HIV-associated nonAIDS (HANA) conditions app (VIP-HANA) is an mHealth app that was developed to help people living with HIV self-manage their symptoms by providing self-care strategies [8]. Development of the VIP-HANA app is described elsewhere [9]. In short, the VIP-HANA app is comprised of 728 self-care strategies for the following 28 HANA condition-related symptoms: fatigue, depression, muscle aches, difficulty falling asleep, anxiety, difficulty staying asleep, difficulty remembering, neuropathy, difficulty concentrating, decreased sex drive, diarrhea, maintaining an erection, shortness of breath, constipation, dry mouth, clumsiness, weight loss, dizziness, heartburn, dry eyes, changes in appetite, ringing in ear, cough, nausea/vomiting, fever, difficulty with urination, speech difficulties, and pain during sex [10]. The 728 self-care strategies were tailored based on the symptom, gender, race/ethnicity, and HANA condition of each user. An avatar guides users through the app. Patients then receive self-care strategies with animated videos for ameliorating their symptoms. Users review their symptom experience over time with symptom reports, set a weekly email reminder to complete sessions in the app, and email/download the history of their reported symptoms and suggested self-care strategies [8].

Two versions of the app were created to assess the efficacy of the VIP-HANA app in improving the symptom burden in a 6-month randomized controlled trial (RCT) (NCT03182738) that included 100 people living with HIV with HANA conditions (50 randomly assigned to the intervention group, 50 assigned to the control group). All participants were asked to log in at least once per week. Both study groups received weekly symptom assessment questions through the VIP-HANA app, yet only the intervention group participants were provided with the self-care strategies. Multimedia Appendix 1 presents a comparison of the two versions of the VIP-HANA app features. Participants in both groups were given US $5 per week for their time and data costs associated with completing the weekly symptom assessments.

According to a recent US national survey of mHealth app use, approximately half (46%) of the respondents reported downloading a health app but were no longer using it or had uninstalled it [11]. Given that the success of mHealth apps is related to the acceptance of technology and its subsequent use by intended consumers, there is a need to gain in-depth insights from consumers' perspectives about use of mHealth apps in their daily life. Accordingly, the purpose of this study was to understand consumers' perspectives on mHealth use (VIP-HANA app) following an RCT of an HIV symptom self-management intervention for people living with HANA conditions.

Methods

Sampling and Recruitment

This study was a follow up of a 6-month trial including 100 people living with HIV with HANA conditions (50 randomly assigned to the intervention group, 50 to the control group). We used a convenience sampling approach to recruit a subsample of our study participants to participate in one of five focus group sessions followed by completion of the study trial; the focus group sessions took place once per month [12-14].

Procedures

The Institutional Review Board of Columbia University Medical Center reviewed and approved all research activities. We conducted three focus group sessions with intervention group participants (N=20) and two focus groups sessions with control group participants (N=19). Prior to the focus group sessions, all participants were provided an explanation of the study procedures and completed a signed consent form. Using open-ended questions via a semistructured focus group guide designed based on the app's features/functionality (Textbox 1), a moderator (a faculty member at Columbia University School of Nursing) facilitated the focus group sessions, and participants were encouraged to discuss issues regarding their perceptions related to use of the VIP-HANA app (intervention/control group versions). All focus group sessions were audio-recorded. Data collection continued until saturation of themes was reached. Participants were compensated with US $30 for their time.

Textbox 1. Focus group guide based on 6-month experience of using the video information provider for HIV-associated nonAIDS conditions (VIP-HANA) app.

Experience Using VIP-HANA

- Please describe your experience using the VIP-HANA app in social settings.
    - Probe: where and when did you use it most (house/workplace/clinic/café; after breakfast/when commuting, etc) and why?
- How did this fit into your lifestyle and schedule?
- Please describe your experience navigating the app pages.
    - Probe: basic structure of the app
- After your first app use, how easy/difficult was it for you in follow-up uses?
- What are your thoughts about the design of the VIP-HANA app?
    - Probe: main logo/avatars; font/color; progress bar; Remember Me (save ID/password); Log-In Help; Continue/Skip button
- Please describe your experience with any technical issues.
    - Probe: Log-In, crash, Back button, Continue/Skip button, How Our App Works, reminder/email, error message

(Intervention group only)

- What are your thoughts about the videos displayed in the VIP-HANA app?
    - Probe: watching videos vs reading the content; videos with sounds, the type of sounds; effect of data plan on watching the videos
- What was your experience using the app to review your symptoms and self-care strategies (=Your History)?

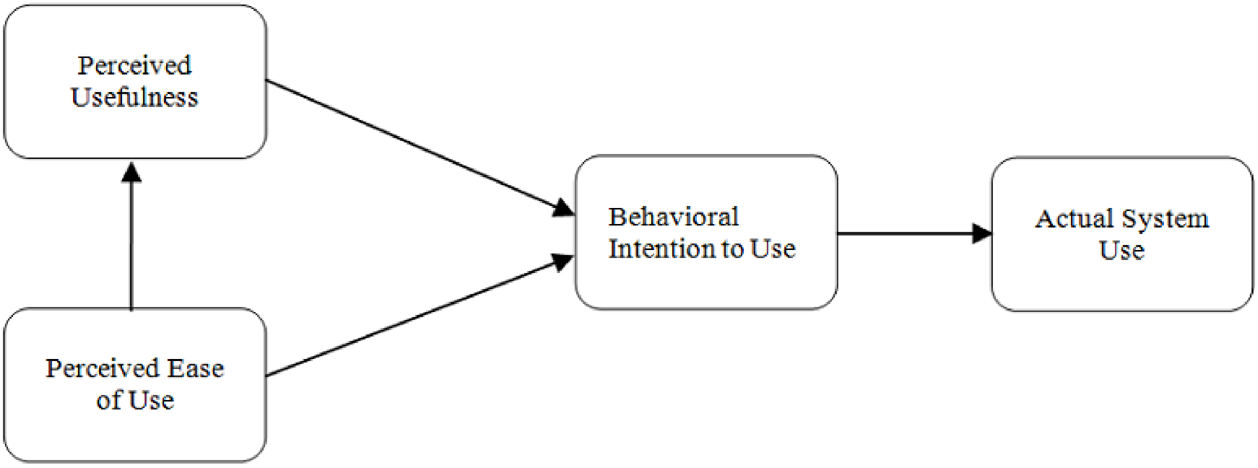
Impact of VIP-HANA

- How did this app help you gain information about relieving your symptoms?
- How do you think that your symptoms changed after using the VIP-HANA app for 6 months?
- How confident are you in your ability to self-manage your symptoms?
- What are some of the ways that your health might benefit through the use of VIP-HANA?
    - Probe: changes of current personal, professional, or health care provider relationships
- Please describe how the app did/can change your quality of life.

Data Analysis

The technology acceptance model (TAM) was used as a guide for the data analysis [15]. The TAM includes the following two key constructs: perceived usefulness and perceived ease of use. Perceived usefulness represents the degree to which an individual believes that using a particular system would enhance one's job performance, whereas perceived ease of use signifies the degree to which an individual believes that using a particular system would be free of effort. The TAM suggests that these two constructs of user acceptance influence the behavioral intention to use a system and predict the extent of adoption of the system (Figure 1).

Figure 1. Technology acceptance model (TAM).



Audio recordings from the focus groups were transcribed. Thematic analysis was used to explore significant themes with similar patterns across focus group sessions. Research team members (HC, TP, and GF) independently reviewed the transcripts at least twice, and two research team members (TP and GF) generated a set of codes through a combination of inductive and deductive content analysis [16-18]. A codebook was developed using a Microsoft Excel spreadsheet, and free text excerpted from the transcripts was entered into the codebook followed by each of the themes. Coding discordance between TP and GF was reconciled by a third researcher (HC). Guided by the TAM framework (Figure 1) [15], each theme in the codebook was categorized into the two constructs of perceived usefulness and perceived ease of use.

Results

Sample

A total of 39 people who completed the 6-month trial participated in the five focus group sessions. The mean age of the study participants was 55 years (SD 10.70). Additional characteristics of the study sample are presented in Table 1.

Table 1. Characteristics of the study participants (N=39).

Characteristic	All participants (N=39)	Intervention (N=20)	Control (N=19)
Gender, n (%)			
Male	22 (56)	12 (60)	10 (53)
Female	15 (38)	7 (35)	8 (42)
Transgender	1 (3)	0 (0)	1 (5)

None	1 (3)	1 (5)	0 (0)
Private (through employer)	0 (0)	0 (0)	0 (0)

[a] ADAP: AIDS drug assistance program.

Main Themes

A total of eight themes related to use of the VIP-HANA app were identified. The themes were organized by the two key constructs of the TAM framework [15], including five themes related to perceived usefulness and three themes related to perceived ease of use. Two themes to enhance the acceptance of the app were additionally identified.

Perceived Usefulness

The five themes related to perceived usefulness were: (1) self-monitoring HIV-related symptoms of HANA conditions, (2) enhanced relationship with clinical providers, (3) improvement in physical and emotional health, (4) long-term impact of self-care strategies on improvement in symptoms of HANA conditions, and (5) inspired lifestyle changes to manage symptoms.

Self-Monitoring HIV-Related Symptoms of HANA Conditions

Participants in both the intervention and control groups felt that the app was helpful for improving self-monitoring of their symptoms. A control group participant expressed that the app helped them realize the frequency of certain symptoms they were having, by stating:

> *I found that it really kept me in touch with my symptoms. And a lot of things were happening that I really didn't realize until I started using the app.* [FG2]

An intervention group participant mentioned:

> *The app shows you certain things that you can have, and what you can do. And you work with that. And it's been great for me. I was getting more confident with tracking and managing my symptoms.* [FG3]

Moreover, intervention group participants described enjoyment in tracking their HANA conditions:

> *So for those of us that do have secondary illnesses such as diabetes, asthma, high blood pressure, and so forth and so on, the app was a great thing, and not just helping us navigate the system and our bodies as far as HIV is concerned, but helped us in those other issues as well.* [FG1]
>
> *And she said the app is wonderful… for diabetes, hepatitis C, and for the different harm reduction. We know what symptoms I have.* [FG3]

Enhanced Relationship With Clinical Providers

Participants in both the intervention and control groups stated that they showed the app to their doctors/clinical therapists to guide their conversations and share their symptom reports, which empowered them to better communicate with their clinical providers and enrich their relationship. An intervention group participant described:

> *The changes that I made were, the app was very useful in that, in conjunction with my doctor. Because I also showed this to my doctor… And they all agreed that it's a wonderful thing.* [FG1]

A control group participant stated:

> *I liked the app because it was times I wanted to ask my doctor questions, but I didn't. But by doing this here app, it made me take a pen and paper and write down what I want to say to her next time I see her.* [FG2]

Improvement in Physical and Emotional Health

Participants in the intervention group noted improvements in their health as a result of app use. Participants commented that the app helped them work through their emotional issues. An intervention group participant stated:

> *It is not just HIV health. It is diabetes, asthma, high blood pressure… and so on… Not just your physical and your medications and stuff like that. But things that you can do to make yourself happier, better, more social.* [FG1]

Long-Term Impact of Self-Care Strategies on Improvement in Symptoms of HANA Conditions

Intervention group participants stated that they continued to use the self-care strategies for their symptoms even after the study was over. They considered that the self-care strategies resulted in a lasting improvement of their symptoms and therefore they continued to use them. An intervention group participant mentioned:

> *When I go through stress, I get those migraine headaches. In the app, it tells you to relax, turn off the TV. Turn off everything and just be calm in a dark room. And that still helps me. I am still doing that.* [FG1]

Inspired Lifestyle Changes to Manage Symptoms

Participants in the control group noted that the symptom questions on the VIP-HANA app helped them to think about their recent symptoms and inspired lifestyle changes. For example, some control group participants stated:

> *I remember one time, I was really depressed that week. And I put down real severe depression. And it made me think... So I'm trying to figure out why am I depressed? What made me depressed this week? What should I do? What changes?* [FG2]

> *But when you're looking at, when you're pressing this button several times every, several times a month, with the same thing, it reminds you. You need to really get serious about what you've been thinking about all this time.* [FG2]

Perceived Ease of Use

The three major themes related to perceived ease of use were: (1) easy to navigate, (2) avatar personalization, and (3) privacy/confidentiality maintained even when changing the location of app use.

Easy to Navigate

Participants in both the intervention and control groups found that the VIP-HANA app was easy to navigate, and they were able to use the app without assistance and did not experience technical issues. An intervention group participant stated:

> *Nothing hard at all. I am not very good to the tech… but this app, easy to get to start… easy to go to the next… very easy to move forward.* [FG3]

A control group participant described:

> *Yeah. The app I thought was pretty easy to navigate through. And the questions were basically always the same. I didn't need any help although I am not good at technology.* [FG2]

Avatar Personalization

Participants in the intervention and control groups noted the usefulness of an avatar to guide them through the VIP-HANA app and help them navigate through the app. They also noted that the avatar promoted their engagement with the app. Some participants in the intervention group mentioned:

> *I feel like I connected to it more by choosing the one that best looked like me or was fitted to me.* [FG1]
>
> *When you see it in the app, where you're actually seeing the cartoon character [avatar], get up and going. It encourages you that you can get up and go. I think it was very practical.* [FG5]

Some participants in the control group stated:

> *I think when you look at it [avatar], it's more personal. It's about you. And I think that it's good for your psyche to realize that you've got to really take care of yourself.* [FG2]
>
> *The app I thought was pretty easy to navigate through because of the avatar. The avatar looks like me… myself!* [FG4]
>
> *I was going to mention that the whole thing is laid out pretty attractively. The little avatar made it, to me, it made it almost like a game.* [FG2]

Privacy/Confidentiality Maintained Even When Changing Location of App Use

Participants in both the intervention and control groups felt comfortable using the app in a variety of locations ranging from their home to doctor's offices and in public spaces (ie, everywhere). They thought that the app was very discrete and did not disclose their HIV status to others if they could see the app on the screen. Several participants in the intervention group described this aspect:

> *To me, I feel like it was enough discretion in the app that if I wanted to explain it to somebody, because I was okay pulling out anywhere… everywhere…* [FG1]
>
> *I feel that that was really good, in the sense of you can do it really anywhere.* [FG5]

Some participants in the control group stated:

> *One of the good things about the program, it doesn't mention anything related to HIV. The reason… If someone want to get into your phone, nobody can access personal information related to the app.* [FG2]
>
> *I was happy because I can use it anytime and anywhere; at work, on the train.* [FG4]

Additional Comments to Enhance App Acceptance

Need for Updates of Self-Care Strategies and Videos

Participants in the intervention group expressed their desire for the app to include more self-care strategies and realistic videos. Participants felt that the app questions (symptoms) and suggestions (self-care strategies) were particularly useful for people living with HIV who were newly diagnosed with HIV/AIDS. They thought that the animated videos showing the suggestions were too simple or not serious enough in some cases. Some participants in the intervention group described:

> *When I look at the study you have to say that it's really geared more to like an HIV 101 plan where it's just basic stuff… For a person that's newly diagnosed and don't know a lot of things about HIV, I think it's the best thing for them.* [FG1]
>
> *Some of it [animated videos] was unrealistic. If you don't have the HIV or the pain or things that we actually experience as patients, you really couldn't understand how serious sometimes it is. It felt to me like they downplayed our experiences with those videos.* [FG3]

Request for Additional Functionality of Symptom Reports

Participants in the control group wanted the app to have an additional functionality to track their symptom reports so that they do not have to remember their weekly answers to the symptom questions (eg, what symptoms they had), as the app feature of symptom reports was limited for the intervention group participants only in this study. For example, a control group participant stated:

> *I don't remember there being an ability to be able to say, to run a report, so to speak, and say; between January and March, I had dry eyes this many times during the month... if I can print something out or if I can open it on the phone and show it to the doctor like that, that would be a nice addition to what you already have.* [FG2]

Discussion

Principal Findings

With the exponential increase of mobile technology use in health care, mHealth apps can be a promising consumer health informatics tool for health behavior change and self-management. Although existing evidence supports the use of mHealth apps to improve health outcomes in people with chronic diseases [3-7], there has been limited assessment of consumers' experience following their use of these apps during a clinical trial. Given the current landscape of discontinuation of mHealth apps use [11], it is imperative to understand how consumers are interacting with the apps in their daily life in an effort to accelerate acceptance of the apps by the consumers as well as ensure their subsequent use. To better understand consumers' use of a self-management app, we included both intervention and control group participants following completion of an RCT that tested the efficacy of the app for improving health outcomes. We captured valuable perspectives of both study group participants on their app use using focus groups guided by a theory-driven framework. This approach facilitated gaining an in-depth understanding of the key factors that would have a critical influence on adoption of the app [15], which is a significant strength of our study.

Participants in both the intervention and control groups perceived the VIP-HANA app to be useful for monitoring their symptoms, and the app enhanced their relationship with their clinical providers. Although self-care strategies of existing symptoms were not provided to the control group participants, all participants described the need to record, track, and share their symptom status with their providers. Participants described that use of the symptom reports would expedite opportunities of health communication and enhance their relationship with their clinical providers. Current research supports that interpersonal communication between HIV patients and their health care provider improves medication adherence and long-term care in HIV, highlighting the importance of patient-provider communication for ensuring that patients remain in the continuum of HIV care [19-21].

Although all three themes related to perceived ease of use were identified in both study groups, only the intervention group participants described the VIP-HANA app as being useful for enhancing their physical and emotional health and supporting long-term symptom management. Existing evidence suggests that perceived usefulness is a stronger factor compared with perceived ease of use for influencing technology adoption, and perceived usefulness has a positive influence on overall use of an app [22,23].

mHealth apps should be visually appealing to consumers [24], but more fundamentally should contain evidence-based health information that consumers can use to improve their health. Participants considered that the app could help improve their health and manage symptoms through the use of self-care strategies. The VIP-HANA app was developed by employing evidence from patient-centered outcomes research studies [25], and the HIV symptom self-care strategies provided within the app were tailored based on symptoms, gender, race/ethnicity, and HANA condition [26,27]. To our knowledge, no mHealth intervention offers health information on how to ameliorate HIV symptoms specifically for people living with HIV with HANA conditions; the VIP-HANA app therefore represents a first step in the development and dissemination of a consumer health informatics tool that incorporates evidence-based self-care strategies.

One of the major themes related to perceived ease of use in this study was avatar personalization. Within both group versions of the VIP-HANA app, participants were guided by an avatar through a series of questions ascertaining the nature and severity of their symptoms. The avatar then recommended self-care strategies for addressing the intervention group participants' symptoms. Even though the avatar in the control group version of the app did not provide any suggestions after the symptom assessment questions, participants in both groups felt that they connected to the app simply by selecting an avatar that most looked like them. Current research suggests that HIV patients feel more comfortable receiving HIV-related questions/answers from avatars compared to receiving health information directly from clinical providers, and users tend to choose an avatar that matches their own ethnicity [28,29]. Given that avatars can encourage user interaction with health-related information, developers of consumer health informatics tools should consider the potential benefits of inclusion of customizable avatars.

Privacy/confidentiality was a factor related to perceived ease of use. Our participants noted that the information (eg, data of participants' experienced symptoms) displayed on an app was secure because the app was installed on their own smartphone, and the app's design did not disclose their HIV status; thus, they felt comfortable using the app everywhere. In designing the app, privacy and confidentiality were strong considerations since people living with HIV in our formative work emphasized their importance [30] and social stigma associated with HIV persists [31]. Findings from our study emphasize the value of using mobile-based interventions, particularly for people living with HIV, and the importance of a user-centered design process with inclusion of users in terms of ensuring data security/protection.

Control group participants highlighted the need for inclusion of symptom reports in order to share their information with clinical providers without needing to memorize their symptom change/progress during the past 6 months. This functionality was only available for intervention group participants. Visual communication displayed on a summary on the app may improve patient comprehension of health information [32,33]. Findings from this work showed that graphical symptom reports enhanced the functionality of the app, which is an important implication for the future development of mHealth apps.

Limitations

There are some limitations to the generalizability of our results. Study participants who participated in the focus groups might have been those who were most likely to be engaged with and used the app who had been retained in the 6-month trial. More than half of our study participants were men, African American/Black, those who had completed some high school or less, and those who reported an annual income of less than

US $20,000. Therefore, the Hawthorne effect might influence the study findings of focus groups [34]. We designed the semistructured focus group guide based on our app's features and functionality, and used open-ended questions to minimize/eliminate concern about the Hawthorne effect.

Conclusions

Understanding factors influencing the use of patient-centered tools is critical. This study highlights participants' experiences, attitudes, and perceptions of their use of a behavioral intervention evaluated in a clinical trial. Participants were able to integrate the app into their daily routine, and used the app to support, track, monitor, and self-manage HIV symptoms related to HANA conditions. Although perceived ease of use was similar in both study groups, perceived usefulness differed between the groups. Participants in both groups found the VIP-HANA app to be useful in monitoring their symptoms of HANA conditions and enhancing communication with their clinical providers over time, but only the intervention group participants perceived the app to be useful for improving overall health and long-term symptom management in the HIV care continuum. Findings from this study highlight factors that are essential to ensure the usefulness of self-management apps to promote sustained use of the apps for people living with chronic illnesses.

Abstract

Background: Facebook's advertising platform reaches most US households and has been used for health-related research recruitment. The platform allows for advertising segmentation by age, gender, and location; however, it does not explicitly allow for targeting by race or ethnicity to facilitate a diverse participant pool.

Objective: This study looked at the efficacy of zip code targeting in Facebook advertising to reach blacks/African Americans and Hispanics/Latinos who smoke daily for a quit-smoking web-based social media study.

Methods: We ran a general market campaign for 61 weeks using all continental US zip codes as a baseline. Concurrently, we ran 2 campaigns to reach black/African American and Hispanic-/Latino-identified adults, targeting zip codes ranked first by the percentage of households of the racial or ethnic group of interest and then by cigarette expenditure per household. We also ran a Spanish language campaign for 13 weeks, targeting all continental US zip codes but utilizing Facebook's Spanish language targeting. The advertising images and language were common across campaigns. Costs were compared for advertisement clicks, queries, applications, and participants, and yields were compared for the final three outcomes. We examined outcomes before and after the Cambridge Analytica scandal that broke in March 2018. Finally, we examined 2 promoted Facebook features: lookalike audiences and audience network placement.

Results: Zip code targeting campaigns were effective for yielding the racial or ethnic groups of interest. The black-/African American–focused versus general market campaign increased black/African American weekly queries (mean 9.48, SD 5.69 vs general market mean 2.83, SD 2.05; *P*<.001) and applicants (mean 1.11, SD 1.21 vs general market mean 0.54, SD 0.58; *P*<.001). The Hispanic-/Latino-focused versus general market campaign increased Hispanic/Latino weekly queries (mean 3.10, SD 2.16 vs general market mean 0.71, SD 0.48; *P*<.001) and applicants (mean 0.36, SD 0.55 vs general market mean 0.10, SD 0.14; *P*=.001). Cost metrics did not differ between campaigns at generating participants (overall *P*=.54). Costs increased post- versus prescandal for the black-/African American–focused campaign for queries (mean US $8.51, SD 3.08 vs US $5.87, SD 1.89; *P*=.001) and applicants (mean US $59.64, SD 35.63 vs US $38.96, SD 28.31; *P*=.004) and for the Hispanic-/Latino-focused campaign for queries (mean US $9.24, SD 4.74 vs US $7.04, SD 3.39; *P*=.005) and applicants (mean US $61.19, SD 40.08 vs US $38.19, SD 21.20; *P*=.001).

Conclusions: Zip code targeting in Facebook advertising is an effective way to recruit diverse populations for health-based interventions. Audience network placement should be avoided. The Facebook lookalike audience may not be necessary for recruitment, with drawbacks including an unknown algorithm and unclear use of Facebook user data, and so public concerns around data privacy should be considered.

smoking; advertisement; social media

Introduction

Background

The distrust of health care and health-related studies among blacks/African Americans and Hispanics/Latinos has been documented extensively [1-3]. To combat racial and ethnic homogeneity in health-related research, emphasis must be placed on recruitment of diverse participants, especially in studies concerning diseases or products in which race or ethnicity is a factor [4,5]. Tobacco companies have traditionally advertised products to communities of color [6-8]. Their targeting methods have included placing advertisements on television shows, in print media, and on websites with high black/African American or Hispanic/Latino viewership [9,10]. Tobacco companies have also spatially targeted communities of color by placing billboards and bus advertisements in neighborhoods primarily comprising black/African American or Hispanic/Latino residents [11]. Tobacco companies have paid people to go into inner-city neighborhoods to hand out free samples of menthol (and sometimes regular) cigarettes in an effort to attract black/African American young adult and adult customers [12-14].

Facebook is a leading web-based social media platform for adults in the United States, with approximately 221 million monthly active users who represent about 69% of the adult population [15,16]. Facebook is also used at similar rates among whites, blacks/African Americans, and Hispanics/Latinos [17]. Facebook advertising has increasingly been used for health-related study recruitment [18]. Cost efficiency and widespread adult use, as well as detailed targeting features, make Facebook advertising a popular choice for study recruitment [18,19]. Participants recruited through the Facebook advertising platform were found to be demographically similar compared with traditional study recruitment methods, such as print materials [18,20]. In some cases, however, participant pools showed an overrepresentation of non-Hispanic white individuals [21]. Race and ethnicity are important aspects of study recruitment, and more emphasis is being placed on inclusion and reporting of racial or ethnic diversity in the participant pool, especially in health-related research [22]. However, there remains little discussion about how to target diverse racial or ethnic groups using Facebook advertising [23].

This paper discusses recruitment of racially and ethnically diverse participants by means of Facebook advertising for a quit-smoking web-based social media study. Our research team developed a web-based Twitter peer-support group intervention for quitting smoking called Tweet2Quit [24,25]. We recruited virtually all participants (N=980) using Facebook advertising and sought an ethnically diverse participant pool.

Study Goals

This study evaluated 4 Facebook advertising campaigns that we used to recruit individuals for our quit-smoking web-based social media study. Our general market campaign reached all continental US zip codes, targeting individuals who expressed an interest in smoking or quitting smoking on Facebook, and it served as our baseline. Two additional Facebook campaigns targeted primarily black/African American or Hispanic/Latino zip codes with high cigarette expenditures. Our final Facebook campaign targeted Spanish language speakers living in continental US zip codes who expressed an interest in smoking or quitting smoking on Facebook. For each campaign, we examined yields and costs for 4 standard advertising campaign outcomes: advertisement clicks, queries, applications, and participants. We hypothesized that zip code campaigns would generate higher yields of diverse ethnic groups without higher costs.

In addition, we compared costs before and after major news broke in March 2018 concerning the Facebook privacy scandal involving Cambridge Analytica’s alleged breach of privacy of 50 million Facebook users, which raised serious concerns about the protection of private user information. Finally, we examined the costs associated with 2 features Facebook recommends to its advertisers, use of lookalike audiences and audience network placement, and compared these to our general market campaign.

Methods

Facebook Advertising Campaigns

Facebook does not allow for direct demographic targeting of advertising by users’ ethnicity or race. The main demographics that Facebook advertisers can choose are age and gender. These demographics are offered because when Facebook users create their accounts, they are required to specify their age and gender. Advertisers can further narrow their audience by using the 3 sections labeled *Demographics*, *Interests*, and *Behaviors*. The *Demographics* and *Interests* sections do not include race or ethnicity. The *Behaviors* section includes Multicultural Affinity, which allows advertisers to choose African American, Asian American, or Hispanic affinity. Facebook does not provide information on how individuals are classified into these behavioral affinity categories or what data are used. In addition, categories within the *Interests* and *Behaviors* sections change often, which then requires advertisers to recreate existing advertising campaigns using new options. Furthermore, advertising using Multicultural Affinity is restricted by Facebook and can lead to extended advertising review times and automated advertisement disapproval [26]. Due to these reasons, we used more standard zip code targeting in our study.

As a baseline, we created a general market campaign, selecting all continental US zip codes. The advertising images and language were common in all 4 advertising campaigns we studied. In addition, in all 4 campaigns, we restricted our advertisements to be seen by individuals aged between 21-59 years. We required individuals to be ≥21 years because many states restrict the sale of tobacco to these individuals. We set the maximum age at 59 to focus on younger and middle-aged adults rather than retirees. Moreover, in all 4 of our advertising campaigns, we targeted appropriate study participants based on their Facebook interests. We showed our advertisements only to individuals who expressed an interest in smoking-related topics such as quitting smoking, nicotine, and tobacco or cigarettes, while logged into Facebook.

For our black-/African American–focused and Hispanic-/Latino-focused campaigns, we also used more specific zip code targeting. We obtained data on all continental US zip codes and sorted the zip codes from highest to lowest based on the percentage of households in the target racial or ethnic group to ensure that those racial or ethnic groups were reached. After this, we sorted the zip codes from highest to lowest based on the mean annual household expenditure on cigarettes to try to ensure that we reached smokers. We removed any zip codes with fewer than 100 households. We then selected the top 1000 zip codes because Facebook only allowed us to upload 1000 customized zip codes out of the 41,702 total zip codes in the United States [27-29]. All chosen zip codes had high percentages of ethnic households and high cigarette expenditures. The 1000 zip codes we used for the black-/African American–focused campaign ranged from 53% to 99% in terms of the households in this ethnic group (mean 70%, SD 0.13%), with annual cigarette expenditures from US $154 to US $568 (mean US $329, SD 62.49) per household. The 1000 zip codes we used for the Hispanic-/Latino-focused campaign ranged from 53% to 99% (mean 71%, SD 0.13%) in terms of the households in this ethnic group, with annual cigarette expenditures from US $70 to US $506 (mean US $266, SD 69.86) per household. We uploaded the targeted zip codes for each campaign on Facebook.

Finally, for our Spanish language campaign, we used all continental US zip codes; however, we selected Spanish as the spoken language, using Facebook's designated Language Targeting feature. This feature allows advertisers to show advertisements to users who speak a specific language and is not related to targeting based on the *Behaviors* or *Interests* sections. Spanish language targeting was chosen to increase the number of Hispanic/Latino applicants to our program. Advertisements across all campaigns were identical, as noted above. Advertising imagery and wording were chosen using Facebook A/B testing campaigns placed in all US zip codes. A/B testing allows advertisers to run nearly identical, simultaneous campaigns to test a singular variable, such as an advertising image.

Data on the ethnic makeup of US zip codes came from the US Census Bureau's American Community Survey and are publicly available [27]. Data on cigarette expenditures came from the US Bureau of Labor Statistics' Consumer Expenditure Survey and, although not publicly available at the zip code level, can be purchased from Experian [28,30].

Outcome Measures

Our study compared 4 different Facebook advertising campaigns: A general market campaign, a black-/African American–focused zip code campaign, a Hispanic-/Latino-focused zip code campaign, and a Spanish language campaign. We compared these campaigns on 4 standard outcome measures: advertisement clicks, queries, applicants, and participants. Our advertisement click measure showed whether an individual tapped or clicked on our web-based advertisement, which automatically directed the individual to our study website. Hence, our advertisement click measure assessed if a campaign possibly brought interested individuals to our website. On our website, individuals could read about the study and fill out a short query form that asked for their contact information (name and email) and their race or ethnicity. Our query measure assessed whether the campaign resulted in individuals providing contact information. Individuals who provided contact information received our full screening survey, and if they finished the survey, they were considered applicants. Hence, our applicant measure assessed whether the campaign resulted in individuals completing the study screener, regardless of whether they passed or failed. Finally, our participant measure assessed whether the campaign resulted in individuals getting enrolled into the study.

