qualitative data indicated that participants changed their behaviors, including that they improved their self-management skills, got their symptoms under control, engaged in physical activity, experienced weight loss, and changed when and how they interacted with their health care professionals. Participants in Ireland also reported improvements in health. The analysis of the sensor and well-being data collected through the platform during the trial is currently underway, focusing particularly on symptom stabilization and physical activity to determine whether engagement with the intervention had a positive impact on these areas.

Previous research has indicated that the adoption of self-management technologies is limited [66]. Studies on the adoption of self-management technologies by older adults, particularly the oldest old, are lacking [67]. A number of studies have focused on conducting interviews, focus groups, or surveys with older adults to gauge interest in health technologies or barriers. Many of these reported negative attitudes. For example, Heart and Kalderon [32] found that older adults lacked interest in such technologies and perceived accessibility barriers. The authors concluded that such technologies would not be accepted by older adults unless they were very easy to use, useful, and there was support available to help with technical difficulties. The authors also suggested that when such factors are present, older adults can embrace self-management. On the basis of data from real-world engagement and participant feedback, our findings support this argument.

A number of possible reasons for sustained engagement during the ProACT trial have been identified. Throughout the trial, participants reported benefits, including improvements in health and well-being related to an increased ability to self-manage. Perceived benefit plays a role in technology acceptance and adoption [68,69] as well as in the activation of effective self-management behaviors [16]. Our findings are in line with those of a systematic review of studies examining older adults' usage of technology to support chronic disease management, which found that participants experienced greater self-efficacy because of technology-supported self-management, which enabled improved communication with health care providers, including personalized feedback and support [17].

Yardley et al [30] state that "successful intervention design demands a user-centered and iterative approach to development, using mixed methods and in-depth qualitative research to progressively refine the intervention to meet user requirements." A notable feature of the ProACT approach to designing and evaluating the platform was that it continually involved people with multimorbidity in a user-centered design process, including interviews, focus groups, co-design workshops, usability testing and evaluation activities, supporting regular, iterative updates to the ProACT platform. Our findings indicate that the majority of trial participants found the ProACT platform to be usable. Usability barriers are recognized within the literature as negatively impacting older adults' adoption of and engagement with technology [70,71]. Our findings also indicated that the participants found using this technology exerted low burden. This is an important finding given that there is significant work associated with self-management of chronic diseases, particularly multiple diseases and comorbidities [41]. Although participants had self-management activities outside of using the platform and their interactions with triage, such as attending appointments and managing medications, which were not evaluated as a part of the trial, it is promising that engaging in symptom monitoring, review, and education did not result in a high level of burden for the majority of participants. The usability and burden findings, along with the engagement data, indicate that the extensive user-centered design process during the project lifecycle cannot be underestimated; without this effort, it is possible that users would not have sustained their use of ProACT.

Research has noted that using digital health platforms for self-management without human support can negatively impact engagement, resulting in dropout and nonusage attrition [30,72]. Human services, including the triage and helpdesk, provided alongside the ProACT technology platform, appeared to be an important factor in terms of contributing to sustained engagement. Participants received feedback and advice on their health and well-being from the triage nurses and experienced continuity of care. Many clinical outcomes were also precipitated by the triage staff. Ancker et al [18] suggested that participants in their study lacked motivation to self-manage, as they perceived that health care professionals were not interested in their data. Furthermore, participants using ProACT had access to a technical helpdesk for the study duration if they experienced any technical issues. As is evident from the Irish helpdesk data outlined above, this was a necessary service because across the trial period for 60 participants, 355 calls were made to the helpdesk, 277 of which were related to technical issues, primarily related to the third-party devices provided to participants for symptom monitoring. Indeed, frustration with the sensing devices, including a poor usability, lack of reliability, and mistrust of the data they produced, were reasons for participants withdrawing from the trial. Given the importance of such devices in health self-management, device providers should strive to ensure that they are usable and reliable. Other research on the abandonment of health tracking devices found reasons that included technology being too complicated, too complex to learn, or failing to help people reach their goals [73].

Future research should also examine the potential role and necessity of helpdesk and triage services over longitudinal periods of time, as the needs of people with multimorbidity, as well as their self-management and technical skills change. Research should examine at what point or points of a self-management journey human support adds value to a digital health intervention. For example, some research has shown that support for self-management is mostly needed when a person first begins using a digital health intervention [56] to ensure adoption. However, research into the type and level of ongoing support that might be required for self-managing with multiple, complex chronic conditions is lacking. This also needs to be considered within the context of aging, as many older adults will experience a decline in health or the diagnosis of additional conditions and comorbidities over time. However, it is important to note that the levels of triage and technical support required also have implications in terms of costs of service provision; for example, the ratio of nurses to patients that is required to

provide an effective service. Hence, this aspect also needs to be further examined.

Limitations

There are several limitations to this study. First, given the resource limitations, the version of the ProACT platform described in this paper and evaluated in the trial did not integrate all of the features required to fully support the self-management of multimorbidity, with development initially focused on symptom and well-being monitoring, education, setting physical activity goals, and data sharing. The inclusion of features such as medication management, care planning, and goal setting beyond physical activity would be required to fully address the challenges of the self-management of multiple conditions. However, the addition of such features could also lead to an additional technological burden, which could negatively impact engagement. The integration of CareAnalytics not currently integrated within the platform and further development of all analytics could help minimize burden while also enhancing the platform's capability to handle recommendations that consider a person's full condition profile. For example, future work aims to further enhance the goal recommender in terms of personalization by considering the person's current health status, as indicated by the Health and Wellness Profiler analytic described above.

A further point with respect to the PoC study design (which was primarily to understand the feasibility of people with multimorbidity engaging with a digital health platform to self-manage their conditions) is that a control group was not included; therefore, it was not possible to assess the effectiveness of individual components of the ProACT platform and related services (access to triage and technical support). Future work will aim to examine the potential impact of these factors in more detail through controlled studies with people with multimorbidity. Implementing an iterative, user-centered PoC trial has helped justify the need for a large-scale controlled study. Therefore, we advocate that such an approach to designing and developing complex interventions for the management of multiple diseases should be considered before progressing toward large-scale studies.

Conclusions

This work is the first to present a digital health platform designed specifically to support multimorbidity self-management for older adults, with results showing high levels of engagement and retention over a 12-month period. There are several strengths to this work. We present a comprehensive digital platform that outlines how various components support the management of multiple diseases. There was active engagement from participants across all stages of the design, development, and evaluation of the platform. The trial involved a large number of participants across 2 EU countries over a longitudinal period. Few studies on digital health solutions to support the self-management of chronic conditions have focused on older adults. Neither do they have such large numbers (especially at the PoC level) nor do they examine long-term usage. Furthermore, comparatively little research has examined the design and evaluation of digital health platforms for people with multimorbidity.

Planned future work includes updating the platform to further enhance the management of multimorbidity and a pragmatic randomized controlled trial to evaluate the effectiveness (including potential cost-effectiveness) of the platform and triage service on quality of life, health care utilization, and a range of other measures, which will begin in 2022.

Acknowledgments

The ProACT project has received funding from the EU's Horizon 2020 Research and Innovation Programme under grant agreement 689996. MMM is funded by a Marie-Sklodowska-Curie fellowship (EU H2020 EDGE program grant agreement 713567). The authors would like to sincerely thank all the participants of this research for their valuable time. The authors wish to thank all consortium partners [74] for input across the project.

Abstract

Background: The popularity of mobile health (mHealth) technology has resulted in the development of numerous apps for almost every condition and disease management. mHealth and eHealth solutions for increasing awareness about, and safety around, intimate partner violence are no exception. These apps allow women to control access to these resources and provide unlimited, and with the right design features, safe access when these resources are needed. Few apps, however, have been designed in close collaboration with intended users to ensure relevance and effectiveness.

Objective: The objective of this paper is to discuss the design of a suite of evidence-based mHealth and eHealth apps to facilitate early identification of unsafe relationship behaviors and tailored safety planning to reduce harm from violence including the methods by which we collaborated with and sought input from a population of intended users.

Methods: A user-centered approach with aspects of human-centered design was followed to design a suite of 3 app-based safety planning interventions.

Results: This review of the design suite of app-based interventions revealed challenges faced and lessons learned that may inform future efforts to design evidence-based mHealth and eHealth interventions.

Conclusions: Following a user-centered approach can be helpful in designing mHealth and eHealth interventions for marginalized and vulnerable populations, and led to novel insights that improved the design of our interventions.

Introduction

In recent years, web-based and mobile health (mHealth) technology has expanded greatly, providing a unique space for individuals to access information and resources to manage and improve health and well-being [1-3]. With upward of 5 billion individuals subscribing to wireless mobile services globally [4], digital space allows those seeking information or support to do so in a user-controlled, discreet, and accessible way [5-7]. This technology fills a unique gap for survivors of intimate partner violence (IPV), giving control to individuals themselves to access information about safety and resources. mHealth tools can be used at any time and any place, and survivors can return to the information as many times as needed to explore their

concerns and their options as their situations change. In the past 20 years, more than 300 mobile or web-based apps for IPV have emerged [3,8], but only few have achieved widespread adoption. One limitation of apps that have failed to gain traction is their inability to meet the needs of specific communities or targeted groups, including the identification of local and appropriate resources.

The Partner Violence Implementation Science group is a collaboration between researchers, service providers, and survivors of IPV; our work is focused on cocreating interventions supporting individuals' safety and self-determination. As part of these efforts, we identified the need for electronic IPV screening and safety planning resources tailored to the communities in which we work [3,4]. While a number of apps are available to assist women with identifying IPV and formulating safety plans, our community partners were concerned that many did not adequately address the nonlinear and multiphase process many women go through in an effort to increase safety for themselves and their children [9-11]. Gaining awareness of the possible dangers involved with taking action is one of these challenges, and women who have experienced IPV often lament that this awareness—along with information about how to increase relationship safety—did not come earlier in the process [12-14]. While our initial intent was to develop a tool to aid health care providers screen for IPV in an outpatient orthopedic clinic, our community partners—including survivors of IPV—felt that a web-based mHealth tool that was easy and quick to use, exclusively focused on identifying "red flags" for abusive behaviors, and that could help users identify safety options tailored for their situation was a critical need across settings. While we recognize that IPV is experienced by persons of all genders, our research focused on the experiences of the largest group of those experiencing IPV: cisgender women who are in relationships with cisgender men.

First, we looked at a variety of screening apps aimed at helping women identify if they are in an abusive relationship. After previewing a variety of publicly available screening apps across North America, we discovered that these tools often left out 1 or more types of violence, or did not use validated screening questions to detect IPV [15,16]. This led to our decision to create our own screening app that could help a wide range of individuals recognize patterns of unsafe behaviors in their own or others' relationships and immediately access information about abuse and local services.

Next, for the smaller subset of women who may be experiencing behaviors related to IPV, a separate app was needed that could help them assess the severity of their situation (including the risk for lethality) and would promote safety planning behaviors tailored for their situations. One existing app provided much of what we were looking for. Developed by researchers at Johns Hopkins University [17-19] and tailored for Canadian audiences by researchers at Western University [20,21], the MyPlan app is an evidence-based mHealth app aimed at increasing users' understanding of potentially dangerous patterns in their relationships reducing their ambivalence, or decisional conflict, about acting to alter these patterns and has been found to reduce future IPV in international randomized control trials [17,20,22-24]. After engaging with our target population and consultation with the teams at Johns Hopkins University and Western University, we decided to build on this evidence base and strong foundation to address additional needs present in our populations of interest as identified by our community partners in the Greater Toronto Area (GTA): women who were looking for more information about IPV, the majority of whom are not currently experiencing any unsafe relationship behaviors, and a second population of women who are living with IPV and need information about the potential for serious consequences of the abuse (up to and including lethality) and access to tailored safety planning that references geographically and culturally relevant strategies and resources.

This paper describes the rigorous process we engaged in to develop 3 evidence-based apps, each of which was developed for a particular audience and tailored to their specific needs. Using elements of human-centered design (HCD) [25], we ensure the end users (women at risk for IPV and those experiencing IPV) are involved in all stages of design and testing of our suite of mHealth tools. This includes iterative elicitation regarding the quality of experience, feelings of safety using the apps, and perceived helpfulness of the tools themselves throughout the design and testing processes [26,27]. Very few IPV screening or safety planning apps provide detailed information about the development or testing of the product, and there is scant peer-reviewed evidence regarding the process of developing the app, user testing, and evaluation [8]. Because of the critical role these tools can play for women who are concerned about the safety of themselves or a loved one, ensuring that the end product both addresses the primary concerns of women in a local community and uses evidence-informed processes to provide knowledge or bring about change is essential. Thus, we begin to shed light on this process by describing our iterative, community-engaged approach to building 3 separate, yet complementary, IPV mHealth interventions: an IPV screening tool (WithWomen), an individualized safety planning web app (Pathways), and the rapid adaptation of this app to the realities of living with IPV during COVID-19 (Promoting Safety in Emergencies, or PROMiSE). This suite of apps is summarized in Table 1.

Methods

Approach

Our approach to the design and adaptation of our suite of apps relied on the formation of partnerships with health care providers working to implement a screening program into their outpatient clinic setting, as well as service providers at IPV shelters, counseling groups for women with lived experience of IPV, and a peer support network for women living with IPV. We felt it important to keep these perspectives present throughout our design and adaptation process. Our partners played many roles: they advised us on key design features and content, connected us with women with lived experience who would provide feedback on the screening questions and functionality of the web apps, informed us of resources within the region which should be listed in the web apps, and connected us with plain language experts to ensure the content was appropriate for our population. The process used to develop each of these is

discussed below. All 3 apps were approved by the St. Michael's Hospital Research Ethics Board (REB # 15-361). Table 1 outlines the components of our suite of apps, their target populations, and main innovations, while Table 2 reviews the demographic characteristics of samples used to develop and test each of the mHealth tools.

The demographic characteristics of those who participated in the various surveys and interviews to inform the development of our screening and safety decision-support app are presented in Table 2.

Developing the WithWomen Screening App

Selecting the Screening Questions

We sought to have valid and reliable screening questions. After reviewing multiple validated IPV screening tools and the peer-reviewed literature [28], we selected the *Hurt, Insult, Threaten, and Scream* (HITS) instrument to serve as the base for our screening app. The HITS instrument is brief, has been used in general practice and emergency department settings [29,30], demonstrated acceptable sensitivity (88%) and specificity (range 86%-97%), and has been extensively tested within different populations (eg, tested in women/men, Hispanic and African American women as well as in Spanish) [31,32]. However, one of the limitations of HITS is its inability to identify subtle experiences of IPV, such as coercive and controlling behaviors, as well as experiences of sexual IPV. We identified several additional questions by consulting the peer-review literature on validated screening questions concerning coercive control and through conversations with our community partners (eg, "partner controlling what you wear").

To be sure we were identifying those app users with the greatest need for immediate assistance, we limited the recall period to the past 12 months and asked questions in terms of frequency, rather than only identifying if behaviors had happened at all. Additionally, we intentionally asked about both short-term (eg, dating) and long-term (eg, partners) relationships.

Testing the Questions

To ensure our screening questions were acceptable and appropriate, we sought input from a cross-section of women.

We conducted anonymous encounter surveys with women in local shopping malls. We approached women in the food courts, explained our research, and asked if they had 10 minutes to complete a short survey. We asked women to give us feedback on the clarity and acceptability of the questions and whether we were missing questions about a particular type of violence. We also consulted with women who were more likely to have lived experience of IPV by posing the same questions to female clients who accessed services at our partner community agencies (eg, women's shelters, organizations serving women involved with the justice system). We also consulted service providers who serve women more generally such as at health clinics or agencies who help women with employment or housing to seek their input.

Next, as we narrowed the set of candidate questions, we conducted 3 cycles of cognitive interviews to ensure the clarity of the questions [33]. These were face-to-face surveys asking women to tell us in their own words what each question was asking and to get their advice on any terms or phrases that were hard to understand or inappropriate. We revised the questions based upon feedback we received in between each cycle. We also sought to test the reliability of our questions by administering the questions to a subset of women and contacting them 1 month later to retake the survey. Agreement between test and retest was assessed through computing the intraclass correlation coefficient (ICC). We also established evidence for convergent validity with questions capturing safety-related activities such as talking to a counselor about relationship concerns or missing work due to relationship issues [34].

The final screening instrument consisted of 9 items. The next step was to assign a level of risk to an individual's summed score on the full screening instrument. To do this, we first assigned a value of risk for the answers to each question. Using information on the severity of the violence described in the question and corroborating it with existing severity ratings for similar questions [17,32], we assigned risk values to each question, with the lowest value of risk being 0 and the highest level of risk being 3. For example, if the respondent's partner, ex-partner, or someone the respondent dated insulted her frequently, she received a question-specific level of risk of 2. On the physical violence item, she automatically received a question-specific score of 3 if she experienced any amount of beating, punching, kicking, strangling, or harm with a weapon. A sum score of 0-4 across all 9 questions indicates few to no safety concerns, 5-8 indicates there may be safety concerns, and 9-24 indicates that there are moderate to high safety concerns in the relationship (see Textbox 1 for scoring summary).

Finalizing Our Screening Questions

Using feedback from the cognitive interviews, we made slight wording changes to our questions to ensure their acceptability to women. For example, the question on sexual violence originally featured the word "coerce"; however, not all women interviewed understood the meaning behind the word and it was changed to "pressure, threaten, or force." Overall, the questions were highly acceptable and clear to potential users, largely due to the fact that we relied on previously validated screening tools as the source of our questions. Almost perfect test–retest agreement was demonstrated via the 16 reliability interviews (ICC 96%; 95% CI 90%-99%). Reliability was similar when the sample was reduced to only those women who reported at least one positive answer to the screening questions (ICC 95%; CI 79%-99%).

Textbox 1. WithWomen final rapid intimate partner violence screening questions with points assigned to answers to reflect level of safety risk in a relationship.

1. Over the last 12 months, how often did you feel uncomfortable doing or saying things around your current partner or someone you're currently dating?

0=never, rarely, sometimes

1=frequently

2. Over the last 12 months, how often did your partner, an ex-partner, or someone you dated INSULT you or talk down to you?

0=Never, rarely

1=Sometimes

2=Frequently

3. Over the last 12 months, how often did your partner, an ex-partner, or someone you dated yell, shout, or curse at you?

0=Never, rarely

2=Sometimes

3=Frequently

4. Over the last 12 months, how often did your partner, an ex-partner, or someone you dated control who you see, where you go, what you do, or what you wear?

0=Never

2=Rarely, Sometimes

3=Frequently

5. Over the last 12 months, how often did your partner, an ex-partner, or someone you dated make you feel afraid or scared of them?

0=Never

2=Rarely, sometimes

3=Frequently

6. Over the last 12 months, how often did your partner, an ex-partner, or someone you dated THREATEN to harm you or someone you care about?

0=Never

2=Rarely

3=Sometimes, Frequently

7. Over the last 12 months, how often did your partner, an ex-partner, or someone you dated physically HURT you?

0=Never

2=Rarely

3=Frequently, Sometimes

8. Over the last 12 months, how often did your partner, an ex-partner, or someone you dated beat, punch, kick, strangle, or hurt you with a weapon?

0=Never

3=Rarely, Sometimes, Frequently

9. Over the last 12 months, how often did your partner, an ex-partner, or someone you dated force, threaten, or pressure you to participate in any sexual activity when you didn't want to?

0=Never

3=Rarely, Sometimes, Frequently

Points for each question are summed and categorized into the following categories. The results screen displays the color (eg, yellow) and the explanation of the result (ie, "there are some things about your relationship that are of concern") at the end of rapid screening.

0-4: Healthy (Green): There are few to no concerns regarding safety in your relationship

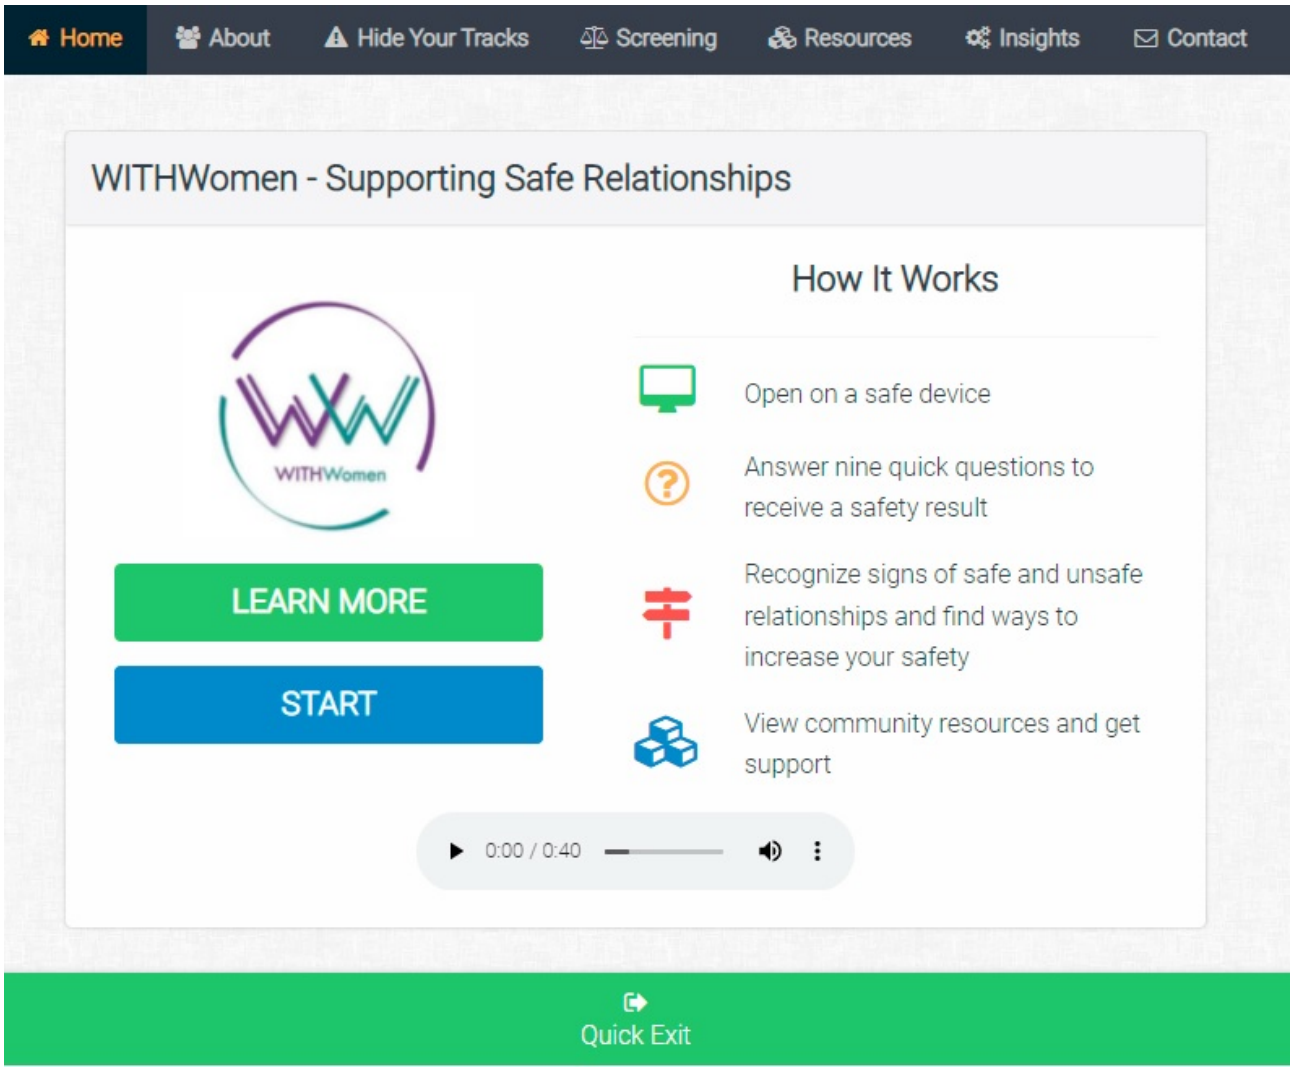
5-8: Caution (Yellow): There are some things about your relationship that are of concern.

9-24: Confirmed abuse (Red): Your relationship has many safety concerns.

We established concurrent validity of our scales by correlating scores on the 9-item violence scale with responses to questions about whether women took part in activities that might be expected for women who were concerned about safety in their relationships: searched the internet for information about IPV; talked to a social worker or other professional or family and

friends about her relationship; missed work because of relationship issues; or called the police due to relationship issues. Spearman correlations between the scores on the IPV screener and the 4 behaviors ranged from 0.72 to 0.82. We did ask about 1 more behavior, sought medical attention due to violence, and its correlation with our IPV screener was lower (0.57). Thus, concurrent validity was moderately high for all but 1 of the items, seeking medical care, but given that this activity happens relatively rarely and is only expected for 1 type of violence, physical violence, this level of correlation might be expected. The WithWomen landing page is shown in Figure 1.

Figure 1. WithWomen Landing Page.



The user journey for our WithWomen Screening app is presented in Figure 2, illustrating the simplicity and completeness of the app as it screens for IPV, provides an interpretation of the screening result, and provides links to resources related to prevention or management of IPV. Moreover, the app can be used to serve the public or be used in a clinic setting providing opportunities to share the screening result with clinic staff.

Figure 2. WithWomen User Journey.

Developing the Pathways Safety Planning App

Overview

As mentioned earlier, existing safety planning and decision-support apps did not meet the unique needs of our target population. In particular, we learned from our work with our community that the current apps required changes in terms of language, levels of interactivity, more flexibility in the user journey, accessibility of populations with literacy challenges, content, and safety features, and thus a new app was required. Since Pathways is intended to be a tool specifically for users who have self-identified as currently or recently experiencing IPV (ideally because they have used the WithWomen app), we designed Pathways to introduce users to the several options

available in the app to begin making safety planning decisions. These options include (1) assessing severity, danger, and potential lethality of violent behaviors in their relationship; (2) identifying their safety priorities; (3) learning about safety actions to take that align with their priorities; and (4) learning about healthy and unhealthy relationships. We drew on existing safety planning and decision-support apps for IPV and made key modifications for our target population of urban Canadian women. These included tailoring the app to address women's top concerns related to safety planning while still in or recently exiting a violent relationship. The goal of this app, then, is to allow women to prioritize their safety planning needs and receive tailored support, tangible action items, and referrals to local resources that match their highest concerns.

Step 1: Prototype Development

To develop the prototype for our app, we recruited 19 service providers and 31 women who identified as IPV survivors to interact with sections of the existing MyPlan app. In addition to this, we asked a smaller subset of participants with lived experience to review the full app online. Participants were recruited from 8 IPV-focused organizations in greater Toronto. We completed this user research over the course of 2 months, making note of their preferences, experiences with interacting with the existing app content and activities, and suggested modifications to inform the development of our Pathways app.

We then drew on 2 sources of data to determine the specific concerns most important to our users, which likely differed from the college-age females for whom the original MyPlan app was intended. We recruited 16 additional women who did not participate in the assessment of the existing safety planning app with different levels of lived experiences of IPV. Participants completed an anonymous survey that asked them to select how important 10 concerns are to women who are experiencing IPV as they make important decisions about their safety. In addition to those considered in the existing app, we reviewed the literature and consulted service provider key informants to arrive at these 10 concerns, which included having resources (finances, housing, legal services), privacy, immigration, and career-related concerns [13,35] (Table 3). When literacy was a challenge, a trained data collector supported respondents by reading out the instructions, explaining the activity, and writing down their responses. These answers were summed across participants and priorities that received the highest ratings were chosen as priority areas to which women could tailor their safety planning activities in Pathways.

