Compared with face-to-face consultation, e-consultation has some natural advantages and unavoidable limitations. Specially, users only use words, pictures, and videos to communicate with doctors and are unable to receive a medical examination. Therefore, e-consultation is only used on nonurgent minor ailments now [6]. However, according to 2020 World Health Statistics, most patients develop common and chronic diseases, which means that e-consultation could meet great medical demands. In addition to medical advice on diagnosis and treatment regimen, e-consultation could provide patients with timelier and more convenient care [7,8], reduce cost for patients [7,9,10], and improve equitable access for underserved patients and to specialist care [11,12]. For the health system, e-consultation could improve the efficiency of referrals and face-to-face consultation [13-17] and improve the quality of health care [13,18]. Therefore, e-consultation might be a potential solution for major challenges that our health care system faces today [12]. However, many patients are unwilling to use e-consultation even if their illnesses are not serious because they prefer to see doctors in person [19]. A study showed that the average workload of doctors providing web-based health care services was 0.38 patients in China [20] and the situation that people lack awareness of e-consultation exists in a developed country too [21]. For the large part, users are unwilling to believe in the judgments of the doctors in web-based health care services without seeing doctors and without undergoing a medical examination [22]. Our previous survey also found that patients with prior experience of using e-consultation went to the hospital later for the same disease because they wanted to check if the judgement of the doctors providing web-based health care services was accurate. There are great risks perceived by patients if they follow the e-consultation judgement completely. Therefore, many people stated that with the help of their primary care providers, they can use e-consultation better in order to avoid mistakes [23].

As mentioned above, there are many researches focused on the clinical and socioeconomic effects of e-consultation, but these researches have not explored the process or the acceptance of e-consultation or the barriers and the promoters of e-consultation [24]. The content of e-consultation is significantly different from the other functions of eHealth; therefore, we cannot simply apply the usage mechanism of eHealth into e-consultation. This study can fill this gap effectively. The acceptance of e-consultation is a matter of accepting medical information technology, and the technology acceptance model (TAM) explains the acceptance behavior of information communication technology for individuals well [25]. However, our preliminary research and field investigation showed that perceived risk was a significant factor influencing usage behavior, which was reported in many studies as well. However, perceived risk is always taken as a simple dimension in prior researches, which lead to the lack of specific and accurate guiding effects on reality. This research aims to further decompose the perceived risk dimension comprehensively. Therefore, combining TAM and perceived risk, we reconstructed a new model to explore the acceptance mechanism of e-consultation, and we hope this research would help governments and providers make effective and efficient intervention strategies.

Theoretical Background

TAM

The TAM was proposed by Davis based on the previous theories. TAM focuses on an individual's intention to accept information technology. In TAM, perceived usefulness is defined as the extent to which people believe apps would help them perform their job better. Perceived ease of use is defined as the extent to which people believe using apps would be free of effort. Perceived usefulness and perceived ease of use are the 2 main elements that have influence on the intention to use, and sufficient intention leads to actual usage behavior [25]. TAM has been successfully adapted in many eHealth [26], mobile health [27], mobile management systems [28,29], and web-based medical websites [30].

Perceived Risk Theories

A lot of researches show that perceived risk is a key factor that influences people to use medical innovations [28,31-33]. In the medical field, the public always makes medical decisions uncertainly due to information asymmetry, especially when using some emerging medical products and functions. e-Consultation has not really realized the maturity of technology and the stability of the service mode, which aggravates the uncertainty. As shown in the research that even if patients reported satisfaction and acceptance of e-consultation, they did not express strong interests in participating in this interaction because of medical responsibility and accuracy of disease description [34]. Therefore, we take perceived risk as one of the core dimensions of this study and integrate it with TAM.

Originally, perceived risk illustrates the mechanism of people for accepting new brands in the commercial market. It is a sense of uncertainty caused by consumers' inability to predict the outcome of their purchases. The components of perceived risk includes performance risk, physical risk, financial risk, social risk, and psychological risk [35]. With the development of the perceived risk theory, more components are added into the construct, including time risk [36] and privacy risk [37]. Perceived risk theory holds the view that people try to minimize the perceived risk of behavior rather than to maximize the perceived benefit when making consumption decisions [38]. In our study, performance risk is defined as the possibility of e-consultation not performing as it is designed [35,39]. Physical risk is the chances that e-consultation could result in delays in treatment or in misdiagnoses [35]. We can find that delaying treatment or a misdiagnosis means performing out of control; therefore, we just need to keep one factor between performance risk and physical risk. Financial risk and time risk refer to the possibility that users may face loss of money and time when using e-consultation [35,39]. Social risk is the chances that the use of e-consultation would affect the way others think of the users [35,39]. Psychological risk is the chance that e-consultation would not fit in well with users' self-image or self-concept [35,39]. Privacy risk is the potential loss of control over personal information [35,39].

Personal Innovativeness

Personal innovativeness is defined as the degree to which a person is relatively willing to adopt e-consultation in this study [40]. The relationship between technology and the degree of receptiveness to innovation determines how quickly a person adopts information and communications technology [41]. Personal innovativeness can explain the individual differences in their perception of e-consultation advantages and risks. Individuals with higher innovativeness prefer change and tend to gather more information of the technical products. The positive attitude of the innovator toward products would be promoted by the increased interaction with products, which makes them pay more attention to the advantages of technical products and not worry about products working in the designed way [42]. This viewpoint has also been tested in several researches of mobile health adoption [27,43].

Research Model and Hypotheses

The public can choose any registered doctor on the e-consultation platform with a limited cost. The platforms provide users with all kind of hospital departments with different service levels from different regions. Thus, the public have more access for better consultation services. Through e-consultation, users can receive valuable suggestions easily and quickly. After obtaining enough suggestions, they are able to make and follow health decisions better. These functions of e-consultation are attractive to the users. Besides, if it is easy to learn how to use e-consultation, it means that the public will accept e-consultation easier without much effort. Thus, we propose the following hypotheses based on TAM:

Hypothesis 1: Perceived usefulness will influence behavior intention positively.

Hypothesis 2: Perceived ease of use will influence behavior intention positively.

Hypothesis 3: Perceived ease of use will influence perceived usefulness positively.

If e-consultation provides incorrect suggestions, users would be delayed in accepting correct treatment or they may receive wrong treatment. Loss of performance means a loss of health. Unlike the common consumer behavior, performance risk and physical risk are always perceived by the public together. Therefore, physical risk could be absorbed into performance risk. In the TAM, perceived usefulness reflects the functions of e-consultation as well. High levels of risk perceived by people means that they have a suspicion on the usefulness of e-consultation. Therefore, it is unnecessary to integrate performance risk and physical risk into the model again. Besides, since e-consultation needs users to submit symptoms, medical records, and other personal information, the operation of e-consultation would be a new challenge for the user. Thus, we propose the following hypotheses:

Hypothesis 4a: Financial risk is a component of perceived risk of using e-consultation.

Hypothesis 4b: Privacy risk is a component of perceived risk of using e-consultation.

Hypothesis 4c: Social risk is a component of perceived risk of using e-consultation.

Hypothesis 4d: Time risk is a component of perceived risk of using e-consultation.

Hypothesis 4e: Psychological risk is a component of perceived risk of using e-consultation.

Hypothesis 5: Perceived risk will influence perceived usefulness negatively.

Hypothesis 6: Perceived risk will influence perceived ease of use negatively.

Hypothesis 7: Perceived risk will influence behavior intention negatively.

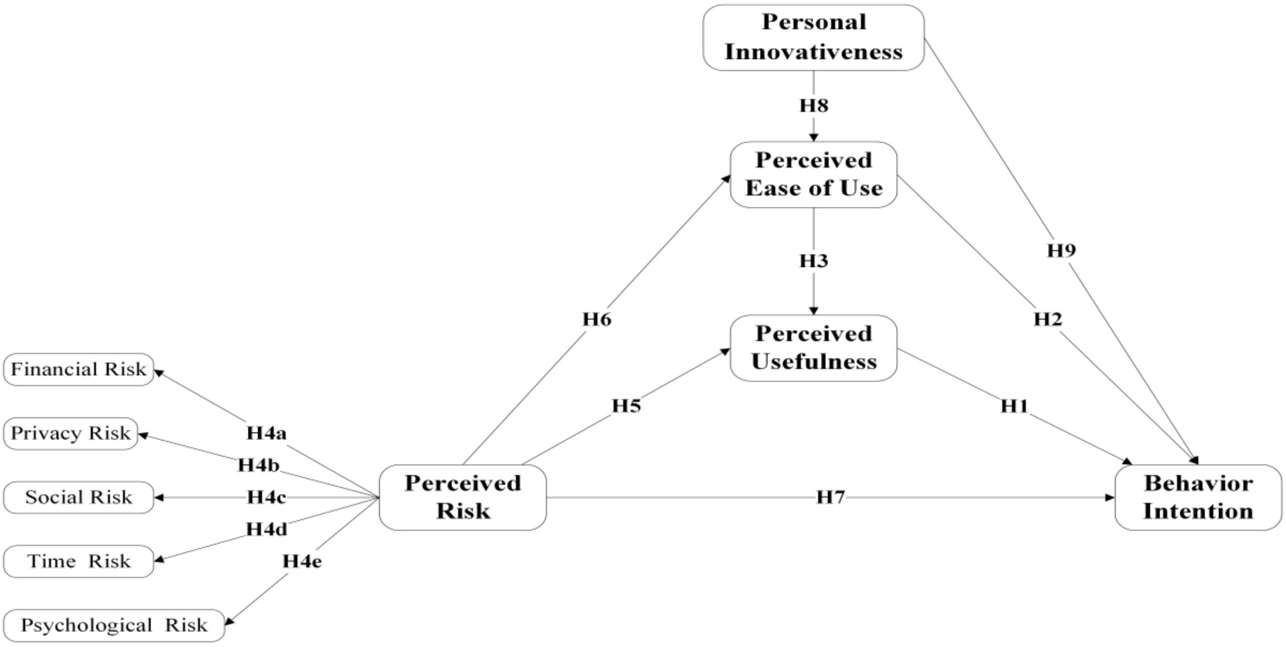
e-Consultation as a combination of information technology and medical services subverts the traditional concept of consultation. Therefore, if people have better innovativeness, they are willing to adopt all kinds of new information technology, including e-consultation. Some other researches show that personal innovativeness also has a direct effect on perceived ease of use. Because people with high level of innovativeness have richer experience in using emerging products, they would think the operation of e-consultation is less difficult. Thus, we propose the following hypotheses:

Hypothesis 8: Personal innovativeness will influence perceived ease of use positively.

Hypothesis 9: Personal innovativeness will influence behavior intention positively.

Overall, the research model is showed in Figure 1.

Figure 1. Research model based on the technology acceptance model and perceived risk theory. Personal innovativeness had effects on behavior intention and perceived ease of use. H: hypothesis.



Aim of This Study

The objective of this study was to investigate people's actual usage of e-consultation and their characteristics. Moreover, based on the TAM integrating with perceived risk and personal innovativeness theory, a questionnaire survey was used to explore the relationships and paths of the factors that influence people's intention to use e-consultation.

Methods

Study Design

All survey items were adopted from previous studies related to eHealth and health information technology. The first version of the questionnaire was directly translated from English to Chinese by a group of researchers. Items were reasonably changed to adapt to the e-consultation. Then, the second version of the questionnaire was completed after 2 rounds of experts' discussions on the first questionnaire. The experts consisted of 2 college professors, 7 staffs from an eHealth company, and 7 doctors with e-consultation using experience. Some items were added or removed or replaced according to the suggestions of experts. The third modification of the questionnaire was completed after a preliminary survey of 222 students majoring in health management from Capital Medical University. Some items were removed or changed to ensure the reliability and validity of the questionnaire. In the end, back translation was performed from Chinese to English by another qualified translator. The final items (Table 1, [44-46]) were measured with a 5-point Likert scale ranging from "strongly disagree" (1) to "strongly agree" (5). The final questionnaire consisted of 2 parts. The first part was the demographic information of the respondents. The second part, which includes the items for constructs, was designed to measure the respondents' perception on each item.

Table 1. Measurement items of the constructs.

Construct	Item
PU[a] [25,44,45]	
PU1	Using e-consultation would make it easier to consult a specialist or a certified doctor.
PU2	Using e-consultation enables me to understand my disease and treatment recommendation more quickly.
PU3	Using e-consultation facilitates complete communication with doctor.
PU4	Using e-consultation enables me to know more about disease prevention and management.
PU5	Using e-consultation enables me to make better treatment-related decisions.
PU6	I find it easy to obtain information on e-consultation.
PEU[b] [25,44,45]	
PEU1	Learning to use e-consultation is easy for me.
PEU2	In e-consultation, my doctor talks to me clearly and helps me understand my situation appropriately.
PEU3	Using e-consultation would not require much mental effort.
PEU4	It is easy for me to become skillful at using e-consultation.
FR[c] [31,35,39]	
FR1	e-Consultation is not effective and is a waste of money.
FR2	e-Consultation may make me spend extra money in case of a misdiagnosis, leading to delayed correct treatment.
FR3	Using e-consultation may lead to potential fraud.
PRR[d] [35,39]	
PRR1	After using e-consultation, my personal information may be leaked.
PRR2	After using e-consultation, my personal information may be used without my knowledge.
PRR3	After using e-consultation, my illness information may be found by others around me.
SR[e] [31,35,39]	
SR1	If I use e-consultation, it would negatively affect the way others think of me.
SR2	If I use e-consultation, my friends and relatives would think less highly of me.
TR[f] [31,39]	
TR1	e-Consultation may be a waste of time because it is not effective.
TR2	e-Consultation may be a waste of time because of wrong diagnoses or treatments.
PSR[g] [31,35,39]	
PSR1	e-Consultation is not my traditional way to consult doctors, which would lead to psychological issues
PSR2	I am unable to communicate with doctors face-to-face thereby leading to psychological issues
PSR3	I am worried that I cannot describe my disease symptoms correctly when using e-consultation.
PI[h] [40,45,46]	
PI1	I often follow new information technologies with interest.
PI2	If I hear about a new information technology, I would look for ways to experiment with it.
PI3	Among my peers, I am usually the first to try out new information technologies.
BI[i] [25]	
BI1	I intend to use e-consultation.
BI2	I intend to use more e-consultation.
BI3	I predict that I will use e-consultation.

[a] PU: perceived usefulness.

[b] PEU: perceived ease of use.

[c] FR: financial risk.

[d] PRR: privacy risk.

[e] SR: social risk.

[f] TR: time risk.

[g] PSR: psychological risk.

[h] PI: personal innovativeness.

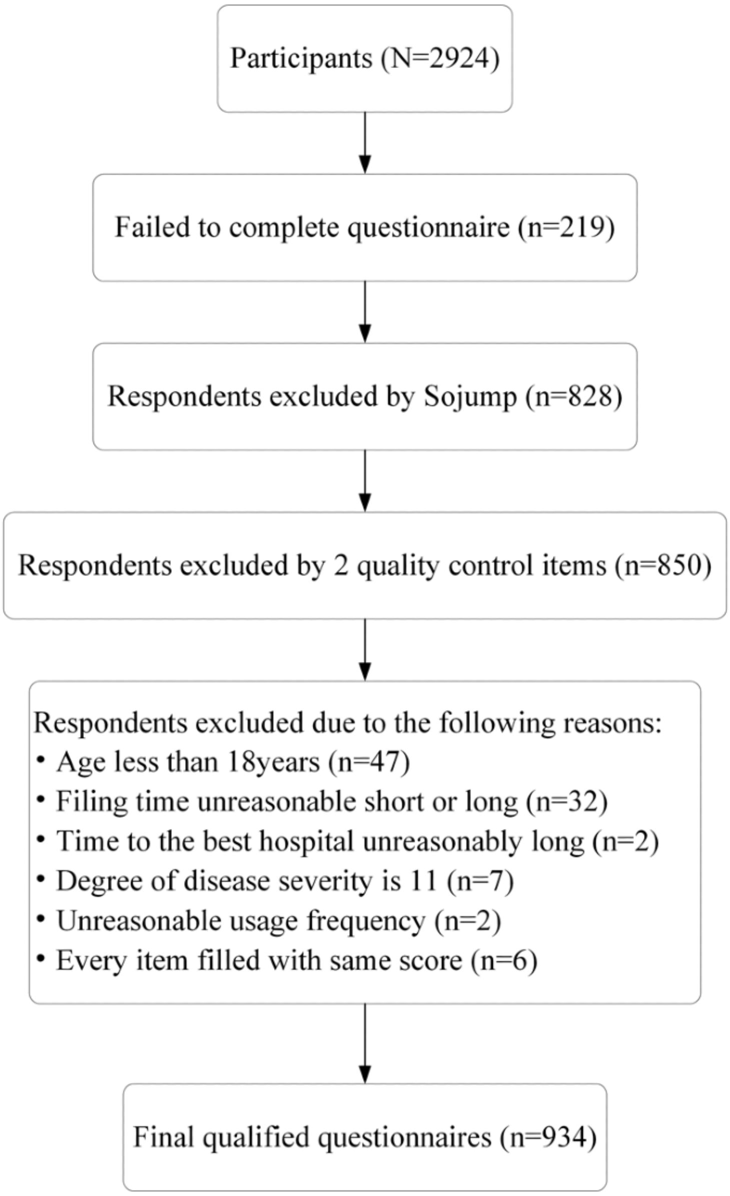
[i] BI: behavior intention.

Data Collection

With the development of information technology, internet protocol restriction, and real-name system, the data quality of web-based surveys meets the requirements of scientific researches. As mentioned above, the users of e-consultation are mainly concentrated in young and middle-aged groups, and the middle-aged group is more willing to accept web-based questionnaires. Therefore, a web-based survey was conducted by Sojump in this research. Sojump is an e-survey company [47], which has 2.6 million samples with all kinds of social demographic characteristics, and unqualified objects can be excluded based on the purpose of the study. The questionnaire was announced on Sojiangwang [48] until the required population was reached. The Sojiangwang is a platform belonging to Sojump, in which all kinds of people can register in. The Sojiangwang asks every registrant to upload the real identity information and audit the identity information. In this platform, the registrant can see all the questionnaires when they meet the included standard of the questionnaires. All different questionnaires would be named with a unified format: "questionnaire + number." In order to ensure the quality of the survey, Sojump uses a series of logical and common sense items to eliminate the halfhearted respondents, and 828 respondents were excluded by this way in our study. Besides, we also designed 2 items to screen the poor-quality questionnaires. The first item listed in the demographic information survey is "e-Consultation could provide surgical and pathological examination services" and the respondents were asked to choose "disagree." The second item listed in the construct is "Now, e-consultation could provide diagnosis and treatment for all kind of diseases" and the respondents were asked to choose "strongly disagree."

At the beginning of the electronic questionnaire, the following information was given first: the purpose of the questionnaire, information and instructions regarding the questionnaire, assurance of proper handling of personal information, and the name of the research institution. The questionnaire link provided on the website (Sojiangwang) could not be copied. After users filled in the questionnaire through the link, the link was removed from the list and could not be used repeatedly. We have reported the results of this survey following the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist, which can be found in Multimedia Appendix 1. The data were collected from March 30, 2020 to April 4, 2020. A total of 2924 participants were involved in this survey, and 934 respondents' questionnaires reached the inclusion criteria of the survey (Figure 2). This study was approved by the ethics committee of the Capital Medical University (number Z2019SY017).

Figure 2. Sampling procedure.



As shown in Table 2, female respondents were more than male respondents. Most respondents were between 18 and 45 years of age (861/934, 92.2%). The education level of the respondents was good because only 21.7% (203/934) of the respondents had a lower level of education than bachelor’s degree. Most respondents were from the more developed eastern region (559/934, 59.9%) and urban region (797/934, 85.4%). The level of income and the access to medical resources were relatively average. Approximately 67.5% (630/934) of the respondents had used e-consultation, of which 80.1% (505/630) had used e-consultation 5 times or less last year. The aims of using e-consultation include helping themselves (352/630, 55.9%) and others (278/630, 44.1%). Both serious and minor diseases could be the subject of e-consultation.

Table 2. Geographical characteristics of the respondents (N=934).

Characteristics	n (%), Value
Gender	
Male	379 (40.6)
Female	555 (59.4)
Age (years)	
18-25	239 (25.6)
26-35	463 (49.6)
36-45	159 (17.0)
>46	73 (7.8)
Education	
Middle school or lower	13 (1.4)
High school	52 (5.6)
Three-year college	138 (14.7)
Bachelor	660 (70.7)
Master or higher	71 (7.6)
Residence	
Rural	137 (14.6)
Urban	797 (85.4)
Location	
Eastern	559 (59.9)
Midregion	164 (17.5)
Western	152 (16.2)
Northern	59 (6.3)
Average annual income (¥, US $1=¥6.475)	
0-10,000	297 (31.8)
11,000-20,000	348 (37.3)
21,000-30,000	174 (18.6)
>30,000	115 (12.3)
Time to the best hospital in district and county (minutes)[a]	
1-10	281 (30.1)
11-20	289 (30.9)
21-30	227 (24.3)
>30	137 (14.7)
Usage experience	
Used	630 (67.5)
Unused	304 (32.5)
Usage frequency last year	
0-2	215 (34.1)
3-5	290 (46.0)
>5	125 (19.9)
Use e-consultation for whom	
Myself	352 (55.9)
Others	278 (44.1)

Characteristics	n (%), Value
Disease severity[b]	
1-5	337 (53.5)
6-10	293 (46.5)

[a] Measures the accessibility of high quality medical resources.

[b] Users themselves assessed the severity of last disease consulted by e-consultation using a 5-point Likert scale ranging from “strongly not serious” (1) to “strongly serious” (10).

Data Analysis

SPSS 20.0 (IBM Corp) was used to analyze the descriptive statistics of respondents’ demographic characteristics and the Cronbach α of the constructs. Amos 24.0 (IBM Corp) was used to evaluate items, measurements, and structural models. Confirmatory factor analysis of the measurement model was used to evaluate the structural model’s path effects, significance, goodness of fit, and moderation effects. Composite reliability and average variance extracted were adopted to evaluate construct reliability and validity.

Results

Measurement Model Testing

The results of reliability and validity are shown in Table 3. The composite reliability, Cronbach α of construct, was greater than the recommended value of .7, and except for financial risk, perceived usefulness, and perceived ease of use, the average variance extracted of constructs was higher than 0.5 [49]. In order to assure the availability of the model, we excluded the low loading items (PU3, PU4) to construct model 2 for testing the result of model 1. We found that although the average variance extracted was promoted a little in model 2, the model fit indices had no substantial improvement (Table 3). Further, the path effects had no substantive difference between model 1 and model 2. Besides, some researches showed that all factors fulfilled a weak or strong validity because factor loadings were statistically significant and the coefficients of path were substantial [50]. Therefore, it was reasonable to accept the results of model 1. As shown in Table 4, the collected data fit well with the research model [51]. The χ^2/df (1111.9/363) of model 1 was 3.1 and was lower than 5. The root mean square error of approximation was 0.047 and was lower than 0.05. The goodness of fit index, comparative fit index, normed fit index, Tucker-Lewis index, and incremental fit index were greater than 0.9 and the adjusted goodness of fit index was 0.9.

Table 3. Item loading and validity.

Structural Model Testing

The judgments of hypotheses based on the SEM results are shown in Table 5. The judgments of model 1 and model 2 exhibited the same results and the standardized factor loadings of path were very closed. Perceived ease of use had no statistically significant effect on behavior intention (β=.117, *P*=.07; β1=.104, *P*=.13). Perceived usefulness had a positive effect on behavior intention (β=.399, *P*<.001; β1=.431, *P*<.001) and was the strongest positive factor of behavior intention. Perceived ease of use had a positive effect on perceived usefulness (β=.537, *P*<.001; β1=.530, *P*<.001). Perceived risk could be well explained by financial risk (β=.972, *P*<.001; β1=.973, *P*<.001), privacy risk (β=.774, *P*<.001; β1=.774, *P*<.001), social risk (β=.871, *P*<.001; β1=.870, *P*<.001), time risk (β=.894, *P*<.001; β1=.894, *P*<.001), and psychological risk (β=.774, *P*<.001; β1=.774, *P*<.001). Among the components, the effect of financial risk was the strongest and that of social risk was the weakest. Perceived risk had negative effects on perceived usefulness (β=–.375, *P*<.001; β1=–.399, *P*<.001) and behavior intention (β=–.297, *P*<.001; β1=–.275, *P*<.001). Personal innovativeness had a positive influence on perceived ease of use (β=.241, *P*<.001; β1=.242, *P*<.001). Compared with other factors, personal innovativeness had a slight effect on behavior intention (β=.124, *P*=.001; β1=.123, *P*=.001).

[h] SR: social risk.

[i] TR: time risk.

[j] PSR: psychological risk.

[k] PI: personal innovativeness.

[l] BI: behavior intention.

Moderation Effect Testing

We further tested the moderating effects of geographical characteristics by multiple-group analysis [52,53]. In order to simplify the data analysis, the total sample was reclassified into 2 subgroups (Table 6). First, to screen the factors with moderation effects from characteristics, we constrained the measurement weights, structural weights, structural covariances, structural residua, and measurement residua of the subgroup model to construct parameter constraints models. If the results of the constraints model and the unconstrained model were significantly different, it indicated that the paths between subgroups are the factors that might have a moderation effect. As showed in Table 6, age (χ^2_{58}=133.5, *P*<.001), income (χ^2_{58}=85.6, *P*=.01), and usage experience (χ^2_{58}=82.5, *P*=.02) might have moderation effects.

Table 6. Dichotomous geographical characteristics of the respondents (N=934).

Characteristics	n (%), Value	χ^2 *(df)*	*P* value
Gender		43.3 (58)	.93
Male	379 (40.6)		
Female	555 (59.4)		
Age (years)		133.5 (58)	<.001
18-30	464 (49.7)		
>30	470 (50.3)		
Education		25.7 (58)	>.99
Three-year college or lower	203 (21.7)		
Bachelor or high	731 (78.3)		
Residence		47.8 (58)	.83
Rural	137 (14.6)		
Urban	797 (85.4)		
Location		38.2 (58)	.98
Eastern	559 (59.9)		
Not eastern	375 (40.1)		
Income (¥, US $ 1 =¥6.475)		85.6 (58)	.01
0-10,000	297 (31.8)		
>10,000	637 (68.2)		
Time to the best hospital (minutes)		35.7 (58)	.99
1-20	570 (61.0)

Usage experience		82.5 (58)	.02
Used	630 (67.5)		
Unused	304 (32.5)		
Usage frequency last year		49.4 (58)	.78
0-2	215 (34.1)		
>2	415 (65.9)		
Use e-consultation for whom		44.1 (58)	.91
Myself	352 (55.9)		
Others	278 (44.1)		
Disease severity		70.5 (58)	.13
1-5	337 (53.5)		
6-10	293 (46.5)		

Second, we estimated the path loadings and the critical ratios for differences of each subgroup (Table 7). If the absolute value of the critical ratio was lower than 1.96, there would be a significant difference between the paths of the 2 subgroups. Compared with the older subgroup (β_{age2}=.235, *P*=.02), it is estimated that perceived usefulness has more positive effect on behavior intention in the younger subgroup (β_{age1}=.537, *P*<.001). The path loading of hypothesis 9 was not significant in the older subgroup (β_{age1}=.054, *P*=.34). Income had no significant moderation influence on the research model. Besides, the usage experience only had some influence on path coefficient. It is shown that the path loading of perceived ease of use to behavior intention has a significant difference, but the coefficients were very close ($\beta_{experience1}$=.532; $\beta_{experience2}$=.534). The path loading of personal innovativeness to perceived ease of use in the used group ($\beta_{experience1}$=.149, *P*=.008) was lower than that of the unused group ($\beta_{experience1}$=.327, *P*<.001). We found that there was no substantial difference in the usage mechanism whether or not the public used e-consultation.

Table 7. Multiple group analysis.

Hypothesis (H)	β_{age1}[a]	β_{age2}[b]	CR[c]	$\beta_{income1}$[d]	$\beta_{income2}$[e]	CR	$\beta_{experience1}$[f]	$\beta_{experience2}$[g]	CR

Discussion

Principal Results

Our study found that perceived usefulness is one of the most important determinants of individuals' intention to use e-consultation, which is similar to that reported in most related studies on the acceptance of information communication technology [27,29,30]. Even in subgroups with different characteristics, the direction and significance of path loading were not changed. Our results indicate that promoting the function of e-consultation is a key to attract the public to use it because the higher perceived usefulness means the public have more trust in the ability and integrity of doctors and platforms [24]. Compared with face-to-face consultation, e-consultation could only be used to diagnose common and chronic diseases lacking necessary medical examinations and the supporting treatment system, but the text suggestions from the specialists are still important for the public. In particular, in some special cases (eg, COVID-19 pandemic), e-consultation could not only achieve the goal of public isolation but also meet the patients' demand of medical services. Although e-consultation cannot be a complete substitute for face-to-face consultations, it may serve as an entry level consultation after integrated into the face-to-face consultation [54]. In addition to the service ability of e-consultation, technical difficulties, including substandard signal construction, virtual device, and video equipment, would significantly weaken people's evaluation on the usefulness of e-consultation [55]. Therefore, while improving the functionality, providers should also pay attention to improve the facilitation condition of e-consultation.

Different from the related researches, our research shows that perceived ease of use has no effect on the behavior intention but it has a strong effect on perceived usefulness. Normally, since the information communication technology products are used in the professional field, learning to use these products is a challenge for users. However, e-consultation just needs users to interact with doctors on the internet by using a personal computer or a smartphone. With the popularity of smartphones in China and worldwide [56], it is reasonable to believe that the public can easily learn how to operate e-consultation; therefore, the ease of use no longer plays a role in the promotion. As shown in a survey of 947 respondents, less than 20% of the people think that the reason they do not use e-consultation is that they are not skillful enough to complete the operation [57]. Another possible explanation is related to the characteristics of the respondents. Perceived ease of use comprises ease of operation, understanding, and expression. In our survey, most of the respondents had high educational backgrounds and were young, which leads to a stronger understanding ability, thereby leading to no significant relationship between perceived ease of use and behavior intention.

Personal innovativeness has a direct effect on perceived ease of use and behavior intention, which is consistent with the findings of a previous study [45]. Although more and more high-tech products are emerging, the public are always keen to try the popular products rather than the new ones. Therefore, it is essential to strengthen the publicity of e-consultation for the public. Of course, formatting innovativeness is a complex and long process [58]; therefore, finding the innovative individual might be a better choice. In the promotion of e-consultation, e-consultation providers should offer advanced services for the innovative and stable services for the common.

Perceived risk has a significantly negative effect on behavior intention. Because of health issues, the public would take risks more seriously and perform risk aversion [59]. Uncertainty and information asymmetry are typical features of medical services, which always leads patients with common diseases to fail in selecting the most effective services (primary health care). They would prefer to go to a tertiary hospital for the minimization of medical risk instead of the maximization of utility [60]. Different from other results that risk influence intention [29,38] or attitude [37] directly, our results show that perceived risk weakens not only behavior intention but also perceived usefulness and perceived ease of use directly. It shows that if we do not control the risk of e-consultation, even if e-consultation could provide services for more diseases, the public would reduce the evaluation and the intention of e-consultation. In addition, perceived usefulness contains performance risk and physical risk and perceived ease of use reflects the risk of operation. It indicates that performance risk, physical risk, and operation risk are components of perceived risk, which is consistent with the theoretical hypothesis and our previous surveys. However, perceived ease of use has no effect on behavior intention. Therefore, we need to take note that ease of operation may not promote the usage intention, but the difficulty of operation may reduce the intention.

There are many studies on the barriers in e-consultation, but these only explored the objective and external factors, for example, signal coverage, equipment, and characteristics of the patients. Even if some qualitative studies ask users' subjective evaluation, the final results are not comprehensive [61]. Our study made up for some gaps in these researches and found that among the other components, financial risk and time risk were the most considered by people. In China, the e-consultation platforms provide free and paid consultation services for users. The choices of doctors and number of questions would be limited in the free services and the cost of paid services cannot be submitted to medical insurance. Therefore, if e-consultation is not effective, the cost and time of using e-consultation will be wasted altogether. Compared with the indirect costs [62] saved by e-consultation, the opportunity cost of e-consultation is more valued by the public. Besides, not all patients believed that e-consultations could play the role in reducing the time to access specialists' advice [63]. Therefore, it is important to strengthen the connection between e-consultation and offline treatment and include the cost of e-consultation into the medical insurance system. These are the 2 keys to promote e-consultation use.

Many studies have found that the key barriers of using e-consultation for patients are privacy concerns and security of their data [5,19,64]. The path of perceived risk and privacy risk showed that providers should strengthen the construction of e-consultation information systems. Privacy disclosure has been a big problem in the medical field [65,66]. Users worry about not only the illegal disclosure but also the exposure to their family members with some special diseases such as mental illness [67]. We should appeal to the government to make related laws and strengthen the supervision of the operation of the e-consultation platform, and then, the public would upload their personal medical information during e-consultation.

e-Consultation, a new consultation model, has been in China for less than 20 years, and the public have little detailed knowledge about it; therefore, the public cannot get used to this kind of non–face-to-face consultation quickly, which has aroused the public's attention to psychological risk. Besides, body language is often accompanied by patients' expression, but the text-based e-consultation cannot reveal the body language, which can easily cause anxiety about the incomplete expression for patients [68]. Real-time video calls could alleviate this problem to some extent, but it is not applicable to all patients because of limitations in different video equipment. Of course, since the public with general health literacy are often unable to describe the uncommon disease symptoms and feelings correctly [69], they would worry about their medical behavior in e-consultation. Therefore, it would be necessary to improve the public's health literacy to decrease the psychological risk. In fact, the lack of people's health literacy is a long-standing problem and it is difficult to be overcome completely [70]. We need to cooperate with certain auxiliary ways to assist the public to use e-consultation, among which keeping a special receptionist [71] may be a good solution.

Although social risk is only a minor component of perceived risk, we need to improve the awareness of e-consultation among the public to help them understand it correctly. As mentioned above, the public know less about e-consultation; therefore, there is no effective consensus on e-consultation in the society. Some researches show that the most prominent reason for nonuse of e-consultation is that the public are not aware of the existence of the service [56,71]. With the improvement of awareness, the public would think it is a reasonable choice to use e-consultation and would not make negative assessments on it.

Our results show that personal innovativeness has an effect on behavior intention for the older population but has no effect for the younger population. A study on users not using e-consultation also showed that age had a moderation effect on behavior intention [57]. We think that for the young, especially between the ages from 18 years to 30 years in our study, their innovativeness generally has a high level; therefore, the path loading of personal innovativeness and behavior intention are not significant. Besides, perceived usefulness has less effect on the behavior intention for the older, because with the increase in age, patients place more emphasis on service attitude and medical process and not just utility [72]. Compared with the age factor, the usage experience has only a slight moderation effect on the usage mechanism. The effect direction of the paths is not changed, which indicates that the mechanisms of factors are consistent between the used and unused. Of course, we can also find that personal innovativeness has more effect on the perceived ease of use for the unused. Therefore, raising the innovativeness of the unused might achieve better effect during the promotion of e-consultation.

Limitations

Our data was collected by a web-based survey; therefore, some selection bias was unavoidable. First, this study showed that 67.5% (630/934) of the respondents were experienced in using e-consultation; however, the usage rate of the students was only 25.7% in our previous survey. These data show that our respondents use mobile devices or computers more frequently. Thus, a higher awareness of e-consultation was observed among these respondents. Second, most respondents came from urban areas (797/934, 85.4%). They might be less willing to use e-consultation because it is easier for them to receive high quality medical resources in the cities. Third, the average age of the respondents was 31 years in our study and 78.3% (731/934) of the respondents had higher education degrees than bachelor’s degree; therefore, our sample may have less medical demand and usage of e-consultation [56]. Besides, the young sample would influence the moderation effect of age. Although it is a better way to survey more people with usage experience through web-based surveys, it is not suitable for all people such as the older adults or the undereducated. Therefore, further offline population-based surveys are necessary, which could be a household survey of residents for small samples with cluster-stratified sampling. In addition, our survey meets the requirements of health care consultations during the COVID-19 pandemic, wherein the public had to stay at home, which might make people have a high intention to use e-consultation.

Conclusions

Our research focuses on the positive and negative factors that influence the public acceptance of e-consultation and supports the use of TAM and perceived risk in explaining public intention to use e-consultation. We found that perceived usefulness and perceived risk are the most important determinants effecting people’s intention to use e-consultation. Therefore, platforms and manufacturers must improve the function of e-consultation, which will promote the public intention to use it fundamentally. Further, to control the perceived risk of public, government should play an important role in enforcing management of e-consultation markets and approving corresponding medical insurance policies. Besides, we found that personal innovativeness has an effect on behavior intention and the path of factors has differences among people with different characteristics to some degree. Therefore, it is necessary to adjust the strategies to adapt to different groups.

Acknowledgments

We thank all experts for offering comments on the design of the questionnaire and Qingdu Meng for editing this manuscript for language. We also thank the Sojump company for assisting in the collection of electronic questionnaires. This work was supported by the Social Science Foundation of Beijing of China (17JDGLA032).

Abstract

Background: COVID-19 has thrust video consulting into the limelight, as health care practitioners worldwide shift to delivering care remotely. Evidence suggests that video consulting is acceptable, safe, and effective in selected conditions and settings. However, research to date has mostly focused on initial adoption, with limited consideration of how video consulting can be mainstreamed and sustained.

Objective: This study sought to do the following: (1) review and synthesize reported opportunities, challenges, and lessons learned in the scale-up, spread, and sustainability of video consultations, and (2) identify transferable insights that can inform policy and practice.

Methods: We identified papers through systematic searches in PubMed, CINAHL, and Web of Science. Included articles reported on synchronous, video-based consultations that had spread to more than one setting beyond an initial pilot or feasibility stage, and were published since 2010. We used the Nonadoption, Abandonment, and challenges to the Scale-up, Spread, and Sustainability (NASSS) framework to synthesize findings relating to 7 domains: an understanding of the health condition(s) for which video consultations were being used, the material properties of the technological platform and relevant peripherals, the value proposition for patients and developers, the role of the adopter system, organizational factors, wider macro-level considerations, and emergence over time.

Results: We identified 13 papers describing 10 different video consultation services in 6 regions, covering the following: (1) video-to-home services, connecting providers directly to the patient; (2) hub-and-spoke models, connecting a provider at a central hub to a patient at a rural center; and (3) large-scale top-down evaluations scaled up or spread across a national health administration. Services covered rehabilitation, geriatrics, cancer surgery, diabetes, and mental health, as well as general specialist care and primary care. Potential enablers of spread and scale-up included embedded leadership and the presence of a telehealth champion, appropriate reimbursement mechanisms, user-friendly technology, pre-existing staff relationships, and adaptation (of technology and services) over time. Challenges tended to be related to service development, such as the absence of a long-term strategic plan, resistance to change, cost and reimbursement issues, and the technical experience of staff. There was limited articulation of the challenges to scale-up and spread of video consultations. This was combined with a lack of theorization, with papers tending to view spread and scale-up as the sum of multiple technical implementations, rather than theorizing the distinct processes required to achieve widespread adoption.

Conclusions: There remains a significant lack of evidence that can support the spread and scale-up of video consulting. Given the recent pace of change due to COVID-19, a more definitive evidence base is urgently needed to support global efforts and match enthusiasm for extending use.

KEYWORDS

delivery of health care; remote consultation; telemedicine; videoconferencing; spread and scale-up; sustainability; mobile phone; COVID-19; remote care; consultation; review

Introduction

There is global interest in video consultation services, including Skype, Teams, FaceTime, and other Voice over Internet Protocol (VoIP) media, to facilitate synchronous patient-to-provider video communication in health care [1,2]. Studies have shown positive patient outcomes, reduced travel and costs, improved communication, decreased waiting times, and increased accessibility for patients [3]. Governments and health administrations view such technologies as a means of better managing demand and improving care [1]. The COVID-19 pandemic, and the requisite need for self-isolation and social distancing, has prompted rapid and widespread adoption of video consultations [4].

Evidence on the use of video consultations in health care is mixed. There is a rapidly growing literature on the feasibility, safety, acceptability, and effectiveness of video consultations across clinical areas [5] including diabetes [6,7], rehabilitation [8,9], mental health and addiction [10], cancer [11], palliative care [12,13], long-term care [14], geriatrics [15], postpartum support [16], and primary care [17]. Studies tend to be small scale and focus on initial adoption in a research context [2,5,18]; adopt a technology-centric approach (in which the technology is the primary focus, rather than the service or organization by which the technology is being used); and use trial methodology to study whether video consultation technology works or not. Despite calls for urgent action [19-22], this trend has continued into the COVID-19 pandemic. Little is currently known about how to successfully spread and scale up video consulting for sustained use across settings [23-25].

A small number of studies have explored the technological, contextual, and practical challenges to be overcome if video consulting is to become more widespread. One multilevel qualitative study, conducted in the English National Health Service (NHS) and undertaken by our team, examined the development, implementation, and use of video consultation services [2]. Focused on national-level policy, organizational-level implementation, and patient-clinician video consultations, the study identified a mismatch between the policy vision of video consultations replacing or supplementing a significant proportion of face-to-face care [26,27], and the substantial setup resources, ongoing human effort, and time needed to embed video consultations in routine care. Findings suggest that, even where there is significant policy impetus and demand [4], those implementing video consultation services face significant challenges in redesigning existing services and implementing new pathways.

Appreciation of the potential for longer term sustainability of this new service model is crucial in the context of the unfolding COVID-19 pandemic, which has brought a rapid need for alternatives to face-to-face contact and hence for the spread and scale-up of video consultations. We therefore conducted a systematic review of the opportunities and challenges to widespread implementation (what we refer to as "scale-up" or "spread") of video consultation services in health care, asking the following questions:

1. What theoretical frameworks have been used in this literature and for what purpose?
2. What opportunities and challenges have been identified in the literature on the spread, scale-up, and sustainability of video consultations?
3. What transferable insights can be useful for policy and practice? What questions remain unanswered?

Our main concern is to identify and evaluate challenges to the scale-up and spread of video consultations from the existing research literature and, from this, to inform the rollout and longer term sustainability of video consulting and the research agenda that can support it. Spread, scale-up, and sustainability are often used as interchangeable terms without a standard definition or adequate theorization (see Multimedia Appendix 1). In this review, we do not adopt a single definition of spread, scale-up, and sustainability, as we are interested in surfacing the different ways in which studies on video consultations have employed and operationalized these terms.

Methods

Information Sources and Search Strategy

In December 2018, we systematically searched 3 databases: PubMed, CINAHL via EBSCOhost, and Web of Science. The search was updated in March 2020. Our search strategies, developed with the help of a research librarian, used a mix of keywords, Medical Subject Headings (MeSH), and Major Headings (MH), as provided in Multimedia Appendix 2. We identified search terms bottom-up by examining titles, keywords, and frequently used phrases in relevant literature. For example, we derived terms such as "telemedicine" and "remote consultation" from literature on virtual health care and terms like "scalability" and "spread" from implementation science articles. We used broad telehealth and telemedicine terms to be able to address the variability in the terminology both in the scale-up and spread literature and in the way video consultation services have been described. The lead author reviewed PROSPERO (International Prospective Register of Systematic Reviews) prior to the study to identify similar reviews, which informed the search strategy and review focus. We referenced our initial search strategy against two published systematic reviews on telegenetics [28] and implementation science [29] to identify supplementary terms. Filters were applied to limit the results to published peer-reviewed articles. We focused on published literature and did not search grey literature. PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) was used to draft the protocol for this review (unpublished) and PRISMA guidelines were consulted throughout the review as a guide.

Eligibility Criteria

Inclusion criteria are summarized in Table 1. Included articles were peer-reviewed and reported on synchronous, video-supported consultations that had been scaled or spread to more than one setting beyond the initial pilot or feasibility stage (either within the same organization or to other organizations or geographic settings). The video consultation technology could be stand-alone, or part of a larger telehealth innovation (eg, a website). We focused on video consultation services connecting a patient to their medical provider(s) as opposed to those connecting providers to specialists. Articles exclusively reporting use, feasibility, acceptance, or pilot implementation with no evaluation of the implementation process were excluded. Video technologies like Skype have only recently come into use in health care [2,30], hence we restricted our search to articles published since 2010. Beyond these restrictions, we kept a broad interpretation of the patient-provider relationship, allowing video-to-home telehealth and hub-and-spoke consulting connecting a rural center to a specialist at a different hospital or institution. Our understanding of the quality of the articles was informed by using the Critical Appraisal Skills Programme (CASP) checklist for qualitative research and the Mixed Methods Appraisal Tool (MMAT) for mixed methods studies; however, we did not exclude articles on the basis of quality appraisal but took this into account in the interpretation of their findings (as reflected in the results section).

Table 1. Inclusion and exclusion criteria.

Criteria	Inclusion	Exclusion
Time period	2010 onwards	Before 2010
Language	English	Not English
Video consultation format	Synchronous and video-based conferencing OR digital health care technologies that include synchronous video conferencing.	Asynchronous, app-based, text-based, or website-based formats.
Actors	Patient and health care provider communication	Any other video consulting service
Context	Relevant technologies that have been scaled or spread to >1 setting in acute or primary care or where scale-up and spread is being actively pursued	Usability studies, feasibility trials, single-location implementation, pilot studies, or studies that had not been scaled or spread beyond one setting
Format	Peer-reviewed articles	Anything else (eg, conference proceedings, books, workshop papers)

Screening

Search results were imported into Zotero. Duplicates were removed, while retaining information from each search and preventing false duplicates from being merged. Each record was first screened by title and abstract (initially by HJ, then verified by JW and SS). Remaining articles were screened by reading the full texts (HJ screening 100%, SS a 15% sample), with any disputes resolved through discussion and consensus with JW. At each stage, articles were eliminated if they did not meet the inclusion criteria (Table 1). Full-text screening was iterative and required slight refinement of our inclusion criteria. We clarified that the articles must place sufficient emphasis on video consulting (rather than mention it in passing) and that different terms could be used to describe processes relevant to widespread implementation, scale-up, and spread.

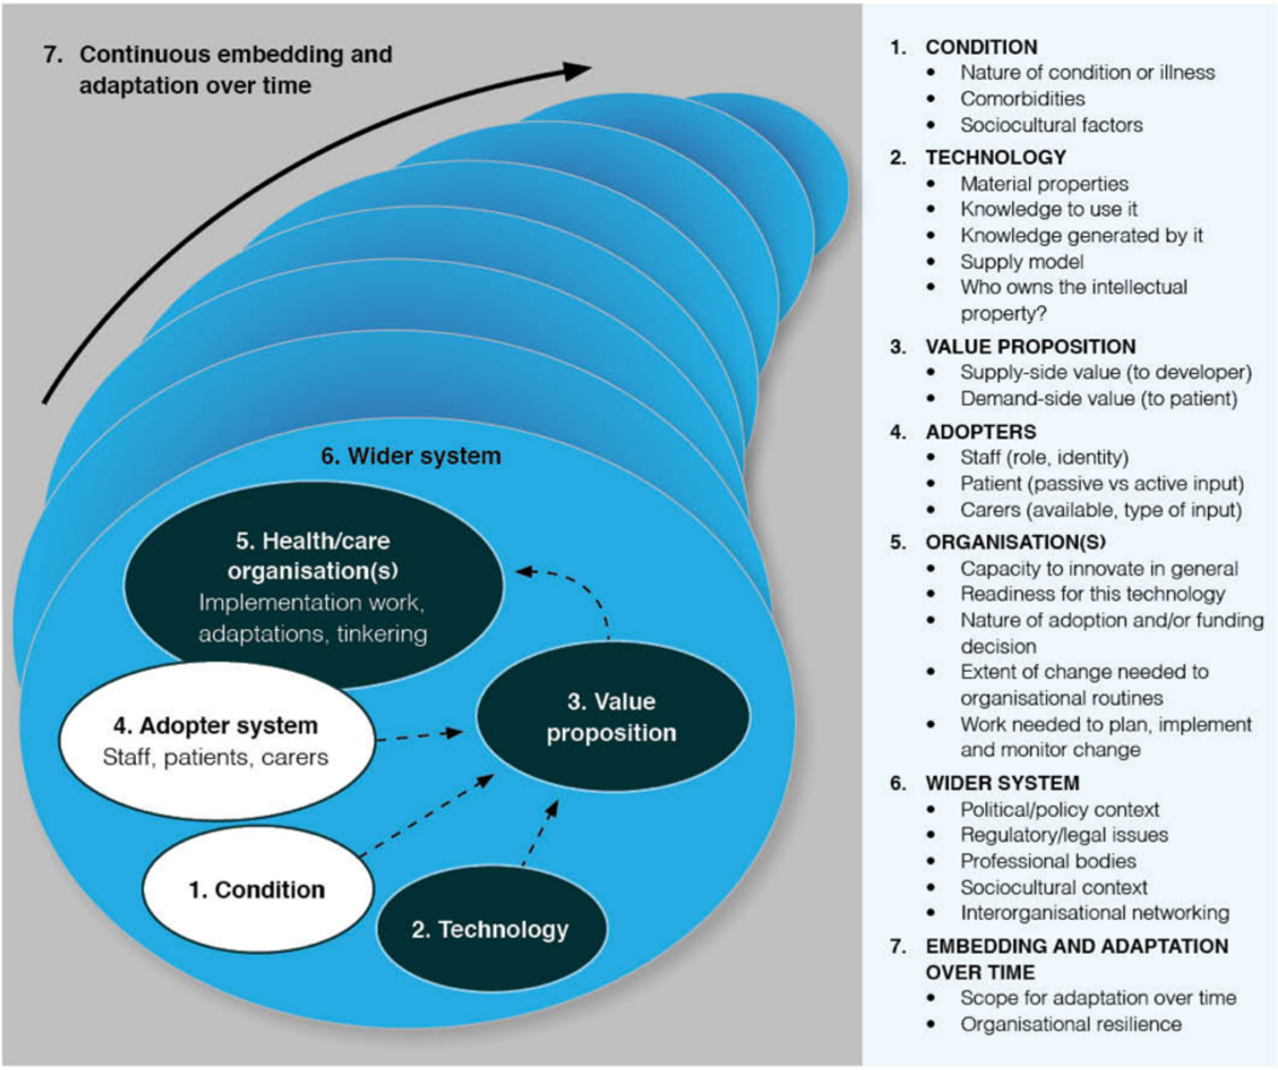
Data Extraction and Synthesis

We extracted data into a Microsoft Excel (Microsoft Corp) spreadsheet. At a descriptive level, we extracted data on study location, setting, clinical focus, definition of telehealth, service model and type of technology, and research design (Multimedia Appendix 3). We extracted data on how each of the papers conceptualized opportunities and challenges for the spread, scale-up, and sustainability of virtual consultations. We also extracted data about the predominant theoretical framework adopted in each study, and connected these with the three theoretical lenses that typically characterize studies of the spread and scale-up of innovations: (1) implementation science (ie, the systematic and structured application of improvement techniques and frameworks), (2) complexity theory (ie, paying attention to unpredictability and interdependencies in complex systems), and (3) social science approaches (ie, emphasizing social, human, and material elements in large-scale change efforts) [31].

We worked inductively to surface the challenges to and opportunities for the spread and scale-up of video consulting across studies. Sensitized by the Nonadoption, Abandonment, and challenges to the Scale-up, Spread, and Sustainability (NASSS) of health and care technologies framework [23], we then worked deductively to ensure we had not missed any of the 7 domains identified as relevant to the widespread adoption and nonadoption of innovations (ie, an understanding of the health condition[s] for which video consultations are being used, the material properties of the technological platform itself, the value proposition for patients and developers, the role of the adopter system, organizational factors, wider macro-level considerations, and emergence over time; see Figure 1).

We piloted and refined this process on one paper and then extended the process across the rest of our data set. Using content analysis, we compiled a descriptive overview of the opportunities and challenges identified in the papers, including frequency distributions. We then applied a more analytical lens to synthesize and interpret our findings using the NASSS framework [23].

Figure 1. The NASSS framework for Nonadoption, Abandonment, and challenges to Spread, Scale-up, and Sustainability of health and care technologies.



Results

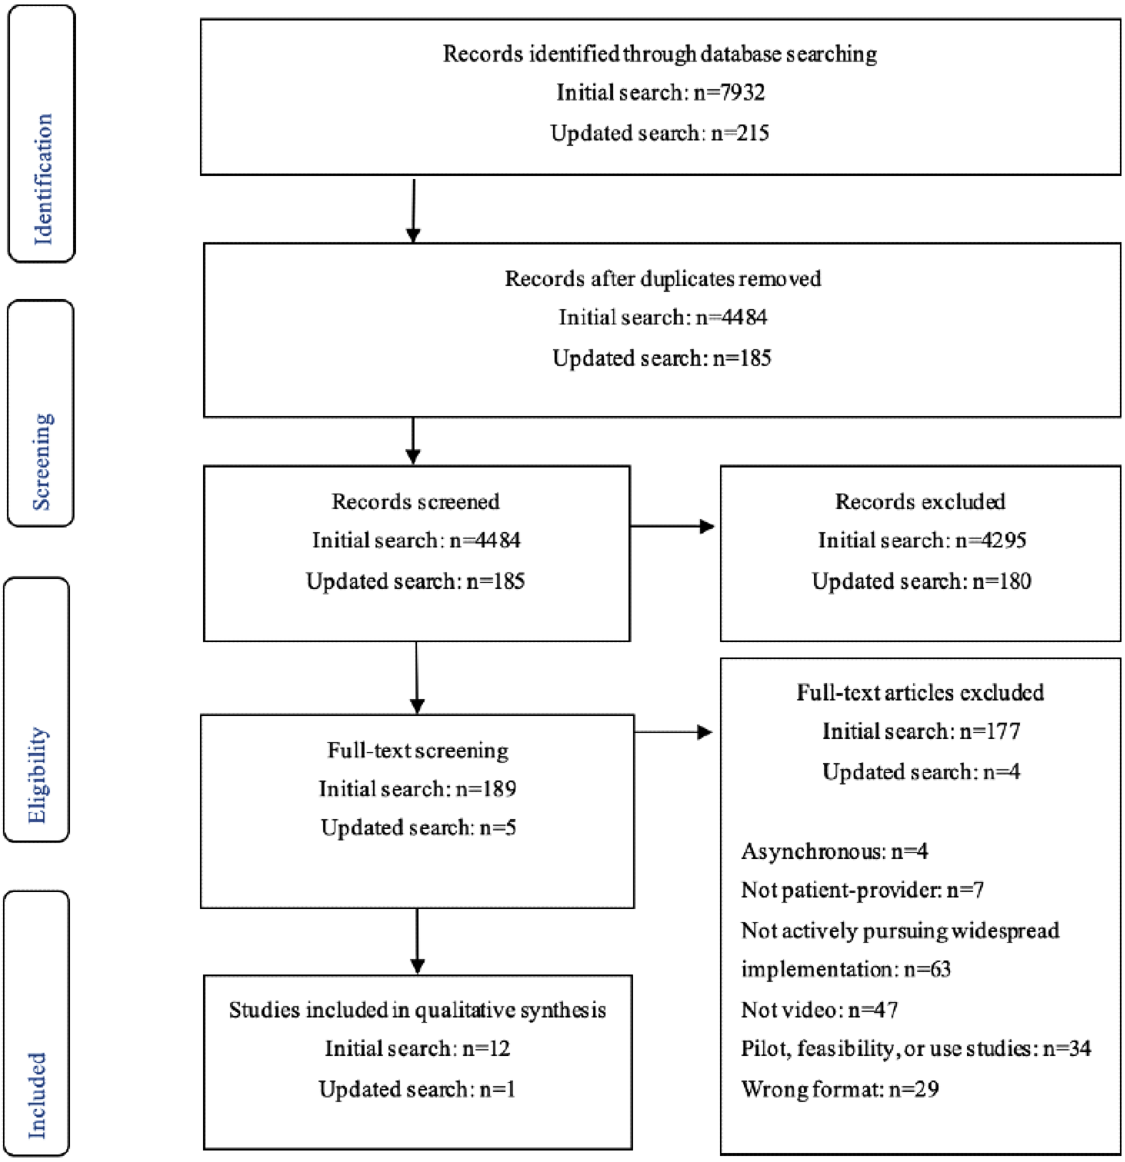
Description of Papers and Overview of Findings

Initial searches identified 4484 unique articles published between January 2010 and December 2018, with 193 articles identified for full-text screening and 12 initially included in the final review. An updated search in March 2020 returned 185 new articles for screening, of which 5 were identified for full-text screening. One new relevant article was identified, bringing the total records included in the review to 13 (Figure 2).

Diverse research designs were employed in the included studies, including interpretive case studies [32], structured or semistructured qualitative interviews [33-35], mixed methods combining qualitative and quantitative data [2,36-38], action research and deliberative methods [39], prospective implementation studies including quantitative activity and performance indicators [40-42], and retrospective case analysis of systemwide use of video consultations [43] (Multimedia Appendix 3). A review of the included studies using the CASP and MMAT appraisal tools indicated that they generally fulfilled relevant quality standards, although in a few articles it was not clear how data collection or analysis methods were applied, sample sizes were small, or there was inadequate information on sampling frame; furthermore, they remained at a highly descriptive or even purely illustrative level of analysis.

There was ambiguity in the use and variations of the term telehealth, with three studies giving no definition and others defining telehealth variably depending on study focus (Multimedia Appendix 3). The terms telehealth, telemedicine, and telemental health were common and often used interchangeably: 11 articles (85%) used the terms “video telehealth,” “telehealth,” “telemedicine,” or “telecare,” while two used the term “video consultations” [2,38].

Figure 2. PRISMA flow diagram depicting search and screening processes. PRISMA: Preferred Reporting Items for Systematic Review and Meta-Analysis.



Papers described 10 different video consultation services in 6 regions: Australia [39], Cabo Verde [41], England [2,38], Nepal [32], Norway [36], and the United States (Multimedia Appendix 3). Studies described 3 types of video consultation services: (1) video-to-home services [2,34,38,39,42] that connected providers directly to a patient who received a video consultation on their own device; (2) hub-and-spoke models [32,33,35,37,40,41] that connected a provider at a central hub to a patient at a rural spoke center who called in with the assistance of a provider at that organization; and (3) large-scale top-down evaluations scaled up or spread across a single country [36] or a nationwide health administration [43]. Services covered various clinical specializations including rehabilitation [35,39], geriatrics [39], cancer surgery [2,38], diabetes [2,38], and mental health [34,37,40,42], in addition to general specialist care and primary care [32,33,36,41,43]. All studies presented empirical findings relating to services that had (to varying degrees) undergone, were undergoing, or were about to undergo scale-up or/and spread.

The different approaches and frameworks used in the papers reviewed reflect different logics of change. This has implications for the way spread, scale-up, and sustainability are operationalized, studied, and conveyed. Many of the articles included in the review emphasized a logic of change underpinned by implementation science (Multimedia Appendix 3). Bauer et al [37] used the Reach, Efficacy, Adoption, Implementation, and Maintenance (RE-AIM) framework in the quantitative arm of their evaluation on telehealth for bipolar disorder in the Veterans Affairs (VA) health care system to quantitatively assess the extent and patterns of implementation and sustainability. They also drew on the integrated Promoting Action of Research Implementation in Health Services (iPARIHS) framework to analyze qualitative data on challenges and opportunities for program implementation and sustainability. The Consolidated Framework for Implementation Research (CFIR; not designed specifically to look at implementation of software) was used in another implementation science–focused study to identify analytical constructs for collecting and analyzing provider perspectives on video telehealth in mental health services for US veterans [34,55]. Wade et al [39] used grounded theory to construct a process model of change management in large-scale home telehealth in South Australia, highlighting leadership support as a key facilitator. When reflecting on the transferability of their findings, this paper also makes reference to complex change and systems theory [39].

The above studies primarily report the use of frameworks as part of evaluating, rather than guiding, spread and scale-up efforts. Another two articles employed frameworks to support spread and scale-up efforts, although they did not draw on relevant approaches such as the Going to Full Scale framework, 3S infrastructure, or the Dynamic Sustainability framework [58-60]. In a prospective analysis in Cabo Verde, the “initiate-build-operate-transfer” approach was described as the basis for delivering a countrywide telemedicine network. This seemed akin to a phased implementation framework, although it was supplemented by a range of additional measures to address sustainability factors as reported in relevant literature, including careful training and capacity development [41]. In a second prospective study, the PARIHS framework, including use of external facilitation, was employed as a systematic approach to guide extensive implementation of psychotherapy for posttraumatic stress disorder (PTSD) by the US Department of Veterans Affairs [40].

Complexity was mentioned in a few articles, although not as a key organizing framework. Alami et al [36] analyzed data from their mixed methods study on national telemedicine implementation in Norway without employing a conceptual framework; however, their discussion emphasizes complexity, adaptive capability, and participatory approaches. Darkins [43] drew on diffusion of innovations theory to organize his analysis of telehealth expansion in the US Veterans Health Administration over a 10-year period, referring as well to the “complex adaptive environment” and “systems approach” taken to achieve spread.

Social science theory was also employed, although rarely in a highly theoretical mode. In their study on telemental health services for rural American Indian communities, Brooks et al [33] used diffusion of innovations theory to retrospectively examine factors that influenced widespread adoption. Martinez et al [35] applied a sociotechnical perspective in their study of health providers’ perspectives on video telehealth for US veterans with spinal cord injuries. This led to identification of social and technical factors that influenced telehealth implementation across care facilities. In their discussion, they also reflected on the interdependencies and relationships between the different sociotechnical aspects of the system, viewing health care teams as complex adaptive systems. Bhatta et al [32] presented a descriptive overview of opportunities and challenges for telemedicine in Nepal and included some, albeit limited, discussion of their findings from an information infrastructures perspective to highlight the importance of installed base. Finally, the VOCAL study took an explicit social science approach by theorizing video consultations using technology-enhanced Strong Structuration Theory, which assumes a dynamic and reciprocal link between the social environment, human interpretations and actions, and technologies [2,38].

Reported Opportunities and Challenges

A total of 38 opportunities to scale-up, spread, and sustainability and 47 unique challenges were reported across the 13 articles. The most common opportunities included the availability of clinical and/or nonclinical telehealth champions or coordinators (n=8), provider acceptance (n=4), absence of billing or licensure restrictions (n=3), adequate funding (n=4), and strong interorganizational communications (n=4). The most common challenges were lack of technical telehealth-specific support for clinical staff (n=6), need for redevelopment of workflows and organizational routines (n=6), financial pressures (n=5), and lack of training (n=5).

Not all articles explicitly reported opportunities and challenges: 10 (77%) reported both challenges and opportunities [2,33-35,37-41,43], 2 (15%) reported challenges exclusively [32,36] and 1 (8%) article focused more on opportunities and how these could be translated to other settings [42].

Challenges to Scale-up, Spread, and Sustainability

We synthesized the data extracted from the 13 articles according to the 7 domains of the NASSS framework [23] (Figure 1).

Domain 1: The Condition

This domain encompasses the clinical and sociocultural aspects of the health condition and associated comorbidities, acknowledging that not all individuals with the same condition would benefit equally from health technologies [23]. The complexity of the condition plays a role in determining the suitability of patients for video consultations and hence influences the potential for scale-up, spread, and sustainability [23]. In total, 7 of the studies reported the conditions for which video consultations were used, including dermatology, diabetes, antenatal diabetes, postoperative cancer, spinal cord injuries, bipolar disorder, PTSD, and other mental health conditions. Of these studies, 6 paid limited attention to how clinical characteristics played a role in the successful spread of video consulting services [32-35,37,42], although there was mention of provider concerns around using video consulting in specific conditions (eg, “for patients who are at high risk of suicide or who have psychotic symptoms”). This was mainly reported by participants with no previous experience of video consulting [34].

Opportunities for and challenges to the spread and scale-up of video consulting by type of clinical condition were reported in detail in only one study [2,38]. For example, video consulting in an antenatal diabetes clinic was abandoned given the involvement of multidisciplinary teams across departments, the duration and severity of the condition (short-term, high-risk), and the use of patient-held medical records that were unavailable to the clinician conducting the video consultation [2,38]. Preoperative cancer surgery was deemed too complex for video consulting given the necessity of a physical exam combined with there likely being no pre-existing relationship between the patient and clinical team, but postoperative follow-up within the same clinic was deemed more appropriate [2,38]. Other studies pointed to the difficulties in conducting physical examinations as constraining spread and scale-up. For example, an investigation of video consulting scale-up for spinal cord injury suggested that a “common concern was the perceived limits to evaluate physical symptoms over [video]” and the difficulty to assess clients’ complaints without being able to physically examine them [35]. One study noted that for patients with agoraphobia, the video medium removed the need to travel to the clinic and allowed patients to more easily receive mental health support [42].

Domain 2: The Technology

The technology domain encompasses the materials, data, knowledge, and supply features of the technology [23]. This domain focuses not only on the physical technology and knowledge required to use it, but also on how the technology shapes (and becomes shaped by) the potential for scale-up and spread [23]. The 13 papers referred to various video consultation programs but focused on their implementation process rather than providing details of the video conferencing technologies used. Some descriptions remained vague; for example, one article referred to a “simple technology that is only used for consultation purposes” [32]. Others provided a brief overview of changes in technological solutions, from early telehealth programs that used “commercial off-the-shelf videoconferencing systems, ones that had been developed for administrative, not clinical purposes” to latter stages using more sophisticated technological tools, such as teleretinal imaging [43]. Companion devices were also mentioned as providing opportunities for enhanced video consulting, including “an e-stethoscope, vital signs monitor, and dermatology camera, but also the e-electrocardiograph and ultrasound probe” [41]. Little emphasis was placed on describing the material features of the technologies; however, 6 studies reported technical challenges restricting spread, including the following: lack of reliability of the video conferencing technology including audio or video interruption/failure [2,32,34,35,38], inadequate maintenance [32], and unreliable internet accessibility or bandwidth [32,35,41].

Brooks et al [33] also reported on challenges setting up the infrastructure to be able to accommodate video consulting: “respondents noted many challenges in the clinic implementation process. Among these were … setting up the telehealth backbone.” In Norway, infrastructural differences between the different regions have challenged the spread of telemedicine and meant that the national eHealth strategy could not be implemented consistently [36]. Elsewhere, unreliable or inconsistent national internet capability and service was reported as a challenge to implementation [32,41]. For example, in Nepal, “due to the irregular supply of electricity and slow internet service, it is difficult … during video conference consultations due to frequent disconnection, blurry images, and unclear sound” [32]. Additionally, widespread implementation requires patients to have access to the appropriate “infrastructure” to participate in a video consultation (computer, webcam, data allowance) [40].

Across all papers reviewed, available technologies for video consultations posed challenges for establishing remote models of care as well as spread and scale-up. Authors reported that support and high-quality training were necessary to achieve widespread growth [2,32-43]. This was illustrated strongly in a large-scale implementation in Nepal: “Another challenge was related with lack of competence and training among the personnel involved in the rural-telemedicine program” [32]. Even when specialist information technology (IT) staff were available, a lack of service and procurement standards hindered spread across the system, as in the example of video consulting in the Veterans Health Administration: “telehealth projects were developed using bespoke interfaces at an individual medical center, ones that were not replicable across the system. Both Veterans Health Administration (VHA) IT and biomedical engineering supported telehealth but without consistent standards for equipment purchase, installation, service, warranty, and help-desk arrangements” [43].

Domain 3: The Value Proposition

The value proposition domain is concerned with whether or not the technology is worth developing or introducing for clinicians, patients, and suppliers [23]. It can influence upstream supply of the technology and uptake and desirability on the demand side, impacting scale-up and spread [23]. The majority of papers (n=10) discussed the value proposition for video consulting and how this was articulated by different program stakeholders. Value proposition was primarily understood in terms of clinical stakeholder perception of patient demand and interest [39,42], perceived clinical need/utility [2,32,33,35,38,41,43], and supplier benefit [2,38]. For example, in an evaluation of video consulting for individuals with bipolar disorder, growth was enabled by technology that was “successfully filling a need perceived by providers” [37]. In another study, Lindsay et al [42] reported that the “natural disaster Hurricane Harvey offered unique motivation for previously reluctant providers to use VTH delivery to connect with their patients during the crisis and beyond,” not only emphasizing the value proposition changing mid-implementation, but also enabling rapid scale-up in ways not previously imaginable.

A weak or poorly articulated value proposition posed challenges for scale-up and spread (n=2). For example, Martinez et al [35] reported that “some providers encountered initial hesitance from individuals with Spinal Cord Injuries or Disorder which they mostly attributed to patients’ uncertain feelings about the new technology.” Interian et al [34] also described how a video consulting program aimed at improving access to mental health care did not spread successfully in an urban environment compared to other settings, because providers did not perceive a local need for the technology: “A second issue involving provider buy-in pertained to the perceived local need for implementation.”

The upstream supply of technology (ie, the relationship between the organization and the supplier or developer) was reported as a facilitator by Greenhalgh et al [38], who explained that scale-up in a Skype-based service was facilitated partially by “clear benefit for both the technology supplier and the patient.” Contrastingly, Bhatta et al [32] reported how uncertain supplier relationships and funding threatened the sustainability and scale-up of their program in Nepal.

Domain 4: The Adopter System

The adopter system considers the staff, patients, and caregivers and their potential and desire to adopt and to continue to use a technology [23]. Staff concerns with video technologies were reported in all papers (n=13) and included the following: lack of provider buy-in and resistance to change [2,33,36,38,39,42]; lack of adequate training and telehealth staff to support sustainable operation of the video consulting programs [32,34,35,37,41], and the mobility of human resources within and between systems including “unplanned transfer of healthcare workers” [32]; the “high turnover of clinicians” [36], and availability of staff, space, and equipment [37]. Providers were slow or reluctant to buy in because they did not trust the technology or consider it clinically applicable [33,34,42]; did not have experience with the technology [34,40]; did not have adequate time to devote to the new technology [2,38]; did not have enough evidence to support video consulting use, resulting in resistance to changes in care models, as they found existing care models to adequately fulfill patient needs [39,40]; or lacked training and technological literacy or ongoing support [32,35].

Spread and scale-up were enabled by an adopter system with engaged and committed staff who were given protected time by the organization to conduct video consultations, as mentioned by Interian et al [34]: “having a team of providers who were detailed solely to provide mental health services by using telehealth technology and had protected time to do so… was rated as having a strong positive impact on V2H [video-to-home telehealth] implementation.” Engaged leadership staff were also reported to be pivotal for promoting uptake and creating conditions for sustained and widespread provider uptake [42].

Challenges to and opportunities for widespread implementation for patients and caregivers were reported in 6 articles [2,32-34,38,42]. Reported patient and caregiver challenges to and opportunities for widespread implementation included patient trust and acceptance of video consulting [2,33,38], the patient’s ability to transport themselves to a “hub” site (for hub-and-spoke video consulting [33]), and patients requiring appropriate technology to participate in video consultations [34]. In Nepal, challenges for patients were numerous and included cultural barriers (eg, patients’ feelings of inferiority to health care workers; women and older patients not speaking for themselves; lack of confidence) and literacy concerns, which were reported to make “it difficult and time consuming to use [video consults] for such patients” [32]. When patients were in front of a screen, it was reported by staff that patients felt uncomfortable participating in the consultation. For mental health care in the United States, patients reported liking the convenience and privacy of video consulting; however, these responses were collected from patients with repeated prior use of video consulting services, possibly excluding important challenges of patients with little or no experience with video consultations [42].

Despite the abundance of challenges to and opportunities for widespread implementation reported from the provider perspective, there was little in-depth consideration of the impact of patient and caregiver adoption on widespread implementation and how the work and acceptance of these groups may have influenced widespread and sustainable implementation. Of the articles that did report patient or caregiver challenges [2,32-34,38,42], these were primarily clinician perceptions, rather than direct reports from patients or caregivers.

Domain 5: The Organization

The organization domain considers the capacity of the organization to innovate, its readiness for change, the nature of the funding decision, the extent of change in routines, and the work needed to implement change in the organization as it relates to the new technology [23]. These elements are crucial in scale-up, spread, and sustainability because they address how the organization might respond to emerging challenges and how the innovation coevolves with organizational structures and processes [23]. Challenges reported in 5 articles included the labor-intensive process of scheduling video consultation appointments within and across organizations and the need to redesign organizational processes around the technology [2,36-38,40]. As Bauer et al [37] reported: “The scheduling process was noted to be labor-intensive, requiring a three-way match among the veteran’s schedule, the consultant’s schedule, and telehealth room availability.” Other challenges included how sites with existing video consulting programs and pre-existing routines may be hesitant or slower to implement new technologies and redesign workflows around a new technology [40] and how embedding video consultations in a clinic “involved significant reworking of … processes in ways that took account of the ‘virtual’ presence of the patient” [38]. In some cases, redesign of organizational processes was prohibitive to implementation. For instance, lack of widespread video consulting implementation in Norway was at least partially attributed to the lack of organizational preparedness required to “integrate changes and initiate restructuring” [36].

Complexity in the organizational domain was managed more effectively when telehealth champions were available, as reported in 11 of the reviewed articles [2,33-37,39-43]. In the words of one author, telehealth champions were “vital to [the] growth of telehealth” [43]. Telehealth champions were typically clinical staff [2,34,36,41-43]. Other roles included health care coordinators or IT staff [33,35,40,43].

Domain 6: The Wider Context

The wider context domain considers the political, regulatory, professional, and sociocultural aspects of video consulting implementation [23]. These factors shape the context in which the technology is implemented and influence the potential for growth and sustainability of video consulting services. At least one challenge or opportunity related to political, regulatory, cultural, contextual, or financial factors was reported in all studies (n=13) [2,32-43]. Political challenges included government instability, which affected related policy development, as a study in Nepal explained: “Due to the unstable political situation and frequent change of government, the policy related with the health care delivery system is fragile” [32]. By contrast, in the island country of Cabo Verde in Western Africa, there was a high-level political mandate for video consulting and a favorable collaboration environment with clear responsibilities between stakeholders, including international nongovernmental organizations. This facilitated the nationwide scale-up and spread of video consulting: "…the collaboration among the … government, the donor, and the implementing agency is superb, with clear terms of references for each of the players" [41].

Even when the political environment was more stable, papers reported that national strategies did not always emphasize the potential for scale-up and spread against other priorities. Take the following report from an evaluation in Norway, which suggests that national approaches "were mainly focused on messaging services and electronic exchange, while less attention was paid towards telemedicine services, especially videoconferencing" [36]. There was a gap in the papers reviewed, on the relevance of interorganizational networking for supporting and sustaining the spread and scale-up of video consulting [24]. Brooks et al [33] highlighted the importance of information (eg, background information about services, clinical protocols) from other organizations using telehealth in promoting take-up and spread. Two other papers reinforced this [2,43], referring to, for instance, "telehealth communities," "collaborations across clinics and staff," and "collaborations with…government partners" not only as important catalysts for change, but also as critical to the ongoing evolution and spread of services. None of the papers mentioned specific interorganizational initiatives (eg, quality improvement collaboratives). This was a surprising silence given the recognized importance of interorganizational networking for the spread of innovation [44,55,61].

Absence of or ambiguity in reimbursement was another common contextual barrier that influenced wider spread of video consultations [36]. In a UK study, the authors reported that, although lack of clarity on remuneration was often raised as a key barrier by implementing teams, published policy documents rarely explained how "reimbursement for virtual consultations would be implemented" [38]. In contrast, centralized funding for video consulting in the Veterans Health Administration in the United States meant that the "availability of national support infrastructure and the absence of billing for services were distinct advantages" [37].

Domain 7: Interactions Between Domains and Adaptation Over Time

The final domain, embedding and adaptation over time, focuses on the scope for adaptation and the resilience of the organization in the face of implementation and potential spread and scale-up [23]. One study explicitly recognized interactions between domains [2,38] by looking across three levels of data relating to spread and scale-up of video consulting: micro (individual users), meso (organizational processes and systems), and macro (national policy and wider context) [2,38]. They reported how challenges such as the condition interact with the organization, determining the ability to scale up video consulting services. For example, in a scale-up of 4 video consulting services, the challenges and opportunities for each service were connected across the domains; simply assessing a patient as having a theoretically appropriate condition for video consulting (micro) and having a supportive national policy (macro) did not guarantee success. Their specific interacting challenges included financial challenges, organizational structure, technical challenges, and the existing structure of treatment [2,38].

Factors impacting resilience, "the intrinsic ability of a system to adjust its functioning prior to, during, or following changes and disturbances so that it can sustain required operations, even after a major mishap or in the presence of continuous stress" [62], and adaptation over time were reported in three articles [32,42,43]. Notably, the absence of sustainable financial models was reported to threaten sustainability [32]. However, in a comprehensive description of the 20-year evolution and adaptation of telehealth within the VHA in the United States, Darkins [43] illustrates a dynamic transition from a fragmented health care system with many short-term pilot telehealth implementations that slowly scaled up and increased the scope of video consulting services and the associated infrastructure [43]. Lindsay et al [42] provided detailed resolution of adaptation over time for one health center within the VHA. In this implementation project, resiliency and sustainability were enabled by introducing video consulting into general practice rather than training specific providers and using a flexible implementation approach that can be modified for different health system contexts. Furthermore, the authors emphasized how measuring and assessing outcomes of implementation and sustainability then sharing those results with stakeholders "increases motivation and momentum for practice change and enables site to respond to challenges in real time" [42].

Discussion

Principal Results

This systematic review contributes valuable insights about the potential for scale-up, spread, and sustainability of video consulting and a novel interpretation through the application of the NASSS framework. A key finding is the paucity of evidence thoughtfully articulating challenges to the scale-up and spread of video consulting, which sits uncomfortably alongside the current global enthusiasm for expanding the use of video consulting services. The review also reveals an absence of concrete operationalization and theorization of scale-up and spread, exemplified by the absence of analysis and concrete definitions and terminology, as well as a lack of appreciation of complexity (particularly, but not only, in relation to the clinical condition and organizational implementation). The articles view spread and scale-up as the sum of multiple implementations, rather than theorizing the distinct processes required to achieve widespread adoption.

Findings from the review pointed to potential enablers of the spread and scale-up of video consulting services, notably regarding the influence of the presence of a telehealth champion, especially during initial spread [63], as well as leadership at multiple levels, appropriate reimbursement mechanisms, user-friendly technology, pre-existing relationships between staff [64], and adaptation (of technology and services) over time [65]. Findings also raised a number of challenges including the following: technically challenged staff, resistance to change, cost, reimbursement, and patient characteristics [24], as well as project management, patient recruitment, leadership involvement, funding, absence of a long-term strategic plan, resistance to change, workflow changes, lack of resources, and liability [64-66]. These challenges are consistent with previous research concerning small-scale implementation and diffusion of video consulting services and the scale-up and spread of other eHealth interventions [67,68]. They also indicate that the same things that interfere with implementation at one site [eg, 48] are also seen as interfering with spread and scale-up [5,7,17,24], although this may be an artifact of how spread is commonly studied as the sum of multiple implementations.

There are gaps in the existing evidence on the spread and scale-up of video consulting. This was particularly the case in relation to interorganizational networking, which is critical in enabling and sustaining innovation [24,30,64], and yet is not explored in-depth. There is also limited data on the material properties and design of different video consulting platforms, and on the value proposition in relation to spread and scale-up when a technology is free (eg, part of a research study) in the place where it was initially developed or implemented, but potentially costly in other settings.

As patients, health care organizations, and nations continue to look toward video consultations, it is essential to continue to theorize this domain. The absence of consistent theorization was demonstrated in this review by the absence of consideration of how challenges and opportunities might interact with each other and influence the process. One proposal to address this oversight is the theorization of scale-up and spread as social processes [69], prioritizing the interactions between actors and context to better inform scale-up or spread. Our review specifically draws on the NASSS framework to contribute a different way of viewing the spread and scale-up of video consultations, understanding opportunities and challenges as emergent, in constant tension, and inherently social. In conditions of complexity, spread and scale-up efforts may be further supported through the facilitation of interdependencies and relational aspects of change, processes that allow sense-making and experimentation, and scope for local adaptations and self-organization [31,70].

The COVID-19 pandemic is producing what is essentially a “natural experiment” as alternatives to traditional face-to-face consultations become a necessity to prevent viral transmission [4]. Interestingly, albeit much more localized, Hurricane Harvey was reported by Lindsay et al [42] to be an opportunity for provider buy-in for video-mediated mental health services. This suggests that the wider context of the COVID-19 pandemic might similarly enable widespread adoption of video consulting services.

Limitations

This review is limited by likely bias within the articles, bias inherent in the reviewing process, and the lack of theorization in the included studies. Publication bias is a long-standing and recognized phenomenon in health research [71] and likely impacts the broadly positive results across studies included in this review. Given the lack of theorization in the included studies, it is hard to know how broadly the factors that may have acted as challenges or opportunities were considered in the evaluations. The consequence of this is that we cannot claim that this evidence provides a conclusive list of the challenges to scale-up and spread generally, nor even specifically to the studies included in this review.

The strengths of this review include the comprehensive searching methods used to identify a breadth of published research (albeit limited in numbers and scope). The analysis and synthesis of the listed challenges has also been framed by a comprehensive theoretical framework.

Comparison With Prior Work

Our review contributes an important synthesis of knowledge about the spread, scale-up, and sustainability of video consulting. Our analysis, guided by the NASSS framework, has enabled us to examine a diverse body of evidence on video consulting services that have scaled or spread to more than one setting. This addresses a fundamental gap in the literature, with prior studies typically focusing on individual technologies or services, rather than organizational implementation and spread across settings [5].

To date, limited attention has been paid to the spread and scale-up of video consulting. Previous systematic reviews have tended to isolate areas of specific interest, focusing on selected aspects of video consulting, such as patient satisfaction [3,72], feasibility [5], clinical effectiveness and cost-effectiveness [73], and specialized clinical areas (eg, cardiology [74], diabetes [75], mental health and addiction [10], teledermatology [76]). Additionally, reviews have focused on telemedicine or eHealth in general without focusing on video consulting [24,77], with which our findings are consistent. Prior reviews have also focused exclusively on the technical aspects of video consulting technology [7]; considered technologies at any stage of implementation, rather than technologies with widespread adoption [24]; or restricted the types of articles included in the review to randomized control trials [78]. Studies have drawn on specific implementation frameworks to support and theorize spread and scale-up of video consulting, with a mechanistic logic of change being dominant. Other frameworks do exist that might support spread and scale-up (see [24] for an overview) but they have yet to be taken up in the context of expanding video consulting.

The studies we reviewed are broadly positive about video consulting. However, the small sample sizes, select nature of samples, and high losses to follow-up call into question any unqualified conclusion that video consulting is “effective.” The trials that have been undertaken on video consulting have provided few or no data on the organizational complexities of implementing a technology-based service, and do not address the question of how video consultation services become embedded in real-world settings.

To date, there have been only a handful of rigorous and theoretically grounded qualitative or mixed methods studies that explore the emergence of video consultation services naturalistically. Such studies have yet to systematically study spread and scale-up beyond the initial implementation.

Conclusions

This systematic review identified opportunities and challenges for the scale-up and spread of video consulting. The application of the NASSS framework surfaced complexity in a number of domains, notably characterizing the importance of organizational support and the wider system in the scale-up and spread of video consulting services. Many articles viewed spread and scale-up purely as the sum of multiple implementations, rather than explicating and theorizing the distinct (social, interorganizational, and policy-related) processes required to achieve widespread adoption.

Given the recent impetus to implement video consulting services at pace and scale due to the COVID-19 pandemic, a more definitive evidence base is urgently needed to support global efforts, and match policy enthusiasm for the widespread use of these technologies. We strongly encourage decision makers and researchers to embrace relevant theoretical lenses that can aid spread and scale-up and ensure the future sustainability of what looks set to be a significant part of future health care delivery.

Acknowledgments

This study formed the basis of an unfunded bachelor's dissertation project. HJ devised the study with SS; led the process of identifying and reviewing papers, with support from SS and JW; and wrote an initial first draft of the paper for her dissertation. Following the start of the COVID-19 pandemic, CP, SS, and HJ theorized spread, scale-up, and sustainability; updated the search; and further built up the analysis with input from TG and JW. All authors contributed to drafts and approved the final version of the paper. Our thanks go to library services at the University of Waterloo for support with searching.

Input on the review from TG, SS, JW, and CP is supported by a Wellcome Trust Senior Investigator Award to TG (grant reference WT104830MA) and funding from the Health Foundation for research on "Video consulting during and beyond the COVID-19 pandemic: implications for scale up and sustainability" (grant reference 2133488). SS and TG are partly funded by the NIHR Biomedical Research Centre (BRC), Oxford, United Kingdom (grant reference number NIHR-BRC-1215-20008). The views expressed are those of the authors and not necessarily those of the NIHR or the Department of Health and Social Care.

Abstract

Background: eCohort studies offer an efficient approach for data collection. However, eCohort studies are challenged by volunteer bias and low adherence. We designed an eCohort embedded in the Framingham Heart Study (eFHS) to address these challenges and to compare the digital data to traditional data collection.

Objective: The aim of this study was to evaluate adherence of the eFHS app-based surveys deployed at baseline (time of enrollment in the eCohort) and every 3 months up to 1 year, and to compare baseline digital surveys with surveys collected at the research center.

Methods: We defined adherence rates as the proportion of participants who completed at least one survey at a given 3-month period and computed adherence rates for each 3-month period. To evaluate agreement, we compared several baseline measures obtained in the eFHS app survey to those obtained at the in-person research center exam using the concordance correlation coefficient (CCC).

Results: Among the 1948 eFHS participants (mean age 53, SD 9 years; 57% women), we found high adherence to baseline surveys (89%) and a decrease in adherence over time (58% at 3 months, 52% at 6 months, 41% at 9 months, and 40% at 12 months). eFHS participants who returned surveys were more likely to be women (adjusted odds ratio [aOR] 1.58, 95% CI

1.18-2.11) and less likely to be smokers (aOR 0.53, 95% CI 0.32-0.90). Compared to in-person exam data, we observed moderate agreement for baseline app-based surveys of the Physical Activity Index (mean difference 2.27, CCC=0.56), and high agreement for average drinks per week (mean difference 0.54, CCC=0.82) and depressive symptoms scores (mean difference 0.03, CCC=0.77).

Conclusions: We observed that eFHS participants had a high survey return at baseline and each 3-month survey period over the 12 months of follow up. We observed moderate to high agreement between digital and research center measures for several types of surveys, including physical activity, depressive symptoms, and alcohol use. Thus, this digital data collection mechanism is a promising tool to collect data related to cardiovascular disease and its risk factors.

eCohort; mobile health; mHealth; smartphone; survey; app; Framingham Heart Study; adherence; agreement; cardiovascular disease

Introduction

eCohorts use new sensor devices and smartphone technology for longitudinal research data collection [1]. Technology permits the identification of digital biomarkers of health and improvement in health-related behaviors [2-5]. Mobile apps may be a promising and feasible tool for health interventions [6,7], and most previous studies have shown that mobile health (mHealth) plays an important role in promoting behavior change for children, adolescents, and young adults [8,9]. However, eCohorts are challenged by low adherence [10,11] and may yield substantial volunteer bias [12], raising concerns about the generalizability of study findings. For example, in the MyHeart Counts Cardiovascular Health Study [11] that examined the feasibility of a smartphone-based assessment of physical activity, less than 10% of enrolled participants completed the full 7 days of physical activity data. Because of low adherence rates and sampling bias, it remains unclear how these previous study results will reflect the whole community.

Establishing the validity and reliability of new electronic data collection methods is required before deploying digital technology in epidemiology settings [13]. A few studies have investigated the equivalence of questionnaires administered on different electronic devices versus traditional paper data collection [14-17]. The electronic modes in these studies included a tablet, touchscreen, interactive voice response system, and personal digital assistant. A few studies attempted to create smartphone apps for specific clinical use, which demonstrated scientific validity [18,19]. However, reliability assessment of mobile app surveys remains scarce, especially for cardiovascular phenotypes.

To integrate digital and mHealth data into a traditional longitudinal cohort, we leveraged an in-person examination as part of the Framingham Heart Study (FHS) to enroll participants into an eCohort (eFHS) using a new smartphone app, digital blood pressure cuff, and smartwatch [20]. Embedding our eCohort in the FHS allowed us to compare the digital measures obtained from a smartphone with the same surveys obtained during in-person clinical examinations at the FHS Research Center using research protocols [21]. To that end, the objective of this study was threefold: (1) to determine the app-based survey adherence over a 12-month period, (2) to compare baseline eFHS app survey measurements to research center measures, and (3) to examine the association of periodic app-based survey measures across different time points. We hypothesized that embedding eFHS in the FHS and leveraging the in-person exam to enroll participants would result in high app-based survey adherence at baseline that would decrease over the 1-year follow-up period. We also hypothesized that app-based surveys would be comparable with surveys collected at the research center.

Methods

Study Sample

Participants of the FHS Third Generation (Gen 3) cohort (n=4095), Omni Group 2 (n=410), and New Offspring Spouse (n=103) were recruited from 2002 to 2005, and underwent periodic research examinations every 6 to 8 years [21]. We leveraged exam 3 (2016 to 2019) to invite English-speaking FHS participants who owned a smartphone (including iPhone 4S or higher with at least iOS 8.2, or an Android phone as of October 30, 2017) to enroll in the eFHS. The eFHS study was approved by the Institutional Review Board at Boston University Medical Center. Beginning in June 2016, at the time of the in-person research examination, participants were invited to download the eFHS smartphone app from the Apple App Store. The participants were not required to register and complete the app-based surveys at baseline at the research center. Some participants chose to register after leaving the research center. Participation in the eFHS was voluntary and participants were not incentivized for participating. All participants were provided with a written protocol that includes information of how to download the app, enter registration information, sign the electronic consent form, and enable notifications on the phone (Multimedia Appendix 1). Participants reached the first screen upon logging into the app after registration. The list of surveys was organized by due date and displayed on the survey screen (Multimedia Appendix 1). Participants received different types of notifications such as welcome messages on enrollment to the study, notifications when new surveys became available, reminder notifications to complete surveys, and thank you messages after completing all surveys (Multimedia Appendix 2). Collected survey data in this study were pushed to a secure cloud server and transmitted to FHS Research Center servers. Among the 3521 participants (Multimedia Appendix 3) who came to the research center (from April 2016 to April 2019), we excluded 1370 participants who were ineligible (did not own a smartphone), did not consent (owned a smartphone but declined participation), or had incompatible phones, and those who enrolled in eFHS but had less than a 12-month follow-up period (n=203).

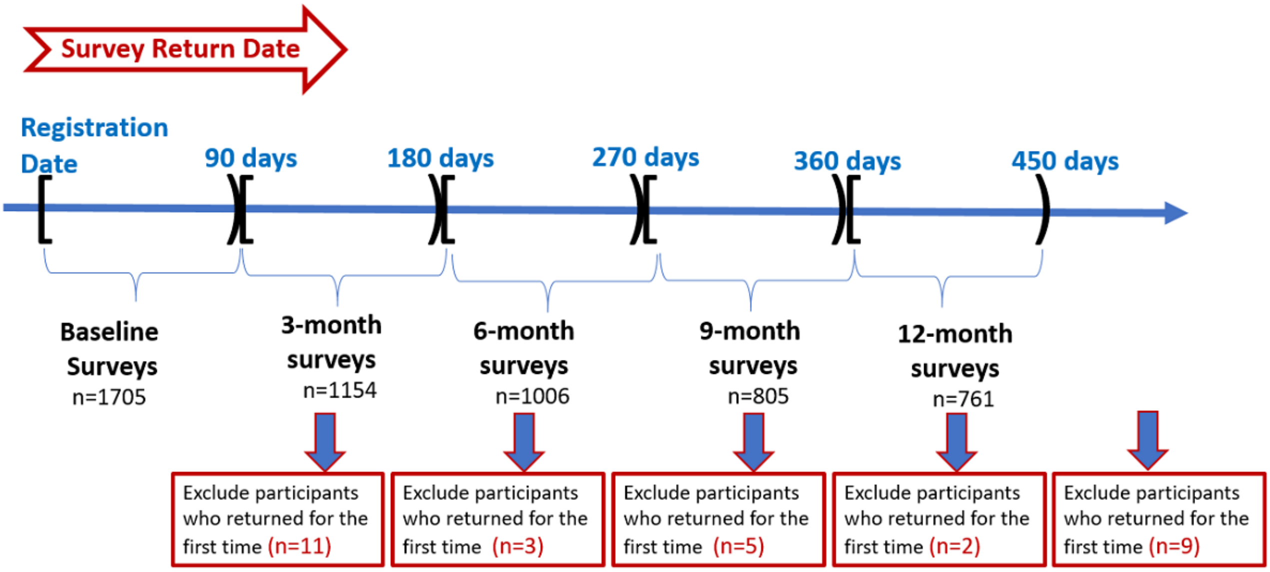
eFHS Smartphone App

Health surveys were distributed at baseline (app download) and at 3-month intervals for 1 year [20] to collect sociodemographic data and variables related to cardiovascular disease (CVD). Corresponding surveys were administered in the research center by trained research technicians or physician/nurse practitioners, except for the sociodemographic survey and health survey questions, which were self-administered. A total of 22 surveys were deployed on the smartphone over the 12-month period after enrollment. Nine baseline surveys for self-reported data were deployed in the following order: sociodemographic information, smoking, medications and self-reported risk factors, baseline CVD history, baseline non-CVD medical history, physical activity, alcohol consumption, health survey, and depressive symptoms (assessed with the Center for Epidemiologic-Studies Depression Scale [CES-D]) [22]. Among the nine baseline surveys, the physical activity survey was deployed at each 3-month interval after registration. A medical history update, depressive symptoms (CES-D), and health survey were gathered at 6 months and 12 months. Surveys for medication use, self-reported risk factors, and smoking and alcohol consumption were collected at 12 months after the baseline survey. A short description of each survey (Multimedia Appendix 4) and the number of steps to complete each survey were provided to the participants. The first step provided the purpose of the survey, intermediate steps contained one or more survey questions, and the last step thanked participants for completing the survey (see Multimedia Appendix 1 for screenshots of some steps of the Physical Activity Index [PAI] survey). Detailed descriptions of screens or steps of each of 10 different eFHS app surveys can be found in our previous report [20].

eFHS Smartphone Survey 3-Month Interval

We evaluated adherence by assessing the return of baseline survey data within 90 days of registration. To distinguish returned survey data from baseline or additional follow-up surveys, we used a time window approach (Figure 1). Thirty participants were excluded because they returned surveys for the first time after 90 days from the registration. We considered the survey data as baseline surveys if participants returned data between 0 to 89 days from registration. If the surveys were returned between 90 to 179 days from the registration date, we considered the data as 3-month surveys. Similarly, we considered surveys as 6-month, 9-month, and 12-month survey data if participants returned their surveys within 180-269 days, 270-359 days, and 360-449 days from the registration dates, respectively.

Figure 1. The time window approach for separating baseline and other follow-up surveys (here, completing a survey means completing 75% of questions in the given survey).



Survey Return Time and Touch Time

To evaluate survey completion time, we examined the survey return time and touch time. The survey return time was calculated by considering the time between the deployment of the survey and the return of a survey. The touch time was calculated by taking the time between the start and return of a survey. We computed the median and IQR of the touch time and survey return time for each type of survey (Multimedia Appendix 5). Furthermore, we calculated the step time (time taken to complete each step) and question time (time taken to complete a question).

Survey Adherence

To minimize frustration, we allowed eFHS participants to skip questions in a given survey. We defined survey completion (completing one survey) if a participant completed 75% of all questions in a given survey (Multimedia Appendix 6). We used two methods for calculating survey adherence. We first calculated the proportion of individuals who completed at least one survey at a given 3-month time window. The second method calculated the proportion of individuals who completed all surveys at a given 3-month time window (Multimedia Appendix 7).

Statistical Analysis

We compared the characteristics of FHS participants who provided consent for eFHS with those of participants who declined or were not eligible for this study. All characteristic variables were collected at research center health examination 3. We used Student *t* tests for continuous variables and χ^2 tests for categorical variables. Among the participants who enrolled in eFHS, we compared the characteristics of participants who returned smartphone app surveys with those of participants who did not return surveys. We used a multivariable (adjusted) logistic regression model, which included an indicator variable (to denote the eFHS participants who returned surveys and those who did not return) as the dependent variable adjusting for age, sex, current smoking, and highest education level.

Surveys collected at the research center health examination and the eFHS app-based surveys provided two sets of measurements for sociodemographic and medical information. To evaluate the agreement of digital survey measures, we compared surveys at eFHS baseline to surveys collected from research center examination 3 using the concordance correlation coefficient (CCC) [23,24] and Bland-Altman plots [25,26]. We used the measurements in the research center as the gold standard for the Bland-Altman analysis. We investigated three different types of surveys deployed at different time intervals: PAI, depressive symptoms surveys (CES-D score), and alcohol consumption surveys. The PAI surveys were deployed every 3 months, CES-D surveys were deployed every 6 months, and the alcohol surveys were deployed at baseline and at 12 months. The surveys collect different health behaviors and mood information that might be reported differently when administered by a trained examiner vs self-reported on a smartphone app.

We calculated PAI as a weighted composite score [27-29] of activity levels with corresponding weights of 1 (for sleep), 1.1 (for sedentary), 1.5 (for slight), 2.4 (for moderate), and 5 (for heavy activities). The number of hours for each physical activity variable (sleep, sedentary, slight, moderate, and heavy) summed to 24 hours. If an individual had one variable missing, we imputed the missing value with 24 minus the sum of hours from the other four variables (n=77).

We analyzed depressive symptoms with two variables: a continuous variable that was the summation of the individual CES-D scores and a binary variable that was defined as 1 if the sum of the CES-D score was ≥16 and 0 otherwise [30,31]. To calculate the continuous CES-D variable, we considered only participants who answered all 20 questions. We found that 72 participants skipped at least one question. We imputed the 61 missing values using the following rule [32]: if more than 5 items were missing, all observations were considered as missing (n=11); if 1 to 5 items were missing, then the average value of the nonmissing items was multiplied by 20.

For alcohol use, we used average drinks per week calculated by the number of drinks per day times the number of days a participant had any type of alcoholic beverage per week.

We used the CCC for continuous measures and the Cohen κ coefficient [33,34] for categorical predictors for agreement analysis between measures from the same participants between eFHS app surveys and research center questionnaires.

We also examined whether three measures (PAI, the sum of CES-D, and average drinks per week) displayed any trend across time points. We used linear mixed models to compare means of PAI and depression symptom measures at each 3-month period. We used the paired *t* test to compare alcohol consumption at baseline and 12 months. We used the R program (version 3.6.1) for all statistical analyses and considered two-sided *P* values <.05 to indicate statistical significance.

Results

Study Sample and Survey Metrics

We included 1948 eFHS participants who met the eligibility criteria and had a follow-up time of 12 months or longer (Multimedia Appendix 3) for analysis. Compared to FHS participants who were not enrolled in eFHS, enrolled participants were more likely to be women, white, married, employed full time, completed bachelor or higher degrees, report excellent health, and have more favorable CVD risk factor levels (Table 1). Among the enrolled eFHS participants, 1735 participants returned surveys. Participants who returned surveys were more likely to be women (adjusted odds ratio [aOR] 1.58, 95% CI 1.18-2.11) and were less likely to be current smokers (Multimedia Appendix 8).

Table 1. Characteristics of participants in the eCohort Framingham Heart Study (eFHS) and Framingham Heart Study (FHS) participants not enrolled in eFHS.[a]

Variable	eFHS participants (n=1948)	FHS participants not enrolled in eFHS (n=1566)	*P* value
Age (years), mean (SD)	52.8 (8.7)	56.6 (9.8)	<.001

[g] eFHS n=1939, FHS n=1539.

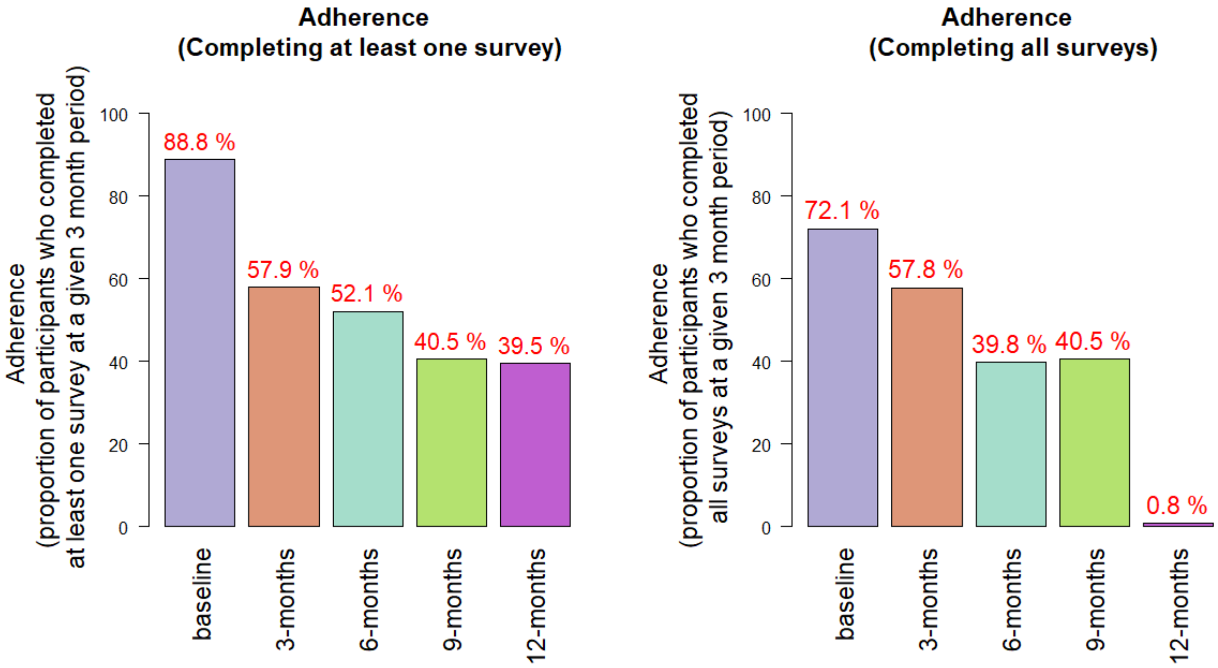
There were 1705 participants who returned baseline surveys within the 3-month interval (Multimedia Appendix 3). Survey return time, touch time, step time, and time spent for each question for each survey at each survey wave are presented in Multimedia Appendix 5. Participants returned baseline and follow-up surveys within 2 weeks with the exception of the 12-month medical history update that was returned within 30 days (Multimedia Appendix 9). The actual time taken to complete surveys (touch time) was less than 5 minutes.

The number of participants who returned a specific type of survey at each survey wave is displayed in Multimedia Appendix 10. Most participants completed 75% of the questions of at least one baseline survey (1704/1918, 88.84%; see Multimedia Appendix 7). Participants continued to return some surveys at 12 months (757/1918, 39.47%; see Multimedia Appendix 7) but only a few participants (28/1918, 1.46%; see Multimedia Appendix 10) completed the 12-month medical history update questionnaire.

Survey Adherence/Completion

Among participants who returned surveys, more than 85% completed more than 75% of the questions across all surveys at all time windows (Multimedia Appendix 6). Considering the proportion of individuals who completed at least one survey at a given 3-month window (Multimedia Appendix 7), eFHS participants had the highest adherence at baseline (89%) and the adherence decreased over time (58% at 3 months, 52% at 6 months, 41% at 9 months, and 40% at 12 months) (Figure 2). We observed similar adherence rates based on the proportion of participants who completed all surveys at a given 3-month period (72% at baseline, 58% at 3 months, 40% at 6 months, 41% at 9 months). At 12 months, adherence was reduced to 1% because most participants did not return the 12-month medical history update survey.

Figure 2. Proportion of eCohort Framingham Heart Study (eFHS) participants who completed at least one survey (left panel) and all surveys (right panel).

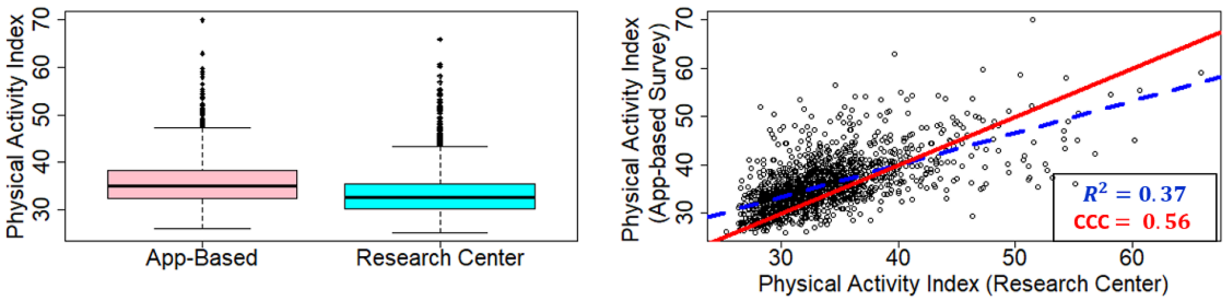


Comparison of Baseline eFHS App Survey With Research Center Measurements

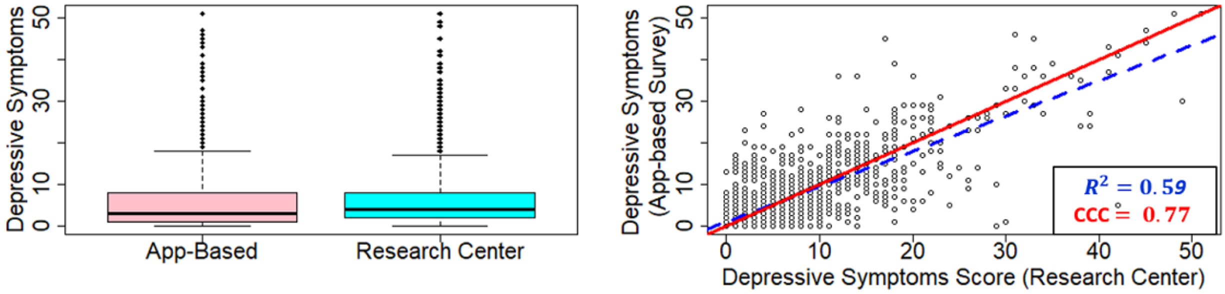
The baseline app-based survey data for PAI (n=1545), CES-D score (n=1628), and average alcohol consumption per week (n=1513) were used to compute the mean difference between the mobile app surveys and the questionnaires collected in the research center. The mobile app survey had a higher PAI compared to the respective in-research center exam (mean difference 2.27). We observed high agreement (CCC=0.82, 95% CI 0.81-0.84) between the two alcohol consumption measures and the two CES-D scores (CCC=0.77, 95% CI 0.75-0.79) (Figure 3). Moderate agreement was observed between the two PAI measures (CCC=0.56, 95% CI 0.52-0.59) and the binary depression variables (Cohen κ=0.51, 95% CI 0.44-0.58). The Bland-Altman plots of PAI, CES-D scores, and alcohol consumption showed that the spread of the difference increased with increasing mean of the observations (bias increased and variability was not consistent across the graph), likely reflecting that the distributions were skewed (Multimedia Appendix 11).

Figure 3. Comparison of baseline surveys: Physical Activity Index (PAI), depression symptoms scale (Sum of Center For Epidemiologic-Studies Depression Scale [CES-D] scores), and alcohol consumption (average drinks per week).

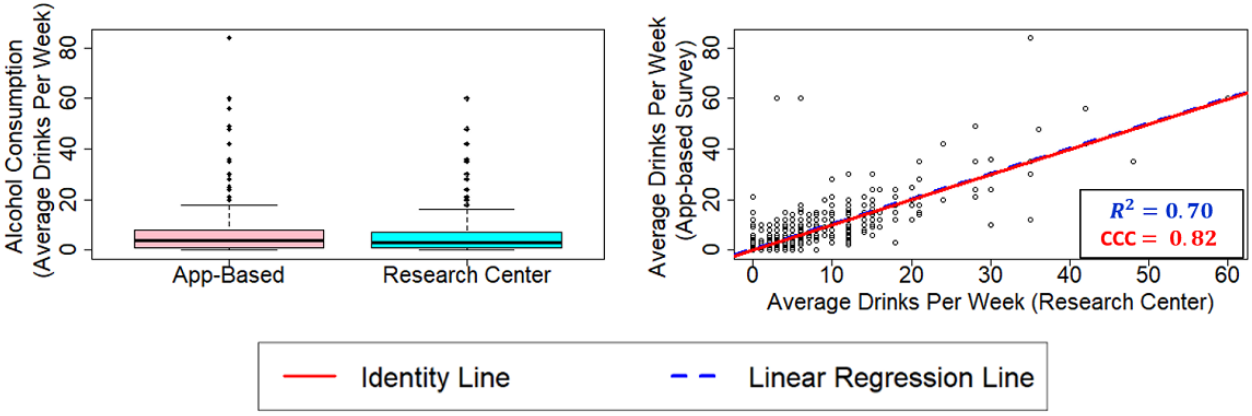
(a) Comparison Of Physical Activity Index



(b) Comparison Of Depressive Symptoms



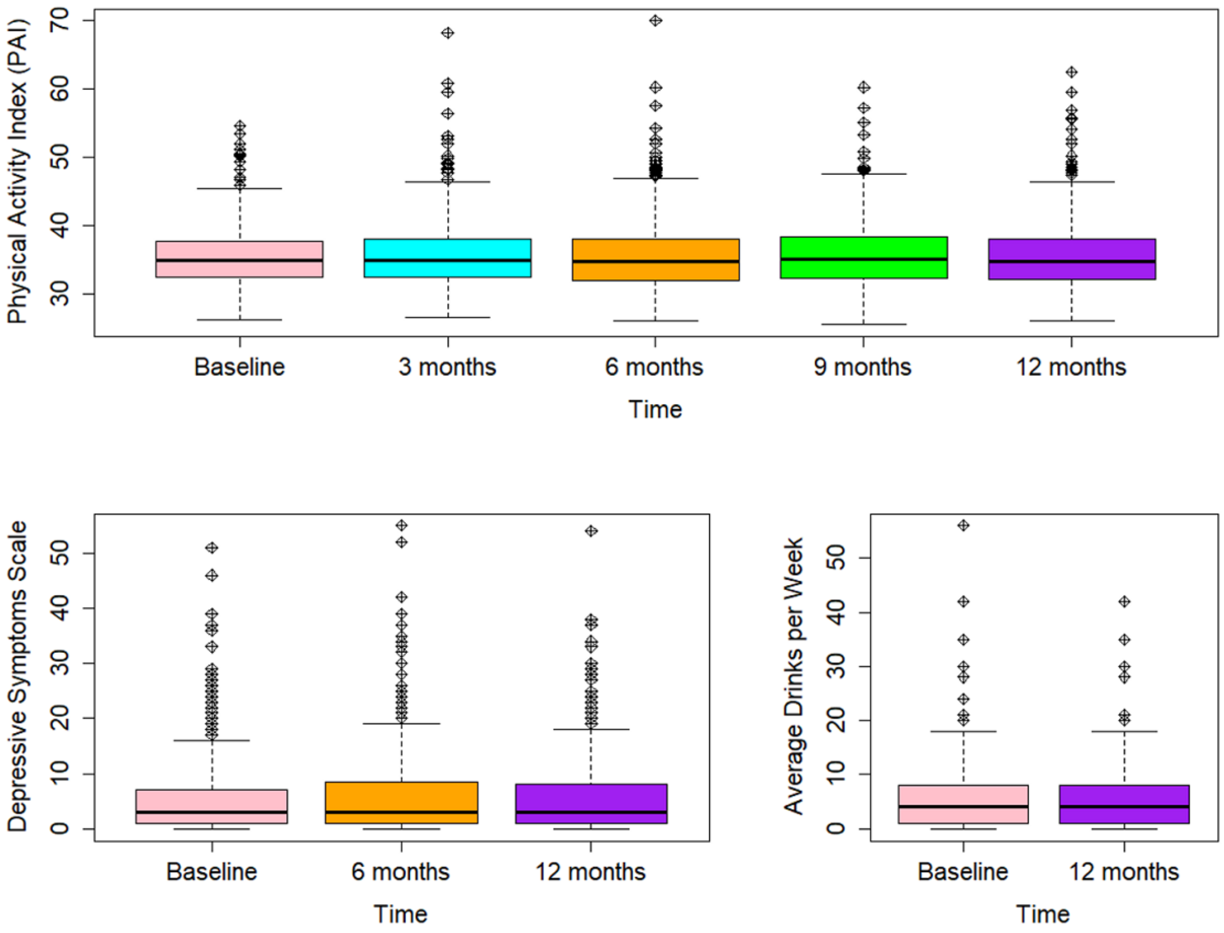
(c) Comparison Of Alcohol Consumption



Association of Periodic App-Based Survey Measures Across Different Time Points

Overall, 539 participants returned physical activity questionnaires at all five time points (baseline, 3 months, 6 months, 9 months, and 12 months), 644 participants returned depressive symptom surveys at all three time points (baseline, 6 months, and 12 months), and 613 participants returned all alcohol consumption surveys (baseline and 12 months). PAI (for all time effects compared to baseline) and alcohol consumption (mean difference of baseline to 12-month questionnaire –0.03, *P*=.82) were at similar levels across several time points, whereas the CES-D score slightly increased from baseline to 6 months (slope=1.01, *P*<.001) and from baseline to 12 months (slope=0.84, *P*<.001) (Figure 4).

Figure 4. Boxplots for Physical Activity Index (PAI), depressive symptoms scale (Center For Epidemiologic-Studies Depression Scale [CES-D] score), and average drinks per week across different time points.



Discussion

Principal Results

Our findings in this middle-aged community-based sample are threefold. First, eFHS study participants had high survey adherence at baseline. The majority of participants who returned surveys completed more than 75% of the survey questions across each 3-month period. Adherence decreased over the 12-month follow-up period but remained high compared with that reported in previous mHealth studies. Second, eFHS is embedded in the ongoing prospective FHS, providing us the opportunity to compare surveys collected on the mobile app to questionnaires collected in the research center using standardized protocols. Our data suggest that app-based surveys and research center questionnaires for physical activity, mood, and alcohol intake had moderate to high agreement. Finally, among the subgroup of participants who returned all follow-up surveys, reports of physical activity (PAI) and alcohol consumption were consistent across all 3-month time intervals over the 12-month follow up.

Comparison With Previous Studies

Although digital and mHealth technologies have great potential to improve health, it is essential to understand engagement challenges with such technologies, as most mHealth studies have observed substantial participant drop offs within a short time period [35]. For example, in the recent Asthma Mobile Health Study [10], more than 40,000 participants downloaded the app, whereas only 7500 participants enrolled in the study and only 175 (2.3%) participants continued to contribute data at the 6-month follow up. Similarly, a study of posttraumatic stress disorder initially had 166,800 participants download the app but only 26,110 (15.7%) users remained after 1 week [36]. The Health eHeart Study is another eCohort that combined the use of social media, smartphones, and wearables to study heart disease. In this groundbreaking cardiovascular study, 86% of consented participants completed at least one survey but 42% of the surveys had missing values [12]. eFHS participants demonstrated considerably higher engagement with a substantial number of participants returning completed surveys at the 12-month follow up (Multimedia Appendix 10). Several reasons may explain the high levels of engagement among eFHS participants. First, the eFHS is embedded in the FHS that consists of loyal participants; the original cohort was followed for more than 70 years, and the present cohort consists of their grandchildren who have been followed in three cycles since the early 2000s. Therefore, the eFHS participants have a long and positive relationship with the study and staff. The smartphone and associated study devices may further connect the participant to the research staff and allow participants to gain insight into their health that could potentially impact engagement [37].

Second, participants received positive notifications, including notifications of thanks and acknowledgement ("Thank you for completing your surveys. Your contribution is a vital part in our ongoing research efforts!"), which may have encouraged participation.

Recent studies have tested the equivalence between electronic and paper administration of patient-reported outcome measures [14,15]. These studies focused on acceptability of the different electronic data collection modes, including personal digital assistants using a tablet or personal computer and interactive voice response systems (automated telephone questionnaire), but did not consider mobile apps. Few studies tested the reliability and validity of mobile apps that were specifically designed for special research purposes. The Burden of Obstructive Lung Disease (BOLD) study was conducted to measure the burden of chronic obstructive lung disease; researchers compared the smartphone and paper-based data collection systems in rural Sudan [19]. A new smartphone app of the International Prostate Symptom Score was also developed and tested [18]. These studies demonstrated that smartphone technology worked well compared to paper-based data collection. Nevertheless, validation studies are limited, and more investigation is needed to recommend a mobile app as an effective method of data collection compared to traditional paper-based surveys. Our study demonstrated good agreement between app-based surveys and surveys collected in the research center using standard protocols across a range of measurements, including physical activity, mood, and alcohol intake. Participants reported a slightly higher PAI in the app-based surveys compared to the same questionnaires filled out at the research center. Another study demonstrated equivalence between the paper and smartphone versions of two scales of depression [38], but some electronic items (such as sad mood and trouble concentrating) were lower compared to items on the paper versions even though they had moderate to high consistency. A randomized study was conducted to compare paper versus electronic mode of delivery of a health and social behavior questionnaire [39]. The majority of mode differences were nonsignificant, but participants reported more exercise in the paper survey compared to the electronic survey. This contrasts with our findings in this study as we observed higher PAI scores in app-based surveys. However, smartphone app surveys can be an efficient method to collect cardiovascular risk factor data.

Participants volunteered in the study and there was no mandatory requirement of answering questions in the smartphone app. Adherence varied across different types of surveys. The difficulty of the survey may impact long-term adherence. For example, we observed adherence rates of 40% even after 12 months of follow up for most surveys (n=757), but lower completion rates were obtained for the 12-month medical history update survey (n=28). It is unclear why participants did not complete the medical history update survey. However, this survey was longer than the other surveys in the eFHS app, and compared to other surveys, the medical history update survey contained many open-ended questions that may have required more time and effort to complete. Indeed, unrestricted or open-ended questions have been reported as the major challenge of app-based surveys [19,40].

We conducted a pilot study using two distinct enrollment methods to compare adherence for device use and two internet surveys. The two methods were on-site support (n=101) and remote (n=93) enrollment [41]. The baseline core internet survey consisted of 34 separate parts for self-reported health outcomes, which was completed at home after enrollment and consent. To address the overall study performance, an end-of-study survey was emailed to the participants at study termination. On-site support increased the participation and the initial rate of device use compared to remote support. The pilot study also demonstrated that on-site research center visit was associated with higher adherence to the end-of-study survey. However, on-site research center visit was associated with lower adherence to the internet survey at baseline compared to the remote arm. Thus, the pilot study suggests that in-person contact may not be as important for studies designed to deliver only surveys. We observed higher adherence to the baseline app-based survey in the eFHS than reported for other eCohorts. The eFHS is embedded in the FHS, which consists of loyal participants, potentially leading to higher baseline app-based adherence in the eFHS [37].

A new, enhanced version of the app was implemented in February 2019, which includes an interactive health dashboard to promote participant engagement and facilitate survey adherence. We did not uniformly collect feedback from users, but we are planning to assess usability of the new enhanced version of the app with the Mobile App Rating Scale (MARS) [42] as a separate study.

Insights and responses from participants may help to identify better strategies to improve adherence in mHealth studies [43]. Monitoring and feedback, reminders, goal setting, social support features, and rewards are tools that can be used to improve short- and long-term engagement [44-46]. In particular, the just-in-time adaptive intervention, which aims to provide a proper amount of support at the appropriate time when it is needed, may lead to a change in health behavior [47]. In future work, we plan to establish an advisory panel of eFHS participants to assist with co-design of the app and engagement methods [48].

Strengths and Limitations

The eFHS is a large community-based cohort designed to study CVD and other risk factors. It is embedded within the ongoing traditional FHS, and the study design provided the opportunity to compare FHS participants who consented vs participants who declined. It also provided the opportunity to compare baseline app surveys and surveys collected in the research center. Importantly, it provided the opportunity to compare eFHS participants to FHS participants who declined enrollment in eFHS to understand the generalizability of the sample.

Our study has several limitations. eFHS included predominantly white, educated, and healthy participants who own smartphones, most of whom resided in the New England region of the United States, thus limiting the ability to generalize the findings from this study to other racial and ethnic groups, individuals with less than high school education, smartphone-naïve, disease-based samples, and other regions/countries. Some participants downloaded the app (n=203) and enrolled in eFHS after January 31, 2019. Since these participants did not have the opportunity to participate in the study for at least 1 year at the time that we began the analysis, we excluded these participants from this study. There were slight differences in the characteristics (Multimedia Appendix 12) of eFHS enrollees who had a greater than 1-year follow-up time vs participants who had a less than 1-year follow-up time (women: 57% vs 50%, married: 75% vs 66%, and median BMI: 27 vs 29), which may not influence the generalizability of the current study. We allowed 90 days to complete baseline app-based surveys, but the participants returned digital surveys within a couple of weeks from the enrollment. The median survey return time varied from 1.35 to 2.40 days and the IQR was about 7 days (Multimedia Appendix 5). Therefore, the survey results relying on self-reported CVD risk factors may not differ according to the time of completing the survey, which would not affect the comparison results of research center measurements (time at enrollment). Moreover, since our study was observational, we cannot exclude residual confounding factors and cannot establish causal relations in our observations of variation in characteristics associated with adherence. A subset of eFHS participants (n=655) were enrolled in a randomized controlled messaging trial (ClinicalTrials.gov NCT03516019) [49] designed to test the impact of personalized notifications on device use. However, the notifications did not impact app-based survey adherence. Recent digital health intervention studies were found to be cost-effective in the management of CVD [50,51]. However, an economic evaluation of digital data was beyond the scope of this study.

Conclusions

We observed high adherence to baseline surveys with a substantial proportion of participants continuing to complete surveys at the 12-month follow up, indicating that the eFHS app may be a promising tool to collect data. App-based surveys were comparable to the research center–administered questionnaires. Therefore, the eFHS app may serve as a reliable data collection mechanism. Further exploration is needed to understand the reasons for the higher PAI in the app-based surveys compared to the surveys administered at the research center.

Acknowledgments

This study was supported by an award from the Robert Wood Johnson Foundation (number 74624) and a grant from the National Heart Lung and Blood Institute (R01HL141434). The FHS is supported by a contract from the National Heart, Lung, and Blood Institute (principal investigator VR; 75N92019D00031), and investigator time from the following grants: R01HL126911 (EB), 2R01 HL092577 (EB), 1R01AG066010 (EB), American Heart Association, 18SFRN34110082 (EB), 2U54HL120163 (EB), R01HL126911 (DM), R01HL137734 (DM), R01HL137794 (DM), R01HL13660 (DM), U54-HL 143541 (DM).

Conflicts of Interest

JM was a guest lecturer at Merck Research Laboratories. DM has received research support from Apple Computer, Bristol-Myers Squibb, Boehringer-Ingelheim, Pfizer, Flexcon, Samsung, Philips Healthcare, and Biotronik, and has received consultancy fees from Bristol-Myers Squibb, Pfizer, Flexcon, Boston Biomedical Associates, and Rose Consulting. DM also declares financial support for serving on the Steering Committee for the GUARD-AF study (NCT04126486) and Advisory Committee for the Fitbit Heart Study (NCT04176926). VK is principal, and CN and EM are employees of CareEvolution, Inc, a health care technology company. As of 2020, EB was an uncompensated member of the MyHeartLab Steering Committee, a principal investigator–initiated study from Samsung to University of California San Francisco (principal investigator, Jeffrey Olgin, MD). Other authors have no relevant disclosures.

Abstract

Background: Using the internet for health information is a widespread phenomenon documented in considerable scholarship. Less common, however, is the analysis of panel data to examine how internet use may relate to change in health status over time.

Objective: This study examines whether internet use and internet use related to health are associated with a change in health status among young adults.

Methods: We used a unique panel survey data set collected about young adults' internet use in 2012 and 2016 (n=384). We applied logistic regression to examine the relationships between sociodemographics, internet experiences, frequency of health-related internet use, and sharing health content online with change in health status over time. We additionally examined the variables characterizing sharing health content online (via Facebook, Twitter, and email) in separate models.

Results: In the second wave, over half (236/384, 61.5%) of the sample used the internet for health at least weekly. Approximately one-third (141/384, 36.7%) used Facebook for health-content sharing, while using Twitter and email for sharing health content were far less frequent (14/384, 3.6%, and 55/384, 14.3%, respectively). A change in health status occurred for 43.0% (165/384) of the sample; 18.5% (71/384) reported an improvement while 24.5% (94/384) reported a decline. Greater frequency of internet use was associated with health decline over time (*B*=–0.58, *P*=.02). We also found that frequent health-related internet use was related to enhanced health or maintained health (*B*=0.58, *P*=.03). Sharing health content on social media or email, however, was not related to young adults' health changes.

Conclusions: Young adults exhibit a pattern of using the internet for health that influences their health status. Our finding that frequent health-related internet use may promote improved or maintained health suggests that this type of online activity might also support healthy living.

KEYWORDS

internet use; health-related internet use; health status; panel data; young adults; internet; healthy living

Introduction

The internet has become an important means through which people engage with health content; among US adults, well over half turn to the internet as a source of health information [1-3]. Young adults—individuals in their late teens and twenties [4]—report even higher levels of internet use for health [5-7]. Young adults are over 2 times as likely to search for a health provider online and over 3 times as likely to search for health information as their older counterparts even when controlling for other sociodemographic characteristics [8]. Younger age is continually reported to be an indicator of a higher likelihood of using the internet for health-related reasons [9,10].

A substantial body of work has documented the relationship between internet use and social inequalities [11-14]. However, how internet use relates to the production of health inequalities or differences in health conditions and care due to social factors is less known [15]. Internet researchers continue to grapple with whether and how the proliferation of digital technology benefits or harms the well-being of individuals and society [16].

The internet offers several pathways to seek and share health-related information that may enhance medical knowledge. Examining the relationship between internet use and health may therefore inform whether the internet has the potential to influence the state of health in positive or negative ways. We address this question by analyzing unique panel data about a diverse group of young adults to see whether their internet uses relate to a change in their health status over time. Panel data are especially relevant to such questions as they sidestep the limitation of cross-sectional studies, which do not allow for conjectures about whether health status is a result of or a cause for the way people use the internet.

Most studies explore health-related internet use in the form of health information–seeking: purposeful searching for health information using reliable sources or those of unknown reliability for one's self or others [17,18]. Such use among young adults is strikingly high; 94% report looking for health information online while 76% have viewed or read about another individual's health experiences [7]. Although such internet use is prevalent, social inequalities persist. Mirroring findings across all age groups [19-22], among young adults, women and those with higher socioeconomic status are more likely to seek health information online than men and people from less privileged backgrounds [6,7,23-25]. Differing from reports on older age groups [22], studies of young adults report little variation across racial and ethnic groups with regard to health information–seeking online [6,7,24].

Compared with the considerable literature that has looked at how people seek health content online, fewer studies have examined the sharing of such content [26]. Similar to research on content-sharing more generally [27], studies vary widely in how they conceptualize and measure the domains of shared health content. Studies also differ by whether they specify social media platforms. Facebook comprises the bulk of research describing posting behavior [28-30], but research has also considered other platforms such as Twitter [31] and health-focused online communities [32]. While some studies do use secondary data sets that leave platform unspecified [10,33], survey questions may group sharing health content with reading health content under the overarching domain of user-generated and shared content [8], which makes it difficult to know what to conclude about sharing in particular in such contexts.

Social network sites attract growing numbers of the US population for reading or sharing about health-related topics, including managing health concerns [1,3]. This figure is higher among young adults, with half sharing such content in 2016 [34]. Age group comparisons over time also find that younger individuals share health-related content more often than older and middle-aged adults [10]. Being younger and female as well as having lower income and education all associate with using social network sites for health [3,8,10,35]. Overall, we conclude that social inequalities related to health information–seeking online also appear to be associated with sharing health content online. These findings, as well as the wealth of research documenting the link between social inequalities and health outcomes [36], set the stage for examining the relationship between health-related internet use and health outcomes.

Research exploring the relationship between internet use and self-reported general health status finds varying results. Some studies point to a positive association where better health relates to both general internet use [29,37,38] as well as more frequent use of the internet [39-41]. The relationship between health-related internet use specifically and health status is mixed and, adding further uncertainty, this variation in relationships occurs whether modeling health status as an independent variable [20,21,42-45] or outcome variable [41,46-48]. We review these streams of research in turn below.

Most research treats health status as an independent variable and models health information–seeking as the outcome of interest. Studies analyzing cross-sectional data from the Pew Research Center found that poor health was associated with health-related internet use [21,43]. Worse health was also related to a greater number of health topics sought online [21]. Among adults who looked for health information online, individuals reporting poorer health searched for health content online more frequently and completed specific searches for health care and treatment [43].

However, studies have also related better health to health information–seeking online. Cotten and Gupta [20] found that those who were healthier were more likely to seek health information online than via offline sources. The same significant relationship between better health and health-related internet use occurred in a multinational sample of adults, although certain indicators of worse health (eg, long-term illness and disability, health care use) did link to more health-related internet use [42]. A secondary analysis found that while health status was not associated with health information–seeking online, presence of a health condition did have a positive relationship [44]. The above findings reveal a clear variation across research studies, warranting further inquiry.

Far fewer studies examine health status as the outcome of interest relative to health-related internet use, yet all report no significant direct relationship between health-related internet use and health state [41,46-48]. Most such studies use cross-sectional samples [47,48], while panel data are much less common [41,46]. Research that looks at other health outcomes such as the presence of health-promoting behaviors does report significant associations with health information–seeking online [49].

Similar to health outcomes associated with health-related internet use, just a handful of studies specifically examine the relationship between health-related social network site use and health status, although none of these studies model health as an outcome variable [3,10,35,40]. Findings are mixed; one study found a positive relationship between having a primary care provider and social network site use for health [35]. Other studies reported no association between health status and health-related social network site use [3,10].

The potential benefits of social media for health communication include a range of positive implications for individuals in terms of social-emotional support, greater and more tailored health content, and increased social interaction [50]. That said, the frequency of time spent online may have a detrimental effect on well-being. A systematic review examining the impact of social media on well-being among adolescents reported overall mixed findings but noted that greater time spent online related to increased risk of exposure to harm [51]. Examining whether and by what mechanisms internet use influences health therefore becomes all the more important to tease out, especially for a group that spends considerable time online—young adults.

The purpose of this study is to examine the relationship between internet use and health change. We use panel data, which to our knowledge is used less often, to explore whether general internet use and internet use related to health are associated with a change in health status. We examine this relationship within a sample of young adults as this population is of particular relevance due to their high consumption of online health information [5,7]. We define the domains of health-related internet use as the frequency of internet use for health and sharing health content online, offering a more in-depth description of a little-explored area than most existing studies.

Methods

Data Collection

We used a unique panel survey data set collected about young adults' internet use in 2012 and 2016. The study received approval from the institutional review board of the principal investigator's home university (Northwestern University) at the time of data collection.

We surveyed students from a required first-year writing course at a US midwestern public university, thus avoiding any bias associated with who may be more likely to take specific classes. We administered the survey to students in 86 of the 92 course sections that agreed to participate in the study. Of the students enrolled in the class, 80.5% (1325/1646) completed the questionnaire. Of these respondents, we focused our study on first-year students under age 30 years; these 1115 people make up our initial 2009 sample. We then administered waves 2 and 3 through postal mail. Wave 2 (2012) occurred 3 years after the initial data collection, and respondents were offered a US $25 gift card for their participation. Wave 3 (2016) followed 4 years later with a US $40 gift card for those who returned their survey. In both years, we sent an introductory letter before the survey and then followed up after the survey with 2 postcard reminders and one more copy of the survey. In wave 2, the response rate was 51.2% (571/1115), but we discarded 24 cases (24/571, 4.2%) for not passing the attention check question, resulting in 547 valid responses. Wave 3 achieved a 34.44% (384/1115) response rate in comparison to the baseline sample, while 70.20% (384/547) of respondents completing the 2012 survey also completed the 2016 survey. Those completing the survey in waves 2 and 3 comprise our sample, and they mirror wave 1 except for a somewhat smaller proportion of African Americans. We used measures of internet use from 2016 (wave 3) data. We used measures of health status from 2012 and 2016 to capture change in health over 4 years. Sociodemographics come from the 2009 (baseline) survey.

Measures

Demographic Characteristics

We measured gender by asking participants whether they identify as male or female (see Multimedia Appendix 1 for all questions used in analyses). We collected additional data on age, race, and ethnicity separately. As a proxy for socioeconomic status, we asked respondents for the educational attainment of both their mother and father. We included the highest level of education completed by either parent in the analyses and recoded categories to high school or less, some college, and college degree or more.

Internet Experiences

As summarized in Table 1, we measured internet experiences in several ways: years of internet use, autonomy of use, frequency of use, and internet skills. We used data collected in 2016 for internet experiences with the exception of length of internet use which we measured in 2009. Measures of length of internet use were not repeated because years reported would increase proportionally in waves 2 and 3. We measured this by asking respondents how long they had been online. We measured weekly time spent online using categorical response options asking separately about weekdays and weekends, which we then recoded by multiplying the weekday response by 5 and the weekend response by 2, and then summing these for a possible range of 0 to 42. We logged this final number of hours to account for diminishing returns of additional time online in the regression models. To measure number of access locations, or autonomy of use, we asked respondents whether they use the internet from 10 different locations. As with number of hours online, we logged number of access points for logistic regression to address the diminishing returns of having greater numbers of internet access points. To gauge internet skills, participants completed a series of questions regarding their understanding of 27 internet-related terms [52]. Past research validated this measure with observational measures and used it with young adult samples [12,53].

Table 1. Sample characteristics (n=384).

Characteristics	Values
Gender, n (%)	
Women	231 (60.2)
Men	153 (39.8)
Race/ethnicity, n (%)	
White	167 (43.5)
African American	29 (7.6)
Hispanic	85 (22.8)
Asian	90 (23.4)
Parental education, n (%)	
High school or less	94 (24.5)
Some college	98 (25.5)
College degree or more	188 (49.0)
Missing	4 (1.0)
Internet experiences, mean (SD)	
Years of use[a] (in 2009)	5.6 (2.2)
Number of access locations	7.8 (1.7)
Weekly web hours	21.4 (10.5)
Internet skills (1-5)	3.6 (0.8)

[a] Years of use: n=382.

Health-Related Internet Use

We assessed two domains of health-related internet use in wave 3 (2016): frequency of overall health-related internet use and sharing health content online. We measured frequency of using the internet to obtain health information using a single question with categorical response options. We dichotomized this variable for regression modeling to monthly or less and weekly or more. To measure sharing health content we asked about such activity in the past year for Facebook, Twitter, and email, separately. We treated the measures of the use of each platform as separate, dichotomous measures in regression modeling.

Health Status

In 2012 and 2016 we measured health status with an extensively used, single-item question derived from the 36-Item Short Form Health Survey [54]. This measure allowed for brevity in questioning and is significantly related to other measures of health, including health care use, functional status, varied health conditions, and mortality [55-57]. We determined change in health over time by taking the 2016 health status measure and subtracting it from the 2012 measure. Positive values indicated improvement, zero indicated no change, and negative values indicated health decline. We recoded this variable into a binary measure of whether someone's health declined (=0) versus improved or stayed the same (=1).

Analysis

Given that none of the correlations of our measures of internet experiences and health-related internet use were higher than 0.2 (i.e., there was no multicollinearity in our data set), we continued with regression modeling. We used logistic regression to examine the relationships between sociodemographics, internet experiences, frequency of health-related internet use, and sharing health content online with change in health status (level of significance: $P<.05$). We examined the variables characterizing sharing health content online (via Facebook, Twitter, and email) in separate models.

Results

Sociodemographics

Table 1 summarizes the sociodemographic characteristics of respondents who completed surveys in waves 2 and 3 of data collection. There were more women than men in the sample (231/384, 60.2% versus 153/384, 39.8%), and their proportion is almost identical to the first wave of the study. The vast majority of respondents were aged 18 or 19 years at the time of the first data collection, and aged 25 to 26 years at the time of wave 3. Since age does not vary in the sample, we do not include it in analyses. Less than half (167/384, 43.5%) were White, almost one-quarter (90/384, 23.4%) Asian, a slightly smaller number (85/384, 22.8%) identified as Hispanic or Latinx, and less than 1 in 10 (29/384, 7.6%) as African American. The remaining respondents (13/384, 3.4%) reported being Native American, other, or did not report race/ethnicity. We found considerable variation in parental education; almost half (188/384, 49.0%) had at least one parent who completed at least a college degree, while roughly one-quarter (98/384, 25.5%)

had completed some college and a quarter (94/384, 24.5%) had no more than a high school degree.

Internet Experiences

Descriptions of internet experiences are found in Table 1 and show that while most participants have considerable online experience, the standard deviations signal that there is plenty of variation in the sample.

Health-Related Internet Use

Our results reveal both high prevalence and variation in internet use for health among young adults. Table 2 summarizes the frequency of such use. In 2016, over half (236/384, 61.5%) of the sample used the internet for health at least weekly, with percentages of the full sample roughly split between once a week, a few times a week, and daily. About a seventh (52/384, 13.5%) of the sample only did this a few times a year and just a handful (14/384, 3.6%) reported never using the internet for health. Sharing health content was a less common phenomenon. Facebook was the most common platform for health-content sharing with approximately one-third (141/384, 36.7%) of the sample doing so in 2016. Using Twitter and email for sharing health content were even less frequent.

Table 2. Characteristics of health-related internet use in 2016.

Characteristics	Values, n (%)
Frequency of health-related internet use (n=384)	
Never	14 (3.6)
Few times a year	52 (13.5)
Monthly	82 (21.4)
Weekly	85 (22.1)
Few times a week	82 (21.4)
Daily	69 (18.0)
Sharing health content online (n=383)	
On Facebook	141 (36.7)
On Twitter	14 (3.6)
On email	55 (14.3)

Change in Health Status

Table 3 describes the health status of the sample in 2012 and 2016. As expected for a young adult sample, in both years the majority of respondents reported either excellent or very good health. Although we found comparable descriptive findings across years, a notable number of young adults reported a differing health status from 2012 to 2016. A change in health status occurred for just under half (165/384, 43.0%) of the sample; about a fifth (71/384, 18.5%) reported an improvement (eg, fair to very good or very good to excellent) while a quarter (94/384, 24.5%) reported a decline (eg, excellent to very good or good to poor). Just over half (216/384, 56.3%) reported the same health status in 2012 and 2016. This is partly due to the fact that there is a ceiling effect. Over a third (136/384, 35.4%) of participants reported excellent health in 2012 meaning that these people could not have reported an improved health status in 2016 given our measure of health status. In fact, a fifth (77/384, 20.1%) of the sample remained in excellent health at the second time point. Given the young cohort, we did not have issues of floor effects with people reporting poor health in 2012 who then could not report worse than poor health in 2016. Just 2 respondents reported poor health in 2012, and both reported good health in 2016.

Table 3. Descriptives for health status and health status change (n=384).

Health status	2012, n (%)	2016, n (%)
Excellent	136 (35.4)	117 (30.5)
Very good	157 (40.9)	159 (41.4)
Good	73 (19.0)	91 (23.7)
Fair	15 (3.9)	11 (2.9)
Poor	2 (0.5)	4 (1.0)
Missing	1 (0.3)	2 (0.5)

Factors Related to Health Improving or Staying the Same

Using logistic regression, we modeled sociodemographic and internet-use factors related to health change, where we looked at health improving or staying the same compared with a decline in health (level of significance: *P*<.05). We completed modeling in which we first added sociodemographic characteristics (gender, race/ethnicity, parental education) to the model, and then internet experiences (autonomy of use, frequency of use, internet skills) followed by frequency of health-related internet use. Finally, we added the variables measuring sharing health content online through different platforms (Facebook, Twitter, and email) each in its own model. Table 4 presents these findings.

In the first model, we found no significant relationships between sociodemographics and health change. Turning to the second step, where we added the variables measuring internet experiences, being female emerged as significant and associated with positive health change/status quo health. Less time spent on the internet was significantly associated with health getting better or staying the same while holding sociodemographic factors constant. Additionally, having better internet skills significantly related to health improving or staying the same. Autonomy of use, or the number of access points for using the internet, was not statistically significant.

The third model included a dummy variable for regular health-related internet use (operationalized as weekly or more). None of the sociodemographics (gender, race/ethnicity, parental education) were significant in this model. Lower frequency of internet use continued to relate to improved or the same health status, while better internet skills no longer associated with better or status quo health. Autonomy of use stayed statistically nonsignificant in the model. Our newly added variable, health-related internet use at least weekly, related to health improving or staying the same when sociodemographics and internet experience variables were held constant.

[b] ref: reference.

We next added sharing health content online using Facebook, Twitter, and email by separately creating three different models. As before, no sociodemographics (gender, race/ethnicity, and parental education) or autonomy of use associated with health change in any of the final modeling. However, less time spent online continued to relate to better or similarly good health as before, as did weekly use of the internet for health. Better internet skills again had a significant association with better or status quo health when modeled with using Twitter to share health information but had no association when sharing health content on Facebook or email. Said another way, when we included sharing health information via Twitter in modeling, having better internet skills significantly related to health improving or staying the same. Since only a tiny portion of respondents in the sample use Twitter for sharing health information, we hesitate to make too much of this finding. We found no significant association across these platforms for health-information sharing. We also ran these models without controlling for health-related internet use; sharing using the various means we examined remained nonsignificant (Table 5).

Discussion

Principal Findings

In this section, we reflect on our findings, discuss the limitations of our study, and suggest avenues for future research. In sum, having a decline in health significantly associated with greater overall time spent online and also less time explicitly using the internet for health. Sharing health content using different social network sites (Facebook or Twitter) or email did not relate to health change. We found that better internet skills related to positive health change or no health change but became nonsignificant when we included health-related internet use variables in the modeling, with the exception of adding health content shared on Twitter.

We found few previous studies that examined health over time in relation to internet use or health information seeking online [37,41,46,59] and the current findings offer a more in-depth look at the relationship between varying types and intensities of internet use and health change. In measuring health change over 4 years, our conceptualization of health improvement included young adults who reported an improvement from poorer health as well as those reporting no change in health. Young adults with no health problems may be accessing information to maintain their currently healthy state [60,61] and yet still gain a positive health change or maintain their health state. Studies examining the relationship between internet use and health in cross-sectional data have found that individuals reporting medical problems and those in a healthy state use the internet for health-related reasons [62].

The finding that greater frequency of internet use is associated with health decline differs from past research, where more frequent internet use associated with better health [40], including in a longitudinal study [37]. Although we recommend the interpretation of a causal relationship with caution, from one perspective having a decline in health may free up time to be online, as one may have health conditions that make it difficult to engage in other activities. While this interpretation may concern different health conditions in varying ways, previous research reports no difference in the frequency of internet use in relation to differing illness types [63]. Alternatively, spending too much time online may be a detriment to health status. The frequency of varying types of online activities may also matter. For example, a survey of first-year college students found that more hours on the internet shopping, doing research, and playing games significantly associated with more depressive symptoms, while more hours spent in online communication associated with decreased symptoms of depression [64]. However, the internet has changed considerably since that study so more work in this domain is needed.

In this paper, we found a clear association between health-related internet use and health change. Our finding that frequent health-related internet use may promote improved or maintained health suggests that this type of online activity might also support healthy living. Recent qualitative and quantitative research supports the notion that these topics are of interest to young adults [60,61]. Our findings differ from previous longitudinal research reporting no association between health-related internet use and change in general health [46]. Cross-sectional studies using young adult samples have also reported varied findings for the relationship between health-related internet use and health status [23,61,65]. One study found a positive relationship between health-promoting behaviors and health-related internet use [23], while another found no relationship between health-related internet use and health status [61]. Further adding to the diversity of study findings for this age group, other research found that young adults who used the internet for health information also reported more adverse health conditions [65]. This variation across study findings may be due to the large variety of health-related activities in which young adults engage online. One study reported that those searching for general health information online reported better health, while individuals searching for disease-specific information reported poorer health [39]. We recommend that future research include more details about the kinds of health topics that young adults explore online in relation to health outcomes.

We found no relationship between three different ways of sharing health content online (using Facebook, Twitter, and email) and health change. The low percentages of respondents using these platforms for health matters may account for our null findings, especially in light of our relatively small sample size. Although recent research notes a significant uptick in health-related internet use among young adults, social network sites were the least used sources and also considered the least reliable [61]. This distrust may hinder how young adults in turn share health content as they may be reluctant to post what they or their peers deem questionable information. Alternatively, we may see an increase in sharing health content online, as increased health information–seeking may create a wealth of online lay experts who have an expressed interest in sharing their health knowledge.

We found a significant association between being female and better or maintained health. Past studies show that male college students may engage in more risky health behaviors [66], yet they may also report better health than their female counterparts [67]. Differing health measures may indeed better explicate the relationship between health and varying ways of using the internet for health reasons as they relate to gender. Internet skills have often been associated with more capital-enhancing uses of the internet [12]—that is, uses from which they may benefit.

Most respondents reported their health as excellent or very good at both time points. Comparing these figures to national survey data of students enrolled in colleges or universities in the fall of 2012 [68] and 2016 [69] suggests that our sample reported better health overall at both time points and more respondents reported excellent health. However, unlike those studies, ours did not focus on health and thus did not prime respondents to think about health, which may explain the differences. It is also important to note that, compared with other studies that investigate the relationship of internet use and health, our study examined both as naturally occurring and is absent of an intervention design. Therefore, noting an association between these domains is all the more difficult to detect.

Health care professionals should understand the roles that health-related internet use plays for young adults, particularly if it has the potential to impact health in positive ways. Our results point to the potential importance of online tools for health that are specifically designed for young adults. To date, reviews find high-quality intervention studies specifically for this age group to be limited [70], although there is a growing body of studies using social network sites as platforms for health-behavior interventions for all ages [71]. How to harness such engagement among young adults for positive health behavior change warrants further exploration.

Limitations

Our findings should be considered with some care. We measured the natural occurrence of internet use and health through self-reports. There may be unobserved variables affecting our findings. Our small sample size, due to attrition typical of panel studies, as well as the low variation in health status and low prevalence of sharing health content online require our findings to be interpreted with caution. Additionally, because our study began when the internet did not offer the multitudes of options it does today, our measures of its uses for health purposes are not as detailed as current options would warrant. Future studies with larger samples sizes and greater variation across measures may further explore whether, in fact, sharing health content online relates to health outcomes. Despite these limitations, given that panel studies of internet use are rare, the paper nonetheless makes a unique contribution to understanding the longer-term consequences of internet use for health.

Conclusions

Analyzing a unique panel survey of a diverse group of young adults, this paper contributes to research on digital media by examining how internet use relates to change in health status over time. We find a relationship between internet use and longitudinal change in health, with frequent health-related internet use related to enhanced health or maintained health. We find no relationship of sharing health content on social media or email with health status. Given the relatively small size of our sample due to attrition in panel studies, future research may revisit that question on larger samples. Other measures of health outcomes, including specific health conditions and behaviors, as well as health care use, may also tease out the impact of internet use on health. Young adults exhibit a pattern of using the internet for health that influences their health status. Finding the avenues of internet use that may be most beneficial to their health and well-being is important to serving this generation just entering adulthood, as well as generations that follow.

Acknowledgments

The authors are grateful to the John D and Catherine T MacArthur Foundation and the Robert and Kaye Hiatt Fund at Northwestern University for their support of the data collection. They thank Sam Mandlsohn, Cierra Levy, Richard Herndon, and Devon Moore for their help with the 2016 data collection and the many research assistants of the Web Use Project in earlier years for their assistance. MM was affiliated with the Department of Communication and Media Research at the University of Zurich while working on this study and is currently affiliated with the European Commission.

Authors' Contributions

EH and AH conceived the research questions and analyzed the data. AH wrote the first draft of the manuscript. EH planned, oversaw, and completed the data collection and contributed to the writing of the manuscript. MM contributed to the writing of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The use of eHealth tools (eg, the internet, mobile apps, and connected devices) in the management of chronic diseases and for rheumatoid arthritis is growing. eHealth may improve the overall quality of care provided to patients with chronic diseases.

Objective: The primary objective of this study was to describe eHealth use by patients with rheumatoid arthritis in France. The secondary objectives were to identify associations between patient demographics and disease characteristics and the use of eHealth tools, and assess their expectations of eHealth.

Methods: In this cross-sectional, multicenter study, patients with rheumatoid arthritis, according to the 2010 ACR/EULAR classification criteria, were recruited from 5 university hospitals (Bordeaux, Clermont-Ferrand, Limoges, Montpellier, and Toulouse). Patients completed an anonymous self-questionnaire, including demographic data, evaluating their eHealth use (ie, access, support, frequency of use, type of use, and reason for use). The rheumatologist in charge of each patient completed an independent medical questionnaire on disease characteristics, activity of rheumatoid arthritis, and treatments. Data were collected between December 2018 and July 2019.

Results: Questionnaires were completed by 575 participants, with a mean age of 62 (SD 13) years, 447 (77.7%) of whom were female. Overall, 82.2% (473/575) of the participants had access to eHealth through a computer (402/467, 86.1%), tablet (188/467, 40.2%), or smartphone (221/467, 47.3%). Of these, 36.4% (170/467) of the participants used the internet for health in general, and 28.7% (134/467) used it specifically for rheumatoid arthritis–related reasons. All these 134 patients used eHealth to learn about disease pathology, and 66.4% (89/134) of them used it as a tool to help monitor rheumatoid arthritis. Most patients (87/125, 69.6%) had a paper file, 19.2% (24/125) used a digital tool (spreadsheets, 10/125, 8%; mobile app, 9/125, 7.2%; or website, 5/125, 4%), and 24.8% (31/125) did not use any tools for monitoring. Few patients (16/125, 12.8%) used tools for treatment reminders. About 21.6% (27/125) of the patients using eHealth used a specific app for rheumatoid arthritis. Univariate analysis showed that age, education level, employment status, treatment, comorbidities, membership of a patient association, and patient education program were associated with eHealth use for rheumatoid arthritis. Multivariate analysis showed that membership of a patient association (odds ratio [OR] 5.8, 95% CI 3.0-11.2), use of biologic disease-modifying antirheumatic drugs (OR 0.6, 95% CI 0.4-1.0), and comorbidities (OR 0.7, 95% CI 0.6-0.8) remained associated with eHealth use for rheumatoid arthritis. Recommendation by a doctor (225/330, 68.2%), ease of use (105/330, 31.8%), and data security (69/330, 20.9%) were factors favoring the use of eHealth.

Conclusions: To date, few patients have used eHealth for disease management. The use of a reliable and validated eHealth tool for rheumatoid arthritis could therefore be promoted by rheumatologists and could optimize therapeutic adherence.

KEYWORDS

eHealth; internet; mobile app; rheumatoid arthritis; patients’ expectation

Introduction

Rheumatoid arthritis (RA) is one of the most common chronic autoimmune inflammatory rheumatic diseases with a prevalence of 0.1%-1% [1]. The disease is primarily characterized by a history of painful and swollen joints leading to joint deformation and destruction and disability. Nowadays, a wide range of disease-modifying antirheumatic drugs (DMARDs) are available (eg, synthetic, biologic, and targeted synthetic DMARDs). Because RA is a chronic disease, DMARDs are long-term maintenance treatments used to control the activity of rheumatism and prevent further joint destruction and disability.

In other chronic diseases such as diabetes, asthma, and hypertension, the use of eHealth has been well established. eHealth could be defined as an overreaching term used to describe the application of information and communication technologies in the health sector [2]. Studies show that eHealth and eHealth tools (ie, mobile apps, internet-based software and websites, connected devices, and personal health records) are ways to enhance medication adherence and disease control [3-5]. These eHealth tools provide information about the disease and help patients to monitor and manage the disease by improving patient autonomy.

Several websites, mobile apps, and connected devices related to RA have been developed for patients to obtain information about, self-monitor, or self-manage the disease. However, the impact of these specific eHealth services on disease management, medication adherence, or quality of life has been poorly assessed in the literature [6-9].

To date, there are no studies investigating the use of eHealth tools by patients with RA in France. Therefore, the main objective of this study was to describe the use of eHealth by patients with RA in France. The secondary objectives were to identify associations between patient demographics and disease characteristics and the use of eHealth tools, as well as to assess patients’ expectations of eHealth.

Methods

Study Design

A cross-sectional, multicenter, observational study was conducted in the rheumatology departments of 5 university hospitals in France (located at Bordeaux, Clermont-Ferrand, Limoges, Montpellier, and Toulouse). Data were collected from December 2018 to July 2019.

Study Patients

All adult outpatients and hospitalized patients were eligible to be included in this study if they were diagnosed with RA according to the 2019 ACR/EULAR (American College of Rheumatology/European League Against Rheumatism) classification criteria [10]. Eligible patients were systematically asked to participate in the survey, and if they agreed, they were included in the study. Patients who refused to participate or had language difficulties were excluded from the study. All patients provided written informed consent and agreed to participation. The local ethics committee (number 2018-A01875-50) approved this study.

Data Collection

Data were collected during a single visit through an anonymous patient self-questionnaire; this included sociodemographic data, medical data, and assessment of the use of eHealth tools (ie, access, support, frequency of use, type of use, and reason for use). The use of eHealth for RA was defined as “to possess an electronic tool” and “to use it to get information or to manage RA.” The rheumatologist in charge of the patient completed an independent medical questionnaire collecting RA characteristics and comorbidities (details on data collected are available in Multimedia Appendix 1).

Statistical Analysis

Qualitative variables were described as absolute values and percentages. Quantitative variables were described as mean (SD) or median (IQR) values. Demographic characteristics, disease characteristics, disease activity, treatment intake, and comorbidity index were compared between eHealth tools users and nonusers. Additionally, chi-square test or Fisher exact test, as required, was used to compare qualitative variables. Student *t*-test was used to compare quantitative variables with normal distribution and homogeneous variances. Logistic regression, with backward procedure to select variables, was used for multivariate analysis to identify patients’ characteristics that were independently associated with eHealth use for RA. All variables associated with eHealth use for RA with $P<.1$ in univariate analyses were tested in the model. The results are described with odds ratio (OR). Statistical analyses were carried out using STATA software (version 13.1; StataCorp).

Results

eHealth Use in RA populations

A total of 575 patients completed the self-questionnaire. We found that 82.2% (473/575) of the patients had an eHealth tool, and 28.7% (134/467) of them used it for RA. All of these 134 patients (100%) used the eHealth tool to obtain information about RA, and 89 (66.4%) of them used it to monitor their rheumatism. Figure 1 shows the use of eHealth tools in the study population. Table 1 shows the modalities of use and the frequency of access to eHealth for RA. Most patients used the internet infrequently.

Figure 1. Use of eHealth tools in the study population.

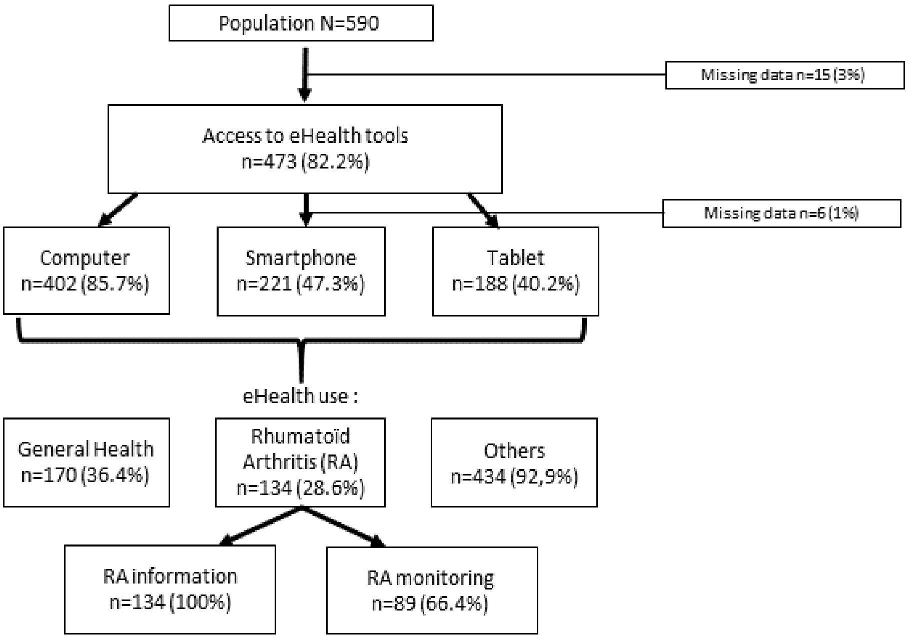

Table 1. Frequency and modalities of use of the internet by study patients using eHealth for rheumatoid arthritis.

Modality of use	Frequency of use		
	Often used (>1/month), n (%)	Sometimes used (≤1/month), n (%)	Never used, n (%)
eHealth content			
Rheumatoid arthritis information (n=128)	15 (11.7)	92 (71.8)	21 (16.4)
Treatment information (n=128)	21 (16.4)	83 (64.8)	24 (18.7)
Patient forums (n=122)	13 (10.6)	45 (36.8)	64 (52.4)
Social network (n=123)	16 (13)	16 (13)	91 (73.9)
Communication with the rheumatologist (n=123)	4 (3.2)	26 (21.1)	93 (75.6)

Websites			
Generic French websites (eg, Wikipedia), (n=121)	16 (13.2)	55 (45.4)	50 (40.9)
Rheumatology-specific French websites (eg, rhumato.net, ANDAR, SPILF), (n=123)	28 (22.7)	55 (44.7)	40 (32.5)
Hospital center websites (n=119)	4 (3.3)	29 (24.3)	86 (72.2)
Pharmaceutical industry websites (n=120)	3 (2.5)	17 (14.1)	100 (83.3)

Association Between Patient Characteristics and eHealth Use for RA

Factors such as age, education level, employment, DMARDs, level of comorbidity, membership of a patient association, and participation in a patient education program were found to be associated with the use of eHealth tools for RA (Table 2).