Our initial Facebook advertising testing began in October 2016 and included testing of the Facebook-recommended audience network placement. We began recruitment for our study in January 2017 but did not commence our sophisticated Pixel-based measurement of our Facebook campaigns (explained below) until mid-June 2017 and that continued until September 2018 for a total of 61 weeks. The Facebook scandal occurred in March 2018 (Multimedia Appendix 1).

Descriptive Statistics on Overall Campaign Response

Across our 4 Facebook campaigns, we received a total of 92,677 advertisement clicks between June 20, 2017, and September 9, 2018. The general market campaign received 66,681 advertisement clicks, the black-/African American–focused campaign received 12,544 advertisement clicks, and the Hispanic-/Latino-focused campaign received 10,969 advertisement clicks. Our shorter Spanish language campaign received 2483 advertisement clicks between June 20, 2017, and September 30, 2017. On average, about 13.92% (12,898/92,677) of individuals who clicked our advertisement filled out the interest form, constituting a query. After receiving an email with a link to our web-based screening survey, about 19.31% (2490/12,898) of individuals completed the survey and about 20.32% (506/2490) of these applicants were enrolled in our study. We could not capture ethnicity at the advertisement click stage because we had no mechanism for doing this. However, we began collecting self-reported race or ethnicity at the query stage and continued this through the applicant and participant stages.

We examined whether study exclusion was related to the individual's race or ethnicity. Race or ethnicity related to study exclusion due to a health contraindication (eg, pregnancy), in that blacks/African Americans (69/259, 26.6%) were more likely to be excluded for health reasons than non-Hispanic whites (295/1544, 19.11%; X^2_1=7.8; P=.005). Ethnicity related to study exclusion because of refusing mobile phone verification, in that whites (308/1544, 19.95%) were more likely to be excluded for this reason than blacks/African Americans (36/259, 13.9%; X^2_1=5.3; P=.02). Ethnicity related to study exclusion because of smoking too few cigarettes per day to permit use of the study-provided nicotine replacement therapy, in that blacks/African Americans (11/259, 4.2%) were more likely to be excluded for this reason than whites (28/1544, 1.81%;

X^2_1=6.2; P=.01). No other effects were significant (all P>.17; Multimedia Appendix 2).

Results

Results Regarding Yields by Racial or Ethnic Group

Overview of Yield Analysis

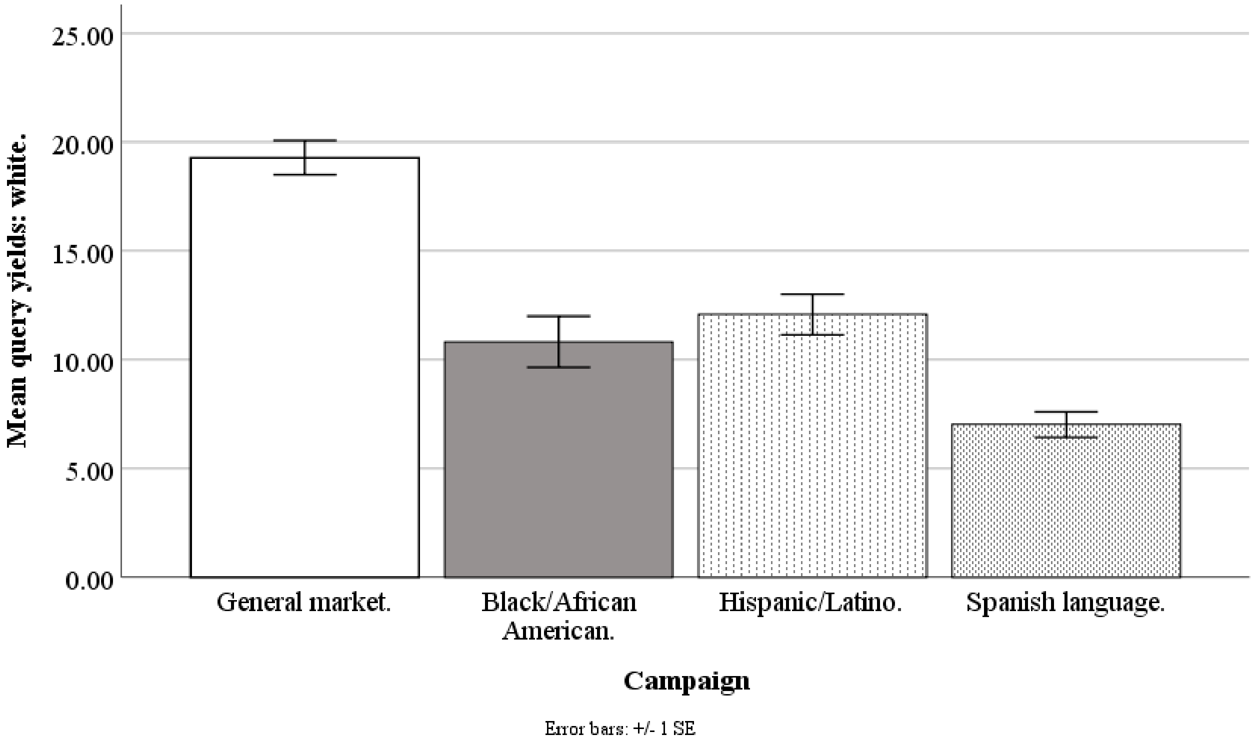
Facebook's basic advertisement reporting system measures advertisement clicks by default. To obtain the query, applicant, and participant metrics, we utilized a Facebook Pixel, which is a web code our website developer installed to measure and track actions Facebook users performed on our study website. The Facebook Pixel also tracked which of our Facebook campaigns drew them to our website [31]. We installed the Facebook Pixel in mid-June 2017. Our yield analysis is based on weekly data from June 20, 2017, to September 30, 2018, excluding major holidays (n=61 weeks), except Spanish language data that are from June 20, 2017, to September 30, 2017 (n=15 weeks). Although the Facebook Ads Manager provides daily yields, we aggregated the daily data to weekly data for accuracy and smoothing (eg, staff did not work weekends to convert queries to applicants). For all statistical analyses, we used analysis of variance, after which we conducted two-tailed pairwise *t* tests that compared specific campaigns (eg, general market vs Spanish language) using the Sidak correction for multiple comparisons.

We could not directly compare campaign yields because expenditures differed by campaign (eg, our budget for the general market campaign was considerably higher than for the black-/African American–focused and Hispanic-/Latino-focused campaigns). To compare yields across campaigns, we standardized expenditures to US $140 per week (US $20 per day), reflecting our average budget for the 2 main ethnic campaigns. For example, on a given week, we may have spent US $700 on the general market campaign versus US $140 on the black-/African American–focused campaign. If we received 100 queries from the general market campaign, we divided this number by 5 and estimated the yield as 20 based on a standardized expenditure of US $140 per week (US $700/5=US $140). This standardized yield of 20 for the general market campaign would be compared with the yield of the black-/African American–focused campaign that ran at US $140.

Non-Hispanic White Query Yields

The Facebook campaigns differed on weekly mean counts of queries by non-Hispanic whites ($F_{3,194}$=19.79; P<.001), with the general market–focused campaign at 19.28 people (SD 6.11), black-/African American–focused at 10.82 people (SD 9.20), Hispanic-/Latino-focused at 12.10 people (SD 7.25), and Spanish language–focused at 7.02 people (SD 2.24). The query yield of whites was higher for the general market campaign than for the black-/African American–focused ($t_{1,194}$=6.33; P<.001), Hispanic-/Latino-focused ($t_{1,194}$=5.39; P<.001), or Spanish language–focused campaigns ($t_{1,194}$=5.77; P<.001). The query yield of whites was similar for the black-/African American–focused campaign versus Hispanic-/Latino-focused ($t_{1,194}$=0.94; P=.92) or Spanish language campaigns ($t_{1,194}$=1.79; P=.37). The weekly mean count of whites was similar for the Hispanic-/Latino-focused versus Spanish language campaign ($t_{1,194}$=2.38; P=.11; Figure 1).

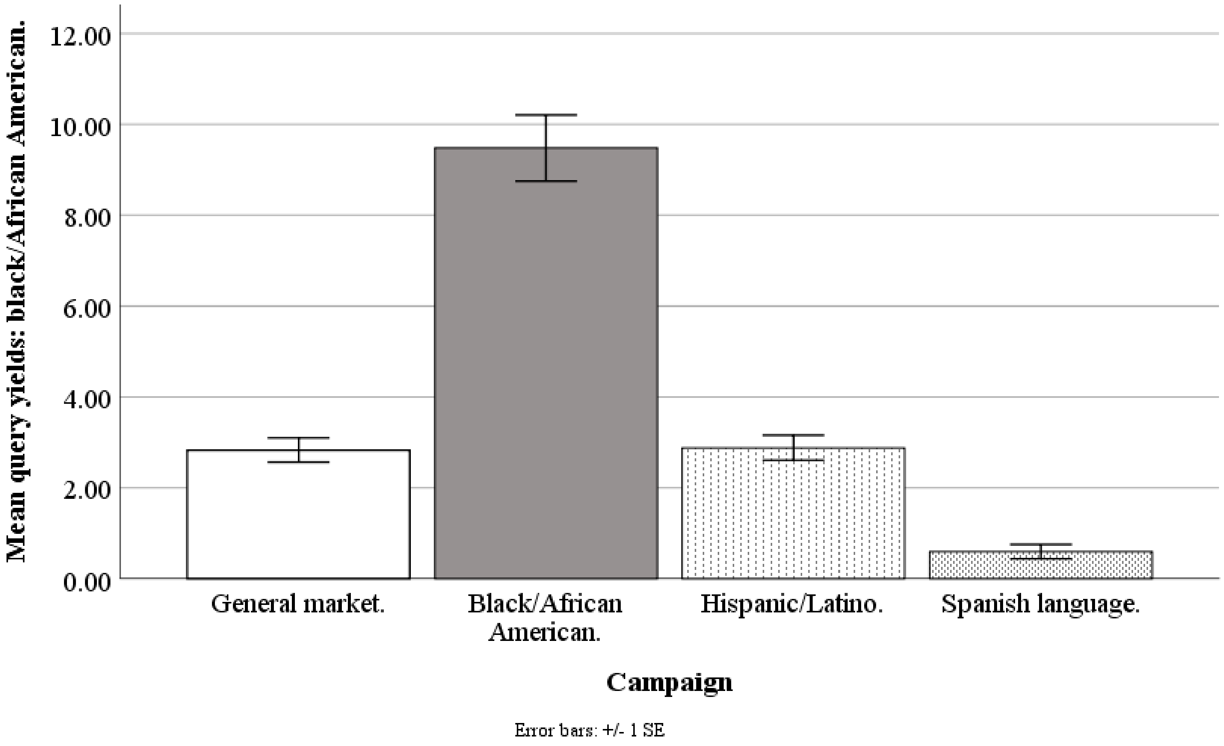
Figure 1. Mean query yields of whites for Facebook advertising campaigns.



Black/African American Query Yield

The Facebook campaigns differed on weekly mean counts of queries by blacks/African Americans ($F_{3,194}$=53.96; P<.001), with the general market–focused campaign at 2.83 people (SD 2.05), black-/African American–focused at 9.48 people (SD 5.69), Hispanic-/Latino-focused at 2.89 people (SD 2.12), and Spanish language–focused at 0.60 people (SD 0.62). The query yield of blacks/African Americans was higher for the black-/African American–focused campaign than for the general market–focused ($t_{1,194}$=10.29; P<.001), Hispanic-/Latino-focused ($t_{1,194}$=10.21; P<.001), or Spanish language–focused campaigns ($t_{1,194}$=8.64; P<.001). The query yield of blacks/African Americans was similar for the general market–focused versus Hispanic-/Latino-focused ($t_{1,194}$=0.08; P=.99) or Spanish language–focused campaigns ($t_{1,194}$=2.17; P=.17). The query yield of blacks/African Americans was similar for the Hispanic-/Latino-focused versus Spanish language–focused campaign ($t_{1,194}$=2.23; P=.15; Figure 2).

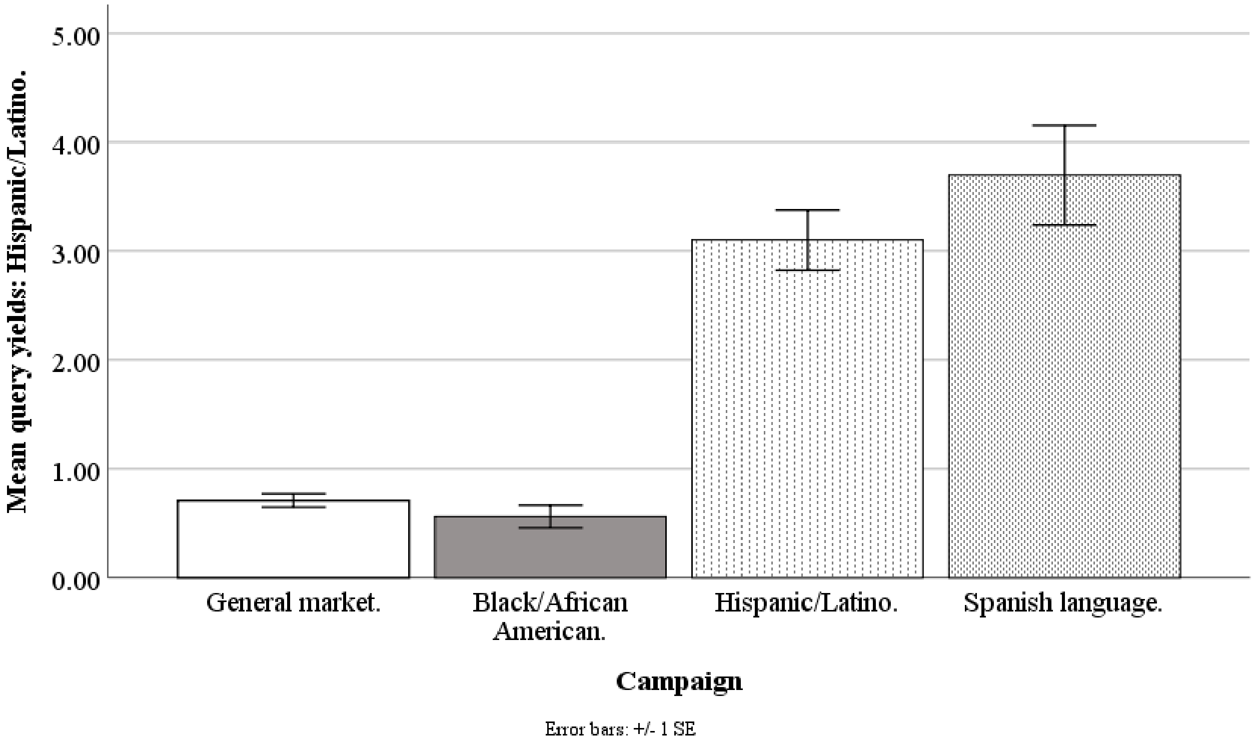
Figure 2. Mean query yields of blacks/African Americans for Facebook advertising campaigns.



Hispanic/Latino Query Yield

The Facebook campaigns differed on weekly mean counts of queries by Hispanics/Latinos ($F_{3,194}$=54.29; P<.001), with the general market–focused campaign at 0.71 people (SD 0.48), black-/African American–focused at 0.56 people (SD 0.82), Hispanic-/Latino-focused at 3.10 people (SD 2.16), and Spanish language–focused at 3.70 people (SD 1.77). The query yield of Hispanics/Latinos was higher for the Hispanic-/Latino-focused campaign than for the general market–focused ($t_{1,194}$=9.45; P<.001) or black-/African American–focused campaigns ($t_{1,194}$=10.04; P<.001) but was similar to the Spanish language–focused campaign ($t_{1,194}$=1.48; P=.60). The query yield of Hispanics/Latinos was similar for the general market–focused campaign as compared with the black-/African American–focused campaign ($t_{1,194}$=0.58; P=.99) but was lower than that of the Spanish language–focused campaign ($t_{1,194}$=7.43; P<.001). The query yield of Hispanics/Latinos was higher for the Spanish language–focused versus African American–focused campaign ($t_{1,194}$=7.79; P<.001; Figure 3).

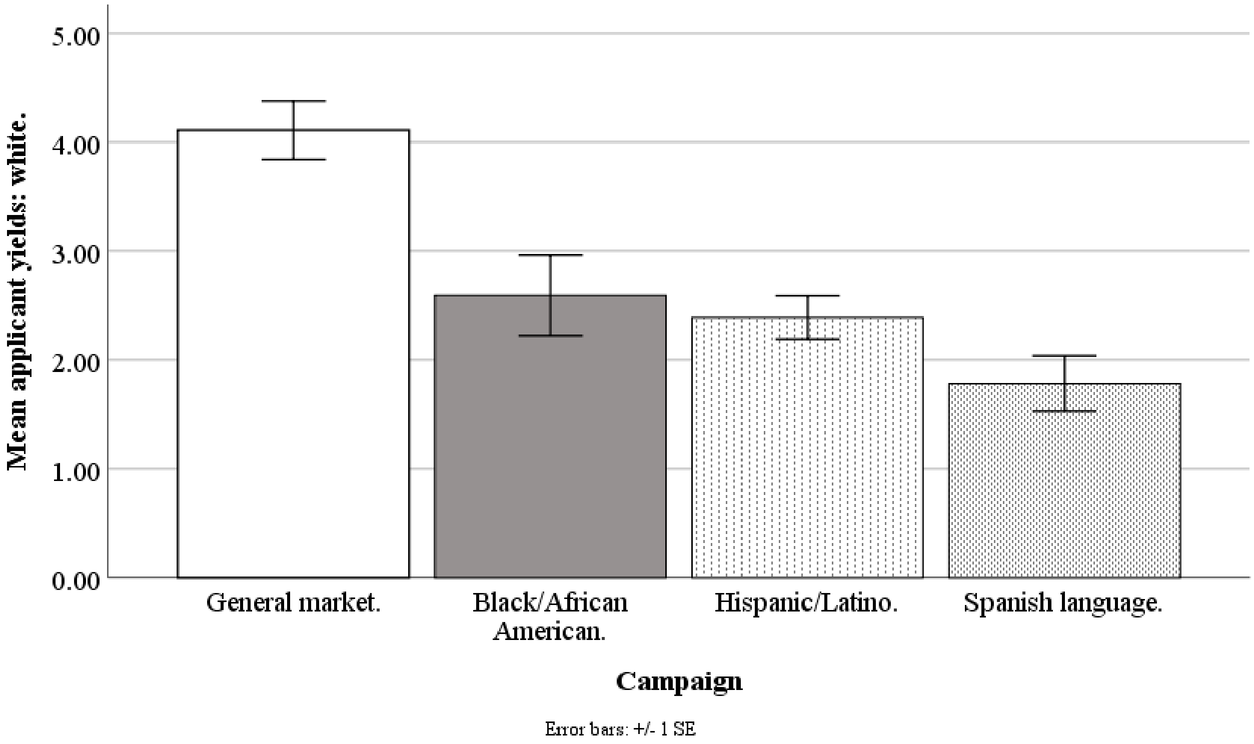
Figure 3. Mean query yields of Hispanics/Latinos for Facebook advertising campaigns.



Non-Hispanic White Applicant Yield

The Facebook campaigns differed on weekly mean counts of applicants who were non-Hispanic white ($F_{3,190}$=9.00; P<.001), with the general market–focused campaign at 4.12 (SD 2.08), black-/African American–focused at 2.59 (SD 2.86), Hispanic-/Latino-focused at 2.39 (SD 1.55), and Spanish language–focused at 1.78 (SD 0.95). The applicant yield of whites was higher for the general market–focused campaign than for the black-/African American–focused ($t_{1,190}$=3.84; P=.001), Hispanic-/Latino-focused ($t_{1,190}$=4.35; P<.001), or Spanish language–focused campaigns ($t_{1,190}$=3.62; P=.002). The applicant yield of whites was similar for the black-/African American–focused versus Hispanic-/Latino-focused ($t_{1,190}$=0.51; P=.99) or Spanish language–focused campaigns ($t_{1,190}$=1.26; P=.76). The applicant yield of whites was similar for the Hispanic-/Latino-focused versus Spanish language–focused campaign ($t_{1,190}$=0.95; P=.92; Figure 4).

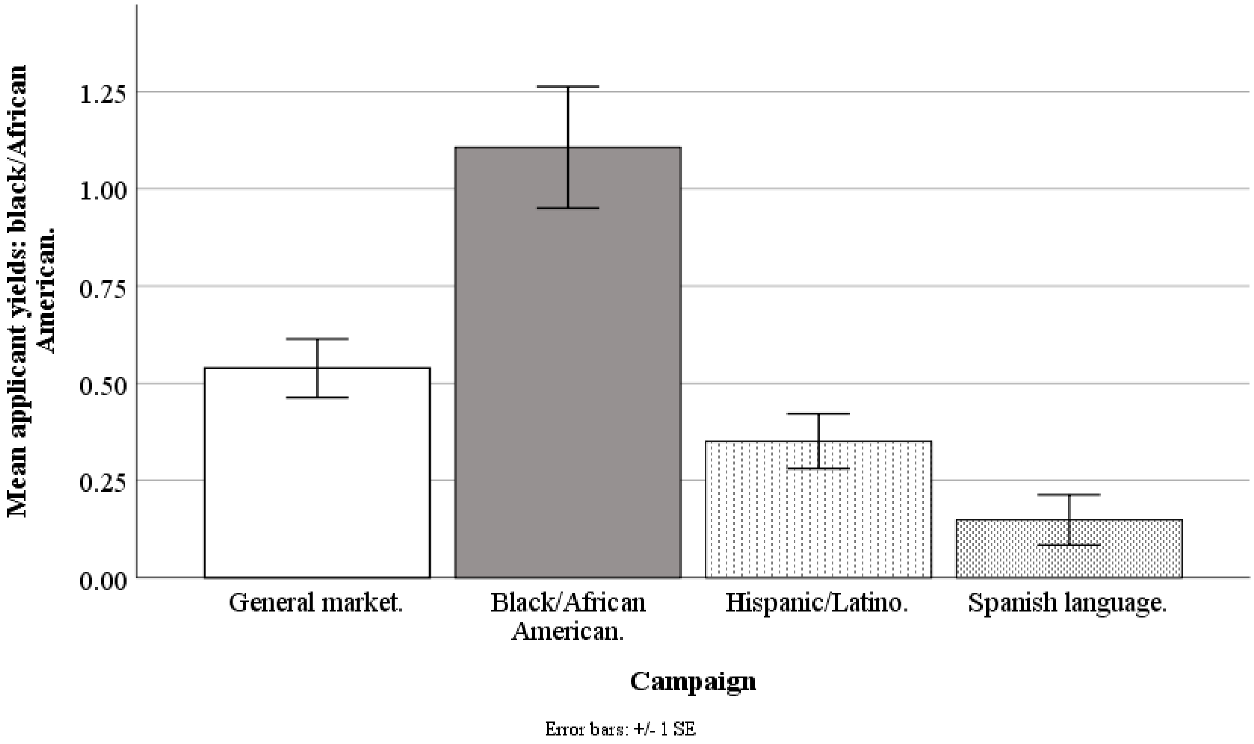
Figure 4. Mean applicant yields of whites for Facebook advertising campaigns.



Black/African American Applicant Yields

The Facebook campaigns differed on weekly mean counts of applicants who were black/African American ($F_{3,190}$=11.19; P<.001), with the general market–focused campaign at 0.54 (SD 0.58), black-/African American–focused at 1.11 (SD 1.21), Hispanic-/Latino-focused at 0.35 (SD 0.55), and Spanish language–focused at 0.15 (SD 0.24). The applicant yield of blacks/African Americans was higher for the black-/African American–focused campaign compared with the general market–focused ($t_{1,190}$=3.84; P=.001), Hispanic-/Latino-focused ($t_{1,190}$=5.11; P<.001), or Spanish language–focused campaigns ($t_{1,190}$=3.96; P=.001). The applicant yield of blacks/African Americans was similar for the general market–focused versus Hispanic-/Latino-focused ($t_{1,190}$=1.27; P=.75) or Spanish language–focused campaigns ($t_{1,190}$=1.62; P=.49). The applicant yield of blacks/African Americans was similar for the Hispanic-/Latino-focused versus Spanish language–focused campaign ($t_{1,190}$=0.84; P=.95; Figure 5).

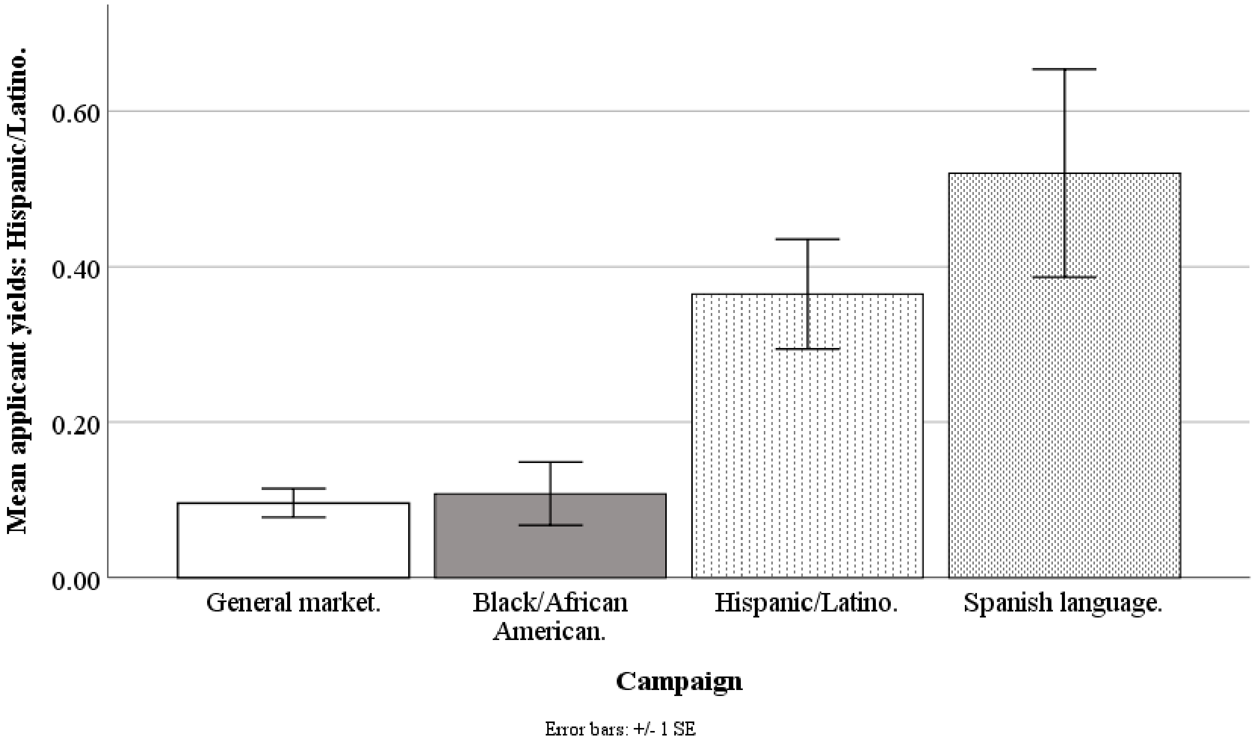
Figure 5. Mean applicant yields of blacks/African Americans for Facebook advertising campaigns.



Hispanic/Latino Applicant Yield

The Facebook campaigns differed on weekly mean counts of applicants who were Hispanic/Latino ($F_{3,190}$=9.48; *P*<.001), with the general market–focused campaign at 0.10 (SD 0.14), black-/African American–focused at 0.11 (SD 0.32), Hispanic-/Latino-focused at 0.36 (SD 0.55), and Spanish language–focused at 0.52 (SD 0.50). The applicant yield of Hispanics/Latinos was higher for the Hispanic-/Latino-focused campaign compared with general market–focused ($t_{1,190}$=3.83; *P*=.001) or black-/African American–focused campaigns ($t_{1,190}$=3.66; *P*=.002) but similar to that of Spanish language–focused campaign ($t_{1,190}$=1.37; *P*=.68). The applicant yield of Hispanics/Latinos was similar for the general market–focused campaign compared with the black-/African American–focused campaign ($t_{1,190}$=0.17; *P*=.99) but lower than that of the Spanish language–focused campaign ($t_{1,190}$=3.72; *P*=.002). The applicant yield of Hispanics/Latinos was higher for the Spanish language–focused campaign versus the black-/African American-focused campaign ($t_{1,190}$=3.61; *P*=.002; Figure 6).

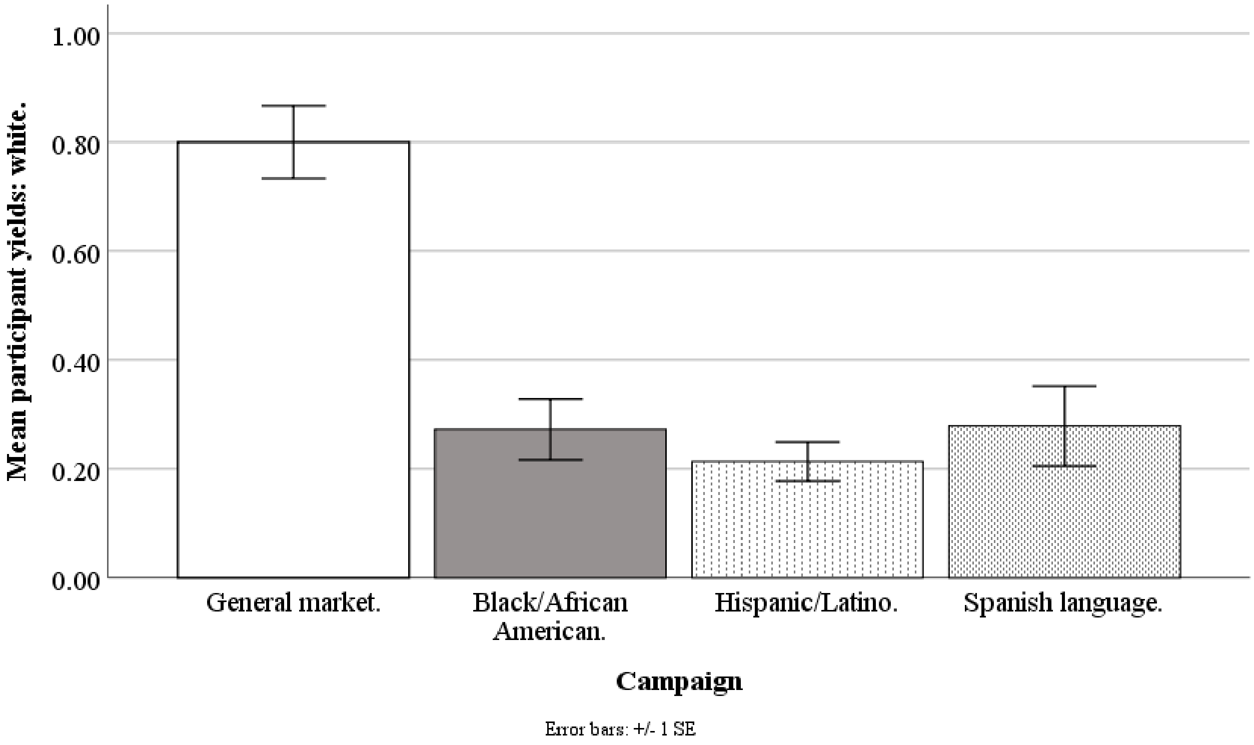
Figure 6. Mean applicant yields of Hispanics/Latinos for Facebook advertising campaigns.