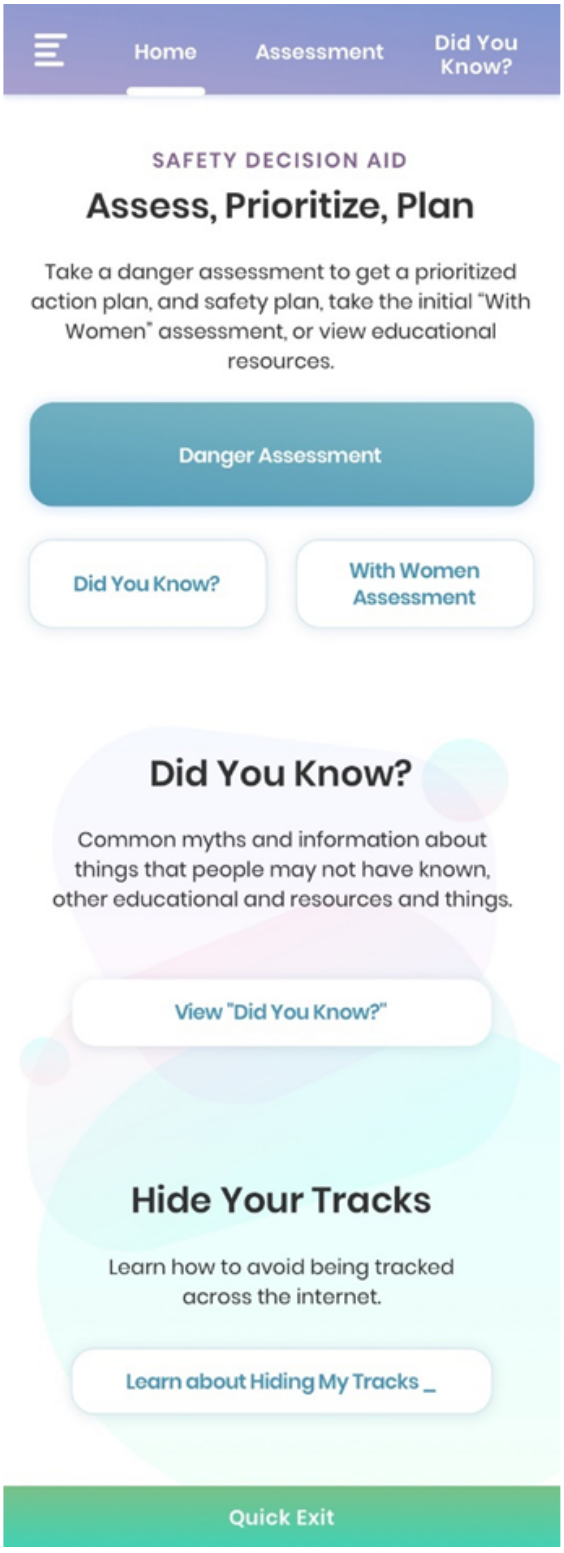
Table 3. Relative ranking for each priority area for the My Concerns section of Pathways.

Rank	Safety priorities	Relative ranking
1	Having resources (finances, housing, legal support)	High
2	The health and well-being of someone close to you	High
3	Housing concerns	High
4	Privacy	High
5	Your personal health and well-being	Moderate
6	Language barriers	Moderate
7	Studies and career	Moderate
8	Immigration concerns	Moderate
9	Feelings for a partner	Low
10	Connections to the community	Low

Step 2: User Testing

Once the prototype data were collected, we worked with a software development firm, Tactica Interactive [36], to develop a working prototype of Pathways. Using this prototype and following HCD principles, we measured user experience with the app, looking specifically at functionality, ease of navigation, and the comprehensiveness of each of the tailored concern sections [26]. This process involved asking IPV survivors and service providers to engage with an online version of the app and provide feedback on usability of the different sections in an anonymous survey. A total of 26 individuals, including 5 IPV service providers, spent approximately 30-40 minutes reviewing all components of the app. User research was conducted at 4 IPV service organizations. One of the organizations provided trained interpreters to non-English speaking clients to make group activities more inclusive. As interpreters were already available in this setting, 5 women who spoke languages other than English were able to participate by working with an interpreter and a trained data collector to complete their survey responses. The user experience with Pathways is outlined in Figure 3.

Figure 3. Pathways Landing Page.



Step 3: App Refinement

Finalizing Content for the Pathways App

For the section on user's priorities, data from surveys conducted with participants and open-ended questions on what might be missing from app content shared with those taking part in the user research provided many options for what we might consider including in the prioritization section of the app.

Linking the safety options to a user's priorities has been demonstrated to reduce decisional conflict about IPV safety planning [17,19,22]. In an effort to more closely align users' concerns with their safety plans, "Resources" was further divided into "Finances," "Housing," and "Legal Support" as separate categories of Resource-based concerns. We removed "Child's well-being" from the priority setting activity and instead incorporated a safety plan focused on children as a

separate section in the Pathways app, where it could be given more prominence for those who select it.

The final 5 categories of concerns selected for inclusion in Pathways were each linked to an action plan, which suggests 3-6 specific actions users can take to address each area of concern. Safety steps associated with lower-ranked priorities were added into the optional viewing sections of the app. For example, suggestions to improve "Privacy" were included in the stalking-related safety plan, and also in the "Hide Your Tracks" section, which includes instructions for safe web browsing, while suggestions to address immigration concerns were added into the "Legal Support" section of the app. Algorithms were added to Pathways such that safety plans for the user's most highly rated priority were presented to the user first.

Finalizing Pathways

Overall, user testing interviews confirmed the usefulness, understandability, appropriateness, and comprehensiveness of Pathways for our population. No major changes to safety planning–related content were suggested by respondents or our advisory groups. However, some common themes emerged about the language and structure of the app. For example, suggestions were made to simplify language, reduce text, and use check boxes whenever possible. In some sites, words such as "cue," "priority," and "prioritize" were not considered common language. We simplified the language and changed section titles (eg, "My Priorities" became "My Concerns" in Pathways). Several clients and service providers commented about the need to use reaffirming, rather than alarming language. Service providers also acknowledged the need to balance between providing validation and affirmations without normalizing severely dangerous behaviors. This was particularly relevant to the Danger Assessment section of the app. Our team removed questions that were in the Danger Assessment section but not used in the ratings of violence severity and prefaced the questions with plain language content explaining the rationale for asking them.

Several participants discussed the benefit of incorporating more tailored resources based on various needs of diverse populations. The recommendations were mostly around community supports specifically for minorities and people with language barriers, culturally sensitive services, and legal advice. Keeping in mind that language, transit access, and cost are barriers to accessing formal supports, we included links to support services that could be accessed by people free of charge or on sliding scale without the need for referrals or health insurance. In many cases, we listed support services in Pathways that are offered in multilingual, multicultural, or multisite service settings, and we included options to search resources by postal code whenever possible to allow women to find the most appropriate resources.

Another key area of concern pertained to the privacy, security, and accessibility of the app. To address these concerns, we incorporated a quick exit bar at the bottom of each app page that allows users to quickly hide their screen by redirecting them to the Google search engine. We also added a separate section in the app called "Online safety" that contains detailed information on secure web browsing. Our inclusive design intern redesigned the "Did You Know" section of our app, which originally described aspects of healthy and unhealthy relationships, into an activity where women interactively explore violence-related information to increase their knowledge about relationship violence. To increase accessibility for users with visual impairments or low literacy, we added an audio feature to each page of the app. The feature reads all text aloud and narrates navigation options on each screen.

The majority of the Pathways beta testers provided positive feedback (good or very good experience using the app) and noted that they would recommend the app to someone else. The lowest scored section of our survey was in relation to ease of navigation, with 15/46 (33%) of respondents identifying sections of the app that had too much text. To address these concerns, we took these sections to plain writing workshops hosted by our hospital's patient education department, where plain language experts reviewed the material and provided feedback. We then hired an editor to incorporate suggestions and reduced the amount of text in flagged sections of the app by 20%. We also simplified the user flow, by moving certain sections of text to separate pages, and making those pages optional to view.

Data for Our Apps

For safety reasons and also to honor concerns around privacy expressed by our informants with lived experience throughout the process of creating this suite of apps, we designed our apps to collect all data anonymously. Thus, no names, IP addresses, or any other identifiers are collected or stored. The research team does, however, collect other data for quality improvement purposes (eg, distribution of scores for screening or the danger assessment or priority concerns of those using Pathways or what time of day the apps are accessed), but we examine all data anonymously. We also ensured that no trace is left on any devices that have accessed any of our apps. The data are stored on servers in North America and the research team owns the data.

Developing PROMiSE

The Pathways app was launched in December 2019. However, by early 2020 it was evident that the COVID-19 pandemic and the policies required to mitigate its spread (eg, stay-at-home orders, reduced service capacity) would lead to increased time spent in close quarters with abusive partners, widespread uncertainty, and financial strain, all stressors known to increase the risk for IPV [37]. Rates of IPV have indeed increased since the advent of the pandemic [38,39], and many women are unable to access IPV services due to reduced capacity and increased demand, making IPV screening and safety planning mHealth interventions critical to maximizing women's safety during this and future public health emergencies. However, we received feedback from community partners that aspects of the Pathways app were not well suited to public health emergencies. For instance, the decision-support tools in Pathways are centered on seeking help outside the home and connecting with community services, many of which are either not open due to government restrictions, have closed due to financial strain, or are over capacity due to increased demand. It became clear that a safety planning tool was needed that responded to the realities women face during public health emergencies and that provides

up-to-date, relevant information, and advises on actions to maximize safety in a safe, discreet way.

Using the same HCD-informed approach, we began a rapid research project to adapt Pathways for use during COVID-19 that involved (1) conducting a rapid systematic search of the peer-reviewed and gray literature on strategies that women experiencing IPV in the context of COVID-19 might find helpful and (2) convening an expert panel of IPV survivors and IPV service providers in the GTA to brainstorm new and modified strategies that women experiencing IPV in the context of COVID-19 might find helpful. This 3-month rapid research yielded 22 strategies that were either highly or somewhat recommended (eg, staying connected with others and planning for safety) and 6 that were not recommended (eg, hiding items that might be used as weapons) as they might make violence worse. Armed with new information about how women who are currently experiencing violence can maximize their safety during COVID-19, we connected again with Tactica to develop the new PROMiSE app from the existing Pathways app.

In addition to updating the content, we felt it was especially important to ensure the look and feel of the app was discreet, given that many more women may be using PROMiSE in close proximity to their abusers. To this end, we partnered with Tactica to develop a disguise feature for PROMiSE, wherein the app content is overlaid onto an innocuous webpage. We chose the main Pinterest board for Home and Garden Television as our innocuous landing page based on feedback from survivors of IPV that this would be unlikely to arouse suspicion from an abuser. When a woman visits the site, she will recognize the PROMiSE logo in the top right corner from advertisements and marketing materials (Figure 4). When this is clicked, the PROMiSE content will appear as a “pop-up” (Figure 5). In addition to the quick exit bar present in WithWomen and Pathways, users who click anywhere outside the “pop-up” box that contains the PROMiSE content will hide the app itself, revealing only the background website. The first time a woman visits the site, she will be offered an interactive tutorial that explains how to hide the content and make it reappear using hotkeys (desktop version) or a hotspot (on touchscreen devices).

Figure 4. PROMiSE Landing Page as Disguised.

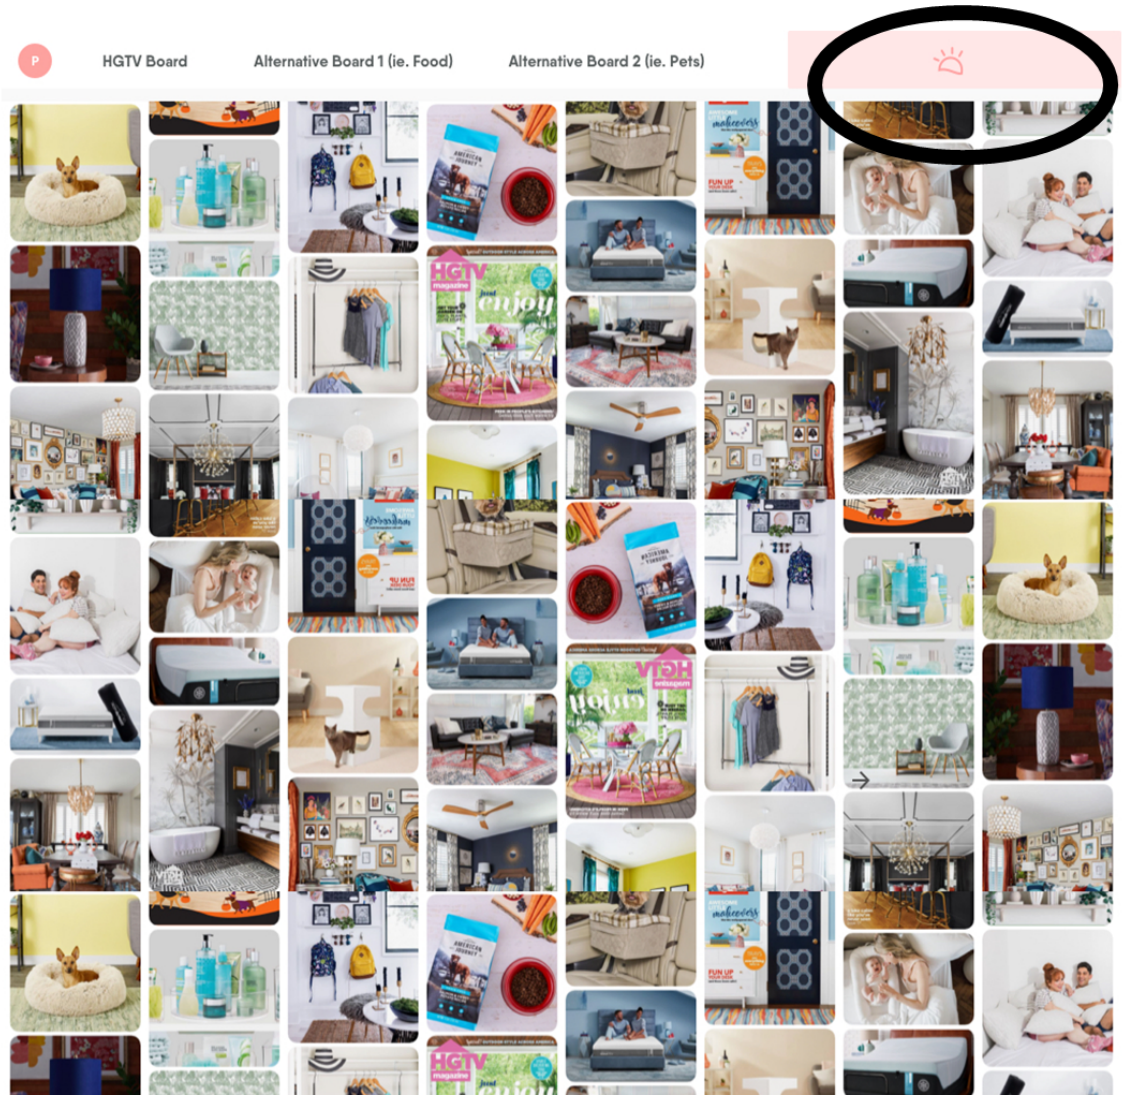


Figure 5. The actual PROMiSE landing page.

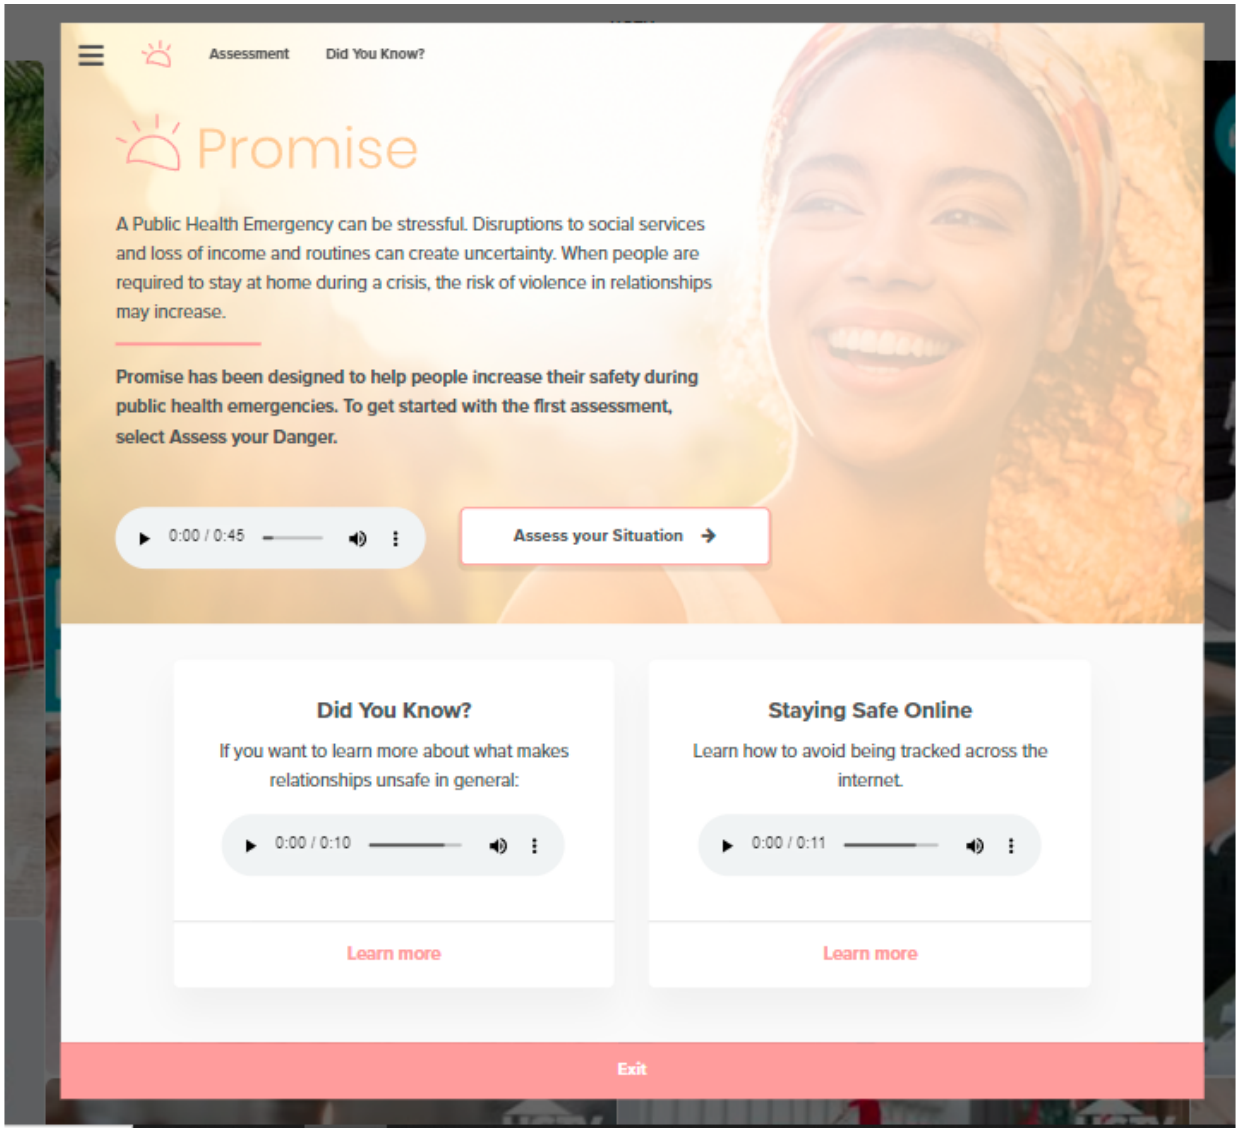

Because the layout and technical aspects of PROMiSE are identical to those of Pathways, we forewent much of the technical user testing in service of a rapid rollout of this app in the midst of the pandemic. However, once a prototype of PROMiSE was available, we invited women with lived experience of IPV and IPV service providers to navigate the app and provide feedback on its new look and feel and to identify any glitches that may have occurred in the creation of the app (n=7; Table 2). This information will be incorporated into later updates of PROMiSE. PROMiSE was launched on December 1, 2020

Discussion

Lessons Learned

Web-based and mHealth apps are increasingly common for IPV [1,3]. This paper demonstrates how we built on the existing set of IPV screening and safety planning web-based apps to tailor and create a suite of tools appropriate for our local population of women who are at risk of or needing to plan for safety around IPV before and during COVID-19. Furthermore, given the range of preventive and educational activities taken up by web-based and mHealth IPV-related apps, we focused our efforts on 2 particular challenges: (1) helping women to learn early on about unsafe relationship behaviors; and (2) once violence is confirmed, tailored safety planning to maximize safety. These apps were designed to complement the vast set of existing resources and services in our metropolitan area but also serve to provide a unique resource by taking into account a woman's particular priorities and being accessible any time of day and any place that the internet is available.

Systematic reviews of mHealth, computer-, and web-based apps have noted the scarcity of engagement with affected communities in the design of applications that impact the relevance and utilization of such apps [3]. We addressed this limitation in our work by using elements of HCD, which sought input from and cocreation with survivors of IPV and health care providers who work closely with this population. While this required that additional time be built into each of our phases of research, this increased the relevance of our apps to our target population. We found this to be critically important given the stage of IPV that we are targeting with these apps: for WithWomen screening we are targeting women who are yet unaware of the safety threats present in their relationships, and

for Pathways and PROMiSE we are targeting women with varying levels of violence in their intimate relationships who are needing to take some kind of action to increase safety in their relationships. While an existing app [18] was the template for our Pathways and PROMiSE, our apps' new features requested and endorsed by intended users included priorities that aligned with their preferences, interactive sections on healthy relationship information, freedom within the user journey to access any part of the app, plain language text, and an audio option.

We learned from survivors, providers, and also from the literature that abuse itself impacts the survivors' trust in others and confidence in themselves for making sound decisions about their relationships and safety-related actions. Furthermore, despite the vast strength and resilience of survivors, their experiences with relationships where they are routinely admonished and denigrated by perpetrators result in pervasive survivor self-doubt and self-blame, further affecting information processing and decision making around safety [40-44]. Our user research and advice from our partners helped shape the language and tone of the text in the apps. Because of the engagement of women and health and social services providers in the process of undertaking user research, we employed affirmative and strength-based language and phrases. Moreover, given levels of self-doubt among survivors who are living with abuse, we also used language that simultaneously prioritized trusting users' own instincts about maintaining safe behaviors while also encouraging safety planning action. One issue we were not able to overcome is the impact of missing data in our screening scales. If a respondent skips 1 or more questions, a value of 0 is used for the skipped question, potentially artificially deflating actual level risk.

Working closely with partners had other benefits. Our fracture clinic partner adopted a technology-enhanced approach to screening for IPV using our WithWomen IPV screening app. We used implementation science strategies to assist them with developing a suitable screening protocol that minimally impacted their busy clinic schedule [45] and for the first time ever the clinic had access to data about screening and IPV prevalence. While we did not plan for the broader use of our apps in service or health care settings, virtual visits with clients have significantly increased due to the pandemic and along with it the opportunity to incorporate technology-enhanced screening or safety planning during or in between client visits. With the release of PROMiSE, with its focus on safety planning during public health emergencies and enhanced safety features, we have been asked by providers to assist with the creation of options for including our apps within their virtual interactions with clients.

Because the key features of MyPlan that led to positive safety planning outcomes were retained in our Pathways app, we feel that another clinical trial demonstrating that use of the app over usual care is not warranted [19]. However, we are planning to use innovative single-case experimental study designs to demonstrate, on a much smaller sample of participants, that the PROMiSE app is safe to use when in the home and generates positive impacts on IPV knowledge and safety planning activities [46].

While we had evidence-based models to draw from, we discovered that creating these apps took far longer than we anticipated for several reasons. The iterative nature and multiple cycles of developing prototypes for sections of the apps, gaining feedback on those, and making modification to the prototypes take time. Our research team had to build capacity in some areas such as learning about the privacy concerns when our initial designs sought to link our rapid IPV screening app to the hospital data system and understanding the technical aspects of discreet app design. As we relied on the expert consultants and our hospital IT department in a set of iterative conversations about the app features that are or are not aligned with privacy requirements (eg, finding a secure way to link our app that is housed on external servers with the hospital-based electronic medical records), our process was further slowed as we were not a priority of the hospital's IT concerns. Finally, we also experienced significant delays due to the initial technology development partner we had chosen. Our team initially engaged the services of a laboratory connecting clinicians with biomedical and computer engineering students to apply technological solutions to the real-world problems faced by clinicians in their practice. We were eager to give a student team the opportunity to build our app while simultaneously cutting down on development costs to accommodate our shoestring budget. Unfortunately, the combination of our lack of experience with developing an app, our inability to communicate the technological specifications to the student team, and our lack of understanding of how short or long the development of these apps should take resulted in a slow process that spanned almost 18 months that ultimately ended in failure. We probably erred by not including a member from the technology team in our discussions of the research process; however, rapid turnover in the student team would have posed another challenge to that strategy. Fortunately, when we subsequently turned to a professional app developer the work was completed in a matter of weeks. While we were fortunate enough to engage a Master's student from the Inclusive Design program at the Ontario College of Arts and Design as an intern to advise on graphic design and user experience for WithWomen and Pathways, a diminishing overall budget precluded allowing us to have a designer or more advanced features to these aspects of our suite. Separate funding for PROMiSE, however, allowed us to make use of a professional designer and more technical consultants, resulting in increased functionality and advanced privacy features.

Conclusion

With the use of technology in health and social service care intervention and delivery becoming more commonplace, there is an opportunity to develop high-quality IPV screening apps to implement in practice. The aim of this venture was to create a suite of IPV screening and safety planning apps for use with local women that contain relevant information and resources in a safe, discreet way. Evidence and user testing feedback have indicated what women want and need from IPV screening and safety planning apps: that is, the product to be relevant to its user population with easy navigation, HCD features, and the ability to access discreetly.

Acknowledgments

This research was supported by a generous donation to the St. Michael's Hospital Foundation. We thank Drs Nancy Glass and Marilyn Ford-Gilboe for their expert input and advise on the creation of our safety decision-support web-based app. We also thank James Case for sharing information about the technological details of MyPlan and for advice on creating our app. Drs Janice du Mont and Robin Mason of Women's College Hospital, Toronto, provided valuable insight and feedback on the development of PROMiSE. Finally, we thank the women who generously spent time providing feedback on early versions of our apps, in particular, the women from Peer2Peer, a survivor-led organization seeking to help women living with or a history of IPV in greater Toronto.

Abstract

Background: Emerging evidence indicates the effectiveness of internet-based mobile-supported stress management interventions (iSMIs) in highly stressed employees. It is yet unclear, however, whether iSMIs are also effective without a preselection process in a universal prevention approach, which more closely resembles routine occupational health care. Moreover, evidence for whom iSMIs might be suitable and for whom not is scarce.

Objective: The aim of this study was to evaluate the iSMI GET.ON Stress in a universal prevention approach without baseline inclusion criteria and to examine the moderators of the intervention effects.

Methods: A total of 396 employees were randomly assigned to the intervention group or the 6-month waiting list control group. The iSMI consisted of 7 sessions and 1 booster session and offered no therapeutic guidance. Self-report data were assessed at baseline, 7 weeks, and at 6 months following randomization. The primary outcome was perceived stress. Several a priori defined moderators were explored as potential effect modifiers.

Results: Participants in the intervention group reported significantly lower perceived stress at posttreatment (d=0.71, 95% CI 0.51-0.91) and at 6-month follow-up (d=0.61, 95% CI 0.41-0.81) compared to those in the waiting list control group. Significant differences with medium-to-large effect sizes were found for all mental health and most work-related outcomes. Resilience (at 7 weeks, P=.04; at 6 months, P=.01), agreeableness (at 7 weeks, P=.01), psychological strain (at 6 months, P=.04), and self-regulation (at 6 months, P=.04) moderated the intervention effects.

Conclusions: This study indicates that iSMIs can be effective in a broad range of employees with no need for preselection to achieve substantial effects. The subgroups that might not profit had extreme values on the respective measures and represented only a very small proportion of the investigated sample, thereby indicating the broad applicability of GET.ON Stress.