Multivariate analysis showed that membership of a patient association remained independently associated with the use of eHealth tools for RA (OR 5.8, 95% CI 3.0-11.2; *P*<.001), whereas a high level of comorbidity (OR 0.7, 95% CI 0.6-0.8; *P*<.001) and use of biologic DMARDs (OR 0.6, 95% CI 0.4-1.0; *P*<.041) were associated with a lower use of eHealth tools.

Table 2. Patient characteristics and factors associated with the use of eHealth tools. Italicized values indicate statistically significant values.

Characteristic	Patients using eHealth for RA[a] (n=134)	Patients not using eHealth (n=441)	*P* value
Demographic characteristics			
Gender (female), n (%)	110/134 (82)	337/440 (76.5)	.18

[a] RA: rheumatoid arthritis.

[b] RF: rheumatoid factor.

[c] ACPA: anticitrullinated protein antibodies.

[d] DAS28: Disease Activity Score-28.

[e] CRP: c-reactive protein.

[f] csDMARDs: conventional synthetic disease-modifying antirheumatic drugs.

[g] MTX: methotrexate.

[h] bDMARDs: biologic disease-modifying antirheumatic drugs.

[i] IV: intravenous.

[j] SC: subcutaneous.

Regarding health applications, 21 (16.5%) and 27 (21.1%) of the 127 patients used ehealth applications (eg, sports, nutrition, diabetes, or cardiovascular) and specific rheumatic applications (Hiboot, J’agis, Arthritis, Sanoia, or myPR), respectively.

A limited group of patients used electronic technology for RA-related follow-up (Excel spreadsheets, 10/125, 8%; mobile app, 9/125, 7.2%; website, 5/125, 4%; paper record, 87/125, 69.6%; and none, 31/125, 24.8%) and medication reminder (electronic diary, 13/125, 10.4%; mobile app, 3/125, 2.4%; clock, 7/125, 5.6%; paper diary, 16/125, 12.8%), whereas 67.2% (84/125) of them used it for no specific reason.

Patients’ Expectations About eHealth for RA

When investigating patients’ expectations, 225 of 330 patients (68.2%) reported they would use eHealth to manage their RA if it were recommended by a doctor. eHealth device characteristics such as ease of use and security were mentioned by 105 (31.8%) and 69 (20.9%) of the 330 patients, respectively, to increase their adherence to eHealth, and 89 (27%) patients declared they would more likely use eHealth in the case of an RA flare.

Discussion

To the best of our knowledge, no study thus far has investigated the frequency of eHealth use in a specific population of RA. In this study, we found that 473 of 575 (82.2%) patients had electronic devices and about one-third of those used eHealth specifically for RA to obtain information about the disease and to help with disease management. However, specific use of a mobile app for RA as digital tool to remind themselves about medications or follow-up was rarely reported.

Digital device possession in this RA population was comparable to that in a French population in a previous study [11] and in other studies examining chronic diseases (eg, cancer and cardiovascular diseases), but it was lower than that reported in a diabetes population (55%-84% in available studies) [12-14] perhaps due to the more recent availability of these devices. Moreover, the therapeutic target is not objectively measurable by patients with RA, whereas blood glucose levels can be self-measured on a daily basis by patients with diabetes and consequent therapeutic changes can be decided by the patient after they have completed an educational program. Therapeutic changes for patients with RA, however, are complex decisions made by a physician.

As previously shown in studies examining other chronic diseases [12,14-16], membership of a patient association is strongly associated with eHealth use, which suggests that networking among patients is an effective way to enhance eHealth use. Closer follow-up (eg, day hospitalizations and consultations) of patients with RA receiving biotherapy may explain the reduced need for eHealth. Similarly, patients with increased comorbidities, who are also older, are more likely to make more frequent medical visits and use eHealth less frequently.

The low frequency of eHealth use for RA could be explained by patients and disease barriers. For example, older patients use eHealth less often, and pain and joint deformations can restrict the use of eHealth devices among these patients. Patients’ habits and disease activity may also affect the usefulness of eHealth (eg, patients in sustained remission might regard the use of eHealth to monitor their disease as futile) [6,17,18].

Other limitations include the lack of information provided by health professionals about the different eHealth tools available and the discrepancy of eHealth use by physicians [19], thus resulting in the lack of promotion of these instruments. Finally, evidence-based medicine [20] and data security [21] are fundamental aspects; however, the utility and data security of the majority of eHealth tools have never been assessed.

Our study has several limitations. First, data were collected with a declarative questionnaire that may not reflect the exact use of eHealth and increase the risk of missing data or false answers. However, the rate of missing data was very low in this study (ie, 3%), and false answers were minimized since the questionnaires were anonymously completed by patients who were informed that their rheumatologists would remain blinded to their answers. The strength of this study was its multicenter design with a systematic inclusion of consecutive patients, which resulted in a representative sample of patients with RA in France.

In the context of the current COVID-19 pandemic where in-person consultations are limited, eHealth, which allows for remote monitoring, remote auto-evaluation of disease activity, and teleconsultation, has gained considerable interest and continues to be developed [22].

In summary, the frequency of eHealth use for RA is low in France, especially in patients with multimorbidities and severe disease and those using biologic DMARDs. Further studies need to be conducted to evaluate the reasons regarding the use and nonuse of eHealth by patients with RA. Furthermore, studies assessing the efficacy of eHealth tools and their impact on patient adherence are necessary before these tools are professionally recommended to patients.

Acknowledgments

The authors are grateful to Roche-Chugai, as this work was initiated during continued medical education sessions on how to conduct scientific study organized by Roche-Chugai. Roche-Chugai had no role in the study design or the collection, analysis, or interpretation of the data; writing of the manuscript; or the decision to submit the manuscript for publication. No specific funding was received from anybody in the public, commercial, or non-profit sectors to carry out this study. The logistics of the investigators’ meetings were financially supported by Roche-Chugai, which had no role in the design, execution, analysis, or interpretation of the study.

Authors' Contributions

MM, EB, TB, CR, BC, MP, CL, PVS, AT, MET, and ARW were involved in conceptualizing or designing the study. MM, BC, CR, MP, and EB were involved in data collection. MM, EB, ADW, MET, and TB were involved in data analysis and interpretation. MM, ARW, and MET were responsible for drafting the manuscript. MM, EB, TB, CR, BC, MP, CL, PVS, AT, MET, and ARW provided critical revisions to the manuscript. All authors have read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The working environment of a suicide prevention helpline requires high emotional and cognitive awareness from chat counselors. A shared opinion among counselors is that as a chat conversation becomes more difficult, it takes more effort and a longer amount of time to compose a response, which, in turn, can lead to writer's block.

Objective: This study evaluates and then designs supportive technology to determine if a support system that provides inspiration can help counselors resolve writer's block when they encounter difficult situations in chats with help-seekers.

Methods: A content-based recommender system with sentence embedding was used to search a chat corpus for similar chat situations. The system showed a counselor the most similar parts of former chat conversations so that the counselor would be able to use approaches previously taken by their colleagues as inspiration. In a within-subject experiment, counselors' chat replies when confronted with a difficult situation were analyzed to determine if experts could see a noticeable difference in chat replies that were obtained in 3 conditions: (1) with the help of the support system, (2) with written advice from a senior counselor, or (3) when receiving no help. In addition, the system's utility and usability were measured, and the validity of the algorithm was examined.

Results: A total of 24 counselors used a prototype of the support system; the results showed that, by reading chat replies, experts were able to significantly predict if counselors had received help from the support system or from a senior counselor (P=.004). Counselors scored the information they received from a senior counselor (M=1.46, SD 1.91) as significantly more helpful than the information received from the support system or when no help was given at all (M=–0.21, SD 2.26). Finally, compared with randomly selected former chat conversations, counselors rated the ones identified by the content-based recommendation system as significantly more similar to their current chats (β=.30, P<.001).

Conclusions: Support given to counselors influenced how they responded in difficult conversations. However, the higher utility scores given for the advice from senior counselors seem to indicate that specific actionable instructions are preferred. We expect that these findings will be beneficial for developing a system that can use similar chat situations to generate advice in a descriptive style, hence helping counselors through writer's block.

Introduction

Worldwide, helplines have been set up to help individuals who are struggling with suicidal thoughts. These helplines are a preventive service to reduce the suicidal ideation or behavior of help-seekers [1]. These help-seekers can contact trained volunteers and professionals (counselors) who can listen to them and assist them with their problems relating to suicide.

Historically, people have been able to contact these helplines over the telephone, but with the advent of the internet, chat services have become increasingly popular. Compared with telephone helplines, online chat helplines show approximately the same beneficial effects [2]. Help-seekers mention several reasons for using counseling through an online chat rather than a traditional phone call, such as privacy and the slow deliberate nature of online chatting [3-6]. In the Netherlands, the 113 Suicide Prevention service saw the number of conversations increase to more than 35,000 via telephone and more than 57,000 via online chat in 2018, an increase of 33% from 2017. However, this increase resulted in a higher need for counselors as well. Because of the difficult nature of crisis counseling, suicide prevention helplines often have difficulty retaining counselors [7].

Studies have indicated that technology can support chat line operators in executing cognitive tasks. For example, in the related field of commercial telephone and chat customer support, there are various supportive technologies developed for operators [8-10]. However, in computing research aimed at suicide prevention, most work focuses on the prediction and detection of suicidal behavior [11,12], while only a few studies have examined assisting online counselors; this could be beneficial, though. Salmi [13] has identified several difficulties that counselors encounter in their work. First, the counselor has to take in a large amount of information about the help-seeker. Here, counselors could be supported in understanding a help-seeker's history without having to read large portions of transcripts. Dinakar et al [14], therefore, have created a support system prototype for text-based crisis counseling called Fathom. Fathom uses visualizations based on topic modeling to provide information at a glance. In comparison to a control interface without a visualization aspect, Fathom was preferred by counselors when eliciting a list of issues and a conversation summary. Another difficulty is that the counselor must be aware of the conversation quality. In this respect, Althoff et al [15] compared the chat conversations of more and less successful counselors with natural language processing techniques to discover the quality differences, defining actionable strategies to improve conversation quality. For example, they showed that more successful counselors spend a longer time exploring solutions, while less successful counselors spend more time defining the problems.

Finally, the complexity and severity of help-seekers' situations may lead to writer's block in counselors. Although not directly related to the suicide prevention domain, Isbister et al [16] have designed a helper agent for human-human interaction. When a conversation lags, the agent suggests topics for the conversation pair to talk about and, thereby, the agent is generally able to make positive contributions to the chat.

In situations where counselors experience writer's block, a straightforward solution would be to approach a senior colleague for help. These senior counselors can read along and describe in as much detail as necessary how they would respond to the help-seeker. However, this requires availability and time from a colleague, and this is not always possible. Responding quickly is important in life-threatening situations, and counselors cannot always wait for somebody to become available. We also suspect that an approach such as suggesting topics to keep a conversation going [16] or providing a conversation summary [12] would not be optimal in difficult situations where counselors have to de-escalate a suicide-related crisis. This paper, therefore, presents a system that uses natural language processing techniques to provide support for counselors in difficult chat conversations. The system recommends parts of similar, previous chat situations for the counselor to draw inspiration from, which might be able to reduce their writer's block. This paper also evaluates the designed support system by comparing it with 1) written, general advice from a senior counselor and 2) receiving no additional help during chats. The system's usability and utility, along with the validity of the algorithm used, were also examined.

Methods

Design

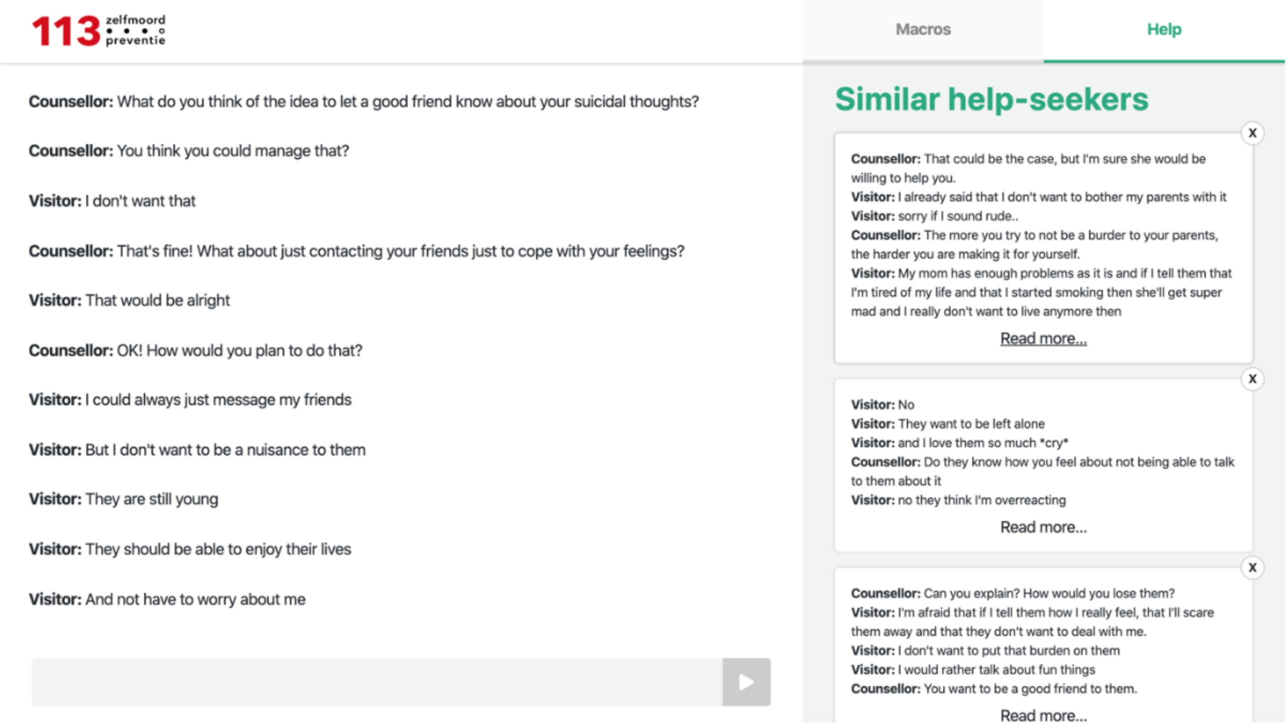
We used a within-subject design to evaluate the impact and usefulness of similar chat situations that could be used as inspiration. In the study, the counselor wrote a chat reply to a simulated chat that was interrupted as a difficult situation. The counselor took part in 3 simulations: 1) the counselor received parts of similar chats from a support system, 2) the counselor received written advice from an experienced counselor, and 3) the counselor received no additional help. A questionnaire was used to measure the support system's usability. Finally, we evaluated the validity of the similarity of the generated chats by testing the algorithm in a small additional experiment with a within-subject design.

The current study received ethical approval from the TU Delft University research ethics committee (id: 688). Before starting the data collection, the experimental setup was also preregistered on the Open Science Framework [17].

Recommender Support System

For the study, we developed a system recommending the transcripts of similar previous chat conversations to a counselor based on the content of the counselor's current chat conversation. Figure 1 shows a chat window on the left and the support system interface on the right. The support system shows the top 10 most similar chat messages, which the counselor could click to read them in their entirety.

Figure 1. Interface support system (right). Content translated from Dutch.



Counsellor: What do you think of the idea to let a good friend know about your suicidal thoughts?

Counsellor: You think you could manage that?

Visitor: I don't want that

Counsellor: That's fine! What about just contacting your friends just to cope with your feelings?

Visitor: That would be alright

Counsellor: OK! How would you plan to do that?

Visitor: I could always just message my friends

Visitor: But I don't want to be a nuisance to them

Visitor: They are still young

Visitor: They should be able to enjoy their lives

Visitor: And not have to worry about me

Counsellor: That could be the case, but I'm sure she would be willing to help you.
Visitor: I already said that I don't want to bother my parents with it
Visitor: sorry if I sound rude..
Counsellor: The more you try to not be a burder to your parents, the harder you are making it for yourself.
Visitor: My mom has enough problems as it is and if I tell them that I'm tired of my life and that I started smoking then she'll get super mad and I really don't want to live anymore then

Visitor: No
Visitor: They want to be left alone
Visitor: and I love them so much *cry*
Counsellor: Do they know how you feel about not being able to talk to them about it
Visitor: no they think I'm overreacting

Counsellor: Can you explain? How would you lose them?
Visitor: I'm afraid that if I tell them how I really feel, that I'll scare them away and that they don't want to deal with me.
Visitor: I don't want to put that burden on them
Visitor: I would rather talk about fun things
Counsellor: You want to be a good friend to them.

A corpus of chat conversations between help-seekers and counselors was used to find similar previous chat situations. We used the corpus from 113 Suicide Prevention in the Netherlands. This corpus contained 7 months of chats spanning from March 2018 to September 2018. The chat data were first filtered, removing all chats that had less than 20 interactions. In total, we used 17,773 chats. Furthermore, any special symbols in the messages were cleaned, and capital letters were replaced by lowercase letters.

Because the chats each contained multiple problems, we used a sliding window algorithm to scan for relevant chat segments instead of comparing complete chats. This algorithm created sets of chat messages, starting with the first 5 messages. The next set removed the first message in the window and added the sixth message; this process was repeated to create every possible set of 5 subsequent messages in a chat. The sliding window algorithm was then used to create the chat segments for the entire corpus.

We used an embedding algorithm to compute the similarity. For each chat segment, an embedding was created using smooth inverse frequency [18], which takes a weighted average of the word embeddings for each word in the text of the window corresponding to the inverse of the frequency of the word in the corpus. This resulted in less meaningful words receiving a lower weight. To create word embeddings, Mikolov et al [19] developed an algorithm dubbed Word2Vec, improving previous methods [20]. The word embeddings we used were obtained from the COOSTO Word2Vec model [21], a model developed using Dutch social media and blog posts. A window of 5 messages resulted in 1,286,659 embeddings, which were stored alongside the corresponding chat and window positions.

When a counselor in an ongoing conversation requested similar chat conversations, a single smooth inverse frequency embedding was created using the same steps as with the corpus, except only the last 5 messages of the ongoing conversation were used. This embedding was then compared with the corpus embeddings through a cosine similarity. Ten windows with the highest similarity were recommended to the counselor.

Difficult Chats

We used 6 chats for the experiment to cover several difficult situations: a situation where a help-seeker 1) was in a dangerous location and had withheld this from the counselor; 2) did not want to inform anybody in their environment of their suicidality because they felt like it would put a burden on others; 3) was afraid of people in their environment not understanding their problems; 4) tried to look for help but was not believed; 5) was excessively rude; and 6) had to contact a psychologist.

Participants

Counselor and expert recruitment, as well as conducting the experiment, happened at 113 Suicide Prevention. In total, 24 counselors participated. On average, the participants' age was 27 years old, and 79% were female. Only counselors who were interns, volunteers, or trainees were eligible to participate. Each counselor met all the components and conditions of the evaluation.

Measures

The perceived utility was assessed with the following question: "How, in your opinion, did the extra information help you with coming up with your response?". The counselors graded each support type on a fixed interval scale from –3 to 3, where –3 indicated the extra information was hindering, 0 indicated the information was neutral, and 3 indicated the information was useful.

To measure usability, the counselors were asked to fill out the System Usability Scale questionnaire [22]; this is a validated

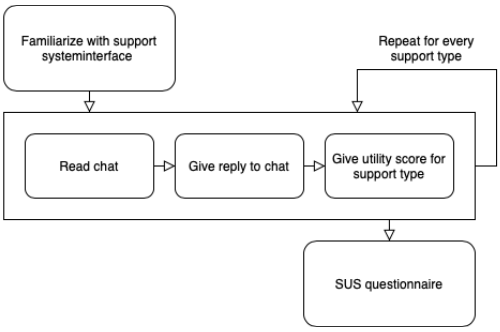
10-item questionnaire with a 5-point scale ranging from "Strongly disagree" to "Strongly agree."

To measure the validity of the algorithm, the counselors used a 7-point fixed interval scale to indicate how much they agreed with the following statement: "The problem in the matched chat is the same as the problem in the ongoing chat." A score of 1 meant the counselor did not agree, whereas a score of 7 meant they did agree.

Procedure

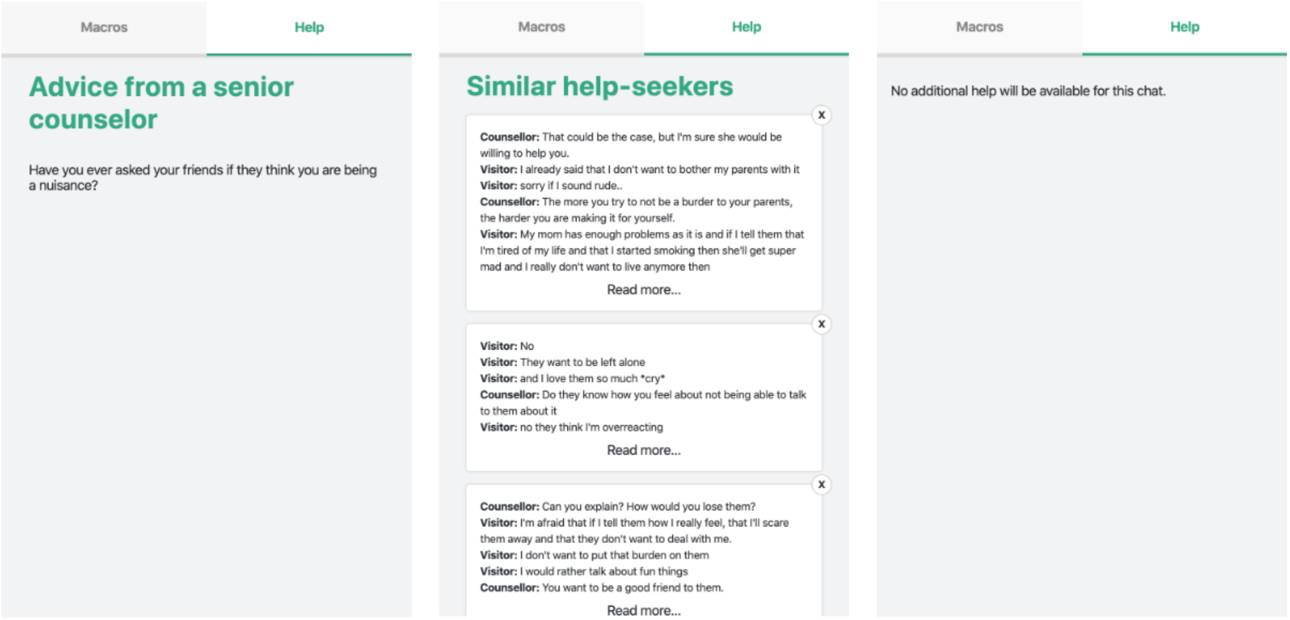
The counselors used a test environment with simulated chats. The experiment consisted of 2 parts. Figure 2 shows a diagram of the procedure for the first part. Before the experiment, the counselor had 5 minutes to explore and familiarize themself with the support system.

Figure 2. Procedure diagram of the first part of the experiment. SUS: System Usability Scale.



Part 1 consisted of a simulated environment where the counselor read and reacted to 3 simulated chats, one after the other. The support information was contained in an extra tab called "Help." Figure 3 shows each support type. Each counselor had the same amount of time to read the chat. To simulate a real situation, each counselor had a 2-minute window to reply. The counselor could not access the support tab before the 2-minute timer started. Directly after the counselor submitted their reply to a chat, they were asked to rate the utility of the support type. These steps were repeated for each condition. Therefore, the participants reacted to 3 chats in total. The chats, support types, and combinations were counterbalanced for the 24 participants. This part ended with the System Usability Scale questionnaire being used to measure the usability of the support system.

Figure 3. Conditions of the experiment: senior counselor written advice (left); support system (center); no additional help (right). Content translated from Dutch.



Advice from a senior counselor

Have you ever asked your friends if they think you are being a nuisance?

Similar help-seekers

Counsellor: That could be the case, but I'm sure she would be willing to help you.
Visitor: I already said that I don't want to bother my parents with it
Visitor: sorry if I sound rude..
Counsellor: The more you try to not be a burder to your parents, the harder you are making it for yourself.
Visitor: My mom has enough problems as it is and if I tell them that I'm tired of my life and that I started smoking then she'll get super mad and I really don't want to live anymore then

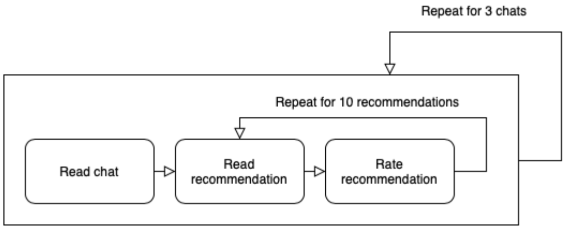
Visitor: No
Visitor: They want to be left alone
Visitor: and I love them so much *cry*
Counsellor: Do they know how you feel about not being able to talk to them about it
Visitor: no they think I'm overreacting

Counsellor: Can you explain? How would you lose them?
Visitor: I'm afraid that if I tell them how I really feel, that I'll scare them away and that they don't want to deal with me.
Visitor: I don't want to put that burden on them
Visitor: I would rather talk about fun things
Counsellor: You want to be a good friend to them.

No additional help will be available for this chat.

Part 2 recorded the measurements for evaluating the validity of the algorithm. Figure 4 shows a diagram of the procedure. The left side of the screen contained the transcript of an ongoing chat. The right side of the screen showed 10 chat segments. Half of these segments were randomly selected, and the other half was matched to the ongoing chat using the embedding algorithm. Below each of the segments was a fixed interval scale from 1 to 7 where the counselor rated the degree to which that chat segment related to the ongoing chat. To enhance generalization, the participants did this for the transcripts of 3 different ongoing chats. Therefore, in total, a participant rated 30 segments.

Figure 4. Procedure diagram of the second part of the experiment.



Data Preparation

Eight experts labeled the reply of the counselor with the type of help (condition) that the expert assumed that the counselor had received. To prevent expert bias, each expert judged all the counselor responses. Furthermore, a reliability analysis for the items of the System Usability Scale questionnaire showed an acceptable level of consistency, with a Cronbach alpha of .89. Therefore, the System Usability Scale items were compiled into a single score.

Analysis

The noticeable difference in counselor outputs was analyzed using generalized mixed-effects analyses [23] to predict the outcome variable support type based on the label the expert assigned to the counselor reply. The analyses were done by comparing 2 support type conditions at a time, thereby excluding the data from 1 of the 3 support type conditions. The models fitted on the remaining 2 conditions hence assumed a binomial distribution. Each model was compared with a null model that did not include an expert label as a fixed effect. Because the test was conducted 3 times, a Bonferroni correction [24] was used to set the significance threshold at .016. In addition, crossed random effects were used with random intercepts for the counselor and expert. Furthermore, for each support type, the utility ratings were analyzed using a one-sample *t* test to examine whether the rating deviated from the neutral zero score on the scale.

To examine the validity of the algorithm, a linear mixed-effects analysis was performed on the counselor’s rating of the similarity between the chat segment and the ongoing chat. As a two-level fixed effect the analysis included the recommendation method, that is, randomly selected versus selected by embedding algorithm. Furthermore, the ongoing chat was added as a three-level fixed variable because the quality of the suggestions was assumed to depend on the specific chat. As a random effect, the intercepts for counselors were used.

Anonymized data and R scripts are available online [25].

Results

Noticeable Difference in Counselor Output

Table 1 shows the effect of support type on the outcome measure of the expert label. The first row shows that the expert label significantly predicts the support type, when the data of no support condition was left out. In other words, the experts could tell the difference between replies given with the support system and replies with help from a senior counselor. Table 2 shows that when the expert labeled the counselor’s response as having received help from the support system, the counselor was 0.47 times less likely to have received the senior counselor support. This effect is further illustrated when looking at the confusion matrix of these conditions, as shown in Figure 5. However, no significant difference was found between the no support condition and any of the other conditions.

Table 1. Results of the comparison between null model and full models that included the expert label as a fixed effect to predict support type counselors had received when writing their reply (n=356).

Outcomes data included in analysis	$\chi 2$ (*df*)	*P* value
Support system and senior counselor written advice	11.31 (2)	.004
No support and support system	1.44 (2)	.49
No support and senior counselor written advice	4.78 (2)	.09

Table 2. Fixed effect of the expert label for the model of support system and senior counselor written advice.

Parameter	OR[a]	Standard error	z Value	*P* value
Intercept	1.29	0.16	1.54	.12
Support system	0.47	0.25	–3.04	.002
Senior counselor written advice	1.01	0.28	0.049	.96

[a] OR: odds ratio.

Figure 5. Confusion matrix for expert labeling of counselor responses.

		Condition		
		No support	Support system	Senior counselor written advice
Expert label	No support	**74**	66	85
	Support system	65	**76**	46
	Senior counselor written advice	39	36	**47**

Utility

The results of the utility ratings are shown in Table 3. The mean score of the support system was –0.21 (SD 2.26) and did not significantly deviate from 0, indicating that there was neither a hindering nor a helping effect experienced by the counselors. However, the mean utility score of the written advice from a senior counselor was 1.46 (SD 1.91) and significantly deviated from 0. This suggests that the written advice was perceived as helpful. It is noteworthy that the support system had a high variance, suggesting that the counselor's opinion on the utility was divided.

Table 3. One-sample t test for counselor utility ratings per support types (n=24).

Support type	Mean (SD)	95% CI	t_{df}	*P* value
Support system	–0.21 (2.26)	–0.84 to 0.43	-0.68_{23}	.5
Counselor written advice	1.46 (1.91)	0.87 to 2.04	5.17_{23}	<.001
No support	–0.21 (0.95)	–0.62 to 0.2	-1.04_{23}	.31

Usability

The mean score of the support system for the System Usability Scale questionnaire was 71, with a 95% confidence interval of 63-78. According to Bangor et al [26], this score can be classified as "good" based on an adjective rating scale.

Validity of the Algorithm

How the chat segments were selected (randomly vs by the embedding algorithm) significantly predicted the rating counselors gave on the chat segment's similarity to the ongoing chat, β=.30, t(7.66), *P*<.001. This means that counselors could tell the difference between the random chats and those generated by the support system. The suggestions from the algorithm increased the similarity rating given by counselors from an average of 2.35 to an average of 3.42 (difference of 1.07).

Discussion and Conclusions

In the current study, we evaluated a prototype support system to assist chat counselors in suicide prevention helplines by providing inspiration from previous chats. The results show that counselors gave different answers depending on whether they received help from the support system or from a senior colleague. Upon inspection, the replies given by the counselors who received written advice from a senior colleague were, for the most part, copied directly and with little to no alterations made. Replies from counselors using the support system were more varied. This could be a possible explanation for the noticeable difference. However, we could not find a significant result for the no-help condition, which also had varied replies. Additionally, we observed that written advice from a senior counselor was given a significantly higher utility score than the other conditions; this suggests that the counselors value short actionable information that is highly accurate to the situation and that is given by someone with expertise. Gunaratne et al [27] have observed similar findings in their study on the effects of expert advice and social comparison on decision making for retirement savings; they showed that expert advice helped people make better decisions, whereas social comparison was seen as a useful mechanism to keep people from deviating too far from the mean and, hence, make safe decisions. However, both of these conditions outperformed a control condition where no additional information was provided.

The main contribution of our study is the idea of retrieving inspiration from a conversation corpus. Other support systems for chats [28-30] have used topics to assist the conversation. Compared with these methods, our approach for combating writer's block in a counseling conversation is novel. Furthermore, an experimental design was used to compare this supportive technology with advice from a senior colleague, showing how the two differ.

Some limitations should be considered regarding the findings and their implications. We used chat transcripts of conversations with situations that previous counselors found difficult to evaluate. However, this might not cause writer's block for every participant because not every counselor will have problems with the same situations. For writer's block to occur naturally, the system would have to be tested in live chats. This was, however, not possible because of the ethical constraints of deploying an unevaluated system in a possible crisis situation. Furthermore, the specification, development, and evaluation were done in the context of counselors working at 113 Suicide Prevention in the Netherlands, with a limited number of counselors. The support system should also be tested in different helplines and with a larger sample size.

We have outlined two major directions for future work. First, the recommendation mechanism could be improved in different ways. This study, as well as other related works such as recommenders for creativity [31] and scientific writing [32], relies on topic modeling and bag-of-word models to find recommendations. Encoding text using attention-based models [33], such as BERT [34], have been shown to perform well on various natural language processing tasks, including semantic sentence similarity for conversation data [28]. These methods could be applied to improve the recommendations to find more relevant and similar examples, which we expect will increase the perceived utility. Additionally, curating the corpus can help denoise the dataset and improve the recommendations. This can also give counselors the knowledge that the information comes from a subset of quality chats, thereby acting on the persuasive principle of authority as outlined by Cialdini [29]. Lastly, there is also an opportunity to apply active learning methods by adding positive labels to the recommendations that the counselors interacted with or explicitly marked as useful [30].

Second, the findings show that the embedding algorithm found similar chats and that written advice from senior counselors had high utility. Compared to the Gunaratne et al study [27], the main difference to the setup of our study is that the social comparison condition provided information as an average; this indicates that refining the output of the support system recommendations to be more instructional could be a possible direction for improving the system. To combine both the extensive coverage of a chat corpus and the high utility of curated written advice, clustering could be used, that is, grouping similar chats together based on a similarity metric and curating the labels based on these clusters. Derrar [35] uses clustering to automate the annotation of customer service chat messages. A similar approach could be used to annotate the chat corpus to create a taxonomy of situations and advice, which then could emulate receiving written advice from a senior colleague. In other words, working together with experts, a set of advice could be formulated in advance for each specific situation. Next, a data-driven algorithm could be trained to classify chats according to categories of the taxonomy, consequently providing counselors with expert advice associated with the category and making the expert advice situation relevant. This approach would be most suitable for assisting counselors with frequently occurring tasks, as these would be the most likely cases to be included in the taxonomy. The focus of the support system might therefore shift from an inspiration source to a system that could reduce workload. Alternatively, the field of conversational information retrieval has explored multiple methods that could be applied to the task presented in this paper. For example, Qiu et al [36] combined both information retrieval methods and generation based models to create a chat bot trained using existing customer service chat logs. These techniques could potentially also be used to allow the system to generate proposal responses that counselors could consider using in their chats with help-seekers.

In conclusion, the current study shows a possible method to provide inspiration during chat counseling in a helpline for suicide prevention and how this supportive technology compares with human assistance. A support system may be a relief for counselors as they handle many cognitively difficult situations. In addition, supportive technology seems useful for helplines to better deal with busy periods, to provide a safety-net for junior counselors, and to help sustain counselors.

Acknowledgments

The authors would like to thank the counselors of 113 Suicide Prevention who participated in the experiment. The authors would also like to thank the floor managers of 113 Suicide Prevention who provided the senior counselor comments and helped select the difficult chat situations.

Abstract

Background: Understanding the social mechanisms of the circadian rhythms of activity represents a major issue in better managing the mechanisms of age-related diseases occurring over time in the elderly population. The automated analysis of call detail records (CDRs) provided by modern phone technologies can help meet such an objective. At this stage, however, whether and how the circadian rhythms of telephone call activity can be automatically and properly modeled in the elderly population remains to be established.

Objective: Our goal for this study is to address whether and how the circadian rhythms of social activity observed through telephone calls could be automatically modeled in older adults.

Methods: We analyzed a 12-month data set of outgoing telephone CDRs of 26 adults older than 65 years of age. We designed a statistical learning modeling approach adapted for exploratory analysis. First, Gaussian mixture models (GMMs) were calculated to automatically model each participant's circadian rhythm of telephone call activity. Second, k-means clustering was used for grouping participants into distinct groups depending on the characteristics of their personal GMMs.

Results: The results showed the existence of specific structures of telephone call activity in the daily social activity of older adults. At the individual level, GMMs allowed the identification of personal habits, such as morningness-eveningness for making calls. At the population level, k-means clustering allowed the structuring of these individual habits into specific morningness or eveningness clusters.

Conclusions: These findings support the potential of phone technologies and statistical learning approaches to automatically provide personalized and precise information on the social rhythms of telephone call activity of older individuals. Futures studies could integrate such digital insights with other sources of data to complete assessments of the circadian rhythms of activity in elderly populations.

Introduction

Background

Circadian rhythms are endogenous processes that regulate the individual's activity over a 24-hour cycle. They are recognized to play a crucial role in nearly all biological and social aspects of the individual's life, as it is evidenced in his or her brain activity [1], rest activity [2], body temperature fluctuation [3], and rhythms of social interactions [4]. Such rhythms of activity, maintained over time, permit the individual to efficiently organize his or her physical and social activities at a daily scale. Such organization has played a significant role in the past from an evolutionary perspective for ensuring the survival of the human species [5]. Nowadays, circadian rhythms continue to be essential for our lives, giving us the ability to ensure a certain stability in the way we routinely interact with ourselves and with each other.

Furthermore, it is recognized that the circadian rhythms of activity significantly change with age (eg, see Hood and Amir, Steponenaite et al, Zhao et al, and Duffy et al [6-9] for recent reviews). At the endogenous level, the aging process may contribute to the occurrence of biological dysregulations that alter the internal clock of an older individual [10,11]. These changes may have potential adverse consequences on his or her body functioning (eg, see Hood and Amir [6] and Leng et al [12] for recent reviews), such as balance control alteration [13], sleep cycle disruptions [2,14], neurodegeneration [14], or cardiovascular complications [15]. Thus, with regard to our traditional health care system, it seems important for the health practitioner to assess the circadian rhythms of activity of his or her older patients in order to understand, and then to properly manage, the mechanisms of health issues that may occur in their life span.

Over the past decades, the assessment of the circadian rhythms of activity in humans has been addressed at the biological and physical levels through, respectively, the field of chronobiology (eg, see Cornelissen and Otsuka [16] and Otsuka et al [17] for two recent reviews) and that of actigraphy (eg, see Tazawa et al [18] and Schwab et al [19] for two recent reviews). On the whole, both of these approaches—chronobiology and actigraphy—have demonstrated the relevance of combining the use of wearable sensors with the implementation of statistical learning algorithms for automatically measuring the biological and gross motor activities of the individual at a daily scale. From a clinical perspective, these approaches may permit the detection in real time of the occurrence of daily risky situations that may affect the older individual's life, such as sedentary behavior [20], nocturnal activity [21], fall occurrences [22], or myocardial infarction [23]. Taken together, these approaches provide innovative and relevant ways to diagnose and manage the older adult's health status over time.

At this point, however, it is also important to mention that the daily rhythms of activity that are of a social nature are evidently not considered by such approaches as relying on biological and physical sources of data. At the clinical level, this issue is of significant importance given that biological circadian dysregulations can be associated with external social factors [24], such as inconsistent mealtime [25], shift work [26], or social isolation [27]. These social disruptions, maintained over time, may lead to a misalignment between biological and social rhythms, so-called "social jet lag" [28]. In the older adult, this misalignment can act as a retroactive feedback mechanism that contributes to the occurrence or worsening of particular symptoms or comorbidity factors, such as fatigue [2,29] and signs of anxiety and depression [30], that are involved in various age-related diseases [12,13,31].

Prior Work

In the field of health care monitoring for older adults, traditional approaches such as clinical questionnaires propose subjective, timely solutions for measuring and characterizing the circadian rhythms of social activity of the individual. Despite their widespread use in practice, this type of approach introduces limitations into their use for both clinical and research applications. One reason is related to the fact that the administration of questionnaires is time-consuming and requires the active participation of the patient for filling in a given questionnaire. These two constraints cannot be easily satisfied regarding specific vulnerable populations that are potentially not able to make such an effort because of their physical or psychological conditions. A second reason is because of the temporal scope of their results. Since these questionnaires are filled out at a set point in time, it is not possible to infer the general daily rhythms of the individual over a long period of time. A third reason is because of their subjective nature. Subjective responses that are provided for measuring objective temporal phenomena, such as the circadian rhythms of social activity, makes it difficult to ensure the precision of the questionnaires' results.

Modern technologies traditionally considered as everyday tools have the potential to get around these limits [32-34]. In particular, it has been recently demonstrated that the telephone may have the ability to passively, objectively, and continuously provide estimation of social rhythms through the analysis of its generated data over time [32,35-37]. Notably, two recent descriptive studies [32,38] have analyzed an 18-month data set of call detail records (CDRs) of 24 young adults. The results of these descriptive studies suggested that young participants seemed to hold their own personal circadian patterns for communicating with their social network. More importantly, these circadian patterns were found to persist over time. More recently, such a descriptive analysis was successfully reproduced, and got the same results, with an older population [39]. To the best of our knowledge, these preliminary results were the first ones that specifically concerned the circadian rhythms of telephone call activity of older adults.

Despite this encouraging pioneering work, key limitations remain to be addressed. In particular, regarding older adults, substantial efforts remain in order to improve the descriptive methodology of the recently completed studies in order to properly model the circadian rhythms of telephone call activity. From a health care monitoring perspective, such efforts are crucial for extracting relevant information from the circadian rhythms of telephone call activity that can be used for completing traditional subjective questionnaires.

Thus, this paper is a secondary analysis of recent analyses [39,40] and is specifically designed to address whether and how the circadian rhythms of social activity observed in the telephone calls of older adults could be modeled. To this end, we analyzed a 12-month data set of outgoing telephone CDRs of 26 adults older than 65 years of age. We designed a statistical learning approach adapted for exploratory analysis. First, Gaussian mixture models (GMMs) were calculated to automatically model each participant's circadian rhythm of telephone call activity. Then, k-means clustering was used for grouping participants into distinct groups depending on the personal characteristics of their GMM curves. The results, the significance, and the limitations of this study are discussed, and perspectives of future research are proposed.

Methods

Data collection, volunteer recruitment, and data preprocessing followed the general principles set in previous investigations of this secondary analysis [39-43] and remain unchanged for consistency.

Data Collection and Volunteer Recruitment

Our data set includes 12 months of outgoing CDRs for 26 volunteers (20 women [77%] and 6 men [23%]; mean age 84 years, SD 4; age range 71-91 years). CDRs provided by the local communication service provider were collected from the personal telephones of the volunteers. Each CDR contained the date, hour, source ID, recipient ID, direction, and duration (seconds) of the call. In addition, volunteers who had several telephones registered with their communication service provider (eg, one or more landlines and/or one or more mobile phones) provided CDRs for all their telephones. Finally, only outgoing calls were considered in this study considering ingoing not resulting from a voluntary activity of the participants. Note that the telephone owners and the telephone contacts remained anonymous. This study and the corresponding experimental protocols were approved by the French Commission for Data Protection and Liberties (Correspondant Informatique et Libertés [CIL] Register France Telecom 2011 n°44) at the time the data collection phase of this project was originally initiated. All methods were performed in accordance with the Commission's regulations, written informed consent was obtained from all participants prior to data collection, and anonymization of participants' data was applied to ensure privacy requirements.

Data Preprocessing

Participants did not all enroll in the survey at the same time, so the dates of inclusion varied. Thus, the CDR data set was filtered to select the time interval of when the greatest number of volunteers were actively participating in the study. The CDR data set was then preprocessed by applying the method described by Saramäki et al [38], namely, by selecting only those participants who used their telephones throughout the entire 12-month observation period, which gave a sample of 21 individuals (see Table 1 for details).

Table 1. Data set structure of call detail records before and after preprocessing.

Participant characteristics	Before preprocessing (N=26)	After preprocessing (N=21)
Number of participants, n (%)		
Female	20 (77)	16 (76)
Male	6 (23)	5 (24)
Age (years)		
Range	71-91	71-91
Mean (SD)	84 (4)	83 (4)
Number of calls, n		
Total outgoing calls	19,198	18,338
Calls by individual, 1st quartile	285	481
Calls by individual, median	590	710
Calls by individual, 3rd quartile	944	1096

Data Analysis

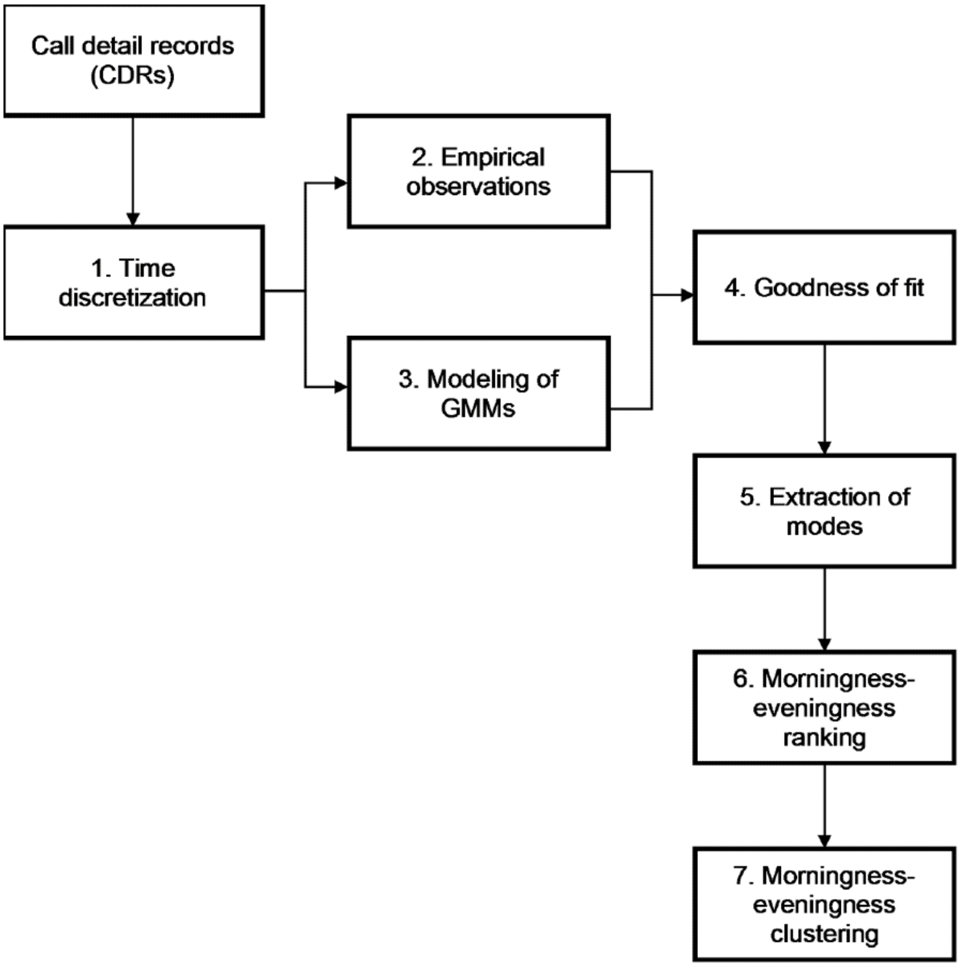
Overview

To identify social interaction patterns in older adults from their CDRs at a daily scale, we developed a statistical learning approach that is divided into two main processes consisting of the following:

1. Modeling daily rhythms of social interactions in older adults from their CDRs by using GMMs [44].
2. Calculating clusters of morningness-eveningness categories stemming from these modeling results by using k-means clustering [45].

These processes were chained together throughout our general data analysis pipeline as discussed in the following seven steps (see Figure 1 for an overview).

Figure 1. Data analysis pipeline. Step 1 corresponds to data preprocessing, Steps 2-4 correspond to circadian rhythm modeling, and Steps 5-7 correspond to social morningness-eveningness clustering. GMM: Gaussian mixture model.



Step 1: Time Discretization

To focus on circadian rhythms of phone call activity, we first discretized the time dimension of CDRs into one unique day of 24 1-hour slots corresponding to the time of day, as previously done in the literature [32,36,39,40,46].

Step 2: Empirical Calculation

From this coarse-grained data set, the empirical circadian rhythm of phone call activity was then obtained by calculating, for each older individual inside of each 1-hour time slot, his or her corresponding frequency of phone calls, as in several studies [32,36,39,40,46]. Formally, if we let N be the number of older participants (N=21), and we let $n_i(t)$ be the number of phone calls of one individual i, with i ranging from 1 to N, at a time t, with t ranging from 0 to 23, then the frequency of phone calls for each individual at a time t is defined as follows:

Step 3: Modeling of GMMs

In parallel with Step 2, a statistical modeling approach caught the distinct periods of phone call activity across the day by calculating, for each older individual, his or her corresponding GMMs from his or her coarse-grained CDRs. In short, this mixture consisted of synthesizing the older individual's circadian rhythm of phone call activity by means of distinct curve components. Since these components stem from the fundamental and well-known Gaussian model, their mean and variance characteristic parameters can be easily calculated and used to further characterize the individual's phone call daily activity. In accordance with the existing literature on the subject [4,47-49], we assumed the existence of two broad periods of activity corresponding to morningness and eveningness in humans, following the diurnal principle, which can be, however, shifted in certain cases toward a potential nocturnal period of activity.

Step 4: Goodness-of-Fit Estimation

The goodness of fit of the estimated GMM with respect to empirical data was assessed for each older individual by using a Kolmogorov-Smirnov comparison test under the null hypothesis H_0—the estimated GMM is similar to the empirical distribution of phone calls across the day—with a *P* value set at .05. Hence, a *P* value greater than .05 represents a significant good fit. This step permits the measurement of the quality of the estimated model with respect to the individual's empirical observations.

Step 5: Extraction of Modes

Next, to focus on the individual's chronotype, the mean parameter of each Gaussian component, which corresponds to an hourly peak of phone call activity, was extracted for each older individual. The duration of each period of activity was also considered by extracting the variance of each period.

Step 6: Morningness-Eveningness Ranking

Since modes were extracted from distinct Gaussian components whose intensities may be different, the individual's morningness-eveningness characteristic was obtained by assigning each older individual to his or her most representative Gaussian component. To this end, the estimated mixing proportion of each Gaussian component was calculated from an expectation minimization approach for each older adult. Next, the individual's modes were ranked together according to these proportions to determine the time of day when the older individual was the most socially active.

Step 7. Morningness-Eveningness Clustering

Eventually, older adults were categorized into distinct groups according to their ranked modes that were calculated above in Step 6. To this end, each older individual was assigned to a point in a 2-dimensional space that corresponded to his or her two periods of phone call activity. We then used k-means clustering to calculate groups of older individuals from the coordinates of their representative points.

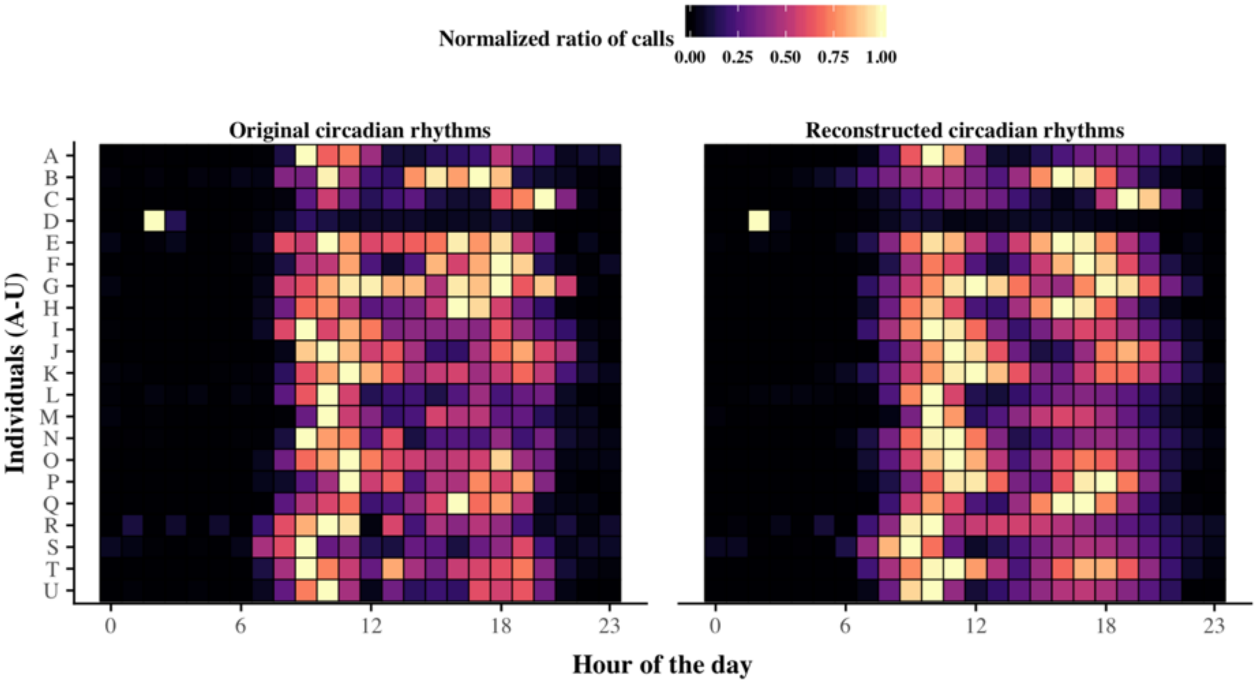
Results

Modeling Circadian Rhythms of Outgoing Phone Call Activity in Older Adults With GMMs

Figure 2 shows, for each older adult, both (1) his or her empirical circadian rhythms of outgoing telephone call activity (see Methods for details) and (2) his or her corresponding GMM (see Methods for details) on two distinct panels. Two observations stand out:

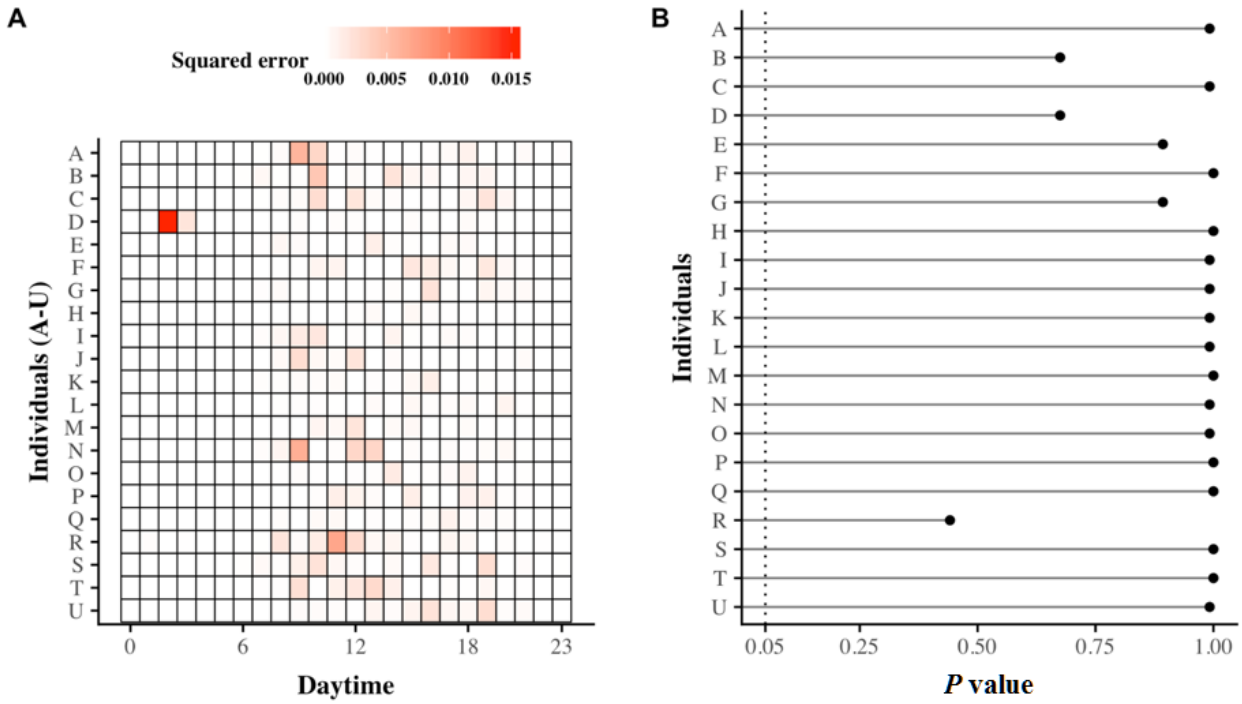
1. On the left-hand panel of Figure 2, the observed empirical circadian rhythms identify the existence of distinct peaks of phone call activity across the day that vary among older individuals. In accordance with previous descriptive results found in Aubourg et al [39], some of them, as with individuals A and I, showed a morning preference for phoning, whereas others, as with individuals C and Q, showed an evening preference. There was also one individual, individual D, who presented a significant shift in his rhythms for phoning, as evidenced by his peak of phone call activity that occurred at night around 2 AM.
2. Comparing empirical data with the models of GMMs for each older individual, we observed on the right-hand panel of Figure 2 the ability of GMMs to highlight periods of high activity and for smoothing periods of weak activity by the smoothing property of the Gaussian curve.

Figure 2. Circadian rhythms of outgoing telephone call activity in older adults and their corresponding Gaussian mixture models (GMMs). These patterns are represented by means of two colored heat maps, where each line corresponds to one older individual and columns correspond to hours of the day. Hence, the outgoing telephone call activity of one individual at a given hour is represented by a colored cell that is all the more bright as the individual increases activity. The left-hand heat map represents the original circadian rhythms of outgoing telephone call activity observed from empirical data, whereas the right-hand heat map represents those modeled by GMMs.



Furthermore, at a statistical level, Figure 3 provides the goodness of fit of the GMMs. In this figure, we observe that the similarity between empirical observations and GMMs cannot be rejected for each of the participants, with a *P* value greater than .05, based on the Kolmogorov-Smirnov comparison test.

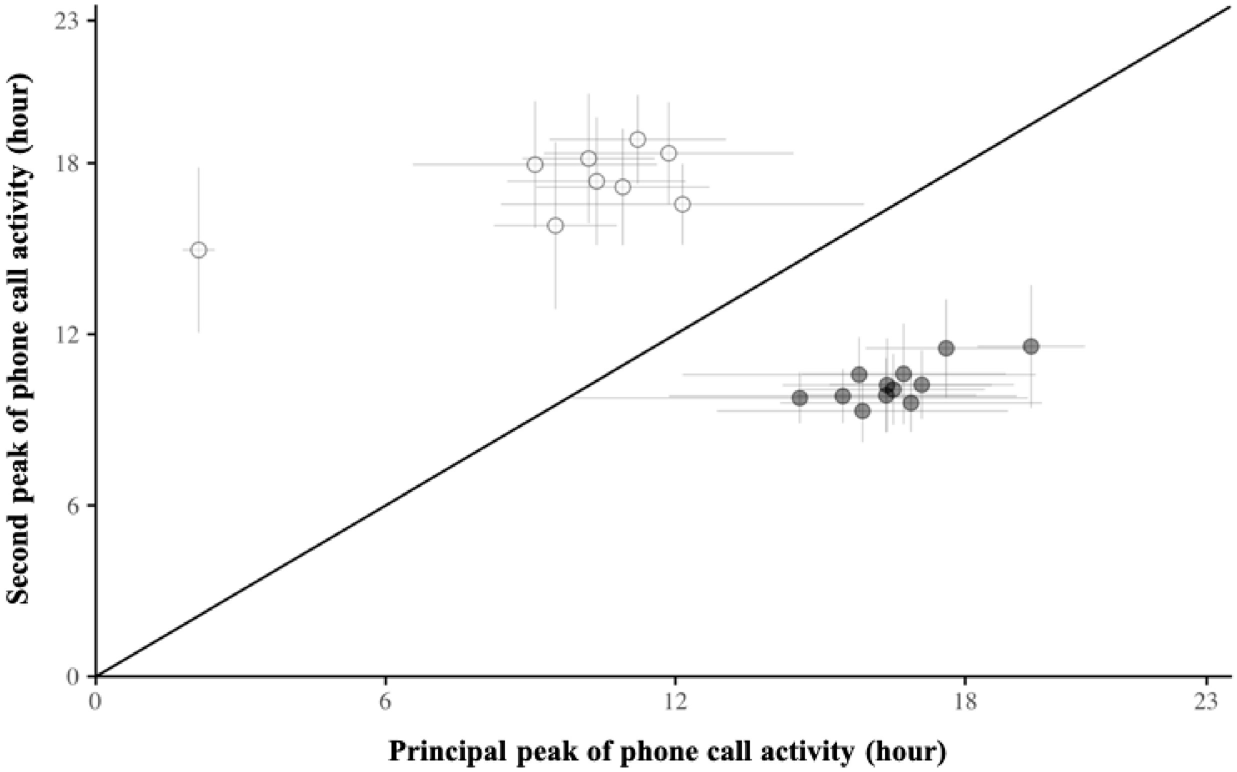
Figure 3. Goodness of fit of Gaussian mixture models (GMMs). Panel A corresponds to a heat map that figures out the squared errors calculated between empirical observations and their corresponding GMMs. Each line corresponds to one older individual, whereas columns correspond to hours of the day. Hence, the squared error between the outgoing telephone call activity and the estimated model at a given hour is represented by a colored cell that is all the more bright as the error increases. Panel B displays the associated goodness of fit by giving *P* values from the Kolmogorov-Smirnov comparison tests. Here, the significance threshold is set at .05 (dashed line).



Social Morningness-Eveningness Is Evidenced in the Telephone Call Activity of Older Adults

The k-means clustering process identified distinct categories of older individuals based on the characteristics of their daily outgoing telephone call activity. Figure 4 shows the k-means clustering results by displaying the two broad periods of telephone call activity of each older individual. This figure highlights the individual nature of social behavior for making telephone calls over the day. In the same way, it stands out that two broad patterns can be conceived in our data set, namely (1) *morningness* individuals have their principal period of telephone call activity in the morning and their second period later in the afternoon or evening and (2) *eveningness* individuals have the exact opposite behavior. Bipartite clustering confirmed this general trend by explicitly exhibiting both of these clusters. Again, we also have to point out that one older adult belonging to the *morningness* cluster, individual D, had an *extreme* behavior whose expression differed from the others, with his first peak of telephone call activity occurring at around 2 AM.

Figure 4. Morningness-eveningness observed in outgoing telephone calls. This figure displays the two broad periods of outgoing telephone call activity. Circles represent peaks of telephone call activity, and each period duration is represented with horizontal and vertical lines. Each circle is colored according to its morningness-eveningness trend given by k-means clustering.



Discussion

Principal Findings

Analysis of daily social interactions by means of CDRs is now recognized as a relevant approach for modeling human activity in an objective, unobtrusive way, which offers new opportunities for improving the field of health monitoring [50,51]. However, in the elderly population, more work is required to confirm the ability of such an approach to model relevant patterns of social interactions at a daily scale. This study is specifically designed to address this issue. To this end, we used a 12-month data set of outgoing CDRs of 26 adults older than 65 years of age. On the whole, our results allowed us to automatically model circadian patterns of outgoing telephone call activity. Interestingly, the results obtained at the individual level suggest the existence of individual hourly preferences for making telephone calls during the day. Despite the evident individual nature of such preferences shown by GMMs, the results also suggest the possibility for assembling these individual observations into broader categories using k-means clustering. In particular, these categories of phone call activity were of two broad types, namely (1) *morningness* older adults that had their main period of telephone call activity in the morning with their second one occurring later, in the afternoon or evening, and (2) *eveningness* older adults that had the exact opposite behavior.

With regard to the field of social physics applied to CDR data sets [52], these results corroborate recent findings about the existence of daily patterns in human social interactions over the telephone, which were exhibited at the population level [53]. Monsivais et al [53] analyzed a 12-month CDR data set containing more than 3 billion calls between 50 million unique identifiers. By aggregating data at the population level, the authors described the existence of an overall bimodality in outgoing telephone call activity that occurred at noon and during the evening periods of around 8 hours. Similarly, they also showed the existence of two periods of around 4 hours of low calling activity occurring (1) at night and (2) after lunch time. Such results permitted the authors to infer the existence of rhythms for representing the resting times of the population in order to study the impact of seasonal and geographical elements on that population. However, the focus on aggregate data from that study [53] does not allow the authors to reach a conclusion regarding the individual rhythms of the studied population because of ecological fallacy, nor within specific populations such as the aging one.

In a complementary way and for the first time to the best of our knowledge, this paper provides evidence at the individual level of the ability of statistical learning approaches to model similar results as those obtained by Monsivais et al [53] within a small cohort of older adults.

Furthermore, two singularities also stand out regarding our results in comparison with those obtained by Monsivais et al [53]. On the one hand, the bimodality exhibited in our older population seemed to appear earlier during the day at midmorning around 10 AM and in the evening around 6 PM. Knowing that the morning transition tends to appear with age, it is plausible that this observed shift, in comparison with the general behavior exhibited in the study by Monsivais et al [53], may reflect such a transitive state and could consequently be a representative element of the aging population [47]. On the other hand, our results also show the existence of nocturnal patterns of telephone call activity within our aging population that could occur in some older individuals. It is plausible that such nocturnal activity could reflect particular disruptions such as sleep disturbances, which are known to occur with age [54].

Hence, the analysis of social interactions in older adults by means of their CDRs does provide evidence about the existence of both social and structural insights about the older individual's daily social life. From a clinical perspective, such insights offer a relevant opportunity to consider modern phone technologies as a new kind of social activity sensor whose captured data can be automatically modeled to identify the fundamental social dynamics in the older individual's life. Social dynamics regarding telephone use could notably be harnessed to detect potential disruptions, such as nocturnal phase shifts or chronotype alterations, or to prevent the occurrence of particular health issues, such as sleep disorders, being presented to the clinician in the form of triggers.

Furthermore, since these pieces of information about social interactions do present the advantage of being collected in a passive, objective, and continuous way, they could be harnessed in complement with other timely subjective methods, such as subjective questionnaires [4,49], but also with innovative digital technological approaches such as *actigraphy*, which already exists for monitoring physical rhythms of the individual [55,56].

Study Limitations and Perspectives

A number of caveats and limitations have to be taken into account. Since this study's analysis was based on a relatively small sample of 26 older individuals, any straightforward generalization of our results to the overall older population should be avoided. Given the sample size of this study, at this stage the interest of our exploratory work is not in providing general knowledge on older adults' social activity on the telephone but, rather, in the ability to gain new insights that deserve to be included for future big data studies on improved data sets. Consequently, whether and how similar results could be observed under different conditions using different sets of data or by implementing alternative statistical methods should naturally be investigated. This could imply working on larger data sets but also, more broadly, leading analyses on distinct populations having their own social characteristics, such as individuals from particular social classes or from different cultures. Given the proportion of women represented in the analyzed data set (76%), whether and how similar works can be replicated with success within populations that have different proportions of male and female participants deserve to be addressed. Furthermore, it could be interesting to focus on specific cohorts suffering from age-related diseases, such as Alzheimer disease [31], Parkinson disease [13], and depression [30,57]. These supplementary works are all the more important insofar as, to the best of our knowledge, this study is the first one that investigates daily patterns of social interactions in an aging population specifically by combining CDR analysis with a statistical learning approach.

Among future perspectives, an essential step that remains to be investigated is whether, and to what extent, the results presented here could be harnessed to enhance already-existing digital frameworks in health research. Such an investigation could consist of developing an adequate complementary framework based on both judiciously used, statistical learning methods and behavioral theory to permit a better understanding of the digital profile of the older individual. In the field of health care monitoring, we do believe that such an investigation could represent a relevant approach for enhancing the interpretability of results and the efficiency of modeling approaches relying on telephone call activity.

Conclusions

Findings from this study support the potential of phone technologies and statistical learning approaches for automatically providing personalized and precise insights on the social rhythms of telephone call activity of older individuals. Such insights can highlight particular individual habits related to being active on the telephone according to the time of day. Furthermore, these individual pieces of information can be automatically analyzed by statistical learning approaches at the group level in order to provide more general information on the observed cohort, such as subtrends for clusters of older individuals, for instance, who are more socially active on the telephone in the morning or in the evening. Futures studies could integrate such digital insights with other sources of data to complete the assessment of the circadian rhythms of activity in the elderly population. In particular, big data studies should be implemented with large cohorts in order to investigate to what extent our study's results that were obtained from our sample of older participants at the group level can be transformed into broad actionable knowledge for the older population.

Acknowledgments

We thank the reviewers for critically reading the manuscript and suggesting substantial improvements.

Authors' Contributions

TA, NV, and JD designed the study. TA performed the data analysis, prepared the figures, and wrote the main manuscript text under the supervision of NV and JD. NV contributed to data acquisition. NV and JD substantively revised the manuscript text. NV contributed to the interpretation of the data.

Abstract

Background: Technological advances have radically changed the opportunities for individuals with chronic conditions to practice self-care and to coproduce health care and research. Digital technologies enable patients to perform tasks traditionally carried out by health care professionals in a more convenient way, at lower costs, and without compromising quality. Patients may also share real-world data with other stakeholders to promote individual and population health. However, there is a need for legal frameworks that enable patient privacy and control in such sharing of real-world data. We believe that this need could be met by the conceptualization of patient-controlled real-world data as knowledge commons, which is a resource shared by a group of people.

Objective: This study aimed to propose a conceptual model that describes how patient-controlled real-world data can be shared effectively in chronic care management, in a way that supports individual and population health, while respecting personal data privacy and control.

Methods: An action research approach was used to develop a solution to enable patients, in a self-determined way, to share patient-controlled data to other settings. We chose the context of cystic fibrosis (CF) care in Sweden, where coproduction between patients, their families, and health care professionals is critical in the introduction of new drugs. The first author, who is a lawyer and parent of children with CF, was a driver in the change process. All coauthors collaborated in the analysis. We collected primary and secondary data reflecting changes during the time period from 2012 to 2020, and performed a qualitative content analysis guided by the knowledge commons framework.

Results: Through a series of changes, a national system for enabling patients to share patient-controlled real-world data to different stakeholders in CF care was implemented. The case analysis resulted in a conceptual model consisting of the following three knowledge commons arenas that contributed to patient-controlled real-world data collection, use, and sharing: (1) patient world arena involving the private sphere of patients and families; (2) clinical microsystem arena involving the professional sphere at frontline health care clinics; and (3) round table arena involving multiple stakeholders from different settings. Based on the specification of property rights, as presented in our model, the patient can keep control over personal health information and may grant use rights to other stakeholders.

Conclusions: Health information exchanges for sharing patient-controlled real-world data are pivotal to enable patients, health care professionals, health care funders, researchers, authorities, and the industry to coproduce high-quality care and to introduce and follow-up novel health technologies. Our model proposes how technical and legal structures that protect the integrity and self-determination of patients can be implemented, which may be applicable in other chronic care settings as well.

Introduction

Moving From Self-Care and Health Care to Co-Care

In high-income countries, the top 1% of high-cost patients, predominantly patients with complex chronic care needs, account for almost one-fourth (24%) of health care expenditure [1]. Over half of high-cost patients are under the age of 65 years [1]. As the population with chronic illness grows, health care is under increasing pressure to use available resources efficiently, without compromising quality of care. In recent years, the necessity of stronger citizen involvement in health care service delivery has been emphasized using several related concepts, such as patient and public involvement [2], shared decision making [3], patient- and person-centered care [4,5], and coproduction [6].

Ostrom defines coproduction as “the process through which inputs used to produce goods or services are contributed by individuals who are not in the same organization” [7]. Von Thiele Schwarz [8] uses the term “co-care” to describe coproduction between patients and other actors involved in their care, such as health care professionals, and emphasizes the usefulness of digital technologies in facilitating the exchange of knowledge and experience between different actors. Digital technologies enable patients to perform tasks traditionally carried out by health care staff in a more convenient way, at lower costs, and without compromising quality [9]. For example, people measure their own blood pressure, adjust their insulin dose based on their own glucose monitoring, and perform intravenous antibiotic treatments at home, without the support or direct monitoring of health care staff.

Learning Health Care Systems as Knowledge Commons

With technology literally in their back pockets, individuals produce large personal health information repositories that can be shared electronically [10]. In the context of this study, we use the term *patient-controlled real-world data* to describe personal health-related data that are controlled by patients. Patient control implies that patients, in line with the General Data Protection Regulation (GDPR) [11], determine the purposes and means of the processing of their personal data, which does not prevent other parties from also being authorized as controllers, by the patient or by law. If adequately utilized, patient-controlled real-world data collected by patients and informal caregivers, in combination with health care collected data, can fuel the development of learning health care systems [12,13]. The information and knowledge that are shared in such collaborative systems can be conceptualized as *commons* [14]. The concept of commons refers to resources that are shared by a group of people and has its roots in the study of shared natural resources (eg, land and water) that are subject to social dilemmas such as competition, freeriding, and overharvesting [15]. In the 1990s, the concept gained application in the study of distributed digital information and knowledge, which Hess and Ostrom describe as knowledge commons [15].

In knowledge commons composed of personal health data, two social dilemmas in particular have been highlighted, namely disempowerment and enclosure [16]. Disempowerment of the individual in relation to the information industry has been described as a problem of unsustainable data practices that can also be labeled as a “privacy harm” resulting from uncontrolled data analytics [16]. As we “*bleed* data when moving a mouse cursor,” large industry actors like search engines gain power over us, which they can use to nudge us into certain behaviors (eg, by directed advertisements) [16]. The enclosure of data refers to the exclusive access to data by certain actors in the information industry, while not allowing others to profit from it, which is a type of appropriation problem [16]. The individual patient is the only source of real-time observations and experiences that span a lifetime of chronic illness. Several stakeholders have large resources and a mission to collect and act on patient-reported real-world data (eg, health care funders, national authorities, and the industry). Disempowerment and enclosure are prevalent social dilemmas in the current system of data flow between stakeholders, which hampers the effective development, introduction, and evaluation of new health technologies.

The knowledge commons is a useful framework to identify such problems based on how information is produced and used by different stakeholders, and to guide the development of suitable solutions to address these, for example, by the definition of social rules and legal mechanisms that enable individuals to effectively share ownership and control of resources [17]. To the best of our knowledge, strategies to explore and effectively manage such dilemmas in the health care and life science industries are limited. Therefore, in this study, we use the knowledge commons framework to explore how to develop adequate technical and legal structures for sharing patient-controlled real-world data.

Aim

This study aimed to propose a conceptual model that describes how patient-controlled real-world data can be shared effectively in chronic care management, in a way that supports individual and population health, while respecting personal data privacy and control.

Methods

Study Design

We used an action research approach that is suitable when the purpose is to bring about change in real-world environments [18]. Action research is focused on solving a specific problem in a specific context. Contribution to both practice and research is achieved through the combined expertise of practitioners and researchers, which mandates a collaborative research approach [19]. While no specific method of data collection is specified, a variety of generally qualitative methods may be applied, including journal keeping, document collection, and case studies [18]. In the following subsections, we first describe the chronic care context that was chosen to address the aim of this study. Thereafter, we describe the action research process and the data collection and analysis methods that were used.

Chronic Care Context

We selected the context of cystic fibrosis (CF) care in Sweden. This context was chosen because CF care and its improvement are strongly dependent on coproduction between patients, their families, and health care [20,21]. CF is a life-limiting recessive genetic disorder that is usually diagnosed within the first few years of life, affects several organs, and leads to chronic infection and inflammation in the airways [21]. Treatment involves drug therapy, daily self-management (eg, airway clearance and physical exercise), and support by multidisciplinary care teams [22]. The recent development of disease-modifying drug therapies has substantially improved the prospect of effective treatment for CF [23]. The availability and use of solutions that enable patients and their families to share patient-controlled real-world data are critical to support the introduction and follow-up of these new therapies. In Sweden, there are approximately 700 CF patients, and about 95% of them are included in the national CF quality registry where care process and outcome data are reported for benchmarking and quality improvement [24].

Action Research Process

The main change agent in the action research process was the first author (AH) who is a lawyer and parent of children with CF, as well as a driver in the development of mobile patient support systems (PSSs) to support patients and their families in self-care and communication with health care. To adequately explore the development of a new infrastructure for sharing of patient-controlled real-world data in the context of CF care in Sweden, the researchers collaborated with AH, combining their contextual and theoretical knowledge to contribute to problem-solving and knowledge generation. Action research is cyclical by nature, which means that changes are continually evaluated, leading to incremental improvements. While the change process itself is not the focus of this study, we analyzed the resulting changes that enabled patients to self-determinedly share patient-controlled real-world data to different stakeholders in CF care. The action research process was guided by the knowledge commons framework.

Knowledge Commons Framework

The knowledge commons framework defines concepts that are central to understanding knowledge as a shared resource. A central concept is the *action arena*, which consists of the individuals and organizations who make decisions that affect patterns of interactions and outcomes in a knowledge commons [25]. To understand the complex nature of information and knowledge sharing, the knowledge commons framework makes a distinction between *ideas*, *artifacts*, and *facilities* [26]. An *idea* is an intangible representation of information in an individual's mind. For example, someone's experiences or thoughts that have not yet been translated into natural language. An *artifact* is a discreet and nameable representation of an idea or a collection of ideas. For example, an electronic health record is a digital collection of ideas about an individual's medical history. Digital artifacts can be used concurrently by multiple users and are stored in information facilities. A *facility* consists of the software and hardware that stores artifacts and makes these available to users. The distinction between ideas, artifacts, and facilities is important for the specification of legal structures in commons. To ensure sustainable use of a shared resource, different sets of rules need to be applied. One set of rules regulates access to the facilities of commons and another set of rules regulates the contribution and withdrawal of artifacts to and from the commons. Seven types of property rights have been identified as relevant in rule setting in digital information commons [25]. These concern the right to access a physical area (*access right*); the right to contribute to content (*contribution right*), extract information (*extraction right*), and remove information (*removal right*); the right to regulate use patterns or make changes to a facility, for example, by adding new functionalities to an application (*management/participation right*); the right to determine access, extraction, and removal rights (*exclusion right*); and the right to sell or lease extraction, management/participation, and exclusion rights (*alienation right*).

Data Collection and Analysis

We collected primary data in the form of formal documents (project plans, meeting notes, technical specifications, contracts, and user manuals) and secondary data in the form of scientific publications [27,28], a master's thesis [29,30], and a conference abstract [31] reflecting the design, development, implementation, and adaptation of changes during the time period from 2012 to 2020. These data were corroborated by the personal experience of AH who was a driver in the change process.

We performed a qualitative analysis resembling a directed content analysis [32], guided by the knowledge commons framework. Two authors (AH and SL) read through the collected documents and identified text that matched any of the knowledge commons concepts described above, that is, descriptions of action arenas, facilities, artifacts, and ideas, as well as descriptions of rules or property rights that were applied to protect personal privacy and control. Text that matched these concepts was extracted, labeled, and categorized. The relations between concepts were explored and summarized into models that visualize these relationships. The models were refined in discussions among all the coauthors, resulting in the conceptual model presented here.

Results

Overview

The first section briefly summarizes the main developments that resulted from the action research project and allowed patients and families to share patient-controlled real-world data with different stakeholders in CF care. Where applicable, references to relevant publications that report these changes are provided in parentheses. The second section presents our analysis of the implemented changes, which is presented as a conceptual model consisting of the different action arenas that we identified and the patterns of patient-controlled real-world data flow between them.

Main Developments

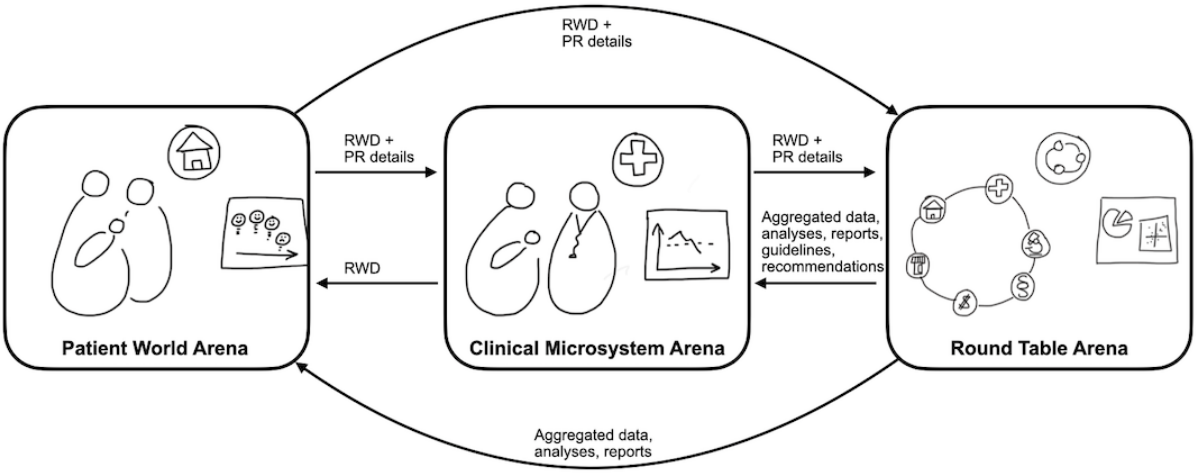
In 2014, a mobile patient-facing application, Genia PSS, was introduced at one of the four national CF centers [27]. The Genia PSS was designed to help patients and their families keep track of patients' health and self-care activities, and to facilitate communication, relationship building, and shared decision making together with their care team. Using the Genia PSS, patients could track and share their own health observations with their care teams. A health information exchange was developed for enabling import of shared data from the Genia PSS into the national CF quality registry.

In late 2015, a new and very costly disease-modifying CF combination therapy, lumacaftor/ivacaftor, was approved for market introduction in Sweden [33]. Not all patients eligible for therapy are responders, and it requires structured follow-up and evaluation of treatment effectiveness, following the national managed introduction process [34]. In 2016, the Sweden CF Coalition was formed as a collaborative learning network involving a variety of stakeholders, comprising representatives from all four national CF Centers, the National Cystic Fibrosis Association, the CF Working Group of the Swedish Society of Medicine, the National Quality Registry Development Group, and the Genia PSS Development Group. Author AH had a role as secretary, and SL served as an advisor. The CF Coalition defined their purpose as follows: "[to make] it easier for everyone – persons with CF, families, clinicians, researchers, and others – to work together to improve health, care, and cost of illness for people with CF" (Sweden Coalition Charter, May 21, 2016). In 2017, they formed a Coordination Group to take on the specific task to implement a national system for the orderly introduction and follow-up of lumacaftor/ivacaftor, using patient-collected and health care–collected real-world data [31]. Through the establishment of a multistakeholder learning network and implementation of new health information exchange services to the national quality registry, the Genia PSS enabled the use of patient-controlled real-world data to support quality improvement, research, and the orderly introduction and follow-up of new CF therapies. In 2018, when the treatment follow-up routines were in place, lumacaftor/ivacaftor was approved for subsidy in Sweden and introduced on the market. At the time of writing, each of the four national CF centers was connected to the Genia PSS, which, in October 2020, had about 240 active users with CF in Sweden.

Three Arenas for Collaboration

The analysis resulted in a conceptual model describing how patient-controlled real-world data can be used and shared across the following three action arenas in CF care: patient world arena, clinical microsystem arena, and round table arena (Figure 1). In the following sections, we describe the three arenas and the property rights that were specified to manage patient-controlled real-world data.

Figure 1. Three central arenas in the collection, use, and sharing of patient-controlled real-world data (RWD). PR details: specification of property rights that translate into use restrictions.



Patient World Arena

The *patient world arena* comprises the private sphere of patients and families living with CF. Using the terminology introduced by Kleinman, the actors in this arena cope with *illness*, *illness problems*, and *illness behavior* [35]. The patient and family together observe and experience health and well-being in the presence of *illness*, as well as the principal difficulties that symptoms and disabilities create for the patient (*illness problems*). They make judgements about how best to cope with the distress and with the practical problems in daily living, including initiating treatment, handling self-management, and deciding when to seek care from professionals and others (*illness behavior*).

Collection and Use of Patient World Artifacts

The Genia PSS enables actors in the patient world arena to capture nonphysical ideas of personal importance about illness, illness problems, and illness behavior, and generate physical artifacts that can be communicated and shared. Artifacts may represent assessments (eg, perceived health benefit from antibiotic treatment), memos (eg, a picture of a run in the forest), or narratives (eg, a treatment diary). The use of additional facilities, such as a blood glucose monitor, a pulse sensor, a scale, and a spirometer, may be necessary to capture health parameters of importance (eg, blood glucose levels, pulse, body weight, and lung function). Personal health data can also be imported for private use in the patient world arena from facilities used in other settings, such as electronic health record (EHR) and pharmacy systems. Collected and imported patient-controlled real-world data are stored in a personal database that can be made available via interfaces with patient-determined members of the patient world arena, such as family members and close friends.

Sharing of Patient World Artifacts With Other Arenas

Health information exchanges were implemented to support sharing of patient-controlled real-world data with other arenas, for example, with health care professionals prior to visits [28]. The sharing of artifacts with other facilities requires mutual agreement and adherence to information standards and terminologies (semantic interoperability), as well as contractual obligations and data protection legislation (legal interoperability). The Genia PSS has implemented a *previsit form* data structure to enable the sharing of patient-controlled real-world data with the clinics via EHR systems and the national quality registry.

Property Rights

The patient world arena represents a private domain within which patient-controlled real-world data are processed with no direct connection to professional or commercial activity. Property rights have been iteratively refined to safeguard personal data privacy and control (Textbox 1). The patient determines who has access to the Genia PSS as a member, the level of interaction with the system, and what patient-controlled real-world data to share. Especially for younger pediatric patients, parents serve as proxies by documenting daily observations about their child [28].

Textbox 1. Seven property rights for patient world arena users of the Genia patient support system.

Access: Two defined user roles have access to the Genia patient support system (PSS) facility: *Patient* (individuals with cystic fibrosis) and *Member* (the innermost network of trusted persons as defined by the patient).

Contribution: Patient and Member users have the right to contribute with data to the patient account they are linked to.

Extraction: Patient and Member users have the right to extract data. Extraction is supported by functionalities in the Genia PSS. The user first selects the data items to extract and generates a report that can be shared. Extractions are logged.

Removal: Patient and Member users have the right to remove data from the patient account they are linked to.

Management/participation: The right to regulate general use patterns and make changes to the Genia PSS is retained by the service provider. Patient and Member users can personalize their individual patient account and activate available feature bundles.

Exclusion: Patient users determine who has the right to access, contribute, extract, and remove data, and how these rights may be transferred to Member users. Certain exclusion rights have been transferred to the service provider under the user agreement. For example, to maintain the integrity of the user's private domain, the service provider has decided to limit the facility to private use, excluding professional or commercial use. This ensures the applicability of legislation that protects the freedom of the domestic domain, medical device regulations, and consumer protection regulations.

Alienation: Alienation rights to the Genia PSS facility (application and servers) have been retained by the service provider, that is, the right to sell or lease management/participation rights. The Patient user has alienation rights to the data, that is, to sell or lease extraction and exclusion rights and how those rights may be transferred.

Clinical Microsystem Arena

The *clinical microsystem arena* comprises the professional sphere at health care clinics. Clinical microsystems are the small, functional, front-line units that provide direct clinical services to patients, that is, the place where health care professionals and patients meet. Health care professionals manage patient care by following clinical practice guidelines that are agreed upon by the professions involved and accepted by their patients. In Sweden, patients meet with their care teams for quarterly check-ups at one of the country's four CF centers, or, for patients who live outside commuting distance, at one of over 60 care centers that collaborate in "shared care" with a designated CF center. All annual check-ups are carried out at CF centers, which represent different clinical microsystem arenas. They are essential building blocks of the larger health system that supports CF patients and the university hospital organizations they are part of.

Collection and Use of Clinical Microsystem Artifacts

Actors of the clinical microsystem arena collect and store patient data in the various EHR systems. If granted access by patients, they may also import patient-controlled real-world data from the Genia PSS. The data are accessed through an export interface in the Genia PSS and imported into a specific module of the EHR, which will here be described as the Genia decision support system (Genia DSS). Once imported into the Genia DSS, the data can be processed according to the rules of the clinical microsystem. At each of the four national CF centers, functional features for processing patient-controlled real-world data that support daily clinical practice and care at home were developed and tested iteratively through small-scale design cycles with health care professionals and patient and family representatives.

Sharing of Clinical Microsystem Artifacts With Other Arenas

The Genia DSS is interoperable with the Genia PSS, as well as the national quality registry through a health information exchange service. To share patient data stored in the EHR system with the patient or the national quality registry, data export areas have been implemented in the Genia DSS, similar to those in the Genia PSS. The export area of the Genia DSS hosts data that have been approved and released for sharing and has an interface that can be accessed by the Genia PSS. For data that are shared with the national quality registry, deidentification of sensitive personal data (eg, through pseudonymization) may be required prior to making data accessible to quality registry users, so that individuals cannot be identified.

Property Rights

The clinical microsystem arena practices under a number of laws, regulations, and guidelines (eg, health information technology and patient safety legislation, and clinical practice guidelines). Therefore, the rules that govern health care professionals' use of patient-controlled real-world data must be aligned with these. Property rights that have been applied in rule setting in the Genia DSS for protecting patients' privacy and control are described in Textbox 2.

Textbox 2. Seven property rights for clinical microsystem arena users of the Genia decision support system.

Access: The Genia decision support system (DSS) can primarily be accessed by health care professional (HCP) users (certified health care professionals). Patients have no user accounts in the Genia DSS, but they have access to designated computer terminals at the cystic fibrosis (CF) centers, with a data input and dashboard module. Also, HCPs can present patient facing dashboards to them during clinical visits.

Contribution: HCP users have the right to contribute data to their patients' records in the Genia DSS. Patients can contribute data through patient-facing input modules at CF center computer terminals.

Extraction: HCP users have the right to extract data, which are constrained by rules in the clinical microsystem, patient consent, as well as guidelines regarding data privacy and patient safety. Extraction is done through standardized report formats. Extractions are logged for auditing purposes.

Removal: Removal rights are restricted in ways similar to accounting systems. Data can be modified and deleted from the user's view in the Genia DSS. For data to be irreversibly deleted from the system, special legislation might apply, such as a Swedish regulation that requires a court decision initiated by the patient. Removal activities are logged for auditing purposes.

Management/participation: The right to regulate general use patterns and make changes to the Genia DSS is retained by the service providers. These rights are influenced by design recommendations and the given health care context, as well as potential constraints by other systems in use.

Exclusion: Generally, the head of the clinic has exclusion rights.

Alienation: Alienation rights to the Genia DSS facility (application and servers) have been retained by the service providers, that is, the right to sell or lease management/participation rights. The controller of data (in general, the clinical department) has alienation rights to patient data artifacts, that is, to sell or lease extraction and exclusion rights and how those rights may be transferred.

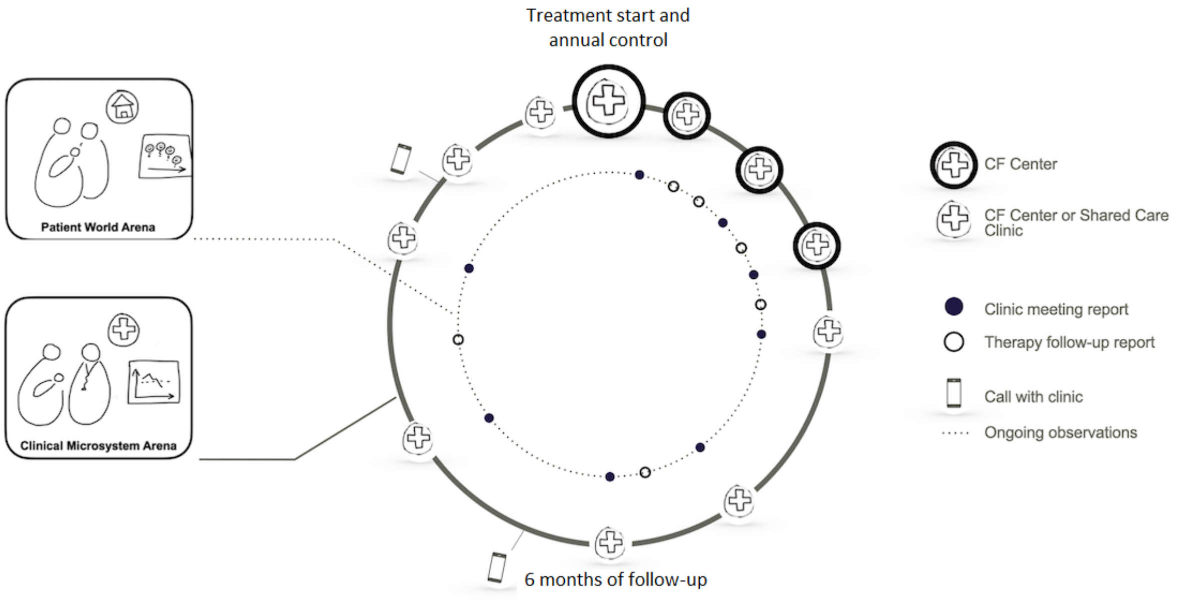
Round Table Arena

The *round table arena* can be defined as a multistakeholder collaborative learning network that works toward common goals. The members of the round table arena may represent individuals (eg, a patient) or institutions (eg, a hospital, authority, or industry actor). A round table arena that includes stakeholders with varying expertise and experience provides distinct advantages, not least of which is the ability to gather and share lessons in real time, contributing to the generation of intellectual and social capital. The Sweden CF Coalition and its Coordination Group are examples of round table arenas that require collective action, that is, the efforts of more than two individuals, to reach their purpose. To implement a system for supporting the orderly introduction and follow-up of lumacaftor/ivacaftor, good coordination is required with national health authorities and councils involved in decisions regarding the introduction and subsidy of the new therapy.

Collection and Use of Round Table Artifacts

With data from the national quality registry as a shared resource, as well as the personal expertise and experiences shared by its members, the Sweden CF Coalition aims to set up crucial conversations among stakeholders, so they can learn about new ways to generate optimal health and high-value care. To implement a national system for the orderly introduction and follow-up of lumacaftor/ivacaftor, changes to existing facilities that hold patient-controlled real-world data were necessary. This involved negotiations on what core data sets could be extracted from the Patient World and Clinical Microsystem arenas. New modules for lumacaftor/ivacaftor follow-up visits with indicators for follow-up and evaluation of the therapy were implemented in the Genia PSS, Genia DSS, and national patient registry. The health information exchange service was modified to enable ethically and legally viable sharing of data across arenas. These modifications enabled the provision of a shared resource to support clinical decision making, quality improvement, administration, and research. The system was implemented in the summer of 2018 upon national approval of market access to lumacaftor/ivacaftor (Figure 2).

Figure 2. First-year customer journey with lumacaftor/ivacaftor therapy (an idealized flow with a new therapy linking the patient world and clinical microsystem arenas).



Sharing of Round Table Artifacts With Other Arenas

Actors in the Sweden CF Coalition share their collaboratively generated ideas through analyses, reports, and clinical guidelines. These artifacts are made available to selected stakeholders through creative commons or fee-for-service agreements in accordance with industry standards and national ethical platforms, or generally made available to the public. The information and knowledge that are produced by the round table arena can be described as *common-pool resources*, which means that they are controlled by stakeholders within the Sweden CF Coalition.

Property Rights

In contrast to the patient world arena and the clinical microsystem arena, where conversations about health concern identified individuals, actors in the round table arena have access to data representing deidentified individuals or a nonidentified collective of individuals [36]. Based on different round table arena actors' roles and affiliations to other settings, the information they contribute to and extract from the facilities they have access to will be governed by different property rights. The data made publicly available by the Sweden CF Coalition are from the national patient registry for CF, which serves as an *open-access common-pool resource* where no one has the legal right to exclude anyone from using the resource, as long as it is in conformance with general legal requirements.

Discussion

Principal Findings

This study used an action research approach to propose a solution for enabling patients to effectively share patient-controlled real-world data in CF care. The case that was presented is an example of coproduction in and beyond health care services, where patients contribute to the orderly introduction and follow-up of new therapies, while retaining control of their data. We identified the following three types of action arenas where patient-controlled real-world data are collected, used, and shared: patient world arena, which comprises the private sphere of patients and their families; clinical microsystem arena, which comprises the professional sphere at health care clinics; and round table arena, which comprises stakeholders from multiple spheres with complementary expertise. The relationships and information exchange between these arenas were illustrated in a conceptual model, which we suggest can be used as a tool to analyze current chronic care systems and as a guide for the development of solutions for patient-controlled real-world data sharing.

Comparison With Prior Work

In the following sections, we discuss our results in relation to prior work. We discuss the conceptualization of the three arenas in our model, the sharing of patient-controlled real-world data, and, finally, the applicability of the model in other chronic care settings.

The Three Arenas

The patient world arena is a central building block of the conceptual model presented in this study. In line with well-known concepts, such as *patient-centered care* [4], it emphasizes the patient's experience and expertise on living with a chronic condition. Our model acknowledges that patients may involve actors outside the health care organization in their self-care. Thus, the patient world arena describes the patient's domestic domain where laws and regulations of the health care setting and general privacy directives do not apply [37]. While each patient world arena has its own (likely implicit) social rules and norms for how data are captured, used, and shared, our model identifies some general property rights that may be applied.

The concept of the clinical microsystem, in contrast to the patient world, is well established. Nelson et al [38] described the clinical microsystem as "the local milieu in which patients, providers, support staff, information, and processes converge for the purpose of providing care to meet health needs" [38]. It can be seen as an arena for coproduction between the patient and his or her self-determined network and the formal care team, aimed at promoting, improving, or maintaining individual health. As Ostrom notes [7], "technologies in use must generate a complimentary production possibility frontier […] rather than merely a substitutive one. […] When coproductive inputs are legally owned by diverse entities and complements, synergy can occur." Thus, while the clinical microsystem may be embedded in the health care organization, the patient represents an own entity when appearing as an actor and guest in the clinical microsystem arena. Here, the specification of property rights helps to clarify the ownership and control of the different inputs to the system, where patient-controlled real-world data that are produced in the health care setting or at home are controlled by the patient, but can be shared with the care team for use in the patient's individual care.

The concept of the round table arena builds on the previous work by Lindblad (SL) et al [36,39] on registry-based learning networks, as well as previous research on collaborative chronic care networks [40-42]. It differs from the other arenas in a number of aspects. First, while the patient world and clinical microsystem arenas deal with coproducing strategies to maximize individual health, the round table arena deals with coproducing strategies to maximize population health. The Sweden CF Coalition that was analyzed in this study can be described as a double-loop learning system [43] that engages a multistakeholder group in following up and discussing the adequacy of new therapy practices and related guidelines, based on an aggregation of data from the patient world and clinical microsystem arenas. It deals with quality improvement on a national level. Second, while the patient world and clinical microsystem arenas are found within the boundaries of the domestic domain and health care organization, respectively, the round table arena crosses organizational boundaries. Third, while the purpose and stakeholders of the patient world and clinical microsystem arenas are well known to the patient, the round table arena may be formed for a variety of purposes and in a variety of settings. The patient who contributes with data may not know the stakeholders and may not gain any direct benefit that contributes to his or her individual care, at least not immediately. Thus, communication of purposes and agreements on the terms of patient-controlled real-world data management may be all the more important.

Sharing of Patient-Controlled Real-World Data Between Arenas

In this action research case study, we identified several different facilities that were used by stakeholders to share and access patient-controlled real-world data (the Genia PSS, Genia DSS, and quality registry). Sweden has long experience with clinical quality registries that allow patient-valued health outcomes and research to be coproduced between different stakeholders and provide open access to quality registry data for quality improvement and benchmarking purposes [36,44,45]. Previous research has shown that the majority of people are willing to share their personal health data, particularly for research purposes [46].

The proliferation of pervasive computing technologies, such as the "internet of things," will greatly increase data collection from the personal and private spheres, which may be conducive to social dilemmas such as disempowerment and enclosure. This all the more emphasizes the need to protect the integrity of individuals and their private life, which is key to support the success of such technologies [47]. Legal requirements like the GDPR have strengthened individuals' rights to the protection of personal data, which, in our opinion, makes patients the only ones who can make sustainable decisions about the sharing of patient-controlled real-world data. Consequently, patients should be in the driver's seat when these data are utilized to develop, distribute, and evaluate new medical technologies, care processes, and systems. By applying the seven property rights suggested by Ostrom and Hess [25] in this study, rules were specified to protect individuals' privacy in line with moral and legal requirements. For example, the access, contribution, extraction, removal, and alienation rights to patient-controlled real-world data in the Genia PSS were exclusively specified for the patient and his or her self-determined network. The service providers' rights were mainly limited to aspects that concern the facility, and its functionalities and use patterns, but no rights to patient-controlled real-world data were specified, which prevents uncontrolled data analytics.

Applicability to Other Chronic Care Settings

Although the model presented in this study is based on the context of CF care, we believe that it is applicable to other chronic care settings that share similarities with CF care in terms of digital technology use to support coproduction. We selected CF care as the context for this case study because of its strong dependence on coproduction between patients, their families, and health care [20,21]. This type of coproduction is not unique to CF care and we argue that, in light of the demographic shift and technological development that we described in the introduction section of this paper, the transition to co-care in chronic care management [8] is a necessary paradigm shift in the organization and management of health care. Apart from CF care, we have observed other examples of chronic care settings where existing technological, legal, and social structures can be analyzed on the basis of the conceptual model we presented in this study. For example, the round table arena concept has previously been described in the context of rheumatoid arthritis [36]. Similarly, the idea of collaborative chronic care networks stems from research on inflammatory bowel disease [40-42]. Further, the Genia PSS has already spread to other chronic conditions in Sweden (juvenile idiopathic arthritis [28] and acute intermittent porphyria), which allows us to speculate that our model involving three action arenas may be applicable at least in these settings and likely other chronic care settings where co-care is aspired.

Initially, the model can be used to raise questions like “What action arenas can we identify in the chronic care management of a certain patient population/in a certain setting?” “Who are (potential) members of the different arenas?” “Which norms and rules apply in the interactions within and between arenas?” “What real-world data flows exist between arenas?” “What facilities are in use?” and “What property rights have been specified and implemented to protect patients’ privacy and control?” We believe that the discussions triggered by these types of questions may help to uncover some of the social dilemmas that may result from data use and sharing not controlled by the patient, such as disempowerment and enclosure [16]. Such dilemmas may be addressed by formulating and implementing appropriate property rights. In summary, we believe that this model may find application as a tool for the analysis and comparison of chronic care systems in different patient groups and settings, as well as a guide for the development of appropriate technical and legal structures to support coproduction between different arenas.

Limitations

This study is not without limitations. The model involving three action arenas that was presented resulted from an iterative cycle of development and analysis based on a single case. Because our intention was to present a model that is also applicable in other chronic care settings, we chose a relatively high level of abstraction, compromising the level of detail. We see our model as a general guide rather than a detailed manual on how to manage the sharing of patient-controlled data in chronic care settings. We acknowledge that AH had a central role in both the development and analysis. To maintain neutrality from preconceived ideas or personal interests, the analysis and results have been discussed among all the authors, guided by theory. To further develop the model and test its transferability to other settings, pilot studies have been initiated in the United States (Clinical Trial ID: NCT03910881) and Argentina, and we plan to conduct an international multiple case study.

Conclusions

To date, little academic research has been devoted to the study of how patient-controlled real-world data can be employed in the introduction and systematic evaluation of novel health technologies. Health care professionals, health care funders, researchers, authorities, and the industry are all dependent on the collection and analysis of real-world data reported by the individual patient whose personal data privacy and control need to be protected. To proactively manage social dilemmas related to shared information and knowledge resources, we suggest the specification of property rights that enable patients to determine how their personal health data are managed and shared in other settings. Our model, developed as a knowledge commons, comprises technical and legal structures that protect the integrity and self-determination of patients in such data sharing to improve individual and population health. Further research is needed to adapt and transfer our proposed knowledge commons model to improve health in other chronic conditions as well.

Acknowledgments

This study is funded by Merck Sharp & Dohme Corp through a strategic partnership between Karolinska Institutet and the company, encouraging collaboration focusing on patient-centered research. AH and CW were also funded by the Swedish Research Council and the Swedish Research Council for Health, Working Life and Welfare (grant number 2018-01472 and 2017-01451), and MB was supported by the Swedish Research Council for Health, Working Life and Welfare (grant number 2014-04238). The authors extend their gratitude to the Sweden CF Coalition, the cystic fibrosis community, Hector Gutierrez, Gabriela Oates, Manolis Nymark, and Eugene Nelson for their valuable support, as well as the reviewers for their valuable comments on several versions of the manuscript.

Authors' Contributions

AH and CW drafted the final manuscript, with contributions from SL and MB. All authors contributed to the study design and analysis, and approved the final version of the manuscript.

Conflicts of Interest

AH is a father of children with cystic fibrosis and an eHealth entrepreneur engaged in developing the Genia patient support system and health information exchanges. All other authors declare no conflicts.

Abstract

Background: Many intervention development projects fail to bridge the gap from basic research to clinical practice. Instead of theory-based approaches to intervention development, co-design prioritizes the end users' perspective as well as continuous collaboration between stakeholders, designers, and researchers throughout the project. This alternative approach to the development of interventions is expected to promote the adaptation to existing treatment activities and to be responsive to the requirements of end users.

Objective: The first objective was to provide an overview of all activities that were employed during the course of a research project to develop a relapse prevention intervention for interdisciplinary pain treatment programs. The second objective was to examine how co-design may contribute to stakeholder involvement, generation of relevant insights and ideas, and incorporation of stakeholder input into the intervention design.

Methods: We performed an embedded single case study and used the double diamond model to describe the process of intervention development. Using all available data sources, we also performed deductive content analysis to reflect on this process.

Results: By critically reviewing the value and function of a co-design project with respect to idea generation, stakeholder involvement, and incorporation of stakeholder input into the intervention design, we demonstrated how co-design shaped the transition from ideas, via concepts, to a prototype for a relapse prevention intervention.

Conclusions: Structural use of co-design throughout the project resulted in many different participating stakeholders and stimulating design activities. As a consequence, the majority of the components of the final prototype can be traced back to the information that stakeholders provided during the project. Although this illustrates how co-design facilitates the integration of contextual information into the intervention design, further experimental testing is required to evaluate to what extent this approach ultimately leads to improved usability as well as patient outcomes in the context of clinical practice.

co-design; participatory design; chronic pain; intervention development; rehabilitation; behavior change; relapse; prevention

Introduction

Only a fraction of intervention development projects is able to bridge the translational gap from scientific research to clinical practice [1-4]. An important factor for this limited uptake may be that contextual factors, such as stakeholder acceptability or implementation in existing practices, receive little attention during earlier development stages [5]. For example, many intervention development guidelines emphasize the formulation of an underlying theoretical construct and subsequent experimental testing to validate each assumed causal step, but only address implementation and feasibility after the intervention development phase has been completed [6-8]. Consequently, theoretically sound interventions may be discarded due to insufficient attention to crucial translational factors such as low perceived utility by patients or health care providers (HCPs), inconvenient navigation, or a discrepancy between the intervention requirements and patients' preferences [9-14].

An opportunity to increase the emphasis on these factors is to incorporate co-design methods. Co-design not only is characterized by an incremental knowledge over multiple development cycles [15] but also specifically emphasizes empathizing with each stakeholder, integrating conflicting requirements, and quickly transitioning ideas to testable prototypes. Co-design differs from other design methodologies in that it involves a range of tools and exercises to optimize collaboration between professional designers and people who are not trained in the design process, such as patients and therapists [16]. Done rightly, co-design brings together different views, input, and competencies of people with a variety of perspectives to address a specific problem [17,18]. As a result, this approach should increase the acceptability and integration of the intervention in existing clinical practice by accommodating relevant contextual factors that have been identified by stakeholders in the development process.

Although co-design is increasingly adopted in the development of health care interventions (eg, [18-23]), prior studies have indicated that effective co-design is not without its challenges. For example, the process of engaging all stakeholders can be time-consuming and intensive. This can be particularly difficult in the context of health care because HCPs generally have a high workload [20], and participating patients often do not directly benefit from the development projects, which could negatively influence their motivation and engagement. Moreover, patients, policy makers, and HCPs can experience conflicting interests during intervention development projects, because the assumed best possible care is generally limited by finite resources or specific treatment guidelines within a particular health care environment [24]. Factors such as these could endanger the main principles of co-design and should be further examined in the context of health care [18,19].

Co-Design in the Context of Chronic Pain

In the present project, called the SOLACE project (grant number: SIA RAAK 2014-01-23), we developed a relapse prevention intervention for patients with chronic musculoskeletal pain who participate in an interdisciplinary, multimodal pain treatment program. The primary reason for adopting a co-design approach was that, despite high prevalence rates of relapse after successful treatment, there is a paucity of available research to explain relapse for this particular population [25,26]. In these situations, a design-based approach may be particularly appropriate, because it allows for new insights to be recursively fed into future development cycles, thereby gradually increasing the knowledge base over time [15,27]. Because patients with chronic pain often experience distrust from their personal and medical environment [28], co-design may also prove effective in empowering patients to participate in the development process and to actively share their opinions and ideas [23,29].

Objectives

To increase understanding of how co-design can be successfully applied in the development of interventions in the health care domain, more examples of good practice are needed [13,18,30]. Therefore, our research question was to what extent co-design practices facilitate the translation of meaningful stakeholder experiences into the design of a health care intervention. Our first aim was to provide a detailed overview of all co-design activities that were employed during the course of an example project. Our second aim was to reflect on this overview and examine how co-design may contribute to stakeholder involvement, generation of relevant insights and ideas, and incorporation of stakeholder input into the intervention design. We hypothesized that co-design activities would facilitate the generation of relevant experiences and insights from stakeholders and stimulate their active participation during this project. Consequently, we expected that this would yield prototypes that were aligned with clinical practice and would resonate with end users.

Methods

Design

We performed an embedded single case study [31], in which we analyzed and evaluated all co-design activities that were related to the development process of the SOLACE project. Throughout the study, the researchers followed a participatory action research (PAR) approach, which is characterized by active collaboration with the people of interest, rather than only researching them. PAR also emphasizes respectful cooperation between stakeholders and researchers including collective decision making and a bidirectional transfer of knowledge over multiple iterative development cycles [32-34], which is in accordance with co-design methods [35]. During each cycle, insight is acquired through action (eg, by letting patients interact with preliminary prototypes), empowerment of stakeholders (eg, by patient involvement in co-design sessions), and subsequent reflection [32].

Participants

The SOLACE project consortium consisted of 2 interdisciplinary multimodal pain treatment centers, the Royal Dutch Society for Physical Therapy, The Dutch National Pain Patient Advocacy Organisation, and 4 research groups with a respective interest in chronic pain treatment (2 groups), co-design, and behavior change. All consortium partners assisted with the recruitment of participants when this was required at specific co-design activities, including patients and their spouses, HCPs, designers, researchers, and students. The core team was composed of 3 researchers, each from a different research group. This team was responsible for the planning and preparation of the co-design activities. To monitor overall progress, a steering committee was formed, which included representatives of all consortium partners. Ethical approval for this study was granted by the local ethics committee (Medical Research Ethics Committee Atrium 15-N-120).

Materials

Co-Design Methods

In interviews and co-creation sessions, the core team adopted various co-design methods, including generative techniques, contextual interviews, system mapping, and prototyping. These methods were adopted to facilitate stakeholder participation during key moments in the design process: generative techniques to elicit tacit knowledge and latent needs, contextual interviews to increase empathy, system mapping to develop a comprehensive overview of the acquired data, and prototyping to make ideas tangible and possible to experience. Co-creation sessions included multiple co-design methods and were specifically employed to empower a variety of stakeholders to participate in the design process.

Semistructured Contextual Interviews

At various time points in the project, we interviewed patients and HCPs. The interviews were performed by 2 researchers and were conducted in the everyday context of the HCPs (treatment facility) and patients (at home). To activate prior knowledge and experiences, all participants received “sensitizers”—assignments that stimulated thinking about relevant topics—before the interview (see page 4 in Multimedia Appendix 1) [36]. During the interview, the primary interviewer explored participants’ beliefs, needs, and experiences using open questions and various generative techniques. The second interviewer took notes and asked additional questions to ensure that all topics that the research team identified during preparatory sessions were covered. Data were collected by audio recording and note taking. Directly after the interview, both interviewers discussed their impressions and updated their notes.

Generative Techniques

To explore participants’ ideas, needs, and values beyond their first response, various generative techniques were employed during interview and design sessions. These techniques aim to bring up “tacit knowledge” by addressing social, emotional, and functional elements related to a topic of interest [36]. For example, to promote a more personal acquaintance during the interview sessions, participants were asked to introduce themselves by selecting 3 pictures from a deck of cards illustrated with ambiguous images that symbolized their personal values. The core team also used journey mapping during interviews (see page 3 in Multimedia Appendix 1). This technique enabled all attendees to collaboratively construct a graphic visualization or a timeline that illustrated their experiences with interdisciplinary multimodal pain treatment [37,38].

Prototyping and Provotyping

A key element of PAR is to increase insight by reflecting on actual interactions with prototypes. As Step 1.3 on page 5 of Multimedia Appendix 1 illustrates, the interaction with these objects stimulated the individual to envision future possibilities or to visualize concept ideas. The process of prototyping allows participants to actively engage with objects that were based on preliminary outcomes and encompass operationalizations of the concept of interest [39]. Provotyping takes place with objects that are not directly related to the final result but are specifically designed to test a specific hypothesis or elicit a particular response [40].

System Maps and Personas

System mapping is a method for creating a visual representation of interacting variables that facilitates the understanding of complex systems [41]. System maps typically include a framework of interrelated components, as well as clarifying examples of quotes and pictures. These maps can be presented in posters or cards and are useful to share data to stakeholders in an accessible way (see pages 7-9 in Multimedia Appendix 1). Moreover, it provides participants with the opportunity to jointly reflect on the data and update ideas during co-creation sessions.

A specific way to represent the data as a coherent “whole” for usage throughout co-design activities is by creating personas: fictitious archetypes of users, each reflecting a distinct pattern in goals, attitudes, and behaviors based on empirical research among potential users. With personas, it is possible to highlight certain areas of tension or to facilitate discussion of important patient characteristics [42].

Co-Creation Sessions

We used co-creation sessions at key moments during the project to discuss and reflect on the collected data, to generate new ideas, and to make decisions regarding future development directions (see page 10 in Multimedia Appendix 1). A typical session would take 4 hours and involved 10-20 stakeholders. The core team prepared the sessions by formulating desired outcomes and setting up system maps to present the data. During the sessions, 2 designers operated as workshop facilitators and used various assignments (eg, prioritizing ideas for prototype concepts) to work towards the desired outcomes in an open atmosphere where everyone was invited to actively participate. All written session data (eg, posters, drawings, notes) were collected and discussed during core team evaluation meetings directly after the session. To maintain involvement and commitment between the sessions, the core team sent bimonthly newsletters and posted updates on the project websites.

Measurements and Analysis

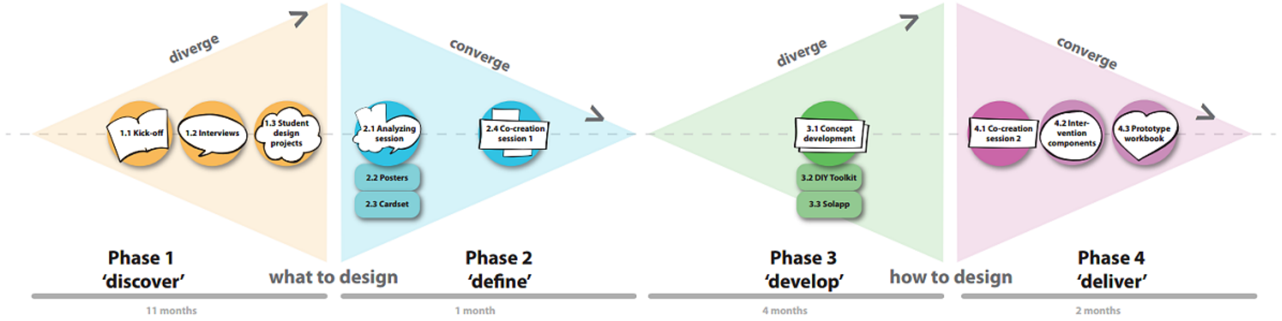
Dataset

The dataset for this case study consisted of 4 different sources. To capture the results of the design methods, researchers documented each design and research activity, using observation notes, pictures, audio files, or video clips. In addition to the session documentation, researchers also organized reflective sessions directly after a co-design activity to summarize the output of co-creation sessions (eg, notes or post-its) into system maps. These maps served both as a descriptive analysis of the data as well as for input during subsequent co-design sessions. The dataset also consisted of minutiae of steering committee meetings and a retrospective project journey. This journey was the result of a reviewing session, where researchers and members of the steering committee chronologically described and discussed critical incidents.

Data Analysis

We used a deductive content approach to identify information within the dataset that relates to our main themes: stakeholder involvement, generation of insights, and incorporation of stakeholder input. We defined stakeholder involvement as the commitment to participate in the development project, to collaborate with other stakeholders during design activities, and to actively participate during these sessions. Generation of insights referred to the extent by which co-design activities resulted in an increased understanding of the problem of interest that could inform subsequent development activities. Incorporation of stakeholder needs was defined as the extent by which prototypes were based on stakeholder perceptions, judgments, and evaluations from co-design activities. Furthermore, we adopted the Double Diamond model to describe the design process along 4 development stages [43]. The Double Diamond model contains 2 sequences of diverging and converging (Figure 1). In diverging phases, choice options and discrepancies are created; in the converging phases, these ideas are refined and considered to make design choices with respect to the prototype. In the first diamond, the “Discover” (diverging) and “Define” (converging) phases relate to acquiring insights on *what* to design. In the second diamond, the “Develop” and “Deliver” relate to further exploring the ideas on *how* to optimally design the final concepts. To illustrate how co-design contributed to the intervention development at each phase, we combined all data sources to provide both a descriptive overview and an in-depth reflection with respect to our main themes. In addition, Multimedia Appendix 1 provides a chronological overview of the development process and includes examples of co-design methods, data segments, and pictures of co-design activities.

Figure 1. Overview of the co-design development process.



Results

Phase 1: “Discover’”

Description

In the “Discover” phase, we aimed to generate a deeper understanding of factors influencing relapse after successful rehabilitation. The primary activities took place over a period of 11 months and consisted of 3 kick-off sessions, 20 stakeholder interviews (12 HCPs, 8 patients), and a student design project. In the first kick-off session, representatives from all consortium partners were present to discuss the project planning and to decide how co-design would be implemented throughout the project. Representatives also participated in co-creation by using their professional and personal experiences to formulate initial ideas on relapse (see page 3 of Multimedia Appendix 1). These activities were repeated during introductory visits by the core team at the 2 participating pain treatment centers. During these visits, the core team also observed multiple treatment sessions and were given a detailed explanation about dose and content of the included treatment modalities. Subsequently, 20 semistructured interviews of approximately 1 hour were conducted and transcribed (see page 4 in Multimedia Appendix 1). During the final activity of phase 1, 60 students divided over 16 teams formulated hypotheses based on the previously collected data and designed provotypes to test their ideas with both healthy participants and patients with chronic pain (see page 5 of Multimedia Appendix 1). At the start of each week, they updated their provotypes based on the received feedback. During the final project session, all teams presented their final provotypes as well as their collected insights to members of the consortium.

Reflection

In phase 1, we were able to create a large qualitative dataset. This dataset not only contained experiences and ideas of stakeholders but also included specific feedback in response to multiple provotypes on a wide array of topics. The consecutive planning of the 3 key activities enabled us to iteratively expand our insights on relapse after pain treatment: Interviews were prepared by using the insights from the kick-off sessions, and the student teams could build upon the preliminary analysis of the available interview data. The participating stakeholders responded positively to the co-design approach and cooperated actively during the sessions and interviews. Despite their inexperience with co-design, the sessions were considered accessible, pleasant, and relevant. However, medical ethical screening procedures and personnel deployment planning limited the possibility for last-minute requests or invitations for including HCPs and patients. The obtained dataset of patient and HCP responses also contributed to a deeper understanding of relevant factors related to relapse, which provided a solid base for further intervention development. For example, the interviews revealed important contextual information such as a “feelings of emptiness after treatment,” “difficulties sharing treatment experiences with friends and family,” and “the different context between the rehabilitation center and the personal environment.”

Phase 2: “Define”

Description

The “Define” phase lasted for 1 month and started with thematically organizing the interviews by means of open coding by the core team (see page 6 of Multimedia Appendix 1) [44,45]. This resulted in 8 main themes and 45 subthemes of factors associated with relapse after successful treatment (see page 7 in Multimedia Appendix 1). To facilitate subsequent co-design activities, the themes were rephrased as questions, plotted on posters, and illustrated with exemplary quotes and figures (see page 8 in Multimedia Appendix 1 for an example). In addition, the core team developed a set of 74 stimulus cards that were designed to facilitate the discussion of specific insights or principles [46]: 36 cards contained insights from the student project, 15 cards contained relevant theory on behavior regulation, and 23 cards contained theory related to chronic pain treatment (see page 9 in Multimedia Appendix 1). Subsequently, patients (4), HCPs (4), researchers (9), designers (6), and students (3) were invited for a co-creation session (see page 10 in Multimedia Appendix 1). During the first assignment, participants were asked to examine the posters and extend them with their own ideas or with stimulus cards. This resulted in 121 notes and 42 cards that were added to the posters. In the second assignment, subgroups were made of participants with varying backgrounds. Each group was instructed to select 1 theme and use the available information to develop an intervention concept. A professional draftsman supported the session by immediately visualizing intervention ideas. The final part of the session consisted of a plenary session where all 5 concepts were presented. During the subsequent discussion, the concepts were compared, and various overarching topics emerged, including “maintaining the positive development after treatment” and “reflection and self-monitoring.” In a subsequent meeting, the steering committee merged these overarching topics into 2 concept ideas: positive reinforcement and direct feedback. The “Define” phase concluded with a design briefing, where the core team commissioned 3 students to develop these ideas into tangible rudimentary prototypes as part of their graduation project.

Reflection

The final system map that included both posters and the card set provided a complete overview of the collected data. This presentation form stimulated participants to combine various insights to develop concept interventions. With respect to stakeholder involvement, the number of patients and HCPs was lower than originally planned. The duration of the session and traveling distance required participants to block a full day, which turned out to be difficult to organize. In line with our findings in phase 1, the co-design methods successfully engaged nonexperts in the design process. The assignment to create concept intervention ideas was concrete and tangible. The resulting 5 concepts were associated with earlier identified patient needs, were grounded in contextual information, and contained relevant insights on relapse prevention. For example, one concept idea focused on monitoring and recognizing early signals of relapse, which was based on stimulus cards (eg, a research insight related to difficulties in unbiased self-monitoring of behavior), interview data (eg, a quote from HCP on the possibility of daily feedback via eHealth), and newly added notes (eg, patient feedback should always be related to patient-specific goals). However, only a fraction of the possible combinations of cards and system maps was explored during this session. Limited time and resources prevented organizing additional sessions to cross-validate the results and achieve saturation.

Phase 3: “Develop”

Description

During the 4 months of the “Develop” phase, students held 5 focus groups to regularly test their ideas with patients and HCPs (see page 11 in Multimedia Appendix 1). For example, by discussing the role of personal values within the treatment program, the students found supporting evidence that these values were strongly related to treatment goals, which subsequently guided the operationalization of the valued-based action plan in one of the rudimentary prototypes. Based on stakeholder feedback and weekly evaluation sessions with the core team, the students worked towards a final rudimentary prototype. One student focused on the transfer of important treatment insights to each patients’ personal context. She developed a toolbox that contained various methods to capture and store therapy insights in order to facilitate retrieval in a relevant personal context (eg, using a personal picture as memory cue for an important moment during treatment). The other 2 students focused on the generation of valued-based goals and the formulation of action plans for each consecutive step towards the goal. Their final rudimentary prototype consisted of a mockup mobile app, allowing participants to browse through all steps that were required to formulate and plan a valued-based goal. In Multimedia Appendix 1, pages 12-13 show the final versions of these rudimentary prototypes.

Reflection

This phase was characterized by a shift from “what” to “how” to design. Accordingly, presentation form, usability, and implementation into existing treatment practice became increasingly relevant. To engage stakeholders, the students visited the treatment centers on multiple occasions. In contrast to other phases, the patients and HCPs could provide feedback on ideas, but were not involved in the decision-making process regarding the final design of the rudimentary prototype, which potentially influenced their commitment. Moreover, their reduced involvement in this phase resulted in limited information regarding the applicability of the rudimentary prototypes in clinical practice.

Phase 4: “Deliver”

Description

In the final phase, the core team merged both rudimentary prototypes into one final prototype intervention over a period of 2 months. To do so, the core team organized a final co-creation session, where the students presented their concepts. The aim of this session was to receive final feedback on the potential value and function of both rudimentary prototypes and to formulate a recommendation to the steering committee with respect to the final prototype design. To facilitate this process, stakeholders (n=14) were instructed to reflect on the concepts by taking various patient perspectives into account. For this purpose, 4 personas were created with variation on 2 characteristics that were often discussed during previous patient interviews. Each persona had either a high or low level of social support and a high or low tendency to protect personal boundaries. In Multimedia Appendix 1, page 14 depicts the discussions between stakeholders as well as the poster that explained the 4 personas. The final conclusion was that both rudimentary prototypes had potential as supportive treatment modalities to prevent relapse after successful treatment. Furthermore, future testing and development should primarily focus on optimizing the active treatment components and calibrating the intervention to the treatment program.

Based on this advice, the steering committee decided to merge both rudimentary prototypes into 1 prototype workbook. The core team composed a list of individual intervention components from each rudimentary prototype (eg, a prompt to set calendar reminders after a goal-setting procedure) and coded these according to the Behaviour Change Technique Taxonomy V1 (see page 15 in Multimedia Appendix 1) [47]. Subsequently, they determined how to transfer the components to a workbook version and performed literature searches to find ideas for optimizing the effectiveness of each component. For example, to assist the formulation of personal values, various value generation procedures were found (eg, [48]) and integrated into the prototype. In addition, the core team checked to which extent the list of intervention components corresponded with the themes of the interview dataset. Of the 19 intervention components, 17 components were related to one or more themes from the dataset, and 27 of the 45 themes were related to one or more intervention components. For example, 4 components in the goal-setting intervention, including specific probing questions to help formulate meaningful values, were associated with the theme “remembering important goals and values after treatment.” A designer, a text editor, and 3 HCPs provided feedback with the conversion to a paper workbook intervention and respectively focused on the design, readability, and appropriate terminology. In Multimedia Appendix 1, page 16 shows examples of the 2 included strategies: the value-based goal forms (b and c) and the Insight Cards (d).

Reflection

Previous difficulties with recruiting sufficient patients for co-creation sessions caused us to search for alternative ways to include their viewpoint. The personas proved a useful method to incorporate various patient perspectives by proxy during the evaluation of the rudimentary prototypes. Furthermore, the validation check indicated that the majority of the intervention components could be traced back to the original stakeholder themes from the interventions in the “Discover” phase and vice versa. This illustrates that stakeholder input has been incorporated in the design. However, the decision to combine both prototype ideas into one intervention was unexpected, which resulted in last-minute planning and consequently in limited stakeholder involvement during the design of the workbook. This may threaten the usability of this prototype in clinical practice.

Discussion

Principal Findings

The primary aim of this study was to reflect on the value and function of co-design methodology during the development of an intervention that prevents relapse after successful pain treatment. In the analysis, we focused on idea generation, stakeholder involvement, and the incorporation of stakeholder input within the development process. Overall, the generative techniques that were employed supported patients and HCPs with sharing their perspectives on pain treatment and relapse, which was in line with our hypothesis. Moreover, the techniques steered the conversations beyond stakeholders' primary responses, often resulting in a detailed account of their personal experiences with the treatment program and of their attempts to integrate treatment insights into their personal environment. In addition, system maps, personas, and prototypes enabled nonexperts to actively participate in design activities. A possible explanation for the successful engagement of stakeholders during the project is that experienced co-designers constantly translated hypotheses and abstract ideas into provotypes or prototypes. This method is particularly useful to provoke user reactions or to rapidly visualize an idea, which evokes interactions with an actual object rather than reflections on past experiences of hypothetical situations [39]. In addition, the used co-design materials helped to transform each location where co-design activities took place (eg, treatment facility or patient home) into a workshop environment that stimulated active participating and emphasized equality between all participants. This is especially important for health care settings, where conventional power relationships between patients and HCPs threaten effective cooperation during design activities [18,19].

With respect to stakeholder involvement, many different patients, HCPs, researchers, students, and designers participated during the study, which was also in line with our hypothesis. The stakeholder interactions mostly consisted of independent design activities that required low commitment and little effort. In contrast, the members of the core team remained active throughout the project, which increasingly created an imbalance in knowledge and involvement between the core team and other participants in co-design activities. This may explain why the role of the stakeholders gradually shifted from “user as partner”—where all participants within the sessions contributed as equals in the design activities—towards “users as subject”—where participants mainly provided expert opinions or performed delimited tasks (eg, usability testing) [49]. Consequently, the concepts underlying the intervention have been thoroughly grounded in stakeholder input and expertise, but the applicability of the current workbook operationalization within the treatment programs requires further testing to examine whether the current strategies fit patient preferences and can be integrated in treatment programs in the form of the current prototype.

This project shows similarities to the experience-based co-design (EBCD) approach, which aims to improve health care services by actively involving stakeholders to collect knowledge and experiences, to set priorities, and to develop solutions [18,50]. Although this project did not follow the 6 stages of EBCD, the overall objectives as well as the systematic partnership with patients, HCPs, designers, and researchers are alike. A notable difference was the focus within this project on actual prototype development throughout all phases, which promoted a solution-focused orientation for the participants. Alternatively, in EBCD, more emphasis is placed on ensuring that the collected patient experiences are received and understood by other stakeholders (eg, by showing a film of patient interview segments that reflect key themes), before continuing to developing improvements [18]. These differences illustrate the versatility of co-design and its potential to adapt to different design environments.

Strengths and Limitations

The extensive documentation of the co-design activities allowed for a detailed reconstruction of the development process. Furthermore, during co-creation sessions, steering committee meetings, and the construction of the retrospective journey, representatives from all research groups were present, which resulted in a continuous integration of various perspectives during the project. However, we did not film or record any of the co-creation sessions. Although analyzing audio or video would have been time consuming, it would have provided further possibilities to observe stakeholder discussions during design activities and to include additional insights that we did not record.

During the project, we experienced a tradeoff between validating the outcomes of co-design activities and analyzing the results for the next iteration. For example, an additional co-creation session during the "Define" phase with different stakeholders could have cross-validated the outcomes of the initial session. However, given limited resources, this would have resulted in fewer development iterations in the remaining period. A key argument in favor of more iterations is that quickly integrating stakeholder input into subsequent sessions directly visualizes the value of their input [51]. However, a tendency towards more iterations increases the uncertainty to what extent the outcomes of this project can be generalized to the population [33].

Future Recommendations

This study adds to the increasing number of initiatives that use co-design to structurally integrate contextual factors into the development of health care interventions (eg, [21,22,52,53]), which help bridge the gap from development to actual implementation [12,13]. When using co-design, it is important to relate the findings of the process to existing theories and treatments, for instance by using the behavior change technique taxonomy [23,47]. This strengthens the co-design approach by combining stakeholder evaluations with existing theory. Importantly, further integration between co-design and theory-driven approaches only becomes possible when using rigorous testing to evaluate the outcomes of the co-design process [13]. Consequently, an important next step in answering the question about whether co-design helps inform the development of health interventions will involve more examples of development projects. In these examples, co-design–based interventions are ideally subjected to experimental testing. Furthermore, we believe that future co-design projects in the health care domain should include detailed planning of activities and take lengthy medical ethical approval procedures into account [51].

Conclusions

To acquire a better understanding of how co-design may benefit the development of interventions in the health care domain, examples of good practice are necessary**.** In this article, we presented such an example. By critically reviewing the value and function of a co-design project with respect to idea generation, stakeholder involvement, and incorporation of stakeholder input into the development process, we demonstrated how co-design contributed to the transition from ideas, via concepts, to prototypes.

Acknowledgments

We thank the researchers Jan Pool, Manon Beetstra-Huszar, Albère Köke, and Roos Tigchelaar for their continuous support with collecting and analyzing the data. We also thank Rianne Schaekens, Deloryan Hommers, and Yasmijn Baas for their assistance in the development phase during their graduation projects.

Abstract

Background: Alcohol consumption is associated with a wide range of adverse health consequences and a leading cause of preventable deaths. Ride-hailing services such as Uber have been found to prevent alcohol-related motor vehicle fatalities. These services may, however, facilitate alcohol consumption generally and binge drinking in particular.

Objective: The goal of the research is to measure the impact of ride-hailing services on the extent and intensity of alcohol consumption. We allow these associations to depend on population density as the use of ride-hailing services varies across markets.

Methods: We exploit the phased rollout of the ride-hailing platform Uber using a difference-in-differences approach. We use this variation to measure changes in alcohol consumption among a local population following Uber's entry. Data are drawn from Uber press releases to capture platform entry and the Behavioral Risk Factor Surveillance Systems (BRFSS) Annual Survey to measure alcohol consumption in 113 metropolitan areas. Models are estimated using fixed-effects Poisson regression. Pre- and postentry trends are used to validate this approach.

Results: Ride-hailing has no association with the extent of alcohol consumption in high (0.61 [95% CI –0.05% to 1.28%]) or low (0.61 [95% CI –0.05% to 1.28%]) density markets, but is associated with increases in the binge drinking rate in high-density markets (0.71 [95% CI 0.13% to 1.29%]). This corresponds to a 4% increase in binge drinking within a Metropolitan Statistical Area.

Conclusions: Ride-hailing services are associated with an increase in binge drinking, which has been associated with a wide array of adverse health outcomes. Drunk driving rates have fallen for more than a decade, while binge drinking continues to climb. Both trends may be accelerated by ride-hailing services. This suggests that health information messaging should increase emphasis on the direct dangers of alcohol consumption and binge drinking.

binge drinking; drunk driving; road traffic safety; ride-hailing; alcohol consumption; difference in differences; Uber

Introduction

Background

Alcohol consumption is a serious public health issue with significant implications for personal health and well-being [1]. Between 2006 and 2010, more than 88,000 people lost their lives as a result of alcohol abuse in the United States; 56% of those deaths occurred because of acute events like motor vehicle collisions or alcohol poisoning [2]. Scholars have tied alcohol consumption to a host of deleterious societal outcomes, including spousal and child abuse [3]; inability to maintain gainful employment [4]; and personal health concerns in the form of diabetes, liver disease, and sexual dysfunction [5]. Prior work has also documented many associated factors that can accelerate alcohol consumption, including peer pressure and social norms [6], financial distress [7], and mobility and public transit accessibility [8], the context of this investigation.

Urban mobility is particularly notable when one considers the changes in the market for individual transportation over the last 10 years (ie, ride-hailing). Whereas people were once forced to drive themselves or depend on often unreliable alternatives (eg, public transit or taxis), ride-hailing services now offer a simple solution that is integrated with an individual’s smartphone. Uber, for example, completed its 10 billionth ride in June 2018, and ride-hailing more generally accounts for a significant share of the urban mobility market. Moreover, recent academic work has begun to assess the relationships between ride-hailing services and public health outcomes (eg, traffic fatalities [9,10], occurrence of assault [11-13], ambulance use [14], and rates of drunk driving [15]). In this work, we delve into the question of whether ride-hailing services affect the extent of alcohol consumption within the population (ie, prevalence) as well as the intensity of consumption (binge drinking).

Research Objectives

Research into the social implications of ride-hailing services is wide ranging. A significant body of work has been devoted to the economic implications of ride-hailing, including the effect on entrepreneurship [16], durable goods purchases [17], and the labor market more broadly [18]. Research has also begun to examine social issues stemming from ride-sharing. Findings are diverse and include diminished rates of sexual assault [12], increases in property crimes [11], and a reemergence of bias based on ascriptive characteristics which has traditionally be absent from online transactions [19,20]. However, the largest body of work in this space has, unsurprisingly, focused on motor vehicle safety [9-11] and, more specifically, the effect on drunk driving [13,15].

The potential drunk driving and ride-hailing relationship is intuitive. Platforms like Uber are more accessible than limousine services and more ubiquitous and reliable than taxis [21,22], and thus people may shift from driving under the influence to ride-hailing. The fact that ride-hailing is often a complement to public transportation [23,24] only underscores this idea. Because ride-hailing services can solve the last mile problem for people reliant on public transportation and provide point-to-point transportation for those not reliant on public transportation, the need to drive should be diminished.

We build on past lines of inquiry and offer a first consideration of whether ride-hailing services facilitate a greater extent of alcohol consumption (a larger number of individuals consuming alcohol) and a greater intensity of alcohol consumption (more binge drinking). Ride-hailing services might simply displace alcohol consumption which used to occur at home by making it easier to go to bars, restaurants, and night clubs. However, past work has found that people elevate their alcohol consumption in the presence of an assured transportation option (eg, a designated driver [25]). For example, when the city of Washington, DC, extended the Washington Metropolitan Area Transit Authority train hours (ie, mass transit) to after last call, there was not only a sharp drop in drunk driving but a significant increase in property crimes associated with drinking to excess [8]. Given the relative ease with which individuals can obtain a ride-hailing trip following a night of drinking, it is plausible that ride-hailing services would increase both the extent and intensity of alcohol consumption. Coupled with the public costs associated with excessive alcohol consumption, approximately $250 billion in the United States in 2010 [26], any connection between ride-hailing access and drinking activity would have important policy implications.

Our analyses test two hypotheses. Our first hypothesis (H1) is that access to ride-hailing services increases alcohol consumption at the extensive margin (ie, raising the number of individuals drinking alcohol). Our second hypothesis (H2) is that access to ride-hailing services increases alcohol consumption at the intensive margin (ie, the amount of alcohol a given individual consumes in a sitting). The distinction between these hypotheses is important. While public health interventions and many laws focus on the intensity of individual alcohol consumption (drinking to excess), recent work suggests that the extent of alcohol consumption may also be a concern in its own right as even one drink of alcohol daily has been associated with negative health outcomes [1].

Considering our two hypotheses, it is also important to note previous research, which suggests that the effects of ride-hailing services are heterogeneous across markets [23,24]. Ride-hailing platforms are subject to network effects (riders require a sufficient supply of drivers and vice versa), thus population density is typically crucial to their adoption. Further, past work notes that ride-hailing services are often employed as complements to public transit [23], and thus their relationship to drinking activity is likely to be more apparent in locations characterized by higher population density, where transit options are more readily available (eg, taking the train into the city and an Uber home). Finally, locations characterized by greater population density are also more likely to bear a greater density of drinking establishments, suggesting a larger upper bound on the possible rise in drinking. Given these points, we conduct our analyses while distinguishing between locations characterized by higher versus lower population density.

Methods

Data

We combine data on the diffusion of ride-hailing services with information on alcohol consumption and population density.

Data on alcohol consumption are drawn from the Behavioral Risk Factors Surveillance Survey (BRFSS). The BRFSS data are collected as part of the Selected Metropolitan Area Risk Trends program from the Centers for Disease Control and Prevention (CDC). These data include annual counts of respondent answers to questions about risky behaviors, including alcohol consumption, for a select set of metropolitan areas. We examine two such questions: respondents' engaging in any drinking in the prior 30 days and binge drinking in the past week (the latter defined as consuming 5 or more drinks in a single session for males and 4 or more drinks for females). BRFSS measures for any and binge drinking are not available for every Metropolitan Statistical Area (MSA) year because the survey is conducted by the CDC only in those locations that meet certain sampling criteria, and positive response counts (responses of yes) are reported only in cases where a minimum threshold of 50 responses was obtained for the MSA. As a result, some locations enter and exit the sample over time. That said, numerous studies have been conducted that speak to the validity and representativeness of the BRFSS data.

Data on Uber's entry into different locations are drawn from public press releases and announcements on Uber's website (see Multimedia Appendix 1 for a list of Uber entry dates for the geographies comprising our sample). Uber presence is coded as a dichotomous indicator equal to 1 once Uber (in any format, whether Uber X or Uber Black) enters any city or township within a given MSA, and 0 in preceding years. We focus our analysis on Uber for 3 reasons. First, competing services (eg, Lyft) systematically enter after Uber, except in a handful of rare instances. Second, Uber is the largest ride-hailing platform by rider base and revenue ($82.4 billion in 2019) [27]. Third, the other dominant ride-hailing service in the United States, Lyft, operates a very similar business model, implying it would have a very similar effect. In fact, they are so similar that drivers and riders frequently multihome, switching between the two services [28].

Finally, we incorporate US Census Bureau measures of MSA population density, because prior work has documented that Uber's influence is particularly pronounced in dense urban areas [15]. Markets with dense populations are thicker—having more potential drivers, consumers, and destinations within a region—and it is reasonable to expect that consumers experience better service with reduced wait times and lower fares. As such, we expect larger associations in these population dense areas.

Our sample spans 2010 through 2016, comprising 113 MSAs in which both ride-hailing entry dates were recoverable, and where BRFSS measures of alcohol consumption were available for at least 2 years. Each MSA is observed for an average of 6.5 years. This combined sample, coupled with the fact that Uber enters different locations at different times, allows us to measure systematic changes in alcohol consumption after ride-hailing service entry. Summary statistics are in Table 1. As can be seen in the table, any drinking is reported by 56.12% (1025.78/1827.91) of respondents on average, while 17.23% (315.03/1827.91) report binge drinking. Uber first enters our sample in 2011. Entry was gradual for the first few years, accelerated rapidly in 2014, and was nearly universal by 2016.

Table 1. Descriptive statistics.

Variable	Mean (SD)	Median	Minimum	Maximum	Observations
Uber presence	0.41 (0.49)	0	0	1	730
Binge drinking[a]	315.03 (311.67)	205	18	2067	728
Any drinking[b]	1025.78 (1016.11)	675	79	6030	730
BRFSS responses[c]	1827.91 (1682.07)	1293.5	464	9333	730
Population density[d]	2469.02 (2191.48)	1953.5	7.2	13,597.50	588

[a] Binge drinking reflect the number of respondents who indicated they had 5 or more drinks (in the case of males; 4 or more drinks in the case of females,)on a single occasion in the prior 30 days.

[b] Any drinking reflects the number of respondents indicating they consumed at least one alcoholic beverage in the prior 30 days.

[c] BRFSS: Behavioral Risk Factors Surveillance Survey.

[d] Population density reflects people per square mile within 10 miles of city hall.

Statistical Analysis

Measuring the relationship between alcohol consumption and ride-hailing service availability is inherently challenging, particularly given that Uber may have selectively entered markets characterized by heavy—or even growing—rates of alcohol consumption in an effort to optimize both its ridership and profits. That is, ride-hailing services are known to be used more intensely on Friday and Saturday nights, and Uber may have selectively entered markets with higher levels of alcohol consumption with the objective of capturing that demand. We address this selection problem by employing a difference-in-differences approach [29,30]. In doing so, we measure the change in alcohol consumption before and after Uber entered into an MSA relative to the change in markets where Uber had yet to enter. Parameters are estimated based on a difference-in-differences Poisson regression, incorporating location (α_l) and time (τ_t) fixed effects, with standard errors clustered by MSA. Equation 1 reflects the regression model that we estimate. Our independent variable of interest is *Uber*, which takes a value of 1 if MSA l had received any form of Uber as of year t. Our coefficient of interest is β, which reflects our estimate of the relationship between Uber entry and alcohol consumption. Additionally, we incorporate BRFSS respondent counts for MSA l as an exposure term in the regression.

$$Log\ (Drinking_{l,t}) \sim \alpha_l + \tau_t + \beta \cdot Uber_{l,t} + \varepsilon_{l,t}\ (1)$$

We calculate and report the estimated change in the incidence rate of any drinking and binge drinking among respondents in a location based on marginal effects. Further, given that ride-hailing's impact should differ across markets based on population density, we split the sample and estimate separate models for markets having above- and below-median population densities, based on measures reported by the US Census Bureau, derived from the 2010 Census.

Robustness and Sensitivity

Before examining the results of the above estimations, we first discuss the robustness and sensitivity checks. First, we began by testing for pre-entry changes in alcohol consumption in the periods leading up to Uber's entry into an MSA. Significant differences prior to Uber's arrival would imply violation of the parallel trend assumption that underlies difference-in-differences estimation. Evaluating the parallel trends assumption is important to ensure our estimates are not driven by Uber systematically selecting into cities, in a manner that merely correlates with expected or ongoing growth in drinking activity. As Uber representatives have emphasized its widespread use in traveling to or from bars on weekend nights, selection effects on Uber's part are certainly possible and of concern. Put another way, while the location fixed effects included in our regression model make it robust to Uber entering markets with higher persistent levels of drinking activity or any other stable and unchanging features of that location, systematic entry by Uber into markets that exhibit growing trends in binge drinking, even before Uber's arrival, would violate the baseline assumptions of the model by creating a dynamic, time-varying, confounder for the estimated association between Uber presence and alcohol consumption.

To implement this test, we estimate a relative time variant of difference-in-differences regression [30]. In doing so, we construct a set of indicators capturing the relative (to Uber entry) year that an observation had taken place, which is defined based on the timing of Uber's arrival in a particular MSA. In this regression, we omit the 2 years preceding Uber's arrival, taking these as a joint reference period. It should be noted that a degree of freedom is lost in the estimation because we jointly estimate both absolute and relative time dummies (ie, year and year from Uber entry), so two reference periods must be omitted for the other model parameters to be identified. This specification allows us to estimate the relationship between Uber entry and drinking flexibly, as we can observe differences (or the absence of difference) in both pre- and postentry drinking trends. With this regression, if the assumptions of the model hold, we expect to observe positive and significant differences in the years following Uber's arrival relative to the 2 years just prior to an Uber arrival in any MSA but no significant differences in the years prior (eg, 3, 4, or 5 years prior).

Second, we explored sensitivity of our results to our choice of population density measure. Our baseline analyses employ a measure from the Census Bureau reflecting the population per square mile residing within 10 miles of city hall. Given that this choice of radius is to some degree arbitrary, our goal is to ensure that any results are not sensitive to the choice. We therefore also considered splits using alternative measures of population per square mile, namely with a radius of 5 miles to city hall and again within 2 miles of city hall.

Results

Statistical Analysis

Results of our primary regression analyses appear in Table 2. We observe no significant relationship between Uber's presence and the extent of alcohol consumption (ie, any drinking). Table 2 indicate a lack of significant change in any drinking across both high- and low-density markets. Uber's entry is, however, associated with a significant rise in binge drinking within high-density MSAs. Table 2 reports a marginal estimate of 0.71 (95% CI 0.133% to 1.289%). This indicates that Uber's entry is associated with an additional ~0.70% increase in the population's binge drinking rate. This corresponds to a 4% relative increase in the binge drinking population in a given MSA.

Table 2. Marginal effects of ride-hailing on alcohol consumption in high- and low-density Metropolitan Statistical Areas.

Characteristic	Uber presence % (SE)	95% CI	Year fixed effects	MSA[a] fixed effects	Observations	MSAs	χ^2
Any drinking							
Low density	–1.10 (0.63)	–2.33 to 0.13	Yes	Yes	264	61	64.99 (7)
High density	0.61 (0.34)	–0.05 to 1.28	Yes	Yes	324	52	120.15 (7)
Binge drinking							
Low density	–0.12 (0.61)	–1.31 to 1.07	Yes	Yes	263	61	700.57 (7)
High density	0.71 (0.30)	0.13 to 1.29	Yes	Yes	324	52	265.65 (7)

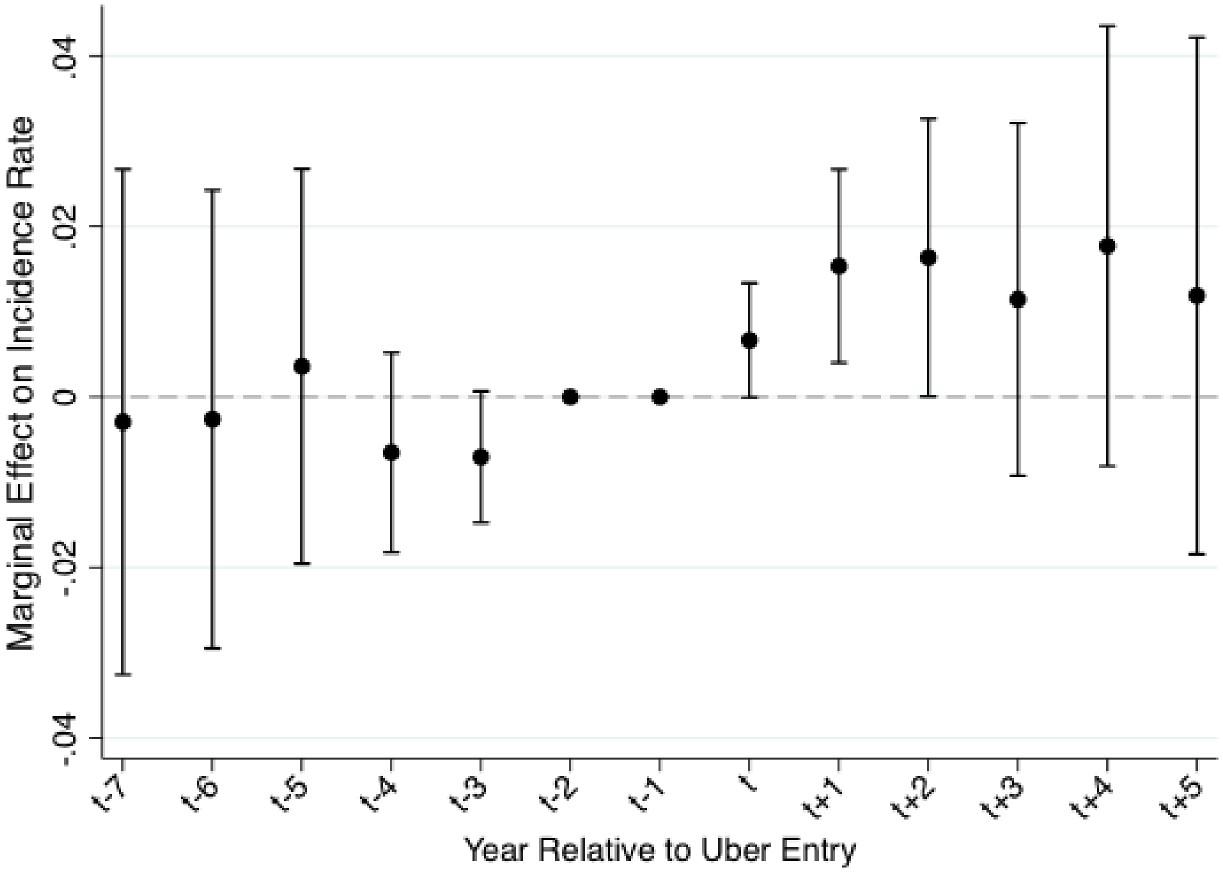
[b]MSA: Metropolitan Statistical Area.

It should be noted that the estimated association between Uber presence and binge drinking in high-density MSAs persists following a correction for multiple comparisons. Specifically, applying a very conservative Bonferroni correction, we would rely on a significance threshold of 0.025 (for a 1-tailed test, consistent with the directional nature of the hypotheses). The observed *P* value associated with the relationship between Uber presence and binge drinking within high-density MSAs is .02. Although we observe a statistically significant association between Uber presence and binge drinking in high-density MSAs, it is important to note that the estimated coefficient is not significantly different from the estimate recovered in low-density MSAs. Thus, our findings only support a conclusion that Uber is significantly associated with a rise in binge drinking in high-density MSAs, not that the association is systematically larger in high-density MSAs as compared with low-density MSAs [31].

Robustness and Sensitivity Results

Figure 1 provides a graphical representation of relative time differences for binge drinking in high-density MSAs. As discussed, we employed this model to test for time-varying differences in binge drinking preceding Uber's entry, which would indicate a possible spurious relationship. Each point is a parameter estimate corresponding to leading (t–7 to t–3) and lagged (t to t+5) differences. Consistent with prior work, all estimates are conducted relative to the 2 years (t–1 and t–2) preceding Uber's entry (period t) [15]. The leading, or preperiod, estimates are uniformly small and statistically insignificant despite our use of relatively conservative (90%) confidence intervals. These results provide empirical support for our difference-in-differences strategy as they suggest no violation of the parallel trends assumption. It therefore appears reasonable for us to believe that Uber's entry is exogenous with respect to drinking activity, conditional upon controls. The significant association with binge drinking persists in years following Uber's entry into a market (ie, t+1 to t+5). These findings are again consistent with our difference in differences strategy. As expected, the confidence intervals are wider in the tails of our distribution (eg, for t–4 or less and t+3 or more) where there is less data available to perform the estimation (ie, there is a lack of power in the estimations because few cities have had Uber for such a lengthy period of time). In sum, our findings are consistent with those reported in Table 2 and provide empirical support for the assumptions of our research design (ie, parallel trends).

Figure 1. Marginal effects of relative year dummies in dense Metropolitan Statistical Areas (90% confidence intervals).



Results of our sensitivity around the population density measure are in Table 3 (ie, population per square mile within 5 miles and 2 miles of city hall). With each alternative measure, we continue to observe that higher density MSAs exhibit a significant increase in the incidence of binge drinking following Uber's arrival. No significant association is observed in low density MSAs.

Table 3. Robustness check: marginal binge drinking effects using alternative density measures.

Characteristic	Uber presence % (SE)	95% CI	Year fixed effects	MSA[a] fixed effects	Observations	MSAs	χ^2
5 miles of city hall							
Low	–0.65 (0.44)	–1.50 to 0.21	Yes	Yes	322	74	125.50 (7)
High	0.63 (0.23)	0.17 to 1.09	Yes	Yes	406	74	345.94 (7)
2 miles of city hall							
Low	–0.14 (0.56)	–1.24 to 0.96	Yes	Yes	317	71	108.53 (7)
High	0.52 (0.24)	0.06 to 0.99	Yes	Yes	406	72	346.20 (7)

Discussion

Principal Findings

We examined the association between ride-hailing platform entry and alcohol consumption. While prior work has tied ride-hailing to decreases in levels of drunk driving [13,15], the secondary implications of low-cost urban mobility have received scant attention. Results are nuanced. On one hand, ride-hailing is not associated with the number of people who consume alcohol in general (ie, the extensive margin). This is encouraging and suggests the presence of ride-hailing is not causing greater numbers of people to consume alcohol. The platform is, however, significantly associated with binge drinking in densely populated markets (ie, the intensive margin). This is cause for concern. Given the national and personal costs associated with binge drinking [32], these findings compound an already alarming national trend [33]. This suggests that although ride-hailing may reduce drunk driving, people update their behavior to exploit the assured mobility ride-hailing offers.

These findings suggest that Uber's entry increases binge drinking by 4% in adult urban populations and point to valuable directions for future research. Prior work indicates that most binge drinking occurs among the young (aged 18 to 34 years) and is twice as common among men [25]. As ride-hailing associates with binge drinking, it is likely that the association would be concentrated in younger populations. However, this is speculative, and it is important to assess where behavioral changes are occurring. To the extent that means of viable travel are already established for younger groups, specifically when they are under the influence, it is plausible that these groups may also fail to exhibit changes in their behavior once Uber arrives. Ride-hailing may, instead, be associated with binge drinking increases among groups that are traditionally less at risk, by affording them greater mobility. It is also important to assess whether or not these differences manifest asymmetrically between men and women. Inasmuch as alcohol consumption has been associated with the incidence of sexual assault [12,34] and lesser infractions like property crime [8], the possible negative implications of Uber arrival for public safety through its relationship with binge drinking are important to consider. These services may also benefit public safety (eg, by affording a secure means of transport home late at night). Additional work is clearly needed to tease out whether ride-hailing services have a net beneficial or detrimental association with public safety measures.

Limitations

This work is subject to certain limitations. Most notably, our estimates focus on the entry of ride-hailing services. The exact reasons that ride-hailing services significantly associate with increases in binge drinking in our sample are not altogether clear. This is a natural limitation of secondary data. Several possibilities exist. For example, recent work has noted that ride-hailing services can, in some instances, enhance access to public transit [23]. As such, the result we observe may be explained not just by ride-hailing services access but access in tandem with public transit options (which tend to be better in areas characterized by high population density).

Because we lack individual level data, the underlying associations are likely to be much larger for subpopulations that are most affected. One potentially valuable path forward, which our sample does not allow us to explore, are to consider effects across different subpopulations (eg, age, gender, and local area characteristics like educational composition and access to mass transit). In this context, where we to explore various sources of heterogeneity in a data-driven, exploratory manner, it would be necessary to implement stringent corrections for multiple corrections effectively reducing our already limited statistical power. Future work can look to address these aspects.

Our findings may be vulnerable to time-varying unobserved confounds (ie, unobserved factors) that might correlate over time with both Uber's entry and binge drinking rates. That said, for this to be a concern, the dynamic confounds would need to vary systematically with Uber's entry timing, which seems unlikely. Finally, our sample is potentially not representative, given the CDC's application of sampling criteria in its administration of the BRFSS. The fact that the BRFSS does not report levels of drinking for all MSA-years does raise concerns of external validity. Yet, as the reported MSAs are almost uniformly larger and more densely populated, it is likely that the unreported MSAs would react in a way that is similar to the less densely populated MSAs reported in the sample. Still, future work is needed to tease out these dynamics robustly.