Non-Hispanic White Participant Yields

The Facebook campaigns differed on weekly mean counts of participants who were non-Hispanic white ($F_{3,190}$=24.96; $P<.001$), with the general market–focused campaign at 0.80 (SD 0.52), black-/African American–focused at 0.27 (SD 0.43), Hispanic-/Latino-focused at 0.21 (SD 0.28), and Spanish language–focused at 0.28 (SD 0.28). The participant yield of whites was higher for the general market–focused campaign than for the black-/African American–focused ($t_{1,190}$=6.95; $P<.001$), Hispanic-/Latino-focused ($t_{1,190}$=7.72; $P<.001$), or Spanish language–focused campaigns ($t_{1,190}$=4.24; $P<.001$). The participant yield of whites otherwise did not differ across campaigns (all $P>.97$; Figure 7).

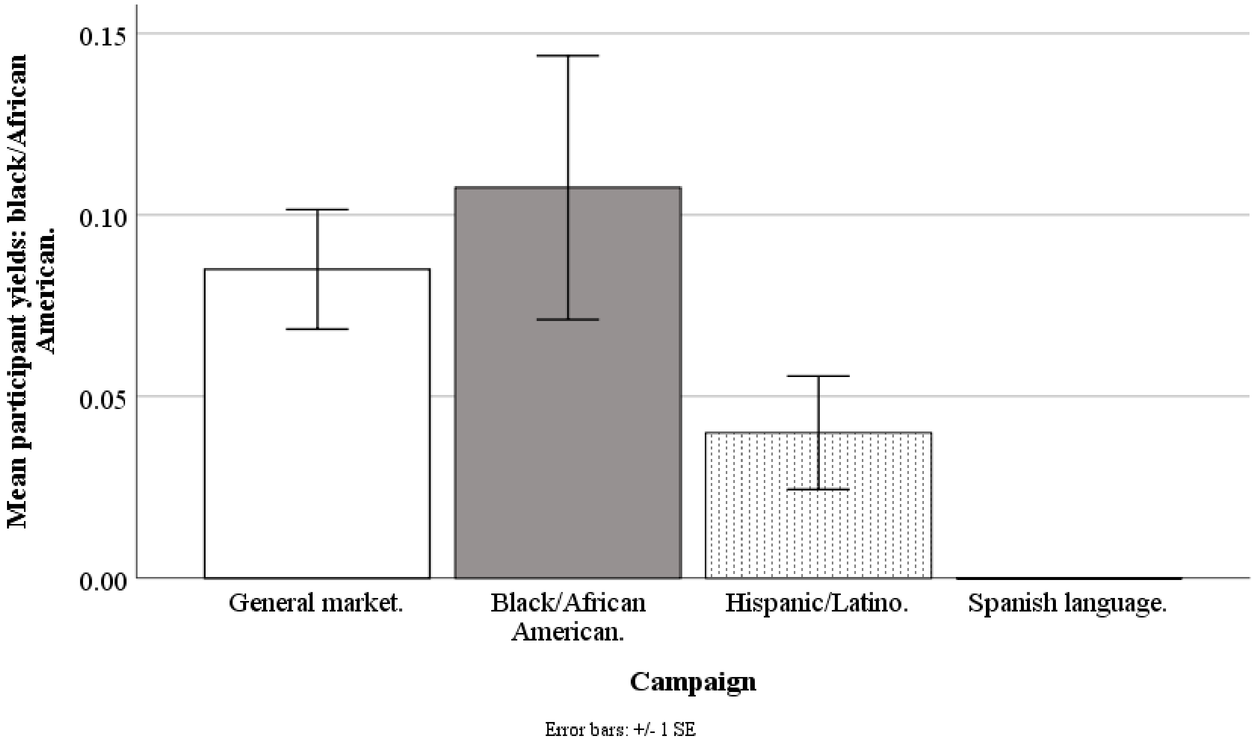
Figure 7. Mean participant yields of whites for Facebook advertising campaigns.



Black/African American Participant Yields

The Facebook campaigns marginally differed on weekly mean counts of participants who were black/African American ($F_{3,190}$=2.14; P=.10), with the general market–focused campaign at 0.09 (SD 0.13), black/African American–focused at 0.11 (SD 0.28), Hispanic-/Latino-focused at 0.04 (SD 0.12), and Spanish language–focused at .001 (SD 0.001). However, none of the pairwise comparisons between specific campaigns were significant (all P>.25; Figure 8).

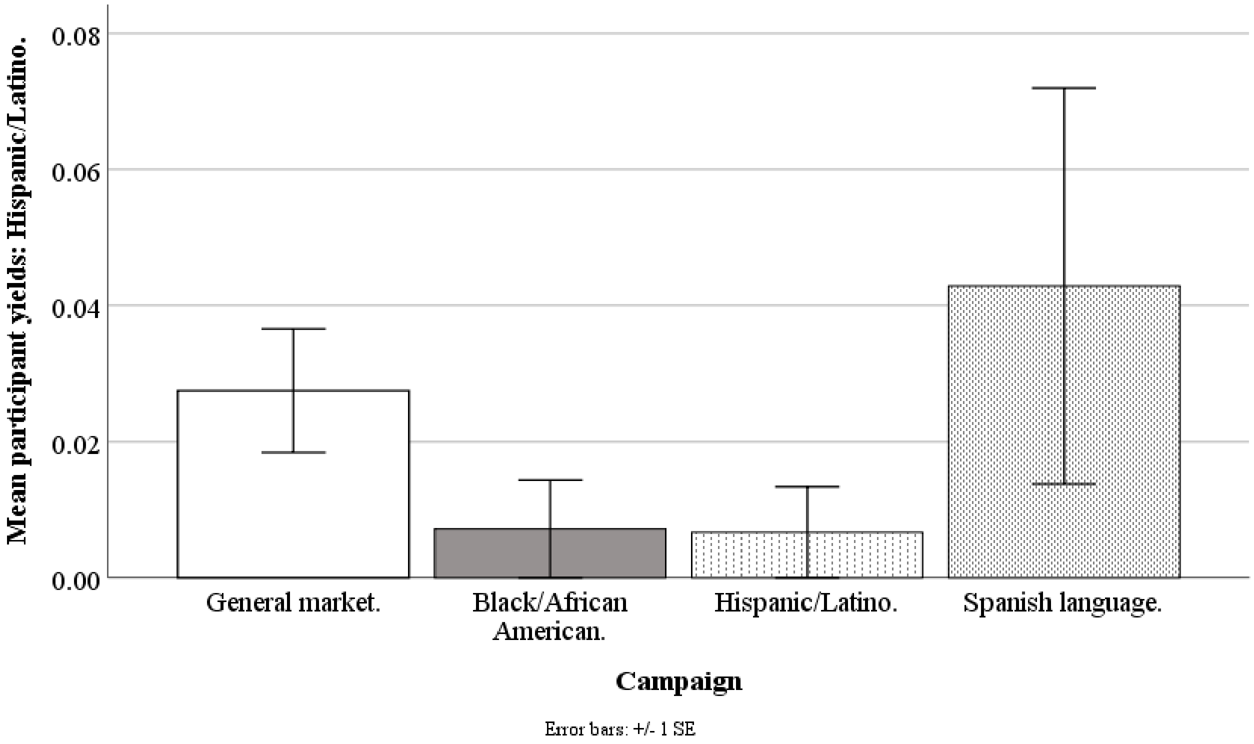
Figure 8. Mean participant yields of blacks/African Americans for Facebook advertising campaigns.



Hispanic/Latino Participant Yields

The Facebook campaigns marginally differed on the weekly mean counts of participants who were Hispanic/Latino ($F_{3,190}$=2.25; P=.08), with the general market–focused campaign at 0.03 (SD 0.07), black-/African American–focused at 0.01 (SD 0.06), Hispanic-/Latino-focused at 0.01 (SD 0.05), and Spanish language–focused at 0.04 (SD 0.11). However, none of the pairwise comparisons between specific campaigns were significant (all P>.31; Figure 9).

Figure 9. Mean participant yields of Hispanics/Latinos for Facebook advertising campaigns.



Results Regarding Costs by Ethnic Group

Overview of Cost Analysis

Facebook advertising costs are available at the campaign level (for instance, for a Hispanic-/Latino-focused campaign) but not at the individual level (eg, for a Hispanic/Latino individual) because at the individual level, internal auctions are used to determine if an advertisement is shown, and Facebook does not share these individual-level costs with its advertisers [32]. The Facebook Ads Manager only provides costs per campaign and per day, and so our best estimate of the recruitment cost of any individual regardless of ethnicity was the average cost for the campaign on the day in which the recruitment took place. Daily data were aggregated to weekly data for accuracy and smoothing (eg, staff did not work weekends to convert queries to applicants). Our cost analysis is based on weekly data from June 20, 2017, to September 17, 2018, excluding major holidays (n=61 weeks), except the Spanish language data that are from June 20, 2017, to September 30, 2018 (n=15 weeks). Refer to Figures 10-13 for campaign costs by ethnicity at the advertisement click, query, applicant, and participant stages.

Figure 10. Mean costs per advertisement click for Facebook advertising campaigns.

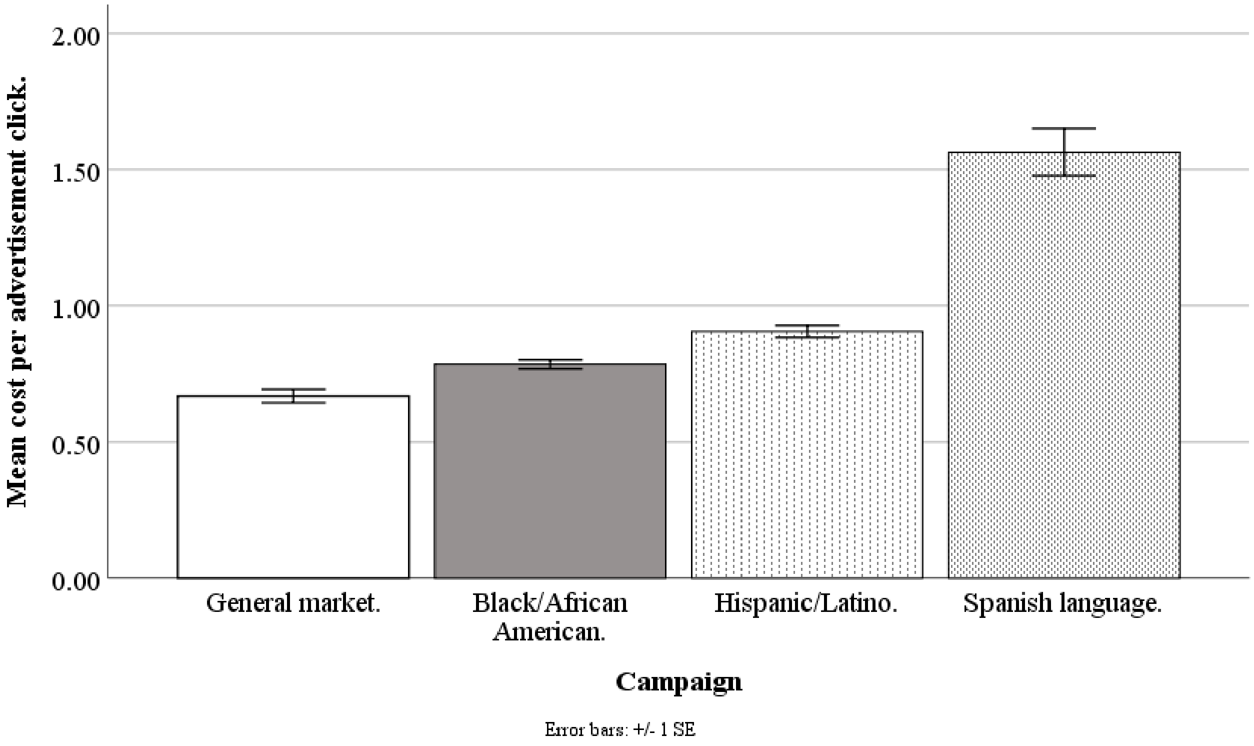


Figure 11. Mean costs per query for Facebook advertising campaigns.

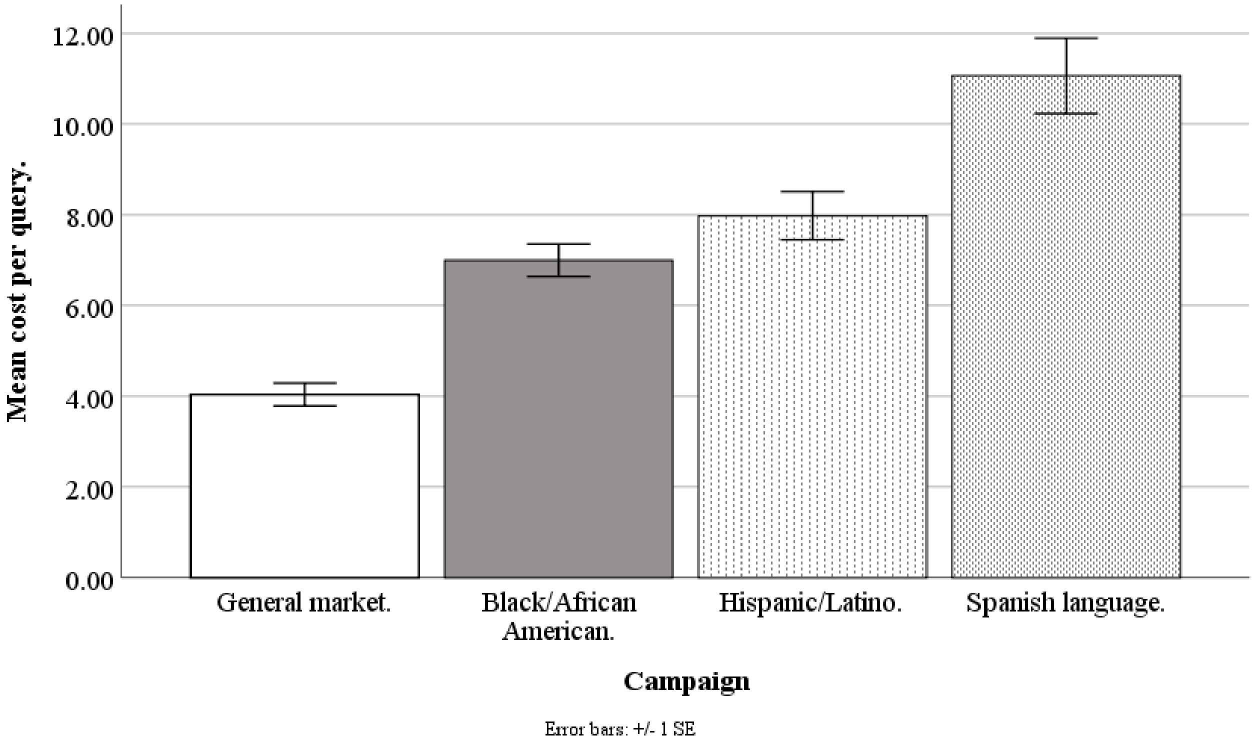

Figure 12. Mean costs per applicant for Facebook advertising campaigns.

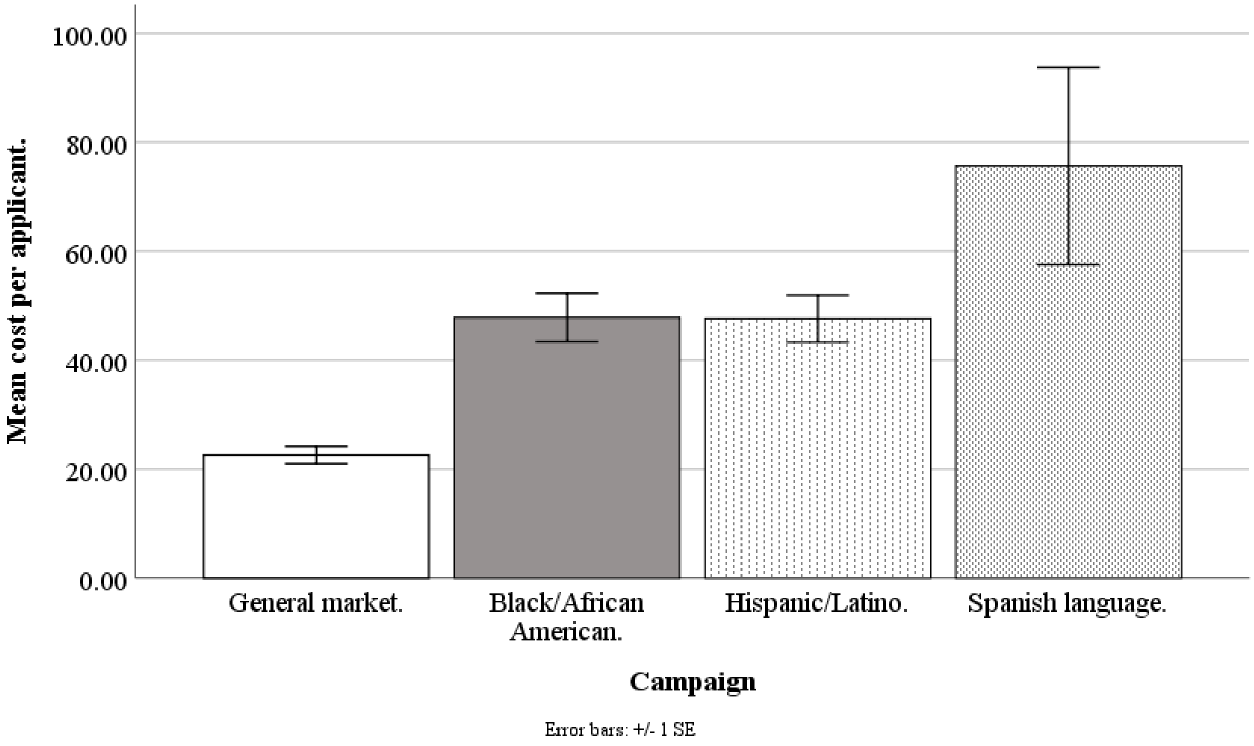

Figure 13. Mean costs per participant for Facebook advertising campaigns.

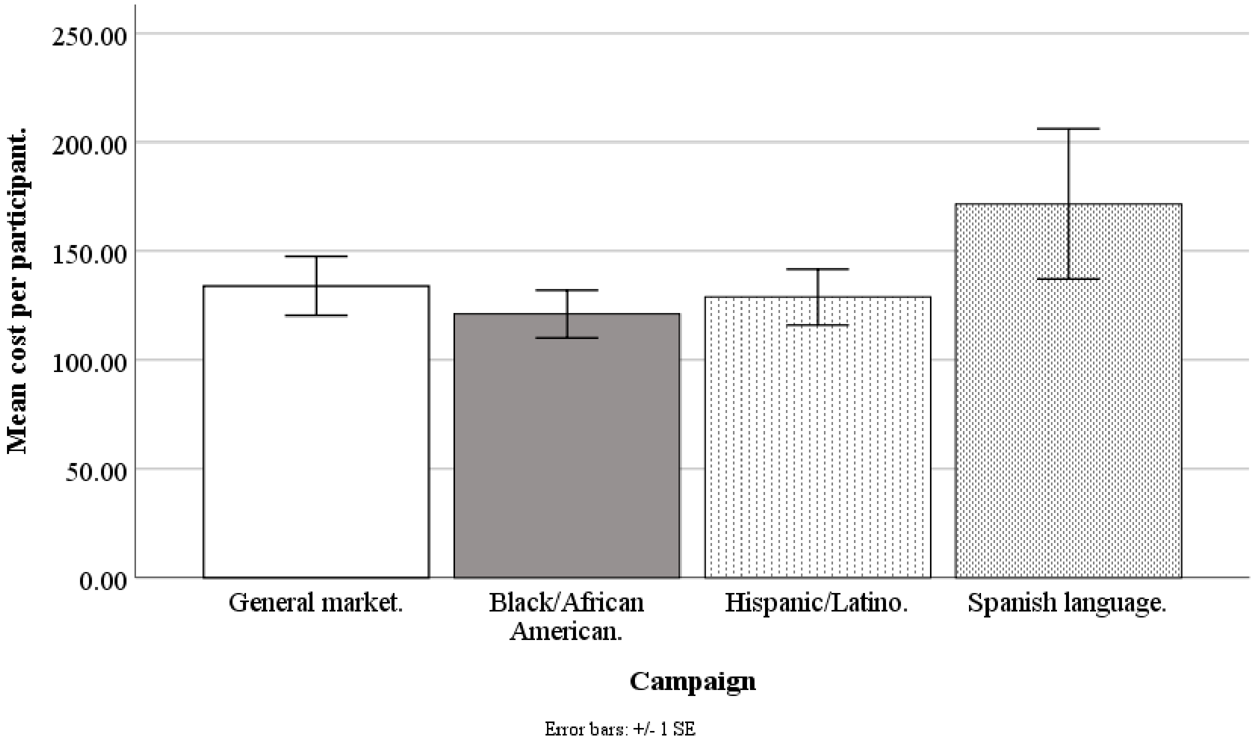

Cost per Advertisement Click

The Facebook campaigns differed on cost per advertisement click ($F_{3,194}$=97.18; P<.001), with the general market–focused campaign at US $0.67 (SD 0.19), black-/African American–focused at US $0.78 (SD 0.13), Hispanic-/Latino-focused at US $0.91 (SD 0.17), and Spanish language-focused at US $1.56 (SD 0.34). The cost per advertisement click was lower for the general market–focused campaign, compared with black-/African American–focused ($t_{1,194}$=3.41; P=.004), Hispanic-/Latino-focused ($t_{1,194}$=6.97; P<.001), or Spanish language–focused ($t_{1,194}$=16.57; P<.001). The cost per advertisement click was lower for the black-/African American–focused campaign than for the Hispanic-/Latino-focused ($t_{1,194}$=3.56; P=.002) or Spanish language-focused ($t_{1,194}$=14.43; P<.001) campaigns, and lower for the Hispanic-/Latino-focused than for the Spanish language–focused campaign ($t_{1,194}$=12.49; P<.001; Figure 10).

Cost per Query

The Facebook campaigns differed in cost per query ($F_{3,194}$=28.42; P<.001), with the general market–focused campaign at US $4.04 (SD 1.99), black-/African American–focused at US $7.00 (SD 2.77), Hispanic-/Latino-focused at US $7.98 (SD 4.13), and Spanish language–focused at US $11.06 (SD 3.23). The cost per query was lower for the general market–focused campaign than for the black-/African American–focused ($t_{1,194}$=5.26; P<.001), Hispanic-/Latino-focused ($t_{1,194}$=7.01; P<.001), or Spanish language–focused campaigns ($t_{1,194}$=7.84; P<.001). The cost per query was lower for the black-/African American–focused campaign than for the Hispanic-/Latino-focused ($t_{1,194}$=3.56; P=.002) or Spanish language–focused campaigns ($t_{1,194}$=4.54; P<.001), and lower for the Hispanic-/Latino-focused than for the Spanish language–focused campaign ($t_{1,194}$=3.45; P=.004; Figure 11).

Cost per Applicant

The Facebook campaigns differed in cost per applicant ($F_{3,182}$=13.80; P<.001), with the general market–focused at US $22.61 (SD 12.21), black-/African American–focused at US $47.82 (SD 33.00), Hispanic-/Latino-focused at US $47.63 (SD 32.16), and Spanish language–focused at US $75.65 (SD 67.60). The cost per applicant was lower for the general market–focused campaign, compared with the black-/African American–focused ($t_{1,182}$=4.26; P<.001), Hispanic-/Latino-focused ($t_{1,182}$=4.23; P<.001), or Spanish language–focused campaigns ($t_{1,182}$=5.61; P<.001). The cost per applicant was comparable for the black-/African American–focused campaign than for the Hispanic-/Latino-focused campaign ($t_{1,182}$=0.03; P=.99) but lower than that of the Spanish language–focused campaign ($t_{1,182}$=2.92; P=.02). The cost per applicant was also lower for the Hispanic-/Latino-focused than for the Spanish language–focused campaign ($t_{1,182}$=2.94; P=.02; Figure 12).

Cost per Participant

The Facebook campaigns were comparable on cost per participant ($F_{3,121}$=0.73; P=.54), with the general market–focused at US $133.90 (SD 103.92), black-/African American–focused at US $121.05 (SD 60.02), Hispanic-/Latino-focused at US $128.90 (SD 67.86), and Spanish language–focused at US $171.66 (SD 97.37). Likewise, comparing the specific campaigns pairwise, there were no differences in cost per participant (all P>.62; Figure 13).

Results of Cambridge Analytica Scandal

Overview of Analysis of Scandal Effects

In March 2018, Facebook started to receive negative publicity because a third-party company, Cambridge Analytica, had allegedly harvested information from more than 50 million Facebook accounts without users' permission [33]. Our advertisements ran before and after this scandal broke, and so we compared our costs for advertisement clicks, queries, applicants, and participants across these 2 time periods, to determine whether the Facebook privacy scandal increased our recruitment costs, and whether this depended on the campaign: general market–focused, black-/African American–focused, or Hispanic-/Latino-focused (our Spanish language campaign was no longer running). Our scandal analysis was based on weekly data from June 20, 2017, to September 17, 2018, excluding major holidays (n=61 weeks). Because the original New York Times article on the scandal appeared on March 17, 2018, all weeks before March 20, 2018, (n=33) were treated as prescandal and the remaining weeks (n=28) were treated as postscandal. Refer to Figures 14-17 for our costs by campaign pre- versus postscandal.

Figure 14. Mean costs per advertisement click for Facebook advertising campaigns before versus after privacy scandal.

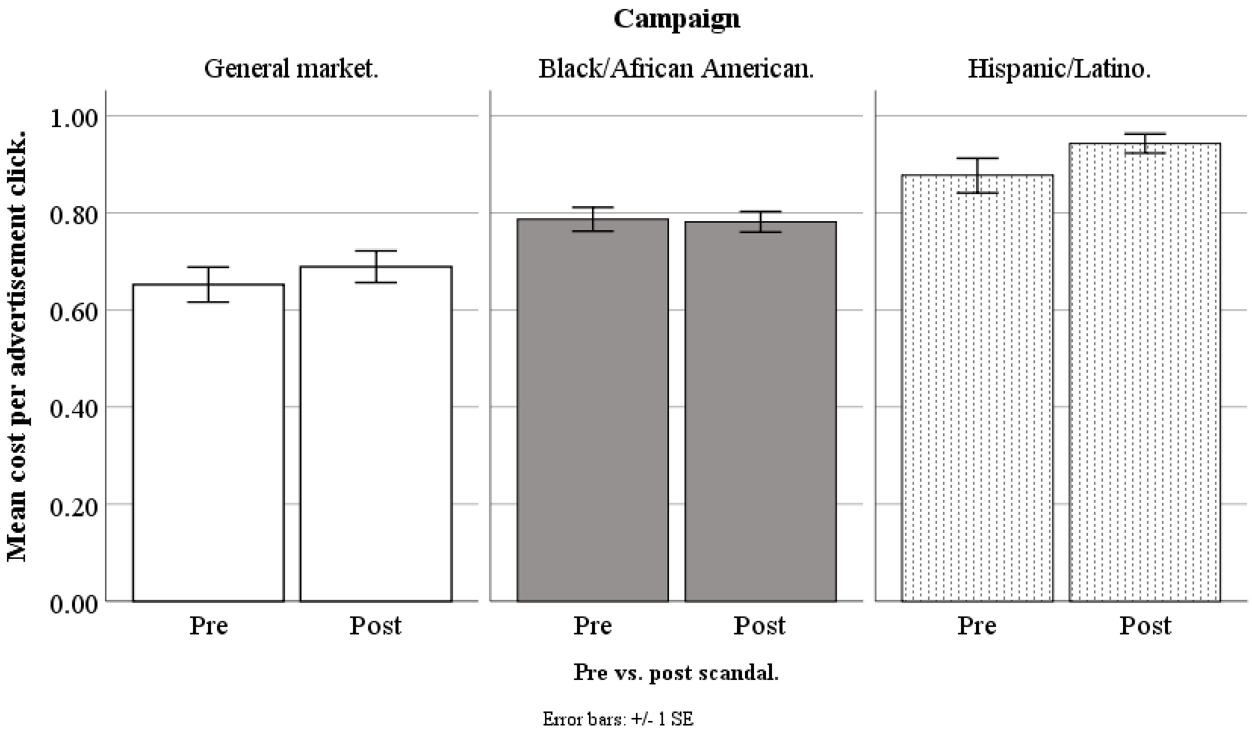

Figure 15. Mean costs per query for Facebook advertising campaigns before versus after privacy scandal.

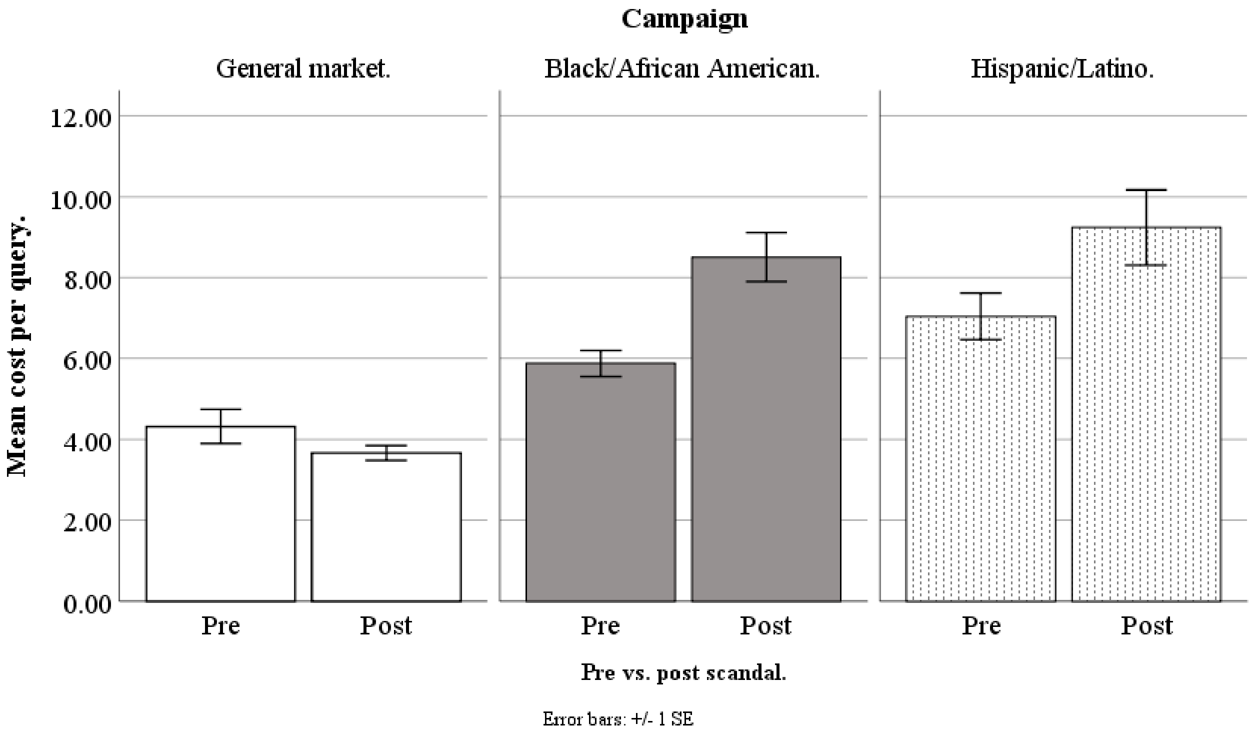

Figure 16. Mean costs per applicant for Facebook advertising campaigns before versus after privacy scandal.