KEYWORDS

stress management intervention; universal prevention; occupational health; moderators

Introduction

Occupational stress is a major public health problem, with high prevalence in western countries [1-3]. It is associated with a range of adverse consequences, including an increased risk for coronary disease [4,5], mental health problems [6,7], and sleeping problems [8]. Moreover, stress-related productivity loss, absenteeism, presentism, and health care usage lead to substantial economic costs [9]. Although manifold meta-analytic evidence exists for the effectiveness of psychological face-to-face stress management interventions for employees [10,11], the high prevalence of stress demands for highly cost-effective and scalable solutions. Internet-based mobile-supported stress management interventions (iSMIs) can be a great solution as they can offer several benefits such as (1) their accessibility at any time and place, (2) the possibility for participants to work and review materials at their own pace, and (3) their high potential for scalability [12]. In theory, only a small increase in resources is required for reaching a greater proportion of the eligible population. However, the real costs of iSMIs are greatly linked to the amount of guidance delivered by professional support [13], thereby limiting the possible reach of these interventions. Therefore, unguided interventions are an important puzzle piece to combat the high prevalence of stress.

The most recent meta-analysis on iSMIs found overall significant effectiveness (d=0.43, 95% CI 0.31-0.54) with small-to-medium effect sizes, but substantial heterogeneity between studies [14]. Subgroup analyses found that guided interventions (d=0.64, 95% CI 0.50-0.79; n=7) were significantly more effective than unguided interventions (d=0.33, 95% CI 0.20-0.46; n=18). Yet, the most effective iSMI GET.ON Stress yielded high effect sizes even when delivered in an unguided format [13], with an effect size (d=0.96, 95% CI 0.70-1.21) significantly exceeding that reported in the overall sample. In regard to the often cited replication crisis in Psychology [15] and other fields [16-18], it is crucial to evaluate if these effect sizes can withhold further inspection. Moreover, replicating these studies can help to address their shortcomings and add to the existing literature.

The first shortcoming relates to the evaluation in selected samples. Evidence for the best evaluated iSMI GET.ON Stress [13,19-25] is based on trials in which participants have been preselected based on the high baseline score in perceived stress (Perceived Stress Scale [PSS-10] ≥22) [26,27]. Using a broad range of eligibility criteria, however, can limit the real-life applicability of the results [28], as in routine preventive occupational health care, iSMIs are usually offered to a wide range of participants. Therefore, it is crucial to investigate treatment effects without preselection in a universal prevention approach [29]. This approach has not only theoretical but also practical advantages: while reaching a wider proportion of the working population, it reaches those that benefit from selected and indicated prevention without the cost for screening them specifically [30,31]. Additionally, it allows the inclusion of adults with lower symptom severity who are still motivated to improve their conditions, which might be a better indicator for their readiness for health behavior change [32].

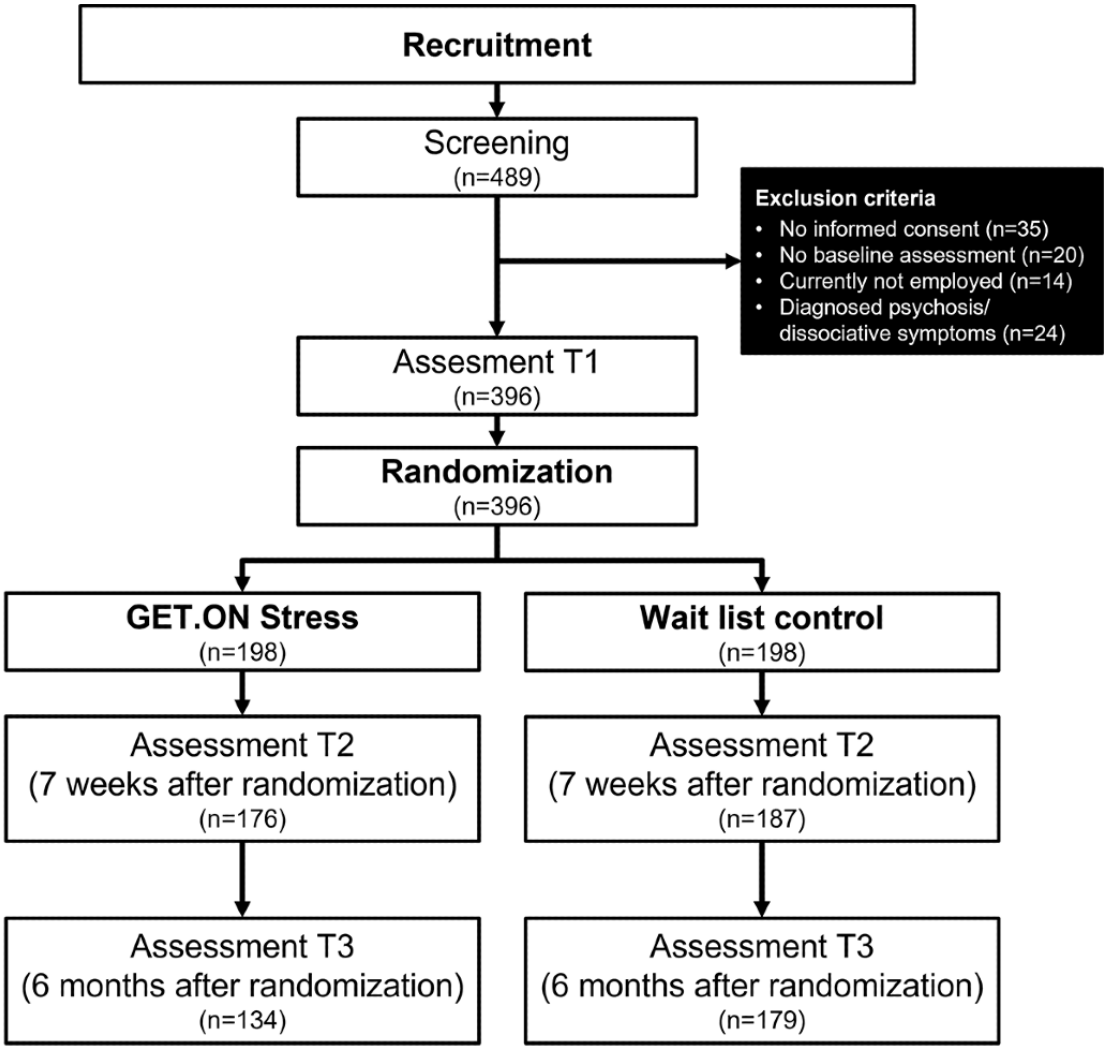
The second shortcoming relates to the lack of moderator analyses. Even though internet-based intervention research is rapidly growing, empirical data on the moderators of internet-based mobile-supported interventions [33-39] and, in particular, internet occupational health interventions are scarce [34]. Furthermore, randomized controlled trials (RCTs) are usually powered to detect effects on the primary outcome and hence, underpowered to reliably test moderator hypotheses [40]. With reported numbers needed to treat of 5.43 for unguided iSMIs (and 4.20 in the overall sample) [14], it is clear, however, that a substantial proportion of the participants do not profit yet from taking part in an intervention. Therefore, identifying the moderators of iSMI effects is crucial for at least 3 reasons: (1) knowing who likely profits from the intervention helps to identify relevant populations, (2) knowing which patients are unlikely to profit from the treatment helps to prevent wasting resources and provides valuable information on where custom-tailoring such interventions to subgroups of patients is necessary, and (3) a better knowledge regarding who is (un)likely to profit from these interventions helps to identify mechanisms of change that are relevant for these interventions [41]. Therefore, the aim of this study was to evaluate the effects of the iSMI GET.ON Stress as a universal prevention approach, without preselecting participants based on symptom severity. Moreover, in an exploratory approach, a broad range of a priori selected potential effect modifiers were tested in a sample adequately powered for moderator analyses.

Methods

Design

A two-armed RCT (N=396) was conducted comparing a self-guided iSMI (GET.ON Stress) condition (intervention group [IG]) and a waiting list control (WLC) condition, with both conditions having full access to treatment as usual. Participants were recruited via the occupational health program of a large health insurance company in Germany (BARMER) in a way that mimics the intended implementation of the intervention in routine practice in the future, that is, by offering the intervention in a public occupational mental health approach to the general working population in a web-based setting. Recruitment was directed at the general working population and not restricted to members of the health care insurance company. Recruitment occurred mainly through reports in the membership magazine of the insurance company, and the insurance company's occupational health management workers informed human resource departments of collaborating small- and medium-sized companies about the possibility for their employees to participate in the trial. Assessments took place at baseline (T1), at posttreatment (7 weeks, T2), and at 6 months (T3; see Figure 1 for a detailed overview of assessments). This study was approved by the University of Marburg ethics committee.

Figure 1. Flow of the study. T1: baseline; T2: at 7 weeks posttreatment; T3: at 6 months posttreatment.



Interested individuals received an email with detailed information about the study procedures and an invitation to take part in the study. If they were interested, they were asked to complete a web-based screening questionnaire. Individuals meeting the eligibility criteria completed the baseline assessment and were invited to complete the informed consent form. Once the full written informed consent was received, participants entered the study and were randomly allocated to 1 of the 2 study conditions. Randomization took place at a ratio of 1:1. An independent third party who did not have any information about the participants performed the allocation. Randomization was carried out using an automated computer-based random integer generator (randlist). Other researchers could not bias the randomization process since participants were randomized in the order of the incoming informed consent form. Participants were not blinded to study conditions. During the randomization process, the allocation was concealed from the participants, researchers involved in recruitment, and the study administration team.

Eligibility Criteria

Inclusion and exclusion criteria were kept to a minimum to mimic routine conditions as closely as possible. Participants were included who (1) were 18 years and older, (2) were currently employed, (3) had internet access, and (4) provided a valid email address. Individuals were only excluded if they were at risk of suicide (indicated by a score of 2 or higher on the Beck Depression Inventory Suicide Item [42]) or if they self-reported to have been diagnosed with psychosis or dissociative symptoms. Besides that, there were no restraints for participants, for example, concerning low or high stress, depression, or other symptom severity criteria.

Intervention

As this study evaluates an intervention that was evaluated in an indicated prevention context before, intervention content and delivery methods mirror those in related studies [20]. The training GET.ON Stress is based on Lazarus' transactional model of stress [43]. According to this model, there are 2 coping strategies to deal with stress. One is a problem-oriented approach in changing the situation. The other approach focusses on situations where only the evaluation of the situation can be adjusted; this is called emotional regulation. Therefore, the training focuses on strategies for systematic problem-solving as well as emotion regulation. The intervention consists of 7 regular sessions and 1 booster session (provided 4 weeks after the last regular session was completed). The program starts with psychoeducation about stress (session 1), which guides participants to understand and find coping strategies for common problem situations. Based on their personal stressors,

participants are asked to record their goals and motivation for the training. This is followed by 2 sessions focusing on problem-solving skills (sessions 2-3) where participants are guided through a 6-step method based on problem-solving therapy [44]. The personal plan will be implemented between the sessions before participants are asked to redo the exercise with the same or a different problem. The next part of the training (sessions 4-6) is based on the Affect Regulation training [45,46]. Each session focusses on 1 emotion regulation strategy: muscle and breathing relaxation, acceptance of emotions, as well as effective self-support with 15-minute audio files guiding users through the different exercises. Participants are encouraged to redo the exercises between sessions on a daily basis. The regular training is completed by a session guiding the creation of a "Plan for the future" (session 7), in which users are asked to review their progress and develop strategies according to their personal stress indicators in the future. Moreover, they are guided to write a letter to their future self. The booster session reviews the essential content of the intervention and allows participants to reassess their goals and plans for the future. Additionally, participants could choose from an array of elective modules in sessions 2 to 6 addressing common stress-related topics such as time management, sleep hygiene, or social support. Participants were advised to complete 1-2 sessions per week.

Across sessions, the training was composed of interactive education, audio and video files, and additional downloadable material. Additionally, testimonials offered impulses and examples concerning the exercises. The intervention is based on responsive design, meaning that it could be completed on a desktop computer, tablet, or smartphone. Through providing multiple choices among various response options, the content of the intervention was automatically tailored to the specific needs and interests of the individual participants. To integrate the newly acquired knowledge into daily life, homework assignments and behavioral planning were a crucial part of the training. Web-based diaries were also offered. The training was not accompanied by therapeutic guidance. However, the participants could opt for automatic text messages on their mobile phones choosing either a light (1 text message every other day) or intensive support (2-3 text messages per day). Text messages focused on ultrabrief exercises to be carried out in daily life routine, aiming to facilitate transfer from training into real life.

Outcomes

All measures were assessed through web-based self-report questionnaires and are described below. The assessment took place on a secured web-based system with 256-bit AES encryption. All outcomes were published a priori in detail in the trial register. The primary outcome was the perceived level of stress as measured by the German version of the PSS-10 [26,27] since it is based on Lazarus' transactional model of stress. The 10 items were answered on a 5-point Likert scale (ranging from 0=never to 4=very often) referring to the past week. Owing to its sum score, the total scale scores range from 0 to 40. Cronbach alpha was .83 at T1, .91 at T2, and .91 at T3 in this study.

Secondary outcomes included measurement of mental health and work-related outcomes. Among those concerning mental health, the following outcomes were measured using specified scales: depression, using the German adaptation of the Center for Epidemiological Studies' Depression Scale (15 items, range 0-45; α=.94) [47,48]; mental health–related quality of life, using the Assessment of Quality of Life (8 items, range 8-41; α=.84) [49]; resilience, using the Connor-Davidson Resilience Scale (10 items, range 10-50; α=.93) [50]; emotional exhaustion, using the subscale of the Maslach-Burnout-Inventory (5 items, range 1-6; α=.93) [51]; mental well-being, using the Warwick-Edinburgh Mental Wellbeing Scale (14 items, range 14-84; α=.96) [52]; and psychological well-being, using the 5-item World Health Organization Well-Being-Index (5 items, range 0-100; α=.91) [53]. The following work-related outcomes were assessed: effort-reward imbalance, using the Effort-Reward-Imbalance Questionnaire-Short Form (10 items, α=.84) [54]; occupational self-efficacy, using the Occupational Self-Efficacy Scale (6 items, range 6-36; α=.93) [55]; work engagement, using the Utrecht Work Engagement Scale (9 items, range 0-6; α=.97) [56]; productivity loss, using the Work-Limitations-Questionnaire (8 items, α=.87) [57]; and absenteeism and presentism days, using the respective questions from the German version of the Trimbos and Institute of Medical Technology Assessment Cost Questionnaire for Psychiatry (2 items) [58].

In addition, the following variables were assessed to be tested as potential moderators: personality, using the Big-Five-Inventory (10 items, subscale range α=.20-.77) [59]; motivation for treatment, using the Psychotherapy Motivation Questionnaire-Short Form (4 items, α=.36) [60]; self-regulation competencies, using the Self-Regulation scale (10 items, range 10-40; α=.84) [61]; and general self-efficacy, using the General Self-Efficacy Scale (10 items, range 10-40; α=.90) [62].

Power Analysis

The sample size of the study was optimized to detect potential moderator effects. Previous studies on the same intervention found effects on the primary outcome of perceived stress at T2 ranging from d=0.84 to d=0.93 [13,23,63] in highly stressed employees. Assuming potentially lower effects, owing to the inclusion of less impaired employees, of approximately d=0.60, we would have needed to include 90 participants. Given that simulation studies showed that the sample size required to detect an interaction effect of the same magnitude needs to be at least threefold to fourfold, compared to the sample sizes needed for the primary analyses [64], we included 396 participants. This sample allowed us not only to detect a small regression effect of f^2 with a power (1-ß) of 80% and an error probability (α) of .05 but also a small intergroup effect size of d=0.25 in a one-tailed test (calculated with G*Power).

Statistical Methods

All analyses are reported following the Consolidated Standards of Reporting Trials guidelines for reporting parallel group randomized trials [65]. Therefore, following the intention-to-treat principle, missing data were handled with multiple imputations [66], using 100 estimations per missing value. Outcome levels of IG and WLC were compared at T2

and T3 by using analysis of covariance (ANCOVA), with baseline levels as covariates. Additionally, Cohen *d* with 95% CIs were calculated based on the imputed data set by comparing means and SDs of the 2 groups at the respective time points. Furthermore, the difference in means along with its 95% CIs was calculated. To improve interpretability, reliable change was calculated according to the method of Jacobson and Truax [67] as an indicator of the number of participants with treatment response. Participants were accredited a treatment response if their PSS-10 score differed more than SD 5.16 in T1-T2 and T1-T3. Besides, the number needed to treat to achieve 1 additional treatment response compared to the control group was calculated. To evaluate the effect of the intervention on the risk for symptom worsening, we also calculated the number of participants with a reliable deterioration of symptoms by using the Reliable Change Index and calculated the absolute and relative reduction of risk, including the respective 95% CIs.

Moderator Analysis

Regression analyses were used to test baseline moderator X intervention condition interaction effects by using the SPSS macro PROCESS [68]. In case of a significant interaction effect, we applied the Johnson-Neyman technique [68,69], which tests the conditional effect of X on Y at different values along the continuum of the moderator and calculates transition points, where the effect changes between statistically significant and not significant (at the α level of significance). This allows to identify a "region of significance" of the effect, giving away at which values of the moderator a significant effect can be found. This warrants essential advantages against the pick-a-point approach in which mostly only 3 arbitrarily chosen values of the moderator are tested since even the widespread use of the mean as well as SD is highly sample-specific and can thus lead to wrong conclusions [68]. Moderation variables were neither standardized nor mean-centered since it makes no difference for the moderation effect [68] and can even harm the interpretation if dichotomous variables are altered before the analysis.

Results

Participants

The study flow is illustrated in Figure 1. All 396 participants provided data at T1. In the IG, 176 (88.8%) participants at T2 and 134 (67.7%) participants at T3 and in the WLC group, 187 (94.4%) participants at T2 and 179 (90.4%) participants at T3 completed the assessment. The demographic characteristics of participants can be found in Table 1. The average age of the participants was 41.76 (SD 10.09) years. The sample was predominantly female (302/396, 76.3%), married, or in a relationship (209/396, 52.8%), as well as highly educated (285/396, 72%). Most participants were employed full-time (296/396, 74.7%), in a permanent employment relationship (306/396, 77.3%), and nearly half of them held a management function (169/396, 42.7%). Only a small portion (35/396, 8.8%) was self-employed. The average working experience was 17.58 (SD 10.36) years and the participants' jobs were in various working sectors, with the majority in the economy (97/396, 24.5%) or social (79/396, 19.9%) sector. Only a small percentage had prior experience with health training (55/396, 13.9%). Having received psychotherapy in the past was stated by 147 (37.1%) participants, whereas only 35 (8.8%) indicated that they were currently receiving psychotherapy. Table 2 and Table 3 summarize the mean (SD) for the IG and WLC. Concerning the primary outcome at T1, participants had an average value of 22.65 (SD 5.63) on the PSS, thereby indicating a moderate stress level.

Table 1. Baseline characteristics of the study population (N=396).

Primary and Secondary Outcomes

Tables 4 and 5 display the results of the intention-to-treat analyses for the primary and secondary outcomes. The ANCOVA showed a significant group effect, indicating that participants in the IG had, compared to the WLC, significantly lower scores on the PSS-10 at T2 ($F_{1,393}$=64.44, P<.001) and T3 ($F_{1,393}$=46.91, P<.001) with medium-to-large between-group-effect sizes at T2 (Cohen d=0.71, 95% CI 0.51-0.91) and T3 (d=0.61, 95% CI 0.41-0.81). At posttreatment, significantly more participants in the IG (109/198, 55.1%) showed a reliable improvement on the PSS-10 compared to the WLC (44/198, 22.2%; P<.001). The number needed to treat to achieve 1 additional treatment response (reliable change) at posttreatment was 3.05 (95% CI 2.39-4.20). Significantly less participants experienced a symptom deterioration in the IG (10/198, 5.1%) compared to WLC (19/198, 9.6%), which reflects an absolute risk reduction of 4.55% (95% CI –0.567% to 9.658%) and a relative risk reduction of 47.88% (95% CI –10.307% to 74.888%).

[o]WLQ: Work Limitations Questionnaire.

Comparing reliable changes from baseline to 6 months, 53.5% (106/198) in the IG showed a reliable improvement in contrast to 36.4% (72/198) in the WLC (*P*<.001). The number needed to treat to achieve one additional reliable improvement at 6 months follow-up was 5.82 (95% CI 3.73-13.30). A reliable deterioration was only present in 2% (4/198) of the IG, which was significantly lesser (*P*<.05) than that in the WLC (13/198, 6.6%).

As shown in Tables 4 and 5, the ANCOVAs for mental health outcomes showed significant between-group effects for all outcomes at both assessment points on a *P*<.001 level in favor of the IG. At T2, all effect sizes were moderate ranging from *d*=0.47 for emotional exhaustion to *d*=0.58 for well-being according to the 5-item World Health Organization Well-Being Index. At T3, moderate-to-large effect sizes could be found ranging from *d*=0.52 for mental health to *d*=0.76 for well-being.

Concerning work-related outcomes, the results were less coherent. At T2, the ANCOVAs for work-related self-efficacy (*P*<.001) and work engagement (*P*=.004) showed significant between-group effects, with a small effect size for work engagement (*d*=0.23) and a moderate effect size for occupational self-efficacy (*d*=0.51). There was no significant difference between groups for effort-reward-ratio (*P*=.06) and productivity loss (*P*=.06). However, at T3, apart from absenteeism days

(*P*=.50), all between-group effects were significant (effort-reward-imbalance T3, *P*=.006; presentism days T3, *P*=.01; work engagement T3, *P*<.001), with a large effect size of *d*=0.77 for effort-reward-imbalance and a small effect size of *d*=0.25 for work engagement and presentism days (*d*=0.13).

Adherence

Of the 198 participants in the IG, 188 (95%) finished session 1. Session 2 was completed by 171 (86.4%), session 3 by 154 (77.8%), session 4 by 135 (68.2%), session 5 by 121 (61.1%), session 6 by 108 (54.5%), session 7 by 94 (47.5%), and the booster session by 66 (33.3%) individuals. On average, participants worked through 5.23 (SD 2.74) sessions representing 66% (5.23/8) of the intervention. A linear regression model controlling for baseline stress indicated that the number of completed sessions significantly predicted stress levels at T2 (*b*=–0.67, SE 0.14; *P*<.001; 95% CI –0.94 to –0.39) and T3 (*b*=–0.39, SE 0.14; *P*=.004; 95% CI –0.66 to –0.12). The regression coefficient suggested that the PSS value decreased 0.67 (T2) and respectively 0.39 (T3) points with each additional module completed.

Moderator Analysis

Baseline symptom severity was not found to be a significant moderator, indicating that the intervention can be effective, irrespective of the baseline level of perceived stress. Resilience, agreeableness, psychological strain, and self-regulation competencies significantly moderated the treatment outcome. Resilience moderated the intervention effect at T2 (*P*=.04) as well as at T3 (*P*=.01). The region of significance at T2 and T3 ranged from 1 to 34.28 and 1 to 30.63, respectively, indicating that there was no significant between-group effect for participants with higher levels of resilience at baseline. In total, 2.8% (11/396) of the sample had resilience scores >34.28; 8.8% (35/396) had scores >30.63. Agreeableness moderated the intervention effect on stress at T2 (*P*=.01) with a region of significance from 1 to 4.55, indicating no significant intervention effects within participants with a higher agreeableness score (2 out of 396 participants had agreeableness scores above 4.55). The intervention effect on stress at T3 was moderated by psychological strain (*P*=.04) and self-regulation (*P*=.04). No significant between-group effect was found for participants with a psychological strain score lower than 7.96 (19/396, 4.8%) or self-regulation scores higher than 33.57 (24/396, 6%). Tables S1-S4 in Multimedia Appendix 1 show the results of the moderation analyses whereas Figures 2-6 show a visual representation of the moderation accompanied by a visual representation of the region of significance.

Figure 2. A visual representation of the moderation of the training effect (X) on perceived stress at T2 (Y) by resilience at T1 (M) accompanied with a visual representation of the area of significance according to the Johnson-Neyman technique. IG: intervention group; T1: baseline; T2: at 7 weeks posttreatment; WLC: waiting list control.

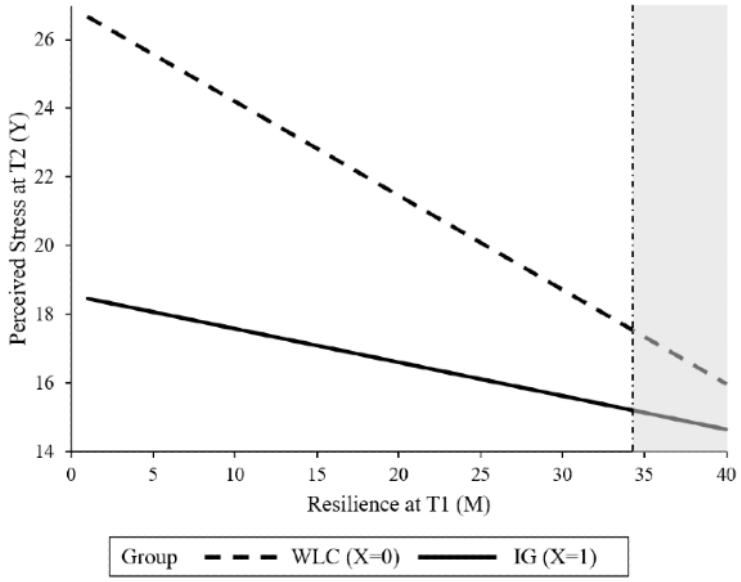

Figure 3. A visual representation of the moderation of the training effect (X) on perceived stress at T3 (Y) by resilience at T1 (M) accompanied with a visual representation of the area of significance according to the Johnson-Neyman technique. IG: intervention group; T1: baseline; T3: at 6 months posttreatment; WLC: waiting list control.

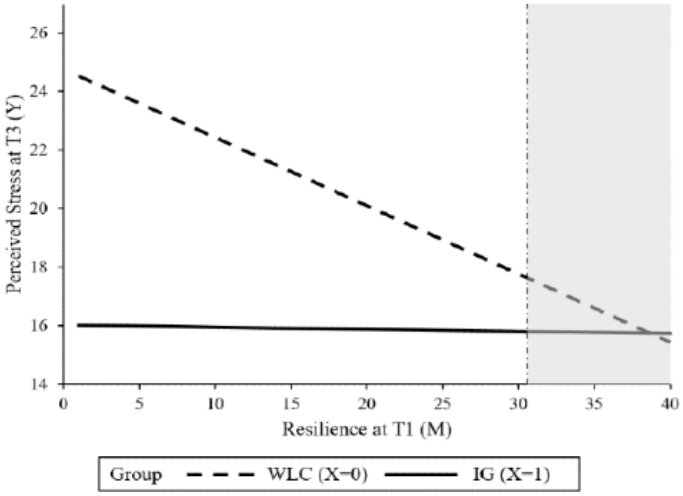

Figure 4. A visual representation of the moderation of the training effect (X) on perceived stress at T2 (Y) by agreeableness at T1 (M) accompanied with a visual representation of the area of significance according to the Johnson-Neyman technique. IG: intervention group; T1: baseline; T2: at 7 weeks posttreatment; WLC: waiting list control.

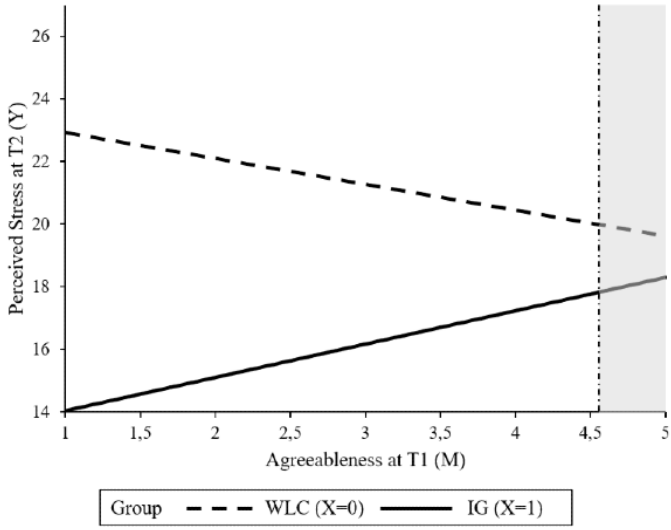

Figure 5. A visual representation of the moderation of the training effect (X) on perceived stress at T3 (Y) by psychological strain at T1 (M) accompanied with a visual representation of the area of significance according to the Johnson-Neyman technique. IG: intervention group; T1: baseline; T3: at 6 months posttreatment; WLC: waiting list control.