Conclusion

Policy makers must consider the full range of public health consequences when regulating ride-hailing services and accordingly design appropriately nuanced interventions. While the observed drop in drunk driving is clearly beneficial, any causal association with increased binge drinking would be problematic. Two paths forward are thus evident. First, traditional health information campaigns have focused nearly exclusively on preventing people from getting behind the wheel. Drunk driving rates have been dropping for more than a decade, and this process may have been accelerated by ride-hailing. However, the evidence presented in this work indicates that messaging regarding alcohol consumption may need to be updated to address the growing problem of binge drinking. That is, while the information campaign against drunk driving should continue, our findings suggest that policy makers may instead wish to focus on the direct health effects of binge drinking. Second, it may be useful to partner with ride-hailing services to incentivize behavior through the platform. Beyond training drivers on how to appropriately manage and deal with intoxicated customers (eg, how to identify when they should be taken to hospital for medical care), opportunities exist to track excessive drinking at either the individual or local level (ie, behavioral surveillance) and incentivize more responsible behavior among citizens (ie, subsidized discounts for not drinking to excess). Critical to the success of these programs will be to ensure the platform is not imposing additional costs on binge drinkers, as this creates an incentive for them to return to driving under the influence.

We hope this work serves as a greater call to continue to explore the relationships between ride-hailing and public population health factors as well as the peer to peer sharing economy more broadly. Given that policy makers can only design effective interventions when presented with a full set of facts regarding the consequences of ride-hailing services, it is incumbent upon the research community to continue to provide rigorous insights, be they positive or negative, for practice or policy. Only in this way can we enable policy makers to implement steps that attenuate the negative aspects of ride-hailing and other digital platforms and amplify the positive aspects.

Abstract

Background: General practices (GPs) in England have recently introduced a nationwide electronic personal health record (ePHR) system called Patient Online or GP online services, which allows patients to view parts of their medical records, book appointments, and request prescription refills. Although this system is free of charge, its adoption rates are low. To improve patients' adoption and implementation success of the system, it is important to understand the factors affecting their use of the system.

Objective: The aim of this study is to explore patients' perspectives of factors affecting their use of ePHRs in England.

Methods: A cross-sectional survey was carried out between August 21 and September 26, 2017. A questionnaire was used in this survey to collect mainly quantitative data through closed-ended questions in addition to qualitative data through an open-ended question. A convenience sample was recruited in 4 GPs in West Yorkshire, England. Given that the quantitative data were analyzed in a previous study, we analyzed the qualitative data using thematic analysis.

Results: Of the 800 eligible patients invited to participate in the survey, 624 (78.0%) returned a fully completed questionnaire. Of those returned questionnaires, the open-ended question was answered by 136/624 (21.8%) participants. A total of 2 meta-themes emerged from participants' responses. The first meta-theme comprises 5 themes about why patients do not use Patient Online: concerns about using Patient Online, lack of awareness of Patient Online, challenges regarding internet and computers, perceived characteristics of nonusers, and preference for personal contact. The second meta-theme contains 1 theme about why patients use Patient Online: encouraging features of Patient Online.

Conclusions: The challenges and concerns that impede the use of Patient Online seem to be of greater importance than the facilitators that encourage its use. There are practical considerations that, if incorporated into the system, are likely to improve its adoption rate: Patient Online should be useful, easy to use, secure, and easy to access. Different channels should be used to increase the awareness of the system, and GPs should ease registration with the system and provide manuals, training sessions, and technical support. More research is needed to assess the effect of the new factors found in this study (eg, lack of trust, difficulty registering with Patient Online) and factors affecting the continuing use of the system.

Introduction

Background

Over the past 2 decades, there has been a rapid and widespread diffusion of electronic personal health records (ePHRs) in health care institutes [1]. The Markle Foundation defines ePHRs as web-based portals that enable users to access their medical records stored by their health care providers [2]. Other services can be added to ePHRs, such as booking appointments, requesting referrals, messaging health care providers, requesting medication refills, and educational materials [3,4]. Several benefits may be gained from using ePHRs, such as empowering patients [5,6], increasing their adherence to medication [7,8], improving their self-management [8,9], enhancing patient-provider relationships and communications [10,11], decreasing adverse events and allergic reactions [11,12], and avoiding duplicated tests [11,12].

General practices (GPs) in England started implementing ePHRs in 2003 when patients were enabled to access their full records through kiosks installed in some GPs. These kiosks allow patients to check their demographic information, consultations, test results, letters, and allergies [13].

In 2007, the National Health Service (NHS) offered patients in England access to their Summary Care Records (SCR) through HealthSpace [14-16]. HealthSpace is a secure web-based personal health record that has several functions: booking or canceling hospital appointments, recording and charting health indicators (eg, vital signs, weight, peak flow), calendar with email reminders, NHS address book, links to educational sources, secure messaging, and access to the SCR [15,17]. The SCR is a summary of key health information (allergies, adverse reactions, current medications, and main diagnoses) extracted from patient electronic medical records held by their general practitioners, and it is stored centrally and accessible by authorized NHS staff in urgent situations [14,16]. Because of the low adoption rate and technical issues, HealthSpace was shut down in December 2012 [18].

In 2015, the NHS implemented ePHRs under a program called Patient Online or GP online services, which enables users to book appointments, request prescription refills, and access coded information in their medical records such as demographics, medications, allergies, test results, problems list, immunizations, and medical and surgical procedures [19]. Currently, it is the largest ePHR in England, given that it has been implemented in more than 99% of GPs [19]. As the system is provided by different companies, it is called by different names such as Patient Access, Patient Services, The Waiting Room, and SystemOnline [19]. GP online services have been introduced in the United Kingdom at a time when funding for the NHS is under pressure. Given the context of austerity, individual practices have limited resources to support the rollout of GP online services.

Research Problem and Aim

Despite the potential benefits of ePHRs, their adoption rate in England was only 28% by the end of June 2019 [20]. Identifying the factors affecting patients' use of ePHRs is important to improve patients' adoption and the implementation success of ePHRs [21-25]. A systematic review of 97 studies found that factors affecting patients' use of ePHRs in England have not been examined, and there is a lack of qualitative studies (8%) in this topic [26]. Accordingly, this study aimed to explore patients' perspectives of factors affecting their use of ePHRs (Patient Online) in England.

Methods

Data Collection

A cross-sectional survey was conducted between August 21 and September 26, 2017. In this study, a self-administered questionnaire was used to collect quantitative data through closed-ended questions and qualitative data through an open-ended question (Multimedia Appendix 1). The qualitative data provide the focus of this study. Note that the findings from the quantitative analysis of the survey data were presented in a previous paper [27]. The survey gained health research authority approval before starting data collection (The Research Ethics Committee reference number: 17/SC/0323).

Sample

A convenience sample of patients was recruited from 4 GPs in West Yorkshire, England. Patients were eligible to participate if they (1) lived in England and were registered at 1 of the 4 GPs, (2) were aged 18 years or older, and (3) had not used Patient Online before (nonusers).

Analysis

The qualitative data were analyzed using thematic analysis. Given the exploratory nature of this study, an inductive approach was used to generate themes directly from the data [28]. The analysis was performed following the steps proposed by Braun and Clarke [29]: (1) familiarizing with the data through scrutinizing and rescrutinizing the transcript; (2) coding data systematically; (3) generating subthemes and themes from codes; (4) checking the fit of those themes and subthemes to the original utterances and drawing an initial thematic map; (5) refining and regrouping some inappropriate codes and generating meta-themes from the themes for more granular grouping; and finally, (6) defining and naming subthemes, themes, and meta-themes. We followed the guidelines of Braun and Clarke, as these are considered the most systematic guide for conducting thematic analysis to date [30,31]. The analysis was carried out by the first author (AA), and the validity of codes and themes was checked by another author (BB). AA and BB discussed codes and themes. Where AA and BB had differing views on the code labels and/or thematic content, these discrepancies were resolved through discussion. In all cases, agreement was reached between AA and BB. Microsoft Excel was used to manage the analysis process.

Results

Collected Data

Out of the 800 eligible patients invited to participate in the survey, 624 (78%) participants completed the questionnaire. Of those participants, 136 (21.8%) answered the open-ended question. The 136 comments contained 221 utterances. A comment refers to the whole text written by a participant as a reply to our question, whereas an utterance refers to a part of the comment that has one idea or thought. In total, 3 of the 221 utterances were excluded because 2 utterances were illegible and the meaning of 1 utterance was not discernible. The final number of utterances included in the thematic analyses was 218. The excluded utterances were all part of longer comments, and for that reason, the final number of comments remained 136. Subsection 3.1 summarizes the characteristics of the respondents, and Subsection 3.2 presents the findings of the thematic analysis.

Participants’ Characteristics

Table 1 summarizes the characteristics of the participants who answered the open-ended question and those who did not. Those who responded to the question had a mean age of 43.7 years (SD 18.3). More female participants answered the question than male participants (80/136, 58.8% were females). The majority of the respondents had a White ethnicity (107/136, 78.7%), had an income of less than US $40,000 per year (95/136, 69.8%), and had access to the internet (112/136, 82.4%). In terms of education, 39.7% (54/136) of the respondents had a bachelor’s degree or higher.

Table 1. Characteristics of respondents (n=136).

Characteristics	Value, n (%)
Age (years), mean (SD)	43.7 (18.3)

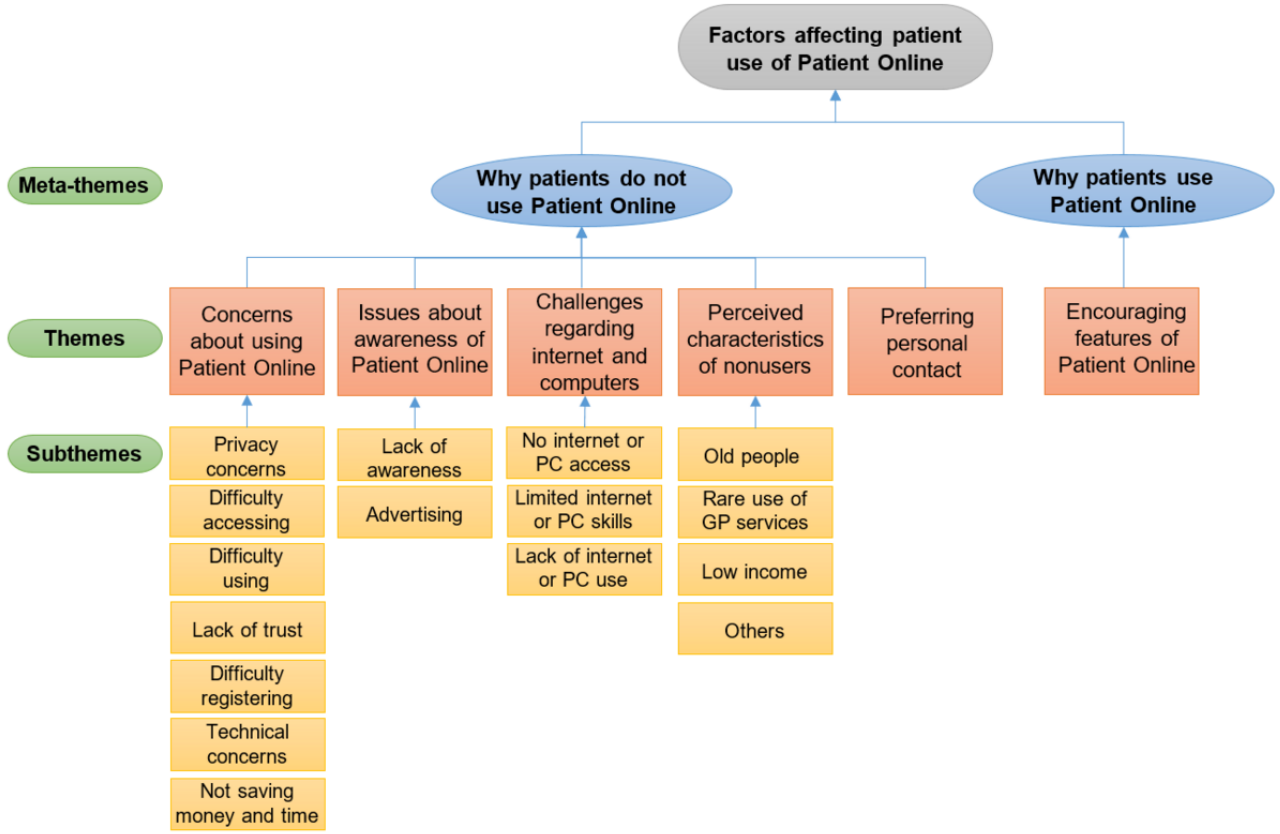
Findings of Thematic Analysis

In total, 2 meta-themes were generated as a result of the thematic analysis. The first meta-theme consists of 5 themes and relates to utterances explaining why patients do not use Patient Online (Figure 1). The second meta-theme pertains to utterances about why patients use Patient Online, and it contains 1 theme: encouraging features of Patient Online. The following sections contain more details about all 6 themes.

Figure 1. Thematic map. GP: general practice.



Theme 1: Concerns About Using Patient Online

The first theme, concerns about using Patient Online, is made up of 7 subthemes: (1) concerns about privacy and security, (2) difficulty accessing Patient Online, (3) difficulty using Patient Online, (4) lack of trust in Patient Online, (5) difficulty registering, (6) technical concerns, and (7) the inability of Patient Online to save money and time (Figure 1).

The security and privacy of Patient Online was a major concern for respondents. Their concerns were attributed to the recent NHS hack attacks, worries that their data will be accessed by third parties, and uncertainty about the security measures of Patient Online:

> *I believe that Patient Online has/ will have too many privacy issues, look what happened when the NHS was hacked.* [Participant #9]
>
> *Only concern is confidentiality of System One as I am aware CIA [Central Intelligence Agency] are now using the system.* [Participant #30]

The second subtheme shows that difficulty accessing (logging in) the system can be a barrier to its use. The main reasons given for difficulty accessing Patient Online were the inability to find its URL link and forgetting passwords and log-in details:

> *I tried to use the system but I can never find the correct link...* [Participant #120]
>
> *...I always forget my password.* [Participant #35]

The third subtheme was generated from comments about difficulty using Patient Online. Although the previous subtheme reflects patients' concerns about logging on to Patient Online, this subtheme represents their worries about using the system after logging in to it (ie, ordering prescriptions, managing appointments, checking their records). According to some respondents, these concerns are exacerbated when nobody can help in using the system:

> *I don't know if this would be easy to use.* [Participant #5]
>
> *If people experience a difficulty and do not know where to find help, or who to ask, they may give up trying.* [Participant #49]

The fourth subtheme indicates that some patients did not trust Patient Online to do what they want it to do. They doubted that an appointment would actually be booked for them if they booked via Patient Online:

> *...I don't trust the service.* [Participant #9]
>
> *...I am not sure I would entirely trust it...* [Participant #123]

Concerns with difficulty registering with Patient Online were brought together to form the fifth subtheme. These concerns were attributed to the fact that they have to visit the practice in person with their ID to be able to register to use the system. To ease the registration process, a respondent suggested that the registration to Patient Online becomes part of the patient registration in practice:

> *You also have to make a trip to the surgery with ID to be able to use the service.* [Participant #28]

> *I think more effort should be made to encourage patients to sign up for this, and the process should be more streamlined-perhaps done as a matter of course when registering.* [Participant #7]

The sixth subtheme encompasses utterances that show concern regarding the technical difficulties of Patient Online. Technical issues here refer to technical errors that people believe they will face when using Patient Online:

> *Technology goes wrong and does not tell you why.* [Participant #58]

The last subtheme brought together utterances from some respondents who were worried about the inability of Patient Online to save money and time. This is reflected in the utterances of the seventh subtheme, that is, respondents, especially those who live near the practice doubted that using Patient Online saves money and time:

> *In my experience many of these things do not end up saving people's time and money. So I don't think I'll be using this except infrequently.* [Participant #38]
>
> *It would not save travel costs because I live next to it.* [Participant #85]

Theme 2: Issues About Awareness of Patient Online

The utterances in this theme suggest that if respondents had more knowledge or awareness about Patient Online, they would use it. This theme consists of 2 subthemes: lack of awareness of Patient Online and advertising about Patient Online. In the first subtheme, the respondents stated that the lack of knowledge about the system's presence, what it is about, how to use, and how to access it was the main reason for not using it:

> *To be honest, I've never heard of Patient Online before and that may be why people haven't used it.* [Participant #88]
>
> *Not been shown what it is about and how to use it.* [Participant #80]

In the second subtheme, several respondents attributed their lack of awareness of Patient Online to the lack of advertisement about it. For this reason, they acknowledged the essential role of the publicity of Patient Online in increasing people's awareness of it:

> *It is not openly advertised in the surgery that Patient Online is available.* [Participant #28]
>
> *...may not be enough advertisement.* [Participant #62]

Theme 3: Challenges Regarding Internet and Computers

The third theme refers to issues regarding prerequisites for using Patient Online (ie, a computer and internet access). Respondents identified 3 challenges regarding the internet and computers, which form the 3 subthemes within this theme. The first challenge is the lack of internet or computer access. Many respondents attributed the nonuse of Patient Online to not having internet or computer access:

> *Those who don't have access to the internet may not use it.* [Participant #57]

Although many respondents have access to the internet and computers, they have limited skills in using them, and this is the second challenge:

> *I can't use a computer so I can't use Patient Online.* [Participant #2]

The third challenge is the lack of use of internet or computers. This subtheme indicates that some users may have access to computers and internet and the required skills but do not frequently use them:

> *I do not use computers of any kind.* [Participant #75]

Theme 4: Perceived Characteristics of Nonusers

The fourth theme was generated from utterances about who is less likely to use Patient Online. The 3 main characteristics of nonusers were related to age, use of GP services, and income. These characteristics formed 3 subthemes, in addition to an extra subtheme that encompasses infrequently reported characteristics.

Age was the most commonly reported characteristic of nonusers. Respondents suspected the ability of older people to use Patient Online for different reasons: lack of computer and internet skills, lack of internet access, lack of awareness of how to use the system, lack of confidence in using it, lack of technology use, and their preference for face-to-face contact:

> *Elderly people may have no understanding or knowledge of how to use a computer or the internet.* [Participant #69]
>
> *Older people may not use it as they don't have access to internet or know how to use services.* [Participant #116]

In the second subtheme, respondents attributed the nonuse of the system to lack of use of GP services in general, such as consultations and medications:

> *I've never used it as it's rare that I attend the surgery and I'm not on any medication.* [Participant #132]

Low income formed the third subtheme. Respondents stated that people need enough income to have internet access or get training to be able to use computers and the internet:

> *I do not have enough income/benefits...* [Participant #20]

The last subtheme encompasses characteristics of other people who are more likely to be nonusers of Patient Online and those who live near the practice, illiterate people, people who cannot read in English, and people who forget to use Patient Online:

> *I would use Patient Online more often if I lived further away from the surgery.* [Participant #15]
>
> *I am not good at reading or spelling so online would not be good for me.* [Participant #70]

Theme 5: Preferring Personal Contact

Preferring personal contact was identified as the main justification for not using Patient Online. Patients prefer personal contact because they think it is more reliable, easier, provides an instant reply, and is important in urgent conditions:

> *It is more reliable to speak to someone directly about their medical records rather than using online.* [Participant #29]
>
> *Picking up the phone and speaking to someone is easier.* [Participant #135]

Theme 6: Encouraging Features of Patient Online

Within this theme, respondents identified features of Patient Online that may encourage them to use the system. One of the main features of Patient Online is that it is useful for different people, such as students, people with mobility needs, people who cannot reach the practice, and busy people:

> *I feel that it would be particularly useful for students.* [Participant #63]

Another feature mentioned by respondents is ease of access. Some respondents thought that Patient Online could be more accessible if it was a mobile app. It is noteworthy that mobile apps were not available for accessing GP online services at the time of data collection. Later, patients have been enabled to access GP online services via a mobile app called NHS App [32]:

> *A mobile application would be more accessible...* [Participant #95]

Respondents reported other features of Patient Online, which may encourage people to use it, namely, secure, quick, user-friendly interface, convenient, and less stressful:

> *If it is secure and fast then people will use it, I suppose.* [Participant #68]
>
> *If the interface is not user-friendly people might not be encouraged to use Patient Online.* [Participant #82]

Discussion

Principal Findings

The aim of this study is to explore why patients in England choose to use ePHRs. Participants identified one leading cause that encouraged them to use Patient Online, which relates to its features being useful, easy to access, secure, quick, user-friendly interface, convenient, and less stressful. However, patients identified many reasons for not using Patient Online, which were categorized into 5 themes: concerns about using Patient Online, lack of awareness of Patient Online, challenges regarding internet and computers, perceived characteristics of nonusers, and preference for personal contact.

In the first theme, concerns about using Patient Online, the most prominent reason for not using Patient Online was privacy and security concerns. This may be attributed to the fact that ePHRs typically contain personal and sensitive information, and patients have previously been shown to be concerned about the accessibility of these data [33]. The hack attacks that happened to the NHS 4 months before data collection may have exacerbated these concerns in this sample. This finding is consistent with the results of the quantitative data in the original study [27], where perceived privacy and security significantly affected patients' intention to use Patient Online. This factor was also found in other quantitative studies [33-36] and qualitative studies [37-43].

Participants also raised their concerns about difficulty logging on to Patient Online because of losing its URL and forgetting passwords and log-in details. This issue posed a challenge for patients because they were given new complex passwords and usernames to access Patient Online. Although passwords can be changed through the system, usernames are fixed. This effect of difficulty accessing the system has also been demonstrated in several studies [41,44,45].

Other worries were reported about difficulty using Patient Online, especially when there is no one to help. This may be attributed to the fact that patients need adequate computer and internet skills to use Patient Online. They may also need to access it without any help from others to protect their privacy. This factor was also found in quantitative analysis in the original study [27], where effort expectancy (ie, ease of use) and behavioral intentions were significantly associated. Furthermore, numerous quantitative and qualitative studies have shown similar findings regarding this factor [37,38,40,41,45-47].

Participants expressed their concerns about the difficulty they experienced registering with Patient Online. Indeed, it could be argued that the process of registration with Patient Online is less flexible than several systems (eg, MyChart, PatientSite, My Health Manager, My Health at Vanderbilt), where patients can register with the system using email, websites, or phone and with no need to visit the practice. To the best of our knowledge, this factor was not found in previous studies. This may be because of the ease of registration with other systems.

The inability of Patient Online to save money and time was a concern for some participants, especially those who live near the practice. This concern may have made patients feel that Patient Online is not useful for them. Thus, this factor is related to perceived usefulness, which was the most influential factor according to the quantitative analysis in the original study [27]. The effect of this factor was also demonstrated by quantitative studies [46-49] and other qualitative studies [37,40,41,45,50].

Finally, 2 further concerns in this group were raised by participants, a lack of trust in Patient Online to book appointments or request medication refills and the technical issues that some patients reported when using Patient Online. To the best of our knowledge, neither of these factors have been reported in previous studies.

In the second theme, lack of awareness of different aspects of Patient Online was an influential factor in not using the system. Lack of advertising about Patient Online was the main reason for this lack of awareness. Although 3 of the 4 GPs had advertisements about Patient Online visibly displayed on screens or brochures in the waiting room during the study, some patients still reported a lack of awareness of the system. This factor was in line with the findings of previous quantitative studies [51,52] and qualitative studies [37,41,45,53].

With regard to the third theme, 3 challenges related to computers and the internet were identified. The first is the lack of internet or computer access. This factor was represented by the construct *facilitating condition* in the quantitative analysis, and it was found to significantly affect the actual use of Patient Online [27]. Furthermore, previous studies have shown a significant deleterious effect of a lack of internet [54-59] and computer access [38,46,52,57].

The limited skills in using the internet or computers was the second challenge in this group. This challenge may have produced reports that patients found Patient Online difficult to use. Hence, this factor is related to perceived ease of use (ie, effort expectancy), which was the most influential factor according to the quantitative analysis in the original study [19]. Numerous studies have supported this effect of computer literacy [38,40,41,53,60] and internet literacy [61,62].

The last challenge was the lack of using internet or computers. This challenge may also be related to perceived ease of use, as those who rarely use computers and the internet may perceive the system difficult to use. Several previous studies showed similar findings regarding the effect of lack of computer use [43,46,62] and internet use on the adoption of ePHRs [39,43,54,63-65].

Regarding the fourth theme, participants determined the following characteristics of nonusers of Patient Online, which were consistent with findings of previous studies: older people [61,66-69], who rarely use GP services [55,66,68,70,71], who have low income [46,52,72,73], who live near the practice [70], and who have lower literacy levels [46,52,72,73].

In the last theme, participants justified their nonuse of the system by indicating their preference for personal contact with their GP. This was attributed to the perceived advantages of personal contact over the system. This factor was found in other studies [40,51,52].

Strengths

This study enabled us to explore new factors that were not examined by the quantitative part of the study (eg, lack of awareness) and previous studies (eg, lack of trust). Furthermore, this study allowed us, to some extent, to support and explain some relationships proposed in the quantitative study (eg, performance expectancy, perceived privacy, security).

To the best of our knowledge, this study had the largest sample size in comparison with all qualitative studies on this topic. This allowed us to explore a wide range of patients' perspectives on the adoption of ePHRs.

Limitations

This study collected data from 4 GPs implementing the same ePHR (ie, SystemOnline), which may limit the generalizability of this study to other practices implementing other ePHRs (ie, Patient Access, Patient Services, The Waiting Room, Engage Consult, and Evergreen Life/i-Patient). However, it should be noted that all these systems provide the same services to the patients (ie, booking appointments, requesting prescription refills, and viewing health records), and no participant had used any of them before. As a result, the participants in this study were unlikely to have made comparisons between the different systems.

Although the qualitative data collected by an open-ended question helped in exploring factors affecting patients' use of Patient Online, such data may not be equivalent to qualitative data collected by interviews or focus groups. Thus, we could not deeply understand the adoption process of Patient Online. However, this qualitative analysis did not aim to understand in depth the phenomenon of interest; rather, it aimed only to help in identifying other factors not included in the model and explaining the findings of the quantitative study. As answering the open-ended question was voluntary, there may be an element of self-selection.

As the open-ended question was put after closed-ended questions, participants' answers to the open-ended question may be influenced by this order. This order was based on researchers' recommendations that questionnaires should start with the most interesting and easy-to-answer questions, and open-ended and demographic questions should be presented at the end of the questionnaire [74-76].

Practical Implications

We believe that adoption of GP online services will significantly increase in the future, given that many factors identified in this study will be automatically and considerably mitigated by time. Specifically, the proportion of patients who are more comfortable with the use of computers, smartphones, electronic systems, and the internet will increase in the future given their increased spread over the world. Thus, these services may be desired and expected by patients. However, developers, marketers, and GPs still play a crucial role in increasing the adoption of GP online services.

During system development, patients should be involved in the process to identify the features that make the system useful and easy to use. Some participants pointed out that the system will be useful when it allows them to book walk-in appointments, communicate with their doctors, and select the required doctor. As Patient Online currently enables patients to choose the required doctor, developers should consider adding these services, which are provided by many ePHRs (eg, MyChart, MyHealtheVet, Patient Gateway) [46,66,77]. Furthermore, users of such systems should be informed and reassured about the different security measures that are in place (eg, strong firewalls, encouragement to use complex and long passwords), and it should be made clear that the provision of GP online services is strictly controlled by legislation to safeguard personal data. To ease logging on to the system, developers should develop a system that allows patients to access it through their fingerprints or face recognitions, instead of using complex usernames and passwords. It is noteworthy that the NHS App, which has been recently developed, is the only system that enables patients to access GP online services using fingerprints or face recognitions [32].

To increase the awareness of the system, its functionality, and its benefits, marketers should improve their publicity through different channels, such as public media (eg, television, radio, newspapers, magazines), social media (eg, Facebook, Twitter, YouTube), emails, mails, automated messages on the practices' telephone system, and advertisements in general public areas (eg, shopping centers, health care settings, highway streets, universities). Face-to-face communication is considered as one of the most effective channels in marketing to persuade potential adopters to adopt an innovation [78,79]. Thus, all staff in practice (eg, physicians, nurses, receptionists) should offer the system to patients during their visits. GP staff may not be keen on publicizing online services because of a lack of incentives and time. Therefore, consideration should be given to providing incentives and resources for GPs to increase patients' awareness of GP online services.

Although patients have been recently enabled to sign up in the GP online services without visiting their surgeries through only the NHS App [80], they still need to visit their surgeries in person to register to use GP online services provided by other systems (eg, SystemOnline, Patient Access). To ease signing up in these systems, GPs should allow patients to register on web or through phone and make the signing up procedure a part of patient registration in the practice. GPs may enhance patients' perceptions of usefulness, ease of use of the system, and their trust in it by helping them in using a beta version of the system through a computer in a waiting room. GPs should provide online assistance, technical support, manuals, and training to allow patients to solve any technical issues that face them when using the system, thereby decreasing their technical concerns. GPs should collaborate with other parties (eg, Patient Online providers and government bodies) to provide computers and/or internet access at affordable prices for those who do not have them and cannot afford them. Given that many UK GPs report being overstretched and limited funding has been provided to support the rollout of GP online services, consideration should be given to providing incentive programs (eg, Meaningful Use policy as issued by the US government). Incentive programs could be used to encourage GPs to publicize their online services and encourage patients to use them.

Recommendations for Future Research

As this study could not provide a deep understanding of the adoption process of Patient Online, a deeper understanding of the adoption of online services could be gained through further qualitative work using interviews or focus groups. Several factors were revealed in this analysis but were not part of the conceptual model in the quantitative study, namely, awareness of Patient Online, lack of trust in the system, difficulty registering, disability, lack of use of GP services, and distance to the GPs. Future studies should consider adding these factors to the model and quantitatively examine them. Finally, more research is needed to identify the factors affecting the continuing use, as long-term viability and eventual success of information technology count on its continuing use more than initial use [81-83].

Conclusions

This research explored patients' perspectives regarding factors influencing their use of Patient Online. We found about 20 factors grouped into 6 themes. The findings of this study supported the findings of the quantitative study (eg, performance expectancy, effort expectancy, perceived privacy). This study found new factors that were not examined by the quantitative part of the study (eg, lack of awareness) and previous studies (eg, lack of trust).

The challenges and concerns that impede the use of Patient Online seem to be greater than the facilitators that encourage its use. To foster use, several practical implications were suggested: Patient Online should be useful, easy to use, secure, and easy to access; different channels should be used to increase the awareness of the system; and GPs should ease registration with the system and provide manuals, training sessions, and technical support. More research is needed to quantitatively assess the effect of the new factors found in this study (eg, lack of trust, difficulty registering with Patient Online) and factors affecting continuing use of the system.

Acknowledgments

The authors would like to thank Dr Hamish Fraser for his help in the initial stages of the study, especially for his contribution to the development of the study design and setting up of links with practices. The authors would also like to thank Tracey Farragher for her help in assessing the nonresponse bias. The publication of this study was funded by the Qatar National Library.

Authors' Contributions

AA and PG developed the protocol. AA collected the data. AA analyzed the data under BB's guidance and supervision. AA and ZS drafted the manuscript, and it was revised critically for important intellectual content by all authors. All authors approved the manuscript for publication and agree to be accountable for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Background: Patient portals have drawn much attention, as they are considered an important tool for health providers in facilitating patient engagement. However, little is known about whether the intensive use of patient portals contributes to improved management of patients' health in terms of their confidence in acquiring health information and exercising self-care. There is a lack of randomized trials with these outcomes measured both pre- and postadoption of patient portals.

Objective: The aim of this study was to examine the causal relationship between the usage of patient portals and patients' self-efficacy toward obtaining health information and performing self-care.

Methods: This study was a secondary data analysis that used data from a US national survey, the National Cancer Institute's Health Information National Trends Survey 5 Cycle 1. Patient portal usage frequency was used to define the treatment. Survey items measuring self-efficacy on a Likert-type scale were selected as the main outcomes, including patients' confidence in obtaining health information and performing self-care. To establish causality using survey data, we adopted the instrumental variables method. To determine the direction of the causal relationship in the presence of high-dimensional confounders, we further proposed a novel testing framework that employs conditional independence tests in a directed acyclic graph. The average causal effect was measured using the two-stage least squares regression method.

Results: We showed that frequently using patient portals improves patients' confidence in obtaining health information. The estimand of the weighted average causal effect was 0.14 (95% CI 0.06-0.23; $P<.001$). This means that when increasing the portal usage intensity, for instance, from 1-2 times to 3-5 times per year, the expected average increase in confidence level measured on a Likert-type scale would be 0.14. However, we could not conclusively determine the causal effect between patient portal usage and patients' confidence in exercising self-care.

Conclusions: The results support the use of patient portals and encourage better support and education to patients. The proposed statistical method can be used to exploit the potential of national survey data for causal inference studies.

KEYWORDS

causal inference; instrumental variable; directed acyclic graph; patient portal; self-efficacy

Introduction

Given the growing evidence showing that patient engagement improves health outcomes and reduces health care costs, patient portals have drawn much attention. A patient portal is a secure online health platform linked to a patient's personal medical record that is 24/7 accessible from any location with an internet connection. Patient portals are considered an important tool for health providers in facilitating patient engagement [1,2]. Characteristics of portal users [3] and barriers to portal adoption [4,5] have been extensively investigated. Regarding the facilitators, it was found that patients who believed the patient portal was empowering demonstrated a higher intention to use [6]. The relationship between the internal use (quantified using engagement measurement) of online health platforms and external growth (its reach), and the social support activities related to users' participation has been examined as well [7,8]. Research has also focused on whether portal or secure messaging usage can affect the frequency of patients' office visits [9-15] and appointment adherence [16-19].

Nonetheless, little is known about whether patient portal usage contributes to the improved management of patients' health in terms of health literacy, communication, confidence in acquiring health information, and the self-monitoring and self-care of health. Interviews have indicated that patient's perception of access to online records are associated with a greater focus on their health and more proactive involvement in self-care [20,21]. However, there is a lack of randomized trials with self-efficacy outcomes measured both pre- and postportal adoption. Consequently, a causal link between patients' portal usage and patients' health information–seeking behaviors (self-efficacy) has not been formally established.

Despite the passage of the Health Information Technology for Economic and Clinical Health (HITECH) Act and the recommendations by the US Institute of Medicine [22], the overall adoption rate of portals remains low [23]. A better understanding of the impact of patient portals and the benefit to patients is needed to increase adoption. To this end, we used the Health Information National Trends Survey (HINTS) data [24] to examine the causal relationship between the usage of patient portals and patients' self-efficacy in obtaining health information and performing self-care.

Methods

Study Setting

This study was a secondary data analysis that used data from the National Cancer Institute's HINTS 5 Cycle 1. HINTS 5 Cycle 1 is a cross-sectional survey of a nationally representative sample of US adults used to assess the impact of the health information environment. The survey was conducted from January 2017 through May 2017 using a self-administered mail questionnaire. Out of 10,265 surveys sent out, data were collected from 3285 (32% response rate) respondents [24]. The characteristics of these respondents are summarized in Table S1 in Multimedia Appendix 1.

Patients' self-efficacy in obtaining health information and performing self-care were considered as the outcomes. Survey items measuring patient self-efficacy were selected based on the Institute of Medicine's recommendations for promotion of patient portals to increase quality of care and reduce medical errors [22], as well as claims that health information technology, like portals, could increase patients' self-efficacy for managing their conditions [25-28]. Perceived confidence was assessed with the following questionnaire items: (1) "Overall, how confident are you that you could get advice or information about health or medical topics if you needed it?" (ConfidentGetHealthInfo, Y_1); (2) "Overall, how confident are you about your ability to take good care of your health? (OwnAbilityTakeCareHealth, Y_2)."

These measures were captured on a 5-point Likert-type scale where a higher score indicated greater confidence. Variables on patients' age, gender, race, ethnicity, marital status, education, employment status, household income, and insurance status were considered to be confounders in the study. Information on patients' portal activities was elicited by the following questionnaire item: "How many times did you access your online medical record in the last 12 months? (0/1 to 2 times/3 to 5 times/6 to 9 times/10 or more times)."

Different usage frequencies were considered to be different levels of treatment. For the instrumental variable (IV), we used the following questionnaire item: "Have any of your health care providers including doctors, nurses, or office staff ever encouraged you to use an online medical record? (yes/no)."

Missing values were sparse and were handled in several ways depending on the variable type: samples missing the outcomes were discarded; for the IVs, missing responses were replaced by "no encouragement"; and for the confounders, missing responses were imputed by the Multivariate Imputation by Chained Equations (MICE) [29] method with the IV and the confounders used as input variables for that method.

Establishing a Causal Relationship

We aimed to test the hypothesis that the exposure to patient portals, or intensively using a patient portal, will improve patients' self-efficacy outcomes. However, since we only used a one-time outcome measurement for each individual, we could not construct the before-after treatment contrast to directly measure the treatment effect. Further, without a randomized experimental design, the causality can be obscured by confounders. To address these issues, we adopted the IV method for causal inference in observational studies [30]. In these studies, IVs are used to adjust for both observed and unobserved confounding effects and to help identify a contrast of outcomes in the absence of temporal data.

We identified the following item as the binary variable and used it as the IV: "Have any of your health care providers including doctors, nurses, or office staff ever encouraged you to use an online medical record?"

Encouragement plays an influential role on patients' use of portals, as care providers' endorsement is an important factor in the adoption of these tools [6-8,31]. However, provider referrals to use patient portals have long been known to vary by race and socioeconomic status and are thought to be dependent on whether the provider believes that the patient will use the portal [32]. The same is true for the HINTS data we used, where income and education were observed to be associated with recommendation, patient portal usage, and self-efficacy. Thus, the requirement of no confounding between the IV and the outcome might not have been met if encouragement (or other candidate IVs, such as internet savviness) were used as an IV.

To further determine whether patient portal usage causes an improvement in self-efficacy, or vice versa, we proposed a testing framework that could both address the confounding issue and determine the direction of the causal relationship. Our testing framework was based on causal directed acyclic graphs (DAGs), which are used as a graphical tool to visually represent and understand the concepts of exposure, outcome, causation, and confounding [33]. To identify an appropriate IV, we generalized the criteria of IVs to allow for known (or observable) confounding among the IV, treatment, and outcome; and unknown (or unobservable) confounding between the treatment and outcome [30]. With this separation of confounders, only the known common confounders were essential for examining the causal relationship. To further identify the direction of causality, a testing framework employing conditional independence tests [34,35] was developed. The detailed description of the testing framework can be found in Multimedia Appendix 2.

Measuring Causal Effect

The proposed DAG-based testing framework aimed to qualitatively evaluate the causality. To quantify the treatment effect, two-stage least squares (TSLS) regression models were built. As the treatment (portal usage) has multiple levels (eg, 1-2 times and 3-5 times annually are different levels), the traditional average treatment effect is not identifiable. However, Angrist and Imbens [36] showed that an estimand, essentially a weighted average of per-unit average causal effects, is identifiable and can be estimated by TSLS regression models. The two major assumptions therein, independence and monotonicity of ordinal treatment effect, were thus naturally satisfied in our causal framework.

Results

Portal Enrollment

After removing the samples with too many missing data, we identified 3198 participants among the 3285 survey respondents. Among these 3198 participants, 1003 (31%) were self-reported patient portal users. For demographic and socioeconomic variables, the user group and the nonuser group had different characteristics (see Table S1 in Multimedia Appendix 1). Patients younger than 65 years old and females were more likely to be patient portal users. Moreover, participants who self-reported as White, married, and non-Hispanic were more likely to be users. In terms of income, higher income was positively correlated with a greater likelihood of being a portal user. Likewise, participants who were employed were more likely to use portals than those who were retired or unemployed. Compared to nonusers, portal users had a higher level of education (eg, undergraduate or postgraduate). Finally, compared to those covered by employer-provided insurance, patients who were covered by private insurance, Medicare, or Medicaid were less likely to enroll in patient portals.

Encouragement and Portal Usage

Next, we characterized the users' portal usage behavior. Of the 1003 portal users, 49% (496) reported using portals 1-2 times in the past 12 months, 31% (313) reported using them 3-5 times, 10% (104) reported using them 6-9 times, and 9% (90) reported using them more than 9 times.

Of the 3198 participants, 1375 (43%) were encouraged to use patient portals and 1823 (57%) were not. Among the 1375 respondents who were encouraged, 549 (40%), 383 (28%), 267 (19%), and 176 (13%) individuals never used a portal, used a portal 1-2 times, 3-5 times, and more than 5 times, respectively. In contrast, there were 1646 (90%), 113 (6%), 46 (3%), and 18 (1%) participants in the nonencouraged group, respectively. It was evident that the IV and the treatment were significantly associated, which was verified by a chi-square test ($P<.001$).

Encouragement and Self-Efficacy

There were more patients with positive responses for the self-efficacy outcomes in the patient population who were recommended to use portals. The distributions of each outcome variable conditioning on the value of the IV are displayed in Table 1, and chi-square test results are provided. Among the 3198 participants, 3111 and 3165 participants were identified as those who answered questions Y1 and Y2, respectively. For ConfidentGetHealthInfo, individuals in the encouraged group (G_e) were more likely to be completely confident or very confident than those in the nonencouraged group (G_n; G_e: 907/1353, 67%; G_n: 1000/1758, 57%; $P<.001$). For OwnAbilityTakeCareHealth, G_e patients were slightly more confident in self-care (G_e: 998/1364, 73%; G_n: 1222/1801, 68%; $P=.001$). All the comparisons suggest that the IV and the outcomes were significantly associated.

Table 1. Chi-square test results for the association between encouragement to use patient portals and self-efficacy outcomes.

Outcomes	IV[a]: encouragement to use patient portals		*P* value
	Yes, n (%)	No, n (%)	
ConfidentGetHealthInfo, Y_1	1353 (100)	1758 (100)	<.001
Not confident at all	21 (1.5)	50 (2.8)	
A little confident	56 (4.1)	108 (6.1)	
Somewhat confident	369 (27.3)	600 (34.1)	
Very confident	566 (41.8)	607 (34.5)	
Completely confident	341 (25.2)	393 (22.4)	
OwnAbilityTakeCareHealth, Y_2	1364 (100)	1801 (100)	.001
Not confident at all	15 (1.1)	31 (1.7)	
A little confident	31 (2.3)	79 (4.4)	
Somewhat confident	320 (23.5)	469 (26.0)	
Very confident	652 (47.8)	815 (45.3)	
Completely confident	346 (25.4)	407 (22.6)	

[a] IV: instrumental variable.

Causal Relationship Between Patient Portal Usage and Self-Efficacy

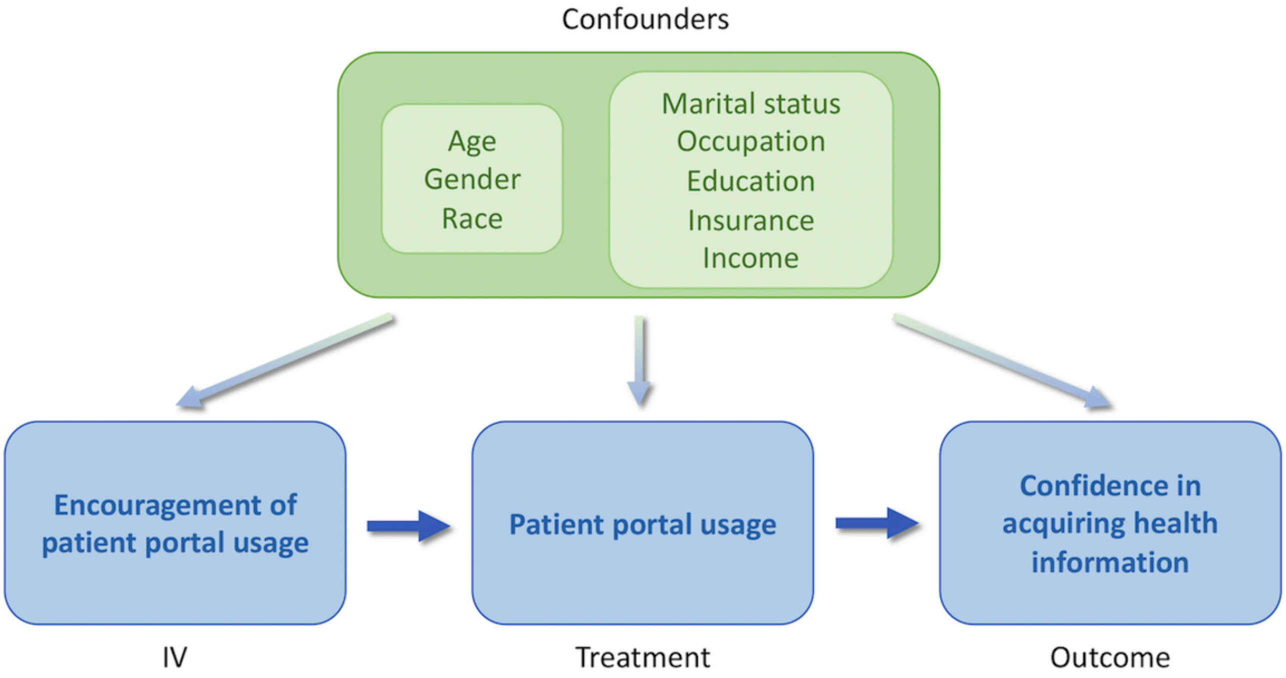
Following the testing procedure described in Multimedia Appendix 2, conditional independence tests were conducted. Test A tested the hypothesis that, given the common confounders and the treatment, the IV is conditionally independent with the outcome. This test examined whether higher self-efficacy is a cause for increased portal usage. Test B tested the hypothesis that the IV and the outcome are conditionally independent, given the common confounders alone. This test examined whether the increase in portal usage is a cause for higher self-efficacy. A *P* value <.05 was used as the statistical significance level for the overall test. The results are shown in Table 2.

Table 2. Results of conditional independence tests.

Outcomes	*P* value	
	Test A: $Z \perp Y \mid$	Test B: $Z \perp Y \mid$
ConfidentGetHealthInfo	.28	.02
OwnAbilityTakeCareHealth	.42	.23

For ConfidentGetHealthInfo, we could not reject the hypothesis for Test A (overall *P*=.28) but could reject Test B (overall *P*=.02), meaning that portal usage did have a causal effect on self-efficacy toward obtaining health information. This relationship is illustrated in Figure 1. However, for OwnAbilityTakeCareHealth, we could not reject the hypothesis for either Test A (overall *P*=.42) or Test B (overall *P*=.23). In this case, we could not determine the causal relationship between patients' portal usage and patients' confidence in exercising self-care.

Figure 1. The causal relationship among encouragement, portal usage, and confidence in seeking health information with the confounders. IV: instrumental variable.



Treatment Effect of Patient Portal Usage on Self-Efficacy

A TSLS regression model was built to quantify the treatment effect of portal usage on self-efficacy toward acquiring health information. The estimand of the weighted average causal effect was 0.14 (95% CI 0.06-0.23; *P*<.001). This indicates that, when increasing the portal usage intensity, for instance, from 1-2 times to 3-5 times per year, the expected average increase in the reported confidence level (measured with a Likert-type scale) would be 0.14. It can be concluded that the more intensely patients engage with portals, the more confident they are in obtaining health information.

Discussion

Identifying Causality

Existing work on survey analysis mainly focuses on the strength of the association between questionnaire items and targeted outcomes [37,38], as there is a lack of understanding regarding the causal path diagram and a lack of methods for determining if the path diagram is congruent with the data. In this study, we developed a new framework that allowed us to detect causality and estimate the magnitude of the treatment effect represented in the path diagram using the HINTS 5 survey. Our framework was able to eliminate the estimation bias due to unmeasured confounders, and guarantee the test efficiency given the limited sample size of the survey. Moreover, the testing framework was robust to the choice of IVs. In addition to using "encouragement" as an IV, we tested internet savviness as an alternative IV and found the conclusion was consistent (see Multimedia Appendix 2).

Effect of Portal Usage

Although we should be cautious in interpreting the relationship between using patient portals and self-efficacy as causal, we did observe a co-occurrence of better outcomes and increased patient portal usage intensity. Despite the benefits of patient portals being well documented [39,40], rates of usage remain low [41], and increasing the adoption of patient portals would provide more patients a trusted source of personalized information. Because patients can be easily misinformed by the large amount of inaccurate information online [42], using patient portals allows patients and their caregivers to stay connected with their providers. This occurs through easy access to their own health information and the ability to contact providers via secure messaging if they have questions or concerns. Our framework further confirmed that portal usage does positively affect confidence in obtaining health information. However, we did not observe a similar level of significance to conclude that higher portal usage will lead to higher self-efficacy in performing self-care. It is possible that other confounding factors, such as income and education levels [43], might have had a more powerful effect on the outcome.

Encouraging Patients' Portal Use

Our analysis shows that being encouraged to use patient portals positively affects the intensity of portal usage, which in turn influences people's confidence in acquiring health information. Other studies have reported that actively using patient portals, such as sending messages to physicians and viewing prescription and lab results, is positively associated with high-quality physician-patient relationships and patients' confidence to understand health information. It is evident that a trusting physician-patient relationship helps promote healing and remove barriers to obtaining medical information [44]. However, efforts to increase the adoption of patient portals often rely on pamphlets and flyers [45] or hurried conversations by medical staff. Given the potential benefits of patient portals and our findings that encouragement affects usage, we believe that an innovative intervention is necessary to increase patient adoption and usage, which ultimately can lead to significant improvements in patient outcomes.

Limitations

The study was conducted using HINTS 5 Cycle 1 data, which were collected in 2017. The study can be improved by combining multiple data sets, including ones published recently [46]. The power of the test can be increased by including more samples, which can potentially help identify the causal relationship between portal usage and self-care. It is worth noting that survey designs are not identical across all three cycles of HINTS 5. For instance, the outcome of ConfidenceGetHealthInfo is available in Cycle 1 (2017) and Cycle 3 (2019) but not in Cycle 2 (2018). Considerable effort will be needed to merge these data sets. Furthermore, the HINTS database contains rich information beyond the variables that were used for this study, and other aspects (eg, health disparities) related to both portal usage and self-efficacy behaviors should be explored.

The establishment of the causal relationship between portal usage and patients' self-efficacy demands that encouragement to use portals is not based on patients' self-efficacy. We have observed that many health care organizations have integrated the facilitation of portal enrollment into their new patients' registration protocol [47]. In addition, portal use encouragement also occurs during a patient's interaction with the front desk when addressing billing and appointment scheduling, as patient portals can be an alternative venue to handle these services. These scenarios correspond to the cases that nurses or office staff encourage patients to use an online medical record. These situations account for the majority of the encouragement during patient encounters and thus support the selection of encouragement as an IV. However, as for personal encouragement from a physician, we are unaware of any health care organizations that have policies or incentives for providers to systematically encourage all patients to use portals, meaning that encouragement can be at the providers' discretion [48]. Therefore, collecting physicians' input concerning their patterns of encouragement would be valuable for further justifying the validity of using encouragement as an IV. To ensure the rigor of our results, we further tested internet savviness as an alternative IV and found a consistent conclusion (see Multimedia Appendix 2).

Although the confounders between the treatment and the outcome can be completely unmeasured, we still require the common confounders to be fully observable. The identification of common confounders largely relies on domain knowledge. It is worth noting that the choice does not have to be unique. In our casual diagram, adding variables to the common confounder set still results in a valid choice. However, chi-square tests can be sensitive to the choice of confounders when the sample size is not sufficiently large [49]. Therefore, to make the results more robust, more survey respondents are needed.

Conclusions

Since the Affordable Care Act mandated portal usage, enthusiasm for portals has declined; however, this study found that using patient portals improves patients' confidence in obtaining advice or information about health or medical topics. Our findings thus attest to the benefit of patient portals and to providing better support and education to patients. In addition, our proposed statistical method exploits the potential of using national survey data such as the HINTS program to examine causal effects to obtain new insights. Theoretically, the treatment effect can be heterogeneous based on different patient characteristics. There is thus a need to develop a testing framework that can identify the disparity in causal effects. For justifying the clinical insights identified in this study, we cannot solely rely on patients' self-reported outcomes, but should also survey physicians on their perception of patients' self-efficacy. Furthermore, how physicians make encouragement decisions should also be investigated, and a randomized controlled study with pre- and posttreatment outcomes being clearly documented is necessary to fully understand the treatment effect on self-efficacy outcomes.

Abstract

Background: Cognitive impairment is one of the most debilitating manifestations of multiple sclerosis. Currently, the assessment of cognition relies on a time-consuming and extensive neuropsychological examination, which is only available in some centers.

Objective: To enable simpler, more accessible cognitive screening, we sought to determine the feasibility and potential assessment sensitivity of an unsupervised, adaptive, video game–based digital therapeutic to assess cognition in multiple sclerosis.

Methods: A total of 100 people with multiple sclerosis (33 with cognitive impairment and 67 without cognitive impairment) and 24 adults without multiple sclerosis were tested with the tablet game (EVO Monitor) and standard measures, including the Brief International Cognitive Assessment for Multiple Sclerosis (which included the Symbol Digit Modalities Test [SDMT]) and Multiple Sclerosis Functional Composite 4 (which included the Timed 25-Foot Walk test). Patients with multiple sclerosis also underwent neurological evaluations and contributed recent structural magnetic resonance imaging scans. Group differences in EVO Monitor performance and the association between EVO Monitor performance and standard measures were investigated.

Results: Participants with multiple sclerosis and cognitive impairment showed worse performance in EVO Monitor compared with participants without multiple sclerosis (P=.01) and participants with multiple sclerosis without cognitive impairment (all P<.002). Regression analyses indicated that participants with a lower SDMT score showed lower performance in EVO Monitor (r=0.52, P<.001). Further exploratory analyses revealed associations between performance in EVO Monitor and walking speed (r=–0.45, P<.001) as well as brain volumetric data (left thalamic volume: r=0.47, P<.001; right thalamic volume: r=0.39, P=.002; left rostral middle frontal volume: r=0.28, P=.03; right rostral middle frontal volume: r=0.27, P=.03).

Conclusions: These findings suggest that EVO Monitor, an unsupervised, video game–based digital program integrated with adaptive mechanics, is a clinically valuable approach to measuring cognitive performance in patients with multiple sclerosis.

Introduction

Cognitive impairment (CI) occurs in 30% to 70% of people with multiple sclerosis (MS) and has a profound influence on a patient's personal functioning, social interaction, employment, and overall quality of life [1,2]. Being able to effectively detect CI is essential to better managing further decline [3] and helping patients navigate problems related to their daily living. The most commonly affected cognitive domains are processing speed, attention, executive function, and memory [4,5]. Currently, clinical cognitive assessment relies on a comprehensive neuropsychological examination, which is time-consuming and extensive. The examination results may be affected by patient fatigue or loss of engagement. Given the large interindividual variability in the pattern of CI in MS [6,7], the traditional nonadaptive assessments may overlook cognitive deficiencies [8]. Taking advantage of technology, digital tools offer a platform to integrate personalizing features, including adaptive staircase algorithms to video game–style mechanics for cognitive assessment [8-15]. This approach can mitigate potential ceiling and floor effects when interindividual variability is high, and leads to more reliable assessments that can be completed in a timely manner [8,16]. Furthermore, digital tools can be easily applied in different settings, including patients' homes, which substantially improves health care accessibility for patients who have difficulties with travel to the clinic due to cognitive or physical disabilities [14,17,18].

Digital tools have been used for functional assessment, rehabilitation, and health care monitoring in clinical populations such as stroke [19,20], schizophrenia [21], depression [10,12], attention-deficit/hyperactivity disorder [15,22-24], and neurodevelopmental disorders [8,9]. In MS, studies have demonstrated that by using digital tools, health care services can be delivered effectively [25,26] and even that comprehensive neurological exams can be performed remotely [27]. However, to the best of our knowledge, applications of serious video game–based digital tools incorporating closed-loop adaptation mechanics as cognitive assessments for people with MS have not been assessed.

We previously evaluated whether a video game–based digital tool, EVO-AKL-T01 (Akili), could improve cognition in MS [17,18]. After these studies, we looked to better characterize cognitive function using similar tools based on these cognitive therapeutics. EVO Monitor (Akili) was developed based on findings that a precursor (NeuroRacer), embedded with adaptive algorithms, is sensitive to age-related cognitive decline across the lifespan and can enhance cognitive control [28]. EVO Monitor, which includes some of NeuroRacer's early closed-loop features, is a novel, tablet-based, digital platform that is incorporated with video game mechanisms, visual and auditory feedback, adaptive algorithms, and sophisticated graphics that is designed to assess executive function, attention, and information processing speed for clinical populations. Specifically, it consists of 3 tasks: perceptual discrimination, visuomotor tracking, and multitasking. In the perceptual discrimination task, the participants complete a go/no go–like paradigm, in which they tap the iPad screen for correctly colored target stimuli while ignoring distracting targets. The visuomotor tracking task requires the participant to tilt the iPad to steer an avatar around obstacles. The multitasking task requires participants to perform both perceptual discrimination and visuomotor tracking concurrently. The tool is designed to challenge attention, goal management, and information processing speed in the setting of interference. EVO Monitor has been validated as a tool to assess cognitive ability in children with and without neurodevelopmental disabilities. For example, it can differentiate between the performance of children with or without 16p11.2 BP4-BP5 deletion and healthy controls, whereas traditional nonadaptive cognitive assessments overlook group differences [8].

In this study, we aimed to determine the feasibility and potential assessment sensitivity of EVO Monitor as an unsupervised, tablet game–based approach with adaptive algorithms to assess cognition in MS. In this context, 100 people with MS and 24 adults without MS were tested with EVO Monitor and standard measures, including the written version of Symbol Digit Modalities Test (SDMT), the most sensitive test for detecting cognitive involvement in the MS course [29,30]. Group-level differences were examined to evaluate whether EVO Monitor is sensitive to differences among participants with MS with and without CI as well as participants without MS. The association between performance in EVO Monitor and standard measures was investigated. Furthermore, since cognition in MS has been shown to correlate with physical fitness, where aerobic capacity and muscular strength outcomes are associated with cognitive processing speed and inhibitory control [31,32], and magnetic resonance imaging (MRI) measures have shown that thalamus damage is associated with the presence of CI, and frontal lesion is associated with executive function [33,34], exploratory analyses of the correlation between performance in EVO Monitor and both physical measures and MRI volumetric data (thalamus and frontal lobes) were conducted to understand whether cognitive performance assessed by a video game–based digital tool (EVO Monitor) would be associated with physical activity and structural MRI measures.

Methods

Participants

A total of 100 adults with a diagnosis of clinically isolated syndrome or MS [35] (mean age: 52.2, standard error of the mean [SEM] 1.24 years) were recruited from the University of California, San Francisco (UCSF) Multiple Sclerosis and Neuroinflammation Center. Patients with clinical relapses or steroid use in the past month or with severe visual, cognitive, or motor impairment that would preclude the use of a tablet-based tool were excluded. A group of 24 adults without MS (non-MS) (mean age: 46.0, SEM 3.72 years) with no chronic autoimmune diseases were also recruited from the UCSF staff, willing family members of patients in the clinic, and other eligible and willing volunteers. All participants with MS were recruited as part of studies to determine the feasibility [18] and preliminary efficacy [17] of the EVO platform as a digital therapeutic to improve processing speed in people with MS. The analysis of this study was based on baseline performance data (ie, before any cognitive intervention) of our feasibility [18] and efficacy [17] trials. All procedures performed in the study involving human participants were approved by the Committee for Human Research at the University of California, San Francisco. Written informed consent was obtained from each participant. The trial is registered with ClinicalTrials.gov (NCT03569618).

Task Description

Standard Measures

The Brief International Cognitive Assessment for Multiple Sclerosis is a cognitive assessment tool that is validated in MS populations as compared with participants without MS [36]. It is a standardized, internationally validated battery [37] including (1) the SDMT, a widely used measure of attention and information processing speed in MS [29,30]; (2) the California Verbal Learning Test Second Edition, a verbal memory immediate recall test [38]; and (3) the Brief Visuospatial Memory Test Revised, a visual memory immediate recall test [39]. Serial versions of all tests were used to minimize practice effects [40].

The MS Functional Composite 4 evaluates 4 key MS-related functional domains [41]: walking speed (Timed 25-Foot Walk [T25FW]), upper extremity function (Nine-Hole Peg Test), vision (Sloan low-contrast letter acuity test), and cognition (with a test of information processing speed, attention, and working memory [Paced Auditory Serial Addition Task] [42]).

EVO Monitor

EVO Monitor is a digital cognitive assessment developed by Akili Interactive Labs (Akili, Boston) to assess cognitive function, including attention and related cognitive control processes in clinical populations (Figure 1). The program is an immersive action video game that has been engineered with adaptive algorithms to target fronto-parietal brain networks fundamentally linked to attentional control among other aspects of cognition. It was developed based on the principles of NeuroRacer, an innovative cognitive intervention that is sensitive to age-related cognitive decline [28]. EVO Monitor comprises 3 tasks: perceptual discrimination, visuomotor tracking, and multitasking. In the perceptual discrimination task, the participants are instructed to respond to colored target stimuli by tapping the iPad screen while ignoring distractors. In the visuomotor tracking task, the participants navigate a character along a dynamically moving road while avoiding walls and obstacles by tilting the iPad. The multitasking task requires participants to perform both perceptual discrimination and visuomotor tracking at the same time until participants complete a minimum number of trials and reach a stable level of performance.

The adaptive algorithms change game difficulty on a trial-by-trial basis for both the perceptual discrimination (adapting the response window for a target) and visuomotor tracking (adapting the speed of the forward path), with real-time feedback making the participants aware of their performance. More specifically, the closed-loop adaptive algorithm makes proportional changes in gameplay difficulty to keep the player's performance at an approximate 80% rate of accuracy based on adaptive psychometric principles [43-45], which ensures that task difficulty is equated across participants [45,46] and enhances participant engagement [47]. It takes approximately 7 minutes to complete the tasks, with a specified number of both correct and incorrect trials allowing the adaptive algorithm to settle on a prescribed level of difficulty (ie, threshold level) that would converge on a consistent accuracy rate. The threshold level represents task performance, as it indicates the task difficulty at which the participants achieve approximately an 80% rate of accuracy.

At the beginning of the EVO Monitor session, a brief instruction is given on the iPad screen with a short practice to ensure the participant understands the tasks, followed by one session of the actual assessment, which takes about 7 minutes, with a task order of multitasking, perceptual discrimination, visuomotor tracking, and multitasking. Each task is about 1.5 to 2 minutes with no break in between. Although the assessment is self-guided, a study coordinator sat in with participants to ensure they were following the instructions. None of the participants had played EVO Monitor before participation. Since EVO Monitor continuously monitors the user's performance at a rate of 30 frames per second, the measured reaction time, perceptual discrimination task sensitivity (eg, hit and false alarm rates), and visuomotor tracking performance generate 39 basic performance metrics. Among the 39 metrics extracted from participants' navigation of EVO Monitor, we prespecified the calculated threshold levels during both single (perceptual discrimination, visuomotor tracking) and multitasking conditions as attentional measures, according to previous studies [8,16].

Basic Reaction Time

To ensure that any observed differences in cognitive measures between groups were not due to differences in motoric speed, we assessed basic response speed of participants on a simple task with minimal loading on executive function skills [28]. This task was designed to index the motoric speed, and the measured data were only included in the analyses as a covariate to control for potential motor speed deficits in participants with MS. In this task, participants were instructed to respond to a target stimulus (40 trials) as fast as they could by tapping a button on an iPad platform. Similar to EVO Monitor, this task used adaptive algorithms that modulate the challenge level of the task on a trial-by-trial basis based on individual performance.

Only data from the dominant hand were included as each participant's basic reaction time (BRT) in the following analyses.

Clinically Acquired MRI Measures

Clinically or research-acquired brain isotropic T1 and T2 fluid-attenuated inversion recovery images were available for 56 participants with MS (16/56, 29% with 1.5-T and 40/56, 71% with 3-T MRIs) at a mean of 76.0 (SEM 33.9) days before the study visit. Lesion segmentation was performed using the LST (lesion segmentation toolbox) lesion probability algorithm 2.0 DICOM (Digital Imaging and Communications in Medicine) v1.4 segmentation pipeline, which creates lesion probability maps, masks, and labels. These were then manually validated by an expert radiologist (SS). Volumetric analysis was performed from T1 anatomical images using 3 complementary tools: FreeSurfer 5.3 and ANTs Morphology 2.1.0 [48], used to segment tissue into cerebrospinal fluid, cortical grey matter, subcortical grey matter, white matter, brainstem, and cerebellum, and Mindboggle 1.0 [49], which combines the morphology outputs of FreeSurfer and ANTs to generate volume images and tabular information for further analysis. Bilateral thalamic and frontal lobe volumetric measures were normalized to individual intracranial volume [50] for exploratory analyses of association between performance in EVO Monitor and MRI volumetric measures. The selection of the thalamus and frontal lobe as regions of interest was based on ample evidence indicating an association between atrophy in these regions and cognitive dysfunction in MS [33,34].

Statistical Analysis

In order to evaluate whether EVO Monitor is sensitive to differences among participants with MS with and without CI as well as participants without MS, participants with MS were divided into 2 subgroups (ie, CI and non-CI) according to their baseline SDMT *z* scores. We characterized the participants with a SDMT *z* score lower than –1 based on published normative data [51] as having CI. Group-level differences were assessed with one-way analysis of covariance (ANCOVA) with age, sex, years of education, and BRT as covariates to control for potential differences in demographic features and motoric quickness. Two-tailed Student *t* tests were carried out for post hoc comparisons when appropriate. To discern the association between EVO Monitor and standard measures, Pearson correlation analyses were performed between performance in EVO Monitor and SDMT. In an exploratory analysis, the correlation between performance in EVO Monitor and both physical MS measures (T25FW) and MRI volumetric data (thalamus and frontal lobes) was assessed with Pearson correlation analyses. Partial correlation analyses including age, sex, years of education, and BRT as covariates were applied when appropriate. All numerical data are presented as the mean and SEM. The statistical analyses were performed using IBM SPSS Statistics version 22.0 (IBM Corp). The significance of the statistical level was set at $P \leq .05$.

Results

Participant Characteristics

A total of 100 participants with MS and 24 participants without MS were enrolled in the study. For analysis purposes, the 100 participants with MS were divided into CI (n=33) and non-CI (n=67) subgroups. Table 1 summarizes their clinical and demographic characteristics. Figure 2 details the completion rate for each test.

Group Differences

To evaluate whether EVO Monitor is sensitive to differences between participants with MS with and without CI as well as participants without MS, one-way ANCOVA with age, sex, years of education, and BRT as covariates was performed for the threshold level, which reflects task performance. Significant group differences in multitasking ($F_{2,109}$=8.33, *P*<.001), perceptual discrimination ($F_{2,109}$=5.63, *P*=.005), and visuomotor tracking ($F_{2,109}$=6.97, *P*=.001) threshold level were found. Post hoc analyses showed a lower threshold level in participants with CI compared with both participants without CI with MS and participants without MS in all 3 conditions (multitasking: CI vs non-CI, 8.85 [SEM 0.28] vs 10.26 [SEM 0.19]; *P*<.001; CI vs non-MS, 8.85 [SEM 0.28] vs 10.01 [SEM 0.37]; *P*=.01; perceptual discrimination: CI vs non-CI, 10.01 [SEM 0.26] vs 11.04 [SEM 0.18]; *P*=.002; CI vs non-MS, 10.01 [SEM 0.26] vs 11.11 [SEM 0.34]; *P*=.01; visuomotor tracking: CI vs non-CI, 11.05 [SEM 0.40] vs 12.83 [SEM 0.28]; *P*<.001; CI vs non-MS, 11.05 [SEM 0.40] vs 12.81 [SEM 0.52]; *P*=.01) (Figure 3). These findings indicate that EVO Monitor, a video game–based assessment designed to assess executive function, attention, and information processing speed, is sensitive to capture group-level differences between participants with MS with or without CI as well as participants without MS.

Association Between Performance in EVO Monitor and Standard Measures

Pearson correlation analyses were performed to scrutinize associations between performance in EVO Monitor and standard cognitive measures. The SDMT showed significant correlations with the EVO multitasking threshold level (Figure 4 and Table 2). Including age, sex, years of education, and BRT as covariates did not change the results (Table 2). Restricting the analyses to only participants with MS showed similar results. Furthermore, associations between clinical characteristics (ie, Expanded Disability Status Scale [EDSS] and disease duration) and the EVO multitasking threshold level were observed. Analyses of EVO perceptual discrimination and visuomotor tracking threshold levels showed similar results (Table 2).

In a planned exploratory analysis, we investigated the correlation between performance in EVO Monitor and both MS-related physical function (walking speed, T25FW) and MRI volumetric data, given that these factors have been reported to associate with cognition in MS [31-34]. A negative correlation was observed between T25FW and multitasking threshold level (*r*=–0.45, *P*<.001) (Figure 5). The results remained similar when including demographic features as covariates (Table 3). Clinically acquired MRI volumetric data were available in 56 participants with MS (17 with CI). We focused on the thalamus and frontal lobes, given their reported relationships with cognition in MS [33,34]. The analyses revealed a positive correlation between the EVO perceptual discrimination threshold level and bilateral thalamic (left: *r*=0.47, *P*<.001; right: *r*=0.39, *P*=.002) as well as rostral middle frontal (left: *r*=0.28, *P*=.03; right: *r*=0.27, *P*=.03) volumes (Figure 6). The association with thalamic volumes persisted after adjusting for age, sex, years of education, and BRT (left: *r*=0.49, *P*<.001; right: *r*=0.38, *P*=.007). These results suggest that EVO Monitor performance is associated with standard MS cognitive and physical measures as well as MRI volumetric data.

Discussion

In this study, we aimed to determine whether in-game assessment features of EVO Monitor, an unsupervised, digital, video game–based tool integrated with adaptive algorithms, could represent a novel and sensitive way to perform unsupervised cognitive evaluations in MS. We found a significant group-level difference in performance on EVO Monitor among participants with MS with and without CI as well as participants without MS. Furthermore, we discovered an association between performance in EVO Monitor and standard cognitive measures, physical measures, and MRI volumetric data. These results provide evidence that EVO Monitor, an unsupervised, tablet game–based digital tool designed to assess executive function, attention, and information processing, could effectively assess cognitive performance in people with MS.

We demonstrated that EVO Monitor is sensitive enough to reveal group-level differences, as shown by a lower threshold level in participants with MS with CI compared to both participants with MS without CI and participants without MS in all 3 task conditions. The EVO Monitor program was developed to challenge nearly all aspects of cognition, including executive function, attention, and information processing. In perceptual discrimination and visuomotor tracking tasks, fast information processing is highly demanded, given that the participants are asked to make a fast response to certain stimuli (ie, colored target) and rapidly changing environment (ie, dynamically moving road with walls and obstacles), respectively. To successfully perform the multitasking challenge, there are additional cognitive requirements for selective attention, sustained attention, task switching, and goal management. Since processing speed, attention control, and executive function are the most commonly affected cognitive domains in MS [4,5], the lower EVO Monitor performance in participants with MS and CI may reflect a lower performance in these cognitive domains in general. These results suggest that cognitive dysfunction in MS can be captured by EVO Monitor, a digital tool with adaptive algorithms developed for cognitive assessment.

Using unsupervised digital tools provides a less stressful context and a high level of standardization of assessment. Moreover, it can be easily applied in multiple settings, including patients' homes, which substantially improves access to these therapies for patients who may face scheduling, geographic, or economic barriers in accessing standard forms of cognitive assessment. With the advances in digital therapeutics, assessment and health care services for people with MS have been transitioning to digital platforms [25,26,52]. These results extended the application of digital tools for cognitive assessments in MS by incorporating advanced visualization and reward loops with closed-loop adaptation mechanics to enhance engagement and reduce interindividual variability, which leads to more reliable assessments [8,47].

An association between performance in EVO Monitor and standard measures was observed. Participants with a better performance in EVO Monitor showed higher SDMT scores. SDMT is considered the most sensitive measurement for the evaluation of cognitive involvement and information processing speed in the MS course [29,30]. While the participant substitutes geometric symbols for numbers while scanning a response key, a number of domains—processing speed, sustained attention, visual scanning and tracking, and motoric quickness—are being challenged. Although the task structures are different between EVO Monitor and SDMT, the shared cognitive functions subserving the two tasks may explain the correlational links. The results suggest that EVO Monitor can reliably reflect performance in cognitive tasks that involve information processing speed, selective attention, sustained attention, visual tracking, and goal management. Importantly, analyses including only participants with MS did not change the results but further revealed a negative correlation between clinical characteristics (ie, EDSS and disease duration) and performance in EVO Monitor, where participants with MS who had a longer disease duration and higher level of disability showed a lower performance in EVO Monitor. Although the correlation was modest, given that cognitive deficits tend to progress with disease duration [53] and disability progression [54] in MS, the observed association was expected.

In an exploratory analysis, we discovered an association between EVO Monitor performance and the T25FW as well as the bilateral rostral middle frontal and thalamic volume. In line with previous studies reporting that cognition in MS is associated with physical fitness and balance [55,56] and the concept of cognitive-motor coupling [57], in this study we found that better EVO Monitor performance is correlated with a faster walking speed as measured by the T25FW. Imaging [58] and postmortem [59] studies have suggested that frontal and subcortical regions involved in executive function and cognitive processing speed are also related to the spatial and temporal aspects of gait. The observed association between EVO Monitor performance and the T25FW may be explained by cerebral injury causing impairment in both domains in MS.

Additionally, the performance in the perceptual discrimination task of EVO Monitor positively correlated with rostral middle frontal and thalamic volume. The rostral middle frontal region is part of the dorsolateral prefrontal cortex, an area that is considered the center of executive function [60] and several domains of cognitive control abilities required to perform the EVO perceptual discrimination task, including sustained attention [61], selective attention [62], and inhibitory control [63]. Studies have also demonstrated that the thalamus mediates arousal states [64], and thalamic atrophy is the most significant MRI correlate of CI in MS [65,66]. It is unclear why performance in multitasking, a task including both perceptual discrimination and visuomotor tracking, did not correlate with thalamus and frontal volumetric data. Given that the posterior cortex has been linked to sustaining attention to spatial locations [67], a key component of the visuomotor task, it is possible that the multitasking task does not solely rely on frontal and thalamic resources but is also supported by the posterior cortex. Therefore, the examined correlation was not strong enough to be detected, as it was in the perceptual discrimination task.

Although our analyses were exploratory, the observed correlations support the need to better understand how EVO Monitor performance is associated with physical performance and the structural and functional changes of the brain in people with MS. Specifically, studies with functional MRI and connectivity data would provide essential information about neural correlates of the EVO Monitor tasks and, more importantly, pathological changes related to CI and neural plastic changes as a result of cognitive remediation.

Previously, we showed that EVO-AKL-T01, a video game–based digital tool similar to EVO Monitor, is an effective in-home cognitive remediation program for MS [17,18]. The high adherence rate during the 4- to 6-week home-based cognitive rehabilitation strategy indicated that remote digital tools are well accepted by patients with MS, who may have limited access to cognitive assessment or treatment. Since EVO Monitor is a digital tool designed as a self-guided assessment, it can be used as an in-home cognitive evaluation with multiple assessments to track either the progression of CI or the responsiveness to cognitive interventions, which can substantially help patients navigate problems related to cognitive issues. Future studies are warranted to evaluate the use of EVO Monitor in everyday situations across different contexts and investigate whether the results would be different due to fluctuations in cognitive ability during the day. Another key factor in cognitive assessment is patient fatigue. Well-designed studies that control for impacts of perceived fatigue and fatigability on cognitive assessments measured by digital tools are needed. Future studies comparing how different aspects of fatigue (eg, physical vs cognitive fatigue) affect cognitive performance as assessed by a comprehensive neuropsychological examination and by a digital tool that provides a shorter assessment time would provide additional insight into the role of fatigue in digital cognitive assessments.

There are some limitations to this study. Since we only included one time point in this cross-sectional analysis, it is difficult to determine the reproducibility of the observed results to conclude the test-retest reliability of EVO Monitor. In the exploratory analysis of the association between performance in EVO Monitor and MRI volumetric measures, clinically acquired MRI scans were only available for about half of the participants with MS (n=56), and the impact of acquisition protocol heterogeneity on our MRI metrics should be taken into account while a robust image processing pipeline was applied. The age difference between the non-MS group and non-CI MS group is one of the caveats in this study. However, in our analyses, age was included as a covariate to control for the potential influence of age difference on the results. Skills using digital tools may be a confounding factor influencing the results, as participants with better digital tool skills or more experience using tablet devices may have performed better. Future studies investigating digital tools should control for participants' experience and skills using digital devices.

This study extended the application of digital tools for cognitive assessments in MS by incorporating built-in adaptive staircase algorithms to enhance engagement and mitigate interindividual variability. Furthermore, the encouraging findings suggest that EVO Monitor, an unsupervised, tablet game–based program, is a clinically valuable approach to capturing CI in MS. Since CI is one of the most debilitating manifestations of MS and traveling to clinics may be burdensome due to deficits in mobility or cognition, some patients may have limited access to cognitive assessments. The application of digital cognitive assessments provides flexibility, as the testing can be performed in different settings, including patients' homes. The development of digital cognitive assessments helps patients effectively detect CI and navigate cognition-related problems in their daily living. Future studies with multiple points of data collection and a deeper investigation of how physical performance and the functional and structural changes of the brain affect cognitive performance as measured by digital tools are warranted to provide additional insight.

Acknowledgments

We would like to thank our research participants. We thank Andrew Heusser, Guillaume Poirier, Vincent Hennemand, and Denise Bonet from Akili Interactive for suggestions concerning the study design.

This work was supported by the Doris Duke Charitable Foundation and Akili Interactive. Akili Interactive provided study tools (EVO Monitor) without charge for the study.

Conflicts of Interest

RB has received research support from the National Multiple Sclerosis Society, the Hilton Foundation, the California Initiative to Advance Precision Medicine, the Sherak Foundation, and Akili Interactive. RB has also received personal compensation for consulting from Alexion, Biogen, EMD Serono, Novartis, Pear Therapeutics, Roche Genentech, and Sanofi Genzyme. RH has received personal compensation for consulting from Roche, Novartis, MEDDAY, Sanofi, Atara, and QIA. AG is cofounder, shareholder, board of directors member, and advisor for Akili Interactive Labs, a company that manufactures investigational digital treatments delivered through a video game–like interface. AG has a patent for a game-based cognitive assessment on which the tool (EVO Monitor) that was used in this study was based. All other authors declare no conflicts of interest.

Abstract

Background: The low levels of control of hypertension and diabetes mellitus are a challenge that requires innovative strategies to surpass barriers of low sources, distance, and quality of health care.

Objective: The aim of this study is to develop a clinical decision support system (CDSS) for diabetes and hypertension management in primary care, to implement it in a resource-constrained region, and to evaluate its usability and health care practitioner satisfaction.

Methods: This mixed methods study is a substudy of HealthRise Brazil Project, a multinational study designed to implement pilot programs to improve screening, diagnosis, management, and control of hypertension and diabetes among underserved communities. Following the identification of gaps in usual care, a team of clinicians established the software functional requirements. Recommendations from evidence-based guidelines were reviewed and organized into a decision algorithm, which bases the CDSS reminders and suggestions. Following pretesting and expert panel assessment, pilot testing was conducted in a quasi-experimental study, which included 34 primary care units of 10 municipalities in a resource-constrained area in Brazil. A Likert-scale questionnaire evaluating perceived feasibility, usability, and utility of the application and professionals' satisfaction was applied after 6 months. In the end-line assessment, 2 focus groups with primary care physicians and nurses were performed.

Results: A total of 159 reminders and suggestions were created and implemented for the CDSS. At the 6-month assessment, there were 1939 patients registered in the application database and 2160 consultations were performed by primary care teams. Of the 96 health care professionals who were invited for the usability assessment, 26% (25/96) were physicians, 46% (44/96) were nurses, and 28% (27/96) were other health professionals. The questionnaire included 24 items on impressions of feasibility, usability, utility, and satisfaction, and presented global Cronbach α of .93. As for feasibility, all professionals agreed (median scores of 4 or 5) that the application could be used in primary care settings and it could be easily incorporated in work routines, but physicians claimed that the application might have caused significant delays in daily routines. As for usability, overall evaluation was good and it was claimed that the application was easy to understand and use. All professionals agreed that the application was useful (score 4 or 5) to promote prevention, assist treatment, and might improve patient care, and they were overall satisfied with the application (median scores between 4 and 5). In the end-line assessment, there were 4211 patients (94.82% [3993/4211] with hypertension and 24.41% [1028/4211] with diabetes) registered in the application's database and 7960 consultations were performed by primary health care teams. The 17 participants of the focus groups were consistent to affirm they were very satisfied with the CDSS.

Conclusions: The CDSS was applicable in the context of primary health care settings in low-income regions, with good user satisfaction and potential to improve adherence to evidence-based practices.

KEYWORDS

clinical decision support systems; primary health care; hypertension; diabetes mellitus; evidence-based practice; telemedicine; patient care management

Introduction

Hypertension and diabetes are leading modifiable risk factors for cardiovascular disease worldwide, major contributors to premature disability, and associated with substantial premature death and morbidity [1]. Despite all the advances in the therapy for these diseases, and the fact that many effective treatments are available, there is a great deal of room for improvement. There is a large gap between detection and control of both diseases, and the majority of patients do not reach therapeutic goals [2-4]. The situation is worse in low- and middle-income countries and even worse in rural communities, where awareness, treatment, and control of hypertension are lower than in urban areas [2,4,5].

To face this challenge, innovative strategies are required. Clinical decision support systems (CDSSs), which are capable of generating suggestions or information that is specific to individual patients, based on the unique individualized patient information, can make a significant contribution to the effective dissemination of evidence-based practice. They may increase practitioners' adherence to guidelines, involving clinicians in the translation of research into practice [6]. Therefore, they may increase the proportion of patients who reach blood pressure and glucose goals, with a potential impact in reducing cardiovascular risk.

However, the evidence of impact of CDSSs on key diabetes care outcomes, such as the control of glucose, blood pressure, tobacco use, or appropriate aspirin use has been marginal or inconsistent. One important barrier in this context is CDSS usability [7]. Many CDSSs were not used regularly or on a sustained basis by primary care physicians [8]. This is true not only for diabetes, but also for CDSS in general. It has been reported that their adoption has been somewhat limited outside of a relatively small number of academic medical centers and integrated health care delivery networks [9,10]. Therefore, in order to translate evidence into practice and develop CDSSs, which can be useful and used in clinical practice, studies that assess usability prior to a large-scale implementation are of utmost importance [11].

Thus, our aim was to develop a CDSS for diabetes and hypertension management in primary care, to implement it in a low-income and mostly rural region, and to evaluate its usability and health care practitioner satisfaction.

Methods

Study Overview

This is a substudy of the HealthRise Brazil Project, a quasi-experimental study, which is part of a multinational study designed to implement and evaluate pilot programs aimed at improving screening, diagnosis, management, and control of hypertension and diabetes among underserved communities [12]. Interventions were designed and implemented in 9 communities in Brazil, India, South Africa, and the United States of America. Each program was designed and implemented by a local grantee and included interventions that were tailored to local needs and contexts [12]. HealthRise Brazil Project was conducted in 2 centers, Vitória da Conquista, in the state of Bahia, and in the region of Teófilo Otoni (Vale do Mucuri), the state of Minas Gerais. In this region, the project was implemented in 10 municipalities: Frei Gaspar, Ouro Verde de Minas, Crisólita, Catuji, Setubinha, Itaipé, Novo Oriente de Minas, Ladainha, Teófilo Otoni, and Ataleia.

This study was conducted by the HealthRise Brazil Teófilo Otoni team in 4 steps, according to the Medical Research Council framework (Figure 1) [13]: (1) identification of gaps in usual care; (2) identification of the components of the intervention through discussions with experts; (3) CDSS development and validation; and (4) pilot testing. Theory of change thinking was used throughout the study: programme design, monitoring, and evaluation [14,15].

Figure 1. Flowchart of the study methodology. CDSS: clinical decision support system.

	Step 1	Step 2	Step 3	Step 4
Objective	Identification of gaps in usual care	Development of a set of criteria regarding the functions and design of the software	Development of a prototype considering the users' and setting's needs and validation	Evaluation of the CDSS as a feasible and usable tool for Brazilian primary care
Task(s)	Identification of user's and setting's needs	Identification of the components of the intervention through discussions with experts	Software development according to the criteria/components defined in step 2 and validation	Pilot testing the CDSS in 34 primary care units in a resource-constrained area for 12 months

Identification of Gaps in Usual Care

To evaluate which gaps were already known, we assessed: (1) epidemiological studies and systematic reviews on hypertension and diabetes management; (2) secondary data, including census, *Sistema de Informação Ambulatorial* (Outpatient Information System), *Sistema de Informação da Atenção Básica* (Primary Care Information System), *Cadastro Nacional de Estabelecimentos de Saúde* (National Registry of Health Establishments), *Programa Nacional de Melhoria de Acesso e da Qualidade da Atenção Básica* (National Program for Improving Access and Quality of Primary Care), social dimensions of the research "Inequalities," and *Pesquisa Nacional de Saúde* (National Health Survey). We also assessed information from workshops and focus groups performed by the sponsor, with the participation of municipal and state government health managers, physicians, pharmacists, nurses, nutritionists, physical educators, university professors, specialists, representatives of patients and local communities, community health workers (CHWs), who discussed barriers and access opportunities, as well as priority areas (diagnosis, treatment, and disease management). This information was available the moment we applied for the research funding [12], and it was the starting point to generate ideas for the intervention design [16].

Identifying the Components of the Intervention Through Discussion With Experts and Stakeholders

In order to identify the components of the intervention, information was derived from the previous step, as well as previous assessments from our group [17,18]; discussions with primary care physicians, cardiologists, endocrinologists, nurses, nutritionists, pharmacists, and physical educators. Besides, meetings and internal workshops were conducted to discuss the topic with primary care practitioners, primary care unit coordinators, local health authorities, and stakeholders. The key stakeholders were identified and involved in the project from the beginning of design of the intervention [15].

A primary care physician, an internal medicine specialist, a cardiologist, and an endocrinologist discussed the gaps with experts in information technology and stakeholders to identify solutions and components of the intervention, to map anticipated change processes, long-term changes that needed to happen in the target group's lives, the barriers to those changes, and to explore assumptions and hypotheses [16].

At that time, all primary care units used a paper-based system to manage patient records; there were different levels of internet connectivity in the primary care centers and health care workers had low technical literacy. All of these factors were taken into account.

Clinical Decision Support System Development and Validation

Software Requirements

A team of clinicians established the functional software requirements necessary to record, track, and support decision making for patients with hypertension, diabetes, or both, according to the information obtained from the previous step and also from national and international guidelines [19-29] to define the technical specifications for digital systems. A list of indicators was defined for data monitoring.

Development of Content and Functionalities

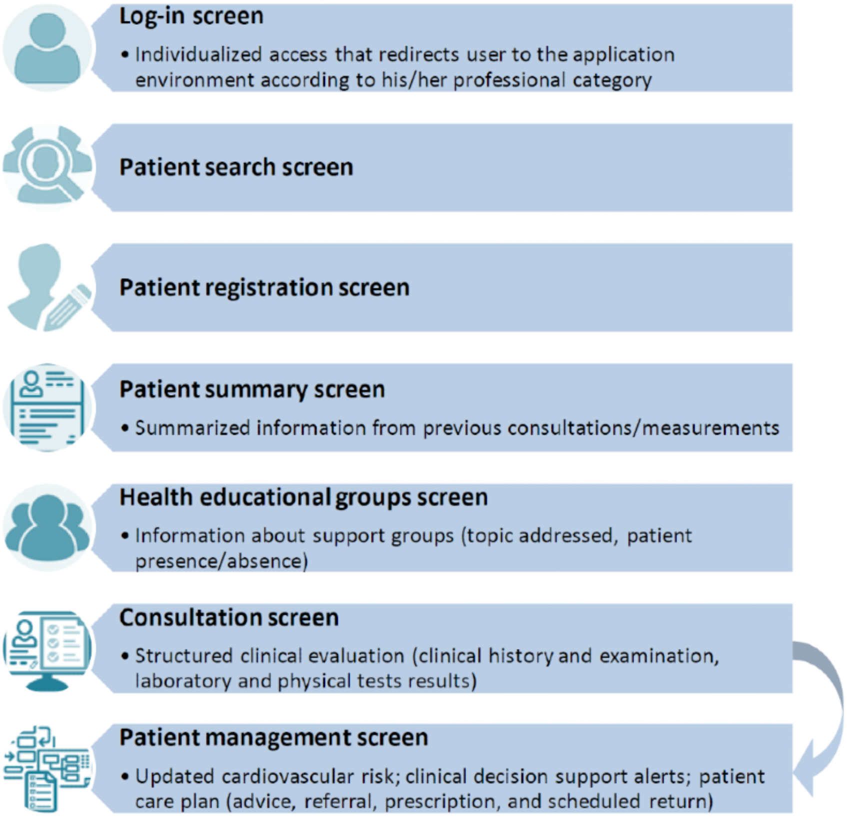
The technologies used for software development were chosen according to the available technological infrastructure in each municipality. In this context, the following aspects were taken into account: (1) existence of internet connection; (2) type of internet connection; (3) quality of internet connection; (4) existence of mobile and landline telephony; (5) equipment available in health units. Given the different realities and often precarious technology and information, the challenges faced were huge.

For the execution of the project, there was an agreement between the mayor of each municipality, the coordinator of each health unit, and the project management team to guarantee a minimum internet connection and the existence and maintenance of a local server network that would guarantee the registration and access to data while assisting patients. Despite this agreement, and because certain locations had few resources and limited or unstable internet connections, the server system was developed to work locally without the need for an internet connection. The internet was required only to synchronize local servers to the central database, whenever there was a connection, for scientific and monitoring purposes. Therefore, small drops in connection would not lead to any data loss or force an abandonment of using the system. With regard to problems in connectivity and transmission, in cases of momentary loss of synchronization of local data with the centralized data pool, data were synchronized whenever the connection was re-established. In remote areas, we used a portable internet router for transmission, and in rare instances of total absence of internet, which impaired the synchronization of the monthly data monitoring, data were copied to a portable storage device. With data from all units transmitted to the central database, these were extracted and exported to an Excel spreadsheet (Microsoft) for analysis by the research team (Multimedia Appendix 1).

The application was developed with an "user-centered design" [15], in Java language 1.8 and JSF 2.2, using NetBeans 8.1 development environment, PostgreSQL database server, and Hibernate framework, to be used in web browsers. The interface was developed to be intuitive and self-explanatory, using Prime Faces, Bootstrap, JavaScript, and jQuery. Security and access control were based on Spring Security, ensuring inviolability of the data. There was an iterative process of development, with close and daily cooperation between clinicians and developers of the application [15].

The application was designed to be used by health care professionals, and consists of: (1) a log-in screen; (2) a patient search screen; (3) a patient registration screen; (4) structured clinical evaluation, clinical decision support, and patient care plan; (5) a health educational groups screen; (6) patient summary screen; and (7) patient management screen (Figure 2).

Figure 2. The main functionalities of the application.



The log-in screen allows individualized access to the system through the credentials (user and password) provided to each professional. Each user is registered by a central administrator and each user account is associated with a professional profile that describes the way the application environment looks and operates for that user: physician, nurse, nurse technician, multidisciplinary primary care support team (*Núcleo Ampliado de Saúde da Família e Atenção Básica [*NASF-AB*]*, explained further in this article), and CHW.

After login, the professional has access to the screen to search for registered patients. If the patient was not registered before, he/she can access the registration screen, to register a new patient (demographic data, address, and telephone number). After registration, the other functionalities become available. Each patient has a specific identification code in the database.

The main functionalities of the application consist of the structured clinical evaluation, the clinical decision support, and the patient care plan. Data requested were manually entered, but data previously entered were saved for the next consultation, for example, medications used. In this case, the health professional could edit the information as necessary. Although few fields are mandatory, the application alerts the health care professional to the importance of completing the information appropriately and completely.

The structured clinical evaluation is shown partially in Figure 3. It includes data on symptoms, medical history, physical examination (including foot examination in patients with diabetes), current medications, and complementary examination results (laboratory and other tests).

Figure 3. Structured clinical evaluation.

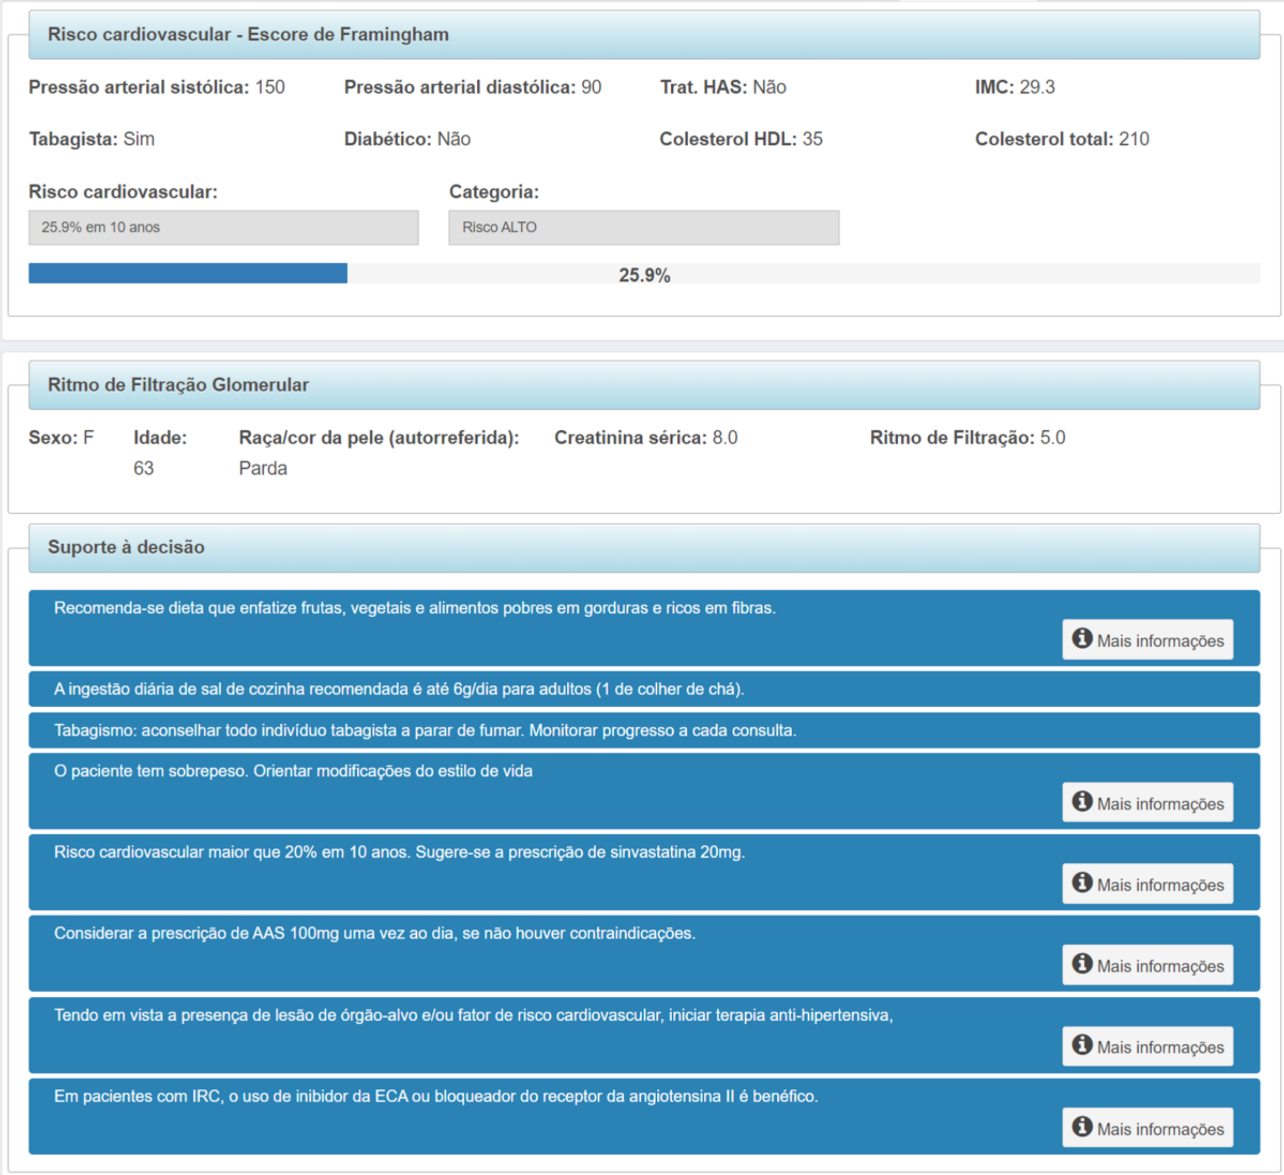
To develop the clinical decision support functionality, recommendations of Brazilian and international evidence-based guidelines assessing hypertension, diabetes, cardiovascular risk, and chronic renal disease were reviewed [19-29]. The most relevant clinical recommendations for the management of patients with hypertension, diabetes, or both were derived and organized into a decision algorithm, which bases the CDSS alerts, reminders, and suggestions. In case of conflicting recommendations, the one with the best level of evidence was chosen. When evidence-based guideline recommendations were not available or if they were considered outdated, evidence-based summaries were assessed [30]. Previous experiences of our group were important for the development of this functionality. Suggestions received about usability in previous opportunities were decisive to improve and create new messages and resources [17,18].

The clinical decision support tab is shown in Figure 4. In this tab, health care professionals could also access personalized messages to guide the management of each patient, generated according to the data entered in each consultation.

Figure 4. Clinical decision support tab.



Risco cardiovascular - Escore de Framingham

Pressão arterial sistólica: 150 **Pressão arterial diastólica:** 90 **Trat. HAS:** Não **IMC:** 29.3

Tabagista: Sim **Diabético:** Não **Colesterol HDL:** 35 **Colesterol total:** 210

Risco cardiovascular: 25.9% em 10 anos

Categoria: Risco ALTO

25.9%

Ritmo de Filtração Glomerular

Sexo: F **Idade:** 63 **Raça/cor da pele (autorreferida):** Parda **Creatinina sérica:** 8.0 **Ritmo de Filtração:** 5.0

Suporte à decisão

Recomenda-se dieta que enfatize frutas, vegetais e alimentos pobres em gorduras e ricos em fibras.

A ingestão diária de sal de cozinha recomendada é até 6g/dia para adultos (1 de colher de chá).

Tabagismo: aconselhar todo indivíduo tabagista a parar de fumar. Monitorar progresso a cada consulta.

O paciente tem sobrepeso. Orientar modificações do estilo de vida

Risco cardiovascular maior que 20% em 10 anos. Sugere-se a prescrição de sinvastatina 20mg.

Considerar a prescrição de AAS 100mg uma vez ao dia, se não houver contraindicações.

Tendo em vista a presença de lesão de órgão-alvo e/ou fator de risco cardiovascular, iniciar terapia anti-hipertensiva,

Em pacientes com IRC, o uso de inibidor da ECA ou bloqueador do receptor da angiotensina II é benéfico.

The following variables were calculated using the data entered: (1) BMI, (2) estimated glomerular filtration rate using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation [31], and (3) cardiovascular risk based on the Framingham score [32]. For the alert messages, each one contained a summarized recommendation, tailored according to each patient's state of health, with auxiliary text containing detailed information and references that support the recommendation.

In the patient care plan, the health care professional can register nonpharmacological interventions, complementary examinations requested, specialist referral and drug prescription (the last 2 functionalities are available only to doctors), and the date for the next consultation. It is also possible to request teleconsultation, defined as a second opinion system that allows an information exchange between distant and local health care professionals, in order to discuss a clinical case when a specialist is not locally available [33]. For this project, it was possible to forward doubts straight to a family physician and an endocrinologist, who were exclusively available for this project, or to other medical and nonmedical specialties, following the workflow of the Telehealth Network of Minas Gerais, a large public Telehealth service which assists 816 municipalities in the state of Minas Gerais [34]. All teleconsultations were asynchronous. The health care professional could choose which specialty he/she was referring the teleconsultation to, and the normal response time did not exceed 48 hours.

In the educational health groups (Figure 5) screen, the health care professional can register activities performed in different groups in which that patient belongs to (such as hypertension, diabetes, smoking, nutrition).

Figure 5. Health educational groups screen.

To conclude the consultation, the health care professional must save the data entered and has the option to print a structured medical record file with all information entered in that consultation, to attach to a physical patient chart. The medical prescription and the referral form can also be printed. Data are recorded in the application and transmitted to a telehealth care center as soon as a stable internet connection was available.

In the patient management screen, it is possible to generate patient lists, according to specific monitoring indicators.

Pretesting

The prototype has been tested multiple times with test cases to ensure that the system was operating as intended, free of bugs, and that the recommendation results matched the prespecified decision tree. A manual insertion of data by 2 physicians, 2 pharmacists, 1 nurse, and 3 medical students with test cases was performed to verify the recommendation response suitability.

Expert Panel Assessment

After adjustments, the prototype was submitted for expert panel assessment, composed of 2 cardiologists, 1 primary care physician, 1 endocrinologist, 1 nurse, 1 pharmacist, and 1 physiotherapist, known as technical reference, who were independent from the project and its implementers, in order to retain a degree of impartiality [15]. The experts used the application for 2 weeks, and were asked to assess functional suitability, stability, appropriateness of CDSS content, clinical benefit, readability, strengths, inconsistencies, perception of usefulness, whether it was appropriate to the local context, and satisfaction with the application. The prototype was then re-adjusted with the necessary changes, according to feedback from the expert panel.

CDSS Implementation

The field study was conducted from October 17 to October 18 in 5 primary care centers in Teófilo Otoni, the main city in the northeast region of Minas Gerais, with 141,934 inhabitants [35], and 29 primary centers in 9 small towns (with population less than 20,000 inhabitants), as part of the HealthRise Brazil Project—Vale do Mucuri. The region has a low human development: a mean Human Development Index (HDI) of 0.701 for Teófilo Otoni and 0.540-0.595 for the other municipalities, similar to poor African countries. About one-third of the population lives in rural areas (32.3%) [36]. The HealthRise Brazil Project (2016-2018) consists of 2 parts: patient screening and management (logic model is shown in Multimedia Appendix 2).

The intervention was multifaceted, including extensive training of primary care teams, empowerment of patients through education, improvements in access to examinations, strengthening of health educational groups, and implementation of the computer decision support application.

This study is part of patient management. For this substudy, 34 primary health centers in urban and rural areas were included, with family health teams composed of 1 physician and 1 nurse, 1 nurse assistant, and 4 to 6 full-time CHWs [37]. Family health service (FHS) teams provided comprehensive, universal primary care to defined geographical catchment areas, covering populations of up to 1000 households each (between 3000 and 4000 inhabitants), with no overlap or gap between catchment areas. Each FHS team member had defined roles and responsibilities, and national guidelines helped structure FHS responses to most health problems [37,38]. Pharmacists, physiotherapists, nutritionists, psychologists, physical education specialists, and social workers were part of the multidisciplinary primary care support teams (NASF-AB). Each NASF-AB team assisted 3 or 4 primary care centers [37]. Despite the existence of a university in Teófilo Otoni, clinicians have limited access to specialist referrals and to continuous learning.

Local health authorities and stakeholders were involved in the implementation of the system. The implementation of the application was stepwise, following a schedule of in-person and practical trainings. The participants had the opportunity to handle the devices that would be used. Different training strategies were developed for each professional category. The participants received printed material for further consultation in case of doubt. Furthermore, an online tutorial about the topic was recorded and was available on a platform where they could access online classes about different topics such as hypertension and diabetes management, cardiovascular risk, and operative group planning and organization. Two technology technicians were available online and by telephone to solve doubts and difficulties that arose while using the application. If necessary, they were able to visit each unit.

Fidelity was monitored periodically through checking whether field implementation altered the functionality and stability of the system, changing the intervention from that which was intended, as recommended by the World Health Organization [15]. Malfunctions and other problems with use of the CDSS were quickly fixed.

Feasibility, Usability, and Satisfaction Assessment

A questionnaire evaluating perceived feasibility, usability, and utility of the application and professionals' satisfaction, previously developed by our group [18], was applied after 6 months. The first part of the questionnaire included participant characteristics: age, specialty, time since graduation, time working in primary care, previous knowledge in dealing with health technologies, previous access to the internet, and previous access to continued education. The second part included Likert scale questions, varying from 1 (strongly disagree) to 5 (strongly agree), to assess feasibility, usability, and satisfaction. This instrument was evaluated in its reliability capacity applied in this context.

At the end of the HealthRise Project, 2 focus groups with primary care physicians and nurses were performed. The health care professionals talked about the advantages of using the software and what they thought should be improved. The sessions lasted for 1.5 hours and were audio-recorded. Questions started out broadly and became more specific as participants felt more comfortable and opened up.

Data Analysis

Distributions of continuous variables were examined for normality by using Kolmogorov–Smirnov tests. As the distributions were asymmetrical, these variables were expressed as median and corresponding IQR. Categorical variables were presented as frequencies and proportions. The reliability of the questionnaire to evaluate the perceived feasibility, usability, and utility was evaluated using Cronbach α. Data analyses were performed using the software IBM SPSS Statistics for Windows, version 21.0 (IBM Corp.).

Ethics

Ethical approval was obtained from the Universidade Federal dos Vales do Jequitinhonha e Mucuri Research Ethics Committee (number 65808517.9.0000.5108). Written and informed consent was obtained from all participants.

Results

Phase I: CDSS Development and Validation

An initial bank of 168 reminders and suggestions was created for the clinical decision support functionality. After message content refinement, a final bank of 159 reminders and suggestions was used. Textbox 1 shows examples of the CDSS messages. As there were many messages, we choose to extensively test 26 messages first; we implemented the application with those messages, and continued testing the other messages extensively. We divided the messages in blocks of 10, ranked the groups according to the priority of the recommendations for diabetes and hypertension management, and tested each group before implementation.

Textbox 1. Examples of clinical decision support system reminders and suggestions. ACE: angiotensin-converting enzyme.

- “Reinforce the importance of adherence to treatment and participation in the educational group. Request a visit from the community health worker”.
- “Cardiovascular risk greater than 20% in 10 years. The prescription of statin is suggested.”
- “Do not prescribe thiazide diuretic for this patient due to reduced renal function.”
- “If you decide to add another anti-hypertensive, choose one of the first-line groups (ACE inhibitor, angiotensin receptor II blocker, thiazide diuretic, long-acting calcium channel blocker), taking the contraindications into account.”
- “Metformin is being used at a dosage above the maximum recommendation. Dose reduction is suggested.”
- “This patient did not have a fundoscopic assessment in the last year”.
- “It is suggested to schedule the next consultation in one month, to reassess blood pressure levels”.

During internal tests, most errors identified were due to misplaced parenthesis and connectors in the commands of the decision algorithm. Posterior manual insertion of data evidenced remaining errors, spelling mistakes, and inconsistencies that were properly revised before the test by the panel of specialists. The expert panel–suggested changes were used to enhance the application.

Phase II: Feasibility, Usability, and Satisfaction Assessment

Quantitative Analysis

At the 6-month assessment, there were 1939 patients registered in the application database and 2160 consultations were performed by primary care teams. Of the 96 health care professionals who were invited for the usability assessment, 26% (25/96) were physicians, 46% (44/96) were nurses, and 28% (27/96) were from other health professionals. The number of participants per town varied from 5 (in Crisólita) to 14 (in Ataleia). Participant characteristics are shown in Table 1. Age varied from 23 to 68 and time since graduation varied from 1 to 29 years. Nurses and other health professionals were predominately women.

Table 1. Characteristics of health care professionals who participated in the study (N=96).

Variable	Physicians (n=25)	Nurses (n=44)	Other health professionals (n=27)	Total
Age (years), median (IQR)	35 (30-43)	33 (30-36)	32 (27-36)	33 (30-36)
Female sex, n (%)	11 (44)	33 (75)	22 (81)	66 (69)

Almost daily	2 (8)	3 (7)	4 (15)	9 (9)
Weekly	2 (8)	0 (0)	0 (0)	2 (2)
Rarely	0 (0)	1 (2)	0 (0)	1 (1)
Participated in an updating activity on management of hypertension, diabetes mellitus, or cardiovascular risk in the last year (yes), n (%)	17 (68)	18 (41)	7 (26)	42 (44)

The results of the questionnaire including 24 items on impressions of feasibility, usability, and utility are presented in Table 2. The reliability analysis of the instrument and 4 dimensions, applied to this population, presented a global Cronbach α of .93 (Table 2 and detailed in Multimedia Appendix 3), showing adequate internal consistency of this instrument for evaluation of the perceived feasibility, usability, and utility of the CDSS.

Table 2. Feasibility, usability, and satisfaction assessment scoresa (N=96).b

Item	Physicians (n=25)	Nurses (n=44)	NASF-AB[c] (n=27)	Total
Feasibility, median (IQR)				
The application can be used in primary care setting	4 (4-5)	5.00 (4-5)	4 (4-5)	4 (4-5)
It is easy to be incorporated in work routine	4 (2-5)	4 (4-4)	4 (3-4)	4 (3-4)
It does not cause significant delays in daily routine	2 (2-3)	3 (2-4)	4 (3-4)	3 (2-4)
Usability, median (IQR)				
Overall, evaluation is good	4 (3.25-4.75)	4 (4-5)	4 (4-5)	4 (4-5)
The screens are easy to understand	4 (4-4)	4 (4-5)	4 (4-4.5)	4 (4-5)
I was able to find the information I was looking for	4 (4-4)	4 (4-4)	4 (4-5)	4 (4-4)
The definitions of comorbidities are clear	4 (4-4)	4 (4-4.75)	4 (4-5)	4 (4-4)
The fields are easy to fill	4 (4-4)	4 (4-5)	4 (4-5)	4 (4-5)
It has proper interface	4 (4-4)	4 (4-5)	4 (4-5)	4 (4-5)
It is stable during the use	4 (2-4)	3 (2-4)	3 (2-4)	3 (2-4)
Utility, median (IQR)				
The application might improve patient care	4 (4-5)	5 (4-5)	5 (4-5)	4 (4-5)
The recommendations brought new information on hypertension, diabetes mellitus, and cardiovascular risk	4 (4-4)	4 (4-5)	4 (4-5)	4 (4-5)
It was useful to calculate the cardiovascular risk	4 (4-4.75)	4 (4-5)	4 (4-5)	4 (4-5)
It was useful to promote cardiovascular disease prevention	4 (4-5)	4 (4-5)	4 (4-5)	4 (4-5)
It assisted me to treat my patients	4 (4-4)	4 (4-5)	4 (4-4)	4 (4-5)
It assisted me to choose complementary examinations	4 (3-4)	4 (4-5)	4 (3.75-4.25)	4 (4-5)
It was helpful to decrease referral to specialists	4 (2-4)	4 (3-4)	4 (4-4)	4 (3-4)
It was useful for different professional categories	4 (3-4)	4 (4-4)	4 (4-4)	4 (4-4)
I believe the recommendations are appropriate	4 (3-4)	4 (4-4)	4 (3.75-4.25)	4 (4-4)
I used the suggestions to modify patient care	4 (4-4)	4 (4-5)	4 (4-5)	4 (4-5)
Satisfaction, median (IQR)				
Overall, I am satisfied with the application	4 (4-4.75)	4 (4-5)	4 (4-5)	4 (3-4)
It may be beneficial for patient care	4 (4-4.75)	4 (4-5)	4 (4-5)	4 (4-5)
I will keep using it for patient care	4 (4-5)	4 (4-5)	4 (4-5)	4 (4-5)
I would recommend this application	4 (3-4.75)	4 (4-5)	4 (4-5)	4 (4-5)

[a] Ranging from 1 to 5.

[b] Cronbach α for the Global questionnaire (24 items) is .93.

[c] NASF-AB: Núcleo Ampliado de Saúde da Família e Atenção Básica (multidisciplinary primary care support teams).

At the end-line assessment, health care professionals registered 4211 patients in the application’s database and 7960 consultations were performed by **primary health care** teams. Patients were predominantly female (2819/4211, 66.94%), median age was 55.0 (IQR 47.0-62.0). A total of 3993 (94.82%) patients were diagnosed with hypertension and 1028 (24.41%) were diagnosed with diabetes and there were 810 (19.24%) patients with diagnosis of both hypertension and diabetes.

Qualitative Analysis

In the focus groups, 13 physicians and 4 nurses participated (71% [12/17] female, median age 34 [IQR 31-39], ranging from 24 to 69 years). With regard to the difficulties dealing with the technology, the majority of participants reported some difficulties in the first days using the software, but no problems afterward. However, there was a statement of more difficulties among older professionals, who received help from the younger team members:

> *I started handling the software for patient assistance, as a nurse. I had no difficulties. Nowadays I help other professionals, such as doctors, who are more used to pen and paper. My unit has a doctor with 30 years experience, who had more difficulty adapting*

> *(using the software). As I showed him step by step and all functionalities of the software, he became interested and found it cool When he learnt that he could write patient prescriptions and print it using the software, he was very satisfied. So now, he prints the patient prescription and the exams, correctly. This way, he saves a lot of time.* [Female, 37-year-old nurse, 13 years' experience working as a primary care nurse]

The structured clinical evaluation was perceived as an advantage, as exemplified below:

> *The questions we always ask (using the software). Are you feeling shortness of breath? Do you wake up out of breath? Sometimes in a rush, we forget (to ask those questions to the patient). But we always ask them (when using the software). It is as if you take the query and say: this is indispensable for you to ask to the patient. You always have to remember to ask about it. So, for me it's great. I will always remember to give counselling, for example, when the patient is a smoker, at the end there is always the 'Did you talk about smoking?' reminder. So there you will remember to tell the patient "Look, you have to stop smoking". For me, this is very cool.* [Female, 31-year-old physician, 4.5 years' experience working as a primary care physician]

> *There was no habit of measuring the blood pressure sitting, lying down and standing. After we started using the software, it became routine. We do not need to say anything. The nurse technician already measures the blood pressure of all patients that way.* [Female, 31-year-old physician, 4.5 years' experience working as a primary care physician]

However, the time spent in the consultation was seen as a challenge for some participants. In some cases, they were forced by the health department to attend each patient for a maximum of 15 minutes, but this time was not sufficient when attending the patients using the software:

> *I take an average of 30 minutes per consultation, i.e. two consultations. This is the same I do with prenatal consultations for pregnant women.* [Male, 39-year-old physician, 6 years' experience working as a primary care physician]

In other cases, there was an organizational issue in the primary care, which made it difficult to attend patients using the software:

> *My primary care center works as an emergency care. So we set aside a day to attend the patients from the project, which is a longer consultation. However, for example, we book ten patients from the program, but 20 show up; six from the project and the rest are patients with acute diseases. It is a challenge to attend the patients using the software, as there are other patients waiting. That makes it difficult.* [Female, 32-year-old physician, 6 years' experience working as a primary care physician]

Often the CHWs were the ones who registered the patients in the software and their educational level was usually low in that region, so some health care professionals interviewed complained that spelling mistakes in patient names made them waste time trying to guess how the CHWs might have registered the patient's name.

With regard to the clinical decision support functionality, all participants were consistent to affirm they were very satisfied with it. They considered the alerts and recommendations very useful for patient care, and reported that it influenced their patient care plan.

> *We usually don't have time to calculate cardiovascular risk and kidney function. The software helps a lot.* [Male, 39-year-old physician, 6 years' experience working as a primary care physician]

> *When attending a patient with high cardiovascular risk, who was taking 40 milligrams of simvastatin, and also amlodipine for hypertension, I received an alert to adjust the dosage of simvastatin to 20 milligrams, as amlodipine may increase the serum concentration of simvastatin and thus increase the risk of adverse effects. I had no idea, I learnt with the alert and changed patient prescription.* [Female, 31-year-old physician, 4.5 years' experience working as a primary care physician]

There was a suggestion to improve the clinical decision support functionality, creating "red flags":

> *I think the abnormal findings or the alerts could be in red. For example, the alert 'This patient is in stage 3a renal failure' should be in red.* [Female, 39-year-old physician, 6 years' experience working as a primary care physician]

Concerning the ability to perform teleconsultations, the majority of participants said they have no time for it during the working hours. The ones who do it usually have to use their off-working hours:

> *I love to do teleconsultations, it helps the patients a lot. So much so that I am currently second (professional who requested the highest number of teleconsultations) in the state of Minas. We can help a lot people in primary care (using the teleconsultations). But I do it (the teleconsultation) at home; That's why it's hard work and a lot of people don't do it, there's no way to do it on the job.* [Male, 69-year-old physician, 29 years' experience working as a primary care physician]

Finally, each software screen was projected and we discussed which variables they felt could be removed. All participants were consistent to affirm that all variables were very useful, except for patient admission, in which they had to fill in the date of admission and patient discharge, as well as the reason for admission. They considered these variables were not necessary, and their work could be reduced if they could be removed.

Discussion

Main Findings

This study described the development, usability, and satisfaction assessment of a web-based CDSS for diabetes, hypertension, and cardiovascular risk management in primary care. Its implementation in a low-resource setting, for users who were used to the paper-based patient records only, has shown to be feasible. Participants with a wide age range and experience in primary care found it to be usable, reported satisfaction, and attended almost 2000 patients using the system over 6 months and over 4000 patients by the end of follow-up.

With the adoption of the 2030 Agenda for Sustainable Development and the 17 Sustainable Development Goals [39], health systems and stakeholders worldwide are interested in innovative approaches to achieving universal health coverage objectives [15,40]. Although the Brazilian Constitution states that health care is free and provided by the public health system to all citizens, patients have unequal access to specialized health care services, especially in remote municipalities. Primary care physicians are often young people (less than 35 years of age) with little professional experience (less than 10 years of medical practice) [41]. Additionally, in those municipalities, there is a strong sense of professional isolation and high turnover of health professionals, which compromises the quality of health care [42]. In a recent meta-analysis, blood pressure control rates ranged from 43.7% to 67.5% in Brazilian patients [43]. Brazil is also one of the “most important examples of the alarming picture of diabetes in emergent societies,” with the fourth largest number of people with diabetes, and a poorer glycemic control rate than that observed in Europe and the United States. Even when a less stringent target was considered, only 48.5% of patients had an HbA1c level less than 8% [44]. In this context, digital health interventions may be very useful, especially those focusing on existing evidence-based health interventions, on the determinant layers of universal health coverage [15].

As CDSS recommendations evolve over time as evidence and the patient’s clinical state evolves, it provides a dynamic and personalized patient care plan that can be easily accessed by any health team member at any point in time [7], and may reduce the likelihood of unhelpful or risky prescriptions [45]. In this study, CDSS was implemented as part of a multifaceted strategy to enhance the delivery of evidence-based care in a resource-constrained area. It is innovative, as the majority of previous studies assessed the use of CDSS for hypertension and diabetes management in high-income countries [46]. Therefore, there is paucity of data on low- and middle-income countries and rural communities, which are the areas in most need and where the access to information technologies may be impaired. In our study, one-third of the total sample (34/96, 35%) and 52% of the doctors (13/25) did not use any form of technology for work before this research project. They did not use any kind of computerized physician order entry or electronic health records, so the implementation of the CDSS brought a significant change in workflow, which could be an important barrier for its usability [9,47]. Therefore, motivating these health care professionals and providing training in using the CDSS were challenging. Developing user-friendly interfaces and avoiding unnecessary information and excess of clicks were essential. Participants agreed that the interface was suitable. Making a tutorial video was important, but it did not replace the need for in-person training, and technical support was of utmost importance. Although the expert panel found the application intuitive, with no need for previous training, the health care professionals did not agree with that, which suggests different levels of technological skills.

With regard to the change in the workflow, health care professionals had to enter all the data items manually. It is reported that the burden of data entry may make them give up and abandon the CDSS [9]. At the same time, there is evidence that arduous data entry facilities adversely affect clinicians’ satisfaction [48], but the specificity level of computer-generated advice is known to highly influence the chance that physicians adhere to the advice [9]. To provide specific advice, is not possible to rely on limited data. A solution we found to try to overcome those barriers, facilitating the integration in the workflow and avoiding duplication of work, was to enable the health care professional to print the consultation using the CDSS and attach it to patient charts. The fact that it could be used by all primary care practitioners, each category with its allowances, and one complementing the other, with the inclusion of the educational groups and a patient management screen, was also important. Additionally, all the data on comorbidities and medications from a previous consultation did not need to be filled in again. Although the majority of primary care practitioners reported satisfaction with the application, doctors gave a low score for the variable “significant delays in daily routine” (median 2.0, IQR 2.0-3.0). Although the median score for doctors for “easy to be incorporated in work routine” was 4.0, 30% (7/23) of them choose a lower score (P25 [first quartile]=2.0). This was also reported in the focus groups. By contrast, when asked about reducing variables in the application, all professionals were consistent with the request to keep it the way it was.

Although the clinical impact assessment was not the focus at the early stages of implementation, there was improvement in outcomes related to hypertension and diabetes management, which are shown in another publication [12]. It is well established that managing the global cardiovascular risk is more important than only reducing blood pressure, glucose levels, or both [49], and this cardiovascular risk should drive preventive strategies. However, the majority of published CDSS did not include the assessment of cardiovascular risk. Choosing the cardiovascular risk calculator to include in the software was challenging, as no score was validated for the South American population [25]. We decided to use the Framingham score [32], as it was widely validated in different populations (European, Asian, Australian, and North American) and assessed important outcomes (coronary artery disease, stroke, peripheral artery disease, and heart failure) with no limitation in number of events (as in the case with the Atherosclerotic Cardiovascular Disease Risk Algorithm [ASCVD], which assessed only the first event) or restricted to fatal events only (as in the case with the Systematic Coronary Risk Evaluation [SCORE]) [50]. Additionally, it includes a number of variables that are easily obtained. In case total cholesterol and high-density lipoprotein cholesterol levels are not available yet, the risk can be estimated using another version of the score, in which BMI replaces the lipid levels [32,51].

Limitations

This is study has some limitations. As was determined by the Ethics Committee, responses to the questionnaire were not identified, so we were not able to assess the results of feasibility, usability, and satisfaction according to the number of patients managed by each user. Additionally, there was no formal evaluation of the effectiveness. The software was part of a multifaceted intervention, whose results were published elsewhere [12], and it is not possible to access the impact of the software by itself. Meta-analyses suggest that CDSS with recommendations to both patients and health care professionals is more effective than providing CDSS to health care professionals only [8,52]. In this study, due to the high levels of illiteracy, we opted not to work directly with patients at that time.

Success Factors

The majority of health care professionals (52/96, 54%) and 32% (8/25) of the doctors had no access to update an activity in the previous year. It is well established that CDSSs are designed to support decision making rather than making the decisions for the user, who makes the final decision based on his/her knowledge, experience, and scientific evidence provided by the CDSS or other sources [47]. Therefore, another important step was clinical training. Professionals had access to online classes, which were designed for each professional category and took into account their reality in terms of resources. Therefore, we believe that the opportunity of updating knowledge via online classes and by using the CDSS may have been one success factor, as has been already reported in the literature [7,8]. For those health care workers who had impaired access to continued education, there was a perception that the CDSS was a useful tool to improve patient care. It may have overcome the delays in daily routine and the perceived difficulty to be incorporated into the clinical workflow.

Management of diabetes and hypertension is a team effort, and many health care professionals may be involved [53,54], so we believe that the fact that all health care practitioners could access the CDSS, each on in their own role, was another important success factor, avoiding keeping patient care completely medical centered.

Careful monitoring of CDSS use rates, requesting feedback from users, and adjusting the application accordingly were other important success factors. Interventions lacking robust monitoring activities are unlikely to generate the impact expected from them and may lead to misjudgment of the digital health intervention as being not effective. As recommended by the WHO, robust monitoring and evaluation plans are essential to support effective implementation and potential intervention scale-up [15].

It is known that the level of adoption of a digital health intervention by users is “dependent on the end-users’ interaction with the technology and their belief/opinion that use of the technology will benefit their health” [16]. The responses to the questionnaire and the comments in the focus groups showed that this was probably another success factor in our study.

To ensure sustainability, the Brazilian Ministry of Health, MG state government, and municipal governments were involved from the beginning, as well as different stakeholders and local health professionals. The successful experience caught the Brazilian Ministry of Health’s interest, who in turn sponsored the continuation of the project’s activities for 2 years in the same region.

Next Steps

We are planning to expand the project to primary care units in other towns, to include other diseases, and to implement in other settings. Our team is now working on the intervention refinement and software improvement, to subsequently conduct a cluster randomized controlled study to test the intervention implementation in other settings. The integration of the CDSS with the incipient electronic medical record of the Brazilian public health system (e-SUS) is a challenge, but we are currently working to overcome this barrier. Although there is limited transferability of the results to other settings, the lessons learnt may be useful for the implementation of other CDSSs in Brazil and around the world.

Conclusion

In this study, a CDSS developed to assist the management of patients with hypertension or diabetes or both was applicable in the context of primary health care setting in a low income region, with good user’s satisfaction and potential to improve adherence to evidence-based practices.

Acknowledgments

HealthRise Brazil Project was designed in partnership with Medtronic Foundation (sponsoring institution), Abt Associates, and Institute for Health Metrics and Evaluation. Those institutions had no influence on software development, implementation, and assessment. AR was supported in part by the Brazilian research agencies CNPQ (*bolsa de produtividade em pesquisa* 310679/2016-8 and IATS 465518/2014-1) and FAPEMIG (*Programa Pesquisador Mineiro* PPM-00428-17 and *Rede de Teleassistência de Minas Gerais* RED-00081-16). AR and MM are members of the National Institute of Science and Technology for Health Technology Assessment (IATS/CNPq). JO received doctoral grant (number 88887.142558/2017-00) from the *Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brasil* (CAPES) – Finance Code 001, as part of the IATS/CNPq. KA received grants from the IATS (number 372857/2019-1). The authors thank Santino Filoso for revising the manuscript.

Authors' Contributions

AR, CC, VP, and MM were responsible for the research protocol and coordinated the study. MM, JO, JM, LB, and TS participated in the CDSS development and testing. CC, JO, JM, LC, LR, MM, TS and VP participated in the CDSS implementation. CC was responsible for coordination of the research team for the application of the questionnaire. MM performed the data analysis and drafted the manuscript. All other authors reviewed and edited the manuscript. JO organized the manuscript references. All authors approved the final version.

Abstract

Background: Liver cancer is a substantial disease burden in China. As one of the primary diagnostic tools for detecting liver cancer, dynamic contrast-enhanced computed tomography provides detailed evidences for diagnosis that are recorded in free-text radiology reports.

Objective: The aim of our study was to apply a deep learning model and rule-based natural language processing (NLP) method to identify evidences for liver cancer diagnosis automatically.

Methods: We proposed a pretrained, fine-tuned BERT (Bidirectional Encoder Representations from Transformers)-based BiLSTM-CRF (Bidirectional Long Short-Term Memory-Conditional Random Field) model to recognize the phrases of APHE (hyperintense enhancement in the arterial phase) and PDPH (hypointense in the portal and delayed phases). To identify more essential diagnostic evidences, we used the traditional rule-based NLP methods for the extraction of radiological features. APHE, PDPH, and other extracted radiological features were used to design a computer-aided liver cancer diagnosis framework by random forest.

Results: The BERT-BiLSTM-CRF predicted the phrases of APHE and PDPH with an F1 score of 98.40% and 90.67%, respectively. The prediction model using combined features had a higher performance (F1 score, 88.55%) than those using APHE and PDPH (84.88%) or other extracted radiological features (83.52%). APHE and PDPH were the top 2 essential features for liver cancer diagnosis.

Conclusions: This work was a comprehensive NLP study, wherein we identified evidences for the diagnosis of liver cancer from Chinese radiology reports, considering both clinical knowledge and radiology findings. The BERT-based deep learning method for the extraction of diagnostic evidence achieved state-of-the-art performance. The high performance proves the feasibility of the BERT-BiLSTM-CRF model in information extraction from Chinese radiology reports. The findings of our study suggest that the deep learning–based method for automatically identifying evidences for diagnosis can be extended to other types of Chinese clinical texts.

KEYWORDS

BiLSTM-CRF; natural language processing; radiology reports; information extraction; computer-aided diagnosis; BERT

Introduction

In the past decades, electronic health records (EHRs) from millions of patients have become massive sources of valuable clinical data. Machine learning–based algorithms, especially deep learning algorithms, have been applied effectively to analyze patient data and they have shown promising results, thereby advancing medical research and better informing clinical decision making for the secondary use of EHRs [1,2]. Owing to the high dimensionality, noise, heterogeneity, random errors, and systematic biases, the data mining of EHRs remains challenging. Natural language processing (NLP) technologies could extract meaningful information, thus facilitating the application of clinical texts. There are 2 types of methods for information extraction, namely, rule-based methods and machine learning methods [1]. The use of machine learning methods for data mining of EHRs can derive previously unknown clinical insights and be applied powerfully in clinical decision-making and computer-aided diagnosis of diseases [3,4]. Recently, deep learning methods have had a profound impact in various areas of research because of their simplicity, efficient processing, and state-of-the-art results [5,6]. In particular, recurrent neural networks and Word2Vec embedding are the most popular methods that are utilized in clinical NLP tasks [2]. Deep learning methods have made improvements in various clinical applications, especially for text classification, named-entity recognition (NER), relation extraction, and question answering [7,8]. With growing acceptance and increasing number of applications, deep learning methods have become a baseline in many clinical NLP tasks.

Word embedding is an essential step for sequencing labelling tasks. Learning word representations from massive unannotated documents is a long-established method. The Word2Vec method [9] is the first word embedding approach based on deep learning methods. The model derives the semantic and synthetic meaning of a word on account of its adjacent words by using unsupervised learning. Global Vector word representation [10] is another effective word embedding method, which constructs a global word-word co-occurrence matrix and utilizes matrix factorization to learn embeddings in a lower dimensional space. However, the word-level representations have a limitation that only a single embedding is provided for a word with no thought for polysemy under different contexts. Unlike the traditional embedding methods, ELMo (Embeddings from Language Models) [11] uses a bidirectional language model to embed the context information into word representations. BERT (Bidirectional Encoder Representations from Transformers) [12] is another prominent contextualized word representation model, which uses a masked language model that predicts randomly masked words in a context sequence. Different from ELMo, BERT targets different training objectives and uses a masked language model to learn bidirectional representations. For clinical sequence labelling tasks such as NER, rule-based approach and conditional random fields (CRFs) have been used widely. Deep learning technologies substantially improve the NER performance through multi-layer data representations. Of the popular deep learning methods, BiLSTM (bidirectional long short-term memory) can capture long-range related information effectively. Furthermore, BiLSTM with CRF, known as BiLSTM-CRF, outperforms the traditional models with feature extraction and reduces the workload of feature selection [13].

Due to the difference in the grammatical features from English and the limitation of the EHR corpus, information extraction of Chinese EHRs using NLP remains challenging. In the medical field, researchers have developed information extraction algorithms for varied implementations, including diagnostic models for different diseases such as cancers [14] and childhood diseases [15]. For Chinese NER tasks, BiLSTM-CRF is the most common and practical approach [16,17]. BERT has also received extensive attention in Chinese EHRs. Zhang et al used fine-tuning BERT for NER and relation extraction in several types of Chinese clinical documents. The comprehensive clinical information related to breast cancer was extracted [14]. Wu et al developed an aided clinical diagnosis service on EHRs by using a deep learning model [3]. Liang et al applied an automatic NLP system and achieved a high diagnostic accuracy in childhood diseases [15].

The radiology report is a crucial component of EHRs, as it is the communication bridge between radiologists and physicians. The accuracy and efficiency of diagnosis are limited since it is formulated based on subjective judgment, especially for inexperienced physicians. Hence, extracting useful radiological information from radiology reports has considerable significance in advancing radiological research and clinical practice [18,19]. NLP technologies have received great attention in the processing of radiology reports and have been successfully applied in identifying biomedical concepts [20], extracting recommendations [21], determining the change level of clinical findings [22], and so on.

With the development of machine learning methods in recent eras, computer-aided early diagnosis for cancer based on massive clinical data becomes feasible. Many diseases have been investigated to date, such as hepatocellular cancer [23] and colorectal cancer [24]. In this study, we focused on the computer-aided diagnosis of liver cancer, which remains to be a substantial disease burden in China. For liver cancer diagnosis, dynamic contrast-enhanced computed tomography (CT) is one of the primary diagnostic tests. Imaging findings of the key enhanced scan phases such as the arterial phase, portal phase, and delayed phase are recorded in the radiology reports. According to the guidelines of the Chinese Society of Clinical Oncology (CSCO), hyperintense enhancement in the arterial phase (APHE) and hypointense enhancement in the portal and delayed phases (PDPH) are significant diagnostic evidences for liver cancer [25].

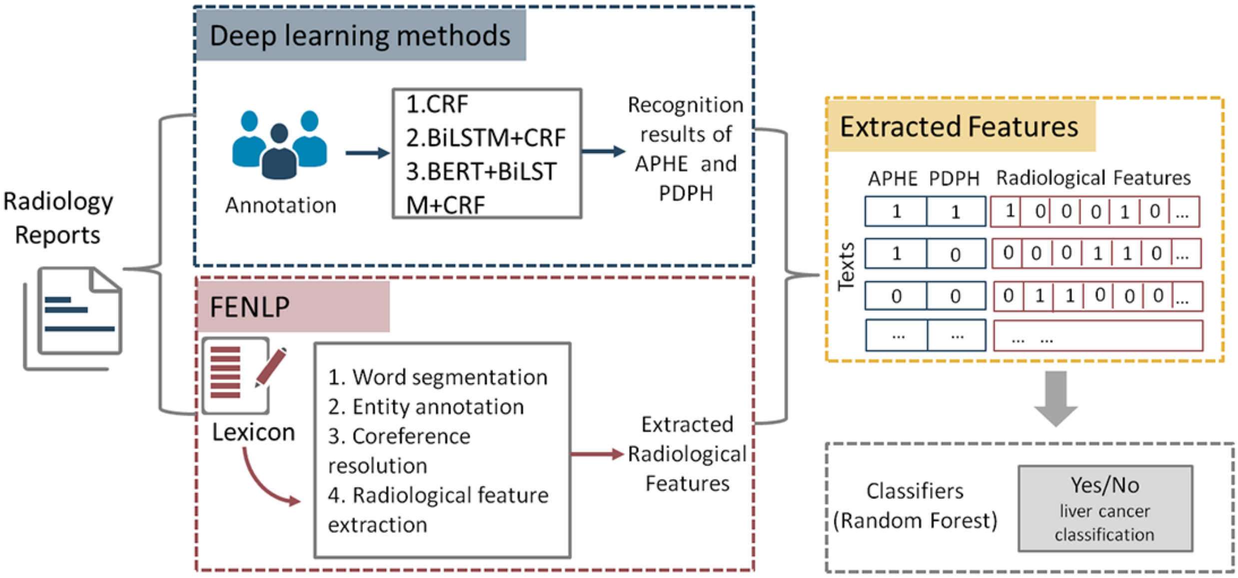
In this study, we designed deep learning–based methods to identify evidences for liver cancer diagnosis automatically. We recognized the phrases of APHE and PDPH by using a BERT-BiLSTM-CRF model by combining a pretrained, fine-tuned BERT language model with BiLSTM-CRF. We also applied the FENLP (feature extraction using the rule-based NLP) method based on the content of radiology reports to extract the radiological features. Therefore, the evidences for diagnosis, considering both clinical knowledge and radiology findings, contained APHE, PDPH, and radiological features extracted by FENLP [26]. With these evidences, we designed a computer-aided liver cancer diagnosis framework by using random forest.

Methods

Evidence Extraction for Diagnosis of Liver Cancer

Figure 1 shows the workflow of the evidence extraction for the diagnosis of liver cancer. We implemented 2 feature extraction methods based on clinical knowledge and the content of radiology reports to generate a radiological feature set. Then, we built a random forest model to predict liver cancer by using these features as inputs.

Figure 1. The workflow of this research. Labels 0/1 represent the absence/presence of a certain feature. BERT: Bidirectional Encoder Representations from Transformers; BiLSTM: bidirectional long short-term memory; CRF: conditional random field; APHE: hyperintense enhancement in the arterial phase; PDPH: hypointense in the portal and delayed phases.



Data Sets

We collected abdomen and pelvic CT radiology reports from a tertiary hospital in Beijing, China, between 2012 and 2019. To protect patient privacy, we removed all the identifying information. An unstructured radiology report has different sections, including Type of Examination, Clinical History, Comparison, Technique, Imaging Findings, and Impressions. The Impressions section summarizes crucial radiology findings from the Findings section and contains a diagnosis indicated by a radiologist. In this study, the diagnosis of liver cancer was determined according to the Impression section and the annotation of experienced radiologists, resulting in 480 patients with liver cancer. We randomly selected 609 patients without liver cancer from our data set. Therefore, 480 and 609 radiology reports for patients with and without liver cancer, respectively, were used in this study. We then trained and evaluated an NER model on the Imaging Findings section. The reports were randomly divided into the training set and the test set in a ratio of 8:2.

BERT-BiLSTM-CRF for Recognition of APHE and PDPH

We considered the recognition of APHE and PDPH as a sequence labelling task at the character level, where the goal was to assign the BIO (Begin, Inside, Outside) tags to each Chinese character. In this study, BIO tags contained B-APHE, I-APHE, B-PDPH, I-PDPH, and O-Outside. We invited 2 radiologists with more than 5 years of medical experience to annotate all the data. If there was any inconsistency, another experienced radiological expert was then asked to make the final annotation, to obtain the gold standard annotated data. To ensure the consistency of the annotation, radiologists were trained in advance. At the report level, APHE and PDPH were not mutually exclusive, that is, 1 report could contain both APHE and PDPH. Of all the reports, 602 had the phrase of APHE and 330 had the phrase of PDPH. For the 480 reports diagnosed with liver cancer, the numbers of APHE and PDPH were 442 and 330, respectively.

BiLSTM-CRF is commonly used in the sequence labeling task. To further improve the recognition performance for the features of APHE and PDPH, we performed the BERT-BiLSTM-CRF model comprising a fine-tuned BERT language model for word embedding and BiLSTM-CRF method for feature recognition. CRF and BiLSTM-CRF model were applied as the baseline. APHE and PDPH in Chinese radiology reports had a variety of presentations such as detailed presentation, CT values of different phases, and abbreviations (Table 1). The deep learning model for the recognition of APHE and PDPH consisted of 3 layers, namely, the word embedding layer, BiLSTM layer, and CRF layer (Figure 2).

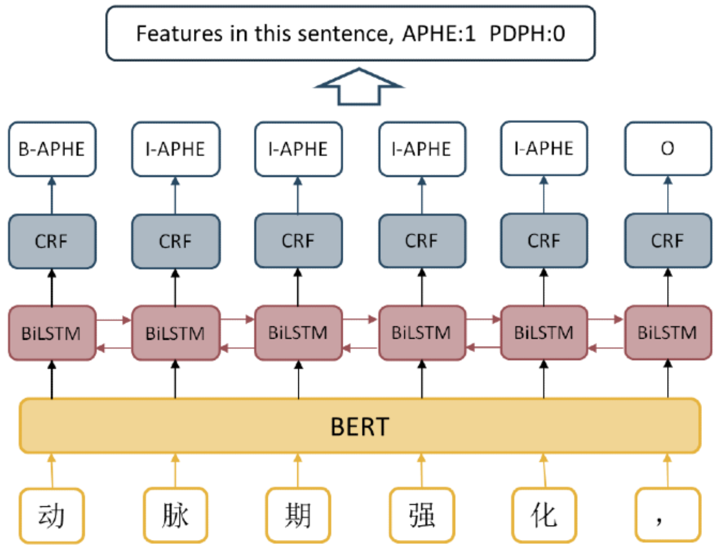
Table 1. Some expressions of APHE[a] and PDPH[b] in Chinese.

Expressions of APHE and PDPH in Chinese	Detailed descriptions
增强后动脉期明显不均匀强化	The arterial phase shows the heterogeneous density in the enhanced scan.
动脉期强化明显	Marked enhancement is shown in the arterial phase.
动脉期可见多发强化灶	Multiple enhancement areas are seen in the arterial phase.
门脉期相对低密度	The portal phase has relatively low density.
门脉期可见消退	PDPH occurs in the portal phase.

[a] APHE: hyperintense enhancement in the arterial phase.

[b] PDPH: hypointense in the portal and delayed phases.

Figure 2. The architecture of the BERT-BiLSTM-CRF model for the recognition of APHE and PDPH. BERT: Bidirectional Encoder Representations from Transformers; BiLSTM: bidirectional long short-term memory; CRF: conditional random field; APHE: hyperintense enhancement in the arterial phase; PDPH: hypointense in the portal and delayed phases.



Word Embedding Layer

The word embedding layer could map and transform the discrete characters into distributed representations. A word-level vector representation learned a real valued vector to represent a word from a large amount of unannotated text. On most NLP tasks, BERT could achieve state-of-the-art performance while requiring minimal architectural modification [27]. In this study, we applied Word2Vec and BERT to train the character vectors, followed by a comparison of the results. The Word2Vec was used with a dimension size of 100 and a batch size of 120. The Word2Vec was pretrained on the Chinese Wikipedia data. The sentence embedding had been pretrained and fine-tuned by BERT on the original Google BERT GitHub repository [28]. The maximum sequence length was set to 256 with a batch size of 64.

BiLSTM Layer

Recurrent neural networks is a family of neural networks, which is usually used for modelling sequential data. The LSTM (Long Short-Term Memory Networks) is a variant of the recurrent neural networks, and it can effectively capture high dependencies and retrieve rich global information. LSTM solves the problem by using the gating mechanism. An LSTM unit consists of 3 gates (ie, Input Gate, Output Gate, and Forget Gate), which can select semantic information in a neural network. Compared with LSTM, BiLSTM can learn forward and backward information of input words by splitting the neurons into 2 directions of a text sequence. We set the number of hidden units in BiLSTM to 100 and the optimizer to Adam.

CRF Layer

For the sequence labelling step in our study, adjacent tags had dependencies. For example, an inside tag I must follow a begin tag B. We applied the sequential CRF to calculate optimal sequence combinations on top of the BiLSTM layer that could consider the dependencies of adjacent tags.

APHE and PDPH Labels at the Report Level

Considering the characteristics of Chinese language and also avoiding the noise, we defined the following as APHE or PDPH features at the report level: (1) 2 continuous characters that were the abbreviations of APHE (ie, 快进) or PDPH (ie, 快出); (2) more than 3 continuous characters that were predicted as APHE or PDPH. Criterion (1) was checked first and was only based on the characters. If not met, criterion (2) was checked, which was based on CRF results.

FENLP for Radiological Feature Extraction

We implemented the NLP pipeline in the Findings section to extract useful features from the unstructured radiology reports to facilitate liver cancer diagnosis. As shown in Figure 1, the

NLP pipeline consisted of 4 successive steps, that is, word segmentation, entity annotation, coreference resolution, and relationship extraction, resulting in radiological features consisting of 1 or more terms. The detailed description of the pipeline is provided in our previous study [26]. The whole pipeline was based on a lexicon that was constructed manually according to Chinese grammatical characteristics. A small number of reports were sampled randomly for generating the lexicon by manual reading. The lexicon contained clinical terms and lists of synonyms. The lexicon was collected in the same hospital and clinical text type with this study. Five entity types (Location, Morphology, Density, Enhancement, and Modifier) were recognized. After coreference resolution, according to the synonym list in the lexicon, we then used several patterns of entity types as rules to obtain the final radiological features (Table S1 of Multimedia Appendix 1). Therefore, the radiological features could be seen as a combination of several entities such as 肝脏+低密度影 (liver + low density) and 肝脏+增强扫描未见强化 (liver + enhancement scan showed no enhancement).

Prediction Models

Using the radiological features obtained by BERT-BILSTM-CRF and FENLP, we used a random forest model for the liver cancer diagnosis. Random forest is an ensemble learning method constructed with a multitude of decision trees, which is widely used in classification tasks. The performance was measured by the recall, precision, and F1 score. Random forest could generate the feature importance score, which was computed by Gini impurity. Gini impurity is a measurement of the probability that a sample is classified incorrectly without a specific feature. In our study, the higher the feature importance score of the radiological features was, the more linked it was with the liver cancer diagnosis. We used the feature importance score to rank all the radiological features.

Results

We extracted the features of APHE and PDPH by using 3 different models, that is, CRF, BiLSTM-CRF, and BERT-BiLSTM-CRF. The recognition results were presented both at the report level and character level (Table 2). At the report level, the performance was computed depending on whether the radiology reports contained a feature of APHE or PDPH. At the character level, the recognition results of BIO tags for each Chinese character were counted. For the character-level recognition results of APHE and PDPH, the BERT-BiLSTM-CRF model obtained the best performance, with F1 scores of 89.14% and 82.19%, respectively. At the report level, the BERT-BiLSTM-CRF model also achieved the best performance (F1 scores of 98.40% for APHE and 90.67% for PDPH). For the other 2 baseline models, the BiLSTM-CRF model outperformed the CRF model but underperformed the BERT-BiLSTM-CRF model. If a single character was recognized as a feature, it would be regarded as noisy information, thereby leading to its exclusion from the report-level results. As a result, the recognition performances at the report level were higher than those at the character level in all the models. We chose the recognition results of APHE and PDPH at the report level by the BERT-BiLSTM-CRF model as the predictors for further liver cancer diagnosis.

The feature extraction method FENLP used the lexicon described in our previous study, which included 831 words and 5 entity types. Entity combinations conforming to specific entity patterns were formulated as radiological features. The patterns included Location + Density, Location + Enhancement, Location + Enhancement + Modifier, Location + Density + Modifier, and Location + Morphology. We retained the radiological features that occurred more than twice. We finally obtained 301 radiological features; among them, 6 features had a frequency higher than 300 (Table S2 of Multimedia Appendix 1).

Table 2. Recognition performance of APHE[a] and PDPH[b] by using different models at the character level and report level.

Models	Accuracy (%)	Precision (%)	Recall (%)	F1 score (%)
Character level				
Conditional random field				
APHE	96.05	84.13	72.19	77.70
PDPH	97.44	80.37	59.02	68.06
Bidirectional long short-term memory-conditional random field				
APHE	97.54	90.86	82.56	86.51
PDPH	98.24	84.56	75.72	79.89
BERT[c]+ Bidirectional long short-term memory-conditional random field				
APHE	97.97	91.14	87.22	89.14
PDPH	98.46	88.60	76.64	82.19
Report level				
Conditional random field				
APHE	94.52	98.28	91.94	95.00
PDPH	89.00	87.69	79.17	83.21
Bidirectional long short-term memory-conditional random field				
APHE	95.89	97.30	94.74	96.00
PDPH	93.61	92.19	86.76	89.39
BERT+ Bidirectional long short-term memory-conditional random field				
APHE	98.17	97.62	99.19	98.40
PDPH	93.61	87.18	94.44	90.67

[a] APHE: hyperintense enhancement in the arterial phase.

[b] PDPH: hypointense in the portal and delayed phases.

[c] BERT: Bidirectional Encoder Representations from Transformers.

According to the presence or absence of each feature extracted from either BERT-BILSTM-CRF or FENLP, each radiology report was represented by a 0-1 vector. The prediction results using different patterns of features are shown in Table 3. F1 scores of random forest using features from BERT-BILSTM-CRF and FENLP were 84.88% and 83.92%, respectively. With a combination of both kinds of features, the final F1 score of prediction model increased to 88.55%. Among all the feature input patterns, the precision and accuracy also obtained the highest value while inputting all the features, while the prediction model had the highest recall rate with only 2 features of APHE and PDPH. Among the features with a frequency higher than 10 in all the reports, the top 10 features linked with the liver cancer diagnosis were identified with the feature importance score computed by Gini impurity (Figure 3). The top 2 features were APHE and PDPH, which had substantially larger feature importance scores than the other features extracted from FENLP.

Table 3. Performance of different patterns of features for liver cancer diagnosis.

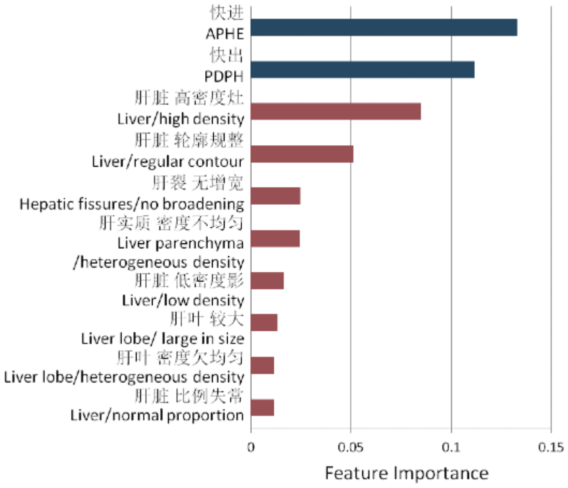
Patterns of Features	Accuracy (%)	Precision (%)	Recall (%)	F1 score (%)
APHE[a] and PDPH[b]	86.11	81.38	88.70	84.88
Radiological features from FENLP[c]	85.71	83.06	84.80	83.92
All features	90.25	91.52	85.77	88.55

[a] APHE: hyperintense enhancement in the arterial phase.

[b] PDPH: hypointense in the portal and delayed phases.

[c] FENLP: feature extraction using the rule-based natural language processing.

Figure 3. Top 10 radiological features linked with liver cancer diagnosis ranked by feature importance score. APHE: hyperintense enhancement in the arterial phase; PDPH: hypointense in the portal and delayed phases.



Discussion

Principal Results

Diagnostic prediction of cancer by using data mining methods is an essential and significant application of EHRs [5]. From previous studies, features extracted from EHRs have proved to be the valid input of the diagnostic model [14,29]. In particular, the use of machine learning methods, especially deep learning methods for clinical information extraction, could facilitate in providing new evidences in computer-aided diagnosis. As the burden of liver cancer is widely accepted as one of the principal and universal challenges in health care and as patients with liver cancer are usually diagnosed at the terminal stage, the early and accurate diagnosis of liver cancer by radiology examination has great significance [30,31]. In contrast with previous studies of liver cancer diagnosis, our study focused on the identification of evidences for live cancer diagnosis from Chinese radiology reports. We selected APHE and PDPH as the known evidences for diagnosis according to the guidelines of CSCO. These 2 features were essential but not sufficient enough to represent the whole report and further be used to diagnose liver cancer. Furthermore, using FENLP, we also extracted uncertain numbers of radiological features from the report content, because we aimed to obtain new evidences for essential diagnosis. Therefore, the evidences for diagnosis were obtained both from clinical knowledge and the content of reports. For the recognition of APHE and PDPH, we applied BERT on word embedding in the deep learning method, which achieved state-of-the-art performance.

Word embedding is an essential step for sequencing labelling tasks. Previously popular models such as Word2Vec and Global Vector word representation focused on learning context-independent word representations. Recent advances in word representations based on language models, including ELMo, CoVe, and BERT, could dynamically improve the word representations and discriminate among multiple meanings of a word. In particular, based on the attention mechanism, BERT exhibited an upward trend and outperformed the previous models in many NLP tasks. Recognition of APHE and PDPH using traditional NLP methods had difficulties, because the related descriptions covered varied Chinese sentence structures and entity types (Table 1). For example, for hyperintense enhancement, the sentence pattern and phrase could have different styles due to the different writing habits of different radiologists or due to the use of Chinese abbreviations. Different from the Word2Vec model, BERT learned context-dependent word representations by using bidirectional transformers. The BiLSTM algorithms are widely used and easily implanted in sequence-related work such as entity extraction. We annotated all the characters in the Findings section manually with BIO tags and then applied the BERT-BiLSTM-CRF model to recognize APHE and PDPH. The high performance proved the feasibility of the BERT-BiLSTM-CRF model in information extraction from Chinese radiology reports.

In this study, among the recognition results of APHE and PDPH obtained by the 3 different models, the BERT-BILSTM-CRF model finally achieved the best performance for both APHE (F1 score 98.40%, precision 97.62%, and recall 99.19%) and PDPH (90.67%, 87.18%, and 94.44%, respectively) at the report level. For the 2 baseline models based on CRF, the model with a BiLSTM layer received a much higher F1 score than the model without a BiLSTM layer. The results indicated that, with the word embedding language model BERT and the BiLSTM model, the recognition of APHE and PDPH could result in much higher performance. To avoid the noise in the recognition results, we used the recognition results at the report level to be the input radiological features of the liver cancer diagnostic model. Report-level recognition concerned only continuous characters longer than 3 characters and specific Chinese abbreviations. Therefore, report-level results could represent whether the report contained the features of APHE or PDPH. The recognition of APHE and PDPH by BERT-BiLSTM-CRF was accurate enough to be the predictors of liver cancer diagnosis.

Only 2 fixed features of APHE and PDPH were not enough for liver cancer diagnosis. Therefore, we further performed the automatic NLP pipeline FENLP to extend the feature set based on Chinese grammar and radiological characteristics. Different from that of BERT-BILSTM-CRF, the number of features generated by FENLP was unknown and changed according to the training texts. In this study, we finally extracted 301 features. The top features were the typical morphology of the different locations, which were essential to the diagnosis of the liver diseases (Table S2 of Multimedia Appendix 1).

We chose the random forest as the liver cancer diagnostic model. With 2 kinds of features obtained by BERT-BILSTM-CRF and FENLP, random forest could reach an F1 score of 88.55%, which was much higher than the model using either kind of features. The performance of the diagnostic model using APHE and PDPH was slightly higher than that of the model using features extracted from FENLP. By contrast, FENLP produced much more features than BERT-BILSTM-CRF. We further ranked the features by the feature importance score computed by Gini impurity, which could reflect the degree of association with liver cancer. APHE and PDPH were the top 2 features with a clearly higher feature importance score compared with other features obtained by FENLP. The results indicated the strong association of APHE and PDPH with liver cancer, which coincided with the current clinical knowledge. Of the top features obtained by FENLP, the feature *high density of liver* had the highest feature importance score, which was the important and basic risk factor for the diagnosis of liver diseases. Broadening of hepatic fissures was an essential feature that existed in liver cirrhosis or in liver cancer progressed from liver cirrhosis [30]. Our results confirmed that the radiological features from FENLP could also be an evidence for diagnosis, which could further improve the diagnostic performance. Furthermore, the top features linked with liver cancer could extend the diagnostic evidence and be the supplementary features of APHE and PDPH.

Designing disease diagnostic models based on EHRs is a significantly important research field. Recently, NLP and deep learning-based models have been widely applied in many studies [7]. For instance, Sada et al designed and performed NLP-assisted radiology document classification for liver cancer detection. The model finally received an F1 score of 0.78 [23]. Compared with previous studies on clinical information extraction, the evidences for diagnosis in this study were identified based on the clinical knowledge from the guidelines of CSCO and the content of the reports. APHE and PDPH are 2 widely accepted evidences for disease diagnosis, and they have also proved to be essential features in our liver cancer diagnostic model. Other radiological features from FENLP enlarged the potential evidences for the diagnosis of liver cancer. Moreover, we utilized the BERT-BiLSTM-CRF model in this study, which achieved the state-of-the-art performance.

Limitations

Our study had the following limitations. The number of radiological features from FENLP was not fixed since all desirable features were retained, which might introduce some noise into the extracted radiological features. Besides, from the clinical knowledge in the guidelines of CSCO, we only extracted 2 characteristic features. In future, we will collect more evidences for diagnosis in order to further improve the performance and make the model more explanatory. Through the analysis of the misjudged samples in the recognition of APHE and PDPH, we identified the main error that occurred when the description of APHE and PDPH only included CT values. With the comparison of CT values in different phases, we could define these 2 features. However, our methods did not focus on the CT value extraction, and the number of these cases were small. In future studies, CT value extraction and analysis can avoid this kind of error and increase the prediction performance.

Conclusion

In this study, we developed a deep learning–based method for the recognition of evidences for disease diagnosis and designed a computer-aided liver cancer diagnosis framework. The diagnostic evidences contained APHE, PDPH, and radiological features extracted by FENLP. We proposed the BERT-based deep learning model BERT-BILSTM-CRF for recognizing the phrases of APHE and PDPH, which are the essential features associated with liver cancer diagnosis. Our work confirms that BERT-based deep learning model can be used and has desirable performance in the radiological feature extraction of Chinese radiology reports. Furthermore, this study was a comprehensive study for NLP and its application, focusing on Chinese radiology reports. The deep learning model proposed in this study for information extraction is expected to be extended to different types of Chinese clinical texts and other kinds of applications.

Abstract

Background: The electronic health record (EHR) contains a wealth of medical information. An organized EHR can greatly help doctors treat patients. In some cases, only limited patient information is collected to help doctors make treatment decisions. Because EHRs can serve as a reference for this limited information, doctors' treatment capabilities can be enhanced. Natural language processing and deep learning methods can help organize and translate EHR information into medical knowledge and experience.

Objective: In this study, we aimed to create a model to extract concept embeddings from EHRs for disease pattern retrieval and further classification tasks.

Methods: We collected 1,040,989 emergency department visits from the National Taiwan University Hospital Integrated Medical Database and 305,897 samples from the National Hospital and Ambulatory Medical Care Survey Emergency Department data. After data cleansing and preprocessing, the data sets were divided into training, validation, and test sets. We proposed a Transformer-based model to embed EHRs and used Bidirectional Encoder Representations from Transformers (BERT) to extract features from free text and concatenate features with structural data as input to our proposed model. Then, Deep InfoMax (DIM) and Simple Contrastive Learning of Visual Representations (SimCLR) were used for the unsupervised embedding of the disease concept. The pretrained disease concept-embedding model, named EDisease, was further finetuned to adapt to the critical care outcome prediction task. We evaluated the performance of embedding using t-distributed stochastic neighbor embedding (t-SNE) to perform dimension reduction for visualization. The performance of the finetuned predictive model was evaluated against published models using the area under the receiver operating characteristic (AUROC).