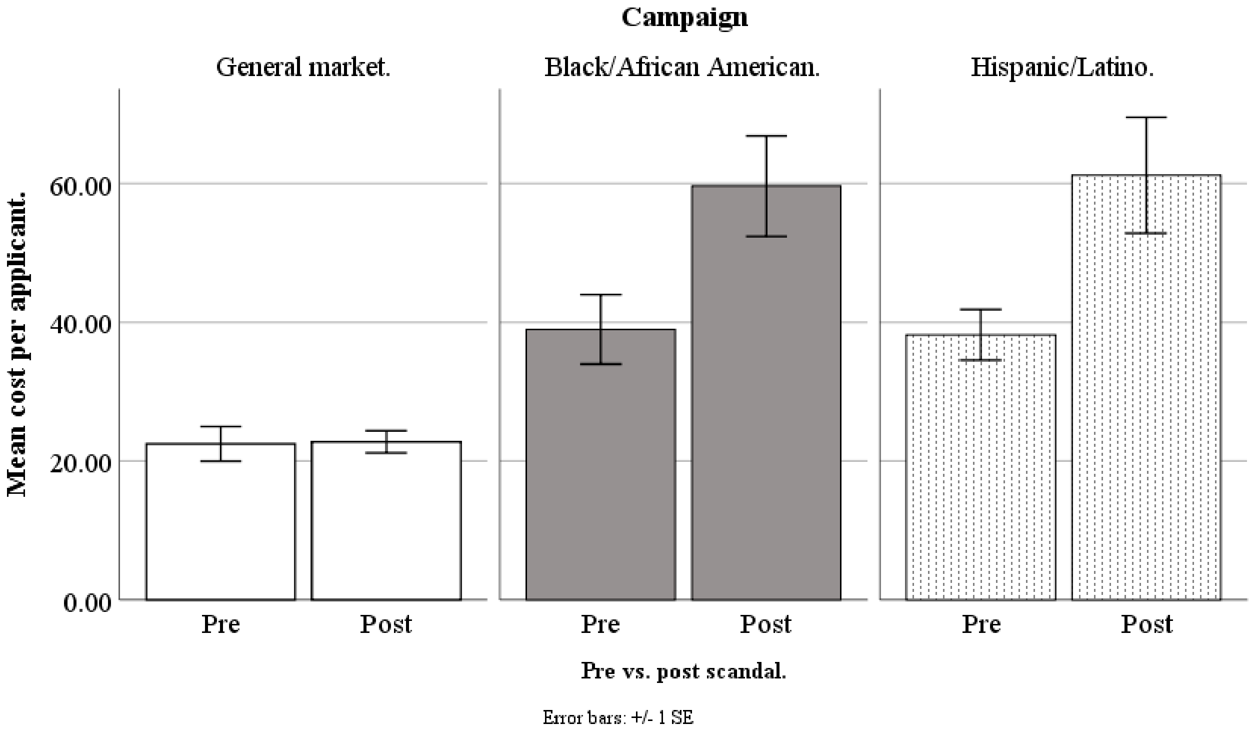

Figure 17. Mean costs per participant for Facebook advertising campaigns before versus after privacy scandal.

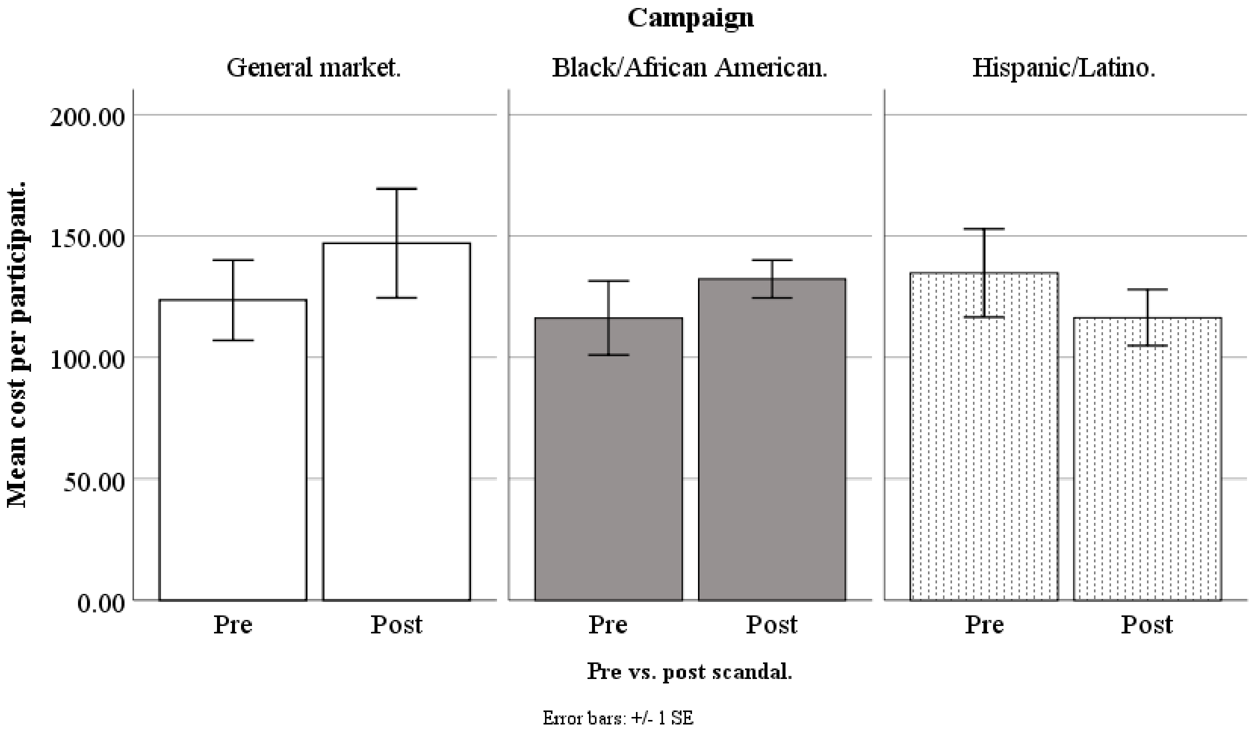

Cost per Advertisement Click

On cost per advertisement click, the effect for pre- versus postscandal was not significant ($F_{1,177}$=1.67; P=.20). Additionally, there were no significant differences in cost per advertisement click when we conducted specific pairwise comparisons of the campaigns (all P>.13; Figure 14).

Cost per Query

On cost per query, there was a significant effect for pre- versus postscandal ($F_{1,177}$=9.93; P=.002) and a scandal by campaign type 2-way interaction ($F_{1,177}$=5.46; P=.005), meaning the scandal effect varied by campaign. For the general market–focused campaign, there was no scandal effect on cost per query ($F_{1,177}$=0.74; P=.39), with prescandal at US $4.32

(SD 2.49) and postscandal at US $3.66 (SD 0.94). For the black-/African American–focused campaign, there was a scandal effect on cost per query ($F_{1,177}$=11.84; *P*=.001), with prescandal at US $5.87 (SD 1.89) and postscandal higher at US $8.51 (SD 3.08). Likewise, for the Hispanic-/Latino-focused campaign, there was a scandal effect on cost per query ($F_{1,177}$=8.28; *P*=.01), with prescandal at US $7.04 (SD 3.39) and postscandal higher at US $9.24 (SD 4.74; Figure 15).

Cost per Applicant

On cost per applicant, there was a significant effect for pre- versus postscandal ($F_{1,166}$=13.29; *P*<.001) and a scandal by campaign type 2-way interaction ($F_{1,166}$=3.30; *P*=.04), meaning the scandal effect varied by campaign. For the general market–focused campaign, there was no scandal effect on cost per applicant ($F_{1,166}$=.002; *P*=.97), with prescandal at US $22.48 (SD 14.68) and postscandal at US $22.77 (SD 8.19). For the black-/African American–focused campaign, there was a scandal effect on cost per applicant ($F_{1,166}$=8.65; *P*=.004), with prescandal at US $38.96 (SD 28.31) and postscandal higher at US $59.64 (SD 35.63). Similarly, for the Hispanic-/Latino-focused campaign, there was a scandal effect on cost per applicant ($F_{1,166}$=10.57; *P*=.001), with prescandal at US $38.19 (SD 21.20) and postscandal higher at US $61.19 (SD 40.08; Figure 16).

Cost per Participant

On cost per participant, the effect for pre- versus postscandal was not significant ($F_{1,111}$=0.15; *P*=.70). Additionally, there were no significant differences in cost per participant when we conducted specific pairwise comparisons of the campaigns (all *P*>.31; Figure 17).

Results Regarding Lookalike Audience

We used Facebook's lookalike audience feature for a short time to determine if it reduced our recruitment costs relative to our baseline general market–focused campaign. Facebook's lookalike audience feature involves a proprietary method of targeting individuals similar to a chosen source audience, that is, an audience that responded favorably to a past campaign based on a specific website response as recorded by the Facebook Pixel. On the basis of the designated source audience, Facebook seeks to generate a similarly interested audience [34]. We designated our source audience as individuals who filled out our query form on our study website, which was recorded by our website's Facebook Pixel. Our analysis was based on daily data from January 3, 2018, to March 26, 2018 (n=26 days). It compared the Facebook lookalike campaign that sought to optimize our queries to our standard general market–focused campaign, which ran simultaneously. We assessed cost per advertisement click, query, and applicant; however, cost per participant could not be estimated due to the short time window. This test was ended soon after it began because of privacy concerns. Facebook's lookalike audience feature has the drawbacks of an unknown and unknowable algorithm and unclear use of Facebook user data to create the algorithm, which might possibly involve using Facebook users' network of friends. Therefore, we could not fully describe the data collection approach to our potential study participants and ask for their informed consent or obtain their friends' consent, if needed.

The cost per advertisement click for the lookalike audience campaign was lower than the general market–focused campaign ($F_{1,50}$=26.64; *P*<.001), with the lookalike audience at US $0.73 (SD 0.30) and general market–focused at US $1.07 (SD 0.14). However, the cost per query for the lookalike audience campaign did not differ from the general market campaign ($F_{1,49}$=0.23; *P*=.64), with lookalike audience at US $3.98 (SD 2.24) and general market at US $4.27 (SD 2.19). The cost per applicant for the lookalike audience campaign also did not differ from the general market campaign ($F_{1,40}$=2.75; *P*=.11), with lookalike audience at US $15.58 (SD 6.07) and general market at US $20.13 (SD 10.13).

Results Regarding Audience Network Placement

Audience network placement is a feature recommended by Facebook to its advertisers, which involves placing their advertisements on other websites or mobile apps rather than on Facebook itself, to reach a broader audience. We assessed whether using Facebook's audience network placement reduced recruitment costs. We tried out the audience network placement very early on, before we began study recruitment, and so only costs per advertisement click and query were available. Facebook automatically provides advertisement click data, and we were able to record queries because we had installed and monitored our query form on our website. We used the audience network placement on its own during 2 test weeks in 2016, so we could attribute all queries to it. Later on, our Facebook Pixel would identify queries by campaign.

Here, we compare data from our general market campaign that used audience network placement (August 3, 2016-August 10, 2016, and August 23, 2016-August 30, 2016, n=16 days) to standard advertisement placement on Facebook alone (1 year later, on exactly the same dates, n=16 days). The analysis shows that the cost per advertisement click was lower when the audience network placement was used compared with placement on Facebook alone ($F_{1,30}$=262.10; *P*<.001), with audience network at US $0.11 (SD 0.05) and Facebook alone at US $0.69 (SD 0.13). However, the cost per query was substantially higher when audience network placement was used compared with placement on Facebook alone ($F_{1,30}$=4.26; *P*=.048), with the audience network at US $13.40 (SD 14.83) and Facebook alone at US $5.62 (SD 2.76). After 2 test weeks, based on noticeably poor query results, we stopped using the audience network placement.

Discussion

Principal Findings on Zip Code Targeting

Our results indicate that researchers can successfully recruit diverse individuals for web-based health-related studies using Facebook advertising campaigns with zip code targeting. By placing advertisements in zip codes ranked first on the percentage of households of the target ethnicity and then on the focal health behavior (in this case, cigarette expenditure per household), we successfully increased our outreach to and yield of black/African American– and Hispanic/Latino applicants. Table 1 shows our expected yields if we had continued these campaigns for 2 years, spending US $20 per day or US $140 per week, compared with our baseline general market campaign. Although we were concerned about higher costs, costs were not significantly higher for these ethnic-focused campaigns compared with our baseline general market campaign. We also recruited Hispanic/Latinos using Facebook's option to reach Spanish language speakers, and this produced a similar yield to our Hispanic/Latino campaign using zip codes. But it was more costly to produce this yield, perhaps because our study required English fluency.

Table 1. Estimated campaign yields based on spending US $20/day on each campaign for 2 years.

Yield type and campaign[a]	White, n (%)	Black/African American, n (%)	Hispanic/Latino, n (%)	Total[b], N
Queries				
General market	2005 (84.5)	294 (12.4)	74 (3.1)	2373
Black/African American	1125 (51.9)	986 (45.5)	58 (2.7)	2169
Hispanic/Latino	1258 (66.9)	301 (16.0)	322 (17.1)	1881
Spanish language	730 (62.0)	62 (5.3)	385 (32.7)	1177
Applicants				
General market	428 (86.6)	56 (11.3)	10 (2.0)	494
Black/African American	269 (68.1)	115 (29.1)	11 (2.8)	395
Hispanic/Latino	249 (77.3)	36 (11.2)	37 (11.5)	322
Spanish language	185 (72.5)	16 (6.3)	54 (21.2)	255
Participants				
General market	83 (87)	9 (9)	3 (3)	95
Black/African American	28 (70)	11 (27)	1 (2)	40
Hispanic/Latino	22 (81)	4 (14)	1 (3)	27
Spanish language	29 (87)	0 (0)	4 (12)	33

[a] The estimates are based on the yield of US $140/week (US $20/day) multiplied by 104 weeks to show estimated results for 2 years. The estimates in this table come from the observed yields of these campaigns extrapolated to reflect a standard expenditure of US $20/day for 2 years. The observed yields are based on US $77,133 spent, out of the US $87,425 in total spending on Facebook for the randomized controlled trial. The remainder was spent before the Facebook Pixel install or on weeks or test campaigns not reported here. The US $77,133 spent was divided up across campaigns as follows: general market 427 days at US $126/day, black/African American 427 days at US $23/day, Hispanic/Latino 427 days at US $23/day, and Spanish language 105 days at US $36/day.

[b] Row percentages add up to 100. Other ethnicities that were recruited during the campaigns were not factored into these estimates.

Principal Findings on Audience Network Placement and Scandal Effects

This study also found that Facebook's recommended audience network placement, although cheaper at producing advertisement clicks, was far more expensive at producing website queries. This means that many individuals who clicked on our advertisements were not interested. Many individuals may have clicked on our advertisements to use a free app (eg, play a game), not because they were interested in our study. Thus, we do not recommend using the audience network placement. We also learned that the Facebook privacy scandal involving Cambridge Analytica had a negative impact on recruitment for our campaigns that were black/African American–focused and Hispanic-/Latino-focused. This scandal increased our cost per query and cost per applicant. Hence, researchers should keep Facebook scandals in mind, as they may raise recruitment costs.

Principal Findings on Audience Lookalike Feature

Facebook's recommended audience lookalike feature produced advertisement clicks at a lower price point than our baseline general market campaign; however, query and applicant price points were similar to our general market campaign. Researchers may want to consider using Facebook's audience lookalike feature because it may cost less at the advertisement click stage, if this is a high priority, and if the required *source audience* can be identified based on website behavior as tracked by a Facebook Pixel (we used queries on our website). Potential drawbacks to this feature include privacy and institutional review board (IRB) concerns. Facebook's audience lookalike feature seems to involve using data collected whenever people are logged into Facebook, including data that are both public and relatively more private, including likes, posts, visits to other websites, friend networks, and friends' web-based behavior. This data use could raise potential privacy and IRB approval issues because it is not possible in IRB consent forms or information sheets to describe to potential participants what Facebook data of theirs will be used for the audience lookalike feature (this is proprietary) and it is not possible to obtain consent from their Facebook friend networks.

Principal Findings on Advertising Costs

Facebook-based recruitment for health-related research has been the focus of previous studies, allowing for cost and yield comparisons with our study. Looking at cost per advertisement click, Whitaker et al [21] reported a mean of US $0.57 across several studies (range US $0.20-US $1.74), whereas Ramo and Prochaska reported a mean of US $0.45 [35]. Our costs per advertisement click across campaigns are within this range (US $0.67, SD 0.19-US $1.56, SD 0.34). Cost per participant varies widely; Whitaker et al [21] found that the cost per participant ranged from US $1.36 to US $110.00 depending on study length and engagement. Although our cost per participant ranged from US $121.05 (SD 60.02) to US $171.66 (SD 97.37), we recruited for a 3-month study that involved daily engagement in a web-based group and complete cessation from smoking. We were able to generate detailed cost and yield findings because we directed our website developer to install a Facebook Pixel on our study website. This Pixel allowed us to track which Facebook advertisement campaign a query came from and determine whether the individual who queried applied to the study and participated. We, therefore, recommend that researchers install the Facebook Pixel.

Study Limitations and Strengths

Our findings on recruitment yields standardize for spending at US $140 per week, so they are relatively independent of costs. However, our findings on recruitment costs are limited by the fact that recruitment costs are strongly affected by study inclusion/exclusion criteria, participation time demands, and study benefits and incentives. Recruitment costs can also fluctuate daily and seasonally. In addition, we recruited throughout the continental United States for our web-based study, and studies that are more local may yield different outcomes. Moreover, our costs per yield for a Spanish language campaign may be overestimated because English fluency was a requirement for inclusion in our study. Studies with translated materials and no English-speaking requirements may find higher enrollments and lower costs.

A strength of our study is that it was a national study with a large sample size; 980 people were recruited overall. Furthermore, we examined Facebook advertising campaigns considering both yields and costs and considered 4 separate outcomes: advertisement clicks, queries, applicants, and participants. In addition, our study lasted for 61 weeks, allowing us to compare costs of Facebook recruitment both before and after a major Facebook privacy scandal. Our main goal was to innovatively test the efficacy of targeting specific zip codes on Facebook to reach ethnically or racially diverse populations. Advertiser intent can have ethical ramifications when utilizing zip code targeting, especially when protected characteristics are targeted such as race or ethnicity. As of August 2019, Facebook restricts audience targeting options, including zip code targeting in the case of housing, credit, or employment to help prevent discrimination [36]. In our case, advertiser intent is heath promoting, and therefore zip code targeting is justifiable.

Conclusions

Our main conclusion is that Facebook advertising campaigns that employ suitable zip code targeting can help to find and recruit blacks/African Americans and Hispanics/Latinos for web-based health-related studies.

Acknowledgments

This research was funded by the National Cancer Institute Grant # R01CA204356-04 and the Stanford Cancer Institute Grant # P30CA1244351. The sponsors were not involved in any of the studies or analyses.

Conflicts of Interest

Unrelated to this project, JP has provided consultation to pharmaceutical and technology companies that make medications and other treatments for quitting smoking and has received funding from Facebook for planning evaluation of a mobile health intervention. JP and CP have served as expert witnesses in lawsuits against tobacco companies.

Abstract

Background: The written format and literacy competence of screen-based texts can interfere with the perceived trustworthiness of health information in online forums, independent of the semantic content. Unlike in professional content, the format in unmoderated forums can regularly hint at incivility, perceived as deliberate rudeness or casual disregard toward the reader, for example, through spelling errors and unnecessary emphatic capitalization of whole words (online *shouting*).

Objective: This study aimed to quantify the comparative effects of spelling errors and inappropriate capitalization on ratings of trustworthiness independently of lay insight and to determine whether these changes act synergistically or additively on the ratings.

Methods: In web-based experiments, 301 UK-recruited participants rated 36 randomized short stimulus excerpts (in the format of information from an unmoderated health forum about multiple sclerosis) for trustworthiness using a semantic differential slider. A total of 9 control excerpts were compared with matching error-containing excerpts. Each matching error-containing excerpt included 5 instances of misspelling, or 5 instances of inappropriate capitalization (*shouting*), or a combination of 5 misspelling plus 5 inappropriate capitalization errors. Data were analyzed in a linear mixed effects model.

Results: The mean trustworthiness ratings of the control excerpts ranged from 32.59 to 62.31 (rating scale 0-100). Compared with the control excerpts, excerpts containing only misspellings were rated as being 8.86 points less trustworthy, those containing inappropriate capitalization were rated as 6.41 points less trustworthy, and those containing the combination of misspelling and capitalization were rated as 14.33 points less trustworthy (*P*<.001 for all). Misspelling and inappropriate capitalization show an additive effect.

Conclusions: Distinct indicators of incivility independently and additively penalize the perceived trustworthiness of online text independently of lay insight, eliciting a medium effect size.

Introduction

Trustworthiness of Online Health Information: Background, Context, and Importance

As of 2019, 90% of all British adults use the internet at least weekly [1], and as patients, they often search online for health information to solve their medical problems [2]; furthermore, they are likely to be influenced by the online information, including changing their health care decisions and their frequency of ambulatory care visits [3]. In a survey of 2200 adults with chronic health conditions in the United States who were active social media users, 57% used a health condition–specific website (eg, specializing in multiple sclerosis or rheumatoid arthritis) on a monthly basis, and 5% used such sites daily; half of the patients surveyed had asked a health-related question to others online within the previous 6 months, and 87% of those were seeking responses from other patients with the health condition [4].

In response to this explosion of unvetted potential sources providing online health care information that is acted upon, researchers, experts, and medical professionals have repeatedly expressed concern about the inaccuracy of online information and the limited ability of lay consumers to adequately assess its validity [2,5,6]. In particular, it has long been known that when lay users determine whether to use and trust online health care information, they are strongly influenced by nonmedical criteria that experts do not use [7-11]. Broadly, although academics favor a checklist approach of transparency criteria [12], the approach of nonexperts appears to be more variable and situation dependent, and it prioritizes factors such as ease of understanding and the attractiveness of graphic design [9]. More generally, in research on the factors that influence judgments of trust, all aspects of trustworthiness can be relational and depend on the type of person (or group being studied); major relational factors include accessibility, both cognitive as well as physical [13], and correctly accommodating language to the intended audience [14].

Understanding lay assessment of the trustworthiness of online health information is important because false online information presented to the general public, if believed, has the potential to undermine correct medical advice [15], to elicit unhealthy behavior [16], and to influence sociopolitical discourses on health care and other topics [17-19]. Sbaffi and Rowley’s [20] recent review of how laypeople assess the trustworthiness and credibility of online health information concluded that so far, much less research has been performed to understand what interferes with trust (we describe these as penalties to trustworthiness [21]), compared with what causes trust.

Trust and credibility are closely related to one another and information quality, although there remains disagreement among researchers as to the exact definitions of these terms. In general, the definitions emphasize the likelihood of information use, believability, reliability, and dependability [20,22]. Correspondingly, there is little evidence to suggest that the general population reliably make fine conceptual distinctions between trustworthiness and credibility of information.

Online health support often is divided into seeking information or emotional reassurance and can be gender specific (eg, prostate cancer vs breast cancer) and person specific [23,24]. Trustworthiness remains pertinent to online emotional reassurance and sharing, as shown by the many occurrences of large-scale hoaxes designed to manipulate emotions [8]. For example, between 2010 and 2011, a Macmillan cancer forum was inundated with posts in response to an elaborate hoax by a purported mother about her 6-year-old daughter struggling with cancer. On the exposure of the hoax (perpetrated by a lonely 16-year-old girl), many users of the forum—who had formed close online relationships with the supposed mother—refused to believe it had all been a hoax [25]. In light of the range of uses that online health information has for the general public, we contend that it is important to build knowledge of the factors that influence how trust and its absence are formed online beyond source analysis and fact checking. As this study shows, both linguistic and metalinguistic factors affect how trustworthiness is instinctively rated.

Theoretical Underpinnings for Factors Influencing Trustworthiness

The range of elements that influence online trustworthiness includes issues related to the sources (eg, author identification and the absence of advertising), issues related to the content (eg, a date stamp and inclusion of medical evidence), issues related to design and engagement (eg, inclusion of images), and issues affecting all the above (eg, the absence of typographical errors) [20,26]. For some time, credibility has been subdivided into aspects such as source credibility, message credibility, and media credibility, which strongly influence each other [22]. All such aspects of credibility include accessibility, which can be relational and cognitive as well as physical [13]. More recently, Sun et al [6] have divided the elements that influence consumer evaluation of online health information into 25 *criteria* and 165 *quality indicators*; criteria are rules that reflect notions of value and worth (eg, expertise and objectivity), whereas quality indicators are properties of information objects to which criteria are applied to form judgments (eg, the owner of the website and inclusion of statistics). In line with Diviani et al [5], Sun et al [6] have suggested that indicators can be positive or negative (in terms of trustworthiness), and that consumers’ perceived online health information quality could conceivably be measured by a small set of core dimensions (ie, a few groups of criteria might incorporate many of the quality indicators that explain most of the trustworthiness judgments).

So far, Lederman et al [8] have proposed a five-category model that highlights verification processes via the comparison of different websites or other online statements. This model includes argument quality, source credibility, source literacy competence, and crowd consensus. An extended six-category model [26] proposes that the lay reader may assess some or all of the following: reputation, endorsement, consistency with other sources, self-confirmation (agreement with the reader's own opinions), persuasive intent, and expectancy violation. For this research, we have adopted Lederman et al's [8] model of credibility; however, the choice among these models for this research is moot because all the models [5,6,20,22,26] are concordant with the idea that spelling errors will detract from judgments of trustworthiness (ie, they are negative quality indicators).

Incivility, Literacy Competence, and Errors of Writing Mechanics

Although institutionally produced websites and curated online health content (cf. [6]) will usually be both grammatically correct and civil, the responses by the general public may be uncivil [27], and patient-authored text is known to have many misspellings [28] (and so do discharge summaries written by doctors [29]). Inappropriate capitalization (including inappropriate capitalization of entire words, sometimes called online *shouting*) and misspelling are examples of errors in literacy competence [8] and writing mechanics [30]; writing mechanics is defined as elements of a language that only manifest when communication is in written form. Both inappropriate capitalization and misspelling have been highlighted by qualitative investigations as explicit criteria used by lay readers in judgments of online credibility [8,31]. The rationales given to explain why these two error types undermine trustworthiness are that either (1) the errors imply a lack of intelligence (expertise, ability, authority, and education) [8,32,33] or (2) that they suggest a lack of motivation (objectivity, attention to detail, and conscientiousness) to be trustworthy [34,35]. The term incivility is used to describe this latter lack of motivation or effort to make statements that are compliant with rules of communication. Hargittai [33] distinguishes between spelling errors (errors because of the levels of education or social inequalities) and typographical errors (errors because of accidentally hitting the wrong keys on the keyboard). The fact that these errors are not corrected during proofreading is another form of incivility. Incivility implies a lack of respect for the reader, the platform, and the rules of social exchange [36,37], and it is fundamentally relational. Quantitative research on incivility in the mainstream World Wide Web demonstrates that civil statements are rated as more trustworthy and influential than uncivil ones [38,39].

Integration Versus Heuristics: Lay Judgments Based on Multiple Cues

The reader who must judge unvetted online health information is faced with a wealth of cues that indicate the degree of trustworthiness, and those cues may have contradictory effects (eg, a cogent message that is misspelled). There are three broad theories for how individuals (both lay and expert) make judgments based on multiple cues. The rational approaches are represented by the information integration model [40], in which an individual accounts for all the different pieces of information by a complex (but often subconscious) mathematical process that is usually based on addition, multiplication, or averaging; extensive observations of integration in judgments occur across cultures and individuals. This is the process that Sun et al [6] allude to when they propose that the consumer integrates the relevant trustworthiness criteria and quality indicators in a "complex cost-benefit analysis." In 2003, Fogg's [41] Prominence-Interpretation Theory proposed explicit mathematical relationships for how to predict the effects of multiple factors on credibility, but the theory never detailed how to measure the relevant quantities independently. Computational models typically assume that the elements of incivility (eg, inappropriate capitalization) act together either additively or nonlinearly [42-44], although hypothesis-led proof for this assumption is minimal. The elucidation of this integration is only just starting in the literature [45], and the relative importance of each indicator in this intuitive cost-benefit analysis remains unknown; the relative values for each cue may be elucidated empirically by statistical methods such as regression, but it is unlikely that these values would be explicit or transparent in the minds of most lay decision makers. This is an area that needs to be further researched.

An alternative theory to cost-benefit analysis (ie, for how judgments are made based on multiple cues) is the process-level cognitive perspective [46]; this has been made famous by the heuristics and biases research program from behavioral economics [47]. Heuristics are rapid cognitive strategies or shortcuts (either explicit or subconscious) formulated as practical, bounded rational decision systems for multiple cues that can be more transparent than complex cost-benefit analyses, for example, hierarchical lexicographic decision models [48]. In a take-the-best judgment [49], first, a single cue (the most important one) is searched for in the environment and considered independently of all others, and if a tie or no clear result occurs, then the second most important cue is sought and decided upon, and so on. For example, when deciding whether you have the right of way when driving your car through an intersection, first, you follow the signal of any policemen present, and only if there are no police present, do you seek and consider a traffic light (including a temporary traffic light for construction), and only if there are no traffic lights present, do you then consider static road markings and the positions of the other cars.

In biased heuristics, only a limited subset of information (often only one cue) is used to make a fast and ecological judgment outside of conscious awareness [46]; when biased, these heuristics are used to support preferred or preconceived outcomes. With biased heuristics, the prioritization of the cue, and even the cue's basic validity for the judgment being made, is dubious. Such biased heuristics have been used to explain seemingly irrational preferences that individuals make in situations involving slot machines and organ donation [50]. Examples of biased heuristic processes include representativeness, where some cues are weighted disproportionately compared with their real representativeness—and availability—where a cue that is easily recalled (such as occurs with recency and news) determines the judgment. None of these judgment models so far proposed have explicitly assessed specific issues within literacy competence.

Determining the Criteria and Weighting of Judgments Based on Multiple Cues

A key feature of heuristics is that they are typically made subconsciously, and that post hoc explanations for such choices are often self-serving justifications or rationalizations [51]. That is, in the case of heuristics, the decision maker does not have privileged information on how the judgment was made, and furthermore, the decision maker can be wrong about themselves [52]. For example, university students have been shown to greatly overestimate how much they actually learned from excellent lecturers (conflating it with how much they feel they learned, which is discounted by effort and exertion) [53]. This creates potential issues for researchers, in which insight-based techniques (both qualitative interviews and quantitative questionnaires) can lead to judgments and explanations of causes that are inaccurate because of demand characteristics or social desirability [54,55]. It has long been known that when evaluating credibility (eg, website privacy policy), the importance of factors that lay individuals say they would use to make their judgment diverge from the factors they are observed to use [41]. Recent sophisticated measurements suggest that although multiple factors can interact when quantifying perceived credibility (of information for an online health forum), these interactions do not support Petty and Cacioppo’s Elaboration Likelihood Model (ELM) [56]. Furthermore, there is a gap in the literature for any data showing how spelling errors interact with other writing mechanics violations that might also affect trustworthiness [57]. This suggests that lay insight into the influences on their perceptions of trustworthiness are imperfect, and that research on trustworthiness should be supplemented by approaches that do not rely on such insight.