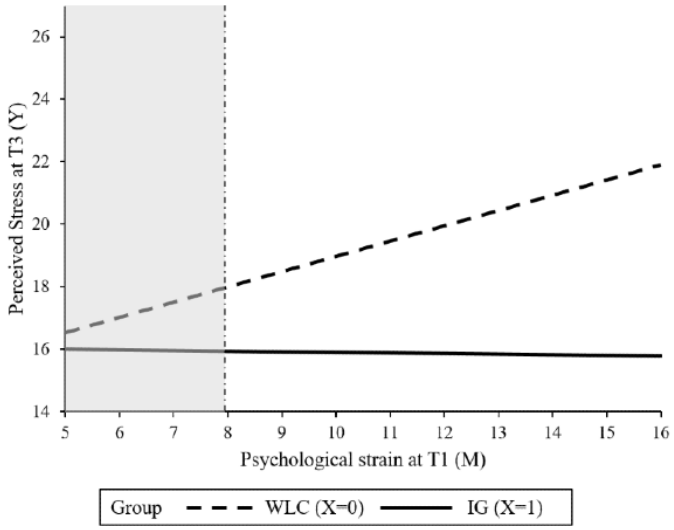

Figure 6. A visual representation of the moderation of the training effect (X) on perceived stress at T3 (Y) by self-regulation at T1 (M) accompanied with a visual representation of the region of significance according to the Johnson-Neyman technique. IG: intervention group; T1: baseline; T3: at 6 months posttreatment; WLC: waiting list control.

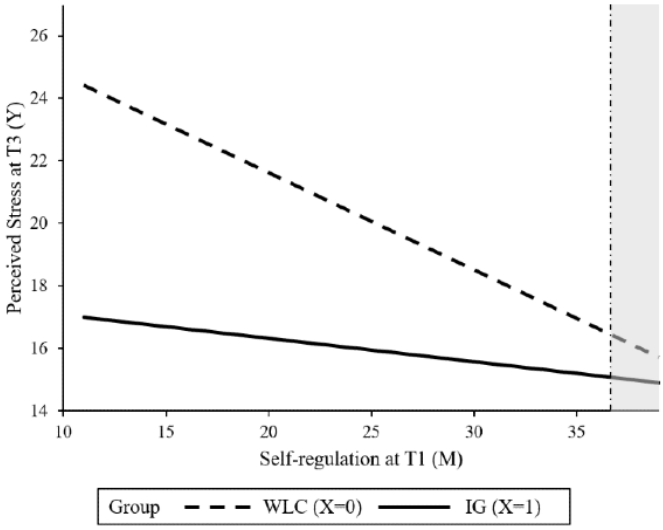

No demographic variable (age, gender, relationship status, having kids), other work-related characteristics (full-time work, having a management function, work experience, employment status, working sector, gross annual income), as well as other symptom severity indicators were significantly associated with the intervention effects. *P* values of nonsignificant interaction effects ranged from *P*=.08 (T2) for gender to *P*=.99 for conscientiousness.

Discussion

This study aimed to evaluate the effectiveness and moderators of treatment outcome of a self-guided iSMI as a universal prevention approach without an elaborative inclusion process based on baseline symptom severity. The results of our study indicate that the training was highly effective in reducing stress levels in the short term (*d*=0.71) and long term (*d*=0.61). Significant moderate-to-large effects were found for several secondary mental health and work-related outcomes, including outcomes such as occupational self-efficacy for which no evidence of iSMIs was yet available. Moreover, this study is one of the first to investigate moderator effects in iSMIs in an adequately powered sample. The intervention was suitable for a wide range of participants. Only a few moderators of the intervention effect were identified, indicating that employees with very high resilience, very low psychological strain, very high agreeableness, and very high self-regulation might not profit from the iSMI.

The effects in this study were lower than those in the 4 previously conducted RCTs that examined the same iSMI but in which participants were preselected (PSS>22 or PSS-4 ≥8). With therapeutic guidance, large effect sizes of *d*=0.83 at posttreatment (95% CI 0.58-1.08) were found compared to that of WLC [63], whereas with adherence-focused guidance [23], the between-group effects were *d*=0.79 (95% CI 0.54-1.04), and as a purely self-guided intervention in employees [13] or students [25], the effect size was *d*=0.96 (95% CI 0.70-1.21) or *d*=0.69 (95% CI 0.36-1.02), respectively. However, the CIs in this trial (95% CI 0.51-0.91) overlapped those of all previously conducted studies.

When comparing the results with those from unguided iSMIs not necessarily conducted in the work settings, the effect sizes found in this trial were larger than those found in a recent meta-analysis on the topic (*d*=0.33, 95% CI 0.20-0.46) [70] also when taking 95% CIs into account. Potential reasons for the higher effect sizes compared to other interventions might lie in the strong theoretical basis and the possibility to tailor the intervention to individual need or interest. An alternative explanation might be the strong focus of the intervention on supporting participants to implement health behavior changes in daily life routine. Although the study was powered to test moderation hypotheses adequately, and although we included a broad range of theoretically potential effect modifiers, only few baseline variables significantly moderated the intervention effects. Baseline perceived stress was not associated with intervention outcome, indicating that GET.ON Stress can also be effective in heterogeneous samples that are not preselected based on high baseline symptom severity. That said, it needs to be noted that the sample showed a substantial level of baseline impairment, indicated by a mean of 22.65 (SD 5.63) on the PSS. Despite being lower than that in previous studies that have been conducted on GET.ON Stress (PSS, 25.26-23.90), and although 40.3% (160/396) of the participants in this trial would have been excluded in previous trials, the average baseline symptom severity was still approximately 1 SD above the average perceived stress level in a large working population (mean 15.3 [SD 6.2]) [71]. This might indicate that the intervention might especially be attractive for employees who already experience a substantial stress level. Future studies should hence test whether the utilization of universal preventive approaches in employees can be further increased, for example, by utilizing acceptance-facilitating interventions [72-75] that are designed to reduce the barriers of intervention utilization, such as low perceived risk. Another possibility might be that the format is not adequate for employees with low perceived burden and interventions with even a lower threshold, for example, mobile

apps, focusing on less burdensome behavior changes are necessary to reach this target group.

Resilience, psychological strain, agreeableness, and self-regulation moderated the treatment outcome. Our findings clearly show that the difference in the perceived stress between the IG and the WLC is dependent on the resilience score at baseline. This difference (in the perceived stress between the IG and the WLC) is greater in those that show a lower resilience at baseline, whereas the difference almost becomes nonexistent if the baseline resilience is very high. One potential explanation for this finding might be that very resilient participants manage to cope with perceived stress also in the control group without the help of an additional psychological intervention. Such an interpretation is in line with the theoretical framework around resilience assuming that resilience helps to deal with stressors [76,77]. Several systematic reviews show that high resilience might serve as a protective buffer against the development of psychopathological symptoms [78-82].

Interestingly, employees with low self-regulation profited to a much greater extent from participating compared to those with high self-regulation. This is in contrast to our a priori expectation as we assumed that self-regulation competencies, the ability of an individual to regulate and control their thoughts and behavior enabling them to adapt to a broad range of demands [83], might be a necessary prerequisite for making effective use of such self-help approaches, which require the self-regulated implementation of behavior changes. However, one explanation for the finding might be that participating in the iSMI helps employees with low-self regulation to effectively counteract the missing necessary competencies required to effectively implement health behavior changes in daily life that are needed in order to reduce perceived stress, whereas employees with high self-regulation might manage to realize these necessary self-regulatory tasks also without an additional intervention. Such an assumption of a compensatory effect is supported by the data in the control group showing very high perceived stress level at follow-up in the control group for those with low self-regulation in comparison to low perceived stress levels in the control group for those with high self-regulation. In the IG, the difference between low and high self-regulation is, however, not reflected in the major differences in perceived stress. Nonetheless, empirical studies are needed to confirm these assumptions.

The finding that the intervention was found to be ineffective in individuals with very low current psychological strain (<7.96) has relevant implications for the implementation of such approaches. If these results are confirmed in future studies, such interventions should not be used solely as a universal preventive intervention, for example, to increase protective factors that might help to cope with future stressors. Instead, such interventions should only be offered to employees experiencing at least a minimal level of psychological strain, as this might serve as an important source of motivation that is required for self-help approaches. However, our study was limited to a 6-months follow-up, and future studies are needed to investigate the potential protective effects in such populations regarding future stressors. This study also found agreeableness as a moderator, which has not emerged in the previous literature. Future research should investigate if this was a spurious finding or could lead to a new understanding of the interaction between personality traits and iSMIs.

This study also has some limitations to be considered. First, as usual with RCTs, there was a screening process preceding trial participation, that is, informed consent, which might have caused some applicants with lower motivation to drop out before the study began, potentially resulting in a more homogenous sample. Moreover, the exclusion of suicidal individuals limits the generalizability to such samples. Therefore, although this was a pragmatic trial and eligibility criteria were kept to a minimum to mimic routine care, intervention effects might be overestimated compared to the intervention under routine conditions. Second, one needs to keep in mind that the evidence generated by this study is based on an RCT, which brings a rather high structuring of participants and a high research attention with it, which is usually not the case in routine occupational care. Since the securing of commitment represents an adherence-promoting element in self-help interventions, it can be assumed that the effect sizes for pure self-guided interventions found in RCTs are significantly overestimated for what can be expected in occupational routine care [84] when no additional measures to increase adherence are applied. Hence, a clear concept for ensuring adherence such as through minimal guidance from a professional seems favorable, especially when considering that guided internet-based interventions have found to be superior over pure self-help interventions, both for stress-management [70] as well as other areas [85-87]. Preference should be in routine care, whenever possible, given to self-help approaches with at least some form of adherence-promoting guidance. Moreover, although the study was powered for moderator analyses, we did not stratify for extreme values on assessed moderator variables. Hence, some expressions on the investigated moderators, for example, very low stress levels, were probably not included in sufficient numbers so that a moderator analysis could have detected an existing effect. Further, the power was not sufficient to detect small moderator effects that may nevertheless be of clinical relevance. Since this is one of the first trials on iSMIs as well as SMIs, in general, investigating moderator effects, future empirical studies are needed to confirm our findings.

This study confirms GET.ON Stress to be effective in a heterogeneous sample of employees and to be applicable for a broad range of participant characteristics. Based on the available evidence, iSMIs should be implemented on a broad scale to reduce the adverse consequences of occupational stress.

Acknowledgments

The European Union funded this study (EU EFRE: ZW6-80119999, CCI 2007DE161PR001). BARMER supported the recruitment for this study.

Authors' Contributions

DDE and DL designed the study. DDE, DL, HR, and MB developed the intervention content. DDE and MF performed the outcome analyses. MF prepared the first draft of the manuscript, DDE supervised the writing process, and MF integrated the coauthor comments and edits. All the authors contributed to the further writing of the manuscript and approved the final manuscript.

Conflicts of Interest

DDE and HR are members of the board of the International Society for Research on Internet Interventions. DDE has served as a consultant on the scientific advisory boards of Sanofi, Novartis, Minddistrict, Lantern, Schoen Kliniken, Ideamed, and German health insurance companies (BARMER, Techniker Krankenkasse) and a number of federal chambers for psychotherapy. DDE, MB, BF, and DL are stakeholders in the Institute for health training online (formerly GET.ON, now HelloBetter), which aims to implement scientific findings related to digital health interventions into routine care. HelloBetter distributes the digital intervention under study.

Abstract

Background: Walking is a simple but beneficial form of physical activity (PA). Self-monitoring and providing information about social norms are the 2 most widely used "mobile health (mHealth)" strategies to promote walking behavior. However, previous studies have failed to discriminate the effect of self-monitoring from the combination of the 2 strategies, and provide practical evidence within Chinese culture. Some essential moderators, such as gender and group identity, were also overlooked.

Objective: We aimed to investigate the effectiveness of social norm and self-monitoring interventions for walking behavior and assess the moderating effects of gender and group identity, which could guide optimal mHealth intervention projects in China.

Methods: In 2 longitudinal tracking studies (study 1, 22 days; study 2, 31 days), Chinese college students wore trackers for at least 8 hours per day (MASAI 3D Pedometer and Xiaomi Wristband 2) to record their daily step counts in baseline, intervention, and follow-up stages. In each study, participants (study 1: n=117, 54% female, mean age 25.60 years; study 2: n=180, 51% female, mean age 22.60 years) were randomly allocated to 1 of the following 3 groups: a self-monitoring group and 2 social norm intervention groups. In the 2 intervention groups and during the intervention stage, participants received different social norm information regarding group member step rankings corresponding to their grouping type of social norm information. In study 1, participants were grouped by within-group member PA levels (PA consistent vs PA inconsistent), and in study 2, participants were grouped by their received gender-specific social norm information (gender consistent vs gender inconsistent). Piece-wise linear mixed models were used to compare the difference in walking steps between groups.

Results: In study 1, for males in the self-monitoring group, walking steps significantly decreased from the baseline stage to the intervention stage (change in slope=−1422.16; *P*=.02). However, additional social norm information regardless of group consistency kept their walking unchanged. For females, social norm information did not provide any extra benefit beyond self-monitoring. Females exposed to PA-inconsistent social norm information even walked less (slope during the intervention=−122.18; *P*=.03). In study 2, for males, a similar pattern was observed, with a decrease in walking steps in the self-monitoring group (change in slope=−151.33; *P*=.08), but there was no decrease in the 2 social norm intervention groups. However, for females, gender-consistent social norm information decreased walking steps (slope during the intervention=−143.68; *P*=.03).

Conclusions: Both gender and group identity moderated the effect of social norm information on walking. Among females, social norm information showed no benefit for walking behavior and may have exerted a backfire effect. Among males, while walking behavior decreased with self-monitoring only, the inclusion of social norm information held the level of walking behavior steady.

Introduction

Background

Walking is a simple but highly beneficial form of physical activity (PA) [1]. It can lower the risk of premature death [2] and prevent numerous chronic diseases such as obesity, type II diabetes, and cardiovascular disease [3]. In addition to providing reasonably accurate daily walking records [4], smartphones are also capable of additional functions such as tracking the number of steps walked. Such functionality has led to the use of mobile devices to promote a healthier lifestyle. Indeed, this concept of a mobile health (mHealth) strategy has become an increasingly popular public health intervention tool to promote walking behavior [5].

Providing social norm information and providing one's self-monitoring information (ie, a record of one's behavior) are currently 2 of the most widely used strategies in mHealth. In self-monitoring interventions, pedometers or pedometer apps on smartphones (eg, Apple Health and Accupedo) provide users with daily step counts, which enable them to monitor and improve their own walking behavior [5-8]. Combined with this self-monitoring strategy, several leading online social media platforms (eg, Facebook and WeChat) have also implemented a social norm strategy to form an mHealth intervention for walking behavior [9,10]. The biggest difference between the 2 strategies is that the latter strategy allows users to view their own records and the walking records of their peers. By exposing users to a highly social norm sensitive context, users might be impacted by the perceived levels of others' PA and might thereafter increase their own walking behavior [11-13]. Previous studies examining the effect of social norms have shown that there is still some debate regarding its veracity [14,15], and others have failed to consider the influence of some potential moderators [16]. Thus, it is still unclear as to whether a social norm strategy would be effective in promoting walking behavior.

In this study, we aimed to optimize mHealth walking interventions and provide more practical evidence about the effectiveness of interventions based on social norms. To address these aims, we implemented 2 longitudinal tracking studies in order to compare and isolate the mixed effects of social norm and self-monitoring interventions on promoting walking. In particular, we focused on 2 theoretically essential factors and ignored moderators regarding the influence of social norm interventions (group identity and gender).

Self-Monitoring Intervention: Effect of One's Own Walking Records

Self-monitoring refers to a systematic self-observation or recording of target behaviors (eg, walking and food intake) [17]. Based on the self-regulation theory, self-monitoring is an essential component of a successful self-regulation process, preceding self-evaluation and self-reinforcement [18]. Self-monitoring thus motivates individuals to make changes by stimulating them to focus, evaluate, and regulate the target behavior [17]. Several studies have shown that the strategy of self-monitoring plays a positive role in promoting a variety of healthy or healthier behaviors such as reduction in smoking [19] and improvements in diet [20].

Data from several studies suggest that a self-monitoring strategy, typically informing people how many steps they have walked, can be effective in boosting walking behavior [6-8]. For example, one study showed that by wearing a pedometer and setting a self-monitored goal of walking 10,000 steps each day, overweight women were able to increase their average walking steps by 85% (from 4972 to 9213 steps per day) [21]. A recent meta-analysis based on 6 interventions from 2005 to 2017 also showed that a self-monitoring strategy was associated with an increase in walking of up to 3090 steps per day in cardiovascular patients [22]. In a review of 88 intervention studies (N=18,804), Knittle et al concluded that self-monitoring is one of the most widely used strategies and represents an essential component for increasing both the intention of PA (b=0.30) and actual PA behavior (b=0.28) [23]. As a consequence, self-monitoring has generally been adopted as the centerpiece of most public health intervention programs [24,25].

However, there has been some controversy surrounding the effect of self-monitoring. For example, some researchers have argued that, despite its numerical effectiveness, the act of self-monitoring does not have a positive influence on walking behavior. Self-monitoring may also not guarantee high levels of exercise adherence, with rates of adherence shown to decline significantly over time [26].

More importantly, previous studies have paid little attention to exploring the mechanisms that underlie self-monitoring interventions in practice, thus limiting its application value and generalizability to other areas. For example, in order to optimize effectiveness, interventions have implemented a combination of strategies with self-monitoring included in a package of self-regulation processes [17], such as goal setting [21]. As a consequence, it is difficult to disambiguate the actual effect of self-monitoring from the mix of other potential effects. In addition, the majority of previous intervention studies have

failed to consider the potential for certain demographic variables to exert a moderating effect on the relationship between self-monitoring and PA behavior [17]. Gender represents a key example whereby females may benefit more from a self-monitoring intervention and maintain an active lifestyle for longer than males [27].

Social Norm Intervention: Effect of the Walking Information of Peers

Numerous theories of behavioral change, including the theory of planned behavior as an example, have listed social norms as an essential predictor of actual changes in behavior [28]. Previous studies have demonstrated that 2 types of social norms [29,30] are important for behavior change across areas ranging from reducing alcohol use [15,31] to reducing environmental damage [30]. These are descriptive norms, which refer to the perceived prevalence of target behaviors, and injunctive norms, which refer to perceived approval or disapproval of target behaviors by the society. Descriptive social norms may guide the behavior of individuals because of implied social proof that the behavior of the majority should be right, as the focus theory of normative conduct posits [30]. Injunctive norms may guide behavior because of a need by individuals to obtain social approval for meaningful relationships with other ingroup members [29,30].

In particular, the perception of social norms about PA was positively correlated with the actual PA level of individuals [13,32], and providing social norm information can even lead individuals to do more PA [12]. For example, compared with traditional online tracking or sending of promotional messages, interventions based on social norms, such as sharing the information of peers, led to participants spending more time on PA [10]. The typical use of descriptive norms, such as sending a message containing exercise information of colleagues, was more effective in increasing mild physical exercise than interventions that did not have any norm manipulation, such as sending general information about physical exercise and health [12]. McEachan et al analyzed 100 empirical studies from 1990 to 2010 (N=22,849) and found social norms to be a strong predictor for PA (mean correlation ρ=0.21, 95% CI 0.18-0.24) [33]. A series of meta-analyses [28,34] also revealed that changing one's perception of social norms can produce a small to moderate effect (Cohen *d*=0.36) in increasing healthy behavior, including physical exercise.

However, the notion that social norm interventions are reliably effective has been complicated by some studies that have found its effect on behavioral change to be unstable or even negative [14,15]. For example, a meta-analytic review reported only a weak correlation (*r*=0.17, 90% CI −0.07 to 0.43) between social norms and PA [35]. The relationship between social norms and exercise intention may disappear after controlling for other relevant factors such as attitude to sports [36]. Indeed, a situation in which a desirable behavior is only a minority norm (eg, only a few people walk over 10,000 steps every day) or in which an undesirable behavior is the majority norm (eg, the majority only walk 2000 steps every day) may even lead to a backfire effect where an individual's healthy behavior is reduced [37,38], suggesting that social norm interventions must be applied with caution. Even from a methodological level, since social norm interventions are generally combined with self-monitoring (ie, users may track their own walking and their peers' walking at the same time [39]), it can become difficult to detect the pure effect of social norm interventions. Consequently, given that the implied factors that can lead to success or failure in these social norm intervention studies are unclear, researchers have argued that the likelihood of both type 1 and type 2 errors is high [38]. This has led some to suggest that social norm interventions should be dropped from further use [36]. Moreover, compared with correlational studies measuring subjective social norms, evidence-based interventions targeting social norms are still limited [36].

Group Identity and Gender as Moderators of the Effects of Social Norm Interventions on PA

With the development of social norm theories, researchers have increasingly declared that the relationship between social norms and target behavior cannot be explained by a simple one-way causal model. Recent studies have attempted to explain the weak effect of social norm interventions on PA by investigating previously ignored moderators such as group identity [16]. However, most previous interventions simply provided social norm information by sending a message without investigating any other potential variables [10,12]. This may lead to a disparity between an up-to-date theory framework and previous practical interventions.

As one of the most widely used and effective theories in predicting and intervening in health behaviors, such as reducing alcohol intake [40] and promoting hand-washing [41], the theory of normative social behavior (TNSB) has proposed group identity as a factor moderating the effect of descriptive norms on behavior [42]. Group identity is defined as the degree to which an individual perceives similarity with the group and aspires to emulate group members [42]. The TNSB predicts that the effect of social norm interventions on behavioral change would be stronger when individuals perceive a higher similarity between themselves and the reference group [42], that is, social norms from a closer group work better at changing behaviors due to higher group identity, and individuals are more willing to perform the target behavior as an expression of group solidarity [42]. This moderating effect of group identity on the effect of social norm interventions can also be explained by the phenomenon of groupthink. Groupthink is more likely to take place in groups with higher identity and may put pressure on group members to conform to the social norms of the group [43]. Empirical studies support the prediction of the TNSB. For example, the closer individuals felt to a group, the closer their own behavior was to their perception of the social norms of that group [44]. Social norm interventions have been found to promote office colleagues with a high group identity to play more sports, while the effect was insignificant among college students who had a low group identity [12].

As an innate label, information regarding individuals with the same gender may feel more relevant and relatable. Therefore, according to the TNSB, because of a higher group identity, social norms within males or females (gender-consistent or gender-specific social norms) may have a greater impact on the

behaviors of individuals [45]. For example, one study showed that perceived gender-consistent norms were stronger predictors of alcohol consumption than gender-inconsistent norms, and this was especially evident for females [46]. However, although previous studies have suggested that manipulating gender-consistent norms may be more beneficial in norm-based interventions [45,46], the availability of practical evidence is still limited and controversial. For instance, an intervention using gender-consistent norms did not show a better effect on reducing alcohol consumption than gender-inconsistent norms [47]. Gender may also interact with the effect of social norm interventions on target behaviors (different genders may have divergent reactions after receiving the same normative information). For instance, a social norm intervention regarding driving behavior may be effective for males but not females because of stronger normative pressure regarding this particular behavior in men compared to women [48]. On the other hand, females may be more sensitive to norms related to their body appearance than males due to their increased tendency to engage in appearance-related social comparison [49]. Even though these studies clearly suggest that the effectiveness of social norm interventions is strongly associated with gender, the importance of this factor has been largely overlooked in previous studies investigating mHealth interventions.

Moreover, the finding of systematic gender differences in the target behavior of this study (ie, PA) (see Pollard and Wagnild's review [50]) calls for the need to consider gender as a moderating factor for the effect of social norm interventions on walking behavior. For example, walking has been observed to be a type of PA preferred by females [51], although consistent evidence has shown that males did more physical exercise than females [51-53]. According to evidence showing that self-regulation was the best predictor of PA in female college students but not males, females may be more sensitive to self-monitoring interventions [52]. Given that China currently has one of the widest gender gaps in the world [54], these gender differences within the Chinese cultural context may be more pronounced than those within other regions. In contrast to the commonly accepted gender-consistent attitude to sports, in China, males reported a more positive attitude to sports than females [55]. Compared with female college students, male students were also found to exercise more frequently, and they also showed both a higher participation rate and voluntary motivation to practice sports [56].

Our Study

Since 2018, China has been the home of over 500 million mHealth users [57], making it an ideal region to evaluate the effects of different interventions. The use of smartphone pedometer apps has been found to be more favorable to traditional wearable pedometer devices in improving walking behavior [58]. Consequently, some social media platforms began to design their own pedometer plugins. WeChat, one of the most popular social media platforms with over 1 billion users in China [59], designed WeRun to provide daily step tracking and step ranking among the contacts of WeChat users. In addition to viewing rankings, users can give a thumbs-up or follow the step records of their contacts. With 15.3% of users taking advantage of its novel social functions, WeRun has become one of the most widely used features of WeChat since its launch in 2015. According to WeRun users, they use it to not only get data about their own exercise behavior, but also increase exercise frequency as well as interaction with friends [60]. As a consequence, WeChat represents a highly appropriate platform for investigating the effect of social norm interventions.

Although there are increasing numbers of apps, smart devices, and high-tech companies trying to promote PA among individuals through systems that utilize self-monitoring or social norms, little is known about the comparison of the effects of social norm interventions with self-monitoring interventions. The absence of substantial research investigating the underlying mechanisms of social norm interventions has obstructed the development of more personalized and optimized mHealth interventions. This disconnection between up-to-date social norm theories (eg, the TNSB) and antiquated intervention techniques may have weakened the potential for practical benefits from the existing evidence base.

Moreover, previous studies have suffered from some limitations, both methodologically and practically. For example, since most previous studies on social norms lacked a corresponding self-monitoring control group [39], the mixed-strategy approaches may have not only resulted in ambiguous comparisons of the effects of social norm and self-monitoring information on walking behavior, but also led to the collection of data characterized by low reliability and high error rates [38]. In addition, given that most mHealth interventions are specific to a certain app or device, the particular results of the corresponding interventions were device-specific and were thus not stable enough to be generalizable. In the context of mHealth, China is a rapidly developing country, but it is also suffering from a specific social issue in the shape of a wide gender gap. We have very limited understanding as to how gender and different mHealth interventions interact, and thus, there is no useful guidance as to how mHealth interventions in China can be optimized.

To address this, we aimed to answer the following 2 primary questions in this study: (1) In China, is an intervention based on social norms more effective than self-monitoring at promoting walking behavior? (2) Do gender and group identity moderate the effect of social norm interventions on walking? Specifically, we conducted 2 longitudinal tracking studies to compare the effects of self-monitoring and social norms on walking behavior. In study 1, we compared the effects of social norm and self-monitoring interventions on PA between genders by randomly assigning participants to a self-monitoring group, a PA-consistent intervention group (ie, similar levels of PA among group members), or a PA-inconsistent group (ie, varying levels of PA among group members). In study 2, after observing a gender-specific effect of social norm interventions on PA, we attempted to replicate the main finding of study 1 using a more precise measure of steps walked. We also assigned participants to a self-monitoring group, a gender-consistent intervention group (ie, providing social norm information that is gender-specific), or a gender-inconsistent intervention group (ie, providing social norm information that is not gender-specific). Our hypotheses were as follows: hypothesis 1 (H1), in China, providing social norm information, in the form

of step ranking, can promote walking more effectively compared with self-monitoring; hypothesis 2 (H2), gender will moderate the effect of social norm interventions on the promotion of walking, and the walking behavior of males will be more impacted by social norms; and hypothesis 3 (H3), group identity will moderate the effect of social norm interventions on the promotion of walking, and a higher sense of group identity will strengthen the effect of social norm interventions. Furthermore, H3 had the following 2 parts: H3a, an intervention using PA-consistent norms will have a larger effect on walking behavior than that using PA-inconsistent norms; H3b, an intervention using gender-consistent norms will have a larger effect on walking behavior than that using gender-inconsistent norms.