Results: The performance of our model on the outcome prediction had the highest AUROC of 0.876. In the ablation study, the use of a smaller data set or fewer unsupervised methods for pretraining deteriorated the prediction performance. The AUROCs were 0.857, 0.870, and 0.868 for the model without pretraining, the model pretrained by only SimCLR, and the model pretrained by only DIM, respectively. On the smaller finetuning set, the AUROC was 0.815 for the proposed model.

Conclusions: Through contrastive learning methods, disease concepts can be embedded meaningfully. Moreover, these methods can be used for disease retrieval tasks to enhance clinical practice capabilities. The disease concept model is also suitable as a pretrained model for subsequent prediction tasks.

Introduction

Background

Diagnosing a disease is like putting together a puzzle. When more pieces match, we can decipher the picture more easily. Or, if we have a reference picture of the puzzle, matching the pieces can be accomplished more easily. Many "puzzles" have been collected in electronic health records (EHRs), which contain abundant information about patients and diseases and represent a treasure trove for medical research. However, EHRs are challenging to use effectively due to the heterogeneity of the data types they can contain [1-3].

Sometimes, doctors in emergency departments must develop treatment plans based on limited information from seriously ill patients. In such cases, only demographic information, vital signs (eg, blood pressure, respiratory rate, and blood oxygen saturation), and major discomfort information can be obtained. However, a patient's medical history may be collected through old records in the hospital database, and these records can provide doctors with vital information that can help them to identify serious diseases [4]. Based on the doctor's knowledge and experience, the patient's information can characterize the disease, enable the doctor to diagnose the patient, and allow the doctor to develop an appropriate treatment plan to prevent the disease from worsening.

Doctors can make great use of the rich information contained within patients' EHRs. However, it is almost impossible for EHRs to be of help to doctors if they are not organized. Full use of the medical information contained within EHRs in clinical practice greatly enhances doctors' abilities to treat patients [3,5,6].

The International Statistical Classification of Diseases and Related Health Problems 10th Revision (ICD-10) code [7] is a well-established classification system for diseases that contains approximately 70,000 diagnoses. These diagnoses are highly specific and contain meaningful words that can be used for patient medical records. ICD codes can easily be used as keywords to search for an EHR. However, it is difficult to search for records without the ICD code of a patient.

With the rapid development of natural language processing and deep learning during this decade, several models have been released to manage EHRs [1,8-10] using several primary tasks, including disease classification, prediction of clinical events, and concept embedding [2]. Due to the lack of gold standard label data for model training, concept embedding is critical to all EHR-related tasks [1,2,11,12]. Concept embedding can be regarded as a pretrained model that can be finetuned with limited label data for further event prediction, disease classification, and detection, including the diagnosis of diseases. Concept embedding can also be used for data retrieval [13,14], and can be further integrated into medical software, web services, and apps used by patients for disease screening purposes.

Therefore, the concept-embedding model is essential to EHR research because it can organize rich medical experience and knowledge. We aim to develop a disease embedding model that can cluster disease patterns based on initial data (eg, demographic information, vital signs, chief complaint, and medical history) collected from patients who have just arrived at a hospital.

Related Works

Structural data (eg, demographic information, blood pressure, and heart rate) and free text records are collected in an EHR. In traditional medical research, free text records are more difficult to analyze, and significant human resources are required to classify free text into tables using rule-based methods [1,2,10]. With the vigorous development of deep learning, several language models for extracting features from free text records have become available [15-17]. Long short-term memory [18] is a model architecture that can feed sequence data and properly ignore input or memory history data to extract accurate features. It was widely used on natural language processing tasks before Transformer [19] was proposed.

Transformer contains the multihead self-attention model, which can learn the attention (attention can be regarded as relevance) of words within the text. Transformer was released to perform translation tasks and speed up learning by feeding all data simultaneously (instead of feeding them one-by-one as is the case with long short-term memory). Bidirectional Encoder Representations from Transformers (BERT) [16] is an extension of Transformer, which has achieved excellent performance ratings in several competitions. The first version of BERT contained only Transformer's encoder, which pretrained the embedding of subwords (words broken into pieces) unsupervised through a cloze procedure and subsequent sentence prediction. Because translation was the original goal of Transformer, the multilingual pretrained BERT is suitable for EHR research in Taiwan because Taiwanese medical records contain English and Chinese.

Previous methods for concept embedding of the EHR model include long short-term memory, convolutional neural networks, and autoencoders [1,2,11,12]. An autoencoder is a widely used unsupervised method for concept embedding. It contains an encoder that converts the original input data into a hidden embedding vector, while the decoder reconstructs a result similar to the input data from the hidden embedding vector. In the EHR field, autoencoders outperform traditional machine learning methods [1]. However, the risk of reidentification is a critical issue for autoencoders. Some studies exist on protecting patient privacy with autoencoders [20,21]. However, if the autoencoder is not designed to protect privacy, there is still a risk of reidentification because the decoder is designed to minimize the difference between the original data and the output.

In the EHR field, the contrastive self-supervised learning methods that belong to unsupervised learning, including Deep InfoMax (DIM) [22] and Simple Contrastive Learning of Visual

Representations (SimCLR) [23], may be superior. DIM adopted discriminators (replacing the autoencoder's decoder) that maximize mutual information between the input data and the embedding vectors. SimCLR minimizes the embedding distance within groups while maximizing the embedding distance among groups. Compared with autoencoders, contrastive self-supervised learning methods demonstrate superior results when performing classification tasks [22], even at the level of supervised learning [23], but no decoder model produces the risk of reidentification.

Due to the vectorization of objects of interest, disease concept-embedding can be used for retrieval [24]. Vector representation of big data can be operated simultaneously using linear algebra methods [25]. EHR-based clinical information retrieval [3,13,26,27] has been proposed. One study [13] focused on creating test sets for information retrieval research. Two studies [3,26] used keyword-based information retrieval systems, which did not use the semantic analysis method and could not identify negation semantics. Another study [27]developed a document-level semantic-based query recommendation search engine. Furthermore, these studies only focused on EHR-related retrieval methods that cannot be directly applied to predictive models. No objective score or standard exists to evaluate the performance of the concept-embedding model or the information retrieval [3]. However, visualization is a widely used method for evaluating the performance of concept embedding [10]. The t-distributed stochastic neighbor embedding (t-SNE) [28] method reduces the embedding's dimensionality to visualize the clustering effects of unsupervised learning. Although not objective, another evaluation method is sampling each cluster group and determining its topic [13,29]. Therefore, we can use a patient's data to retrieve neighbor samples and verify the consistency of the samples' concepts. Furthermore, if a new patient data is provided, concept embedding can be used to retrieve the top five most similar data, after which we can evaluate the retrieval capabilities.

In some papers, subsequent applications of classification have been adopted [2]. For emergency department employees, a patient's condition severity and emergency information are most relevant. We introduced a label for critical care outcome, defined as either (1) an intensive care unit admission or (2) death in the hospital after an emergency department visit [30-35]. This outcome was used to finetune the pretrained embedding model for the classification task. Furthermore, we compared the performance of the embedding model with that of state-of-the-art models.

Objective

This study aims to create a model that uses limited patient information to extract disease concept-embedding for disease retrieval and classification tasks. Accordingly, we present a disease concept-embedding method, the EDisease model, based on Transformer and the contrastive self-supervised learning method.

Methods

Materials

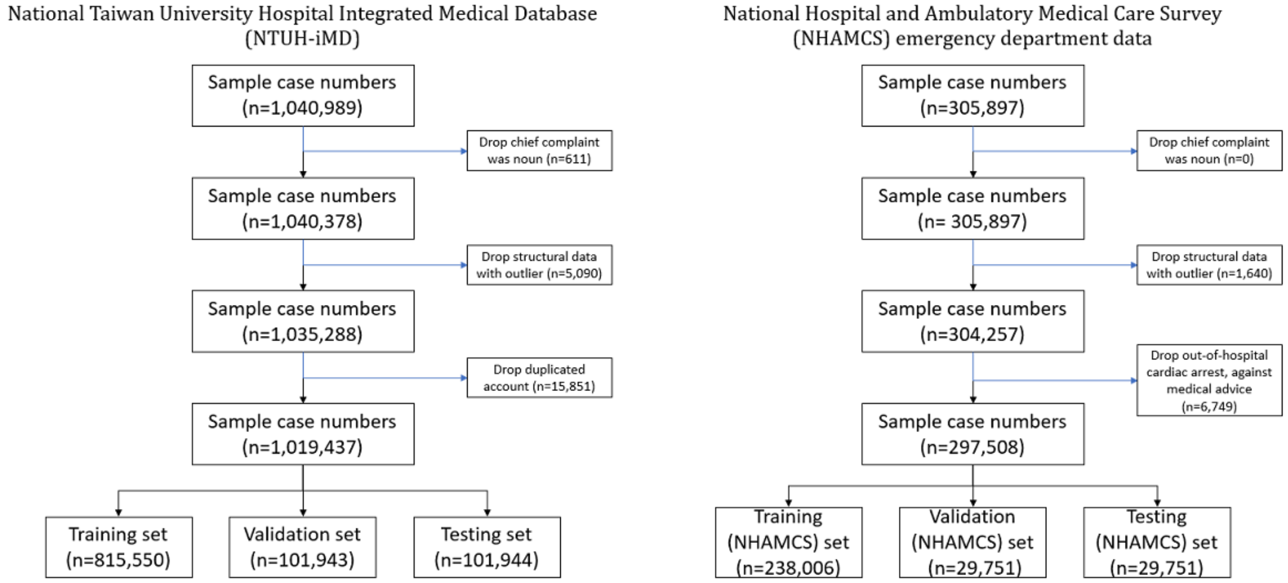
A sample of 1,040,989 emergency department visits was collected from the National Taiwan University Hospital Integrated Medical Database, a private EHR data set. The sample included the patients of National Taiwan University Hospital (one medical center in Taipei City and two regional hospitals in Hsinchu City and Yunlin County), who visited the hospital from January 1, 2013 to December 31, 2017. This study was approved by Research Ethics Committee B at National Taiwan University Hospital (201902078RINB).

In the data preprocessing stage, if the chief complaint was missing data or the structural data were unreasonable (eg, blood pressure was higher than 300 mmHg, diastolic blood pressure was higher than systolic blood pressure, heart rate was higher than 250 beats/minute, respiration rate was higher than 100 times/minute, body temperature was higher than 48°C or lower than 20°C, and body weight and height were higher than 400kgs and 250cms, respectively), the samples were discarded. In this stage, structural data with missing values were retained.

Individual patients may have visited the hospital several times during the specified period, and each visit corresponded to one account. Thus, each patient's ID number may have been associated with multiple EHRs. In the National Taiwan University Hospital, if a patient visits more than once within 24 hours, the last account number can be retained for reuse using another revisit flag. In this study, we retained only the last sample with the same account but different revisit flags. Furthermore, for each ID number, there are several medical records in the EHR, and we used the triage time to filter future records.

We then split the sample of 1,019,437 visits into sizes of 815,550 (80.0%), 101,943 (10.0%), and 101,944 (10.0%) for the training, validation, and test sets, respectively (Figure 1).

Figure 1. Data analysis flowcharts.



We also collected National Hospital and Ambulatory Medical Care Survey emergency department data from 2007 to 2017 [36]. This survey data is available in a public EHR database provided annually by the Centers for Disease Control and Prevention National Center for Health Statistics. We preprocessed the structured data using the same preprocessing method described previously and excluded patients with death on emergency department arrival, or those who left before being seen by a practitioner or against medical advice. Structured chief complaints and comorbidities were converted into free text as the chief complaints and past medical history, respectively. For the National Hospital and Ambulatory Medical Care Survey data, we split the 297,508 visit sample into sizes of 238,006 (80.0%), 29,751 (10.0%), and 29,751 (10.0%) for training, validation, and test sets, respectively (Figure 1).

The means and standard deviations were counted after discarding the missing data. Moreover, critical care outcome was selected as the outcome. Critical care outcome refers to the union of intensive care unit admission and death. We distinguished the definitions of intensive care unit admission and death for each data set. In the National Taiwan University Hospital Integrated Medical Database, intensive care unit admission is defined as whether an intensive care unit record existed within three days after a patient's emergency department visit. Death is defined as whether a death record existed within three days after a patient's emergency department visit [30,31]. In the National Hospital and Ambulatory Medical Care Survey, intensive care unit admission is defined as direct admission to an intensive care unit, and death is defined as in-hospital death (Table 1).

Emergency staff work in shifts to treat emergency patients promptly. Therefore, an alert system for impending emergency events is useful. Consequently, we chose a three-day interval as the cut-off point for disease progression, resulting in the outcome in the National Taiwan University Hospital Integrated Medical Database being defined as any critical event within three days after an emergency department visit. In contrast, our definition of critical care outcome in the National Hospital and Ambulatory Medical Care Survey was identical to that of the reference [32-34].

Model Architecture

Transformer was adopted as the central architecture in this study, based on BERT with the PyTorch adaptation released by the HuggingFace team [37]. Initially, we collected structural data $S \in \mathbf{R}^{15}$, including age, gender, blood pressure, heart rate, blood oxygen saturation, respiratory rate, body temperature, height, weight, subjective pain score, and Glasgow coma scale. We filled each unavailable data point with the average value of each S and performed noise processing on each element in S with a random scale based on the standard deviation of each element [38]. The fully-connected neural network for structural data L_S is a multilayer perceptron, which converts S to $M_S \in \mathbf{R}^{96}$ (Figure 2). For the free text medical record data, the pretrained "bert-base-multilingual-cased" model (ie, *BERT*-pretrained) is used to extract features CC, Hx, $\in \mathbf{R}^{768}$ from the free text (chief complaint, C, and past medical history, P). Because the number of past medical history data points changes, we averaged the features of all Hx and obtain the Hx^{mean} that represents the patient's medical history. If there is no medical history in the EHR, we use a padding vector to fill the Hx^{mean}. The fully-connected neural network L_B for $BERT$ is a multilayer perceptron that converts CC and Hx^{mean} to M_{cc} and $M_{Hx} \in \mathbf{R}^{96}$, respectively.

n is the total number of samples, k denotes the numbers of medical history.

$EDisease'_4$	0	0	0	1	0	0	0	1

We embed the diseases to concepts by adopting another BERT architecture as *BERT*-Disease (β_{ED}), a 12-layer Transformer encoder with 12 self-attention heads and a hidden size of 96. We concatenate M_S, M_{cc}, M_{Hx} and modify it with a leading head [CLS] as the input embedding. Position embedding indicates each element's position in the input embedding sequence, and segment embedding indicates the level to which the element belongs [16]. All segment embeddings are of the same level at this stage, but we reserved this settable variable for the subsequent work in this study. We obtain the sum of input embedding, position embedding, and segment embedding as the input of β_{ED}.

The *Mask* ∈ {0,1} indicates whether the element is valid (1) or invalid (0). For example, some patients did not have any medical history records in their EHRs. In these cases, the padding Hx^{mean} will be used as the input; however, the padding element should be ignored. Furthermore, when we gathered more information from some patients, *Mask* enabled us to ignore other padding elements and is, therefore, essential to this extensible model. We also used the random mask on M_{Hx} for the augmentation of *M* to improve the ability to embed the disease concept in a state with less information. This augmentation of a random history mask is also adopted in the subsequent work with another modification *M*. In this part, we obtained the embedding of disease:

DIM was adopted to further construct accurate disease embedding. DIM's core principle is to maximize the mutual information between the samples and embedding [22]. The mutual information on *M* and *EDisease* is as follows, where *p(m)* denotes the probability of each visit in the sample.

We assumed that each visit was unique. Therefore, $p(m), \forall m \in M$ are the same constant. Moreover, we assumed the number of disease embedding data points was limited and smaller than the number of visits, such that . The result is that $B_{ED}: M \rightarrow EDisease$ is a surjective function also known as onto, so we then obtain $p(\varepsilon) = p(\varepsilon|M)p(M)$.

We then set the function *DIM Loss* as follows and minimized it to maximize the mutual information.

We achieved this goal by adopting another BERT architecture, *BERT-Discriminator* (β_D), which shares the same model architecture as B_{ED} and estimate $\beta_D(\varepsilon, m) = p(\varepsilon|m)$. In this stage, *M* is modified not only by [CLS] but also by *EDisease* and [SEP]. The [SEP] is used to separate *EDisease* and *M* and this modification is similar to “the next sentence prediction” task in BERT [16]. We used segment embedding with a level of 0 to modify the [CLS] and *EDisease* with a level of 1 to modify [SEP] and *M*. We set $Y_{(\varepsilon,m)}=1$, when $i=j$, $\forall m_i,\varepsilon_j$ and $Y_{(\varepsilon,m)}=0$, when $i\neq j$, $\forall m_i$, ε_j and simplified as follows.

A part of *Loss* could now be discovered using the cross-entropy loss, similar to noise-contrastive estimation [39,40]. However, one part remained to be solved. We had to establish an adequate prior distribution to constrain the embedding distribution as proposed by DIM [22] and to minimize the $\sum p(\varepsilon)\log(p(\varepsilon))$.

The function $F(x) = x \log x$ is convex [41]. Then,

and two parts are equal if and only if every number x_i is the same (it can be proved by the Lagrange multiplier), which is equivalent to the uniform distribution that can minimize *Loss*. Consequently, we adopted a uniform distribution *Prior* on $[–1,1]^{96}$ to constrain $p(\varepsilon)$.

Generative adversarial networks [42] can be used to constrain an embedded distribution to a prior distribution [22]. The final distribution of EDisease is difficult to distinguish from the prior distribution uniform distribution using a linear domain discriminator L_{DD}. This discriminator detects whether each input distribution belongs to the prior or EDisease domain and estimates the distribution divergence of each domain. Moreover, this goal can be achieved using the generative adversarial network iteration algorithm.

Therefore, we simplify our goal to the following equation:

For a more robust concept embedding, we also introduced the SimCLR loss. Just as with the augmentation in SimCLR, each m_i is augmented to another m'_i by random noise. Ideally, the cosine similarity of $B_{ED}(m_i)$ to $B_{ED}(m'_i)$ is 1 (positive sample), and the cosine similarities of $B_{ED}(m_i)$ to $B_{ED}(m_j)$ and $B_{ED}(m'_j)$ are -1 (negative sample), $\forall j \neq i$.

Therefore, the final loss function is:

$$Loss = DIM\ Loss + SimCLR\ Loss$$

In the further finetuning stage for predicting the outcome, EDisease is fed to a multilayer linear model FL_C (Figure 2).

We can add an extended model for the extended information to enhance the architecture (see Multimedia Appendix 1). We demonstrated the extensible model by obtaining M_{PI} after feeding an illness to the model and concatenating it to the vanilla *M*. The subsequent training methods are identical to those in Figure 2.

For improved performance with free text feature extraction, we again pretrained *BERT-pretrained* using the free text medical records in the National Taiwan University Hospital Integrated Medical Database. In the medical record, the chief complaint in triage was the patient’s words for their discomfort, and present illness, *I*, was the doctor’s word for the patient’s problem; thus, the similarity between the chief complaint and patient illness should, ideally, be high. Furthermore, some patients had several medical history records, and their subsets may also have been highly similar. Consequently, CC, PI, Hx_1^{mean}, $Hx_2^{mean} \in \mathbf{R}^{768}$ were extracted by *BERT-pretrained*, the pair CC, PI representing the same patient’s complaints, and the pair Hx_1^{mean}, Hx_2^{mean} representing the same patient’s medical history. We then used the contrastive learning method used previously to pretrain *BERT-pretrained*. Due to graphic processing unit memory limitations, after again pretraining the language model, we fixed the model’s weights such that the grading of subsequent training would not change the weight of the model.

We used Adam optimization [43] for the hyperparameters and set the learning rate as $1\times10^{–4}$, with a minibatch size of 1024. The hyperparameter γ=0.1 was chosen in this study. The source code is available on GitHub [44].

Evaluation

We selected the training set and fed it into the model to obtain the set of disease embedding. We then used the t-SNE to reduce the dimensionality of the embedding to two for visualization. We enhanced visualization based on demographic information, hospital level, triage level, whether medical history existed, and outcome. Furthermore, we illustrated the model’s ability to cluster diseases by selecting patients from the validation set as queries to retrieve similar patients in the training set. The relevance of each result to the query was judged by a seasoned doctor, who used the number of hits on the top 5 results to score from 0-5.

Furthermore, we finetuned the model based on the outcome and compared it with the published model based on the receiver operating characteristic curve. In order to check whether the embedding could be used as a pretrained model, even if only a small amount of label data was collected, we also took 10,000 samples from the validation (National Hospital and Ambulatory Medical Care Survey) set as a small data set for finetuning. Then, we performed ablation studies by deleting each unsupervised learning method and comparing them.

Results

We used the t-SNE method to reduce the 96-dimensional embedding to 2-dimensional embedding and enhance the visualization by gender, age (10-year intervals), hospital level, triage level, existence of a medical history, and outcome (see Multimedia Appendix 2).

We sampled the patients in the validation set as queries to retrieve the 5 most similar patients in the training set in the embedding space. Moreover, a doctor evaluated the relevance of 25 random query results (see Multimedia Appendix 3, Figure 3, and Multimedia Appendix 4).

Figure 3. Disease Retrieval Demonstration. The query subject (orange) was a 53-year-old female patient who suffered from abdominal pain in the upper-right quadrant to right flanks for three days and noticed dizziness and tarry stool on the day of the interview. Through the retrieval, we obtained the top five similar patients (green) whose symptoms were hematuria, bloody stools, abdominal distention, abdominal pain, dizziness, and abdominal pain in the upper-right quadrant. The query subject (orange) was a 53-year-old female patient who suffered from abdominal pain in the upper-right quarter to right flanks for 3 days and noticed dizziness and tarry stool on the day of the interview. Through the retrieval, we obtained the 5 most similar patients (green) whose symptoms were hematuria, bloody stools, abdominal distention, abdominal pain, dizziness, and abdominal pain in the upper-right quarter.

In the subsequent finetuning based on the outcome, our proposed EDisease model demonstrated the highest performance among all compared models based on the area under the receiver operating characteristic of 0.876 (Table 2, Figure 4).

Table 2. Area under the receiver operating characteristic results.

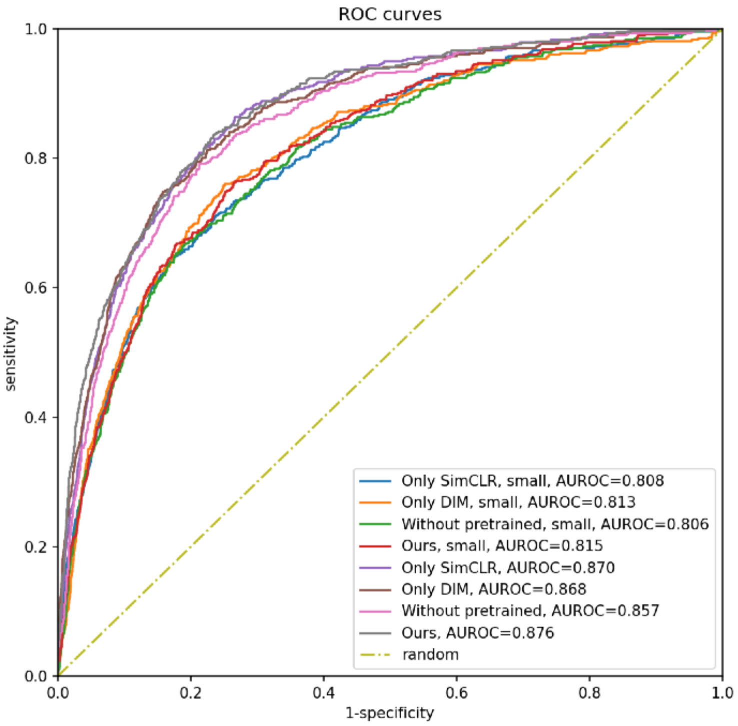
Model	Critical care outcome	
	NTUH-iMD[a]	NHAMCS[b]
Deep neural network [33] (age≤18)	N/A[c]	0.85
Deep neural network [32] (age≥18)	N/A	0.86
Hierarchical model [34]	N/A	0.84
Proposed model (without pretraining)	0.83	0.86
Proposed model	0.84	0.88

[a] NTUH-iMD: National Taiwan University Hospital Integrated Medical Database.

[b] NHAMCS: National Hospital and Ambulatory Medical Care Survey.

[c] N/A: not applicable.

Figure 4. Ablation study ROC curves. Both DIM and SimCLR can improve prediction performance through pretrained embedding. Small: denotes finetuned on the smaller data set. ROC: receiver operating characteristic. DIM: Deep InfoMax. SimCLR: Simple Contrastive Learning of Visual Representations. AUROC: area under the receiver operating characteristic.



The ablation study results demonstrate that our model outperformed those using fewer or no unsupervised methods, both on the large and small finetuning set. Unsurprisingly, the models finetuned on the smaller data set performed worse than those finetuned on the large National Hospital and Ambulatory Medical Care Survey training data set (Figure 4).

Discussion

The EDisease model performed well in the disease concept-embedding task and illustrated suitable clustering performance for the disease pattern. It also demonstrated promising results in the subsequent finetuning of the outcome.

The embedding of disease is meaningful. The enhanced label with the triage level indicates that the fifth level was clustered and illustrates some influence on different classification levels (see Multimedia Appendix 2). This embedding system can be used as a disease retrieval model, which encodes queries and finds the most relevant patients and diseases. In the retrieval demonstration, the query subject was a 53-year-old female patient who suffered from abdominal pain in the upper right quarter to right flanks for 3 days and noticed dizziness and tarry stool on the day of the interview. Through the retrieval, we obtained the five most similar patients with similar symptoms that were possibly related to different diseases (Figure 3). In another example of retrieval, the query subject was a 63-year-old male patient who suffered from sudden nausea, vomiting, and weakness and felt facial numbness at work. Patients with cardiogenic symptoms or neurologic symptoms were the retrieval results (see Multimedia Appendix 4). These results are meaningful for clinical practices, such as treating cardiogenic or neurological problems, as they characterize the most likely differential diagnoses.

Furthermore, because the multilingual BERT model is used as the text feature extractor, the proposed model can search for free text in English or Chinese. The retrieval results included relevant symptoms and possible diseases, likely from the co-occurrence relationship [27] of structural data or the feature extracted from the multilingual BERT model. The multilingual BERT model was pretrained again by the chief complaint and present illness pair. Even if we only use the chief complaint with structured data and medical history as input, the characteristics of the chief complaint may reflect those patients with the same complaint but different diseases discovered by the doctor.

The potential of the semantic vector on the EHR search engine has already been demonstrated [27]. Our main contribution to the development of EHR retrieval is the construction of patient-level conceptual embeddings. However, in some cases, such as complaints about epileptiform (query 12) and shingles-like skin lesions (query 6) (see Multimedia Appendix 3), retrieval performance was poor. They would also result from a co-occurrence relationship with structural data or medical records. In future work, more EHR data could be used to extend the model, which may enrich the performance for differential diagnosis and retrieval.

This pretrained model is also suitable for finetuning the outcome prediction. For the National Hospital and Ambulatory Medical Care Survey, our pretrained model outperformed the reference. The pretrained method of disease concept-embedding can improve the performance of subsequent tasks. The outcome prediction performance we obtained for National Hospital and Ambulatory Medical Care Survey data was slightly higher than for data from the National Taiwan University Hospital Integrated Medical Database. This result may be related to the structured chief complaints and comorbidities in the National Hospital and Ambulatory Medical Care Survey data. These structural features had been well extracted by humans using rule-based methods. In future work, we will use all medical histories instead of their average values or preprocess them using extractive summarization methods.

We proposed a model that uses limited information for embedding. The model is a useful contribution, given that the input data can be collected by people without a medical background. For instance, a sick person who has no idea what occurred to him or her can still collect information and feed it into the model to obtain more information about his or her problem. Simultaneously, the model can also help hospital staff determine a patient's disease with limited information. Most doctors (not only emergency department doctors) develop treatment plans based on limited information. Initially, doctors can obtain basic demographic information only after the patient has made an appointment. The doctor will then collect more information when the patient visits, including the chief complaint, symptoms, and medical histories. Furthermore, physical examination and some blood laboratory examinations, radiology, or ultrasound examinations are arranged to help establish a diagnosis and finalize the treatment plan. The disease concept was initially established by limited information and prompted doctors to arrange specific examinations; the disease concept will become more prominent. Similarly, disease embedding obtained through limited information can only be used for preliminary differential diagnosis. It can be further applied to suggest the most relevant information for the final diagnosis. After more information is appended to the embedding model, a precise diagnosis could be identified.

Some EHR models use ICD codes as inputs. However, problems may arise; for example, the disease might not have the correct ICD code in EHRs [9], or ICD coding rules might change, invalidating the model trained on the old ICD codes. In this study, we did not use ICD codes as inputs. In addition to the time-varying ICD coding rules, ICD coding requires experts, which is difficult for people with no medical background. Sometimes, if there is not enough information, even experienced doctors have difficulty with ICD coding. However, doctors can collect more information during treatment and observation, and then determine the disease and choose the most appropriate ICD code. Consequently, some of the ICD codes recorded in an EHR may be future information and may not be suitable for input to predictive models in some retrospective studies.

For machine learning methods used to embed disease concepts, vast amounts of patient data are required. Therefore, protecting personal privacy is a crucial issue in the research process. A leak of a patient's disease information would be disastrous and would infringe upon the patient's legal rights. Although several studies have focused on this issue, no accurate quantitative method exists to assess the privacy of research data sets [2]. For private EHR data sets that have not been evaluated for de-identification quality, encoding the patient's records and decoding them outside the hospital could create legal issues. In this study, DIM and SimCLR were used as the unsupervised methods, which have greater embedding capabilities [20] and do not train the decoder together, so there is no risk of leaking private information.

For the DIM method that maximizes mutual information, we assume each patient's visit is unique. This assumption is also critical for the SimCLR method, because the self-supervised learning methods require negative samples to maximize the embedding distance among groups. If the same input exists in the negative sample, it will disrupt the training process and cause failure to converge. This assumption is reasonable because everyone is undoubtedly unique. The only problem arises when the same patient revisits a health care facility because of the same disease. However, this problem can be solved by deleting duplicate accounts in the data set. For patients with several accounts, these visits can still be regarded as different due to different health conditions, chief complaints, or previous medical histories. We also assume that the number of diseases is limited and fewer than all visits. This assumption is also reasonable because the total number of visits is set to the size of the training set, and in medical experience, at least two patients suffer from the same disease.

The SimCLR method proposed a simple method to use a large amount of negative samples for self-supervised learning. In this study, ideally, we would have randomly masked the tokens in the input free text data. However, owing to graphic processing unit memory limitations and the heavy BERT model, if an ideal augmented method is adopted for a positive sample, only 8 samples could be used in each mini-batch, thereby sacrificing the advantage of a large number of negative samples. Consequently, we ended up adding a little noise to each m_i as a positive sample; in other words, we sacrificed the advantage of a positive sample.

Based on the ablation study results, both DIM and SimCLR can improve prediction performance through pretrained embedding. Although the improvement gap was small, the embedded pretraining method may be useful in future work. Furthermore, combining these two self-supervised methods can further improve prediction performance. These results are similar to those of DIM, which used two different discriminators on the training process and achieved a higher score [22].

Limitations

Although the National Taiwan University Hospital Integrated Medical Database included one medical center and two regional hospitals and had many patients and staff with extensive disease treatment experience, there is still a problem of “out-of-disease,” which indicates that the disease is not in the EHR data set. This problem will result in poor performance for newly diagnosed diseases (eg, COVID-19), but diseases with related symptoms can be found for reference. Because the National Taiwan University Hospital Integrated Medical Database data set was not public, we only recruited one doctor to evaluate the relevance of the search results. Although the evaluation results were subjective, no objective score exists (according to previous studies) for evaluating information retrieval performance. We recognize that other evaluation methods in this study might have been more meaningful.

Conclusions

The EDisease model uses limited information from patients and appropriately represents concept embedding. It can be further expanded as more data about the patient is collected.

The suitably-pretrained EHR model can be used as a medical experience retrieval system online in conjunction with the clinic staff. Moreover, it can be further finetuned to predict emergency events and enhance employees’ capabilities. The EDisease model could be widely adopted in the near future to help ease emergency department overcrowding: “ED-is-ease.”

Acknowledgments

We would like to thank the Ministry of Science and Technology, Taiwan, for financially supporting this research (grant MOST109–2634-F002–031, MOST109–2634-F002–041 and MOST 109–2634-F-002–029). We would also like to thank Huggingface for providing several excellent deep-learning codings. We are grateful to GitHub for providing the code repository used for the EDisease model.

Multimedia Appendix 2
Visualization of Embedding of Disease by t-SNE(2D). The embeddings were displayed in a list of (A) non-enhanced, (B) enhanced by gender, (C) age (10-year interval), (D) hospital level, (E) triage level, (F) whether a medical history exists, (G) outcome of ICU admission, and (H) death. There seems to be no specific difference in disease embedding based on (B) gender, (C) age> 10 years, (D) hospital grade, and (F) medical history. Triage level five, purple, was clustered together (E). In this disease embedding, the outcome of ICU or death did not appear to be linearly separable.

Multimedia Appendix 3
Disease Retrieval Relevance. The relevance of each result to the query was judged by a seasoned doctor, who used the number of hits on the top five results to score from zero to five. Retrieval performance was high, but in some cases, such as shingles-like skin lesions (query 6) and epileptiform (query 12), the retrieval performance was poor.

Abstract

Background: Despite the introduction of the Web Content Accessibility Guidelines and legislations, many websites remain poorly accessible to users with disability, especially those with visual impairment, as the internet has become a more visually complex environment. With increasing reliance on the internet and almost 2 million people in the United Kingdom being affected by vision loss, it is important that they are not overlooked when developing web-based materials. A significant proportion of those affected have irreversible vision loss due to rare genetic eye disorders, and many of them use the internet as a primary source of information for their conditions. However, access to high-quality web-based health information with an inclusive design remains a challenge for many. We have developed a new web-based resource for genetic eye disorders called Gene.Vision that aims to provide a holistic guide for patients, relatives, and health care professionals.

Objective: Through a usability testing session of our website prototype, this study aims to identify key web-based accessibility features for internet users with vision impairment and to explore whether the contents provided in Gene.Vision are relevant and comprehensible.

Methods: A face-to-face testing session with 8 participants (5 patients, 2 family members, and 1 member of the public) and 8 facilitators was conducted on a prototype website. Remote testing was performed with another patient due to COVID-19 restrictions. Home page design, navigation, content layout and quality, language, and readability were explored through direct observation and task completion using the think-aloud method. A patient focus group was organized to elicit further feedback. Qualitative data were gathered and analyzed to identify core themes through open and axial coding.

Results: All participants had good computer literacy; 6 patients with visual impairment used visual aid software including iOS VoiceOver and Speak Screen, iOS Classic Invert, ZoomText 2020, Job Access With Speech, and Nonvisual Desktop Access. The features identified by the participants that will enhance accessibility and usability for users with visual impairment were a consistent website layout, a structured information hierarchy with a clear description of links, good chromatic and luminance contrast, a simple home page with predictable and easy navigation, adaptability to various assistive software, and readable and relevant content. They reported that dynamic content (such as carousels) and large empty spaces reduced accessibility. Information on research, support available, practical advice, and links to charities were incentives for repeated website visits.

Conclusions: We demonstrated the importance of developing a website with a user-based approach. Through end user testing, we identified several key web-based accessibility features for people with visual impairment. Target end users should always be involved early and throughout the design process to ensure their needs are met. Many of these steps can be implemented easily and will aid in search engine optimization.

Introduction

Background

People with disabilities have been recognized to experience inequalities in multiple aspects of their lives from education and employment to health care, finances, and leisure [1], with the internet being a key accessibility feature in all areas. It was intended to be user-friendly for every individual regardless of any mental or physical disability but poor design and coding of what is usually thought of as a graphical user interface poses difficulties, particularly for users with visual impairment [2-4]. With an increasing reliance on the internet and almost 2 million people in the United Kingdom being affected by vision loss, of which 360,000 are registered with visual impairment or severe visual impairment (blind), it is important that they are not overlooked when developing web-based materials lest they risk being socially excluded altogether [5,6].

To make the internet more accessible, the World Wide Web Consortium first introduced the Web Content Accessibility Guidelines (WCAG) in 1999; its current iteration (WCAG 2.1), published in 2018, serves as an update rather than as a replacement of WCAG 2.0 (introduced in 2008). It contains 13 guidelines based on 4 main principles: perceivable, operable, understandable, and robust, with each guideline having 3 levels of testable success criteria—A (lowest level of accessibility) and AA and AAA (highest level of accessibility) [7]. Both the United Kingdom and the European Union have adopted it into their legislation, making it a legal requirement for public sector websites to be accessible to people with disabilities [8,9].

Despite this, only a small number of websites are compliant with the UK accessibility standard of WCAG 2.1 AA [10]. With consumers increasingly turning to the internet as a primary source of health-related information, websites should not only contain relevant and helpful information for patients but should also not exclude anyone with a disability. To help developers of web-based health platforms achieve this, the UK National Health Service (NHS) published a Digital Service Manual focusing on building consistent, usable, and accessible services using a patient-centric approach [11]. It provides guidance on various aspects of web design, such as conducting user research, building user interface prototypes, content styles, and optimizing accessibility.

A significant group of web-based health information consumers are those affected by rare diseases that together affect 1 in 17 people [12]. Owing to the nature of their conditions, their physicians often lack the experience or familiarity to provide expert care for them. They end up searching the web to keep abreast of current research and look for support through online communities. However, the quality of these websites tends to be poor, either they lack credibility or the contents are not kept up-to-date or pitched at the right level [13]. Furthermore, most of these sites are found to be poorly accessible to users with visual impairment, which can have a profound impact on patients affected by rare genetic eye disorders who usually have visual disability [13,14]. Inherited retinal diseases are the most common causes of severe visual impairment registration among working adults in England and Wales, whereas globally, 60% of blindness among infants is due to genetic diseases [15,16].

Objectives

To fill this void, we are developing a new web-based resource for these conditions with information written in 2 formats: one using more lay terms for patients and families, while the other has more technical details tailored toward health care professionals. It aims to provide a holistic resource, including the causative gene or genes of a condition, current research, management, and support services. Most importantly, we prioritized creating a usable and highly accessible website for our target end users, who mainly have visual impairment.

Although automated testing tools can help identify some of the website's accessibility barriers, most of the WCAG 2.1 guidelines require human testing and judgment. Failing to trial a specific design with users with disability will result in a website with limited *usable accessibility*, as the human interface aspect is not evaluated [17]. Therefore, the NHS Digital Service Manual recommends that research and testing with real-world users are performed early and throughout the design process [18]. In line with this recommendation, we conducted a usability testing session on a prototype of our website with patients to identify website features that would increase accessibility for users with visual impairment. Our secondary objective is to explore whether the contents provided on our website were relevant and comprehensible to both patients and clinicians.

Methods

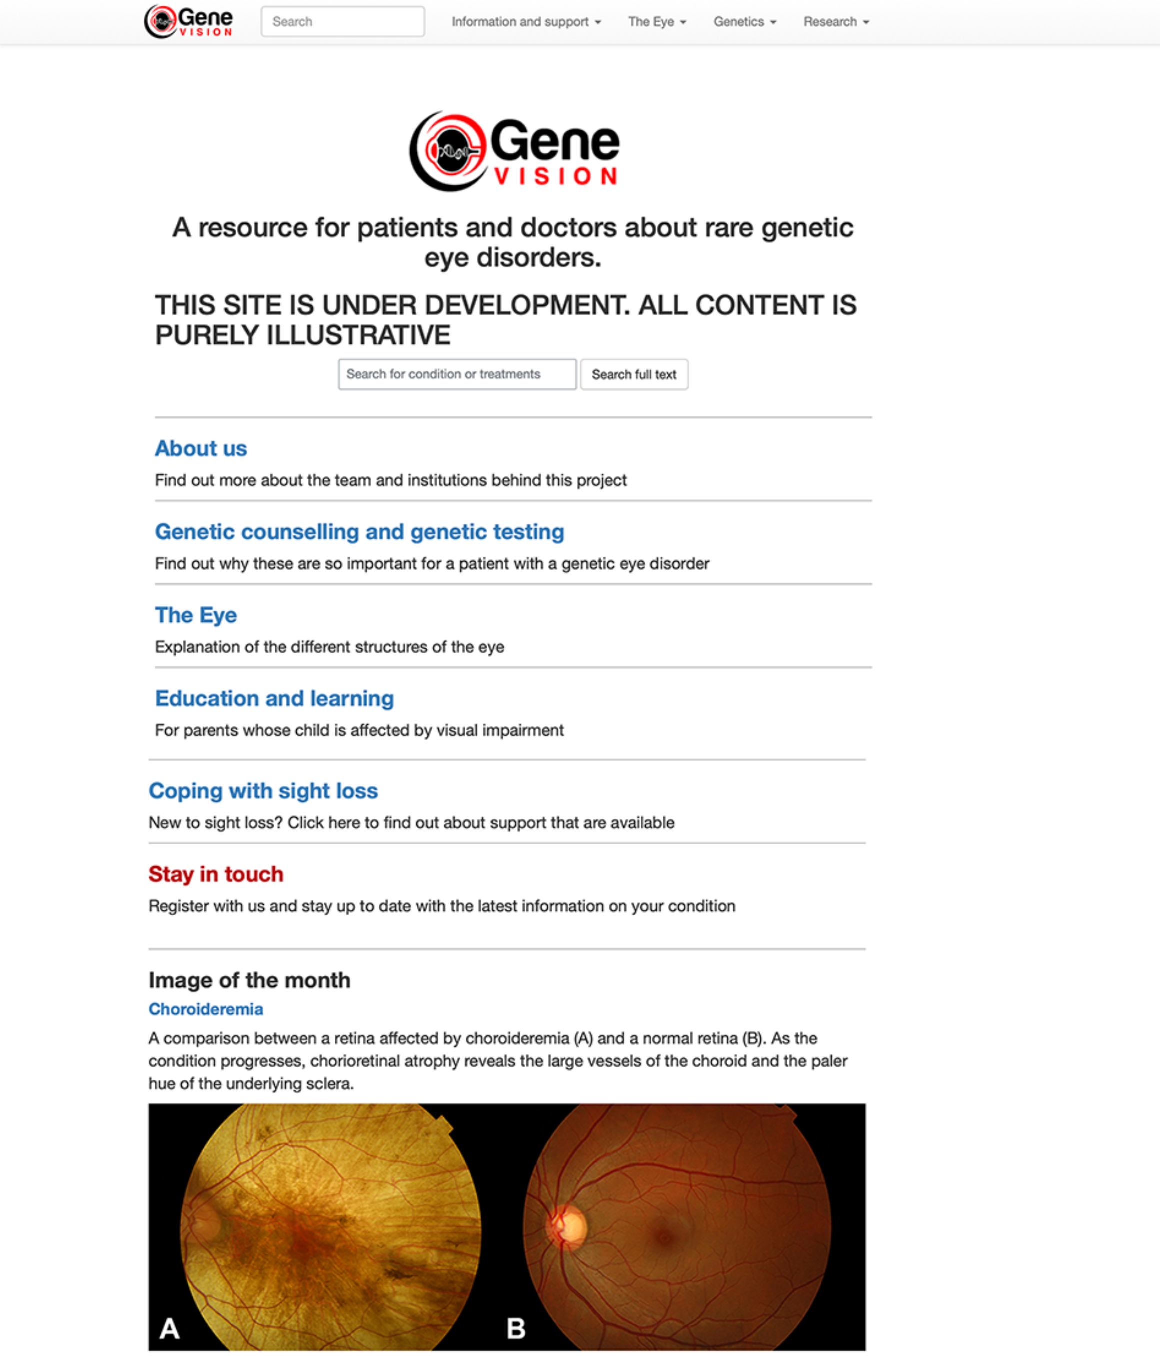
Prototype

Before development, we spoke to patients with genetic eye disorders and their families to identify potential *pain points*, which were websites with poor accessibility, unreliable and outdated information, contents written with excess medical jargon and insufficient material on research, practical advice, and available support. An accessibility specialist, who was a patient herself (see the Acknowledgments section), was also consulted to identify key accessibility features for those with visual impairment. On the basis of feedback from these interactions, we built a prototype of our website using the Wikimedia platform (Wikimedia Foundation, Inc) [19], which contained the following components.

Home Page

The home page's navigation bar is organized into 4 main items: information and support, the eye, genetics, and research (Figure 1). The subcategories of each main item are listed in Textbox 1 along with a description for each category. There is a search box in the center whereupon a search term or terms is entered, all pages containing the term or terms are displayed on a new page (Figure 2).

Figure 1. Home page of the Gene.Vision Wikimedia prototype. The navigation bar serves as the header of the page. The search box is above the listed menu items. Our participants pointed out that the navigation bar and search box had poor chromatic and luminance contrast. The large area of white space on the right in portrait mode can disorientate magnifier users.



A resource for patients and doctors about rare genetic eye disorders.

Image of the month

Choroideremia

A comparison between a retina affected by choroideremia (A) and a normal retina (B). As the condition progresses, chorioretinal atrophy reveals the large vessels of the choroid and the paler hue of the underlying sclera.

Textbox 1. Subcategories of each main item on the navigation bar in the Gene.Vision prototype with a brief explanation of each category.

Information and support

- Coping with sight loss: outlining support services that are available for patients recently diagnosed with vision loss. It also explains the roles of low vision clinic and eye clinic liaison officers and directs patients to resources on assistive technology
- Registration for sight impairment: the process of certification and registration are outlined here along with the associated advantages
- Driving: the minimum driving standards in the United Kingdom are explained here with further links to the government information portal. Patients are also signposted to alternative ways of transportation if they are no longer able to drive
- Education and learning: the various supports that are available for children with visual impairment are listed here with advice on how to access these services
- Charles Bonnet Syndrome (CBS): an explanation about CBS, coping mechanisms, current research and links to organizations offering support to those affected

The Eye (pages providing lay explanations of the following ocular structures):

- Conjunctiva
- Sclera
- Cornea
- Trabecular meshwork
- Iris and pupil
- Lens
- Vitreous humor
- Retina
- Optic nerve
- Choroid

Genetics

- Introduction to genetics: a brief overview of DNA, genes, and chromosomes
- Inheritance patterns: explanations on the more common inheritance patterns encountered in genetic eye disorders (autosomal dominant, autosomal recessive, X-linked, and mitochondrial)
- Genetic counseling and genetic testing: the role of genetic counselors, the process of genetic testing and its associated benefits and limitations are explained in this page

Research

- Clinical trials: explaining the different aspects of clinical trials including the various phases, the role of ethics committees, and the benefits of participation
- Treatments under research: this section contains various investigative therapies for genetic eye disorders with links to their corresponding pages. Only gene therapy was prepared in this prototype
- Participate in research: This link aims to connect to a website listing all the current ongoing trials in Moorfields Eye Hospital. This website has not been set up yet during the testing session nor at the time of writing this manuscript

Figure 2. Search results for the term aniridia. Our participants found the display confusing compared to what they are used to from popular search engines.

To highlight certain relevant topics to users, some of the subcategories from the main navigation bar were placed into a list below the search box, each having a brief excerpt (Figure 1).

In addition to the Wikimedia-based home page, we also designed another home page prototype using WordPress for the purpose of this testing. The screen recordings of both home page designs are available in Multimedia Appendices 1 and 2.

Content Pages

Conditions

Two versions are available for each condition page: one for the patients and general public, and the other for health care professionals. Users can toggle between these 2 versions using the tabs below the main page title (Figure 3).

Figure 3. Example of a condition page. Users can toggle between the patient and health care professional versions using the For patients and For doctors tabs. A table of contents is placed under the Quick links section, where users can go directly to the topic of interest without additional scrolling. Jump-to-top links are available under every heading to facilitate quick navigation back to the Quick links section.

Overview

Jump to top

Aniridia is a rare condition affecting 1 in 40,000 to 100,000[1] people. It is caused by genetic changes to the *PAX6* gene, resulting in the characteristic appearance of an under-developed or absent iris. Apart from the iris, other structures of the eye could be affected as well, namely the cornea, the trabecular meshwork, lens, fovea, optic disc and overall size of the eye.

An eye affected by aniridia where the iris is absent (A) and an eye with a fully developed iris (B)

Consequently, patients experience a variety of symptoms such as glare, severe light sensitivity, poor vision and nystagmus. It typically affects both eyes and is present at birth, although it may be noticed later in infancy. Aniridia can either be inherited from a parent in an autosomal dominant inheritance pattern, or develop spontaneously in an individual (when they were developing in the womb during

The former focuses on aspects that we believe patients will find helpful, such as current research, information on available support, and links to both umbrella and condition-specific charities. When possible, we asked a patient representative from a charity related to the condition to review our material for readability. The health care professional version focuses more on the clinical presentation, investigations, general management guidance including genetic counseling, genetic testing, and updates on current research. Full citations are listed in both versions.

A total of 3 conditions were prepared for this prototype: choroideremia; aniridia; and Wilms tumor, aniridia, genitourinary anomalies, and range of developmental delay (WAGR) syndrome. The patient versions of the choroideremia and aniridia pages were reviewed by patient representatives from Retina UK and Aniridia Network, respectively. The review of the WAGR syndrome page was still pending at the time of testing.

Other Pages

For pages listed in Textbox 1, only the patient or general public version was available in the prototype.

The pages that were prepared for this prototype were as follows: *Coping with sight loss*, *Driving*, all the pages listed under *The eye*, *Genetic counseling and genetic testing*, *Clinical trials*, and *Gene therapy*.

To improve user navigation, a table of contents is listed at the top of each page termed *Quick links* (Figure 3). Users are able to navigate to each subheading by clicking on the topic of interest. They can easily navigate back to *Quick links*, by using the *Jump to top* link. A screen recording of this function is available in Multimedia Appendix 3. Each page always starts with a brief overview of the selected topic, with the structure and font used consistently throughout the website. The information provided on all pages is based on current UK practices. All images on the website were accompanied with the alt-text function, except those that were for decorative purposes only. The prototype was tested manually with the NonVisual Desktop Access screen reader (NV Access) by one of the authors (JY) before the usability testing session to ensure compatibility and troubleshoot any fundamental accessibility barriers (eg, unclear alt-text, missing or ambiguous links).

Usability Testing

Participants were recruited through the vision loss charity Retina UK and from the senior author's (MM) genetic eye disease clinic in Moorfields Eye Hospital NHS Foundation Trust, London.

A face-to-face usability testing session and patient focus group (1 participant to 1 facilitator) of our prototype was conducted at the University College of London Institute of Ophthalmology computer laboratory on November 11, 2019. Participants were encouraged to bring their personal devices that they usually used to access the web. For those who chose to use the laboratory's Windows PC desktops, assistive software was installed upon prior request. They also chose which web browser to use based on their experience and comfort level. The device, web browser, and assistive software used to access the website were recorded by the facilitators.

A short survey (Multimedia Appendix 4) was conducted at the beginning of the session to gather information about the demographics and computer literacy of each participant. This was assessed using a 5-point Likert scale based on the UK government digital inclusion scale [20]:

- Not at all confident: someone who does not know how to use the internet at all.
- Slightly confident: able to perform tasks on the internet with full guidance.
- Somewhat confident: able to perform certain tasks independently, does not tend to deviate from these tasks when using the internet (task-specific).
- Very confident: someone considered to have basic digital skills and able to use the internet effectively.
- Extremely confident: someone who usually has a background in computing or is able to code or design content.

The last 2 questions of the survey focused on the participant's current source of information about their condition and the type of information they considered important but currently lacking.

During the testing session, we used 2 usability techniques: direct observation and task completion. The tasks outlined for the participants (Textbox 2) were designed to identify specific features and issues pertaining to the home page design, site navigation, and content. For our condition pages targeted to the patients and general public, we used identical pages from Wikipedia as a benchmark because it is one of the most viewed medical resources globally and tends to appear as one of the top results in general search engines for keywords associated with rare diseases compared with other web-based health resources [21,22]. Furthermore, Wikipedia has a standardized information structure optimized for accessibility (WACG 2.0) and contributors are encouraged to follow the guidance provided in their *Manual of Style* to maintain this standard [23].

Textbox 2. The tasks set out for the participants of the usability testing session.

Home page

1. Home page design: Participants were asked to compare the 2 home page designs, Wikimedia (Wikimedia Foundation, Inc) and WordPress, and highlight the aspects that improved or affected accessibility for each design
2. Navigation: navigating to the *Driving, Retina,* and *Genetic counselling* and *genetic testing* pages by using a combination of the navigation bar, search box, and the listed home page menu. While testing the navigation bar, we wanted to find out if participants preferred a drop-down menu displaying the full list of items (eg, *Information and Support* section) or a tab that links to a separate page containing the full list of items (eg, *The Eye* section). Participants were asked to explore each of the assigned pages and assess the relevance and readability of the content provided

Condition pages

- Participants were required to read 2 condition pages on our website: choroideremia and aniridia. They were asked to compare identical pages from Wikipedia with regards to information layout, readability, and quality of content. They then had to point out features that they liked and disliked from both the prototype and Wikipedia

While performing the assigned tasks, participants were encouraged to verbalize their initial impressions of the website, its accessibility and ease of use, comprehensibility of the content, and suggestions for improvement (think-aloud method). They were prompted by the facilitators to explain their actions and expectations. All responses were recorded by each facilitator in a standardized proforma. The facilitators primarily served as passive observers (direct observation) and were only allowed to assist if their respective participant reached an obstacle, at the same time noting how the participant encountered this.

A patient focus group for all the participants was conducted by the main facilitator at the end of the usability testing session to encourage feedback and discussion. Participants were asked about their general thoughts about the website, whether the current version was usable by individuals with visual impairment, any features that they liked or disliked, and if there were any changes or additions they would like to see. Further discussions were prompted by asking participants to expand their answers and seek opinions or counter-opinions from the rest of the group. The focus group was audio taped and transcribed after obtaining informed consent from all participants. A summary of the discussions was prepared after recording by the main author (JY).

Clinician Testing

The website was also created as a resource for health care professionals who may see patients with genetic eye diseases and require further information on the condition and management advice. Hence, the content was assessed remotely by a range of health care professionals from various disciplines, including a consultant general practitioner, a consultant pediatrician, 2 ophthalmology trainees, 3 ophthalmology consultants of different subspecialties (general, pediatrics, and medical retina), and a genetic counselor. Their assigned tasks were similar to those outlined in Textbox 2, with particular focus on home page navigation, information layout, and content quality in the professional versions of choroideremia, aniridia, and WAGR syndrome. Feedback was recorded in the same proforma used in the usability testing session.

Qualitative Data Analysis

The data collected in the standardized proformas and the audio transcripts from the patient focus group were analyzed by one author (JY) in an inductive manner rather than theory based, as we wanted to understand participants' experiences with the prototype. Codes were attributed to various key phrases and paragraphs in both the written and audio transcripts (open coding) to identify core themes. Axial coding was then applied to develop connections between the open codes. Coding was performed with the qualitative software program NVivo 12 (QSR International).

Results

Participant Characteristics

There were 8 participants in our usability testing session and their demographics are presented in Table 1. A participant (P9), who used the popular Job Access With Speech (JAWS) screen reader, tested the website remotely during the COVID-19 lockdown period in the United Kingdom. In total, 6 participants were affected by genetic eye disorders, while 2 were parents of a patient with type II Usher syndrome. One participant had full sight and worked as an information specialist in a library. Most participants had basic digital skills, but 3 participants were considered experts. One participant considered herself a *task-specific* web user. The devices, web browsers, and assistive software used by the participants are shown in Table 2. The full results of the pretesting survey (including P9) are presented in Multimedia Appendix 5.

Table 1. Demographics of the participants in the usability testing session.

Participant	Gender	Age (years)	Employment status	Internet usage	Confidence in using the internet	Health status	Diagnosis
P1	M[a]	53	Employed	Yes	Very confident	Unaffected parent	Son-type II Usher syndrome
P2	F[b]	52	Employed	Yes	Very confident	Unaffected parent	Son-type II Usher syndrome
P3	F	41	Unemployed	Yes	Somewhat confident	Patient	Retinitis pigmentosa
P4	F	62	Retired	Yes	Very confident	Patient	Cone-rod dystrophy
P5	M	40	Employed	Yes	Extremely confident	Patient	Aniridia
P6	M	37	Employed	Yes	Very confident	Patient	Retinitis pigmentosa
P7	F	25	Employed	Yes	Extremely confident	Patient	Type II Usher syndrome
P8	M	45	Employed	Yes	Extremely confident	Unaffected individual	N/A[c]
P9[d]	M	70	Retired	Yes	Very confident	Patient	Cone-rod dystrophy

[a] M: Male.

[b] F: Female.

[c] N/A: not applicable.

[d] P9 was only able to test the website remotely due to COVID-19 lockdown rules.

Table 2. Device, web browser, and assistive software used by each participant.

Participant	Device	Web browser	Assistive software
P1	Windows PC	Google Chrome (Google LLC)	N/A[a]
P2	Windows PC	Google Chrome (Google LLC)	N/A
P3	iPhone	Safari (Apple Inc)	iOS VoiceOver (Apple Inc)
P4	Windows PC	Mozilla Firefox (Mozilla Foundation)	Zoomtext 2020 (Freedom Scientific) with invert color setting
P5	Windows PC	Google Chrome (Google LLC)	Windows magnifier at 200% magnification (Microsoft)
P6	iPad	Safari (Apple Inc)	iOS Classic Invert, iOS VoiceOver (Apple Inc)
P7	iPad	Safari (Apple Inc)	iOS Large Text, color filters, iOS VoiceOver and Speak Screen (Apple Inc)
P7	Windows PC	Google Chrome (Google LLC)	NVDA[b]
P8	Windows PC	Google Chrome (Google LLC)	N/A
P9	Windows PC	Google Chrome (Google LLC)	JAWS[c]

[a] N/A: not applicable.

[b] NVDA: NonVisual Desktop Access.

[c] JAWS: Job Access With Speech.

Qualitative Analysis

Participant Feedback

The positive features of the website that enhanced accessibility for users with visual impairment are outlined in Textbox 3. One of the main features highlighted by the participants was the consistent layout throughout the website. These included having left-aligned texts, using a consistent font and color along with having the Quick links section in all pages. They identified that having a zigzag alignment of text, as in the case of the WordPress-designed home page (Multimedia Appendix 2), limited accessibility. For the content pages, our participants noted that having clear and concise information helped with accessibility. These included having accurate and logically ordered headings, arranging information using bullet points for ease of reading (Figure 4) and the purpose of each link clearly identified from the link text alone. Another important aspect that favored accessibility was good adaptability to various assistive software and devices, especially in this day and age where mobile devices are increasingly popular and accessible. The participants also favored a simple home page that was easy to navigate to other pages on the website. Participants with and without visual impairment liked that minimal scrolling is required on the home page. They also particularly liked the *Quick links* and *Jump to top* functions, as they offered straightforward navigation. In addition, they stated that content written in an easily understandable language and arranged in a structured manner added value to the website and improved the overall user experience.

Textbox 3. Positive accessibility features of the website.

Consistent layout and navigation:

"I like the uniform layout and colour theme. The text all have the same size throughout which is good as I did not have to change my magnification level often. The left-aligned texts make it easier to read as well. The texts on the Wordpress design can be easily missed on magnified view as they are not all properly aligned." [P4, 62-year-old cone-rod dystrophy patient]

"The zig-zag arrangement of icons in the Wordpress design can be bad for accessibility." [P5, 40-year-old patient with aniridia]

Structured information hierarchy with a clear description of links:

"The headings and subheadings of each page are very clear. Each heading describes exactly what is written." [P8, 45-year-old unaffected individual]

"I found it easy to navigate through the different headings for each page using the 'Insert-F6' function on JAWS which lists all the headings." [P9, 70-year-old patient with cone-rod dystrophy]

"I like the bullet point arrangement which made it easy to read. The targets of the links are also very clear with accurate descriptions." [P5, 40-year-old patient with aniridia]

"The Wikipedia articles have too long paragraphs; having bullet points will make it easier to read." [P1, 53-year-old unaffected father of a patient with type II Usher syndrome]

"The links are relevant in gene.vision and work well. There are too many links to read with a screen reader on Wikipedia." [P6, 37-year-old patient with retinitis pigmentosa]

Adaptability to different assistive software:

"The website works really well and is really fluid when using Voiceover on my iPhone." [P3, 41-year-old patient using iOS Voiceover with retinitis pigmentosa]

"I am still able to see the whole page at 200% magnification." [P5, 40-year-old patient using Windows magnifier with aniridia]

"The website works well with my Zoomtext settings." [P4, 62-year-old patient using ZoomText 2020 with cone-rod dystrophy patient]

"I found the website easy to understand and JAWS friendly." [P9, 70-year-old patient using JAWS with cone-rod dystrophy]

Simple home page with easy navigation:

"The home page is all on one page, which I like. No sliding or scrolling required." [P1, 53-year-old unaffected father of a patient with type II Usher syndrome]

"The drop-down menu at the top works well and as expected. The simpler the navigation the better. Gene.vision is easier to navigate through compared to Wikipedia." [P3, 41-year-old patient with retinitis pigmentosa]

"I like the drop-down menu as less scrolling is involved. I really like the 'Jump to top' button to navigate around when reading." [P4, 62-year-old patient with cone-rod dystrophy]

"I really like the table of contents at the top as I can go straight into any topic that interests me." [P2, 52-year-old unaffected mother of a patient with type II Usher syndrome]

Readable content:

"The gene.vision page speaks to a patient or a family member. I think it addresses the issues they want to know about. The content is not too detailed, digestible and easy to understand." [P8, 45-year-old unaffected individual]

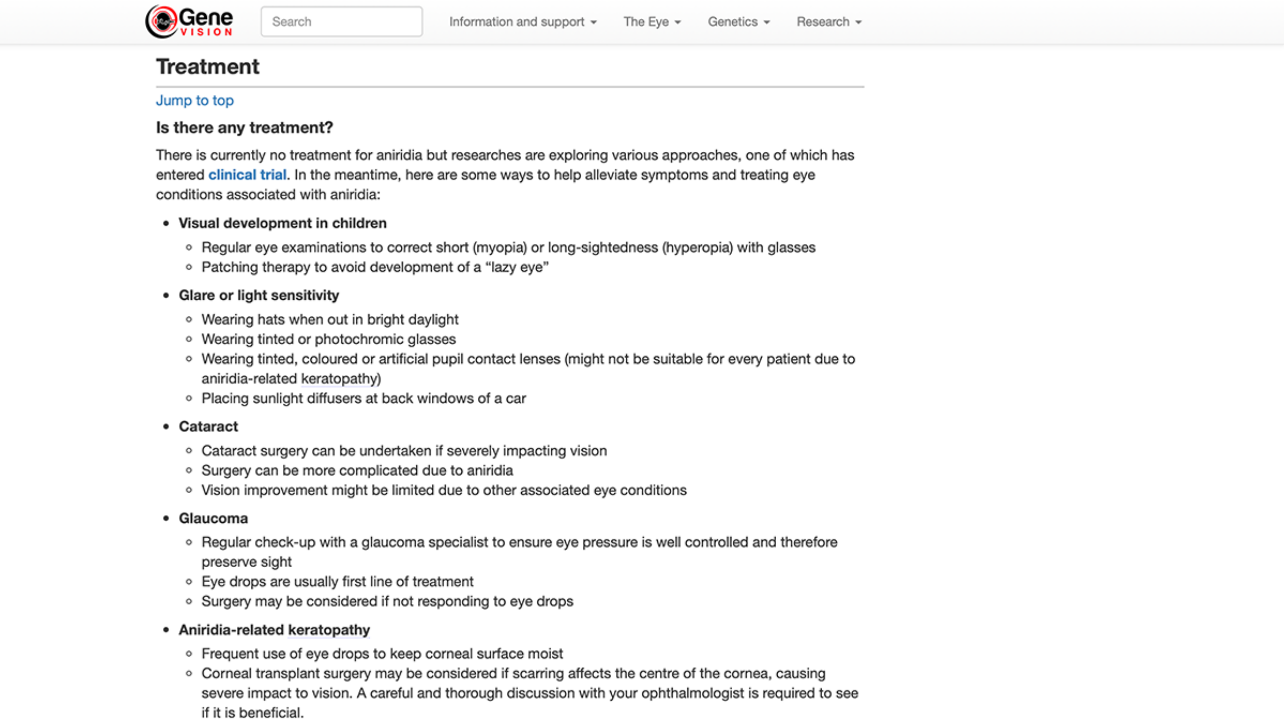
"The language used in gene.vision is good and at a good level, simple enough if you have just been diagnosed. It works well and simpler than the Wikipedia page with Voiceover." [P3, 41-year-old patient with retinitis pigmentosa]

"Gene.vision is easier to read and have a softer tone than Wikipedia. The layout is more user friendly as well." [P6, 37-year-old patient with retinitis pigmentosa]

Although unrelated to accessibility, our participants pointed out that content quality was equally important to attract users. With respect to the prototype, they felt that content related to research, support available, practical advice, and links to charities were incentives for repeated visits. They also suggested that knowing the information is coming from a reliable source will make the website more trustworthy. Quotes from participants that illustrate this point are as follows:

> *Reading stuff that is tough or difficult to absorb, it is good to have links to support. I also like the practical advice section with further links to topics that are important to me as a mother.* [P2, 52-year-old unaffected mother of a patient with type II Usher syndrome]
>
> *The content is pitched about right with links to more scientific content or papers available for doctors or patients who wanted to find out even more and look at the research themselves. It would be good to know that the website is definitely accurate if endorsed by an approved authority.* [An excerpt from the patient focus group]

Figure 4. Example of content arrangement using bullet points for ease of reading. The clinical trial link is not underlined here, which may confuse users with sight impairment.



Treatment

Jump to top

Is there any treatment?

There is currently no treatment for aniridia but researches are exploring various approaches, one of which has entered **clinical trial**. In the meantime, here are some ways to help alleviate symptoms and treating eye conditions associated with aniridia:

- **Visual development in children**
  - Regular eye examinations to correct short (myopia) or long-sightedness (hyperopia) with glasses
  - Patching therapy to avoid development of a "lazy eye"
- **Glare or light sensitivity**
  - Wearing hats when out in bright daylight
  - Wearing tinted or photochromic glasses
  - Wearing tinted, coloured or artificial pupil contact lenses (might not be suitable for every patient due to aniridia-related keratopathy)
  - Placing sunlight diffusers at back windows of a car
- **Cataract**
  - Cataract surgery can be undertaken if severely impacting vision
  - Surgery can be more complicated due to aniridia
  - Vision improvement might be limited due to other associated eye conditions
- **Glaucoma**
  - Regular check-up with a glaucoma specialist to ensure eye pressure is well controlled and therefore preserve sight
  - Eye drops are usually first line of treatment
  - Surgery may be considered if not responding to eye drops
- **Aniridia-related keratopathy**
  - Frequent use of eye drops to keep corneal surface moist
  - Corneal transplant surgery may be considered if scarring affects the centre of the cornea, causing severe impact to vision. A careful and thorough discussion with your ophthalmologist is required to see if it is beneficial.

On the other hand, our participants also identified some features on our website that impaired its usability not only for people with visual impairment but also for individuals with unimpaired vision (Textbox 4). It was highlighted to us that having good contrast is essential to accessibility. Certain aspects of our prototype, especially the navigation bar and the accompanying search box (Figure 1), had poor contrast and proved difficult for some participants to identify. One participant also pointed out that links should be underlined as default for easy identification (Figure 4). Furthermore, we found that implementing dynamic content such as an automatic timed *carousel* function (Multimedia Appendix 2) and large white spaces may frustrate and confuse screen reader and magnifier users. Having predictable navigation on a website is also crucial for accessibility. Most users are familiar with how popular search engines (Google, Bing, etc) work and they would expect similar functions when using other search boxes. This was proven when our participants found the search results page on our prototype confusing (Figure 2).

Textbox 4. Negative accessibility features of the website.

Poor chromatic and luminance contrast:

"The navigation bar is not easily found due to low contrast. I could not identify the search box on the navigation bar as it is very faint. When my pointer is at the genetics menu, it did not 'light up' very well to indicate that I am there. I find it difficult to tell if it is a link without hovering over the text with my mouse in gene.vision." [P4, 62-year-old patient with cone-rod dystrophy]

"The navigation bar is difficult to find. Grey is not visible, making it hard to see at first." [P8, 45-year-old unaffected individual]

"The 'for patients' and 'for doctors' tabs are not obvious due to poor contrast. The search box and search button could be more visible." [P5, 40-year-old patient with aniridia]

Dynamic content and large white spaces:

"I don't like the distraction of a carousel, especially one that I can't manually control. It doesn't allow me enough time to read its content." [P5, 40-year-old patient with aniridia]

"There are a lot of white space on the right side of the gene.vision page, magnifier users may get lost. The spacing is better in portrait mode on an iPad. It needs a more responsive layout." [P6, 37-year-old patient with retinitis pigmentosa]

Unpredictable search behavior:

It is difficult to find links to click on from the search results page. The 'Page title matches' and 'Page text matches' are confusing. [P8, 45-year-old unaffected individual]

"How would I use the top search box to get all the pages including the word aniridia? I have to go down to the 'containing' bit." [P5, 40-year-old patient with aniridia]

Clinician Feedback and Recommendations

All the health care professionals who tested our website felt that the information provided was comprehensive and useful. They particularly liked the *Quick links* function, which enabled them to skip to the section of interest instantly. Both consultant and trainee ophthalmologists found the information on current research very helpful, as the listed investigational therapies were explained in a simple yet detailed manner, enabling them to gain a basic understanding without having to read multiple papers. They also liked that they had quick access to scientific abstracts of seminal papers through the hyperlinks provided in each condition page. Finally, the *Information and support* menu and links to condition-specific charities were highly welcomed by all, regardless of discipline or subspecialty, as such queries are commonly posed by patients and their families in clinics. In addition, the involved health care professionals also provided some suggestions to further enhance the usability of our website. These and the improvements we have introduced to our current iteration are summarized in Textbox 5.

Textbox 5. Suggested features that we have added to the current version of the Gene.Vision website.

Suggestions

- Changing the *Overview* section of each condition to a table format for easy reference in a busy clinic
- Having a dedicated page explaining about clinical genetic testing so that clinicians can gain a basic understanding of the various sequencing techniques that are currently available
- Knowing the associated phenotypes of a specific gene can be helpful in directing further clinical management (ie, if there are any associated systemic features)
- Referral centers for specialist clinics and/or treatment should be listed where appropriate to improve practicality (eg, centers in the United Kingdom that administer a recently approved retinal gene therapy called Luxturna [24])

Actions

- The *Overview* section for each condition has been changed to a comprehensive table format
- A page on clinical genetic testing has been added to the site, providing a brief overview of the different types of sequencing methods and also covering the benefits, limitations and potential ethical concerns associated with genetic testing
- A feature called *gene cards* has been added (Multimedia Appendix 6), covering some of the more common genes listed on the Great Ormond Street Hospital for Children oculome panel [25]
- Specialist clinics for very rare conditions (eg, Bardet-Biedl syndrome) and referral centers for Luxturna treatment in the United Kingdom are listed in their associated pages

Discussion

Principal Findings

We evaluated the initial designs of a health information website focused on rare genetic eye disorders for patients, relatives, and health care professionals. Early development centered on meeting the user requirements of our patients, most of whom had visual impairment or blindness. We wanted to identify features that optimized or impaired accessibility for users with visual impairment to ensure that this vulnerable group was not excluded from information that could potentially benefit them and to improve overall user uptake.

From this testing session, we identified the following features that will enhance accessibility and usability for users with visual impairment:

- Consistent website layout and fonts.
- Structured information hierarchy with a clear description of links.
- Good chromatic and luminance contrast.
- Simple home page with consistent, predictable, and easy navigation.
- Readable content (appropriate to the intended audience).
- Adaptability to various assistive software and mobile devices.
- Avoidance of dynamic content and large *white spaces*.

In addition to good accessibility, content quality and reliability were highly rated as potential factors that may influence user traffic. They also suggested that having an authority endorsing a website will increase its trustworthiness.

On the basis of the above feedback, we updated our website by changing the features that negatively impacted accessibility for our participants. These changes were as follows:

- Improving the contrast of the navigation bar.
- Hyperlinks are bolded and underlined as default.
- Making the search box larger.
- Having a more conventional search behavior with an autocomplete function.
- Incorporating the *breadcrumb* functionality so that users can go back to the previous page that they were visiting.

We have kept features that our participants found useful as listed under *positive accessibility features of the website* in the Results section. The screen recording of the updated website is in Multimedia Appendix 6. The navigation bar and home page menu have also been updated after adding more content to the current version.

Limitations

Our study was limited by a small cohort of participants, none of whom were Braille keyboard users. Most of the participants were technologically adept (8 participants had at least basic digital skills) and belonged to the middle age bracket. Therefore, for future testing sessions, users with lower digital skills and a broader age spectrum inclusive of younger and older patients are recommended. This will consequently provide a wider opinion about web-based accessibility for people with visual impairment.

Comparison With Previous Work

The web-based behaviors of users with visual impairment differ significantly from those of individuals with full sight. Users with visual impairment tend to employ tactics to navigate around websites more efficiently. These include probing (getting a glimpse of a page by traversing it in a sequential fashion or by jumping between headings) [26], gambling scanning (skipping a determined number of lines until bumping into content that draws their interest) [27], and memorizing the amount of links that need to be skipped to get to the main content [28]. Some users may listen to the content sequentially from the beginning (exhaustive scanning), especially when visiting unfamiliar pages or sites [29].

Web accessibility for users with visual impairment can be improved by understanding the barriers they commonly encounter through usability testing and leveraging on the aforementioned navigational strategies. By having a consistent and well-structured information layout with clear headings, users were able to quickly orientate themselves without getting lost in a sea of texts [30]. This was further enhanced on our website by the *Quick links and Jump to top* functions where participants were able to navigate directly to the topic of interest without scrolling. The *Jump to top* function also served as a *shelter* if users lost their orientation within the page as they can go back to the beginning of the page instantly, which is a tactic some users employ when they are lost [30]. Clear description of links is also equally important for effective navigation, particularly for screen reader users [31].

Users with visual impairment may feel frustrated and give up on exploring a particular website further if they are faced with overwhelming situations such as a large number of search results or taking too many steps to complete a transaction [30]. The search behavior of our prototype is a prime example (Figure 2), where the search term *aniridia* yielded multiple results under the heading *page title matches* and *page text matches* with confusing excerpts. Hence, we have updated our search behavior to reflect conventional search engines and also incorporate an autocomplete function as many medical terms are not in common usage, which can make it challenging for lay users to spell accurately.

It is believed that many websites are not accessible to users with disability because developers fear that optimizing accessibility can be costly and may affect the attractiveness of a website to sighted users [32,33]. However, there is an abundance of evidence showing that usability problems are shared regardless of visual disability and everyone stands to benefit from good accessibility [34-36]. Participants with and without visual impairment in our testing session demanded similar features, such as having a simplistic design without any dynamic content. A simple and well-designed page has fewer elements to navigate and requires less time to load [31]. Furthermore, carousels cannot be manipulated with keyboards, which can lead to frustration among screen reader users. Other features such as easily readable fonts and good contrast are also crucial and are covered in the WCAG guidelines [7].

Another factor taken into consideration when designing the website was the increasing popularity of mainstream mobile devices such as smartphones and tablet computers, both among those with and without visual impairment [37]. Thus, having a *responsive* website skin that adapts to different screen sizes has been highlighted by our participants as an important accessibility feature. This will have a direct and significant impact on everyone, as nearly three-fourth of internet users are predicted to access the web solely through smartphones by 2025 [38].

This study also demonstrated the benefits of designing a website with a user-centric approach that was previously outlined by Abelse et al [39] and further emphasized in the design principles of the NHS Digital Service Manual [40]. By understanding the challenges and requirements of users, we can then create solutions and further refine them based on feedback. This is assisted by having various prototype versions so that multiple features can be tested in a single session. For example, we were able to quickly identify features that optimized or affected accessibility for those with visual impairment by having our participants test 2 home page prototypes.

Testing with target users can also provide developers with a more accurate idea of subjective features such as readability of the content and website navigation. Although most of the accessibility characteristics identified by our participants were covered by the WCAG guidelines, such parameters are often difficult or even impossible to assess with automated tools. Even if a website conforms to the WCAG guidelines, it may not ensure good accessibility as pointed out by Power et al [6]. Their study found that the WCAG 2.0 guideline only covered half of the user problems encountered by their cohort of screen reader users. Furthermore, they reported that user problems still existed despite the implementation of some of the recommendations. The authors suggested that enhancing website accessibility should shift from a traditional problem-based approach to gathering user data from testing sessions with real-world users, which is the approach we took.

Content quality is equally crucial in attracting users [39]. As a website aiming at patients and families affected by rare genetic eye disorders, we believed that having information on *soft* content, such as practical advice, available support, and charities were important to our target audience. This resonated well with our cohort and one of them, a mother of a patient affected by type II Usher syndrome (P2) stated that knowing where to look for support and learning about practical tips that will help her son’s daily living was more important as these were issues that “kept me up at night.” Litzkendorf et al [41] reported similar findings in their study where patients with rare diseases were interviewed about their information needs and acquisition. The main themes that were lacking in rare disease websites were current research, practical tips to cope with a condition, genetic counseling and family planning options, social and educational support, and the ability to connect with similar people.

The lack of exposure to rare diseases among clinicians has often led to delayed diagnoses and incorrect care for many patients. Recent surveys of primary and secondary care physicians in Belgium and Spain have identified a huge demand for information on rare diseases, particularly on genetic screening and counseling, investigational therapies, specialist referral centers, and locating reliable resources [42,43]. Although information portals for rare diseases such as Orphanet already exist, health care professionals who tested our website believed that Gene.Vision is highly relevant as it offers more in-depth information on genetic eye disorders and covers the available social support for individuals with visual impairment in the United Kingdom. Furthermore, as genomic sequencing becomes more accessible and affordable in the United Kingdom, nonmolecular ophthalmologists, with appropriate training and guidance, are encouraged to undertake genetic testing for their patients to aid diagnosis, management, and trial enrollment [44]. Once a molecular diagnosis is received, the *gene card* feature on our website supplements this by providing a quick overview of the associated phenotype or phenotypes and information on current research.

Conclusions

To make a website accessible to users with visual impairment, attention should be focused on making simple, well-designed pages with consistent layout and information structure, good contrast, and simple navigation, all of which will directly improve the overall user experience. Although most of these features are part of the WCAG 2.0 and 2.1 recommendations, usability testing with real-world users should be conducted as well as examination by professional testers and use of automated web accessibility evaluation tools. More generally, a website's design and content should be developed with the input of target users from the earliest stages to ensure that it meets their needs. Many of these steps can be implemented easily and will help in search engine optimization.

Acknowledgments

The authors would like to thank their participants for giving their time. They would also like to thank Molly Watt (Molly Watt Trust) for providing her expertise in accessibility to the development of their website and Kate Arkell from Retina UK, Linda Van de Sande, and Kelly Trout from the International WAGR Syndrome Association for reviewing the choroideremia and WAGR syndrome pages. There are no financial disclosures from all the authors. The project is funded by the Wellcome Trust (grant number: 205174/Z/16/Z), Retina UK, and the National Institute for Health Research Moorfields Biomedical Research Centre.

Authors' Contributions

JY and PT contributed equally to the development of the website, organization of the user testing session, and writing of this paper. JY also analyzed the data gathered from this testing session. JB advised on accessible website design, testing, and user research and reviewed the final manuscript. MM conceived the idea of the website, recruited participants, provided input to website content, and reviewed the final manuscript.

Abstract

Background: Misinformation about COVID-19 is common and has been spreading rapidly across the globe through social media platforms and other information systems. Understanding what the public knows about COVID-19 and identifying beliefs based on misinformation can help shape effective public health communications to ensure efforts to reduce viral transmission are not undermined.

Objective: This study aimed to investigate the prevalence and factors associated with COVID-19 misinformation in Australia and their changes over time.

Methods: This prospective, longitudinal national survey was completed by adults (18 years and above) across April (n=4362), May (n=1882), and June (n=1369) 2020.

Results: Stronger agreement with misinformation was associated with younger age, male gender, lower education level, and language other than English spoken at home ($P<.01$ for all). After controlling for these variables, misinformation beliefs were significantly associated ($P<.001$) with lower levels of digital health literacy, perceived threat of COVID-19, confidence in government, and trust in scientific institutions. Analyses of specific government-identified misinformation revealed 3 clusters: prevention (associated with male gender and younger age), causation (associated with lower education level and greater social disadvantage), and cure (associated with younger age). Lower institutional trust and greater rejection of official government accounts were associated with stronger agreement with COVID-19 misinformation.

Conclusions: The findings of this study highlight important gaps in communication effectiveness, which must be addressed to ensure effective COVID-19 prevention.

Introduction

False, misleading, or inaccurate health information can pose a serious risk to public health and public action [1]. Misinformation about COVID-19 is common and has spread rapidly across the globe through social media platforms and other information systems [2-5]. In February 2020, the World Health Organization’s Director-General declared the global “overabundance” of COVID-19 information an “infodemic” [6]. The term “misinfodemic” has since been coined to capture the corresponding increase in misinformation surrounding the virus [7].

Misinformation, which is typically compelling, persuasive, and emotive, spreads on social media platforms significantly farther, faster, deeper, and more broadly than factual information [8]. This is particularly true within tight-knit communities, as has been observed with the spread of vaccine misinformation among some communities in the United States, Sweden, and the Netherlands [9-12]. Common COVID-19 beliefs circulating in mainstream media include framing the pandemic as a leaked bioweapon, a consequence of 5G wireless technology, a political hoax, and that the pandemic has been made up by governments to control people. Others detail ineffective measures that individuals can take to prevent or treat the disease, such as exposing themselves to sunlight or taking vitamin C [13].

Misinformation can undermine public health efforts by shaping beliefs and attitudes, particularly if encountered within a social network, and reinforcing pre-existing values and positions [14]. Importantly, lower perceived risk or perceived efficacy of prevention behaviors and altered perception of social norms might influence individuals' willingness to follow recommendations such as voluntary testing, isolation and, potentially, vaccination [15].

Understanding what the public knows about COVID-19 and identifying beliefs based on misinformation can help shape effective public health communication to ensure effort to reduce its impact, such as debunking [16].

This paper uses data from a longitudinal cohort study of the Australian public. Our aims were to: (1) investigate the prevalence of COVID-19 misinformation beliefs in the study sample; (2) examine whether any demographic, psychosocial, and cognitive factors are associated with these beliefs; and (3) investigate how these misinformation beliefs change over time.

Methods

Data Collection

The data used in this study are from a prospective, longitudinal, national survey in Australia that aimed to evaluate variation in the public's understanding, attitudes, and implementation of COVID-19 health advice during the first lockdown period in 2020 [17,18]. A total of 4362 participants were recruited between April 17 and 24, 2020; these participants completed the baseline survey (Round 1). This survey was administered 1 month after the first measures of prevention (physical distancing and quarantine) were introduced in Australia when an increasing number of COVID-19 cases were being reported. A subset (n=3214) of this sample was invited for a longitudinal follow-up to assess changes in attitudes, beliefs, and behavior over the course of the pandemic. Of the 3214 participants, 1882 (58.5%) were invited for the Round 2 survey, which was administered from May 8 to 15, 2020 (ie, 3 weeks after the baseline or Round 1). Round 3 survey was administered to 1369 of the 3214 participants (43%) from June 5 to 12, 2020 (ie, approximately 6 weeks after the baseline survey), when restrictions in Australia showed signs of easing, and the number of new COVID-19 cases and reported community transmission had drastically reduced. Round 3 survey was administered prior to the resurgence of COVID-19 cases in some areas of Australia.

Recruitment

Participants were recruited via advertisements on social media (ie, Facebook and Instagram) and by a market research company (Dynata). We used 2 different methods for recruitment with the aim of achieving a more diverse sample. Only those participants who were recruited via social media were invited for the longitudinal follow-up.

Dynata is a market research company with access to a database of 600,000 members in Australia who are willing to be involved in online research studies. Dynata invites members to participate in a certain research study only when they meet the study's eligibility criteria. For instance, only participants who met the following eligibility criteria were included in this study: adults (ie, age 18 years or older), currently living in Australia, and ability to read and understand English.

Participants recruited via Dynata received points for completing the survey; these points could then be redeemed against gift vouchers, donations to charities, or cash. Participants recruited via social media were given the opportunity to enter into a prize draw for the chance to win one of ten $20 gift cards upon completion of each survey round.

Ethics Approval

Ethics approval was obtained from the Human Research Ethics Committee of The University of Sydney (2020/212). Participants were informed about the purpose of the study, confidentiality, and risks and benefits of participation at the beginning of the survey. Completion and submission of the online questionnaire were considered as evidence of consent.

Measures

The survey was built and administered using Qualtrics (SAP SE), an online survey platform, and it was piloted within the health literacy lab. Survey items included in each round were modified from the national longitudinal study [17] to reflect psychological, behavioral, and knowledge factors considered most relevant at that stage of restrictions. Relevant measures for this study are detailed in Table 1. Age, gender, education, language other than English (LOTE) spoken at home, and socioeconomic status were assessed in Round 1, as detailed in our previous study [17].

Table 1. Measures evaluated in this study.

Item	Description and reference (if applicable)	April	May	June
Main outcomes				
COVID-19–related misinformation beliefs[a]				
	Data on the effectiveness of vaccines is often made up[b].	✓		
	Herd immunity would be beneficial for COVID-19 and this fact is covered up.	✓	✓	
	The threat of COVID-19 is greatly exaggerated.	✓	✓	✓
	Government restrictions are stronger than is needed.	✓	✓	✓
Specific COVID-19 misinformation[c]				
	5G networks are spreading the virus.			✓
	Hot temperatures kill the virus.			✓
	Vitamin C is an effective treatment.			✓
	Ibuprofen exacerbates COVID-19.			✓
	The flu shot provides immunity to COVID-19.			✓
	Hydroxychloroquine is an effective treatment.			✓
	UV rays kill the virus.			✓
	There is a cure/vaccine for COVID-19.			✓
	Parcels from China can spread the virus.			✓
	The virus causing COVID-19 was engineered and released from a Chinese laboratory in Wuhan.			✓
Explanatory variables				
Digital health literacy[d]				
	I know what health resources are available on the internet.	✓		
	I know where to find helpful health resources on the internet.	✓		
	I know how to find helpful health resources on the internet.	✓		
	I know how to use the internet to answer my questions about health.	✓		
	I know how to use the health information I find on the internet to help me.	✓		
	I have the skills I need to evaluate the health resources I find on the internet.	✓		
	I can tell high-quality health resources from low-quality health resources on the internet.	✓		
	I feel confident in using information from the internet to make health decisions.	✓		
Perceived threat of COVID-19[e]				
	Perceived public threat of COVID-19 (scale: 1=no threat at all to 10=very serious public health threat)	✓		✓
	Perceived likelihood of personally getting sick from COVID-19 (scale: 1=not at all to 5=I definitely will)	✓		✓
Confidence in the government[f]				
	I am confident in the information about COVID-19 provided by the government.	✓		✓
	I am satisfied with the amount of information about COVID-19 provided by the government.	✓		✓
	I follow government advice on social distancing to help protect the wider community.	✓		✓
	I am concerned that government recommendations about COVID-19 are not safe, or not enough is being done.	✓		✓
Trust in institutions[g]				
	Scientists involved in developing and testing new ways to control COVID-19	✓		
	Researchers involved in tracking and predicting COVID-19 cases	✓		
	Medical institutions (general practitioners, hospitals) involved in managing COVID-19 cases	✓		
COVID-19 information sources: social media				

Item	Description and reference (if applicable)	April	May	June
	Social media reported as being used as a top-3 information source	✓		✓
Rejection of official accounts[h]				
	Much of the information we receive is wrong.			✓
	I often disagree with commonly held views about the world.			✓
	Official government accounts of events cannot be trusted.			✓
	Major events are not always what they seem.			✓

[a] Four items, adapted from validated vaccine conspiracy beliefs scale [19]; scale: 1=strongly disagree to 7=strongly agree.

[b] This question was from a validated scale and referred to vaccines in general, not a COVID-19 vaccine.

[c] Ten items, taken from Australian Government Myth busting website [13]; scale: 1=definitely false to 5=definitely true.

[d] Mean of 8 items from the eHealth Literacy Scale (eHeals) [20]; scale: 1=Strongly disagree to 5=Strongly agree.

[e] Two individual items, adapted from [21].

[f] Mean of 4 items, adapted from national Australian survey on vaccination [22]; scale: 1=strongly disagree to 7=strongly agree.

[g] Mean of 3 items adapted from [23]; scale: 1=strongly disagree to 7=strongly agree.

[h] Mean of 4 items, adapted from [24]; scale: 1=strongly disagree to 5=strongly agree.

Statistical Analysis

Analyses were conducted using Stata/IC (v16.1; StataCorp LLC). The threshold for statistical significance was set at *P*<.05. Descriptive statistics (means and SD for continuous variables, and frequency and relative frequency for categorical variables) were calculated for participant characteristics and study outcomes. To reduce the number of outcomes for analysis, misinformation beliefs at baseline were combined into a single measure using principal component analysis (PCA). Associations between the extracted misinformation component and possible explanatory variables were explored using truncated linear regression (with lower-bound truncation based on the minimum numerically possible value of the extracted misinformation component that would result from responding "strongly disagree" to all question items included in the PCA) controlling for sociodemographic factors previously shown to be associated with misinformation beliefs [17].

Changes in misinformation beliefs across study rounds were examined using linear mixed models with random intercepts by the participant and robust standard errors. These items were analyzed individually owing to changes in the items included in each round.

Dimension reduction using PCA was applied to the 10 specific COVID-19 myth items (included in Round 3 of the study). Multivariable truncated regression models (with lower-bound truncation as described above) were used to examine associations with the extracted components, using the same explanatory variables as for the analysis of misinformation beliefs from Round 1. Where survey items were repeated in Round 3 (ie, perceived threat of COVID-19, confidence in government, and use of social media as a "top-3" information source), this version of the variable was included; otherwise, the response at baseline was carried forward (ie, digital health literacy, institutional trust, and sociodemographic variables). An additional explanatory variable added in Round 3 (ie, rejection of official accounts) was also included in these models.

Results

Sample Characteristics (Cross-Sectional and Longitudinal)

Sample characteristics by each month are summarized in Table 2. When compared to national data, our sample was slightly older, included more females, had higher educational attainment, and was less likely to speak a LOTE at home.

Table 2. Sample characteristics by study round (1-3).

Sample description	Values			
	Cross-sectional	Longitudinal		
	April: Round 1 (n=4362)	April: Round 1 (n=2006)[a]	May: Round 2 (n=1882)	June: Round 3 (n=1369)

Northern Territory	28 (0.6)	6 (0.3)	6 (0.3)	4 (0.3)

[a] Round 1 longitudinal sample is a subsample of those included in the cross-sectional Round 1 sample, and who responded to at least one follow-up survey. This group was recruited via social media only.

[b] Certificates I-IV are tertiary qualifications; see Australian Qualifications Framework [25].

[c] Languages other than English spoken at home with cell counts <10 at baseline.

[d] Socioeconomic Indexes for Areas and Index of Relative Socioeconomic Advantage and Disadvantage Quintiles [1-5] based on participants’ residential postcode.

Misinformation Beliefs and Associations with Sociodemographic, Cognitive, and Psychosocial Variables (Cross-Sectional Sample in April)

One month into lockdown in Australia, of the 4362 participants, 753 (17.3%) agreed that data about the effectiveness of vaccines is often made up (this survey question referred to vaccines in general, not a COVID-19 vaccine); 652 (15%) agreed that herd immunity would be beneficial for COVID-19, but this is covered-up; 603 (13.8%) agreed that the threat of COVID-19 is greatly exaggerated; and 595 (13.6%) agreed that the Australian government restrictions are stronger than required. Responses on these items were moderately correlated (pairwise *r* was between 0.36 and 0.63), with good internal consistency (Cronbach α=.78) and sufficient sampling adequacy (Kaiser-Meyer-Olkin or KMO=0.76). PCA of these items resulted in the extraction of a single component with an eigenvalue greater than 1, accounting for 60.7% of the variance (component loadings are provided in Table S1 in Multimedia Appendix 1). Estimated marginal mean values from the multivariable regression model of misinformation beliefs at baseline are provided in Table 3. Stronger agreement with misinformation beliefs was significantly associated with younger age, male gender, lower education, and primarily speaking a LOTE at home (*P*<.001 for all). After controlling for these variables, misinformation beliefs were found to be significantly associated (*P*<.001 for all) with lower levels of digital health literacy, perceived threat of COVID-19, confidence in the government, and trust in scientific institutions.

Table 3. Multivariable truncated linear regression of strength of agreement with misinformation beliefs at Round 1[a]. Higher values of the outcome indicate greater support for misinformation.

Explanatory variables	Value	Estimated marginal mean differences (95% CIs)	*P* value
Sociodemographic variables			
Age in years, mean (SD)	42.5 (17.4)	−0.023 (−0.028, −0.018)	<.001
Female gender (vs male)[b], n (%)	2568 (59.9)	−0.384 (−0.541, −0.226)	<.001
Education (vs high school or less), n (%)			<.001
Certificate I-IV[c]	609 (14.2)	0.114 (−0.133, 0.360)	.37
University education	2760 (64.4)	−0.270 (−0.459, −0.080)	.005
Language other than English spoken at home, n (%)	270 (6.3)	0.847 (0.569, 1.126)	<.001
Socioeconomic status quintile, mean (SD)	3.60 (1.40)	−0.050 (−0.105, 0.005)	.08
Additional explanatory variables			
Digital health literacy[d], mean (SD)	4.04 (0.74)	−0.250 (−0.356, −0.144)	<.001
Perceived public threat of COVID-19[e], mean (SD)	7.64 (2.17)	−0.336 (−0.372, −0.300)	<.001
Not likely to get sick, n (%)	1091 (25.5)	0.649 (0.475, 0.823)	<.001
Confidence in government[f], mean (SD)	5.15 (1.06)	−0.143 (−0.222, −0.063)	<.001
Institutional trust[g], mean (SD)	5.95 (1.06)	−0.663 (−0.738, −0.587)	<.001
Social media used as a top-3 information source, n (%)	1923 (44.9)	0.151 (−0.001, 0.307)	.06

[a] Sample for analysis comprised 4286 complete records; occasional instances of missing data for explanatory variables were not imputed due to the small proportion of missingness (76/4362, 1.8%).

[b] Marginal mean differences are not reported for gender reported as “not specified” or “other” due to small sample size, but this data was included in the regression model.

[c] Certificates I-IV are tertiary qualifications; see Australian Qualifications Framework [25].

[d] Mean of 8 items, range: 1-5.

[e] Likert scale, range: 1-10.

[f] Mean of 4 items, range: 1-7.

[g] Mean of 3 items, range: 1-7.

Changes in Misinformation Beliefs Over Time (Longitudinal Sample in April-June)

The prevalence of agreement with misinformation beliefs across the study period is shown in Figure 1, which appears to be generally consistent over time. Estimated mean values from the fixed portion of linear mixed models are presented in Table 4. A significant effect of time (*P*=.006) was identified for the misinformation belief that the threat of COVID-19 is greatly exaggerated, with pairwise contrasts showing an increase in this belief between April and May; however, this difference was not maintained in June. There was a decrease in the belief that herd immunity is beneficial for COVID-19 but is covered up between April and May (*P*<.001). No difference was observed in across the study period with regard to the strength of government restrictions belief (*P*=.41).

Figure 1. Prevalence of agreement (i.e., responding as somewhat agree (5) to strongly agree (7) on the 1 to 7 Likert scale) with misinformation beliefs by study month. Error bars indicate 95% confidence intervals.].

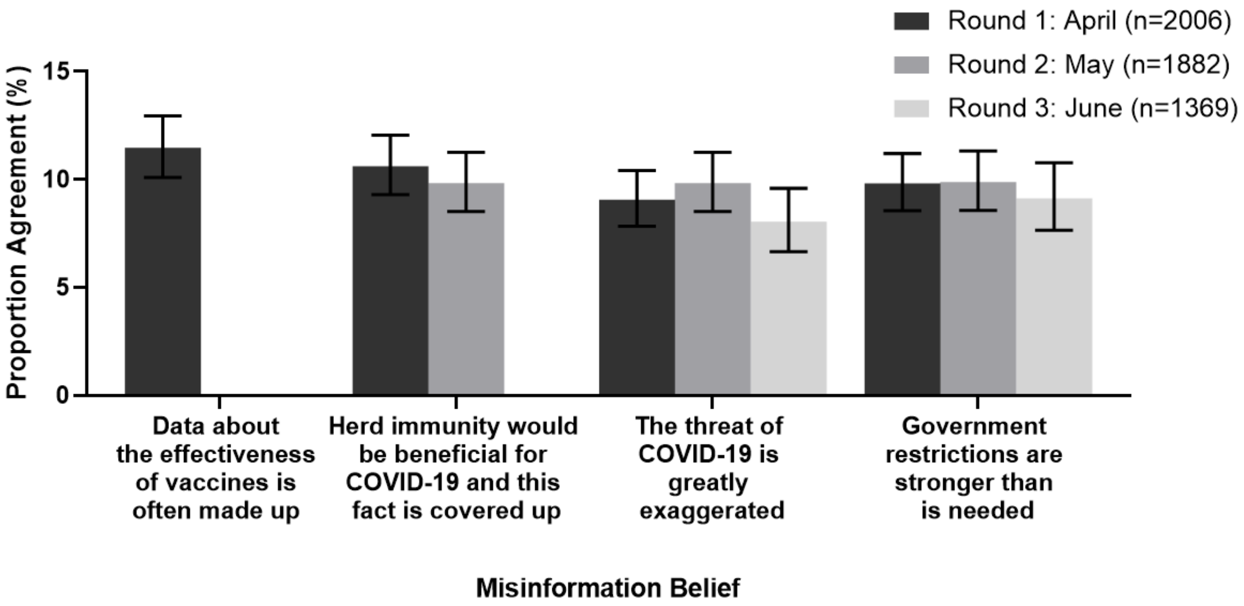

Table 4. Estimated means (95% CIs) of fixed effects from linear mixed models analyses (with random intercepts by the participant) of agreement with misinformation beliefs by study month and estimated mean differences (95% CIs) for pairwise comparisons to Round 1 (April).

Misinformation belief (scale range: 1-7)	April: Round 1 (n=2006)	May: Round 2 (n=1882)			June: Round 3 (n=1369)		
	Mean (95% CIs)	Mean (95% CIs)	Mean difference[a] (95% CIs)	*P* value	Mean (95% CIs)	Mean difference[a] (95% CIs)	*P* value
Data about the effectiveness of vaccines is often made up	2.37 (2.30, 2.44)	N/A[b]	N/A	N/A	N/A	N/A	N/A
Herd immunity would be beneficial for COVID-19 and this fact is covered up	2.52 (2.46, 2.59)	2.39 (2.32, 2.46)	−0.13 (−0.19, −0.07)	<.001	N/A	N/A	N/A
The threat of COVID-19 is greatly exaggerated	1.99 (1.93, 2.05)	2.07 (2.01, 2.14)	0.08 (0.03, 0.13)	.002	2.04 (1.98, 2.10)	0.05 (−0.01, 0.10)	.11

[a] Mean difference compared to Round 1 completed in April 2020.

[b] N/A: not applicable.

Specific Misinformation Beliefs and Associations With Sociodemographic, Cognitive, and Psychosocial Variables (Longitudinal Sample In June)

The level of agreement across the 10 COVID-19 misinformation items from the Australian Government website had moderate internal consistency (Cronbach α=.693) and sufficient sampling adequacy (KMO =0.761). Application of PCA (with varimax rotation) identified a 3-component solution with eigenvalues greater than 1, which cumulatively accounted for 51.15% of the variance (see Table S2 in Multimedia Appendix 1 for component loading and proportion agreement with each item). Examination of the contributing items to each component resulted in the following 3 labels:

1. Symptom management and prevention misinformation: principal component (PC)1 (explaining 18.9% of the total variance)
2. Causes and transmission misinformation: PC2 (explaining 16.7% of the total variance)
3. Immunity and cure misinformation: PC3 (explaining 15.6% of the total variance)

Regarding specific misinformation concerning symptom management and prevention, of the 1369 participants in Round 3, 301 (22%) participants agreed that hot temperatures kill the virus, 295 (21.5%) participants agreed that UV rays kill the virus, and 179 (13.1%) participants agreed that ibuprofen exacerbates COVID-19 (see Table S2 in Multimedia Appendix 1). Greater support for symptom management and prevention misinformation (PC1) was significantly associated with younger age and male gender, as well as with lower institutional trust and greater rejection of official accounts (PC1) after controlling for demographics (age, gender, education, and LOTE; see Table 5). For misinformation regarding causes and transmission, of the 1369 participants, 167 (12.2%) participants agreed that the virus causing COVID-19 was engineered and released from a Chinese laboratory in Wuhan, 57 (4.2%) participants agreed that parcels from China could spread the virus, and only 8 (0.6%) participants agreed that 5G networks are responsible for the spread of the virus. Causes and transmission misinformation (PC2) was significantly associated with less education and more social disadvantage. Greater belief in these statements was also associated with lower digital health literacy, reduced perceived public threat, reduced institutional trust, and greater rejection of official accounts after controlling for sociodemographic variables (PC2; see Table 5). Regarding misinformation about immunity and cure, of the 1369 participants in the sample, 62 (4.5%) participants agreed that vitamin C is an effective treatment, 55 (4%) participants agreed that there is a cure or vaccine for COVID-19, 32 (2.3%) participants agreed that hydroxychloroquine is an effective treatment, and 15 (1.1%) participants agreed that the flu shot provides immunity. Greater support for immunity and cure misinformation (PC3) was significantly associated with younger age. After controlling for sociodemographic factors, lower digital health literacy, reduced perceived public threat, reduced institutional trust, and greater rejection of official accounts were associated with greater belief in these statements (PC3; see Table 5).

Table 5. Multivariable truncated linear regression of the misinformation beliefs in June (Round 3)[a]. Higher values of the outcome indicate greater support for these beliefs. Data are presented as estimated marginal mean differences (95% confidence intervals) and *P* values.

Explanatory Variable	Value	Estimated marginal mean differences (95% CIs) and *P* values					
		Symptom management and prevention (PC1)	*P* value	Causes and transmission (PC2)	*P* value	Immunity and cure (PC3)	*P* value
Sociodemographic variables[b]

Rejection of official accounts[i], mean (SD)	2.36 (0.83)	0.172 (0.031, 0.313)	.02	0.451 (0.245, 0.657)	<.001	0.337 (0.169, 0.506)	<.001

[a] Sample for analysis (n=1366); occasional cases of missing data for explanatory variables were not imputed due to a small proportion of missingness (3/1369, 0.2%).

[b] Values obtained in April (Round 1) and carried forward.

[c] Marginal mean differences are not reported for gender reported as "not specified" or "other" owing to small sample size but were included in the regression model.

[d] Certificates I-IV are tertiary qualifications; see the Australian Qualifications Framework [25].

[e] Mean of 8 items, range: 1-5.

[f] Likert scale, range: 1-10.

[g] Mean of 4 items, range: 1-7.

[h] Mean of 3 items, range: 1-7.

[i] Mean of 4 items, range: 1-5.

Discussion

Principal Findings

Our analysis showed lower institutional trust, lower digital health literacy, and greater rejection of official accounts were associated with a stronger agreement with COVID-19 misinformation beliefs. Misinformation was also more common among participants who primarily spoke a LOTE at home, in younger age groups, and in males. The most commonly held misinformation beliefs were concerning symptom management and prevention. We found small changes between April and May in two of the misinformation items: an increase in agreement with “COVID-19 is greatly exaggerated” and a decrease in agreement with “herd immunity is beneficial for COVID-19 but is covered up.” Despite these differences being statistically significant, they likely have little to no practical importance (ie, only a 0.08- and 0.12-unit change, respectively, on a 7-point scale). Notably, the proportion of participants agreeing with each item remained generally consistent over time during and after lockdown restrictions.

The agreement rates of COVID-19 misinformation beliefs were lower than those reported in other countries [26,27], but we note that our study was not sampled to be representative of the Australian population. An Australian poll conducted in May 2020 found relatively high support (12%-77%) for misinformation beliefs relating to the creation, spread, and prevention of the virus [28]. Interestingly, compared with the results of this poll, we found a much lower prevalence of people agreeing that 5G networks are spreading the virus. The poll found demographic patterns similar to our findings, wherein male and younger participants agreed with a range of COVID-19 misinformation beliefs more than other groups. Studies have shown that in the United States and the United Kingdom, younger people are more likely to hold conspiracy beliefs about COVID-19 [29,30]. Moreover, other studies have found that American men are more likely to agree with COVID-19 conspiracy theories than women [31].

The association between misinformation beliefs and lower education, LOTE, younger age, and male gender point toward important gaps in public health messaging to these specific groups. Our recent study highlights similar disparities in knowledge and behavior [17], as well as issues with the complexity of government health information about COVID-19. People with less education and LOTE had a poorer understanding of COVID-19 symptoms and were less frequently able to identify behaviors to prevent infection. Recently, attention has been focused on the importance of reaching people who do not speak English as their first language [32]. Our study further highlights the need for health information to be written to meet diverse health literacy requirements and targeted to specific study groups. For instance, young people and representatives of culturally and linguistically diverse groups should be involved in the design of COVID-19 messages to ensure appropriate tonality and delivery of the message. This can be achieved by testing communications with these groups, running consumer focus groups before releasing messages to the public, and ensuring representation on public health communication teams [33]. Ideally, a coproduction approach should be used to ensure targeted community messages about COVID-19 prevention are relevant and effective.

The provision of quality information online is unlikely to be a sufficient strategy to counter the influence of misinformation if digital health literacy is not accounted for. Messaging and debunking must be delivered on multiple trusted channels [34], consistent in content and style, and conveyed in local languages to ensure engagement with all communities [35]. Emerging evidence supports the idea that psychological inoculation—pre-emptively exposing people to small doses of misinformation techniques—can build resistance to false information across cultures [36]. It will be important to invest in programs teaching digital health literacy and healthy skepticism of health news, including interventions nudging people to consider the accuracy of COVID-19–related news content before sharing it further [37]. Finally, partnerships between public health authorities and trusted organizations to deliver information and correct misinformation should be utilized where possible [38]. Corrective messages are most successful when they offer a coherent explanation for how and why a belief based on misinformation is incorrect [39]. Research shows that corrective information can counter misperceptions and improve belief accuracy after an individual has been exposed to misinformation [40].

Timely, accurate, and transparent messaging is vital to gaining public trust in communication from authorities ahead of other, less credible sources [41]. Although there now is intense global interest aimed at limiting the spread of misinformation in the first place [2,36,42], this will require “a sustained and coordinated effort by independent fact-checkers, independent news media, platform companies, and public authorities to help the public understand and navigate the pandemic” [43].

Around the world and in Australia, antilockdown protests have taken place in capital cities, with protesters voicing opposition to vaccination, telecommunication towers, and COVID-19 hoax. Researchers have recently investigated the degree to which misinformation about COVID-19 is associated with people’s willingness to adhere to public health recommendations and government-enforced measures; they found that willingness decreases significantly as the strength of misbeliefs increases [44,45]; this also includes decreased intentions to avail a COVID-19 vaccination [46]. In some cases, misinformation has led to serious harm, such as the Iranian methanol poisoning episode [47]. The spread of misinformation is an ongoing area of concern as Australia and other countries worldwide continue to live with the fluctuating realities of a global pandemic. Correcting misinformation should be viewed as a vitally important science and health policy activity [48]. Importantly, the more extreme conspiracy beliefs were rare; for example, fewer than 1% of the participants in our study sample endorsed the 5G conspiracy. However, other beliefs were held by over 20% of the participants in certain demographics, indicating widespread confusion or simply outdated information spread among people, such as that regarding the use of ibuprofen.

Strengths and Limitations

The study was large and diverse but not representative of the national population. Given this, caution is needed in generalizing from these prevalence findings. The sample was recruited via an online panel and social media. The majority of participants were well educated and a low proportion were from culturally and linguistically diverse groups. Therefore, this sample may not represent the demographics of all people concerned by COVID-19 and vulnerable to misinformation, including older adults. Participants recruited via Dynata were not included in the follow-up (ie, Rounds 2 and 3) due to funding constraints. Moreover, details of the specific social media platform(s) used by the participants (eg, YouTube, Twitter, and Facebook) were not captured in our survey, but it is important to note that both good- and poor-quality information may be obtained through these channels. (Mis)information can come from various sources such as family and friends, television, radio, print media, or misinformed health care providers (including primary, allied, alternative, and complementary health sectors). The use of social media as a "top-3" information source was comparable across education categories (ie, 45% for all 3 categories); however, given the abovementioned limitation, it is unclear which platform is being used by whom.

The longitudinal design of this study enabled us to evaluate whether misinformation beliefs changed over the course of the pandemic. By design, the survey items changed across time; however, this prevented us from being able to determine longitudinal changes in the PC derived at the baseline. Finally, some of the misinformation items are likely contextual and subjective (eg, "the government restrictions are stronger than is needed"), which may have influenced the interpretation and responses of some participants.

Incorrect information about COVID-19—whether labeled as misinformation, myth, conspiracy theory, or rumor—circulates every day, and our knowledge regarding the value of various preventive interventions has progressed during the course of the pandemic. While we acknowledge that some of the misinformation items included in this survey were subject to legitimate inquiry (eg, advice recommending against the use of ibuprofen was issued by the World Health Organization early in the pandemic but then retracted), they have since been demonstrated to be scientifically incorrect, classified as misinformation, and included on myth-busting lists of leading public health institutions. The broader implication is that the groups identified in this study are more likely to agree with misinformation, including younger age, male, lower education, lower health literacy, and LOTE, may not be receiving up-to-date, evidence-based advice.

Conclusions

Misinformation can undermine public health efforts. The findings of this survey-based study highlight important gaps in communication effectiveness in the context of the COVID-19 pandemic. In efforts to prebunk and debunk misinformation, public health authorities must urgently build new partnerships with trusted, influential stakeholders and social media companies to reach the groups identified in this study. Communicators must pay close attention to ensuring that all communities can access, understand, and act on reliable COVID-19 advice.

Acknowledgments

We would like to thank all participants of this longitudinal COVID-19 survey for their ongoing participation in this research.

Conflicts of Interest

None declared.

Abstract

Background: The internet has changed the way of people acquiring health information. Previous studies have shown that Wikipedia is a reasonably reliable medical resource, and it has been ranked higher than other general websites in various search engines. Baidu Encyclopedia is one of the most popular encyclopedia websites in China. However, no studies have shown the quality of the content provided in the Baidu Encyclopedia.

Objective: This study aimed to evaluate the quality of liver disease information provided by Wikipedia (in English) and Baidu Encyclopedia (in Chinese) and to perform a comparison of the quality and timeliness of the articles published in these two encyclopedias. Moreover, a 3-year follow-up study was conducted to compare if the information in both these websites was updated regularly over this period.

Methods: We searched for information on liver diseases by using the International Statistical Classification of Diseases and Related Health Problems 10th Revision Version 2016 codes on Wikipedia (in English) and Baidu Encyclopedia (in Chinese). The quality of the articles was assessed using the DISCERN instrument, which consists of 3 sections. We recorded the latest editing date of the webpages and calculated the date interval to evaluate the update timeliness of these websites.

Results: We found 22 entries on liver diseases in Baidu Encyclopedia and 15 articles in Wikipedia between September 15, 2016, and September 30, 2016, and we found 25 entries in Baidu Encyclopedia and 16 articles in Wikipedia between September 15, 2019, and September 30, 2019. In section 1 of the DISCERN instrument, the mean (SE) scores of Baidu Encyclopedia entries were significantly lower than those of Wikipedia articles. In section 2 and section 3 of the DISCERN instrument, the DISCERN scores of Baidu Encyclopedia entries were lower than those of Wikipedia articles, but the differences were not statistically significant. The total DISCERN scores of Baidu Encyclopedia entries were significantly lower than those of Wikipedia articles. The update interval of the entries in Baidu Encyclopedia was found to be significantly longer than that of the articles in Wikipedia.

Conclusions: This study shows that the quality of articles and the reliability of the research content on liver diseases in Wikipedia are better than those of the entries in Baidu Encyclopedia. However, the quality of the treatment choices provided in both Wikipedia and Baidu Encyclopedia is not satisfactory. Wikipedia is updated more frequently than Baidu Encyclopedia, thereby ensuring that the information presented has the most recent research findings. The findings of our study suggest that in order to find accurate health information, it is important to seek the help of medical professionals instead of looking for a prescription amid the confusing information provided on the internet.

(J Med Internet Res 2021;23(1):e17680) doi:10.2196/17680

KEYWORDS

Baidu Encyclopedia; Wikipedia; internet; website; liver disease; health information; DISCERN instrument; timeliness

Introduction

Over 4.5 billion internet users were reported worldwide in June 2019, with 854 million of them being in China [1,2]. Nowadays, the internet has become the primary source of information, and it has changed the way of people acquiring medical and health information. More than 50% of the internet users in the United States of America have been reported to search for web-based health care–related information [3,4]. A study in China found that 87.8% of the patients with scoliosis searched for scoliosis-related information on the internet, thereby indicating the high proportion of internet usage as a source of health information [5]. Increasing number of patients are seeking information about their diseases on the internet, but the reliability of web-based health care–related information is still questionable [6,7].

Wikipedia is a web-based encyclopedia that provides valuable web-based health information; it contains more than 5,956,750 articles in English [8-10]. Previous studies have shown that Wikipedia is a reasonably reliable medical resource and it was ranked higher than other general websites in search engines [8,11], although there are some errors in Wikipedia articles compared to peer-reviewed sources [12]. Baidu Encyclopedia, Wikipedia’s equivalent in China, contains more than 16,244,000 entries in Chinese [13]. Wikipedia and Baidu Encyclopedia are the most popular and consulted encyclopedia websites in English and Chinese, respectively [14-16]. On December 9, 2012, Baidu Encyclopedia announced the “rainbow plan,” wherein all medical entries could only be edited and revised by certified medical experts, which would improve the quality of the health information provided in Baidu Encyclopedia [17]. However, no study has yet examined the quality of the data provided in Baidu Encyclopedia.

Liver disease is among the top 10 causes of death in middle-income and high-income countries [18]. We have been engaged in hepatic surgery for many years and we are competent in the diagnosis and treatment of liver diseases. Therefore, we selected liver diseases as the object of analysis in this study. This study aimed to evaluate the quality of liver disease information provided by Wikipedia in English and Baidu Encyclopedia in Chinese and we aimed to perform a comparison of the quality of the research in these resources and the timeliness of the recent updates in the research between these 2 resources. Since the update frequency on the internet is high by day and by hour, 3 years can be considered as an extended period for evaluating the changes in the information over a long interval during follow-up. Thus, 3-year monitoring was conducted to compare whether the information on these websites was improved over this period. Our research results will help readers judge the reliability of web-based encyclopedia entries and avoid the medical problems caused by believing unreliable materials on the internet.

Methods

Data Sources

The articles analyzed in this study are available in Wikipedia [9] in English and in Baidu Encyclopedia [13] in Chinese. Data were compiled between September 15, 2016, and September 30, 2016. For the 3-year follow-up, data were compiled between September 15, 2019, and September 30, 2019. We chose 3 years for the length of the comparison because 3 years is a widely used and acceptable follow-up time [19-21].

Retrieval of Liver Disease Articles

The selection of topics was based on the International Statistical Classification of Diseases and Related Health Problems 10th Revision (ICD-10) version 2016. ICD defines almost all of the health-related conditions, and it is the diagnostic classification standard for all clinical and research purposes. In the ICD-10 version 2016, diseases of the liver are classified under Chapter XI Diseases of the digestive system, with categories K70 to K77 [22]. The Baidu Encyclopedia (in Chinese) and Wikipedia (in English) were investigated for articles on ICD-10 version 2016 codes. All ICD-10 code titles on the diseases of the liver were used for the search. Entries without search results were excluded from the study. Search terms on Baidu Encyclopedia (in Chinese) and Wikipedia (in English) are listed in the Multimedia Appendices 1 and 2, respectively. The proportion of the available search results were recorded and analyzed.

Assessment of the Quality of the Research Articles

The quality of the articles was assessed using the DISCERN instrument, which is used for judging the quality of health information on treatment choices [23]. The use of the DISCERN instrument for information in encyclopedias is controversial. Although some studies believe that the original edition of the DISCERN instrument is not suitable for evaluating Wikipedia articles [24,25], there are still many recent studies that have used the DISCERN instrument to evaluate the quality of Wikipedia articles [15,16]. Thus, the DISCERN instrument can be considered as an appropriate tool for evaluating the quality of Wikipedia articles in the absence of a better instrument.

The DISCERN instrument consists of 16 questions that are rated on a 5-point scale (1=definitely no, 5=definitely yes) (Multimedia Appendix 3). All these 16 questions are categorized into 3 sections. Section 1 (questions 1 to 8) assesses the reliability of a paper, section 2 (questions 9 to 15) focuses on the quality of the treatment information, and section 3 (question 16) evaluates the overall quality [23]. A higher DISCERN score indicates better paper quality. The overall DISCERN score ranges from 16 to 80 and the articles were categorized as very poor (16-26), poor (27-38), fair (39-50), good (51-62), and excellent (63-80) based on the scores [15,16].

All 3 authors have been engaged in hepatobiliary and pancreatic surgery for many years and are competent in the diagnosis and treatment of liver diseases. We have mastered the professional knowledge of liver diseases and can make professional evaluations. Sun and Yang used the DISCERN instrument to evaluate the articles in Baidu Encyclopedia (in Chinese) and Wikipedia (in English), respectively. The DISCERN score was determined through discussions. If no agreement was reached during the debate, Zheng was consulted to make the final judgment. Subsequently, Sun and Yang agreed on all the ratings.

Timeliness of the Updated Articles

We recorded and analyzed the last editing date of the web page. In 2016, the update interval was calculated as the date interval between the updated date and September 20, 2016. In 2019, the update interval was calculated as the date interval between the updated date and September 20, 2019. The update interval reflects the update frequency of a webpage. We compared the update interval of each paper to evaluate the update timeliness of the website.

Statistical Analysis

For the statistical analysis, means and standard errors (mean [SE]) were calculated. *P* values less than .05 were considered significant. Differences between groups were assessed using two-tailed Student *t* test with Welch correction. Statistical analyses were performed using GraphPad Prism 6 software (GraphPad Prism Software Inc).

Results

Retrieval of Liver Disease Articles

We searched Baidu Encyclopedia and Wikipedia with the entries in the ICD-10 diseases of the liver category. A total of 8 liver disease categories were classified, with categories K70 to K77. Only a portion of the entries were retrieved as articles in the search results. We found 22 entries in Baidu Encyclopedia and 15 articles in Wikipedia in 2016 and 25 entries in Baidu Encyclopedia and 16 articles in Wikipedia in 2019 (Table 1). In general, we were able to retrieve more entries in Baidu Encyclopedia than in Wikipedia.

Table 1. The proportion of the available search results in Baidu Encyclopedia and Wikipedia in 2016 and 2019.

ICD-10[a] category	Entries included in the ICD-10 classification (n=50)	Baidu Encyclopedia entries in 2016 (n=22)	Wikipedia articles in 2016 (n=15)	Baidu Encyclopedia entries in 2019 (n=25)	Wikipedia articles in 2019 (n=16)
K70 Alcoholic liver disease	6	4	3	4	3
K71 Toxic liver disease	10	1	1	1	1
K72 Hepatic failure, not elsewhere classified	3	1	1	2	1
K73 Chronic hepatitis, not elsewhere classified	5	3	1	3	1
K74 Fibrosis and cirrhosis of liver	7	4	1	5	1
K75 Other inflammatory liver diseases	7	3	2	3	2
K76 Other diseases of liver	10	6	6	7	7
K77 Liver disorders in diseases classified elsewhere	2	0	0	0	0

[a] ICD-10: International Statistical Classification of Diseases and Related Health Problems 10th Revision.

Assessment of the Quality of Articles

We used the DISCERN instrument to score the articles retrieved in Baidu Encyclopedia and Wikipedia and compared the section 1, section 2, section 3, and total scores (Figure 1). The results of the DISCERN instrument were comparable in 2016 and 2019. In section 1, the mean (SE) DISCERN score of Baidu Encyclopedia entries was significantly lower than that of Wikipedia articles (18.00 [SE 1.040] vs 26.60 [SE 1.359], *P*<.001 in 2016, respectively; 19.00 [SE 0.9110] vs 27.88 [SE 0.8892], *P*<.001 in 2019, respectively). In section 2 and section 3 of the DISCERN instrument, the mean DISCERN scores of Baidu Encyclopedia entries were lower than those of Wikipedia articles, but the differences were not statistically significant. Overall, the total scores of Baidu Encyclopedia entries were significantly lower than those of Wikipedia articles (33.68 [SE 2.265] vs 44.67 [SE 3.172], *P*=.009 in 2016, respectively; 34.72 [SE 1.943] vs 46.44 [SE 2.669], *P*=.001 in 2019, respectively) (Table 2).

The total DISCERN scores were categorized. In Baidu Encyclopedia in 2016, 9 entries were found to be of fair quality, 8 were of poor quality, and 8 were of very poor quality. In 2019, 10 entries were of fair quality, 11 were of poor quality, and 4 were of very poor quality. In Wikipedia in 2016, 5 articles were of good quality, 5 were of fair quality, 3 were of poor quality, and 2 were found to be of very poor quality. In 2019, 6 articles were found to be of good quality, 4 were of fair quality, and 5 were of poor quality.

Over time, the number of entries in Baidu Encyclopedia and Wikipedia showed an increase (Table 1). However, no significant differences were found on comparing the changes in the DISCERN scores of Baidu and Wikipedia entries over 3 years.

Figure 1. The DISCERN scores of Baidu Encyclopedia entries and Wikipedia articles on liver diseases in 2016 and 2019. $^{**}P<.01$, $^{****}P<.001$. BE-2016: Baidu Encyclopedia entries in 2016; BE-2019: Baidu Encyclopedia entries in 2019; W-2016: Wikipedia articles in 2016; W-2019: Wikipedia articles in 2019; ns: no significant difference.

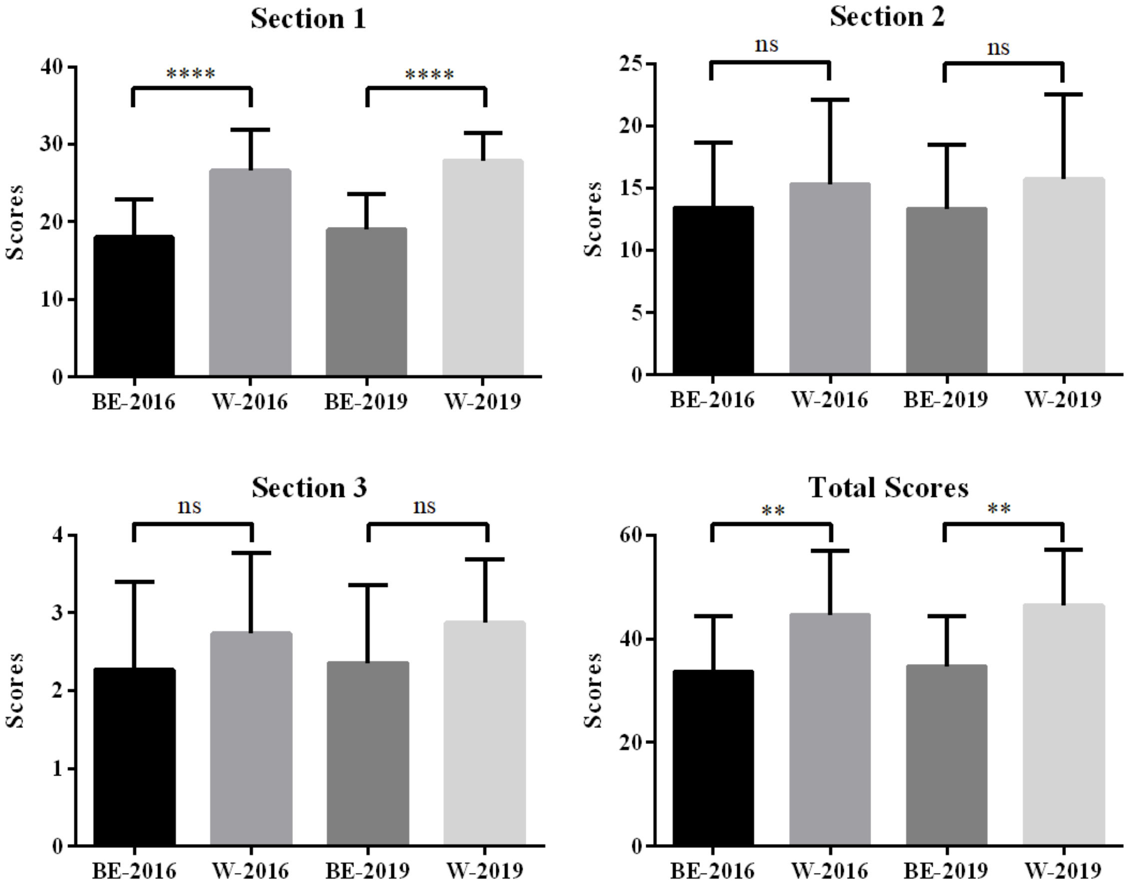

Table 2. The DISCERN scores of Baidu Encyclopedia and Wikipedia articles on liver diseases.

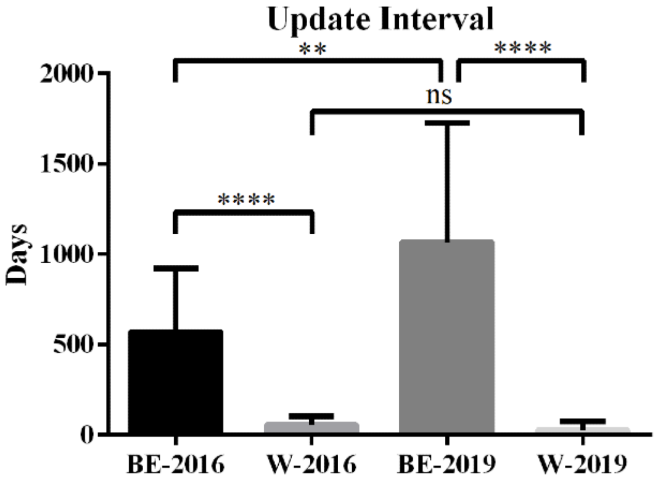
Year, sections of DISCERN	Baidu Encyclopedia, mean (SE)	Wikipedia, mean (SE)	*P* value
2016			
Section 1	18.00 (1.040)	26.60 (1.359)	<.001
Section 2	13.36 (1.023)	15.69 (1.717)	.25
Section 3	2.273 (0.2389)	2.733 (0.2667)	.21
Total	33.68 (2.265)	44.67 (3.172)	.009
2019			
Section 1	19.00 (0.9110)	27.88 (0.8892)	<.001
Section 2	13.36 (1.023)	15.69 (1.717)	.25
Section 3	2.360 (0.1990)	2.875 (0.2016)	.07
Total	34.72 (1.943)	46.44 (2.669)	.001

Timeliness of Articles

The update interval represents the timeliness of the updates on the website. We compared the update interval between Baidu Encyclopedia and Wikipedia (Figure 2). In 2016, the mean (SE) update interval of Baidu Encyclopedia entries was 571.6 (74.96) days and the mean (SE) update interval of Wikipedia entries was 55.93 (11.92) days. The update interval for entries in Baidu Encyclopedia was significantly longer than that for articles in Wikipedia (*P*<.001). After 3 years of follow-up, it was found that 11 of the 25 entries in Baidu Encyclopedia were recently edited before September 20, 2016, which meant that they had not been updated in the last 3 years and were in a state of loss of maintenance. In 2019, the mean (SE) update interval of Baidu Encyclopedia entries was 1067 (131.2) days and the mean (SE) update interval of Wikipedia articles was 27.44 (11.98) days. The update interval of the entries in Baidu Encyclopedia is significantly longer than that of the articles in Wikipedia (*P*<.001) (Figure 2). Therefore, the update timeliness of the articles in Wikipedia in 2016 and 2019 is significantly better than that of the entries in Baidu Encyclopedia.

Figure 2. The update interval of Baidu Encyclopedia entries and Wikipedia articles on liver diseases in 2016 and 2019. ***P*<.01, *****P*<.001. BE-2016: Baidu Encyclopedia entries in 2016; BE-2019: Baidu Encyclopedia entries in 2019; W-2016: Wikipedia articles in 2016; W-2019: Wikipedia articles in 2019; ns: no significant difference.



Discussion

Principal Findings

The main findings of this study were that the reliability of the articles on Wikipedia is better than that of the entries in Baidu Encyclopedia. However, the quality of the treatment information in both the encyclopedia websites is not satisfactory. With the increasing popularity of the internet, increasing number of patients are seeking health information and even treatment plans for their diseases on the internet [4]. However, the quality of the medical information on the internet is uneven, and a large proportion of the information is unreliable [6]. Previous research has shown that health information in a search engine is less reliable [26-28]. Wikipedia is a remarkable source of web-based health information [8]. Therefore, we analyzed the information on liver diseases in Baidu Encyclopedia in Chinese and Wikipedia in English to compare the quality of the medical information in these encyclopedia websites. The quality of the health information on the internet was studied over a 3-year follow-up period to see if it improved over time.

We evaluated the articles on liver diseases in Baidu Encyclopedia and Wikipedia in terms of quantity and quality. The Baidu Encyclopedia has more overall entries than Wikipedia; therefore, it is reasonable for Baidu Encyclopedia to have more entries in the category of liver disease than Wikipedia. In Wikipedia, terms can be easily linked to each other, making it easier for readers to build connections of knowledge [29,30]. In Baidu Encyclopedia, although there are abundant entries, the isolated entries are not linked with the other related entries, thereby making it unconducive to the formation of knowledge networks for some concepts.

We used the DISCERN instrument to evaluate the quality and reliability of the articles in Baidu Encyclopedia and Wikipedia. The DISCERN scores of Wikipedia entries were significantly higher than those of Baidu Encyclopedia entries. Consistent with that reported in previous studies, Wikipedia is a good resource of health information on the internet [8,14]. In section 1 of the DISCERN instrument, which reflects the reliability of articles, the scores for the entries in Baidu Encyclopedia were significantly lower than those for the articles in Wikipedia, indicating that the entries in Baidu Encyclopedia were less reliable than those in Wikipedia. We observed that most of the Baidu Encyclopedia entries lacked reference sources, while Wikipedia includes a detailed source for almost every entry. A high-quality citation source is an essential guarantee for the reliability of a paper [31]. However, several studies have found that Wikipedia is difficult for the general public to read and is not a reliable source for medical students [25,32]. During the 2019 follow-up, we observed the source of citations for each paper. The sources of Baidu Encyclopedia references were found to be ambiguous; they were mostly search results of Baidu academic search (an academic search engine of Baidu) and did not represent the literature cited by the entry. However, citations in Wikipedia can be explicitly identified and have original links to academic databases such as PubMed. Accurate referencing is crucial for improving the authoritativeness and credibility of a paper [31,33]. In this regard, Wikipedia was found to be better than Baidu Encyclopedia, as the basic ideas are cited and most of the references are academic papers, which guarantee scientific accuracy and reliability. In section 2 of the DISCERN instrument, which assesses the quality of the information on treatment choices, the average score of the articles in Wikipedia was found to be higher than that of the entries in Baidu Encyclopedia. However, the difference between them was not statistically significant. The scores of both Wikipedia and Baidu Encyclopedia entries were low in section 2. The quality of the information on treatment choices in both Wikipedia and Baidu Encyclopedia was not satisfactory, which is in accordance with that reported in previous studies [16,25,32]. After all, Wikipedia and Baidu Encyclopedia are not professional medical websites. Both Wikipedia and Baidu Encyclopedia have room for further improvement in providing information on treatment. Since the choice of treatment is an important target for patients to search for, adequate information should also be provided for the choice of treatment. References to international guidelines for various diseases and attracting, encouraging, and even recruiting more medical professionals to participate in the editing of the medical information provided in these websites can improve the quality of the information provided in these websites. Further, patients should be advised to seek treatment advice from more professional medical websites, and it would be more reliable to seek professional advice directly from medical personnel [34]. In section 3 of the DISCERN instrument, the score for Baidu Encyclopedia entries was lower than that for Wikipedia articles, which is consistent with the evaluation result of the total score.

In terms of the update timeliness, Wikipedia was significantly better than Baidu Encyclopedia in 2016 and 2019. During the 3-year follow-up, all Wikipedia pages were updated on time. As for Baidu Encyclopedia, among the 25 entries, 11 entries were not updated in 3 years and the longest update time reached 2564 days. Wikipedia is updated regularly and it evolves continuously while the content in Baidu Encyclopedia has been rarely maintained since its generation. The low update frequency has caused some information to be outdated, and some outdated information may even be wrong. Therefore, the timeliness of information is also an important aspect influencing the quality of medical information.

Our study uses the DISCERN instrument to evaluate the quality of Baidu Encyclopedia entries and compares the quality of these entries with that of Wikipedia articles. This is the first study to assess the quality of health information in Baidu Encyclopedia with the DISCERN instrument. Moreover, this is the first study to follow up on the quality of encyclopedia websites for 3 years. In 3 years, we found that the quality of the articles of both websites had not improved significantly.

Limitations

Our study design does have some limitations. First, the results of our research only reflect the information on liver diseases in Baidu Encyclopedia and Wikipedia on September 20, 2016, and September 20, 2019. Second, the DISCERN instrument is the only tool used to evaluate article quality in this study. Although the DISCERN instrument is widely used to evaluate website information, comprehensive use of more evaluation tools may make the results more convincible. The LIDA tool is a web-based validation instrument to measure the design and content of health information on the internet [35]. We plan to use the LIDA tool to evaluate the quality of articles in Baidu Encyclopedia and Wikipedia in our future research.

Conclusion

Although Wikipedia is not as good as the Baidu Encyclopedia in terms of the number of entries, its reliability is better than that of Baidu Encyclopedia, thereby making it more helpful to web-based health information seekers. However, the quality of the treatment choices in both Wikipedia and Baidu Encyclopedia's entries is not satisfactory. Wikipedia is updated frequently to keep the information up-to-date. The entries in Baidu Encyclopedia lack maintenance and are not updated on time; some information is outdated and some new content are lacking. In order to find accurate health information, people are advised to seek the help of medical professionals instead of looking for a prescription amid the confusing information on the internet.

Acknowledgments

Fei Sun would like to thank his wife, Wenchao Kong, for her patience, understanding, and great support during this work.

Abstract

Background: Internet-based risk assessment tools offer a potential avenue for people to learn about their cancer risk and adopt risk-reducing behaviors. However, little is known about whether internet-based risk assessment tools adhere to scientific evidence for what constitutes *good* risk communication strategies. Furthermore, their quality may vary from a user experience perspective.

Objective: This study aims to understand the extent to which current best practices in risk communication have been applied to internet-based cancer risk assessment tools.

Methods: We conducted a search on August 6, 2019, to identify websites that provided personalized assessments of cancer risk or the likelihood of developing cancer. Each website (N=39) was coded according to standardized criteria and focused on 3 categories: general website characteristics, accessibility and credibility, and risk communication formats and strategies.

Results: Some best practices in risk communication were more frequently adhered to by websites. First, we found that undefined medical terminology was widespread, impeding comprehension for those with limited health literacy. For example, 90% (35/39) of websites included technical language that the general public may find difficult to understand, yet only 23% (9/39) indicated that medical professionals were their intended audience. Second, websites lacked sufficient information for users to determine the credibility of the risk assessment, making it difficult to judge the scientific validity of their risk. For instance, only 59% (23/39) of websites referenced the scientific model used to calculate the user's cancer risk. Third, practices known to foster unbiased risk comprehension, such as adding qualitative labels to quantitative numbers, were used by only 15% (6/39) of websites.

Conclusions: Limitations in risk communication strategies used by internet-based cancer risk assessment tools were common. By observing best practices, these tools could limit confusion and cultivate understanding to help people make informed decisions and motivate people to engage in risk-reducing behaviors.

KEYWORDS

health communication; personalized medicine; internet; risk assessment

Introduction

Background

Epidemiological risk prediction models use a patient's medical history, demographic characteristics, and/or behaviors to estimate their likelihood of experiencing a variety of clinical outcomes, such as disease incidence, progression, and survival [1]. The basic premise of many of these models is that providing people with personalized risk information will foster informed decision making (eg, engage in risk-stratified cancer screening [2,3] and take medications to prevent cancer [4]) and encourage healthy lifestyle behaviors (eg, increase physical activity engagement [5]). Furthermore, such risk models are central to a key precision medicine goal of making medical decisions based on personalized risk data [6,7]. Before the internet became widely accessible by the general public, the use of these models was restricted to clinical and research settings [4,8]. With the advancement of computing and internet technology, it has become easier for researchers to translate risk prediction models into tools that allowed for the rapid assessment of an individual's risk (hereafter, *risk assessment tool*). In 2009, a content analysis reported finding 47 websites that contained cancer-specific risk assessment tools by simply entering keywords into common search engines [9]. Since then, the number of cancer risk prediction models that could potentially be translated into risk assessment tools has dramatically increased. From 1993 to 2009, an average of 4 models were published and indexed on PubMed each year; this number increased to an average of 40 per year from January 2010 to August 2020 [10]. However, despite the increased number of risk prediction models, little is known about how internet-based risk assessment tools have (or have not) changed in the last decade.

Public-Facing Risk Assessment Tools Need to Use Good Communication Practices

The US National Cancer Institute (NCI) created the Health Information National Trends Survey (HINTS) in response to a paucity of data about the US population's cancer information needs and cancer information–seeking experiences [11]. The NCI launched the first survey in 2003, and additional iterations were administered approximately every 2 years. Data from HINTS have revealed that, from 2003 to 2019, the percentage of US residents who reported having ever sought cancer information rose from 45% to 54% [12]. More strikingly, those who used the internet as their first source of cancer information rose from approximately 46% to 75% [13,14]. Unfortunately, not only have many information seekers had negative experiences during their search, but such experiences have not improved from 2003 to 2018. Approximately 60% to 65% of HINTS respondents reported that the information was difficult to understand [15] or they were frustrated during the search process [14]. Over half of them reported concerns about the quality of the information [16].

The 2009 content analysis of internet-based cancer risk assessment tools also identified serious concerns about the quality of experiences that people might have had while searching for personalized risk assessment tools [9]. One major limitation was related to the accessibility of the information to the general public. Specifically, using medical terminology like *biopsy* without explaining what the terms meant likely limited accessibility to individuals with limited health literacy. Similarly, few tools provided an option for people who spoke a language other than English to obtain information in their native language.

The second major limitation was that only half of the websites provided information needed to evaluate their credibility, such as a citation of a peer-reviewed journal or a description of the risk prediction model used to calculate personalized estimates [17,18]. Without this information, it would be reasonable for website users to doubt the credibility of the information.

The third major category of limitations was how the actual risk information was communicated. Although most websites in the 2009 review adhered to some general principles, such as communicating numerical information as percentages or frequencies (ie, 6 in 100) and providing advice for reducing risk (eg, stop smoking), the use of other important risk communication principles was limited. Fewer than half of websites supplemented numeric estimates with qualitative labels (eg, *very high*), provided a visual display, or indicated the timeframe for which the risk was relevant (eg, 5-year risk of breast cancer) [19] (Table 1).

Table 1. Recommended risk communication formats.

Risk communication format and selected relevant citations	Why the format is important
1. Specify the duration of risk [20,21]	Time is an integral element of many risk prediction algorithms. Estimates for 1-year, 5-year, and lifetime risks can differ greatly. Consequently, specifying whether the risk estimate is applicable to the next 1 year, 5 years, 10 years, or lifetime is critical for helping people contextualize the risk and determine how much they should be concerned about it in the immediate future. For example, a 7% risk of breast cancer would be more worrisome if it was applicable to the next 5 years (in which case, it would be considered a high risk) than over one's lifetime (in that case, it would be considered a low risk). [22]
2. Provide absolute risk estimates [23,24]	Absolute risk represents the likelihood that an individual will develop a disease. It is the most basic element of risk information people need to understand their risk. Absolute risk can be communicated as numbers (eg, 12%) or as qualitative labels (eg, "very high").
3. When communicating numeric risk estimates, use percentages or simple frequencies (eg, N in 100)[a]. Do not include the 1 in N format, NNT[b], or odds ratios [25-28]	Risk comprehension is highest when risk estimates are presented as a percentage or as simple frequencies (eg, N in 100). However, both recommended formats have drawbacks. The N in 100 format can encourage people to overemphasize risk by "imagining the numerator," but the percentage format is more difficult to use while conducting complex calculations (eg, the probability of a woman having breast cancer given a positive mammogram). The 1 in N and NNT formats are very difficult to use and should be avoided.
4. When communicating numeric risk estimates, also include qualitative categories (also referred to as verbal labels; eg, high risk) [19,20,25,28,29]	Providing only numbers is problematic because of the population's low levels of numeracy (ie, the ability to use numeric information) and a lack of contextual information (eg, should a 7% lifetime risk of breast cancer be considered a high risk or a low risk?). Providing qualitative categories (also, "verbal labels") yields contextual information needed to interpret the importance of the numeric information. However, qualitative categories should be used in the absence of numeric information only with caution; people interpret qualitative categories as representing a wide range of possible probabilities (eg, "small" can mean "2%" to some people and "10%" to others). Qualitative categories can also prompt people to overestimate their risk. Providing both numeric estimates and qualitative categories yields both the detailed and contextual knowledge needed for informed decisions.
5. Frame the risk in positive and negative terms [20,21,25,30]	Framing the risk in negative terms only (eg, "Your risk of cancer is 5%") places focus only on the negative outcome and might result in exaggerated risk perceptions. Adding positive framing (eg, "This means you have a 95% chance of not getting cancer") helps participants place the risk in context.
6. If relative risk estimates are provided, then supplement it with absolute risk estimates [20,25,31]	Providing relative risk information in the absence of absolute risk information could lead people to believe that they will receive more benefit (or harm) from the action or treatment than what is possible (eg, a 50% risk reduction is much less impactful when the individual is at 4% absolute risk than at 40% absolute risk).
7. Include a visual display that depicts the individual's risk [19,20,25,28,32]	Using a visual display can increase the comprehension of risk information. However, care must be taken to avoid biasing perceptions of risk (eg, displays that focus attention on the number of people affected by a disease can exaggerate a risk as compared with displays that include information about the number of people affected and the number of people who are not affected). In addition, some visual displays are more difficult for people to understand than others (eg, pie charts).
8. Acknowledge that the risk estimate contains an element of uncertainty [25,28]	Personalized risk estimates are based on the statistical modeling of population-level data. Consequently, they always contain a level of uncertainty due to (a) limitations in the reliability or adequacy of the information used to specify the risk prediction model or (b) the randomness of future events. Informing the audience that the risk estimate is just that—an estimate—is essential to prevent them from attributing an unreasonable degree of certainty to the estimate.
9. Provide information about risk reduction strategies [23,33,34]	Understanding how to reduce risk is an essential component of understanding one's risk. Informing people how to reduce their risk is an important component of risk communication messages, particularly for individuals who have not learned risk reduction strategies previously. Providing risk information without such safety messages may undermine risk communication efforts by encouraging people to control their fear (eg, by trying to ignore the risk) rather than encouraging people to control the danger (eg, by engaging in appropriate health behaviors).
10. Consider providing comparative risk information (also called "social comparison" information) [23,28,35] but see a different perspective in studies by Fagerlin et al and Janssen et al [36,37]	Helping people understand how their risk compares to the risk of the average person of their age and sex may help them place their risk in context and evaluate its meaning and importance. For example, telling a woman that she has a 5% 5-year risk of developing breast cancer might not be meaningful unless she recognizes that it means that she is at above average risk. However, this can backfire; telling people only that they are at below-average risk might reduce motivation to engage in preventive behavior. [36]
11. Consider comparing the estimated risk to the risk of other hazards [23,28], but see different perspective in studies by Fischhoff and Covello [38,39]	Helping people understand where their risk of cancer falls in relation to other hazards such as heart disease, diabetes, or being in a car accident allows them to place the risk in context and thereby helps them determine where to invest their limited time, energy, and economic resources. However, care should be taken to avoid being perceived as condescending [38,39], lest the risk information be rejected.

[a] One controversial strategy sometimes used by risk assessment tools that aim to encourage healthy lifestyle behaviors is to communicate absolute risk information by only using qualitative (also referred to as verbal) labels [37,40] and to exclude numerical estimates [37,40]. This idea originates from

the fact that numerical estimates that public health scientists would consider high may be perceived as quite low by the public, even when a verbal label is added. For example, a person who has a 3% risk of developing lung cancer in the next 6 years would be considered high risk [41]. However, research suggests that people may consider anything below 20% risk to be *low risk*, and anything between 20% and 70% to be *medium* risk [29]. Thus, it seems likely that a person advised to quit smoking because he or she has a 3% risk of lung cancer may decide that the effort involved in quitting is not *worth* the reduction of a very small risk. However, as noted in recommendation number 4, interpretations of qualitative labels are quite variable [42] and may result in an overestimation of risk [43]. In addition, providing quantitative information may increase trust among the general public [44].

[b] NNT: number needed to treat.

Since 2009, the scientific understanding of the complexities of risk communication—including what should be considered *good* risk communication strategies—has grown. Some principles remain the same, such as avoiding the 1 in X format, acknowledging uncertainty, including visual displays, using qualitative labels to provide context for numerical risk information, and providing advice for reducing risk [19,23,25,27,45,46]. However, one piece of new knowledge (or, rather, existing knowledge made explicit) is the importance of providing risk information in a way that is likely to achieve what the communicators wish to accomplish [47,48].

One goal of providing personalized risk information is to communicate information needed to make an informed decision about preference-sensitive treatment or screening options. Examples of such decisions include mammography screening at the age of 40-49 years, prophylactic mastectomy, chemopreventive medications to reduce breast cancer risk, prostate-specific antigen screening, lung cancer screening, and colorectal cancer screening modality (eg, fecal-occult blood test, fecal immunochemical test, colonoscopy, or sigmoidoscopy). These decisions necessitate communication strategies that allow users to evaluate information in a way that, to the greatest extent possible, fosters unbiased interpretations of the risks and benefits of each option [25,48,49].

Another goal of providing personalized risk information is to motivate people to engage in risk-reducing behaviors [5,48]. Such behaviors are not preference sensitive and, barring medical contraindications, are generally recommended for entire populations. For example, many public health agencies advocate reducing cancer risk by making universal, population-wide recommendations to avoid smoking tobacco; maintain a healthy weight; be physically active; limit alcohol intake; and engage in sun protection behaviors [50]. From this perspective, providing highly detailed risk and benefit information is not as important as conveying information in a way that alerts people to their general level of risk [48] and that convinces them to engage in risk-reducing actions [47]. However, it is also critically important to provide information in such a way that is simultaneously true and persuasive. Table 1 shows the risk communication formats and strategies that can be used for both informed decision making and persuasive contexts (items 1-9) and also offers suggestions for solely persuasive purposes (items 10-11).

Study Objectives

From 2010 to 2020, many peer-reviewed articles and book chapters that describe current best practices in risk communication have been published [19,25,46,51]. In this study, we aim to understand the extent to which these practices have been applied to internet-based cancer risk assessment tools. To achieve this objective, we aim to (1) describe what risk communication formats and strategies internet-based cancer risk assessment tools use to facilitate their accessibility to the general public and demonstrate the credibility of their information, and (2) describe which risk communication formats and strategies internet-based cancer risk assessment tools use to present personalized risk information to the public.

Methods

Search Strategy and Website Selection

On August 6, 2019, we conducted an internet search to identify websites that provided people with personalized assessments of their cancer risk or the likelihood of developing cancer. One research assistant used Google and Bing (Microsoft) to search for the terms *calculate cancer risk*, *cancer risk calculator*, *estimate cancer risk*, *assess cancer risk*, and *cancer risk assessment*. Google and Bing accounted for over 80% of the world market share as of April 2020 [52]. She copied the URLs for the first 100 results for each of the 5 search terms for each of the search engines, which equaled 1000 results, into a Microsoft Excel spreadsheet. JF conducted an initial examination of these results and excluded 831 websites that were obviously not relevant (eg, risk of radiation from nuclear fallout). JF then more closely examined the remaining 169 results and excluded websites that were duplicates, redirected to another website already on the list (eg, a blog post that linked to a website already on the list), required a software download or installation of an app, had a link that no longer worked, did not provide personalized estimates of the risk of developing cancer, and/or required the user to provide medical information that must be obtained through consultation with a doctor (eg, prostate-specific antigen levels). When JF needed clarification about the appropriateness of a website, he consulted with EW; for these 13 websites, EW and JF discussed the elements of the website that were confusing and came to a decision by consensus. This process resulted in 37 websites being eligible for inclusion. Finally, we compared this list of 37 websites with the 47 websites included in the previous content analysis by Waters et al [9]. We found that 41 of the 47 websites from the 2009 analysis were no longer available. Only 6 active websites included in this review were also included in the 2009 review; 4 were identified during the search for this paper and 2 were located only by searching the 2009 paper. A total of 39 websites were included in this analysis (see Multimedia Appendix 1 for website URLs).

Measures and Coding Procedures

A total of 3 broad categories of codes were examined: general website characteristics, accessibility and credibility, and risk communication formats and strategies. The coding categories, including descriptions and/or examples of each code, were developed based on the study by Waters et al [9]. For website characteristics, we coded cancer type as assessed by the tool and the type of organization that either developed or hosted the risk assessment tool. For accessibility and credibility, we coded aspects related to accessibility to the general public, aspects of website transparency, the apparent purpose of the website (ie, whether the website appeared to be intended to provide information, recruit users, or sell products), and whether and what type of details about where to seek more information were provided. For risk communication formats and strategies, we coded whether the duration of risk was specified, whether absolute and/or comparative information was provided, whether risk was communicated qualitatively or quantitatively, the format of quantitative information (eg, percent, N in 100) if relevant, whether positive framing was used, the type of visual display used if relevant, whether or how uncertainty was acknowledged, and whether the website included information about risk reduction strategies.

Each website was independently coded by 2 of the authors (EW and JF) according to the standardized coding criteria. After independently coding the first 5 websites, the coders discussed the results and revised the coding criteria as needed. The first 5 websites were independently coded again using the updated coding scheme, and the results were discussed. Then, the remaining 34 websites were independently coded by both the coders. Finally, the codes were reviewed by both the coders to identify any discrepancies. When discrepancies occurred, the coders discussed them until a consensus was reached. In the rare case where consensus could not be reached, the coders consulted another author (JT) to make a decision. As inter-coder agreement was obtained through inter-coder checks and consensus agreement, we do not report a quantitative calculation of kappa [53].

Data Analysis

Simple frequencies were calculated and recorded for all the coding categories. We did not conduct significance testing because of the small sample sizes.

Results

General Website Characteristics

General website characteristics are summarized in Table 2. Altogether, the 39 websites provided users with up to 68 cancer risk estimates. Four websites allowed users to determine their risk of developing more than one type of cancer. In total, 16 cancer types were addressed by the calculators, with colon or colorectal, breast, and lung being the most common. The most common developer was the health care industry (eg, nonacademic-affiliated hospitals and insurance companies), which hosted just over one quarter of websites.

Table 2. General characteristics of internet-based cancer risk assessment tools (N=39 websites).

Website characteristic and description or examples of code[a]	Value, n (%)
Cancer type[b]: the type of cancer for which the tool provided personalized risk estimates	
Colon or colorectal	13 (33)
Breast	13 (33)
Lung	10 (26)
Melanoma	6 (15)
Prostate	4 (10)
Kidney	3 (8)
Ovarian	3 (8)
Pancreatic	3 (8)
Cervical	2 (5)
Stomach	2 (5)
Uterine	2 (5)
Cancer (general)	2 (5)
Other[c]	5 (13)
Website affiliation[d]: the type of organization that developed and/or hosted the tool	
Health care industry: nonacademic-affiliated hospitals or insurance companies (eg, Cigna, Merck, or Mayo Clinic)	10 (26)
Government agency: any national or international governmental agency (eg, US National Cancer Institute)	6 (15)
Educational institution: academic organization whose primary purpose is education (eg, University of California at Los Angeles)	6 (15)
Independent medical expert: risk assessment tool was developed by a specific person who purports to have relevant expertise	6 (15)
Advocacy, nonprofit: any organization that advocates and/or provides services on behalf of the public but does not fall into any other category (eg, American Cancer Society)	5 (13)
Cancer center: any organization whose primary purpose is cancer prevention and treatment (eg, Fox Chase Cancer Center)	2 (5)
General health information website: websites that do not provide services but provide health information (eg, WebMD, Yahoo! Health)	1 (3)
Other, unspecified: websites that do not fall under any existing criteria	3 (8)

[a] In most instances, the text in this column represents the explanation from the coding scheme.

[b] Categories are not mutually exclusive.

[c] The 5 *other* cancer types were blood, gastroesophageal, oral, renal, and bladder cancer.

[d] In all but one case, the organization who hosted the website also developed the website.

Accessibility and Credibility

As shown in Table 3, undefined medical terminology was widespread: close to 90% (35/39) of websites included technical language that a layperson may find difficult to understand without additional searching for information or help from a medical professional (eg, *biopsy* or *mastectomy*). However, only 23% (9/39) of websites had a statement indicating that medical professionals were the intended audience. Over half (23/39, 59%) of the websites indicated the scientific model used to calculate users' cancer risk and most provided contact information for users to ask follow-up questions about either their risk or the website (32/39, 82%). Most websites simply provided information (31/39, 80%), but a subset also appeared to attempt to recruit patients (5/39, 13% either allowed or required individuals to enter their names and contact information if they wished to be contacted by a provider) or sell products (3/39, 8% provided links to purchase materials). Most websites referred users to a doctor (34/39, 87%) and provided links to additional websites with cancer-related information (32/39, 82%).

Table 3. Accessibility and credibility of internet-based cancer risk assessment tools (N=39 websites).

Website characteristics and description or examples of code[a]	Value, n (%)
Limited accessibility for the general public: the information was not provided in a way that can be easily understood by the general public	
Undefined medical terminology: medical terminology that was not defined was included anywhere on the website (eg, ductal carcinoma in situ and biopsy)	35 (90)
Professionals only: explicit statement that the website was intended for use by medical professionals	9 (23)
Non-English option: a version of the risk assessment tool in a language other than English was provided (eg, Spanish-language version)	4 (10)
Website transparency[b]: information that allows the user to obtain information about the quality of the website	
Contact information[c]: provides information about how to contact the developers of the website	32 (82)
Indication of scientific basis of model: provides citation to peer-reviewed article about the risk prediction model; indicates which model was used (eg, Gail Model for breast cancer)	23 (59)
Last modified[c]: indicates when website was last modified	11 (28)
Underlying purpose[c]: the apparent goal of the website	
Information provision: provides risk information to website users without trying to recruit them as patients or advertise products	31 (80)
Recruit website users: provides risk information with the apparent goal of recruiting website users to use their services (eg, requires user to provide contact information before receiving risk results and asking people to fill out form with contact information if they needed a provider)	5 (13)
Sell products: provides risk information with the apparent goal of convincing users to purchase a product of theirs (eg, provide a link to purchase a book about cancer)	3 (8)
Additional resources[b,c]: details about where to seek more information	
Doctor: website advises user to seek professional assistance (eg, talk to your doctor about your risk information)	34 (87)
Links to additional websites: website provides links to locations to obtain additional cancer information (eg, to the American Cancer Society or National Cancer Institute)	32 (82)
Social media: website had a link to one or more social media pages (eg, Facebook and Twitter)	18 (46)

[a] In most instances, the text in this column represents the explanation from the coding scheme.

[b] Categories are not mutually exclusive.

[c] Code not present in the study by Waters et al [9].

Risk Communication Formats and Strategies

There was a wide variation in adherence to risk communication formats and strategies recommended for both informed decision making and encouraging behavior change. As shown in Table 4, a majority of websites followed best practice recommendations to specify a duration of risk (22/39, 56%), to provide absolute risk estimates (31/39, 80%), and to provide information about risk reduction strategies (27/39, 69%). Of the websites that provided quantitative risk information (23/39, 59%), all of them used percentages and/or natural frequencies, as recommended, and none of them used formats that are difficult for the general public to understand (eg, 1 in N, number needed to treat, and odds ratio). Very few websites followed recommendations to add qualitative labels to quantitative information (6/39, 15% of all websites and 6/23, 26% of websites that provided numbers), and only a small minority of websites framed risk information in both positive and negative terms (2/39, 5%). Consistent with recommendations, the single website that provided relative risk information also provided absolute risk information. The websites that included a visual display (20/39, 51%)—a strategy that is recommended to increase comprehension—tended to use recommended displays such as bar graphs (6/39, 15%) or icon arrays (also called stick figures; 4/39, 10%), but some websites used more difficult displays such as pie charts (3/39, 8%), line graphs (2/39, 5%), or speedometers or other less common displays (4/39, 10%). A solid majority of websites presented statements acknowledging uncertainty (23/39, 59%), as recommended. Most often, these statements indicated that the risk estimate is uncertain (19/39, 49%) or acknowledged the difficulty of estimating an individual's risk using population-based data (15/39, 39%). Few websites provided a range for the estimate or confidence intervals (2/39, 5%).