To avoid insight bias from our lay participants, the approach of this study is to compare and contrast *marginal differences* in penalties to trustworthiness elicited by different combinations of literacy or writing mechanics violations. Our experiments on changes in marginal trustworthiness were specifically organized so that the participating healthy volunteers were unaware that the experiment tested the effects of capitalization or misspelling *per se* (with full institutional ethical approval). We did not explicitly ask lay individuals for their beliefs regarding how their process for judging message credibility incorporates quality indicators relating to source credibility and media credibility. That is, instead of asking directly, “How much less would you trust a web post that is misspelled?” we simply presented the participants with some posts that had misspellings and asked the same question as usual, “How trustworthy do you find this information?” while subtly varying misspelling and capitalization (ie, *shouting text*, not acronyms or beginnings of sentences).

Research Questions

The research questions (RQs) were as follows:

- RQ1: Do errors in writing mechanics and incivility lead to marginal changes (ie, without signposting) in judgments for message trustworthiness?
- RQ2: Are the marginal effects of incivility, such as with inappropriate capitalization, on trustworthiness judgments quantitatively comparable with the known effects of writing mechanics such as spelling errors?
- RQ3: How, if at all, do the effects of writing mechanics (eg, spelling errors) and incivility (eg, inappropriate capitalization) integrate? Is there a ceiling effect or a binary effect in which once a message source is judged as incompetent, no further trustworthiness penalty is added to the judgment (similar to a take-the-best heuristic) [49]? Or is there some additive, multiplicative, synergistic, or otherwise integrative function that increases the penalty on the judgment to a new higher level when both cues are present [40]?

Methods

Participants, Recruitment and Ethical Approval

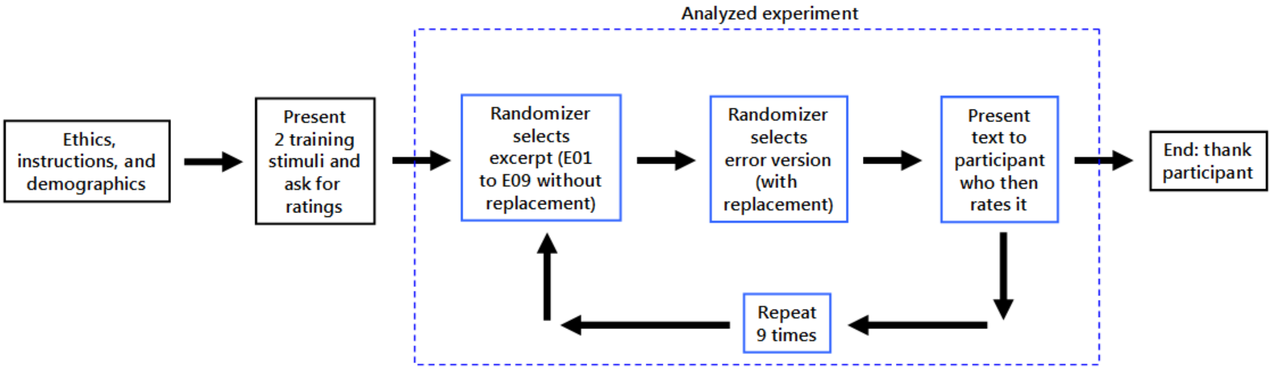
The project was approved by our local ethics committee (Brighton and Sussex Medical School’s Research Governance and Ethics Committee, University of Sussex, approval 16/044/WIT). All experiments were performed according to the Declaration of Helsinki. All individuals provided informed consent via a welcome page in each online study. Participants were recruited via the Prolific website. We specified that the recruitment should focus on UK-based members of the public. Participants consented to participate with the understanding that the research concerned *responses to online text*; none of the advertising, web URLs or experimental information to the participants mentioned that the experiment was related to graphics, formatting, incivility, and spelling. This feature of the advertising was approved by our ethics committee, not least because the paragraphs were not considered misleading or potentially emotionally adverse.

Study Design Process

The study design was a confirmatory, cross-sectional experiment with a balanced incomplete block design; it was a randomized experiment with lay participants, each of whom experienced only a limited number of the possible options. The total number of experimental excerpts that were tested in the entire cohort was 36; there were 9 excerpts, each in 4 possible versions: no errors, inappropriate capitalization only (Caps only), misspelling only, or the combination of both errors. The stimulus texts (and the versions) are shown in the Multimedia Appendix 1. There were two additional paragraphs that always appeared as the first two stimulus texts, which were training stimuli. The training stimuli were not labeled as being different from other stimuli in any way and were never included in the statistical analyses. The only purpose of the training stimuli was to allow participants to familiarize themselves with the rating task and with the range of the trustworthiness scale: training stimulus 1 was quite believable (mean trustworthiness rating 54.33, SD 23.39; n=301), and training stimulus 2 was less plausible (mean trustworthiness 40.20, SD 25.80; n=301; $P<.001$, paired t test).

Each participant experienced and rated only 9 (of the possible 36) experimental excerpts, and those 9 included exactly one version of each excerpt, and among those 9, that participant would experience a mix of different error types (Figure 1). For example, participant number 001 experienced the capitalization-only version of excerpt E07 and then the *both* *errors* (capitalization and misspelling) version of excerpt E02. This double randomization prevented any participant from seeing the same excerpt twice.

Figure 1. Experiment design: what each participant experiences.



The goal was to present to participants a set of coherent text excerpts of similar lengths (70-100 words) on the topic of multiple sclerosis, each excerpt being a coherent answer to a question. The rationale for presenting excerpts in a question-then-answer format was that it was possible to ask whether readers trusted the advice enough to believe it or act upon it. To make these excerpts, a range of comments were found in the public domain (Table 1); these texts often had to be edited substantially to fit within the word count or to avoid explicitly endorsing commercial products (see Multimedia Appendix 2 for a comparison of the original and presented texts).

Initially, the excerpts and the presentation system were tested online by a small group of testers, who then provided verbal feedback on the test to the experimental team. After that, a cohort of 40 participants was recruited online to test the paragraphs and demonstrate that the paragraphs elicited similar standard deviations in ratings (19-28 units out of 100) and elicited a wide range of mean trustworthiness ratings (from 20 to 70). These excerpts were to be presented either as they were (*no errors* or the negative control) or in one of the three error versions stated above.

Table 1. Sources of excerpts on multiple sclerosis.

Code	Brief topic description	Website	Length
L01	Numerous artificial sweeteners	blogspot.com	78

Text Interventions

For the error versions of the texts (inappropriate capitalization or misspelling), we wanted to include 5 of the relevant errors per excerpt (a total of 10 errors for the combination of both errors version), with the errors spread throughout the excerpt (rather than bunched together). In excerpts where inappropriate capitalization was required, there would be 5 *sets* of words or phrases. Normally, a set was 1 or 2 words, although one of the 5 sets had to be a 4-word series. The priorities for selecting words to capitalize were (in this order) as follows:

- Adverbs (especially those suggesting extremity such as *very* or *never*)
- Judgments (*rubbish*, *hopeless*, and *horror*)
- Strong emotions (*worried* and *angry*)
- Words implying danger (*fatal* and *death*)
- Amounts (*all*, *every*, and *ten*)
- Adjectives (rather than nouns)
- Action verbs (especially gerunds)
- Conjunctions (*and*)

To verify that each word that we capitalized was naturally capitalized on the web, we analyzed words that were capitalized online on Twitter. We used the Claritin corpus, which is a crowdsourced data set of all the Twitter tweets that contained the word *claritin* in the month of October 2012 [58]. This corpus has some 4900 tweets, and we used MATLAB (MathWorks) to find all the words that were in all capitals (which did not have a hashtag or an at-sign in them); this resulted in a list of 343 capitalized words (Multimedia Appendix 3), many of which were short words, acronyms, and internet memes. From this list of words spontaneously capitalized on the web, we selected words in our excerpts to capitalize.

The rationale for how we selected words to misspell was that misspellings should be quite noticeable, and that the meaning of the words should remain clear to the reader even when misspelled. We avoided homonyms and words that looked plausibly English when misspelled. To make sure that misspelled words were noticeable, short words were preferred, or we placed the misspellings in the first syllable of a multisyllable word. In addition, one of the misspelled words had to be in the first 5 words of a paragraph. The misspelled word had to be completely understandable (in the absence of other words or context) even when misspelt. Thus, a misspelled word with missing or added letters should be pronounceable in English (eg, *yu* plainly means *you*). The types of misspellings were as follows:

- Swap one letter for another letter that is next to it on a qwerty keyboard (*pisitive*)
- Double a consonant (*esstimate*)
- Double a vowel or add an extra vowel (*theere*)
- Leave out a vowel (*expsure*)

To verify that each word that we misspelled was naturally misspelled on the web, we searched for the misspelled word along with the words *health* and *forum*; if we could not find at least two examples of a misspelling on online health forums, we did not use it. A complete listing of the misspellings and where we found them online is in Multimedia Appendix 4.

Study Delivery

The study was presented to participants using the Qualtrics portal, which allows for a wide range of question types and keeps track of answers and total response time. A full description of the survey in the Checklist for Reporting Results of Internet E-Surveys format [59] is included as part of the Multimedia Appendix 5 for this paper. The web-based study welcome page explained in brief what the study was about and what it entailed (estimated 8 min participation time, including reading the ethics and filling in demographics), the ethics of the study (include the ability to withdraw at any time), and a brief complaints procedure. The ethics page explicitly excluded participants aged younger than 18 years or those from vulnerable populations. A pointer to a full-length participant information sheet (3 pages) was shown; the welcome/ethics page had an “I agree” button at the bottom. After the welcome page, participants filled in a brief multiple-choice demographics page, which included questions on gender, age, field of work (eg, health care, agriculture, and retired), and familiarity with the English language/Roman alphabet. All demographic questions included an option for “rather not say.” After the demographics page, participants saw the instructions page and then were launched into the experimental ratings pages.

Each ratings page consisted of a short excerpt of text (which was randomized as to whether or not it had the spelling or capitalization errors), followed by a horizontal slider for rating how *trustworthy* the participant found the statement to be; the slider had anchors of *completely untrustworthy* (Figure 2, left) and *completely trustworthy* (Figure 2, right). Although the data collection was numerical (0-100, left to right), there were no numerical cues or tic marks seen by the participants. The instructions to the participants for the trustworthiness ratings were, “If you find something trustworthy, you would be prepared to act upon it; an untrustworthy statement you would ignore, and a rating in the middle represents information where you would want more proof or confirmation that it is correct.” As explained in the instructions to participants, each stimulus excerpt was written as if it was an answer to a question written on an unmoderated health forum, with a specific focus on multiple sclerosis. Multiple sclerosis was chosen as a topic because the information was obviously important, but healthy participants would be unfamiliar with the veracity of each statement; thus, we predicted that the trustworthiness ratings would be more susceptible to nonverbal cues. The questions were as follows: (1) Is multiple sclerosis preventable? (2) How risky is Tecfidera as a treatment for multiple sclerosis? and (3) Does multiple sclerosis decrease intelligence/IQ? The nominal responses to these questions were the experimental stimulus excerpts being rated.

Figure 2. Unnumbered horizontal slider for trustworthiness ratings.

Study Design, Analysis, and Statistics

Sample Size

To detect a difference in rating scores between two groups (ie, no errors vs misspellings, inappropriate capitalization, or both), with 80% power at the 5% significance level, assuming the standard deviation within each group is 25 and the difference between groups is 15 (equivalent to a medium effect size of 0.517), would require 60 participants per group (120 total). Each participant was asked to rate 9 text excerpts, randomly divided between the 4 conditions, and assuming an intraclass (ie, within participant) correlation coefficient of 0.185 gives a design effect of 2.48. The product of the design effect and the sample size for a nonrepeating experiment is 2.48×120≈300 total.

Modeling

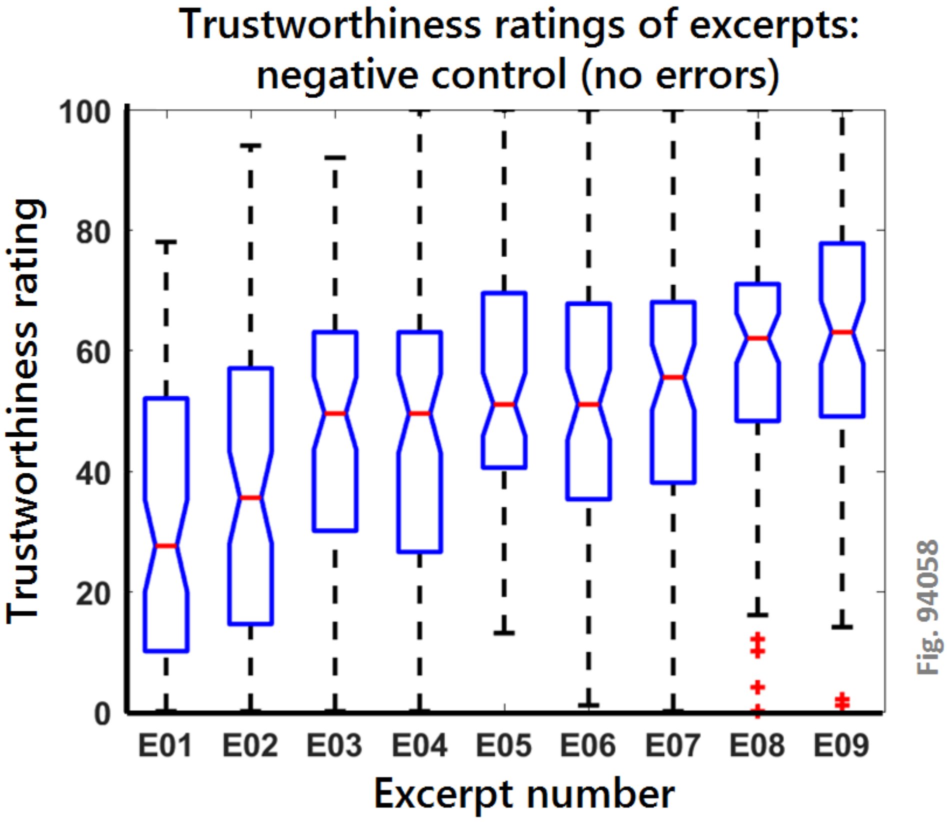
Linear mixed effects (LME) models were fitted in Stata version 16.0 using the *mixed* command. Residuals were checked for normality and homoscedasticity at the cluster and individual levels. Where the assumption of residual homoscedasticity was not appropriate, robust standard errors were used to allow for the calculation of appropriate 95% CIs and *P* values [60].

Results

Differences Between the Paragraphs

We ran an experiment in which we gathered data from 301 volunteers, each making 9 experimental observations (2709 ratings in total). We estimated that this task (rating 11 excerpts plus instructions and demographics) would take 8 min; in fact, it took a mean time of 6.25 min (mean 375.74 seconds, SE of mean 12.94 seconds). The median trustworthiness ratings of each of the excerpts (E01 to E09) in the negative control condition (ie, without any errors or incivility) are shown in the box and whisker plot in Figure 3. On each box, the red line in the center indicates the median, and the bottom and top edges of the box indicate the first and third quartiles, respectively. When the notches for two boxes do not overlap, this implies that the true medians do differ with 95% CI. The whiskers extend to the most extreme data points not considered outliers, whereas outliers are shown using red plus signs; outliers are any points that fall more than 1.5 times the IQR away from the main box. Excerpt 01 generally elicits low ratings of trustworthiness (median 27.5), whereas excerpts 08 and 09 generally elicit high ratings of trustworthiness (medians 62 and 63, respectively). As illustrated by the nonoverlapping notches, these two sets of excerpts elicit significantly different ratings of trustworthiness, which has been true in all our previous cohorts rating these excerpts for trustworthiness (data not shown). Excerpts 03, 04, 05, and 06 all elicited median ratings in the middle range from 45 to 55, whereas excerpt 02 is a transitional excerpt between E01 and the middle range and E07 is a transitional excerpt between the middle range and the most trustworthy excerpts.

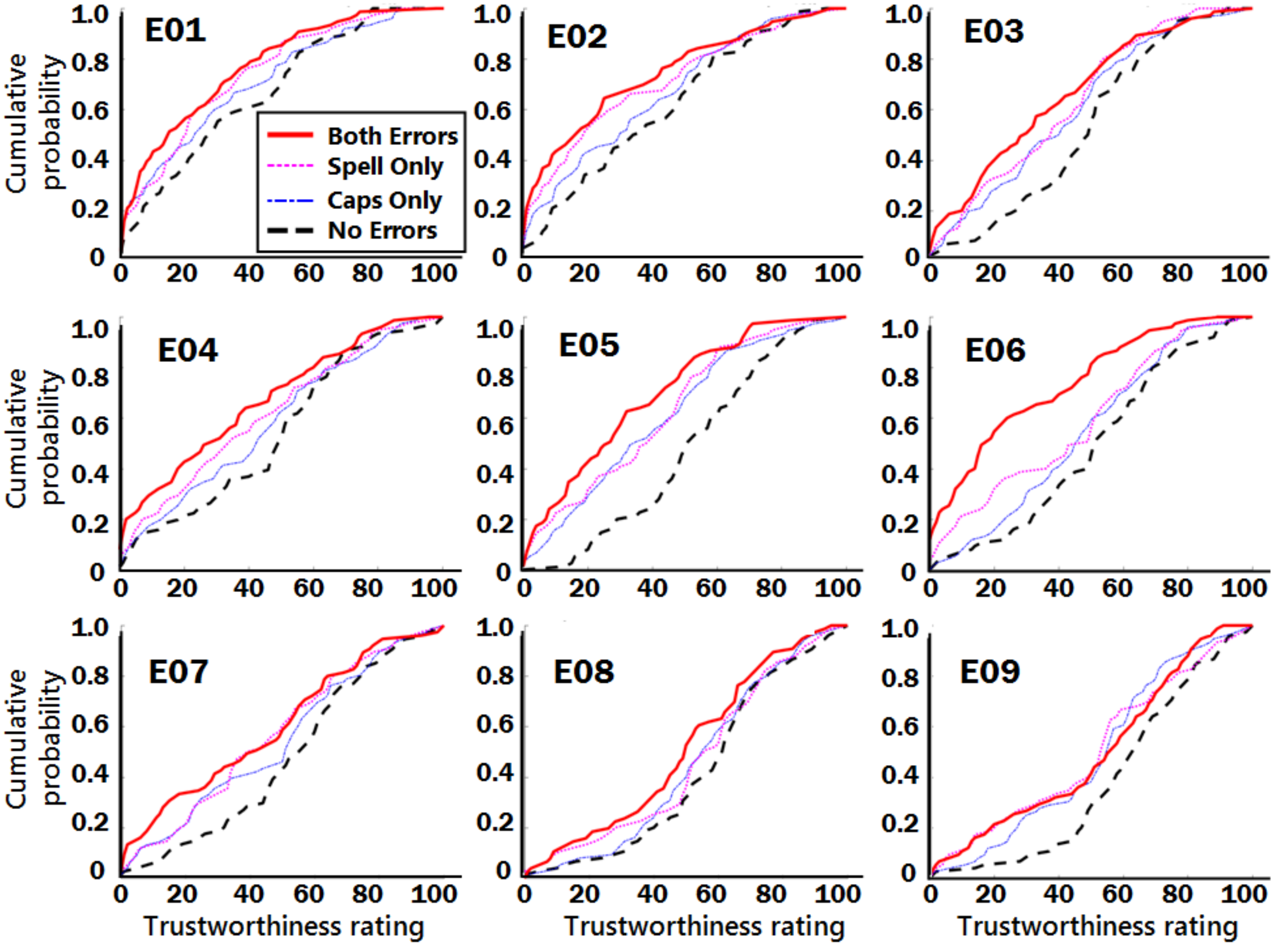
Figure 3. Trustworthiness ratings of the different excerpts in the negative control (no errors) condition. For each box, N=75.



Cumulative Distributions Shifted Left by Errors

Figure 4 shows how the errors in writing mechanics and incivility led to changes in the cumulative probability distributions for each of the excerpts. As expected, for each excerpt, compared with the negative control with no errors (black, thick dashed line), all three alterations (inappropriate capitalization (blue, thin dot-dash line), misspelling (magenta, thin dotted line), and both errors together (red, thick solid line) led to a decrease in the ratings of trustworthiness (ie, a leftward-upward shift in the curve). For most of the excerpts, at most points on the cumulative distribution curve, the combination of errors (both inappropriate capitalization and misspelling) led to decreases in trustworthiness ratings (ie, a shift left and up) compared with either of the single errors. That is, the lines for inappropriate capitalization only (blue, thin dot-dash) and misspelling only (magenta, thin dotted) fall between the thick black dashed line (no errors) and the red solid line (both errors); this result suggests that the two errors together have an additive or integrative effect.

Figure 4. Cumulative probability distribution plots for each excerpt (E01 to E09), comparing the alternative writing errors (lighter colored lines) with negative control (thick, black dashed line).



Mixed Linear Effects Model With Four Conditions of Alteration

We tested these data in a mixed linear effects model (model 1), where trustworthiness rating was the dependent variable, whereas alteration (no errors/misspellings/inappropriate capitalization/both misspellings and inappropriate capitalization) and excerpts (1-9) were included as fixed effects. A random effect for participant was included in the model to account for clustering of observations within volunteers. The reference group/condition for this model was E05, with no literacy errors. This model (and the following model) was calculated with robust standard errors [60] to allow for the heteroskedasticity of the residuals. The results of model 1 are shown in Table 2. The intracluster correlation (correlation within the individuals) coefficient estimate for model 1 is 0.334 (95% CI 0.287 to 0.384).

There is strong evidence against each of the null hypotheses that inappropriate capitalization only (result 1), misspelled only (result 2), and both errors (result 3) do not affect trustworthiness ratings compared with the negative control group; stated positively, our data suggest that there is a statistically significant penalty to trustworthiness for inappropriate capitalization (result 1), misspelling (result 2), and for both errors together (result 3). Inappropriate capitalization reduces trustworthiness ratings by −6.41 (95% CI −8.96 to −3.86), and misspelling reduces trustworthiness ratings by −8.86 (95% CI −11.61 to −6.11). The effect on trustworthiness ratings of combining both inappropriate capitalization and misspellings together is −14.33 (95% CI −17.11 to −11.55), which appears to be an additive effect.

Our further analysis aimed to test whether there was likely to be either an additive or integrative effect [40] of combining inappropriate capitalization and misspelling. Such an effect should lead to a significantly larger trustworthiness penalty when both error types are combined compared with either error individually. To test for this, an alternative specification of the LME model of the same data was formulated (model 2). In model 2, the condition *both errors* was specified as an interaction between 2 binary variables, (1) misspelling and (2) capitalization errors, instead of considering all the errors as 4 conditions in a categorical independent variable. The specification of the rest of the model was identical to model 1. In this model (Table 3), the main effects and an interaction between them provide no evidence for an interaction effect between the 2 variables; that is, the main effects for inappropriate capitalization only and for misspelled only were as in the original model 1 (Table 2), whereas the coefficient for the interaction was not significantly different from zero. This supports the interpretation that the effects of the two error types are additive, rather than partially summative or synergistic.

Table 2. Mixed effect model 1 for trustworthiness rating, with errors and excerpts as fixed effects and a random effect for the clustering of data by participant.

Categorical variables	Coefficient	Robust SE	*P* value	95% CI
Alteration				
Caps only	−6.41	1.30	<.001	−8.96 to −3.86
Misspelled	−8.86	1.40	<.001	−11.61 to −6.11
Both errors	−14.33	1.42	<.001	−17.11 to −11.55
Excerpt				
E01	−11.94	1.71	<.001	−15.28 to −8.59
E02	−8.29	1.58	<.001	−11.38 to −5.19
E03	−0.70	1.56	.65	−3.77 to 2.36
E04	0.03	1.54	.98	−2.99 to 3.05
E06	1.80	1.62	.27	−1.39 to 4.98
E07	6.19	1.71	<.001	2.83 to 9.55
E08	14.75	1.53	<.001	11.75 to 17.75
E09	14.22	1.46	<.001	11.36 to 17.09
Constant	47.06	1.53	<.001	44.06 to 50.06

Table 3. Model 2: Alternatively specified linear mixed effect model with 2 binary variables for capitalization and spelling errors and an interaction term to account for combining both types of error (all unlisted values are identical to above).

Categorical variables	Coefficient	Robust SE	*P* value	95% CI
Alteration				
Caps only	−6.41	1.30	<.001	−8.96 to −3.86
Misspelled	−8.86	1.40	<.001	−11.61 to −6.11
Interaction	0.94	1.68	.58	−2.34 to 4.24

The output for model 1 shows the following comparisons: (1) capitalization only versus no errors, (2) misspelled only versus no errors, and (3) both errors versus no errors. Table 4 shows the additional comparisons between (4) capitalization only versus misspelled only, (5) both errors versus misspelled only, and (6) capitalization only versus both errors.

Comparison 4 indicates there is weak evidence (*P*=.06) against the null hypothesis of no difference between the effects of capitalization only and misspelled only. That is, misspelled only leads to a larger trustworthiness penalty by −2.45 (95% CI −5.02 to 0.12) compared with capitalization only. There is strong evidence against the null hypothesis of there being no difference between the effects of capitalization only versus both errors combined (comparison 6). Compared with capitalization only, the combination of both errors significantly reduces trustworthiness ratings by a further −7.92 (95% CI −10.28 to −5.56). Similarly, there is strong evidence against the null hypothesis of there being no difference between the effects of misspelled only and the combination of both errors (comparison 5). Compared with misspelling only, the combination of both errors leads to a further penalty to trustworthiness ratings of −5.47 (95% CI: −7.83 to −3.11).

Table 4. All possible alterations tested in between-group comparisons (model 1).

Comparison	Coefficient	Robust SE	*P* value	95% CI
(1) Caps only versus no errors	−6.41	1.30	<.001	−8.96 to −3.86
(2) Misspelled versus no errors	−8.86	1.40	<.001	−11.61 to −6.11
(3) Both errors versus no errors	−14.33	1.42	<.001	−17.11 to −11.55
(4) Caps only versus misspelled	2.45	1.31	.06	−0.12 to 5.02
(5) Both errors versus misspelled	−5.47	1.20	<.001	−7.83 to −3.11
(6) Caps only versus both errors	7.92	1.20	<.001	5.56 to 10.28

Statistically Significant Differences Between the Excerpts

In model 1, when compared with E05, the effect of the various excerpts' contents on trustworthiness ratings varies from −11.93 to 14.75 (a range of 26.68). This range is roughly twice as large as the effect of both errors (−14.33), suggesting that the errors in incivility and writing mechanics that we tested can together have an overall effect of nearly half of the effects of the content of the excerpts we tested.

Discussion

Original Contributions

This study sought to quantitatively determine how two different errors of writing mechanics (contributing to incivility) combine to penalize subjective ratings of trustworthiness in the medically relevant context of materials typical of an unmoderated online health forum. Using an LME model of a suitably powered study, we found that all three interventions (inappropriate capitalization, misspelling, and the combination of the two) were significantly different from the negative control (no added errors or incivility), which clearly answers RQ1. The data also show that (for these 70- to 100-word long excerpts about multiple sclerosis), the trustworthiness penalty for 5 instances of inappropriate capitalization was of a similar magnitude to the penalty for 5 instances of misspelling. Note that there was a trend for the penalty of misspellings to be larger, but as a generalized rule, the 2 are similar in magnitude, and the precise difference will depend on exactly how many words and which words are capitalized or misspelled. This finding answers RQ2. Finally, with a combination of different LME models, the data show that the combination of two different types of errors had a significantly greater trustworthiness penalty than either of the error types alone, and that the effect in this study was almost perfectly additive (RQ3); thus, the effects of the combination of errors were integrative [40] rather than a simplified heuristic such as take-the-best [48], multiplicative, or affected by ceiling effects in this study. This begins to answer the question recently posed of how spelling interacts with other quality indicators on credibility [57]. To the best of our knowledge, this is the first study that was specifically designed to test and quantify these kinds of specific additive effects on trustworthiness independently of the lay participants' insight.

We also showed that the stimulus excerpts that we designed are appropriate for studies that test the trustworthiness of online health information independently of lay insight. Although our study did not preclude lay insight (ie, participants might notice that some words were misspelled), the study was not dependent on such insight, which is useful for interrogating intuitive evaluations of information (ie, cost-benefit analyses [6]). In this study, the semantic content of the excerpts engendered consistent effects on trustworthiness ratings (at least among this type of online psychology experiment cohort, see Figure 3). In addition, this is the first time that numerical values have been gathered for the isolated effects of inappropriate capitalization.

The Results in Context

This study reaffirms an earlier observation that incivility decreases message credibility [38,39]. As suggested previously, inappropriate capitalization (shouting) is histrionic and induces a strong effect of incivility on readers' subjective ratings [37]. In our study, the effect of shouting text showed a trend for eliciting a smaller trustworthiness penalty than the effect of similar quantity of misspelling. One could easily speculate about new experiments where we might change the quantities of literacy errors; our experiment used either 5 misspellings or 5 shouting phrases, but one could run experiments to titrate errors, for example, to determine the relative effects of 3 misspellings or 10 inappropriate capitalizations. Furthermore, the effects of text shouting may be moderated by whether the statements are controversial [38]. We deliberately chose statements about multiple sclerosis that would be unfamiliar to the general public. This lack of familiarity makes the content and context not particularly emotional or controversial, likely weakening the effect of inappropriate capitalization.

The debate between how accessibility (ie, cost and speed) versus information quality (ie, accuracy and presumed benefit) quantitatively affect the use of (and search for) information continues [13]. Categorical frameworks have long been proposed to provide a theoretical underpinning for the factors, grouping specific elements that influence perceptions of trustworthiness in a variety of ways. The most well-known 2-category grouping of factors affecting how people respond to communication is Petty and Cacioppo's ELM for persuasion [56], in which elements contributing to a central pathway (eg, argument quality) are complemented by seemingly less rational elements that contribute to a peripheral pathway (eg, website design) [20,41]. Another two-category persuasion model that has been used to explain online trustworthiness is Chaiken's dichotomy of heuristics versus systematic information [61,62]. In both the Heuristic-Systematic Model and the ELM, diminishing motivation/involvement (or diminishing user dependency [45]) is associated with a switch from focusing on the effortful systematic evaluation of information (quality) to low-effort heuristics (accessibility).

In purchasing decisions, the type of product affects how strongly grammar and mechanics errors affect credibility [30]. In particular, *experience goods* (nontechnical items such as body lotion that are used personally) are more affected by grammar and writing mechanics than *search goods* (technical items such as printers). The implication is that when objective signals about trustworthiness are absent, heuristics play a stronger role [56,61]. In this study, where laypersons made judgments about unfamiliar medical issues, we might expect to find a stronger response to misspelling and capitalization. A necessary future approach is to repeat this experiment with multiple sclerosis patients who would exhibit user dependence when evaluating the statements [45].

Limitations

Our study had several important constraints. We deliberately tested laypersons' judgments on unfamiliar ideas about multiple sclerosis and showed that literacy errors can have a strong effect. Nevertheless, this effect may be smaller in a cohort that is more dependent on knowing the information. In particular, if readers are dependent, then preexisting points of view and feeling of *homophily* [63] will influence perceived credibility, in a way that would not influence the general public with less interest in statements for and about multiple sclerosis.