Methods

Participants

In both studies, we recruited graduate students from the University of Chinese Academy of Sciences, Beijing, China as our participants by sending advertisements during university courses (744 students in study 1, and 986 students in study 2). To avoid the possible confounding effect of walking habits or previous mHealth app experience, all recruited students completed a 5-minute online screening and customized sports habit questionnaire. The inclusion criteria were as follows: (1) used WeRun or other walk-related mHealth apps less than twice a week; (2) not a member of any WeChat sports group; (3) self-reported being mentally and physically healthy; (4) consented to participate in the entirety of the experiment. Next, according to their self-reported sports habits, participants were labeled as either low PA (sports fewer than twice a week and run a total distance of less than 5 km per week) or high PA (sports more than three times per week and run a total distance of more than 10 km per week).

Given that the motivation of this study was to promote walking behavior among the low-PA sample, we only selected low-PA students as our formal participants (high-PA students were only recruited in study 1 to set up the PA-inconsistent group, but were not included for further analysis). We preset our sample size to at least 40 participants in each group. Thus, we included a total of 127 low-PA participants in study 1 (with another 42 high-PA students), while 182 low-PA participants were recruited for study 2.

This study was approved by the Institutional Review Board of the Institution of Psychology, Chinese Academy of Sciences, and all participants took part in the study voluntarily and completed written informed consent. To record the number of steps walked, all participants were asked to wear step trackers (MASAI 3D Pedometer, study 1) or smart bands (Xiaomi Wristband 2, study 2) during the entire experimental period. After the study, participants were allowed to keep their step trackers (and approximately US $18 in study 1) or smart bands as payments for participation.

Design and Procedures

Study Design

To compare the effects of self-monitoring and social norms, both studies consisted of 3 stages (baseline, intervention, and follow-up; Figure 1 and Figure 2), with slight variations in the length of each stage. Study 1 was conducted from April to May 2017 and consisted of 22 days, with 3, 14, and 5 days in each stage, respectively. Study 2 was conducted from October to November 2017 and consisted of 31 days, with 10, 15, and 6 days in each stage, respectively. All participants were required to wear the trackers during the entire experiment and were able to check their step counts at any time in order to monitor their own walking behavior.

Figure 1. Flow diagram for study 1. The diagram shows the complete experimental procedure including enrollment, randomization, and intervention. All participants (valid n=117) in 3 groups were tracked for 22 days. PA: physical activity.

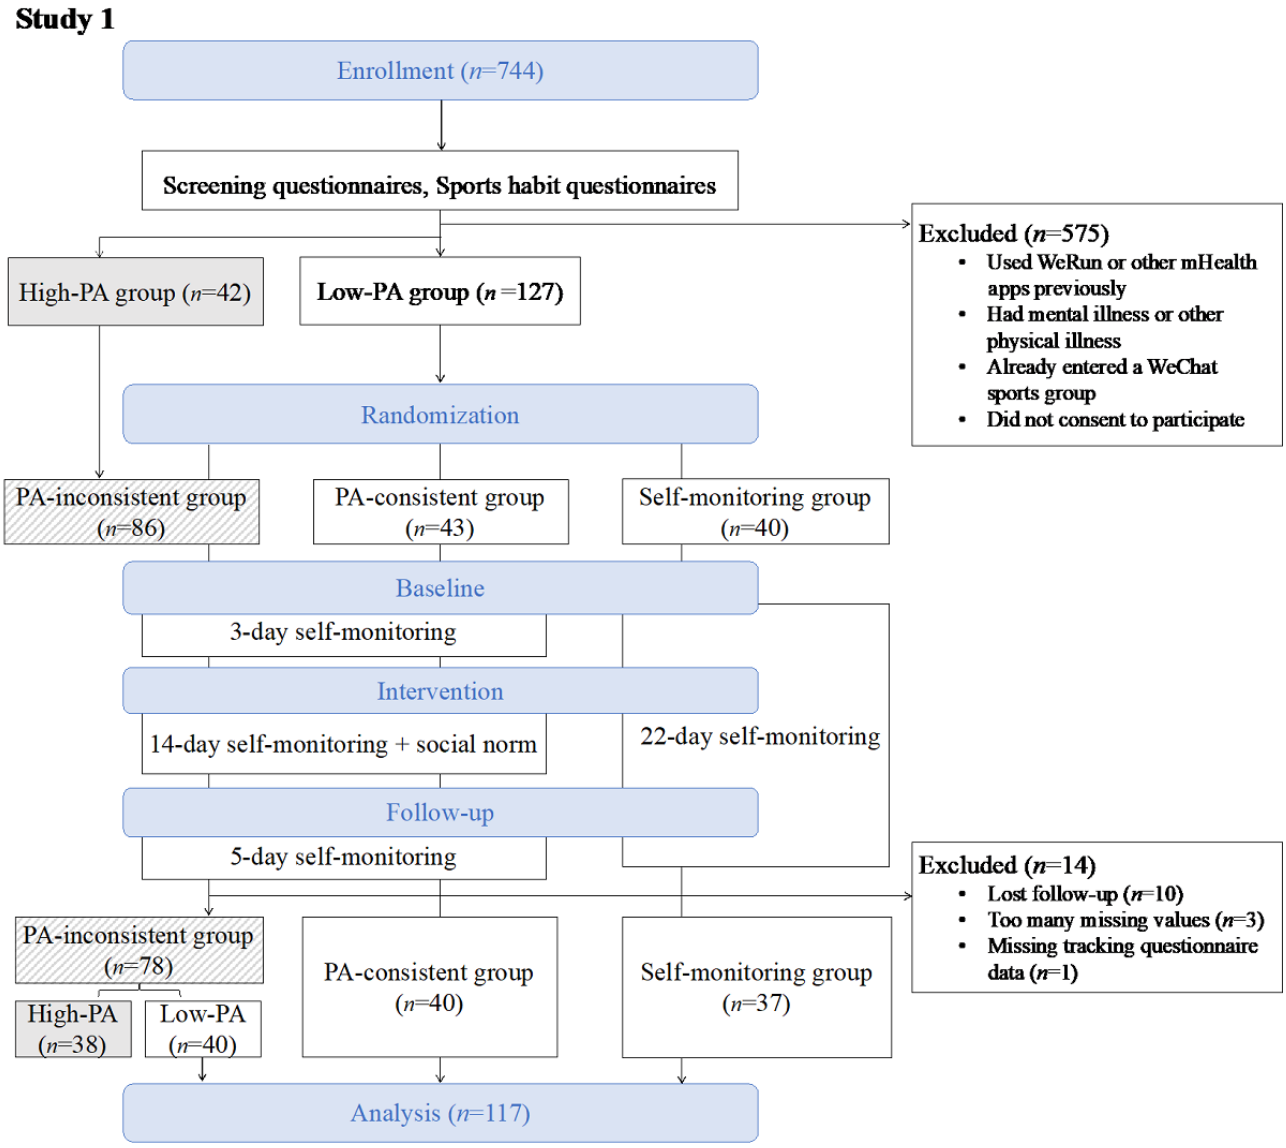

Figure 2. Flow diagram for study 2. The diagram shows the complete experimental procedure including enrollment, randomization, and intervention. All participants (valid n=180) in 3 groups were tracked for 31 days. PA: physical activity.

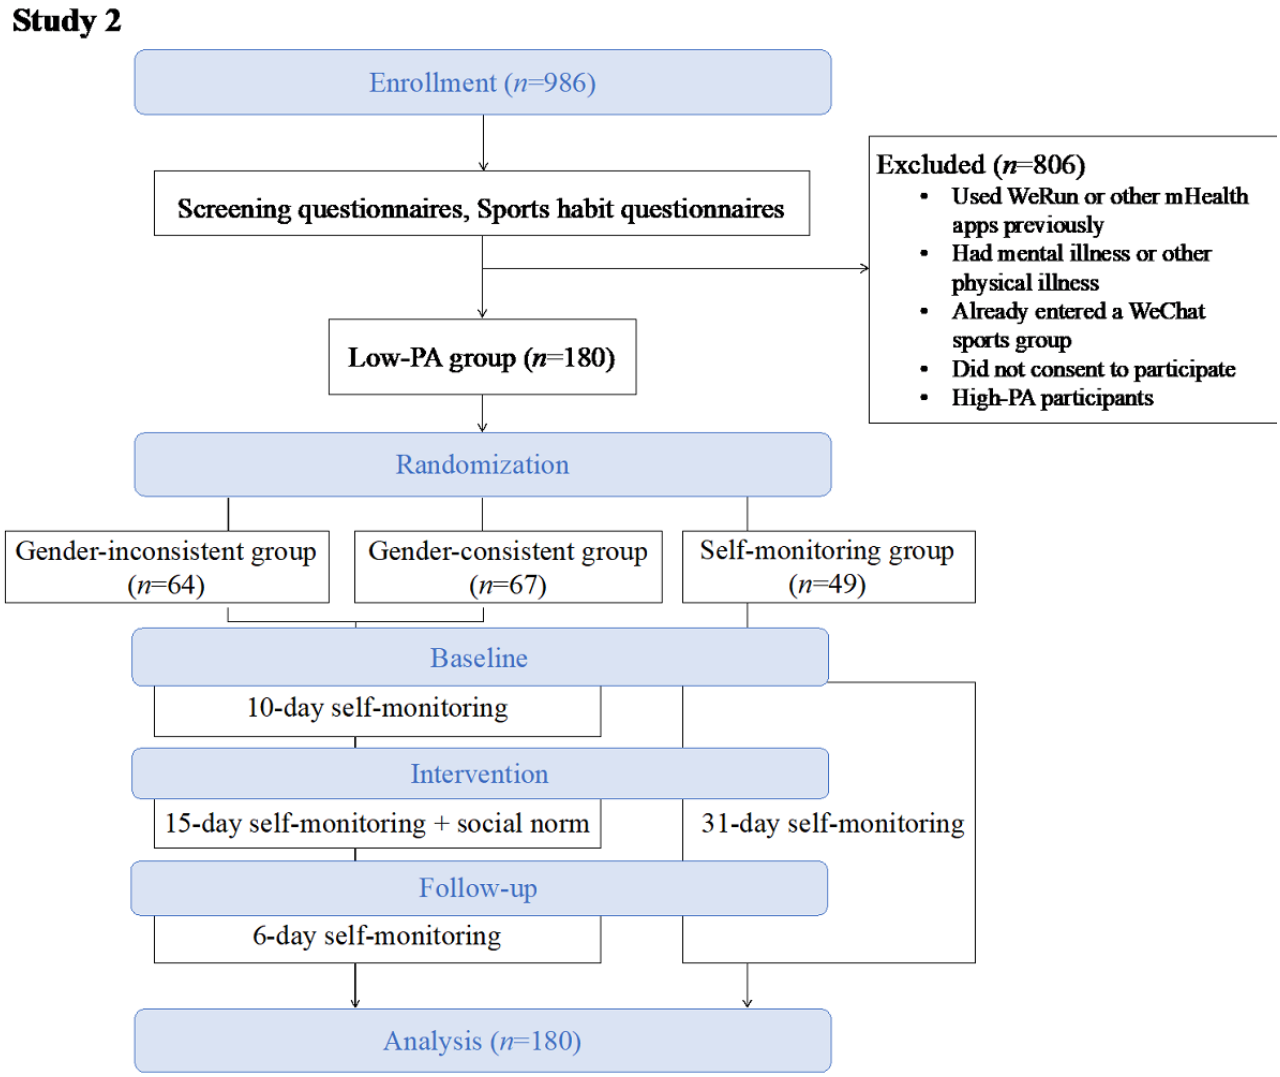

To compare the effects of self-monitoring and social norms, we randomized all participants in both studies into 3 groups according to the interventions they received, namely, a self-monitoring intervention group and 2 social norm intervention groups. Participants in the 2 social norm intervention groups received social norm information from experimenters during the intervention stage, whereas participants in the self-monitoring intervention group did not receive any extra message during the experimental stages.

To test the moderating effect of group identity on the effect of social norm interventions, we aimed to compare the effects of providing social norm information among groups that should theoretically have a stronger sense of group identity (ie, PA-consistent and gender-consistent groups) against those that should theoretically have a weaker sense of group identity (ie, PA-inconsistent and gender-inconsistent groups). In particular, in study 1, we randomly assigned participants to either the self-monitoring group or 2 social norm intervention groups (the PA-consistent intervention group and PA-inconsistent intervention group). In the PA-consistent intervention group, all participants had a low PA level, while in the PA-inconsistent intervention group, half of the participants had a low PA level and half had a high PA level. In study 2, we randomly assigned participants to either a self-monitoring group or 2 social norm intervention groups (the gender-consistent intervention group and gender-inconsistent intervention group). In the gender-inconsistent (but PA-consistent) intervention group, participants received general gender-mixed social norm information as in study 1 (ie, gender-mixed information simply showing the rank of each member in the WeChat group), while in the gender-consistent (and PA-consistent) intervention group, participants received 2 gender-separate social norm information sets (ie, 2 gender-specific information sets showing the rank of each female student among all the female members and each male student among all the male members). Through this design, participants in the PA-consistent group in study 1 and gender-consistent group in study 2 will theoretically have a stronger sense of group identity than participants in the other groups.

Except for high-PA participants in study 1, all low-PA participants in both studies were randomly allocated to 1 of the 3 groups according to randomly generated numbers. All participants were single-blind to the nature of our experimental design during the entire experimental period.

Intervention Procedures

During the whole experimental period (including baseline, intervention, and follow-up), each participant was able to monitor his/her own steps by checking the trackers at any time. In addition, in order to send social norm information within the 2 social norm intervention groups of both studies, during the intervention stage, we set up separate WeChat groups for participants within each intervention group. Participants in the WeChat groups were asked to send a picture of their step trackers (study 1) or smart bands (study 2) before sleep every day. The next day at 10 AM, experimenters sent a personalized step ranking to each WeChat group member regarding their performance from the previous day.

To ensure that participants received the daily step ranking and paid sufficient attention to it, they were asked to finish an online daily tracking questionnaire containing 3 questions about step rankings (eg, How many steps did the person rank first in the group walk yesterday?) and their step tracker wearing habits (eg, When did you start to wear the tracker today?).

Social Norms and Other Measurements

To measure social norms as our secondary outcomes, participants also completed a social norm questionnaire on the last day of each stage (total of 3 times) that was adapted from a previous study [61]. The injunctive social norm questionnaire (6 items) asked participants to judge on a 7-point Likert scale (1, not agree at all to 7, totally agree) whether they agreed on some positive statements about playing sports (eg, most successful people have habits associated with playing sports). The descriptive gender norm questionnaire (2 items) measured participants' descriptive male gender norms on walking (estimation of the percentage of male students in the same university walking over 6000 steps) and descriptive female gender norms on walking (estimation of the percentage of female students in the same university walking over 6000 steps). Moreover, participants were asked to self-report some demographic information, including their age, subjective health (on a 5-point Likert scale; 1, very unhealthy to 5, very healthy), height (m), and weight (kg), and BMI was calculated (weight/height^2).

Data Cleaning

Consistent with previous studies [39], we deleted data points for the following reasons: participants failed to answer all the daily tracking questions, device wear time was shorter than 8 hours (in study 1), or step count was less than 1000. In study 1, 4.72% of data points of step counts were missing, and in study 2, 0.79% of data were missing. Days with nonmissing data from the same participant were still included in the final analyses.

In study 1, we excluded a total of 14 participants from all analyses for the following reasons: 10 were lost in the follow-up stage, 1 did not answer the tracking questionnaire during the intervention stage, 1 had no valid baseline step data, and 2 lacked sufficient intervention step data (more than five missing values). The final valid sample included 155 participants (75 males and 80 females; mean age 25.75 years, SD 1.27 years; age range 23-33 years), of which 117 participants were from low-PA groups. In study 2, 2 participants quit the experiment halfway through and were thus excluded from all analyses. This left a valid sample of 180 participants (92 males and 88 females; mean age 22.60 years, SD 1.16 years; age range 20-30 years).

Statistical Methods and Data Analysis

Baseline Comparison

In order to ensure the homogeneity of all the experimental groups, we conducted analysis of variance (ANOVA) to compare participant characteristics (age, subjective health level, and BMI) and baseline average step counts between the 3 groups. The homogeneity of variance was tested and satisfied. The significant factor (BMI in study 1) was included as a covariate in the analyses for the main outcomes.

Analysis for Social Norms

In order to compare changes in social norms (injunctive norms, male descriptive norms, and female descriptive norms) among groups across different experiment stages, we used a linear mixed-effects (LM) model with the stage (baseline, intervention, and follow-up) as a within-group factor, group and gender (male and female) as between-group factors, BMI in study 1 as a covariate, and the participant as a random intercept term in the model.

Analysis of Walking Step Data

Walking step data in our studies had 2 key features. First, there were 3 different stages (baseline, intervention, and follow-up) in the entire experiment. Second, each stage consisted of a segment of repeatedly measured daily step counts from each participant (in study 1, a total of 22 daily step counts, while in study 2, a total of 31 daily step counts). Given these features, to better capture the variability of participants' daily step counts, both at the individual level and the trend during each stage, we applied a piece-wise linear mixed-effects (PLM) model. Compared with a traditional simple linear model with a constant slope, a piece-wise linear model implements several segmented regression lines with different slopes, and thus is suitable to perform staged and especially time-segmented prediction [62]. Meanwhile, the mixed effects of the PLM take into account the individual differences during repeated measurements in each experiment stage [63].

The PLM model for walking step data was conducted for each gender separately. The predictors of the model were group, time, and their interactions, with BMI as a covariate in study 1 and the participant as a random intercept term in the model. The predictor "time" was defined by combining the continuous variable "day" during the entire observation period (22 days for study 1; 31 days for study 2) and the dummy categorical variables to reflect "stage" (defined as baseline days 1-3, intervention days 4-17, and follow-up days 18-22 for study 1; and baseline days 1-10, intervention days 11-25, and follow-up days 26-31 for study 2) to allow different linear trends over different stages. The resulting 3 independent slopes represented the different changes of each group from baseline to the intervention stage, as well as from the intervention stage to the follow-up stage. The model also allowed different intercepts for each participant to control for possible variability in individuals' overall levels of steps. In this study, as participants

in all 3 groups could self-monitor their steps during the entire experimental period (baseline, intervention, and follow-up), the changes in the slopes from baseline to the intervention stage in the 2 social norm intervention groups will represent the extra effects of social norm information on walking (isolated from the effect of self-monitoring information in the entire experimental period).

Next, to more closely examine the intervention effect, we also created an LM model by only including the data from the intervention stage (14 days in study 1 and 15 days in study 2). The predictors of the model were group, day, and their interactions, with BMI as a covariate in study 1 and the participant as a random intercept term in the model. Then, by comparing the slopes of "day," we were able to compare the effects on walking performance between providing self-monitoring alone and providing social norm information and self-monitoring.

Considering that the ranking position may impact the effect of social norms, we also added ranking position as a new covariate in the PLM. The results remained the same with the ranking position as a covariate (see detailed information in Table S1 in Multimedia Appendix 1 and Table S1 in Multimedia Appendix 2).

We performed all data analyses using R 4.0.3 (R Project for Statistical Computing). We set the level of significance for all analyses to .05. A *P* value between .05 and .10 was considered marginally significant.

Results

Study 1

Participant Characteristics

Detailed information about participant characteristics is provided in Table 1. ANOVA showed that, for both males and females, control variables were not significantly different among groups, except for BMI (*P*=.03 and .03 for males and females, respectively). Consistent with our grouping criterion that the high-PA group would walk more, we observed a significantly higher baseline step count (male high-PA group: mean 11,775, SD 3970; female high-PA group: mean 10,860, SD 3879; *P*<.001), compared with the mean of the 3 low-PA groups. These results indicate that, except for BMI, the 3 low-PA groups were basically homogenous for both males and females. Thus, we added BMI as a covariate in all subsequent analyses for study 1.

Changes in Social Norms

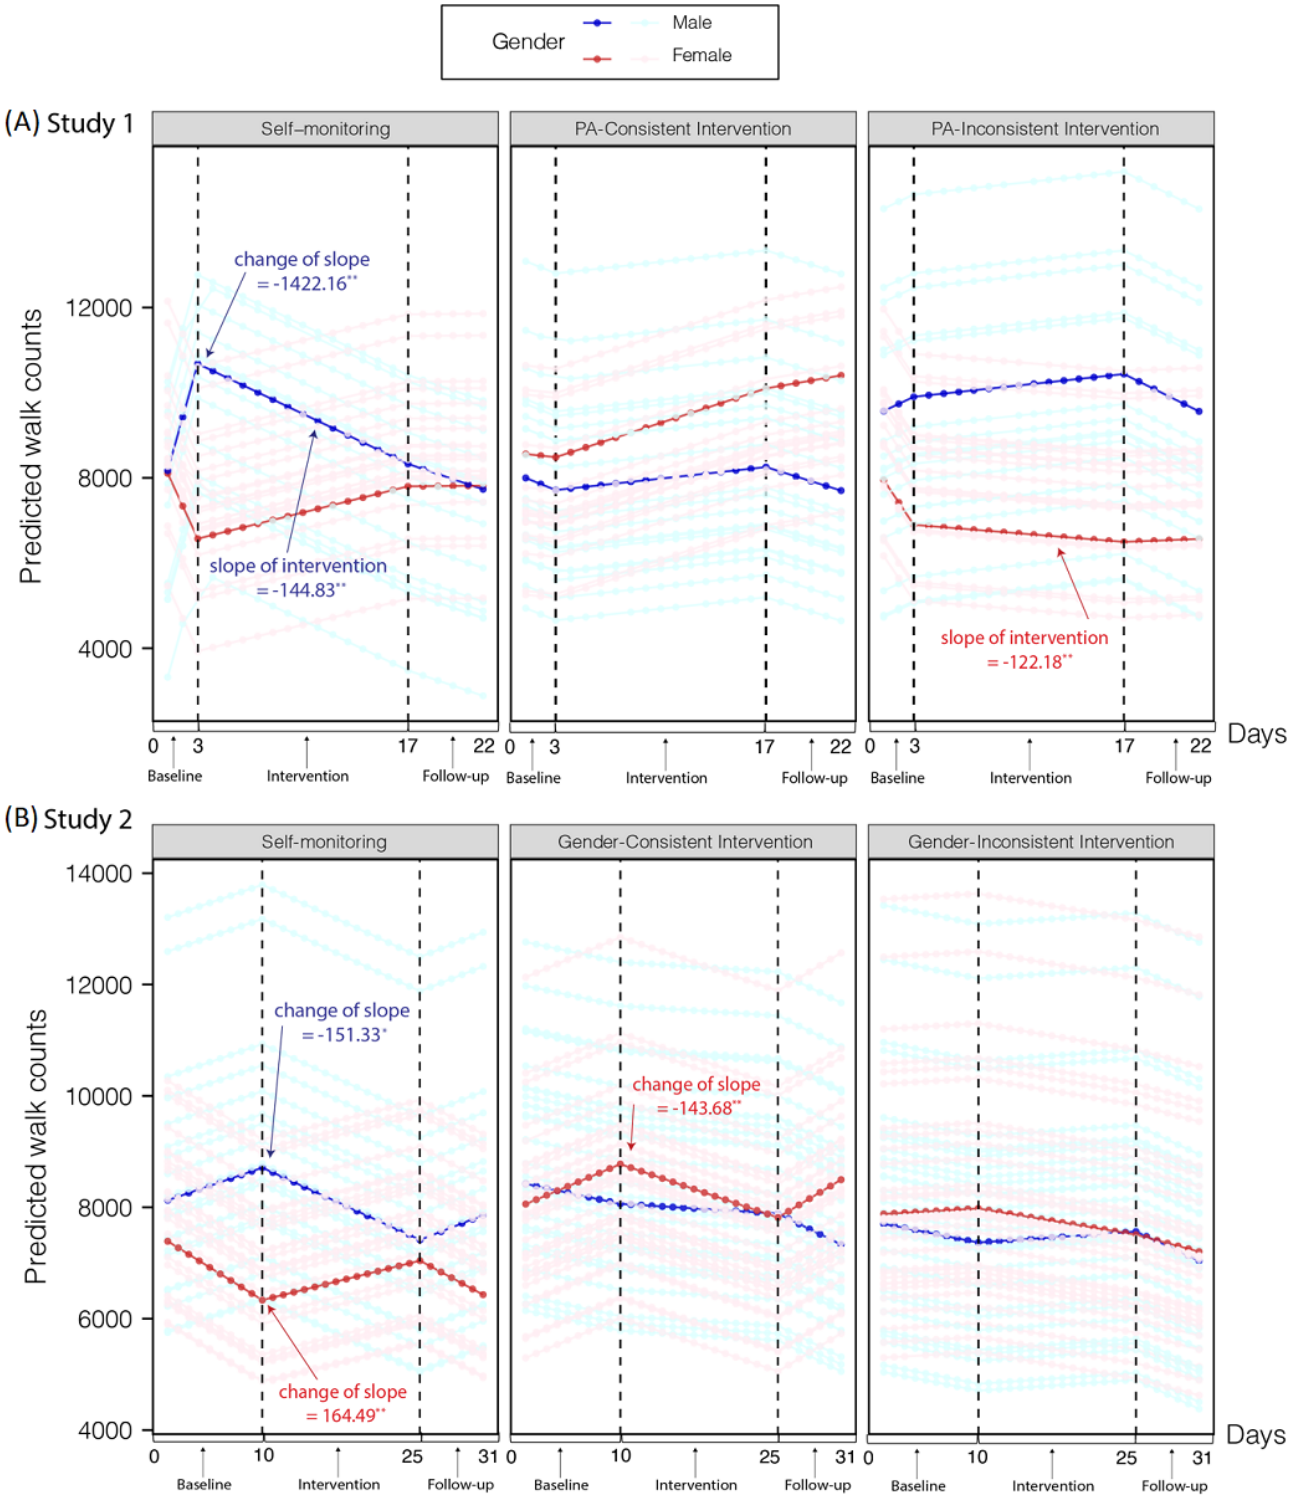
The LM model results (Table S1 in Multimedia Appendix 3) showed a significant main effect of stage on descriptive gender norms (male gender norm: $F_{2,222}$=28.70; *P*<.001; female gender norm: $F_{2,222}$=29.16; *P*<.001) and injunctive social norms ($F_{2,222}$=5.23; *P*=.01). In particular, during the experimental stages, the descriptive gender norm perceptions among all 3 groups increased progressively (*P*<.001). Participants' estimations about the percentage of male students walking over 6000 steps increased from a mean of 40.84% (SD 20.69%) to 49.80% (SD 18.62%) and then to 55.97% (SD 17.56%). Moreover, participants' estimations about the percentage of female students walking over 6000 steps increased from a mean of 31.83% (SD 19.32%) to 41.31% (SD 18.56%) and then to 47.21% (SD 17.85%). Among female students, injunctive social norm perceptions also increased significantly (*P*=.004) from baseline (mean 5.35, SD 0.92) to the follow-up stage (mean 5.66, SD 0.74). Surprisingly, however, we failed to observe a significant group difference in changes in social norms. This suggests that the self-monitoring intervention alone may be capable of leading people to perceive a higher level of social norms about walking.

Effect of the Social Norm Intervention on Step Count

As shown in Table 2 and Figure 3A, the PLM model showed separated patterns for genders with regard to step count. For males in the self-monitoring group, we detected a significantly negative change in slope over time from baseline to the intervention stage (*P*=.02), suggesting that they walked less after the 3-day baseline. For males within the 2 social norm intervention groups, walking did not change during the whole experiment. For females, however, no significant slopes or changes in slopes over time were found, suggesting that the

walking behavior of females did not change in any of the 3 groups during the whole experiment. BMI was also a significant predictor in females but not males. Specifically, a higher BMI predicted more steps taken by females (slope=328.13; $F_{1,59.23}$=6.21; P=.02), a pattern which was not repeated by males (slope=101.91; $F_{1,49.92}$=0.57; P=.45). These results suggest that higher BMI motivated females, but not males, to walk more steps.