Formats and strategies that can be useful for encouraging behavior change were present in less than half of the websites: 44% (17/39) provided social comparison information and 8% (3/39) compared the risk of cancer with other hazards. Several websites (16/39, 41%) also adopted the controversial practice of providing qualitative information but not quantitative information [48] (Table 4).

Table 4. Frequency of risk communication formats and strategies used by internet-based cancer risk assessment tools (N=39 websites).

Formats and strategies	Description and/or examples of code[a]	Value, n (%)
Duration of risk	Risk information specifies the timeframe for which it applies (eg, your risk of developing melanoma in the next 5 years has been estimated as very high)	22 (56)
Absolute risk	Risk estimate includes the baseline likelihood that the individual will develop a disease; can be presented with either quantitative or numeric risk estimates or qualitative or verbal labels	31 (80)
Quantitative risk[b]	Risk estimate included numbers	23 (59)
Percent (%)	N/A[c]	23 (59)
N in 100	N/A	5 (13)
1 in N	N/A	0
Number needed to treat	N/A	0
Risk score	N/A	0
Relative risk	N/A	1 (3)
Odds	N/A	0
None provided	No quantitative risk estimate was presented	16 (41)
Qualitative risk	Risk estimate included a verbal description of risk (eg, very large)	22 (56)
Both quantitative and qualitative risk	Risk information was presented using both numbers and verbal description	6 (15)
Positive framing	Risk estimate presented as one's risk of not getting cancer (eg, this means you have a 99.2% chance of not getting cancer)	2 (5)
Visual display[b]	Whether or not there is a visual depiction of risk	20 (51)
Color[d]	Risk information is represented by at least one color	20 (51)
Bar graph[d]	Risk information presented using a bar graph	6 (15)
Icons or stick figures[d]	Risk information presented using icons (eg, smiley faces) or stick figures	4 (10)
Pie chart[d]	Risk information presented using a pie chart	3 (8)
Line graph[d]	Risk information presented using a line graph	2 (5)
Risk ladder[d]	Risk information presented in comparison with other risks on a vertical continuum	0
Table[d]	Risk information presented using a table of numbers	0
Other[d]	Risk information presented in a visual way not described above (eg, a needle on a dial pointing to where a user's risk falls)	4 (10)
Acknowledges uncertainty[b]	Website indicates there may be error or uncertainty in the risk estimate	23 (59)
Emphasizes estimate	Mentions that there is uncertainty about the accuracy of the risk estimate (eg, this is only an estimate, your actual risk may be higher or lower; the model or estimate is incomplete)	19 (49)
Individualizing population risk	Mentions the difficulty of drawing conclusions about an individual from population-based data (eg, risk is based on population, not individual; cannot determine which individuals will or will not get cancer)	15 (39)
Range or confidence intervals[d]	Provides a range of possible estimates (eg, 1.0%-2.0%)	2 (5)
Risk reduction strategies	Website provides information about how a user can reduce their risk of getting cancer (eg, quitting smoking)	27 (69)
Social comparison[b]	The website compares the user's risk with the risk of other people	17 (44)
Direct comparative[d]	The estimate is provided in a way that explicitly mentions how the user's risk compares with others (eg, your risk is higher than average)	13 (33)
Indirect comparative[d]	Separate information about the user's risk and the average person's risk is required in such a way that the user must make the comparison to determine how their risk compares with others (eg, your risk is 2%; the average woman's risk is 5%)	8 (21)
Compared with other hazards	The risk of cancer is compared with the risk of other hazards (eg, your risk of breast cancer is 10%. The risk of being involved in a car accident is 20%)	3 (8)

[a] In most instances, the text in this column represents the explanation from the coding scheme.

[b] Categories are not mutually exclusive; individual websites may have received more than one code in this category.

[c] N/A: not applicable.

[d] Code not present in the study by Waters et al [9].

Discussion

Principal Findings

Despite a decade's worth of risk communication research being conducted between our 2009 report of internet-based risk assessment tools and the investigation presented here, we found that many websites that host risk assessment tools continue to communicate information in such a way that is likely to be confusing or misunderstood. Therefore, this limits the effective translation of risk prediction models into risk assessment tools [46]. There are 3 key limitations.

First, several communication strategies limit accessibility to the general public. Although few websites state that they are only intended for medical professionals, the vast majority include medical terminology without explaining what it means. This finding is consistent with other research indicating that most internet-based risk assessment tools are difficult to use for individuals with limited health literacy [54].

Second, consistent with previous work by ourselves and others [9,18], the websites that develop and host the risk assessment tools typically do not provide sufficient information for people to determine the credibility of the tools. Although all but one website we reviewed indicated who developed it, and most websites provided a way to contact the developers in case of questions, not all websites provided information about the risk prediction model that was used to calculate their risk or provided information about when the website was last updated. Thus, users may find it difficult to determine the extent to which their personalized estimate is scientifically valid and/or personally relevant [18] and may instead rely on the credibility of the website as a heuristic to determine the credibility of the tool [55].

Third, although the use of some risk communication formats and strategies known to foster unbiased comprehension were more common than they were in 2009 (eg, using either percentages or natural frequency format to communicate quantitative risk estimates), others remain uncommon (eg, including qualitative labels when communicating quantitative risk estimates). This observation suggests that lessons learned about risk communication formats and strategies that are published in widely read journals [20,23,51] are not reaching organizations that develop and/or host websites that include risk assessment tools. This is concerning because as more risk prediction models are being developed, there is an increased likelihood of them being translated into a risk assessment tool and posted on the internet in the absence of guidance from risk communication experts [46].

One notable finding was that a considerable minority of websites used a controversial risk communication strategy that involved providing qualitative risk category labels but not quantitative risk estimates. This strategy is seen by some researchers as one that should not be used because the variability in people's interpretations of qualitative labels impedes unbiased interpretations of risk information and informed decision making [25]. However, other researchers assert that, in circumstances wherein risk information is intended to promote behavior change, only qualitative categorical information is needed, not quantitative risk estimates [48]. This latter perspective is generally consistent with health communication and promotion campaigns that inform people that engaging in a particular behavior will increase their risk, but they do not provide details about the exact extent to which their risk is increased [56]. Providing qualitative labels in the absence of quantitative data may also overcome people's tendencies to view any percentage estimate of less than 20% as a small risk [29]. This may be especially useful in situations in which researchers attempt to promote lifestyle behaviors to reduce cancer risk among healthy populations, who seldom have lifetime cancer risks of more than 20% in the absence of a high-penetrance genetic variant.

We also report 2 important differences between the work reported here and the work reported in 2009. First, 41 of the 47 websites examined in the 2009 review were no longer accessible or usable at their original URLs. Indeed, one of the websites we identified for this review was no longer accessible after 6 months. Second, this review identified several websites and tools that appeared to be developed and/or hosted by individuals who indicated they had medical or scientific expertise, but most did not appear to be affiliated with a health care institution or university. Both these findings point to the potential difficulty of verifying the validity of the risk prediction models over time. In addition, independent experts without formal affiliations to scientific institutions may have less access to collaborators with expertise in risk prediction modeling, risk communication, and behavior change than developers affiliated with governmental, educational, or health care institutions.

Limitations and Future Directions

It is possible that the initial search overlooked some relevant websites or the triage process miscategorized sites. However, our process ensured that if there were any doubts about the relevance of a website or tool, at least one other member of the coding team was consulted. We did not involve patients or members of the public in the assessment of the websites. Future research should consider doing so to increase the applicability of the results to these key end users. We also engaged in double coding for the websites included in this report; a third coder acted as a tiebreaker in particularly difficult circumstances. Unfortunately, we do not have data about how often each risk assessment tool was accessed, who accesses them, or what users do with the information they obtain from the tools. Future research should investigate this issue. We considered creating a summary score indicating how many risk communication formats and strategies were used per site, but determined that doing so was unwise because there is little research examining how many formats or strategies should be used and in which combinations. Several researchers have determined that simpler communications are either more easily understood or just as easily understood as more complex communications [37,57,58], but future research should determine which formats and strategies should be prioritized. Finally, the number of websites was too small to determine whether there were statistically significant differences between the website affiliation category and the use of risk communication formats or strategies.

Conclusions

This study found extensive variability in the extent to which internet-based risk assessment tools and the websites that host them provide information in a way that facilitates understanding among the general population. Gaps in information accessibility, in the availability of information needed to evaluate the website's credibility, and in the use of risk communication formats and strategies that foster comprehension limit the translation of risk prediction models to wider public health practice [46]. Improving the quality of communication of such tools will likely limit confusion and foster an understanding of the information among users.

Abstract

Background: Adverse drug events are unintended and harmful effects of medication use. Using existing information and communication technologies (ICTs) to increase information sharing about adverse drug events may improve patient care but can introduce concerns about data privacy.

Objective: This study aims to examine the views of patients and their caregivers about data protection when using ICTs to communicate adverse drug event information to improve patient safety.

Methods: We conducted an exploratory qualitative study. A total of 4 focus groups were held among patients who had experienced or were at risk of experiencing an adverse drug event, their family members, and their caregivers. We recruited participants through multiple avenues and iteratively analyzed the data using situational analysis.

Results: Of the 47 participants recruited, 28 attended our focus groups. We identified 3 primary themes. First, participants felt that improved information sharing about adverse drug events within their circle of care would likely improve care. Second, participants were concerned about data handling and inappropriate access but believed that the benefits of information sharing outweighed the risks of privacy breaches. Finally, participants were more concerned about data privacy in the context of stigmatized health conditions.

Conclusions: Current conditions for maintaining health data privacy are consistent with participants' preferences, despite the fact that health data are susceptible to breaches and mismanagement. Information sharing that increases patient safety may justify potential privacy risks. Greater attention to patient concerns and the effect of social and contextual concerns in the design and implementation of health information technologies may increase patient confidence in the privacy of their information.

KEYWORDS

health information technology; adverse drug events; privacy of patient data

Introduction

Background

Adverse drug events are unintended and harmful outcomes of medication use and a leading cause of emergency department visits and unplanned hospital admissions [1-4]. More than 30% of patients presenting to hospitals with adverse drug events are affected by repeat events that occur because care providers unintentionally re-expose patients to medications that previously caused harm [5]. A lack of effective automated processes to communicate adverse drug event information between health providers and across locations of care contributes to the recurrence of these events.

Poor communication about adverse drug events reflects broader fragmentation and siloed information in health. Recent initiatives at the provincial and federal levels of the government in Canada aim to address these communication gaps. In Ontario, the Digital First for Health Strategy intends to increase the availability of patient records for frontline clinicians and reduce barriers to integration [6]. British Columbia's Digital Health Strategy seeks to modernize the health system through integration, improved care delivery, and data accessibility for clinicians and patients [7]. This includes increasing access to clinical information through end-to-end medication management using existing clinical information systems [8]. Enabling PharmaNet, British Columbia's medication dispensing database, to receive and transmit adverse drug event information may support such an undertaking.

Objectives

Enhanced communication about adverse drug events may improve patient safety but can also reveal sensitive diagnoses to a broader range of clinicians than those currently aware of them. This could introduce privacy concerns for patients, particularly among those living with stigmatized illnesses. We examined patients' perceptions about the need to share information about adverse drug events to optimize patient safety while maintaining data privacy.

Methods

Study Design

We conducted a qualitative study to explore patients' perceptions of information privacy and sharing in the context of developing software to facilitate adverse drug event documentation and communication. Research ethics boards of the University of British Columbia and Simon Fraser University reviewed and approved the protocol. All participants provided written informed consent.

Study Setting and Sample

Our target study population included adults (≥19 years) who had lived experience with or were at risk of an adverse drug event and family members and caregivers of patients who had experienced an adverse drug event. All participants lived in the Vancouver area or Whistler, British Columbia, between September 2016 and May 2017. We excluded patients who were living in long-term care facilities, did not manage their own medications, were receiving palliative care, were from out of province, or did not speak English. If we approached a patient who was excluded based on the above criteria, we attempted to recruit a family member or caregiver for participation, if they were present during recruitment.

Recruitment

We used multiple sampling strategies to recruit patients who had lived experience with an adverse drug event or who were at risk of an adverse drug event because of their age (≥65 years) or exposure to polypharmacy and the family members and caregivers of patients who had experienced an adverse drug event. We recruited in person, through posters, and through web-based advertisements.

From September to November 2016, we recruited those who were experiencing or who were at risk of experiencing an adverse drug event. Emergency department pharmacists recruited a convenience sample of patients presenting to the emergency department of Vancouver General Hospital, a tertiary care hospital in Vancouver, Canada, when completing medication reviews. We placed posters in high-traffic areas in the emergency department and at a hospital-based research center to encourage patients and their family members to contact the research team if they were interested in participating. We also sought to recruit members of the general population by posting web-based advertisements on Kijiji and Craigslist and by snowball sampling from personal connections. In recruitment advertisements, we stated that we were seeking patient opinions on having information about their medication-related problems shared among care providers. Our intent was to reach a broader range of individuals who met our target sample criteria, including those that may not have had direct contact with the acute care setting at the time of the focus groups.

From February to May 2017, we recruited individuals with stigmatized illnesses (HIV and/or substance use disorder) by placing posters at a clinic that provides care to HIV-positive women. We hypothesized that these patients may have specific privacy concerns and also because HIV medications are currently not documented in the provincial medication dispensing database, PharmaNet, in part because of privacy concerns at the time of PharmaNet's implementation [9].

Among those recruited through snowball sampling from personal connections, there was an established relationship between the researchers and participants before the study. For all others, beyond contact for recruitment purposes, there was no prior established relationship.

Data Collection

The focus groups followed a semistructured discussion guide developed collaboratively by the research team to address themes relevant to adverse drug event information sharing (Multimedia Appendix 1). The principal investigator (EB) and a research assistant (SS) with expertise in qualitative research created the first draft. Other members of the research team then revised and edited the discussion guide to offer different disciplinary perspectives.

Key themes addressed in the discussion guide were experiences with adverse drug events, knowledge of information-sharing practices, and attitudes about data privacy and privacy policy. We allowed participants to engage in open dialog and ask questions beyond the discussion guide and identify and discuss new concepts that we had not considered.

We held focus groups in a research office at the Vancouver General Hospital. The principal investigator (EB), a female social scientist with extensive experience in qualitative methods, led the focus groups, and a research assistant (SS) attended to take notes. At the beginning of each group, we introduced the researchers present and provided a brief definition of adverse drug events, including examples, providing rationale for the groups. Recruitment materials informed prospective participants that we sought to gather opinions to guide the development of a system to support sharing of information about adverse drug events among health care providers. We reiterated this at the time of the focus groups.

We gathered additional information about the participants, including demographic information, using a short debriefing survey at the conclusion of each focus group (Multimedia Appendix 2). We audio recorded the focus groups, which were then transcribed by a research assistant (SS).

Data Analysis

We coded and analyzed transcriptions using *NVivo 11* qualitative data analysis software (QSR International, version 11, 2015). We created a provisional coding frame to reflect the thematic structure and discussion guide questions. The structure of the coding frame organized participant comments conceptually along the following themes: data privacy, information sharing, awareness of privacy policy, policy preferences, experience with adverse drug events, and recommendations. We (SS and EB) iteratively coded and analyzed the data using situational analysis, a theoretical and methodological approach that examines contextual, relational, and discursive elements in the data through the concurrent creation of memos and mapping exercises [10].

Results

Focus Groups and Participant Characteristics

Of the 47 participants we recruited, 28 attended a focus group. Each focus group had 5 to 8 participants (Table 1). A total of 20 participants (20/28, 71%) were in groups A, B, and C. Of these participants, 65% (13/20) were aged above 65 years and at risk of an adverse drug event, 25% (5/20) were from the general population, and 10% (2/20) were caregivers or family members of patients with adverse drug events. Group D consisted of 8 women (8/28, 29%) recruited from a clinic serving HIV-positive women.

Table 1. Focus group composition (N=28).

Group ID	Participants, n (%)
A	8 (29)
B	7 (25)
C	5 (18)
D	8 (29)

Each focus group lasted for 120 min. Most participants (25/28, 89%) completed the debriefing survey (Table 2). Most participants were female and aged above 51 years. Many participants had lived experiences with an adverse drug event, knew someone else who had, or both. Most participants had completed at least some postsecondary education.

Table 2. Participants’ characteristics (N=28).

Variable	Participants, n (%)
Gender	
Male	6 (21)
Female	19 (68)
No response	3 (11)
Age (years)	
<20	0 (0)
20-35	2 (7)
36-50	5 (18)
51-65	10 (36)
>66	8 (29)
No response	3 (11)
Experience with adverse drug events	
Yes, have lived experienced with an adverse drug event	3 (11)
Know someone who has experience with an adverse drug event	7 (25)
Both lived experience and know others who have experienced an adverse drug event	6 (21)
No, have not experienced an adverse drug event	6 (21)
Unsure	3 (11)
No response	3 (11)
Highest level of education	
Some high school	3 (11)
Completed high school	3 (11)
Some postsecondary	7 (25)
Completed college or university	7 (25)
Some graduate school	2 (7)
Master’s degree	1 (4)
Doctoral degree	1 (4)
No response	4 (14)

Primary Themes

We identified 3 primary themes about information sharing and privacy in the context of adverse drug event communication. Participant quotes to support each theme are presented in the corresponding textboxes, which are representative of the findings for each theme.

Participants Believed Enhanced Information Sharing Among Clinicians Would Improve Care

Experiences With Informational Discontinuity of Care

Many participants described experiences with fragmented information sharing (Textbox 1). In some cases, participants experienced negative outcomes as a result of poor information sharing. Participant 1, for example, described how their father-in-law’s experience with poor communication of an adverse drug event affected his long-term health, resulted in unnecessary costs, and emotionally affected the patient and his family. Several participants noted that in the absence of effective information-sharing processes, they took responsibility for information sharing themselves.

Textbox 1. Participant quotes about experiences with informational discontinuity of care.

- “I don’t think there’s a lot of communication between the doctors. Say you have a GP, you have a rheumatologist, you have an HIV specialist – you tell one doctor one thing and they say, ‘oh I didn’t know that, when did that start?’…So you gotta follow up yourself because he can’t…they get so busy, or they forget, or they don’t care or whatever.” [Participant 25, group D]
- “I have been to [the] emergency department with an adverse reaction twice, and it’s very busy. The doctors who see you don’t have time to write your discharge report up in time for you to take a copy away with you…I would like to have further information and would like to be able to pass it on to my GP.” [Participant 11, group B]
- “I think in my father-in-law’s case, [the lack of information sharing] cost our system more money…there were more doctors involved…there was more angst involved…my father-in-law’s condition plummeted. And there were more people involved, there was more testing done, ambulance was called ten times.” [Participant 1, group A]
- “I don’t think it’s very well shared. If it is, it’s pretty piecemeal.” [Participant 3, group A]
- “I’ve just always heard that adverse effects are supposed to be reported…but I never had any confidence that they were.” [Participant 8, group A]
- “I have learned that in many cases, the people to whom I go for one medical event or another don’t always share the information.” [Participant 12, group B]
- “My family doctor gets everything, but I particularly have to make a point of asking for copies to be sent to a couple of my specialist physicians.” [Participant 11, group B]

Benefits of Better Communication

Participants felt that better communication between providers in their circle of care would have a positive effect on health outcomes and could improve their experience with the health system, including improved disease and medication management (Textbox 2). They suggested that communication would lessen the recall burden for patients and their families and that broader information sharing would support clinical decision making, especially in situations in which a patient would be unable to communicate or recall the required information.

Textbox 2. Participant quotes describing the benefits of better communication.

- “And then…someone who is elderly, who may have dementia, who doesn’t have someone advocating for [them] – that information needs to be shared so that somebody can make sure that they’re making good decisions around their health care and prescription medications.” [Participant 1, group A]
- “[My father-in-law’s] health would have been maintained at a higher level for a longer period of time, had the information been shared more regularly.” [Participant 1, group A]
- “Yes, the more [my care providers] know [about my] medications…the better they’re taking care of me.” [Participant 27, group D]
- “When my mother was admitted and all they need is her care card number…all the information [is] there already, so it’s a lot easier for us.” [Participant 19, group C]
- “You’d think that the more information that your caregivers have…the better off you’re going to be if you have a problem or if you’re unconscious or whatever.” [Participant 20, group C]
- “I think the more we share the information, it’s a huge financial benefit…both the emotional and financial side.” [Participant 7, group A]
- “…We have the language barriers, we have culture barriers, we have all of those things to deal with and it makes things very, very difficult, so another reason for having this information [available] to so many people.” [Participant 3, group A]
- “My view is that I am less concerned about privacy, and more concerned about people [caring] for me having the information that they need.” [Participant 8, group A]

Most Participants Preferred Electronic Information Sharing

Many participants supported the use of health information technologies to share adverse drug events and medication information (Textbox 3). Participants viewed electronic communication as quick, easy, and environmentally sustainable while also reducing the risk of lost or misplaced files. Although recognizing these advantages, participants were concerned about data security threats (eg, hackers) and system failure (eg, because of an earthquake). As a result, participants felt that clinicians should not rely exclusively on electronic information sharing and storage. Participants suggested backups to electronic information sharing, including telephone-based communications between clinicians, and electronic or paper-based backups.

Textbox 3. Participant quotes about electronic information sharing.

- “I personally would want it electronically, just because with the technology age nowadays it’s…the easiest method and the quickest method to transfer information…also it’s more eco-friendly than having all these pieces of paper that might get lost…” [Participant 18, group C]
- “I think I’d want it electronic because it is simpler, and mounds of more paper aren’t necessary…or needed.” [Participant 16, group C]
- “All I’ve gotta say is: is there an app for that?” [Participant 3, group A]
- “I don’t think we should lose the ability to ever…pick up the phone, because there are quick emergency situations that can save a life…but generally I think that electronically is the most practical.” [Participant 7, group A]
- “I’m in favour [of] electronically, but with ensured back up because you could lose everything.” [Participant 8, group A]
- “Digital is my first choice.” [Participant 14, group B]
- “There’s been breaches with confidential medical files when it comes to computers.” [Participant 21, group D]
- “I would want it electronically and [on] paper because…we live in an earthquake zone.” [Participant 17, group C]

Participants Were Concerned With Data Handling and Inappropriate Access

Participants Believed Professional Roles Should Determine Access Permissions

Participants focused on the different professional groups that would access their health information rather than the information systems that would mediate information sharing (Textbox 4).

Role-based access was a recurrent theme, and participants discussed whether access to information was pertinent to every clinical role. For example, group A agreed that pharmacists needed access to patient information but debated whether pharmacy assistants also did. Similarly, participants in groups A and D questioned whether care providers in long-term care facilities (eg, care aides) or allied health professionals (eg, physiotherapists) required full access to medical information or if they had adequate training to manage confidentiality.

Textbox 4. Participant quotes about role-based access.

- “I would say it would be ok for [my information to be shared] as long as it’s…the doctor... Say…someone on a team…like maybe a social worker of something, they might be valuable on the team, but the medication part would have absolutely nothing to do with them. So, they shouldn’t be having access to that information because they can’t do anything about it.” [Participant 21, group D]
- “When it comes to doctors and nurses…they share. But if…the definition of ‘care team’ is broader than that, then I would need to know who they were and what they were doing [with my information.]” [Participant 17, group C]
- “[Care aides are] usually wonderful people, but they don’t have the information…on how to deal with the ethics of private information. This is my experience with my mother. But yeah, it would depend who it was. I mean my physio doesn’t need to know, right?” [Participant 17, group C]
- “It’s more of a question of what is their education, what is their guidelines…Like a pharmacist…keeps everything confidential. Does the assistant?” [Participant 7, group A]
- “Maybe…the key is who gets the information [is] anybody that has to do with the prescription.” [Participant 3, group A]
- “You run into a whole hornet’s nest when you’re talking about other people getting that information, like for example insurance companies.” [Participant 12, group B]
- “[The doctors] always have [medical] students in their office, right? They come in with the doctors…So the [medical student has] your information, they’ve got everything in that conversation…And where does it go from there?” [Participant 25, group D]
- “I was just going to say that all the medical and allied health, secondary health professions, have confidentiality and privacy as a really major, serious part of their curriculum…It’s as secure as it can be given people.” [Participant 8, group A]

Participants Perceived Internal and External Threats to Their Information in Medical Facilities

Participants believed that data stored electronically in medical facilities were unlikely to be secure (Textbox 5). When asked whether they were aware of any breaches of medical information, a small number of participants said yes. At least one breach was mentioned in each group. Several said that they had heard of both clinical and administrative staff mishandling data, including improper disposal, private conversations in public spaces, and inappropriate access of records. Participants had also heard of external threats, including hacking and breaches of Canadian data by American companies; however, none had been firsthand victims of data breaches in medical facilities. Despite this awareness, most agreed that hearing about breaches did not affect their willingness to share their health data. One participant summarized this sentiment by stating that they thought the benefits of information sharing exceeded the risks of privacy breaches.

Textbox 5. Participant quotes about data security.

- “I think if someone really wanted to get [my medical information] they could get it…People within the office [of] the hospital, if they wanted to get access to it, I think they could get it. Even if they don’t have…official approvals. And, data hacking is advancing.” [Participant 17, group C]
- “I never thought of it as being that confidential…It’s on a computer and in your pharmacy, and there’s a zillion people [that] have access to it. I just accept the system the way it is.” [Participant 20, group C]
- “[Information is] only as secure as the individuals handling it.” [Participant 3, group A]
- “I don’t think pharmacies are very secure.” [Participant 15, group B]
- “There’s a lot of hackers out there that can get access to [your information].” [Participant 25, group D]
- “There’s faxes that have…gone to the wrong fax number, so there’s a breach of confidentiality there.” [Participant 21, group D]
- “And where the breaches occur are chatting down the hallway, nurses chatting in the elevator, people in the cafeteria…” [Participant 8, group A]
- “I’ve heard of…an operator throwing some CDs or…storage device in the garbage and then somebody went in the garbage and pulled it out, and there’s half a million records on there.” [Participant 3, group B]
- “I mean, there have been serious privacy breaches on record with the provincial government specifically.” [Participant 15, group B]
- “A whole stack of personal information and somebody just dumped it out in the back lane somewhere.” [Participant 14, group B]

Privacy Concerns Are Amplified When Considering Stigma and Potential Discrimination

Discussions about stigma and discrimination around health data emerged in most groups (Textbox 6). Many felt that sharing information about stigmatized illnesses, which could occur if an adverse drug event to HIV medication was recorded, should occur only within a patient’s circle of care, which is consistent with current data privacy standards. Among participants in group D (who live with stigmatized illnesses), concerns about the effects of stigma and discrimination were amplified. Previous experience with the health system that had reduced complex lived experiences with negative labels colored this group’s perception of the system. There was a relationship between trust, willingness to share health information, and stigma. One participant, for example, commented that they might withhold medical information if they did not trust their care provider or had concerns about where their information was going and who could access it. Although we sought to understand information-sharing preferences in clinical settings, several participants mentioned unprompted that their sensitive medical information should not be shared with colleagues or employers. Participants suggested ways to reduce stigma, including educating clinicians and providing information for patients during care encounters.

Textbox 6. Participant quotes about stigma and discrimination.

- “When [a care provider] comes in and [is] talking about someone’s health, you just don’t outright say ‘hey how’d you get that?’ That’s really disrespectful to a person whether they have diabetes, cancer, HIV, or Hep C, or whatever their medical situation is.” [Participant 21, group D]
- “So, depending on who’s accessing that information…that’s where stigma, discrimination comes in, because [the patient] could…end up being judged from the medication they’re on because [the care provider] knows what those medications are used for.” [Participant 21, group D]
- “I remember all the stigma around cancer when I was a child. It was like the ‘c-word’. You didn’t even call it cancer. And it’s great to see the shift now…It would be lovely if we could get that way with stuff like mental health, Hep C, HIV. You know, there’s definitely more awareness out there but unfortunately there’s…the ignorance.” [Participant 21, group D]
- “I’ll tell you right now, the honest truth about the Downtown Eastside is [care providers] don’t care about you. You’re just a number, you’re just an addict, you’re just a prostitute, you’re just a drunk…You’re not a human being…You’re just shuffled through, seen by whoever’s there [at the clinic] …They don’t [have] your files.” [Participant 28, group D]
- “There was the case of the woman refused entry into the US because she was on anti-depressants.” [Participant 17, group C]
- “I have a mental illness…if I’m a danger to myself or to others, and I’m not taking my meds…then yes, my diagnosis along with my meds need to be passed on to somebody…if I’m stable, then just my medication [information should be shared].” [Participant 4, group A]
- “You know, [doctors] want you to tell them everything…but I don’t want to tell you [doctors] this part, because I don’t trust you guys.” [Participant 25, group D]
- “I just feel…the students…or the…residents, they need to be better educated on…bedside manners.” [Participant 21, group D]
- “I do see more often that…the confidentiality blurbs are out there more often when you’re signing things, [saying] this is how we protect information. That never used to be out there, so I think there is more awareness out there, but I think it needs to continue, like even…ramp it up. And not [allow] people [to] get…complacent about it.” [Participant 21, group D]

Discussion

Principal Findings

We explored patients' perceptions about information privacy and sharing in the context of developing a health information technology that will enable electronic documentation and automated communication of adverse drug event information between providers and across care settings. Most participants supported improved information sharing about adverse drug events, expected technologies, and clinicians to protect their privacy and understood that a lack of information sharing could pose a greater risk to their safety than potential threats to privacy. In the following sections, we explore how existing organizational and institutional measures to protect data privacy are consistent with participant expectations.

Privacy legislation provides a framework for data management. In British Columbia, the Freedom of Information and Protection of Privacy Act (FIPPA) governs the collection, use, and dissemination of personal information by public entities, including health authorities and hospitals. Under FIPPA, public entities must enact and enforce security measures to prevent unauthorized collection, use, access, disclosure, and disposal of personal information. Public entities such as hospitals and clinics must notify individuals that their information is being collected and used but do not require patient consent to share patient information with other members of the care team [11]. Our study participants' privacy preferences were consistent with these legislative requirements: participants were favorable toward information sharing among clinicians but were wary of giving access to those outside their circle of care (eg, an insurance company) or among those within the circle of care for whom information about an adverse drug event is irrelevant to their role (eg, a physiotherapist). A system that supports adverse drug event data sharing among a patient's circle of care must minimize the barriers to effective communication and should not require additional patient consent.

Improvement in communication about adverse drug events may be achieved by leveraging existing health information technologies, such as PharmaNet. PharmaNet employs numerous data management safeguards, including physical security (eg, limited access to equipment), operating system security (eg, user access keys), network security (eg, firewall), and screen security (eg, only certain items viewable based on each user's security profile) [12]. It also adheres to the principles of role-based access, wherein different user groups have different access permissions, which was strongly preferred among participants. In addition, individuals can find out when their record is accessed and those with further privacy concerns can add a password to their PharmaNet profile, allowing them to determine who can or cannot view their profile. This is valuable for individuals living with stigmatized illnesses.

Despite the privacy measures implemented in health information technologies, security under real-world conditions is more volatile. Breaches of health data have been a recurrent focus of media attention and critique, including incidents involving PharmaNet. In 2014, for example, approximately 1600 profiles were compromised by an unknown, unauthorized individual using a doctor's account [13]. In 2017, more than 20,000 profiles were breached [14]. These breaches exemplify our participants' concerns and demonstrate the challenge of managing the risks associated with privacy breaches while ensuring that data are accessible in the interest of patient care. Following these events and other privacy concerns, the provincial Ministry of Health introduced a new project to support user management for PharmaNet, which will streamline access approval when implemented [15].

In addition to legislative frameworks, concerns about handling sensitive health information can be addressed in the design of systems by implementing role-based access functionality, building complex password requirements, and regularly auditing use and users. Participants' concerns regarding threats to data security among staff in medical facilities can be addressed through other nontechnical approaches. Implementation should incorporate education that addresses safe information handling, including proper methods of sharing data and disposing of paper records, and strategies for maintaining the security of log-in credentials. These measures may increase clinicians' ability to maintain the security of information in their custody while increasing patients' confidence in the privacy of their information and in the efficacy of information sharing in health.

Limitations

Sample composition is the primary limitation of this study. Participant self-selection and recruitment from an urban area may have introduced selection bias. More women participated than men. Participants in rural regions, men, and those with other health trajectories or access points within the health system may have different experiences in the health sector that are not reflected. As such, our findings may not translate to other regions, populations, and health conditions. In addition, we did not screen participants who volunteered via classified websites (n=5) to determine whether they met the defined sample criteria (ie, at risk of or experienced an adverse drug event or a family member or caregiver). Therefore, we cannot verify whether all responses are representative of these sample criteria.

Conclusions

Participants were generally supportive of enhanced informational continuity of care about adverse drug events to facilitate care delivery. The belief that enhanced information sharing would improve care and that a lack of information sharing poses safety risks indicates patient support for broader use of information and communication technologies (ICTs) in health. Privacy considerations were important to participants but largely in the context of the human actors handling the data rather than the electronic systems that mediate information transfer. Fears about stigma and discrimination were prominent drivers, particularly among patients who had experienced stigmatization. Our findings suggest the need to consider the ways that social and contextual factors (eg, living with a stigmatized illness) that affect patient privacy can be addressed at both the human and technical levels in the design and implementation of ICTs in health.

Abstract

Background: Although web-based psychoeducational programs may be an efficient, accessible, and scalable option for improving participant well-being, they seldom are sustained beyond trial publication. Implementation evaluations may help optimize program uptake, but few are performed. When the US Department of Veterans Affairs (VA) launched the web-based psychoeducational workshop Building Better Caregivers (BBC) for informal caregivers of veterans nationwide in 2013, the workshop did not enroll as many caregivers as anticipated.

Objective: This study aims to identify the strengths and weaknesses of initial implementation, strategies likely to improve workshop uptake, whether the VA adopted these strategies, and whether workshop enrollment changed.

Methods: We used mixed methods and the Promoting Action on Research Implementation in Health Services (PARIHS) implementation evaluation framework. In stage 1, we conducted semistructured interviews with caregivers, local staff, and regional and national VA leaders and surveys with caregivers and staff. We collected and analyzed survey and interview data concurrently and integrated the results to identify implementation strengths and weaknesses, and strategies likely to improve workshop uptake. In stage 2, we reinterviewed national leaders to determine whether the VA adopted recommended strategies and used national data to determine whether workshop enrollment changed over time.

Results: A total of 54 caregivers (n=32, 59%), staff (n=13, 24%), and regional (n=5, 9%) and national (n=4, 7%) leaders were interviewed. We received survey responses from 72% (23/32) of caregivers and 77% (10/13) of local staff. In stage 1, survey and interview results were consistent across multiple PARIHS constructs. Although participants from low-enrollment centers reported fewer implementation strengths and more weaknesses, qualitative themes were consistent across high- and low-enrollment centers, and across caregiver, staff, and leadership respondent groups. Identified strengths included belief in a positive workshop impact and the use of some successful outreach approaches. Implementation weaknesses included missed opportunities to improve outreach and to better support local staff. From these, we identified and recommended new and enhanced implementation strategies—increased investment in outreach and marketing capabilities; tailoring outreach strategies to multiple stakeholder groups; use of campaigns that are personal, repeated, and detailed, and have diverse delivery options; recurrent training and mentoring for new staff; and comprehensive data management and reporting capabilities. In stage 2, we determined that the VA had adopted several of these strategies in 2016. In the 3 years before and after adoption, cumulative BBC enrollment increased from 2139 (2013-2015) to 4030 (2016-2018) caregivers.

Conclusions: This study expands the limited implementation science literature on best practices to use when implementing web-based psychoeducational programs. We found that robust outreach and marketing strategies and support for local staff were critical to the implementation success of the BBC workshop. Other health systems may want to deploy these strategies when implementing their web-based programs.

Introduction

Background

Evidence-based online psychoeducational programs may offer an efficient, accessible, and scalable option for improving participants' health and well-being [1-9] but only if they succeed in reaching the participants for whom they are designed [10,11]. Unfortunately, few web-based interventions are widely implemented following study completion [3,12]. Programs for informal caregivers offer a case in point [13]. Informal caregivers are family members, friends, or acquaintances (hereafter referred to as *caregivers*) who provide essential support to persons living with major health conditions or disabilities in the community [14,15]. Although web-based psychoeducational programs for caregivers have proliferated, the best strategies for optimizing their implementation remain unknown [7,16-19].

Among caregivers, those providing support to US veterans have some of the highest documented rates of caregiving burden, stress, depression, and neglect of self-care [20,21]. They have expressed a desire for help from the US Department of Veterans Affairs (VA) Health Care System, which is the largest integrated health care system in the United States [20]. Galvanized by a 2010 Act of the US Congress [22], the VA Caregiver Support Program (CSP) commissioned the development of a web-based psychoeducational and self-management workshop, *Building Better Caregivers* (BBC), for these caregivers. In earlier studies, BBC participants experienced reduced stress and depression and increased self-efficacy [23,24]. On the basis of this evidence, the VA adopted the BBC workshop nationally in 2013 at all VA medical centers in the United States and its territories [22]. However, BBC program uptake was lower than expected at many medical centers.

Objectives

We seek to determine why the national web-based BBC workshop did not reach caregivers at some centers and whether uptake could be improved by performing a multistage mixed methods implementation evaluation involving national and regional VA leadership, staff and informal caregivers at local centers, and national VA CSP operations data sets. Specifically, our objectives were organized into 2 stages:

Stage 1: initial evaluation.

- 1a. Identify initial implementation strengths and weaknesses.
- 1b. Identify and recommend implementation strategies likely to improve uptake.

Stage 2: follow-up evaluation.

- 2a. Determine whether new or enhanced implementation strategies were subsequently adopted.
- 2b. Determine whether workshop enrollment changed.

Methods

Study Design

We employed a convergent mixed methods design for both stages of research because the implementation of a web-based caregiver workshop nationally among VA medical centers was a complex health services intervention that required multilevel processes, which we felt would be best assessed with a mixed methods approach [25]. We used the revised Promoting Action on Research Implementation in Health Services (PARIHS) framework as our implementation evaluation framework [26,27]. The PARIHS constructs include (1) evidence (eg, research evidence supporting innovation effectiveness, participant experiences); (2) context (eg, resources necessary to support staff activities, data management and evaluation capabilities); (3) facilitation (eg, skills and attributes of local staff, staff training, and mentoring and assistance from experts); and (4) successful—or unsuccessful—implementation (eg, achievement of desired outcomes of innovation, extent of uptake). These PARIHS constructs were represented throughout our mixed methods process, including in the structure of our sampling frame, survey questions, interview questions, and the analysis and interpretation of both quantitative and qualitative data. The Stanford University Institutional Review Board approved the evaluation (protocol no. 29965), and participants provided verbal consent. Caregivers received US $40 as compensation for study participation. The staff and leaders did not receive compensation.

Stage 1: Identification of Initial Implementation Strengths and Weaknesses and Strategies Likely to Improve Workshop Uptake

In stage 1, we collected and assessed survey and interview data concurrently to enable planned triangulation between the data sets and results (October 2014 to January 2015). The qualitative (interview) approach was the higher priority approach because it enabled the collection of detailed, nuanced feedback on implementation strengths and weaknesses and suggestions for changes not achievable in a survey. However, the quantitative (survey) approach was integral to the implementation evaluation because it enabled anonymized structured feedback on prespecified, discrete implementation elements derived from the PARIHS constructs and subconstructs that might or might not be mentioned during interviews and that we could compare and integrate with emergent themes from the qualitative data. Surveys also generated contextualizing data on respondent characteristics (eg, age, caregiving relationship, care partner health conditions). The quantitative and qualitative analyses were performed by the study team, and the study team, the advisory board, and a national VA CSP leader integrated findings and reached consensus on strategies likely to improve workshop uptake during a half-day virtual retreat (May 2015). The study team communicated findings and recommendations to VA CSP national leaders in a final report and webinar meetings (June to July 2015).

Characteristics of the Workshop

The BBC workshop is an evidence-based, 6-week, interactive psychoeducational and self-management program designed to reduce caregiver stress and depression and increase caregiver skills and self-efficacy [23,24]. Each workshop includes 20-25 participants and is guided by 2 trained cofacilitators. During workshops, caregivers read weekly lessons, perform self-management- and caregiving-related activities to solidify new skills and interact with and receive social support from peers and facilitators. Examples of self-management and caregiving skills include techniques for stress reduction, creating weekly action plans that are realistic and achievable, problem solving when challenges occur, managing difficult care partner behaviors, communicating with family, friends, and health professionals, and planning for the future, among others. The workshop is delivered on a secure online platform developed specifically for the workshop that, at the time, supported use on a computer or tablet device and has since expanded to include smartphone delivery. The workshop is only available in English.

Workshop facilitators are caregivers of persons with chronic conditions. They receive a 5-day training that teaches them facilitation skills and about the workshop (its theoretical basis, structure, and content). Facilitators must demonstrate mastery of the material and adhere to a comprehensive workshop facilitator manual. Master facilitators monitor each workshop for fidelity. Facilitators can lead workshops remotely from anywhere in the United States and are paid to do so.

Implementation Evaluation Context and Advisory Board

The VA adopted the BBC workshop nationally in 2013, making it available at no cost to caregivers registered at any VA medical center in the United States or its territories [22]. The VA CSP leadership and our study team at the VA Center for Innovation to Implementation identified that BBC uptake was lower than expected. Using CSP operations data, we determined that 5.74% (1265/22,022) of eligible caregivers enrolled in the workshop in the first 2 years of the rollout, but that center-specific enrollment rates varied widely—from 0% to 37%—with 10.6% (15/142) of all the centers enrolling no participants. Thus, the VA CSP and our study team partnered to perform the current implementation evaluation. As the study team, we convened an advisory board composed of representatives of key stakeholder groups and experts to advise us at all stages of the evaluation. The advisory board included a veteran caregiver, veteran care partner, expert on informal caregiver research, expert on self-management research, clinical psychologist with expertise in eHealth interventions for veterans and their families, and director of web services for the VA.

Eligibility Criteria and Sample Selection

All 4 national leaders involved in the workshop rollout were invited to participate in the implementation evaluation and all agreed to do so. National leaders were defined as those overseeing or directly managing the BBC implementation at the national level—for example, the VA CSP director, national VA BBC program manager, and BBC project director at the national organization contracted to administer the workshop on behalf of the VA. To identify regional leaders, local staff, and caregivers for participation, we used stratified purposive sampling (Table 1). BBC enrollment rates at all VA medical centers (standardized by catchment size) were calculated to identify high- and low-enrollment centers and the regional networks to which they belonged. At the time, there were 142 medical centers belonging to 21 regional networks. Low-enrollment centers were defined as those in the 10th percentile of referrals during the first 2 years of workshop rollout, and high-enrollment centers were those in the 90th percentile. We identified 5 regional networks that encompassed both low- and high-enrollment centers and invited their CSP regional leaders to participate and all agreed. We then selected 2 regions for local evaluation based on geographical diversity and variation in medical center catchment size: the Northeast region with 2 paired medium-sized centers (1 high-enrollment center and 1 low-enrollment center) and the Gulf Coast with 2 paired large centers (1 high-enrollment center and 1 low-enrollment center). At selected centers, we recruited local staff most involved in the workshop rollout—all CSP social workers who worked as caregiver support coordinators at each center (hereafter referred to as *coordinators*) and other staff whom they identified as involved in the BBC implementation. Among the 14 local staff members approached, 13 (93%) agreed to participate. The staff member who declined had been a substitute coordinator for a short period but had returned to unrelated prior duties by the time we contacted her.

Table 1. Participant sampling frame and subsequent enrollment.

Participant characteristics	Sampling frame			Enrollment
	Nation (United States)	Region	Locality	
Targeted characteristics				
Role	National leaders of BBC[a] rollout (all)	Regional leaders (subset)	Local staff and caregivers (subset)	N/A[b]
Setting	2 national offices	5 regional networks	4 medical centers	N/A
N/A	Both in Washington, DC	N/A	N/A	4 national leaders
N/A	N/A	West	N/A	1 regional leader
N/A	N/A	Midwest	N/A	1 regional leader
N/A	N/A	South	N/A	1 regional leader
N/A	N/A	Gulf Coast	2 large centers[c]	1 regional leader; 9 staff; 16 caregivers
N/A	N/A	Northeast	2 medium centers[c]	1 regional leader; 4 staff; 16 caregivers
Final sample	N/A	N/A	N/A	54 total participants

[a] BBC: Building Better Caregivers.

[b] N/A: not applicable.

[c] Within the regions selected for additional evaluation, we identified and included one high-enrollment medical center and one low-enrollment medical center matched by catchment size—large size in the Gulf Coast and medium size in the Northeast.

We also recruited 8 veteran caregivers per center (32 in total). Caregiver eligibility criteria were being registered with the VA as a veteran caregiver and being 18 years of age or older. Exclusion criteria included having limited English proficiency and inability to speak by phone for a telephone interview (eg, due to hearing loss). We used VA operations data to identify all registered caregivers at each center and cross-referenced these with operations data on workshop referrals and enrollments. Sampling was divided into target groups of (1) caregivers enrolled in the workshop, (2) caregivers aware of the workshop but not enrolled, and (3) caregivers unaware of the workshop. We randomly generated the order of attempted contact with caregivers and performed a maximum of 2 telephone calls per caregiver. We attempted to contact 163 caregivers and, of these, 10 (6.1%) had a nonworking phone number and 101 (62.0%) did not respond to repeated attempts. We spoke with 54 (33.1%) caregivers. Among these, <1% (1/163) was ineligible because of limited English proficiency, 1.8% (3/163) called us back and desired to enroll but could not because we had reached our enrollment targets, 11.0% (18/163) actively refused, and 19.6% (32/163) enrolled. Reasons for refusal included no time, having no one to take care of veteran or other household responsibilities during the interview, veteran having passed away, being 39 weeks pregnant, and wanting to answer questions by mail only. All potential participants (caregivers, staff, and leaders) received information on the study objectives and researcher identities before their agreement to participate.

Survey Approach and Data Reporting

The quantitative evaluation consisted of surveys of caregivers and local staff. Caregivers completed paper-based surveys within a week of interview completion (Multimedia Appendix 1). Questions were asked about their demographic and caregiving characteristics and veteran care partners' demographic and health characteristics. Caregivers who participated in the workshop also indicated whether they would recommend it to others and whether it had improved their quality of life using Likert scale response options 1 to 5 that were anchored by descriptors—strongly disagree, disagree, neither disagree or agree, agree, and strongly agree—and the option of answering do not know/not applicable. The staff survey questions were adapted from the Organizational Readiness to Change Assessment (ORCA), a validated implementation sciences survey structured according to PARIHS constructs (Multimedia Appendix 2) [28]. An additional survey question asked respondents to indicate whether, "At our facility, implementation of the Building Better Caregivers program has been a success," using Likert scale response options 1 to 5 anchored by descriptors—strongly disagree, disagree, neither disagree or agree, agree, and strongly agree—and the option of answering "do not know/not applicable." The ORCA is designed for local staff within organizations implementing evidence-based programs. Therefore, it was completed by local staff only (ie, *not* by regional or national leaders). As survey respondent numbers are small, we report results with descriptive statistics rather than comparative statistics—specifically, the number (%) of respondents who gave the response of interest.

Interview Approach and Data Analysis

The qualitative team consisted of 4 coinvestigators, (RG, CK, AN, and VY) with training and expertise in interview-based data collection and analysis as well as content expertise in the following areas: public health and palliative care (RG), sociology and linguistics of medicine (CK), medical anthropology (AN), and caregiving, primary care, and health services research (VY). All 4 were investigators at the National VA Center for Innovation to Implementation based at the Palo

Alto VA Health Care System. With the exception of VY, who worked with one of the national BBC leaders in a separate study 5 years before this study, the qualitative team did not have prior relationships with the study participants. The qualitative team codeveloped the semistructured interview guides based on PARIHS constructs and pilot tested them with 1 caregiver and 2 staff members at the Palo Alto VA Medical Center before finalizing them (Multimedia Appendix 3).

Data collection consisted of 45-min one-to-one phone-based interviews that were audio-recorded and transcribed by professional transcriptionists and field notes that were recorded by interviewers immediately following interview completion. Transcripts were not returned to the participants for comments or corrections. In caregiver interviews, we asked about caregiving responsibilities, experiences with the VA, use of online technology, and preferences for caregiver support, education, and skills training. Among caregivers who had not enrolled but were aware of the workshop, we asked about outreach or enrollment processes they had experienced, why they had not enrolled, and for any other feedback they chose to share. Among caregivers who had enrolled, we asked about reasons for enrollment and feedback on their outreach, enrollment, and workshop experiences, suggestions for improvements, and whether the workshop had impacted them. In interviews with local staff and regional and national leaders, we collected feedback corresponding to all PARIHS constructs, including asking about their role, training, activities, and observations during the BBC rollout and suggestions for improvements.

The qualitative team codeveloped the codebook. Deductive codes were based on PARIHS constructs, whereas inductive codes were developed using content analysis of transcripts of a subset of 10 interviews and accompanying field notes [29]. Following the development of the initial codebook, 3 coders (VY, RG, and AN) applied a rapid analysis matrix coding form to evaluate an additional 13 interviews, with 2 coders coding each interview (double-coding) [30]. The initial matrix coding form consisted of rows for participants, codes as column headers, and transcript quotes and notes in the pertinent cells displayed in an Excel spreadsheet (Microsoft Corp). The full qualitative evaluation team then met and reviewed the matrices, including codes, quotes, and notes. CK (noncoder) examined quotes and codes to ensure consistency and facilitated discussion of these (eg, of areas of agreement or contention or areas that required clarification), suggested modifications or additions to the codes, and elicited team agreement on the final coding form. Coders applied the final coding form to all interview data, including interviews previously coded at earlier stages. The full qualitative team met again to identify, define, and reach consensus on emergent themes. The team identified themes that addressed strengths and weaknesses of workshop implementation, similarities, and differences in participant feedback from low- and high-enrollment sites and possible strategies for optimizing uptake. Participants did not provide feedback on the findings.

Integration of Survey and Interview Results

Next, we convened a half-day virtual meeting with our study team, advisory board, and a CSP representative using web-based conferencing capabilities. Attendees viewed survey and interview results displayed concurrently by the relevant PARIHS construct. Nonstudy team attendees (advisory board and CSP representative) commented on and confirmed the face validity of the results. All attendees then discussed and interpreted the results and reached a consensus on the integrated study findings.

Identification of Strategies Likely to Improve Workshop Uptake

Building from integrated study findings, at the same meeting, attendees identified broad strategies likely to improve workshop uptake and agreed that these strategies should be recommended to VA BBC national leaders. The study team reported both integrated study findings and recommendations to national leaders in the form of a written report and webinar meetings.

Stage 2: Determination Whether New or Enhanced Implementation Strategies Were Adopted and Whether Workshop Enrollment Changed

In 2018, we performed a follow-up evaluation consisting of interviews and longitudinal workshop enrollment data from the VA CSP operations databases to determine whether new or enhanced implementation strategies had been adopted and whether workshop enrollment changed.

Follow-Up Interviews With National Leaders

In spring 2018, we conducted one-on-one phone interviews with 3 of the original 4 national leaders. The 4th leader was no longer working in the same position and was unavailable for the interview. Our goal was to learn about changes that had been made in response to the initial implementation evaluation. Questions focused on whether existing implementation strategies (from the 2013-2014 timeframe) had been enhanced and new strategies had been adopted (eg, based on stage 1 recommendations) and whether the workshop itself had been maintained. We used the same codebook established from the original 2015 interviews to analyze data from the follow-up interviews.

Longitudinal Data on Workshop Enrollment

Following interviews, we used VA CSP operations data to retrospectively evaluate longitudinal workshop enrollment for the VA as a whole from 2013 to 2018. Data were available by VA fiscal year (FY; October 1 to September 30 of the following year). FY data correspond to the following periods of interest in this study:

1. 2013-2014: BBC workshop rolled out nationally.
2. 2015: study team performed initial implementation evaluation.
3. Late 2015 and early 2016: VA adopted expanded implementation strategies (as determined in follow-up interviews).
4. 2016-2018: follow-up period.

We graphically displayed the longitudinal data for visual inspection to determine the potential impact of expanded implementation strategies on workshop enrollment.

Results

Stage 1: Participants

Thirty-two caregivers, 13 local staff, and 9 regional and national leaders participated in surveys and interviews (Table 2). Approximately half of the caregivers (15/32, 47%) and local staff (7/13, 54%) were from low-enrollment centers. A total of 17 (53%) caregivers supported younger veterans from the post-9/11 era of service. All cared for veterans at high risk for morbidity and mortality based on their health conditions. Most were White, female, above the age of 40 years, and married to their care partners. Their care partner relationships (eg, spouse, child) were similar in distribution to those reported by caregivers enrolled in BBC during the first 2 years of workshop rollout (Multimedia Appendix 4). The chronic conditions of their care partners were also broadly similar to those of caregivers enrolled in BBC (Multimedia Appendix 4). Among the local staff, 69% (9/13) were caregiver support coordinators. Among regional and national leaders, 78% (7/9) were VA based and 2 (22%) were from the national organization responsible for administering the workshops on behalf of the VA.

Table 2. Characteristics of caregivers, local staff, and regional and national leaders.

[c] Other staff include 3 primary care social workers and 1 clinical psychologist.

[d] VA: US Department of Veterans Affairs.

Survey Results

A total of 72% (23/32) of caregivers completed the surveys. They reported high rates of increased stress (21/23, 91%), depression symptoms (19/23, 83%), sleep deprivation (19/23, 83%), neglect of healthy physical activity (15/23, 64%), neglect of healthy eating habits (14/23, 61%), and delay of own health care (11/23, 48%) since becoming a caregiver, which are comparable with national data on veteran caregivers [20]. Among caregivers enrolled in the workshop, 71% (10/14) completed surveys. In response to questions that correspond to the PARIHS evidence construct, 100% (10/10) reported that they would recommend the workshop to others and that their quality of life had improved (8/10, 80%) or may have improved (2/10, 20%) as a result of what they had learned in the workshop.

Among the local staff, 10 (77%) completed surveys: 71% (5/7) from low-enrollment centers and 83% (5/6) from high-enrollment centers. Describing whether workshop implementation at their center had been a success, all 5 staff members from high-enrollment centers agreed, whereas none of the 5 from low-enrollment centers agreed. Nonetheless, most felt that the BBC workshop had been accepted by caregivers and was supported by research and that they had received useful informational materials for caregivers and educational materials for themselves (Table 3). In contrast, a minority reported having a regional mentor who could assist them or having a system for tracking caregivers.

Table 3. Local staff survey results according to Promoting Action on Research Implementation in Health Services constructs.

PARIHS[a] construct	Survey question	Staff in agreement with statement (n=10), n (%)	Linkages to Table 4 theme and whether survey responses are consistent with Table 4 theme[b]
1. Evidence—caregiver experiences	BBC[c] has been well-accepted by VA[d] caregivers	7 (70)	• Theme 2a: Yes[e]
2. Evidence—research evidence	BBC is supported by research evidence	7 (70)	• Theme 2b: Yes
3. Context—staff resources	Informational materials are available for caregivers and staff to raise awareness about the workshop	7 (70)	• Theme 3b: Yes[f] • Theme 4d: No[f]
4. Facilitation—staff skills and attributes	Resources to educate staff about workshop structure and content are available	7 (70)	• Theme 5a: Partial[g]
5. Facilitation—availability of external facilitator to mentor and assist staff	A regional mentor who can help answer questions or solve problems is available	3 (30)	• Theme 5a: Yes
6. Context—information technology capabilities	An approach used at our facility to evaluate and improve implementation includes a system of tracking which caregivers have been referred to BBC	4 (40)	• Theme 5b: Yes

[a] PARIHS: Promoting Action on Research Implementation in Health Services.

[b] Linkages (including areas of consistency and inconsistency) between quantitative and qualitative results were discussed during our process of integrating stage 1 findings, as described in the Methods section.

[c] BBC: Building Better Caregivers.

[d] VA: US Department of Veterans Affairs.

[e] Caregiver responses to survey questions on the PARIHS evidence construct are described in the text and are consistent with these staff responses, as well as with Theme 2a.

[f] Explanation for both a *yes* and a *no* designation: qualitative results in the text and Table 4 indicate that certain outreach materials, particularly those useful for post-9/11 caregivers, were readily available (and used by staff) during workshop rollout, which is consistent with Theme 3b. However, outreach materials, mechanisms, and contacts for pre-9/11 caregivers and others were insufficient (as summarized by Theme 4d), which explains why this survey finding was felt to be inconsistent with Theme 4d.

[g] Explanation for *partial* designation: qualitative results in the text and Table 4, Theme 5a, explicitly recognize that training was insufficient for many new staff members but, conversely, they also imply that experienced staff (present during the early rollout) were generally satisfied with their training, which explains why this survey finding was determined to be partially consistent with Theme 5a.

Table 4. Qualitative themes on workshop implementation: overarching theme and themes on strengths and weaknesses.

Theme and subtheme	Exemplar quotes	PARIHS[a] construct	Linkages to Table 3 rows
Overarching theme			
1. Importance of outreach and marketing to prompt workshop enrollment	- Local staff, low-enrollment center: "If it was more advertised and marketed, I think that would be good." - Regional leader: "I feel like it's an easy sell. We have the promotional materials to send out." - National leader: "I've learned that it's important to have marketing materials for caregivers. That's a big lesson."	Spans all PARIHS constructs and implementation strengths and weaknesses	N/A[b]
Implementation strengths			
2. Belief in positive impact of workshop encouraged uptake			
2a. Positive caregiver experiences during rollout	- Caregiver: "You learned a lot of really good tools that I use in my daily life. And you could also communicate with the other class members." - Local staff, high-enrollment center: "When the caregivers took the course, I got such positive feedback from them, it made me a believer." - Regional leader: "Anybody that has participated in it has really given lots of positive feedback. And probably the most telling thing is the fact that staff continue to make the referrals."	Evidence—caregiver experiences are positive	Row 1
2b. Value of evidence from prior research[c]	- Local staff, low-enrollment center: "You want something that's, you know, evidence-based." - Regional leader: "The research definitely does matter. Because like I said, you're pitching an additional task to [caregivers] who are super busy."	Evidence—research evidence is convincing	Row 2
3. Successful outreach to some caregiver groups			
3a. Use of stories and testimonials from trusted sources	- Caregiver: "[Caregivers will enroll] if they have good caregiver coordinators that push the program and say, "This is something that you really need to do." Or the therapists, whoever they trust." - Local staff, high-enrollment center: "My suggestion [for other centers] would be short little testimonials of people who've taken the course and it would say, 'See what Mary said about the course.'" - Regional leader: "I always tell people when promoting it—caregivers when they link up they've really enjoyed it."	Evidence—materials help caregiver determine that program is likely to meet their needs; Facilitation—staff have necessary skills	N/A
3b. Multiple contact episodes and materials	- Caregiver: "First I heard verbally about it. Then they sent me a flier regarding it and said, 'Here is what it is – read it and see if this is what you're looking for.' Then he followed up with a phone call. I think the more information, the better." - Local staff, low-enrollment center: "I would say the biggest thing [hindering enrollment] is that we don't have a follow-up plan—a reminder. Because sometimes that reminder helps. To talk about it and you know, give them a little push." - Regional leader: "We've sent out like a large volume of fliers—and I've pitched it to people in person and over the phone and things like that. You can't just do it once. You have to repeatedly send stuff out or bring it up."	Context—staff have sufficient resources; Facilitation—staff have necessary skills	Row 3
Implementation weaknesses and the needs they suggest			
4. Missed opportunities for improved outreach			

Theme and subtheme	Exemplar quotes	PARIHS[a] construct	Linkages to Table 3 rows
4a. Detailed information on workshop content and structure	• Caregiver—who knew about the workshop but had not enrolled: “Provide more actual information on the content, not just a link on the computer.” • Local staff, low-enrollment center: “I don't see how the system works. I would like that. One caregiver was telling me that she didn't feel there was enough information, but without seeing it, I couldn't respond to her.” • Regional leader: “Some of the CSCs[d] do not understand the details. I think it would be helpful to train the coordinators on what actually is in [it]. Because—marketing wise—you're not going to refer people as readily to something that you don't have knowledge about.”	Evidence—caregiver cannot determine if program is likely to meet their needs; Evidence—staff cannot observe program	N/A
4b. Expanded online mechanisms for outreach and enrollment	• Local staff, low-enrollment center: “My suggestion would be a link on the site [portal to electronic health records]—on the same page, if caregivers could just click on right there.” • Local staff, high-enrollment center: “If the general caregivers [caregivers of older, pre-9/11 era veterans] could access it from the caregiver website, that might be really good.” • National leader: “There's a barrier in that you have to pick up the phone and find your CSC. So the recruitment process is interrupted by the fact that it's not a complete online experience, even though the rest of their experience will be online.”	Context—lack of technology tools	N/A
4c. Partnership with communities and community groups	• Only 1 caregiver learned about the workshop through a community group: “Crossroads [VA-funded nonprofit] is where he goes once a month. They just said, ‘Well, try this and maybe they can help you.’ So I picked up a brochure.”[e] • Only 1 local staff member, at a high-enrollment center, described doing outreach to the community: “I do community outreach events where I put out that fact sheet.”[e] • National leader: “We have tremendous access to community-based organizations that are working with caregivers all over the country. And we've wanted to promote the program through that [but have not been able to].”	Context—limited awareness among external networks and communities	N/A
4d. Increased outreach to certain caregiver groups and their health care teams	• Pre-9/11 era caregiver: “I don’t think it’s widely known that you have this. None of the doctors told me about it.” • Local staff, low-enrollment center: “I definitely think outreach and mailers could be made more regularly to the general [pre-9/11 era] caregivers. It just kind of goes by the wayside.” • National leader: “One of the goals is to increase the number of general [pre-9/11 era] caregivers in the program. I don't think the coordinators have as much contact with them.”	Context—limited awareness among some stakeholder groups; Context—limited staff resources and time	Row 3
5. Missed opportunities to support staff in outreach efforts			

Theme and subtheme	Exemplar quotes	PARIHS[a] construct	Linkages to Table 3 rows
5a. Training and mentoring for new staff	• Local staff hired after the rollout began, low-enrollment center: “I had no one to collaborate with, no one to talk to. I think new CSCs need to be more knowledgeable of the program.” • Regional leader: “The initial rollout was either really early in my assuming responsibility for this role or shortly thereafter. Initially it flew right past me.”	Facilitation—lack of training and mentoring from experts	Rows 4 and 5
5b. Improved data management capabilities to • Generate outreach contacts • Track caregivers • Target follow-up outreach	• Local staff, low-enrollment center: “A quarterly flier might just remind people of the opportunity to participate in this program. At the national level can they generate mailers?” • Local staff, high-enrollment center: “It would be very beneficial to have a way to pull up the list of people that we have referred that have never taken any steps forward, so that we can hit a button and they get a reminder email.” • Regional leader: “The website where you can see where the caregiver is in the process, I don't always check it. It probably would be helpful. But you don't always have the time to check individually.” • Regional leader: “Once we make referrals, we’re not involved. Unless there was some sort of process where if the caregiver didn’t follow through, [workshop organizers] came back to the coordinator and said, ‘Will you see if they're still interested?’ There’s no mechanism for that.”	Context—lack of information technology capabilities	Row 6

[a] PARIHS: Promoting Action on Research Implementation in Health Services.

[b] N/A: not applicable.

[c] Caregiver participants did not make comments about research evidence.

[d] CSC: caregiver support coordinator.

[e] These are not exemplar quotes. They are the only cases in which respondents described using these outreach mechanisms and thus highlight their relative absence from use.

Interview Results

During interviews, participants from low-enrollment centers identified fewer implementation strengths and a greater number of weaknesses than those from high-enrollment centers. However, both groups generated similar implementation themes. As the analyses identified common themes, we report findings from low- and high-enrollment centers together.

Theme 1: Importance of Outreach and Marketing to Prompt Workshop Enrollment

We identified an overarching, general theme on the need for effective outreach and marketing to promote workshop enrollment and thereby implementation success (Table 4, theme 1). This theme emerged from comments on implementation strengths and weaknesses and spanned all PARIHS constructs. All participant groups (caregivers, staff, and leaders) emphasized this need:

> *They need to spread the information. Blast it out. Just get the word out.* [Caregiver]

In addition, staff and leaders used marketing language (eg, “market,” “advertise,” “sell,” “promote”) to describe characteristics of the rollout, even in cases where they were not reaching as many caregivers as they would have liked. Of note, none of our survey questions were designed to elicit input on outreach and marketing efforts other than the questions for staff on *informational materials*, as described above.

Respondent feedback also generated themes on specific implementation strengths and weaknesses. Identified themes map onto the PARIHS constructs of evidence, context, and facilitation. They include 2 themes on implementation strengths and 2 on implementation weaknesses, each with respective subthemes.

Theme 2: Belief in Positive Impact of Workshop Encouraged Uptake

All participant groups described an overall positive impact of the workshop. In doing so, they commented on the experiences, needs, and preferences of caregivers as well as research evidence. Both forms of *evidence* were highlighted as important to successful implementation because they made the workshop attractive (to caregivers and staff) and easier to promote.

Subtheme: Positive Caregiver Experiences During Rollout

Caregivers, staff, and leaders identified the workshop as a positive experience for most caregivers (Table 4, subtheme 2a). Caregivers reported that it met expectations of improving their skills and social support, and staff reported receiving similar feedback directly from their local caregivers:

> *In the hallways, they'll stop me saying, “I've been using that online support group, it's really good.”* [Local staff, low-enrollment center]

All groups valued such feedback as evidence of workshop effectiveness.

Subtheme: Evidence From Prior Research

Local staff and regional and national leaders expressed that they also valued research evidence as a motivating factor for their implementation efforts (Table 4, subtheme 2b):

> *Research support matters because it's a waste of time if it's not proven to be effective. And the last thing we want to do is waste caregivers' very precious time.* [Local staff, high-enrollment center]

Research evidence assured them that the workshop was worthwhile for busy caregivers. Caregivers did not mention research evidence in their comments.

Theme 3: Successful Outreach Consisted of Trusted Stories and Multiple Contacts

Another noted strength of the rollout was the achievement of effective outreach to some caregiver groups—specifically, caregivers of younger veterans from the post-9/11 era. These caregivers were best known to local caregiver support coordinators because an act of Congress in 2010 enabled many of them to receive a caregiving stipend from the VA, but payment required quarterly contact with coordinators. In contrast, caregivers of older, pre-9/11 era veterans were not eligible for the stipend, making them less likely to come to the attention of coordinators. Among the post-9/11 caregivers for whom outreach efforts were more successful, certain strategies were identified as important to that success.

Subtheme: Use of Stories and Testimonials From Trusted Sources

Comments from caregivers, local staff, and leaders highlighted that outreach was more effective if it involved caregiver stories and testimonials from trusted sources (Table 4, subtheme 3a):

> *The person who I talked to gave me all the caregiver feedback about its friendly atmosphere. It was a good fit.* [Caregiver]

This type of information was characterized as trustworthy and relatable for caregivers. Knowing that the workshop was helpful to other caregivers prompted them to try it for themselves.

Subtheme: Use of Multiple Contact Episodes and Materials

Caregivers, staff, and leaders described successful outreach as requiring multiple outreach contacts (*touches*) and a variety of formats, for example, in person, fliers, emails, and phone calls (Table 4, subtheme 3b):

> *They teach us in sales that sometimes it takes quite a few touches to convince somebody to even take a look at what you're trying to sell them. We're trying to sell them on the idea of doing this course.* [Local staff, high-enrollment center]

These repeated contacts reminded caregivers that they could enroll in the workshop when they were at a place in their busy lives to be ready and able to do so.

Theme 4: Missed Opportunities for Improved Outreach Limited Workshop Uptake

Caregivers, local staff, and leaders also identified a number of implementation weaknesses. They described missed opportunities for providing effective outreach to caregivers overall and to particular caregiver subgroups, such as caregivers of older, pre-9/11 era veterans, and suggested the need for implementation changes described in the subthemes below.

Subtheme: Detailed Information on Workshop Content and Structure

Some caregivers felt that a lack of detailed information about the workshop on outreach materials inhibited their interest in the program (Table 4, subtheme 4a). Local staff recognized a parallel issue—that their lack of detailed information on the workshop or opportunity to observe it for themselves limited their understanding of it, which constrained their ability to market it:

> *It would be great if we could actually see the information that the caregivers are receiving. Because we could give more feedback on it to caregivers that way—on the modules and what it all entails.* [Local staff, high-enrollment center]

Regional leaders had similar insights on the need to improve staff familiarity with the workshop.

Subtheme: Expanded Online Mechanisms for Outreach and Enrollment

Given that the workshop was web-based, many caregivers were confused by the minimal amount of online information about it and the absence of an online enrollment mechanism. They found these to be barriers to enrollment:

> *When I go on the VA website, there's not too much on the web about it. You got to call this number to find out who the coordinator is, then get in contact. I mean it's so much work to get there.* [Caregiver]

Local staff also desired online options for caregivers to receive information and enroll, particularly caregivers with whom they had little ongoing contact (eg, pre-9/11 era caregivers; Table 4, subtheme 4b). Some leaders agreed that the lack of online mechanisms for outreach and enrollment was an implementation weakness.

Subtheme: Partnership With Communities and Community Groups

Caregivers reported participating in or seeking support from a variety of community groups and community networking sites, many of which were well-established at local, regional, and national levels, such as Veterans of Foreign Wars, Hearts of Valor, the Wounded Warriors Project, Operation Homefront, and Facebook groups for veteran wives. However, there is little evidence to suggest that these community groups were engaged as partners in workshop outreach efforts. Only 1 caregiver reported receiving information on the workshop from a community organization and, in this case, it was a VA-funded nonprofit (Table 4, subtheme 4c). Other caregivers reported hearing about the workshop by word of mouth from veteran spouses who had completed the workshop. Caregivers identified the lack of effective outreach in the community as a missed opportunity:

> *I didn't even know it existed. I had to find it out through somebody I work with. People should know*

> *that this program exists and not just stumble upon it.* [Caregiver]

Similarly, among local staff and regional leaders, only 1 person described performing outreach to community groups. Some leaders recognized community outreach as an important component missing from existing outreach efforts.

Subtheme: Increased Outreach to Certain Caregiver Groups and Their Health Care Teams

Caregivers of older, pre-9/11 veterans expressed insight into the limited outreach efforts made to reach them (Table 4, subtheme 4d). Local staff and leaders made parallel comments about the need to improve targeting of these caregivers as well as other caregiver subgroups (eg, male caregivers of female veterans). They suggested working with health care teams and other support services that commonly interact with older veterans and their caregivers—for example, those in primary care, home health, mental health, respite care, physical and occupational therapy, transportation, and social work outside of the CSP:

> *Partner with the home-based primary care, community-based care, and the PACT [patient-centered medical home] teams. Because that's where you are going to get your older population.* [Regional leader]

Theme 5: Missed Opportunities to Support Staff in Outreach Efforts

Many staff and some regional leaders reported that they did not have the support necessary to perform or maintain effective workshop outreach and indicated the need for improvements described in the subthemes below.

Subtheme: Training and Mentoring for New Staff

Staff who attended the original webinar training on the workshop and rollout gave overall positive feedback (although many still desired to observe the workshop itself, as described above). However, some new staff who began as coordinators after the initial training reported a lack of knowledge, skills, and mentoring. This undermined their motivation and ability to promote the workshop (Table 4, subtheme 5a). Even experienced staff observed this as a problem:

> *I think another national training needs to happen, so that the newer coordinators will see it. Because then I think that they would utilize it.* [Local staff, high-enrollment center]

Leaders also recognized the need for new staff to receive timely and thorough training and mentoring.

Subtheme: Improved Data Management Capabilities

Staff and regional leaders reported having inadequate data management capabilities for many outreach-related activities (Table 4, subtheme 5b). They described ad hoc, inefficient, or nonexistent processes:

> *I think we did have an internal spreadsheet going at one time, but I don't think we've followed up with that.* [Local staff, low-enrollment center]

Staff desired efficient approaches to data processing, especially if they could be performed at the level of the national VA *to generate regular, multiple outreach contacts* to caregivers at their local centers. Second, staff and regional leaders noted that they lacked standardized tools *to track caregivers* along the outreach-to-enrollment pathway. Some staff improvised their own local tracking tools but had trouble maintaining them. Third, the national workshop enrollment database was not integrated with local databases, making it time-consuming to access and infrequently used. These poor data management capabilities undermined the ability of staff *to target follow-up outreach* to specific caregivers. Although local staff felt these deficiencies most acutely, regional leaders also recognized them.

Divergent and Lone Comments

We identified divergent comments from caregivers and staff. Two caregivers expressed that their workshop experience would have been improved by having the other caregivers in their workshop be more like them, according to certain characteristics. One desired to be in a group with younger caregivers, whereas the other wanted to be in a group with caregivers whose care partners had the same medical condition as her care partner. Both recognized beneficial aspects of the existing workshop. A local staff member was supportive of the web-based workshop as a valuable option for caregivers but felt that in-person programs were more beneficial if caregivers could attend them. Finally, another staff member desired to have a Spanish workshop for Spanish-speaking caregivers.

Integrated Findings on Implementation Strengths and Weaknesses

Our study team, advisory board, and a representative from VA CSP leadership determined that the survey and interview findings were consistent with a number of implementation strengths—specifically, that caregiver experiences with the workshop were positive, research evidence supported its use, and staff received some useful outreach materials and resources that helped them support the rollout (Table 3, last column, and Table 4, last column). Findings also converged on implementation weaknesses—that outreach materials and approaches were insufficient in multiple areas, certain staff and regional leaders did not receive necessary training or mentoring, and that data management capabilities were inconsistent or lacking. When we noted areas of apparent inconsistency between quantitative and qualitative results (Table 3, rows 3 and 4), we discussed and noted potential explanations (Table 3, footnotes f and g).

Recommended Strategies for Improving Workshop Uptake

On the basis of the integrated findings, we identified multiple strategies likely to improve workshop uptake and recommended them to VA leadership in the form of a report. The strategies included investment in robust outreach and marketing capabilities, tailoring outreach strategies to all key stakeholder groups and subgroups, use of stories, testimonials, repetition, details, and diverse delivery options in marketing campaigns, recurrent training sessions and mentoring for new staff, and comprehensive data management and reporting capabilities (Table 5).

Table 5. Strategies identified as likely to improve workshop uptake and whether US Department of Veterans Affairs adopted them.

Strategies	Further details	Whether VA[a] adopted
Invest in outreach and marketing capabilities	- May need to contract out	Yes
Tailor specific outreach strategies to all key stakeholder groups	Groups include the following: - Potential workshop participants—may require identifying and targeting important subgroups of caregivers - Local implementation staff with primary responsibility for implementing workshop (ie, caregiver support coordinators) - Other staff who interact with caregivers or their care partners - Community groups	Partially
Use campaigns that are personal, repeated, include workshop details, and have diverse delivery options	- Use personal stories and testimonials—from peers (ie, caregiver peers and staff peers) - Repeat outreach contacts over time—with all key groups, not just caregivers - Include adequate information on workshop details - Enable diverse delivery mechanisms—both electronic and nonelectronic	Yes
Conduct recurrent training and mentoring for new staff	- Is especially important for new staff at locations with no other experienced staff on-site	Yes
Perform comprehensive, ongoing data management and reporting	- To support and track outreach efforts, enrollments, and follow-up on unsuccessful enrollments	Partially

[a] VA: US Department of Veterans Affairs.

Stage 2: Findings on New and Enhanced Implementation Strategies

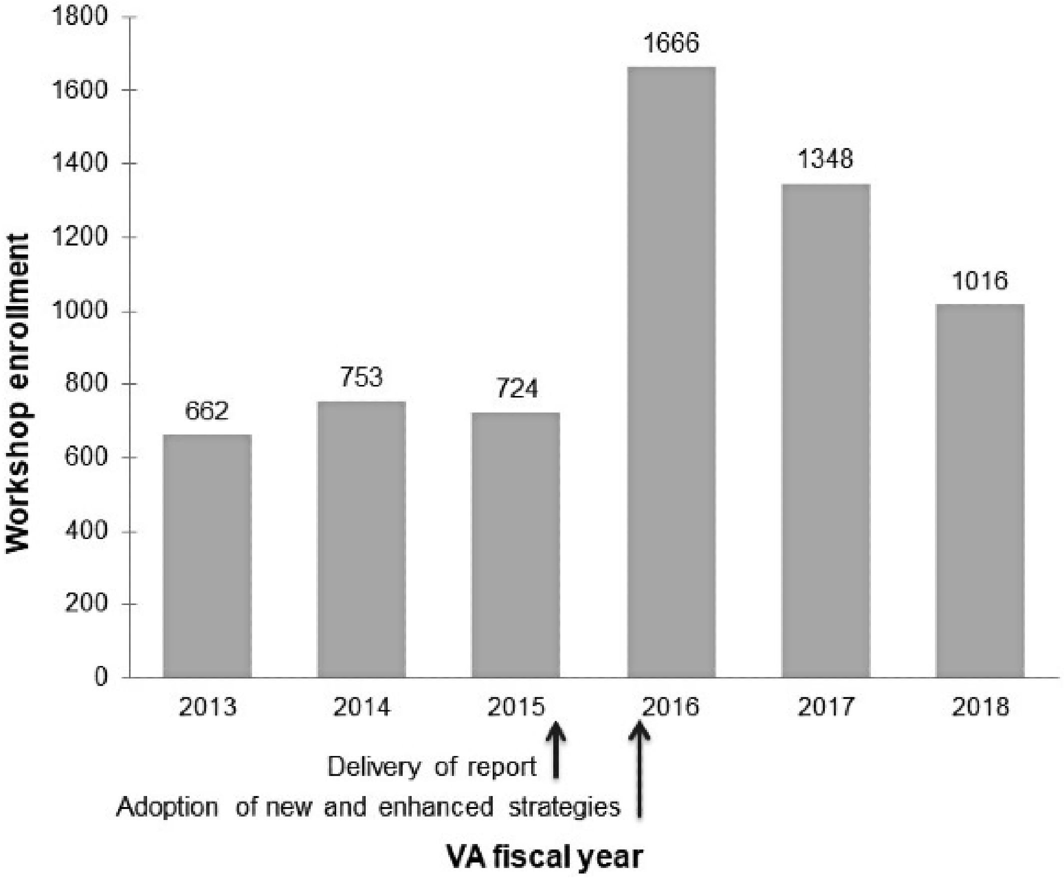
During follow-up interviews in 2018, VA leaders identified multiple implementation changes made in response to stage 1 findings and recommendations (Table 5, last column; see Multimedia Appendix 5 for additional details). The VA CSP contracted with a new organization with greater marketing expertise to administer the workshop, and together they developed and adopted both new and enhanced outreach approaches. They tailored new marketing materials and outreach to implementation staff (eg, new monthly newsletters for caregiver support coordinators), some VA nonimplementation staff and services in close contact with pre-9/11 veterans and their caregivers (eg, primary care social work, home health nursing), and some veteran service organizations and communities (eg, through presentations and press releases). They highlighted stories for caregivers in multiple new ways (eg, videos, quotes, photographs) and did the same for implementation staff (eg, caregiver support coordinators sharing their *BBC stories* with each other in videos or listservs). Outreach campaigns incorporated more repeat *touches* with both groups (eg, regular email invitations to caregivers), diverse forms of delivery (eg, social media posts and phone-based blurbs) and more detailed information on workshop structure and content. For instance, leadership approved and built a demonstration workshop so that staff could learn about workshop details firsthand and then pass the information to the caregivers with whom they worked. Expanded materials for new staff include recurring national training and reminders about how to access outreach resources. Finally, the workshop platform began regularly to email staff with reports on the enrollment status of caregivers at their respective medical centers.

Leaders also reported that they were unable to address some implementation weaknesses. The CSP website, which was managed by a different VA entity with limited funding, was not updated to include more information on the workshop and links to it. The VA national database of registered caregivers remained unlinked from the workshop database, and so it could not be used to generate workshop outreach invitations or other communications to caregivers. Finally, there was no plan to develop a workshop in Spanish.

Longitudinal Workshop Enrollment

Visual inspection of longitudinal enrollment data indicates a possible impact of the new and enhanced implementation strategies. During the initial BBC rollout period (2013 to 2014) and the implementation evaluation period (2015), annual enrollment was approximately 700 caregivers per VA FY (Figure 1). Following implementation changes made in late FY 2015 and early FY 2016, annual workshop enrollment increased. In FYs 2013 to 2015, cumulative enrollment was 2139, which rose to 4030 in FYs 2016 to 2018. Over 6 years, cumulative BBC enrollment reached 6169, which equates to 12% of approximately 50,000 caregivers registered with the VA.

Figure 1. Workshop enrollment, 2013-2018. US Department of VA fiscal years encompass October through the end of September the following year. The study team reported integrated study findings and recommended new and enhanced strategies likely to improve workshop uptake to VA Building Better Caregivers national leaders in the late fiscal year 2015. In late 2015 and early 2016, the VA adopted a number of these recommended implementation strategies. VA: Veterans Affairs.



Discussion

Principal Findings

This study expands the limited implementation science literature on best practices for health systems to use when implementing web-based psychoeducational programs [13,31]. In our evaluation of the BBC workshop rollout among VA centers nationwide, we identified implementation strengths and weaknesses, including belief in the positive impact of the workshop, use of some successful outreach approaches for caregivers, and missed opportunities to improve outreach and to support both new and experienced implementation staff. On the basis of these findings, we identified and recommended to VA leadership new or enhanced implementation strategies likely to improve workshop uptake—specifically, increased investment in outreach and marketing capabilities, tailoring outreach strategies to key stakeholder groups and subgroups, use of campaigns that are personal, repeated, detailed, and have diverse delivery options, recurrent training and mentoring for new staff, and comprehensive data management and reporting capabilities to support staff implementation efforts. We determined that the VA adopted many of these strategies and, in the years following adoption, national BBC enrollment increased.

Limitations

Our evaluation has a number of limitations. We initiated this after the workshop rollout was underway, rather than prospectively. At the same time, this enabled us to quickly identify low- and high-enrollment sites for inclusion in the evaluation. Our evaluation is also limited to a single health care system. Nonetheless, the VA health care system is the largest integrated health care system in the United States and, as such, it has numerous medical centers. These demonstrated variation in implementation success as well as geography and catchment size, which enhanced the robustness of our evaluation. The VA workshop is available only in English, which precludes use by caregivers who have limited English proficiency.

Comparison With Prior Work

Among caregiver programs, many have been funded as research projects but few, if any, have been the focus of published implementation evaluations. A recent systematic review identified 17 studies of web-based caregiver programs focused on education, health, and well-being [7]. However, we were unable to identify any with a published implementation evaluation. Among web-based caregiver programs identified by other means [32, 33], no implementation evaluations were found. Finally, we identified a process evaluation of a web-based intervention to support frail older adults that, at their discretion, could also involve their caregivers but was not designed for caregivers [34]. Thus, it remains to be seen how results from the current implementation evaluation may compare with findings from implementation evaluations of other web-based psychoeducational programs for caregivers.

Among caregivers who care for military veterans, US VA caregivers may be unique in the amount of support they receive. Since 2010, the VA and VA CSP have received substantial federal funding for caregiver programs and research. This has enabled the US VA and VA investigators to develop the BBC workshop and other VA caregiver programs (eg, Resources for Enhancing All Caregivers Health [REACH] VA); assess such programs for efficacy; fund their implementation; and in the case of this study, evaluate their implementation [22,35]. We are unaware of funding opportunities on the same scale in other countries. This may explain why evidence on the efficacy and implementation of veteran caregiver programs outside the United States is limited. In an environmental scan of resources (defined as programs and services) for families of veterans with operational stress injuries, investigators identified 42 non–United States resources but concluded, "Information on evaluation and evidence for resources is limited" [36]. To our knowledge, none were the focus of an implementation evaluation.

If one examines web-based or technology-based interventions for patients rather than caregivers, implementation data remain sparse [4,31,34,37,38]. A 2013 systematic review of studies of web-based patient self-management workshops determined that 87% "did not describe any measures taken to sustain the tested programs past designated study time periods" [31]. The remainder reported on the number of participants reached but not the strategies that were successful or unsuccessful in achieving participation. Not surprisingly, a similar 2013 review of web-based interventions for psychosocial health determined that issues of reach and adoption of web-based interventions were a crucial area for further research [4]. Four years later, a 2017 review of 268 randomized controlled trials described a proliferation of evidence-based self-guided internet health programs but concluded, "Unfortunately, most of the Internet delivered health interventions that were efficacious through RCTs were not available after the conclusion of the trials" [3] and we could not identify implementation evaluations of these same trials. Finally, in the case of eHealth services broadly defined (eg, telehealth, patient portals, web-based decision aids), others have identified a taxonomy of implementation barriers and facilitators from multiple studies and expert input [11], but there are few follow-up studies to determine whether making implementation enhancements suggested by the taxonomy does indeed boost uptake. Thus, experts have highlighted implementation research as the crucial next step in spreading the benefits of evidence-based digital health interventions to all those who might benefit [39].

This evaluation suggests that implementation research can help boost uptake of web-based psychoeducational interventions for caregivers and perhaps others. Among the results, we were most surprised by the prominence of findings related to outreach and marketing. The implementation science literature has not emphasized these concepts to any great extent, although this may be changing. This evaluation was performed before the publication of the most recent iteration of the PARIHS implementation framework known as the i-PARIHS framework [40]. i-PARIHS adds a new construct, "recipients" to existing constructs (evidence, context, and facilitation) and defines it as "the people who are affected by and influence implementation [of the intervention] at both the individual and collective team level" [40]. In this study, we found implementation could be strengthened when specific groups and subgroups of *recipients* (eg, caregivers, staff, community organizations) were explicitly identified for tailored outreach campaigns, which aligns with this new PARIHS construct. Implementation scientists have started to note that marketplace principles and storytelling may contribute to implementation success [41,42]. Similarly, the recent report on a US National Cancer Institute implementation accelerator program concluded that "researchers can benefit from learning the 'language' of business" when "trying to move their research from the lab to the real world" [43].

Conclusions

In this mixed methods implementation evaluation of the web-based psychoeducational BBC workshop for US veteran caregivers, we identified initial implementation strengths and weaknesses as well as multiple strategies likely to improve workshop uptake—including strong investment in outreach and marketing capabilities, tailoring of specific outreach strategies to all key stakeholder groups, use of outreach campaigns that are personal, repeated, detailed, and have diverse delivery options, ongoing training and mentoring for new implementation staff, and comprehensive data management and reporting capabilities. Upon follow-up assessment, we determined that the VA enhanced or newly adopted a number of these recommended strategies nationally and that workshop enrollment subsequently increased. Other health systems may want to deploy these strategies when implementing their web-based programs.

Acknowledgments

VY conceived and designed the study, designed data collection instruments, interviewed participants, performed qualitative analyses as part of the qualitative evaluation team, interpreted findings, wrote the manuscript, and guaranteed the integrity of the work as a whole. RG (deceased) helped to design the interview guides and modify the survey, interviewed participants, performed qualitative analyses as part of the qualitative evaluation team, contributed to interpretation of findings, managed the study, and revised an earlier draft of the manuscript critically for important intellectual content. AN helped design the interview guides, interviewed participants, performed qualitative analyses as part of the qualitative evaluation team, contributed to interpretation of findings, and revised the manuscript critically for important intellectual content. LO helped design the interview guides, performed caregiver participant recruitment, managed study data, and revised the manuscript critically for important intellectual content. CK contributed to the design of the study and interview guides, performed qualitative analyses as part of the qualitative evaluation team, and revised the manuscript critically for important intellectual content. RT contributed to the design of the study and interpretation of findings and revised the manuscript critically for important intellectual content. ND contributed to the acquisition of data and interpretation of findings and revised the manuscript critically for important intellectual content. MK contributed to the acquisition of data and interpretation of findings and revised the manuscript critically for important intellectual content. SA contributed to the design of the study and the interpretation of findings and revised the manuscript critically for important intellectual content.

This study was supported by a grant from the VA Quality Enhancement Research Initiative (Project 14-195-1). The funder was not involved in the design of this study, the collection, analysis, and interpretation of the data or the writing of the manuscript. The views expressed herein are those of the authors and do not necessarily reflect the position or policy of the US Department of Veterans Affairs.

Abstract

Background: Customer churn is the rate at which customers stop doing business with an entity. In the field of digital health care, user churn prediction is important not only in terms of company revenue but also for improving the health of users. Churn prediction has been previously studied, but most studies applied time-invariant model structures and used structured data. However, additional unstructured data have become available; therefore, it has become essential to process daily time-series log data for churn predictions.

Objective: We aimed to apply a recurrent neural network structure to accept time-series patterns using lifelog data and text message data to predict the churn of digital health care users.

Methods: This study was based on the use data of a digital health care app that provides interactive messages with human coaches regarding food, exercise, and weight logs. Among the users in Korea who enrolled between January 1, 2017 and January 1, 2019, we defined churn users according to the following criteria: users who received a refund before the paid program ended and users who received a refund 7 days after the trial period. We used long short-term memory with a masking layer to receive sequence data with different lengths. We also performed topic modeling to vectorize text messages. To interpret the contributions of each variable to model predictions, we used integrated gradients, which is an attribution method.

Results: A total of 1868 eligible users were included in this study. The final performance of churn prediction was an F1 score of 0.89; that score decreased by 0.12 when the data of the final week were excluded (F1 score 0.77). Additionally, when text data were included, the mean predicted performance increased by approximately 0.085 at every time point. Steps per day had the largest contribution (0.1085). Among the topic variables, poor habits (eg, drinking alcohol, overeating, and late-night eating) showed the largest contribution (0.0875).

Conclusions: The model with a recurrent neural network architecture that used log data and message data demonstrated high performance for churn classification. Additionally, the analysis of the contribution of the variables is expected to help identify signs of user churn in advance and improve the adherence in digital health care.

Introduction

Customer churn prediction is one of the most important concerns for almost every company. If customers leave, then sales are reduced, and new customers are needed to replace the previous ones [1]. However, the cost of attracting new customers is 5- to 10-times higher than the cost of retaining customers [2]; therefore, it is much more effective to predict potential churn and prevent these customers from leaving by utilizing promotions or marketing.

Digital health care refers to public health services ranging from simple weight management to professional medicine using mobile devices [3]. With smartphone use becoming more common, the digital health care industry is growing, and numerous health-related apps have been launched [4]. This has provided many people with convenient access to digital health care; however, for them to achieve actual improvements in health, they need to use the apps consistently [5,6]. Therefore, the prediction of churn and the retention of digital health care service customers have significant implications for companies and for users.

Because of the importance of predicting customer churn, studies [7,8] have been performed. However, these studies have generally been conducted using statistical methods and time-insensitive machine learning techniques (eg, decision tree, logistic regression, or support vector machine) [7], by which some information can be lost during the preprocessing sequence [8]. Therefore, a model structure that can accept time-series patterns is necessary.

Many studies have used structured information about customers, which is generally stored in customer relationship management databases [9]. However, more customer text data are becoming available, such as online posts and messages, and it is known that analyzing text data improves predictive performance in customer churn problems [10,11].

We aimed to apply a recurrent neural network structure to leverage time-series patterns in user lifelog data and text message data to predict user churn for digital health care apps. We also aimed to examine the impact of time-series data on model performance and whether the presence of text data affects the performance of churn prediction.

Methods

Health Care App

This study was conducted using data from Noom (Noom Inc), a global digital health care app that provides lifestyle-related functions, such as food logs, exercise logs, weight logs, in-app group activities, and in-app articles. Users are encouraged to log their food intake, exercise every day, and record their weight every week [12]. Users of this digital health care service can also send messages to personal coaches to ask questions about dietary intake, exercise, mindset, or program descriptions. Personal coaches offer feedback to users, in the form of praise, emotional support, encouragement, and validation, based on the user's entries [12].

Study Design

This study predicted customer churn based on lifelog data provided during the customer’s use period. Both paid and free services are available in this digital health care app, and the study defined customers who were refunded for their paid services as churn users.

We received anonymized and unidentified payment information and log data from the company for Korean users only. User data were randomly selected among users who had service payment records between January 1, 2017 and January 1, 2019. Users can select a program lasting 4, 8, 16, or 24 weeks; we limited our analysis to the 16-week program because the largest number of customers chose this period. Additionally, the service use period of the program varied depending on the date of payment and whether the users churned; therefore, we used only log data corresponding to each user’s paid service period for analysis.

Because the proportion of customers who request a refund is generally very small compared with the proportion of total users, the same ratio of retained users was extracted to match the number of churn users to address the problem of data imbalance associated with machine learning [13]. First, users who cancelled their subscriptions, with the refund date recorded, were selected. If their refund occurred after the end of the 16-week program, users were considered retained users and were excluded from the churn user group. The paid program includes a trial period lasting 7 days; during that time, users can request a refund after the initial payment. Therefore, users who received refunds during the trial period were excluded from the churn group because data for fewer than 7 days are insufficient for analysis reliability and generalization. Finally, 934 users were included as the churn group, and 934 retained customers were randomly selected for inclusion as the retained group; the 2 groups were equally matched with respect to gender [14].

This study was approved by the institutional review board (2017-1253) of the Asan Medical Center. The need for informed consent was waived because this study used routinely collected log data that were anonymously managed at all stages, including during data cleaning and statistical analyses.

Model Structure

The overall predictive model structure was designed to include both time-variant and time-invariant inputs. Inputs that occur over time include lifelog data such as step records, daily weight measurement records, diet intake records, and user text messages. Inputs that were considered constant included age, sex, initial BMI, or target BMI of each user (Figure 1).

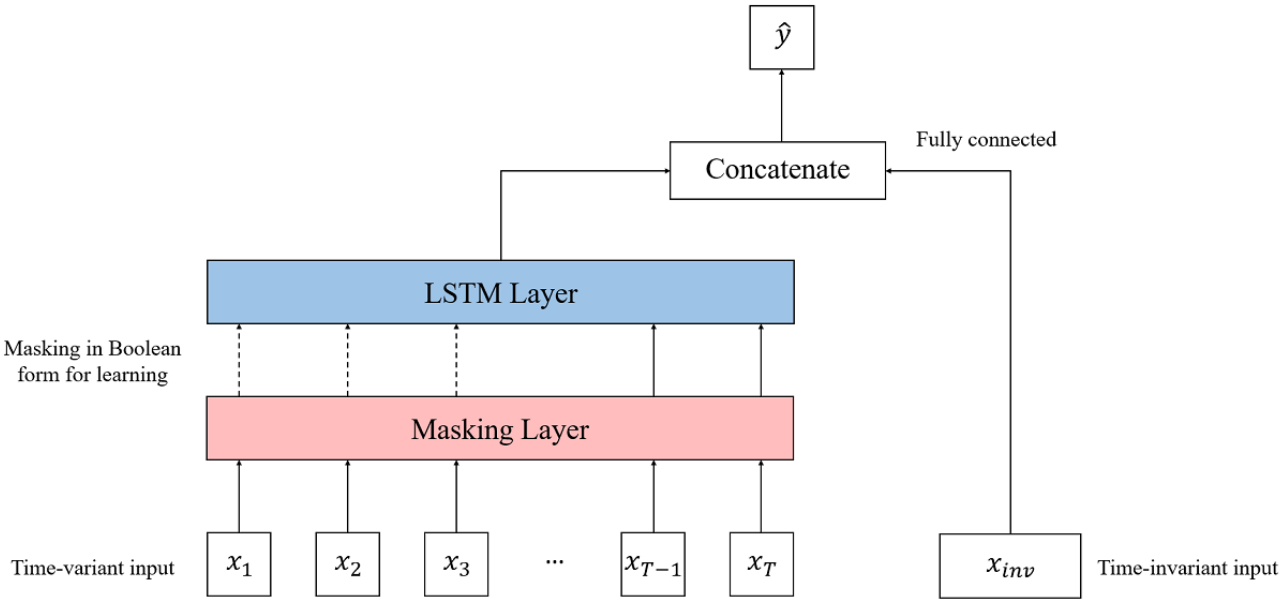
The time-variant node used a long short-term memory structure, which belongs to the recurrent neural network family and is good for processing time-series data. Long short-term memory was developed to solve the vanishing gradient problem that can occur when training a basic recurrent neural network [15,16]. Long short-term memory has a memory cell that contains a node with a self-connected recurrent edge of a fixed weight, thereby ensuring that the gradient can exist over long time steps without vanishing or exploding [17].

Long short-term memory, as in other recurrent neural network-based models, should have the same sequence length input for time; therefore, the time steps of every sample need to be adjusted to ensure that they are the same. The period of service use was constant for retained users; however, for those in the churn group, the period of service varied depending on the time of departure of the user. Therefore, zero padding was used to lengthen the service period data of the churn group to 16 weeks.

One possible critical problem is that the day data of churn users are padded with zeros. Another is that the actual existing data of churn users are relatively short compared with the data of the retained users. If our algorithms notice that part of the sequence is padded with zeros (ie, in the case of churn users), then the problem of leaking the actual labels occurs. A masking layer was added to keep the model unaware of the length of the input sequence. The masking layer produces a Boolean-type tensor for learning whether to use certain values or to ignore them in downstream tasks, and it is used to handle time-series data of different lengths [18].

After padding and masking, time-variant inputs were processed in the long short-term memory layer and the outputs of the layer were concatenated with the time-invariant inputs. Finally, binary classification of the churn was performed.

Figure 1. Overall model architecture. LSTM: long short-term memory.



Text Message Preprocessing

The Noom app provides a function for users and coaches to communicate with each other through text messages. The messages that users receive from coaches can vary depending on their assigned coach; therefore, only messages sent by users were included in this study. User intentions can be more directly inferred from text messages than from log data. To input text message data in the model, the messages were vectorized. Although there are many advanced word-level and sentence-level embedding techniques, topic modeling with latent Dirichlet allocation was used in this study.

Topic modeling assumes each document is a set of random topics and probabilistically presents the importance of the topics and words in the document [19]. Latent Dirichlet allocation was used to estimate the probability that a word corresponds to a particular topic and the probability that a particular topic exists to find the topics in each unstructured document [20]. After topic modeling, each topic name was labeled as intended by the researcher (ie, the name of the topic is not determined by any criteria, but rather by discretion), taking into account the distribution of words corresponding to each topic. Topic modeling has the advantage of easy implementation and intuitive interpretation by examining the proportion of topics in sentences. For each text message, topic modeling was conducted to demonstrate the distribution of the topic proportion of each message. Additionally, since one person could send multiple messages during 1 day, the means of topic vectors was calculated to check the overall topic of the day, and the maximum of the vectors was taken to ensure that important topics that do not appear frequently were not diluted in the average.

Although topic modeling is popular because it is simple to use and easy to understand, there is a limitation: researchers must determine the optimal number of topics present in the documents [21]. This is not a serious problem if the exact number of topics is known, but it is very difficult to select the optimal number of topics without prior knowledge. To solve this problem, the optimal number of topics was determined using the coherence score, which calculates the similarity between the words included in the topic and calculates whether the topic consists of words that have semantic similarity [22].

Interpretation Method

Identifying signs of churn in advance is extremely important for a company; however, because of its nested nonlinear structure, most deep learning models, including our model, are black boxes that, despite their good performance, do not provide information regarding the basis of the predictions [23]. To compensate for this uninterpretability, integrated gradients, which are part of an attribution method, were applied.

Attribution methods produce explanations of an analytic model by assigning an attribution value (relevance or contribution) to each input feature [24]. We used integrated gradients—a final prediction is calculated by multiplication of each variable and coefficient, and the output of the model is also a product of inputs and gradients in the deep learning structure, similar to linear regression [25]. The integrated gradients method was designed to improve the simple gradient approach, which does not satisfy implementation invariance (ie, the attributions are always identical for 2 functionally equivalent networks). Integrated gradients attempt to capture the effects of nonlinearities by computing the gradient along a line between the input data and given reference baseline data [26]. The integrated gradient of the dimension i is defined as follows:

where

which represents a deep neural network function; $x \in R^n$ represents the input; and $x' \in R^n$ represents the baseline data (eg, zero-embedding vector for text neural network) [27]. Using this method, we can examine the effect of each variable on the final output of the model; to explain the effect of each variable on the model, we investigated the average value of the integrated gradients for each variable.

Model Evaluation

During the model performance evaluation, we compared the performance from 2 perspectives: (1) how the performance of the model changes as data close to the point of churn (or retention) is determined at the last date, with some daily data excluded sequentially from the end of the period and (2) the performance differences in the model depending on the data regarding the presence of the text message vectors at every time point. Classification accuracy, F1 score, and area under the receiver operating characteristic curve were calculated.

This study was implemented with Python programming language (version 3.6.8). Data preprocessing procedures related to topic modeling were implemented using the gensim package (version 3.8.3). All neural network modeling including long short-term memory and masking layer were implemented using TensorFlow (version 1.14.0) and Keras (version 2.3.1).

Results

Baseline Characteristics

A total of 1868 eligible users (934 churn and 934 retained), were included in this study. The churn and retained groups showed no statistical differences in gender (*P*>.999) and age (*P*=.20). Both groups comprised mostly women (both groups 825/934, 88.3%), and the mean age was approximately 31 years. The initial BMI and target BMI were calculated based on the height, initial weight, and weight targeted by service use, and both showed no statistically significant differences (*P*=.41 and *P*=.19, respectively). Statistically significant differences were found for the total service period (*P*<.001) and the number of input days for meals (*P*<.001), messages (*P*<.001), walking (*P*<.001), and weight tables (*P*<.001), which are time-variant log data (Table 1).

Table 1. Demographic characteristics.

Variables	Churn users (n=934)	Retained users (n=934)	*P* value
Gender, n (%)			>.999
Female	825 (88.3)	825 (88.3)	
Male	109 (11.7)	109 (11.7)	
Age (years), mean (SD)	31.3 (7.1)	31.7 (7.9)	.20
Initial BMI, kg/m^2, mean (SD)	25.2 (4.1)	25.1 (3.8)	.41
Target BMI, kg/m^2, mean (SD)	22.0 (3.6)	21.8 (3.4)	.19
Total number of days of service use, mean (SD)	43.9 (31.3)	112.0 (N/A[a])	<.001
Meal input days	24.0 (23.2)	53.8 (35.8)	<.001
Message sent days	11.8 (11.1)	22.3 (16.9)	<.001
Walk days	40.3 (29.5)	82.9 (32.9)	<.001
Weigh-in days	9.2 (11.4)	20.6 (19.9)	<.001

Topic Modeling

The value of coherence according to the number of topics is shown in Figure 2. The scores steadily increased for up to 9 topics (0.6469); then, they repeatedly fluctuated and did not show much further increase. Therefore, the optimal number of topics was determined to be 9.

The results—the weighted proportion of the top 10 words—of topic modeling with 9 topics are shown in Table 2.

Figure 2. Coherence score by the number of topics.

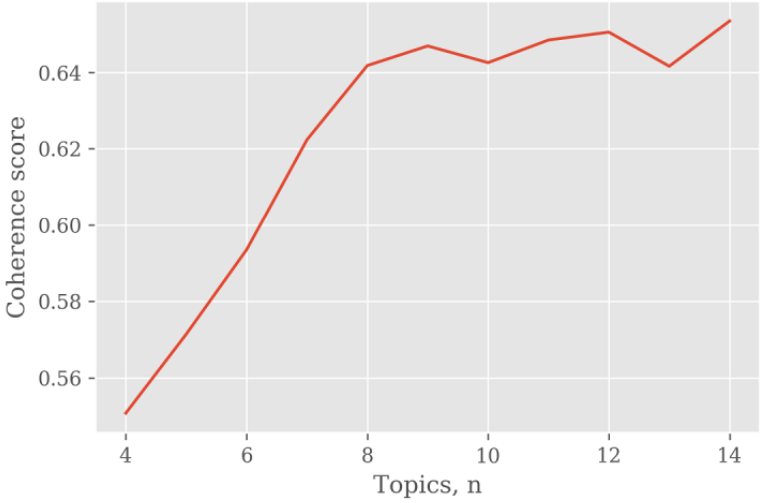

Table 2. Topic modeling results using a combination of the top 10 keywords and weight.

Model Performance

The results shown in Table 3 show the classification accuracy, F1 score, and area under the receiver operating characteristic curve for the same test data when (1) some daily data were excluded sequentially from the end of the period and (2) with or without the text message vectors at every time point.

The results showed that the performance gradually increased as more data included the latter time. There was a performance difference of approximately 0.12 (F1 score, with text vector) when the whole-period data were included compared to when the last week data were excluded. The classification performance was generally better if text was included at almost all time points. When text data were included, the predicted performance increased by a mean of approximately 0.085 (F1 score), at every time point.

Table 3. Performance comparison.

Data period and text inclusion	Accuracy	F1 score	AUROC[a]
Excluding the last week			
Without text vector	0.70	0.68	0.70
With text vector	0.78	0.77	0.77
Excluding the last 5 days			
Without text vector	0.70	0.68	0.71
With text vector	0.79	0.78	0.78
Excluding the last 3 days			
Without text vector	0.71	0.70	0.72
With text vector	0.80	0.79	0.80
Including full duration data			
Without text vector	0.83	0.83	0.82
With text vector	0.89	0.89	0.89

[a] AUROC: area under the receiver operating characteristic curve.

Model Interpretation

According to the results, the contribution of the *steps per day* variable, which denotes that the number of daily steps collected automatically, not those input by the user, was larger than the contributions of the other variables (0.1085). This was followed by *afternoon snack cal* (calorie intake from snacks during the afternoon) at 0.0999 and *receive sent ratio* (ratio of the received messages to the sent messages) at 0.0967.

Among the top 20 variables, there were 12 variables related to text messages, 6 variables related to meals, 1 variable related to walking, and 1 variable related to weight. Among the 9 topic vectors, *topic bad habit max*, which corresponds to poor lifestyle patterns (such as drinking alcohol, overeating, and late-night eating) showed the highest contribution (0.0875) (Figure 3).

To verify the contribution of each variable to the churn prediction model over time, the contribution of the variables corresponding to each time over 112 days (for the 16-week program) is expressed in line plots in Figures 4 and 5 (using force_plot [28]). Overall, the contributions of the variables appeared larger as they approached the later time points of churned and retained users.

Because the model in this study outputs the probability of churn, the graph increased to make the probability of churn high for churn users and low for retained users to decrease the probability of churn. Box plots show the contribution of the variable on each date. For example, when we check each graph of the last day's churn and retained users showing the largest contributions, *steps per day* showed the greatest value, as seen for the overall variable contribution (Figure 6). Although several topic variables appeared for both churn and retained users, such as *bad habit*–related and *coaching*-related variables, the impact of each variable on the predicted performance was in the opposite direction.

To determine if the high contributing variables also showed differences in actual values between the 2 groups (churn and retained users), we checked the actual values of the *steps per day* variable, which had the greatest contribution in Figure 3. For retained users, the graph showed the entire 112 days; however, for churn users, the service use period varied depending on the user; therefore, the data were selected at varying intervals suitable for each user's start and end dates. Comparisons of actual values showed that the churn group had maintained a relatively constant value or that the value decreased slightly from the initial date to the last date of service use (from 4774.02 to 4532.35). However, the value of the retained group had a tendency to continue to decrease by half (from 5048.37 to 2485.48) starting from a value at the time of initial service use that was similar to that of the churn group (Figure 6).

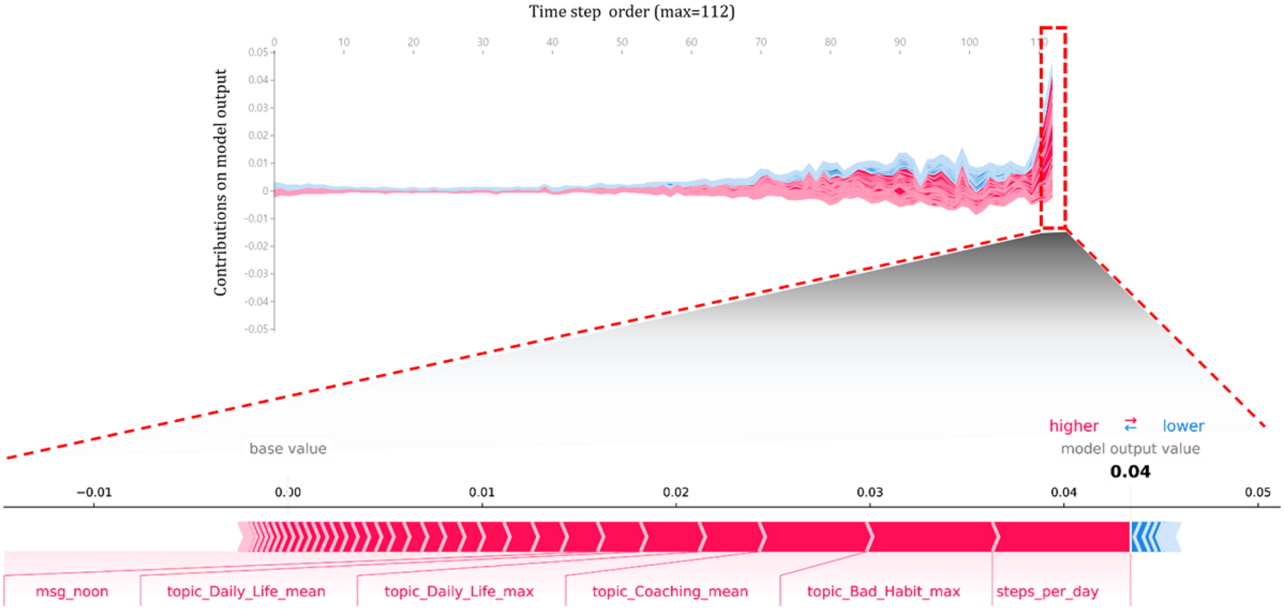

Figure 5. Retained users' daily average contribution of variables over time (above, line plot) and contributions of each variable on the last day (below, bar plot).

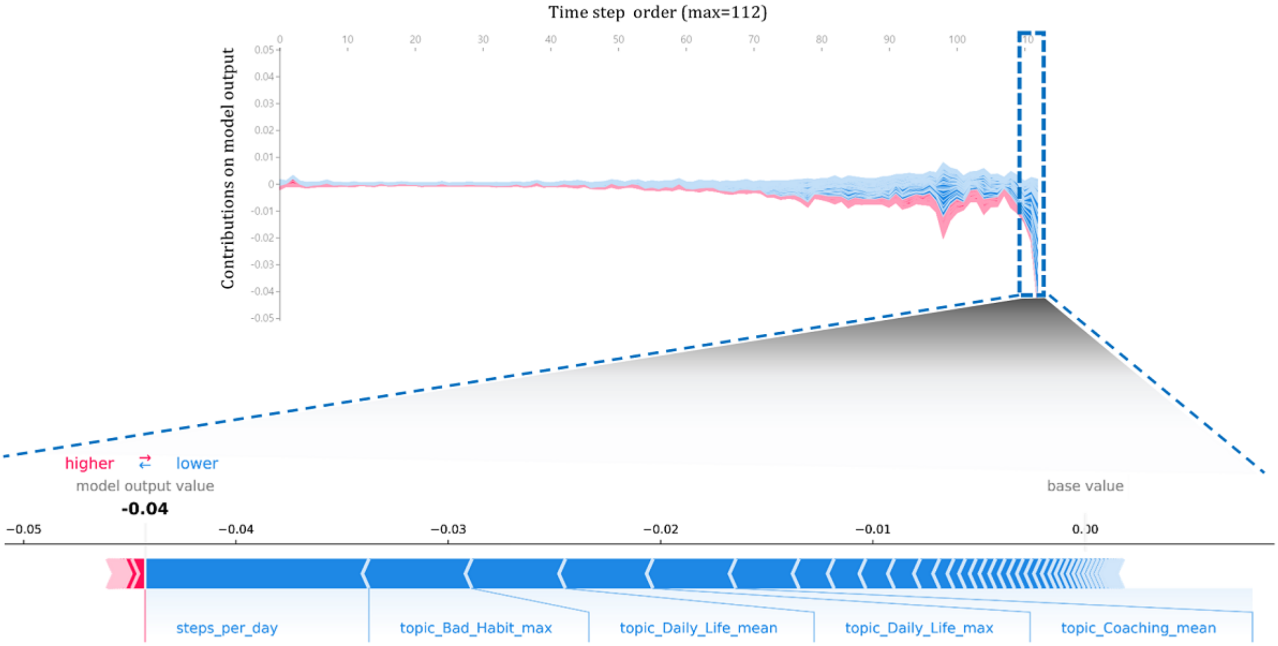

Figure 6. Changes in the mean number of steps_per_day from start to end.

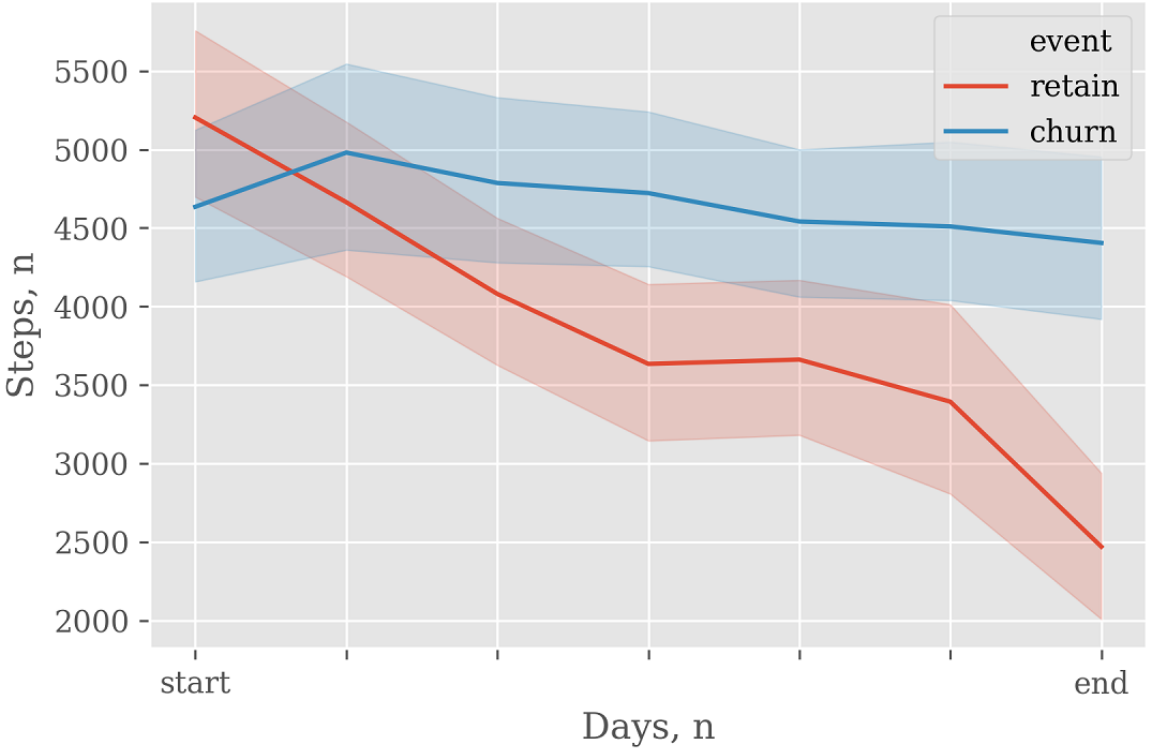

Discussion

Principal Findings

First, as evidenced by the model performance comparisons, for the end time-point, when there were more data, the predictive performance increased for churn and retained users. This could also be seen during the interpretation stage: the closer the end point, the higher the contribution of variables. A previous study [7] compressed the time-series data to input them in models that do not receive time-series patterns. Even in studies [29,30] using a model that could receive time-series data as input, data were lost when inputs were reduced (ie, data cut-off) in order to match the input shape of the models. In these cases, the performance of the model may be relatively poor because it does not reflect the fact that as the end of the period is approached, there is a greater difference between the churn and retained groups [31,32]. However, in our study, by including all the data for different durations of service use by each customer, our model was able to identify churn or retained patterns of the entire time period of service use, thereby improving the predictive performance. The ability to use data of different time lengths allows for the consideration of significant characteristics of the last moment and the immediate training and prediction of churn using only the data collected at that time without waiting for a certain period of time to collect data of equal lengths from all users. This makes it possible to promptly find users who are expected to churn. Therefore, companies can focus on such users and intervene, possibly improving user adherence to their mobile app. Because the steady use of mobile health care apps is closely related to improvements in the users' health [33,34], increasing adherence is crucial to enhance satisfaction with the mobile app and for practical health promotion. Therefore, churn predictions with different lengths of data are important not only for companies but also for users.

Second, including text data can also provide better predictive performance. Because of the growing amount of unstructured customer data that can be collected both inside and outside a company, companies are studying unstructured data [35,36]. In particular, textual information can serve as important information for predicting churn [10]. Nevertheless, companies still struggle with extracting meaningful information from text [37]. In our study, we were able to increase the performance of churn prediction using vectors of messages sent by users as input to the model. We created message vectors through topic modeling to understand which specific topics affected the churn prediction by checking the contribution of each topic vector. For example, the topic that had the greatest impact on churn prediction was *bad habit topic* (eg, drinking alcohol, overeating, and late-night eating, which is known to have a negative influence on weight and health [38]). In other words, mentioning and conversing about these bad habits can also affect the churn of digital health care apps. With knowledge of this beforehand, companies can take measures to encourage the user not to churn by identifying and resolving the user's problems or complaints. Therefore, adding text data not only increases the predictive performance of the churn predictive model but also enhances interpretability by providing intuitive understanding. Companies that want to identify signs of user churn in advance should consider collecting and analyzing unstructured data that directly project customers' thoughts.

Limitations

This study was conducted, using data from churn users until the day before the churn occurred and data for the entire service period of the retained users, as a proof of concept study. However, this assumption may not be appropriate in the real world because the company may not know when the customers will leave. Nevertheless, the probability distribution of the predictions for retained users tended to change the final prediction from churn to retention. In other words, the sensitivity of the churn user data are high; therefore, from the company's point of view, the possibility of missing the churn user can be reduced. However, for practical forecasting by real-world companies, further studies of variations in probability of churn over time are needed. This study was retrospective. It used past records of mobile app users to identify signals of churn and identify the churn users. Because our analysis was retrospective, there was a constraint on its effectiveness for prospective data. Therefore, it is necessary to study whether early interventions for groups expected to be churn users provide more clinical indicators.

Conclusion

We used a model with recurrent neural network architecture that used user log data and text data to determine the churn of digital health care users. Our analysis of variables is expected to help identify signs of user churn in advance and improve adherence in the field of digital health care.

Abstract

Background: Mobile health (mHealth) interventions offer great potential to reach large populations and improve public health. However, high attrition rates threaten evaluation and implementation of mHealth intervention studies.

Objective: We explored factors associated with attrition of study participants in an mHealth randomized controlled trial (RCT) evaluating an intervention to reduce unintentional child injury risk in China.

Methods: The cluster RCT compared two groups of an app-based intervention for caregivers of 3-6–year-old children (Bao Hu San). The intervention group received unintentional child injury and parenting education, whereas only parenting education was implemented in the control group. The trial included 2920 study participants in Changsha, China, and lasted 6 months. Data on participant engagement (using the app) were collected electronically throughout the 6-month period. Associations between participant attrition and demographic characteristics, and between attrition and intervention engagement were tested and quantified separately for the intervention and control groups using the adjusted odds ratio (aOR) based on generalized linear mixed models.

Results: In total, 2920 caregivers from 20 eligible preschools participated, with 1510 in the intervention group and 1410 in the control group. The 6-month attrition rate differed significantly between the two groups ($P<.001$), at 28.9% (437/1510) in the intervention group and 35.7% (503/1410) in the control group. For the intervention group, the only significant predictor of attrition risk was participants who learned fewer knowledge segments (aOR 2.69, 95% CI 1.19-6.09). For the control group, significant predictors of attrition risk were lower monthly login frequency (aOR 1.48, 95% CI 1.00-2.18), learning fewer knowledge segments (aOR 1.70, 95% CI 1.02-2.81), and shorter learning durations during app engagement (aOR 2.39, 95% CI 1.11-5.15). Demographic characteristics were unrelated to attrition.

Conclusions: Engagement in the app intervention was associated with participant attrition. Researchers and practitioners should consider how to best engage participants in app-based interventions to reduce attrition.

KEYWORDS

app-based intervention; unintentional injury; attrition; influencing factors

Introduction

Owing to recognized advantages such as cost-effective dissemination, real-time data collection and feedback, reduced burden, flexible customization, self-monitoring capacity, and visually attractive multimedia presentation [1-3], mobile health (mHealth) technology has become increasingly popular in health intervention research and practice over the past decade. A wide range of mHealth interventions have been developed to prevent diseases and injuries, increase the compliance to recommended health interventions, and offer remote access to health services [4-10].

Despite these advantages, mHealth interventions suffer from the challenge of high dropout attrition rates compared to studies adopting traditional interventions. For example, a recent 6-month large intervention study for smoking cessation reported an attrition rate of 57% in the intervention group using an app and of only 52% in a control group using a self-help booklet as usual education [11]. Several app-based intervention studies reported high attrition rates, with estimates ranging from 38% to 84% [12-16].

When attrition is high, occurs unequally between intervention and control groups, or occurs in a nonrandom way, it threatens the validity of evaluation studies [17,18]. When dropout attrition is high in public health practice, the efficacy of an intervention is lower than desired. Therefore, researchers must prioritize exploration and understanding of the factors associated with dropout attrition of study participants. Increased understanding would lead to feasible approaches to prevent and reduce dropout attrition.

Previous research examining predictors of dropout attrition from app-based intervention studies in reducing alcohol intake [19], improving health-related behavior [20], and weight loss [21] focused primarily on the demographic characteristics of individuals who are more likely to fail to complete follow-up surveys and therefore are not retained in the research study. For example, in an evaluation of the efficacy of an app-based child burn prevention program, Burgess et al [22] reported a higher proportion of university degree holders among participants who remained in the study (28.7%, 70/244) than those who were lost to follow up (16.5%, 42/254). Despite the value of this line of research, it is equally important to explore relationships between attrition and other indicators such as engagement with the app-based intervention. Such analyses may offer new clues to reducing attrition in app-based intervention studies.

Therefore, the aim of this study was to examine associations both between attrition and demographic characteristics and between attrition and participants’ engagement in the intervention. We hypothesized that a more active and attractive type of intervention would result in greater engagement and thus a lower attrition rate in the intervention arm compared with the control arm. Replicating Burgess et al [22] and others, we also hypothesized that greater education might be related to higher retention in the intervention study. We used data collected from a cluster randomized controlled trial (RCT) examining an app intervention to prevent unintentional child injury in China to test our hypotheses.

Methods

Design

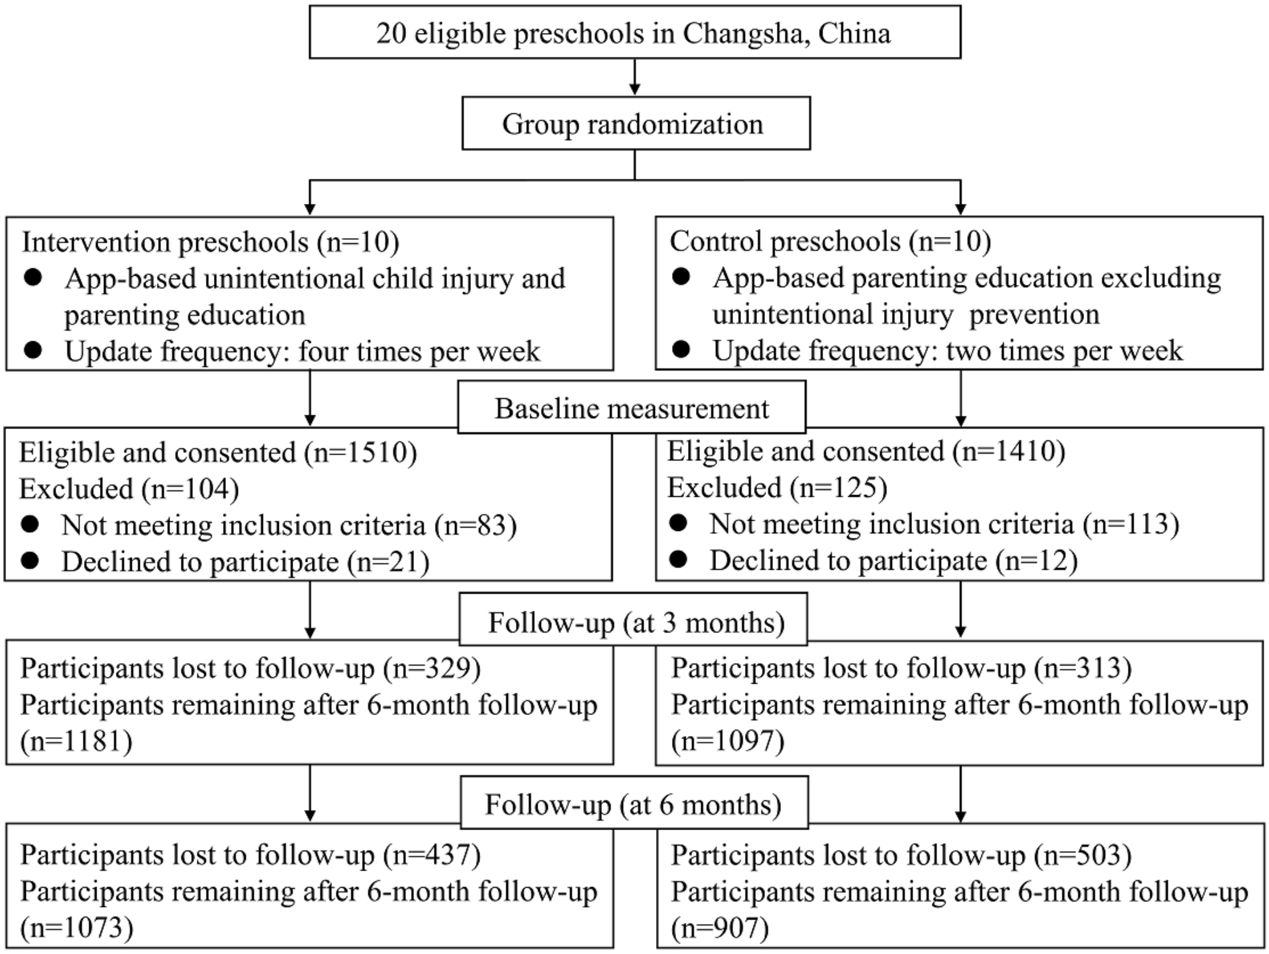
This research comprises secondary analyses of data from a published single-blinded cluster RCT assessing the effectiveness of an app-based intervention for caregivers to prevent unintentional injury among Chinese preschoolers [8]. The trial recruited 2920 caregivers of 3-6–year-old children from 20 eligible preschools using cluster random sampling. The randomization was performed at the school level and was stratified by type of preschool (public vs private), yielding five public and five private schools in both the intervention group (implementing unintentional child injury and parenting education) and the control group (implementing parenting education only).

Both groups engaged in a 6-month intervention delivered through a smartphone app. The intervention group received a more active and attractive intervention than the control group. Specifically, the control group received essays, games, comics, and videos twice a week, and users conducted thematic discussion activity once a month to learn about common children’s diseases and to practice parenting skills outside unintentional injury prevention. In contrast, the intervention group received all content that the control group received, but the participants were also exposed to additional similar essays, games, comics, and videos twice a week, and engaged in a second set of thematic discussions once a month to learn about parenting skills related to unintentional child injury prevention. The intervention group also had access to an app-based portal that supported communication between users and professionals concerning injury prevention knowledge and skills.

Data were collected through three caregiver surveys that were completed at baseline in December 2017 and then two follow-up surveys in March and June 2018, which corresponded to the 3rd and 6th month after the initiation of the interventions in both groups. To encourage adherence in using the app, reminders about newly released knowledge segments appeared on the scroll screen when users opened the app. Users who did not read the content in a timely manner were reminded again. We also provided financial incentives to participants after completing study of the knowledge segments and asked the preschool teachers to remind caregivers regularly to use the app. In addition, an automatic message to remind participants about using the app was sent if the user failed to log in for 1 month. To encourage compliance in completing the study surveys, we provided financial incentives and sent two automatic reminder messages to users who did not complete the follow-up surveys 3 days after they were released.

Figure 1 illustrates the study design. The protocol was approved by the Ethics Committee of Xiangya School of Public Health, Central South University, Changsha, China (approval number: XYGW-2017-02). Full details of the RCT evaluation are published elsewhere [23].

Figure 1. Flow diagram of the app-based intervention study.



Outcome Measure

Attrition from the study was defined as a study participant who failed to complete both follow-up surveys at the 3rd and 6th months after initiation of the interventions.

Independent Variables

Based on our study hypotheses and previous studies [17,22], we considered demographic factors and engagement with the app-based intervention as potential factors that would predict dropout attrition of study participants. We also considered previous training experience on unintentional injury prevention, as we hypothesized that participants might engage in the intervention or study only if they valued parenting education and if they were receiving new information that they had not learned in the past.

Data on demographic characteristics and previous training experience were obtained via a baseline survey. Caregiver demographic factors included sex, age, level of education, and monthly household income per capita. Caregiver's age was divided into three approximately equally sized groups (less than 31 years, 31 to 34 years, and 35 years and above). Level of education was classified into three categories: junior high school and below, high school (including technical secondary school), and junior college and above. Monthly household income per capita was divided into two levels: below and above 3500 yuan (approximately US $540), according to the average income of Changsha residents in 2015 [24].

Data on engagement with the intervention were collected using the app's backend system across full implementation of the trial; that is, user engagement information was collected in an automated fashion when users logged into the app. Available data included the webpages on the app that were visited, and on what occasions, how frequently, and for how long. This kind of information offers insight into engagement by participants based on how much time they spend with the app, and with what app features.

For this study, we collected app engagement data using four indicators: monthly login frequency, single login duration, knowledge segments learned per login, and single learning duration. Monthly login frequency was defined as the average number of times each participant used the app per month before quitting the study. Quitting was defined as the date of the last login recorded in the app backend system. Single login duration was the average online duration between opening the app and exiting it in the same session. Knowledge segments learned per login was the average number of short written statements with pictures, cartoon episodes, video recommendations, and interactive games learned in each login. Finally, single learning duration was defined as the average time spent on reading and learning individual knowledge segments during each login. To facilitate interpretation of the results, we divided all participants into three equal groups for each indicator according to the percentiles of $P_{33.4}$ and $P_{66.7}$ ($<P_{33.4}$, $P_{33.4}$ to $P_{66.7}$, and $>P_{66.7}$).

Statistical Analysis

Attribution rates and 95% CIs were estimated based on binomial distributions. The χ^2 test was used to examine the difference in attrition rates between the intervention and control education groups. Differences in app intervention engagement measures between the two groups were evaluated using the Kruskal-Wallis *H* test. Generalized linear mixed models were used to test the associations between attrition and all independent variables. The intraclass correlation coefficient was calculated to quantify the clustering of study participants at the preschool level. Adjusted odds ratios (aORs) were calculated to quantify the size of associations after adjusting for other independent variables. All analyses were performed using SAS 9.2 (SAS Institute). Statistical significance was based on two-sided tests at the level of .05.

Results

Sample Characteristics

In total, 2920 caregivers from 20 eligible preschools in Changsha, China participated, with 1510 caregivers assigned to the intervention group and 1410 assigned to the control group (Table 1). Participants in the intervention group were slightly more likely to be male, to have a higher monthly household income per capita, and to have received injury prevention education in the past 3 months. There also were differences in engagement: participants in the intervention group were more likely to engage in the website based on all four metrics than those in the control group (P<.001).

Table 1. Demographic and engagement characteristics of study participants.

Characteristic	Intervention (n=1510)	Control (n=1410)	*P* value
Age (years), mean (SD)	32.7 (5.0)	33.1 (5.7)	.06
Sex, n (%)			
Male	490 (32.5)	364 (25.8)	<.001
Female	1020 (67.5)	1046 (74.2)	
Educational level, n (%)			
Junior high school and below	1017 (67.3)	951 (67.5)	.98
High school	386 (25.6)	357 (25.3)	
College and above	107 (7.1)	102 (7.2)	
Household income per capita per month (US $), n (%)

≥540	1143 (75.7)	1138 (80.7)	
Injury prevention education in past 3 months, n (%)			
Yes	918 (60.8)	708 (50.2)	<.001
No	592 (39.2)	702 (49.8)	
Monthly login frequency, median (IQR)	3.9 (5.5)	3.0 (5.5)	<.001
Single login duration (seconds), median (IQR)	204.9 (221.8)	176.8 (198.7)	<.001
Knowledge segments learned per login, median (IQR)	0.7 (1.7)	0.5 (1.2)	<.001
Single learning duration (seconds), median (IQR)	61.9 (162.8)	44.9 (131.0)	<.001

Engagement Indicators Between the Intervention and Control Groups

The intervention group had significantly higher engagement than the control group based on all four engagement indicators. This was true both for participants who completed the study and for those who failed to complete the study (Table 2).

Table 2. Differences in app engagement indicators between the intervention and control groups within 6 months.

Variable	Completers (n=1980)			Lost to follow up (n=940)		
	Intervention, median (IQR)	Control, median (IQR)	*P* value	Intervention, median (IQR)	Control, median (IQR)	*P* value
Monthly login frequency (N)	3.9 (6.0)	3.5 (6.0)	.03	3.9 (4.6)	2.0 (4.0)	<.001
Single login duration (seconds)	222.2 (232.6)	195.0 (214.2)	<.001	156.3 (174.2)	142.6 (192.9)	<.001
Knowledge segments learned per login (N)	1.0 (1.7)	0.8 (1.3)	<.001	0.2 (0.9)	0.1 (0.7)	.02
Single learning duration (seconds)	86.0 (172.2)	72.7 (163.7)	.01	16.0 (82.8)	7.4 (54.3)	.009

Attrition Rate

The 6-month attrition rate for the intervention group was 28.9% (437/1510; 95% CI 26.6%-31.2%), whereas that for the control group was 35.7% (503/1410; 95% CI: 33.2%-38.2%). The attrition was significantly higher in the control group than in the intervention group (OR 1.36, 95% CI 1.17-1.59) (Multimedia Appendix 1).

Influencing Factors

Given the distinct attrition rates across the two groups, we performed multivariable analysis separately for each group. As shown in Table 3, the attrition rates of caregivers in the intervention group with “sometimes” monthly login frequency was higher than that of those with “often” monthly login frequency (*P*=.03). The attrition rates of caregivers with short and average single login durations were significantly higher than those for caregivers with long single login durations (*P*<.001 and *P*=.03, respectively). The attrition rates of caregivers with few and average number of knowledge segments learned per login were significantly higher than that for caregivers completing many knowledge segments learned per login (*P*<.001 and *P*=.003, respectively). Caregivers with short and average single learning durations had higher attrition rates than those with a long single learning duration (*P*<.001 and *P*=.002, respectively). The multivariable analysis showed that caregivers who learned fewer knowledge segments per login had a substantially higher attrition risk than those who learned more knowledge segments per login after adjusting for sex, age group, level of education, monthly household income per capita, receiving injury prevention education in the past 3 months or not, and the three other intervention engagement measures (Table 3).

As shown in Table 4, the attrition rate of caregivers in the control group with “seldom” monthly login frequency was higher than that for those with “often” monthly login frequency (*P*=.003). The attrition rates of caregivers with short and average single login durations were higher than that of caregivers with long single login durations (*P*<.001 and *P*=.009, respectively). The attrition rates of caregivers with few and average knowledge segments learned per login were much higher than that for caregivers with many knowledge segments learned per login (*P*<.001 and *P*=.001, respectively). The attrition rates of caregivers with short and average single learning durations were higher than that for caregivers with long single learning durations (*P*<.001 and *P*=.002, respectively). The multivariable analysis for attrition yielded three significant predictors of attrition. Caregivers with a lower monthly login frequency, who learned fewer knowledge segments per login, and who had shorter single learning durations had significantly higher attrition rates than those using the app more often per month (seldom vs often), learning more knowledge segments per login (average vs many), and having a longer single learning duration (short vs long) (Table 4).

Discussion

Principal Findings

The 6-month attrition rate of study participants was 28.9% in the intervention group and was 35.7% in the control group. As hypothesized, higher attrition risks were associated with low app intervention engagement in both the intervention and control groups after controlling for demographic variables and previous training experience on unintentional injury prevention. Compared to the intervention group, the control group had a higher attrition rate, which was primarily explained by lower app intervention engagement. Demographic factors seemed to not be associated with attrition in either group.

Interpretation of Findings

Attrition in our study was quite similar to that reported at 6-month follow up for an educational app on car seat use [25] (34.3%, 387/1129), but was significantly lower than the rate of 51% (254/498) reported in an app-based study of scald burn prevention [22]. A wide range of factors likely explain participant attrition from engagement in an app-based intervention, including design of the app, assessment measures for participant compliance, individual characteristics of participants, and cultural differences across countries.

Previous studies [13,22,26] generally report that female, younger, and less educated individuals have a higher likelihood of attrition. We could not confirm these findings in either the univariable or the multivariable analyses. One possible explanation for this result is the fact that we conducted our study in China, a middle-income country with a collectivist culture that differs from other countries and regions where the previous studies were conducted, such as the United States and Australia. Another possible explanation is related to our multivariable findings, which indicate that participant engagement was a strong predictor of participant attrition after controlling for participant demographics. In both groups, engagement in the intervention was significantly associated with attrition. These results support the hypothesis that a high proportion of participants lost to follow up in app-based interventions may simply be a result of nonusage of the app [17]. If participants perceive the app as helpful and beneficial, they continue to use it and then engage in research surveys.

We found that the attrition rate in the intervention group was lower than that in the control group, a finding we attribute to the less engaging aspects of the parenting education app for the control group. Specifically, the control group received new material twice a week and thematic discussions once a month, while the intervention group received new material four times a week and engaged in thematic discussions twice a month. The intervention group also had access to experts to ask questions and receive consultation, a feature not provided to the control group. These data concord with the findings of Kelders et al [27] who reviewed 101 web-based intervention studies and found that increased interaction with a counselor, more frequent intended usage, more frequent updates, and more extensive employment of dialogue support better adherence.

Implications

Our findings have two major implications. First, they emphasize the unignorable impact of high dropout attrition in mHealth intervention studies. High attrition must be evaluated strictly before drawing conclusions about the efficacy of an intervention, and research findings should be interpreted cautiously when attrition rates are high, vary substantially across comparison groups, or when missing values (dropouts) occur in a nonrandom fashion. Second, the results underscore the need for careful design and implementation of mHealth interventions. The comparatively high attrition rate among participants with less frequent and engaging exposure to educational materials highlights the need for mHealth interventions to be designed and implemented with appealing features. They must attract users and increase engagement in the intervention.

Study Limitations

This study was primarily limited by the RCT design. We do not have data concerning engagement or attrition rate after 6 months since the study ended at that point. Further, other potentially relevant factors for dropout were not available for analysis, including participant preferences, attitudes, and views about the app-based interventions, all of which may influence attrition [28]. These limitations should be considered in future research.

Conclusions

Dropout attrition was high in an RCT examining app-based interventions for unintentional child injury and parenting education versus only parenting education among caregivers of Chinese preschoolers. Engagement in the interventions differed across the two groups, and attrition was significantly associated with intervention engagement in both groups. Greater engagement with the app led to lower attrition. Attrition must be considered by researchers, policymakers, and practitioners when evaluating and implementing mHealth interventions. Efforts to engage users are critical to reduce attrition. Future research might consider feasible strategies to improve and maintain compliance of study participants to mHealth intervention programs.

Abstract

Background: Virtual reality (VR) relaxation is a promising mental health intervention that may be an effective tool for stress reduction but has hardly been tested in clinical trials with psychiatric patients. We developed an easy-to-use VR self-management relaxation tool (VRelax) with immersive 360° nature videos and interactive animated elements.

Objective: To investigate the immediate effects of VR relaxation on negative and positive affective states and short-term effects on perceived stress and symptoms in patients with a psychiatric disorder, compared to standard relaxation exercises.

Methods: A randomized crossover trial was conducted in 50 patients receiving ambulatory treatment for anxiety, psychotic, depressive, or bipolar disorder. Participants were randomly assigned to start with VRelax or standard relaxation and used both interventions for 10 days at home. They completed 8 visual analog scales of momentary negative and positive affective states before and after each session. Global perceived stress and psychiatric symptoms were measured before and after both intervention periods. Treatment effects were analyzed with multilevel mixed model regression analyses and 2-way analysis of variance.

Results: Both VRelax and standard relaxation exercises led to a statistically significant immediate improvement of all negative and positive affective states. Compared to standard relaxation, VRelax resulted in a significantly greater reduction of total negative affective state (change 16.2% versus 21.2%; $t_{1684}=-2.02$, 95% CI −18.70 to −0.28; $P=.04$). Specifically, VRelax had a stronger beneficial effect on momentary anxiety ($t_{1684}=-3.24$, 95% CI −6.86 to −1.69), sadness ($t_{1684}=-2.32$, 95% CI −6.51 to −0.55), and cheerfulness ($t_{1684}=2.35$, 95% CI 0.51 to 5.75). There were no significant differences between short-term effects of the two treatments on global perceived stress and symptoms.

Conclusions: If the results of this trial are replicated and extended, VRelax may provide a much-needed, effective, easy-to-use self-management relaxation intervention to enhance psychiatric treatments.

KEYWORDS

virtual reality; stress; relaxation; negative affect; positive affect; depression; anxiety; randomized controlled trial

Introduction

Stress refers to the physiological, psychological, and behavioral responses to demands or perceived threats that challenge individuals' resources to manage them [1,2]. This study focuses on the psychological stress response, operationalized as the level of perceived distress and corresponding affective states (eg, feeling anxious, nervous, or down, and less calm, cheerful, or content).

Stress responses are often adaptive but also can increase vulnerability to disease. In psychiatry, stress is a transdiagnostic factor that has been related to both onset, course, and recurrence of mood, anxiety, and psychotic disorders [3,4]. Stress-reducing interventions such as breathing exercises, mental imagery, progressive muscle relaxation, and mindfulness are commonly applied in routine mental health care. These interventions are effective for reducing anxiety, stress, and sleeping problems [5,6], have some effects on level of depressive symptoms [7,8], and have hardly been investigated in patients with psychotic disorders [9]. Another intervention known to reduce stress is exposure to natural environments. Consistent associations have been reported between stress level (physiological and subjective) and time spent in green and blue spaces [10-12]. Negative impact of stress on health may be alleviated by presence of green space [13].

Although stress-reducing interventions may be effective, they are challenging for people with mental health problems. They require initiative, concentration, sustained attention, and energy, which are reduced in many psychiatric disorders, especially in association with exposure to stress [14]. There is a need for easy-to-use stress-reducing interventions that require less effort. Virtual reality (VR) technology offers opportunities to overcome the aforementioned challenges. A combination of visual and auditory stimuli in VR can be used to create an immersive experience that may reduce perceived distress and negative affect without much effort and induce relaxation and positive affect. VR treatments have been developed for various psychological and psychiatric problems, including anxiety and psychosis [15-17]. Most of these VR interventions are therapist-led and include exposure treatment, cognitive behavioral therapy, cognitive training, skills training, and stress management. Over the past decade, several studies have tested stress-reducing VR interventions in clinical and nonclinical samples [17]. A VR program for patients with a stress-related psychiatric disorder showed that confrontation with emotionally charged VR objects improved relaxation and negative mood significantly more than conventional cognitive behavioral therapy [18]. A VR intervention combining roleplays with teaching stress management techniques in a natural VR environment reduced perceived stress in workers with high-stress jobs [19]. A systematic review of VR stress management interventions in the military found 14 small studies, showing that VR stress inoculation decreased perceived stress and negative emotions [20]. Several studies specifically investigated the effect of VR relaxation on stress levels, both in healthy volunteers and people with psychiatric problems, mainly using exposure to VR natural environments [17]. Immersion in VR nature showed improvement of perceived stress, affective responses, and physiological stress measures, to a greater degree than neutral VR environments or two-dimensional nature videos [21-26]. These results suggest that VR-based stress management, in particular immersive VR nature relaxation, is a promising approach for stress reduction that merits further clinical research [17,27]. To the best of our knowledge, no randomized controlled trials investigated the effects of VR nature relaxation as a self-management intervention for stress reduction in patients with a psychiatric disorder. We developed VRelax, a VR self-management relaxation intervention with high-quality 360-degree videos of natural environments and interactive elements that enhance relaxation and focused attention to the environments (see Methods). In this study, we investigated the immediate effects of VRelax on negative and positive affective states of patients receiving outpatient treatment for a psychiatric disorder.

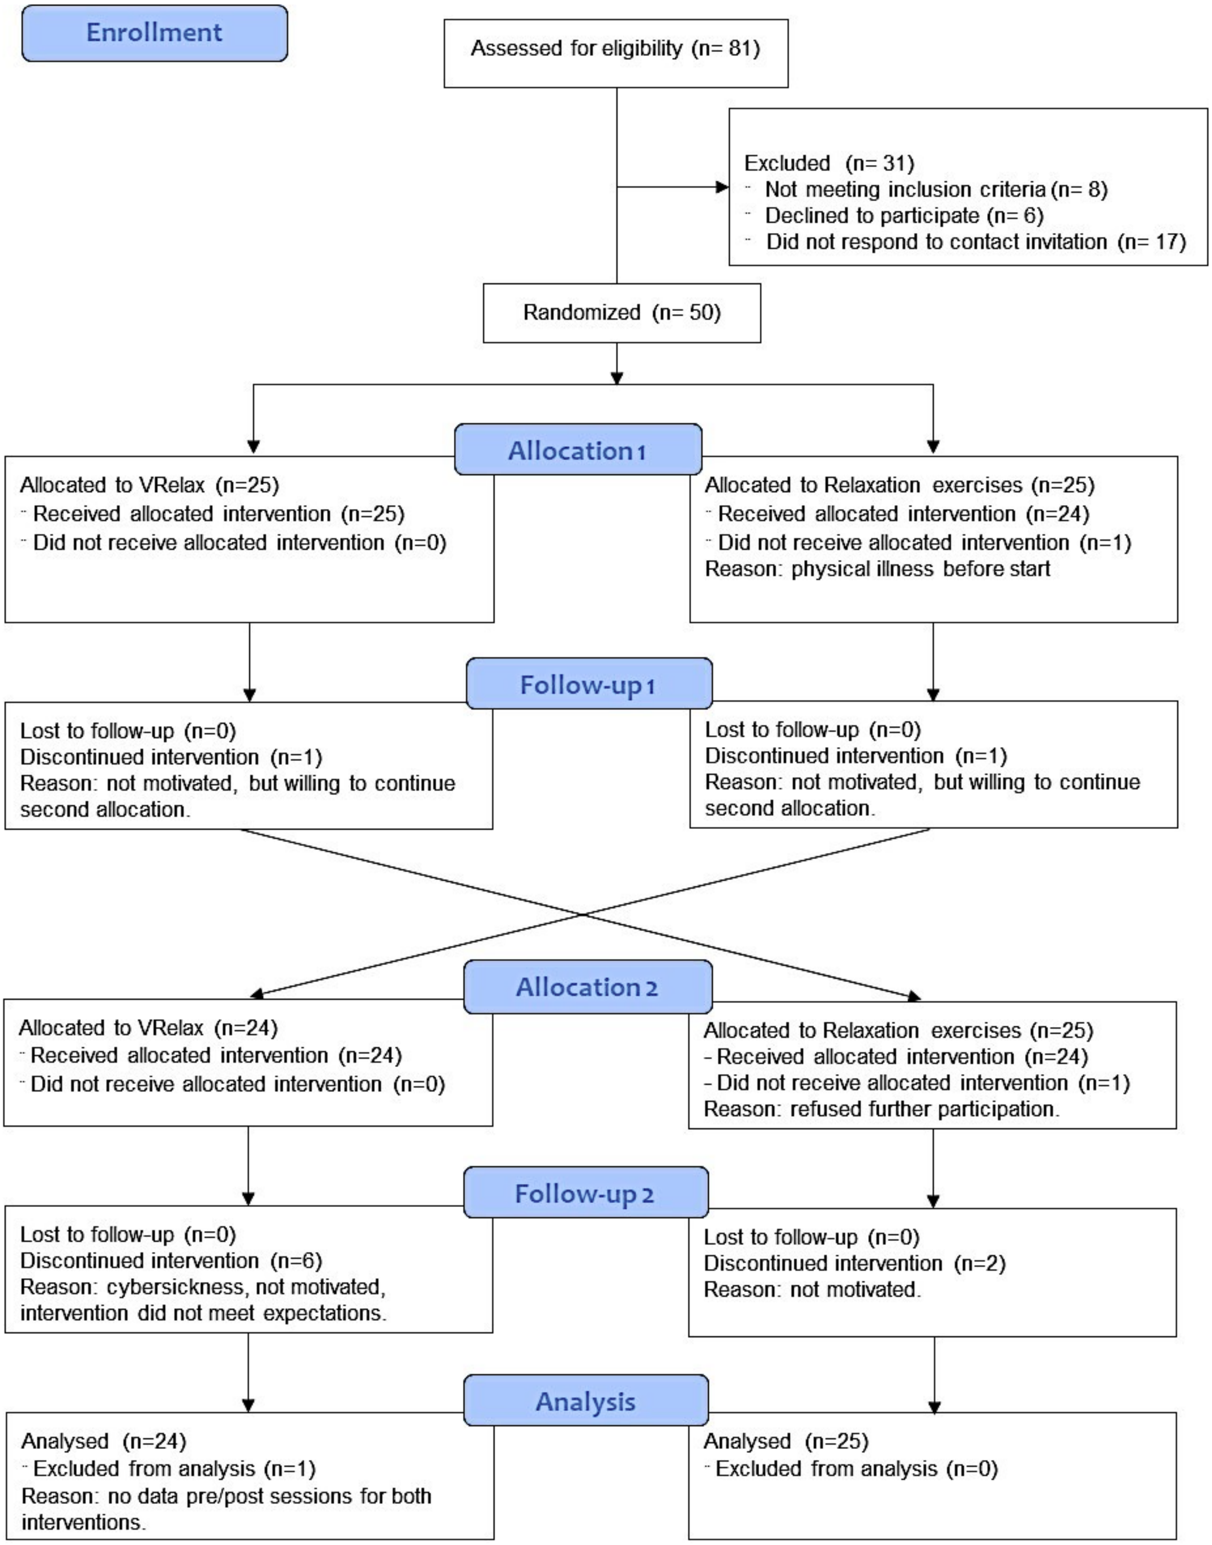
We conducted a crossover randomized controlled trial comparing VRelax with standard relaxation exercises. To evaluate immediate effects, momentary levels of negative and positive affective states were assessed before and after each session. As secondary outcomes, short-term effects (after 10 days) were measured with questionnaires on global perceived stress and psychiatric symptoms (anxiety, depression, paranoia). We hypothesized that (1a) VRelax results in an immediate improvement of negative and positive affective states, (1b) VRelax has a short-term effect on global perceived stress and psychiatric symptoms, and (2) the immediate and short-term effects of VRelax are stronger than the effects of standard relaxation exercises.

Methods

Participants

Patients receiving ambulatory treatment at University Medical Center Groningen (UMCG) Department of Psychiatry, Lentis Center for Integrative Psychiatry, or one of the two participating local general practices were eligible for the study. As stress is a major transdiagnostic factor in psychiatry, and psychiatric disorders often co-occur and partly overlap, a transdiagnostic approach was chosen [28]. Patients could participate if they had a diagnosis of depressive disorder, bipolar disorder, anxiety disorder, or psychotic disorder. Participants were referred to the study by their psychiatrist, psychologist, or general practitioner. A member of the study team contacted potential participants, provided information about the study, checked eligibility, and obtained informed consent. Patients reported their psychiatric diagnosis upon referral to the study; the clinicians who were involved in their regular treatment completed a brief checklist, including diagnosis according to the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5). The other inclusion criteria were perceived stress, based on self-report or clinician report; older than 18 years; and having a desktop computer or laptop computer at home. Exclusion criteria were a DSM-5 diagnosis of substance use disorder; benzodiazepine use greater than 10 mg per day of diazepam equivalent; diagnosis of epilepsy; and insufficient command of Dutch. A flowchart of the study participants is shown in Figure 1.

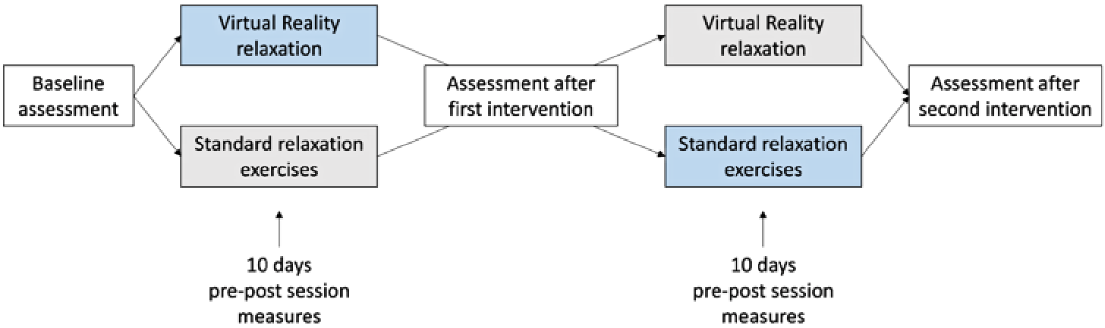
Figure 1. Flowchart of crossover randomized controlled trial.



Study Design and Procedures

The study was a randomized controlled crossover trial with two stress-reducing interventions: (1) the VRelax relaxation app and (2) standard relaxation exercises. Study procedures are shown in Figure 2. After informed consent, participants were randomly assigned to either start with VRelax or standard relaxation exercises. Randomization was conducted by an independent UMCG research coordinator using 1:1 randomization, drawing the assignment numbers not in series, but for each participant individually after informed consent was signed. After 10 days, they crossed over to the other intervention. Participants used both interventions consecutively for 10 days at home for a minimum of 10 minutes a day. Negative and positive affective states were assessed before and after each session; other measures were obtained at baseline (T0), after the first intervention period (T1), and after the second intervention period (T2). A crossover design was chosen because patients are very heterogeneous in clinical characteristics and behavior, and many confounding variables can be expected. As the primary outcome was immediate effect of interventions, carry-over effects were expected to be small. Ethical approval was obtained from the UMCG medical ethical committee (protocol number NL64380.042.17). The trial was registered prospectively in the Netherlands Trial Register (number NTR7294).

Figure 2. Study procedures.



Sample Size Calculation

Several studies provided preliminary evidence that VR relaxation reduces psychological and physiological stress, but to the best of our knowledge, no randomized controlled trials investigated the treatment effect of VR relaxation as a separate intervention in patients with a psychiatric disorder. As this was the first randomized VR stress reduction intervention study using VR nature relaxation and an active control condition, there was no estimation of effect size available. The sample size was therefore based on recommendations for a clinical pilot study and determined to be N=50 [29,30].

Interventions

All patients received regular treatment for their mental health problems throughout the study period. VRelax and standard relaxation were add-on interventions.

VRelax

The VRelax tool [31] was used with a Samsung Galaxy S6 or S7 smartphone, connected to a head-mounted display, the Samsung Gear VR. Three-dimensional audio was played with headphones. When VRelax was activated, the participant entered a white-walled waiting room. Presession measures (see Measures section) started automatically within the virtual waiting room. After completion of the presession measures, the walls of the waiting room disappeared, and the participant was standing on a beach, from which he or she could choose where to go. Participants could navigate between interconnected 360-degree video nature environments by looking at hotspots within their field of view that were activated after 2 seconds. VRelax included the following videos: several beaches, a coral reef with tropical fishes, swimming underwater with wild dolphins, a drone flight over a river landscape, a mountain meadow with animals, another mountain scenery in the Alps, a sea view from a cliff, and a beach session of Tibetan singing bowl therapy (Figure 3). Interactive elements were added as an extra layer on top of some videos; for example, audio tracks of guided meditation and progressive muscle relaxation could be activated by looking at hotspots; animated underwater floating air bubbles popped when looking at them; and a pattern of animated circles in the air produced a harmonious melody when looking at them in a particular order.

Figure 3. Impression of virtual relaxation environments from VRelax app.

The 360° videos were created by VIEMR, The Dolphin Swim Club, and Atmosphaeres; the VRelax tool was developed in collaboration with UMCG (first author WV).

Participants received a VRelax set to take home, including Gear VR, smartphone, and headphones. They were completely free to choose which video or videos within the app they preferred to use but were instructed to use the VRelax app at least once daily for 10 minutes. After 10 days, they returned the VR set to the study team.

Standard Relaxation

As active control intervention, participants received headphones and a USB stick with audio tracks of guided meditation and progressive relaxation exercises. They could play the tracks on devices they had at home (desktop or laptop computer, or smartphone). They were instructed to use it at least once daily for 10 minutes. After 10 days, participants returned the headphones and USB stick to the study team.

Measures

Primary Outcome

The primary outcome was the immediate effect on level of momentary negative and positive affective states, measured with visual analog scales (VAS; range: 0-100). The VAS items were scored immediately before and after each session, for VRelax within the virtual waiting room, and for the standard relaxation exercises with paper and pencil. Eight ecological momentary assessment items were selected that have been used in previous studies and have been related to psychological stress [32]. The following items were for negative affective states: I feel distressed; anxious; down; nervous (Cronbach α in our sample=.865). The following were for positive affective states: I feel relaxed; calm; cheerful; content (Cronbach α=.897).