It is also notable that in this study, the highest mean trustworthiness rating was 62.3 (0-100 scale), despite the statement being medically correct. Multiple factors may account for why this mean rating is not higher for trustworthiness. For example, participants in this psychology experiment saw the statements *in vacuo*, so that they could not verify the statement, check source credibility, or look for crowd consensus [8]. In real-life situations, other aspects of trustworthiness may dominate, and among some individuals, there may be ceiling and floor effects within this dataset, given the very wide standard deviations.

Conclusions

Incivility and literacy competence are proposed factors in how lay web users assess the trustworthiness of online health information. These results support Lederman et al's [8] theory of credibility assessment in online forums; the results also fit with Anderson's [40] description of integrative assessment of multiple cues. Here, we have shown that literacy competence errors have additive effects. The additive effects are strikingly precise. This implies that when people make seemingly rapid judgments about the trustworthiness of online text—no more than rough estimates—that their intuitive estimates seemingly add up quite accurately, at least at the population level. This completely vitiates binary models of judgment where a writer is judged as either competent or incompetent, with no further penalty for additional errors in writing mechanics [57]. The implication for writers is that for this level of errors (5 in 1 paragraph), multiple errors can add up.

Many other factors also contribute to trustworthiness, notably the argument quality of the content (logic), verification with other sources, reference credibility, and crowd consensus [8]. How these additional factors interplay with literacy competence will require further extensive research. A start would be to determine how persons with multiple sclerosis (with similar education levels to our current cohort) respond to these stimulus excerpts, as those readers would understand the information in a more self-relevant context.

Acknowledgments

The authors gratefully acknowledge Tom Ormerod and the School of Psychology at the University of Sussex for access to Qualtrics. The authors acknowledge Matthieu Raggett for information technology set up. The authors also acknowledge the BSMS Independent Research Project program for funding. Finally, the authors acknowledge the late Fayard Nicholas for the original idea on civility.

Authors' Contributions

HC, HW, GT, BM, AN, and CW conceived the experiments. HW, GT, CW, and JR conducted the experiments. HW, CJ, and GT analyzed the results. CJ performed the statistical analyses. HW, GT, and HC drafted the manuscript. All authors reviewed the manuscript.

Conflicts of Interest

BM owns and JR worked for a commercial enterprise (Dalton Maag) that creates typefaces and graphical designs for commercial clients. AN acts as an ad hoc Scientific Consultant for Dalton Maag. This enterprise and those authors will not benefit directly or indirectly from data supporting incivility, misspelling, or shouting text. HW, GT, CW, CJ, and HC have no competing interests to declare.

Abstract

Background: Three main changes were implemented in the Australian National Cervical Screening Program (NCSP) in December 2017: an increase in the recommended age to start screening, extended screening intervals, and change from the Papanicolaou (Pap) test to primary human papillomavirus screening (cervical screening test). The internet is a readily accessible source of information to explain the reasons for these changes to the public. It is important that web-based health information about changes to national screening programs is accessible and understandable for the general population.

Objective: This study aimed to evaluate Australian web-based resources that provide information about the changes to the cervical screening program.

Methods: The term *cervical screening* was searched in 3 search engines. The first 10 relevant results across the first 3 pages of each search engine were selected. Overall, 2 authors independently evaluated each website for readability (Flesch Reading Ease [FRE], Flesch-Kincaid Grade Level, and *Simple Measure of Gobbledygook* [SMOG] index), quality of information (Patient Education Materials Assessment Tool [PEMAT] for printable materials), credibility (*Journal of the American Medical Association* [JAMA] benchmark criteria and presence of Health on the Net Foundation code of conduct [HONcode] certification), website design, and usability with 5 simulation questions to assess the relevance of information. A descriptive analysis was conducted for the readability measures, PEMAT, and the JAMA benchmark criteria.

Results: Of the 49 websites identified in the search, 15 were eligible for inclusion. The consumer-focused websites were classed as *fairly difficult to read* (mean FRE score 51.8, SD 13.3). The highest FRE score (easiest to read) was 70.4 (*Cancer Council Australia Cervical Screening Consumer Site*), and the lowest FRE score (most difficult to read) was 33.0 (*NCSP Clinical Guidelines*). A total of 9 consumer-focused websites and 4 health care provider–focused websites met the recommended threshold (sixth to eighth grade; SMOG index) for readability. The mean PEMAT understandability scores were 87.7% (SD 6.0%) for consumer-focused websites and 64.9% (SD 13.8%) for health care provider–focused websites. The mean actionability scores were 58.1% (SD 19.1%) for consumer-focused websites and 36.7% (SD 11.0%) for health care provider–focused websites. Moreover, 9 consumer-focused and 3 health care provider–focused websites scored above 70% for understandability, and 2 consumer-focused websites had an actionability score above 70%. A total of 3 websites met all 4 of the JAMA benchmark criteria, and 2 websites displayed the HONcode.

Conclusions: It is important for women to have access to information that is at an appropriate reading level to better understand the implications of the changes to the cervical screening program. These findings can help health care providers direct their patients toward websites that provide information on cervical screening that is written at accessible reading levels and has high understandability.

KEYWORDS

cervical screening; internet; consumer health information; Australia; papillomavirus infections

Introduction

Background

In Australia, the latest figures for cervical screening from 2017 to 2018 show a 2-year participation rate of 53% for women aged 25 to 69 years [1] and an overall incidence of cervical cancer at 7 cases per 100,000 women [2]. Prevention of cervical cancer through the Australian National Cervical Screening Program (NCSP) was first introduced in 1991 and screened women aged 18 to 69 years every 2 years using cytology-based screening (Pap smear). The program was renewed in December 2017, and women aged 25 to 74 years are screened every 5 years using primary human papillomavirus (HPV) screening (Cervical Screening Test) [3]. This renewal was based on a greater understanding of the natural history of HPV and cervical cancer, successful uptake of the HPV vaccination leading to a subsequent reduction in vaccine-related HPV types, evidence that the HPV test is more sensitive than the Pap smear, and economic modeling demonstrating HPV screening to be more cost-effective [3]. Recent modeling studies have predicted that the new program will reduce the incidence and mortality of cervical cancer in vaccinated women by 31% and 36%, respectively [3,4]. A limited understanding of the rationale behind these changes has been demonstrated by the general population [5,6]. This highlights a need for information explaining these changes that is easy to understand and access to not undermine the confidence women have in the screening program.

Almost 80% of Australians now use the internet as a source of health information, suggesting that the internet could be a powerful tool to educate and inform readers, with the potential to alleviate anxiety or concern [7]. As health models lean toward greater patient empowerment, patients may feel a greater sense of responsibility for their health care. However, because of the largely unrestricted nature of the internet and limited governance, there is a risk that users may be exposed to inaccurate, unreliable, biased, or potentially harmful information [8]. Exposure to information that is not presented in an accessible manner may cause unnecessary anxiety and distress. This could result in inappropriate care or people ignoring evidence-based recommendations because of being exposed to contradictory information [9].

Moreover, health information is only useful if it can be understood by the target population. The ability to read and understand written text is key for the comprehension of health information. Readability tools can measure the reading ability needed to understand the information presented. South Australia Health recommends that the readability level for health information is grade 8 (12-14 years old with 8 years of Australian education) [10,11]. In the United States, the National Institutes of Health and the American Medical Association recommend patient education materials to be written at or below the sixth-grade reading level (age 11 or 12 years), whereas the Joint Commission recommends a fifth-grade level (age 10 or 11 years) or lower [12]. There are limitations to using only readability measures to evaluate health care information [13], so it is important to ensure that web-based health information is of sufficient quality and is suitable to people from diverse backgrounds and varying levels of health literacy. Web-based health information may also require higher literacy levels than printed patient education materials, as previous studies have demonstrated that web-based patient education materials are often written above the recommended reading level of grades 6 to 8 [14-17], and these may be perceived as more difficult than print materials [13].

There is little to no value of health information that is trustworthy and credible if it cannot be easily understood and acted upon by the general population. A commonly cited disadvantage of web-based health information is the inability of consumers to evaluate the quality of websites [9,18]. In addition to being able to read health care information, consumers need to be able to understand the information presented, evaluate the credibility of websites, and find the information they are looking for.

Objectives

To the best of our knowledge, no previous research has evaluated the readability of health information provided on websites about cervical screening in Australia, particularly regarding the changes to the NCSP. Therefore, this study aimed to evaluate the information available on the internet regarding the renewal of the NCSP in Australia, with a particular focus on website readability, understandability, design, credibility, and usability.

Methods

Identification of Websites

In April 2019, the term *cervical screening* was searched for in Australian versions of the 3 most popular search engines: *Google, Yahoo, and Bing*. The incognito window on Google Chrome was used to conduct the search, and browser history, cache, and cookies were cleared before running the search to ensure that previous searches would not impact the search results. The first 10 relevant results from the first 3 pages of results from each search engine were selected. Relevant websites (in the English language and related to cervical screening) were identified from each search engine, and any duplicate websites were removed and noted. Websites were excluded if they were advertisements, news reports, Wikipedia pages, social media pages, online discussion forums, blogs, videos, books, articles, or private websites.

Measures

Readability

Readability was measured using Flesch Reading Ease (FRE), Flesch-Kincaid Grade Level (FKGL) [19], and the Simple Measure of Gobbledygook (SMOG) index [20].

Flesch Reading Ease and Flesch-Kincaid Grade Level

FRE uses a formula based on the average number of syllables, words per sentence, and the number of sentences to generate a readability score between 0 and 100 (Multimedia Appendix 1). Higher scores indicate greater ease of comprehension. A readability score above 60 is considered easy to follow by the general population [19]. The FRE has high reproducibility and correlation with other readability measures [21].

FKGL is a modified version of the FRE that generates the average US grade level required to understand the information. For example, an FKGL score of 8 indicates that the text can be understood by readers who have completed the equivalent of US grade 8 (Australian year 8; approximate age of 12-14 years) [19,22].

Simple Measure of Gobbledygook Index

The SMOG index assesses 10 consecutive sentences at the beginning, middle, and end of the relevant text and counts the number of polysyllabic words in each sentence [20]. These results are entered into a formula to establish the required grade level. A SMOG score of 3 to 8, 9 to 12, and 13 to 18 indicates that completion of primary, secondary, or tertiary education, respectively, is required to understand the information. For both FKGL and the SMOG index, a higher score indicates that a higher education level is required to understand the information.

The combination of our chosen readability measures (FRE, FKGL, and the SMOG index) is considered optimal, as they have been validated in the context of web-based health information and have high reliability for analyzing biomedical information [21].

Understandability and Actionability

The websites were evaluated for understandability and actionability using the validated Patient Education Materials Assessment Tool (PEMAT) for printable materials [23]. The PEMAT consists of 2 subscales: (1) understandability, which is a measure of the extent to which patient education materials can be understood by people of varying health literacy levels and diverse backgrounds; and (2) actionability, which measures how well a health consumer is able to identify what action to take based on the information provided [23]. Items are given a score of either 0 (disagree) or 1 (agree), with some items having a *not applicable* option. Final scores are calculated as a percentage of *agree* responses for all items, excluding those rated as *not applicable*. Higher percentages indicate higher understandability or actionability. A score higher than 70% indicates that materials are understandable and/or actionable [18]. As actionability was less relevant to this context, it was given less weight when determining the best overall website.

Website Credibility

Health on the Net Foundation Code of Conduct

The Health on the Net (HON) Foundation created a code of conduct that allows certified websites to display the Health on the Net Foundation code of conduct (HONcode) logo as a seal of approval [24]. The HONcode is recognized as an ethical code for websites and is based on 8 principles: authority, complementarity, privacy policy, attribution and date, justifiability, transparency, financial disclosure, and advertising policy. Website developers or information providers can apply for membership and request HONcode certification free of charge. The HONcode seal of approval is given to websites that comply with the principles mentioned earlier. Each website was evaluated for the presence of the HONcode logo.

Journal of the American Medical Association Benchmark

The *Journal of the American Medical Association* (JAMA) benchmark criteria enable the reader to easily discredit websites that lack reliability and transparency [25]. The criteria are as follows: (1) authorship—provides details about authors, contributors, affiliations, and credentials; (2) attribution—all references, sources, and copyright information to be provided; (3) currency—provision of the dates that content was updated; and (4) disclosure—website ownership, sponsorship, advertising policies, and potential conflicts of interest are prominently disclosed [25]. Websites were evaluated against each of the 4 benchmarks and given 1 point for each criterion met (final score 0-4).

Website Design

We used information on readability from the National Institute of Adult Continuing Education (NIACE) [26] to evaluate the design features that make the content of health care information more accessible and easier to understand (Multimedia Appendix 2). We analyzed the use of clear and distinct font styles (NIACE recommends fonts similar to Helvetica) and the adaptability of text (the ability to change the text size) and responsive web design (ie, the website displays differently according to the type of device, screen size, and orientation). Google Chrome features a *toggle device toolbar*, which allows the user to view how a website will be displayed on different screen sizes. We tested the responsiveness of each website by emulating different device types. We analyzed whether the font size appropriately reflected the purpose of the text (eg, larger text size for titles and headings). We also assessed whether the information was broken into *chunks* of text separated by white space as well as the presence and relevance of illustrations.

Usability: Simulation Questions

To emulate real life, 2 researchers, separately and independently, attempted to answer the following questions that women are likely to have related to the renewed NCSP: (1) Why did they change the interval from 2 to 5 years? (2) Why did they change the test? (3) Why did they change the age? (4) What are the benefits of the new test? and (5) Who should have the new test? Each researcher assessed whether the question was answered, and if yes, how well it was answered and how long it took to find the answer. The average time taken by both researchers was reported.

Analysis

Readability statistics were obtained by copying and pasting each website URL into a web-based analysis tool, the *Readability Test Tool* [27], which uses an algorithm to calculate readability measures. If there were several pages on a website, statistics for each page were obtained, and the mean was calculated. An exception to this was if a website had a *publications and resources* page; the statistics for this page were not calculated. The analysis was stratified by the intended audience: consumer focused *versus* health care provider focused. Websites were categorized according to their primary target audience (ie, websites with most content aimed toward consumers were treated as consumer focused).

The quality of websites was evaluated by 2 independent researchers using Microsoft Excel. A third researcher independently coded 40% (6/15) of the websites. Descriptive statistics were calculated using IBM SPSS version 25. Means and SDs were calculated for understandability and actionability (PEMAT), readability statistics (FRE, FKGL, and SMOG), and JAMA benchmark criteria. Interrater reliability between the 2 reviewers was assessed using the Cohen kappa coefficient. Correlations between PEMAT and readability measures were calculated using the Pearson correlation coefficient. The Kruskal-Wallis test was conducted to detect differences in mean readability, understandability, actionability, and JAMA benchmark scores between consumer-focused and health care provider–focused websites.

Ethical Approval

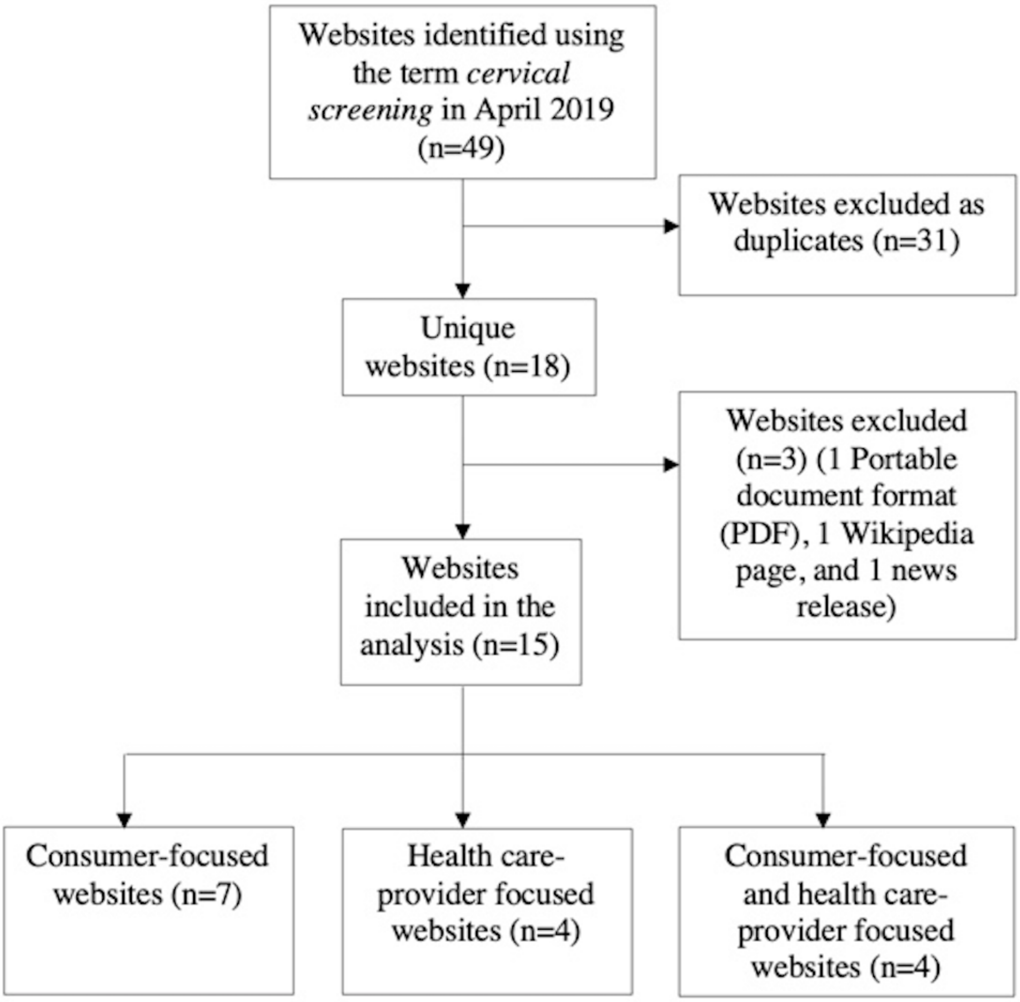
Ethical approval was not required, as the websites were in the public domain, and no human participants were involved.

Results

Search Results

A total of 49 websites were identified using *Google* (n=16), *Yahoo* (n=15), *and Bing* (n=18; Multimedia Appendix 3). After applying the exclusion criteria, 15 unique websites remained and were included in the evaluation (Figure 1). Duplicates (n=31) were excluded; therefore, a greater number of eligible websites were included from *Google*: *Google* (n=10), *Yahoo* (n=1), and *Bing* (n=4; full URLs can be found in Multimedia Appendix 3). The included websites were federal (*Cancer Australia)* or state government–owned (eg, *Cancer Institute NSW*), government-funded (*Health Direct)* or nongovernmental organizations (*Cancer Council).* Of the 15 included websites, 10 were targeted toward consumers, and 5 were targeted toward health care providers, including *National Prescribing Service (NPS) MedicineWise* that consisted of training modules for health care providers. In addition, 4 websites had information for both consumers and health care providers but were categorized according to the primary target audience. Abbreviations, target audience, and organizations of websites included in the analysis are described in Multimedia Appendix 4.

Figure 1. Flow diagram of inclusion and exclusion of websites for evaluation.



Readability

The mean FRE of consumer-focused websites was 51.8 (SD 13.3; Table 1), which is considered *fairly difficult to read*. Health care provider–focused websites were considered *difficult to read*, with a mean FRE of 43.7 (SD 7.3). Of the consumer-focused websites, the *Cancer Council Australia Cervical Screening Consumer Site* had the highest FRE (70.4; Table 2), and the *Cancer Council Australia Main Site* had the lowest FRE (37.8). Consumer-focused websites had a mean reading grade level of 7.8 (SD 1.5), compared with a mean reading grade level of 8.1 (SD 1.4; Table 1) for health care provider–focused sites. *Health Direct* was the only website to score below the US-recommended sixth-grade level using the FKGL (Table 2). The mean SMOG index of consumer-focused sites was 6.7 (SD 1.2), compared with a mean SMOG index of 7.5 (SD 0.7; Table 1) for health care provider–focused sites. The SMOG index ranged from 4.6 (*Cancer Australia Cervical Screening)* to 9.1 *(Victoria Cervical Screening Program [CSP]).* Overall, 13 out of 15 (87%) of all included websites (9 consumer focused and health care provider–focused) scored between the sixth and eighth grade reading level using the SMOG index. *Victoria CSP* had the highest grade level (FKGL and SMOG) and the lowest reading ease (FRE). The differences in the FRE, FKGL, and SMOG index scores of consumer-focused and health care provider–focused websites were not statistically significant.

Table 1. Descriptive statistics of included websites by target audience.

Target audience of website	Flesch Reading Ease[a] (0-100)	Flesch-Kincaid Grade Level[b] (0-12)	SMOG[c] index (3-18)	PEMAT[d] understandability[e] (0-100)	PEMAT actionability[e] (0-100)	JAMA[f] benchmark criteria[g] (0-4)
Consumers (n=10)

[p] NCSR: National Cancer Screening Register.

Understandability and Actionability

The mean understandability score of consumer-focused websites was significantly higher than that of health care provider–focused websites (87.7%, SD 6.0% vs 64.9%, SD 13.8%; X^2_1=6.9; *P*=.01). Overall, 90% (9/10) of consumer-focused websites and 80% (4/5) of health care-provider focused websites met or exceeded the 70% threshold for understandability. The mean PEMAT actionability score was significantly higher in consumer-focused websites than in health care provider–focused websites (58.1%, SD 19.1% vs 36.7%, SD 11.0%; X^2_1=4.8; *P*=.04). Two consumer-focused websites met the threshold for actionability, whereas no health care provider-focused website was found to have actionable information. The *NCSP Main Site* and *Jean Hailes* were the only 2 websites to score over 70% in both the understandability and actionability domains. Interrater reliability was substantial for PEMAT ratings with 0.73 for understandability and 0.75 for actionability.

All 15 websites made their purpose evident and defined terms; however, only 13% (2/15; Table 3) of websites were judged as using visual aids whenever possible, and 53% (8/15) of the websites were judged to use the active voice. All consumer-focused websites, and 60% (3/5; Table 3) of health care provider-focused websites identified at least one action for the reader to take. Overall, 53% (8/15) of websites broke down the action into explicit steps, and 7% (1/15) of websites provided tangible tools whenever possible to help the reader take action. A correlation analysis was conducted between the FRE and PEMAT understandability to determine if websites that were easier to read were also easier to understand. There was no significant correlation found between reading ease and understandability.

Table 3. Percentage of *agree* responses on Patient Education Materials Assessment Tool (PEMAT) for Printable Materials items of the 15 included websites.

PEMAT[a] items	Agree, n (%)[b]		
	Consumer-focused websites	Health care provider–focused websites	All websites
Understandability			
Content			
Makes its purpose completely evident	10 (100)	5 (100)	15 (100)
No distracting information	10 (100)	5 (100)	15 (100)
Word choice and style			
Common everyday language	10 (100)	3 (60)	13 (87)
Medical terms are defined and used only to familiarize readers	10 (100)	3 (60)	13 (87)
Active voice	6 (60)	2 (40)	8 (53)
Use of numbers			
Numbers are clear and easy to understand[c]	5(100)	3(75)	8 (73)
Does not expect readers to do calculations	10 (100)	5 (100)	10 (100)
Organization			
Chunks information into short sections[d]	9 (100)	3 (100)	12 (100)
Sections have informative headings[d]	9 (100)	3 (100)	12 (100)
Presents information in a logical sequence	10 (100)	5(100)	15 (100)
Provides a summary[d]	6 (67)	2 (67)	8 (67)
Layout and design			
Provides visual cues whenever possible	9 (90)	4 (80)	13 (87)
Use of VA[e]			
Uses VA whenever possible	2 (20)	0 (0)	2 (13)
VA reinforce rather than distract[f]	4 (100)	1 (100)	5 (100)
VA have clear titles and captions[f]	2 (50)	1 (100)	3 (60)
VA are clear and uncluttered[f]	4 (100)	1 (100)	5 (100)
Tables are simple with short, clear row and column headings[g]	3 (100)	1 (100)	4 (100)
Actionability			
Identifies at least one action for the user	10 (100)	3 (60)	13 (87)
Addresses the user directly	9 (90)	3 (60)	11 (73)
Breaks down actions into explicit steps	6 (60)	2 (40)	8 (53)
Provides tangible tools whenever it could help	0 (0)	1 (20)	1 (7)
Instructions and examples for calculations[h]	N/A[i]	N/A	N/A
Explains how to use the charts, diagrams etc[j]	2 (100)	0 (0)	2 (67)
Uses VA whenever possible to help take action	2 (20)	2 (40)	4 (27)

[a] PEMAT: patient education materials assessment tool.

[b] Agree (%) was calculated by the following formula: total number of *agrees*/total number of applicable websites.

[c] Not applicable for 4 websites.

[d] Not applicable for 3 websites.

[e] VA: visual aids.

[f] Not applicable for 10 websites.

[g] Not applicable for 11 websites.

[h] Not applicable for all 15 websites.

[i] N/A: not applicable.

[j] Not applicable for 12 websites.

Credibility: Journal of the American Medical Association Benchmark Criteria and Health on the Net Foundation Code of Conduct

Overall, 3 websites met all 4 of the JAMA benchmark criteria (*Cancer Council Australia Main Site*, *NCSP Clinical Guidelines*, and *the Royal Australian College of General Practitioners [RACGP]).* The mean number of JAMA benchmark criteria satisfied was 2.4, ranging from 1 to 4. Overall, currency was the most well-adhered principle, with 8 of 10 consumer-focused and 4 of 5 health care provider–focused websites providing update information (Table 4). Authorship was the most commonly missed criteria, with only 3 consumer-focused and 3 health care provider–focused websites properly attributing the authors of information, including their qualifications and affiliations. There was no significant difference in the mean number of criteria satisfied between consumer-focused and health care provider–focused websites.

The HONcode was only present on 2 websites (*NPS MedicineWise* and *Health Direct*; Table 2). No websites displayed an explicit conflict of interest statement (represented as part of the disclosure criteria); therefore, the existence of any actual or potential conflicts cannot be determined. *RACGP* provided a link to a conflict of interest management policy, which states that no one with a conflict of interest can be involved in the decision-making process. *NCSP Clinical Guidelines* provided a register of all interests, leaving it up to the end user to determine the presence and significance of any conflict.

Table 4. Number of included websites adhering to the Journal of the American Medical Association benchmark criteria.

JAMA[a] benchmark criteria	Websites adhering, n (%)		
	Consumer-focused websites	Health care provider–focused websites	All websites
Authorship	3 (30)	3 (60)	6 (40)
Attribution	6 (60)	2 (40)	8 (53)
Disclosure	7 (70)	4 (80)	11 (73)
Currency	8 (80)	4 (80)	12 (80)

[a] JAMA: Journal of the American Medical Association.

Website Design

All websites had consistent use of white space, separating paragraphs of information into smaller *chunks* of text. All websites used distinct and easy-to-read font styles and had clear subheadings in a text size larger than the main text. An adaptable font size was available in 2 of 15 websites (*Cancer Council Australia Main Site* and *Cancer Australia Cervical Cancer).* All 15 websites used a responsive web design. Of 15 websites, 3 (*NSW CSP, Cancer Council Australia Cervical Screening Consumer Site,* and *Jean Hailes)* used illustrations to reinforce key messages.

Simulation Questions

Of 15 websites, 3 (*NCSP Main Site, Cancer Council Australia Cervical Screening Consumer Site,* and *NSW CSP*) provided answers to all 5 simulation questions. The question most frequently answered by websites was question 5: “Who needs the new test?” *NPS MedicineWise, RACGP, National Cancer Screening Register,* and *Queensland CSP (B)* did not provide answers to any of the questions. The time taken to find the answers ranged from approximately 10 seconds to 2 min. The answers were found the fastest on *NSW CSP* (average time of 34 seconds per question) and the slowest on *NCSP Clinical Guidelines* (average time of 146 seconds per question).

Discussion

Principal Findings

This study is the first to evaluate web-based information available to consumers about the renewal of the Australian NCSP. Overall, the readability of consumer-focused websites providing information about the renewed NCSP was fairly difficult to read by the general population (ie, below the threshold of 60); however, there was high variability in scores. Overall, the evaluated websites demonstrated a high level of understandability. The *Cancer Council Australia Cervical Screening Consumer Site* scored highest for understandability assessed using the PEMAT. There was no significant correlation between reading ease and understandability, demonstrating that they measure different constructs. This is in line with previous studies and highlights the importance of using both measures to evaluate quality [17]. Most websites met some criteria to assess their credibility, and all websites demonstrated some thought had been given to the design of the websites. Of the 5 key questions that could be frequently searched by consumers, the following 3 websites provided answers to all questions: *NCSP Main Site, Cancer Council Australia Cervical Screening Consumer Site,* and *NSW CSP.* These findings demonstrate great variability in the readability, understandability, and credibility of websites available on the internet, which provide both consumers and health care providers with information about the changes to the NCSP.

Across all measures, the *Cancer Council Australia Cervical Screening Consumer Site* was judged to be the most accessible website overall. This site was considered the easiest to read based on the FRE score and had a reading level between grade 6 and 7 using both the FKGL and SMOG index, which is in line with recommendations from South Australia Health [11]. Furthermore, it scored highly on the understandability criterion of the PEMAT and was one of only three websites to answer all 5 simulation questions. This website was developed by Cancer Council Australia in response to the renewal of the NCSP and has a clear purpose to educate women about the changes to cervical screening and seeks to answer possible frequently answered questions. It provides comprehensive content about the changes in an accessible manner. Australian women with questions or concerns about the renewed NCSP may benefit from being directed to this website by their health care provider.

Strengths and Limitations

This study used validated tools and a combination of several measures to independently evaluate websites providing information about cervical screening. Objective readability measures provide limited data about the health literacy level required to understand information, so by combining this with the PEMAT, this enabled us to determine how well people of various backgrounds and levels of health literacy may be able to understand and act upon the provided health information. These tools were selected because the items were most relevant to the health information we were evaluating. Other available tools, such as DISCERN [28], have a number of items aimed at treatment-related information, which are not relevant for the content of cervical screening information. A limitation of our study is the small number of websites included in the analysis, which may have prevented seeing differences in readability between health care provider–focused and consumer-focused websites. However, the search term *cervical screening* returned over 50,000,000 results on Google alone, and as internet users rarely look past the first 3 results pages, it is likely that the websites included in our analysis would be those most commonly accessed by consumers [18]. Some of the measures we used are subjective (eg, PEMAT), but by having 2 independent evaluators score all 15 websites and a third evaluator score 40% (6/15) of websites, this will have helped ease any discrepancies, and the interrater reliability between the evaluators was rated as substantial. The websites in this study were only examined using their content and were not examined for accuracy of the information presented, as this was not an aim of the study. This study was limited to the evaluation of printable material on the websites; therefore, information delivered in video format was excluded.

Comparison With Previous Work

This study is particularly relevant in light of the renewed NCSP and the public misconception about the rationale behind the changes [5,6]. Our findings show that most consumer-focused web-based information on cervical screening in Australia is written at a reading level inaccessible to the general population. This is similar to previous studies that have found web-based health information to often be written above the recommended reading level [29]. This may be because the authors have insufficient awareness of health literacy considerations and readability [30].

In this study, websites with the lowest readability tended to be those targeted toward health care providers. Making the target audience of the website more explicit may help avoid potential confusion for consumers and the frustration of not having questions answered. Although this may be obvious for some websites (eg, *NCSP Clinical Guidelines*), health consumers should be able to determine at a glance the target audience of the information they are reading for all websites. This may minimize their exposure to inaccessible material. Sites aimed toward health care providers could provide links to guide consumers to reputable consumer-focused websites (eg, *NCSP Main Site* or *Cancer Council Australia Cervical Screening Consumer Site*).