Figure 3. Step counts (piece-wise linear mixed-effects model predicted) of the self-monitoring and 2 social norm intervention groups in study 1 (A) and study 2 (B). Each polyline represents a participant. One highlighted polyline is used for each group and gender (male, blue line; female, red line). All (marginally) significant changes of slope and slope of the intervention are labeled. *P<.10 but >.05, **P<.05.



These results partially supported H1 and H2, suggesting that the effect of social norm interventions is gender-specific. For males in the self-monitoring group, the promoting effect of self-monitoring on walking was short-lived. Although the social norm intervention did not robustly increase walking in males, the extra social norm information, regardless of its PA consistency, could at least prevent their walking steps from decreasing. For females, self-monitoring showed a stable but

nonsignificant effect on walking behavior, and we found no evidence that social norms worked better than self-monitoring.

Table 2. Results of the piece-wise linear mixed-effects model in study 1 across all experimental stages.

Gender and group	Intercept	Baseline		Intervention		Follow-up		Conditional R^2
		Slope	*P* value	Change in slope	*P* value	Change in slope	*P* value	
Male (N=54)								0.27
Self-monitoring (n=15)	8169.98	1254.20	.03	−1422.16	.02	48.66	.84	
PA[a]-consistent intervention (n=21)	7930.21	−142.53	.77	181.10	.71	−148.91	.46	
PA-inconsistent intervention (n=18)	9267.26	166.57	.75	−128.39	.82	−213.44	.32	
Female (N=63)								0.15

[a]PA: physical activity.

Comparing the Effects of Self-Monitoring and Social Norms on Step Count

Results from the LM model at the intervention stage indicated (details in Table 3) a clear distinction between genders in terms of sensitivity to self-monitoring and social norm interventions. For males, the interaction between time and group was marginally significant ($F_{2,682.11}$=2.48; *P*=.09). In the self-monitoring group, we observed a significantly negative slope (*P*=.04), suggesting that steps taken by males in this group decreased during the intervention stage, while both the PA-consistent and PA-inconsistent interventions arrested this decreasing trend. For females, however, the interaction between time and group was significant ($F_{2,793.57}$=3.39; *P*=.03). A significantly negative slope (*P*=.03) for the PA-inconsistent intervention group also suggested that the PA-inconsistent intervention led to a decrease in steps walked during the intervention stage. No such effect for females in either the self-monitoring or PA-consistent intervention group was found. Consistent with findings from the PLM model, a higher BMI in females was a significant predictor of more steps walked ($F_{1,59.35}$=4.22; *P*=.04). Again, this pattern was not found in males ($F_{1,49.91}$=0.75; *P*=.39).

Table 3. Results of the intervention-focused linear mixed-effects model in study 1.

Gender and group	Intercept	Slope	SE	*P* value	Conditional R^2
Male (N=54)					0.31
Self-monitoring (n=15)	8448.02	−144.83	71.43	.04	
PA[a]-consistent intervention (n=21)	8068.35	37.04	60.92	.54	
PA-inconsistent intervention (n=18)	9520.74	48.70	65.76	.46	
Female (N=63)					0.21
Self-monitoring (n=22)	7800.66	81.14	57.49	.16	
PA-consistent intervention (n=19)	7973.10	32.73	61.70	.60	
PA-inconsistent intervention (n=22)	8141.32	−122.18	57.44	.03	

[a]PA: physical activity.

Taken together, these results partially supported H1 and H2, with several restrictions. For males in the self-monitoring group, self-monitoring only was not able to exert any long-term effect since steps decreased significantly, while for males in the 2 social norm intervention groups, steps were kept unchanged by the provision of social norm information. In contrast, for females, social norms did not work more effectively than self-monitoring. The hypothesized moderating effect of group identity (H3a) was supported, but it also interacted with gender. In particular, for females, PA-inconsistent social norms had a negative effect on walking behavior.

In summary, these results preliminarily confirmed H2 and H3, revealing a gender-specific moderating effect of group identity on social norms. Given the finding that gender did play an

essential role in moderating the effect of the social norm intervention and considering the reliability of our results, we conducted study 2 to replicate this study. Moreover, we modulated gender consistency to further examine the effect of group identity.

Study 2

Participant Characteristics

Detailed information of participant characteristics can be found in Table 4. ANOVA showed that, for both males and females, these baseline characteristics were not significantly different among groups (Table 4), indicating a fair homogeneity for the 3 experimental groups among both males and females.

Table 4. Participant demographic characteristics and baseline steps in study 2.

Variable	Male (N=88)				Female (N=92)			
	Self-monitoring (n=23)	Gender-consistent intervention (n=33)	Gender-inconsistent intervention (n=32)	*P* value	Self-monitoring (n=26)	Gender-consistent intervention (n=34)	Gender-inconsistent intervention (n=32)	*P* value
Age (years), mean (SD)	22.57 (1.20)	23.06 (1.50)	22.88 (1.29)	.41	22.58 (0.95)	22.24 (1.02)	22.28 (0.63)	.29
Subjective health, mean (SD)	3.30 (0.82)	3.42 (0.61)	3.41 (0.50)	.77	3.35 (0.56)	3.29 (0.72)	3.44 (0.56)	.65
BMI, mean (SD)	22.40 (3.56)	21.71 (2.52)	21.41 (3.72)	.54	19.89 (2.59)	19.42 (1.16)	20.54 (2.52)	.14
Baseline steps, mean (SD)	8737 (2279)	8750 (2211)	8012 (2647)	.39	7358 (1518)	8099 (1732)	8307 (2788)	.22

Changes in Social Norms

Similar to study 1 (Table S1 in Multimedia Appendix 4), for the 2 types of descriptive gender norms, LM model results showed a significant main effect of the stage (male gender norm: $F_{2,348}$=13.80; P<.001; female gender norm: $F_{2,348}$=22.39; P<.001). Post-hoc analysis showed that both descriptive male and female norms increased (P<.001) as the experiment progressed (from baseline to intervention to follow-up). However, in terms of injunctive social norms, LM model results showed no significant main or interaction effect. These findings indicate that injunctive norms in participants across all 3 groups did not change significantly with the experiment process.

In contrast to study 1, we found that females perceived higher descriptive gender norms than males. When asked "What is your estimation of the percentage of male/female students in the same university walking over 6000 steps?" (descriptive male/female gender norms), female participants estimated that 52.53% (SD 20.68%) of male students and 40.13% (SD 19.76%) of female students would walk over 6000 steps, while male participants estimated that 42.00% (SD 19.98%) of male students and 33.99% (SD 19.06%) of female students would walk over 6000 steps. In addition, there was a significant interaction between group and gender (P=.01) for the descriptive male norm. Post-hoc analysis showed that there was no significant group difference for female participants (adjusted P>.10). However, for male participants, the gender-consistent group had significantly higher norms than both the self-monitoring (adjusted P=.01) and PA-consistent groups (adjusted P=.09). In detail, males in the gender-consistent group estimated that 48.29% (SD 19.91%) of male students walked over 6000 steps, while male participants in the self-monitoring and gender-inconsistent groups estimated that 35.54% (SD 19.51%) and 40.16% (SD 18.67%) of male students walked over 6000 steps, respectively. In contrast, their estimations for female students were not significantly different.

Again, these results indicated that descriptive gender norms kept increasing for both genders as the experiment progressed from baseline to intervention to follow-up. We found that the gender-consistent manipulation was effective in influencing the gender norm perceptions of males but not females.

Effect of the Social Norm Intervention on Walking Behavior

Results of the PLM model in Table 5 and Figure 3B replicated the finding in study 1 of a different effect of self-monitoring and social norms for each gender. For males, a self-monitoring–only intervention led them to walk less after baseline, while additional social norm information may help keep their walk steps unchanged. Only males in the self-monitoring group walked less after baseline as indicated by a marginally significant negative change of slope over time from baseline to the intervention stage (P=.08). On the other hand, males in the 2 social norm intervention groups did not show any change in walking behavior during the entire experiment.

However, in contrast to study 1, we found a backfire effect of gender-consistent social norms among females. Females in the self-monitoring group walked more after baseline, and the slope changed in a positive direction over time from baseline to the intervention stage (P=.03). However, females in the gender-consistent group walked less compared to baseline (ie, the backfire effect), and the slope changed in a negative direction over time from baseline to the intervention stage (P=.03). These results again suggested that social norms might help males to maintain long-term walking behaviors, while they do not provide the same benefit and could even exert a negative effect

(gender-consistent social norms) on the walking behavior of females.

Table 5. Results of the piece-wise linear mixed-effects model in study 2 across all experimental stages.

Gender and group	Intercept	Baseline		Intervention		Follow-up		Conditional R^2
		Slope	*P* value	Change in slope	*P* value	Change in slope	*P* value	
Male (N=88)								0.25
Self-monitoring (n=23)	8159.99	64.89	.30	−151.33	.08	160.51	.20	
Gender-consistent intervention (n=33)	8518.26	−39.97	.45	28.29	.69	−81.14	.44	
Gender-inconsistent intervention (n=32)	7839.48	−37.16	.49	50.25	.49	−100.37	.35	
Female (N=92)								0.22
Self-monitoring (n=26)	7303.92	−117.33	.04	164.49	.03	−148.91	.19	
Gender-consistent intervention (n=34)	8014.41	79.70	.11	−143.68	.03	177.38	.07	
Gender-inconsistent intervention (n=32)	7970.47	10.94	.83	−42.36	.54	−19.19	.85	

Comparing the Effects of Self-Monitoring and Social Norms on Walking Behavior

We did not find any significant slopes in the intervention-focused model. Detailed results from the LM model over the intervention period are shown in Table S1 and S2 in Multimedia Appendix 2. These results partially supported H1 and H2, and essentially replicated results from study 1, suggesting that the effect of social norm interventions on walking is only weak among males but not females. For males, walking behaviors that were driven by self-monitoring only began to decrease slightly after 10 days, while for those receiving social norm information, regardless of whether this information was gender-specific (ie, in the gender-consistent group) or not (ie, in the gender-inconsistent group), the walking behaviors remained unchanged. However, contradicting H3b, for females, gender-consistent social norms produced a backfire effect on the promotion of walking, suggesting that without these social norms, self-monitoring only may have led to females walking more.

Discussion

Principal Findings

Through 2 longitudinal tracking studies in a sample of Chinese college students, we made several findings. First, gender moderated the effect of the social norm intervention on walking. For males, the effect of the self-monitoring–only intervention was short-lived, while the addition of social norm information, regardless of its PA consistency or gender consistency, was able to keep the walking behavior unchanged. For females, we found no evidence to show that social norms performed better than self-monitoring. Second, an additional higher level of group identity in females did not consistently guarantee an improved effect of the social norm intervention on PA. With PA-inconsistent social norms (study 1) and gender-consistent social norms (study 2), the results suggested even a backfire effect on walking steps among females.

Gender-Specific Effectiveness of Social Norm Interventions for Walking

Most previous intervention studies considered self-monitoring and social norms as 2 independent and effective strategies for promoting PA [7,8,12]. Little attention was paid to how these 2 strategies might compare in terms of effectiveness. In our studies, we combined these 2 strategies (self-monitoring–only intervention vs social norms and self-monitoring intervention) in order to directly compare their effects. Consistent with previous work [10,12,26], both studies consistently revealed that the effects of self-monitoring on PA (especially among males) were short-term (at least no longer than 3 or 10 days). We found that, among males, the addition of sharing social norms could outperform the effects of self-monitoring only. These results were partially consistent with those of Rote et al [9]. They reported that young women who shared PA information with Facebook group members were able to increase their PA more than those who only used a self-monitoring strategy. These results differed from our results in terms of gender.

As a meta-analysis [23] has previously suggested, our results revealed a notable separation in the patterns of PA outcomes according to gender. Specifically, for males, with self-monitoring as a baseline condition, we found that the effect of the intervention with social norm information can keep walking unchanged among males. However, for females, we found no evidence that social norms performed better than self-monitoring. A reasonable explanation for gender differences in the effect of a social norm intervention is that a relatively weak self-monitoring effect among males may leave more potential for a social norm intervention to produce a protective effect. Previous studies suggested that male students may be less self-disciplined [64] and less likely to use self-regulation strategies [65] than females. As a result, both of our studies

showed a marginally significant decrease in walking in males after the baseline stage (in study 1, the change of slope over time was −1422.16; *P*=.02; in study 2, the change of slope over time was −151.33; *P*=.08), revealing a short-lived effect of self-monitoring among males when no social norm information was provided. Thus, as the effect of self-monitoring began to fade over time [66], additional social norm information was able to encourage males to perform social comparisons between themselves and their peers, thus motivating them to pursue a better rank position by walking more. For females, however, the self-monitoring intervention tended to benefit them more significantly, as they represent a more self-disciplined group [64]. A previous meta-analysis also concluded that the effect size of wearing a pedometer is much greater for females (95% CI 0.64-0.97) than males (95% CI −0.18 to 0.79) [66]. Therefore, a simple wearable pedometer may already lead highly motivated females to walk more, thus making it more difficult for other interventions to produce an additional enhancement or further increase the PA of females. This may be the reason why social norm information or supplemental PA intervention strategies [67], other than self-monitoring, work better for males than females.

An alternative explanation may be related to a counterproductive cultural stereotype, prevalent in Chinese culture, that females should be less active and petite than males [68]. From this perspective, constant PA may be deemed as an obstacle to adhering to such a stereotype regarding femininity, which may consequently discourage some female college students from engaging in PA. This explanation is supported by our results that the descriptive female gender norms were consistently lower than the male gender norms in both studies. Taking study 2 as an example, participants estimated that only 37.13% (SD 19.65%) of female students would walk over 6000 steps; however, for male students, the estimation was 47.38% (SD 20.99%). Still, these stereotypes of walking gender difference may only be effective as a self-serving bias for males. In study 2, the actual within-group rankings of females were even better than those of males; 53% of the highest quarter of the step ranking involved females in the gender-inconsistent intervention group. As a result, a relatively high level of individual PA may be perceived as a quality outside the “normal” confines of femininity, thus deviating from the traditional female stereotype, or, even worse, it could be considered as having an atypical female behavior. Previous studies have shown that a high level of PA may expose females to feelings of social pressure [69] and being stigmatized [70]. Thus, even if a female could have a similar step ranking to a male, the psychological meaning of ranking (the social norm information) might be different because, among females, having a high PA level might be perceived as an outside-gender group behavior rather than a within-gender group social norm. However, males may be motivated purely by the desire to pursue a better rank position, since walking more or having high PA is consistent with their own gender stereotype and set of social expectations. Thus, ranking as a motivational device was only effective for males, and in light of cultural expectations regarding femininity, no positive effect of social norm information was found among females. Future studies may benefit from comparing the effects of self-monitoring and social norm interventions on PA within different cultural backgrounds, or perhaps examining gender stereotypes unique to the cultures of participants’ countries.

It should be pointed out that, based on the current evidence, providing social norm information might have no more than a protective effect. Since neither study revealed a significantly positive change in slope in any social norm intervention group during the intervention stage, the provision of social norm information did not produce any additional enhancement in PA. Among males, however, both studies suggested that self-monitoring on its own may lead to a reduction in steps walked following the baseline stage. The addition of social norm information was, at least, shown to hold the level of PA steady in males, which can be considered as a protective effect.

A Higher Group Identity Does Not Equal A Better Effect of Social Norm Information

In both studies, we found that group identity moderated the effect of social norm information on walking behavior. According to predictions of the TNSB, social norm information shared between members with a high group identity should make its effect more powerful [42]. However, we found that this type of effect of group identity was not reflected among males, while, among females, a higher group identity appeared to be a double-edged sword in terms of its effect on PA.

In particular, in study 1, we found that providing social norms with lower group identity (PA-inconsistent social norms) led to a reduced effect on walking in females, a finding which is consistent with the TNSB. This finding among females who were part of the PA-inconsistent group engaging in a low level of PA may be driven by 2 possible factors. First, we have to note the large disparity in performance between high-PA participants and low-PA participants in our study. For high-PA participants, the mean count of steps walked during the intervention stage was 11,997 (SD 3165), but for low-PA participants, the mean count of steps walked was 7868 (SD 2341). The later participants may have been likely to perceive themselves as outgroup members, thus weakening the effect of any social norm intervention. Second, these members may also have perceived a greater sense of upward social comparison, that is, comparison with peers who are relatively better off [71]. Thereafter, there may have been a subsequent loss of motivation to achieve a better ranking, leading to a reduction in walking. This effect is consistent with previous studies in which more upward comparison on social media platforms was associated with a decrease in self-esteem or well-being [72], as well as more depression or shame [73]. It has been suggested that interventions that lead to inappropriate types of social comparison, either upward or downward, may indeed be counter effective for one’s PA. Further studies should take the type of social comparison into account when considering the application of other potential factors (eg, age consistency [46]) to increase (or decrease) group identity theoretically.

In study 2, however, social norm information from a gender-consistent source, which should theoretically lead to a higher group identity, surprisingly led to a decrease in PA among females compared with PA in the self-monitoring control group. Although there are few interventions using gender-consistent social norms, our results are consistent with the finding in

another health intervention study (providing gender-consistent social norm information is ineffective in reducing alcohol intake) [47]. One possible explanation might be that for females, sharing gender-consistent social norm information, that is, sharing gender-specific information, may provoke increased feelings associated with femininity and thus bring about concerns regarding their own social gender role. An alternative explanation could be that the separation of genders in ranking may unintentionally sharpen some undesirable social norms for females (eg, few females walk a lot), thus negatively impacting the intervention. For future interventions, we would argue that, at least in the context of promoting PA among females, tailoring social norm interventions to be gender consistent may not be advisable, since an unexpected side effect may conceal or even reverse the desired effect of the interventions.

Implications

Based on WeChat groups and step ranking information as an ecological intervention, our study can provide new empirical evidence with high ecological validity regarding the effect of social norm information in promoting PA within the Chinese context. Our study contributes to the field of mHealth and PA interventions in 3 ways. First, by using a self-monitoring control group, our study avoided the high statistical error rate typically brought about by a mixed-strategy intervention. Second, our findings highlighted salient gender differences associated with the effects of social norm information and self-monitoring on PA. These findings suggest the necessity to take gender into account when designing mHealth interventions for Chinese users. Third, we advise caution in using group identity to promote PA. This is especially true for gender-specific manipulations, since the increase in identification with females may, in the context of promoting walking or general PA, conflict with the target behavior.

Given the critical role of personalization in mHealth interventions, our results provide some useful insights into PA-targeted mHealth intervention projects in China. First, a gender-specialized intervention is essential to the goal of nudging walking behavior in China. For males, compared with a more traditional passive presentation of walking data, proactively pushing PA-related social norm information to users may be a more effective method for pedometer apps and other self-monitoring interventions. For example, WeRun or other mHealth apps could push a daily reminder containing the walking data of the friends of male users in order to maintain the initial beneficial effect of self-monitoring. However, among females, since social norm information did not have a beneficial effect on walking behavior, rather than adding extra social norm manipulations, maximizing the effect of self-monitoring may be a better approach. Female-targeted interventions should make full use of self-monitoring strategies. For example, they could push a daily personal step count to female users and track the overall walking step count record for each week. Second, nonessential gender-specific social norm information should be used with caution in PA interventions, since heightened gender identity may conflict with the target behavior, thus leading to an undesired outcome. Therefore, further mHealth interventions or smart devices should tailor their plans according to the gender of users; the provision of social norm information may be “the icing on the cake” for males but would be superfluous for females.

Limitations

Several limitations of this research should be noted. All of our participants were Chinese college students, and this may limit the external validity and generalizability of our results. Although the main results were replicated across 2 studies to ensure their reliability, more empirical evidence is needed before generalizing our findings to other samples (eg, older adults) or other cultural backgrounds (eg, those with relatively weak gender stereotypes or gender gaps). Given that college students have a relatively high PA level (the average step count recorded by WeRun was 6932 steps/day in 2019 [74], while participants reached 7900 step/day in both our studies), further studies may investigate lower PA groups, such as office staff and retirees, to replicate our results.

In addition, previous studies have suggested that the effect of self-monitoring on PA can be attributed to the Hawthorne effect [26]. Although we aimed to compare the pure effect of self-monitoring and a social norm intervention, the nature of our study design means that we cannot rule out this possibility, that is, any effects observed may have been related to participants’ awareness that their walking activity was being monitored.

Finally, we did not provide sufficient empirical evidence to attribute our finding that females reduced their PA in the gender-consistent group to the presence of a backfire effect of high group identity on social norms. Other potential variables, such as trait competitiveness, may also impact the effect of social norm information. Further studies may benefit from controlling these variables to directly address this unexplained result.

Conclusion

Gender and group identity are 2 moderators of the effect of social norm interventions on walking. In female Chinese college students, a higher sense of group identity does not guarantee a better effect of social norm information on PA, that is, PA-inconsistent or gender-consistent social norm information reduces walking in females. However, in male Chinese college students, social norm information and group identity do not show such an effect. Specifically, while walking may decrease with self-monitoring only, the inclusion of social norm information may help to keep the level of walking steady in males.

Abstract

Background: New innovative technologies, such as mobile apps, have been developed to increase pre-exposure prophylaxis (PrEP) adherence and the use of log sex diaries. The contiguity of mobile apps reduces the recall bias that generally affects reported condom and PrEP use. However, none of the currently used mobile apps were designed for event-driven PrEP users, and few studies have demonstrated the potential usage of sex diary data to facilitate the understanding of the different HIV risks among heterogeneous profiles of sex diaries and PrEP use.

Objective: We aim to discriminate the heterogeneous profiles of sex events and PrEP use and examine the risk of condomless anal sex among different types of sex events.

Methods: We recruited 35 adult men who have sex with men from two medical centers in Taiwan since May 2020 and followed up for four months. Participants were on PrEP or willing to take PrEP. They were asked to log their sex events, PrEP use, and dosing regimens on a mobile app to improve their PrEP adherence. Latent class analysis was used to distinguish profiles of sex events and PrEP use. Indicators included correct intake of PrEP for each sex event, participants' sexual positioning, partner's HIV status, and age.

Results: A total of 551 sex events were classified into three classes by latent class analysis: PrEP nonadherent flip-flopping (234/551, 42%), PrEP imperfect-adherent power bottoming (284/551, 52%), and PrEP adherent serodiscordant topping (33/551, 6%). "PrEP nonadherent flip-flopping" sex events were more likely to involve condomless anal sex than "PrEP imperfect-adherent power bottoming" (OR 1.83, 95% CI 1.03-3.25) after considering random intercepts for individuals, and this class needed to increase their PrEP adherence and use of condoms. "PrEP imperfect-adherent power bottoming" realized their own risk and packaged PrEP with condoms to protect themselves. Up to 99% (32/33) of sex events in "PrEP adherent serodiscordant topping" were protected by PrEP, but all of the sex events in this group were condomless.

Conclusions: Using the sex diary data could advance the capacity to identify high-risk groups. HIV prevention strategy should be more flexible and combine PrEP with condom use for future HIV prevention.

Introduction

Pre-exposure prophylaxis (PrEP) is an effective tool for HIV prevention [1]. The number of PrEP users has increased in recent years [2]. In Taiwan, the majority of PrEP users are men who have sex with men (MSM) [3], and it is estimated that 8.9% of MSM were on PrEP in 2019 [4]. A question has emerged from the scale-up of PrEP use regarding whether MSM have decreased their intention of using condoms since they are on PrEP. MSM PrEP users may tend to practice condomless anal sex because they perceive PrEP use decreases their risk of HIV infection [5-8]. A few studies did not find support for the increase of condomless anal sex after PrEP initiation [1,9,10]. The evidence of the association between condomless sex and PrEP use remains inconsistent. The practice of condom use needs to be addressed in PrEP implementation because other sexually transmitted infections may increase. Moreover, if PrEP users are stigmatized as those who prefer condomless sex [11], PrEP scalability may be impeded.

To address whether PrEP use is associated with condomless anal sex in MSM requires measurement of condom use during sex and PrEP intake. Most studies have used self-reported surveys to measure condom use and PrEP adherence [12-15], but recall bias affected the accuracy when participants were asked to recall how many times they used condoms or took PrEP over a long period. Some studies asked participants whether they used condoms during the last anal sex event to reduce the recall bias [16-18], but a one-time sex event neither reflects the long-term decision-making of condom use nor assesses the longitudinal change of PrEP adherence. Although self-reporting bias is still inevitable, using a website survey or mobile apps to measure condom and PrEP use can be more immediate than traditional surveys [19-22]. Additionally, PrEP adherence could be measured by drug concentrations in hair or dried blood spots and Wisepill bottle openings [23]. However, drug concentration testing is costly and time-consuming, and Wisepill bottle openings may underestimate PrEP adherence if the bottle is not being used [23]. There has been no perfect measurement for condom and PrEP use until now, but a mobile app that allows users to log their PrEP use and sex diary at any time or place may be more suitable for monitoring HIV risk in MSM. Sex diaries have been used to track sexual encounters, reduce risky sexual behavior [19-21], and facilitate PrEP uptake [19]. Therefore, a sex diary on a mobile app that gathers the information of each sex event, such as condom use and partner's HIV status, is important for researchers to examine condom use with different sexual partners and track whether or not PrEP is taken correctly.

Because the data from sex diaries contain various characteristics, latent class analysis has usually been used for classifying the characteristics of sexual partners in each sex event to reduce the dimensions of data and create profiles of sexual activities to facilitate outcome analysis. Classifying the patterns of sex events and PrEP use is crucial to identifying which patterns were associated with condomless anal sex. Factors such as a partner's HIV status and age, sex position, condom use, and dosing regimen of PrEP should be considered in relation to whether one has adhered to PrEP as those factors affect the decision-making of condom use. For example, having sex with an older partner was more likely to involve condomless anal sex [24]. MSM who identified as bottoms were less likely to use condoms than those identified as tops [18]. MSM were more likely to practice condomless anal sex with a partner whose HIV status was the same as themselves, compared with those who had sex with a partner whose HIV status was different [25]. Using mobile apps for MSM to log PrEP uptake and sex diaries, including the risk factors mentioned above, can help researchers identify the subgroups of sex events and their relationship with condom use.

In this study, we used event-level data collected from sex diaries in a mobile app that allowed MSM PrEP users to record their PrEP intake, choice of dosing regimen, and information for each sex event. We aimed to understand whether the decision of condom use in a sex event could be evaluated based on one's PrEP use and perception of HIV risk. Specifically, we described the pattern of sex diaries and the proportion of correct PrEP use in relation to condom use and the sexual partners' HIV status. We then used latent class analysis (LCA) to identify heterogeneous sex diaries and PrEP use profiles. Lastly, we examined whether condom use was related to the various sex diaries profiles involving PrEP use. This study demonstrates innovative implications for sex diary data, and the findings will broaden applications in further HIV interventions.

Methods

Study Population and Procedure

We recruited participants referred by physicians and PrEP navigators from two medical centers in two major cities of Taiwan (Taipei and Tainan). The following MSM were eligible for inclusion: (1) HIV-negative, (2) age ≥20 years, (3) currently taking PrEP or willing to initiate PrEP after enrollment, (4) had at least 4 episodes of anal sex with men in the previous month, and (5) are willing to install our mobile app—the UPrEPU app—on their smartphone device. Eligible participants interested in this study were informed about the purpose and goal of the study. In the informed consent process, research assistants explained which types of data would be collected by the UPrEPU app. All the data were de-identified, and participants' personal information was unrecognizable. People who agreed to join the study were asked to provide signed informed consent, and research assistants tutored them regarding the use of the UPrEPU app. Data collected on the app was kept private and confidential. Recruitment began in May 2020, and each participant was followed for 4 months. Participants were tested

for HIV at each monthly follow-up. Participants could receive US $20 cash for each follow-up as an incentive. More detailed study procedures were described elsewhere [26].