Secondary Outcomes

Before the first intervention period, after the first intervention period, and after the second intervention period, patients completed questionnaires to assess short-term changes in perceived stress and psychiatric symptoms.

Perceived Stress

Global perceived level of stress over the past week was measured with the 10-item version of the Perceived Stress Scale [33], assessing the degree to which situations are appraised as stressful. The Perceived Stress Scale has good psychometric reliability and validity, including in samples of psychiatric patients [34]; in our sample, Cronbach α was .865.

Psychiatric Symptoms

Severity of depressive symptoms was measured with the Inventory of Depressive Symptomatology–Self-Report, a widely used 30-item questionnaire with good psychometric characteristics in psychiatric outpatients [35]. Cronbach α was .834 in the study sample. Level of anxiety symptoms was assessed with the 21-item Beck Anxiety Inventory, an instrument with high internal consistency, convergent and discriminant validity [36], and a Cronbach α of .908 in this study. With the Green Paranoid Thoughts Scale, ideas of social reference (16 items) and of persecution (16 items) were assessed [37]. This scale has been developed to assess paranoia over the spectrum of severity and has been recommended as the most reliable and valid self-report measure of paranoia [38]. In our sample, Cronbach α was .982.

Other Measures

Demographic and clinical information was obtained from participants: age, gender, marital status, level of education, work situation, DSM-5 classification, illness duration, and psychotropic medication use. During VRelax sessions, how long participants spent in each environment was automatically recorded in log files. Cybersickness was assessed to monitor adverse effects with the self-report Simulator Sickness Questionnaire (SSQ) before and after the VRelax intervention [39].

Statistical Analyses

All analyses were conducted in SPSS version 26 (IBM Corporation). Analyses of the primary outcome were done by the intention-to-treat approach.

Total negative affective state was calculated by summing the scores of the items anxious, down, distressed, and nervous. Similarly, the items relaxed, calm, cheerful, and content were summed for the total positive affective state. Changes of VAS items and total negative and positive affective state were calculated as 1 – (before session score / after session score). Descriptive statistics (mean, standard deviation, minimum and maximum scores) were calculated for all sociodemographic, clinical, and outcome variables.

As the primary outcome data had a multilevel structure (multiple VAS session scores within participants), VAS scores were analyzed with mixed model multilevel regression analyses (MIXED command), including the factors time (before vs after session), treatment (VRelax compared vs relaxation exercises), order of treatment administration (to adjust for carry-over effects), and the interaction time × treatment. Models had a random intercept for participant and a random slope for order of treatment administration. The estimation method was set to restricted maximum likelihood and the covariance structure to unstructured. First, the immediate effects of interventions were analyzed by comparing mean VAS scores before and after sessions for VRelax and relaxation exercises separately. Second, effects of VRelax compared to relaxation exercises were established by the time × treatment interaction.

Third, 2-way repeated-measures analysis of variance (ANOVA) was used to test differences between VRelax and standard relaxation exercises on global perceived stress, level of psychiatric symptoms, and cybersickness. Finally, carry-over effects were investigated by comparing outcome measures at baseline, T1, and T2 with paired *t* tests (baseline vs T1, T2 vs T1).

Results

Overview

Fifty patients were enrolled in this study between March 27 and December 17, 2018. One patient dropped out after randomization and did not start either condition, leaving 49 patients for analyses. For the primary outcome, 1.5% of data was missing (26 of 1762 VAS scores completed by 49 participants). Missing secondary outcome data ranged between 0% and 8.2%. Sociodemographic and clinical characteristics are shown in Table 1.

Table 1. Sociodemographic and clinical characteristics of the study sample.

Characteristic	Values
Participants, n	50
Age (years), mean (SD)	41.6 (14.2)
Sex, n (%)

The mean number of sessions was 9.4 (SD 3.5; range: 0-16 sessions) for relaxation exercises and 8.7 (SD 4.4; range: 0-24 sessions) for VRelax; the difference was not statistically significant. VRelax log files showed that the average time spent in VRelax video environments was 17 minutes (SD 9.5) per session. Use of different VRelax environments is shown in Table 2. Environments with interactive elements and swimming with wild dolphins were used most frequently.

Table 2. Time spent in VRelax, by environment.

VRelax environment	Mean time spent, min:sec	Visits, n	Total time spent, min (%)
Beach with interactive relaxation exercises	8:51	143	1265 (27.7)
Scuba diving with dolphins	5:11	166	862 (18.9)
Sea view from cliff with interactive music element	3:32	136	480 (10.5)
Quiet beach, start position	1:44	275	477 (10.4)

Mountain meadow with cows	2:23	68	162 (3.5)

Primary Outcome: Immediate Effects

Both VRelax and standard relaxation exercises led to a statistically significant reduction of negative affective states and improvement of positive affective states, as indicated by improvements on all VAS items (Tables 3 and 4). Mean changes in VAS item scores from before to after sessions within individuals were between 11.4%and 28.2% with VRelax, and between 4.6% and 28.3% with relaxation exercises (Table 5). VRelax reduced negative affective states significantly more than relaxation exercises (16.2% versus 21.2%; $t_{1684}=-2.02$, 95% CI −18.70 to −0.28; *P*=.04). Of the separate momentary affective state items, VRelax had a larger beneficial effect than relaxation exercises on feeling anxious, down, or cheerful.

Total negative affective state	−21.2	−16.2	4.082	−2.02	−18.70 to −0.28	.04

[a] VAS: visual analog scales.

[b] Percentage of change, mean scores after sessions compared to scores before sessions.

[c] Mixed model regression analyses. Treatment effect is estimated as interaction between time (before/after sessions) and type of intervention, adjusted for order of interventions.

Secondary Outcomes: Short-term Effects

Short-term effects on perceived stress and symptoms are shown in Table 6. Symptoms of depression and anxiety were reduced significantly after VRelax use. Perceived global stress level, symptoms of depression, and paranoid thoughts were significantly lower after standard relaxation exercises. There were no significant differences between effects of the two treatments, only a trend toward a superior effect of VRelax on anxiety symptoms (interaction time × treatment, F_1=3.650; *P*=.06).

We found period effects on momentary mood states and psychiatric symptoms (Table 7), with stronger effects in the second period than in the first.

No serious adverse events occurred. Several participants reported cybersickness, and 2 stopped using VRelax because of nausea and dizziness. Mean total score on the SSQ, however, was lower rather than higher after VRelax (43.1, SD 10.9) compared to before VRelax (48.3, SD 12.7).

Discussion

This randomized crossover clinical trial found that VR relaxation immediately reduced negative affective states and improved positive affective states in patients who concurrently received ambulatory psychiatric treatment. VRelax had a stronger effect on negative affective states than standard relaxation exercises, in particular on feeling anxious, down, or cheerful. Psychiatric symptoms, measured over a 10-day period, improved somewhat in both conditions.

The results suggest that immersive VR nature exposure is an effective tool for immediate improvement of affective states and reduction of psychological stress, more powerful than conventional relaxation exercises for making people feel better. The standard relaxation exercises were audio tracks that participants played on their computer or smartphone. Some tracks included 2-dimensional nature pictures. Numerous VR studies have shown that immersion in a virtual environment and the experience of being in a different world strongly induce psychological and physical effects [40]. Although viewing 2-dimensional nature images and videos has previously also been related to stress reduction [41], the immersive nature experience of VR is likely to have contributed to the superior effect.

The immersive VR experience is likely to distract attention from negative thoughts and stimuli, as is found in VR pain distraction studies [42,43]. Attention restoration has been proposed as a key mechanism of health-promoting effects of nature exposure [44-46]. Attention fatigue occurs when, after prolonged and intense use, the capacity to direct voluntary attention is reduced, and the capacity to ward off negative internal or external distractions is reduced [47]. The salient and pleasant characteristics of natural environments capture attention automatically and effortlessly, enabling recovery of voluntary, cognitively directed attention [11,48]. Another potential mechanism originates from psycho-evolutionary theory, stating that exposure to natural environments rapidly restores positive affect and reduces stress-related physiological activation because in earlier times, rapid recovery of stress increased chances of survival [49]. In both theories, nature exposure leads to positive affect and stress reduction, in accordance with the results that were found in the present study.

The effect of VR relaxation was not so strong on global perceived stress over the past 10 days. The perceived stress measure in this study included other aspects of psychological stress besides negative affective states, such as level of perceived control over things that happen, confidence to cope with problems, and ability to overcome difficulties [33]. Whereas affective states are sensitive to immediate and short-term changes [32], the cognitive and behavioral components of stress are likely to change more gradually. Optimal duration of VR relaxation for this purpose may be longer than 10 days, or the study period may have been too short to capture such changes.

Capturing and keeping attention is likely to be more difficult in patients with psychiatric disorders than in healthy individuals because vigilance is impaired and their cognitively directed attention is more severely fatigued [50]. Feedback of psychiatric inpatients during the prototyping phase of VRelax suggested that repeated passive viewing of calm, uneventful virtual nature environments was not always sufficient to distract from negative thoughts and feelings. We therefore added interactive elements to some of the videos, (ie, a relaxation exercise, a simple game of air bubble popping, and musical tones played in response to head movements). Indeed, in this study, the VRelax log files showed that the interactive videos were used longer and more frequently than the “passive” videos.

There was one notable exception: scuba diving with wild dolphins had the highest number of visits. The popularity of the dolphin video can be explained by several factors. Throughout the 7-minute video, there is a lot to be seen all around, with more than 20 active dolphins constantly moving, which may have created a stronger sense of immersion than the other videos. In addition, health-promoting effects on humans have been ascribed to dolphins. Dolphin-assisted therapy is offered for a range of physical and psychological problems, including autism and depression, albeit scientific evidence for efficacy is limited and debated [51,52].

Participants did not report many problems with the use of VR. Only 2 patients stopped using VRelax because of cybersickness, and SSQ scores were low after the intervention. It has been suggested that patients with a psychiatric disorder may experience increased psychiatric symptoms when using VR [16,53]. This may be caused by challenging VR content such as exposure to anxiety-evoking stimuli, which was not part of VRelax. Another potential cause of anxiety and paranoia may be that wearing a head-mounted display disconnects people from their real environment. These issues did not occur during the study, perhaps because participants used VRelax in the safe environment of their own home.

Strengths of this study include the randomized crossover design. Participants served as their own control, minimizing the impact of confounding factors. Analyses of temporal effects suggest carry-over effects of both interventions. Effects on primary and secondary outcomes were stronger in the second intervention period than in the first. However, the impacts of carry-over or period effects on the results of the study are likely to be small because participants were randomized in a 1:1 ratio for order of interventions, and analyses of the primary outcome were adjusted for order of interventions. As a consequence of the crossover design, it was not possible to investigate the effects of VR relaxation on medium- or long-term outcomes. It is conceivable that VR experiences have a longer-lasting impact than standard relaxation exercises because of the immersive character, or simply because people may find it easier to keep using VRelax than to keep doing relaxation exercises. We did not observe such a pattern during the short duration of this study.

Patients used the interventions multiple times over a (double) 10-day period, with effect measures before and after each session. These frequent assessments and detailed longitudinal data increased real life ecological validity and reliability of the primary outcome measure and increased statistical power of the study. A disadvantage was that patients had to reflect on their affective state immediately after relaxation sessions, which may have reduced the beneficial effects to some extent.

Another limitation is that we did not measure physiological effects of VR relaxation, which would have been a valuable outcome measure and a possible way to study biological mechanisms of VR nature exposure. Relaxation therapy, as well as nature exposure, has been related to changes in physiological stress parameters, such as vagal tone, electroencephalography alpha and theta waves, heart rate variability, blood pressure, gene expression, and cortisol level [54,55]. Recent research of VR nature videos found that electroencephalography event-related potentials may be used as a marker of attention restoration [56].

If the results of this trial are replicated and extended, VR nature exposure may provide an effective relaxation intervention to support and enhance psychiatric treatments. Stress management is a cornerstone of psychiatric therapies, but there is a dearth of effortless, pleasant, and powerful self-management tools for improvement of affective states and reduction of stress. Longer-term effects of VR relaxation on perceived stress, psychiatric symptoms, and relapse prevention should be investigated, as well as cost-effectiveness. In addition, integration of biofeedback and more interactive elements (eg, breathing exercises) may increase efficacy of VRelax. Finally, a broader use of VR relaxation can be envisioned for people in need of distraction, for example, during unpleasant medical interventions, during long isolated hospital stays, or for bedridden (terminally) ill patients. VR applications are rapidly growing and may have a profound impact on the landscape of mental health interventions.

Acknowledgments

Funding for this study was provided by UMCG, Healthy Ageing grant, number CDO17.0014/2017-1/308. The authors wish to thank The Dolphin Swim Club for sharing the 360-degree dolphin video and for their contribution to the development of the VRelax tool.

All statistical analyses were independently checked by Dr Klaas Wardenaar, statistician at University of Groningen, UMCG.

Authors' Contributions

WV designed the study, obtained funding, analyzed the data, and drafted the manuscript. BL contributed to the development of the interventions, collected the data, and critically reviewed the manuscript. MJ contributed to development of the VRelax tool, data collection, and analyses and commented on the manuscript. RH and CvD contributed to data collection, interpretation of the data, and writing and editing of the manuscript.

Conflicts of Interest

WV is cofounder and chief scientific officer of VRelax BV, the company that has developed the VR in collaboration with UMCG, and holds shares in VRelax BV. MJ is cofounder of VRelax BV and holds shares. The remaining authors have no conflicts to declare.

Abstract

Background: Alcohol use disorder (AUD) has been associated with diverse physical and mental morbidities. Among the main consequences of chronic and excessive alcohol use are cognitive and executive deficits. Some of these deficits may be reversed in specific cognitive and executive domains with behavioral approaches consisting of cognitive training. The advent of computer-based interventions may leverage these improvements, but randomized controlled trials (RCTs) of digital interactive-based interventions are still scarce.

Objective: The aim of this study is to explore whether a cognitive training approach using VR exercises based on activities of daily living is feasible for improving the cognitive function of patients with AUD undergoing residential treatment, as well as to estimate the effect size for this intervention to power future definitive RCTs.

Methods: This study consisted of a two-arm pilot RCT with a sample of 36 individuals recovering from AUD in a therapeutic community; experimental group participants received a therapist-guided, VR-based cognitive training intervention combined with treatment as usual, and control group participants received treatment as usual without cognitive training. A comprehensive neuropsychological battery of tests was used both at pre- and postassessments, including measurement of global cognition, executive functions, attention, visual memory, and cognitive flexibility.

Results: In order to control for potential effects of global cognition and executive functions at baseline, these domains were controlled for in the statistical analysis for each individual outcome. Results indicate intervention effects on attention in two out of five outcomes and on cognitive flexibility in two out of six outcomes, with effect sizes in significant comparisons being larger for attention than for cognitive flexibility. Patient retention in cognitive training was high, in line with previous studies.

Conclusions: Overall, the data suggest that VR-based cognitive training results in specific contributions to improving attention ability and cognitive flexibility of patients recovering from AUD.

KEYWORDS

alcohol use disorder; cognitive training; virtual reality

Introduction

Alcohol is a psychoactive substance that acts on the central nervous system, leading to dependence while causing severe physical, mental, and social problems [1]. Around 400 million people worldwide have problems related to excessive alcohol use, which is the third cause of death globally [2]. Alcohol abuse is also associated with diverse brain modifications [3], both at the structural and functional levels related to long-term, transient, or compensatory effects of alcohol [4], which have an impact on the integrity of the prefrontal brain cortex [5], causing deficits across a wide range of cognitive skills. These effects are particularly evident at the level of executive dysfunction, including attention, inhibitory control, behavioral control [3], verbal fluency, and decision making, similar to the effects of other substances, such as cannabis and cocaine [6]. Alcohol abuse in extreme cases may also lead to Korsakoff syndrome, which is characterized as an irreversible condition of anterograde amnesia [7].

These impairments at the brain level may disrupt behavior in such a way that individuals become overreactive to external cues related to the substance; this causes them to be unable to control substance-seeking behaviors and to make long-term decisions [8], which also affects treatment outcomes [9].

However, cognitive deficits resulting from chronic alcohol consumption are usually at least partially reversed during inpatient recovery periods, mostly as a result of abstinence [10]. While alcohol abuse is associated with morphological changes and reduced volume in multiple brain regions, mostly in the frontal lobe [5], abstinence from alcohol by patients recovering from alcohol use disorder (AUD) has been associated with significant recoveries in brain volume. The brain volume in these patients increases with the duration of the abstinence period; they also experience cognitive recoveries in speed and processing and shorter reaction times to stimuli [11]. Well-established treatments for alcohol dependence are, therefore, mostly designed with a focus on patients maintaining alcohol abstinence. Nevertheless, there is also agreement that the positive effects of abstinence at the cognitive level can be enhanced by cognitive interventions specifically designed to recover functions most compromised by alcohol abuse [12]; tests of the effectiveness of these interventions in the context of substance use disorders (SUDs) have been growing in recent years [13]. These cognitive interventions may be delivered in different formats. Cognitive stimulation typically involves group interventions for improvements not only in cognition but also socialization and does not focus on particular cognitive abilities. In contrast, cognitive training is a systematic training approach in which cognitive tasks are more focused on specific cognitive functions [14]. Its aim is to recover individuals' potential and minimize the impact of brain lesions via a set of programmed behavioral activities involving different cognitive functions [15]. For instance, Yohman and colleagues [16] found that patients who underwent classic cognitive training that focused on memory and problem-solving abilities showed greater improvements in the cognitive areas related to those abilities, but not to memory, than did control patients. Goldstein and colleagues [17] found that AUD participants exhibited significantly increased levels of perceptual and visuospatial skills, speed of information processing, and attention.

Meanwhile, recent technological progress has allowed new solutions for cognitive training based on the use of computerized systems to be developed. This trend is known as computerized cognitive training (CCT) and includes a growing number of systems available for cognitive training in different clinical contexts. An early study involving CCT did not show significant cognitive improvements from this treatment among individuals in residential treatment for AUD in comparison to controls [18], but more recent studies suggest that there are specific contributions from CCT for improving cognition in AUD patients. For instance, Fals-Stewart and Lam [12] found that individuals recovering from SUD, including abuse of alcohol, who underwent cognitive intervention within residential treatment programs reported better treatment outcomes than controls who underwent computer typing training and treatment as usual. Individuals in the experimental group reported being more involved both in the treatment and in the recovery program and stayed abstinent for longer periods of time; they also reported improved social and family behaviors. Two more recent studies using CCT have found specific cognitive improvements among patients in recovery programs for alcohol or other substances, with effects in executive functions [19], attention, delayed memory, and working memory [20].

A recent systematic review of cognitive training in AUD recovery suggests that these approaches may be useful to promote cognitive functioning on top of improvements due to mere abstinence. However, the available data with AUD individuals only provide evidence for near-transfer effects to very similar tasks, with no evidence regarding far-transfer effects to dissimilar tasks or to everyday functionality [13].

Some authors argue that virtual reality (VR)–based cognitive training is an especially ecologically valid form of CCT because it includes exercises that mirror everyday life activities and those that involve similar demands to those of everyday living [21]. For example, using VR-based serious games makes it possible to replicate different activities of daily living, such as tasks related to hygiene, having breakfast, choosing clothes, and going shopping, thus providing a function-led cognitive training approach [22], which may promote far-transfer effects of training to everyday living activities [23]. VR-based serious games have other advantages over traditional methods: immediate dynamic feedback, repeated practice, no physical consequences after an error, the setting, the fact that the task can be customized to the patient, and the fact that training involves progressive learning [19].

Thus, previous research suggests that there are positive effects of computer-based cognitive training, but the specific contributions of VR-based cognitive training reproducing everyday life activities have not yet been demonstrated. In particular, randomized controlled trials (RCTs) have been lacking. This study builds on previous research but proposes a pilot RCT to estimate the effects of a VR-based cognitive intervention on patients with AUD at the level of memory, attention functions, and executive functions; this approach will help in reducing biases associated with previous noncontrolled studies [13], while contributing to the estimation of effect sizes to determine necessary power for future definitive RCTs.

Methods

Trial Design

The study design consisted of a two-arm pre-post RCT in which participants were assigned either to an experimental group that underwent VR-based cognitive training combined with treatment as usual in residential community rehabilitation or to a passive control group comprising treatment as usual but without VR-based cognitive training. This trial consisted of an open-label RCT in which patients, researchers, assessors, and therapists were not blinded to group allocation. The allocation ratio was 1:1. Both groups underwent the same treatment program for alcohol recovery that is administered to all inpatients in residential treatment. Random allocation was concealed prior to the start of the study and was based on simple randomization after baseline assessment with random number generation in Microsoft Excel, Office 365. The intervention model consisted of a parallel design. The trial was retrospectively registered at ClinicalTrials.gov (NCT04505345).

Recruitment

The sample was recruited from September 2017 to May 2018 at a clinic for recovery from AUD, *Casa de Saúde do Telhal*, in the Lisbon region of Portugal. Recruitment was conducted during the psychological appointment of each patient's first week of treatment. Treatment for recovery from AUD in this institution is based on a 4-week residential treatment program following the Minnesota Model. To be included in the study, participants had to be at least 18 years old, with normal or corrected-to-normal vision and hearing, without a history of psychiatric or neurological disorders, and attending the inpatient program at the institution where the data were collected. Exclusion criteria were the presence of a psychosis episode during the program and withdrawal from the inpatient program. These criteria were checked by the clinician who conducted patient recruitment.

Outcomes

The outcomes of this study were selected from well-established neuropsychological tests. Primary outcomes were based on general cognitive functioning and executive functions, while secondary outcomes were based on specific cognitive tests for memory, attention, and cognitive flexibility.

Global Cognition

The Montreal Cognitive Assessment (MoCA) [24] was developed as a rapid tool for cognitive screening and has been validated for the Portuguese population [25]. The average duration of assessment completion ranges from 10 to 15 minutes, with no specified time limit. It consists of 11 items assessing cognitive domains, such as visuospatial orientation, naming, memory, attention, language, abstraction, evocation, and orientation. The maximum score is 30 points, with the cutoff point at 24 points.

Executive Functions

The Frontal Assessment Battery (FAB) [26] is a neurocognitive evaluation tool used to assess executive functions and has also been validated for the Portuguese population [27]. This test assesses six constructs: conceptualization, mental flexibility, programming, sensitivity to interference, inhibitory control, and environmental autonomy. The maximum score is 18 points, with three cutoff points: less than 12 indicates dementia, 12 to 14 indicates dysfunction, and 15 to 18 is in the normative range.

Memory

The Rey Complex Figure test (RCF) [28] was used to evaluate the capacity of motor perceptual organization, attention, and immediate nonverbal visual memory. This test is divided in two parts: the first part consists of an exercise in visual reproduction, followed by an interval of about three minutes, after which participants are asked to reproduce the same figure by memory (ie, the second part). The maximum total score of both parts is 36 points. Evaluation of the task is both quantitative (ie, performance time and points) and qualitative (ie, assessment of the level of reproduction). In this study we used only the quantitative scoring.

Attention

The Toulouse Pierón test (TP) [29] was used to evaluate permanent voluntary attention, concentration, resistance to fatigue, and stimulus processing. The test has a timed duration of exactly 10 minutes. During this time the participants have to identify the largest number of characters in a proof sheet from those that are indicated at the top of the sheet. The test measures the total number of characters processed (ie, hits) and omissions. The outcomes consist of correct responses, errors, and omissions along with dispersion index (DI) and working efficiency, which are given as follows:

$$\text{Dispersion index} = (\text{errors} + \text{omissions}) / \text{hits} \times 100$$

$$\text{Working efficiency} = \text{hits} - (\text{errors} + \text{omissions})$$

Cognitive Flexibility

The Wisconsin Card Sorting Test (WCST), developed by Grant and Berg [30] and studied by Nyhus and Barcelo [31], assesses strategic planning, abstract thinking, and capacity for perseveration and conceptualization. It also assesses the ability to use environmental feedback in modeling cognitive functioning, object-directed behaviors, and modeling of response impulsiveness. The test consists of 128 cards divided into two decks of 64 each. The cards vary in color (ie, red, green, yellow, and blue), shape (ie, triangles, stars, crosses, and circles), and number (ie, one, two, three, and four). Participants must match the 128 cards to the 4 stimulus cards that the examiner places on the table. The WCST was scored on six performance parameters: number of trials administered, number of total errors, number of perseverative errors, number of trials to complete first category, failure to maintain set, and conceptual-level responses.

Procedure

Overview

The ethics committee of the School of Psychology and Life Sciences of the host institution approved the human subjects protocol used in this study. It was conducted according to best practices on human research and the principles of the Declaration of Helsinki.

After reading and signing the offline informed consent document, participants from both groups first completed a sociodemographic and clinical data questionnaire and then a flexible neuropsychological assessment battery consisting of tests of global cognition (ie, MoCA), executive functions (ie, FAB), attention (ie, TP), memory (ie, RCF), and cognitive flexibility (ie, WCST). Participants took between 1 and 1.5 hours to complete this session. Participants were given a code to ensure anonymity, and the questionnaires and battery of tests were identified with this code to pair them with posttreatment assessments.

Participants in the experimental group underwent the VR intervention plus treatment as usual during their second and third weeks of hospitalization. This intervention consisted of 10 sessions, each lasting 30 to 40 minutes, which ran twice a week over a period of 5 weeks; these sessions consisted of the performance of VR exercises based on activities of everyday life guided by one therapist in individual sessions, increasing in difficulty from session to session. Participants in the control group underwent treatment as usual for AUD.

The training intensity can be considered low in terms of the number of sessions, session duration, and total treatment dose, which fell below the common range of 10 to 14 hours [13]. These sessions were conducted at *Casa de Saúde do Telhal* during the patients' psychological appointments for AUD recovery.

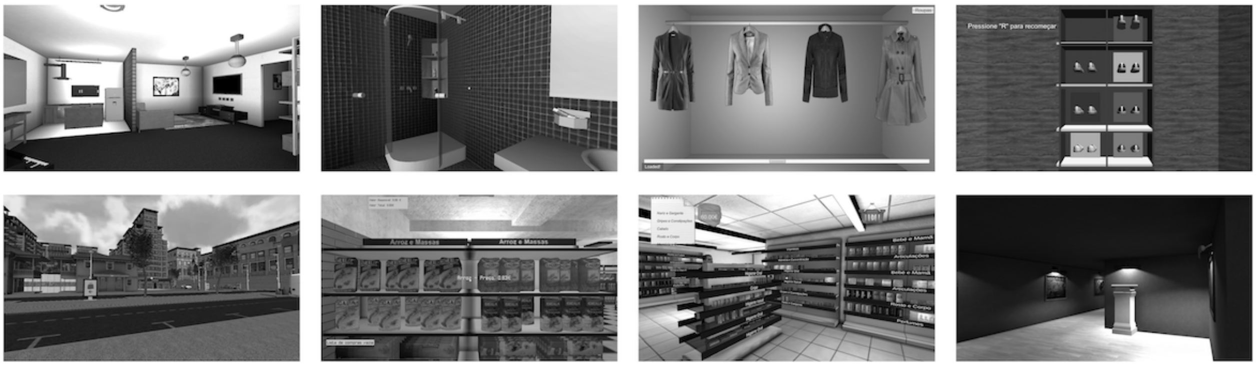
In the last week of hospitalization, both the control group and the experimental group participants completed the same battery of neuropsychological evaluation tests that were applied in the first session. This session was led by the same evaluator of the first assessment. None of the therapists or evaluators involved in these sessions were the owners of the software used.

Systemic Lisbon Battery

Cognitive training was conducted with the Systemic Lisbon Battery (SLB), release 2016 [19], a VR-based serious games platform that has been tested for cognitive training and assessment developed with Unity3D (Unity Technologies) for the Windows 10 system (Microsoft). Prior studies with the SLB for cognitive assessment have provided normative data with subsamples from the Portuguese population [19]. Regarding cognitive training, the SLB has been tested among different samples of participants with cognitive deficits due to brain injuries [32] and was also adapted to different technological platforms, such as mobile technology [33].

The SLB was developed as an alternative to the conventional methods of neurocognitive rehabilitation, but in this study it was used only for cognitive training. The platform consists of a virtual city with several built-up areas, a mini market, a pharmacy, an art gallery, and an interactive home; it also includes nonplayer characters walking around the city. The user is free to walk around the city and is given tasks to pick up certain objects in order to achieve a number of preset goals (eg, buy ingredients from a list at a grocery store). Elements from serious games, such as amount of money used or saved being used as a performance score along with visual and auditory feedback following completion of the tasks, are included in this platform to increase patients' motivation and retention rates with therapy. Figure 1 depicts some of the tasks comprising the SLB.

Figure 1. Examples of the virtual reality tasks used for cognitive training.



Statistical Analysis

The data were analyzed using SPSS Statistics for Windows, version 21.0 (IBM Corp). Normality was assessed by analyzing the distributions for each outcome according to skewness and kurtosis and was tested with the Shapiro-Wilk test. Skewness and kurtosis were within limits (±2) for the study variables, except for the DI of the TP. Shapiro-Wilk tests revealed that only the DI of the TP at both assessments and the copy trial from the RCF at postassessment violated the normality assumption. Therefore, those variables were assessed with nonparametric tests.

The baseline characteristics of the groups were compared using Student *t* tests for independent samples for outcomes with normal distribution and Mann-Whitney tests for independent samples for outcomes without normal distribution.

To test the effects of the treatment, we used repeated-measures analyses of covariance (ANCOVAs) with one within-subjects factor (ie, pretreatment vs posttreatment assessment) and one between-subjects factor (ie, experimental vs control group) while controlling for potential confounders. Effect sizes in the ANCOVAs are reported as η^2 and are given by the following equation:

$$\eta^2 = SSB / SST$$

where SSB is the sum of squares for between-subjects factors and SST is the sum of squares for the total model. Following Cohen [34], we consider a small effect size as starting from 0.01, medium as starting from 0.06, and large as starting from 0.14, so as to inform future definitive RCTs. The statistical tests were explored with post hoc tests using the Bonferroni correction method. The statistical results were tested with an analysis of simple effects using Bonferroni correction. For nonnormal distributions, Wilcoxon signed-rank tests for two related samples were conducted separately for the experimental group and the control group. The significance level was set at α=.05.

Results

User Statistics

The final sample consisted of 36 patients; 30 (83%) were male, they were aged between 24 and 65 years (mean 44.83, SD 12.04), and the mean number of years they consumed alcohol was 14.31 (SD 4.34). From those 36 patients, 19 (53%) were assigned to the experimental group and 17 (47%) were assigned to the control group. From the total sample of 36 participants, 5 (14%) reported having used other substances in addition to alcohol in the past. Out of 36 participants, 6 (17%) had completed only 4 years of school (ie, elementary school), 22 (61%) had completed 6 years of school (ie, middle school), 7 (17%) had completed 9 years of school (ie, high school), and 1 (3%) had completed more than 12 years of school (ie, a higher degree). No differences were found between the experimental and control groups regarding gender distribution (*P*=.29) or level of education (*P*=.38). However, age did differ between the experimental and control groups; it was significantly higher in the control group (mean 51 years, SD 12.34) than in the experimental group (mean 40 years, SD 9.21; *P*=.004). Years consuming alcohol did not correlate with neuropsychological performance in these tests. The initial pool consisted of 41 patients who were recruited for the study, but 1 (3%) was excluded based on the exclusion criteria, while 4 (11%) were lost to follow-up: 3 from the experimental group were lost due to difficulties in using the computer and a lack of motivation to continue with cognitive training and 1 from the control group had discontinued residential treatment (see flow diagram in Figure 2).

Evaluation Outcomes

Baseline Comparisons Between Groups for Each Outcome

The comparisons between groups at the baseline assessment for each of the outcomes showed statistically significant differences in the total scores on the MoCA test (t_{34}=3.049; P=.004) and the FAB test (t_{34}=2.587; P=.01), suggesting better cognitive and executive functioning in the experimental group than in the control group.

However, because these differences could be due to the higher average age of controls, further analyses accounted for this by using the MoCA and FAB scores at baseline as covariates. Age did not correlate with MoCA (P=.62) or FAB scores (P=.58).

Pre-Post Comparisons for Each Outcome

Pre-post comparisons were performed using ANCOVAs with treatment assessment point (ie, time 1 vs time 2) as a within-subjects factor and treatment (ie, experimental vs control group) as a between-subjects factor controlling for baseline MoCA and FAB total scores on outcomes that were normally distributed. For outcomes that violated normal distribution, separate Wilcoxon tests were conducted for the experimental and control groups controlling these confounders. These analyses revealed a significant effect of the intervention on attention in two out of five of the TP outcomes and on cognitive flexibility in two out of six of the WCST outcomes. Improvements between pre- and posttreatment assessments in the experimental group were found for attention, concentration, cognitive flexibility, visual perception, and memory; these are discussed in more detail in the following three sections.

Attention and Concentration

The ANCOVA revealed a significant interaction effect between factors for correct responses ($F_{1,32}$=19.512; η^2=0.609; P<.001) and for working efficiency ($F_{1,32}$=10.986; η^2=0.343; P=.002). Simple effects (ie, Bonferroni corrected) showed a more pronounced improvement in both outcomes for the experimental group (P<.001). The same analysis comparing groups at each assessment point showed a difference between groups only at the posttreatment assessment for correct responses (P=.02) and for working efficiency (P=.03), as depicted in Table 1.

Table 1. Attention outcomes through the Toulouse Pierón test (TP).

Attention outcome	Experimental group score, mean (SE)		Control group score, mean (SE)	
	Pretreatment	Posttreatment	Pretreatment	Posttreatment
TP no correct responses	128.47 (7.95)	192.76 (10.12)	140.17 (8.48)	155.85 (10.79)
TP working efficiency	106.54 (8.40)	171.34 (17.57)	112.79 (8.96)	108.61 (18.73)

Wilcoxon tests were conducted separately for the experimental and control groups, controlling for MoCA and FAB scores that were divided into two groups by median split. Therefore, eight Wilcoxon tests were conducted comparing pre-post assessments for the DI: experimental group MoCA score of 23 and below (ie, median) versus experimental group MoCA score above 23, and experimental group FAB score of 14 and below (ie, median) versus experimental group FAB score above 14; the same design was used for the control group. These comparisons showed significant differences between pre-post assessments only for the group below the median score for the FAB, revealing a decrease in the DI for both the experimental group (*Z*=–2.240; *P*=.03) and the control group (*Z*=–2.934; *P*=.003), thus suggesting no group effects in pre-post assessments of the DI.

Cognitive Flexibility

The ANCOVA for each of the WCST outcomes indicated a significant interaction effect for the total number of errors ($F_{1,28}$=12.482; η^2=0.446; *P*=.001) and the number of trials to complete the first category ($F_{1,28}$=4.653; η^2=0.166; *P*=.04). Simple effects (ie, Bonferroni corrected) suggested more pronounced improvements in these outcomes in the experimental group (*P*<.001). A difference between groups was observed at the pretreatment assessment for the number of trials to complete the first category (*P*=.02), while at the posttreatment assessment a difference was found for the total number of errors (*P*<.001). A main effect was also observed for the number of trials administered ($F_{1,28}$=9.041; η^2=0.244; *P*=.006), indicating an improvement from pre- to posttreatment assessment in both groups. These results are shown in Table 2.

Table 2. Cognitive flexibility outcomes through the Wisconsin Card Sorting Test (WCST).

Cognitive flexibility outcome	Experimental group score, mean (SE)		Control group score, mean (SE)	
	Pretreatment	Posttreatment	Pretreatment	Posttreatment
WCST no errors	74.72 (3.14)	52.43 (2.70)	71.79 (3.62)	72.45 (3.12)
WCST no trials to complete first category	40.31 (3.92)	15.86 (1.62)	23.95 (4.53)	12.89 (1.87)

Visual Perception and Memory

Despite the fact that the ANCOVA did not reveal a significant effect in the total score from the RCF for the memory trial, the analysis of simple effects (ie, Bonferroni corrected) showed a significant improvement between pre- and posttreatment assessments in memory ability for the experimental group (*P*=.002) (see Table 3). The copy trial from the RCF was assessed using Wilcoxon tests conducted separately for the experimental and control groups, controlling for the MoCA and FAB scores: experimental group MoCA score of 23 and below (ie, median) versus experimental group MoCA score above 23, and experimental group FAB score of 14 and below (ie, median) versus experimental group FAB score above 14; the same design was used for the control group. Only one comparison was significant in the control group with FAB scores below the median (*Z*=–2.684; *P*=.007), which indicates that there were no consistent intervention effects on this outcome.

Table 3. Memory outcomes through the Rey Complex Figure test (RCF).

Memory outcome	Experimental group score, mean (SE)		Control group score, mean (SE)	
	Pretreatment	Posttreatment	Pretreatment	Posttreatment
RCF memory trial	21.54 (4.92)	37.80 (5.68)	22.16 (5.24)	24.99 (6.06)

Discussion

Principal Findings

There is evidence that cognition improves during recovery treatment for AUD, while such improvements may be enhanced by the specific effects of cognitive training [10]. Moreover, the use of VR tasks for CCT is better suited to promote the transfer of skills to everyday living, as these tasks are closer to real-life activities than most of the exercises used in classic cognitive training [23]. The aim of this study was to determine the specific contributions to cognition of a multidomain CCT using VR among residential patients recovering from AUD. For that, a pilot RCT was carried out to study the feasibility of this approach in distinguishing the effects of treatment with CCT. RCTs are the emerging gold standard for unbiased testing of treatments and have been lacking from this area of research.

The results found in this study converge with previous research [19,20] in which patients with AUD who underwent cognitive training showed greater cognitive improvements, particularly in areas related to executive functions, than those who did not undergo any particular cognitive treatment. In this study, specific attention effects and cognitive flexibility effects (ie, executive functions) were found.

At the initial assessment, the two groups had different results in the MoCA and FAB measures, suggesting different levels of general cognitive ability and executive functions. In order to control for the effect of this difference on the outcomes, these variables were controlled in the pre-post analyses. In those analyses, we found significant differences in cognitive performance between pre- and posttreatment for both groups in attention, as assessed with the TP, and in cognitive flexibility, a component of executive functions, as assessed with the WCST; this shows evidence of the positive effects of the residential treatment plan and alcohol abstinence, confirming a robust finding in the literature [10,11]. In addition, it was found that effect sizes in these outcomes were large and were more pronounced in attention outcomes than in cognitive flexibility.

However, in-depth analyses show that there were significant differences between the groups at the final assessment point for the correct responses and DI of the TP and total number of errors in the WCST; however, in other indicators (ie, number of trials to complete the first category in the WCST) that showed improvements between pre- and postassessments, the experimental and control groups did not significantly differ. This pattern of results suggests that there were effects by the VR training sessions in the experimental group beyond simple abstinence-related effects; this also suggests that the task-specific learning in cognitive training promoted neuroplasticity more clearly than abstinence by itself, thus promoting more consistent improvements in attention and cognitive flexibility, as specific components of executive functioning. In fact, executive dysfunctions typically associated with the prefrontal cortex are among the most pronounced deficits due to alcohol abuse [5].

Patient retention was another positive feature of this intervention that speaks to its feasibility, as only 14% (3/22) of patients discontinued the cognitive training intervention, which is near the lower bound of the range of 8% to 41% found in a recent review of previous studies [13].

Overall, this study suggests that the use of VR scenarios is a feasible option to enhance cognitive recovery in patients with AUD, specifically at the level of attention, and that it may also support improvements in cognitive flexibility; these are important cognitive abilities also underlying decision making and retention in recovery programs for AUD [35].

Limitations

One main limitation of this study was the small dose of the intervention. Given the time of stay for rehabilitation in residential treatment at the partner institution, it was not possible to extend rehabilitation over a longer intervention period. Thus, training intensity was inferior to most studies with cognitive rehabilitation [13], which may have compromised the ability of this trial to detect other positive intervention outcomes, enhancing a type II error. The small sample size and low power also enhanced a possible type II error, and replication with larger samples is still needed. On the other hand, the fact that this study was not double-blinded could have increased a type I error. The use of a passive control group consisting of treatment as usual, but without virtual training, precluded the use of blinding procedures to both patients and evaluators. It is important that further studies have an independent evaluator blinded to patient assignment.

Conclusions

In this study, we found a positive impact of the VR training on the cognitive rehabilitation, particularly on attention and executive functions, of individuals with AUD. Although the residential treatment according to the Minnesota Model has as its main objective the promotion and maintenance of abstinence behavior in relation to alcohol, it can also promote a recovery from alcohol dependence. Such cognitive improvements may not only contribute to a better quality of life among patients but also to their social and family functioning and, therefore, their ability to maintain abstinence.

Future studies should focus on more general outcomes related to functionality, well-being, or quality of life to help understand whether such cognitive-focused approaches also contribute to overall psychological adjustment or whether there are far-transfer effects of skills to dissimilar tasks than those trained in the program. It is also worth studying whether these effects remain stable with time when assessed at longer follow-ups.

Acknowledgments

PG was responsible for study conceptualization, writing the original draft, methodology, and software development and is the owner of the software used in this study. JO was also responsible for study conceptualization, conducted the formal analysis, and wrote, reviewed, and edited the manuscript. MM and EC, under the supervision of AD and PL, prepared the evaluation protocol and conducted the data collection. PL was also involved in study conceptualization. RB was responsible for revising and editing the final manuscript. All authors contributed to, and have approved, the final manuscript.

Abstract

Background: Since the rise of the internet, online health information seeking has become a worldwide phenomenon. However, health and health communication are inherently culture bound. A data-driven cross-country comparison enables us to better understand how cultural factors moderate the association between individual-level determinants and online health information seeking.

Objective: The objective of the study was to examine similarities and differences in determinants of internet cancer information seeking between the US and Chinese general public (excluding cancer patients and survivors) under the framework of a behavioral model of health services use.

Methods: This study used Health Information National Trends Survey (HINTS) 2017 (US data) and HINTS-China 2017 data to answer the research question. It focused on people with no cancer history and with internet access. For the HINTS 2017, the sample size was 2153; for the HINTS-China 2017, the sample size was 2358. To compare China and the United States, the researchers selected the same set of study variables for each dataset. Under the framework of the behavioral model of health services use, these predictors were predisposing factors, enabling factors, and need factors.

Results: In terms of the predisposing factors, a higher age, college degree or above, being currently unemployed, and having a family history of cancer were associated with internet cancer information seeking for the Chinese respondents; none of these factors were related to information seeking for the US respondents, although a lower age was associated with information seeking. Regarding the enabling conditions, lower trust in family members and friends as reliable information sources was the only factor associated with information seeking for the Chinese respondents, while no enabling factor was related to information seeking for the US respondents. Regarding the need factors, perceived health status was not related to information seeking for the Chinese respondents, while perception of poorer health condition was related to information seeking for the US respondents. Higher cancer fear was related to information seeking for both groups, but the magnitude of association was smaller for the Chinese respondents than for the US respondents.

Conclusions: Overall, under the framework of the behavioral model of health services use, the results based on multivariate logistic regression reveal clear patterns of cross-country/cultural differences in the factors associated with internet cancer information seeking behaviors: predisposing characteristics and enabling conditions are more important in China, while perceived needs are more significant in the US. Such differences might reflect possible US-China differences in job environment (eg, job pressure) and culture (individualism vs collectivism and family structure).

Introduction

Background

A milestone in monitoring the US public's access to and use of health information is the Health Information National Trends Survey (HINTS) initiated by the National Cancer Institute [1], which provides valuable guidance for practitioners. With the cultural sensitivity approach becoming increasingly popular [2], calls for the expansion of the HINTS research programs into other parts of the world have been made, and HINTS-China pioneered this international expansion [3]. The pilot international HINTS survey has been conducted twice in China, in 2012 and 2017 [3]. The replication of the HINTS research program in countries and regions outside the US based on similar measurement schemes benefits global health communication research in numerous ways; one is that it allows scholars to compare health information seeking behaviors among countries [3]. Data-driven, multicountry comparisons enable us to better understand how cultural factors moderate the association between individual-level determinants and health information seeking, which further helps practitioners evaluate the probability of successful health communication intervention designs in one country being transferable to other countries [3].

To fulfill the mission of the international expansion of the HINTS program, this study used HINTS and HINTS-China data collected in 2017 [4] to examine similarities and differences in determinants of online cancer information seeking between the US and Chinese general public (excluding cancer patients and survivors) under the framework of the behavioral model of health services use [5,6]. Since the rise of the internet, online health information seeking has attracted worldwide scholarly attention. However, most scholars have conducted such studies in a single country. Some scholars have designed comparative studies across countries [7,8], but they have normally been based on small nonprobability college student samples. Therefore, the results of this study can contribute to the health communication literature by generating more reliable insights into country differences in health information acquisition, such as internet cancer information seeking.

Literature Review

Determinants of Online Health Information Seeking

We not only reviewed studies on cancer information seeking on the internet, which are limited in number, but also reviewed research concerning generalized online health information seeking to present a more complete picture of the factors that potentially play a role. Regardless of the theoretical models used, the predictors of major concern in existing studies include mainly demographics [9], structural characteristics [9], and perception variables [10]. Additionally, such studies often assess physiological indicators, but they have rarely been found to be statistically significant [11].

The effects of demographic and structural variables are rather stable. According to HINTS data, Americans who refer to the internet for health information are younger than those who do not [9,11]. Additionally, age moderates the positive association between trust in internet information and online health information seeking [11]. Previous research has generally found that higher socioeconomic status is associated with greater health information acquisition [9,12,13]. Married people reported a higher frequency of internet use to search for health information [12]. However, the results related to gender are mixed. Some studies have found that women are more likely to use the internet to obtain health information than men [12,14], while others have found that gender does not make a difference [9,15].

Most studies on generic health information seeking concentrate on people's perceptions of risk, personal health status, self-efficacy, media trust, social support, and satisfaction with caregivers. Those with higher levels of perceived risks and fears and lower levels of confidence about their health status are more likely to search for health information on the internet [10,16-18]. Those with higher internet self-efficacy are more likely to obtain health information online [10,19-21]. Those who trust the internet as an accurate and reliable information source or channel are more likely to rely on it to obtain medical information [11,18,19]. Additionally, trust in other players or information sources is positively associated with online health information seeking behaviors. Trust in health information from family members, for instance, is positively related to internet health information seeking behaviors among the US population [22]. Social support is positively associated with web searches for health information [21,22]. People with more social ties can seek health information from their social ties when finding it difficult to obtain online [23]. In a similar vein, patients who are unsatisfied with doctors tend to use the internet for medical information [24].

Behavioral Model of Health Services Use and Health Information Seeking Predictors

We used the behavioral model of health services as the theoretical framework to organize the predictor variables of internet cancer information seeking, as the model evaluates the extent to which 3 sets of predictor variables (predisposing factors, enabling factors, and need factors) influence people's use of health services [5,6,25]. The model also suggests a causal order: predisposing characteristics such as demographics and social structures are exogenous; enabling factors are necessary conditions for people to use medical services; and need variables (perceptions of needs) must be defined for use to take place [25]. According to the model, the 3 categories of factors encompass both contextual and individual characteristics [26]. Contextual characteristics refer to the environment and circumstances of health care service access, health care provider characteristics, and community characteristics, which are often measured at the aggregate level instead of the individual level [26]. Individual characteristics include demographics, social factors, personal beliefs, personal financial status, personal perceptions of health status, and objective evaluation of one's physical status [26]. Contextual characteristics may influence access to health care services through individual characteristics [26]. Although the behavioral model of health services was originally proposed to explain people's use of health services, scholars have successfully applied it to explain variations in health information seeking or channel use [27,28]. Additionally, the model incorporating both contextual and individual characteristics is suitable for the comparative nature of this study because the US and China differ in terms of community structure, culture, and health traditions [29-32].

This study focused on how individual-level predisposing, enabling, and need factors are associated with information seeking and how their relationships vary as a function of the country group. Predisposing characteristics were age; gender; education; ethnicity; the status of a person in his or her community; general health attitudes, values, and knowledge; and genetic characteristics [25,26]. Enabling resources were access to health facilities, access to medical personnel, and access to the medical system, including health care policies, personal income, health insurance, social relationships, and organizational factors [25,26]. Need factors were an individual's evaluation of his or her health status, need for medical services, and concerns about health problems [25,26]. With reference to a study that analyzed HINTS-China 2012 data [27], the researchers of this study selected age, gender, educational attainment, marital status, and BMI as predisposing factors. Enabling factors were current occupational status, household income, and trust in social institutions and information channels. Need characteristics were perceived health status, fatalism about cancer, fear of cancer, and perceived cancer risks. Although these variables were measured at the individual level, Anderson's model suggests that contextual characteristics can exert an influence through individual-level characteristics, which can reflect meso- or macrolevel contextual influences [29-32]. For instance, occupational status and household income can reflect the influence of the mesolevel working environment; trust in family members as health information sources can reflect mesolevel family influences; and perceived need factors can reflect macrolevel cultural influences.

Differences Between the US and China

Health communication scholars have paid increasing attention to internet health information seeking in the US and Europe, but little is known about China, where more than 4 million patients were diagnosed with cancer in 2015 [33]. Health and health communication are inherently culture bound [2]. Research findings generated from the West may not be readily applicable to countries such as China and Japan, which differ significantly from the US and other Western countries. Because this study compares China and the US, the following sections focus on cultural and structural differences between the two countries.

China and the US vary in issues related to cancer control. First, the types of common cancers in China differ from those in the US. In China, lung cancer has the highest incidence rate [34]. In the US, prostate cancer has the highest incidence rates for men and breast cancer for women [35]. Second, the Chinese medical care system is not as well established as the US medical care system [36]. With market-oriented reforms, the traditional system of the government and state-owned enterprises taking care of all medical needs has collapsed, while the emerging medical insurance system is far from satisfactory [36,37]. Third, many Chinese people believe in Chinese traditional medicine based on a holistic worldview [32]. Some Chinese cancer patients choose integrated therapies combining Western and Chinese traditional medicines [38]. Fourth, the doctor-patient relationship in China has been deteriorating for more than a decade [39]. Unlike their US counterparts, Chinese families do not have family doctors and, as such, visit comprehensive and specialized public hospitals even for minor conditions such as colds and coughs; as a result, a huge workload makes it difficult for doctors and nurses in China to find time to communicate with patients and their family members [39]. Workplace violence involving doctors and patients/family members has often made Chinese media headlines [40]. The commercialized medical care system in China has further eroded public trust in doctors, who people believe conspire with pharmaceutical companies to make money off of patients [41].

Chinese culture differs from US culture. China is collectivistic, while the US is more individualistic [30]. Individualism versus collectivism is an important construct in health psychology; individuals in individualistic cultures tend to emphasize personal wellbeing [42]. Individualism versus collectivism moderates the relationship between negative affect and psychological wellbeing, and the strength of the negative association between negative affect and wellbeing is stronger in individualistic cultures than in collectivistic cultures [43]. Additionally, Chinese people are commonly believed to be more family oriented than their US counterparts [44]. In terms of social structure, although the one-child policy has destroyed the traditional Chinese extended family structure, families remain central in Chinese life [45]. Family members remain close to each other by staying in a so-called networked family, even though it is no longer characterized by physical proximity among members [45]. Comparing differences in the strength of family-related variables can partly address criticism that the behavioral model of health services use lacks consideration of social relationships [25].

Although the US has a longer history of internet commercialization, China has recently begun to take the lead in the commercialization of new media applications, which have penetrated every social stratum [46]. A case in point is that most street beggars print out QR codes to collect donations in the street. Therefore, Chinese people increasingly use various types of internet applications to obtain health information [47]. Additionally, China is ahead of the US in the delivery of internet medical services because venture capitalists and entrepreneurs have invested heavily in the internet medical care industry [48]. It is common for Chinese people to make medical appointments with doctors using internet applications such as hospital portals, social media, and mobile applications [47].

On the basis of the preceding discussion, this study plans to answer the following research question:

> *How do China and the US differ in the associations between predisposing/enabling/need factors and internet cancer information seeking behaviors among people without a history of cancer?*

Methods

Data Sources

This study used HINTS 2017 (US data) and HINTS-China 2017 data to answer the research question. HINTS 2017 had a final sample size of 3285. Of the respondents, 2756 had no history of cancer (current patients or survivors); thus, these respondents were the focus of the study.

HINTS-China is an effort jointly launched by the Chinese Ministry of Health Center for Health Education, Renmin University of China, the Chinese National Cancer Center, and George Mason University and was recently joined by Beijing Normal University [27]. HINTS-China modeled the majority of the question items in HINTS and was adapted to local Chinese characteristics and the Chinese population. In the pilot phase, the Chinese survey was conducted twice, in 2012 and 2017, and was administered only in the Chinese capital city, Beijing, and Anhui Province's capital city, Hefei. Beijing was chosen because it is a megacity and the economic center of China, and Hefei was selected because it is a less developed, second-tier Chinese city that represents a more typical Chinese city. HINTS-China 2017 followed the multistage stratified random sampling strategy of HINTS-China 2012 [25]. HINTS-China 2017 was conducted using in-person interviews, had a valid response rate of 64%, and resulted in a sample size of 3090, of whom 10 had a history of cancer.

Because online health information seeking is directly related to physical access to the internet, this study excluded those without internet access from the final model because it is obvious that those without internet access cannot search for cancer information on the web. The US sample contained 750 respondents who had never accessed the internet, and the Chinese sample had 723. Thus, the sample sizes of cancer-free populations with internet access were 2,153 and 2,358 for the US and China, respectively.

To compare China and the US, the researchers selected the same set of study variables as predictors in HINTS 2017 and HINTS-China 2017. Additionally, there were slight differences in the measurement scales of these predictors between countries, so recoding was conducted to facilitate comparison. Measurements of the predisposing, enabling, need, and outcome variables were as follows.

Variable Measurement

Predisposing Variables

Gender was recoded as female, with 1 = female and 0 = male. Educational attainment for the US and China was converted from 7-point and 6-point scales, respectively, to 4-point scales, with 1 = "Less than high school," 2 = "High school," 3 = "Vocational school," and 4 = "College and above." Marital status for both countries was recoded as "Currently married," with 1 = "Yes" and 0 = "No." Similarly, current occupational status was converted to "Currently employed," with 1= "Yes" and 0 = "No." Current smoking status was assessed by 2 items, which were the same in both countries' surveys. The first item was a filter question, "Have you smoked at least 100 cigarettes in your entire life?," with 2 choices, (1) "Yes" and (2) "No." Only those who answered "Yes" were presented with the second item, "How often do you now smoke cigarettes?," with 3 choices (1) "Every day," (2) "Some days," and (3) "Not at all." To combine the items into a single item, the researchers counted "No" for the first item as "Not at all" for the second item. BMI was calculated from height and weight using the standard formula. Both the Chinese and US surveys collected height and weight data. Family cancer history was measured using one item in both surveys. The US survey had 3 choices, (1) "Yes," (2) "No," and (3) "Not sure." The Chinese version broke "Yes" into "Close relatives" and "Distant relatives." They were recoded as a single variable, with 1 = "Yes" (including "Close relatives" and "Distant relatives") and 0 = "No or not sure."

Enabling Variables

Household annual income was originally measured at the interval level in China, which differs from the categorical income range used in HINTS 2017. Income in the Chinese version was recoded as a categorical variable in 4 quartiles (from "50,000 RMB yuan and below" to "150,001 RMB yuan and above" with a 50,000-RMB interval). Income in the US version, with 9 original categories, was also recoded in quartiles: "$0 to $19,999," "$20,000 to $49,999," "$50,000 to $99,999," and "$100,000 or more."

HINTS in both countries measured people's trust in social institutions and information channels as reliable health information sources. However, the Chinese and US surveys differed slightly in the design of the attributes of each question item. First, the US survey measured only people's trust in the generic internet, while the Chinese survey measured people's trust in 8 typical internet applications. Then, the researchers averaged the trust score for the 8 internet applications to create an overall score for trust in the internet for the Chinese data. Second, the US survey used a single item to measure people's trust in family or friends, while the Chinese survey measured them separately. Thus, the researchers averaged them to create a single score. Third, the US survey measured people's trust in newspapers or magazines, while the Chinese survey measured them separately. The researchers created a new item using the mean score. Fourth, the US survey measured trust using a 4-point scale, with 1 = "Not at all" and 4 = "A lot." In contrast, the Chinese survey measured trust using a 5-point scale, with 1 = "Very untrustworthy" and 5 = "Very trustworthy." The 4-point scale used in the US survey was converted numerically into a 5-point scale to make the comparison more straightforward. Taking into account the goal of the study, the researchers categorized trust variables into 5 groups. The first category was trust in social institutions, including government agencies, religious organizations, and charities, which were combined into an additive index. The second category was trust in traditional media channels, including print media, television, and radio, which were combined into an additive index (Cronbach alpha for US=.77; Cronbach alpha for China=.85). Trust in the internet, doctors, and family members and friends were used as they were in the following logistic regression analysis.

Need Variables

Self-confidence about personal health or perceived health status was measured on a 5-point scale, with 1 = Poor and 5 = Excellent. The scales for both countries were the same.

Both surveys measured fatalism about cancer, which was assessed by 4 items such as "It seems like everything causes cancer" and "When I think about cancer, I automatically think about death.” The US survey used a 4-point scale, with 1 = “Strongly agree” and 4 = “Strongly disagree.” The scale in the Chinese survey was slightly different, with 1 = “Strongly disagree” and 5 = “Strongly agree.” The scale in the US survey was reversed and numerically converted into a 5-point scale, thus allowing the researchers to more easily compare the magnitudes of the coefficients. They were added to an index (Cronbach alpha for US=.63; Cronbach alpha for China=.75).

Fear of cancer was assessed using a single item on a 5-point scale, with 1= “Not at all” and 5= “Extremely.” The surveys for the two countries were identical.

Perceived cancer risk was assessed by asking the respondents, “How likely are you to get cancer in your lifetime?” with 1 = “Very unlikely” and 5 = “Very likely.” The surveys for the two countries were identical.

Outcome Variable

Online cancer information seeking was the outcome variable. In HINTS 2017, online cancer information seeking was binary, with 1 = “Yes” and 0 = “No,” while HINTS-China 2017 measured it using a 4-point scale. To make them comparable, the researchers recoded “Never” and “Rarely” as “No,” and converted “Often” and “Sometimes” to “Yes.”

Data Analysis

In the first step, the researchers presented descriptive statistics of all the variables under examination. In the second step, the researchers used multivariate logistic regression to explore US-China differences in the associations between the 3 categories of the predictor variables and internet cancer information seeking (Table 1). The first model of the multivariate analysis examined only the main effects of the predictors; odds ratios, which are exponentiated log odds, were presented. The second model incorporated interaction terms of the country group (the US vs China) and predictor variables to examine between-country variation. The odds ratios of interaction terms are ratios of odds ratios. In the third step, the researchers presented conditional odds ratios of each predictor variable for each country group separately, and those predictor variables with statistically significant interaction terms were the focus of the discussion.

The US HINTS sample had missing values in most variables selected for comparison, and the listwise approach would have resulted in the loss of 569 observations (over 25% of the US sample cases). To maximize the number of observations used in the analysis, this study used the R package MICE (Multivariate Imputation via Chained Equations) to impute the missing values. Specifically, the researchers applied the CART (classification and regression trees) algorithm for categorical variables and PMM (predictive mean matching) for numerical variables [49]. A total of 50 sets of data with imputed values were generated for the US and China, and the coefficients and standard errors of the logistic regression results for the 50 imputed datasets were pooled together using the Rubin rules [50].

Table 1. Odds ratio of logistic regressions of predisposing, enabling, and need variables of internet cancer information seeking.

Variables	Model 1 odds ratio (95% CI)	Model 2 odds ratio (95% CI)
Predisposing variables		
Female (vs male)	1.07 (0.89-1.28)	1.11 (0.83-1.49)
Age	0.99 (0.99-1.00)*	1.02 (1.00-1.03)*
Education (vs less than high school)		
High school	0.88 (0.62-1.24)	1.08 (0.72-1.62)

Results

Descriptive Statistics

As seen in Table 2, the HINTS 2017 and HINTS-China 2017 had roughly the same percentage of cancer-free male and female respondents. However, the US sample had a much higher mean age, greater educational attainment, a lower rate of being currently married, and fewer employed people than the Chinese sample. The average BMI for the Chinese sample was lower than that of the US sample, and the percentage of regular smokers in the Chinese sample was slightly higher.

Regarding the other selected variables, the Chinese sample had higher perceived health status, while the US sample had slightly higher cancer risk perception and fear of cancer. The cancer fatalism scores for both did not differ much. The US respondents reported many more relatives diagnosed with cancers than their Chinese counterparts. The US respondents reported higher trust in social institutions, the internet, and doctors, while the Chinese respondents had more trust in family members/friends and traditional media.

Table 2. Descriptive statistics of dependent and independent variables for cancer-free respondents of the Health Information National Trends Survey (HINTS) 2017 and the HINTS-China 2017.

Variables	Categories or scales	US (N=2756)	China (N=3080)
Online cancer information seeking	Yes, n (%)	411 (14.90%)	322 (11.70%)
Predisposing variables			
Female	Yes, n (%)	1607 (58.30%)	1686 (61.17%)
Age	Years, mean (SD)	54.4 (16.1)	35.0 (11.5)
Education	Less than high school, n (%)	190 (6.90%)	494 (17.92%)
	High school, n (%)	507 (18.40%)	744 (27.01%)
	Vocational school, n (%)	813 (29.50%)	719 (26.10%)
	College and above, n (%)	1246 (45.20%)	798 (28.96%)
Currently married	Yes, n (%)	1428 (51.80%)	1944 (70.55%)
Currently employed	Yes, n (%)	1499 (54.40%)	2065 (74.94%)
BMI	kg/m^2, mean (SD)	28.45 (6.46)	22.6 (3.17)
Smoking status	Every day, n (%)	282 (10.25%)	421 (15.26%)
	Some days, n (%)	104 (3.78%)	65 (2.37%)
	Not at all, n (%)	2370 (85.98%)	2270 (82.37%)
Family cancer history	Yes, n (%)	1915 (69.47%)	620 (22.50%)
Enabling variables			
Annual family income	$0 to $19,999 / 50,000 RMB and below, n (%)	511 (18.55%)	757 (27.47%)
	$20,000 to $49,999 / 100,001 RMB to 150,000 RMB, n (%)	752 (27.27%)	1081 (39.22%)
	$50,000 to $99,999 / 100,001 RMB to 150,000 RMB, n (%)	840 (30.47%)	400 (14.52%)
	$100,000 or more / 150,001 RMB and above, n (%)	653 (23.71%)	518 (18.79%)
Trust in social institutions	3 items; 3-15, mean (SD)	8.72 (2.66)	8.49 (2.33)
Trust in traditional media	3 items; 3-15, mean (SD)	7.54 (2.62)	8.78 (2.66)
Trust in internet	1-5, mean (SD)	3.32 (1.07)	2.72 (0.75)
Trust in doctors	1-5, mean (SD)	4.51 (0.83)	3.87 (0.96)
Trust in family and friends	1-5, mean (SD)	3.10 (0.95)	3.85 (0.81)
Need variables			
Perceived health status	1-5, mean (SD)	3.41 (0.95)	3.98 (0.78)
Cancer fatalism	4 items; 4-20, mean (SD)	12.48 (3.34)	12.30 (3.19)
Cancer risk	1-5, mean (SD)	3.06 (0.96)	2.24 (0.86)
Cancer fear	1-5, mean (SD)	2.51 (1.10)	2.18 (1.01)

Logistic Regression Analysis

Table 1 presents the results of logistic regressions of the factors of online cancer information seeking for both countries. Model 1 examined the main effects, and Model 2 analyzed the moderation by country group of the associations between the three sources of predictors and internet cancer information seeking.

The results of Model 1 suggest that younger people (OR=0.99, 95% CI 0.99-1.00) who had obtained at least a college degree (OR=1.53, 95% CI 1.08-2.18), were currently not employed (OR=0.80, 95% CI 0.66-0.98), and had a family history of cancer (OR=1.51, 95% CI 1.25-1.82) were more likely to search for cancer information on the internet. In terms of enabling conditions, those who earned a moderate income (OR=0.74, 95% CI 0.58-0.94; OR=0.65, 95% CI 0.49-0.86), trusted the internet as a reliable source of information (OR=1.18, 95% CI 1.05-1.32), and distrusted family members and friends as reliable information sources (OR=0.87, 95% CI 0.78-0.97) were more likely to search the internet for cancer information. In addition, those who perceived themselves to be in poor health (OR=0.83, 95% CI to 0.75-0.93) and feared cancer (OR=1.45, 95% CI 1.33-1.58) were more likely to search the internet for cancer information.

According to the results of the tests of interaction terms in Model 2, as shown in Table 1, the Chinese and US groups differed in the associations between predisposing, enabling, and need factors and internet cancer information seeking. Three predisposing factor interaction terms were statistically significant: age (OR=0.97, 95% CI 0.95-0.99), educational attainment (OR=0.40, 95% CI 0.18-0.90) and family history of cancer (OR=0.42, 95% CI 0.29-0.61). The coefficient of family history of cancer, the only enabling factor, differed across country groups (OR=1.36, 95% CI 1.08-1.73). In terms of need factors, perceived health status (OR=0.81, 95% CI 0.65 to 1.00]) and cancer fear varied (OR=1.24, 95% CI 1.03-1.49) between the Chinese and US sample groups.

On the basis of the significance tests of the interaction terms, the researchers further calculated conditional odds ratios of predictor variables for each country group (Table 3). The relationship of age with the outcome variable differed across the country groups: senior respondents in the US sample were less likely to seek cancer information on the web (OR=0.99, 95% CI 0.98-1.00), while the opposite was true for the Chinese sample (OR=1.02, 95% CI 1.00-1.03). For the US sample, education did not play a role, while Chinese respondents with degrees from vocational schools (OR=1.58, 95% CI 1.03-2.42) or colleges and universities (OR=2.35, 95% CI 1.50-3.68) were more likely to seek cancer information online than those who had not graduated from high school. The employment status of US respondents was not a statistically significant predictor (OR=0.95, 95% CI 0.71-1.25), while a working Chinese respondent was less likely to search for cancer information online (OR=0.66, 95% CI 0.50-0.89). Chinese respondents with close and distant relatives diagnosed with cancer were more likely to search for cancer information on the internet (OR=2.23, 95% CI 1.73-2.88), which did not apply to US respondents (OR=0.94, 95% CI 0.72-1.23).

According to Table 3, the odds ratio of trust in family and friends for the Chinese sample was negative and statistically significant (OR=0.71, 95% CI 0.59- 0.86), which did not hold true for the US sample (OR=0.97, 95% CI 0.84-1.11). Although the interaction terms between family annual income/trust in the internet and the outcome variable were not statistically significant, Table 3 suggests that the conditional odds ratios for the Chinese sample were statistically significant, while those for the US sample were not. While family annual income was not related to the outcome variable for the US sample, the Chinese respondents in the two income categories between 50,001 RMB and 150,000 RMB were less likely to use the internet for cancer cognition than those below 50,000 RMB ($OR_{50,001\text{-}100,000\ RMB}$=0.70, 95% CI 0.51-0.96; $OR_{100,001\text{-}150,000\ RMB}$=0.65, 95% CI 0.43-0.99). Additionally, the conditional odds ratio of trust in the internet for the Chinese respondents was statistically significant (OR=0.71, 95% CI 0.59-0.86), while that for the US respondents was not.

The odds ratios for two need variables were statistically significant. Perceived health status was associated with internet cancer information seeking only in the US sample (OR=0.76, 95% CI 0.65-0.87]), not for the Chinese sample (OR=.94, 95% CI 0.79-1.11). Cancer fear was related to the dependent variable for both samples. However, the conditional odds ratio for the US sample (OR=1.59, 95% CI 1.41-1.79) was larger than that for the Chinese sample (OR=1.28, 95% CI 1.12-1.47), and Table 1 suggests that the difference is statistically significant.

Table 3. Bivariate and conditional odds ratios (ORs) for logistic regression of predisposing, enabling, and need variables of internet cancer information seeking.

Variable	US		China	
	Bivariate OR (95% CI)	Conditional OR (95% CI)	Bivariate OR (95% CI)	Conditional OR (95% CI)
Predisposing variables				
Female (vs male)	1.18 (0.93-1.49)	1.07 (0.83-1.37)	1.17 (0.92-1.47)	1.11 (0.83-1.49)
Age	0.99 (0.98-0.99)*	0.99 (0.98-1.00)*	1.01 (1.00-1.02)*	1.02 (1.00-1.03)*
Education (vs less than high school)				
High school	0.46 (0.23-0.90)*	0.53 (0.26-1.08)	1.01 (0.69-1.48)	1.08 (0.72-1.62)

Discussion

Principal Findings

This study used HINTS 2017 of the US and HINTS-China 2017 data to compare the associations between factors related to online cancer information seeking. Under the framework of the behavioral model of health services use, the results reveal clear patterns of cross-country differences: the Chinese respondents' internet cancer information seeking was associated more with the predisposing and enabling variables, while the US respondents' information seeking was related more to the need variables. Specifically, the internet cancer information-seeking behavior of the Chinese respondents was associated with the predisposing characteristics educational attainment, employment status, and family cancer history, while that of the US respondents was not related to any of the predisposing characteristics. For enabling conditions, the internet cancer information seeking of the Chinese respondents was related to trust in family and friends as reliable health information sources, while that of the US respondents was not correlated with any enabling factor. For need variables, the internet cancer information seeking of the Chinese respondents was not related to perceived health status, while that of the US respondents was negatively associated with perceived health condition, and the magnitude of the association between cancer fear and internet cancer information seeking was stronger for the US respondents than for the Chinese respondents. These cross-country differences reveal that the extent to which predisposing characteristics, enabling conditions, and perceived needs are related to internet cancer information seeking is possibly subject to the nature of a country's cultural and structural characteristics. The importance of predisposing characteristics and enabling conditions outweighs perceived needs in countries where, for example, the culture is more collectivistic or information channel credibility is of greater concern. The perceived needs of individuals may play a larger role in more individualistic cultures.

Conventional wisdom holds that people with high socioeconomic status have high internet and health literacy, which in turn allows them to use new technologies to satisfy their cognitive and emotional needs. However, the association between being employed and information seeking suggests that working overtime and having a more active social life, by-products of being employed and financially secure in China, may limit the available time for online cancer information seeking. China has a fairly strong family-oriented culture [45]. In the context of this study, as family members remain close to each other, when certain family members are diagnosed with cancer, such news spreads very quickly within the so-called networked family. Primed by such news and vividly aware of the serious psychological and physical consequences of being a cancer patient, Chinese people might go to the internet to search for cancer-related information such as preventive measures.

Additionally, the Chinese online cancer information seekers trusted family and friends as reliable information sources more than nonseekers did, which did not apply to the US respondents. This shows that when family members are trusted as sources of information, they can displace the internet as cancer information sources in China. Although Table 1 suggests that the interaction term of trust in the internet and seeking is not statistically significant, the results in Table 3 show that the conditional odds ratio of trust in the internet was positive and statistically significant only for the Chinese sample and not for the US sample. This might be attributed to the difference in the internet between China and the US. Chinese cyberspace has long been overwhelmed with misinformation about health [51]. Thus, trust in the internet may need to become a very salient factor before Chinese people decide to use the internet as a source of cancer-related information.

The US-China differences in the associations of need factors, such as perceived personal health status and cancer fear, might reveal individualistic versus collectivistic cultural influences. Perceived personal health status was associated with online cancer information seeking only for the US respondents and not for the Chinese respondents. Previous studies have suggested that people in individualistic cultures tend to pay more attention to personal wellbeing [42]. Naturally, when perceiving their health to be deteriorating, the US respondents were more likely than the Chinese respondents to take measures such as seeking information related to cancer prevention or treatment to regain psychological or physical wellbeing. The nonsignificant results for the Chinese population are consistent with a previous study analyzing HINTS-China 2012 data [27]. In that study, the authors speculated that cancer information seeking among Chinese people might be performed only for the good of others. By resorting to a comparative design, this study can offer more convincing evidence of the close relationship between culture and health information seeking. This study also found that the odds ratio of cancer fear was much smaller for the Chinese respondents than for the US respondents, which shows that cultural characteristics might influence cancer information seeking. In individualistic cultures, negative affect is considered to be an individual's responsibility and is conceptualized as harmful, while in collectivistic cultures, negative affect is considered to be external to individuals and natural [43]. This difference sheds light on the moderating effects of culture on the correlation between negative affect (fear of cancer, in this study) and online cancer information seeking. In the context of this study, Americans' fear of cancer might result from beliefs that cancer risks are related to unhealthy personal behaviors, so they might react to cancer fears more intensely than Chinese people and strive to correct the perceived problematic situation and regain wellbeing by seeking cancer information on the internet.

In this study, differences in the associations of age and educational attainment may be related to the composition of the sample respondents. For the Americans, the higher the age, the less likely they were to search for cancer information on the web; for the Chinese, the opposite was true. As Table 2 suggests, the US sample had a much higher average age. Commonly, younger people are more technologically savvy, and older people pay more attention to personal health. In other words, age carries two types of information here. For the US sample (older age) who already paid sufficient attention to health, age was more likely to approximate internet literacy, while for the Chinese sample (younger age) who already had sufficient internet skills, age was more likely to approximate attention to health. According to Table 2, the variation in educational attainment was lower for the Americans than for the Chinese, as almost 50% of the US respondents had a college degree and above, while the educational attainment in the Chinese sample was more equally spread across the four different categories. The lack of statistically significant results may be related to the lower variance in the predictor on the American side.

Limitations

This study is not without limitations. First, as it tried to select the exact same set of variables to be compared, it excluded several important variables related to health cognition because either the Chinese or US survey did not measure them. Although the researchers made the utmost efforts to unify the measures of all the variables used in the analysis, some, such as trust in social institutions and information channels, were not identically designed, which may have impacted the results to some extent. This study is based on secondary data from HINTS. Explanations of cross-country/cultural differences involve speculation based on theoretical and practical reasoning, so future researchers are advised to further explore the precise mechanism of how culture influences internet cancer information seeking by measuring antecedents to variables such as cancer fear.

The study has other limitations as well. The researchers used two cross-sectional surveys, so causal relationships cannot be truly established. The data used in this study were only from the HINTS, and cross-country/cultural differences could be confirmed only with more replications based on additional sources of data. In this study, all the measures were self-reported, and in this context, cultural differences in response style are likely to occur, or respondents may differ in their interpretation of the questions.

Conclusions

Despite these limitations, this study makes unique theoretical and practical contributions to the literature and practice. By comparing HINTS 2017 and HINTS-China 2017 data, this study found that predisposing characteristics and enabling conditions were more associated with internet cancer information seeking for the Chinese sample and that need factors were more related to information seeking for the US respondents. Such differences might reflect possible US-China differences in job environment (eg, job pressure) and culture (individualism vs collectivism and family structure). Future health communication researchers may consider incorporating cultural values into the study design when possible. Additionally, future studies in non-Western countries may consider focusing more on predisposing factors such as structural characteristics and enabling factors related to family structure. Because international charities and health nonprofits actively promote health causes in Asian and African countries, practitioners should consider not only being culturally sensitive but also placing culture at the center of their campaigns.

Abstract

Background: An increasing number of people are visiting hospital websites to seek better services and treatments compared to the past. It is therefore important for hospitals to develop websites to meet the needs of their patients. However, few studies have investigated whether and how the current hospital websites meet the patient's needs. Above all, in radiation departments, it may be difficult for patients to obtain the desired information regarding modality and diagnosis because such information is subdivided when described on a website.

Objective: The purpose of this study is to suggest a hospital website search behavior model by analyzing the browsing behavior model using a Bayesian network from the perspective of one-to-one marketing.

Methods: First, we followed the website access log of Hokkaido University Hospital, which was collected from September 1, 2016, to August 31, 2017, and analyzed the access log using Google Analytics. Second, we specified the access records related to radiology from visitor browsing pages and keywords. Third, using these resources, we structured 3 Bayesian network models based on specific patient needs: radiotherapy, nuclear medicine examination, and radiological diagnosis. Analyzing each model, this study considered why some visitors could not reach their desired page and improvements to meet the needs of visitors seeking radiology-related information.

Results: The radiotherapy model showed that 74% (67/90) of the target visitors could reach their requested page, but only 2% (2/90) could reach the Center page where inspection information, one of their requested pages, is posted. By analyzing the behavior of the visitors, we clarified that connecting with the radiotherapy and radiological diagnosis pages is useful for increasing the proportion of patients reaching their requested page.

Conclusions: We proposed solutions for patient web-browsing accessibility based on a Bayesian network. Further analysis is necessary to verify the accuracy of the proposed model in comparison to other models. It is expected that information provided on hospital websites will be improved using this method.

Introduction

Hospital Web Marketing in Japan

For patients to choose a preferred hospital, information transmission using a hospital website is important because the external environment is constantly changing, owing to improvements to the internet and new competitive relationships as a result of the declining trend of patients [1,2]. It is assumed that there are 2 major reasons why information on websites has become increasingly important for hospital management. First, patients can choose a hospital based on their personal preferences. The “paternalism model,” where physicians make decisions, was previously the mainstream; however, patients have shifted to an “informed decision model,” where they make decisions themselves [3]. A previous study conducted by the Japanese Ministry of Health, Labor, and Welfare revealed that the percentage of those who responded that “I have obtained information” for the item “Is information usually obtained when you visit the hospital?” increased by 30% compared to 2011 [4]. Second, the popularization of smartphones among all age groups has led to significant lifestyle changes [5,6]. Patients can select a hospital based on the information available on a website. According to the National Federation of Health Insurance Societies [7], the information from a hospital website has the largest impact on hospital selection. The internet serves as an important source of medical information [8]. A study showed that “hospital websites” and “information websites about hospitals”’ account for a high proportion of the available credible information.

In previous research targeting hospitals in Japan, the introduction of marketing departments in hospitals has recently been proposed [9]. However, medical advertising guidelines make it difficult for hospitals to advertise as a company [10]. In today’s society, with advances in the internet, it is expected that the proportion of individuals who choose to seek information from such sources when deciding on a hospital for an examination or treatment will continue to increase, despite the strict regulations. Therefore, hospitals need their own web marketing methods.

Improve Information Provision on Hospital Websites

Through recent marketing, CRM, one-to-one marketing, and personalization aimed at increasing patient satisfaction and loyalty by reaching individual consumers through the spread of the internet and intensified competition are attracting attention [11,12]. It is therefore desirable to transmit appropriate information to the websites according to the needs of each visitor. For this reason, to improve information provisioning on websites, it is common to analyze the current state of websites using quantitative data such as access logs. As advertising regulations were adopted on websites in Japan, the study focused on whether the information posted on websites followed the regulations [13,14]. In the United States, there are weaker advertising regulations on websites than Japan; a study evaluated the accessibility of websites to provide high-fidelity information from the viewpoint of public health [15]. Few have focused on the browsing behaviors of visitors on hospital websites. Suzuki et al [16] attempted to develop a method for creating browsing behavior models and assessing the intentions of patients on hospital websites. However, no models have been proposed that allow medical staff to intuitively understand the browsing behavior of patients and propose improvements to meet the needs of visitors seeking radiology-related information. Therefore, we focused on a Bayesian network that can easily understand variable relationships.

Owing to the market trends, we decided to analyze not all visitors but specific visitors. Our research target, Hokkaido University Hospital, is one of the largest hospitals in Japan with 944 beds. Furthermore, Hokkaido University Hospital has one of the 17 proton therapy facilities in the country and therefore provides advanced medical care in the field of radiotherapy [17]. It is possible that there was a certain need at this hospital to provide information in response to citizen requests for the transmission of radiology-related information. In addition, after the Great East Japan Earthquake (March 11, 2011), several individuals have become interested in radiology-related information. Some studies have reported that few people have sufficient knowledge of radiology, and many people are concerned about exposure to radiation [18,19]. Owing to these situations, several patients have sought information on the safety and effects of radiotherapy and radiological diagnosis. Furthermore, there are various types of radiological diagnoses, such as radiography, computed tomography, and magnetic resonance imaging, which make it difficult for patients to understand each type of examination. This study conducted a behavioral analysis focusing on visitors seeking radiology-related information.

The purpose of this study is to propose a hospital website search behavior model in which medical staff can easily understand the browsing scenario by analyzing the browsing behavior of visitors who are looking for radiology-related information based on the results of a Bayesian network from the perspective of one-to-one marketing.

Methods

Scheme

A flowchart of our research is shown in Figure 1. The page that we believe the target wants to browse was defined as the “request page (RP).” In addition, a target reaching the requested page was defined as a “conversion,” and the ratio of conversion as the “conversion rate (CVR),” as shown in .We attempted to enhance the CVR using a Bayesian network with an access log. We used the website data access log of the Hokkaido University Hospital website (Figures 2 and 3), which has 208 pages. Our research focused on the patients seeking radiology-related information at Hokkaido University Hospital as the target visitors.

Traffic Confirmation

First, we collected the website access log of Hokkaido University Hospital from September 1, 2016, to August 31, 2017. Knowing the purpose and needs of the visitors is useful for improving a website; however, this information usually cannot be observed, and it is necessary to understand this information through an analysis of the data access log. This research analyzed the access log using Google Analytics. Google Analytics is a tool that allows users to visualize the access status without a server that even medical clerks can easily handle. Google Analytics has been widely used in public institutions, including hospitals [16,20]. We used "page view," which shows the number of pages viewed by visitors, "session," which shows the number of times any visitor accessed the website, and "page depth," which shows the number of pages viewed in a single session.

Data Extraction

First, we acquired data from the access log by designating 8 indicators using Analytics Edge, which is an add-in service of Google Analytics. The following metrics were collected from the user's http request: 1, page title; 2, retrieval keyword by visitor; 3, municipalities of visitors; 4, browsing date by visitor; 5, network domain of the visitor; 6, page depth; 7, operation system of the visitor; and 8, page views. Although Google Analytics issues a "Client ID," which identifies the user, the website administrator cannot obtain the ID. Thus, the administrator cannot identify the individual user data from the raw data. Therefore, the behavior data of each user was identified by generating a pseudo user ID from indicators 2 to 7, which led to the identification of the user. We used only indicators 3 to 7 to identify the user. We extracted data for 870 sessions using 32 radiology-related keywords that the target would use as a retrieval keyword, as shown in Multimedia Appendix 1. This selection was made by a specialist in the field of radiology. The exclusion conditions in the data extraction used were as follows: we excluded the records of the session with a page depth of 1 because of the difficulty in interpreting the intention to visit [21]. To acquire patient data, we excluded the following types of data used in retrieval keywords: recruitment-related words (eg, touring and recruitment), technical terms (eg, academic society and doctor names), and words related to needs other than treatment and examination. We also excluded data with ".ac.jp" at the end of the network domain, which is called the second-level domain.

Second, we classified the extracted sessions into 3 types of needs using retrieval keywords: 1, sought radiotherapy information; 2, sought information on nuclear medicine examination; and 3, sought information on radiological diagnosis. The judgment of the 3 classifications was based on an interpretation of indicator 1: retrieval keywords by a specialist in radiology.

Third, the RP for the 3 groups were selected, as shown in Table 1. However, the RP was an estimate because we could not know for certain what information was needed. Thus, we chose the RP in order of high scores for "Explanation of flow of examination," "Request/notes," "Explanation of technical terms," and "Explanation of equipment" in reference to the previous study, for the 3 groups from the target website [22]. Table 2 shows the evaluation criteria. The Center Navigation page, that is, the link source of the Radiology Center page, was set as RP1. Because the Radiology page was an external link, we could not examine the access log.

Table 1. Request pages in each model.

Group	Request pages

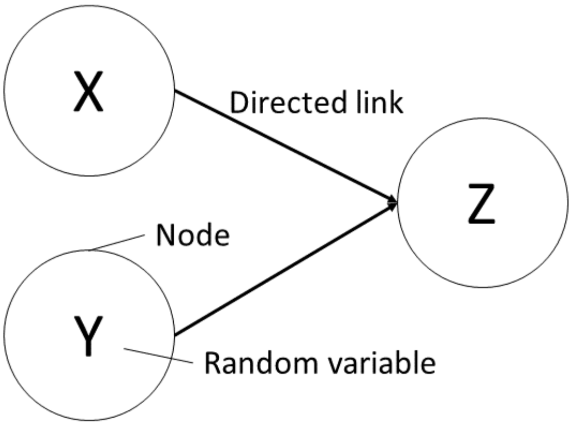
Fourth, we converted the extracted access log into behavioral data. These behavioral data show whether each visitor browsed each page. After calculating CVR, these data were applied to the Bayesian network.

Browsing Models

Behavioral models were built based on the Bayesian network model, using BAYOLINK version 7.0.1. A Bayesian network is a probabilistic model that expresses the qualitative dependence among multiple random variables using a graph structure and expresses the quantitative relationship between individual variables based on their conditional probability. Variables are nodes, and a linked node is referred to as a "child node," and a link source node is referred to as a "parent node," as shown in Figure 4. In addition, Bayesian network can be used to determine the probability distributions of child node by observing the parent node. When using statistical models in marketing, it is crucial to determine whether the model is useful for decision making. Bayesian networks can express relationships between explanatory variables and even model the entire structure [23]. Although previous studies on predicting website-browsing behavior used Markov models and n-grams, such approaches were based on the premise that recent page access records have a significant influence on future page accesses [24,25]. In our models, the input value was binary for the browsing or nonbrowsing of each page for the visitors based on the premise of prior research. In other words, whether the page was browsed was represented as a node of the network. To determine the structure of the network and the parameters, we adopted Akaike's information criterion as the standard for selecting the models and the greedy search algorithm as the standard for deciding on the construction of the models. Their criterion shows adaptability to data and simplicity. The greedy search algorithm is a method of dividing the problem element into a plurality of partial problems, independently evaluating each parent combination with the highest evaluation value. In this study, all nodes were designated as parent node candidates. In addition, to show the models briefly, we built each of the models by setting pages with a small number of views as "Other pages." In our models, all the variables were binary and indicated whether browsing was performed. The joint probability indicates the probability of an arbitrary behavior being observed, and the conditional probability distribution indicates the distribution of the browsing status of the target pages considering that of a certain page. Therefore, our models show the cause-and-effect relationship between the browsing pages of the target visitor. For example, in a model in which the child node is the treatment page and the parent node is the department page, we interpret this to mean that the browsing probability for the treatment page is affected by the browsing probability for the department page. A method was then necessary to judge the strength of the influence.

Figure 4. Bayesian network outline.



After structuring the browsing model, the sensitivity analysis was performed to determine the influence of other variables in the model on any variable and searched for pages that affected the browsing probability of the RP using mutual information. Mutual information content represents a measure of the independence of 2 random variables. Referring to the results of the sensitivity analysis, hypothetical experiments called a probability inference were conducted to determine the probability distribution of any other variable when observing certain variables and predicted the resulting variable, that is, the browsing probability of the RP.

Finally, some improvements were discussed to increase the browsing probability of the RP and meet the needs indicated from the models.

Results

Traffic Summary of the Target Website

There were 2,521,279 sessions during the study period, as presented in Table 3. Access to the department pages was concentrated next to the TOP page, as listed in Table 4. After data extraction, a behavior analysis was conducted for a total of 90 sessions, including 35 sessions for the radiotherapy interest group, 35 sessions for the nuclear medicine examination interest group, and 20 sessions for the radiological diagnosis interest group. The CVR for the 3 groups is presented in Table 5. In our study, 74% (67/90) of the targets could reach the RP.

Table 3. Access during the study period.

Indication	Values
Page views, n	2,521,279
Sessions, n	663,213
Users, n	381,307
Average pages viewed per sessions	3.8
Average session time (second)	146

Table 4. Access rate of main pages and radiology-related pages.

Page title	Page views, n (%)
TOP	362,785 (14.39)
Department Navigation	187,558 (7.44)
Medical Department Navigation	153,454 (6.09)
Department and Center Navigation	123,462 (4.90)
Access	99,806 (3.96)
Center Navigation	28,190 (1.12)
Radiotherapy Department	7757 (0.31)
Radiological Diagnosis Department	4839 (0.19)
Nuclear Medicine Examination Department	4651 (0.18)
Examination and Treatment	2407 (0.10)

Table 5. Accessibility to request pages in each model.

Group	CVR[a] (%)				
	RP[b]1 (%)	RP2 (%)	RP3 (%)	RP4 (%)	Total (%)

Nuclear medicine examination	2.9	31	9.0	57	83
Radiological diagnosis	0	45	5.0	—	50

[a] CVR: conversion rate.

[b] RP: request page.

[c] The lower rank RP in certain groups was not set in our judgement. Therefore, certain CVRs were treated as not applicable.

Radiotherapy Interest Group

The model described in Figure 5 was structured using 35 sessions from the learning data. The browsing of RP2, the "Radiotherapy Department page," was affected by the browsing of the Proton Therapy News page, which affected the browsing of the radiology-related department and Medical Expenses pages. The results of the sensitivity analysis are illustrated in Figure 6. The mutual information volume of the Proton Therapy News page was the largest, indicating that browsing this page had the greatest effect on the browsing of RP2. Based on the results of the sensitivity analysis, we calculated the change in the browsing probability of RP2 owing to browsing or nonbrowsing of the pages based on a probability inference, as shown in Figure 7. When the target visitor browses the Radiological Diagnosis Department page, the probability of RP2 increased by 17% from the prior probability.

Figure 5. Radiotherapy model.

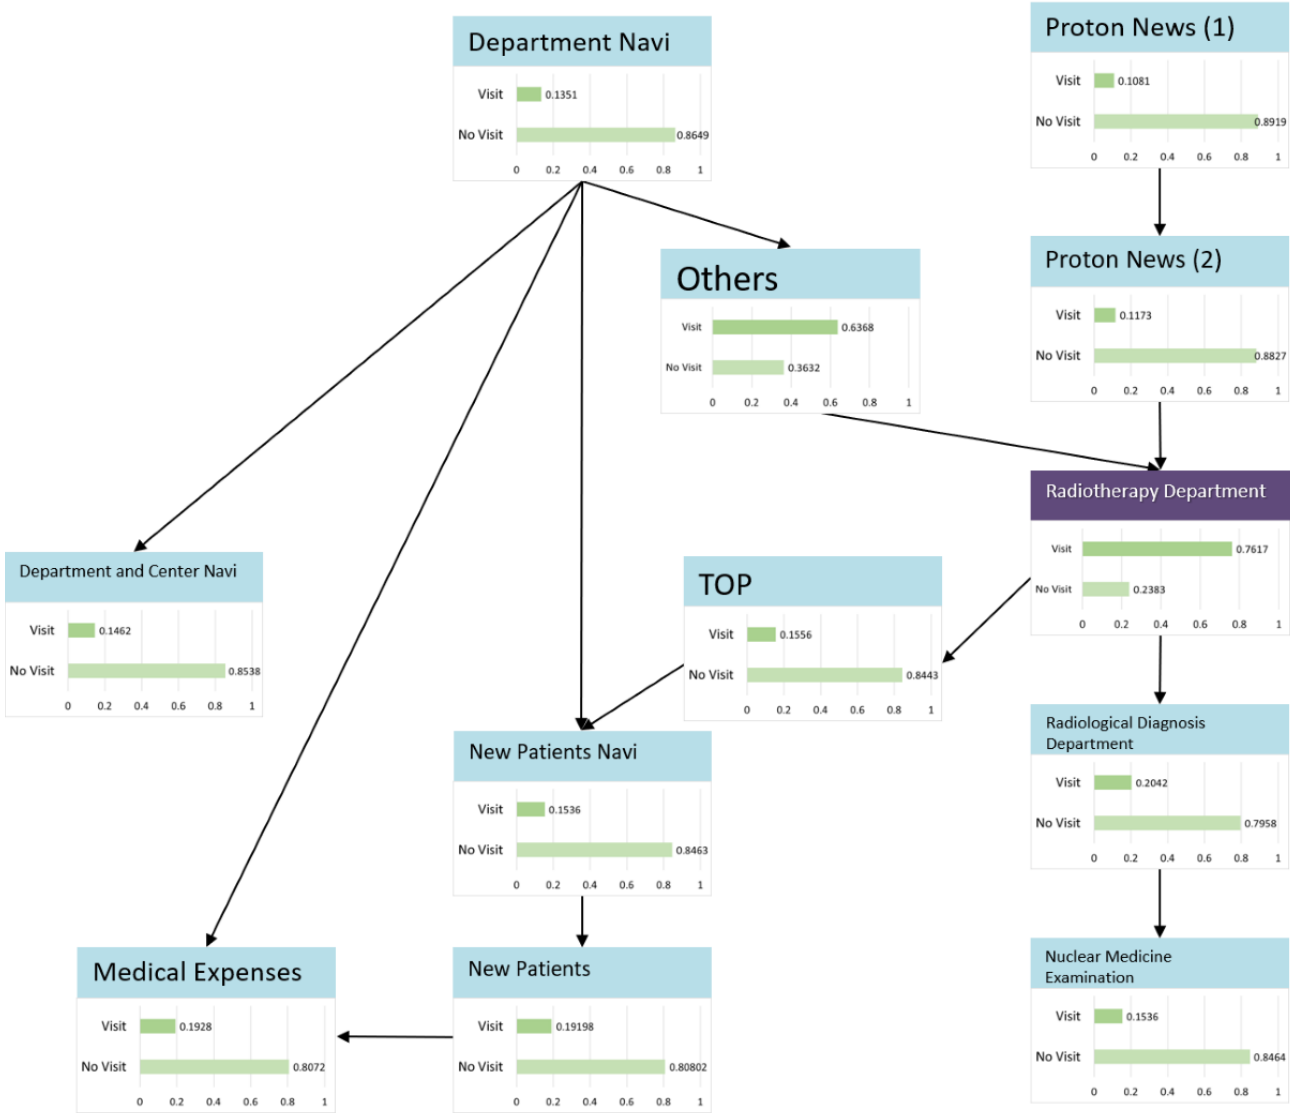

Figure 6. Sensitivity analysis (radiotherapy interest group).

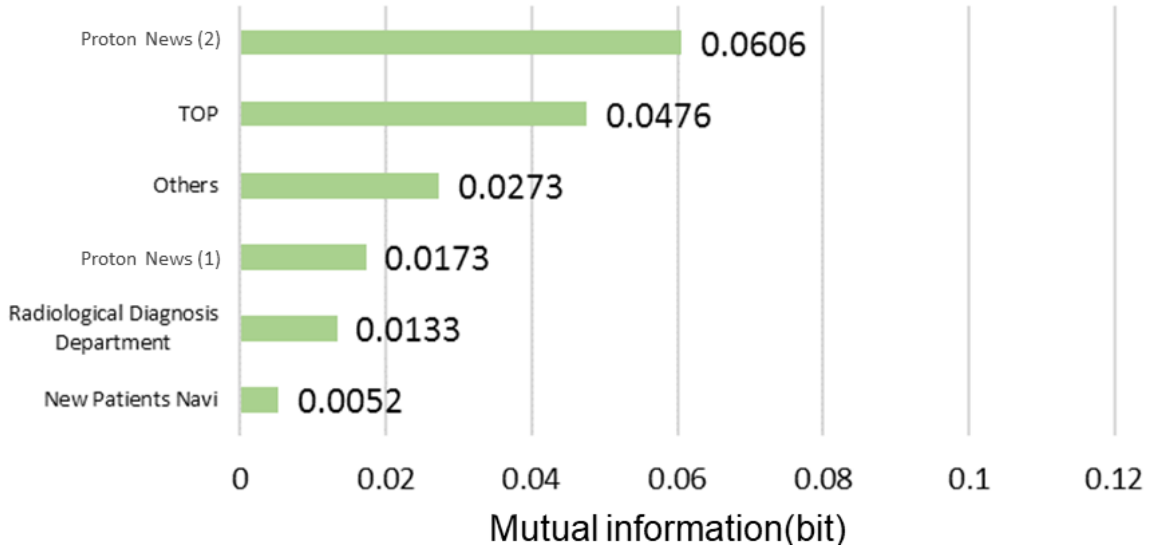

Figure 7. Probability inference (radiotherapy interest group, Radiotherapy Department page).

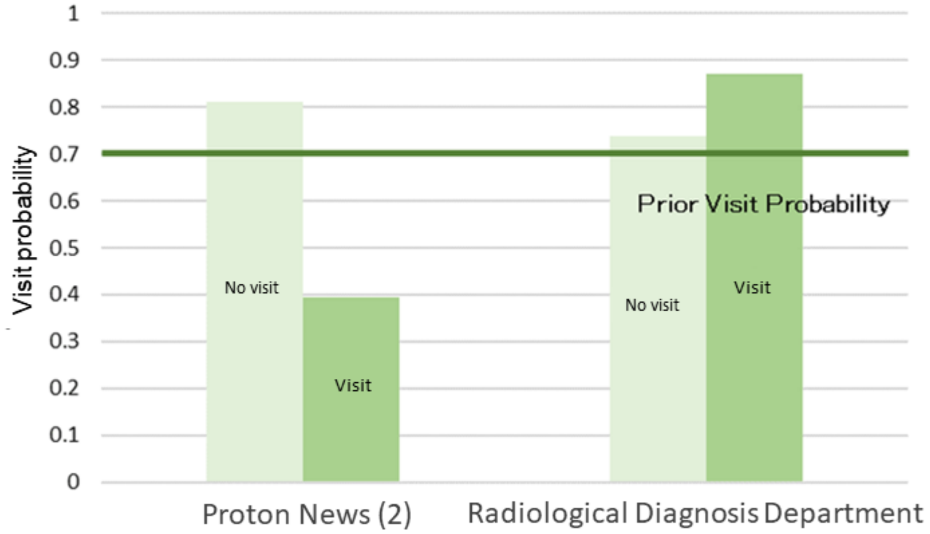

Nuclear Medicine Examination Interest Group

The model, as described in Figure 8, was structured using 35 sessions from the learning data. Browsing of the RP2 “Nuclear Medicine Department page” was affected by the browsing of RP4 “PRT-CT and Nuclear Medicine Examination” and was related to the browsing of the reservation and the medical staff pages. The results of the sensitivity analysis are shown in Figure 9. The interaction between the browsing of RP2 and that of RP4 was also demonstrated. We then calculated the change in the browsing probability of RP2 and RP3 owing to the browsing or nonbrowsing of the pages, as depicted in Figures 10 and 11. The browsing probability of RP2 increased when browsing the Medical Staff page. When the target visitors browsed the FAQ page, the browsing probability of RP3 increased by 15% from the prior probability.

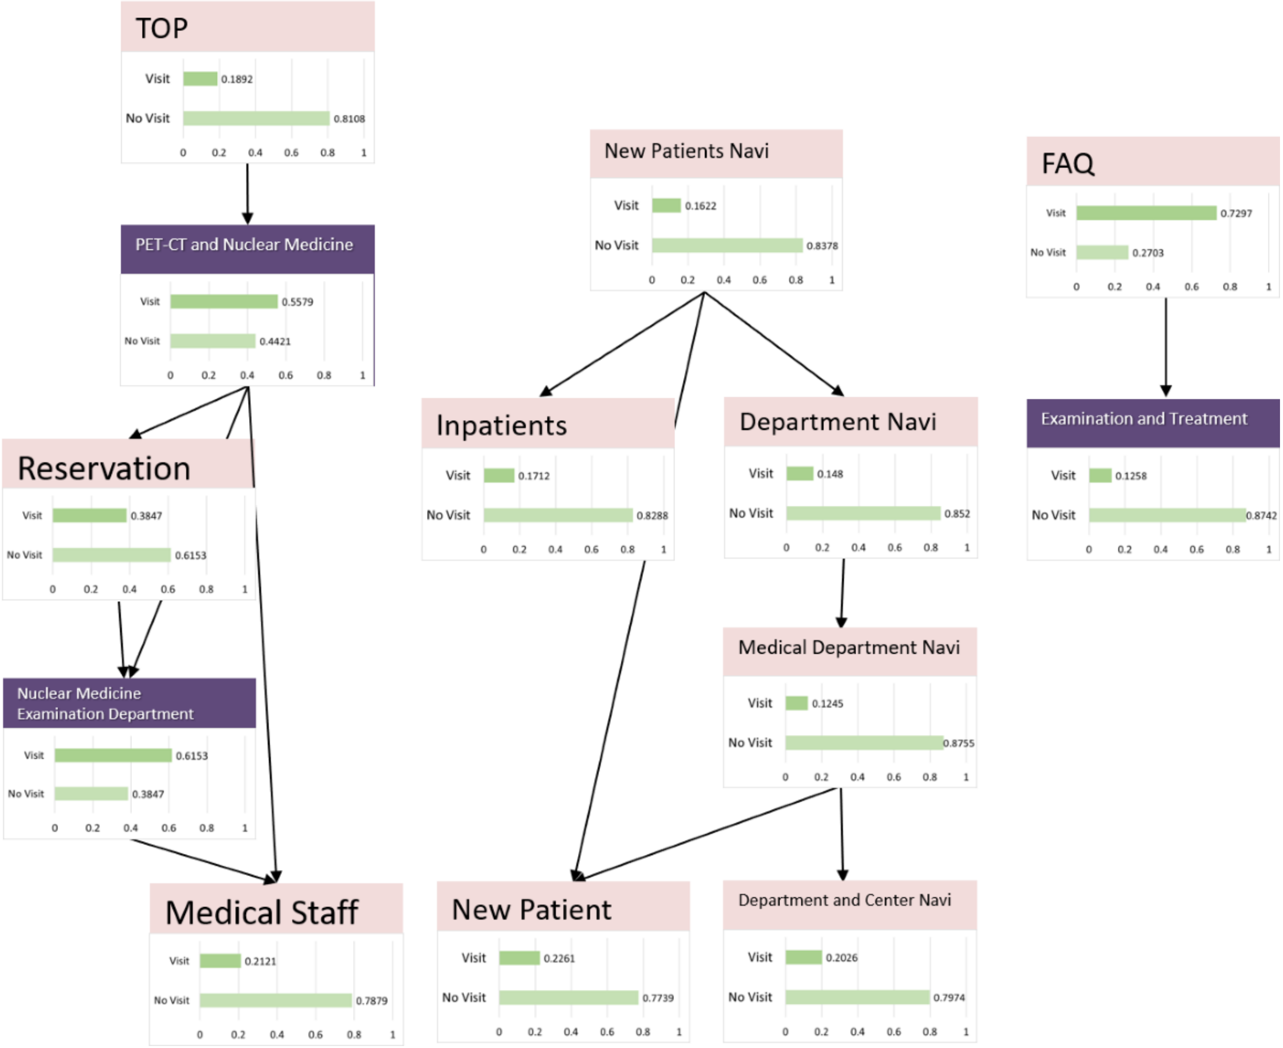

Figure 9. Sensitivity analysis (nuclear medicine examination interest group). PET-CT: positron emission tomography-computed tomography.

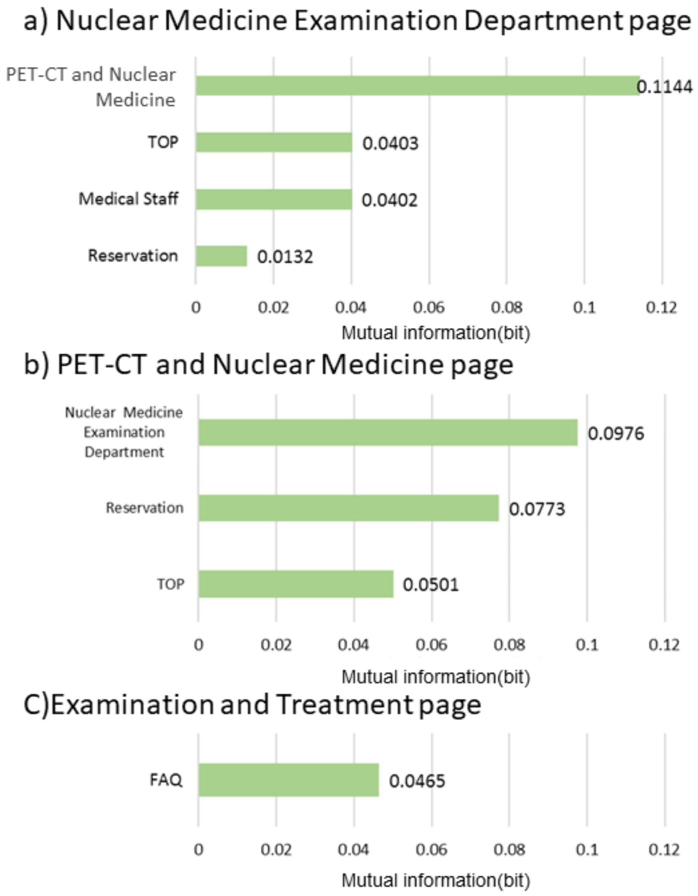

Figure 10. Probability inference (nuclear medicine examination interest group, Nuclear Medicine Examination Department page). PET-CT: positron emission tomography-computed tomography.

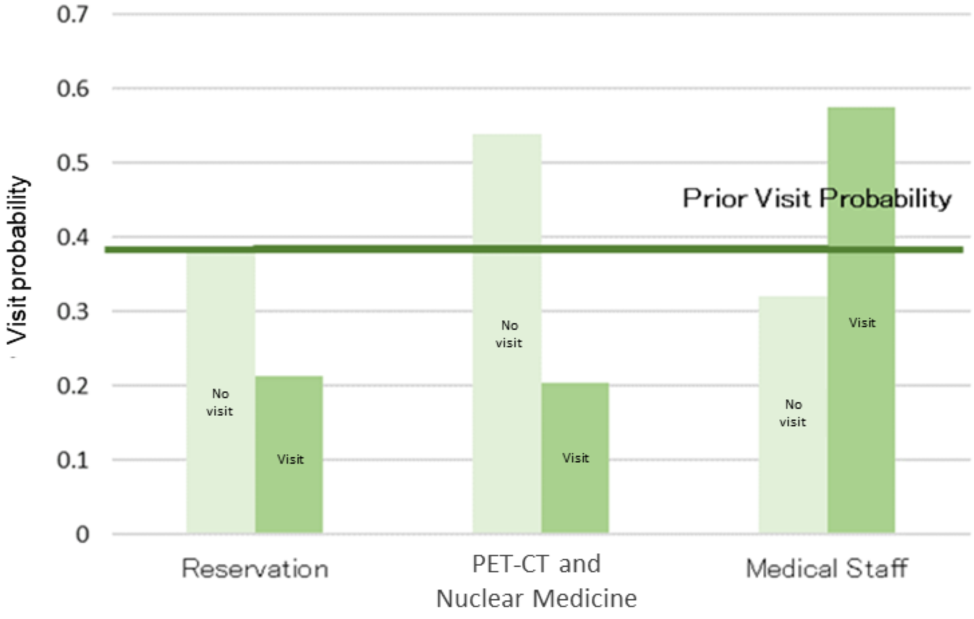

Figure 11. Probability inference (nuclear medicine examination interest group, Examination and Treatment page).

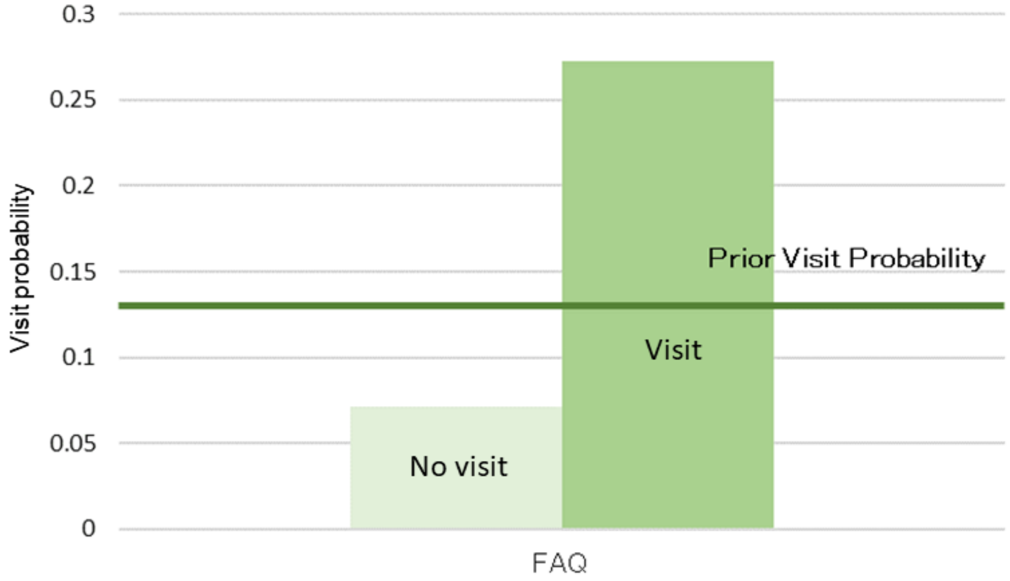

Radiological Diagnosis Interest Group

The model described in Figure 12 was structured using 20 sessions from the learning data. The browsing of the RP2 “Radiological Diagnosis Department page” affected the browsing of the Radiotherapy Department and related department pages, such as Orthopedics. The results of the sensitivity analysis are shown in Figure 13. Browsing of the Radiotherapy Department page had the greatest impact on RP2 viewing. We then calculated the change in the browsing probability of RP2 owing to the browsing or nonbrowsing of the Radiotherapy Department page, as shown in Figure 14. When the target visitors browsed the Radiotherapy Department page, the probability of RP2 increased by 35% from the prior probability.

Figure 12. Radiological diagnosis model. PET-CT: positron emission tomography-computed tomography.

Discussion

The number of visiting sessions on the Hokkaido University Hospital website is over 650,000 per year. This number is comparable to the number of actual patients to the hospital annually (approximately 740,000 in 2015) and indicates that the website plays a key role as an information provider for many individuals.

Only 2% (2/90) of the target visitors could reach the Radiology Center page (RP1), which describes its inspection information. There are 3 possible reasons for this finding: browsing behavior (the visitor started with the department pages, not the Center page), the visitor could not distinguish the Radiology Center pages from the radiology-related department pages that describe the department information, and that there are some pages for which we could not obtain the data access log. In total, 2 plans were considered for improving the browsing probability of RP1: linking the radiology-related department pages and the Radiology Center page, and summarizing radiology-related information on the website rather than posting according to the hospital's organizational structure.

According to the radiotherapy model, when browsing the Proton Therapy News page, the browsing probability of the RP2 "Radiotherapy Department page" decreased. Therefore, we found that interest in radiotherapy and interest in news differed from one another, or that there was no conductor design. In addition, because the child node of the Radiotherapy Department page had the pages of new patients and medical expenses pages, patients who receive radiation treatment tend to seek information on receiving medical treatment such as medical expenses owing to the high price of proton therapy [26]. In a questionnaire survey of medical radiological specialists, it was reported that a certain number of technicians were asked about the cost of radiotherapy in treating patients receiving cancer radiotherapy [27].

In the nuclear medicine examination interest group, the browsing probability of the FAQ page was higher than that of the other 2 groups. In addition, as a result of the probability inference, a positive relationship was found between browsing the FAQ page and the Examination and Treatment page. Because the FAQ page is generally used for posting information on exceptional cases such as product guidelines and specific topics [28], target visitors may be concerned about specialized information, except for the content of the RP. From Figure 10, the browsing probability of the RP2 "Nuclear Medicine Examination Department page" was higher than the prior probability when browsing the Medical Staff page. Because neither of these pages were designed with a link that allows direct access, it is mainly the medical staff that browse them.

In the radiological diagnosis model, the RP2 "Radiological Diagnosis Department page" contained child nodes, such as the Orthopedics Department page, indicating that visitors are interested in the contents of the departments they are associated with. Table 6 presents the proportion of radiological diagnosis conducted at Hokkaido University Hospital, with the proportion of "bone/soft" being the second highest after "respiratory organs." Therefore, the site design was considered, linking radiology-related department pages with their related department pages and redesigning the website considering the flow of treatment and inspection.

Table 6. Number of radiological examinations at Hokkaido University Hospital (April 2018 to March 2019).

Classification	Inspections, n (%)
Respiratory	53,322 (41.9)
Bone and soft part	30,230 (23.8)
Digestive organ	27,141 (21.3)
Tooth	16,685 (13.1)
Others	18 (0)

From the results of the probability inference, the browsing probability of the RP2 "Radiological Diagnosis Department page" was higher than the prior probability when browsing the Radiotherapy Department page. According to these results, visitors interested in radiology-related departments would access RP2, which indicates that CVR can be improved by linking radiology-related departments. The percentage of visitors who browsed the RP3 "Examination and Treatment page" was small. This is thought to be due to the low interest of the target visitor or their inability to reach the page. In the latter case, we suggest that CVR can be increased by linking to the "Radiology Department page," where the targets have a high percentage of browsing.

Table 7 presents the site design proposals to increase the CVR, as examined from the results. Thus, this research concluded that our method is effective in improving the provision of information because improving the quality of decision making is crucial in data analytics, as exemplified through business intelligence tools [29]. The proposed method can be applied to departments other than radiology-related areas.

Table 7. Proposals for site design to meet the needs of visitors seeking radiology-related information.

RP[a]	Improvement 1	Improvement 2	Improvement 3
A. Improve CVR[b] of radiotherapy interest group			
RP1: Radiology Center page	Link the Radiology Center page and radiology-related department pages	Link the Radiology Center page and pages such as the New Patients page and Re-examination page	Set tracking code
RP2: Radiotherapy Department page	Link the Radiotherapy Department page and Radiological Diagnosis Department page	Link the Radiotherapy Department page and the Medical Expenses page	—[c]
B. Improve CVR of nuclear medicine examination interest group			
RP1: Radiology Center page	Same as above	Same as above	Same as above
RP2: Nuclear Medicine Examination Department page	Link the Nuclear Medicine Examination Department page and the Medical Staff page	—	—
RP3: Examination and Treatment page	Review of posted contents on the Examination and Treatment page	—	—
RP4: PRT-CT[d] and Nuclear Medicine Examination page	Link the PRT-CT and Nuclear Medicine Examination page and the Nuclear Medicine Examination Department page	—	—
C. Improve CVR of radiological diagnosis interest group			
RP1: Radiology Center page	Same as above	Same as above	Same as above
RP2: Radiological Diagnosis Department page	Link Radiological Diagnosis Department page and the Radiotherapy Department page	Link the Radiological Diagnosis page and the Orthopedics page	—
RP3: Examination and Treatment page	Link the Radiological Diagnosis Department page and the Examination and Treatment page	—	—

[a] RP: request page.

[b] CVR: conversion rate.

[c] The certain CVRs were treated as not applicable in our behavioral analysis.

[d] PRT-CT: positron emission tomography-computed tomography.

Limitations

One of the limitations of this study is the low accuracy of the models applied. The number of samples (20-35 sessions) used to build the models was small compared with the actual usership for Hokkaido University Hospital's website. Owing to the recent shift to Secure Sockets Layer for use in search engines, the sample size has remained limited. Future studies should substitute search keywords. Furthermore, some data may have been missing because there were some pages set with the no web tracking code in Google Analytics. By increasing the sample size, factors such as browsing time can be incorporated into the model, improving the prediction accuracy for the probability distribution of each page. However, the effects of the visitor's interest on each page regarding factors such as the browsing time and browsing devices for hospital websites are still unknown. Therefore, it is necessary to clarify the effects of the browsing factors before modeling.

As another limitation, we were unable to verify the accuracy of the proposed model compared to other approaches. To evaluate our model, we need to accurately set the web tracking code and extract data without using retrieval keywords because we have obtained few retrieval data in recent years.

Third, the RP we set during the page-evaluation phase is uncertain. Thus, setting an RP objectively to obtain information by means of questionnaires to accurately understand visitor needs will be an issue in the future. Similarly, it will be possible to evaluate pages suitable for each visitor by clarifying the above relationship between visitor interests for each page and access indicators such as the browsing time. In recent years, Japan has been rapidly aging, and older adults are using hospital websites. However, previous studies have reported that age-related deterioration in visual acuity and changes in color vision affect the use of older adults to use such websites [30,31]. Therefore, we hope that the factors affecting CVR differ between older adults and young adults. In the future, we would like to consider improving the CVR by modeling the categorization of young and older adults.

Conclusions

This study structured 3 browsing models, each based on specific patient needs: radiotherapy, nuclear medicine examination, and radiological diagnosis. A total of 74% (67/90) of the target visitors could reach their requested page, but only 2% (2/90) could reach the inspection information page owing to the site structure. Furthermore, for the radiological diagnosis interest group, browsing of the "Radiological Diagnosis Department page" affected the browsing of the related department pages, such as Orthopedics.

Plans were considered for improving the browsing probability of the inspection information page such as summarizing radiology-related information on the website rather than posting according to the hospital's organizational structure. Thus, our method has the potential to increase the probability of delivering the desired information to the users. In the future, we plan to improve the accuracy of the models by using a large number of samples. We believe that an increase in the number of subjects will reveal the characteristics of the browsing scenario in more detail.

We built models with the objective of improving the provisioning of radiology-related information; however, because the structure of a hospital website is not unique, we hope to apply the proposed method to other hospitals. It is expected that the provisioning of information on hospital websites will be improved using this approach.

Abstract

Background: Interpreting health information and acquiring health knowledge have become more important with the accumulation of scientific medical knowledge and ideals of patient autonomy. Health literacy and its tremendous success as a concept can be considered an admission that not all is well in the distribution of health knowledge. The internet makes health information much more easily accessible than ever, but it introduces its own problems, of which health disinformation is a major one.

Objective: The objective of this study was to determine whether objective and subjective health literacy are independent concepts and to test which of the two was associated more strongly with accurate judgments of the quality of a medical website and with behavioral intentions beneficial to health.

Methods: A survey on depression and its treatments was conducted online (n=362). The Newest Vital Sign was employed to measure objective, performance-based health literacy, and the eHealth Literacy Scale was used to measure subjective, perception-based health literacy. Correlations, comparisons of means, linear and binary logistic regression, and mediation models were used to determine the associations.

Results: Objective and subjective health literacy were weakly associated with one another (r=0.06, P=.24). High objective health literacy levels were associated with an inclination to behave in ways that are beneficial to one's own or others' health (Exp[B]=2.068, P=.004) and an ability to recognize low-quality online sources of health information (β=–.4698, P=.005). The recognition also improved participants' choice of treatment (β=–.3345, P<.001). Objective health literacy helped people to recognize misinformation on health websites and improved their judgment on their treatment for depression.

Conclusions: Self-reported, perception-based health literacy should be treated as a separate concept from objective, performance-based health literacy. Only objective health literacy appears to have the potential to prevent people from becoming victims of health disinformation.

Introduction

Background

Patients' knowledge of health matters and their capacity to acquire such knowledge have recently become more important than ever [1]. This has to do with the immense accumulation of health knowledge in medical science and, consequently, the medical profession since the enlightenment. More recently than that, a new ideal emerged, which was to replace older paternalistic conceptions of the relationship between physicians and their patients [2,3]. In the earlier concept, well-meaning physicians based their decisions on their far superior medical knowledge, experience, physical examination, and understanding of what their patients conveyed about their symptoms [3]. Based on this information, physicians developed a diagnosis and prescribed medication accordingly. In the new ideal of patient autonomy, physicians make suggestions to patients, and patients choose which suggestions to follow [3]. Other autonomy concepts include the expert patient, shared decision making, and patient-centered health care [4].

Patient autonomy requires that patients are knowledgeable, which is another reason why knowledge and knowledge acquisition in the field of health are so important today. In addition to knowledge, functional reading and writing abilities, adequate information processing, critical thinking skills, and the capability to make decisions that are beneficial to one's health [5] are all elements of health literacy. Health literacy is an immensely successful concept in health communication and public health [6]. Its success may be due in part to an intuitively felt paradox that it would be absurd indeed to train health care providers for years and produce expensive pharmaceuticals and high-tech machinery only to witness that patient outcomes are not as good as they could be because patients do not understand what their physician says and physicians fail to notice patients' lack of understanding [4]. In a sense, the existence of the term "health literacy" is the admission that not all is well with the distribution of medical knowledge in contemporary societies. Not everyone is knowledgeable enough to meet the requirements of the ideal of patient autonomy or capable enough to participate in the communication processes demanded by health care today [7].

When health literacy was first conceptualized, nobody could have known how digital communication would soon change health communication. Due to its extraordinary potential of overcoming traditional limitations to information finding, the internet is today a primary focus of health literacy research [8]. In some respects, it provides solutions or answers to problems associated with the distribution of health knowledge and the spread of health information.

In spite of the many opportunities the internet offers in providing information, social support, conversation exchange, and more advice on prevention than one could ever use, it has also magnified the quality issue in medical care for laypersons who have contact with it. The quality of the information found online is sometimes deplorable [9], and that creates its own problems. For individuals and organizations, advocating the potential benefits offered by information technology is fairly frustrating. A new, two-sided medium was introduced, which offered a way to seek and find health information more or less everywhere, at any time, on every subject, and at a very low cost. However, what people have put on the medium is, to a considerable degree, medical disinformation.

Fortunately, a solution was at hand: health literacy. If health literacy were to include the ability to discriminate true and reliable health information websites from fraudulent and misleading ones, information seekers online could learn which sources provide high- or low-quality information and could base their conclusions about the quality, and hence the credibility, of specific information on the general quality of the source. Individuals who did not have adequate health literacy could receive training to increase their health literacy or physicians could talk to them on the patient's level. This raises the question of whether individuals with a high level of health literacy also have the capability of appraising the general quality of digital sources of health information.

The hope is that when people with adequate online health literacy encounter low-quality health information, they will recognize it for what it is, and when a website is of low quality and the patient knows it, they will not accept its content and not change their stored knowledge of the subject. Some might even scan their existing knowledge when they meet a website with health disinformation and erase the knowledge that is associated with the problematic website newly encountered. That is to say, people with high health literacy might indeed be protected against the influence of disinformation and, in favorable conditions, even improve their knowledge. In contrast, people with inadequate eHealth literacy will not recognize the low quality, accept its content, and store it as newly gained knowledge of the subject.

Although people's awareness of their health literacy has not yet been considered, it should be. People might perceive themselves as more health literate than they actually are, and they might act on that misperception. It is obvious that an exaggerated misperception of one's own health literacy cannot be a good advisor for medical judgment, decisions, and behaviors. Earlier publications referred to these persons as "dangerous self-managers" [10]. Misperception of one's self is a rather well-known phenomenon in social psychology, where it exists under labels such as optimistic bias, third-person perception, and looking-glass perception.

Although health literacy is conceptualized as an objective feature, it has increasingly been measured subjectively—that is, as a self-perception—in academic research [11]. Measures of health literacy based on self-perceptions are often problematic because people might deceive themselves about their health literacy abilities [12]. At the same time, such measures gain ground in research. One example is the Brief Health Literacy Screen (BHLS), which asks the respondent 3 questions about their confidence in understanding medical information when they seek help from health care institutions [13]. Another example is the eHealth Literacy Scale (eHEALS), which consists of 8 items measuring consumers' knowledge, comfort, and perceived skills as they relate to finding, evaluating, and applying electronic health information to health problems [14].

The final example is the European Health Literacy Survey Questionnaire (HLS-EU-Q47), which assesses how easy or difficult the patient perceives health-related tasks to be [15].

Most commonly, the objective, performance-based measures require individuals to demonstrate their knowledge and familiarity regarding medical terms (eg, Rapid Estimate of Adult Literacy in Medicine [REALM] [16]) or their understanding of sentences by their ability to fill in gaps within them (eg, Test of Functional Health Literacy in Adults [TOFHLA] [17]), or to complete tasks demanding numerical ability (TOFHLA [17], STAT-interest and STAT-confidence scales [18], and Lipkus Numeracy Scale [19]). Self-reported measures of health literacy involve individuals describing themselves and their skills. Self-reported measures target the individuals' self-perceived ability to find information and understand it, and to assess individuals' confidence in their own health literacy. Subjective measures of objective concepts have long been used in survey research, often for concepts that could be openly labeled, such as knowledge or intelligence [20]. Subjective impressions of how much of these qualities individuals think they have can be ascertained directly because the concepts have spilled over into normal, nonacademic language. That has not yet happened to the concept of health literacy. Inquiry into individuals' subjective perception of their health literacy must, therefore, be performed indirectly and include questions about behaviors and processes that indicate health literacy. Self-reported measures are much more susceptible to individual and cultural influences, such as social desirability and beliefs about health and illness [21]. Conversely, a performance-based measure assumes that it is unlikely that someone would purposefully cheat on it by intentionally appearing less capable than they are [21].

The validity of a self-perceived indirect measure of health literacy can, therefore, be judged by comparing its results with the results of performance-based instruments.

Self-report and performance-based measures of health literacy have been extensively investigated in their ability to predict a range of health-related behaviors. One study [22], for example, demonstrated that performance-based numeracy and literacy, considered together, predicted skills to perform health tasks among older adults. Along the same lines, Gazmararian et al [23] showed that patients with inadequate performance-based health literacy were less likely to adhere to their physicians' treatment a year later. People with limited health literacy were less likely to have sought cancer information and more frequently endorsed fatalistic beliefs about their decision making [24].

On the other hand, even low levels of self-reported health literacy seem to be associated with worse health outcomes. One study in patients with diabetes [25] found that low self-reported health literacy was associated with less diabetes knowledge, glycemic control, and physical activity. Mitsutake et al [26] found mixed results. Individuals with high self-reported health literacy were significantly more likely to exhibit good health behaviors, perform physical exercise, and eat a balanced diet. Still, there were no associations of health literacy with cigarette smoking, alcohol consumption, hours of sleep, or eating between meals. Wångdahl et al [27] found that refugees with limited self-reported health literacy reported worse health, impaired well-being, and fewer health care–seeking behaviors than those with high health literacy.

A systematic review [11] found a paucity of research analyzing the relationship between objective and subjective health literacy and health outcomes. Haun et al [28] found no significant relationship between limited health literacy and patient self-report of having or not having hypertension, diabetes, or a past stroke after adjusting for covariates (ie, gender, race, education, self-reported reading level, retiree status, and having a functional disability). Hirsh et al [29] found a significant association between the self-reported measure of health literacy and a multidimensional measure of health, which did not hold with a performance-based tool. Kiechle et al [11] found no differences in the relationship between performance-based and self-reported health literacy for 4 of 6 outcomes (self-reported diabetes, stroke, hypertension, and a physician-completed rheumatoid arthritis disease activity score).

Hypotheses

The broader question that this research addressed was the utility of self-perceived health literacy in health communication research. The considerations outlined above suggest three comparisons that should help to assess this utility: (1) the association of self-perceived and objective health literacy, (2) the influence of health literacy on choice of behavior, and (3) the ability to recognize disinformation on the web. These variables were seldom studied together and the results were inconsistent [30-36]. In a unique study by Benotsch et al [37], they found an overall positive association between low health literacy levels and wrong perceptions of information quality. Specifically, low health literacy was associated with lower quality ratings of a high-quality website and higher quality ratings of a low-quality website.

Therefore, our primary research question (RQ1) was as follows:

- RQ1: How strongly will a self-perceived measure of health literacy be associated with a performance-based measure?

Four hypotheses were formulated to present the associations in a testable format:

- H1: Participants who score high on an objective, performance-based test of health literacy will make better treatment choices for depression than participants who score low.
- H2: Participants who score high on an objective, performance-based test of health literacy will make better judgments on the quality of mental health websites.
- H3: Participants who score high on an objective, performance-based test of health literacy will make better treatment choices based on their judgments of the quality of mental health websites, reflecting a mediation of the relationship between health literacy and depression-related decision making by the perception of website quality.
- H4: Self-reported health literacy will not produce similar associations.

Methods

Study Design

The study is part of a larger experiment testing an aspect of the order of persuasive communication content. This experiment and the order of presentation are of no concern to this paper. Therefore, we did not include order as a variable here.

The experimental design, however, had consequences for the structure of the data collection. We considered it important for the experiment to have roughly equally sized groups of high and low objective health literacy. For this purpose, data were collected in two steps. The first step involved an assessment of objective health literacy and the collection of sociodemographic information. The findings of the first step were used to define high and low literacy and to assign participants into experimental groups randomly. The second step consisted of all other measures. Two pilot studies were carried out before the study was conducted (see Multimedia Appendix 1).

Variables and Measures

The independent variables were two measures of health literacy: (1) a subjective, perception-based measure, and (2) an objective, performance-based measure. The measures were available as total scores or as dichotomous summaries (low/inadequate versus high/adequate level). An intervening variable was the perception of the quality of two websites, one of dubious quality, the other of high quality. The dependent variable was treatment choice, considered as a dichotomous variable. Several covariates were also considered.

Performance-based health literacy was measured using the Newest Vital Sign (NVS) [38], which uses a fictitious ice cream label. It measures literacy, comprehension, numeracy, application/function, and evaluation skills by asking questions that are answered after a person observes the label. The final score ranges from 0 (limited literacy) to 6 (adequate literacy); the dichotomy separated participants with low/inadequate health literacy (scores of 0-4) from those with high/adequate health literacy (scores of 5-6). The scale demonstrated good internal reliability (α=.62).

Self-reported health literacy was measured using the eHealth Literacy Scale (eHEALS) [14,39]. Online health literacy, or eHealth literacy, refers to “the ability to seek out, find, evaluate and appraise, integrate, and apply what is gained in electronic environments toward solving a health problem” [40]. The scale is an 8-item, self-reported measure developed to assess consumers’ combined knowledge, comfort, and perceived skills at finding, evaluating, and applying eHealth information to health problems. Responses are measured using 5-point Likert scales whose options range from 1 (“strongly disagree”) to 5 (“strongly agree”). The total scores were calculated as the mean, with the ratings formatted such that higher scores (ie, closer to 5) represented higher self-reported eHealth literacy. The scale demonstrated good internal reliability (α=.89) and internal consistency (r_s>0.58; mean 3.17, SD 0.78). The dichotomous form was computed based on the median split (median 3.25), thus generating one group with low (n=178) and one group with high (n=184) self-reported health literacy.

Website Quality

Two versions of a mock website informing about treatment options for depression were produced, one of high quality and the other of low quality. To provide our study with ecological validity, we retrieved the contents from real websites, one of high quality [41] and the other of low quality [42]. Both appeared among the top results on Google.it when the keywords “anti-depressive” and “natural remedies for depression” were searched. The criteria that we used to identify a high-quality website were having a main focus on the most effective treatment options according to scientific research (namely antidepressant medication and psychotherapy), and a clear debiasing intention toward the most popular misconceptions about them [43]. Conversely, the criterion for low-quality was the emphasis on common misbeliefs about treatment [43], including the overestimation of the curative effect of natural and self-help remedies [44]. However, in contrast with the real websites, the amount of information on the mock websites was shortened in order to make the stimuli comparable in terms of number and pieces of information provided, number of words, and overall cognitive effort required. Moreover, we used the same layout for both stimuli (eg, color, graphics) and a simple screenshot instead of an interactive website in order to limit the effects due to uncontrolled variables (see Multimedia Appendix 2). A 1-item manipulation check was included to identify if people had read, understood, and could recall the information on the website.

Perceived Information Quality

Participants’ perceptions of information quality were assessed using 7-step semantic differential scales [30,45]. Positive adjectives were “accurate,” “reliable,” “complete,” and “understandable,” while the respective opposites were “inaccurate,” “unreliable,” “incomplete,” and “nonunderstandable.” High numbers on the scales indicated positive perceptions. The data showed good internal reliability (α=.88 for high-quality websites, and α=.90 for low-quality websites) and internal consistency (r_s>0.68 for high-quality websites, and r_s>0.75 after removing the item understandability). Consequently, the scores for reliability, accuracy, and completeness were considered in the analyses.

Outcome Variable

From a list, participants were asked to choose one or more treatments for depression for themselves (help-seeking behavior), a family member, and a close friend (advice-giving behavior). The Kuder-Richardson 20 coefficient indicated good internal consistency among the three items (KR20=0.96), thus providing the basis to develop a single measure of the construct. The final score ranged from 1 (correct choice) to 0 (wrong choice). Examples of the right choices were psychotherapy, antidepressant medications, and seeking help from a doctor. Examples of wrong decisions were treating depression with St John’s wort or vitamins or yoga without any mention of antidepressant medications or psychotherapy.

Covariates

The frequency of online health-related information–seeking behavior in general as well as about depression in particular were both asked with a single item. The response options ranged from 1=never to 6=more than two times a week. During the scoring procedure, both items were reversed, with higher scores indicating lower frequency. Participants' previous experience with depression was assessed in terms of having ever suffered from depression or helping someone close to them, such as a family member or a close friend, who was suffering from depression. The response options were "no previous experience" or "yes previous experience."

Sample

The study was conducted in Italy using a snowball sampling method by posting the link to the survey on several public and private Facebook pages. The survey was implemented on QualtricsXM software (version 2019; Qualtrics). The inclusion criteria for study participation were adults aged between 18 and 65 years who were residing in Italy, with a good command of the Italian language and internet access. Mental health workers (psychiatrists, psychologists, and psychotherapists) and psychology graduates/students were excluded from the sample.

An a priori power analysis was conducted using G*Power 3.1.9.4 software [46] to determine the sample size (with α=.05, power=.95, η^2=0.05), and the final estimate was 331 participants.

A total of 501 participants completed the first part of the survey (ie, performance-based health literacy and sociodemographics). Among them, 380 participants completed the second part of the survey and 121 participants dropped out. Of the 380 participants, 18 were excluded because their answers to the postmanipulation check were incorrect, suggesting deficiencies in their perception of the website being assessed. Comparisons between dropouts and participants who completed the surveys did not show any significant difference in terms of gender, age, educational level, or performance-based health literacy. The final number of participants was 362. The subjects were aged between 18 and 66 years (mean age 35.54 years, SD 13.76 years) and 72.1% (261/362) were female. The majority of the participants had a high school degree (145/362, 40.1%), a bachelor's degree (73/362, 20.2%), or a master's degree (134/362, 37.0%).

Statistical Analysis

SPSS Statistics for Windows (version 25.0; IBM Corp) and Hayes' PROCESS macro v3.4 for SPSS 25.0 [47] were applied. The internal reliability and consistency of the continuous scales were calculated using α and r_s, and the Kuder-Richardson 20 coefficient was used for noncontinuous scales. Normality distribution was found with skewness values ranging between –1.1 and 0.44 and kurtosis values ranging between 0.9 and –0.62, except for the variable assessing the information-seeking behavior about depression (skewness 2.5, kurtosis 6.6). Chi-square tests and *t* tests were calculated to compare the subsample of participants who completed only the first part of the survey with those who completed the entire survey. Pearson correlations were calculated between continuous variables and point-biserial correlation coefficients (r_{pb}) were calculated between binary and continuous variables. We conducted *t* tests to compare the mean differences in perceived information quality and the level of health literacy. Logistic regression was performed with treatment choice as the outcome variable and gender, age, past experience with depression, both measures of health literacy, and an interaction term between health literacy and perception of website quality as independent variables. Using the entry method, we ran a three-step model, including the relevant sociodemographic variables first, then the possible predictors of the main effects on treatment choice, and lastly the interaction term. Finally, mediation analyses were carried out on perceived information quality as a mediator between health literacy and treatment choice.

Results

Bivariate Findings

The two measures of health literacy were not associated (r=0.06, P=.24, n=362). In response to RQ1, it can be said that the correlation shows that there is little reason to hold that the two scales measure the same thing.

Correlation analysis also showed that respondents with higher (as compared with lower) levels of performance-based health literacy perceived a low-quality website as more negative and were inclined to choose beneficial behaviors for themselves, family, and friends. In contrast, when respondents were grouped according to perception-based health literacy, no such difference appeared. However, those with high health literacy levels rated a high-quality website as more positive than those with low levels did. This supports H1 and also H2, but only for the judgment of low-quality websites. It also supports H4, except for positive websites, which were perceived more positively by individuals who perceived themselves as highly health literate and for whom no such association was expected. Correlations between health literacies and dependent variables are displayed in Table 1.

Table 1. Correlations between two health literacy measures and perception of website quality/choice of depression treatment.a

	Objective, performance-based measure (NVS)[b], n=362		Subjective, perception-based measure (eHEALS)[c], n=362	
	r	*P* value	*r*	*P* value
Perception of high-quality website	0.02	.78	0.14	.009
Perception of low-quality website	–0.14	.006	–0.08	.13
Treatment preferences	0.12	.007	0.01	.81

[a] High numbers indicate high health literacy, positive perception, and beneficial preferences for treatment.

[b] NVS: Newest Vital Sign.

[c] eHEALS: eHealth Literacy Scale.

An independent samples *t* test was conducted to evaluate whether the performance-based health literacy level (low versus high) had an effect on the perceived information quality of the low-quality website. The analysis was significant ($t(360)=2.81$, $P=.005$), with participants who had higher performance-based health literacy achieving lower scores (mean 3.70, SD 1.53) than participants who had lower performance-based health literacy (mean 4.17, SD 1.61). The same analysis was conducted considering self-reported health literacy, but the result was not significant ($t(360)=1.064$, $P=.29$).

In the next step, we tried to build linear regression models for predicting the perception of high- and low-quality mental health websites and treatment choice. We expected respondents with high levels of objective health literacy to evaluate the two websites more consistently than respondents with low levels of health literacy and make a better treatment choice. Consistent evaluation means that the high-quality and low-quality websites were assessed positively and negatively, respectively. A similar difference was not expected to emerge for respondents with different levels of subjective health literacy. Predictors were entered stepwise: the sociodemographic variables (gender, age, education) were entered first, then the covariates indicating experience, and finally the measures of health literacy. Table 2 shows the coefficients of the regression analyses.

Table 2. Regression analyses for predicting the perception of high- and low-quality mental health websites and treatment choice.

Step	Evaluation of high-quality website (linear regression)		Evaluation of low-quality website (linear regression)		Treatment choice (binary logistic regression)	
	β	*P* value	β	*P* value	Exp(B)	*P* value
Step 1: Sociodemographics						
Gender (0=males)	–.056	.30	.035	.497	1.866	.02

Low-quality site	N/A	N/A	N/A	N/A	1.088	.74
R^2 (%)	N/A		N/A		18.6	
Step 5: Interaction						
Interaction between objective health literacy and perception of a low-quality site	N/A		N/A		0.886	.035
R^2 (%)	N/A		N/A		20.1	

[a] NVS: Newest Vital Sign.

[b] eHEALS: eHealth Literacy Scale.

[c] N/A: not applicable.

The first noteworthy result was that the only predictor of a favorable perception of a high-quality website was self-perceived health literacy. A low-quality website was evaluated negatively by highly educated persons, by persons with past experience of depression, and almost (missing significance by a small margin) by objective health literacy. Treatment choice was influenced by gender, as well as by objective health literacy (beneficially) and subjective health literacy (detrimentally). Recognition of a high-quality website by positive perception also increased participants' likelihood of making a sound treatment choice.

The interaction analysis showed that individuals with a high level of objective health literacy and an accurate recognition of a low-quality website as being problematic exercised good judgment regarding treatment behaviors. In particular, participants with high performance-based health literacy were more likely to choose the right treatment for depression than participants with low performance-based health literacy.

The mediation analysis yielded similar results. First, an overall path led from health literacy to treatment choice, but only when health literacy was operationalized as NVS—that is, an objective, performance-based measure. The subjective measure showed no relationship between health literacy and treatment choice. Second, when health literacy was operationalized objectively and respondents were given a low-quality website to assess, they recognized the low-quality website for what it is, and that recognition improved their judgment of treatment alternatives. Third, individuals with high levels of subjective health literacy did not have better insight into the quality of websites and did not assess website qualities differently than individuals with lower health literacy; however, if they recognize the poor quality of the website, they are also capable of opting for better treatments. In other words, individuals with high levels of subjective health literacy were prone to overlook the poor quality of web content, but if they do not overlook it, they will make better treatment decisions (Table 3 and Figure 1).

Discussion

Association of Performance-Based and Perception-Based Hypotheses (RQ1)

For a summary of the results, we feel that the research question highlights the necessity to differentiate subjective and objective health literacy more clearly, conceptionally as well as in terms of measurement. One finding to support this view is the weak association that was found between the two kinds of information. Another reason to differentiate them is because of the different influences that the two kinds of health literacy had on the study outcomes—the assessment of the quality of internet information (as an intermediate variable) and the choice of treatment behaviors, in line with official recommendations.

Effect on Outcomes (H1 and H4)

In general terms, the answer to RQ1 was that performance-based and perception-based health literacies were uncorrelated, and they played very different parts in predicting the dependent variables. These results and other published research [10] suggest that we need to think seriously about referring to apparently very different concepts by the same name. The study clearly shows that health literacy positively affects patients' choice of treatment, "positively" indicating that high health literacy and beneficial decision making are linked. However, this was true only for objective, performance-based health literacy and not for subjective, perception-based concepts of health literacy. This clearly supports H1 and H4, and it means that the perception-based version of health literacy is lacking the major asset of the concept—improved judgment regarding medical treatments.

Role of Intermediate Variables (H2 to H4)

Health literacy helps patients to identify low-quality health information on the web (H2), and those who recognize websites of low quality tend to make better treatment choices (H3). Both assertions are true for patients whose health literacy is defined objectively; when it is defined subjectively, the link between literacy and quality perception disappears (H4), although the effect of recognizing the problematic site remains. In other words, patients who recognize a low-quality website have better judgment, but a subjective classification of health literacy does not play a role in that recognition.

The objective, factual ability to find one's way through the communicative maze of present-day health care has several components, including the ability to describe one's symptoms to the doctor and understand the doctor's reasoning of diagnosis and treatment. It is something genuinely different from patients' personal impressions that a consultation went well, that they succeeded in presenting their case, and that they understood what the doctor had to say [7].

Some but not all expectations about performance-based health literacy were met in this study. Performance-based literacy predicts the recognition of the shortcomings of low-quality mental-health websites (H2) and good judgment with regard to treatment (H1), and health literacy and accurate perceptions together predict good treatment choices even better (H3). Favorable evaluations of websites, in contrast, seem unrelated to this kind of health literacy, other than what was hypothesized in H2, which pertained to both low- and high-quality websites. Although perception-based health literacy was associated with favorable perceptions of high-quality websites, which went against H4, H4 was otherwise supported.

In the wake of this analysis, health literacy no longer appears to provide the certain benefits that we initially described. However, objective health literacy can still be perceived to be a valuable asset. Its association with sound judgments on treatment and its relationship with negative evaluations of low-quality websites reflect its value. After reviewing our results, the same value cannot be placed on subjective, perception-based health literacy, which might fail to lead to a successful result even if it does not actually do harm.

Actions aimed at enhancing health literacy should not stop at influencing subjective health literacy. The more important point of attack seems to be objective health literacy, and leaving it out of the picture runs the risk of failing to reach the desired outcome. The autonomy policies in health care today are an example of this. They might easily induce in patients a desire to make treatment choices by themselves, and with this growing desire, patients may increasingly consider themselves to be the agency in charge; this might blind individual patients to the fact that nothing much has changed with regard to the objective abilities they possess.

Health literacy on one side and autonomy ideals on the other side complement one another. The abilities that come with health literacy can be used to prevent patients from making too many detrimental decisions, and the autonomy granted would give their health literacy a raison d'être as it would provide a chance to apply their newly acquired ability in the real world, under real circumstances and with real consequences. It has to be noted, though, that health literacy is understood as being of assistance to physicians, not as their replacement.

The desire to counter internet disinformation by increasing health literacy is based on patients' ability to recognize the low quality of some of the messages on the web. According to our results, this can work for objective, performance-based health literacy, but not for the subjective version of the concept. This might be explained by a specific shortcoming of thinking: one is relatively satisfied with their communication abilities because one cannot imagine how much better they could be. This would apply to the ease with which one communicates in health contexts as well as to the quality of websites. Low standards, applied to oneself and to websites as well, could be the common problem behind the measured association.

We expected to find a differential effect on an individual's decision making based on what they know and what they think they know on the given topic [5,10]. In this vein, we expected that self-reported health literacy (ie, what individuals thought they knew) would not make any difference in the depression-related decision making compared with performance-based health literacy (ie, what individuals actually knew). The hypothesis was confirmed because we found that high objective health literacy predicted sound treatment choice, whereas high subjective health literacy did not. Measuring concepts as subjective entities, as is done for intelligence and knowledge [20], goes back to the idea that people react primarily not to objective states but to their perception of those states. Asking people what they think they know, or how intelligent they think they are, works well because these are everyday terms. Health literacy, however, is not an everyday concept, and therefore its measurement must be performed indirectly.

Moreover, subjective and objective health literacy did not correlate. This result was in line with the literature supporting the inadequacy of self-reported measures to detect one's actual health literacy level [48] and demonstrated the fact that the two measures evaluate different constructs [21,39,48,49].

We also tested whether information quality mediated the relation between health literacy and depression-related decision making, first considering performance-based and then self-reported health literacy. The analyses revealed that the perceived quality of a low-quality message partially mediated the relation between the performance-based health literacy level and the treatment choice. Therefore, the performance-based health literacy level not only had a positive direct effect on treatment choice but it also had a positive effect on treatment choice through its effect on the perceived quality in the case of a low-quality message. In other words, the higher the actual health literacy level, the lower the perceived quality of a low-quality website, and the better the treatment choice, while the lower the actual health literacy, the higher the perceived quality of a low-quality message, and the worse the decision making. This finding is meaningful because it suggests that efforts to increase the objective health literacy level have the potential to improve not only the judgment of information quality but also the appropriateness of the decision making.

Moreover, in the various mediation models examined, the main effect of performance-based health literacy on treatment choice was always significant (H1), while the main effect of self-reported health literacy was not (in any of the cases [H4]). This result suggests that the self-reported health literacy level does not have the potential to improve the quality of judgments and decisions.

To sum up, believing oneself to be health literate does not imply that one is able to make accurate perceptions of the quality of health information presented to them, nor does it mean that one is able to make good health-related decisions. Feeling empowered, indeed, was argued not to be a sufficient requisite for making good decisions [5,10]. These findings provide further support to the hypothesis that a difference actually exists between performance-based and self-reported measures of health literacy. Interpreting self-confidence as health literacy does not suffice; the more consequential performance-based level of health literacy counts more [21,29,48,49], especially in terms of making accurate judgments of health information.

Strengths and Limitations

One main limitation of the present study is the generalizability of its results. We recognize that there might have been a selection bias due to the sampling method used; however, a positive aspect was that the sampling was conducted via Facebook. Therefore, we were very likely to sample actual internet users. Another limit to the generalizability of our findings pertains to the ecological validity of the study. Indeed, we selected the mock versions of two actual websites as experimental stimuli. However, in the future, better selection criteria could be established by reviewing the main Italian information websites about depression using appropriate tools, such as DISCERN [50].

Strictly speaking, the analysis cannot claim to say anything beyond the findings on mental health and depression websites and their users. The results were nevertheless formulated without constant reminders of this limitation. This can be interpreted as a hint that we expect to find similar associations for other health topics as well.

Conclusions

The take-home messages of the present research are as follows. Our findings provide further support to the hypothesis that a difference exists between performance-based and self-reported measures of health literacy. In particular, performance-based health literacy is associated with the ability to recognize faulty information, sound judgment and health-related decision-making skills, and good health outcomes. These are largely the consequences that make health literacy such a cherished concept. On the other hand, individuals who boast of experience that might indicate health literacy (ie, the items in the subjective, self-reported measures) cannot be regarded as having similar abilities, especially in the absence of objective health literacy to support their conception of their own abilities. Simply because someone believes that they communicate well in health care environments does not mean they actually do and no one should assume that they do. The state of not knowing what one does not know has several consequences. First, other individuals in the health care system have to assume that, despite the professed communicative abilities, these individuals are prone to become victims of medical disinformation. Second, some questions arise. For performative measures, research should ask how much health literacy is needed to avoid adverse decisions in health care. For self-reported literacy measures, the poor construct validity for health literacy suggests that these measures need to be tested directly to determine whether they are valid measures of empowerment [10].

In terms of health policies, the conclusion is that patients should not be encouraged to claim a larger share in medical decision making unless it is clear that a sufficient basis of objective health literacy exists.

Acknowledgments

PJS conceived the project and wrote, together with UH, the final version of the paper. AP collected data as a part of her Master's thesis. PJS and SP supervised AP's work and performed the analyses, and SP wrote the first draft of the paper. All authors read and approved the final version.

Abstract

Background: The internet has emerged as a main venue of health information delivery and health-related activities. However, few studies have examined how health literacy determines online health-related behavior.

Objective: The aim of this study was to investigate the current level of health-related information-seeking using the internet and how health literacy, access to technology, and sociodemographic characteristics impact health-related information-seeking behavior.

Methods: We conducted a cross-sectional study through a survey with Minnesotan adults (N=614) to examine their health literacy, access to technology, and health-related information-seeking internet use. We used multivariate regression analysis to assess the relationship between health-related information-seeking on the internet and health literacy and access to technology, controlling for sociodemographic characteristics.

Results: Better health literacy (β=.35, SE 0.12) and greater access to technological devices (eg, mobile phone and computer or tablet PC; β=.06, SE 0.19) were both associated with more health-related information-seeking behavior on the internet after adjusting for all other sociodemographic characteristics. Possession of a graduate degree (β=.28, SE 0.07), female gender (β=.15, SE 0.05), poor health (β=.22, SE 0.06), participation in social groups (β=.13, SE 0.05), and having an annual health exam (β=.35, SE 0.12) were all associated with online health-related information-seeking.

Conclusions: Our findings indicate that access to online health-related information is not uniformly distributed throughout the population, which may exacerbate disparities in health and health care. Research, policy, and practice attention are needed to address the disparities in access to health information as well as to ensure the quality of the information and improve health literacy.

KEYWORDS

digital divide; health literacy; internet; technology; access

Introduction

Health information access and use are essential for optimal health outcomes [1]. For example, a meta-analysis found that health information access and use were associated with better compliance with medical treatment in patients with chronic and acute illnesses [2]. Another study demonstrated that health information access and use are associated with self-care behavior among patients with heart failure [3]. Furthermore, several previous studies revealed that health information access and use predict other health-related behaviors, including having an annual medical checkup and undergoing cancer screenings, because increased cognitive knowledge in health can lead to behavioral outcomes such as receiving preventive screenings [4-6]. This association shows that securing adequate access to and use of health information plays a key role in improving health outcomes in varied domains.

Since its advent, the internet has served as a primary medium to convey health information [7,8]. For the last few decades, the dramatic increase in the usage of internet-embedded devices such as laptops, tablets, and smartphones has enabled people to access and use health information at any place and time [9]. According to recent national surveys [10,11], in the United States, approximately three-quarters of adults have broadband internet service at home, nearly 90% use the internet, nearly two-thirds of adults own a smartphone, and nearly 80% use the internet for various health-related purposes such as seeking health information, communicating with doctors, and purchasing medicine or vitamins [12-14].

Although the internet has contributed to enhancing the potential for health information access and use while reducing barriers to obtaining health information in the US general population, not all people have obtained these benefits. For example, gender is a key predictor of use of the internet and online health information behavior [15]. Previous studies have shown that men are less likely than women to use the internet for health information–seeking and to trust online sources [13,16-18]. There remain some groups of people who still experience difficulties in accessing and utilizing health information because of barriers such as a digital gap and limited health literacy [1,19,20].

A digital gap is defined as unequal access to technology and capability of its usage [21]. These variations in access to and use of technology often lead to disparities in health outcomes [22]. Existing research shows that predictors of the digital gap include age, gender, education attainment, and income [20]. Closing the digital gap is important because it is significantly associated with the enhancement of health-related decision making, health behavior, and health care system navigation [23,24]. In addition to the digital gap, health literacy also influences health information access and use. Health literacy is defined as “the degree to which individuals can obtain, process, understand, and communicate about health-related information needed to make informed health decisions” [25]. Researchers agree on the importance of health literacy in that people with low health literacy are at a high risk of varied poor health outcomes [26-29].

Despite consistent emphasis on the importance of health literacy as a determinant of health outcomes [30,31], and the emergence of the internet as a main venue of health information delivery and health-related activities, few studies have examined how health literacy determines online health-related behaviors such as the usage of the internet for health information–seeking and health-related activities, including online scheduling for visits to clinics. Therefore, this study had a threefold purpose: (1) to investigate the levels of online health-related behavior, (2) to assess whether health literacy is associated with online health-related behavior, and (3) to examine whether sociodemographic characteristics are associated with online health-related behavior. The findings of this study will offer insights into health literacy and sociodemographic-specific interventions for improving online health-related behaviors and health outcomes.

Methods

Research Design and Data Collection

The research team collected survey data from 732 adults aged 18 years or older at the 2016 Minnesota State Fair with approval from the University of Minnesota Institutional Review Board. The survey included questions about health literacy and health behavior in addition to general sociodemographic information. Participants received a small gift (a backpack with the University of Minnesota logo, which is worth about US $3) after they completed their voluntary survey using REDCap software via an iPad. Owing to missing values, data from 614 respondents (241 men and 373 women) out of the original 732 were used in the study as the analytic sample. Comparing the included analytic sample of 614/732 (83.9%) to the excluded sample of 118/732 (16.1%) due to missing values, we found that people in the included sample, who completed the survey, were more likely to have a family cancer history (included sample: 480/614, 78.2%; excluded sample: 49/76, 64.5%; P=.02), have both a smartphone and a computer or tablet PC (included sample: 485/614, 79.0%; excluded sample: 36/63, 57.1%; P<.001), and use internet for health information (included sample: 549/614, 89.4%; excluded sample: 57/74, 77.0%; P=.02) at the 5% significance level.

Instruments and Measures

To measure health-related information-seeking behavior, the main outcome variables of this study were based on two sets of questions about seeking health-related information on the internet. First, a survey question asked whether the respondent used the internet for health information, which was used as a binary outcome variable for health-related internet use. Second, the total score of the 12 health-related internet use items from the Health Information National Trends Survey [32] questionnaire was used to measure the participants’ health-related information-seeking internet use score. Each question was assigned a value of 0 (no) or 1 (yes). The Cronbach α of the 12 items for the health-related internet use score was .71. Higher health-related internet use scores indicate more health-related information-seeking behavior using the internet.

The two key independent variables were health literacy and access to technology devices. Health literacy is comprised of the total score of the following three health literacy items from the Behavioral Risk Factor Surveillance System Questionnaire [33] developed by the US Centers for Disease Control and Prevention, and was used as the primary measure of health literacy in this study: (1) “How difficult is it for you to get advice or information about health or medical topics if you needed it?” (2) “How difficult is it for you to understand information that doctors, nurses, and other health professionals tell you?” and (3) “You can find written information about health on the internet, in newspapers and magazines, and in brochures in the doctor’s office and clinic; in general, how difficult is it for you to understand written health information?” Each health literacy item was measured by a 5-point Likert scale ranging from 1 (“not at all”) to 5 (“always”), and the Cronbach α of the three items was .74. Access to technology devices was measured by a categorical variable assessing the type(s) of devices the respondent had access to. Respondents chose one of the following options: “no device,” “computer or tablet PC at home,” “mobile phone,” “mobile phone and computer or tablet PC at home,” “smartphone,” or “smartphone and computer or tablet PC at home.”

In addition to the measures on health literacy and technology devices, the sociodemographic and health information of participants, including gender, age, marital status (never married vs married/partnered), educational level (less than a bachelor’s degree, bachelor’s degree, or graduate degree and higher), annual health checkup in the past 12 months, any family cancer history, health status (poor/fair vs good/very good/excellent), and participation in a social group, were included as covariates.

Data Analysis

We first investigated the association of health-related information-seeking internet use with sociodemographic characteristics using *t* tests for binary variables and *F* tests for categorical variables with more than two values. We report the Pearson correlation coefficients (*r*) for continuous variables. In particular, we focused on gender differences in health-related information-seeking internet use because previous studies have shown gender differences in internet use and health information–seeking behavior [13,15]. Next, we used multiple regression analyses for both binary and continuous outcome values of health-related internet use. We used logistic regression analysis for binary outcomes and ordinary least-squares regression analysis for the continuous health-related internet use score. We used heteroscedasticity robust standard errors for the multiple regression analyses. We conducted all analyses in Stata 14.1, using a 5% statistical significance level criterion.

Results

Sociodemographic Characteristics and Bivariate Analysis

Table 1 summarizes the sociodemographic characteristics of the study sample. A total sample of 614 was used in the study, with a majority of women. The mean health-related information-seeking internet use score was significantly higher for women than for men. The mean age of the sample was 41.87 years (SD 16.83), and the correlation between age and health-related internet use score was negligible (r=0.025, P=.54). Only 408 of the 614 participants (66.4%) in the sample reported their race/ethnicity.

The total health-related internet use score was significantly different among educational level groups, which was the lowest among individuals with less than a bachelor’s degree and was the highest among individuals with a graduate degree. This demonstrates that participants with higher education had higher health-related information-seeking internet use. The majority of respondents indicated having gone for an annual health checkup, and their health-related internet use score was significantly higher than that for those who had not had an annual health checkup. The majority of the sample reported that their health status was good, very good, or excellent; participants with a lower self-reported health status had higher health-related internet use scores than those with a higher self-reported health status.

The majority of the sample had a smartphone and a computer or tablet PC at home, followed by those with a smartphone only. The health-related internet use scores across the different technology device possession groups were significantly different, with the highest scores for those using a smartphone and a computer or tablet PC, followed by the scores for those who possessed a smartphone only. The mean score for those who owned a mobile phone and computer or tablet PC at home was higher than that of respondents who owned a computer or tablet PC only at home or those who had only a mobile phone. The score for those who did not own any technology device was the lowest, as expected. The mean value of the health literacy total score was 12.37 (SD 2.41, range 0-15), and the Pearson correlation coefficient with the health-related internet use score was 0.079, which is moderate (P=.04).

Table 1. Sociodemographic characteristics and their relation to health-related internet use of the study sample (N=614).