The high understandability scores indicate that web-based cervical screening information can be understood relatively easily by consumers of diverse backgrounds and levels of health literacy [23] and demonstrate that the PEMAT and readability tools measure different constructs. Greater awareness of how the mode of delivery may affect consumers’ understanding of the health information could help to create and distribute better patient materials. The low actionability scores suggest that it may be difficult for consumers to act upon the information they read. Most websites failed to provide tangible tools or visual aids and lacked explicit instructions for the user to follow (eg, a tool to help consumers decide whether they are eligible for screening under the new guidelines). The general purpose of these websites is to inform and educate the reader about the changes rather than encouraging an action. Consequently, the actionability domain of the PEMAT may have limited applicability to this context. The large range in PEMAT scores may be partially explained by the fact that some websites were solely targeted toward health care providers. As such, the content on these websites (*NCSP Clinical Guidelines, RACGP,* and *NPS MedicineWise*) would not be considered *patient* education materials, and consequently, the PEMAT score may not be an accurate measure of quality. Most existing literature on web-based health information is related to disease and treatment information, where there may be more explicit actions to take than for cervical screening (eg, different treatment options for a chronic disease). This may, in part, contribute to the low actionability scores for our websites, but because of actionability not being an aim of these websites, less weight was given to these scores.

Noting the presence of the HONcode logo is a simple way for consumers to recognize that the information they are reading is trustworthy, but because HONcode certification is a voluntary registration process, it is possible that websites may comply with the principles despite not being certified [10]. As most of the included websites are federal or state government owned, they would likely be instantly recognized as trustworthy and credible sources of information; therefore, there may be no added benefit of HONcode certification. It is unclear how recognizable the HONcode is among both consumers and website developers. The only 2 websites displaying the HONcode are government-funded not-for-profit organizations (*Health Direct* and *NPS Medicine Wise*). As these sites may not be as easily recognized as reputable sources, HONcode certification may be more valuable; however, there is little value if a consumer does not know what it is or how to interpret it.

Most websites failed to provide adequate detail about the authors of the information or to provide sources and references for information. This information was seldom displayed prominently, often located on the *about us* or *disclaimer* pages, which are rarely accessed by consumers [18]. Sources that were provided were rarely primary research and often linked to related websites, raising the potential of consumers to be exposed to inaccurate, inaccessible, or unreliable content if the linked websites are of poor quality or lack credibility. It could be argued, however, that the omission of primary sources on consumer-focused websites may be a deliberate decision by the website developer. Primary research papers are often behind paywalls or written at a reading level inaccessible to the general public. This has the potential to cause greater confusion and may offer little benefit to the reader. Furthermore, consumers generally judge the credibility of websites based on the hosting organization (ie, whether it is from a reputable and recognizable organization such as the Australian Government or Cancer Council Australia), language, and professional-looking design [18]. Web-based information can be biased, with little to no scientific evidence [18]. In addition to providing credit to the original source, appropriate attribution can help the end user evaluate the quality and ensure the trustworthiness of information on the web. This leads to a discussion of whether there should be mandatory criteria to follow when setting up websites to ensure their credibility. Furthermore, it raises the question of whether details about sources, authors, and conflicts of interest can be displayed in a way that is more accessible and meaningful to health consumers.

The 3 websites that satisfied all 4 JAMA benchmarks were targeted specifically toward health care providers. If websites targeted toward health consumers lack the aforementioned principles, it raises potential issues. The general population, particularly those of lower health literacy, may be less equipped than health care providers to evaluate and discredit websites. It is critical that consumer-focused websites are credible, but it may be necessary for a tradeoff between accessibility, readability, understandability, and credibility. This area requires further research to minimize this tradeoff, as each component contributes toward consumers’ experience of accessing health information on the web. Appropriate attribution and references are a particularly important credibility indicator of health care provider–focused websites; however, they may be considered less relevant for consumer-focused sites. Existing credibility assessment tools (such as the JAMA benchmark criteria and the HONcode criteria) are limited in their ability to evaluate consumer-focused websites. The development of a new credibility framework for consumer-focused websites could mitigate this limitation. Taking into consideration other factors that influence credibility, such as placing more weight on the hosting organization, could enable consumers to discredit unreliable information without reducing the overall quality.

Owing to an increasing interest in the literature about conflicts of interest, it was interesting to find that none of the websites in this study explicitly disclosed a conflict of interest. It is important to note that the absence of a conflict of interest statement is not equivalent to having no conflict. There is increasing research into the management of conflicts of interest and whether or not disclosure is the most appropriate strategy [31]. Disclosing conflicts merely indicates the possibility of a bias; however, it does not provide guidance for resolving it or how the conflict was managed. For the consumer, a lack of disclosure may hinder their ability to mitigate any potential risk of bias, as conflicts of interest may impact decision making [31].

Simulation questions were helpful in establishing whether these websites explained the changes to the CSP. The majority of these websites did not answer the questions in detail, raising concerns about whether consumers reading the information would be fully informed about the changes. A total of 3 websites provided answers to all the questions (*NCSP Main Site*, *Cancer Council Australia Cervical Screening Consumer Site*, and *NSW CSP*), with the time taken to find answers to these questions being the quickest for the *NCSP Main Site.* The websites that either did not provide answers to the simulation questions or it took a long time to find the answers were those aimed toward health care providers, further highlighting the need for the target audience of the website to be made more explicit.

Finally, all websites were designed to improve the accessibility of information through the use of white space and appropriate font style. The layout and design of materials can be a contributing factor to how consumers comprehend the information or how accessible the information is [22]. Only 2 websites showed adaptable font size, which may cause potential difficulties for those with impaired sight. An important consideration when designing websites now is also about how the interface looks on mobile phones, given the increasing number of consumers who will view health information on their mobile phones [7]. It was therefore reassuring to observe that all websites used responsive web design. The use of illustrations can reinforce messages and aid interpretation of written text or they can distract away from the purpose [26]. The *NSW CSP* and *Cancer Council Australia Cervical Screening Consumer Site* use photographs of culturally and demographically diverse women, which may help consumers understand that the information is relevant to them.

Conclusions

The findings from this study can help health care providers direct their patients toward websites that have information about the renewal of the CSP, which is easy to read and has high understandability (eg, *Cancer Council Australia Cervical Screening Consumer Site*). Encouragingly, web-based information about the renewed CSP is generally of good quality. There is a need to promote increased awareness of the importance of web-based health information that is credible, user friendly, and easily understood by people with wide levels of health literacy. Web-based information should be produced with particular consideration to people with low health literacy, with those responsible for creating these websites to be accountable for ensuring that this information is accessible, accurate, and credible. There may be potential for web-based health information to be improved through the introduction of mandatory criteria to ensure the credibility and quality of consumer-focused websites.

Authors' Contributions

RD conceived and designed the study and contributed to the drafting of the manuscript. AT and ST acquired the data set, analyzed the data, and contributed to the manuscript. OM drafted the manuscript and contributed to the analysis.

Conflicts of Interest

Abstract

Background: Tobacco companies include on the packaging of their products URLs directing consumers to websites that contain protobacco messages. Online media tend to be underregulated and provide the industry with an opportunity to present users with protobacco communication.

Objective: The objective of our study was to document the content of websites that were advertised on tobacco packs in 14 low- and middle-income countries.

Methods: We purchased tobacco packs from 14 low- and middle-income countries in 2013 and examined them for the presence of URLs. We visited unique URLs on multiple occasions between October 1, 2016 and August 9, 2017. We developed a coding checklist and used it to conduct a content analysis of active corporate websites to identify types of protobacco communication. The coding checklist included the presence of regulatory controls and warnings, engagement strategies, marketing appeals (eg, description of product popularity, luxury/quality, taste), corporate social responsibility programs, and image management. We coded brand websites separately and also described social media and other website types.

Results: We identified 89 unique URLs, of which 54 were active during the search period. We assessed 26 corporate websites, 21 brand websites, 2 nontobacco websites, and 5 social media pages. We excluded 2 corporate websites and 14 brand websites due to limited accessible content or incomplete content. Corporate social responsibility was discussed on all corporate websites, and marketing appeals were also common. Corporate websites were also more likely to include more nonspecific (12/24, 50%) than specific (7/24, 29%) health warnings. Promotions (6/7, 86%) and sociability appeals (3/7, 43%) were common on brand websites. The small number of social media webpages in our sample used gendered marketing.

Conclusions: URLs appearing on tobacco packs direct consumers to websites where users are exposed to marketing that highlights the “positive” contributions of tobacco companies on corporate websites, and extensive promotions and marketing appeals on brand websites and social media pages. It is essential that marketing regulations become more comprehensive and ban all protobacco communication, a policy that is in line with articles 5.3 and 13 of the World Health Organization Framework Convention on Tobacco Control. For countries that already ban internet tobacco advertising, enforcement efforts should be strengthened. Tobacco companies’ use of URLs on packs may also be compelling for plain packaging advocacy, where all branding is removed from the pack and large graphic health warning labels are the only communication on the tobacco packaging. Future research should consider including tobacco websites in marketing surveillance.

(J Med Internet Res 2020;22(6):e15160) doi:10.2196/15160

advertising; developing countries; product packaging; product labeling; tobacco industry

Introduction

Background

Tobacco is the most dangerous consumer product in the world, and tobacco product marketing has been recognized as a cause of tobacco use initiation and failed quit attempts for over a decade [1-10]. The internet provides an additional platform for protobacco communication via tobacco industry websites. The importance of these websites is highlighted by the millions of dollars the industry spends on them; for example, US tobacco companies have been increasing spending on internet marketing since the early 2000s, spending US $25.1 million in 2017 on company websites [11,12]. The continually evolving nature of the internet and tobacco industry marketing strategies makes these websites a public health surveillance priority [13].

Tobacco companies use these websites to promote both their product branding and their corporate image. Given the broad public awareness of the harms of smoking and their deceptive tactics, tobacco companies have taken steps to try to counteract negative perceptions by engaging in activities that they describe as serving to build credibility [14]. The industry touts green business practices, publicizes support for what they see as reasonable (one might imagine, restricted) approaches to regulation, acknowledges some harms caused by smoking, and promotes the future of “reduced-harm” products in order to manage their corporate image and normalize tobacco companies’ practices [14-16]. Although normalization of the industry is itself harmful, these activities additionally enhance industry access to policy makers, influence the credibility of industry-proposed policy alternatives, and weaken opposing political constituencies [17,18]. While the industry formerly relied on traditional media and opinion leaders to spread these messages, they now also incorporate online content, such as company websites [16,19-22]. Tobacco companies print URLs to their websites on their product packaging, presumably increasing exposure. URLs on packs link consumers to much more protobacco communication than can otherwise be contained on the pack.

There are several types of tobacco websites, which tend to fall into 3 main categories: corporate [20], brand [23,24], and social media [25]. Corporate websites represent the company as a formal business and present their corporate image to the public [26,27]. Brand websites market specific products through “interactivity, multidirectional communication and meaningful engagement” [24]. Social media pages can be associated with either a company or a brand, or may be the product of consumer-generated content [28]. Tobacco companies can make “pages” or accounts on unaffiliated social networking platforms that people can like or follow. As an example, Dunhill, a brand of British American Tobacco cigarettes, had a page on Facebook in 2009 to promote Dunhill events, including parties at nightclubs, where free Dunhill cigarettes were distributed [29]. Nontobacco websites, websites not visibly associated with a tobacco company, are also sometimes listed on tobacco packs.

Despite its potential to influence both consumer and policy-maker perceptions of the tobacco industry, online tobacco marketing is still relatively new and underregulated [28,30]. Legislation on tobacco marketing rarely mentions internet marketing specifically, leaving the status of what types of marketing are allowed online up to interpretation (Multimedia Appendix 1). It is also unclear whether corporate marketing for specific companies that promotes the company rather than its products is allowed under advertising and marketing bans.

Tobacco control researchers have already started to document activity on tobacco websites. Previous studies on corporate websites have focused on corporate social responsibility (CSR), the provision of limited health information, and image management [20,26,31,32]. Brand websites were found to tout interactive games, contests, event information, and coupons, and even to allow users to select their own music to enjoy while browsing [22,33-36].

The literature on tobacco internet marketing is, however, somewhat limited. Content analyses of corporate websites have focused on samples of US websites or only the websites of the largest multinational companies [20,26,34]. Research has not investigated websites, even for multinational companies, in low- and middle-income countries (LMICs), where 80% of daily smokers live and where tobacco companies are focusing efforts to expand the cigarette market [37,38]. Research on brand websites also tends to be older and limited to a case study approach, and the constantly changing nature of the internet may make some of those findings less relevant today than when they were originally published [22,23,39,40].

Objective

To help fill these gaps, we conducted a quantitative content analysis of corporate tobacco and brand tobacco websites and described nontobacco websites and social media pages associated with URLs that we found on tobacco packs purchased in 14 LMICs. Our objective was to assess the marketing strategies to which tobacco companies are linking their consumers. This descriptive analysis may inform marketing regulations and further support packaging restrictions and plain packaging initiatives.

Methods

Sample

As part of the Tobacco Pack Surveillance System (TPackSS) study [41], 3307 cigarette, kretek (clove cigarettes common in Indonesia) [42], and bidi (hand-rolled cigarettes common in India and Southeast Asia) [43] country-unique packs were systematically purchased from 14 LMICs in 2013 [41]. We recorded each specific URL using pack photos available from TPackSS [44] and in-person examination of the pack when the URL was not legible from photos (n=56). URLs were located on all sides of the pack (front, back, sides, top, and bottom), as well as on the inside of the packs (inside lid and on paper inserts included in the packs). We entered URLs into an internet search to locate the website, and downloaded and saved screenshots of the home page and each main tab of the menu that was one click away from the home page. While this approach did not allow for the assessment of all content on each website, we established a limit, as it was not feasible to follow every link to every page. We visited websites multiple times between October 1, 2016 and August 9, 2017 to maximize the number of active websites in our sample, as it was common for websites to go through cycles of inactivity and activity.

Procedure

If an English-language version of the website was not provided, we asked a translator to write the English translation of the text on the saved PDFs of website images. Translators were then present (either physically or via Skype; Microsoft Corporation) while coders coded these PDFs in the event that coders had questions about the meaning of the translation. We used codes from a content analysis of Russian e-cigarette websites [45] and common features found on US tobacco websites during field testing to develop a codebook to quantitatively inventory website content. Categories were engagement strategies, marketing appeals, regulatory controls and warnings, and CSR and image management. We considered graphic content only for codes related to flavor and marketing appeals that could be easily and reliably identified (ie, luxury/quality, sociability, masculinity, and femininity appeals). We programmed the coding checklist into Qualtrics software version 05.2017 to 09.2017 (Qualtrics, LLC) to facilitate coding (Multimedia Appendix 2).

Due to high interrater reliability assessed after coding the first 20 websites, not all of the remaining websites were double coded, resulting in 81% (25/31) of quantitatively coded (ie, corporate and brand) websites being double coded. We coded the websites' home page and each main tab from the website menu for presence versus absence of each feature. We assessed interrater reliability using percentage agreement, as well as a method to account for the low prevalence of some marketing strategies (prevalence-adjusted and bias-adjusted kappa) [46-48]. Overall percentage agreement was .95 and prevalence-adjusted and bias-adjusted kappa was .89. Discrepancies were reviewed and reconciled via in-person discussion between the coders, with clarifications made to the codebook as needed.

Analysis

Data were exported from Qualtrics into an Excel spreadsheet version 16.6 (Microsoft Corporation) and analyzed using Stata version 15 (StataCorp LP). We calculated the proportion of websites whose content reflected each of the codes.

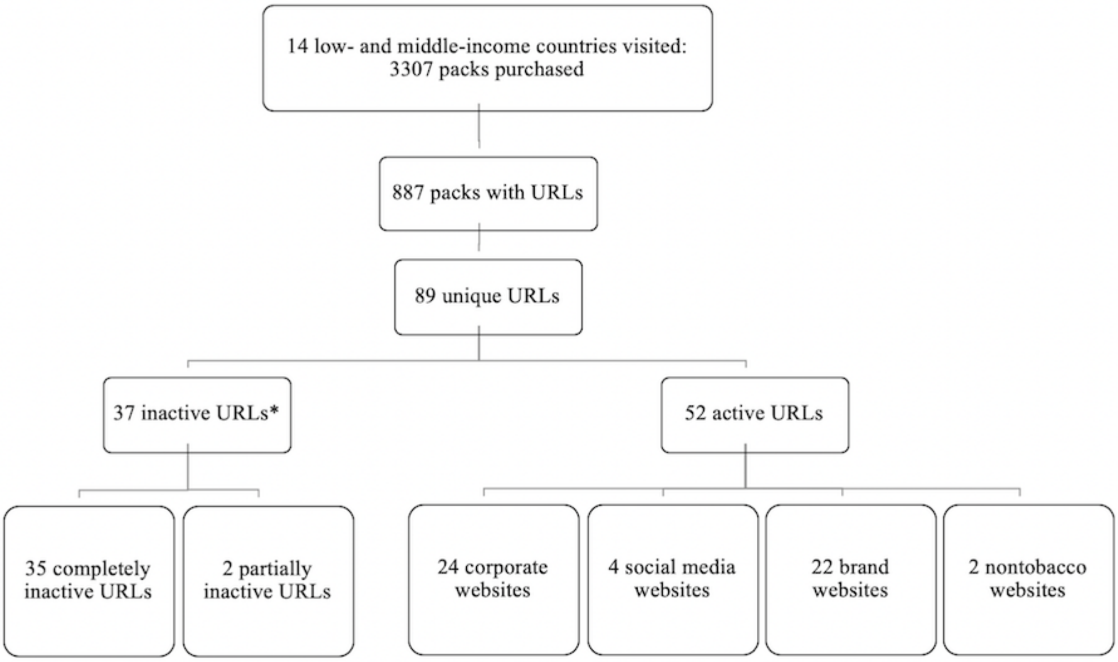
We assessed brand websites using the same coding checklist used for corporate websites, although we present the results separately due to the limited amount of content visible without registration. We briefly described the social media pages and nontobacco websites, since their characteristics were not adequately captured by the codebook.

Results

Website Characteristics

We noted the presence and location of an URL on 880 packs (857 cigarette packs and 23 kretek packs). Of these, 7 packs included 2 URLs. There were 54 active and unique websites: 26 were corporate websites, 21 were brand websites, 5 were social media websites, and 2 were nontobacco websites. We excluded 2 corporate websites because not all website pages were active (see Figure 1 for details). All brand websites but 1 required the user to register in order to see complete website content. Registration required local addresses, verification of country citizenship, and verification that you were a tobacco product user. We excluded 14 brand websites with no content visible prior to registration, as we could not breech the terms and conditions of the websites per university requirements.

Figure 1. Breakdown of coded websites. *37 websites considered inactive for the following reasons: the page could not be found (n=17), the page took too long to respond (n=7), the site was closed for construction (n=5), the domain name had expired (n=4), some parts of the page were inactive (n=2), the company had been sold (n=1), or access was not allowed (n=1).



The 38 websites that were accessible for analysis were from 560 packs, or 63.6% of all 880 purchased packs with URLs. These packs were from 13 countries, and the websites were available in over 20 languages, counting all languages available on each webpage (Multimedia Appendix 3). We found the 24 active corporate websites included in this analysis on 486 packs purchased in 13 countries, or 14.70% of all 3307 purchased packs and 55.2% of all 880 purchased packs with URLs. We categorized 8 websites as multinational and 16 as nonmultinational. In line with work by others, we considered the 4 leading multinational tobacco companies, Philip Morris International, British American Tobacco, Japan Tobacco International, and Imperial Tobacco [49], to be multinational. Other corporate websites were from state-owned and other regional or national companies. The 7 active brand website URLs with at least some content visible were on 52 packs from 6 countries, the 5 social media webpage URLs were on 19 packs from 3 countries, and the 2 nontobacco website URLs were on 3 packs from 2 countries (Multimedia Appendix 3).

Corporate Websites

Regulatory Controls and Warnings

Of the 24 corporate websites, 14 (58%) had statements regarding the legal age for product purchase or website use (Table 1). We found pop-up windows asking whether the user was over the age of 18 years (known as click-through verifications) on 3 (13%) websites, but no website had a specific verification requirement (eg, exact date of birth). Of the 24 websites, 7 (29%) had specific health warnings (eg, from the Turkish Imperial Tobacco website: “Smoking is a cause of serious diseases in smokers, including lung cancer, heart disease and emphysema”), whereas 12 (50%) had only general acknowledgements of the health risks of smoking (eg, from the Tutun company website: “Smoking is negatively impacting your health”).

Table 1. Codebook used for corporate (n=24) websites and proportion of corporate websites by the presence of each code.

Domain	Code prevalence on corporate websites, n (%)

[a] CSR: corporate social responsibility

Engagement Strategies

A few corporate websites offered opportunities for further engagement with their company by offering mobile apps (n=2, 8%) and prompting users to sign up for email alerts (n=3, 13%) (Table 1). British American Tobacco's website had an app for investors to track company performance. British American Tobacco and Imperial Tobacco both offered email alerts for company media coverage. Some websites also linked to other corporate websites, including the parent company (n=7, 29%), brand (n=2, 8%), and social media websites and webpages (n=14, 58%).

Marketing Appeals

Every corporate website contained at least one marketing appeal for their products or company (Table 1). Luxury and quality appeals were the most common (n=21, 88%), such as British American Tobacco's description of its "superior quality next generation products." National appeals (n=19, 79%) and appeals to company tradition or history (n=16, 67%) were common. Hongta Tobacco Group Co., a Chinese tobacco company, appealed to company tradition by dedicating a page of its website to the history of the company from its founding in 1956 to its "courageous" introduction of advanced foreign technology. We found popularity appeals, such as Altria Group's boasting of their ownership of Philip Morris USA ("Leading cigarette manufacturing in the U.S. and has been for more than 30 years") and that of U.S. Smokeless Tobacco Co. (the "World's leading producer of moist smokeless tobacco"), on 13 (54%) websites. Appeals to the taste or sensation of tobacco were present on 10 (42%) corporate websites. For instance, the Djarum website described how the "exotic flavors of Djarum kretek has captured the imagination of a growing international audience" [50], using both taste or sensation and international appeals. We also observed international appeals (n=19, 79%), including international appeals mentioning American culture or values (n=6, 25%).

Corporate Social Responsibility and Image Management

All 24 corporate websites mentioned CSR or a specific CSR program at least once. Examples of CSR were providing scholarships or other academic support (n=8, 33%), caring for employees and providing support (n=16, 67%), being a provider of jobs (n=14, 58%), and using or investing in harm reduction technology (n=5, 21%). The website for British American Tobacco Russia stated that they were one of the best employers in Russia and claimed to offer employees "all possibilities for professional and career growth." Hongta publicized several educational initiatives on their websites, including a ¥4 million (about US $565,000) donation to a middle school and the completion of a dormitory building project for another school. Youth smoking prevention programs were referenced on 3 (13%) websites: 2 British American Tobacco websites and Hongta's websites. A total of 10 (42%) websites discussed support for communities, including Japan Tobacco International via their ARISE program that is "bringing an end to child labor by working with tobacco farming communities to create new traditions." A total of 11 (46%) websites contained general references to environmental sustainability, such as British American Tobacco's "comprehensive environmental management program" [51]. A further 6 (25%) websites provided specific examples of sustainable or environmentally friendly practices, including Shaanxi's "energy-saving emission reduction program." Company corporate image was portrayed via mention of company transparency (n=9, 38%), descriptions of the company as innovative (n=19, 79%), discussion of the importance of consumer education (n=6, 25%), and mention of awards won for performance or CSR activities (n=13, 54%). The Russian company Donskoy Tabak endorsed their "principles of openness and transparency" and showcased their awards for "Quality and Technological Effectiveness." In addition, 9 (38%) websites expressed support for tobacco control legislation or emphasized compliance with such legislation. For example, Imperial Tobacco stated that "We recognize the controversial nature of our product and believe it is important to have it produced and handled by a responsible business. We both comply with and exceed current regulatory standards as we apply our own corporate standards."

Brand Websites

Although we coded only 7 brand websites because the other 14 brand websites in the sample set conditions for access incompatible with our university research standards, there are a few observations of note. Of these 7 websites, 6 limited the content visible without registration, while 1 was totally accessible without registration. Despite the limited content visible without registration, we observed promotions such as games, contests, and sponsored events (n=6, 86%), and youth appeals (n=2, 29%). A total of 3 (43%) brands websites included sociability appeals, which were illustrated on Bond Street's website through images of a small group of attractive young adults playing a guitar by the water. We noted national appeals, including a Marlboro-sponsored event called M-City, which attempted to express the culture of Kiev through art by inviting artists and musicians to the city, on 5 (71%) of the websites. Images of cities at night were common, and some websites included music. Most websites (n=6, 86%) used video or scrolling images, such as scenes of dance parties and cities at night on the Clas Mild websites and videos of "life hacks" on the L&M website.

Social Media

Of the 5 social media pages in this sample, 4 required that users request to join the group or register to see all content. Our requests to join were not accepted, so only a small amount of content was visible. The 2 social media pages for Kiss cigarettes were both characterized by femininity appeals, with flowers and text describing the page as a group for "modern girls." The Style Super Slim Tumblr-style social media page included posts on makeup, nail art, fashion, decorating, and baking. Another social media page for 21 Bek, however, used explicit masculine appeals, calling the page a group for "real men." Black Xperience also used masculine messaging and was a Tumblr-style website with images of cars, motorcycles, attractive women, and something called the "Black Innovation Challenge."

Websites Not Related to Tobacco

Two URLs found on packs led to websites that were not for tobacco companies or for tobacco products. One website was for the Programme for the Endorsement of Forest Certification, which described an agenda of caring for the world's forests and promoting sustainable forest management. Information on sustainability was available, and there was an option to sign up for newsletters from the organization. The other website was for the Japanese Ministry of Health, and the URL is part of the pack warning label required in Japan, although the 2 packs with this URL in the warning were purchased in Turkey. The Japanese Ministry of Health website contained information about the health hazards posed by tobacco, tobacco cessation, a passive smoke-free society movement, and a discussion of the Japanese Ministry's involvement with the World Health Organization (WHO) Framework Convention on Tobacco Control (FCTC).

Discussion

Principal Findings

URLs on tobacco packs purchased in LMICs led to corporate, brand, social media, and other websites that linked consumers to protobacco communication, including marketing for tobacco products and the companies that produce them. Several findings regarding the low prevalence of specific health warnings, use of CSR and other image management techniques, and use of marketing and engagement strategies highlight the potential of tobacco websites to communicate positive messages about the tobacco industry and tobacco products to users. These findings highlight the importance of tobacco websites in the tobacco marketing landscape in LMICs. There is a need for focused research on tobacco marketing in LMICs, as this is where the majority of tobacco users reside and where the industry has increasingly marketed its deadly products [37,38]. Tobacco websites should be explicitly included in marketing restrictions and regulations to protect the public from protobacco communication.

Corporate websites largely failed to communicate many of the harmful effects of smoking to website users. While half of the websites in this sample had a health warning, most of these warnings described vague risks associated with using tobacco, and risk of death and specific diseases were uncommon. However, having a health warning, even a nonspecific one, could be a way for a company to mitigate its liability [52] while presenting a more positive and responsible face to the public [32].

The emphasis of CSR programs on corporate websites was also of particular concern, as these programs can increase perceptions that the company is socially responsible, liking for the company, and positive associations with the company's products [53]. CSR has been used as a reputation and impression management tool to gain access to decision makers and increase tobacco company influence [17], and has been found to directly interfere with attempts to denormalize the tobacco industry and its products [54]. The very act of selling cigarettes, an addictive product that kills half its long-term users, is antithetical to CSR [55]. Additionally, corporate websites describe themselves as transparent, responsible, innovative companies that acknowledge the importance of consumer education, support tobacco control legislation, and even receive awards for their performance and CSR efforts. These strategies are used to promote an image of tobacco companies as socially responsible. This image serves their own monetary gain rather than the well-being of current and future tobacco consumers, who would be better served by the tobacco industry abandoning advertising and promotion of their products, and not opposing government regulation that aims to reduce tobacco-caused death and disease [56]. Articles 5.3 and 13 of the FCTC further recommend that parties mitigate the effect of "commercial and other vested interests of the tobacco industry" by denormalizing or regulating tobacco industry CSR or by banning CSR entirely by defining it as a form of sponsorship [57,58].

Corporate websites also promoted youth smoking prevention programs. Industry-funded youth smoking prevention advertising has been associated with increased intentions to smoke [59]. The WHO calls on FCTC parties to decline any industry involvement in tobacco use prevention [60], but our research demonstrated that the industry is still involved in tobacco use prevention online. Efforts should be made to keep the tobacco industry out of all tobacco control initiatives, across all media and both online and offline.

While corporate websites did not have contests, coupons, and games that have been documented on brand websites [22,33,34], corporate websites used other types of engagement strategies such as apps and email alerts. Corporate websites also included additional links to other corporate tobacco websites, brand websites, and social media pages, connecting users with even more protobacco content. This is in line with other recent findings on brand websites, which similarly found that all assessed brand websites contained at least one link to a social media page [34,61]. Tobacco companies used each communication platform left open to them to link to other platforms to further spread their messages.

Although our assessment of brand websites was limited by registration requirements, the high prevalence of promotional material visible even from the registration page is cause for concern. Exposure to promotions is associated with youth and young adult initiation, as well as lower likelihood of smoking cessation [1,62-65]. The use of music, both playing in the background and as part of some promotions, is also concerning given that the industry has previously employed music as a way to target youth and racial and ethnic minorities [66]. Brand websites frequently used sociability appeals and were often portrayed through images of attractive young people gathering with friends. Such marketing may be more likely to reach young people online, where they are increasingly spending more of their time. The limited amount of information we were able to observe on social media webpages indicated that this type of website may be more focused on marketing to specific subgroups, as evidenced by the explicitly gendered appeals found on parts of the websites that we were able to access.

URLs on cigarette packs can link consumers with corporate and brand marketing that in turn may undermine restrictions imposed on the physical marketing environment. Monitoring how the tobacco industry adapts to an increasingly restrictive physical marketing environment through the use of URLs on packs and other innovations could be used to inform increased packaging restrictions and plain packaging to reduce the industry's ability to link tobacco users with additional protobacco messaging. Future marketing restrictions should explicitly include the online environment, and surveillance efforts should monitor industry websites to ensure proper enforcement of existing marketing restrictions.

Limitations and Strengths

The codebook for this project assessed a finite number of topics. Additionally, we did not code every webpage, leaving some content undocumented. Given the massive amount of content on websites we would have obtained if we had assessed every possible web component (including both internal and external links), we had to establish a limit on what was possible to code.

A total of 15 websites required translation; while translators were fluent in the translated language and in English, it is possible that there were some inaccuracies. To try to account for any confusion about translation, translators were present either in person or via Skype for clarification. Tobacco packs where the websites were found were purchased in 2013, and at the time of analysis (2016-2017) some websites were inactive, reducing the number of websites in our sample.

We were able to include coding only of corporate websites, nontobacco websites, and a limited number of brand and social media websites due to the terms and conditions regarding who was allowed to register and access website content. This limitation prevented us from deeply exploring brand and social media websites and allowed only a cursory glimpse of the content on these types of websites. There is a need for the research community to recognize and address such restrictions and establish norms for conducting critical public health surveillance research in online spaces.