The UPrEPU was designed to remind the users to take PrEP based on their dosing regimen, potential time, and pre-arranged date for the sex event and monitor their PrEP adherence. More than half of MSM in Taiwan (56%) chose to take PrEP with an event-driven (ED) dosing regimen [27], a regimen that required individuals to take two pills 2 to 24 hours before sex, and followed by taking one pill 24 hours after sex and another pill 48 hours after sex [28]. This is the first app that considered the complexity of the ED dosing regimen, and the reminders for taking ED PrEP were contingent on the timing of sex events. The UPrEPU app allowed users to track whether their sex events were protected by PrEP and log their dynamic PrEP-dosing choices. Participants could also record relevant information regarding each sexual event, including whether a condom was used, participants' sexual positioning, sexual partner's age, and HIV status. The present study was approved by the Institutional Review Board of the National Cheng Kung University Hospital (IRB: B-BR-107-076-T).

Latent Class Indicators

Correct Intake of Prep for Each Sex Event

For each sex event, whether or the MSM had correctly used PrEP was based on their dosing regimen and categorized as: (1) correct use of the daily dosing regimen, (2) correct use of the ED dosing regimen, and (3) incorrect use of either dosing regimen. Because taking at least 4 pills per week was suggested to provide enough protective PrEP concentrations [29], correct use of a daily dosing regimen was defined as at least 4 pills taken 168 hours before each sex event. Correct use of an ED dosing regimen was defined as taking 2 pills before and another 2 after each sex event. More specifically, the 2 pills before should be taken 2 to 24 hours before each sex event. However, if at least one pill was taken 25 to 168 hours before each sex event, taking only one pill 2 to 24 hours before each sex event was allowed [28]. The selection of when to take the 2 pills after each sex event was based on when the pill was taken right before sex. Our measurement allowed a 2-hour buffer for the participant to log his PrEP use into the app. Participants could also log their previous PrEP use. For example, if participants took 1 or 2 pills X hours before each sex event (X ranged from 2 to 24), they should take another single pill from 22 to 26 hours after the time X. The last pill should be taken 46 to 50 hours after the time X. Incorrect use referred to those in neither of the above groups.

Participants' Sexual Positioning

Participants were asked to report whether they practiced insertive, receptive anal sex, or both during each sex event.

Partner's HIV Status

Response options of each participant's sex partner's HIV status consisted of the following: unknown HIV status, negative and on PrEP, negative but not on PrEP, positive with an undetectable viral load (UVL), or positive with an unknown viral load.

Partner's Age

We asked participants to estimate the age of their sexual partner for each event; the options included less than 20, 21 to 30, 31 to 40, 41 to 50, 51 to 60, and above 60 years old. The comparison between the participants' and their sexual partners' age was used as the latent class indicator, including "partner was at least one age category younger than I," "the same as participant's age category," and "partner was at least one age category older than I."

Statistical Analysis

The pattern of sex events during 4 months was presented for each participant. For each sex event, we measured whether a condom was used and whether PrEP was taken correctly, along with the choice of the dosing regimen. LCA was conducted using R version 4.0.3 (R Core Team) and the poLCA package [30]. We used LCA to classify sex events into subgroups. Latent class indicators included participants' PrEP dosing regimens during each sex event, their sexual positions, their sexual partner's HIV status, and the age comparison between participants and their sexual partner. The models were estimated 10 times, with 500 iterations for each run; the solutions with the largest likelihood values were considered maximum likelihood estimates. The model with the lowest Akaike Information Criteria (AIC) [31], lowest Bayesian Information Criteria (BIC) [32], and highest entropy was considered the best-fitting model [33].

Posterior class membership probabilities were used to assign a predicted class to each sex event. Logistic regression analysis was used to compare the difference in condom use between classes. Since one participant could provide more than one sex event, we further used mixed-effects logistic regression with random intercepts for participants.

Results

Participants

The study enrolled 35 users who installed the UPrEPU app. We excluded 3 (8.6%) users who did not enter any sex event in the app. The average age of the remaining 32 (91.4%) users was 29.3 years (SD 4.9). During 4 months, no seroconversion was reported. The number of sex events in 4 months ranged from 1 to 66 (mean number: 17.2). A total of 551 sex events were recorded in this study. Table 1 lists the characteristics of sexual partners and sex events. Condoms were used in 22% (123/551) of sex events. Participants reported correct use of ED PrEP in 64% (352/551) of sex events and correct use of daily PrEP in 14% (79/551). Insertive anal sex was practiced in 35% (193/551) of sex events; receptive anal sex was practiced in 54% (295/551); 11% (63/551) of sex events reported practicing both insertive and receptive anal sex in the same sex event. Among the HIV and PrEP status of users' sexual partners in all events, 38% (209/551) of sexual partners' HIV status was unknown, 21% (118/551) were on PrEP, 30% were negative and not on PrEP, 11% (59/551) were positive with UVL, and there were no positive partners with unknown viral load. Half of the sexual partners (273/551) were reported in the same age category as the participants.

Table 1. Characteristics of sexual partners and sex events (N=551).

Participant characteristics	Values, n (%)
Whether condom was used	
Yes	123 (22)
No	428 (78)
Participants' PrEP[a] dosing regimens during the sex event	
Correct use of daily PrEP	79 (14)
Correct use of ED[b] PrEP	352 (64)
Incorrect use of PrEP	120 (22)
Participants' sexual positioning	
Insertive anal sex	193 (35)
Receptive anal sex	295 (54)
Both insertive and receptive anal sex in the same sex event	63 (11)
Partner's HIV status	
Unknown HIV status	209 (38)
Negative and on PrEP	118 (21)
Negative but not on PrEP	165 (30)
Positive with an undetectable viral load	59 (11)
Positive with an unknown viral load	0 (0)
Partner's age[c]	
Partner was at least one age category younger	154 (28)
The same as participant's age category	273 (50)
Partner was at least one age category older	124 (23)

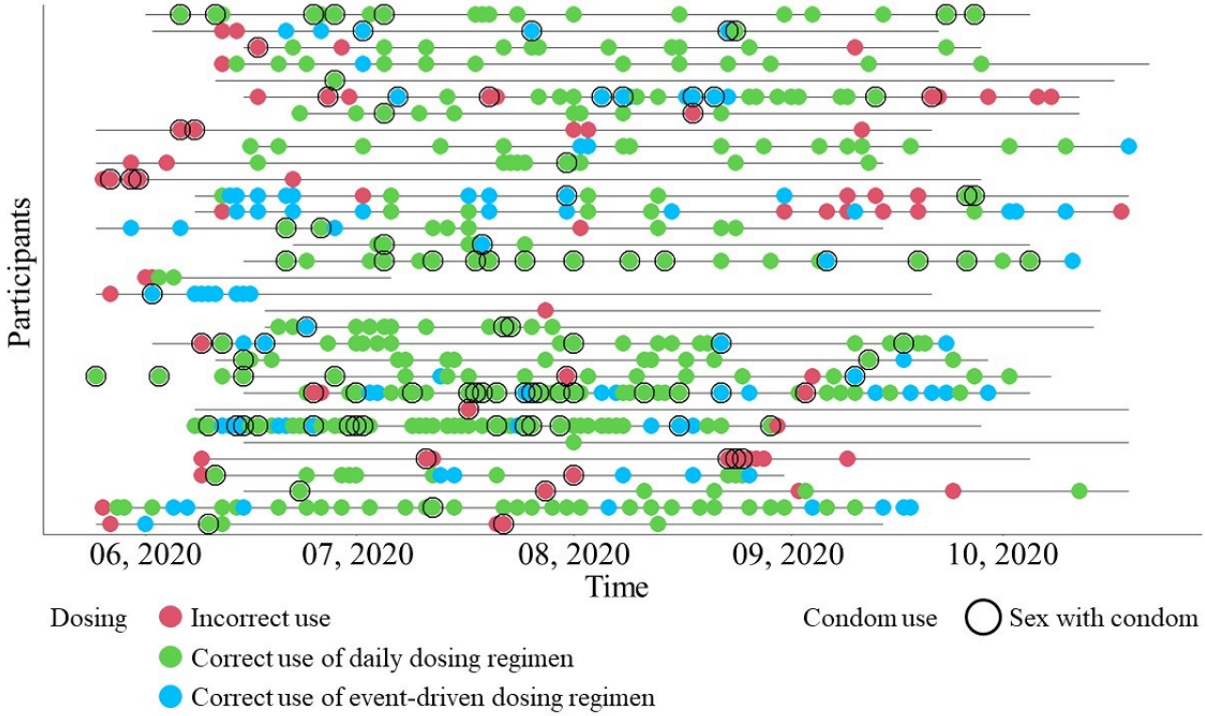
[a]PrEP: pre-exposure prophylaxis.

[b]ED: event-driven.

[c]Age category difference was based on the following age categorical variables of the sexual partners reported by the participants: less than 20, 21 to 30, 31 to 40, 41 to 50, 51 to 60, and above 60 years old.

Among 551 sex events, 83% (455/551) were protected by either PrEP or condoms, 18% (99/551) were protected by both PrEP and condoms, and 17% (96/551) were protected neither by PrEP nor by condoms (Figure 1). Among 32 participants, only one (3.1%) person was protected by PrEP and wore condoms during every sex event. There were 7 (22%) MSM protected by PrEP every time that had at least 1 condomless sex event and 24 (75%) MSM that had at least 1 sex event protected neither by PrEP nor a condom.

Figure 1. Sex events of each participant with dosing regimen and condom use (N=551).



Latent Class Analysis

The statistics of one-class to five-class models are shown in Table 2. Compared with a four-class model, the three-class model had lower BIC. Although the four-class model had lower AIC than three clusters, BIC is more appropriate to indicate the best-fitting model [34]. The three-class model also had the highest entropy. Therefore, we selected the three-class model as the best solution.

Table 2. Tests of model fit to identify the optimal number of latent classes.

	Log likelihood	AIC[a]	BIC[b]	Entropy
1 Class	–2306	4629	4668	1.00
2 Class	–2251	4540	4622	0.56
3 Class	–2213	4484	4609	0.76
4 Class	–2187	4453	4621	0.71
5 Class	–2177	4452	4664	0.77

[a]AIC: Akaike Information Criteria.

[b]BIC: Bayesian Information Criteria.

Characterization of Latent Classes

The conditional probabilities of sex events within each class are listed in Table 3. Class 1 comprised 42% (234/551) of the sex events and was named "PrEP nonadherent flip-flopping," showing the highest proportion of incorrect use of PrEP (45/234, 19.2%), performing both insertive and receptive anal sex in the same sex event (58/234, 24.8%), HIV status of partner unknown 103/234, 44.0%), and partner on PrEP (86/234, 36.8%). This class showed the lowest proportion of having a partner at least one age category older (21/234, 9%). Class 2 had the highest proportion of performing receptive anal sex in sex events (281/284, 98.9%), HIV-negative partners, but not on PrEP (130/584, 45.8%). PrEP protected almost 90% (251/284) of sex events in Class 2. Class 2 comprised 52% (284/551) of sex events and was named "PrEP imperfect-adherent power bottoming." Class 3 had the highest proportion of correct use of ED PrEP (29/33, 88.0%), HIV-positive partner with UVL (31/33, 94.0%), performing insertive anal sex (33/33, 100%), and having a partner who was at least one age category older (24/33, 72.7%). It also had the lowest proportion of incorrect use of PrEP (1/33, 3.0%), HIV status of partner unknown (2/33, 6.1%), and having a partner who was in the same age category as the participant (0/33, 0%). Class 3 comprised 6% (33/551) of sex events and was named "PrEP adherent serodiscordant topping."

Table 3. Latent classes and conditional probabilities of sex events (N=551).

	PrEP nonadherent flip-flopping (n=234)	PrEP imperfect-adherent power bottoming (n=284)	PrEP adherent serodiscordant topping (n=33)
Participants' PrEP[a] dosing regimens during the sex event			
Correct use of daily PrEP	0.285	0.165	0.120
Correct use of ED[b] PrEP	0.524	0.720	0.867
Incorrect use of PrEP	0.191	0.114	0.013
Participants' sexual positioning			
Insertive anal sex	0.613	0.011	1.000
Receptive anal sex	0.139	0.989	0.000
Both insertive and receptive anal sex in the same sex event	0.248	0.000	0.000
Partner's HIV status			
Unknown HIV status	0.441	0.363	0.048
Negative and on PrEP	0.368	0.094	0.000
Negative but not on PrEP	0.177	0.457	0.000
Positive with an undetectable viral load	0.014	0.086	0.952
Partner's age[c]			
Partner was at least one age category older	0.090	0.288	0.746
The same as participant's age category	0.563	0.495	0.000
Partner was at least one age category younger	0.347	0.217	0.254

[a]PrEP: pre-exposure prophylaxis.

[b]ED: event-driven.

[c]Age category difference was based on the following age categorical variables of the sexual partners reported by the participants: less than 20, 21 to 30, 31 to 40, 41 to 50, 51 to 60, and above 60 years old.

Clusters and Condomless Anal Sex

The proportion of condomless anal sex in each class was 85% (198/234), 69% (197/284), and 100% (33/33), respectively (Table 4). Since the sex events in "PrEP adherent serodiscordant topping" were all condomless, we only compared the probability of condomless anal sex between "PrEP nonadherent flip-flopping" and "PrEP imperfect-adherent power bottoming."

In logistic regression, "PrEP nonadherent flip-flopping" events were 1.43 times more likely to be condomless anal sex compared to "PrEP imperfect-adherent power bottoming" (OR 2.43, 95% CI 1.57-3.76; $P<.001$). After adjusting for the random intercepts, the odds for condomless anal sex were still significantly different between "PrEP nonadherent flip-flopping" and "PrEP imperfect-adherent power bottoming" (OR 1.83, 95% CI 1.03-3.25; $P=.04$).

Table 4. Logistic regression for condomless anal intercourse among three classes.

	% of condomless anal sex	OR	95% CI	*P* value
Model 1				
PrEP[a] nonadherent flip-flopping	85%	2.43	1.57-3.76	<.001
ref: PrEP imperfect-adherent power bottoming[b]	69%	—	—	—
PrEP adherent serodiscordant topping[c]	100%	—	—	—
Model 2				
PrEP nonadherent flip-flopping[d]	85%	1.83	1.03-3.25	.04
ref: PrEP imperfect-adherent power bottoming[b]	69%	—	—	—
PrEP adherent serodiscordant topping[c]	100%	—	—	—

[a]PrEP: pre-exposure prophylaxis.

[b]PrEP imperfect-adherent power bottoming was the reference group; hence, empty cells were shown in the table.

[c]PrEP adherent serodiscordant topping was not included in logistic regression due to 100% of condomless anal intercourse; hence empty cells were shown in the table.

[d]Adding random intercepts for individuals.

Discussion

Our study outlined 3 types of users and their behavioral patterns through analyzing their logs. This is the first study to classify event-level data and investigate the relationship between condom use and the heterogeneous profiles of sexual activities, including PrEP uptake among MSM. We demonstrated the use of event-level data of PrEP intake and sex diary logs from a mobile app to capture PrEP adherence in the real world. The sex diary allowed users to self-monitor and researchers to track unprotected sexual behavior and PrEP adherence. Even though high PrEP adherence was observed in our sample, only one-quarter (8/32) of participants had 100% PrEP adherence during the study period. If other HIV prevention methods such as condoms were practiced, imperfect PrEP adherence would not always be a concern; however, if neither PrEP nor condom use is well-adhered, such sexual activities would be exposed to higher HIV risk.

For example, “PrEP nonadherent flip-flopping” required more public health attention because they were neither PrEP nor condom protected. “PrEP nonadherent flip-flopping” comprised both bottoms and tops on a mixed PrEP-dosing regimen with unknown HIV status partners and had significantly lower odds of using condoms versus the “PrEP imperfect-adherent power bottoming” group. One possible reason for not using condoms among the “PrEP nonadherent flip-flopping” group may be that up to one-third (86/234, 36.8%) of sexual partners in this group were HIV-negative and on PrEP. The probability of HIV infection from a partner who was on PrEP was relatively low, and it may have resulted in reduced intention to use condoms [5,6]; however, 44% (103/234) of partners were still HIV-unknown in this group. Even though no participants acquired HIV in the 4-month study period, this group may have been exposed to HIV risk longitudinally. MSM require interventions to assist in taking PrEP correctly, such as reminders or notifications from mobile apps or individualized consultations with their PrEP navigators about their difficulties.

We identified one class, the “PrEP imperfect-adherent power bottoming,” mainly comprised of bottoms with HIV-negative partners, not on PrEP. This group may have been aware of their own risk and therefore practiced HIV prevention behavior: 90% (251/284) of sex events were protected by PrEP, and almost one-third (87/284, 30.6%) were protected by condoms. A discrete choice experiment study used conditional logic analysis to understand the preference for PrEP and condoms based on the hypothesized risk of HIV among gay, bisexual, and other MSM and showed that condoms were used as additional protection besides PrEP when there is a perceived increase in HIV risk [35], which was similar to the behavior of condom use in the “PrEP imperfect-adherent power bottoming.” Whether MSM in this class used condoms depended on their perception of the HIV risk in each sex event. This was also the largest class in our sample, which showed a potential for a combination prevention intervention that adapts to the fluctuating risk for each individual.

The “PrEP adherent serodiscordant topping” class, mainly comprised of tops and partners who were HIV positive with UVL, chose to protect themselves with PrEP instead of condoms—all sex events in this class were condomless. Reasons for MSM to have sex without condoms if they were already on PrEP include reduced fear of HIV, lessened anxiety of having sex due to PrEP use, and maintaining sexual pleasure [6,7]. Furthermore, MSM might decide not to use condoms when having sex with a regular sexual partner due to the mutual trust that friends would not put them at risk [6]. Some MSM indicated that they did not want to use condoms, and therefore they showed strong adherence to PrEP [6]. In this class, we found that PrEP had been successfully implemented, and the concept of “undetectable equals untransmissible” had been well-accepted. Public health researchers still need to stress the importance of using condoms to prevent other sexually transmitted infections. However, with the broadened options for HIV prevention, condoms might not be the first choice for many people in the real world. Therefore, health educational

campaigns may need to reprioritize prevention information to achieve optimal effectiveness.

Sex diary data used in this study uniquely included measurement for ED PrEP adherence, such as hours of sex events, instead of only dates. Compared to the apps designed for a daily dosing regimen, the UPrEPU app provided reminders for ED PrEP users to take PrEP based on when sex happened and users' previous dosing regimens. Adherence to ED PrEP can be calculated only when the hours of the sex event can be logged on an app such as UPrEPU. Such a feature is particularly important since ED PrEP use is more prevalent during the COVID-19 pandemic [36].

The strength of our study was its use of sex diaries to capture the fluctuating HIV risk of sexual behaviors and to classify the diverse patterns of sex events. Most studies have identified the different HIV risks based on the individual level [12-15]. They categorized MSM into different subtypes, but MSM perform various types of sexual behaviors in the real world, which suggests that analyzing event-level data is closer to reality. Identifying the risky class from the diverse patterns of sex events helps researchers build up a specific intervention more intentionally. We offer a more comprehensive recommendation for MSM by looking at different sex roles and PrEP adherence. Based on our findings, future mobile apps can consider giving notifications according to each user's previous patterns of sex events.

Limitations

This study has the following limitations. First, participants could see whether they took PrEP correctly in each sex event from the UPrEPU app. This may have interfered with their own judgment for whether they were protected by PrEP and affected their decision to use condoms. Without the app's assistance, PrEP users might not perceive the PrEP adherence correctly, and the decision-making of condom use would be relying solely on their self-perception, which could either be over-estimating or underestimating PrEP adherence.

Second, some contexts of sexual activities were not yet collected in our study. More details of sexual activities may change the categorization in LCA. Information such as whether the partner is a steady sex partner, uses chemsex/sexualized drugs, and belongs to particular sexual networks may be confounders for the association between PrEP adherence and condom use. Lastly, the representative of the study population may be limited due to the recruitment and inclusion criteria. We included participants from only two medical centers and those who had a relatively high frequency of sex events, which restricted the generalizability to MSM who did not use PrEP to protect themselves or whose frequency of sex events was low.

Conclusions

Our study advances the understanding of the association between HIV risk and the different types of sexual activities. We demonstrated the potential to use mobile app-based sex and PrEP diary for the future development of effective intervention programs by identifying high-risk groups. This study identified that one class, "PrEP nonadherent flip-flopping," demanded more support for implementing an HIV prevention strategy. "PrEP imperfect-adherent power bottoming" demonstrated that condoms were used as extra protection other than PrEP, and "PrEP adherent serodiscordant topping" showed almost perfect PrEP adherence but risked other sexually transmitted infections. Future HIV interventions should consider combining various strategies to improve the effectiveness of HIV prevention programs.

Acknowledgments

This study was supported by the Taiwan Ministry of Science and Technology (MOST 108-2636-B-006-004, 109-2636-B-006-004, and MOST 110-2636-B-006-011) and the Taiwan Ministry of Health and Welfare, Centers for Disease Control (MOHW 109-CDC-C-114-000104). All authors are very appreciative of all participants involved in the pilot study of the UPrEPU app. The MOST and the Taiwan Centers for Disease Control had no role in the design of the study and the collection, analysis, or interpretation of data or writing of the manuscript.

Authors' Contributions

CS, HW, and YY conceived, designed, and performed the study. HW and YY analyzed the data and drew the figure and tables. YY and CS wrote the manuscript. YY, CS, HW, SK, PH, CL, and PH revised the manuscript. All authors reviewed and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The transition to parenthood can be challenging, and parents are vulnerable to psychological disorders during the perinatal period. This may have adverse long-term consequences on a child's development. Given the rise in technology and parents' preferences for mobile health apps, a supportive mobile health intervention is optimal. However, there is a lack of a theoretical framework and technology-based perinatal educational intervention for couples with healthy infants.

Objective: The aim of this study is to describe the Supportive Parenting App (SPA) development procedure and highlight the challenges and lessons learned.

Methods: The SPA development procedure was guided by the information systems research framework, which emphasizes a nonlinear, iterative, and user-centered process involving 3 research cycles—the relevance cycle, design cycle, and rigor cycle. Treatment fidelity was ensured, and team cohesiveness was maintained using strategies from the Tuckman model of team development.

Results: In the relevance cycle, end-user requirements were identified through focus groups and interviews. In the rigor cycle, the user engagement pyramid and well-established theories (social cognitive theory proposed by Bandura and attachment theory proposed by Bowlby) were used to inform and justify the features of the artifact. In the design cycle, the admin portal was developed using Microsoft Visual Studio 2017, whereas the SPA, which ran on both iOS and Android, was developed using hybrid development tools. The SPA featured knowledge-based content, informational videos and audio clips, a discussion forum, chat groups, and a frequently asked questions and expert advice section. The intervention underwent iterative testing by a small group of new parents and research team members. Qualitative feedback was obtained for further app enhancements before official implementation. Testing revealed user and technological issues, such as web browser and app incompatibility, a lack of notifications for both administrators and users, and limited search engine capability.

Conclusions: The information systems research framework documented the technical details of the SPA but did not take into consideration the interpersonal and real-life challenges. Ineffective communication between the health care research team and the app developers, limited resources, and the COVID-19 pandemic were the main challenges faced during content development. Quick adaptability, team cohesion, and hindsight budgeting are crucial for intervention development. Although the effectiveness of the SPA in improving parental and infant outcomes is currently unknown, this detailed intervention development study highlights the key aspects that need to be considered for future app development.

Introduction

Background

In recent years, depression has displaced many chronic diseases to be the leading cause of disability worldwide and the main contributor to the overall global burden of diseases [1]. Although depression can occur at any point in life, women and men are at increased risk of depression in the postpartum period [2,3]. The transition to parenthood, coupled with emotional, physiological, hormonal, and psychosocial changes experienced during childbirth, could have increased women's susceptibility to postpartum depression [4-6]. The psychological state of women could influence their partners' psychological well-being because maternal postpartum depression is a known predictor of paternal postpartum depression, affecting 24%-50% of all fathers [7]. Fathers also have the highest risk of developing paternal postpartum depression 3 to 6 months after childbirth [8,9]. Moreover, research has shown the ripple effects of postpartum depression adversely affecting an infant's subsequent cognitive, physical, social-emotional, and behavioral development over the years [10,11]. Children of mothers who were depressed were found to score lower in intellectual and motor development, and they tend to display insecure attachment, behavioral problems, poor emotional regulation and academic performances, and are at an increased risk of developing psychiatric disorders [12-14]. In addition, a child's internalizing and externalizing behavior problems are significantly related to paternal postpartum depression [15].

Given the potential widespread consequences of postpartum depression on the family unit, there is a strong impetus for couple-based interventions to curb postpartum depression. However, to date, the cause of postpartum depression among parents remains inconclusive, thus inhibiting the development of direct intervention. Instead, research has suggested a multifactorial etiology, as there has been evidence that various psychosocial variables, such as life stress, marital conflict, childcare stress, parenting self-efficacy, poor childcare knowledge, the lack of social support, and antenatal anxiety, are key predictors of postpartum depression [5,6]. Hence, a perinatal intervention targeting these predictors may help to alleviate feelings of stress and depression among parents. Reviews on previous interventions implemented during the perinatal period have indicated the need for more multimodal family-oriented educational programs that focus on parental physical, emotional, and social well-being [16-18]. Furthermore, theory-based educational interventions are scarce, and current interventions are often compartmentalized as antenatal or postpartum [16-19] and focus on specific groups of parents such as those with infants in the neonatal intensive care unit or with behavioral problems [16-18,20,21]. Therefore, there is an urgent need for a comprehensive perinatal educational intervention for parents with healthy infants to enhance parental psychological well-being and infant developmental outcomes.

Value of Technology

Technology-enhanced health care and telemedicine have been gaining popularity because of their better accessibility, flexibility, cost-effectiveness, and ability to provide patient privacy and reduce stigmatization [22,23]. The rapid proliferation in technology-based health care is enabled by the increased use and advancements of mobile apps, wearable devices, live audiovisual communication, and telecommunication. The value of telehealth care and technology-based interventions has been further amplified during the ongoing COVID-19 pandemic as most households worldwide have faced lockdown restrictions, quarantine measures, and social isolation, which limit couples' access to help and support [24]. Moreover, such technology-based interventions are especially crucial in a conservative society such as Singapore's, where traditional views and postpartum practices (eg, home confinement) as well as the stigmatization of mental health disorders restrict parents from seeking help in the postpartum period [25,26].

Previous studies examining the needs of fathers and mothers during the perinatal period have also highlighted parents' preferences for technology-based educational programs, especially mobile health (mHealth) apps [26,27]. mHealth apps have a relatively new edge in health care innovation that allows the delivery of health care and dissemination of educational information [27]. In 2010, more than 200 million mHealth apps were downloaded, and approximately 70% of the population worldwide has access to at least one mHealth app [28]. mHealth pregnancy-related apps are particularly popular among young parents, suggesting a shift in patient empowerment in terms of maternity care [29,30]. However, parents have expressed difficulty in finding pregnancy apps that provide localized and individualized advice and feedback from health care professionals [27,30]. Current literature has also revealed that most of the available mHealth apps are not validated or developed by health care professionals [31], thus calling into question the trustworthiness and credibility of the information provided.

Given the benefits of mHealth apps and the paucity and limitations of current pregnancy-related mHealth apps, this study aims to develop the Supportive Parenting App (SPA), a theory-based perinatal educational mobile app for parents, and to subsequently examine its effectiveness in preventing postpartum depression and enhancing parenting self-efficacy, perceived social support, parent-child bonding, and physical and social-emotional development of an infant. According to the Singapore Infocomm Media Development Authority [32], 98% of households in Singapore in 2019 had internet access and 89% of individuals were internet users. In addition, the smartphone penetration rate of 82% in Singapore is one of the highest in the Asia Pacific region [33]. Therefore, technology is available in most households to support the implementation of the SPA during the perinatal period.