Characteristics[a]	Value	Health-related internet use[b]		
		Mean (SD)	Test statistic[c]	*P* value
Gender, n (%)			$t_{489.585}=2.95$	.003
Male	241 (39.3)	3.27 (2.49)		
Female	373 (60.7)	3.87 (2.35)		
Marital status, n (%)			$t_{610.169}=1.41$	.16
Never married or other	315 (51.3)	3.50 (2.54)		
Married or partnered	299 (48.7)	3.78 (2.28)		
Educational level, n (%)			$F_{2,611}=14.28$	<.001
Less than bachelor’s degree	197 (32.1)	3.06 (2.50)		
Bachelor’s degree	262 (42.7)	3.60 (2.31)		
Graduate degree	155 (25.2)	4.42 (2.30)		
Annual health checkup, n (%)			$t_{277.588}=4.31$	<.001
No	147 (23.9)	2.95 (2.14)		
Yes	467 (76.1)	3.85 (2.46)		
Family cancer history, n (%)			$t_{200.472}=1.70$	.09
No	134 (21.8)	3.31 (2.57)		
Yes	480 (78.2)	3.73 (2.37)		
Self-reported health status, n (%)			$t_{135.037}=2.81$	.006
Very poor/poor/fair	106 (17.3)	4.32 (2.85)		
Good/very good /excellent	508 (82.7)	3.49 (2.30)		
Participating in a social group, n (%)			$t_{611.881}=1.81$	.07
No	321 (52.3)	3.47 (2.53)		
Yes	293 (47.7)	3.82 (2.28)		
Technology devices, n (%)			$F_{5608}=6.28$	<.001
No device	10 (1.6)	0.80 (1.23)		
Computer or tablet PC	7 (1.1)	2.57 (2.07)		
Mobile phone	9 (1.5)	2.00 (1.80)		
Mobile phone + computer or tablet PC	35 (5.7)	2.86 (2.05)		
Smartphone	68 (11.1)	3.13 (2.06)		
Smartphone + computer or tablet PC	485 (79.0)	3.87 (2.46)		

[a] The total sample size of each variable may not be the same as the total sample size of the study due to missing values.

[b] Based on health-related internet use total score (range 0-12).

[c] Two-tailed *t* test assuming unequal variances with Satterthwaite degrees of freedom for binary variables, and *F* test for categorical variables with more than two values.

Table 2 shows the results of the descriptive analysis on internet use for health information and health-related information-seeking internet use items. For the question asking about internet use for health information, 89.4% (549/614) of the sample reported that they have used the internet to look for health or medical information for themselves, with a significant gender difference. Among the 12 health-related internet use items, 6 items were significantly different between men and women at the 5% significance level; women used the internet more for these 6 items, which included “used email or the internet to communicate with a doctor or doctor’s office”; “used a website to help you with your diet, weight, or physical activity”; “looked for a health care provider”; “visited a social networking site such as Facebook or LinkedIn to read and share about medical topics”; “kept track of personal health information such as care received, test results, or upcoming medical appointments”; and “looked for health or medical information for someone else.”

Table 2. Descriptive analysis on health-related internet use.

Question	Total (N=614), mean (SD)	Males (n=241), mean (SD)	Females (n=373), mean (SD)	*t* statistic (df)[a]	*P* value
Internet use for health information (Yes=1, No=0)					
In the past 12 months, have you used the internet to look for health or medical information for yourself? (N=614)	0.89 (0.30)	0.83 (0.37)	0.93 (0.25)	3.63 (379.481)	<.001
Health-related internet use items[b] (Yes=1, No=0)					
Looked for information about quitting smoking (N=610)	0.05 (0.21)	0.06 (0.23)	0.04 (0.19)	0.97 (447.531)	.33
Bought medicine or vitamins online (N=610)	0.18 (0.38)	0.18 (0.39)	0.18 (0.39)	0.11 (504.817)	.91
Participated in an online support group for people with a similar health or medical issue (N=609)	0.06 (0.24)	0.054 (0.23)	0.06 (0.25)	0.65 (540.24)	.52
Used email or the internet to communicate with a doctor or doctor's office (N=611)	0.46 (0.50)	0.39 (0.49)	0.51 (0.50)	2.91 (516.579)	.004
Used a website to help you with your diet, weight, or physical activity (N=611)	0.52 (0.49)	0.47 (0.50)	0.55 (0.49)	2.02 (505.537)	.04
Looked for a health care provider (N=608)	0.42 (0.49)	0.36 (0.48)	0.47 (0.50)	2.75 (519.359)	.006
Downloaded health-related information to a mobile device such as an MP3 player, cell phone, tablet computer, or electronic book device (eg, download mobile apps) (N=610)	0.28 (0.45)	0.30 (0.46)	0.27 (0.45)	0.64 (495.534)	.52
Visited a social networking site such as Facebook or LinkedIn to read and share about medical topics (N=611)	0.29 (0.45)	0.24 (0.43)	0.32 (0.47)	2.23 (537.405)	.03
Wrote in an online diary or "blog" (ie, web log) about any type of health topic (N=605)	0.04 (0.19)	0.03 (0.18)	0.04 (0.20)	0.58 (538.839)	.56
Kept track of personal health information such as care received, test results, or upcoming medical appointments (N=606)	0.43 (0.50)	0.37 (0.48)	0.47 (0.50)	2.59 (518.015)	.01
Looked for health or medical information for someone else (N=599)	0.52 (0.49)	0.44 (0.49)	0.57 (0.49)	3.23 (497.276)	.001
Done anything else health-related on the internet (N=610)	0.39 (0.48)	0.40 (0.49)	0.38 (0.49)	0.60 (506.309)	.55

[a] Two-tailed *t* test assuming unequal variances with Satterthwaite degrees of freedom.

[b] Cronbach α=.708.

Multiple Regression Analyses

Table 3 shows the results of the logistic regression analysis that examined the association of health-related information-seeking internet use with health literacy, sociodemographic factors, and other health-related factors. Women were more likely to use the internet for health-related information-seeking, controlling for other factors, consistent with the bivariate gender comparison for the health-related internet use score (Table 1). Participants who had a postgraduate degree were more likely to use the internet for health-related information-seeking than those who had less than a bachelor's degree. Respondents who had participated in a social group were more likely to use the internet for health information than those who were not in a social group. Respondents with a higher health literacy score were more likely to use the internet for health information. Compared with those who did not have a technology device, those who had a mobile phone and computer or tablet PC at home, those who had a smartphone only, and those who owned a smartphone and computer or tablet PC at home were more likely to use the internet for health-related information. The Wald χ^2 test (Wald χ^2_{17}=53.30, $P<.001$) and pseudo R^2 (0.15) indicated a good model fit to the data.

Table 3. Multiple regression analyses for factors associated with health-related internet use for binary and continuous outcomes (N=614).[a]

Variable	Internet use for health information[b]		Health-related internet use total score[c]	
	Odds ratio (95% CI)	*P* value	Regression coefficient (SE)	*P* value
Female (Reference: Male)	2.68 (1.43-5.00)	.002	0.15 (0.05)	.007
Age	1.40 (0.95-2.07)	.09	0.11 (0.03)	<.001
Age^2	0.99 (0.98-1.00)	.14	–0.002 (0.00)	<.001
Age^3	1.00 (1.00-1.00)	.22	0.00001 (0.00)	.002
Married or partnered (Reference: Not married or partnered)	0.84 (0.41-1.71)	.63	–0.04 (0.05)	.46
Education level				
Less than bachelor’s degree	Reference	N/A[d]	Reference	N/A
Bachelor’s degree	1.19 (0.61-2.34)	.61	0.08 (0.06)	.18
Graduate degree	2.99 (1.15-7.73)	.02	0.28 (0.07)	<.001
Annual health checkup (Reference: No annual health checkup)	1.19 (0.61-2.32)	.61	0.147 (0.06)	.02
Family cancer history (Reference: No family cancer history)	1.19 (0.63-2.27)	.59	0.07 (0.06)	.21
Good/very good/excellent health (Reference: Very bad/bad/fair)	0.61 (0.27-1.40)	.24	–0.22 (0.06)	<.001
Participating in a social group (Reference: not participating)	1.90 (1.03-3.52)	.04	0.13 (0.05)	.008
Log of health literacy total score	7.19 (2.07-25.02)	.002	0.35 (0.12)	.004
Technology devices				
No device	Reference	N/A	Reference	N/A
Computer or tablet PC	4.28 (0.27-68.49)	.31	0.43 (0.31)	.17
Mobile phone	1.89 (0.16-21.81)	.61	0.42 (0.30)	.17
Mobile phone + computer or tablet PC	13.37 (1.53-117.09)	.02	0.60 (0.19)	.002

Smartphone + computer or tablet PC	8.13 (1.49-44.44)	.02	0.81 (0.17)	<.001

[a] Heterogeneity robust standard errors are used.

[b] Logistic regression for the dichotomous health-related internet use variable.

[c] Ordinary least-squares regression for the continuous health-related internet use total score; the natural logarithm of the health-related internet use score was used as the dependent variable.

[d] N/A: not applicable.

Table 3 also presents the results from the multiple ordinary least-squares regression analysis that investigated the association of the total health-related internet use score with health literacy, health-related factors, and sociodemographic factors. The health-related internet use score and the health literacy score were transformed using the natural logarithm function, which allowed us to interpret the results in approximate percentage changes in the analysis. Women were also more likely (by 14.50%) to have a higher health-related internet use score than men. Age was not significantly associated with the health-related internet use score when we added the age term only; however, age was significantly associated (at a 1% threshold) with the health-related internet use score when we included quadratic and cubic terms of age in addition to the linear term. This means that age was significantly associated with the health-related internet use score in a cubic manner, whereas there was no linear relationship between age and the health-related internet use score. Solving the cubic equation, we found that the health-related internet use score increased with age until about 38 years, decreased between the ages of 38 and 71 years, and increased again after the age of 71 years.

Respondents who had a postgraduate degree had a nearly 27.5% higher health-related internet use score than those who had less than a bachelor’s degree. Participants who had gone for an annual health checkup in the last 12 months had a nearly 14.7% higher health-related internet use score on average compared with those who had not gone for an annual health checkup. People who reported that their general health status was poor or fair had about a 22.6% higher health-related internet use score than those who reported their health status as good, very good, or excellent. The respondents who had participated in a social group had a 12.5% higher health-related internet use score than that of those who do not participate in a social group. People with a 10% higher health literacy score had a 3.5% higher health-related internet use score on average. In addition, health-related internet use scores for people who owned a computer or tablet PC or a mobile phone only were not significantly different from the scores of those without any kind of technology device. By contrast, compared with those without any technology device, people who possessed a mobile phone and computer or tablet PC had a 60.0% higher health-related internet use score, those who owned a smartphone only had a 72.5% higher health-related internet use score, and those who had a smartphone and computer or tablet PC had an 81.5% higher health-related internet use score. The *F* statistic ($F_{17,596}$=10.30, *P*<.001) and R^2 value (0.20) indicated a good model fit to the data.

Discussion

Principal Findings

This study found that better health literacy and greater access to technological devices were associated with higher levels of health-related information-seeking behavior online. We found that the higher the health literacy level and the higher the accessibility to technological devices (eg, access to a mobile phone and computer or tablet PC at home or access to a smartphone), the more likely the respondents were to use the internet to seek health-related information. We also found differences in online health-related information-seeking behavior by sociodemographic characteristics; being female, having a graduate degree, and reporting a poor/fair health status were associated with higher usage of the internet for seeking health-related information.

It is possible that individuals with higher health literacy are more comfortable seeking out health information, are more adept at knowing what to search for and how to find it, and are more comfortable interpreting the information that they access. Our findings about access to technological devices are logical; individuals with more advanced, faster potential for online connectivity are more likely to use those devices for a variety of information-seeking purposes compared with individuals who have more limited access to technology. However, these findings signal a concerning disparity in access to information. As all types of information, including health information, are increasingly delivered online, individuals without access to efficient, effective technological devices are at risk of being left further behind.

The findings about differences in health-related information-seeking by sociodemographic characteristics indicate potential areas of inequity. For example, individuals with graduate degrees were more likely than individuals without college degrees to use the internet for health information. Again, this finding is not necessarily surprising, given already known disparities in access to and use of technology by socioeconomic status, but it could heighten disparities in access to health information [34,35]. On many of the individual items measuring online health-related information-seeking behavior, and in the multivariate model predicting ever using the internet for health information (vs never), women were more likely than men to obtain health information online. This may be related to a broader trend of gender differences in health care utilization [36]; however, this also presents an opportunity to implement more strategies to make online health information appealing and useful for men [37]. Additionally, we detected differences by age in online health information-seeking; younger adults and older adults were more likely than middle-aged adults to seek out health information online. For people of all ages who do not access health information online, it is important to ensure that comparable information is easily accessible in other forms. For example, for clinics and hospitals moving toward online-only scheduling and online communication with providers, careful thought should be given to who might potentially be left out and what alternative forms of communication, scheduling, and information delivery can and should be offered. For other sources of online health information (eg, websites, social media, hospital websites), care should be taken to ensure that people of all ages have equitable access to high-quality information, and that people who do not access such information online have equitable access to other forms of information.

Limitations

This study should be considered in light of its limitations. We relied on a cross-sectional design, which therefore limits the ability to determine causality between online behavior and health literacy. We also did not have a random sample, but rather relied on a sample of adults who attended the Minnesota State Fair and were willing to respond to a survey. Nevertheless, we collected a robust sample capable of detecting meaningful differences in online health-related information-seeking behavior. To the extent that we did not capture a fully representative sample, we are likely to understate the differences we identified. We also did not examine intersectional differences by sociodemographic characteristics (eg, the potential multiplicative impact of gender and age), which should be explored more fully in future research. Finally, although we were able to examine differences in a range of health-related information-seeking behaviors, we were not able to determine the intensity or quality of these online interactions. Not all health information delivered online is good, and more attention should be paid to ensuring high-quality content and to educating the public on how to filter good from bad information.

Practice Implications

Health information and health care are increasingly being delivered online. Prior research has shown that nearly 4 out of every 5 Americans are currently using the internet for health-related purposes [10,11]. Nearly half of the adults in our sample reported using the internet to communicate with their health care provider; more than half used it to look for information about their diet, weight, or physical activity; and more than half used the internet to look for health-related information for someone else. Clearly, the internet plays a large and growing role in how Americans manage and learn about their own health and the health of their loved ones. Thus, the internet has the potential to improve access to health information [9], to reduce barriers in communicating with health professionals [38], and to offer assistance to caregivers [39]. However, our findings also show that the internet is neither universally accessible nor universally used for obtaining health information. More attention needs to be paid to improving access to technology and to offering alternative forms of health information and communication for those without it. This might include expanding access to broadband internet and cellular connectivity in rural areas that do not have it; ensuring that public spaces such as libraries have ample access to computers where people can go online, as well as privacy protections for sensitive health information, such as cubby walls or dividers; and providing ample health information through other free sources, including libraries, clinics, and community spaces.

Finally, our study did not measure the quality of the information that individuals receive or the interactions they have. As health care, along with many other sectors of society, increasingly moves online, providers and educators are faced with the enormous task of assisting the public in filtering good information from bad and in advocating for high-quality health information online. This process might start early, in schools working with children on online literacy, but should also expand to include people of all ages, including in workplaces, senior centers, and health care settings.

Conclusion

In this study, we demonstrated differences in online health-related information-seeking behavior according to the degree of health literacy, access to technological devices, and sociodemographic characteristics. We found that individuals with better health literacy, more access to sophisticated technological devices, and more education are more likely to access health information on the internet. Although these findings may not be surprising, they should be concerning; access to information is an important predictor of behavior [40,41] and disparities in access to health information may exacerbate disparities in health and health care access. Research, policy, and programmatic attention should be paid to improving access to technology, to ensure access to alternative forms of health information for those who cannot or will not access information online, and to improve the quality of online health information.

Abstract

Background: A growing number of health care practices are adopting software systems that link with their existing electronic medical records to generate outgoing phone calls, emails, or text notifications to patients for appointment reminders or practice updates. While practices are adopting this software technology for service notifications to patients, its use for collection of patient-reported measures is still nascent.

Objective: This study assessed the mode preferences, response rates, and mode effect for a practice-based automated patient survey using phone and email modalities to patients of primary care practices.

Methods: This cross-sectional study analyzed responses and respondent demographics for a short, fully automated, telephone or email patient survey sent to individuals within 72 hours of a visit to their regular primary care practice. Each survey consisted of 5 questions drawn from a larger study's patient survey that all respondents completed in the waiting room at the time of their visit. Automated patient survey responses were linked to self-reported sociodemographic information provided on the waiting room survey including age, sex, reported income, and health status.

Results: A total of 871 patients from 87 primary care practices in British Columbia, Ontario, and Nova Scotia, Canada, agreed to the automated patient survey and 470 patients (45.2%) completed all 5 questions on the automated survey. Email administration of the follow-up survey was preferred over phone-based administration, except among patients aged 75 years and older ($P<.001$). Overall, response rates for those who selected an emailed survey (369/606, 60.9%) were higher ($P<.001$) than those who selected the phone survey (101/265, 38.1%). This held true irrespective of age, sex, or chronic disease status of individuals. Response rates were also higher for email (range 57.4% [58/101] to 66.3% [108/163]) compared with phone surveys (range 36% [23/64] to 43% [10/23]) for all income groups except the lowest income quintile, which had similar response rates (email: 29/63, 46%; phone: 23/50, 46%) for phone and email modes. We observed moderate (range 64.6% [62/96] to 78.8% [282/358]) agreement between waiting room survey responses and those obtained in the follow-up automated survey. However, overall agreement in responses was poor (range 45.3% [43/95] to 46.2% [43/93]) for 2 questions relating to care coordination.

Conclusions: An automated practice-based patient experience survey achieved significantly different response rates between phone and email and increased response rates for email as income group rose. Potential mode effects for the different survey modalities may limit multimodal survey approaches. An automated minimal burden patient survey could facilitate the integration of patient-reported outcomes into care planning and service organization, supporting the move of our primary care practices toward a more responsive, patient-centered, continual learning system. However, practices must be attentive to furthering inequities in health care by underrepresenting the experience of certain groups in decision making based on the reach of different survey modes.

KEYWORDS

response rates; primary care; mixed-mode survey

Introduction

The development of an information infrastructure to support a learning health system in primary care has advanced significantly with the application of advanced analytics applied to data from electronic medical records and routinely collected administrative data [1]. However, in Canada most primary care is delivered in small community-based practices and, unlike the United Kingdom, there is no national or provincial infrastructure to measure and report patient experience data for primary care. Such data collection remains logistically challenging and relatively expensive for smaller practices [2]. While waiting room surveys often provide good response rates, they are costly, burdensome to practices, introduce a sampling bias toward older and more complex patients, and are limited to patients who physically attend a practice [1,3].

A growing number [4] of health care practices are adopting software systems [5] that link with their existing electronic medical records to generate outgoing phone calls, emails, or text notifications to patients for appointment reminders or practice updates. While practices are adopting this software technology for service notifications to patients, it is not clear whether such an approach would be acceptable to survey a practice's patients on experience or outcome measures selected by the practice to advance their quality improvement efforts. The data on response rates for electronic surveys in primary care is rudimentary compared with that for hospital surveys [4], but response rates of 20% to 30% [6,7] have been found recently for emailed surveys linked to primary care practices [6-8]. The objective of this study is to assess the mode preferences, response rates, and mode effect for a practice-based automated patient survey using phone and email modalities to patients of primary care practices.

Methods

Study Sample

This cross-sectional study analyzed mode preferences, response rates, and respondent demographics for a short, fully automated, telephone or email patient survey to consenting individuals who had recently attended their regular primary care practice. Within our larger study, Transforming Community-Based Primary Health Care Delivery through Comprehensive Performance Measurement and Reporting (TRANSFORMATION), patients from 87 primary care practices in British Columbia, Ontario, and Nova Scotia, Canada, were asked to complete a waiting room survey between 2014 and 2016. The automated patient survey system was tested on a convenience sample of those participants who consented to receiving an additional postvisit survey by email or phone. Eligible patients had to speak English or French and have a valid telephone number or email address. Patients were asked to specify their preferred contact modality, phone or email, and provide their name and contact information to an on-site research team member.

The contact information and unique identifying number for consenting patients was entered manually by survey administrators and uploaded to a cloud-based server via a software console. Upon receipt of the information, the administering information technology company collaborator, Cliniconex [9], programmed the appropriate survey mode and language (English or French) and randomly assigned the order of 5 survey questions. Once the survey was administered by Cliniconex, all contact information was deleted, and only the unique identifying number was retained on the server.

Survey Administration

Participants received an automated phone or email survey within 72 hours of visiting the practice. A phone survey response was recorded as completed only if the patient could be reached at the phone number on file, accepted the call, and completed all 5 survey questions. The phone survey was initially attempted twice, and then registered as incomplete if no answer was received. Partway through the study, the number of attempts was increased (4 call attempts) to facilitate higher response rates. For those who chose an email survey mode, an email was sent once containing the introduction and a web link to the survey. An email survey was recorded as complete if all 5 survey questions were answered.

Each survey consisted of 5 questions drawn from the TRANSFORMATION study's waiting room patient survey [10]. The questions were selected to relate to patients' experience with primary care and/or their practice. Two question prompts were modified from their original form in the paper waiting room survey to reflect the timing of the survey administration. When administered in the waiting room, questions 1 and 2 were prompted with "After seeing the family doctor or nurse today..."; on the automated patient survey, patients were prompted with "At your last visit with your family doctor or nurse practitioner...." See Multimedia Appendix 1 for the wording of the survey questions in the paper waiting room survey and the postvisit automated survey. Phone survey responses were stored in a secure password-protected site on a secure server. Email responses were sent directly to a hospital-based server and managed using Research Electronic Data Capture tools [11].

The unique identifying numbers were used to link automated patient survey responses to self-reported sociodemographic information on the paper waiting room survey, completed during the participant's visit to their practice, including age, sex, reported income, and health status.

Data Analysis

To detect any response bias inherent in using an automated email or phone survey system, we used Pearson chi-square tests to compare the sociodemographic profile of those who completed the automated patient survey (responders) with those who did not complete the automated patient survey (nonresponders). The comparison group of nonresponders contained those who either participated in the paper waiting room survey but refused the automated survey or agreed to the automated survey but did not complete all 5 questions. We also conducted Wilcoxon rank-sum tests on the paper waiting room survey responses, comparing differences in mean responses between those who completed the automated patient survey and those who did not. We conducted chi-square tests to compare automated patient survey mode preference (email or phone) and response rates both across and between patient sociodemographics. A Cochran-Armitage test for trends was also used to examine variation in mode preference by age and income. All analyses were performed using SAS software version 9.4 (SAS Institute Inc).

The primary outcome measure response rate was pooled across all practices as we were interested in differences across dependent variables of age and attributed socioeconomic status rather than regional variations.

To identify a potential mode effect, secondary analyses explored responses for each question across the 3 survey modes, email and phone (automated patient survey) and paper (waiting room). Test-retest analysis was undertaken, comparing each patient's responses from the waiting room survey to their responses to the corresponding automated survey question. The percentage of concordant and discordant responses were determined by comparing waiting room derived responses with those from subsequent survey data. Weighted kappas were calculated to compare this concordance in survey responses by survey mode. Mean responses were also compared (using Wilcoxon signed-rank test) across responses to the corresponding questions from the paper waiting room survey and the automated patient survey (total and by mode).

This study was approved by the behavioral research ethics boards at Fraser Health (RHREB 2015-017), University of British Columbia (H13-01237), Ottawa Health Science Network (20140485-01H), Bruyère Continuing Care (M16-14-029), and the Nova Scotia Health Authority (CDHA-RS/2015-150).

Results

Response Bias

Of those who agreed to the automated patient survey, 69.6% (606/871) of participants chose to receive the survey by email compared with telephone. This group represented 45.15% (871/1929) of the participants who initially consented to completing a paper waiting room survey (Table 1). Of those who agreed to the survey, 55.6% (484/871) responded and 97.1% (470/484) completed all 5 questions (24.36% [470/1929] of those who completed the paper waiting room survey and 54.0% [470/871] of those who agreed to the automated patient survey). Respondents to the automated patient survey tended to be older, were more likely to be women, had higher income, and reported a larger number of chronic conditions than those not completing the survey. There was no significant difference in paper waiting room survey responses between those who completed the automated patient survey and those who did not (Table 2).

Table 1. Comparison of those who completed the automated patient survey to those who did not[a].

[a] Total counts within categories vary due to missing data.

[b] Includes those who did not consent to having their automated patient survey linked to their waiting room survey responses.

[c] Excludes those who did not consent to having their automated patient survey linked to their waiting room survey responses.

[d] N/A: not applicable.

[e] χ^2 *P* value is comparing the distribution of the subgroup (eg, age, gender) between completed and not completed, for each mode and overall.

[f] Cochrane-Armitage *P* value for the presence of linear trend in proportions of completed and not completed across ordinal subcategories, for each mode and overall.

Table 2. Comparison of waiting room survey responses between those who completed the automated patient survey to those who did not[a].

Waiting room survey questions	Response for those who also completed automated patient survey[b], mean (SD)	Response for those who did not complete automated patient survey[c], mean (SD)	*P* value[d]
Given enough time	4.67 (0.60)	4.63 (0.75)	.88
Explained tests and treatments	4.70 (0.61)	4.66 (0.71)	.85
Told about potential side effects of medications	2.64 (0.60)	2.69 (0.55)	.30
Times when provider didn't have access to recent tests or exam results	1.26 (0.51)	1.25 (0.52)	.63
Times when provider didn't know about changes in treatment plan that another person recommended	1.23 (0.47)	1.20 (0.44)	.37

[a] Total counts within categories vary due to missing data.

[b] Excludes those who did not consent to having their automated patient survey linked to their waiting room survey responses.

[c] Includes those who did not consent to having their automated patient survey linked to their waiting room survey responses.

[d] Wilcoxon rank-sum test *P* value is comparing paper waiting room survey responses between completed and not completed.

Response Rates

In this sample, email administration of the follow-up survey was preferred over phone-based administration, except among patients aged 75 years and older (Table 3). Among those who answered the automated patient survey, 97.1% (470/484) completed of all 5 questions. Thus, response rates include only those who answered all 5 questions. Overall, response rates for those who selected an emailed survey (369/606, 60.9%) were higher than those who received the phone survey (101/265, 38.1%). This held true irrespective of the age, sex, or chronic disease status of individuals. Response rates were also higher for email compared with phone surveys for all income groups except the lowest income quintile, which had similar response rates for phone and email modes. There was variation in response rates within email mode, with higher responses among more affluent individuals.

Table 3. Mode preference and response rates by subgroups.

[a] Comparing percentage distribution of mode preference across subgroups.

[b] Comparing percentage completed across subgroups.

[c] N/A: not applicable.

[d] Cochran-Armitage test for trend also gives *P*<.001.

[e] Indicates suppressed due to cell count less than 5.

[f] Comparing completion rates between subgroups (overall or by mode).

[g] Cochran-Armitage conducted to test for trends.

Mode Effect

We observed moderate agreement between waiting room survey responses and those obtained in the follow-up automated survey (see Multimedia Appendix 2). However, overall agreement in responses was poor for 2 questions relating to care coordination.

Among phone respondents, agreement in responses was generally poor, and phone responders were particularly critical with respect to care coordination (Table 4). Agreement between waiting room responses and subsequent email survey regarding interpersonal aspects of care was moderate and poor for items relating to care coordination.

Table 4. Comparison of responses to paper waiting room surveys and automated surveys among those who completed the automated patient survey.

Description	Waiting room response, mean (SD)	Automated patient survey response—by mode			
		Phone, mean[a] (SD)	*P* value[b,c]	Email, mean[d] (SD)	*P* value[c,e]
Given enough time (range 1-5[f])	4.67 (0.60)	4.66 (0.72)	.15	4.67 (0.65)	.27
Explained tests and treatments (range 1-5[f])	4.70 (0.61)	4.42 (0.97)	.04	4.57 (0.79)	<.001
Told about potential side effects of medications (range 1-3[g])	2.64 (0.60)	2.63 (0.70)	>.99	2.68 (0.68)	.28
Times when provider didn't have access to recent tests or exam results (range 1-3[h])	1.26 (0.51)	1.97 (0.90)	<.001	1.65 (0.79)	<.001

[a] The final N available for analysis for each question varies slightly due to nonresponse (or not applicable choice). Mean responses are calculated only for those who answered both versions of the questions. Ns for each question for those who completed the automated patient survey by phone are as follows: Q1: 96; Q2: 96; Q3: 92; Q4: 93.

[b] Comparing phone automated patient survey response to waiting room response.

[c] Wilcoxon signed-rank test.

[d] The final N available for analysis for each question varies slightly due to nonresponse (or not applicable choice). Mean responses and paired mean differences are calculated only for those who answered both versions of the questions. Ns for each question for those who completed the automated patient survey by email are as follows: Q1: 358; Q2: 357; Q3: 290; Q4: 336; Q5: 360.

[e] Comparing email automated patient survey response to waiting room response.

[f] 1=very poor; 5=very good.

[g] 1=no; 3=yes, often, or always.

[h] 1=never or rarely; 3=often or very often.

Discussion

Principal Findings

We successfully deployed an automated multimodal practice-based patient survey in 87 primary care practices. Overall, patient preference for the email survey mode was demonstrated; however, this was modified by age group and socioeconomic status. Indeed, completion rates for email were higher than most health care automated surveys [8] versus comparable response rates in the total sample [6]. However, it is unclear whether the lower consent rate (45.2%) from the total patient sample reflects lack of acceptability of an automated low-burden survey or survey fatigue among participants who had already completed a long waiting room survey. Despite this, the relatively high completion rate to the short email survey suggests this is a feasible and acceptable approach to collect patient reported data.

Our results show that the lowest income group had the lowest preference for the email mode and lowest response rate for the email survey while having the highest response rates for the phone survey. Our finding of the email responders being more likely to be female and of higher income echoes the pattern of a recent practice-based single-site email survey in Ontario [6]. A move to use email surveys to collect patient experience data would need to carefully monitor underrepresentation by lowest income groups to not exacerbate inequities in health care. The survey software, as it is used currently for appointment reminders, is usually deployed after linking with the electronic medical record to use patient contact information, so it is possible for automated surveys to track information such as approximate income based on postal code and oversample a population found to be underrepresented in responses.

Opportunities to match surveys to reported language preferences and the capacity to reach people by phone or email who do not frequently attend a practice or have a stable home address raises the potential for an automated survey to be particularly valuable in understanding the experience of some of the most vulnerable members of a practice population. However, there are still inequities in access to the internet, with lower income individuals and people living in rural areas having lower access [12-14]. Text messaging might be preferable to phone for some patients and increase the reach across sociodemographic groups.

The low concordance rate of responses on questions of care coordination between paper and automated survey, especially the phone survey, raises important questions about a mode effect and/or the role of true anonymity in responding to questions about one's health care provider or practice in a waiting room compared with online or automated phone response. It is also possible that the paper survey questions on care coordination sensitized participants to the issue, and after their visit, they were more aware of breakdowns in optimal care, accounting for their more negative responses with the automated survey following their practice visit. Additionally, the care coordination questions had negative phrasing, which may have been more confusing for phone responders.

Cost-effectiveness was not the focus of this study. However, at two-thirds the completion rate compared with email, a phone survey would cost one and a half times as much. The cost of deploying a tailored automated patient outreach message and linked survey from the software company we collaborated with includes a 1-time practice start-up fee of $500 CAN (US $390) and an annual per-provider fee of $600 CAN (US $468). For an average practice of 4 providers and 5200 patients, an email survey would cost about 25 cents (US 20 cents) if each patient were sent a message and survey twice per year or less than 15 cents (US 12 cents) if most patients were sent a survey 4 times per year. Higher response rates make the approach more cost-effective for the email mode since automated systems frequently charge per survey sent. For quality improvement data collection, practices would not need to seek prior consent to contact patients. However, efforts to enhance patient buy-in and achieve higher response rates would be key to the cost-effectiveness of this approach. As practices seek better ways to engage patients and collect patient-reported experience measures and patient-reported outcome measures, it is essential to be sensitive to the response burden on patients and promote a culture in which patients understand the purpose of surveys and feel their insights and time are valued [15]. This may help build a partnership with patients in practice-based surveying as a way to give patients more influence in the system and their care.

The capacity of this proposed system to link collection of patient-reported measures with clinical services, such as appointment reminders or preventive care reminders, could improve the response rates received on general surveys of patient experiences, improving quality and reducing costs [2]. Such an approach would have the benefit of being able to deploy surveys to all patients or ones with prespecified criteria (eg, people who just attended the practice, have not attended in over a year, have a recent hospital discharge). Such a survey could be linked with data automatically extracted from electronic medical records or a registry developed by providers, offering an even greater opportunity to understand patient experiences and outcomes. Additionally, an automated system can spread the burden of response across a wide and/or randomly selected segment of a practice's patient population, asking different questions to different patients on an ongoing or rolling basis, enhancing reach and reducing cost compared with traditional waiting room surveys.

Increasingly, electronic medical records are being used to collect patient-reported outcome measures that are inputted directly into the patients' chart. This approach offers the benefit of supporting a patients' immediate care. However, this approach creates a burden for the provider or practice to review data automatically put into a patient chart in a timely manner. Keeping a patient automated survey function distinct from clinical care may be attractive to providers and practices who need to manage their workflow and feel overburdened with data and data requests already.

As a survey method, an automated patient survey offers some attractive features. Response rates and sample bias can be easily calculated for parameters such as age, gender or income as estimated by postal code without adding to patient burden of filling this information in. Based on continually updated information on filled surveys, ongoing distribution (sampling) parameters can be set to minimize or account for any bias that may arise. Automated surveys can be deployed at regular intervals determined by the practice and would not burden practice staff, providers, or even patients during a visit, thus avoiding interruptions or additional work.

As more practices are collecting email addresses from their patients and patients expect email communication options, an automated patient engagement system with an embedded survey is feasible. Practices already using this or a similar technology to serve patients through outreach reminders may be more willing to participate in data collection initiatives that use this same infrastructure for quality improvement or research.

Limitations

There are some limitations to consider in interpreting the findings of this study. Initial recruitment into the TRANSFORMATION study was through a convenience sample of patients from primary care practices across British Columbia, Ontario, and Nova Scotia. As such, patients who were recruited into the study may not be representative of patients generally across Canada, potentially limiting generalizability. Additionally, potential for selection bias is further compounded by relatively low overall response rates by participants of the automated patient survey, who were recruited from the initial convenience sample of patients enrolled into the larger study.

Conclusions

An automated practice-based patient experience survey achieved significantly different response rates between phone and email and increased response rates for email as income group rose. The higher response rates of the email surveys make a phone approach less cost-effective. However, care must be paid to furthering inequities in health care by underrepresenting the experience of certain groups in decision making. Further, potential mode effects for the different survey modalities may limit multimodal survey approaches.

An automated communication system will become even more valuable as the stock of high-quality and validated instruments to measure patient-reported outcomes grows over the next decade [16]. An automated system that enables targeted outreach surveys with minimal burden on patients and providers could facilitate the integration of patient-reported outcomes into care planning and service organization, supporting the move of our primary care practices toward a more responsive, patient-centered, continual learning system.

Abstract

Background: The impending scale up of noncommunicable disease screening programs in low- and middle-income countries coupled with limited health resources require that such programs be as accurate as possible at identifying patients at high risk.

Objective: The aim of this study was to develop machine learning–based risk stratification algorithms for diabetes and hypertension that are tailored for the at-risk population served by community-based screening programs in low-resource settings.

Methods: We trained and tested our models by using data from 2278 patients collected by community health workers through door-to-door and camp-based screenings in the urban slums of Hyderabad, India between July 14, 2015 and April 21, 2018. We determined the best models for predicting short-term (2-month) risk of diabetes and hypertension (a model for diabetes and a model for hypertension) and compared these models to previously developed risk scores from the United States and the United Kingdom by using prediction accuracy as characterized by the area under the receiver operating characteristic curve (AUC) and the number of false negatives.

Results: We found that models based on random forest had the highest prediction accuracy for both diseases and were able to outperform the US and UK risk scores in terms of AUC by 35.5% for diabetes (improvement of 0.239 from 0.671 to 0.910) and 13.5% for hypertension (improvement of 0.094 from 0.698 to 0.792). For a fixed screening specificity of 0.9, the random forest model was able to reduce the expected number of false negatives by 620 patients per 1000 screenings for diabetes and 220 patients per 1000 screenings for hypertension. This improvement reduces the cost of incorrect risk stratification by US $1.99 (or 35%) per screening for diabetes and US $1.60 (or 21%) per screening for hypertension.

Conclusions: In the next decade, health systems in many countries are planning to spend significant resources on noncommunicable disease screening programs and our study demonstrates that machine learning models can be leveraged by these programs to effectively utilize limited resources by improving risk stratification.

KEYWORDS

machine learning; diabetes; hypertension; screening; global health

Introduction

Noncommunicable diseases, including diabetes, hypertension, and cardiovascular disease, are a global health priority [1]. Noncommunicable diseases disproportionally affect low- and middle-income countries, wherein more than 75% of all noncommunicable disease deaths (~31 million per year) occur, including over 16 million annual deaths in adults between the ages of 30 years and 69 years [1]. India faces the largest burden of noncommunicable diseases in the world with an estimated

73 million reported with diabetes and over 400 million people reported with hypertension [2,3]. Moreover, an estimated 58% of the patients with diabetes and 60%-75% of the patients with hypertension in India are undiagnosed, thereby creating a population health crisis [4]. Early detection via screening and subsequent treatment initiation can significantly reduce the burden of both diabetes and hypertension [5,6]. However, health systems in many low- and middle-income countries are already overburdened with an unfinished agenda on infectious diseases [7] and do not have enough capacity to conduct national-level noncommunicable disease screening programs [8].

Community-based screening programs can be leveraged to augment the capacity of the existing health systems by using community health workers (with limited training to conduct diabetes and hypertension screening) [9]. Owing to the large number of undiagnosed patients and the lack of awareness of noncommunicable diseases, community health workers typically conduct door-to-door and camp-based (ie, a tent staffed with community health workers) screenings to identify patients with undiagnosed diabetes and hypertension and subsequently refer them to a physician for assessment.

Community-based screening programs in low- and middle-income countries typically employ risk stratification methods that have been developed in high-income countries, leading to 3 key limitations [10,11]. First, at-risk populations in low- and middle-income countries differ significantly in social, lifestyle, and genetic aspects, thereby limiting the validity of models from high-income countries [12,13]. Second, a community-based approach severely limits the amount and complexity of data that can be collected by community health workers. Consequently, many models from high-income countries, which rely on advanced data (eg, triglyceride levels for diabetes [14]), are not applicable. Third, models from high-income countries are often calibrated to estimate the long-term risk of developing the disease [11,15] (eg, 2-10 years) rather than identifying the short-term risk of developing the disease. Owing to these limitations, application of approaches from high-income countries to community-based screening programs in low- and middle-income countries can result in poor risk stratification accuracy, reduced screening program yield, and increased cost per case identified [16].

In this study, we developed new risk stratification algorithms that are tailored for community-based screening programs in low- and middle-income countries with limited screening data. In particular, we used data collected by community health workers in Hyderabad, India and developed risk stratification models to estimate the short-term (2-month) risk for both diabetes mellitus and primary hypertension. We compared our results with several approaches from the literature, including previously developed risk scores from the United States and the United Kingdom. We also analyzed the trade-off between model accuracy and data availability by quantifying the incremental value of each data type collected during screening. Lastly, we quantified the expected reduction in the number of patients incorrectly stratified and the expected cost of incorrect risk stratification per patient.

Methods

Study Setting

Our study was based in Hyderabad, the capital of the state of Telangana and the fourth largest city in India with a population of 7 million [17]. Hyderabad has more than 1.7 million people living in 1400 urban slums [18]. Our catchment area included 52 urban slums and the surrounding communities. This population comprises individuals working as drivers, daily wage earners, domestic helpers, vendors, and self-employed professionals in the unorganized sector of the economy. The average family income of these residents ranges between INR 15,000 and INR 30,000 per month, which is equivalent to US $200-US $400, while the median income in Hyderabad is INR 25,000 (US $1=INR 75) per month [19].

Data Collection

We obtained retrospective data from a social enterprise based in Hyderabad that provides screening and management of diabetes and hypertension for low-income households. These data were collected through door-to-door and camp-based screenings conducted in the urban slums of Hyderabad between July 14, 2015 and April 21, 2018 by community health workers. The door-to-door screenings were conducted in low-income areas throughout Hyderabad. In our context, "camp-based" refers to individuals that were screened at a "screening camp"—a tent staffed with community health workers and setup in a low-income area. These "screening camps" were conducted in the same locations that community health workers conducted door-to-door screenings and allowed individuals to present themselves for screening.

Each community health worker was equipped with a "Doc-in-the-Bag" kit that included a weighing scale, measuring tape, blood glucose monitor, and blood pressure/heart rate cuffs (see Figure S1 of Multimedia Appendix 1 for photographs of the kit). A mobile tablet was used to record patients' responses to the questionnaire about family history, lifestyle, demographics, symptoms of common ailments, and to record certain anthropometric measurements and vitals (see the Data Description or Screening Questionnaire sections in Multimedia Appendix 1 for more details).

We included all individuals who visited a physician within 2 months following the screening to be assessed for a diagnosis of diabetes and hypertension. Hypertension was diagnosed based on 2 physician visits by using the JNC-VII (Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure) definition of hypertension [2]. Diabetes was diagnosed based on one of the following criteria: glycated hemoglobin (HbA_{1c}) higher than 6.5% (48 mmol/mol) or fasting blood glucose level higher than 126 mg/dL (7 mmol/L) [10].

Data Analysis

We developed separate models to estimate the risks for diabetes and hypertension. In each model, the outcome variable (the target) was a binary variable, indicating that a physician made a positive disease diagnosis and the predictor variables (features) were obtained from the screening data. Our primary analysis focused on determining the best models for predicting diabetes and hypertension risk and compared these models to previously developed risk scores from the United States and the United Kingdom. We compared the performance of 5 commonly used risk prediction models: decision trees, regularized logistic regression, K-nearest neighbors, random forest, and AdaBoost decision trees. We compared the performance of these models with several baseline approaches from the United States and the United Kingdom (see Table S2 of Multimedia Appendix 1). For each baseline, we calculated 3 variants (where applicable): (1) the original version based on a regression model with parameters derived from the original dataset, (2) an approximate score-based version that is intended for ease of computation by patients and providers, and (3) a version of the original regression model retrained using our Hyderabad data. In total, we considered 6 baseline models for diabetes (2 original, 2 score-based, and 2 retrained) and 2 baseline models for hypertension (1 original and 1 retrained). The hypertension model that we considered did not have an approximate score-based version (see the Baseline Approaches section in Multimedia Appendix 1 for more details).

In line with common practice, we used disjoint training (train the model), validation (tune the hyperparameters), and testing sets (test the model). We used a 10-fold cross-validation procedure to partition our data into training and testing sets. We then used 3-fold cross validation on the training set to choose our hyperparameters (see the Hyperparameter Tuning section in Multimedia Appendix 1 for more details). Once the final hyperparameters were selected, we applied the final model to the test set (that was not used as part of the model selection or fitting process in any way) to estimate generalization. We repeated the entire process 25 times to obtain more robust estimates and error bars.

For each model, we varied the discriminant threshold applied to the test set, calculated the resulting true and false positive rates, plotted them in the form of a receiver operating characteristic curve, and calculated the area under the receiver operating characteristic curve (AUC), which we used as a metric to compare different models. In total, we generated 250 test sets (25 repetitions * 10-fold) receiver operating characteristic curves for each model.

As a secondary analysis, we compared the performance of our risk stratification models, each trained with 5 different feature sets, where each set incrementally adds measurements obtained using an additional device: (1) only the questionnaire (no device measurements), (2) questionnaire and weight (weighing scale), (3) questionnaire, weight, height, and waist circumference (weighing scale and tape measure), (4) questionnaire, weight, height, waist circumference, blood pressure, and heart rate (weighing scale, tape measure, and blood pressure/heart rate cuffs), and (5) questionnaire, weight, height, waist circumference, blood pressure, heart rate, and blood glucose (weighing scale, tape measure, blood pressure/heart rate cuffs, and glucometer).

Finally, we performed a cost analysis to estimate the expected cost of incorrect risk stratification per screening for both diabetes and hypertension. We relied on previous research to estimate the cost of false positives, the cost of false negatives, and disease prevalence in India for both diabetes and hypertension. We also conducted a sensitivity analysis on each component used to estimate the expected cost of incorrect risk stratification per screening (see the Cost Analysis section of Multimedia Appendix 1 for more details).

Statistical Analysis

For all model comparisons, we conducted a 2-sided Wilcoxon signed rank test [20] (with a significance level of .05) to check whether the medians of the AUC distributions (or cost distributions) of the 2 models were different from each other. All models and statistical tests were implemented using Python 3.5, SciPy package, and the Scikit-learn package [21]. The data and source code that support the findings of this study are available from the corresponding author.

Results

Data Summary

A total of 51,474 individuals were screened between July 14, 2015 and April 21, 2018. Of these individuals, 2278 (4.6%) visited a physician within 2 months following the screening (see Figure S2 of Multimedia Appendix 1). Table S1 (Multimedia Appendix 1) displays the summary statistics for individuals who did and did not visit a doctor. Table 1 displays the summary statistics of all 2278 individuals in the final data set grouped by outcome. The average age was 50.6 years and 62% (1410/2278) of the patients were female. Both random blood glucose and blood pressure were notably high with averages of 167.8 mg/dL and 145/93 mmHg across all individuals, respectively.

Table 1. Summary of individual screening data (N=2278).[a]

Characteristic	Diabetes diagnosis		Hypertension diagnosis		All (N=2278)
	Positive (n=833)	Negative (n=1445)	Positive (n=1676)	Negative (n=602)	
Female, n (%)	496 (59.5)	914 (63.3)	1043 (62.2)	367 (61.0)	1410 (61.9)
Age (years), mean (SD)	52.9 (11.8)	49.3 (14.0)	52.3 (13.0)	45.8 (12.9)	50.6 (13.6)
Height (m), mean (SD)	1.6 (0.1)	1.6 (0.1)	1.6 (0.1)	1.6 (0.1)	1.6 (0.1)
Weight (kg), mean (SD)	66.5 (13.1)	62.1 (12.9)	64.5 (13.2)	61.5 (12.7)	63.7 (13.1)
BMI (kg/m²), mean (SD)	27 (5.4)	25.1 (5.4)	26.2 (5.5)	24.7 (5.2)	25.8 (5.5)
Waist circumference (cm), mean (SD)	93 (11.9)	90.4 (10.3)	91.9 (11.2)	90 (10.0)	91.4 (10.9)
Heart rate (per minute), mean (SD)	88 (12.2)	84 (11.6)	86 (12.1)	86.3 (11.2)	86.1 (11.9)
Random blood sugar (mg/dL), mean (SD)	233.6 (99.2)	129.9 (44.2)	166.7 (85.3)	171 (86.6)	167.8 (85.6)
Systolic blood pressure (mmHg), mean (SD)	144.4 (22.5)	144.6 (21.0)	147.6 (21.4)	136 (19.8)	144.6 (21.6)
Diastolic blood pressure (mmHg), mean (SD)	91.1 (12.2)	93.5 (12.0)	93.6 (12.0)	89.8 (11.8)	92.6 (12.1)
Urinations per night, mean (SD)	2 (1.2)	1.5 (0.9)	1.8 (1.1)	1.5 (1.0)	1.7 (1.1)
Parental diabetes, n (%)	244 (29.3)	297 (20.6)	410 (24.5)	131 (21.8)	541 (23.7)
Parental hypertension, n (%)	210 (25.2)	319 (22.1)	408 (24.3)	121 (20.1)	529 (23.2)
Dizziness, n (%)	124 (14.9)	106 (7.3)	184 (11.0)	46 (7.6)	230 (10.1)

[a] Diabetes and hypertension are doctor-reported diagnoses and correspond to our outcome (target) variable.

[b] Proportion of individuals currently using some type of medication, but no further details on type or reason for medication were collected.

Model Performance

Figure 1 displays the AUC distribution across all 250 test sets of the 10 models based on 5 machine learning approaches (5 for diabetes and 5 for hypertension). For diabetes, the random forest model had the highest average AUC value (mean [SD], 0.910 [0.001]), followed by logistic regression (mean [SD], 0.909 [0.001]), AdaBoost decision trees (mean [SD], 0.896 [0.002]), K-nearest neighbors (mean [SD], 0.857 [0.001]), and decision trees (mean [SD], 0.776 [0.005]). For hypertension, random forest (mean [SD], 0.792 [0.002]) performed slightly better than logistic regression (mean [SD], 0.776 [0.001]) and AdaBoost decision trees (mean [SD], 0.770 [0.003]). K-nearest neighbors (mean [SD], 0.705 [0.004]) and decision trees (mean [SD], 0.610 [0.01]) had poorer performance. All pairwise differences were found to be statistically significant. Given these results, we focused on the random forest model when comparing with baseline approaches for both diabetes and hypertension.

Figure 1. A comparison of area under the curve (AUC) distributions across 250 test sets between 5 risk stratification models for both diabetes and hypertension. The random forest model had the highest AUC for both diabetes (mean [SD], 0.910 [0.001]) and hypertension (mean [SD], 0.792 [0.002]). The upper and lower boundaries of the boxes correspond to the first and third quartiles, respectively. The line inside the box represents the median and the whiskers correspond to the minimum and the maximum of the distribution. KNN: K-nearest neighbors algorithm.

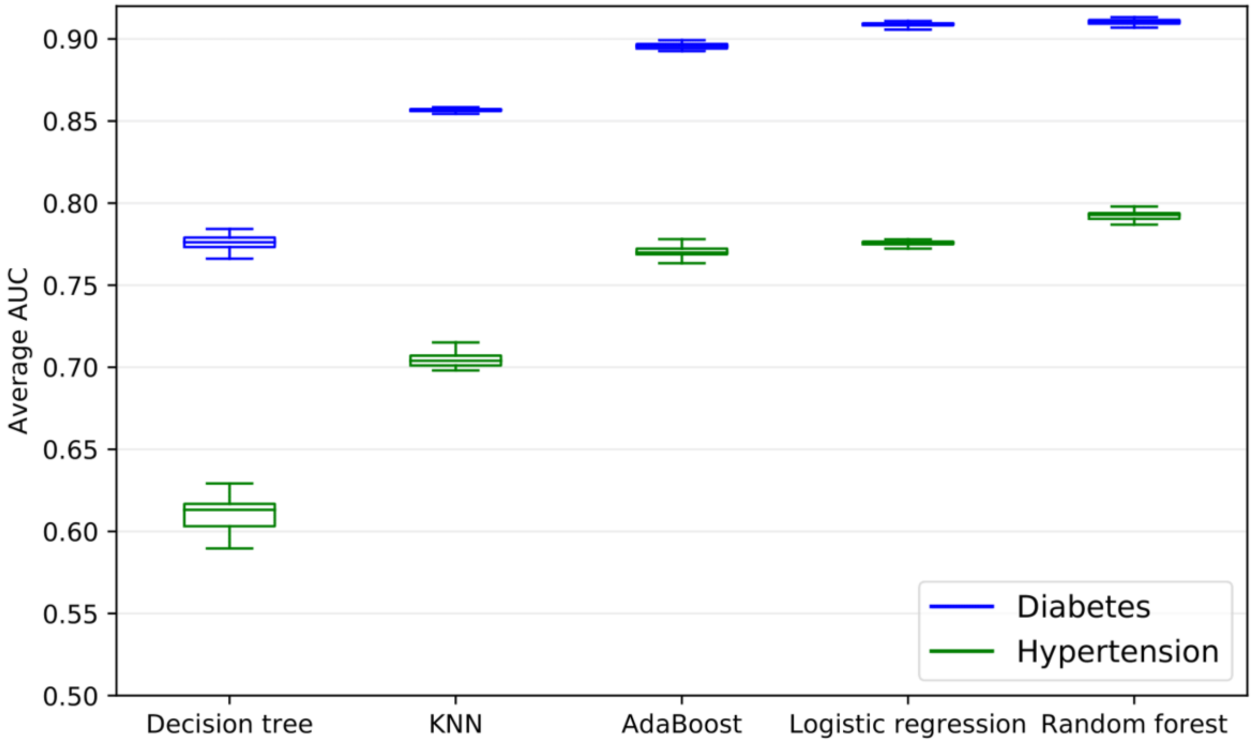

Figure 2 displays the AUC distribution for the random forest model and all baseline approaches for both diabetes and hypertension. For diabetes, the American Diabetes Association (ADA)–retrained (mean [SD], 0.671 [0.032]) and UK Diabetes–retrained (mean [SD], 0.671 [0.032]) performed best, followed by the UK–original model (mean [SD], 0.657 [0.031]) and the ADA–original model (mean [SD], 0.643 [0.033]). The ADA-scoring (mean [SD], 0.540 [0.021]) and UK-scoring (mean [SD], 0.604 [0.031]) methods performed considerably worse.

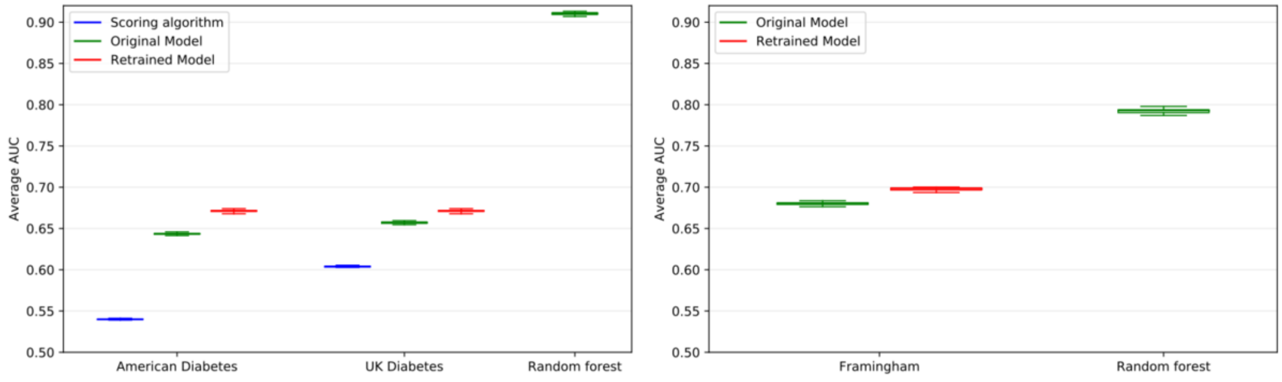
For hypertension, Framingham-retrained (mean [SD], 0.698 [0.037]) performed slightly better than the Framingham–original model (mean [SD], 0.680 [0.036]). The random forest model significantly outperformed all baseline approaches. Retraining the baseline models using our data provided a statistically significant increase in their accuracy. Nevertheless, the accuracy of these retrained models was still lower than the accuracy of our random forest model.

Figure 2. A comparison of the area under curve (AUC) distributions for the random forest model and all baseline approaches. A. For diabetes, the AUC of the random forest model improved upon the best baseline approach (UK diabetes–retrained) by 0.239 (0.910 vs 0.671, *P*<.001). B. For hypertension, the AUC of the random forest model improved upon the best baseline approach (Framingham-retrained) by 0.095 (0.792 vs 0.697, *P*<.001).



A. Diabetes

B. Hypertension

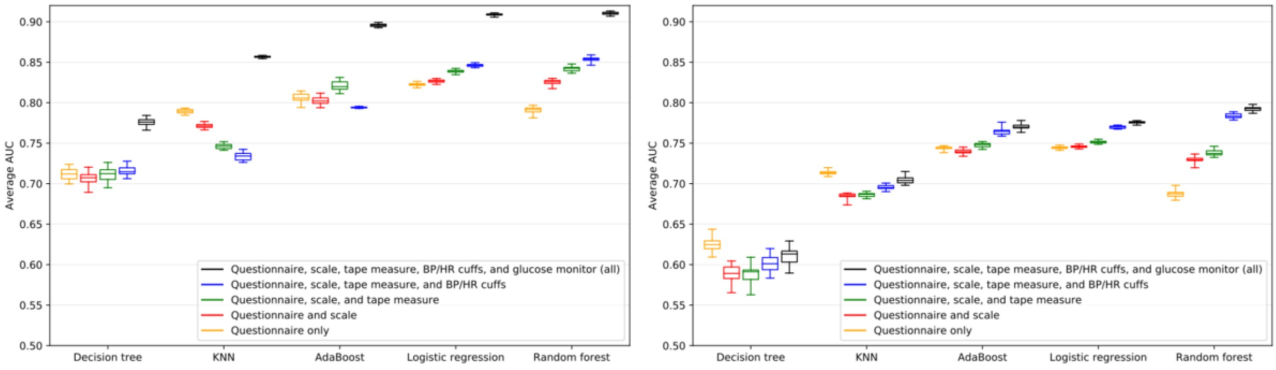
To visualize the trade-off between false positives and false negatives, Figure S3 (Multimedia Appendix 1) displays receiver operating characteristic curves from a single randomly selected test set (out of 250) of the random forest model and baseline approaches for both diabetes and hypertension. For a fixed screening specificity of 0.9, the random forest model was able to reduce the false negative rate, on average from 0.79 to 0.17 for diabetes and from 0.72 to 0.50 for hypertension. In other words, the random forest model can reduce the number of false negatives by 620 patients per 1000 screenings for diabetes and 220 patients per 1000 screenings for hypertension.

Figure S4 (Multimedia Appendix 1) displays the normalized feature importance extracted from the random forest model. As expected, blood sugar was the most important feature for diabetes risk prediction, but several other features including many self-reported symptoms (eg, urination, dry tongue) provided predictive power. For hypertension, systolic blood pressure was the most important, followed closely by blood sugar, which is not used for hypertensive risk prediction in high-income countries, even though there is a known link between these diseases.

Model Performance as a Function of Data Availability

Figure 3 displays the AUC distributions for the 5 risk stratification models and the 5 different features sets. For both diabetes and hypertension, a random forest model with access to only questionnaire-type features was able to capture 87% of the AUC obtained from a model with access to all features. We found that the use of a glucose monitor had the largest impact on diabetes model performance, increasing the average AUC by more than 0.05 for all models, while the use of a blood pressure/heart rate cuff had the largest impact on hypertensive risk prediction, increasing the average AUC by a mean of 0.05 across all models. See Figure S5 (Multimedia Appendix 1) for a visualization of the trade-off between false positives and false negatives.

Figure 3. Area under the curve (AUC) distributions for 5 risk stratification models and 5 different features sets. A. Including a glucose monitor had the largest effect on diabetes risk stratification, increasing average AUC by more than 0.05 for all models. B. Including blood pressure/heart rate cuffs had the largest effect on hypertension risk stratification, increasing the average AUC by up to 0.05. BP: blood pressure; HR: heart rate; KNN: K-nearest neighbors algorithm.



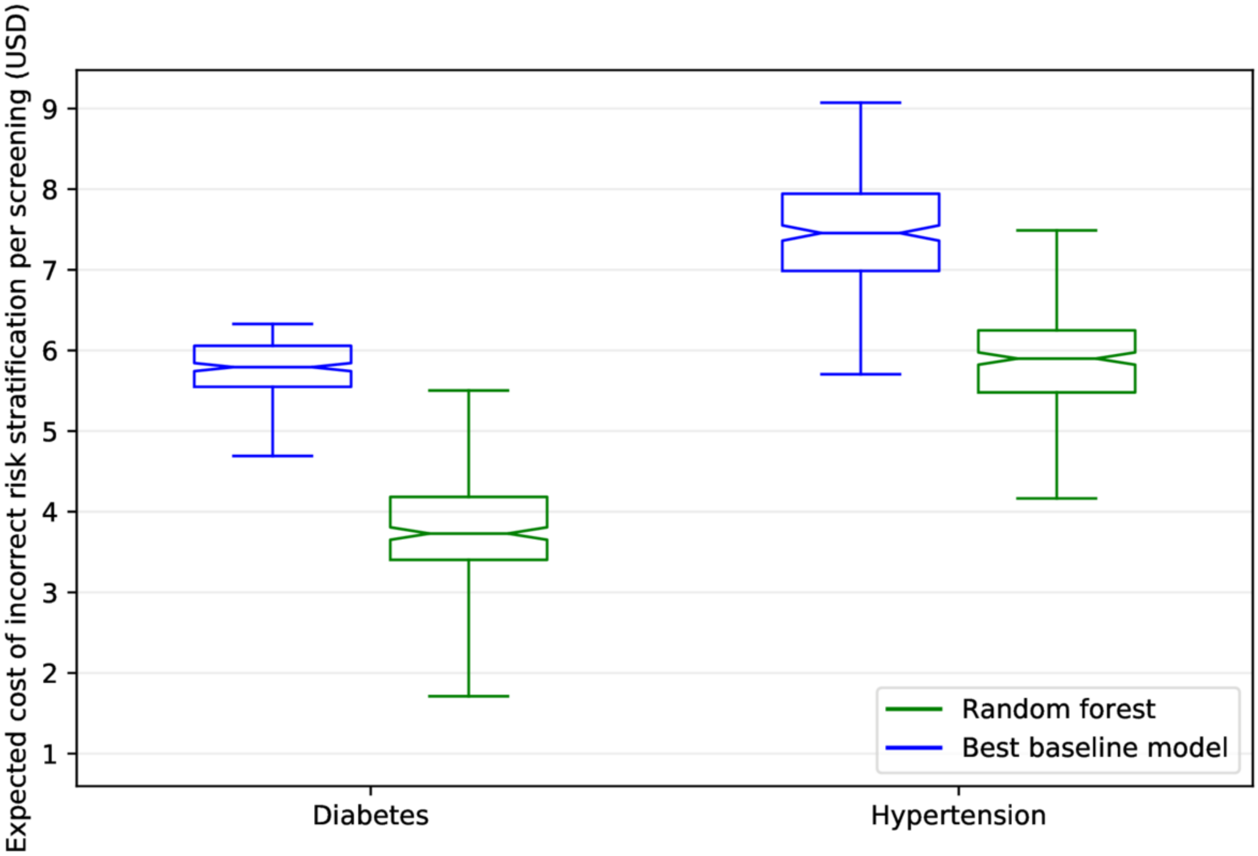
A. Diabetes

B. Hypertension

Cost Analysis

Figure 4 displays the expected cost of incorrect risk stratification per screening for the random forest model and the best baseline approach for diabetes (UK Diabetes–retrained) and hypertension (Framingham-retrained). For the baseline models, the expected cost of incorrect risk stratification per screening was US $5.76 and US $7.47 for diabetes and hypertension, respectively. The random forest model was able to reduce the expected cost of incorrect risk stratification per screening by US $1.99 (or 35%) for diabetes and US $1.60 (or 21%) for hypertension. All cost reductions were found to be statistically significant. Figure S6 (Multimedia Appendix 1) displays the results of our sensitivity analysis.

Figure 4. A comparison of the expected cost of incorrect risk stratification per screening across 250 test sets between the random forest and best baseline approach for both diabetes and hypertension. The random forest reduced the expected cost of incorrect risk stratification by US $1.99 per screening for diabetes (US $5.76 vs US $3.77, *P*<.001) and by US $1.60 per screening for hypertension (US $7.47 vs US $5.87, *P*<.001). The upper and lower boundaries of the boxes correspond to the first and third quartiles, respectively. The line inside the box represents the median, the whiskers correspond to the minimum and the maximum of the distribution, and the notches in the box represent the 95% confidence interval around the median.



Discussion

This study developed risk stratification models to predict the short-term (2-month) risk in a resource-limited setting for both diabetes and hypertension. Our primary analysis demonstrated that models from high-income countries do not generalize well to the low- and middle-income countries. In particular, the random forest model had the highest prediction accuracy for both diseases and was able to outperform the best baseline approach in terms of AUC by 35.5% for diabetes and 13.5% for hypertension. Our secondary analysis found that risk stratification can be accurately performed with limited data. A random forest model with access to only questionnaire-type features was able to capture 87% of the AUC obtained from a model with access to all features, suggesting that diabetes and hypertension risk stratification can be accurately conducted in extremely resource-limited settings. Although there are circumstances where advanced measurements may be required, eliminating the need for the corresponding tools means that community health workers require less training and can travel with fewer devices.

The observed performance difference between the baseline approaches and our models can be attributed to 3 improvements. First, our models were designed for short-term risk prediction, while the baseline models were designed for long-term prediction. Even though we retrained the baseline models with our data, the features included in the models were selected for long-term prediction. For example, none of the baseline models included self-reported symptoms (eg, dry tongue, urination), which may be more suitable for short-term prediction. Second, our models include additional features not used by the baseline approaches that may provide additional insight into the social, lifestyle, and genetic differences in the population. For example, none of the risk scores from high-income countries use self-reported symptoms or random blood glucose. Although random blood glucose is not typically used in high-income settings where HbA_{1c} is preferred, it is often captured by community-based screening programs due to its operational simplicity (eg, no fasting required). For diabetes, random blood glucose was the most important feature and increased the AUC by 0.13, while for hypertension, random blood glucose was the second most important feature (see Figure S4 of Multimedia Appendix 1) and also led to an AUC increase. Third, we believe that the advanced machine learning models allowed us to extract maximum value from the small sample size and simple features available to us, whereas simple models with advanced features and large data sets may be equally effective in high-income settings.

As a by-product of our analysis, we externally validated the previously developed baseline approaches by using India-specific data. Although many of these models have been externally validated in a variety of settings, they have not been compared using India-specific data [10,11]. For example, the Framingham model for hypertensive risk has been validated in 7 countries with an average AUC of 0.80 (range 0.73-0.84) [11]. Our results show that the model is not as effective in India, where it had an average AUC of 0.70 after being retrained using local data. It is challenging to determine why the model performed poorly, but we believe that it may be due to subtle differences in the at-risk population, which manifest in the features selected by the model. Overall, our validation and comparison of baseline models highlights the importance of developing risk prediction models specifically for the low- and middle-income countries of interest.

The translation of our findings to the design and implementation of nation-wide screening programs must carefully consider costs, field accessibility, and disease management. The results of our secondary analysis indicate that the most impactful features (blood glucose, blood pressure, and heart rate) are measured using the most expensive field equipment (glucose monitor and blood pressure/heart rate cuffs). Even though these devices are more expensive, we find that including glucose monitors for diabetes screening and heart rate/blood pressure cuffs for hypertension screening can reduce the expected cost of incorrect risk stratification by US $1.35 and US $0.70, respectively (see Figure S7 of Multimedia Appendix 1). A formal cost-effectiveness analysis is needed to determine whether the gain in accuracy (and subsequent reduction is risk stratification cost) is worth the capital investment required to purchase glucose monitors and heart rate/blood pressure cuffs in low-resource settings.

There is also an important cost-tradeoff between a high false positive rate and a high false negative rate, which is determined by the discriminant threshold used to stratify patients into risk categories. Research suggests that the financial cost of a false positive is minimal (US $7 for diabetes and US $15 for hypertension) compared to that of a false negative (US $288 for diabetes and US $45 for hypertension) [22]. Our results demonstrated that the random forest model can reduce the number of false negatives by 620 patients per 1000 screenings for diabetes and 220 patients per 1000 screenings for hypertension. Extrapolating these results to a nationwide screening program in India that screens 600 million people [23] could save approximately US $1.19 billion for diabetes and US $960 million for hypertension by reducing the false negatives. In the next decade, the central government of India is planning to spend significant resources on noncommunicable disease screening programs [8] and our models can be leveraged by these screening programs to effectively utilize limited resources by improving risk stratification accuracy.

Despite the complex nature of our models, they can be easily implemented and computed into handheld tablets (or other mobile health devices) carried by community health workers without the need for a simplified, hand-computable risk score, which means we can provide the most accurate prediction without any extra effort or calculations by the community health workers. Furthermore, mobile health applications have demonstrated the ability to increase access to health care for low-income populations and to improve the capacity of the existing health systems [24]. Future research is needed to understand how to best integrate and present the risk stratification results into the community health worker workflow.

It is important to note that screening is only the first step to reducing the burden of noncommunicable diseases. Once high-risk patients are identified, they need to be linked to appropriate care and put on a disease management plan [25]. Linking patients to care and initiating disease management is a nontrivial process and governments need to carefully design nationwide disease management plans because otherwise, screening programs are unlikely to have the desired impact. Therefore, an important direction for future research includes studying the effect of screening programs on population health outcomes in the presence of current and enhanced linkages to care and disease management plans.

Our work has several limitations. First, we did not have access to an external validation set from a different study population (eg, rural slums, different state or country) to test our models. Second, our data displays a clear selection bias toward sicker patients visiting a physician within 2 months (see Table S1 of Multimedia Appendix 1). From a risk stratification perspective, the selection bias toward sicker individuals makes the problem more difficult because the model must discriminate between similar individuals. In other words, we need to identify those who actually have diabetes or hypertension from a pool of individuals who all appear to be at high risk. Finally, the differences in disease prevalence and overall health between our sample and the National Family Health Survey, Hyderabad suggest that, if applied broadly, our model may experience data shifting, which occurs when the training data differs from the application data [26]. See Table S3 of Multimedia Appendix 1 for a comparison of our data sample with the urban sample from India's National Family Health Survey. Data shifting can negatively impact accuracy (similar to how the models from the United States and the United Kingdom performed poorly in India) and future research is needed to test our models in other settings.

In conclusion, this study found that a machine learning–based risk stratification model tailored to data collected by community-based screening programs can significantly improve risk stratification accuracy for both diabetes and hypertension in low-resource settings. Researchers and international organizations have proposed machine learning as a game changer in global health, [27-29] but there is limited documented evidence that machine learning can be effectively utilized in the resource-limited settings indicative of global health projects [30]. This study adds evidence to support machine learning in global health by quantitatively demonstrating the benefit of using these models in a novel resource-limited context.

Abstract

Background: Artificial intelligence (AI)-driven chatbots are increasingly being used in health care, but most chatbots are designed for a specific population and evaluated in controlled settings. There is little research documenting how health consumers (eg, patients and caregivers) use chatbots for self-diagnosis purposes in real-world scenarios.

Objective: The aim of this research was to understand how health chatbots are used in a real-world context, what issues and barriers exist in their usage, and how the user experience of this novel technology can be improved.

Methods: We employed a data-driven approach to analyze the system log of a widely deployed self-diagnosis chatbot in China. Our data set consisted of 47,684 consultation sessions initiated by 16,519 users over 6 months. The log data included a variety of information, including users' nonidentifiable demographic information, consultation details, diagnostic reports, and user feedback. We conducted both statistical analysis and content analysis on this heterogeneous data set.

Results: The chatbot users spanned all age groups, including middle-aged and older adults. Users consulted the chatbot on a wide range of medical conditions, including those that often entail considerable privacy and social stigma issues. Furthermore, we distilled 2 prominent issues in the use of the chatbot: (1) a considerable number of users dropped out in the middle of their consultation sessions, and (2) some users pretended to have health concerns and used the chatbot for nontherapeutic purposes. Finally, we identified a set of user concerns regarding the use of the chatbot, including insufficient actionable information and perceived inaccurate diagnostic suggestions.

Conclusions: Although health chatbots are considered to be convenient tools for enhancing patient-centered care, there are issues and barriers impeding the optimal use of this novel technology. Designers and developers should employ user-centered approaches to address the issues and user concerns to achieve the best uptake and utilization. We conclude the paper by discussing several design implications, including making the chatbots more informative, easy-to-use, and trustworthy, as well as improving the onboarding experience to enhance user engagement.

Introduction

Background

Medical consultation has historically been conducted between patients and their physicians during clinical encounters. However, some barriers may hinder effective communication in a clinical setting. For example, patients and their caregivers often face great challenges obtaining timely medical advice and information from health care providers due to the long wait time for an appointment [1,2]. The increasing demand for health care services also places a large burden on health care providers due to the shortage of medical professionals [3,4]. Medical professionals, therefore, have to overcome a range of temporal, geographical, and organizational barriers to provide a high quality of health care to patients [5]. Even more concerning is that health care infrastructures (the underlying foundation that supports the operations of a health care system) are complex and fragmented in many countries [6]. The scarceness and imbalanced distribution of health care resources (eg, facilities and medical professionals) often impede people in rural areas from accessing health care services and obtaining professional medical advice in a timely and effective manner [7,8]. Therefore, patients often use other mechanisms, such as online health forums and “Ask the Doctor” services, to seek medical help by asking questions and receiving answers from peers and health professionals who are willing to share their knowledge and opinions [1,9-12]. Even so, patients may still not be able to get instant responses using these online platforms [13,14]. Furthermore, there is much inaccurate information online, which may easily mislead patients [15].

With the advances in artificial intelligence (AI) technology in recent years, there is an opportunity to tackle the challenges and barriers faced by patients in seeking timely health information and to reduce the burdens posed on medical professionals [16,17]. That is, AI-driven intelligent systems, such as health chatbots, have emerged to support patients seeking medical advice irrespective of time and place [18]. These chatbots can provide live feedback to help patients get an overview of their symptoms, become aware of their illness, triage and manage their conditions, and ultimately improve their health [19-22]. Such chatbots act as a virtual conversational agent mimicking human interactions and offering medical advice (eg, diagnostic suggestions) directly to patients in a timely and cost-effective manner. In this way, health chatbots provide a form of triage into the health care system and become the first point of contact for health. While this technology is still in its developmental phase, chatbot systems could potentially alter the landscape of health care by increasing access to health care services, enhancing patient-centered care, and reducing unnecessary clinical visits [23,24].

Despite these potential benefits, similar to many other mobile health (mHealth) applications, chatbot systems have been inadequately adopted by those who might benefit most from this novel technology [4,25]. It is therefore important to examine how to design health chatbots to increase user adoption and engagement. Furthermore, prior work has focused primarily on developing advanced algorithms to improve the accuracy and effectiveness of chatbots’ diagnoses [21,26,27]. Few studies, however, have focused on the use of health chatbots in the real world [25]. More specifically, little is known about the “who, how often, and why” of chatbot use, what barriers and issues exist in using this novel technology, and how to overcome the barriers. This research gap is caused partly by the lack of large-scale deployment of health chatbots [28]. That is, most studies only examined the use of health chatbots in controlled settings rather than in real-world settings, where users interact with chatbots on their own.

To bridge this knowledge gap, we examined one widely deployed chatbot in China—DoctorBot [29]—which had attracted hundreds of thousands of users by the time this study took place. The large-scale deployment of DoctorBot provides us with a unique opportunity to gain an in-depth, empirical understanding of how people use health chatbots in the real world and what barriers hinder the delivery of these novel services. To the best of our knowledge, this is the first study that examined these issues using large-scale, real usage data. More specifically, we took a data-driven approach to analyze the system log of DoctorBot, which consisted of 47,684 consultation sessions initiated by 16,519 users between September 2018 and March 2019. Through this study, we make three contributions. First, we present a detailed analysis of how people use an AI-driven self-diagnosis chatbot, which remains understudied in the health informatics community. Second, we report issues and barriers that hinder the effective use of health chatbots. Third, our results can shed light on how to better design health chatbots to optimize user experience and achieve the best uptake and utilization.

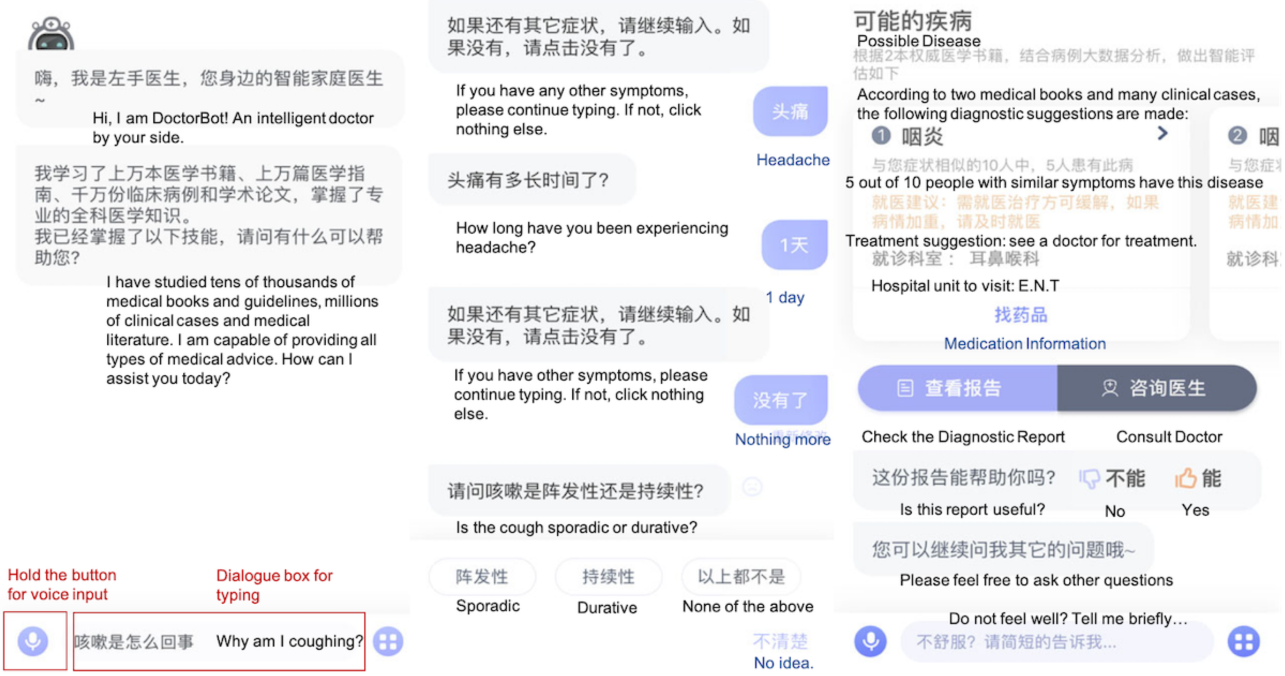
Features of DoctorBot

DoctorBot is an AI-driven, mobile-based medical consultation platform [29]. It utilizes large data sets (eg, numerous medical literature and clinical cases) and state-of-the-art AI techniques (eg, deep learning and knowledge graphs) to process users’ inquiries and provide personalized medical advice. Users can interact with DoctorBot by typing information into a chatbox and/or recording a voice message to express their health concerns (the voice message can be converted into text in real time). DoctorBot provides different health services to users, such as self-diagnosis, drug use instructions, diet suggestions, and so forth. Among those, self-diagnosis is one of the most popular and demanding services. Users can explain their health concerns to the chatbot and receive medical advice (eg, diagnostic suggestions and treatment options) to make informed decisions. Given the current heated debate on the readiness and usefulness of self-diagnosis chatbots [30,31], we chose to focus on the use of the self-diagnosis feature in this study.

A typical consultation session starts with a prompt for the user to describe their main symptom or chief complaint (Figure 1, left). After being prompted, the user provides input, such as, “Why am I coughing?” This inquiry triggers DoctorBot to take the initiative and ask the user a series of questions related to the symptoms (eg, “How long has the cough been present?”). The chatbot may also inquire if the user is experiencing other relevant symptoms (Figure 1, middle). For example, if a user indicates that he/she has been coughing, the chatbot would consecutively ask if the user is also experiencing a sore throat, shortness of breath, and so forth. If the answer is “yes,” the chatbot then asks the user more questions about each relevant symptom. Finally, DoctorBot asks the user to provide his/her medical history to conclude the consultation.

When a consultation is complete, DoctorBot generates a report detailing potential diagnoses, prediction confidence, treatment options, and which hospital unit (eg, cardiology, urology) to visit (Figure 1, right). Such information is expected to help users decide when, where, and whether or not to seek further medical help. It is also worth noting that DoctorBot explicitly instructs users to use the diagnosis for reference only, in light of AI liability issues and medical ethics [32].

Figure 1. DoctorBot interfaces (all Chinese dialogue was translated into English in this figure). Left: the starting point of a consultation; after greetings, the user is prompted to explain health concerns. Middle: DoctorBot asks the user a series of symptom-related questions; users can select from the offered options at the bottom to provide an answer. Right: a report detailing potential diagnoses (ranked by their possibility) and other medical advice is provided to the user. E.N.T: ear, nose, and throat clinic.



嗨，我是左手医生，您身边的智能家庭医生~

Hi, I am DoctorBot! An intelligent doctor by your side.

我学习了上万本医学书籍、上万篇医学指南、千万份临床病例和学术论文，掌握了专业的全科医学知识。
我已经掌握了以下技能，请问有什么可以帮助您？

I have studied tens of thousands of medical books and guidelines, millions of clinical cases and medical literature. I am capable of providing all types of medical advice. How can I assist you today?

咳嗽是怎么回事 Why am I coughing?

如果还有其它症状，请继续输入。如果没有，请点击没有了。

If you have any other symptoms, please continue typing. If not, click nothing else.

头痛 Headache

头痛有多长时间了？

How long have you been experiencing headache?

Do not feel well? Tell me briefly…

Methods

Data Collection and Processing

To understand the use of self-diagnosis chatbots in the real world, we took a data-driven approach to analyze the system log of DoctorBot collected between September 2018 and March 2019. The data set consisted of 47,684 consultation sessions initiated by 16,519 users over the 6-month period. The log of each consultation session included a session ID, the user’s general information (eg, age, gender), consultation details (eg, time stamps, and conversation content between DoctorBot and the user), a diagnostic report automatically generated by the chatbot after the consultation was completed, and user feedback (if the user voluntarily provided feedback regarding the usefulness of the chatbot at the end).

The first author worked closely with the chatbot company to determine the type, amount, and format of usage data that needed to be extracted to fulfill the study’s purpose. To protect users’ privacy, all identifiable information (eg, phone number) was removed from the data set by the chatbot company before sending it to the researchers. Therefore, the data we analyzed was completely anonymized. Moreover, the users consented at the point of registration that researchers were allowed to analyze their usage data for research purposes. The study procedure was approved by the first author’s university’s Institutional Review Board.

The initial data set had some noisy data; for example, one consultation session could be stored as two separate sessions, and two consultation sessions could be merged. Therefore, we preprocessed the data by splitting the sticky conversations and spliced the broken conversations. After data processing, the research team examined the entire data set to ensure the accuracy and appropriateness of the data format. Since the study context was based in China, the content of the dialogues between the chatbot and users was in Chinese. To ensure the validity of the data, we decided to analyze the content in its original language. We used the Jieba [33] word segmentation library to segment the user input to extract semantic information.

Data Analysis

To understand who uses chatbots, how often, and why, we first performed descriptive statistical analysis on the entire data set, focusing on user characteristics (eg, gender and age) and general patterns of chatbot use (eg, duration, frequency, and purpose of use). This analysis helped us not only to obtain a general overview of chatbot use but also to identify an interesting scenario—only 30,710 of 47,684 consultation sessions were completed, with the remaining 16,974 sessions being terminated by users before the chatbot reached a diagnosis. Therefore, we decided to split the entire data set into "completed" and "uncompleted" consultation sessions for further analysis. In particular, we used content analysis [34] and statistical analysis in combination to analyze both types of sessions to investigate the issues and barriers that may occur during the interactions between DoctorBot and users. More specifically, because an uncompleted consultation session may suggest that a user encountered barriers in using the chatbot, we investigated the exact moment when a consultation was terminated to understand what questions were asked by DoctorBot and how much time users spent on answering these questions. We also performed statistical analysis (ie, logistic regression and principal component analysis [PCA]) to explore the characteristics of uncompleted consultations. Examining these aspects could help us gain a preliminary understanding of the factors that could potentially lead to user dropout. In addition to the analysis of uncompleted sessions, two researchers performed a content analysis on 3000 completed sessions that were randomly selected to examine interaction issues that may exist in the use of the chatbot, such as miscommunication between DoctorBot and users. The content analysis was augmented by statistical analysis to further explore the influencing factors on the emerged interaction issues. Finally, as DoctorBot usually prompts the user to provide feedback (eg, positive versus negative experience) toward the end of the consultation, we performed a content analysis on the user feedback to identify user concerns and issues related to the use of DoctorBot and explored what factors could contribute or lead to these user concerns.

Results

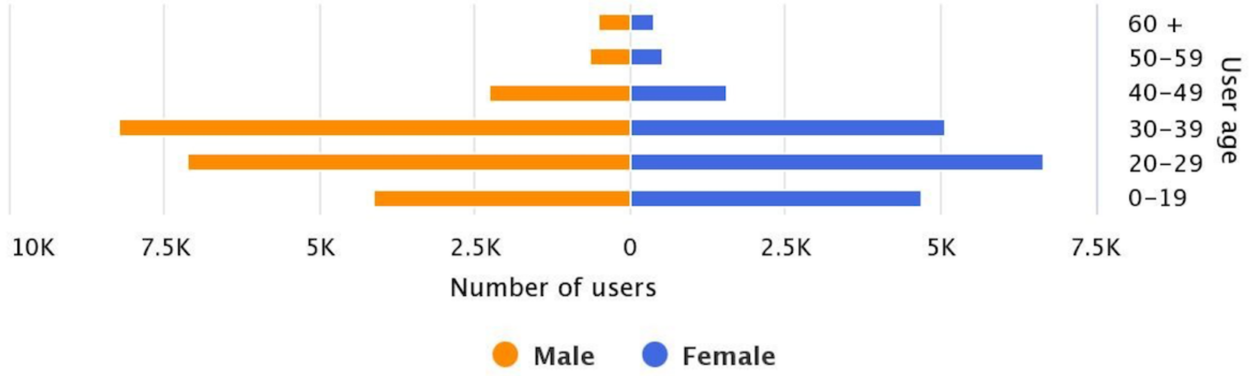
General Patterns of Chatbot Use

We first report the results that emerged from the statistical analysis on the entire data set. This analysis helped us understand several patterns of the large-scale use of DoctorBot, including who used it, the length of each consultation, how often users used the application, and what health concerns users had queried about.

Who Used DoctorBot?

During the data collection period (September 2018 to March 2019), 16,519 users interacted with DoctorBot to present health concerns. Our analysis of users' demographic information allowed us to obtain an understanding of the user groups and their characteristics. As Figure 2 shows, more than one-half of the consultations (9052/16,519, 54.80%) were initiated by male users, and the mean ages of male and female users were 30 years and 27 years, respectively. In particular, the majority of DoctorBot users were between ages 20 and 39 years, which may be due to the relatively high technology proficiency and willingness to use advanced technologies (ie, intelligent chatbot) among this age group. Many users in the 20 to 39 years age group also consulted the application concerning their childrens' illnesses (eg, "May I ask the reason why a 6-year-old girl often vomits?"). In contrast, only a small number of older adults (aged >60 years) or their caregivers (n=885) attempted to use the chatbot. This finding aligns with previous research showing that older adults are lagging in the adoption of novel health-related technologies [35]. To bridge the gap, more research is needed to examine how to design advanced health technologies (eg, chatbots) tailored to the aging population.

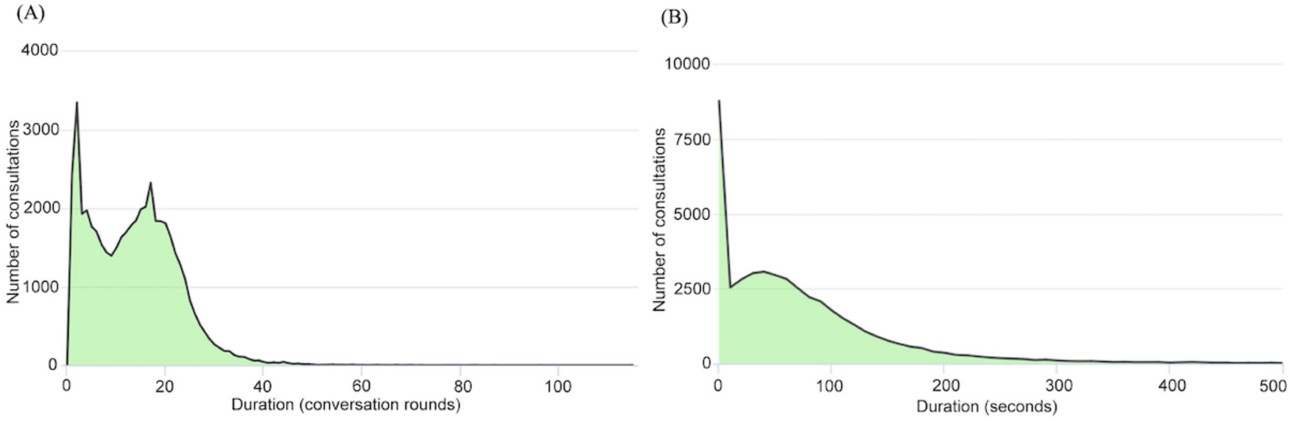
Figure 2. Characteristics of DoctorBot users. K: thousand.



What Were the Length and Frequency of Chatbot Sessions?

As shown in Figure 3, the duration of each consultation varied. Many consultation sessions only lasted a few conversation rounds or seconds, whereas some others took more than 20 conversation rounds or 5 minutes. This finding highlights that many users only interacted with the chatbot for a brief time, which may not have allowed them to complete a consultation session.

Figure 3. (A) Consultation duration in conversation rounds. (B) Consultation duration in seconds.

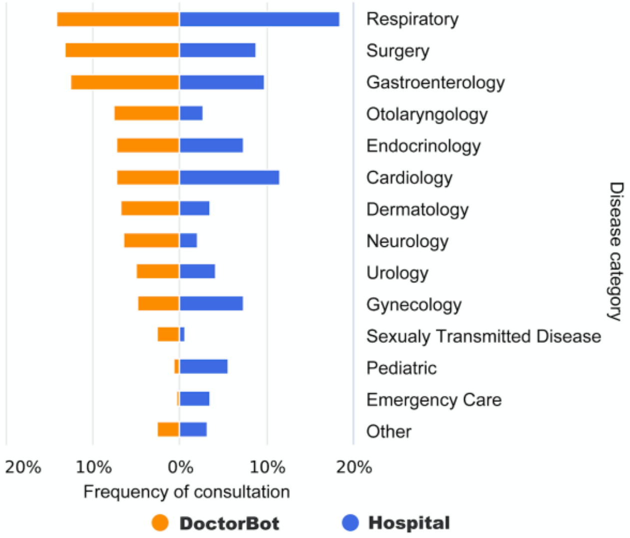


Regarding the frequency of chatbot use, we found that a large number of users (10,371/16,519, 62.78%) attempted to use the application only once. In some sessions, users presented more than one health issue and never used the application again. For those who used the chatbot more often (n=6148), some used the consultation service on one or two specific days. For example, one user who initiated 23 consultations with the chatbot only used the application on February 20, 2019, and March 13, 2019, to present two different health concerns (headache and palpitation). These findings suggest that even though DoctorBot attracted a lot of users, it was not used extensively. Furthermore, the significant number of "single-use" sessions reveals the issue of user engagement and retention; therefore, it is vital to understand what caused the low usage and how to optimize user experience to achieve the best uptake [23].

What Health Concerns Were Presented to DoctorBot?

Each completed consultation session immediately returned a diagnostic report to the user. A typical report contains the major health concerns expressed by the user and their association with possible diseases that are automatically classified by DoctorBot based on a widely adopted disease classification schema [36]. We analyzed the generated diagnostic reports to understand what health concerns or diseases people usually presented to DoctorBot and the frequency with which each disease was presented. This step was followed by a comparison with the usage of health services in hospitals. In particular, we measured the frequency of consultation on DoctorBot for each disease type and compared that with the health service usage reported by three primary hospitals in China [37]. As Figure 4 shows, diseases with mild symptoms, such as those in the gastroenterology and dermatology categories, appeared in a lot of chatbot consultations, in proportions that were significantly higher than those seen in primary hospitals. One possible explanation is that people with mild symptoms would prefer using the chatbot to query the necessity of clinical visits first, rather than going to hospitals directly. In contrast, using DoctorBot to address emergency care issues was not very common. We also noticed the use of DoctorBot to seek help on medical conditions that often entail considerable privacy and social stigma issues, such as sexually transmitted diseases.

Figure 4. Comparison of the frequency of consultations according to the major disease category of the presenting illness between DoctorBot (orange bars) and primary hospitals (blue bars).



Issues in the Use of DoctorBot

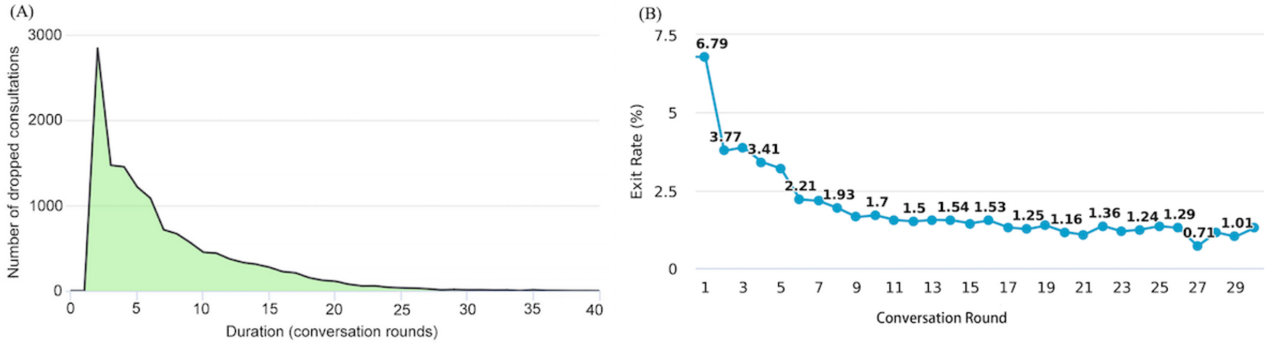
In this section, we report our analysis on the completed and uncompleted sessions, as well as on the user feedback, to present the major issues in the real-world use of DoctorBot.

Dropping Out of Consultations

Our data showed that there was a large number of uncompleted consultations, where users withdrew at a certain point without completing the process (16,974/47,684, 35.60%). In particular, more than one-half of the uncompleted consultations (9542/16,974, 56.22%) occurred within the first five conversation rounds (Figure 5A). To further verify our observation, we built a model to measure the exit rate for each conversation round:

where ER(x) is the exit rate of dropping a conversation in round x, D_x is the number of conversations that drop in round x, and N_x is the number of all conversations.

Figure 5. (A) Distribution of dropped consultation sessions over conversation rounds. (B) The exit rate for each conversation round.



As Figure 5B shows, the exit rate spiked at the beginning, signaling that a lot of users dropped out after a very brief interaction with the chatbot (ie, after just one round of conversation). Furthermore, the exit rate of the first five conservation rounds was much higher than for the rest. These findings are consistent with our observation that users most likely terminated the consultation at an early stage.

To further understand what caused user dropout, we examined the specific question asked by DoctorBot when a consultation was terminated and how much time users spent on answering those questions. As Table 1 demonstrates, transition questions, such as the ones prompting the user to answer the question again, often led to a termination of chatbot use. Furthermore, many uncompleted conversations occurred when users were asked to provide a detailed account of the symptoms they were experiencing. Our analysis also showed that such questions usually took longer than other relatively simple questions, such as questions about demographic information (91.1 s versus 17.6 s, respectively). One possible explanation is that symptom-related questions were usually hard to answer and could easily overwhelm or even confuse users, leaving them unsure of what input to provide and eventually causing them to terminate the conversation. For example, during a consultation for a headache, the chatbot asked whether the user was experiencing a series of symptoms related to headaches, such as fever, vomiting, stuffy nose, cough, and chest tightness. When the chatbot attempted to ask another follow-up question, the user suddenly terminated the consultation.

Table 1. The categories of questions asked by DoctorBot before users terminated the consultation.

Question category	Number of times users terminated their consultation when question was asked (%[a])
Demographic information	58 (4.39)
Physiological data	208 (2.58)
Transition questions	5274 (14.74)
Symptoms	8469 (20.23)
Medical history	795 (4.26)

[a] Calculated as the number of times users terminated their consultation when a question was asked divided by the number of conversations that contained questions from that category.

Lastly, we analyzed the differences between completed and uncompleted sessions to identify the major characteristics of dropped consultations. In particular, we conducted PCA and built a binary logistic regression model using the following features: gender, age, duration of the consultation, number of conversation rounds, and average duration of each round. We included gender and age in the model because these two factors may influence users' acceptance and use of technology [38,39].

As Figure 6 shows, despite that there were twice as many completed consultations as uncompleted consultations, most of the completed consultations (blue dots) were plotted in a small area in the two-dimensional feature space while the dropped consultations (red dots) were distributed horizontally, illustrating that considerable differences existed between completed and uncompleted consultations.

When we controlled the other features (eg, gender, age, and duration of consultation), logistic regression analysis showed that the number of conversation rounds ($P<0.001$) and the average duration of each round ($P<0.001$) significantly correlated with the dependent variable (whether the user dropped out in the middle of the consultation session) (Table 2). More specifically, as the number of conversation rounds with the chatbot increased, the likelihood of terminating the consultation decreased (odds ratio 0.7320, 95% CI 0.7298-0.7341). This finding is consistent with our observation that users most likely terminated the consultation at an early stage.

Figure 6. A principal component analysis (PCA) scatterplot of consultations for 30,710 completed (blue dots) and 16,974 dropped (red dots) consultations. PCA has successfully found linear combinations of the different features in a two-dimensional feature space that separate two different clusters corresponding to whether or not the consultations were completed.

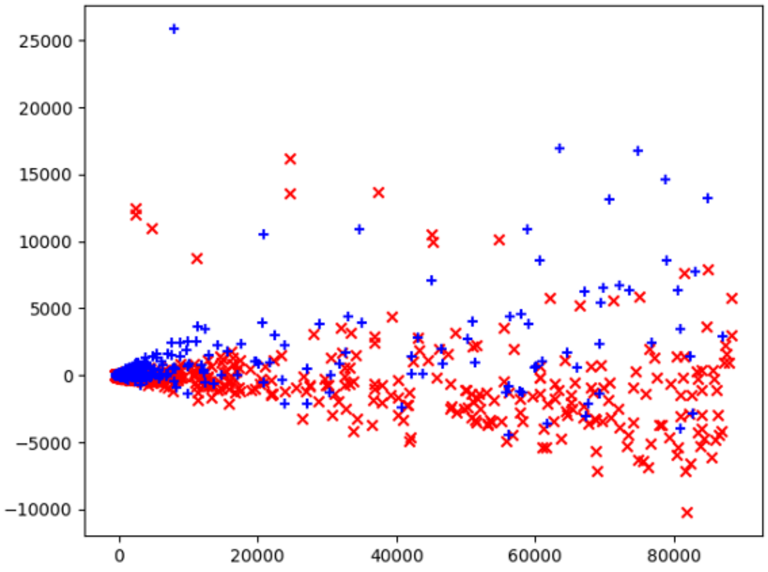


Table 2. The estimated coefficients, odds ratio, and *P* value of each feature in the logistic regression model with terminating consultation as the dependent variable.[a]

Feature	Estimated coefficients (SE)	Odds ratio (95% CI)	*P* value
Gender	3.19e–02 (2.95e–02)	1.0324 (1.0023-1.0633)	.28
Age	1.20e–03 (1.07e–03)	1.0012 (1.0001-1.0023)	.26
Duration of consultation	5.04e–05 (6.64e–06)	1.0001 (1.0000-1.0001)	<.001*
Number of conversation rounds	–3.12e–01 (2.99e–03)	0.7320 (0.7298-0.7341)	<.001*
Mean duration of each conversation round	–3.17e–04 (8.57e–05)	0.9997 (0.9996-0.9998)	<.001*

[a] McFadden pseudo R^2=0.4338884.

*P<.001.

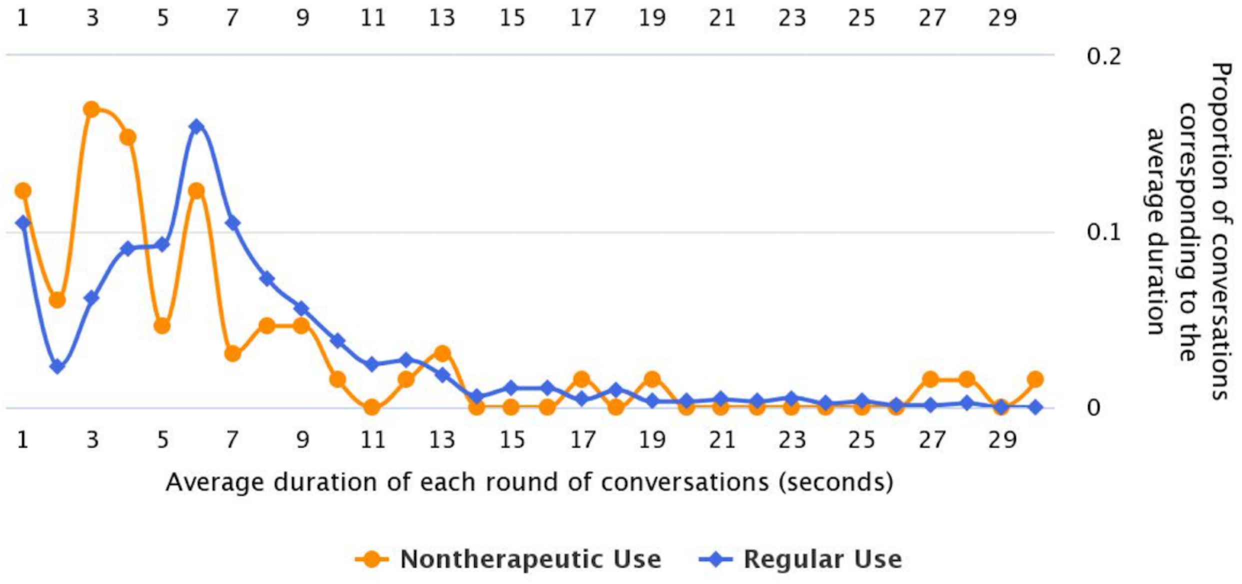
Using Chatbot for Nontherapeutic Purposes

Through the analysis of 3000 randomly selected completed consultation sessions, we noticed another issue in the use of DoctorBot: users often pretended to have health concerns and did not always use the chatbot for therapeutic purposes (ie, medical consultations). In fact, they "gamed" the chatbot, a user behavior that has been reported in intelligent tutoring systems [40] and workplace chatbot systems [41]. This behavior was exhibited in 241 of 3000 (8.03%) consultation sessions. We characterized the "nontherapeutic" use of DoctorBot into 5 patterns (Table 3). For example, people used nonsense/illogical words (eg, "I miss you") or contradictory statements to describe their health concerns. They might have even used the same word (eg, "nothing," "unclear") throughout the entire consultation. We also compared regular and nontherapeutic consultation sessions in terms of the mean duration of conversations. It was shown that the proportion of nontherapeutic and regular sessions with a conversation round lasting up to 4 s was 50.76% and 17.53%, respectively (Figure 7). This finding revealed that users who used the chatbot for nontherapeutic purposes attempted to complete each round of conversation as quickly as possible. We also analyzed the standard deviation of time taken per conversation round, which showed that users with real health concerns spent various lengths of time on different questions (mean 11.85 s, SD 17.06 s). In contrast, users who didn't actually use the chatbot for medical consultation spent an equally short time on each question (mean 7.74 s, SD 14.33 s).

Table 3. Patterns of nontherapeutic chatbot use and illustrative examples.

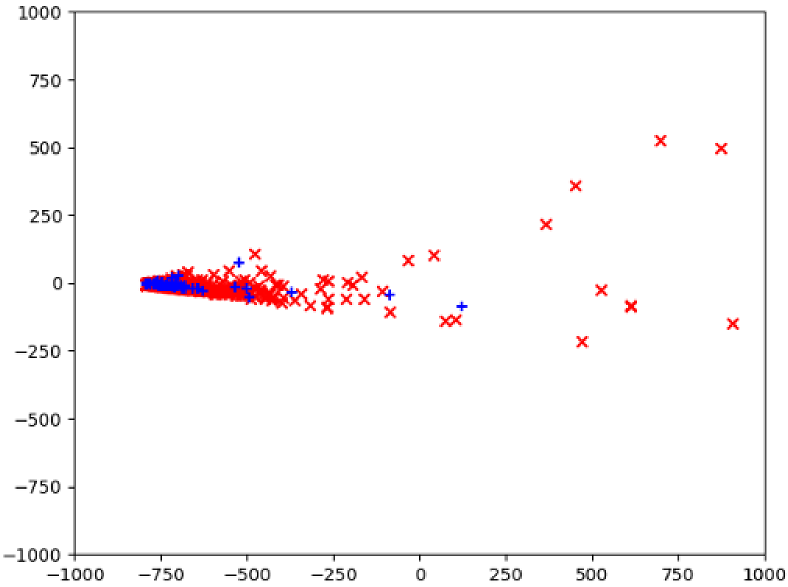
Patterns	Example
Extensive use of nonsense/illogical words	Chabot: If you have any other symptoms, please continue typing. User: I miss you.
Contradictory statements	Chatbot: Please tell me your symptoms. User: How can I deal with a headache? Chatbot: Which of the following symptoms does your description fit? User: Fever. Chatbot: What is your highest temperature? User: Unknown. Chatbot: How about the degree of headache? User: Painless.
Continuously use the same word to answer all the questions	Chatbot: Please tell me your symptoms. User: Headache. Chatbot: What kind of headache is it? User: Unclear. Chatbot: Do you have dizziness? User: Unclear. Chatbot: Is it accompanied by elevated blood pressure, chills, and other symptoms? User: Unclear. Chatbot: Is it accompanied by neck pain? User: Unclear. […]
Answering each question quickly	In the previous example, the user went through 19 rounds and spent 49 seconds, averaging only 2.6 seconds per question.
Spending an equally short time on each question	In the previous example, the user answered almost all of the questions in 2-3 seconds, and the SD of time was 1.2 seconds.

Figure 7. The distribution of the average duration of conversations.



To further verify our findings of the patterns of nontherapeutic chatbot use, we conducted PCA and built a binary logistic regression model using the following features: gender, age, duration of a consultation, number of conversation rounds, mean duration of each round, time spent in each round, and number of conversation rounds with continuous repetition of the same response. We did not consider contradictory statements or extensive use of nonsense/illogical words in the analysis because it was not appropriate to quantify them. As shown in Figure 8, the regular consultations (blue dots) are plotted in a small area (the number of blue dots is 10 times greater than the number of red dots), whereas the nontherapeutic use cases (red dots) are scattered. This shows that there were obvious abnormalities in many nontherapeutic use cases.

Figure 8. A principal component analysis (PCA) scatterplot of consultations for 2759 regular (blue dots) and 241 nontherapeutic (red dots) consultations. PCA has successfully found linear combinations of the different features in a two-dimensional feature space that separates two different clusters corresponding to whether or not the chatbot was used for a therapeutic purpose.



Our logistic regression analysis showed that, when controlling other features, the mean duration of each round (*P*=0.03), the standard deviation of time spend in each round (*P*=0.05), and repetition of the response (*P*<0.001) significantly correlated with the occurrence of nontherapeutic chatbot use (Table 4). This suggests that for a consultation session, the shorter the average duration of each round was, the more likely the user was gaming the chatbot (odds ratio 0.9618, 95% CI 0.9409-0.9892). Also, the result suggests that if the duration of different conversation rounds was more varied, users were less likely to be using the chatbot for a nontherapeutic purpose (odds ratio 0.9835, 95% CI 0.9733-0.9939).

Table 4. The estimated coefficients, odds ratio, and *P* value of each feature in the logistic regression model, with using the chatbot for nontherapeutic purposes as the dependent variable.[a]

Feature	Estimated coefficients (SE)	Odds ratio (95% CI)	*P* value
Gender	6.28e–02 (2.98e–02)	1.0648 (1.0335-1.0970)	.09
Age	–1.66e–02 (1.05e–02)	0.9835 (0.9733-0.9939)	.11
Duration of consultation	–3.31e–03 (1.81e–03)	0.9967 (0.9949-0.9985)	.07
Number of conversation rounds	–4.60e–02 (3.17e–02)	0.9550 (0.9252-0.9858)	.15
Average duration of each round	–3.89e–02 (2.20e–02)	0.9618 (0.9409-0.9892)	.03*
SD of time spent in each round	–2.31e–02 (1.22e–02)	0.9772 (0.9653-0.9892)	.05*
Rounds of continuous repetition of the same response (unclear or unknown)	4.56e–01 (6.24e–02)	1.5778 (1.4823-1.6793)	<.001**

**$P<.001$.

User Concerns

Toward the end of each consultation, DoctorBot prompted the user to rate the experience as either positive or negative (Figure 9). If a negative rating was chosen, the system asked the user to provide further feedback, which users could choose to do by either typing into a comment box or selecting from a list of predefined reasons (eg, “diagnosis is not accurate” or “overwhelming information”). Despite this step being optional, many users provided feedback. In total, we collected 3832 pieces of user feedback, with 2172 positive ratings and 1660 negative ratings. As negative ratings usually suggest that users had concerns, we examined the specific reasons for negative ratings by analyzing the textual feedback and the predefined reasons selected by users.

Figure 9. Interface for collecting user feedback: rating (left), predefined reasons (top right), and comment box (bottom right).

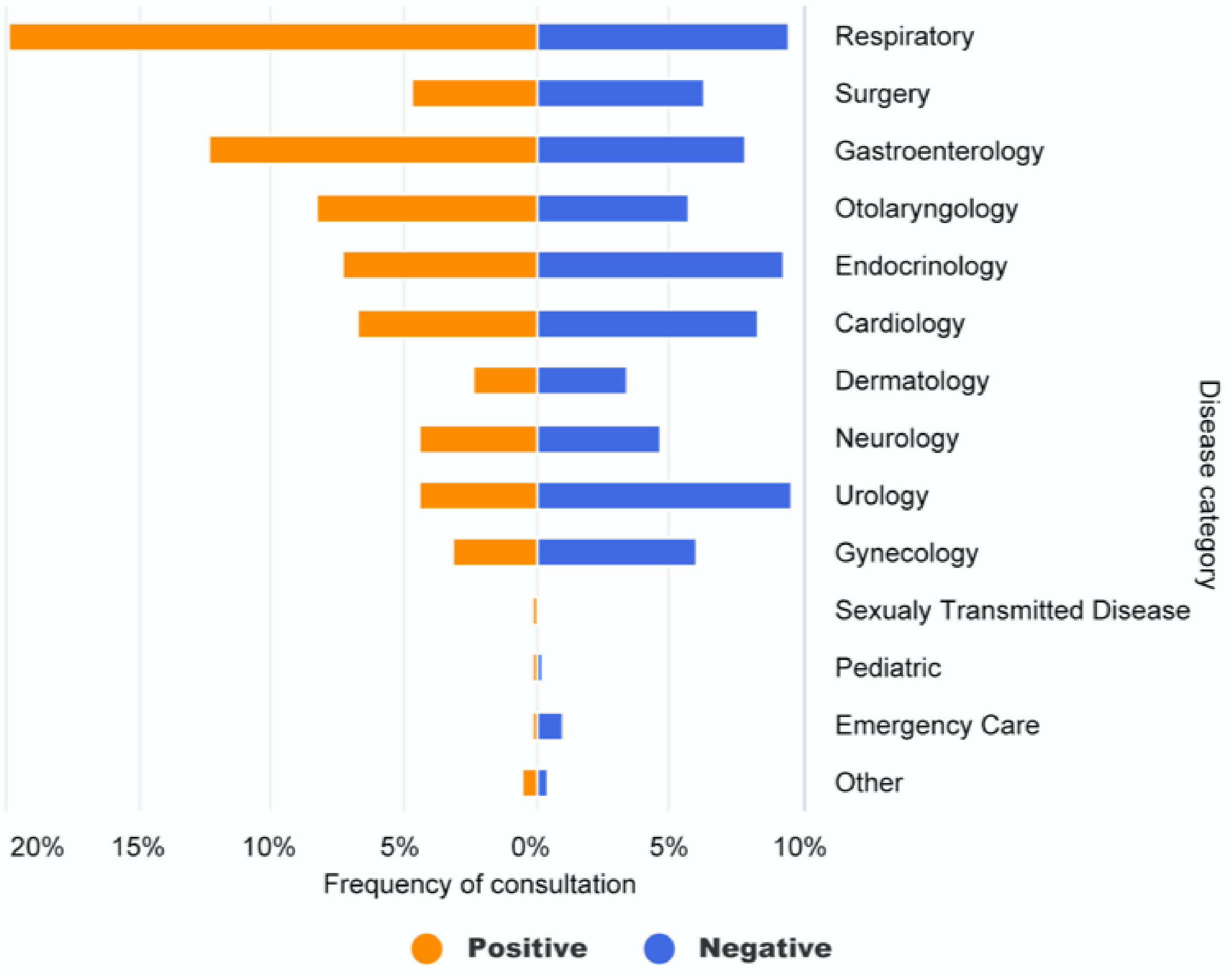
We characterized five user concerns that led to negative ratings (Table 5). We found that users usually expressed dissatisfaction when they believed that the diagnostic suggestion was not accurate; as one user stated, “I’m 21 years old with a regular lifestyle. I don’t smoke or drink. I eat and exercise regularly. You told me I have diabetes!!!” Some users even compared the diagnostic suggestions of DoctorBot with their physician’s diagnosis and stated that there was a discrepancy: “My doctor told me there is nothing to worry about and prescribed me an herbal medication. But the chatbot suggested a different diagnosis and I don’t trust it.” Furthermore, if users had difficulty comprehending the diagnostic report generated by DoctorBot or determining which diagnostic suggestion was more reliable, users also gave negative ratings. For example, one user commented, “I have no clue about the suggested diagnosis. What is that?” In other cases, users complained that the provided information on the diagnostic report was overwhelming. Indeed, due to different levels of health literacy, knowledge, and experience, users may have had challenges in comprehending the technical aspects of the diagnostic report (eg, medical jargon and professional medical knowledge) [42-44]. Lastly, users tended to give negative ratings if their information needs were not fully met. The analysis of textual feedback revealed that users desired to receive more personalized and actionable information, including medical information related to their health concerns, where to seek medical help, what to do next, and detailed explanations about the suggested diagnoses.

Table 5. Reasons cited by DoctorBot users for giving a negative rating of their experience.

User concern	Number of users
Suggested diagnosis is perceived to be inaccurate	1084
Difficult to assess, which suggested diagnosis is correct	164
Insufficient information	247
Report is not easy to understand	113
Provided information is overwhelming	52

We also analyzed the relationship between negative ratings and several intrinsic factors (eg, age, gender, duration of consultation, and disease type) to further examine if the user experience was affected by other factors that were not revealed by the analysis of user feedback. In particular, we found that the total time spent on the consultation had a significant impact on user experience. If a consultation lasted more than 2 minutes, users tended to rate their experience as negative. Interestingly, the disease type was also highly related to users’ experiences and their satisfaction level (Figure 10). For example, medical advice about common diseases, such as respiratory issues, usually received positive ratings. One possible explanation is that the chatbot could easily diagnose these diseases and provide pertinent information and medical advice to fulfill the users’ needs. However, it is challenging for the chatbot to provide an accurate diagnosis of and meaningful information about diseases with complex causal mechanisms, such as gynecopathy, based on only a few rounds of conversation; as such, negative ratings against DoctorBot-generated outputs were fairly common under such circumstances.

Figure 10. Relationship between user ratings and disease category of presenting illness of DoctorBot consultations.



Discussion

Principal Findings

The scarceness and imbalanced distribution of health care resources (eg, facilities and doctors) are major health concerns worldwide [7,8]. Many people, especially those in rural areas, may not have immediate and convenient access to the medical services they need. Furthermore, due to the complex organization and workflow of conventional health care services, it is challenging for patients and caregivers to navigate the health care system [45]. As such, more digital tools have been introduced to help patients triage before seeing a doctor and gain information to fill their knowledge gap. For example, as predecessors of self-diagnosis chatbots, online symptom checkers have been launched to more effectively provide possible alternative diagnoses to patients and direct them to the appropriate care settings [46]. Prior work illustrated that symptom checkers have an acceptable level of patient compliance with medical advice [47] and triage accuracy [48]. However, symptom checkers often use some proprietary diagnostic algorithms, such as branching logic and Bayesian inference, that are not optimal for processing complicated and sometimes ambiguous user inputs, compromising not only user experience but also diagnostic accuracy [47,49].

With the recent advent of AI technologies such as knowledge graphs and deep neural networks, more sophisticated self-diagnosis health chatbots are emerging to simulate the conversations between patient and care providers and provide more accurate and comprehensive care advice and services. The application of chatbot technology in the health domain, including mental health [21] and behavioral therapy [50,51], is becoming more and more common. Despite the effectiveness of chatbots in delivering health care services to improve well-being, this novel technology has not been adopted at the rates predicted based on the high level of interest [25]. Due to the lack of large-scale deployment, prior work primarily examined the use of health chatbots in controlled settings rather than in a real-world context [28]. This study aimed to bridge the knowledge gap in how people use health chatbots in real-world scenarios.

To that end, we analyzed the system log of a self-diagnosis chatbot to understand how health care chatbots would be used in the real world and what issues could impede the optimal use of this novel technology. We found that users in all age ranges, including middle-aged and older adults, had used the chatbot. A considerable number of people used the chatbot only once. Users consulted the chatbot about a wide range of topics, including mild medical conditions, as well as those that often entail considerable privacy and social stigma issues. We also observed several issues in the use of the chatbot, including user dropout and use for nontherapeutic purposes. Finally, we identified a set of user concerns that should be addressed to optimize user experience, including receiving insufficient actionable information and perceived inaccurate diagnostic suggestions. We argue that designers and developers of health chatbots need to employ user-centered approaches to address users' concerns and issues. Below we discuss design implications for health chatbots to enhance user experience and engagement.

Design Implications

Designing Informative Health Chatbots

The analysis of user feedback revealed that users expressed the need to receive more actionable information, such as next steps to take. This suggests that users' information needs were not adequately met by the chatbot. Also, users complained that the system-generated diagnostic report was difficult to interpret. These findings highlight the importance of providing more useful information that patients need. For example, in the diagnostic report, chatbots could provide links to consumer-friendly and credible information sources to help patients better understand the content of the report [42].

Designing Easy-To-Use Health Chatbots

Chatbots typically ask consecutive questions about concomitant symptoms so that they can generate a more accurate diagnosis. However, these questions are usually hard to answer and can easily overwhelm the user. For example, we found that users tended to terminate the consultation when they were asked to describe their symptoms or chief complaints. To address these issues, it would be useful to allow users to share and describe information in the form of voice recordings to reduce the amount of time and effort spent on typing. The chatbots should also be designed to inform users as to why a particular piece of information is needed [52].

Another interesting finding is that a small number of elderly people also used the application. Given the rise in the aging population and its associated health care costs in many countries, health chatbots will likely become a promising approach to aid older adults' independent living [53]. This raises a new set of questions for chatbot designers about how to make health chatbots more accessible and user-friendly for older adults. For example, a speech interface can be incorporated into chatbot systems to facilitate communication between elderly users and health chatbots [54].

Designing Trustworthy Health Chatbots

Through the analysis of user feedback, we found that perceiving the chatbot's output (eg, recommended diagnosis) as inaccurate was highly associated with a negative user experience. This is not surprising because health care has a high degree of criticality and users tend to have doubts about the diagnosis suggested by chatbots. Therefore, to better engage users, it is very important to increase the trustworthiness of health chatbots. Prior literature on AI-driven intelligent systems has suggested presenting system outputs in a format that is meaningful, understandable, and trustworthy to help users better understand the system's hidden intelligence and then determine whether it is appropriate to trust the recommendations and use them to make decisions [55]. In particular, prior work suggested presenting a variety of system-related information to the user, including system reliability and performance data, logic, and reasoning (eg, how the system operates and how its outputs are generated), as well as the information sources that the system leverages to produce the output [52,56,57]. Aligning with those arguments, we suggest that health chatbots need to explain data sources, prediction accuracy, and how the diagnostic report is generated to the users to build trust. For example, chatbots could provide more appropriate explanations to indicate what types of diseases they are knowledgeable of and their degree of confidence in their diagnostic suggestion.

Designing Onboarding Experiences for Users

We observed that many users dropped out of consultations, especially during their early phases. This finding highlights the necessity of enhancing user engagement at an early point. Furthermore, the chatbot was sometimes used for nontherapeutic purposes. We speculate that because self-diagnosis chatbots are an emerging technology, some users may just want to navigate through the application to explore how the chatbot works. However, gaming the chatbot could generate a large amount of noisy data, some of which might be used to train models; therefore, nontherapeutic use cases, if not taken care of properly, could adversely affect the performance of health chatbots. To prevent these issues and better engage users, it may be useful to provide them with onboarding materials during the initial interactions. Prior work has suggested that onboarding materials could educate users about the most effective way to use advanced technologies (ie, AI-driven health chatbots) [58]. As an example, the onboarding materials could introduce users to the basic functions (eg, capabilities and limitations) of the chatbot and the process of consultation (eg, what types of questions will be asked and why). Moreover, the chatbot should be designed to automatically detect and tag nontherapeutic use cases so that developers could easily remove such noisy data when training AI models.

Limitations

The present study has several limitations. First, this study relied heavily on log data. Even though the analysis of log data could provide valuable insights into the use of the chatbot in real-world settings, it didn't allow us to capture the perceptions and opinions of users when interacting with the chatbot, such as what features they liked and disliked, what barriers they encountered, and how the chatbot should be improved to optimize the user experience. In the future, we will employ social theories on the explanatory factors of the use of technology (eg, diffusion of innovation) to conduct user studies (eg, interview, survey, and usability evaluations) with different groups of people to form a more comprehensive view of users' attitudes and experiences about this novel technology. Second, we only examined the use of one health chatbot, which is likely to compromise the generalizability of the findings. To assess and expand our results' generalizability, it would be useful to examine other chatbots, including specialist chatbots that serve a particular population with specific conditions. Lastly, cultural and social factors could also play a vital role in the utilization of health chatbots. We will also examine those issues in our future work.

Conclusions

In this paper, we conducted both quantitative and qualitative analysis on the system log of a self-diagnosis chatbot, which has been widely deployed in China. To the best of our knowledge, this is the first study examining the use of health chatbots in the real world using a large-scale, heterogeneous data set. We described our general observations of the chatbot's use, including who used it, how long and how often they used the application, and what health concerns were presented. Furthermore, we analyzed both completed and uncompleted consultation sessions as well as the user feedback to investigate issues that may hinder the effective use of the chatbot. These results shed light on the design of health chatbots to improve user experience and increase user engagement.

Abstract

Background: Chatbots have been used in the last decade to improve access to mental health care services. Perceptions and opinions of patients influence the adoption of chatbots for health care. Many studies have been conducted to assess the perceptions and opinions of patients about mental health chatbots. To the best of our knowledge, there has been no review of the evidence surrounding perceptions and opinions of patients about mental health chatbots.

Objective: This study aims to conduct a scoping review of the perceptions and opinions of patients about chatbots for mental health.

Methods: The scoping review was carried out in line with the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) extension for scoping reviews guidelines. Studies were identified by searching 8 electronic databases (eg, MEDLINE and Embase) in addition to conducting backward and forward reference list checking of the included studies and relevant reviews. In total, 2 reviewers independently selected studies and extracted data from the included studies. Data were synthesized using thematic analysis.

Results: Of 1072 citations retrieved, 37 unique studies were included in the review. The thematic analysis generated 10 themes from the findings of the studies: usefulness, ease of use, responsiveness, understandability, acceptability, attractiveness, trustworthiness, enjoyability, content, and comparisons.

Conclusions: The results demonstrated overall positive perceptions and opinions of patients about chatbots for mental health. Important issues to be addressed in the future are the linguistic capabilities of the chatbots: they have to be able to deal adequately with unexpected user input, provide high-quality responses, and have to show high variability in responses. To be useful for clinical practice, we have to find ways to harmonize chatbot content with individual treatment recommendations, that is, a personalization of chatbot conversations is required.

(J Med Internet Res 2021;23(1):e17828) doi:10.2196/17828

KEYWORDS

chatbots; conversational agents; mental health; mental disorders; perceptions; opinions; mobile phone

Introduction

Background

Mental disorders are a growing global concern. Approximately 29% of individuals may experience such disorders in their lifetime [1]. Mental disorders have a negative effect on the quality of life and are one of the most common causes of disability [2]. Globally, the lost labor and capital output caused by mental disorders are predicted to cost US $16 trillion between 2011 and 2030 [3]. For many, accessing mental health care services is challenging because of the shortage of mental health care providers [4-7], lack of health care insurance coverage [8], and perceived stigma [9-11]. The lack of access to mental health care services increases the risk of self-harm and suicide [12,13].

Technological advancements have improved access to mental health care services [3]. According to the World Health Organization, more than one-fourth of 15,000 mobile health (mHealth) apps focus on mental health diagnosis or support [13]. Chatbots, also called conversational agents, virtual agents, and dialog systems, are one of the main mobile apps used for mental health.

Chatbots are programs able to converse and interact with a human using voice, text, and animation [14]. There are 2 types of chatbots: rule-based chatbots and intelligent chatbots. Although the former uses some predefined rules or decision trees to manage its response and dialog, the latter uses artificial intelligence (AI) to generate its dialog [14]. Chatbots have been employed in businesses across different industries, such as e-commerce and retail (eg, eBay’s ShopBot), hospitality (eg, Chatobook), real estate (eg, Apartment Ocean), entertainment (eg, Mojihunt), news (CNN’s Chatbot), travel (eg, Hello Hipmunk), finance and banking (eg, Wells Fargo’s chatbot), insurance (eg, ABIE), education (eg, Feed.Mind), legal (eg, Immigration Virtual Assistant), and personal assistance (eg, Apple’s Siri). In addition to the abovementioned industries, chatbots have become popular in health care (in general) and mental health (in specific) in the past 5 years. According to a scoping review conducted by Abd-alrazaq et al [14], there were 41 different chatbots used for several purposes in mental health, such as therapy, training, education, counseling, and screening. A systematic review of 12 studies showed that chatbots are effective in improving some mental disorders, such as depression, stress, and acrophobia [15].

Research Problem and Aim

The adoption of new technology relies on the perceptions and opinions of users. Numerous studies have been conducted to assess the perceptions and opinions of patients about mental health chatbots [14]. There is a need to explore perceptions and opinions that may help in predicting the adoption of chatbots and improving them [14]. Although several reviews have been conducted on chatbots in mental health [4,14-17], none have summarized the findings of previous studies regarding perceptions and opinions of patients about mental health chatbots. Accordingly, the aim of this study is to review the perceptions and opinions of patients about mental health chatbots, as reported in the previous literature.

Methods

Study Design

We conducted a scoping review to accomplish this objective. A scoping review was conducted as the aim was to map the body of literature on this topic [18]. Owing to the broad nature of the inquiry, we expected a diversity of study designs. Scoping reviews are more suited to broader aims [18]. As we were not seeking to summarize the best available research on a specific question, a systematic review was not the ideal choice. Using chatbots for mental health is a field in relative infancy; therefore, a broader aim was necessary. The range of study designs currently used in the field makes equitable risk of bias assessment difficult; it is acknowledged that the risk of bias assessments is not required in scoping reviews [18,19]. Scoping reviews are generally accepted as more appropriate when diversity of study designs is expected. The PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) Extension for Scoping Reviews guidelines were followed to carry out a systematic and transparent review [20].

Search Strategy

Search Sources

The following electronic databases were searched in the current review: MEDLINE (via Ovid), Embase (via Ovid), PsycINFO (via Ovid), Scopus, Cochrane Central Register of Controlled Trials, IEEE Xplore, ACM Digital Library, and Google Scholar. Given that Google Scholar usually finds several thousands of references, which are ordered by their relevance to the search topic, we screened only the first 100 references [14,15,21]; these references are the most relevant. The search was conducted from October 25 to October 28, 2019. We also conducted backward reference list checking, where reference lists of the included studies and reviews on the search topic were screened for additional studies of relevance to the review. In addition, we carried out forward reference list checking, where the *cited by* function available in Google Scholar was used to find and screen studies that cited the included studies.

Search Terms

To derive search terms, we checked previous literature reviews [4,14-17] and opinions of informatics experts interested in mental health (which were collected in informal meetings). The search terms were selected based on the target intervention (eg, chatbots and conversational agents) and condition (eg, mental disorder and anxiety). The controlled vocabulary search terms (eg, MeSH, Emtree) were used, as appropriate. The search strings used for searching each electronic database are detailed in Multimedia Appendix 1.

Study Eligibility Criteria

The intervention of interest in this review was chatbots that operate as stand-alone software or a web browser (Textboxes 1 and 2). We excluded chatbots that were integrated into robotics, serious games, SMS, or telephone systems and those that depended on human operator–generated dialog. No restrictions were applied regarding the type of dialog initiative (ie, use, system, mixed) and input and output modality (ie, spoken, visual, and written). The eligible population included individuals who used chatbots to improve their psychological well-being or mental disorders but not physicians or caregivers who use chatbots for their patients. To be included, studies had to assess patients' perceptions and opinions about chatbots for mental health. The review included peer-reviewed articles, dissertations, and conference proceedings, and it excluded reviews, proposals, editorials, and conference abstracts. Only studies written in English were included in this review. No restrictions were applied regarding the study design, study setting, comparator, year of publication, or country of publication.

Textbox 1. Inclusion criteria.

- Intervention: chatbots operate as stand-alone software or a web browser
- Population: patients who use chatbots for improving their psychological well-being or mental disorders
- Outcome: patients' perceptions and opinions about mental health chatbots
- Type of publication: peer-reviewed articles, dissertations, and conference proceedings
- Language: English

Textbox 2. Exclusion criteria.

- Intervention: chatbots integrated into robotics, serious games, SMS, or telephone systems and those depend on human operator–generated dialog
- Population: physicians or caregivers who use chatbots for improving their psychological well-being or mental disorders
- Outcome: other outcomes
- Type of publication: reviews, proposals, editorials, and conference abstracts
- Language: other languages

Study Selection

In this review, MA and NA independently screened the titles and abstracts of all retrieved studies and independently read the full texts of studies included from the first step. AA resolved any disagreements between the reviewers. Cohen kappa was calculated to assess the intercoder agreement [22], which was 0.86 and 0.90 for screening titles and abstracts and for reading full texts, respectively, indicating excellent agreement [23].

Data Extraction

Multimedia Appendix 2 shows the data extraction form used in this review, which was pilot tested using 4 included studies. Data were extracted from the included studies by 2 reviewers independently (MA and NA), and the third reviewer (AA) resolved any discrepancies in decisions between the reviewers. Cohen kappa showed an excellent agreement (0.83) [23].

Assessment of Risk of Bias

Scoping reviews do not usually assess the risk of bias of the included studies because they have broad aims and include studies with diverse study designs [18,19]. The aim of this review was very broad, and the included studies had different study designs. Thus, the risk of bias of the included studies was not assessed in this review.

Data Synthesis

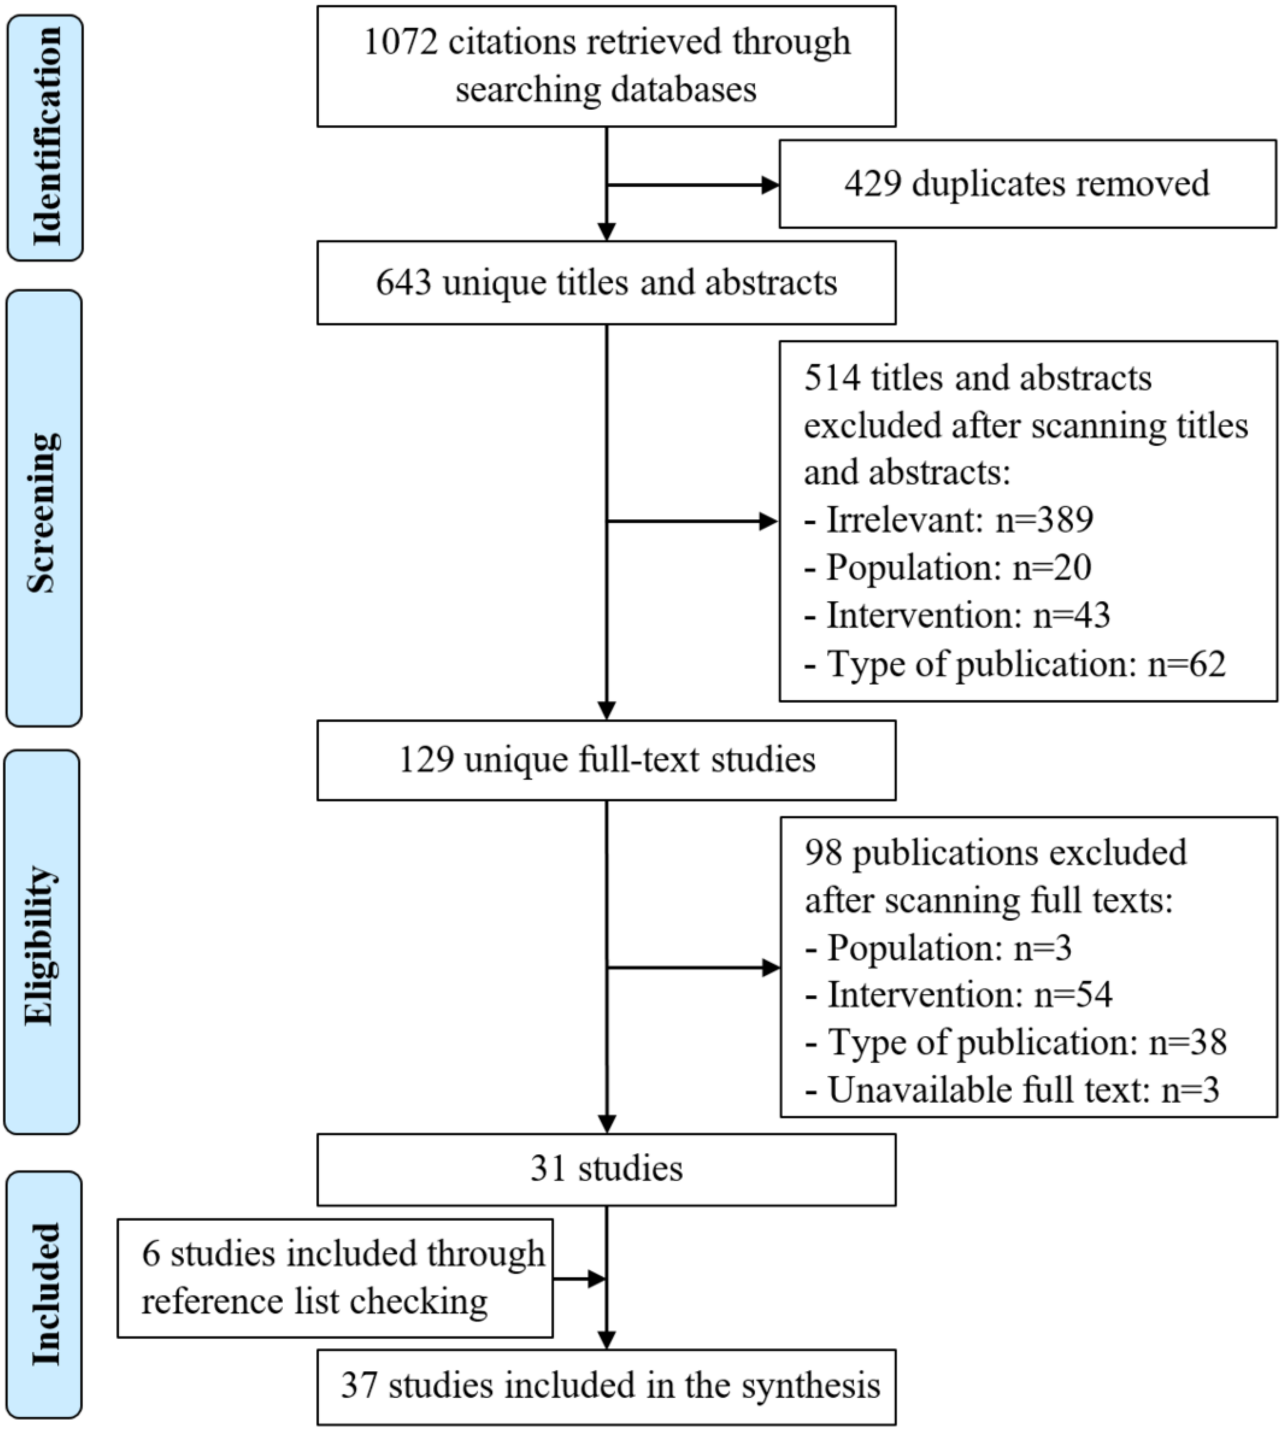
A narrative approach was used to synthesize the data extracted from the included studies. Thematic analysis was used to generate themes based on the findings of the included studies. This data synthesis approach (ie, thematic analysis) has been applied in numerous systematic and scoping reviews [24-28]. Given the exploratory nature of this review, an inductive approach was used to generate themes directly from the data [29]. The thematic analysis was conducted following the steps proposed by Braun and Clarke [30], as it is the most systematic guide for conducting thematic analysis to date [31,32]. Specifically, the first author (AA) scrutinized and rescrutinized the extracted data to familiarize himself with it. AA then coded the data systematically. On the basis of the assigned codes, themes were generated. All authors checked the fit of the generated themes to the extracted data and assigned codes. Where authors had differing opinions on the assigned codes and/or generated themes, these discrepancies were resolved through discussion. Finally, all authors participated in defining and naming the themes. Microsoft Excel was used to manage the analysis process.

Results

Search Results

As shown in Figure 1, 1072 citations were found by searching the electronic databases. After removing 429 duplicates of these citations, 643 titles and abstracts were screened. In the screening process, we excluded 514 titles and abstracts. Reading the full text of the remaining 129 citations resulted in a further 98 citations being excluded. The reasons for the exclusion are detailed in Figure 1. In backward and forward reference checking, we found 6 additional studies. In total, 37 studies were included in this review.

Figure 1. Flowchart of the study selection process.



Characteristics of Included Studies

As shown in Table 1, the most commonly used study design was a cross-sectional survey (34/37, 92%). About two-thirds of the studies were published as journal articles (24/37, 65%).

The included studies were conducted in more than 15 countries, but approximately 46% (17/37) of them were carried out in the United States. Approximately 62% (23/37) of the studies were published between 2015 and 2019.

[a] Percentages were rounded and may not sum to 100.

[b] Mean age was reported in 24 studies.

[c] Sex was reported in 29 studies.

[d] Setting was reported in 34 studies.

[e] Numbers do not add up as several chatbots target more than one health condition.

The sample size was 50 or less in 24 studies and more than 200 in 2 studies (Table 1). The participants' age was reported in 24 studies, with a mean age of participants was 33.4 years (SD 15.2; range 13-79 years). The sex of participants was reported in 29 studies, where the mean percentage of men was 49.5%. In 57% (21/37) of the studies, participants were from clinical populations (ie, they had mental disorders). The sample was recruited from clinical (n=14), educational (n=12), or community settings (n=8). Multimedia Appendix 3 shows the metadata and population characteristics of each included study.

The 37 included studies assessed patients' perceptions and opinions about 32 different chatbots. Chatbots were used for therapeutic purposes (n=12), training (n=9), self-management (n=6) counseling (n=5), screening (n=4), and diagnosis (n=1; Table 1). Chatbots were implemented in stand-alone software in 65% (24/37) of the studies, whereas the remaining chatbots were implemented in web-based platforms. In the majority of studies (32/37, 86.5%), chatbots generated their responses based on predefined rules or decision trees (rule based). Chatbots in the remaining studies generated their responses based on machine learning approaches. Chatbots led the dialog in most studies (n=32/37, 86.5%); both chatbots and users could lead the dialog in the remaining studies. Virtual agents (eg, avatar or virtual human) were embodied in chatbots in 30 of 37 studies (81.1%). The most common disorder targeted by chatbots was depression (n=15, 40.5%). Multimedia Appendix 4 shows the characteristics of the intervention in each included study [33-69].

Study Findings

The thematic analysis generated 10 themes from the findings of the studies: usefulness, ease of use, responsiveness, understandability, acceptability, attractiveness, trustworthiness, enjoyability, content, and comparisons. More details about these themes are elaborated in the following subsections.

Theme 1: Usefulness

In total, 20 studies investigated the usefulness of chatbots and/or their features for patients [33-52]. In 3 studies [41,47-49,51], the overall usefulness of chatbots was rated as high. Participants reported that chatbots are useful for practicing conversations in a private place [33,46], learning [37,38,42,46], making users feel better [40], preparing users for interactions with health care providers [43], implementing the learned skills in daily life [46], facilitating a sense of accountability from daily check-in [37,38], keeping the learned skills more prominently in users' minds [46], increasing users' self-efficacy [46], improving users' self-confidence and readiness for job interviews [47-49], and recalling users' memories [51]. However, participants in one study doubted the usefulness of chatbots for smoking cessation [39].

Users considered the following components of chatbots useful: real-time feedback [33,45,50], diary [52], weekly summary [42], presenting the helpline during the conversation [36], and psychoeducation [52]. Some studies found that virtual agents embodied in chatbots are useful for motivating users to use chatbots [34], establishing a relationship with them [35], and feeling supported by them [45]. However, other studies demonstrated that participants had neutral perceptions and opinions about the added value of embodied virtual agents with speech [52] or without speech [44].

Theme 2: Ease of Use

The ease of use and usability of chatbots were assessed in 20 studies [33,34,36,39,43,46-51,53-61]. Participants in 15 studies rated the overall ease of use of chatbots as high [36,39,43,47-50,53-55,57-61]. A total of 5 studies assessed the usability of chatbots [34,36,46,51,56], and it was rated high in all these studies (ranging from 69 to 88.2). Participants in 3 studies reported that chatbots are easy to learn and become familiar with [33,39,55]. Although participants did not find chatbots difficult to navigate in one study [33], they rated the navigation of the chatbot as low in another study [36].

In 3 studies, participants faced difficulty in using the chatbot because they did not know when [60] and how [61] to reply to it, and they did not have enough options to reply to it [62]. Some participants in 3 studies criticized chatbots because of technical glitches that happened during their use, such as screen freezing [37,45,60]. Users suggested that chatbots allow them to respond by speaking and not typing to make them easy to use [57].

Theme 3: Responsiveness

This theme brings together perceptions and opinions of participants about verbal and nonverbal responses generated by chatbots in terms of realism, repetitiveness (variability), speed, friendliness, and empathy. A total of 10 studies assessed participants' perceptions and opinions about how real the chatbots were in terms of verbal and nonverbal responses. Although participants in 7 studies had mixed or neutral perceptions and opinions about the realism of verbal and nonverbal responses [33,35,38,45,46,50,56], most participants in 3 studies held corresponding positive perceptions and opinions [52,57,60]. Participants believed that chatbots may be more realistic if they have an embodied virtual agent [44] and are able to communicate verbally [33].

Most participants in several studies stated that chatbots were able to show friendly [34,52,59,60,63] and emotional [35,37,38] responsiveness. However, participants in other studies had mixed perceptions and opinions about the ability of chatbots to generate friendly [35,44,64] and emotional [64] responses. Participants in one study found chatbots with an embodied virtual agent friendlier than those without an embodied virtual agent [44].

A total of 7 studies demonstrated that chatbot responses were repetitive [35-38,40,42,61]. Participants in one study reported that the repetitiveness of responses made the chatbot look less real [42]. Moreover, 3 studies concluded that the speed of chatbot responses was appropriate [57,60,61]. Yet, participants in 2 studies criticized the speed of chatbot responses as either too fast [38] or too slow [33]. In 6 studies, participants did not face any difficulties in understanding and interpreting chatbot responses [45,57,59,60,65,66].

In general, participants in 6 studies were satisfied with chatbot responses [33-36,62,63,67]. Participants attributed their satisfaction to the accuracy and consistency of chatbot feedback with what their therapist recommended in the past [33], appropriate use of high-quality elements (eg, Graphics Interchange Format images) [36], consistency of voice and tone of the chatbot [36], and quality of information provided [62,63]. However, participants in 4 studies were not satisfied by the conversation of chatbot because of confusing responses [57], disturbing users [40], the robotic quality of its voice [62], using emoticons (emojis) [37], conversations being too short [37], and shallowness of the conversations [42].

Participants suggested several enhancements related to the responsiveness of chatbots, such as the ability to speak [44], more flowing speech [33], friendlier voice [44], immediate responses [33,45], faster blinks [33], more explanation [33], providing feedback on each answered question [44], and more precise feedback [45].

Theme 4: Understandability

This theme brings together perceptions and opinions of participants about the ability of chatbots to understand their verbal and nonverbal contact. Chatbot understandability for verbal responses was rated as high among participants in 3 studies [33,45,61]; however, participants in other studies criticized the inability of the chatbot to understand their verbal responses in general [36-38,40,57], misspelled words (eg, anious instead of anxious) [36], different languages [36], unexpected answers [37,38], and nonverbal responses (eg, images, emojis, and facial expressions) [33,36,56]. Therefore, participants in 3 studies suggested that future chatbots should better understand and recognize their verbal and nonverbal responses [33,37,43].

Theme 5: Acceptability

This theme concerns participants' acceptability of chatbots and its functionalities and their intentions to use them in the future. The acceptability of chatbots was rated high by users in 12 studies [34,37,38,43,45,46,53,54,57,61,66,68]. Wearing eye tracker goggles [62] or the inclusion of an embodied virtual agent [65] was acceptable for participants. There were mixed opinions about the acceptability of chatbots in one study [35]. Chatbots connected with a perception system (camera) for extracting data about user behavior was not acceptable for most participants in one study [60]. Users in one study indicated that the acceptability of chatbots could increase if the purpose of chatbots was clearly explained [33]. Note that the lack of clarity of the purpose of chatbots was highlighted by participants in 2 studies [33,42].

Furthermore, 6 studies demonstrated that people would like to use chatbots in the future [35,43,45,46,50,53,54,61,65], whereas participants in 2 studies were ambivalent about the future use of chatbots [33,39]. This ambivalence resulted from participants perceiving chatbots as a conversational tool for children [33]. Some participants reported that they probably would not use chatbots unless they popped up on their screens [33]. Although participants in one study showed high intention to use the chatbot in the future, they highlighted that it is inconvenient or inappropriate to use it every day [35].

Theme 6: Attractiveness

Participants in one study rated the attractiveness of a chatbot as low [57]. Furthermore, Demirci [55] found that perceptions and opinions of users about attractiveness changed from positive before using the chatbot to neutral after using it. Participants suggested improvements of the controls (eg, icons, combo boxes, buttons, and font size) [33,34] and the appearance of the embodied virtual agent [34] to obtain a more attractive graphical user interface.

Theme 7: Trustworthiness

This theme concerns participants' trust in chatbot. In 7 studies, participants believed that chatbots are trustworthy [34,44,46,52,54,57,63]. One study concluded that participants were satisfied with the anonymity, confidentiality, and objectivity of chatbots [63]. Most participants in the 2 studies were comfortable to share and did share personal information with the chatbot [56,63].

Theme 8: Enjoyability

Participants in 9 studies considered using chatbots as enjoyable and fun [36,42-44,47-49,52,55,59]. However, one study found that perceptions and opinions of users about enjoyment changed from positive before using the chatbot to neutral after using it [55].

Theme 9: Content

This theme contains participants' opinions about the content of chatbots. In 6 studies, participants were satisfied with the contents of chatbots such as videos, games, topics, suggestions, and weekly graphs [34,37,38,42,43,52]. However, the content of chatbots was criticized by users because of its superficiality [33,38], irrelevancy [38], having too long videos [37], and having overwhelming information [57]. Participants in 3 studies appreciated the personalization feature in chatbots that allowed them to customize the session length and the gender and appearance of the virtual agent [35,57,60]. Participants suggested that chatbots should contain psychoeducation [35], more therapy-based activities [34], longer and more frequent intervention sessions [43], more customizable content [35,43], and interventions for other chronic health conditions [43].

Theme 10: Comparisons

This theme brings together participant perspectives about chatbots in comparison with other chatbots or traditional methods. Although most participants in one study preferred interacting with a chatbot rather than a human for their health care [53], participants in another 2 studies had mixed preferences about that [33,45]. In 2 studies [44,58], participants preferred using chatbots with an embodied virtual agent compared with chatbots without an embodied virtual agent.

Participants in one study preferred that chatbot provides real-time feedback on their nonverbal behavior rather than postsession feedback [33]. According to Morris et al [67], participants preferred the chatbot's responses drawn from an existing pool of web-based peer support data rather than those generated by the chatbot itself. Users preferred to use chatbots that provide information in an interactive fashion [43], are added on a device that they already own (eg, smartphones, tablets, computers) [60], and call them by their first name [60].

A chatbot without an embodied virtual agent (text-based chatbot) was compared with 2 chatbots with an embodied virtual agent (one reacts to the user with verbal and nonverbal empathic reactions, whereas the other did not) in another study [58]. The study found that the empathic chatbot was more acceptable, enjoyable, empathizing, understanding, nicer, sociable, trustworthy, realistic, private, anthropomorphic, animated, intelligent, socially influencing, friendlier, and safer than the nonempathic chatbot and the text-based chatbot [58]. Furthermore, the study demonstrated that participants are more willing to disclose information to the text-based chatbot than to empathic and nonempathic chatbots and a human counselor [58]. The study also found that participants were more willing to use empathic chatbots than nonempathic chatbots and text-based chatbots [58].

One study compared AI chatbots with an individual or a chatbot controlled by the same individual (Wizard-of-Oz) [56]. The study found that the Wizard-of-Oz chatbot was rated by participants as more usable and listened better than the AI chatbot [56]. Furthermore, users of the Wizard-of-Oz chatbot felt greater rapport than users of the AI chatbot and, surprisingly, than those who were interviewed by humans [56]. However, there was no difference between users of the AI chatbot and those interviewed by a human in their ratings of rapport [56].

In another study [69], participants felt a greater rapport with the real expert than with a rule-based chatbot. Participants also indicated that the rule-based chatbot is less able to understand their responses and feelings than a real expert [69]. Furthermore, participants found the real expert more trustworthy than the rule-based chatbot [69]. Participants reported that the chatbot is more enjoyable and engaging than traditional methods of learning and practicing dialectical behavior therapy skills [46].

Discussion

Principal Findings

The main finding of this review is that there are features of chatbots that health care providers cannot deliver over a long period. These features have been identified as useful in mental health chatbots: real-time feedback, weekly summary, and continuous data collection in terms of a diary. Usefulness and ease of use are aspects of chatbots that have been studied most comprehensively in the analyzed papers. Overall, the usefulness of mental health chatbots is perceived as high by patients. According to these studies, patients find chatbot systems easy to use. Interactional enjoyment and perceived trust are significant mediators of chatbot interaction [70]. Although chatbots are perceived as useful and easy to use, participants of reported studies recognized the existing conversational limitations of those systems: conversations are perceived as shallow, confusing, or too short. This points to an important issue to be addressed in future mental health chatbot development (see the *Practical and Research Implications* section). The conversation quality still needs to be improved. In this context, chatbot quality in terms of responsiveness and variability of responses is an important issue. Currently, systems are rather restricted in the number of responses, which might be because of the early development stage of many chatbots, as has already been reported by Laranjo et al [71]. Another relevant aspect judged important is the quality of provided information and consistency with recommendations of treating physicians. The implications of these principal findings toward practice and research are described in the *Practical and Research Implications* section.

Comparison With Existing Literature

This is the first review that summarizes perceptions and opinions of patients about mental health chatbots, as reported by previous studies. Palanica et al [72] assessed physicians' perceptions of health chatbots. They found that physicians see the benefits of those apps basically in support of patients in managing their health and improving physical, psychological, and behavioral health outcomes. As limitations of health chatbots, they mentioned the inability to comprehend and express human emotions and a lack of medical expert knowledge and intelligence. Our results provide the counterpart of this observation, namely, patients recognizing limitations in the conversation quality of health chatbots. A recent paper on a chatbot for regulating emotions shows that perceptions of patients and psychologists differ regarding attractiveness, efficiency, and stimulations of health chatbots [73]. Although psychologists see these aspects rather positive, patients are more critical and complain about the restrictions of chatbot conversations.

In their review of the landscape of psychiatric chatbots, Vaidyam [4] identified studies that showed high satisfaction with the interventions they received. Participants reported the interventions as helpful, easy to use, and informative and rated satisfaction highly (>4.2 out of 5) on all scales, including ease of use, desire to continue using the system, liking, and trust. In addition, the results of Bendig et al [16] suggest the practicability, feasibility, and acceptance of using chatbots to promote mental health. Our results confirm these observations: patients consider chatbots as useful, and acceptability is rated high.

A study assessed the use of mobile technologies in health-related areas from various perspectives [74]. It points to the following risks for mHealth app usage: lack of functionality, dissemination of false information, misdiagnosis, mistreatment, and unknown unwanted side effects. From the patient perspective, these issues could also be identified in our review: quality of provided information and consistency with recommendations of treating physicians are relevant aspects. The results of the study by Albrecht [74] go beyond our results by pointing to the risks of mHealth apps in case of an emergency. Implemented algorithms still lack reactivity (eg, in the case of self-endangerment or hazards of others). In addition, Singh et al [75] showed that only 23% of mHealth apps responded adequately to dangerous user input (eg, suicidal ideations). This illustrates the enormous need for improvement in terms of responsiveness of mHealth apps in potentially dangerous situations. According to our results, the patients did not seem to be too concerned about this issue of chatbot behavior in emergencies. It was not mentioned in the reviewed studies.

Practical and Research Implications

Practical Implications

The study results have the following practical implications. To be useful, we need to create high-quality chatbots that are able to respond to a user in multiple ways. A mental health chatbot must be empathic to be perceived as motivating and engaging and to establish a relationship with the user. A study by de Gennaro [76] supports this by demonstrating that empathic chatbots have the potential to provide emotional support to victims of social exclusion.

The patient-doctor or patient-therapist relationship in standard health care settings is characterized by trust and loyalty. Measurements must be undertaken to make the chatbot-patient relationship also trustworthy. This could be realized by providing information on the secondary use of the collected patient data on data storage and analysis procedures. Another approach is blended therapy [77], a combination of face-to-face and web-based or digital therapy, which shows the potential of a cost-effective and accessible format in cognitive behavioral therapy. This would also address another practical implication, which is that the chatbot has to be related to the therapy. In particular, recommendations provided by a chatbot must be consistent with the recommendations of the treating health care professionals. This demands the integration of chatbots into the health care process; the chatbot should be aware of the recommendations or treatment plans of the health care provider. Finally, to increase the acceptance of chatbot use in patients, physicians need to be convinced of the usefulness of those systems so that they will recommend them to patients. Studies suggest that there are already physicians who are convinced of the usefulness [72]. Given the strong bond of trust among patients toward their physicians, patients will be convinced of the usefulness of an app once their physician recommends it.

Research Implications

From the practical implications, we can derive the following research implications. There is still a need to improve the linguistic capabilities of mental health chatbots [71]. Their ability to understand and react appropriately to user input has to be increased. Furthermore, methods are required to generate dynamic answers to ensure the variability of chatbot responses. Linguistic or lexical variability can be added to the knowledge base of rule-based chatbots, but the capabilities will always depend on the completeness of the knowledge base. Methods for slightly adapting or reformulating responses from the knowledge base could help in addressing this issue. In domains outside the health care domain, crowdsourcing has been applied to improve conversation quality [78]. However, in health care, we have to be careful with learning from data because we have to ensure that responses and recommendations are in line with clinical evidence. It is still an open research question on how to learn clinical evidence to train health chatbots.

Furthermore, methods have to be developed to deal with unexpected user input and to detect critical situations. In mental health, it is crucial to react appropriately for people who are at risk of suicide or self-harm [79]. Sentiment analysis methods have proven to be successful in analyzing social media messages with respect to suicide and self-harm [80]. These methods could be useful in health chatbots as well. The main challenge is the use of an appropriate reaction once an emergency situation has been detected. Another interesting research topic is the customization or personalization of chatbots to individual users. This topic is still in its infancy [81]. As long as mental health chatbots rely on decision trees or fix implemented rule bases, they will not be able to adapt to specific user needs. We can construct the knowledge base in such a way that there are responses for different types of users, but this will be time consuming and will always be incomplete. Learning from conversations with users could help. The style or complexity of language can be adapted based on the given user input. Patient-specific knowledge, for example, on treatment plans could be retrieved from health records. Methods are required to include such knowledge dynamically to a chatbot. In this way, the chatbot content is adapted to match individual needs.

For evaluating the mental health chatbot, benchmarks have to be created, and consistent metrics and methods have to be developed. Laranjo et al [71] reviewed the characteristics, current applications, and evaluation measures of health chatbots. Evaluation measures were divided into 3 main types: technical performance, user experience, and health research measures. The first attempts toward evaluation frameworks for digital health interventions [82] and health chatbots [83,84] have been recently published. Depending on the facet under consideration, different metrics can be used: system performance and effectiveness can be evaluated using different computational metrics (eg, usability, ease of use, usefulness) [85]. Software quality can be measured by reliability, security, maintainability, and efficiency using software engineering metrics [86]. If the system uses AI and machine learning techniques, the metrics comprise the accuracy and precision of predictions and recommendations. Furthermore, the efficiency of the systems has to be evaluated and compared with existing care models. With regard to safe app use, 3 criteria should be evaluated: (1) quality of the therapeutic content, (2) functionality, and (3) data safety and protection [87].

Strengths and Limitations

Strengths

This review was developed, executed, and reported according to the PRISMA Extension for Scoping Reviews [20]. This enabled us to produce a high-quality review.

The most commonly used databases in health and information technology were searched to retrieved relevant studies as many as possible. Searching Google Scholar and carrying out backward and forward reference list checking enabled us to identify gray literature and minimize the risk of publication bias as much as possible. As no restrictions were applied regarding the study design, study setting, comparator, year of publication, and country of publication, this review can be considered comprehensive.