To our knowledge, this is the most extensive analysis of an international sample of corporate tobacco websites. The sampling frame is unique in that URLs were from cigarette packs purchased in 14 LMICs, therefore covering a broader range of available websites, including state-owned and regional and national company websites in addition to country-specific multinational websites. Research on marketing, specifically internet marketing, in LMICs is rare.

Conclusions

The very existence of tobacco websites, whether corporate, brand, or social media, challenges existing laws concerning tobacco marketing in the countries where packs with URLs were purchased. According to legal analysis from the Tobacco Control Laws website [67] (see Multimedia Appendix 1), at least 7 of the 13 countries where packs were purchased currently ban online tobacco advertising. Bans in China and Thailand were passed after packs were purchased in 2013, but even these 2 later bans were in place before we conducted our content analysis and should have resulted in these websites being removed. An additional 3 countries have legislation that could be interpreted as banning online advertising, and 2 have some restrictions on online advertising. Brand and social media tobacco website URLs appeared on packs purchased in Russia and Vietnam, where online marketing is banned. It's unclear whether corporate websites, which clearly include marketing appeals and engagement strategies, as well as the promotion of CSR programs, are included in these bans. What is clear is that tobacco companies are taking advantage of this lack of clarity in legislation and lack of enforcement to use the internet to further disseminate both corporate and brand marketing that serves to improve their corporate image and keep people using tobacco products. It is essential that marketing regulations become more comprehensive and ban all protobacco communication, a policy that is in line with articles 5.3 and 13 of the FCTC [57,58]. Plain packaging and other packaging restrictions would also limit the industry's ability for mass dissemination of their websites and should also be considered. These policy recommendations are especially important for LMICs, where the tobacco industry has concentrated their marketing efforts to take advantage of the looser regulatory environment [37,68,69]. Efforts to monitor tobacco company marketing should consider including online marketing, as well as social media activities, in light of their growing ubiquity.

Acknowledgments

This work was supported with funding by Bloomberg Philanthropies' Bloomberg Initiative to Reduce Tobacco Use. CVW was supported by T32 CA009314 during manuscript development.

CVW was responsible for study design, coding, reliability calculations, analysis, and manuscript preparation. AYH assisted with coding and manuscript preparation. KS and JEC reviewed the study design and assisted in manuscript preparation.

Abstract

Background: The Australian Collaboration for Coordinated Enhanced Sentinel Surveillance (ACCESS) was established to monitor national testing and test outcomes for blood-borne viruses (BBVs) and sexually transmissible infections (STIs) in key populations. ACCESS extracts deidentified data from sentinel health services that include general practice, sexual health, and infectious disease clinics, as well as public and private laboratories that conduct a large volume of BBV/STI testing. An important attribute of ACCESS is the ability to accurately link individual-level records within and between the participating sites, as this enables the system to produce reliable epidemiological measures.

Objective: The aim of this study was to evaluate the use of GRHANITE software in ACCESS to extract and link deidentified data from participating clinics and laboratories. GRHANITE generates irreversible hashed linkage keys based on patient-identifying data captured in the patient electronic medical records (EMRs) at the site. The algorithms to produce the data linkage keys use probabilistic linkage principles to account for variability and completeness of the underlying patient identifiers, producing up to four linkage key types per EMR. Errors in the linkage process can arise from imperfect or missing identifiers, impacting the system's integrity. Therefore, it is important to evaluate the quality of the linkages created and evaluate the outcome of the linkage for ongoing public health surveillance.

Methods: Although ACCESS data are deidentified, we created two gold-standard datasets where the true match status could be confirmed in order to compare against record linkage results arising from different approaches of the GRHANITE Linkage Tool. We reported sensitivity, specificity, and positive and negative predictive values where possible and estimated specificity by comparing a history of HIV and hepatitis C antibody results for linked EMRs.

Results: Sensitivity ranged from 96% to 100%, and specificity was 100% when applying the GRHANITE Linkage Tool to a small gold-standard dataset of 3700 clinical medical records. Medical records in this dataset contained a very high level of data completeness by having the name, date of birth, post code, and Medicare number available for use in record linkage. In a larger gold-standard dataset containing 86,538 medical records across clinics and pathology services, with a lower level of data completeness, sensitivity ranged from 94% to 95% and estimated specificity ranged from 91% to 99% in 4 of the 6 different record linkage approaches.

Conclusions: This study's findings suggest that the GRHANITE Linkage Tool can be used to link deidentified patient records accurately and can be confidently used for public health surveillance in systems such as ACCESS.

Introduction

Background

The Australian Collaboration for Coordinated Enhanced Sentinel Surveillance (ACCESS) of blood-borne viruses (BBVs) and sexually transmissible infections (STIs) monitors diagnostic testing and other episodes of care for priority BBVs and STIs [1,2]. ACCESS extracts deidentified patient data from a network of laboratories and clinics, including those that manage high caseloads of patients from populations with heightened risk for BBVs and STIs, including gay, bisexual, and other men who have sex with men and people who inject drugs. The main objective of ACCESS is to measure and report key indicators such as disease incidence and prevalence (measured as proportion positive) to monitor and support Australia's efforts to reduce the transmission of morbidity and mortality caused by BBV and STI [3-5].

A key challenge for ACCESS (and similar sentinel surveillance systems) is that patient outcomes can be inaccurately measured if individuals attend multiple health services, leading to potential reporting bias. For example, markers of testing frequency, an important indicator for BBV/STI prevention and management [3-5], may be underestimated if individuals test at multiple services. Accurate linkage of individuals within and between services in ACCESS provides more accurate measures of (1) the key indicators relating to Australia's BBV and STI National Strategies and (2) the effect of interventions aimed at reducing the impact of BBVs and STIs.

The linkage of deidentified ACCESS records across sites relies on specialized health data extraction software GRHANITE, which is installed at participating clinics and laboratories. GRHANITE interfaces with patient databases, securely extracting line-listed consultation, demographic, BBV and STI clinical and pathology data [6]. Before data are transferred from ACCESS sites, GRHANITE creates a unique record ID to identify an electronic medical record (EMR) and uses patient-identifying information to generate irreversible hash-coded linkage keys associated with that record. The record ID and linkage keys, rather than the personal identifiers, are transferred with the patients' clinical and pathology data to a secure data bank, preserving patient privacy [7]. A link ID is then generated [8] when the same patient is linked across different EMRs by matching linkage keys using a companion software called the GRHANITE Linkage Tool [9].

Objectives

The GRHANITE Linkage Tool has been validated to perform large-scale population-level record linkage [10] to achieve similar sensitivity and specificity data linkage profiles as per traditional person-identifiable data linkage mechanisms [9]. Given that there is variation in the available person-identifiable data at clinical and laboratory sites in ACCESS, the focus of this paper is to assess the quality of linkage results by applying different approaches to using the GRHANITE Linkage Tool in ACCESS. To evaluate the GRHANITE Linkage Tool for ongoing public health surveillance, we measured the outcomes of record linkage using the tool against gold-standard linked datasets derived from ACCESS data.

Methods

Australian Collaboration for Coordinated Enhanced Sentinel Surveillance Data Extraction and Linkage via GRHANITE

Electronic Medical Records

Typically, when a patient first attends a medical facility, an EMR is created in the facility's patient database, containing the patient's identifying information, including the name, date of birth, contact details, and Medicare number (an Australian government–issued health care card number used for Medicare billing). Most clinics will also have recorded other demographic information, such as preferred language, country of birth, and indigenous background in the EMR.

Every individual's EMR has a unique medical record number generated by the patient database, linking all of a patient's consultations, tests, and prescription records. Multiple EMRs may be created for one patient at the same facility if the patient's details change and are not updated, leading to the creation of a new EMR; if the patient uses an alias; or if the patient attends a clinic that allows anonymous or free testing.

Data Extraction in the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance

Data were extracted from participating ACCESS clinical sites that included an EMR for every patient available in their databases at the time of extraction. GRHANITE generated a new unique record ID and up to four irreversible hash-coded linkage keys for each EMR. Personal identifying information (eg, name, date of birth, Medicare number) in the patient's EMR was passed through advanced encryption to generate both record ID and linkage keys [7]. The record ID and linkage keys were extracted by GRHANITE alongside the patient demographics, consultation, test request, pathology, and prescription information related to BBV and STI care, without the identifying information. Data extraction was similar for laboratories; however, only BBV and STI test records related to diagnosis and care and a limited set of demographic variables were available for extraction (Figure 1).

Figure 1. Data extraction in the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance: using GRHANITE to deidentify electronic medical records and create linkage keys.

Linkage Key 2: <missing>
Linkage Key 3: 2TReY8765
Linkage Key 4: <missing>

Record Linkage in the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance

The data components used by GRHANITE to create the linkage keys include the following patient identifiers: 5 digits of the Medicare number, date of birth, sex, first name, last name, and residential postcode. However, not all EMRs have the same set of patient identifiers recorded in the same way. For example, a patient name may be recorded as *William* in one clinic with a full date of birth and *Bill* in another clinic with only a year of birth recorded. GRHANITE utilizes data preprocessing to remove unwanted characters and words and to resolve nicknames utilizing an Australian national nickname list. Phonetic encoding (double metaphone) is then employed, which permits fuzzy matching based on misspellings of the surname and forename. Transposition of day and month of birth is also supported. After preprocessing, identifiers are combined and then encrypted utilizing secret seeding keys and cryptographic hashing to generate the GRHANITE privacy-preserving cryptographic hashed linkage keys [7,9].

GRHANITE creates up to four linkage keys for each EMR, using combinations of identifying information that is recorded at each site (Textbox 1) [11]. For example, if the Medicare number was not recorded for a patient, then linkage keys that require 5 Medicare digits (Textbox 1: linkage key types 1, 2, and 4) could not be created, resulting in EMRs extracted via GRHANITE having only one linkage key (Textbox 1: linkage key 3 does not require the Medicare number; Figure 1).

Textbox 1. Types of linkage keys generated by GRHANITE.

Linkage key and components of base identifying information:

- Type 1: 5 Medicare digits; date of birth; and sex
- Type 2: 5 Medicare digits; postcode; first three characters of first name; and year of birth
- Type 3: Last name and first name (either order permitted) and fuzzy matching used; date of birth with day/month (transpositions permitted)
- Type 4: Last name and first name (either order permitted) and fuzzy matching used; 5 Medicare digits

Applying the GRHANITE Linkage Tool

There are three steps in the record linkage process in ACCESS when applying the linkage tool. The first step finds pairs of EMRs based on at least one linkage key matching and records the linkage key type/s used to match each record pair. The second step examines the strength of the link using other available data within the matched pair of records to accept or reject linked records as described in Table 1. The third step assigns an identifier (a link ID) to the accepted matched pairs to label all matched records as belonging to the same individual (Figure 2).

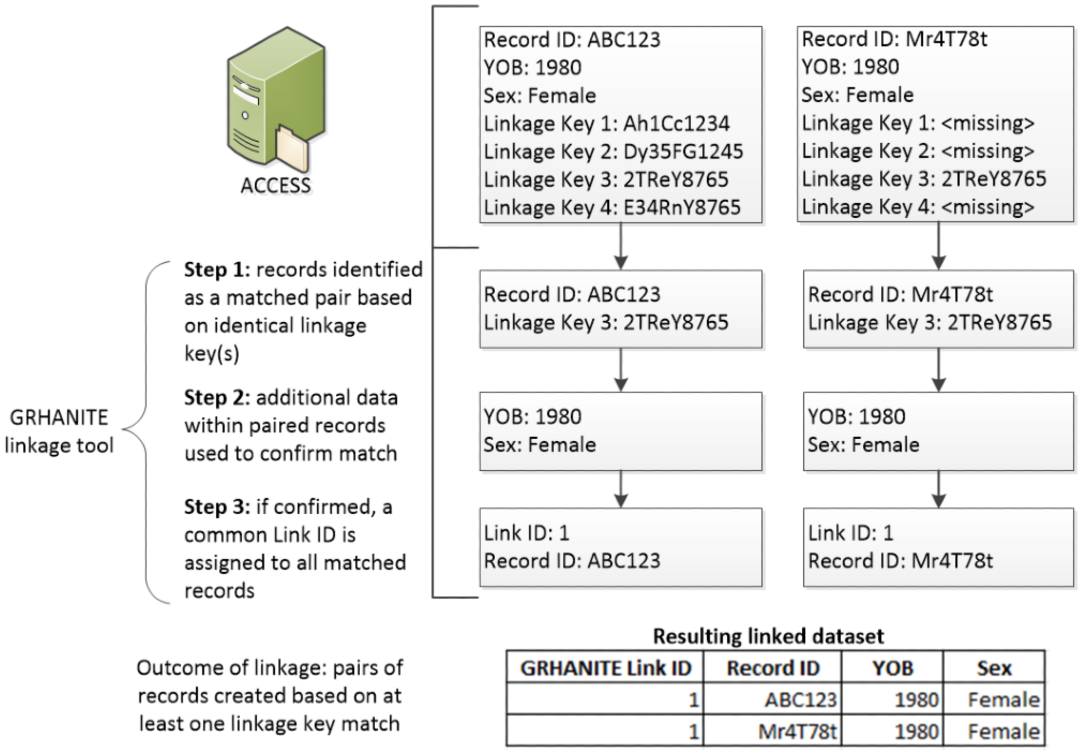
Table 1. GRHANITE Linkage Tool approaches to accepting matches.

Linkage approach	Description
Accept all	Accept all record links as determined by the linkage tool
Year of birth match	Accept only record links if year of birth matches
Sex match	Accept only record links if sex matches
Year of birth and sex match	Accept only record links if year of birth and sex match
Two or more linkage keys[a]	Accept record links only if matched on two or more linkage key types
Linkage key type 3 plus sex match[b]	Accept only record links that match on linkage key type 3 and match on sex

[a] Given that 3 out of the 4 linkage key types are generated using the Medicare number, this approach requires the Medicare number to be present in the EMR (Textbox 1).

[b] This approach only relies on linkage key type 3, which does not require the Medicare number to be present in the EMR.

Figure 2. Record linkage in the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance: using the GRHANITE Linkage Tool to identify and accept matches.



Record ID: ABC123
YOB: 1980
Sex: Female
Linkage Key 1: Ah1Cc1234
Linkage Key 2: Dy35FG1245
Linkage Key 3: 2TReY8765

Linkage Key 3: 2TReY8765
Linkage Key 4: <missing>

Step 1: records identified as a matched pair based on identical linkage key(s)

Record ID: ABC123
Linkage Key 3: 2TReY8765

Record ID: Mr4T78t
Linkage Key 3: 2TReY8765

Step 2: additional data within paired records used to confirm match

YOB: 1980
Sex: Female

YOB: 1980
Sex: Female

Step 3: if confirmed, a common Link ID is assigned to all matched records

Link ID: 1
Record ID: ABC123

Link ID: 1
Record ID: Mr4T78t

Outcome of linkage: pairs of records created based on at least one linkage key match

Resulting linked dataset

GRHANITE Link ID	Record ID	YOB	Sex
1	ABC123	1980	Female
1	Mr4T78t	1980	Female

Evaluating the Record Linkage

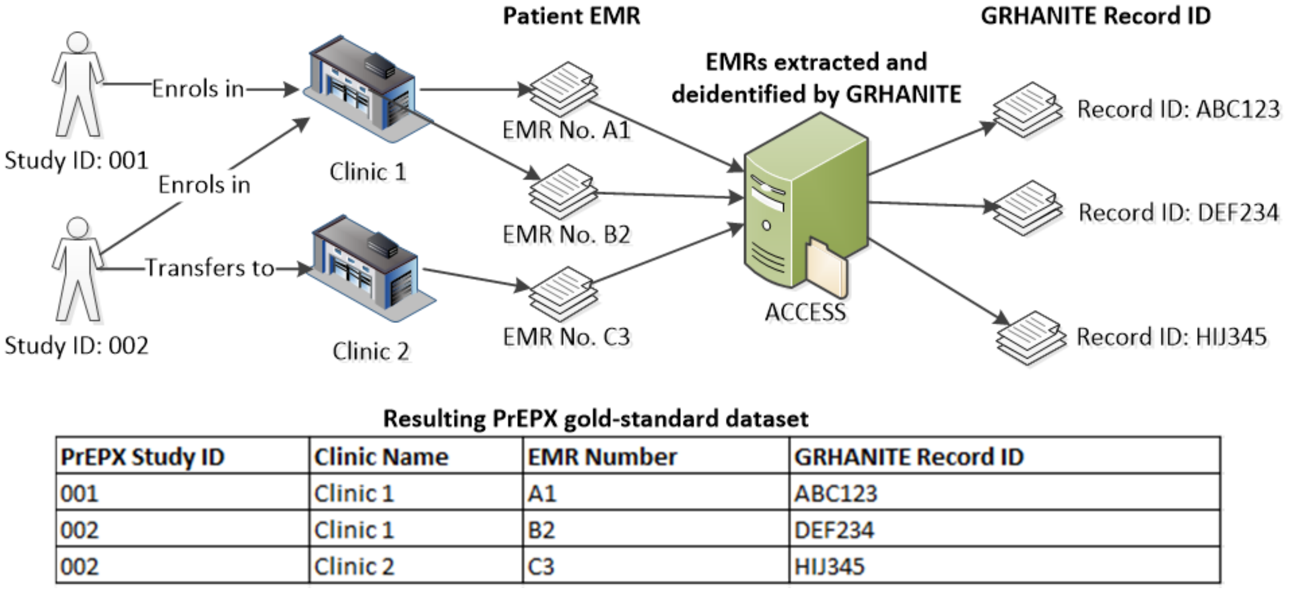
Creating the Gold-Standard Datasets

To evaluate the record linkage in ACCESS, we generated two gold-standard datasets, using a deterministic record linkage method, where the true match status could be identified [12]. To assess the outcomes of the six linkage approaches described in Table 1, using the GRHANITE Linkage Tool for matching the records in the gold-standard datasets, we measured the sensitivity, specificity, and positive and negative predictive values, where possible.

The PrEPX Gold-Standard Dataset

PrEPX is a population-level intervention study in Victoria in which HIV pre-exposure prophylaxis was made available to eligible individuals, and the study used ACCESS data to monitor participants' BBV and STI testing [13]. Eight clinical sites and one hospital clinic participating in ACCESS had PrEPX participants enrolled between July 2016 and March 2018. At enrollment, a PrEPX study ID was sequentially assigned and recorded alongside each participant's enrollment-clinic EMR number in a study database. Following enrollment in PrEPX, if a participant attended a different clinic within the network during the study period, the EMR number from the new clinic was also recorded in the study database. ACCESS had ethics approval to extract the EMR number from the participating clinics for the purpose of matching the records of participants who moved among clinics. To create the gold-standard dataset, EMRs were matched on clinic EMR number, clinic name, and clinic visit date. The gold standard included one record per PrEPX participant who attended only one clinic during the study period and multiple records per PrEPX participant who attended multiple clinics linked by study ID (Figure 3).

Figure 3. Data flow of electronic medical records in PrEPX and deterministic linkage for the gold-standard dataset.



Resulting PrEPX gold-standard dataset

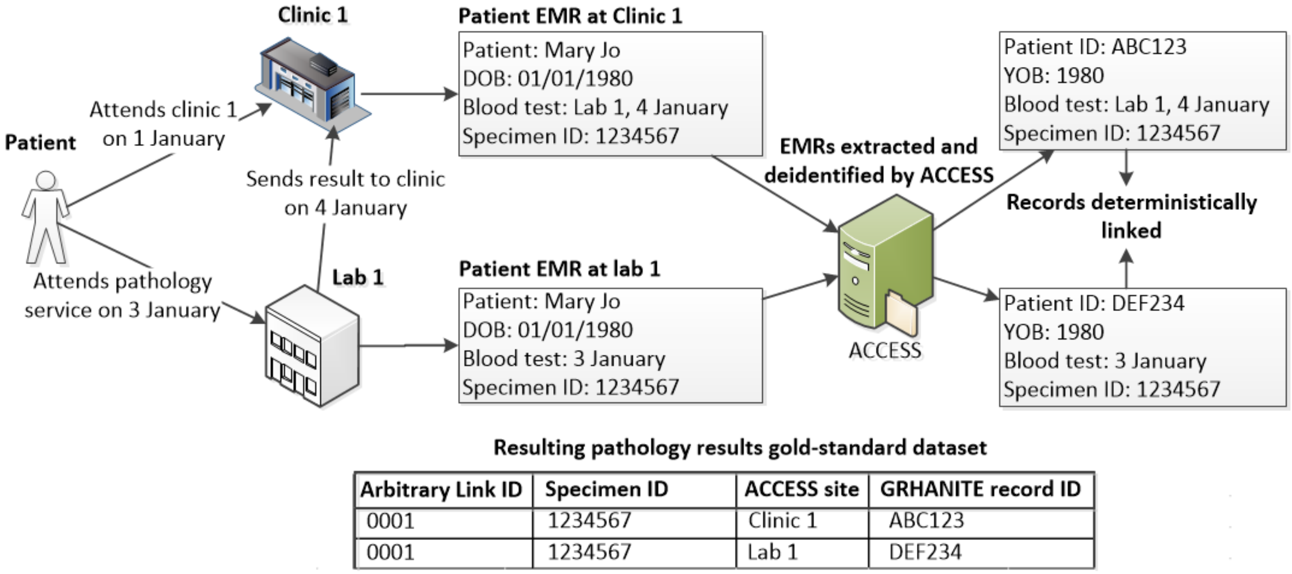
PrEPX Study ID	Clinic Name	EMR Number	GRHANITE Record ID
001	Clinic 1	A1	ABC123
002	Clinic 1	B2	DEF234
002	Clinic 2	C3	HIJ345

The Pathology Results Gold-Standard Dataset

A second and much larger gold-standard dataset was generated from the EMRs extracted from 7 clinics and 4 laboratories participating in ACCESS between January 2009 and April 2018. To be included in this dataset, patients had to have at least one specimen sent from one of the ACCESS clinics to one of the ACCESS laboratories. A unique laboratory specimen ID was assigned to the specimen at the laboratory, and when laboratories returned pathology results to the clinic, this specimen ID was also recorded at the clinic. To create the gold-standard dataset, clinic and laboratory records were matched using the laboratory specimen ID, year of birth, and test date. We allowed for a 7-day difference in test dates, as in medical records, the recorded date can commonly vary for the same specimen. Only matched records were included in the gold-standard dataset and linked using an arbitrarily assigned link identifier (Figure 4).

An EMR in the pathology results gold-standard dataset may match to many other EMRs for several reasons, including the following: individuals may have had multiple specimens sent to multiple laboratories for testing, individuals may have attended different clinics and therefore had the same test result sent from the laboratory to more than one clinic, or individuals may have had multiple EMRs at the laboratory or clinic as a result of outdated or incomplete personal identifiers.

Figure 4. Data flow of pathology results in electronic medical records and deterministic linkage for the gold-standard dataset.



Arbitrary Link ID	Specimen ID	ACCESS site	GRHANITE record ID
0001	1234567	Clinic 1	ABC123
0001	1234567	Lab 1	DEF234

Data Analysis

Sensitivity

The sensitivity was calculated as the number of correctly linked EMRs, as identified using the GRHANITE Linkage Tool, as a percentage of the total number of linked EMRs in the gold standard dataset.

Specificity

In the PrEPX gold-standard dataset, the specificity was calculated as the number of single EMRs correctly identified as unlinked using the GRHANITE Linkage Tool as a percentage of the total number of unlinked EMRs. The positive predictive value (PPV) and negative predictive value were also calculated to provide probabilities of true matches and missed matches.

Given the deidentified nature of the ACCESS data, it was not possible to include unmatched specimen IDs in the pathology results gold-standard dataset because there was no way to confirm whether they belonged to different individuals (correctly unmatched), making it impossible to calculate specificity. Therefore, to evaluate specificity, we assessed the concordance of chronological HIV and hepatitis C test records to identify EMRs that should not have been linked. By identifying the linked EMRs with discordant results, the PPV (the proportion of linked records with concordant antibody results) could be determined. The specificity was then estimated using the PPV and the sensitivity for each linkage approach as summarized in Figure 5.

Figure 5. Estimating specificity when positive predictive value and sensitivity are known.

		Gold-Standard	
		Linked EMR	Unlinked EMR
Observed GRHANITE Linkage Result	Linked EMR	True Positive (TP)	False Positive (FP)
	Unlinked EMR	False Negative (FN)	True Negative (TN)

When PPV is known, the number of false and true positives can be derived:

- FP = (1-PPV) x Observed number of linked EMRs
- TP = Observed number of linked EMRs – FP

When sensitivity is known, the number of false and true negatives can be derived:

- FN = (TP/Sensitivity) - TP
- TN = Observed number of unlinked EMRs – FN

The number of true negative and false positives can then be used to estimate specificity:

- Specificity = [TN/(FP + TN)] × 100

Measuring Incorrect Matches Using Discordant Pathology Results

Following infection, any HIV or hepatitis C antibody test that subsequently occurs should always return a positive result. Using the pathology results gold-standard dataset provided only a small number of HIV and hepatitis C results; therefore, a dataset of linked EMRs was derived using all available EMRs from the same clinic and laboratory sites used to create the gold-standard dataset. Two datasets were created, one that contained any HIV western blot or antibody result and one that contained any hepatitis C antibody result. EMRs containing discordant results before record linkage were excluded from the sample so as not to confuse it with discordance resulting from record linkage. Records within each dataset were then linked using all six approaches (Table 1) of the GRHANITE Linkage Tool. Linked EMRs where there was no history of a positive result were removed from the sample, as a discordant test result can only be determined after an initial positive result. Therefore, in the HIV and hepatitis C datasets, only linked EMRs that contained an antibody result after an initial positive HIV western blot or hepatitis C antibody result were retained for evaluation.

To calculate the PPV, the linked EMRs were then inspected for negative antibody results occurring at least seven days after a positive test result, which were then classified as incorrectly matched. Where most subsequent antibody tests were negative, the initial and any subsequent positive results were considered incorrectly matched records.

Results

Record Linkage Using the PrEPX Gold-Standard Dataset

The PrEPX gold-standard dataset identified 28 joins among 56 EMRs, indicating 28 study participants had attended two different clinical sites during the PrEPX study period. The remaining 3644 EMRs were from participants who only attended a single clinic during the study and therefore did not have any linked records.

Over 99% of EMRs had all four linkage key types present in 8 of the 9 sites, indicating that the patient-identifying information to generate those linkage keys was near fully recorded at the clinics. One site was missing data needed to generate linkage types 1, 2, and 4 (which all require the Medicare number) in 11% (8/76) of their EMRs (Table 2).

In all linkage approaches, except the approach requiring two or more linkage keys, all pairs of EMRs from the 28 individuals who attended two sites were correctly joined (100% sensitivity). With the approach which required two or more linkage keys for matching, one pair was not identified (96% sensitivity). Specificity was 100% using all linkage approaches, without any of the remaining 3644 EMRs in the dataset being falsely linked (Table 3).

Table 2. Percentage of electronic medical records in the PrEPX gold-standard dataset by linkage key type and site.

Site	Number of electronic medical records, N	Percentage of electronic medical records with Linkage Key			
		Type 1, n (%)	Type 2, n (%)	Type 3, n (%)	Type 4, n (%)
Site 1	76	68 (89)	68 (89)	76 (100)	68 (89)
Site 2	853	853 (100.0)	853 (100.0)	853 (100.0)	853 (100.0)
Site 3	1087	1087 (100.00)	1084 (99.72)	1087 (100.00)	1087 (100.00)
Site 4	582	582 (100.0)	582 (100.0)	582 (100.0)	582 (100.0)
Site 5	40	40 (100.0)	40 (100.0)	40 (100.0)	40 (100.0)
Site 6	135	135 (100.0)	135 (100.0)	135 (100.0)	135 (100.0)
Site 7	106	106 (100.0)	103 (99.2)	106 (100.0)	106 (100.0)
Site 8	314	314 (100.0)	314 (100.0)	314 (100.0)	314 (100.0)
Site 9	507	507 (100.0)	507 (100.0)	507 (100.0)	507 (100.0)
Total	3700	3692 (99.78)	3686 (99.62)	3700 (100.00)	3692 (99.78)

Table 3. Evaluation measures derived from using the GRHANITE Linkage Tool on the PrEPX gold-standard dataset.

Linkage approach	Sensitivity (N=56), n (%)	Specificity (N=3644), n (%)	Positive predictive value (N=56), n (%)	Negative predictive value (N=3644), n (%)
Accept all	56 (100)	3644 (100.00)	56 (100)	3644 (100.00)
Year of birth match	56 (100)	3644 (100.00)	56 (100)	3644 (100.00)
Sex match	56 (100)	3644 (100.00)	56 (100)	3644 (100.00)
Year of birth and sex match	56 (100)	3644 (100.00)	56 (100)	3644 (100.00)
Two or more linkage keys	54 (96)	3644 (100.00)	54 (100)[a]	3644 (99.90)[b]
Linkage key type 3 plus sex match	56 (100)	3644 (100.00)	56 (100)	3644 (100.00)

[a] N=54.

[b] N=3646.

Record Linkage Using the Pathology Results Gold-Standard Dataset

Using the GRHANITE Linkage Tool on the pathology results gold-standard dataset created 50,484 linked records among 86,538 EMRs, with a maximum of six EMRs identified as belonging to the same individual.

A total of 99.69% (86,273/86,538) of EMRs contained at least one linkage key type, and all four linkage key types were present in 73.51% (63,610/86,538) of records, suggesting that the completion of patient-identifying information in the patient database was very high overall. However, 21.62% (18,709/86,538) of EMRs had only linkage key type 3 available for matching. One or more of linkage types 1, 2, and 4 (which all require the Medicare number) was missing in 97.42% (7914/8124) of EMRs from one public laboratory, 53.95% (5967/11,060) of EMRs from the sexual health clinic, 48.25% (1403/2908) of EMRs from a private laboratory, and 23.42% (6134/26,186) of EMRs from another public laboratory (Table 4).

For the first 4 linkage approaches, the GRHANITE Linkage Tool correctly linked 94% to 95% of EMRs in the pathology results gold-standard dataset, dropping to 66% (57,330/86,538) where two or more linkage keys are needed to form a match (Table 5). In the final linkage approach, where pairs were only accepted when matched on linkage key type 3 (which does not require the Medicare number) and sex, 89% (76,928/86,538) of records were correctly linked.

Table 4. Percentage of electronic medical records in the pathology gold-standard dataset by linkage key type and site.

Site	Number of electronic medical records, N	Number of electronic medical records with no linkage keys, n (%)	Percentage of electronic medical records with Linkage Key			
			Type 1, n (%)	Type 2, n (%)	Type 3, n (%)	Type 4, n (%)
Clinic 1	3165	0 (0.00)	3083 (97.41)	3077 (97.22)	3165 (100)	3083 (97.41)
Clinic 2	6342	0 (0.00)	6031 (95.10)	6015 (94.84)	6342 (100)	6031 (95.10)
Clinic 3	2514	0 (0.00)	2493 (99.16)	2489 (99.01)	2513 (99.96)	2492 (99.12)
Clinic 4	9679	0 (0.00)	9351 (96.61)	9322 (96.31)	9676 (99.97)	9350 (96.60)
Clinic 5	1369	1 (0.07)	1357 (99.12)	1356 (99.05)	1368 (99.93)	1357 (99.12)
Clinic 6	2489	5 (0.20)	2315 (93.01)	2288 (91.92)	2484 (99.80)	2315 (93.01)