Selection bias in this review was minimal because study selection and data extraction were performed independently by 2 reviewers. Furthermore, the agreement between reviewers was very good for study selection and data extraction. This study is one of the few reviews that used thematic analysis to synthesize the findings of the included studies. The thematic analysis followed the highly recommended guidelines proposed by Braun and Clarke [30].

Limitations

This review focused on chatbots that only work on stand-alone software and a web browser (but not robotics, serious games, SMS, or telephones). Furthermore, this review was restricted to chatbots that are not controlled by human operators (Wizard-of-Oz). Therefore, perceptions and opinions of patients found in this review may be different from their perceptions and opinions about Wizard-of-Oz chatbots and/or chatbots with alternative modes of delivery. The abovementioned restrictions were applied by previous reviews about chatbots, as these features are not part of ordinary chatbots [4,14,17].

Owing to practical constraints, we restricted the search to English studies and we could not search interdisciplinary databases (eg, Web of Science and ProQuest), conduct manual search, or contact experts. Consequently, it is likely that we have missed some English and non-English studies. Most included studies were conducted in developed countries, particularly in the United States. Therefore, the findings of this review may not be generalizable to developing countries, as patients in such countries may have different perceptions and opinions about mental health chatbots.

Conclusions

In this paper, we explored perceptions and opinions of patients about mental health chatbots, as reported in the existing literature. The results demonstrated that there are overall positive perceptions and opinions of patients about mental health chatbots, although there is some skepticism toward trustworthiness and usefulness. Many important aspects have been identified to be addressed in research and practice. Among them are the need to improve the linguistic capabilities of chatbots and seamless integration into the health care process. Future research will have to pick up those issues to create successful, well-perceived chatbot systems, and we will start developing corresponding concepts and methods. The research implications are also relevant for health care chatbots beyond mental health chatbots. Their consideration has the potential to improve patients' perceptions of health care chatbots in general.

Acknowledgments

The publication of this study was funded by the Qatar National Library. This study was a part of a project funded by the Qatar National Research Fund (NPRP12S-0303-190204). The project title is *A Personalized and Intelligent Digital Mental Health Platform for Qatar and the Arab world*.

Authors' Contributions

AA developed the protocol and conducted a search with guidance from and under the supervision of MH and BB. Study selection and data extraction were performed independently by MA and NA. AA executed the analysis, and all authors checked the validity of the generated themes. AA and KD drafted the manuscript, and it was revised critically for important intellectual content by all authors. All authors approved the manuscript for publication and agree to be accountable for all aspects of the work.

Conflicts of Interest

Abstract

Background: Recent years have witnessed a constant increase in the number of people with chronic conditions requiring ongoing medical support in their everyday lives. However, global health systems are not adequately equipped for this extraordinarily time-consuming and cost-intensive development. Here, conversational agents (CAs) can offer easily scalable and ubiquitous support. Moreover, different aspects of CAs have not yet been sufficiently investigated to fully exploit their potential. One such trait is the interaction style between patients and CAs. In human-to-human settings, the interaction style is an imperative part of the interaction between patients and physicians. Patient-physician interaction is recognized as a critical success factor for patient satisfaction, treatment adherence, and subsequent treatment outcomes. However, so far, it remains effectively unknown how different interaction styles can be implemented into CA interactions and whether these styles are recognizable by users.

Objective: The objective of this study was to develop an approach to reproducibly induce 2 specific interaction styles into CA-patient dialogs and subsequently test and validate them in a chronic health care context.

Methods: On the basis of the Roter Interaction Analysis System and iterative evaluations by scientific experts and medical health care professionals, we identified 10 communication components that characterize the 2 developed interaction styles: deliberative and paternalistic interaction styles. These communication components were used to develop 2 CA variations, each representing one of the 2 interaction styles. We assessed them in a web-based between-subject experiment. The participants were asked to put themselves in the position of a patient with chronic obstructive pulmonary disease. These participants were randomly assigned to interact with one of the 2 CAs and subsequently asked to identify the respective interaction style. Chi-square test was used to assess the correct identification of the CA-patient interaction style.

Results: A total of 88 individuals (42/88, 48% female; mean age 31.5 years, SD 10.1 years) fulfilled the inclusion criteria and participated in the web-based experiment. The participants in both the paternalistic and deliberative conditions correctly identified the underlying interaction styles of the CAs in more than 80% of the assessments ($X^2_{1,88}$=38.2; $P<.001$; phi coefficient r_ϕ=0.68). The validation of the procedure was hence successful.

Conclusions: We developed an approach that is tailored for a medical context to induce a paternalistic and deliberative interaction style into a written interaction between a patient and a CA. We successfully tested and validated the procedure in a web-based experiment involving 88 participants. Future research should implement and test this approach among actual patients with chronic diseases and compare the results in different medical conditions. This approach can further be used as a starting point to develop dynamic CAs that adapt their interaction styles to their users.

Introduction

Background

The interaction between patients and physicians is recognized as a critical success factor for treatment satisfaction, adherence, and subsequent treatment outcomes [1,2]. Its importance has been shown in face-to-face encounters between patients and physicians and in distance therapy via, for example, phone or internet [3,4]. A previous study [5] has differentiated between 4 distinct interaction styles between patients and physicians: paternalistic, informative, interpretative, and deliberative interaction styles. The paternalistic interaction style is characterized by physicians acting as “guardian” [5] of patients and paternally making decisions grounded in the assumption of objective and shared values between them and their patients. Although applying the informative interaction style, physicians act as “competent technical expert” [5], passing on information to their patients who ultimately have decision control based on their personal values. Within the interpretative interaction style, patients are confronted with medical information but are unsure about how to deal with them. Here, physicians act as a “counsellor or advisor” [5], helping patients to make their decision based on better self-understanding. Finally, physicians act as a “teacher or friend” [5] while engaging in a deliberative interaction style. They present medical information, promote particular health-related values, and conjointly discuss the best way forward together with their patients. This style can also be described as shared decision making and is advocated by contemporary medical research [6]. Especially while addressing patient autonomy in chronic care, a deliberative patient-physician interaction is thought to activate patients’ intrinsic values and goals better than any other interaction style and is, therefore, believed to be preferable [7].

However, such shared decision making is not always possible or even desired by patients. For example, patients seem to prefer paternalistic interactions in acute care conditions, especially when they have low health literacy or are emotionally overburdened by the situation [8]. Recent works have also shown that older people [9,10], men [9,10], less educated patients [10], patients with physical problems, and patients with severe exacerbation of their condition [11,12] prefer paternalistic interactions with their physicians. In addition, personal preferences for a preferred interaction style can change over time [13].

The personalization of physician-patient interactions thus seems to be appropriate while aiming at optimally adapting to the needs of the patients. This holds special importance in the context of chronic diseases, where patients have to deal with their condition for a prolonged period, experience functional limitations, require ongoing medical support, and often undergo several exacerbations of their condition [14-16]. In addition to continuing treatment and medical supervision of such chronic conditions, which pose an increasingly higher risk to the world population and are an enormous financial burden for global health care systems [17], it is important to engage in active disease management. Effective disease management includes educational measures, behavior modification, and psychological support [18] and can minimize overall harm and long-term effects of chronic conditions as well as confine exacerbation risks [19]. However, disease management is labor intensive, time-consuming, and costly for trained medical staff [20-23].

Against this background, emerging digital health tools such as conversational agents (CAs) offer hope in supporting patients’ self-management of their conditions. CAs are software programs that imitate natural interactions with human users by engaging in a human-like text-based and/or voice-enabled dialog [24,25]. Recent research has shown the ability of CAs to positively affect patient satisfaction [26], therapeutic alliance [27,28], and health-related outcomes [29,30]. Moreover, an overall acceptability has been established in various populations [31]. As scalable and ubiquitous digital tools, CAs facilitate personalized disease management outside the traditional health care system. Relevant aspects for developing personalized CAs, such as the required level of anthropomorphic appearance [32] or necessary design features [33], have been extensively investigated. However, to date, there has been no investigation of different interaction styles between patients and health care professionals where CAs play the role of medical experts. As mentioned above, these several forms of patient-physician interaction styles exert a significant effect on treatment success. We thus assume that appropriate interaction styles are also indispensable for patient-CA interactions. As a first step for developing personalized CAs that can adapt to the needs of the patient at hand and even adjust to changing individual preferences over time, it is essential to first develop and validate a systematic approach to develop and induce several interaction styles into patient-CA interactions.

Objectives

To this end, the objectives of this study were to (1) create and present a systematic approach to develop and induce specific interaction styles specifically for health care CAs and (2) validate whether individuals can correctly differentiate between the induced interaction styles. Our overarching research question for this paper is as follows: are humans capable of correctly identifying and labeling either an induced deliberative or paternalistic interaction style while interacting with a health care CA?

Methods

Development of CAs

In a 3-step process, we have developed a comprehensive mechanism to induce a deliberative and paternalistic interaction style into a CA interaction. These 3 steps are (1) development of the 2 interaction styles in the form of interaction items and a corresponding measurement scale, (2) scripting of CAs based on developed interaction styles, and (3) validation of the developed CAs in a web-based experiment.

We decided to induce deliberative and paternalistic interaction styles [5] as they are the 2 endpoints of a patient's autonomy spectrum [34]. Here, by means of education, patient autonomy and mutual trust increase from the paternalistic to the deliberative interaction style. Patient autonomy is understood as the ability to accept one's treatment preferences or to change to higher-order preferences through deliberation [34].

We first compiled an initial list of 28 communication components (Multimedia Appendix 1 [1,35-39]) that we adopted from the communication behaviors established by the Roter Interaction Analysis System (RIAS) [35]. The RIAS is a widely applied communication coding scheme for medical dialogs and assigns recorded verbal utterances to distinct categories [35]. Communication components combine communication clusters with communication categories to specify an explicit utterance in a dialog. To illustrate, consider the communication component "Therapeutic regimen_closed-ended question." It combines the communication cluster "Therapeutic regimen" with the communication category "closed-ended question" and denotes a remark by the physician about a patient's therapeutic regimen, posed as a closed-ended question. All communication components are described from the physician's point of view. On the basis of the related scientific literature [1,36,40-42], we assigned frequency levels (high or low) that are characteristic of a deliberative and paternalistic interaction style to each of the 28 communication components in the next step. For example, we allocated a high-frequency level of the communication component "Medical condition_Open-ended question" to the deliberative interaction style and a low frequency to the paternalistic one. Three health care practitioners of a European University Hospital have close experience with and exposure to both teaching and various medical communication techniques. They were thus qualified to review and endorse the authors' work.

To refine our proposed approach and improve its practicability, we aimed at reducing the total number of communication components. First, we excluded 6 communication components with identical frequency assignments for both the deliberative and paternalistic interaction styles, as they did not yield exclusive information on any of the 2 interaction strategies. An example would be "Biomedical information_About medical condition," where frequency levels were high for both the interaction styles. This initial triage resulted in a total of 22 remaining communication components. On the basis of our theoretical knowledge, we selected a binary choice between including and not including 15 of these components that seemed most relevant to distinguish between paternalistic and deliberative patient-physician-interactions. To triangulate our item selection and minimize the risk of bias, we asked 2 junior medical doctors with work experience less than 5 years since graduation and 2 experienced medical practitioners with more than 20 years of work experience to identify the 15 components they felt were the most relevant to differentiate between the 2 interaction styles. We deliberately chose to incorporate junior physicians because they are trained in the currently advocated deliberative interaction style and senior physicians because they are still familiar with the traditional paternalistic interaction style. The 4 physicians had different medical specializations. This approach allowed us to include both theoretical and practical perspectives while reducing the risk of bias in the item reduction process. To determine the intersecting set of communication components, we calculated the inter-rater reliability (IRR) across all the communication components [43]. Following this approach, we ensured the highest objectivity in the selection process. Consistent with a previous work [43], we chose 80% as the cut-off rate for the inclusion of an item. The evaluation ratings can be found in Multimedia Appendix 2. The final list resulted in 10 communication components, as listed in Table 1 (with example statements detailing the communication components) with their respective frequency measures for the 2 interaction styles. Among the final choices of the 10 communication components, 7 showed an IRR of 100%. Hence, all the 6 raters (ie, the main authors, TS and CG, and the 4 medical practitioners) selected these components to be the most relevant to differentiate between the 2 interaction styles.

Table 1. A final list of communication components.

ID	Communication component	Communication frequency		Example statement
		Paternalism	Deliberative	
CC1	Medical condition_open-ended question	Low	High	What can you tell me about the pain? [35]
CC2	Therapeutic regimen_open-ended question	Low	High	How are your symptoms developing since you take the new pills? (developed by authors, adapted from the studies by Ong et al, 1995; Cavaco and Roter, 2010; Roter et al, 1997; and Cegala, 1997 [1,35-37])
CC3	Therapeutic regimen_closed-ended question	High	Low	Did you reduce your cigarette consumption to max. 10 cigarettes/day as discussed? (developed by authors, adapted from the studies by Ong et al, 1995; Cavaco and Roter, 2010; Roter et al, 1997; and Cegala, 1997 [1,35-37])
CC4	Psychosocial Exchange about problems of daily living, issues about social relations, feelings, emotions	Low	High	It is important to talk about your worries regarding your condition (developed by authors, adapted from the studies by Ong et al, 1995; Cavaco and Roter, 2010; Roter et al, 1997; and Cegala, 1997 [1,35-37])
CC5	Emotional Talk_Reassurance/Optimism	Low	High	Your arm will feel better soon, no worries! (developed by authors, adapted from the studies by Ong et al, 1995; Cavaco and Roter, 2010; Roter et al, 1997; and Cegala, 1997 [1,35-37])
CC6	Emotional Talk_Empathy	Low	High	I can see how worried you are from hearing these results of your lung test. (developed by authors, adapted from the studies by Ong et al, 1995; Cavaco and Roter, 2010; Roter et al, 1997; and Cegala, 1997 [1,35-37])
CC7	Emotional Talk_Partnership	Low	High	We'll get through this together [35]
CC8	Partnering and activation_Asking for patient opinion	Low	High	Do you want to bring your husband to the next session? (developed by authors, adapted from the studies by Ong et al, 1995; Cavaco and Roter, 2010; Roter et al, 1997; and Cegala, 1997 [1,35-37])
CC9	Partnering and activation_Asking for understanding	Low	High	Can you follow all my instructions? (developed by authors, adapted from the studies by Ong et al, 1995; Cavaco and Roter, 2010; Roter et al, 1997; and Cegala, 1997 [1,35-37])
CC10	Partnering and activation_Paraphrase and interpretation	Low	High	Ok, let me summarize what you told me about your symptoms; so you cough every night at least five times, you have constant pain in the left leg (developed by authors, adapted from the studies by Ong et al, 1995; Cavaco and Roter, 2010; Roter et al, 1997; and Cegala, 1997 [1,35-37])

The next step is dedicated to scripting the 2 CA interventions designed for patients with chronic obstructive pulmonary disease (COPD). We focused on COPD as a chronic condition, as the number of people affected by COPD continues to rise inexorably on a global scale, hence causing hardships among the affected and a tremendous financial burden on health care systems [44]. We based the content of the CA dialog on the teaching workbooks of "Living well with COPD," an evidence-based disease-specific self-management program originally developed at the Montreal Chest Institute in collaboration with the Respiratory Health Network of the Fonds de la Recherche en Santé du Quebec and Boehringer Ingelheim [45]. We decided to model the first day of this hypothetical patient-CA intervention as it incorporates relevant interaction categories (eg, introduction and patient education) of a comprehensive disease management intervention. In a two-step process, we first scripted a base-case CA interaction whose interaction style was as neutral as possible. In the second step, we followed our systematically developed specifications of communication components and corresponding frequency-level characteristics for the 2 interaction styles to develop 2 distinct CA scripts. This means that we reverse-engineered the labeling process of utterances depicted in the RIAS methodology to induce either a paternalistic or a deliberative interaction style into the base-case intervention, that is, editing, adding, or deleting separate sentences, parts of sentences, or terms to differentiate the frequency of communication items of the base-case CA interaction. We ensured that both the scripts were approximately of the same length, with 38 conversational turns (with 96 individual messages) in the deliberative and 32 (with 85 individual messages) in the paternalistic version. The 2 scripts differed in 40 instances, whereas this number included differences in the level of a single word as the smallest adjustable part of a sentence. These discrepancies are caused by the characteristics of the 2 interaction styles, and these discrepancies are to ensure the realism of the conversation flow. For instance, we defined that a deliberative interaction style has a high frequency of emotional talk around a partnership. In one of the first conversational turns, we thus scripted “Okay. Understood, then we are ready to start.” as a potential possibility of an answer in the deliberative script versus solely “Okay. Understood.” in the paternalistic script. The conversation tree had only one level of branch points and was then reverted to the main conversational flow. The average overall reading duration was 13.5 min for the deliberative and 12 min for the paternalistic version. The scripts were written in German. The 2 intervention variations were then presented to senior medical experts working in the pulmonary division of a European University Hospital, who assessed and confirmed realism. Excerpts of the scripts are shown and discussed in the Results section, and the complete scripts can be found in Multimedia Appendix 3. The intervention was purely text based without any visual or spoken cues to reduce any bias toward visual CA design features, such as gender, age, or visual appearance [33,46]. Hence, we named the CA Robo, a gender-neutral name.

Validation of CAs’ Interaction Styles

In the second phase, we validated the interaction styles and assessed whether participants engaging with 1 of the 2 CAs could identify the correct interaction style.

Experimental Design and Procedure

We conducted a closed, between-subjects web-based experiment, in which the participants were randomly prompted to engage with a CA that follows either a deliberative or paternalistic interaction style. Following the Checklist for Reporting of Results of Internet E-Surveys [47], we report on the design, procedure, and results of this experiment. Qualtrics software (Qualtrics XM), a software- and web-based survey and data collection platform, was used to design the experiment and to randomly assign participants to 1 of the 2 CAs. Collect.chat, a commercially available chatbot software, was used to develop chatbot dialogs. The CA was integrated into the Qualtrics HTML using an iframe. Before starting the web-based experiment, we tested its usability and technical functionality. The experiment was conducted between March 27 and April 11, 2020. The questionnaire comprised a total of 35 questions distributed over 8 pages (between 1 and 17 items per page). The respondents were not able to review and change their answers.

The experimental procedure was set up as follows: first, we informed the participants about the structure and length of the survey, its potential risks and confidentiality, data protection, and possible uses of the data. We also provided contact details of the investigators in the case of questions and comments. After receiving informed consent, we checked the participation conditions, such as being aged above 18 years and speakers of German language. We then queried a set of sociodemographic questions (age, gender, mother tongue, and education). Second, the participants were presented with a short and easy-to-comprehend scenario description that depicted the day of a patient with COPD who started using a CA (for details, refer to Multimedia Appendix 4), an established approach in health care for the investigation of specific aspects in a medical context [48,49]. The scenario prompted participants to put themselves in the position of a patient with COPD to be able to relate to the subsequent interaction with the CA [50,51]—a targeted health outcome was not included. We ensured that the necessary heterogeneity of participants was much better than that with a limited set of patients who are often homogeneous on the key characteristics such as age due to their shared medical condition (eg, COPD becomes clinically noticeable only from the age of 40-50 years [52]) by applying a scenario description with healthy participants instead of conducting the experiment with actual patients. Third, after presenting the scenario, the interaction with the CA started, which we embedded in a separate, dedicated page of the survey. The interaction was purely text based and comprised a prescripted dialog based on the 2 developed scripts, that is, one for the paternalistic and another for the deliberative interaction style. Participants chose between 1 to 3 predefined answer options. They interacted with the respective CA on their individual pace, with no supervision or guidance from the researchers. Fourth, after the interaction, the participants answered questions about the interaction style. Here, the participants were asked to choose which of the following 2 statements better described their perception of Robo’s interaction style with them: (1) Robo decides paternally, based on objective principles, or (2) Robo and I discuss and decide together. The former refers to a paternalistic, whereas the latter to a deliberative interaction style.

Participants

A priori power analysis was conducted using the R package (version 3.5.2) power analysis [53]. To identify a medium effect (r=0.30) in a chi-square test of independence at an α level of .05 and statistical power of 0.80, a total of 88 participants were required. Inclusion criteria of this study are as follows: participants had to be of aged above 18 years and German-speaking. The participants were recruited via email and social media through an anonymous link. The participants who were invited to participate in this study were from the authors’ academic institutions, networks, and cooperating partners, and participation was entirely voluntary, with no incentives offered. We intended to actively drive heterogeneity in the sample to ensure external validity. We recruited a total of 112 participants. Of these 112 participants, 24 did not complete the questionnaire and were thus excluded. Thus, the final sample comprised 88 persons (42/88, 48% female, mean age 31.5 years, SD 10.1 years), resulting in a completion rate of 79%. Table 2 shows an overview of the demographics of the participants. On average, the participants needed 29 min for the whole experiment, including the questionnaire and the CA interaction.

Table 2. Demographic characteristics of participants (n=88).

Characteristic	Value
Age in years, mean (SD)	31.5 (10.1)
Gender (female), n (%)	42 (48)
Education, n (%)	
<High school	15 (17)
High school	9 (10)
University degree	64 (73)

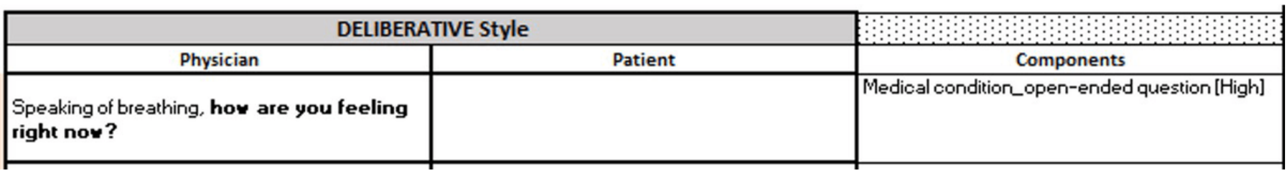
Data Analysis

To test whether the participants correctly identified the interaction type of the CAs, we applied a chi-square test of independence for a 2×2 contingency table and calculated the related phi coefficient using the statistical software R (version 3.5.2). The phi coefficient is a measure of the strength of the association between 2 binary variables. If it is positive, that is, the 2 variables are positively associated, then most of the data fall along the diagonal cells. To acknowledge the validation of the CAs as successful, we set 2 criteria based on the previous literature: (1) a significant chi-square test statistic with at least 80% of participants correctly identifying their assigned respective CA in each condition [43] and (2) a positive phi coefficient of at least a medium effect size ($r_\phi \geq 0.30$) [54].

Results

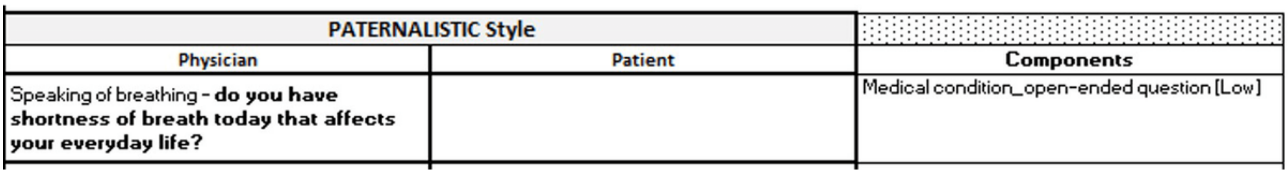
The results of the development of the deliberative and paternalistic interaction styles are presented in this section, whereas the development process of the interaction styles themselves is described in the Methods section. The described process resulted in 2 written scripts that were used for scripting the paternalistic and deliberative versions of the CA Robo. The scripts further included the answer options of the participants, the underlying communication items, and the applied communication frequency for each utterance. Figures 1 and 2 show an example of how the different interaction styles were induced into the CA script. The scripts were initially developed in German. This conversation has been translated into English by the authors for this study.

Figure 1. An example of the developed script for the deliberative version of the conversational agent (CA) Robo is shown here. The column labeled “Components” depicts the applied communication item and its respective communication frequency for the respective interaction style. The column labeled “Physician” describes what the CA Robo says, whereas the column “Patient” shows the reply options of the participant.



DELIBERATIVE Style		
Physician	Patient	Components
Speaking of breathing, **how are you feeling right now?**		Medical condition_open-ended question [High]

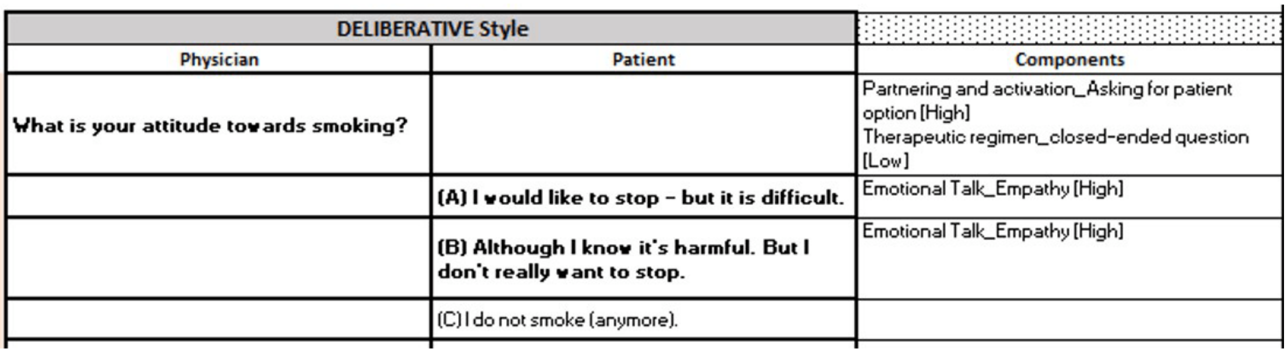
Figure 2. An example of the developed script for the paternalistic version of the conversational agent (CA) Robo is shown here. The column labeled “Components” depicts the applied communication item and its respective communication frequency for the respective interaction style. The column labeled “Physician” describes what the CA Robo says, whereas the column “Patient” shows the reply options of the participant.



PATERNALISTIC Style		
Physician	Patient	**Components**
Speaking of breathing - **do you have shortness of breath today that affects your everyday life?**		Medical condition_open-ended question [Low]

Figures 3 and 4 show an example of the interaction style scripts where the answers of the patients needed to deviate between the 2 interaction styles. This is because the interaction would have felt artificial when the same answer options would have been used for both the interaction styles.

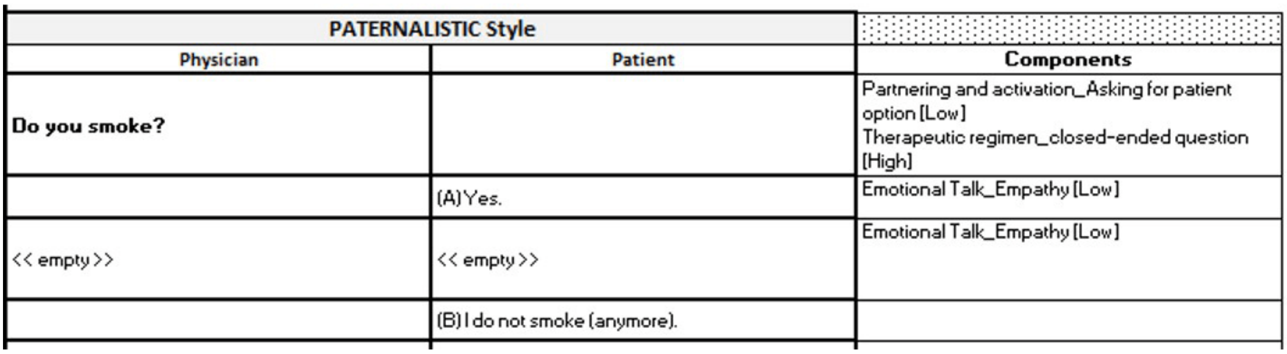
Figure 3. An example of the developed script for the deliberative version of the conversational agent Robo is shown here. Here, the answer options for patients, as depicted in the column "Patient," deviated between the 2 conditions.



DELIBERATIVE Style		
Physician	**Patient**	**Components**
What is your attitude towards smoking?		Partnering and activation_Asking for patient option [High] Therapeutic regimen_closed-ended question [Low]
	(A) I would like to stop – but it is difficult.	Emotional Talk_Empathy [High]
	(B) Although I know it's harmful. But I don't really want to stop.	Emotional Talk_Empathy [High]
	(C) I do not smoke (anymore).	

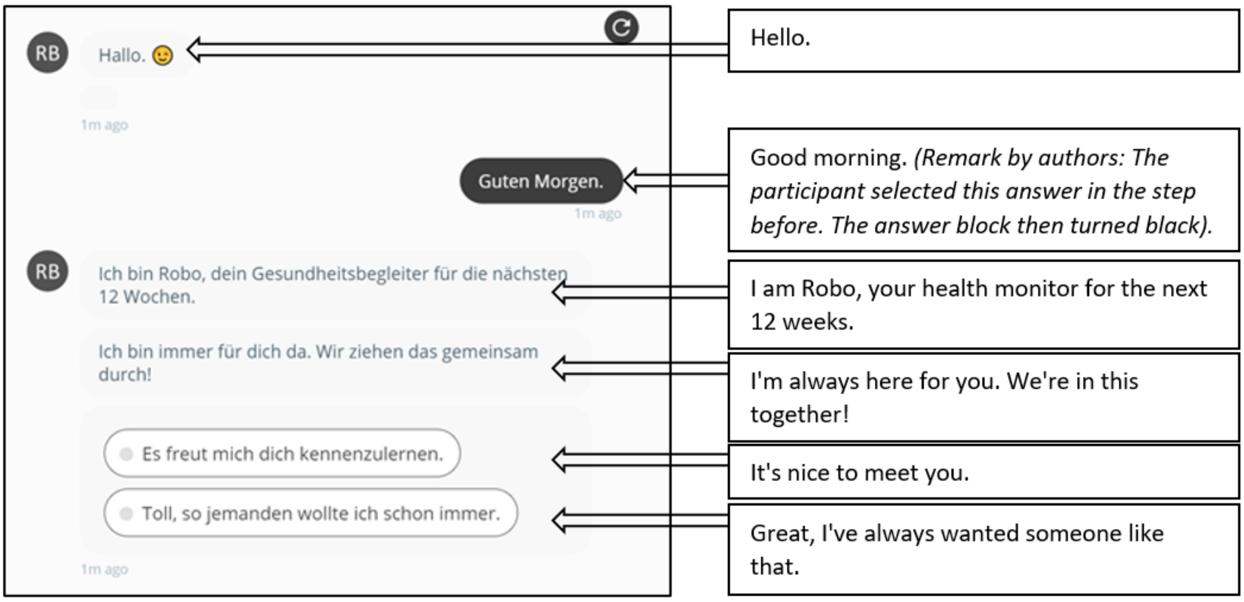
The developed scripts were implemented into the technical CA environment. In the web-based experiment, the participants could only see the utterances of the CA Robo (noted in the column "Physician" of Figures 1-4) and their possible answer options (noted in the column "Patient" of Figures 1-4). Figure 5 shows an exemplary conversational turn between a participant and the CA Robo as implemented in the web-based experiment.

Figure 4. An example of the developed script for the paternalistic version of the conversational agent Robo is shown here. Here, the answer options for the patients, as depicted in the column "Patient," deviated between the 2 conditions.



PATERNALISTIC Style		
Physician	**Patient**	**Components**
Do you smoke?		Partnering and activation_Asking for patient option [Low] Therapeutic regimen_closed-ended question [High]
	(A) Yes.	Emotional Talk_Empathy [Low]
<< empty >>	<< empty >>	Emotional Talk_Empathy [Low]
	(B) I do not smoke (anymore).	

Figure 5. An exemplary conversation snapshot between the conversational agent Robo and a participant. This figure depicts the start of the interaction, here applying the deliberative interaction style. The interaction was conducted in German; the authors added the English translations in the callouts for this study.



RB Hallo. 😊

1m ago

Guten Morgen.

1m ago

RB Ich bin Robo, dein Gesundheitsbegleiter für die nächsten 12 Wochen.

Ich bin immer für dich da. Wir ziehen das gemeinsam durch!

○ Es freut mich dich kennenzulernen.

○ Toll, so jemanden wollte ich schon immer.

1m ago

Hello.

Good morning. *(Remark by authors: The participant selected this answer in the step before. The answer block then turned black).*

I am Robo, your health monitor for the next 12 weeks.

I'm always here for you. We're in this together!

It's nice to meet you.

Great, I've always wanted someone like that.

We describe the results of the web-based experiment in the following section. On the basis of a 2×2 contingency table, a chi-square test of independence was performed to examine the relationship between the randomly assigned CA type and the correct identification of CA type by the participants (Table 3). The relationship between these variables was significant ($X^2_{1,88}$=38.2; P<.001), thereby indicating unequal frequency distributions between the cells. The associated phi coefficient of correlation was r_ϕ=0.68, corresponding to a large effect size [54]. Participants in both the paternalistic and deliberative conditions correctly identified their respective CA type more than 80% of the time: the probability of recognizing the paternalistic interaction style when it was, in fact, paternalistic was 37/(37+7)=84%. The same was true for the deliberative condition. Thus, based on the previously defined set of criteria (significant results of the chi-square test, 80% of participants correctly identified the respective CA in each condition, and phi coefficient $r_\phi \geq 0.30$), the validation of the interaction styles was successful.

Table 3. Contingency table of assigned and identified conversational agent interaction styles[a].

Identified by participants	Random assignment	
	P[b]	D[c]
P[b]	37	7
D[c]	7	37
	37/(37+7)=0.84	37/(37+7)=0.84

[a] 2x2 contingency table. The performance of 2 developed conversational agents was assessed by comparing the categories randomly assigned to participants by the experimenters with participants' own perception which category the assigned conversational agent belonged to. The type of conversational agent assigned by the experimenters is designated as paternalistic (P) or deliberative (D) and is listed above the 2x2 table.

[b] P: paternalistic.

[c] D: deliberative.

Discussion

Principal Findings

We developed an approach to induce deliberative and paternalistic interaction styles into a purely text-based patient-CA conversation [5]. It was developed for chronic health care applications against the background of the high relevance of chronic diseases and the patients' support potential of CAs. To our knowledge, this is the first attempt to develop and evaluate 2 different interaction styles for the interaction between a CA and a human user in a chronic health care context. This study successfully proves that humans can correctly identify and label an induced interaction style under experimental conditions. When randomly assigned, participants in both the paternalistic and deliberative experimental conditions correctly identified the interaction style in more than 80% of the cases. The procedure is based on modifying the frequency of communication items that are adopted from human-human medical interactions. Although we focused on the deliberative and paternalistic interaction styles, we expect the underlying methodology to be also applicable for inducing other interaction styles.

In the context of chronic diseases, a rising number of medical interventions is already based on the application of CAs [24,28,30,55-57]. However, studies investigating the interaction styles between humans and CAs are still scarce. Examples include a range of applications from health care to real estate and implicitly assume a default interaction between the agent and user [58-60]. In our opinion, this assumption of a standardized human-agent interaction disregards patients' preferences of different interaction styles as derived from human-human interactions. We addressed this shortcoming with our study; our approach allows the repeated and independent development of any patient-agent medical conversation with a deliberative and paternalistic interaction style. We therefore enable other researchers to develop and test these interaction styles in different health care contexts. This is the first but important building block to develop personalized CAs by better understanding and investigating which interaction styles offered by CAs are relevant in which health care situations (eg, acute vs chronic care situations or disease-specific situations), for which patient group (eg, for patient segmentation), and at which stage in the course of the disease and diseases-related dynamics (high- vs low-pain situations). By considering these additional factors in future work, we assume that the effectiveness of CAs can be further increased by deploying more personalized CA-based conversations that fit the specific medical context and the patient situation at hand.

As indicated above, the quality and effectiveness of the interaction between patients and physicians has already been established as decisive for treatment outcomes in human-human medical encounters [61,62]. This patient-physician interaction is acknowledged as a dynamic process in which personal preferences for the most effective communication can change over time [61,63]. Skilled physicians can adapt their interaction style to each patient and his or her situation, thereby improving the treatment outcome [63]. Until now, such dynamic and individual adaption of patient-physician interactions can only be realized within a human-human context. However, it would be beneficial to have digitized solutions that are capable of the same dynamic alterations in the form of adaptive CAs for providing on-demand individualized medical support. Such solutions would yield hope for increased treatment adherence and subsequently improved medical outcomes, especially within the context of chronic diseases that often require prolonged medical oversight and support. The first part of developing such dynamic interactive CAs is to build their ability to provide more than one interaction style for communication with human users. In this paper, we provided this first stage by showing that 2 different interaction styles can be successfully developed, implemented into a CA-patient communication, and correctly identified and labeled by humans in the context of chronic disease health care.

Strengths and Limitations

This study has several strengths. By adapting the RIAS [35], a validated and widely used coding scheme for medical dialogs, we ensured an objective approach to identify the key communication items that induce the interaction styles. We detailed and refined the procedure by integrating the knowledge of novice and experienced medical experts, thereby ensuring a broad range of expertise in terms of patient-physician interaction behavior taught in medical school as well as practical experience with patients. We further measured the IRR to objectively calculate the agreement between the experts and our assessment and to select the most important items. Moreover, we tested the developed scripts with additional medical experts before scripting the CAs used in the web-based experiment.

A limitation of this study is that participants were all German-speaking and based in Switzerland, Germany, and Austria. Other languages might have different requirements regarding essential communication items for representing a deliberative and paternalistic interaction style. Cultural differences with respect to power distance, individualism, and uncertainty avoidance, as analyzed by Hofstede [64], might also play a significant role. Another limitation is the focus on one specific chronic condition. Although we consider our methodology sufficient to model medical conversations for other disease conditions, we only tested it in the context of COPD. Patients with other conditions—acute or chronic—might have other demands for their interaction with a digital CA. In addition, the CA in our experiment was rule based with prescripted answer possibilities. Although this was necessary to control the experimental conditions between the 2 interaction conditions, there is a rising number of artificial intelligence (AI)–based CAs for health care apps. These agents do not rely on prescripted conversations but often allow for natural interaction using unconstrained written, spoken, or visual input [24,25,56]. The applicability of our procedure for AI-based agents should be evaluated in future research.

Suggestions for Future Research

In general, we advise future research in the field of digital health care to put a stronger focus on the consideration of different interaction styles between human users and CAs. We propose that such CAs are based on our approach for inducing either a paternalistic or deliberative interaction style. It still must be determined which of the 2 interaction styles is the best situational fit for an individual engaging with a CA. In the following step, dynamic CAs can adapt their interaction style to both the personal and situational circumstances of individual users, much like human physicians are already able to do [61,63]. We suggest evaluating the implementation of human-agent interaction styles in different medical contexts, such as various acute and chronic conditions, as well as with different health care goals such as diagnosis, treatment, or patient education.

Furthermore, CAs with varying interaction styles should be developed in various languages and in different cultures. This would allow the investigation of the role of language and culture in interaction preferences. In addition, there might be more than the described 2 interaction styles that are of interest in the medical context. For example, Emanuel and Emanuel [5] also described an informative and interpretative interaction style. These could also be adapted for and integrated into CAs to develop a broader range of options for patient-CA interactions, for example, in the context of the information about invasive examination or interventions.

Moreover, we only modeled and tested the first day of an interaction between a patient and a CA. It would be interesting to see the effect of longer interventions. This is especially relevant for chronic conditions, as they require ongoing treatment and accompanying digital interventions for potentially the entire treatment period.

Furthermore, we suggest the implementation of our approach to the architecture of an AI-based CA to evaluate its applicability for this type of technology. Finally, because our CA was purely text based, it would be interesting to see what role other communication forms such as visualizations, embodiment, or spoken interaction play for the induction of particular interaction styles.

Conflicts of Interest

FvW co-chairs the Center for Digital Health Interventions (CDHI), a joint initiative between the Department of Management, Technology and Economics at Eidgenössische Technische Hochschule Zürich and the Institute of Technology Management at the University of St. Gallen, which is funded in part by the Swiss health insurer CSS. TK is the Scientific Director of the CDHI. He is also a co-founder of Pathmate Technologies, a university spin-off company that delivers digital clinical pathways with the help of CAs. However, Pathmate Technologies is not involved in the study described in this paper. CG, TS, and AH report no conflicts of interest.

Abstract

Background: The increasing incidence of inflammatory bowel disease (IBD) has imposed heavy financial burdens for Chinese patients; however, data about their financial status and access to health care are still lacking. This information is important for informing patients with IBD about disease treatment budgets and health care strategies.

Objective: The aim of this study was to evaluate the economic status and medical care access of patients with IBD through the China Crohn's & Colitis Foundation web-based platform in China.

Methods: Our study was performed in 14 IBD centers in mainland China between 2018 and 2019 through WeChat. Participants were asked to complete a 64-item web-based questionnaire. Data were collected by the Wenjuanxing survey program. We mainly focused on income and insurance status, medical costs, and access to health care providers. Respondents were stratified by income and the associations of income with medical costs and emergency visit times were analyzed.

Results: In this study, 3000 patients with IBD, that is, 1922 patients with Crohn disease, 973 patients with ulcerative colitis, and 105 patients with undetermined colitis were included. During the last 12 months, the mean (SD) direct and indirect costs for per patient with IBD were approximately US $11,668.68 ($7944.44) and US $74.90 ($253.60) in China. The average reimbursement ratios for most outpatient and inpatient costs were less than 50%. However, the income of 85.5% (2565/3000) of the patients was less than ¥10,000 (US $1445) per month. Approximately 96.5% (2894/3000) of the patients were covered by health insurance, but only 24.7% (741/3000) of the patients had private commercial insurance, which has higher imbursement ratios. Nearly 98.0% (2954/3000) of the patients worried about their financial situation. Thus, 79.7% (2392/3000) of the patients with IBD tried to save money for health care and even delayed their medical treatments. About half of the respondents (1282/3000, 42.7%) had no primary care provider, and 52.2% (1567/3000) of the patients had to visit the emergency room 1-4 times per year for the treatment of their IBD. Multivariate analysis revealed that lower income (P=.001) and higher transportation (P=.004) and accommodation costs (P=.001) were significantly associated with the increased number of emergency visits of the patients.

Conclusions: Chinese patients with IBD have enormous financial burdens and difficulties in accessing health care, which have increased their financial anxiety and inevitably influenced their disease outcomes. Early purchase of private insurance, thereby increasing the reimbursement ratio for medical expenses, and developing the use of telemedicine would be effective strategies for saving on health care costs.

Introduction

Inflammatory bowel disease (IBD) is a group of disorders that cause sections of the gastrointestinal tract to become inflamed and ulcerated. IBD imposes a significant impact on the quality of life through ongoing symptoms, including reduced ability to work, social stigma, and restriction in career choices. IBD causes a great burden globally because of the direct costs of care and the indirect costs associated with disability and missed work [1-4]. In the United States, IBD ranks as 1 of the 5 most expensive gastrointestinal disorders despite it being the lowest in prevalence in the list of gastrointestinal disorders [5]. The total financial burden of IBD in the United States was estimated to be US $14.6 billion to US $31.6 billion in 2014 [6]; however, recent data have indicated that the total costs may far exceed these earlier estimates [7]. In Canada, wherein the prevalence of IBD is one of the highest in the world, the economic cost for IBD was conservatively estimated to be over US $0.9 billion in 2018 [8]. In Europe, 2.5-3 million people have been estimated to be affected with IBD with a direct health care cost of 4.6-5.6 billion Euros/year [9]. However, the treatment for IBD is not curative. Clinical management aims at inducing and maintaining remission by using pharmaceutical agents and surgery, and evolving treatment guidelines advocate rapid scale-up to biological agents for improving health outcomes and quality of life. Consequently, the health care costs are driven by the increasing use of biological agents—most importantly by anti-tumor necrosis factor-α therapy [10]. In China, retrospective analysis has shown an increasing incidence of IBD; it is estimated that the IBD prevalence in China, which includes up to 11.6 ulcerative colitis cases per 100,000 person-years and 1.4 Crohn disease cases per 100,000 person-years [11,12], is the highest in Asia [13].

China is facing a growing burden with the increased use of health care resources, including outpatient visits, emergency room visits, hospital admissions, and surgeries [14]. Medical insurance policies vary widely among provinces in China. It is important to understand the financial burden and health care access of Chinese patients with IBD to measure treatment values and optimize health care policies. However, the collection of accurate epidemiologic data in China has been hampered by the lack of a nationwide IBD registry. One study from China in 2017 reported that 30.6% of the patients with IBD spent over half of their income to cover medical costs [15]. A retrospective cohort study in Hongkong reported that the total direct medical expenditure was US $7,072,710 for 435 patients with IBD, wherein hospitalizations (33%) and 5-aminosalicylic acid (23%) therapy accounted for the most part [16]. However, economic data and association between financial burden and health care access in mainland China are still lacking.

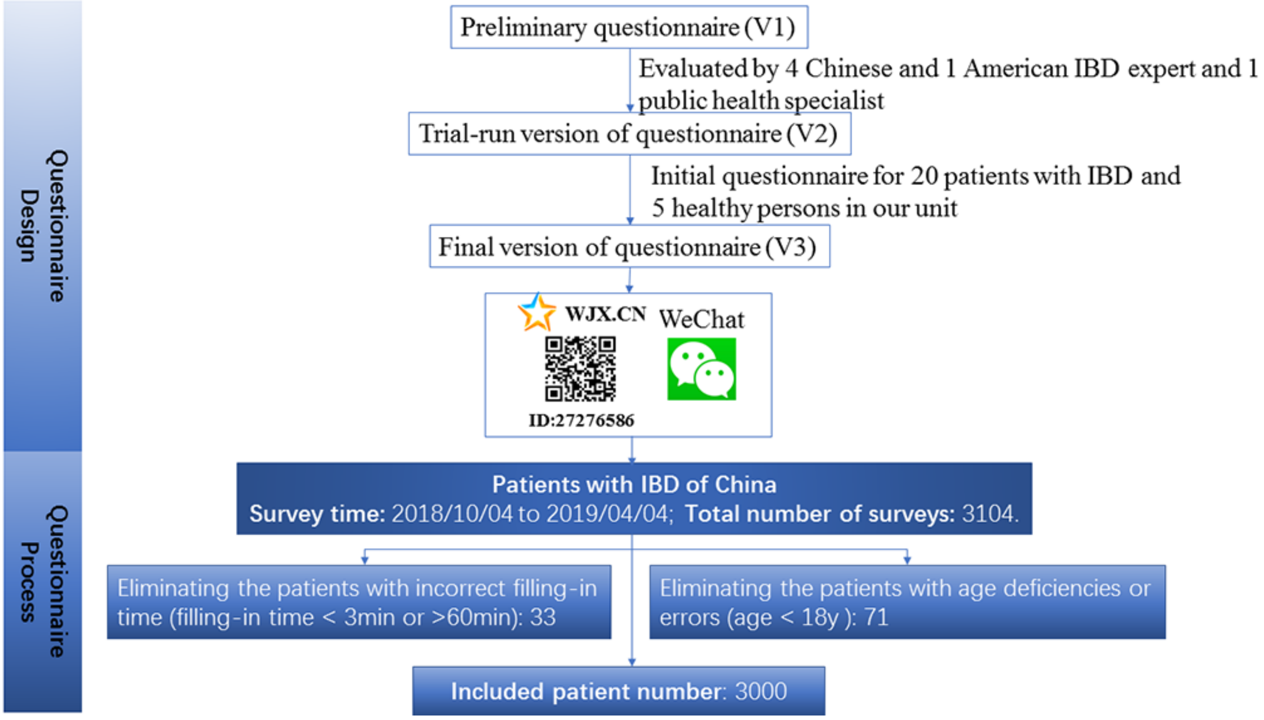
The China Crohn’s & Colitis Foundation (CCCF) serves as a nonprofit, volunteer-driven organization dedicated to improving the quality of life of patients with IBD in China [14]. With the support of the CCCF platform, we sought to provide a national snapshot of the current status of care for patients with IBD through electronic questionnaires in 14 IBD centers in mainland China. The contents of our survey focused on health care expenditures and insurance, access to care and therapies, affordability, and financial stress related to IBD.

Methods

Survey Development and Delivery

We used a 64-item questionnaire developed by Rubin et al [1], which was modified from the IBD questionnaire and guidelines for the comprehensive intervention of chronic diseases in China to assess the financial burdens and health care access of patients with IBD in China. Our questionnaire focused on topics, including respondent disease type, disease severity, disease duration, IBD-related treatment, access to provider care, employment and insurance status, income, and strategies for affording care. As shown in Figure 1, the questionnaire was evaluated and modified by CCCF doctors from 14 IBD centers in mainland China and was produced by Wenjuanxing [17], which is a free and open platform for survey design. We delivered the web-based survey from October 4, 2018 to April 4, 2019 through the CCCF’s WeChat public platform, which is a popular source for patient education about IBD in China [18]. The inclusion criteria were informed consent, older than 18 years, and diagnosed with Crohn disease, ulcerative colitis, or indeterminate colitis. The questionnaires without age information were excluded. This study was approved by the medical ethics committee of the Second Affiliated Hospital, School of Medicine of Zhejiang University (No. 314).

Figure 1. Flow chart depicting the selection of the survey sample for analysis.



Clinical Variables

Demographic variables included IBD type (Crohn disease, ulcerative colitis, or indeterminate colitis), marital and work status, education level, income, and insurance status. Direct costs in this study mainly included outpatient costs, hospitalization costs, biological agent costs, and surgery costs. As biological agent costs were partly repeated with hospitalization costs, it was not calculated into the direct costs here. Indirect costs were defined as nonprescription medications, transportation costs, accommodation costs, etc; however, we only calculated the transportation and accommodation costs in our study. The clinical variables of indirect costs included transportation and accommodation costs. Variables of health care access included emergency room visit frequency, hospitalization duration, and waiting time for hospitalization.

Statistical Analyses

Statistical analyses were conducted using SPSS software (version 25.0, IBM Corp). To estimate the average expenses, the mean and variance were calculated from the median value of the finite interval and the minimum value of the infinite interval. A binary logistic regression model was used to analyze the association between income or costs and variables of health care access.

Results

Population Characteristics

As shown in Figure 1, 3104 individuals from 14 IBD centers completed the questionnaire. Of those, 3000 respondents with a diagnosis of IBD were included for the analysis. Participants were eliminated from the data if they were younger than 18 years or did not provide age information (n=71) or if they completed the survey in less than 3 minutes or more than 60 minutes (n=33). The patients with IBD who completed the survey were distributed throughout all regions of mainland China. Most respondents were patients with Crohn disease (1922/3000, 64.1%), followed by those with ulcerative colitis (973/3000, 32.4%) or unclassified IBD (105/3000, 3.5%). Most respondents reported a disease duration of IBD of less than 5 years (2486/3000, 89.3%). The median age of the respondents was 34 years (range 18-73 years). Approximately 68.1% (2042/3000) of the patients were married (Table 1). The employment status of the patients with IBD was also assessed in our survey; 36.4% (1789/3000) of the patients had full-time work, 18.5% (555/3000) had part-time work, 6.9% (207/3000) were temporarily unemployed due to IBD, 20.7% (621/3000) were under the working age, 6.5% (196/3000) reported nonparticipation attributable to IBD, 6.7% (201/3000) were out of work, and 4.2% (127/3000) were retired.

[b] As identified by the patients.

Financial Burden of IBD

The financial burden of IBD includes the direct and indirect costs incurred by individuals and society beyond the health care system. In estimation, the mean (SD) direct and indirect costs for per patient with IBD per year were conservatively ¥80,743.73 (¥54,973.12) (US $11,668.68 [$7944.44]) and ¥518.27 (¥1754.85) (US $74.90 [$253.60]), respectively. As shown in Table 2, for total outpatient costs, 41.7% (1252/3000) of the respondents with IBD reported spending more than ¥20,000 (US $2890) during the last 12 months. However, 46.5% of the patients (1394/3000) had no reimbursement for the outpatient costs. With respect to inpatient costs, 69.3% (2080/3000) of the patients with IBD reported paying less than ¥50,000 (US $7226) for hospitalizations during the last 12 months, while 30.7% (920/3000) of them paid more than ¥50,000 (US $7226) for their hospitalizations. The proportion of reimbursement for the hospitalization costs was more than 50% for 54.6% (1171/2143) of the patients with IBD. Among all the respondents, only 26.6% (799/3000) of the patients with IBD received more than 3 infusions of biological agents per year. However, 61.7% (626/1014) of them covered the costs of the biological agents at their own expense without any reimbursement. Moreover, 23.6% (707/3000) of the patients with IBD reported experiencing at least one surgery throughout their disease duration.

Table 2. Health care costs for inflammatory bowel disease treatment during the last 12 months.

Type of health care costs, expenses and reimbursements	n (%), Value
Outpatient costs	
Total outpatient expenses[a] (n=3000)	
¥0-¥4999 (US $0-$722)	727 (24.3)
¥5000-¥9999 (US $723-$867)	474 (15.8)
¥10,000-¥19,999 (US $1445-$2890)	547 (18.2)
over ¥20,000 (≥US $2890)	1252 (41.7)
Proportion of reimbursement (n=3000)	
Unknown	53 (1.8)
0%	1394 (46.5)
1%-49%	743 (24.7)
50%-99%	801 (26.7)
100%	9 (0.3)
Hospitalization costs	
Total hospitalization expenses (n=3000)	
0	857 (28.6)
¥1-¥9999 (US $0-$1445)	268 (8.9)
¥10,000-¥49,999 (US $1445-$7226)	955 (31.8)
over ¥50,000 (≥US $7226)	920 (30.7)
Proportion of reimbursement (n=2143)	
0%	140 (6.5)
1%-49%	832 (38.9)
50%-99%	1169 (54.5)
100%	2 (0.1)
Biological agent costs	
Frequency of use of biological agents (times) (n=3000)	
0	2072 (69.1)
1-9	874 (29.1)
Over 10	54 (1.8)
Proportion of reimbursement (n=1014)	
All at one’s own expense	626 (61.7)
Partial reimbursement	378 (37.3)
Complete reimbursement	10 (1.0)
Surgery costs	
Surgery costs (n=707)	
¥0-¥10,000 (US $0-$1445)	122 (17.3)
¥10,001-¥20,000 (US $1445-$2890)	129 (18.2)
¥20,001-¥49,999 (US $2890-$7226)	162 (22.9)
over ¥50,000 (≥US $7226)	294 (41.6)
Proportion of reimbursement (n=707)	
0%	40 (5.7)
1%-49%	295 (41.8)
50%-99%	370 (52.3)

Type of health care costs, expenses and reimbursements	n (%), Value
100%	2 (0.3)

[a] US $1=¥6.9197.

The costs of the surgeries were more than ¥50,000 (US $7226) for 41.6% (294/707) of the patients, but only 52.3% (370/707) of these patients reported receiving reimbursements of over 50% during the last 12 months. Additionally, 76.4% (2292/3000) of the patients had dietitian costs, including nutrition powder, nutrition solutions, or a specific carbohydrate diet during the last 12 months. Most of them (1300/3000, 43.3%) reported paying less than ¥20,000 (US $2890) during the last 12 months. However, 56.3% (1290/2292) of those who had dietitian costs paid these costs at their own expense without any reimbursement. Of note, for those who underwent special treatments such as fecal bacteria transplantation and stem cell transplantation, 30.2% (152/475) of them reported receiving no reimbursement.

Health Care Access

We assessed the health care access of patients with IBD by mainly focusing on the health and life insurance, primary care providers, emergency room visits, and hospitalization utilization. The majority of the respondents (2894/3000, 96.5%) had regular medical insurance. However, 75.3% (2259/3000) of the respondents had no private commercial insurance; the reasons for patients being without private commercial insurance included that they had been refused coverage by an insurance company after their diagnosis of IBD (1399/2576, 54.3%), they had not thought about commercial insurance (741/2576, 28.8%), or they had not decided to buy it yet (647/2576, 25.1%) (Figure 2A). Approximately half of the respondents (1282/3000, 42.7%) had no primary care provider (Table 1). Of those who were identified with a primary care provider, 73.5% (1262/1718) of them had a gastroenterologist, 68.8% (1182/1718) had an IBD expert, 11.8% (203/1718) had an anorectal surgeon, 7.2% (123/1718) had a gynecologist, 2.7% (46/1718) had an abdominal surgeon, 1.0% (18/1718) had community physicians, and 0.6% (10/1718) had a family practitioner. Of note, some patients with IBD had more than one primary care provider. Moreover, 84.4% (2532/3000) of the patients with IBD were without IBD surgeons, and of the 15.6% (468/3000) of the patients with IBD who had IBD surgeons, only 60.9% (285/468) of their surgeons were considered full mastery. As shown in Table 3, we further assessed the experience of emergency room visits and found that 68.0% (2040/3000) of the total surveyed patients had visited an emergency room each year after IBD diagnosis: 52.2% (1567/3000) reported going to the emergency room 1 to 4 times per year and 15.8% (473/3000) reported going to the emergency room more than 5 times. Moreover, 74.8% (2243/3000) of the patients reported having experienced hospitalization, with 38.1% (1144/3000) of them reporting 1-3 occurrences, 31.5% (946/3000) reporting 4-10 occurrences, and 5.1% (153/3000) reporting more than 10 occurrences.

Figure 2. Analysis of the feelings of patients with inflammatory bowel disease (IBD) with regard to the health care and the associated costs. A. Reasons for patients with IBD to not have commercial insurance (n=3000). B. Reasons identified by patients with IBD for delaying health care (n=1389). C. Patients' anxiety about medical expenses (n=3000). D. How patients with IBD save money and delay care (n=3000).

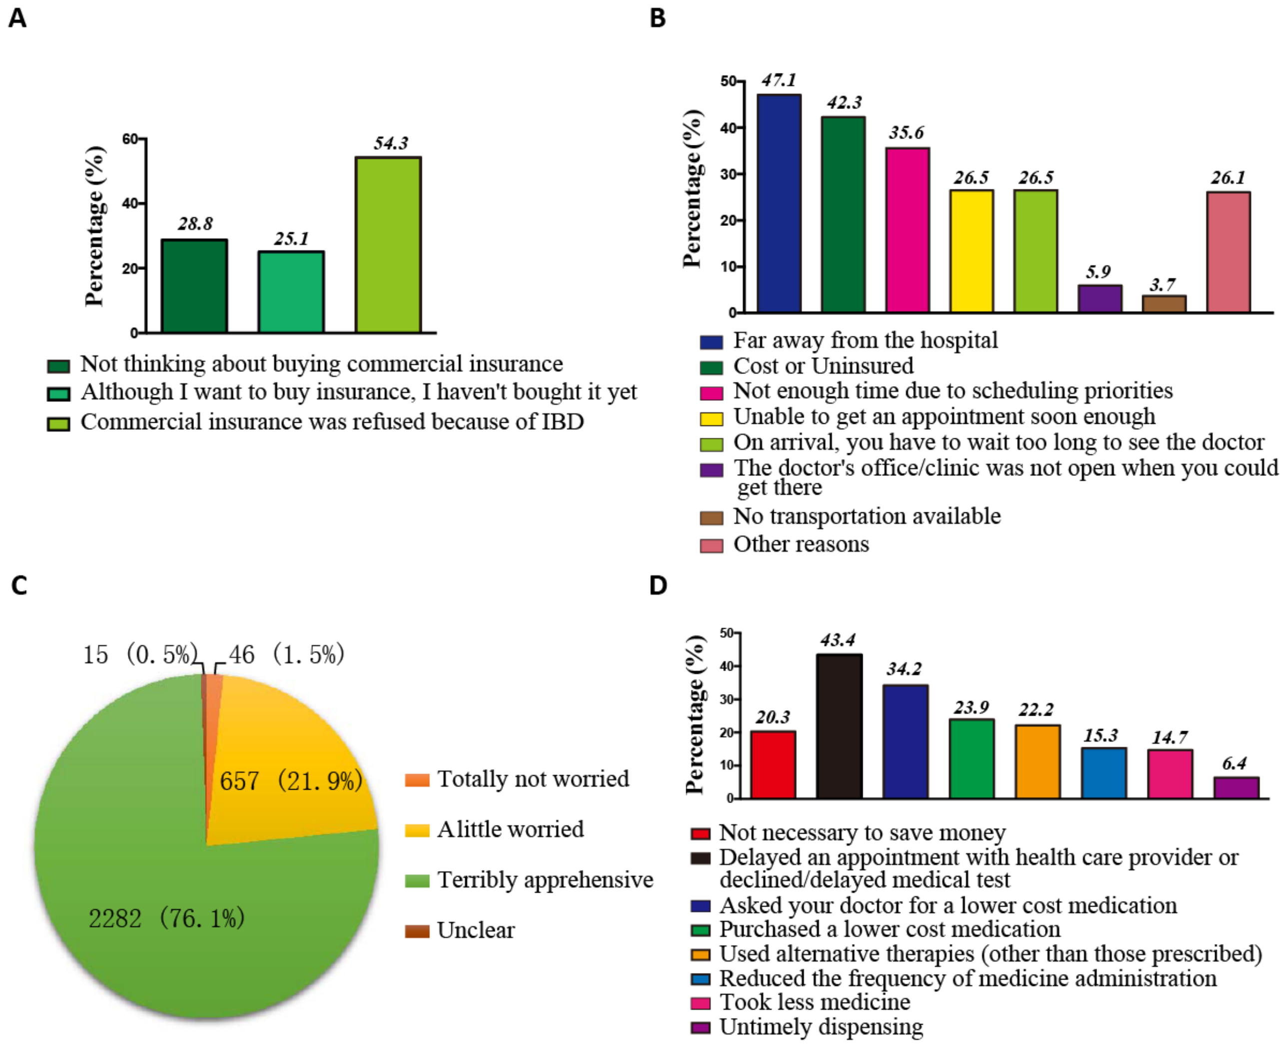

Table 3. Health care access of patients with inflammatory bowel disease (n=3000).

Health care access	n (%), Value
Average emergency visits per year after IBD[a]	
0	960 (32.0)
1-4 times	1567 (52.2)
Over 5 times	473 (15.8)
Hospitalization during last 12 months[b]	
0	757 (25.2)
1-3 times	1144 (38.1)
4-10 times	946 (31.5)
over 10 times	153 (5.1)
Average waiting time for hospitalization (days)	
1	443 (16.0)
2-7	1547 (55.9)
8-30	634 (22.9)
Over 30	143 (5.2)
Diagnosis and treatment of IBD in nearby medical institutions with nonspecialists in IBD treatment	
None	1411 (47.0)

Others	231 (7.7)

[a] IBD: inflammatory bowel disease.

[b] Injections of biological agents or their dispensing are all performed in the hospitals.

The optimal treatment of IBD requires specialized health care; however, patients might travel a long distance to obtain care for IBD, and a greater distance to the referral health care center was demonstrated to be associated with an increased risk of needing IBD-related surgery and outcomes [16]. As shown in Table 4, 42.2% (1266/3000) of the patients covered a distance of more than 100 km, and 73.2% (2197/3000) of the patients needed more than 1 hour to reach the closest IBD center. The transportation cost for 62.4% (1871/3000) of the patients to the nearest IBD center was more than ¥100 (US $14), and the accommodation cost for 75.4% (2262/3000) of the patients to the nearest IBD center was more than ¥100 (US $14). Consequently, 53.0% (1589/3000) of the patients with IBD reported going to nearby medical institutions without IBD specialists. As shown in Figure 2B, there were several reasons for patients to delay health care, including being far away from the hospital (654/1389, 47.1%), the cost or being uninsured (587/1389, 42.3%), not having enough time due to scheduling priorities (494/1389, 35.6%), being unable to get an appointment soon enough (368/1389, 26.5%), and having to wait too long to see the doctor after arrival (368/1389, 26.5%). When asked about how they felt about the financial cost (Figure 2C), 98.5% (2954/3000) of the patients with IBD were worried about the medical expenses. Nearly 79.7% (2392/3000) of the patients with IBD sought ways to save money for their health care. As shown in Figure 2D, 79.7% (2392/3000) of the IBD patients sought ways to save money for their health care. Almost 43.3% of the patients (1303/3000) delayed an appointment with a health care provider or declined/delayed medical tests, 34.2% of the patients (1026/3000) asked doctors for a lower cost medication, and 22.2% of the patients (667/3000) used alternative therapies (other than those prescribed), while 30% of the patients (900/3000) even reduced the administration frequency or dosage of their medicine or 6.4% of the patients (192/3000) engaged in the untimely dispensing of their medication.

Multifactor Analysis

We then focused on the influencing factors of emergency room visit times (Table 4). We found that patients with lower income (less than ¥5000 or US $723/month) were more likely to get into emergency rooms compared to patients with income more than ¥10,000 (US $1445) per month (odds ratio [OR] 1.947, 95% Cl 1.555-2.437; *P*<.001). Patients with lower transportation costs (¥0-¥99, US $0-$14) for visiting IBD specialists were less likely to visit emergency rooms compared to patients with higher transportation costs (>¥500, US $0-$72) (OR 0.622, 95% Cl 0.500-0.875; *P*=.004). Patients with ¥0-¥99 (US $0-$14) accommodation costs for visiting IBD specialists (OR 0.632, 95% Cl 0.494-0.810; *P*<.001) and ¥100-¥499 (US $14-$72) accommodation costs (OR 0.712, 95% Cl 0.584-0.866; *P*=.001) had less emergency room visit times than patients with >¥500 (US $72) accommodation costs (Table 4).

Table 4. Transportation costs and additional costs for medical treatments (n=3000).

Factor	n (%), Value	Emergency visit times		
		Odds ratio	95% Cl	*P* value
Distance to the nearest medical institution with IBD[a] specialists				.63
>100 km	1266 (42.2)	1	N/A[b]	N/A

Discussion

In conjunction with large at-risk populations, the absolute number of patients with IBD in newly industrialized countries has the potential to approximate that in the western world by 2025 [3]. IBD places an economic strain on health systems due to expensive pharmaceutical therapy, the risk of hospitalization and surgery, and long-term monitoring. Our study provides a detailed description of the financial burdens and health care access for patients with IBD in China. We found that heavy financial burdens due to health care and travelling long distances to receive health care were the main problems faced by Chinese patients with IBD at present.

Our conservative data showed the mean (SD) direct and indirect costs for per patient with IBD per year were US $11,668.68 ($7944.44) and US $74.90 ($253.60) by estimation. Recent studies reported that in the United States, the lifetime financial burden of Crohn disease or ulcerative colitis per person was estimated at US $622,000 to US $405,000. The total financial burden for Crohn disease and ulcerative colitis in 2016 was US $498 billion and US $377 billion, respectively [19]. In Canada, the economic cost for IBD was estimated at over US $3520 per person per year in 2018. Moreover, for rheumatoid arthritis in China, the mean (SD) direct and indirect costs were US $1917.21 ($2559.06) and US $492.88 ($1739.74) per patient year [20]. This did not include the intangible costs such as out of study or work. These findings demonstrate that IBD incurs a heavier financial burden than other chronic disease such as rheumatoid arthritis in China, with similar cost status reported in other western countries.

Our study showed that in over one-third of the surveyed patients, the outpatient and inpatient expenses exceeded ¥20,000 and ¥50,000 (US $2890 and US $7226, respectively) during the last 12 months. Only one-third of the inpatient costs were reimbursed at a rate of 60%, while the reimbursement ratio was even lower for the outpatient expenses for most patients. In addition, more than half of the patients who received biological agent treatment reported paying for the biological agents by themselves, and nearly half of the surgical costs had a reimbursement rate of less than 50%. However, the income of 49.5% (1485/3000) of the patients with IBD was less than ¥5000 (US $722) per month. Moreover, IBD affects the prime working years of patients with IBD and potentially has considerable effects on employment. IBD-related work losses have received great attention worldwide [21]. As shown above, 1907 (63.5%) of the 3000 patients with IBD in our survey reported not being able to work full-time.

Medical insurance policies in China vary widely between different provinces and are also different between urban and rural areas. In our study, 96.5% (2894/3000) of the patients had health insurance, 33.7% (1011/3000) had coverage under a new type of rural cooperative medical care system, and 5.2% (157/3000) had student health insurance. This is due to the government’s universal coverage of basic medical insurance for citizens. In China, social health insurance programs generally consist of 3 programs: the rural New Cooperative Medical Scheme launched in 2003, the Urban Residents Basic Medical Insurance program launched in 2007, and the Urban Employee Basic Medical Insurance program launched in 1998 [22]. Although insurance programs have rapidly expanded during the past decade, the benefit packages and deductibles vary between the programs. Rural populations have more restricted access to health care than urban residents do, with a larger financial burden, mainly due to a lower funding level for the New Cooperative Medical Scheme, for which the coverage of outpatient services is almost nonexistent [16,22-24]. However, 75.3% (2259/3000) of the surveyed patients did not have commercial insurance, with 54.3% (1399/2576) of the patients having been refused commercial insurance because of IBD. IBD is a chronic disease and cannot be cured, and the purchase of commercial private insurance for patients with IBD is generally rejected in China. Therefore, IBD-related costs have become a heavy financial burden for patients.

We also found that 76.1% (2282/3000) of the patients with IBD reported experiencing tremendous apprehension due to medical expenses and seeking ways to save money, such as delaying an appointment with a health care provider or declining/delaying medical tests, asking their doctors for a lower cost medication, purchasing a lower cost medication, using alternative therapies (other than those prescribed), reducing the frequency of medicine administration, taking less medicine, or engaging in untimely dispensing. However, all these are very harmful approaches to disease management, which in turn may lead to disease recurrence and further aggravating the economic pressures.

In our study, 52.2% (1567/3000) of the patients reported needing to go to the emergency department 1-4 times per year because of IBD. Both transportation costs and accommodation costs for visiting IBD specialists were positively associated with emergency room visit times. One possible reason may be that those patients with lower income level saved money by decreasing the follow-up times, which might lead to disease status becoming uncontrollable. The other reason could be that patients with lower income or without commercial private insurance cannot afford such expensive but effective biological agents, which resulted in a lower level of remission. This is consistent with that reported previously that travelling long distances to obtain medical treatment for IBD hinders regular care and adversely affects the outcomes—especially increasing the risk of needing IBD-related surgery [25].

Effective measures for solving the economic problems are reducing the expenses and improving the disease status for IBD. The reimbursement ratio for IBD should be increased especially for outpatient expenses, which may be difficult for this large population. Moreover, IBD experts are very scarce, especially in the city community. Approximately 42.7% (1282/3000) of the patients with IBD were without a primary care provider, and gastroenterologists and IBD experts were the most important primary care providers. Patients with IBD have difficulty obtaining medical services in China because community physicians account for 1% of the primary care providers and family practitioners account for 0.6% of the primary care providers [26]. As a result, 28.3% of the patients reported engaging in emergency dispensing. Therefore, telemedicine might be a good solution. In 2020, one web-based study showed that the use and need of telemedicine have been increasing especially since the outbreak of COVID-19 [27]. In the same year, we performed a web-based research [28] about patterns of care for patients with IBD in China during COVID-19; the results showed that a quarter of the patients sought care via telemedicine with their IBD physicians. One randomized controlled study conducted by de Jong et al [29] compared the cost-effectiveness of telemedicine and standard care for management of IBD; they found that telemedicine was safe and reduced outpatient visits and hospital admissions compared with standard care. Del Hoyo et al [30] suggested that compared with standard and telephone care, telemedicine with web-based programs decreased the direct and indirect costs for patients with IBD; other studies by Elkjaer [31] and de Jong [32] have shown similar results. Mao et al [33] mentioned that CCCF has organized a group of volunteer gastroenterologists that specialize in IBD to offer web-based consultancy to patients with IBD. Another study [34] reported that they sent educational and instructional alerts and messages to web-based IBD groups of patients via WeChat and mailed the drugs to the patients who lived far from the hospital. Therefore, telemedicine was shown to be not only cost-saving but also a medium to provide more accurate disease information for patients with IBD, which will also improve their medical adherence.

This is the first large-scale nationwide patient survey to assess the financial burdens and health care access of patients with IBD in China. Our results reflect the current status of Chinese patients with IBD and are vital for the national policy design for patients with IBD and the planning of CCCF projects in the future. Moreover, it is vital for IBD doctors and nurses to know more about the specific situation of patients with IBD in China and to understand more about the behaviors of patients with IBD. Our study plays a significant role in strengthening the disease management and improving the quality of life of patients with IBD in China. The imperfect and inherent self-report survey methodology, including its reliance on respondents to provide accurate and bias-free responses, was one limitation of our study. However, the aim of this survey was to assess patients' perception of access to health care and their financial burdens; thus, the self-report survey data are reasonable although they are imperfect. Moreover, patients with IBD who had limited access to the internet could not be included in our study, which was a potential source of selection bias in our study. While our study assessed patients with IBD in most regions of China, a large number of the included patients were mainly located in the provinces of Zhejiang, Anhui, and Jiangsu, wherein the economic status is higher than that in other areas; therefore, patients who could not access the internet may have worse economic status than our respondents. Thus, our study was just a mirror, reflecting part of the economic issues, but the reality is even worse than our estimation.

In conclusion, serious financial burdens and difficulties in health care access are the 2 major difficulties faced by patients with IBD in China. These problems need to be confronted by national health care systems, social force communities, and the patients themselves. Early purchase of private insurance and increasing the imbursement ratio of medical costs will cut the direct costs of IBD, and increasing use of telemedicine may be beneficial for decreasing both the direct and indirect costs for Chinese patients with IBD.

Acknowledgments

We thank the following professors for their great help in data collection: Dr. Xiaocang Cao (Department of Gastroenterology, Tianjin Medical University General Hospital), Dr. Min Chen (Department of Gastroenterology, Zhongnan Hospital of Wuhan University), Dr. Yihong Fan (Department of Gastroenterology, First Affiliated Hospital of Zhejiang University of Traditional Chinese Medicine), Dr. Yubei Gu (Department of Gastroenterology, Ruijin Hospital Affiliated to Medical College of Shanghai Jiaotong University), Dr. Hong Guo (Department of Gastroenterology, Second Affiliated Hospital of Military Medical University), Dr. Sun Jing (Department of Gastroenterology, Dr. Ruijin Hospital Affiliated to Medical College of Shanghai Jiaotong University), Dr. Yue Li (Department of Gastroenterology, Peking Union Medical University Hospital), Dr. Youyou Luo (Department of Gastroenterology, Children's Hospital Affiliated to Medical College of Zhejiang University), Dr. Yan Jia (Department of Gastroenterology, Former Army General Hospital of the Chinese People's Liberation Army), Dr. Chunhui Ouyang (Department of Gastroenterology, Second Xiangya Hospital of Central South University), Dr. Jun Shen (Department of Gastroenterology, Renji Hospital Affiliated to Medical College of Shanghai Jiaotong University, Shanghai Institute of Digestive Diseases, Shanghai Inflammatory Bowel Disease Research Center), Dr. Yuan Xiao (Department of Pediatrics, Ruijin Hospital Affiliated to Medical College of Shanghai Jiaotong University), and Dr. Min Zhi (Department of Gastroenterology, Sixth Hospital Affiliated to Sun Yat-sen University). We also thank Prof. Langting Lv (Chinese public health specialist, Health policy and management, Renmin University of China) for designing the questionnaire, critically reviewing, and providing constructive comments for this manuscript. This work was supported by research grants from National Natural Science Foundation of China, No. 81602516 and 81700455; Zhejiang Provincial National Science Foundation of China, No. LY20H160031, and Intestinal Barrier Research Foundation of Li Jieshou, No. LJS-201703.

Authors' Contributions

ZCP and CY designed the study. CY, ZCP, HSR, CHW, and YS collected and analyzed the data. YQ, XLY, and CY wrote the manuscript.

Abstract

Background: The use of social media assists in the distribution of COVID-19 information to the general public and health professionals. Alternative-level metrics (ie, altmetrics) and PlumX metrics are new bibliometrics that can assess how many times a scientific article has been shared and how much a scientific article has spread within social media platforms.

Objective: Our objective was to characterize and compare the traditional bibliometrics (ie, citation count and impact factors) and new bibliometrics (ie, Altmetric Attention Score [AAS] and PlumX score) of the top 100 COVID-19 articles with the highest AASs.

Methods: The top 100 articles with highest AASs were identified with Altmetric Explorer in May 2020. The AASs, journal names, and the number of mentions in various social media databases of each article were collected. Citation counts and PlumX Field-Weighted Citation Impact scores were collected from the Scopus database. Additionally, AASs, PlumX scores, and citation counts were log-transformed and adjusted by +1 for linear regression, and Spearman correlation coefficients were used to determine correlations.

Results: The median AAS, PlumX score, and citation count were 4922.50, 37.92, and 24.00, respectively. The New England Journal of Medicine published the most articles (18/100, 18%). The highest number of mentions (985,429/1,022,975, 96.3%) were found on Twitter, making it the most frequently used social media platform. A positive correlation was observed between AAS and citation count (r^2=0.0973; P=.002), and between PlumX score and citation count (r^2=0.8911; P<.001).

Conclusions: Our study demonstrated that citation count weakly correlated with AASs and strongly correlated with PlumX scores, with regard to COVID-19 articles at this point in time. Altmetric and PlumX metrics should be used to complement traditional citation counts when assessing the dissemination and impact of a COVID-19 article.

Altmetric; PlumX; social media; impact factor; COVID-19; information; dissemination; citation

Introduction

The SARS-CoV-2 virus is the pathogen responsible for the latest global pandemic that has exhausted the global economy and health care system to a degree that has not been seen since the 1918 influenza outbreak. The virus originated from Wuhan, China in December 2019, and as of May 1, 2020, more than 230,000 COVID-19 fatalities have been reported worldwide, which is higher than the number of fatalities reported for both severe acute respiratory syndrome and Middle East respiratory syndrome combined [1,2]. Due to the rapid spread of the virus and the massive number of casualties, there has been a rapid rate of research dissemination across medical journals and social media platforms to provide real-time guidance for understanding the epidemiology, disease characteristics, and clinical management of, and future treatment development for, COVID-19 to all stakeholders who are invested in managing the COVID-19 pandemic [3,4].

In contrast to medical journals, social media can serve as a useful platform for informing the wider general public (ie, both medical professionals and laypeople alike) and disseminating crucial and novel information during this evolving crisis [5,6]. To capture the level of an article's dissemination across social media (ie, an article's "online attention"), many metric tools, such as Altmetric and PlumX, have been created [7]. As opposed to the traditional metrics of article dissemination, such as article citation count, metrics that describe article dissemination across social media are known as alternative metrics or "altmetrics." The Altmetric Attention Score (AAS), which was developed by Altmetric, is a weighted score of the amount of "online attention" a research article has received across social media platforms. This score solely refers to the number of citations, linkouts, and abstract views, and such social media platforms include Twitter, Facebook, Google+, Wikipedia, blogs, and many others [8]. Similarly, PlumX has developed the PlumX Field-Weighted Citation Impact score (ie, PlumX score), which is also a weighted metric score of the level of article dissemination across similar social media platforms, based on the number of citations, linkouts, and abstract views [9].

Given that AASs and PlumX scores use relevant information from social media platforms, including Twitter and Facebook, these scores can be potentially useful adjunctive metric tools for holistically evaluating an article's impact or effect on a field of research, instead of just evaluating scholarly impact [10]. These impacts or effects include information uptake, information engagement, and the relevance of results. Citation counts and impact factors reflect the number of citations in other articles or journals, whereas altmetrics reflect the instantaneous attention that an article garners among news outlets, blogs, Twitter, Facebook, and other media platforms [4]. Additionally, since paper journals are moving toward internet-based platforms, the development of these new internet-based technologies provides researchers with a new approach to assessing the effect of research [4]. In terms of biomedical research, the use of Twitter to disseminate article information has increased dramatically over the years. This showcases the degree of social media use in the medical community [11]. Previous studies have assessed the utility of new bibliometrics (ie, AASs and PlumX scores) as complements to citation count in various medical fields, but these studies have reported variable results [4,9,10,12,13]. Furthermore, the utility of altmetrics in COVID-19 research has not yet been evaluated.

Given the lack of research, the massive influx of COVID-19 publications since early 2020, and the fact that altmetrics allow for the rapid assessment of an article's level of dissemination upon publication, altmetrics have the potential to be used complementarily with traditional bibliometrics (eg, article citation), which typically take years to accumulate [8]. The purpose of this study was to determine the utility of adjunctively using AAS and PlumX altmetrics as complements to traditional bibliometrics in the assessment of the 100 most "trending" COVID-19 articles across social media, as determined by Altmetric. Given that both the scientific community and the general public frequently check for new information in journals and social media platforms to gain a better understanding of how to prevent and manage COVID-19 [14], we hypothesized that there might be a significant correlation between AAS and PlumX metrics and citation count. Such a correlation would suggest an alignment between the interests of academic scholars and the general public. The primary objective of this study was to investigate the correlations between both Altmetric and PlumX scores and citation count.

Methods

Altmetric Explorer was used to identify COVID-19 publications from December 2019 to May 2020, by using the PubMed search terms "COVID-19," "SARS CoV-2," and "coronavirus." Articles that were retracted by May 2020 were excluded from analysis. The top 100 articles with the highest AASs were selected from the list of included articles. The number of mentions from the following Altmetric data components were extracted and examined: news mentions, blog mentions, policy mentions, Twitter mentions, Facebook mentions, Wikipedia mentions, Reddit mentions, Mendeley readers, and the number of Dimensions citations [9]. In addition to the extraction of Altmetric data components, we also collected data on the impact factors of the journals that the included articles were published in, article type, and article citation count [8,10]. For traditional citation analysis, article citation counts were found by using the Scopus database. To assess whether the results from the Altmetric analysis could be generalized across multiple social media metric tools, PlumX scores were collected from the Scopus database. AASs, PlumX scores, and citation counts were log-transformed and adjusted by +1 for linear regression, and Spearman correlation coefficients were used to determine correlations. Statistical significance was defined as $P<.05$.

Results

The majority of articles were published in biomedical journals (Table 1, Textbox 1). Compared to the other journals, the New England Journal of Medicine published the most articles (18/100, 18%). Of the 100 articles, 42 (42%) were original investigations. The article with the highest AAS (AAS=33,828) was a biomechanistic basic science letter that delineated the features of the SARS-CoV-2 genome and provided evidence that SARS-CoV-2 was not constructed in a laboratory (AAS=33,828; citation count=30) [15]. The article with the highest PlumX score was a prospective cohort study that described the clinical characteristics of patients with COVID-19 [16]. The median AAS, PlumX score, and citation count were 4,922.50, 37.92, and 24.00, respectively. All articles were classified as the top 5% in terms of scientific output [10]. This means that in terms of AAS, these articles ranked in the top 5% when compared to more than 15.5 million research publications. In other words, these articles garnered the most attention. A total of 1,022,975 mentions in social media platforms were assessed. The highest number of mentions for the selected articles (985,429/1,022,975, 96.3%) were found on Twitter. Additionally, 99 articles were open access. In total, 9283 Mendeley mentions and 18,011 Dimensions citations were present. A weak positive correlation was observed between AAS and citation count (r^2=0.0973; P=.002) (Figure 1). However, a strong positive correlation was observed between PlumX score and citation count (r^2=0.8911; P<.001). Stronger positive correlations were observed between the number of Mendeley readers (r^2=0.958; P<.001) and citation count, and between the number of Dimensions citations (r^2=0.984; P<.001) and citation count.

Table 1. Characteristics and components of the top 100 COVID-19 articles with the highest Altmetric Attention Scores.

Characteristic	Value
Altmetric Attention Score, median (range)	4922.50 (2841-33828)
PlumX score, median (range)[a]	37.92 (0-1862.23)
Journal impact factor, median (range)	41.06 (1.29-70.67)
Traditional citation count, median (range)[b]	24.00 (0-1096)
Number of news mentions, total (range)	32509 (1-2021)
Number of blog mentions, total (range)	2630 (0-131)
Number of policy mentions, total (range)	154 (0-21)
Number of Twitter mentions, total (range)	985429 (1381-84022)
Number of Facebook mentions, total (range)	1138 (0-58)
Number of Wikipedia mentions, total (range)	177 (0-11)
Number of Reddit mentions, total (range)	938 (0-40)
Number of Mendeley Readers, total (range)	9283 (0-2581)
Number of Dimensions citations, total (range)	18011 (0-2233)
Article type, n (%)	
Original investigation	44 (44)
Correspondence	31 (31)
Editorial	14 (14)
Review	4 (4)
Viewpoint	6 (6)
Open access	100 (100)
Study design of original investigations (n=44) , n (%)	
Clinical trials	4 (9)
Prospective/retrospective cohort studies	21 (48)
Cross sectional	1 (2)
Case series	7 (16)
Basic science in vitro/in vivo studies	8 (18)
Model validation studies	3 (7)

[a] In total, 16 articles had a PlumX score of 0, because they did not have a score on Scopus at the time of this study. Therefore, these articles were not part of the analysis.

[b] In total, 3 articles did not have a citation count on Scopus or PubMed Central at the time of this study. Therefore, these articles were not part of the analysis.

Textbox 1. Journals categorized based on journal impact factor. The number of included articles published in each journal are reported.

Journals with an impact factor of >40

- New England Journal of Medicine (articles: n=18)
- The Lancet (articles: n=14)
- Journal of the American Medical Association (articles: n=12)
- Nature (articles: n=2)
- Science (articles: n=6)

Journals with an impact factor of 20-40

- Cell (articles: n=1)
- Nature Biotechnology (articles: n=1)
- Nature Medicine (articles: n=5)
- British Medical Journal (articles: n=2)
- Lancet Infectious Disease (articles: n=3)
- The Lancet Respiratory Medicine (articles: n=2)

Journals with an impact factor of <20

- Annals of Internal Medicine (articles: n=2)
- Cell Research (articles: n=1)
- Morbidity and Mortality Weekly Report (articles: n=8)
- ACS (American Chemical Society) Nano (articles: n=1)
- Proceedings of the National Academy of Sciences of the United States of America (articles: n=2)
- Emerging Infectious Diseases (articles: n=4)
- Biomedicine (articles: n=1)
- Eurosurveillance (articles: n=1)
- Pediatrics (articles: n=1)
- Circulation: Arrhythmia and Electrophysiology (articles: n=1)
- International Journal of Antimicrobial Agents (articles: n=1)
- Cell Discovery (articles: n=1)
- Engineering (articles: n=1)
- Journal of Travel Medicine (articles: n=1)

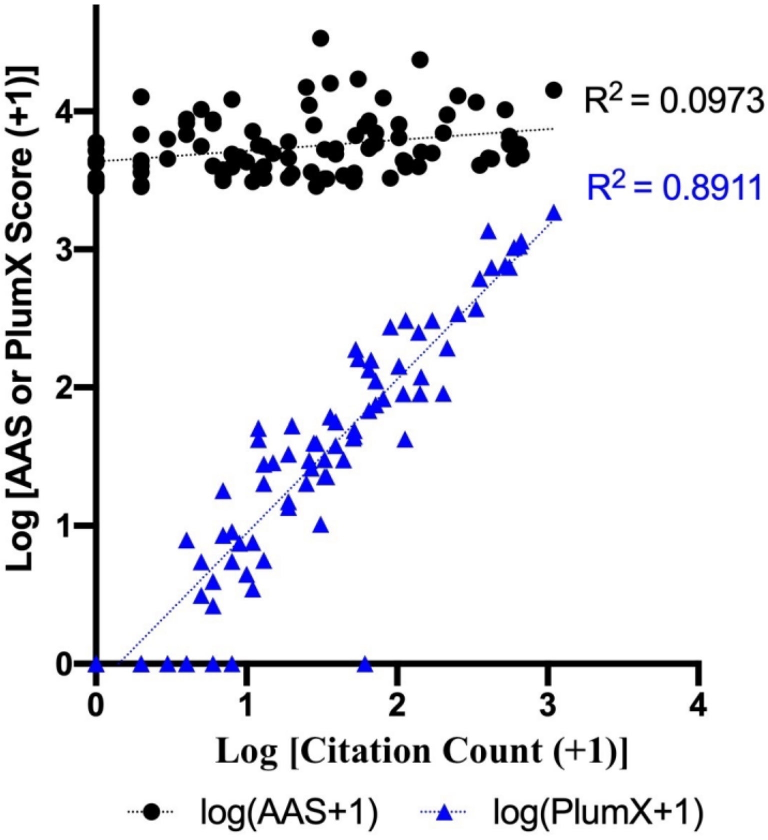
- Journal of Medical Virology (articles: n=2)
- BioScience Trends (articles: n=1)
- The Lancet Child & Adolescent Health (articles: n=1)
- Médecine et Maladies Infectieuses (articles: n=1)
- JAMA (Journal of the American Medical Association) Network Open (articles: n=1)

Figure 1. Correlations between citation count and AAS and between citation count and PlumX score. AAS: Altmetric Attention Score.



Discussion

In the past several months since COVID-19 has spread globally, many articles pertaining to the pandemic have been disseminated. Traditionally, high-quality and highly regarded articles can be ascertained via citation count; however, this method is not always possible in a rapidly evolving pandemic, such as the COVID-19 pandemic. Our study assessed the utility of adjunctively using AASs and PlumX scores with citation count in the evaluation of the top 100 "trending" COVID-19 articles. According to the results of our study, AAS weakly correlated with citation count (r^2=0.0973; *P*=.002), whereas PlumX score strongly correlated with citation count (r^2=0.8911; *P*<.001). This suggests that there is an alignment in information dissemination between both peers within the scientific community and those in the general public.

Our results are consistent with the findings of some of the previous literature and inconsistent with those of other literature. Previous studies have shown that PlumX and Altmetric scores positively correlate with traditional citation count [12,17-21]. In more current literature, citation count has been shown to weakly positively correlate with PlumX score and AAS. However, PlumX and AAS measures have not consistently positively correlated with impact factor. It has also been shown that compared to all other alternative metric platforms, PlumX is able to capture the widest range of data regarding the dissemination and popularity of a scientific article [7]. Interestingly, current literature has noted that journals with a high Twitter presence also have high PlumX scores and AASs [22]. Our data also reinforces this finding. In our analysis, we observed that Twitter was the most frequently used social media platform, and that the highest number of mentions for the selected articles (985,429/1,022,975, 96.3%) were found on Twitter. These results are also in line with those of previous studies [23]. All of these studies have stated that PlumX score and AAS are most effective when they are used complementarily with traditional bibliometric measures, and that PlumX score and AAS should not necessarily be used on their own to assess an article's quality [4,7-10].

Although AASs can be used to estimate how widely an article has been disseminated, its correlation with citation count was lower than the correlation between PlumX scores and citation count in our study, making AASs less useful than PlumX scores. There are likely multiple reasons for this. For instance, there are several challenges with regard to the utility of AASs, such as the heterogeneity of the platforms that Altmetric uses to calculate the score, the dynamic nature of AASs, and the fact that many of the platforms we assessed (eg, Twitter, Facebook, etc) were not focused on academia [4]. These challenges allow for the possibility of article misinformation and the review of an article that may be retracted a few days later, which may why explain the weak correlation between AAS and citation count. Based on the platforms that Altmetric uses to calculate its weighted score and those that the scientific community finds interesting, it was not surprising to observe the strong correlations between citation count and Mendeley citations, and between citation count and Dimensions citations. Mendeley and Dimensions are 2 well-known platforms that are used by scientific researchers to source, organize, and cite preexisting literature. These platforms attract a more professional group of users who typically work in the biomedical science field compared to other platforms (ie, Twitter or Facebook), which attract a broader demographic group of the general public. Furthermore, although PlumX scores are also dynamic, these scores account for citation count in their weights, which make PlumX scores longer to report and more stable than other bibliometrics [9].

It is important to note that original articles, particularly observational cohort studies, were disseminated more quickly in social media platforms than in scientific journals. Furthermore, the top-scoring biomechanistic basic science article [15] was also rapidly disseminated in social media platforms. This is most likely because this article addressed the possibility of SARS-CoV-2 being engineered in a laboratory [15]. Additionally, all the articles were open access and freely accessible to the general public. This is likely because there is an alignment between scientists and the general public concerning the need to disseminate new COVID-19–related findings as quickly as possible, given the enormous burden of the ongoing COVID-19 pandemic. Thanks to the removal of barriers to access, the reading of newly published articles and the dissemination of articles to peers has considerably increased.

There are several limitations to our study. For instance, Altmetric and PlumX scores do not necessarily reflect the scientific quality of an article [12,24]. Just because an article generated more attention among the general public and academic community than other articles, it does not mean that more attention correlates with better study designs, results, or evidence quality. Additionally, AASs and PlumX scores are more dynamic than citation count, making the precision, consistency, and reproducibility of altmetric analyses difficult to achieve. However, due to the high volume of social media attention that COVID-19 articles have received, the reproducibility of our data is much better than the reproducibility of data from other medical fields, as the power of our results was much stronger. Despite these limitations, our study shows that altmetrics can be used to complement citation analysis for COVID-19 articles. We highly recommend that medical providers, the scientific community, and the general public use AASs when initially searching for the most pertinent articles that the general public is interested in, given that AASs are immediately calculated. The initial search should be followed by the assessment of the utility of the articles, with respect to PlumX scores or citation count. Given the high correlation between PlumX scores and citation count, we believe that this method will result in great confidence when reviewing a high-quality COVID-19 article and a low risk of article misinformation. We believe that our findings will be helpful in the current COVID-19 pandemic and in future pandemics, as traditional metrics, such as citation count, are not readily available when assessing an article's quality.

Abstract

Background: Health care professionals are required to maintain accurate health records of patients. Furthermore, these records should be shared across different health care organizations for professionals to have a complete review of medical history and avoid missing important information. Nowadays, health care providers use electronic health records (EHRs) as a key to the implementation of these goals and delivery of quality care. However, there are technical and legal hurdles that prevent the adoption of these systems, such as concerns about performance and privacy issues.

Objective: This study aimed to build and evaluate an experimental blockchain for EHRs, named HealthChain, which overcomes the disadvantages of traditional EHR systems.

Methods: HealthChain is built based on consortium blockchain technology. Specifically, three organizations, namely hospitals, insurance providers, and governmental agencies, form a consortium that operates under a governance model, which enforces the business logic agreed by all participants. Every peer node hosts an instance of the distributed ledger consisting of EHRs and an instance of chaincode regulating the permissions of participants. Designated orderers establish consensus on the order of EHRs and then disseminate blocks to peers.

Results: HealthChain achieves functional and nonfunctional requirements. It can store EHRs in a distributed ledger and share them among different participants. Moreover, it demonstrates superior features, such as privacy preservation, security, and high throughput. These are the main reasons why HealthChain is proposed.

Conclusions: Consortium blockchain technology can help to build new EHR systems and solve the problems that prevent the adoption of traditional systems.

KEYWORDS

electronic health record; distributed ledger; privacy preservation; proof of authority; chaincode application programming interface

Introduction

It has long been believed that electronic health records (EHRs) should be maintained across time and space, and could be accessed at any time and any place within the law [1]. In the first stage of digitization, we store a patient's medical history within the jurisdiction of a health care provider irrespective whether electronic medical records (EMRs) are on a local server [2] or in the cloud [3]. Such EMR systems have no essential difference with old-fashioned paper-based ones, since information technology just takes the management of medical records from paper folders to hard drives. EMRs do not travel out of a practice [4], and they make their way to other practices by faxes or signed documents, which is time consuming.

In the second stage, authorized doctors and staff create, manage, and consult EHRs across more than one health care organization, allowing interoperability between disparate EHR systems [5]. That is, EHRs possess the ability to share medical information among health care providers and follow a patient's information across multiple health care organizations [6]. In the United States, EHR exchange involves a common platform, the Nationwide Health Information Network, which is a set of standards, services, and policies that enable secure health information exchange over the internet [7].

However, there are technical and legal hurdles that prevent the adoption of these systems. First, these systems perform poorly in terms of data availability, data integrity, and retrieval rate when EHRs are stored under a distributed or institution-centric model [8]. Second, people always worry about the issues of privacy and data breaches [9] when EHRs are beyond their control, even if health care providers and governmental agencies claim that these systems are Health Insurance Portability and Accountability Act (HIPAA) compliant [10]. After all, 11,581,616,452 records have been breached since 2005, and this has been reported through either government agencies or verifiable media sources [11]. Third, patient-reported data do not always get recorded in a patient's EHRs since doctor-patient communication is not always possible, which impacts the quality of care [12]. Therefore, a kind of patient-reporting mechanism is needed for precision medicine [13].

In this paper, HealthChain is proposed to address the above-mentioned issues. It is a blockchain [14-16] for EHRs, that is, a growing list of blocks that consist of records and are linked using a cryptographic hash [17]. The blockchain has several advantages. First, the blockchain is a distributed peer-to-peer database where data availability, data integrity, and response time are guaranteed [18,19]. Blockchains can facilitate Internet of Things security in eHealth [20]. Second, the blockchain operates under a governance model, which enforces the business logic agreed by all participants. Therefore, we can exploit a smart contract or chaincode to regulate the access control policy [21-23] and achieve HIPAA compliance. Third, the blockchain is managed collectively by its stakeholders, some of whom have the right to record data in the block that cannot be altered retroactively [24]. In our design, even patients can report personal health records (PHRs) [5] on the ledger. From our perspective, applying blockchain technology to EHR systems denotes the advent of the third stage of digitization.

Specifically, the proposed HealthChain is different from other EHR blockchains owing to the following features. First, HealthChain is a consortium blockchain [25]. Multiple organizations, namely hospitals, insurance providers, and governmental agencies, come together to form the consortium. The business logic is determined by the governance model that is agreed by the consortium at the beginning, rather than the trustless model of other medical blockchains [26-28]. Second, HealthChain performs well in the following aspects: data availability, data integrity, and retrieval success rate, that is, HealthChain is always online even if a few servers crash. Genuine EHRs are stored since they are signed by valid stakeholders. We can successfully access the ledger anytime because of load balancing. Third, HealthChain uses proof of authority (PoA) as its consensus protocol. Designated, authenticated, and trustworthy orderers are responsible for generating valid blocks, that is, as long as the blocks are signed by one of these orderers, they are accepted by all participants. PoA is different from other consensus protocols, such as proof of work [21,29,30] and Practical Byzantine Fault Tolerance (PBFT) [31-33]. Fourth, different users possess different chaincode application programming interfaces (APIs) in HealthChain, which is specified by the governance model. Therefore, we can define the way that users interact with the ledger and achieve the access control policy. Fifth, HealthChain performs well in the experimental environment. This paper uses the following four metrics to evaluate performance: read latency, read throughput, transaction latency, and transaction throughput [34].

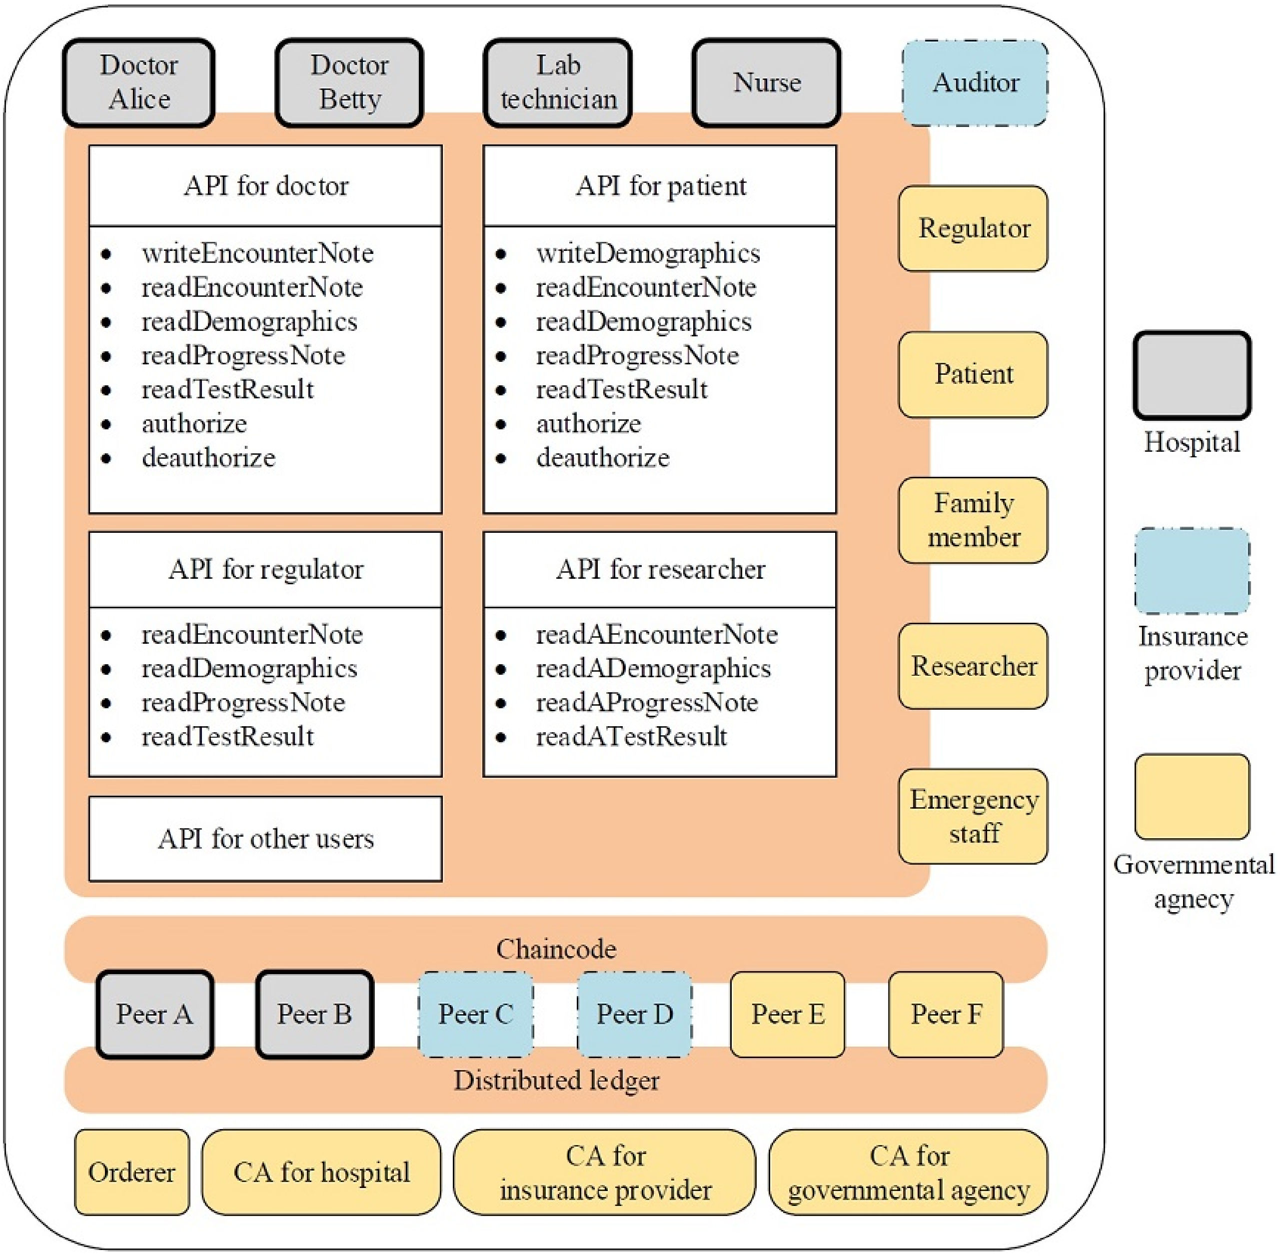
In this paper, we build a consortium blockchain for EHRs, named HealthChain, which has advantages over traditional EHR systems and other medical blockchains recently proposed. Moreover, we evaluate the performance of HealthChain through blockchain-specific metrics.

Methods

Diagram of HealthChain

The consortium consists of the following three kinds of organizations: hospitals, insurance providers, and governmental agencies. Our experimental HealthChain comprises two of each type, as shown in Figure 1. Peers A and B are servers owned by two respective hospitals, and they serve client applications of the following three kinds of users: doctors (such as Alice and Betty), lab technicians, and nurses. Peers C and D are servers contributed by two respective insurance providers, and they serve clients for auditors. Peers E and F are servers belonging to two respective governmental agencies, and they serve client applications of the following five kinds of users: regulators, patients, family members, researchers, and emergency staff. Besides, governmental agencies contribute one orderer and three certificate authorities (CAs) for three kinds of organizations. Note that these servers can reside in the cloud, in the data center of the organizations, or on a single machine.

Figure 1. The diagram of HealthChain. Three kinds of organizations contribute nodes to the blockchain network. API: application programming interface; CA: certificate authority.



Although there is no centralized node in the HealthChain network, the organizations come together under the governance model, which regulates the behavior of all actors such as peers and users. The governance model reflects the business logic of health care in real scenarios. It specifies the way that users interact with the ledger, and enables the privacy and confidentiality of EHRs. HealthChain implements the governance model via the combination of a membership service provider (MSP), chaincode, and consensus protocol. These components are explained below, and we introduce the roles of all nodes constituting the network.

CAs are trusted authorities, generating certificates and key material for actors. The MSP is implemented by these CAs, as the generated certificates can provide information about valid identities for an organization. Moreover, all actors in HealthChain can be verified by each other, and the MSP helps achieve fine-grained access and trace behavior of actors.

Peers make up the physical structure of our network. The distributed ledger and chaincode are shared among them, as illustrated in Figure 1. They are both endorsing and committing peers in HealthChain. As endorsing peers, they are designated by the consortium to execute chaincode in simulation. The chaincode implements APIs, which are divided into different groups granted to different users [32], that is, the chaincode specifies who has what access permissions to which part of the ledger and implements the fine-grained access required by law [1]. In Figure 1, we list APIs for doctors, patients, regulators, and researchers.

As committing peers, they validate blocks and commit them to their copies of the ledger. Most importantly, they check the identity of who executes the EHR request and the identity of who packages EHR transactions into a block. This is why the consensus protocol adopted in HealthChain is called PoA.

Orderers are trusted by all organizations, and they are responsible for ordering EHRs into a block on a first-come-first-serve basis. The signature of the block writer (ie, the orderer) is contained in the block. Prior to the commitment, the peers must make sure that the signature comes from an authenticated and authorized orderer, that is, the validity of a block depends on the identity of the orderer.

Identities and Anonymization

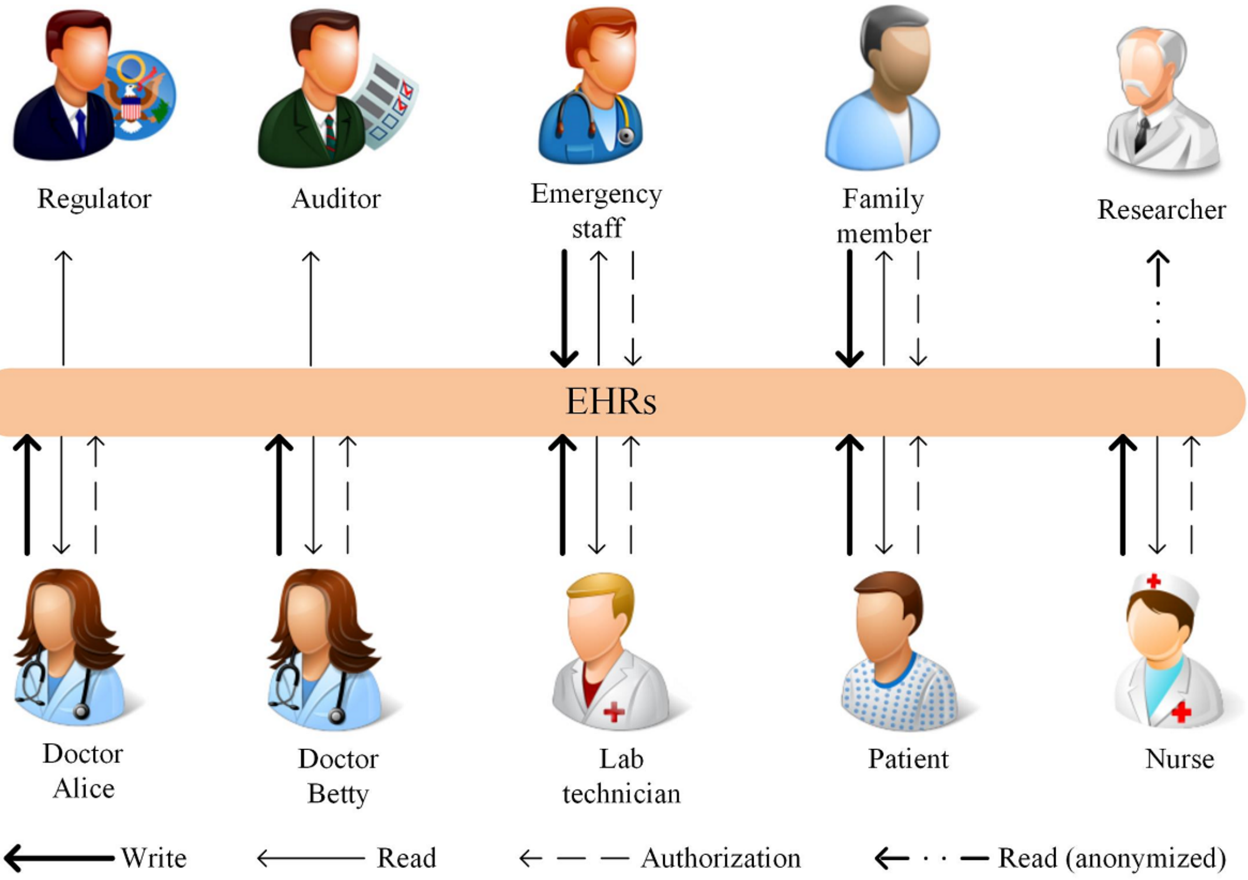
CAs dispense X.509 certificates to identify servers and clients. X.509 certificates are used in the lifecycle of transactions. For example, the EHR request contains the certificate of a client. Meanwhile, the EHR response includes the certificate of an endorsing server. When enforcing the access control of HealthChain, the chaincode extracts the certificate from the transaction request, acquires the identity of the client, and queries whether the access is authorized.

Considering privacy preservation, the identities of patients and health care providers need to be anonymized when researchers access the ledger via the APIs for them. During the anonymization, we use the hash of identities instead of the identities themselves. Thus, the identities are kept private, but the relationship between patients and health care providers is retained. Specifically, SHA256 is adopted as it is the default hash algorithm in Hyperledger Fabric. The hash of the patient ID combined with the timestamp is calculated. The purpose of introducing the timestamp is to prevent getting the same hash among queries.

Access Rights of Users

HealthChain is a distributed and append-only ledger shared among many users with different access rights. To achieve a delicate balance between privacy and availability, fine-grained access to the ledger is implemented. Figure 2 illustrates the following access rights of users in HealthChain: write permission, read permission, authorization permission, and read permission with EHRs anonymized.

Figure 2. The access rights of users in HealthChain. Different users have different access qualifications for electronic health records (EHRs).



Patients manage and control access to the PHRs, conceptually including patient-reported information and EHRs. The former includes various contents, such as demographics, allergies, and monitoring data collected from instruments [5]. The latter refers to medical records updated by doctors and staff. Patients can authorize their family members or health care providers to write and read their health information [35], reducing the risk of data replication and tracking possible trends and changes in their health.

Doctors, nurses, emergency staff, and lab technicians manage and control access to the EHRs updated by themselves. Furthermore, they can use or disclose protected health information for treatment, payment, or health care operations without patients' authorization [36]. Therefore, they have authorization permission to grant write or read permission to other covered entities, whereby the EHRs are shared across health care organizations.

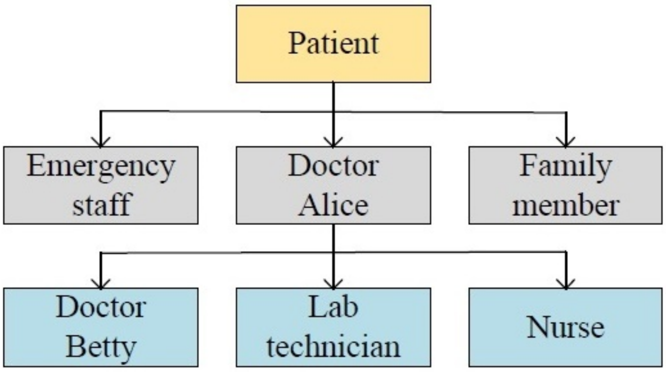
Regulators and insurance providers only have read permission to the ledger. Regulators, such as the Department of Health & Human Services, ensure that the business logic of HealthChain has been respected well, and all participants behave appropriately. When there is a dispute, they can make decisions based on the ledger, which is tamper-resistant and unforgeable [37]. Insurance providers process medical claims and evaluate their validity according to the records on HealthChain.

Researchers are engaged in public health activities such as disease surveillance. HealthChain can provide trustworthy data for this purpose because of the transparency of the data aggregation process [32]. However, the data on the ledger should be anonymized before being used for privacy preservation.

Implementation of the Authorization

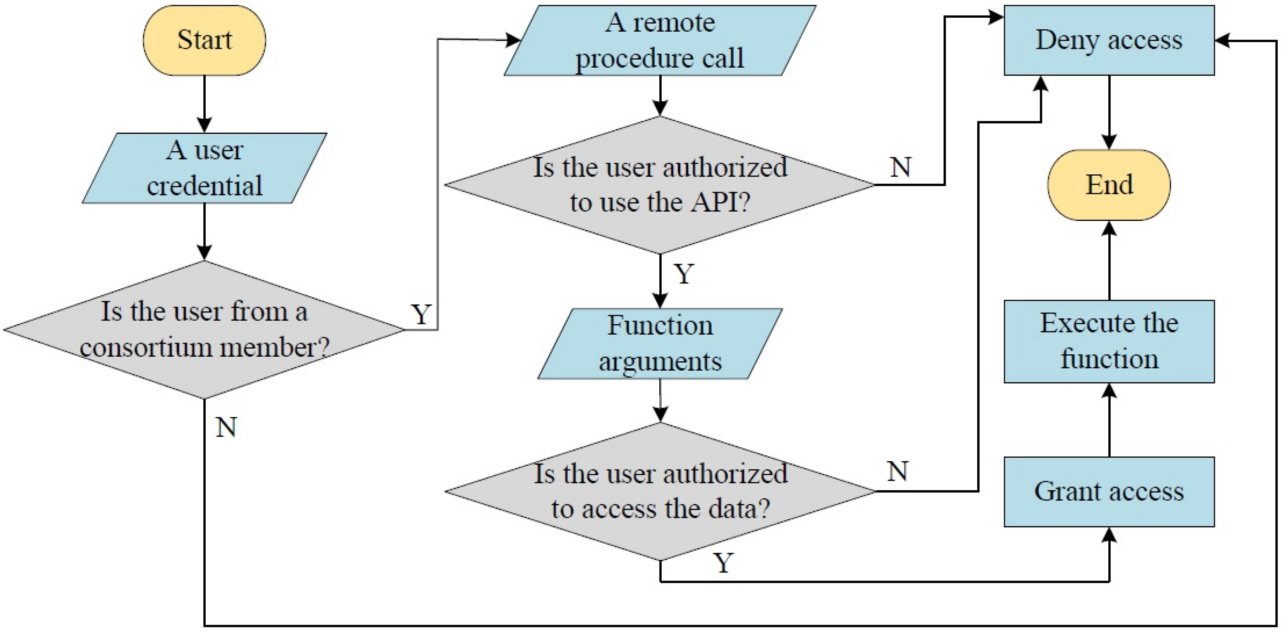
The authorization is represented by a tree data structure, as shown in Figure 3. All access rights are authorized from the patient (ie, the root of the tree). Parent nodes grant child nodes permissions such as read, write, and authorization. For example, the patient grants all three permissions to doctor Alice, and doctor Alice grants all three permissions to doctor Betty, and so on. Besides, the other three roles (ie, regulator, auditor, and researcher) have only read access to the ledger. While the tree data structure is the logical design of the authorization, the records or transactions on the ledger are its physical implementation.

Figure 3. The authorization hierarchy in HealthChain. The arrows denote the authorization operation.



The algorithm addressing authentication and authorization is presented in Figure 4, and it is implemented by the chaincode. The key parts are the three decision symbols, representing the prerequisites for the success of transactions. First, only consortium members can access the ledger; others have no right at all. Second, different types of users have different access permissions for chaincode APIs, even in the same consortium. Third, a user cannot access the data of another if the former is not authorized by the latter. For example, if a person named Carl would like to submit an encounter note about a patient named Steve, he needs to satisfy the following three conditions: he is from a hospital within the consortium, he is a doctor, and he has authorization from Steve.

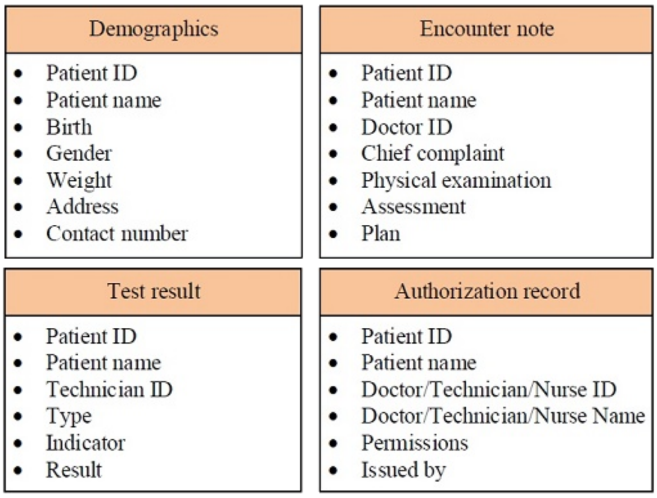
Figure 4. The fine-grained access control implemented by the chaincode. N: no; Y: yes.



Types and Lifecycle of EHRs

There are different kinds of EHRs submitted by different users. For the sake of brevity, Figure 5 lists only four of them, illustrating the data structures of the demographics, encounter note, test result, and authorization record. For example, the encounter note includes the following fields: patient ID, patient name, doctor ID, chief complaint, physical examination, assessment, and plan.

Figure 5. The types of electronic health records. Only four examples are listed here.



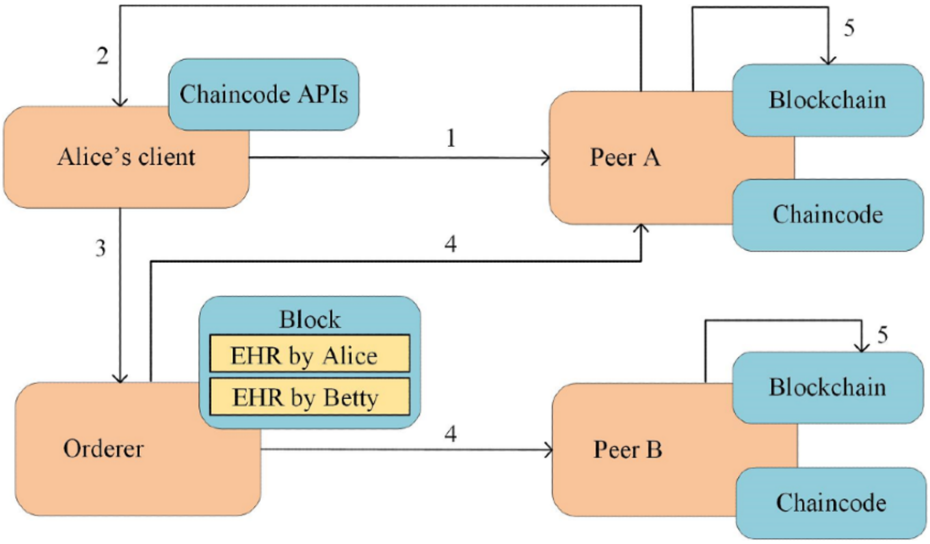
Demographics	Encounter note
Patient ID Patient name Birth Gender Weight Address Contact number	Patient ID Patient name Doctor ID Chief complaint Physical examination Assessment Plan

Test result	Authorization record
Patient ID Patient name Technician ID Type Indicator Result	Patient ID Patient name Doctor/Technician/Nurse ID Doctor/Technician/Nurse Name Permissions Issued by

Every EHR corresponds to a transaction, which needs to be executed and eventually included in the ledger. All EHRs have the same lifecycle [16], which is illustrated in Figure 6 and is explained as follows:

1. When Doctor Alice needs to record an encounter note on the ledger, her client application sends an EHR request to the endorsing peer. The request is formatted as a remote procedure call through chaincode APIs [38].
2. The endorsing peer checks the validity of the incoming request (the format, the signature, and the access permission). Thereafter, the request is processed by the chaincode, which outputs an EHR response, including returned value, read set, and write set.
3. Alice's client checks the signature of the incoming response, assembles the response and the signature into an EHR transaction, and sends the transaction to an orderer.
4. The orderer simply receives transactions from all clients (including Alice's client), orders them chronologically, and creates a block of transactions. Thereafter, the orderer delivers the block to all peers in the network.
5. Every peer checks the validity of the incoming block, including the signature and the version number. After that, the block is committed to the ledger and so is the EHR submitted by Alice.

Figure 6. The lifecycle of electronic health records (EHRs). They start with the request from a client and end with the commitment on all peers. API: application programming interface.



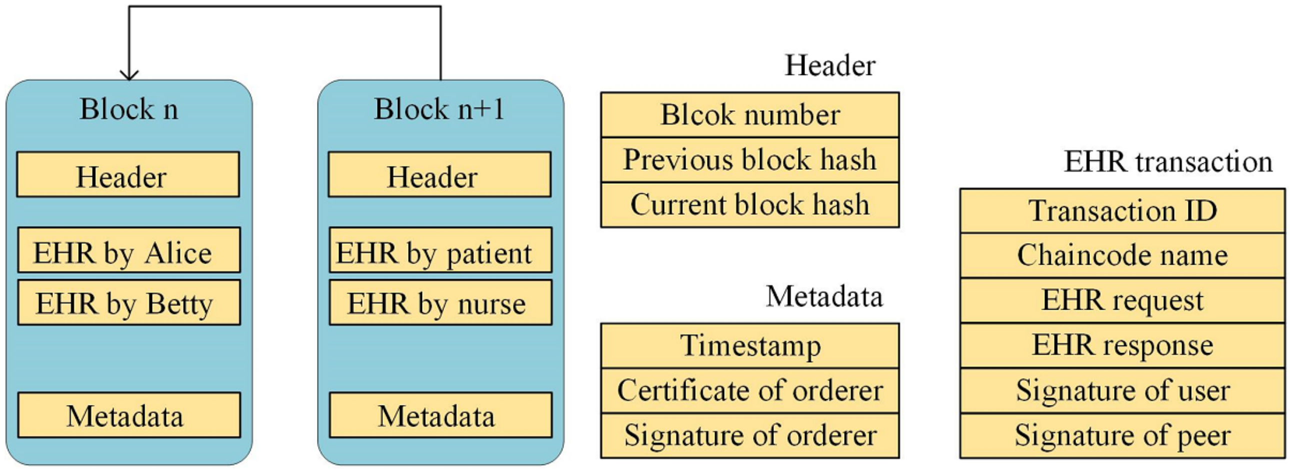
Structure of the Ledger

The ledger is the database of EHRs across time and space. As shown in Figure 7, it is structured as interlinked blocks, each of which contains chronologically ordered EHR transactions.

A block consists of the following three sections: header, EHR transactions, and metadata. The header comprises the block number, the previous block hash, and the current block hash. The EHR transactions are submitted by users such as doctors and patients. The metadata comprises the timestamp, as well as the certificate and signature of an orderer. Besides, an EHR transaction consists of the following six fields: the transaction ID, the chaincode name, the EHR request, the EHR response, and the signatures of the user and peer.

The previous block hash of block n+1 is equal to the current block hash of block n, such that the blocks are interlinked; hence, the name blockchain. The biggest difference between HealthChain and other blockchains is that blocks do not need to contain a nonce field to achieve the given pattern of cryptographic hash values. The validity of the block is only dependent on PoA, instead of proof of work. Thus, HealthChain can achieve low transaction latency.

Figure 7. The structure of the transaction, the block, and the ledger. EHR: electronic health record.



Results

Experimental Environment

The prototype of HealthChain is implemented with Hyperledger Fabric v1.4.1, an enterprise-grade permissioned distributed ledger platform [16]. It is deployed on a machine with an Intel Xeon E5-26xx v4 2.4 GHz CPU and 2 GB RAM running Ubuntu 16.04.1 LTS. All servers are built with Docker 18.06.1-ce, that is, all peers and orderers are virtualized into containers sharing the hardware and the operating system kernel [39]. The HealthChain network is created by Docker Compose, a tool for defining and running multicontainer Docker applications [40].

Besides, the two parameters of batch timeout and batch size have a high impact on the performance of HealthChain. The former denotes the maximum time to wait before creating a block, and the latter is the maximum number of EHR transactions in a block. No matter which one is satisfied first, the block is generated. This paper tests the performance of HealthChain with the parameters varying. We ran every transaction three times, and the average values of latency and throughput are provided in the paper.

Example of the Working of HealthChain

In this section, we present an example to illustrate how HealthChain works. Note that all tasks are completed through our chaincode APIs described in Figure 1. The medical data are extracted from a previous report [41].

First, the patient client of Steve Apple prepares personal information. Consequently, the following demographic record is committed to the ledger.

Second, when Steve decides to see a doctor named Carl Savem, he submits an authorization record to grant permissions for health care. Thus, the doctor is able to perform read, write, and even authorization operations on the ledger.

Third, after knowing Steve’s feelings about the health state and doing a medical examination, Carl enters the diagnosis and the instruction for treatment.

Fourth, to check whether there is a change in the lipid profile, Carl also writes an authorization record to order a test provided by a technician named John Doe.

Finally, John Doe puts the following report on the ledger.

Besides, when researchers read the above encounter note, the anonymization scheme in HealthChain takes effect, resulting in the following record. The first three items are the hashes of corresponding items in the original record and timestamps.

Security Test

We test the security of HealthChain from three aspects. First, a patient tries to access the ledger on an unavailable server, peer E. The below command queries the encounter notes about the patient with ID equal to P01, but it fails due to the unavailability of peer E, whose domain name is peer0.org3.health.com. After peer0.org3.health.com is replaced with peer0.org1.health.com, that is, the domain name of peer A, the command runs successfully since peer A is still available.

Second, an invalid user tries to access the ledger. However, this operation is immediately denied by the system since the identity cannot be authenticated. After we delete the digital certificate of Steve Apple, the above command fails, and the below information is returned.

Third, a doctor tries to tamper with an EHR. However, the history of the EHR is recorded on the ledger. We can query the history of the encounter note about P01. It is easy to figure out that “physicalExamination” has changed from “no acute distress” to “acute distress.”

In conclusion, HealthChain performs well in several aspects, namely data availability, access control, and data integrity.

Test Scenario: A Single Read

The read operation refers to retrieving or querying EHRs, and there is no change to the ledger. Users may read the EHRs submitted by themselves or others. We can give some use cases here. Doctors query the demographics of a patient or the diagnoses from former doctors. Patients read medical notes from doctors or lab results from lab technicians [24]. Insurance providers inspect EHRs to validate the necessity of them. Read latency is the time between when the EHR read request is submitted and when the EHR response is returned, corresponding to steps 1 and 2 in Figure 6.

Table 1 shows the example data of a single read operation under different parameter conditions. It can be seen that HealthChain has the read latency of about 0.1 s irrespective of the parameters. For example, the first row shows the process of a read operation when Doctor Alice retrieves an EHR from peer A. She sends an EHR request at 0 s, peer A finishes retrieving at 0.136 s, and an EHR response is returned to her at 0.142 s. Therefore, the read latency of 0.142 s is obtained with batch timeout equal to 20 s and batch size equal to 1000. The two parameters are irrelevant since there is no block generated during the read process.

Table 1. Example read latency data at different nodes.

Number	Batch timeout (s)	Batch size (n)	Client	Sever	Read request (s)	Read (s)	Response (s)	Read latency (s)
1	20	1000	Doctor	Peer A	0	0.136	0.142	0.142
2	20	1	Insurance provider	Peer C	0	0.117	0.122	0.122
3	2	10	Patient	Peer E	0	0.099	0.105	0.105

Test Scenario: Concurrent Reads

Usually, many users read from the ledger simultaneously and the read operations are executed in overlapping time periods. For example, doctors, patients, and insurance providers may read EHRs from the ledger concurrently in accordance with their needs. Read throughput is obtained by the number of read operations completed in a specific time period, indicated as reads per second (RPS).

Table 2 shows the example data of 1000 concurrent reads under different parameter conditions. It can be observed that every server of HealthChain has a read throughput of around 10 RPS in spite of varying parameters. For example, the first row shows the process of 1000 concurrent read operations when users try to retrieve EHRs from peer A at the same time. The first EHR request happens at 0 s, peer A finishes the 1000th read at 97.513 s, and the 1000th response happens at 97.521 s. Therefore, the read throughput reaches 10.259 RPS with batch timeout of 20 s and batch size of 1000. The two parameters are irrelevant as no block is written on the ledger. Furthermore, the read throughput of the whole network is the summation of the throughput of all peers as the read operations on one peer are independent of those on another.

Table 2. Example read throughput data at different nodes.

Number	Batch timeout (s)	Batch size (n)	Sever	1st read Request (s)	1000th read (s)	1000th response (s)	Read latency (s)	Read throughput (reads per s)
1	20	1000	Peer A	0	97.513	97.521	97.521	10.259
2	20	1	Peer C	0	95.847	95.855	95.855	10.440
3	2	10	Peer E	0	98.871	98.876	98.876	10.115

Test Scenario: A Single Write

The write operation refers to submitting EHRs to the ledger, and there are changes involved. Users may create and submit EHRs regarding a patient. We can list some use cases here. Doctors create encounter notes after meeting with patients or progress notes during the course of a hospitalization. Patients update demographics or report their clinical status [22]. Lab technicians report test results. Transaction latency is the time between when an EHR write request is submitted and when the EHR transaction is widely available in the network, corresponding to all five steps in Figure 6.

Table 3 shows the example data of a single write operation with different parameter conditions. It can be seen that the transaction latency depends on the two parameters. For example, the first row shows the process of a write operation when doctor Alice submits an EHR to the ledger. She sends an EHR request at 0 s, peer A endorses the EHR at 0.118 s, and the orderer generates a block containing the EHR transaction at 20.166 s. Subsequently, six peers separately commit the block to the ledger at 20.370 s, 20.352 s, 20.379 s, 20.379 s, 20.363 s, and 20.379 s. Therefore, the EHR transaction is available on all peers at the latest time, namely 20.379 s. Consequently, the transaction latency of 20.379 s is obtained with batch timeout of 20 s and batch size of 1000.

Table 3. Example transaction latency data at different nodes.

No.	Batch timeout (s)	Batch size (n)	Client	Write request (s)	Endorsement on A (s)	Write on orderer (s)	Commitment on A (s)	Commitment on B (s)	Commitment on C (s)	Commitment on D (s)	Commitment on E (s)	Commitment on F (s)	Latest (s)	Transaction latency (s)
1	20	1000	Doctor	0	0.118	20.166	20.370	20.352	20.379	20.379	20.363	20.379	20.379	20.379
2	20	1	Patient	0	0.110	0.163	0.434	0.424	0.423	0.428	0.437	0.418	0.437	0.437
3	2	10	Lab technician	0	0.099	2.141	2.292	2.306	2.290	2.305	2.306	2.291	2.306	2.306

We explain the transaction latency in Table 3. In the first and third cases, the orderer has to wait for 20 s and 2 s, respectively, before creating a block because there is only one incoming EHR transaction that needs to be packaged into the block and the batch timeout occurs first. In the second case, the batch size is 1 and there happens to be one EHR transaction, so the batch size is satisfied first, and the orderer does not have to wait for 20 s before creating the block.

Test Scenario: Concurrent Writes

Usually, many users write to the ledger simultaneously and the write operations are executed in overlapping time periods. For example, doctors, patients, and lab technicians may write EHRs to the ledger concurrently as needed. Transaction throughput is calculated by the number of EHR transactions committed by the network in a specific time period, expressed as transactions per second (TPS).

Table 4 shows the example data of 1000 concurrent writes with different parameter conditions. It can be seen that the transaction throughput is determined by the two parameters. For example, the first row shows the process of 1000 concurrent write operations when users try to submit EHRs to the ledger at the same time. The first EHR request occurs at 0 s, peer A finishes the 1000th endorsement at 132.224 s, and the orderer generates the last block at 139.930 s. Subsequently, six peers of the network separately commit the last block at 141.498 s, 141.936 s, 141.933 s, 141.400 s, 141.042 s, and 141.976 s. Therefore, the 1000 EHR transactions are available on all peers at the latest time, namely 141.976 s. Consequently, the transaction throughput reaches 7.043 TPS with batch timeout of 20 s and batch size of 1000.

Table 4. Example transaction throughput data at different nodes.

Number	Batch timeout (s)	Batch size (n)	1st write request (s)	1000th endorsement on A (s)	Last write on orderer (s)	Last commitment on A (s)	Last commitment on B (s)	Last commitment on C (s)	Last commitment on D (s)	Last commitment on E (s)	Last commitment on F (s)	Latest (s)	Transaction latency (s)	Transaction throughput (TPS)
1	20	1000	0	132.224	139.930	141.498	141.936	141.933	141.400	141.042	141.976	141.976	141.976	7.043
2	20	1	0	241.035	241.519	633.266	608.020	635.720	608.755	636.811	609.583	636.811	636.811	1.570
3	2	10	0	157.787	157.818	158.096	158.202	158.153	158.100	158.094	158.126	158.202	158.202	6.321

We can account for the transaction throughput in Table 4. In the first case, blocks are created every 20 s. Because it takes more than 20 s for 1000 transactions to come, the batch timeout happens first. In the second case, blocks are created every EHR transaction since the batch size is 1. In the third case, blocks are created every 10 EHR transactions. Because it takes less than 2 s for 10 transactions to come, the batch size happens first. It can be observed that the transaction throughput is inversely proportional to the number of blocks generated. Generating more blocks increases the likelihood of network congestion caused by the gossip protocol [16].

Discussion

Features of HealthChain

Based on the content that we have covered, the features of HealthChain are summarized as follows. First, HealthChain is permissioned. Unlike with a public permissionless network, all users like doctors and patients are certificated by the MSP and therefore are identifiable to each other, rather than anonymous and fully untrusted. Unauthorized or unknown users are not allowed to access the ledger. Second, HealthChain is immutable, that is, once EHRs have been added to the chain, they cannot be changed. This append-only property depends on the fact that the blocks are interlinked via hash references. Thus, HealthChain is the authoritative source of patients' treatment history. Third, HealthChain is transparent. Health care stakeholders come together to constitute the blockchain network, and none of them controls the whole system. Every operation initiated by users is checked against the governance model, which regulates and monitors the behavior of all actors. Furthermore, EHRs like encounter notes and lab results are shared among covered users, who know what is going on during the course of treatment. Fourth, HealthChain is HIPAA compliant with the privacy rule and security rule. Privacy policies are implemented through chaincode. The use of patient information is denied without authorization. Patients have final control over the EHRs, and they can grant write and read permissions to other covered entities. Besides, HealthChain exploits the Transport Layer Security (TLS) protocol to provide communication security over the network [16]. Fifth, HealthChain is scalable. Not all peers are involved in the transaction execution, and not all orderers are involved in the block generation. Therefore, parallel transaction execution and block generation are allowed, and HealthChain can easily support more nodes, though there are only six peers and one orderer in our experimental environment. Sixth, HealthChain has good performance. Even in our experimental environment, the read latency was about 0.1 s, and the read throughput of every peer was about 10 RPS. HealthChain achieves a transaction latency of about 0.4 s with batch size of 1, and it supports a transaction throughput of about 7 TPS with batch timeout of 20 s and batch size of 1000. In contrast, Bitcoin and Ethereum take 600 s and 10 s, respectively, to write a transaction on the ledger [42].

Parameter Setting

Performance of HealthChain is affected by many variables such as network size and limits of the hardware. Here, we discuss two parameters that we configure in the experiments, that is, batch timeout and batch size.

To achieve good performance, we should adjust batch timeout considering the permitted maximum transaction latency and set the batch size according to the rate indicating how many EHR transactions are submitted to the orderer during a specific period. The two parameters should be separately proportional to the permitted latency and the rate. As shown in the experiments, HealthChain obtains the lowest transaction latency when there is only one EHR transaction and the batch size is set to 1. It achieves the highest transaction throughput when there are 1000 transactions and the batch size is 1000.

Limitations

The prototype of HealthChain has two disadvantages. First, the only orderer causes a single point of failure. If the orderer fails, EHR transactions cannot be ordered into a block, causing failure of the entire system. To address this problem, we can deploy an ordering service consisting of a set of ordering service nodes and a Kafka cluster with its ZooKeeper ensemble [16]. This will help to not only build a crash fault-tolerant system but also increase the performance owing to load balancing.

Second, the read latency increases with the growth of the ledger. The ledger is implemented as a file on the disk considering the append-only write operation. At the same time, the read operation is also common in HealthChain. However, EHRs may scatter over the file with time, resulting in difficulty in searching for them. To solve the problem, we can create an index of patients on the ledger, making the read operation fast.

Conclusions

In this study, we built and evaluated HealthChain, which is an EHR consortium blockchain that operates under a governance model. It ensures data availability and data integrity. It provides chaincode APIs to accommodate the requirements from different clients and implements fine-grained access control. Besides, a way to anonymize EHRs is introduced. HealthChain adopts PoA as its consensus algorithm. The functionality of HealthChain was observed in the experiments. We described the performance of the system through latency and throughput.

(J Med Internet Res 2021;23(1):e26724) doi:10.2196/26724

In “Electronic Cognitive Screen Technology for Screening Older Adults With Dementia and Mild Cognitive Impairment in a Community Setting: Development and Validation Study” (J Med Internet Res 2020;22(12):e17332) the authors noted the need to revise the “Acknowledgments” section.

In the originally published article, the Acknowledgments section read as follows:

> *The development of EC-Screen is supported by The Hong Kong Jockey Club Charities Trust. We greatly appreciate the contributions of the Jockey Club Centre for Positive Ageing in the design and development of the EC-Screen, and Mindvivid Limited for program development of EC-Screen. We also thank Ms. Anthea Ng for her help in data collection and entry.*

This section has been revised to:

> *We thank Professor JE Morley, Saint Louis University School of Medicine, USA, for having agreed to let us adapt his Rapid Cognitive Screen test into EC-Screen for older Chinese people. We are also grateful for the funding support from the Hong Kong Jockey Club Charities trust, and for the support of the Jockey Club Centre for Positive Ageing for its contribution in design and data collection. We appreciate the support from Mindvivid Limited in software development of EC-Screen. We also thank Ms. Anthea Ng, research assistant of the Division of Neurology at The Chinese University of Hong Kong, for her help in data collection and entry.*

The correction will appear in the online version of the paper on the JMIR Publications website on January 19, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 23.12.20; this is a non–peer-reviewed article;accepted 04.01.21; published 19.01.21.

Abstract

Background: Confirmed COVID-19 cases have been registered in more than 200 countries, and as of July 28, 2020, over 16 million cases have been reported to the World Health Organization. This study was conducted during the epidemic peak of COVID-19 in Italy. The early identification of individuals with suspected COVID-19 is critical in immediately quarantining such individuals. Although surveys are widely used for identifying COVID-19 cases, outcomes, and associated risks, no validated epidemiological tool exists for surveying SARS-CoV-2 infection in the general population.

Objective: We evaluated the capability of self-reported symptoms in discriminating COVID-19 to identify individuals who need to undergo instrumental measurements. We defined and validated a method for identifying a cutoff score.

Methods: Our study is phase II of the EPICOVID19 Italian national survey, which launched in April 2020 and included a convenience sample of 201,121 adults who completed the EPICOVID19 questionnaire. The Phase II questionnaire, which focused on the results of nasopharyngeal swab (NPS) and serological tests, was mailed to all subjects who previously underwent NPS tests.

Results: Of 2703 subjects who completed the Phase II questionnaire, 694 (25.7%) were NPS positive. Of the 472 subjects who underwent the immunoglobulin G (IgG) test and 421 who underwent the immunoglobulin M test, 22.9% (108/472) and 11.6% (49/421) tested positive, respectively. Compared to NPS-negative subjects, NPS-positive subjects had a higher incidence of fever (421/694, 60.7% vs 391/2009, 19.5%; *P*<.001), loss of taste and smell (365/694, 52.6% vs 239/2009, 11.9%; *P*<.001), and cough (352/694, 50.7% vs 580/2009, 28.9%; *P*<.001). With regard to subjects who underwent serological tests, IgG-positive subjects had a higher incidence of fever (65/108, 60.2% vs 43/364, 11.8%; *P*<.001) and pain in muscles/bones/joints (73/108, 67.6% vs 71/364, 19.5%; *P*<.001) than IgG-negative subjects. An analysis of self-reported COVID-19 symptom items revealed a 1-factor solution, the EPICOVID19 diagnostic scale. The following optimal scores were identified: 1.03 for respiratory problems, 1.07 for chest pain, 0.97 for loss of taste and smell 0.97, and 1.05 for tachycardia (ie, heart palpitations). These were the most important symptoms. For adults aged 18-84 years, the cutoff score was 2.56 (sensitivity: 76.56%; specificity: 68.24%) for NPS-positive subjects and 2.59 (sensitivity: 80.37%; specificity: 80.17%) for IgG-positive subjects. For subjects aged ≥60 years, the cutoff score was 1.28, and accuracy based on the presence of IgG antibodies improved (sensitivity: 88.00%; specificity: 89.58%).

Conclusions: We developed a short diagnostic scale to detect subjects with symptoms that were potentially associated with COVID-19 from a wide population. Our results support the potential of self-reported symptoms in identifying individuals who require immediate clinical evaluations. Although these results come from the Italian pandemic period, this short diagnostic scale could be optimized and tested as a screening tool for future similar pandemics.

Introduction

SARS-CoV-2 has led to a global pandemic; on July 28, 2020, over 16 million cases and 650,805 deaths across more than 200 countries were reported by the World Health Organization and Johns Hopkins Center for Health Security [1,2]. Italy was the first European country to be hit hard by the COVID-19 epidemic. It was also the European country with the highest number of COVID-19 deaths recorded (ie, 24,780 as of April 27, 2020) [3]. Besides the immediate human toll, the readily acknowledged and potentially long-lasting effects of the pandemic on global economies, politics, health, and privacy policies at many levels has extended beyond the development of vaccines and treatments. The rapid spread of the COVID-19 disease and its seemingly high degree of variability in its presentation among individuals has led to a level of clinical and scientific focus that has not been previously seen. This focus has encompassed both traditionally reviewed and preprint publications and resources. Collaborative groups are being formed at the local, regional, national, and international levels to address patient data collection, aggregation, and analysis in ways that may change the way research is carried out in the future [4]. To ensure that these efforts are both effective and productive, data must be evaluated in a way that is suitable for their inclusion in these activities, while still recognizing that what we understand about COVID-19 is much less than what we do not understand [5].

Due to the far-reaching scope of the pandemic, we are already confronting (1) the need to implement individual testing at a level far above current capacities to optimize individual treatment, assess disease spread, and anticipate potential strains on health care resources and personnel [6]; (2) the need for improvements in available tests, such as nasopharyngeal swab (NPS) and antibody detection tests, (ie, improvements in accuracy, specificity, and sensitivity) to enable the reliable evaluation and interpretation of data for use in clinical care and policy decisions [7]; and (3) the need to harmonize clinical observations and definitions to support the development of guidelines and prognostic and diagnostic indicators, and to develop a comprehensive understanding of COVID-19 and critical factors that can help differentiate between different patient susceptibilities, presentations of the disease, and responses to treatment [8,9].

The use of web-based surveys can greatly enhance access to broader populations in a cost-effective manner, optimize screening for individuals who may need immediate care, and provide an approach for achieving item 3 in the previous paragraph. A cross-sectional national survey, EPICOVID19, was launched on April 13, 2020 and received more than 200,000 responses [10]. The survey, which represents phase I of this study, was promoted through social media (ie, Facebook, Twitter, Instagram, and WhatsApp), press releases, internet pages, local radio and television stations, and institutional websites that called upon volunteers to contact the study website. The inclusion criteria were as follows: age of >18 years; access to a mobile phone, computer, or tablet with internet connectivity; and on-line consent to participate in this study.

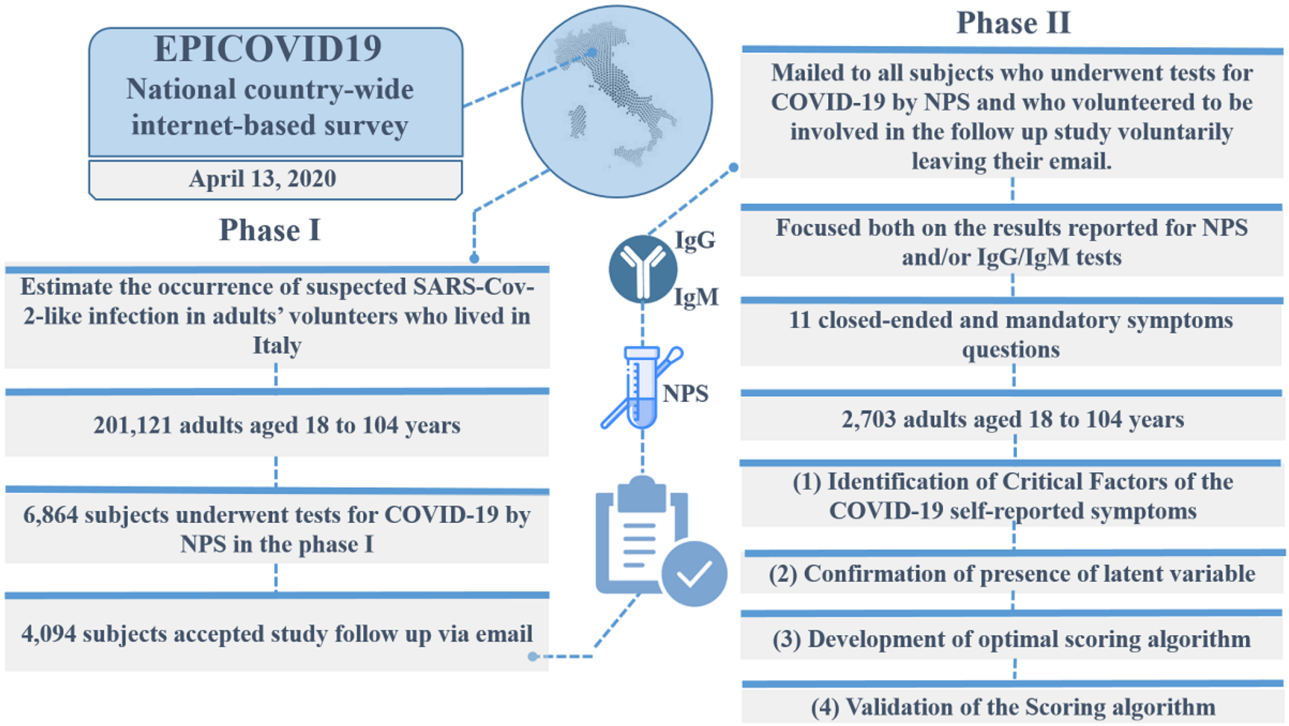
This study was conducted during the epidemic peak of COVID-19 in Italy. The aim of our study was to assess the capability of the self-reported symptoms collected through the EPICOVID19 questionnaire in discriminating COVID-19 among symptomatic subjects, in order to identify individuals with suspected COVID-19 who need to undergo instrumental measurements and clinical examinations (ie, phase II of the EPICOVID19 study). The final objectives were proposing a method for the development of a total score for the self-reported symptoms in the EPICOVID19 questionnaire, and validating the scoring method based on molecular and serological clinical diagnosis data.

Methods

Study Design and Participants

Our study is phase II of the EPICOVID19 Italian national survey [9] (pages 1-8 in Multimedia Appendix 1), which launched in April 2020 and included a convenience sample of 201,121 adults who completed the EPICOVID19 questionnaire. Figure 1 shows the overview of the EPICOVID19 2-phase study. The Phase I questionnaire investigated 6 areas through 38 questions. The 6 areas were as follows: (1) sociodemographic characteristics, (2) clinical evaluation, (3) personal characteristics and health status, (4) housing conditions, (5) lifestyle, and (6) behaviors after the lockdown.

Figure 1. Overview of the EPICOVID19 2-phase study. IgG: immunoglobulin G; IgM: immunoglobulin M; NPS: nasopharyngeal swab.



The Phase II questionnaire was mailed to all subjects who underwent NPS testing for COVID-19 and volunteered to be involved in the follow-up study in their phase I response. Phase II focused on the results of NPS and serological immunoglobulin G (IgG)/immunoglobulin M (IgM) tests and self-reported symptoms, with the aim of better identifying both symptomatic and asymptomatic SARS-CoV-2 infection cases [10].

Phase II was implemented by using an open-source statistical survey framework, LimeSurvey (version 3.17). This is a PHP (Hypertext Preprocessor)–based framework that is distributed under the GNU General Public License.

In phase II, responses to 11 questions were required. These questions covered the administration of the NPS and serological tests and the time that elapsed between observed/reported symptoms and clinical examination (ie, NPS and IgG/IgM tests) (pages 1-8 in Multimedia Appendix 1).

Of the 6864 subjects who underwent NPS testing for COVID-19 in phase I, 4094 subjects were invited by email to complete the Phase II questionnaires via the internet. Of these 4094 subjects, 38 could not participate because their email invitations were not delivered due to various issues (eg, wrong email address, full mailbox, host or domain name not found, etc), 101 refused to provide consent, and 1252 received the email, but did not proceed to complete the questionnaire.

The web-based survey included questions with close-ended answers in order to facilitate questionnaire compilation and avoid errors in digitizing answer values. At the end of the Italian lockdown period on May 2, 2020, the survey was closed and all collected data were exported for analysis with statistical tools. The base data for the statistical analysis was structured as a table that contained 1 row for each survey participant and as many columns as the collected responses. The questionnaire is available in pages 1-16 in Multimedia Appendix 1.

A total of 2703 subjects (response rate: 66%) completed the Phase II survey. After considering the 6864 subjects who underwent the NPS test in the Phase I survey, we compared the characteristics of 2703 respondents and 4161 nonrespondents. Respondents and nonrespondents to the Phase II survey appeared similar with respect to gender, age, the perception of their own health, and self-reported comorbidities. The details of the comparison between these 2 groups of subjects are included in page 9 in Multimedia Appendix 1. The resulting data of the 2703 subjects who completed the Phase II questionnaire were linked to the self-reported symptom results of the Phase I EPICOVID19 questionnaire, which included questions on the presence of 11 symptoms.

Statistical Analysis

We analyzed the self-reported symptoms that were collected in the survey to define a method for calculating a total score and validate the scoring method for serological and molecular clinical diagnoses. This was done by using 4 standard questionnaire validation steps.

The first step was the identification of critical factors. We determined the factorial structure of the COVID-19 self-reported symptom items via exploratory factor analysis (EFA), followed by confirmatory factor analysis (CFA). EFA and parallel analysis were performed to evaluate the performance of specific symptoms (ie, loadings) and define the number of factors underlying these loadings.

The second step was the confirmation of the presence of latent variables. We carried out CFA via structural equation modelling to confirm the presence of 1 latent variable (ie, factor) underlying the 11 symptoms that were chosen to identify

COVID-19. Several goodness-of-fit criteria were used, as follows: (1) standardized root mean square residual (SRSR); (2) root mean square error of approximation (RMSEA), which could not be >0.10; (3) comparative fit index (CFI); and (4) Tucker-Lewis index (TLI), which could not be <0.90.

The third step was the development of an optimal scoring algorithm. We developed an optimal scoring algorithm via homogeneity analysis by means of alternating least squares (HOMALS) and multiple correspondence analysis (MCA). Through the HOMALS procedure, we replaced specific dichotomous responses (ie, Yes/No) with categorical quantifications; the resulting score was the sum of the subject's symptom responses after they were recoded based on category quantifications.

The fourth step was the validation of the scoring algorithm. We validated the score by using an external objective criterion that was based on receiver operating characteristics analysis, in order to evaluate the performance of COVID-19 symptom scores in distinguishing symptomatic individuals in the complete sample (ie, participants aged between 18 and 84 years) and 2 specific age groups (ie, participants aged <60 years and ≥60 years). Since we aimed to discriminate COVID-19 cases, we calculated the sensitivity, specificity, and Youden index with the following 2 reference standards: (1) subjects who tested positive in the NPS tests versus subjects who tested negative in the NPS test, and (2) subjects who tested positive in the serological IgG tests versus subjects who tested negative in the IgG test. The overall predictive performance was evaluated via area under the curve (AUC) analysis.

All statistical analyses were carried out using R software (version 3.6.3), IBM SPSS 23 (IBM Corp), and Stata Statistical Software (Release 15; StataCorp LLC). The details of the performed statistical analyses are reported in pages 10-12 in Multimedia Appendix 1.

Ethical Approval

The Phase II EPICOVID19 study was approved by the Ethical Committee of the Istituto Nazionale per le Malattie Infettive, Institute for Research, Hospitalization and Healthcare Lazzaro Spallanzani as an amendment of the EPICOVID19 epidemiological study (approval number 93 in the trial register). Data transfer was safeguarded by means of password protection and encryption/decryption policies. All data were handled and stored in accordance with the European General Data Protection Regulation 2016/679 [11]. Informed consent details were accessible on the home page of the platform, and participants were asked to review these details before starting the Phase II questionnaire. The home page explained the purpose of the study, which data were to be collected, and how data were stored.

Subjects' email addresses were the personal data provided on a voluntary basis in phase I. In our study, email addresses were only used to (1) send email invitations for participating in the Phase II survey and (2) link the information related to NPS and IgG/IgM test results to the information on symptoms collected during the phase I survey. In the participation mail, subjects were able to participate by clicking on the provided link to the survey, not participate by ignoring the invitation, communicate with the authors by using the provided study-specific email address, and request the deletion of their email address from the database.

Results

Study Design and Participants

The characteristics and NPS, IgG, and IgM results of the 2703 subjects, which were supplied by those who completed the Phase II survey, are shown in Table 1. The sample predominantly consisted of women (1841/2703, 68.1%), and the average age was 49 years (SD 15.0 years) and 52 years (SD 14.1 years) for women and men, respectively. Of the 2703 respondents, 151 (5.6%) had a low educational status, 837 (31%) had a medium educational status, and 1715 (63.4%) had a high educational status. The most reported chronic condition by participants was hypertension (361/2703, 13.4%), followed by immune system diseases (266/2703, 9.8%), and depression and anxiety diseases (194/2703, 7.2%). The least frequently reported chronic symptoms were liver (21/2703, 0.8%) and kidney (22/2703, 0.8%) diseases. All the details are reported in page 13 in Multimedia Appendix 1.

Statistical Analysis

Of the 2703 subjects, 694 (25.7%) tested positive in the NPS test. Of these 694, 84 (12.1%) were asymptomatic. With regard to the subgroup of subjects who underwent serological testing, 472 underwent the IgG test and 421 underwent the IgM test, and 22.9% (108/472) and 11.6% (49/421) tested positive, respectively. Of the 108 IgG-positive subjects, 1 (0.9%) was asymptomatic. Of the 49 IgM-positive subjects, 5 (10.2%) were asymptomatic. With regard to NPS-positive subjects, the average number of days between initial symptoms and the day of swab execution was 9.3 days (SD 9.4 days; median 7 days, IQR 3-7 days). With regard to IgG-positive subjects, the average number of days between initial symptoms and the day of serological test execution was 36.1 days (SD 15.1 days; median 36.5 days, IQR 28-47 days). With regard to IgM-positive subjects, the average number of days from initial symptoms to the day of serological test execution was 26.1 days (SD 17.9 days; median 28 days, IQR 4-40 days). The incidence rate of the 11 symptoms reported by the 3 groups (ie, the NPS, IgG, IgM test groups) was similar between men and women. In the NPS-positive group, women only had a higher incidence of sore throat and cold and tachycardia (ie, heart palpitations) than men. In the IgG-positive group, men only had a higher incidence of headaches than women. In the IgM-positive group, women had a lower incidence of symptoms related to conjunctivitis than men.

The frequency of symptoms among NPS-positive subjects (Table 1) ranged from low rates of observation (eg, tachycardia [ie, heart palpitations]: 120/694, 17.3%; conjunctivitis: 111/694, 16%) to high rates of observation (eg, fever: 421/694, 60.7%; olfactory and taste disorders: 365/694, 52.6%). For all symptoms apart from headache, the incidence rates were significantly higher in NPS-positive subjects than in NPS-negative subjects (*P*<.001). With regard to the subgroup of individuals who underwent serological tests, the symptoms with a high incidence among subjects who tested positive were fever (IgG-positive group: 65/108, 60.2%; IgM-positive group: 28/49, 57.1%) and pain in muscles, bones, and joints (IgG-positive group: 73/108, 67.6%; IgM-positive group: 27/49, 55.1%). In the IgG serological test group, no significant difference was observed in the incidence of sore throat and cold symptoms (*P*=.23) between IgG-positive and IgG-negative subjects. The incidence of respiratory difficulty (*P*=.35), chest pain (*P*=.35), and gastrointestinal symptoms (*P*=.08) did not significantly differ between IgM-positive and IgM-negative subjects.

Table 1. Self-reported characteristics that were obtained from the Phase II survey and analyzed by using SARS-CoV-2 infection test results (N=2703).[a]

Variable	SARS-CoV-2 tests								
	Nasopharyngeal swab test, n=2703			Immunoglobulin G antibody test, n=472			Immunoglobulin M antibody test, n=421