Detailed intervention development studies are limited because of research funding priorities that focused on efficacy or effectiveness studies [34]. However, a comprehensive, systematic, and transparent reporting of intervention development is necessary to help readers understand the challenges and benefits of different intervention development approaches and allow retrospective assessments to be performed to understand how different development approaches may affect the effectiveness of interventions. Therefore, this study aims to provide an insight into the SPA development process and highlight the challenges and lessons faced during the SPA development to improve future mHealth studies.

Project Overview

The SPA project was a multisite study that was conducted in tertiary public hospitals in Singapore. The intervention was delivered to both parents (fathers and mothers), and they were granted access to the SPA during the perinatal period (from the viability age of 24 weeks of gestation to 6 months after childbirth) when the chances of developing antenatal or postpartum depression were very high. The parents were able to access the mobile app anytime and anywhere. The SPA featured educational materials, a discussion forum, chat groups with peer volunteers, and advice from health care professionals. The inclusion criteria were as follows: (1) parents with a female partner who scored ≥9 on the Edinburgh Postnatal Depression Scale, (2) those aged ≥21 years, (3) those who were able to read and speak English, (4) those who had a low-risk pregnancy with more than 24 weeks of gestation (age of viability), and (5) those who had a smartphone with internet access. The exclusion criteria were as follows: parents who (1) had physical or mental disorders that would interfere with their ability to participate in the study; (2) had a high-risk pregnancy, including placenta previa major, preeclampsia, and pregnancy-induced hypertension; or (3) gave birth to a stillborn baby or a newborn with congenital anomalies or medical complications, including pathological jaundice that required special care in hospital. Mothers aged ≥21 years who had previously recovered from postpartum depression were recruited and trained by a psychiatrist to become peer volunteers to befriend and provide adequate web-based support to the parents.

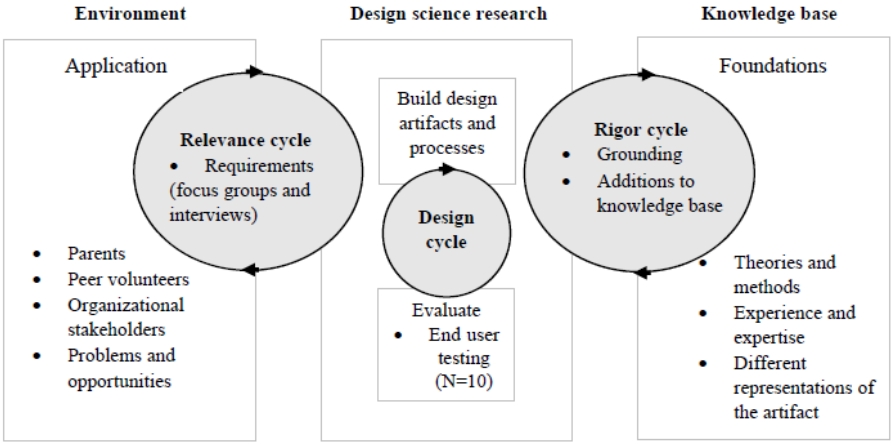
The aims of this research project are to (1) develop a theory-based SPA intervention for parents across the perinatal period; (2) examine the intervention's effectiveness in reducing parental postpartum depression and anxiety and encouraging parenting self-efficacy, help-seeking behavior, parent-infant bonding, parenting satisfaction, and infant developmental outcomes during the perinatal period up to 1 year after childbirth; (3) evaluate the SPA's cost-effectiveness compared with standard perinatal care across major restructured hospitals; and (4) examine SPA user experiences. However, this paper only focuses on the SPA intervention development process, the challenges faced by the research team, and the lessons learned.

Methods

Information Systems Research Framework

The information systems research (ISR) framework, which promotes an iterative, user-centered, nonlinear design process was used to guide the development of the SPA [35]. The ISR framework is commonly used in the creation of technological artifacts and comprises 3 research cycles (relevance cycle, design cycle, and rigor cycle) that link 3 research domains (knowledge base, design science research, and environment). The relevance cycle involves understanding the end users' needs and requirements through feedback and focus groups. The design cycle is where the artifact is developed and evaluated, and the rigor cycle is where theories, past methods, and representations of the artifacts contribute to the current design and development of the new artifact [35]. This study's adaptation of the ISR framework [35] is presented in Figure 1.

Figure 1. Adaptation of the information systems research framework.



Treatment Fidelity

To establish treatment fidelity, the strategies proposed by Bellg et al [36] and Eaton et al [37] for intervention design, training of providers, intervention delivery, and receipt of intervention were adopted. During the intervention design phase, intervention fidelity was ensured by using a theoretical framework (social cognitive theory) as the foundation of the intervention and by preparing a protocol for the intervention. In anticipation of provider and peer volunteer dropout, backup providers and volunteers with the requisite skills were on constant standby. To ensure consistency, delivery of intervention materials (eg, knowledge-based content and expert advice) was standardized by providing briefings and issuing providers and peer volunteers a handbook on the intervention procedures. In terms of receipt of intervention, participants' frequency of access to the app and the use of audio and video materials and peer discussion forum were monitored and recorded through a back-end admin portal. Weekly reminders were sent to parents to reinforce the use of the intervention by accessing the SPA.

Team Development

As the SPA development process involved stakeholders across various departments, immense collaborative effort and a high-performing team were crucial to ensure consistent progress and adherence to the project timeline. The Tuckman model of team development [38] highlighted different phases of team development—forming (initial meeting and beginning of collective work), storming (dealing with confusion and conflict over decision-making and roles), norming (accepting goals, roles, and work positively), performing (focusing on achieving goals and obtaining personal growth), and adjourning (recognizing and celebrating achievements). Although all phases are necessary for successful team building, problem solving, work planning, and delivering of results, the team leader plays a critical role in regulating the team dynamics and ensuring effective workflow by applying appropriate conflict resolution strategies as recommended by Tuckman [38].

Results

Relevance Cycle

The end-user environment and requirements were obtained through a focus group session with new parents. In all, 3 pairs of parents representing each major ethnic group in Singapore (Chinese, Malay, and Indian) were interviewed on their informational and perinatal educational needs and their expectations of the SPA. These parents were not included in the subsequent main study. In addition, because the objectives and components of the SPA were similar to those of the research team's previous research projects—*Home-but-not-Alone* (an mHealth app-based postnatal educational program) and the *Peer-Support Intervention Program*—user requirements were obtained from the projects' focus groups and interviews [39,40]. Previous local research among Singaporean mothers who only received standard routine hospital care indicated a need for more support after childbirth, such as having peer volunteers to talk to, more follow-up appointments with clinicians, and having an educational parenting mobile app catered to parents in Singapore [40]. Mothers who received the intervention requested the inclusion of individualized push notifications to mark important baby developmental milestones and special parenting tips. A study that investigated the use of a technology-based supportive intervention among multiracial Singaporean mothers during the postpartum period suggested the extension of the parenting support programs beyond 1 month after childbirth, introducing the parenting app early in pregnancy, and including a greater variety of educational topics [39].

Rigor Cycle

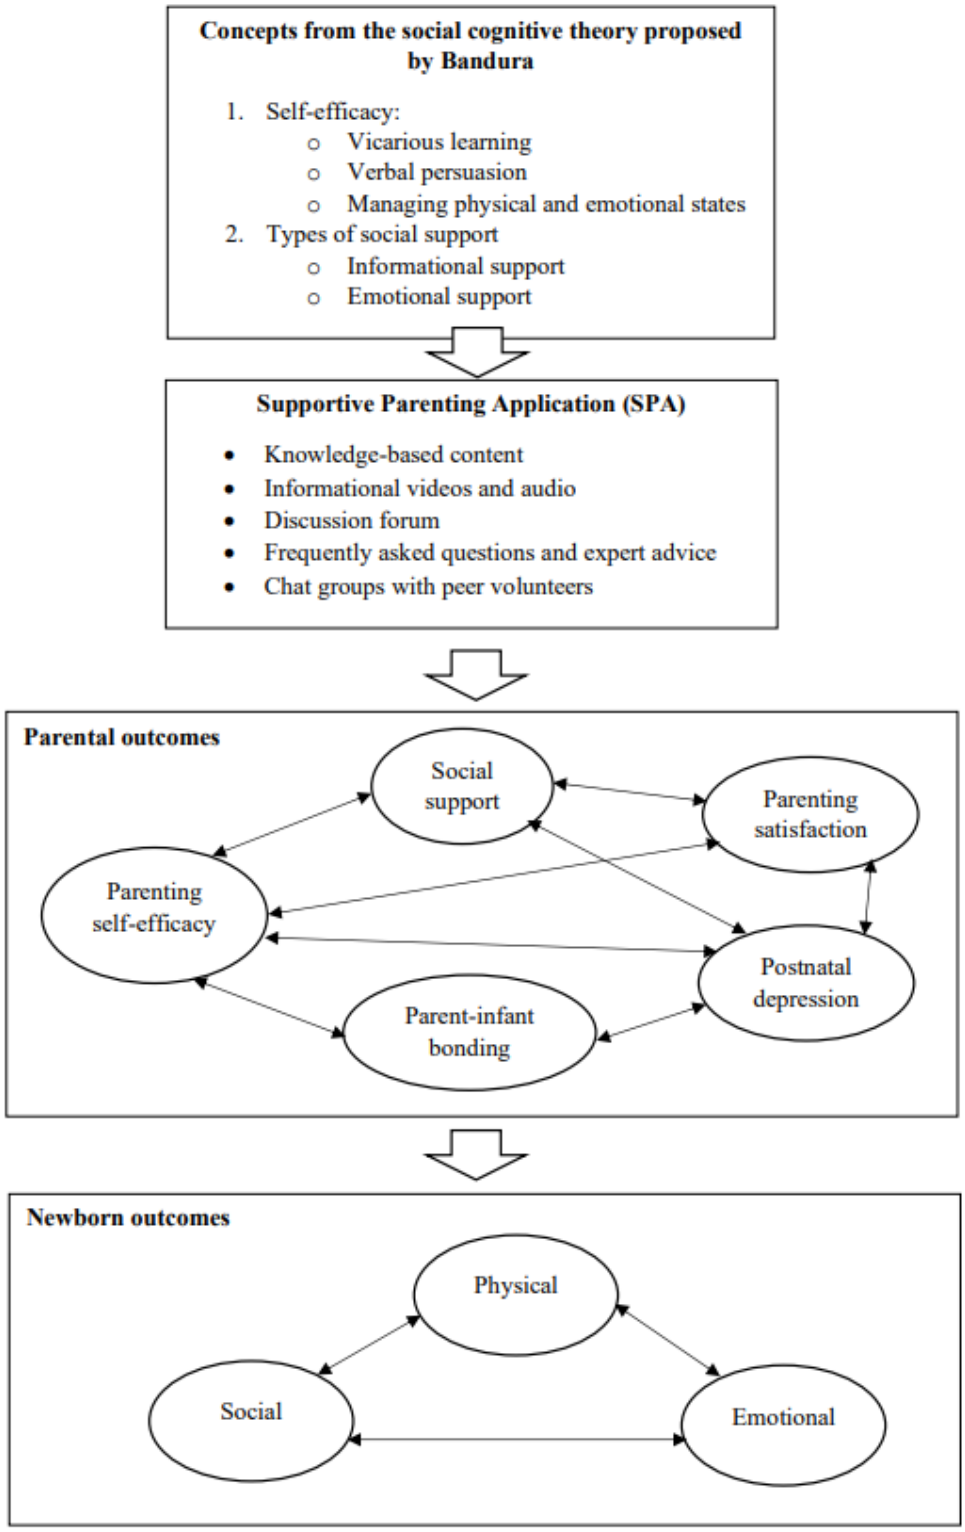
To meet the goals of the rigor cycle, well-established theoretical frameworks were incorporated into the development process of the SPA. The research team referred to the mHealth user engagement pyramid proposed by Singh et al [41] to identify features that could be incorporated into the SPA. Providing educational information is the most fundamental way to engage a patient, and the level of engagement increases with add-on features such as reminders and notifications, records of health information, display and summary of health information, availability of individualized guidance, means of communication between clinicians and family members or caregivers, provision

of support through social networks, and incentivization of behavioral changes [41].

Other theoretical frameworks that guided the development of the SPA's features were the social cognitive theory proposed by Bandura [42,43] and the attachment theory proposed by Bowlby [44]. The social cognitive theory posits that an individual's knowledge acquisition depends on the interaction among the environment, cognitive behavior, and personal factors [43]. An important component of the social cognitive theory is self-efficacy, which is defined as one's belief in one's capability to accomplish a task effectively [42]. Therefore, to ensure successful parenting, Bandura [42,45] emphasized that parents need to possess the self-confidence to perform specific skills and believe that they can achieve their desired outcome. As evidence has shown low levels of parenting self-efficacy as a predictor of postpartum depression [46], the concepts of the self-efficacy theory proposed by Bandura [42,45] were incorporated into the development of the SPA. Mastery of experiences, vicarious experiences, verbal persuasion, and improving physical and emotional states are ways in which self-efficacy can be attained [42]. In addition, Bandura [43] emphasized the importance of social support in achieving self-regulation to aid learning. There are different types of social support (emotional, instrumental, informational, and appraisal) [43]. As the SPA is a mobile app intervention, providing instrumental support was not possible; hence, it focused primarily on emotional and informational support. Appraisal support, which involves the provision of feedback regarding one's performance or qualities, was also not feasible in the context of the SPA. However, specific feedback requested by parents was provided for their individual needs.

According to the attachment theory proposed by Bowlby [44], parenting self-efficacy, social support, and parental emotional well-being are crucial for early parent-infant bonding and infant attachment styles, and these serve as a foundation for the development of positive social relationships in infants. Bowlby [44] postulated that a healthy parent-infant bond may lead to secure attachment, whereas insecurely attached infants may take their insecure patterns (avoidant, anxious ambivalent, or disorganized) with them into adulthood. Congruent to the attachment theory proposed by Bowlby [44], Bandura [45] postulated that self-efficacy will consequently influence parent-infant bonding, which is an important determinant of parental emotional well-being and infant development. Therefore, it is necessary to examine the relationship among parenting self-efficacy, parental outcomes, and infant outcomes. The theoretical framework for this project is presented in Figure 2 [42,43].

Figure 2. Theoretical framework of the Supportive Parenting App [42,43].



Design Cycle: Development Phase

Overview

The research team involved in the development of the SPA comprised maternity health care providers such as obstetricians, midwives, and nurses from the tertiary public hospitals; a psychologist; a pediatrician; and app developers. The intervention consisted of 2 main components: (1) a cloud-based admin portal, which was fully accessible by system admins (midwives and physicians only had access to the frequently asked questions [FAQ] management page) and (2) the SPA, which was accessible by system admins, mothers, fathers, peer volunteers, midwives, and physicians.

The cloud-based admin portal was used to moderate the content in the FAQ section and chat groups, manage user accounts and surveys, and display simple user analytics. The admin portal was developed using Microsoft Visual Studio 2017. The main programming languages used for the back end were ASP.NET

and C#, running on .NET Framework (version 4.5 and above; Microsoft Corporation). The front-end languages used were HTML5, JavaScript, CSS, and jQuery. AJAX techniques were used across the system to facilitate asynchronous data transfer between client and server. The database for the system was Microsoft SQL Server 2016 or later. The system was hosted on Windows Server 2016 or above and Internet Information Services (version 10.0 or above).

The SPA ran on both iOS and Android built using hybrid development tools (Apache Cordova and Ionic Frameworks). All accounts were password protected, and users had to authenticate with their log-in credentials created by the system admin to use the app. Participants were assigned anonymous identifiers, and they remained anonymous throughout.

After the health care research team conveyed the expectations, aims, and thorough overview of the SPA project to the app developers, a logo for the SPA was generated. A pastel-colored theme was chosen to create a soothing and gentle vibe, and the logo displayed an infant lying in the nurturing palm of a parent. The app's aim to highlight the protective and nurturing nature of parents was also demonstrated by the green sprout emerging from the parent's hand that sheltered the infant. The design was finalized after multiple intense discussions between the app developers and the research team; the logo is shown in Figure 3.

The main features of the SPA included knowledge-based content, informational videos and audio clips, a discussion forum, group and private chats with peer volunteers, expert advice from a maternity unit nurse or midwife, and individualized push notifications. Details of the development of each component are described in the following sections.

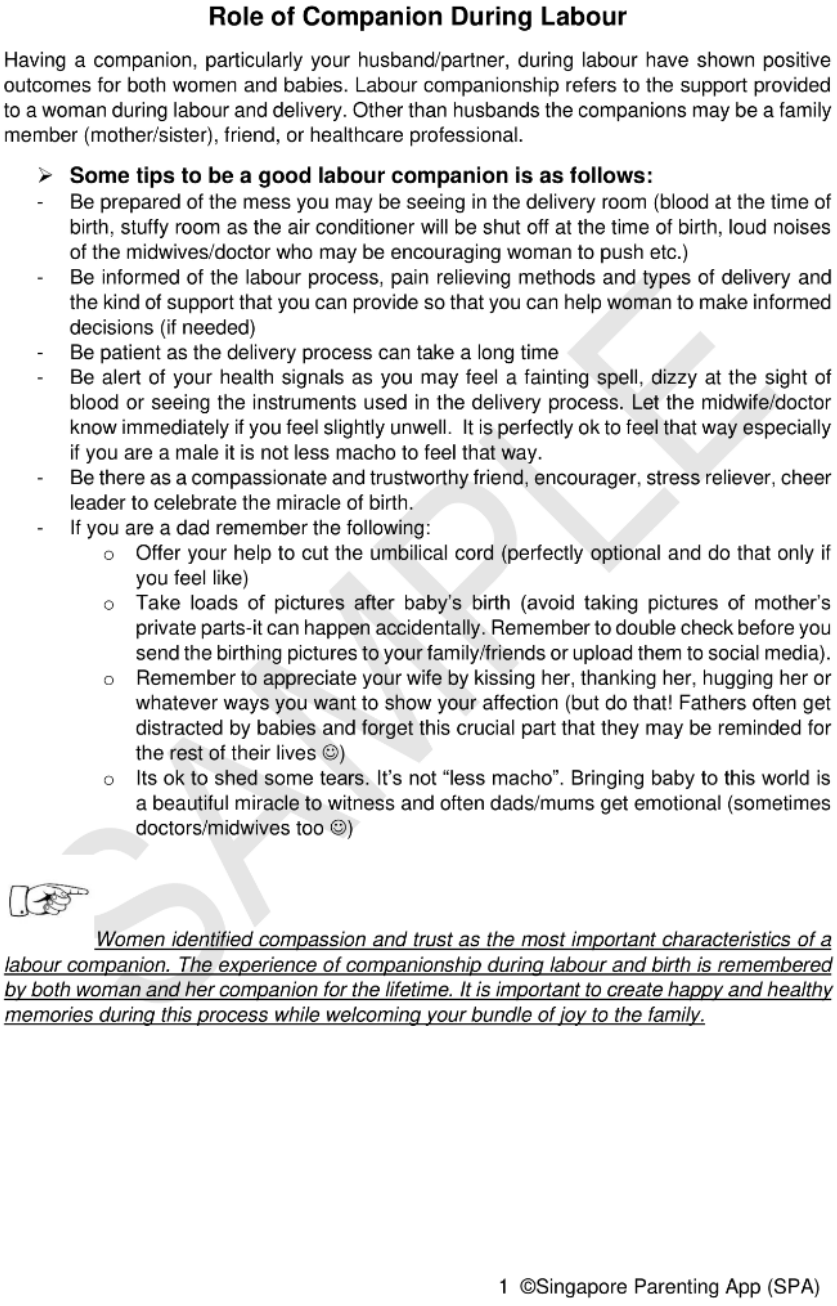
Figure 3. Logo of the Supportive Parenting App.

Knowledge-Based Content

According to Bandura [42,43], the provision of informational support is useful for problem solving and knowledge acquisition. To provide comprehensive information to allay parents' concerns in the perinatal period, knowledge-based content was first brainstormed and then finalized after multiple rounds of intense discussions among a team of health care experts from the psychology, pediatrics, and maternity health care units, as well as a few parent couples. The discussions were held through face-to-face and web-based meetings.

The finalized topics were categorized into 6 groups (general, pregnancy, childbirth, baby care, maternal care, family, and parenthood) to enable users to obtain relevant information. Keyword search was enabled, and the content was sorted by most viewed or most rated. Parents were also allowed to rate the usefulness of the content on a scale of 1 to 5. Knowledge-based content included topics on the prevalence of postpartum depression among mothers and fathers, signs and symptoms of postpartum depression, when to seek help, diet and exercise during pregnancy and after childbirth, preparation for childbirth, types of pain relief during childbirth, newborn and postpartum maternal care, major milestones for the newborn, managing family dynamics, and role of fathers and other caregivers (eg, grandparents) during the perinatal period. There were a total of 42 knowledge-based articles; each knowledge-based article was approximately 500 words long, and the content was written in bullet points to facilitate reading. The *hand symbol* was used consistently to signpost additional parenting tips or highlight instances when parents need to seek emergency help. The English language used was simplified to that of the reading ability of students in primary 6, and this was verified by the publications support unit at the National University of Singapore. An example of a knowledge-based article is shown in Figure 4.

Figure 4. Sample of a knowledge-based article.



Role of Companion During Labour

Having a companion, particularly your husband/partner, during labour have shown positive outcomes for both women and babies. Labour companionship refers to the support provided to a woman during labour and delivery. Other than husbands the companions may be a family member (mother/sister), friend, or healthcare professional.

➢ **Some tips to be a good labour companion is as follows:**

- Be prepared of the mess you may be seeing in the delivery room (blood at the time of birth, stuffy room as the air conditioner will be shut off at the time of birth, loud noises of the midwives/doctor who may be encouraging woman to push etc.)
- Be informed of the labour process, pain relieving methods and types of delivery and the kind of support that you can provide so that you can help woman to make informed decisions (if needed)
- Be patient as the delivery process can take a long time
- Be alert of your health signals as you may feel a fainting spell, dizzy at the sight of blood or seeing the instruments used in the delivery process. Let the midwife/doctor know immediately if you feel slightly unwell. It is perfectly ok to feel that way especially if you are a male it is not less macho to feel that way.
- Be there as a compassionate and trustworthy friend, encourager, stress reliever, cheer leader to celebrate the miracle of birth.
- If you are a dad remember the following:
    - Offer your help to cut the umbilical cord (perfectly optional and do that only if you feel like)
    - Take loads of pictures after baby's birth (avoid taking pictures of mother's private parts-it can happen accidentally. Remember to double check before you send the birthing pictures to your family/friends or upload them to social media).
    - Remember to appreciate your wife by kissing her, thanking her, hugging her or whatever ways you want to show your affection (but do that! Fathers often get distracted by babies and forget this crucial part that they may be reminded for the rest of their lives ☺)
    - Its ok to shed some tears. It's not "less macho". Bringing baby to this world is a beautiful miracle to witness and often dads/mums get emotional (sometimes doctors/midwives too ☺)

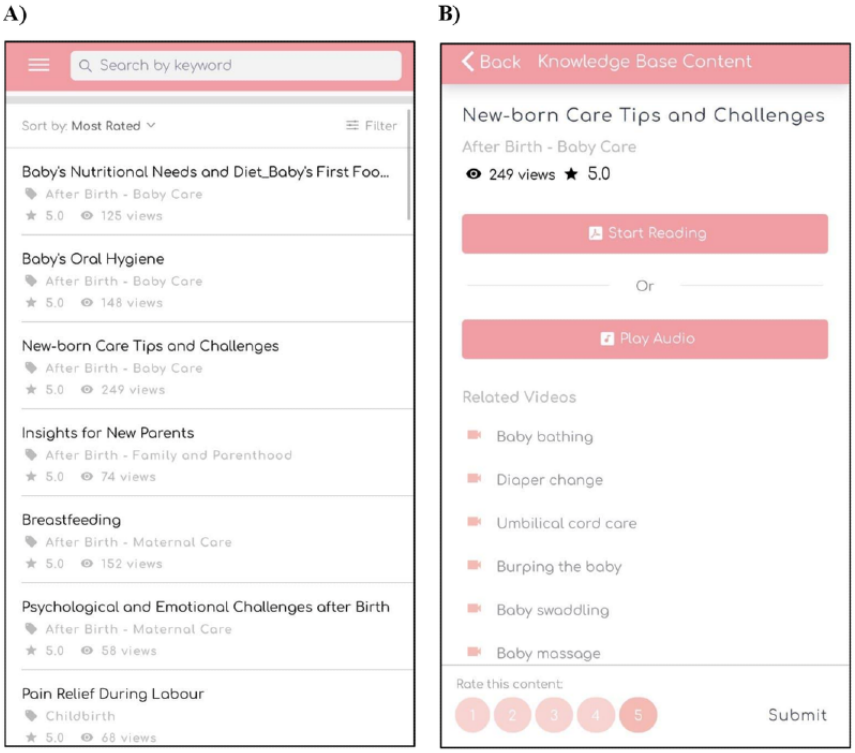
Women identified compassion and trust as the most important characteristics of a labour companion. The experience of companionship during labour and birth is remembered by both woman and her companion for the lifetime. It is important to create happy and healthy memories during this process while welcoming your bundle of joy to the family.

1 ©Singapore Parenting App (SPA)

Informational Videos and Audio Clips

Parenting self-efficacy can be enhanced through vicarious learning or modeling by watching others or personally acquiring a certain behavior successfully [42]. Hence, 27 inspirational and demonstration videos were included in the knowledge-based content section. Video content and scripts were developed by health care experts from different fields. For instance, baby care video scripts were developed by health care professionals from the maternity unit and video scripts on insights into postpartum depression were prepared by psychology experts. The videos consisted of animations, interviews, and skills demonstrations of topics such as personal accounts of mothers who developed and recovered from postpartum depression, diet and exercise during pregnancy, preparation for childbirth, and demonstration of infant care skills and interviews related to a father's role during the perinatal period. Audio versions were also provided to cater to parents who preferred to listen to audio clips or were prohibited from reading or watching videos because of confinement practices. A screenshot of the knowledge-based content page, including videos and audio clips, is shown in Figure 5.

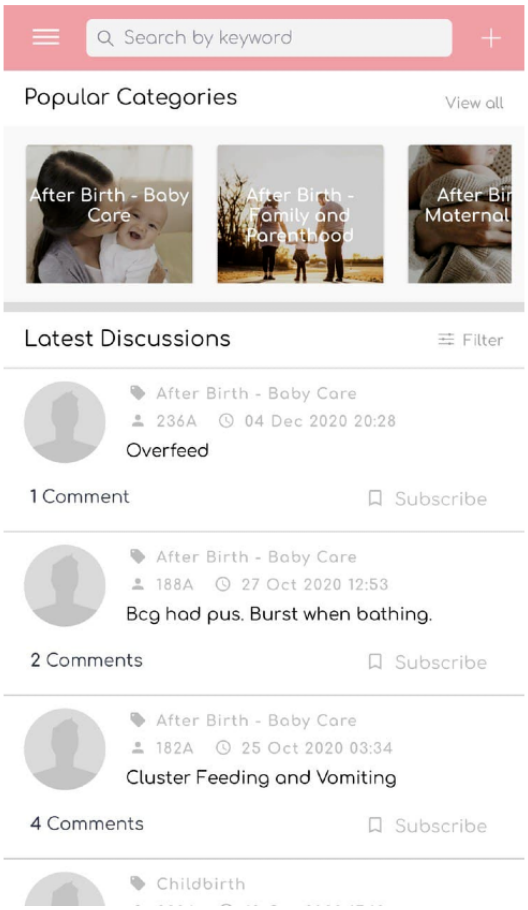
Figure 5. (A) Knowledge-based content page with (B) video and audio materials.



Discussion Forum

Apart from video modeling, a discussion forum was developed to allow parents who faced similar problems to share their tips and experiences. Parents were able to post personal queries and respond to other parents' queries. A midwife or maternity unit nurse was able to moderate the comments to ensure the reliability and accuracy of the information shared. A sample of the discussion forum is shown in Figure 6.

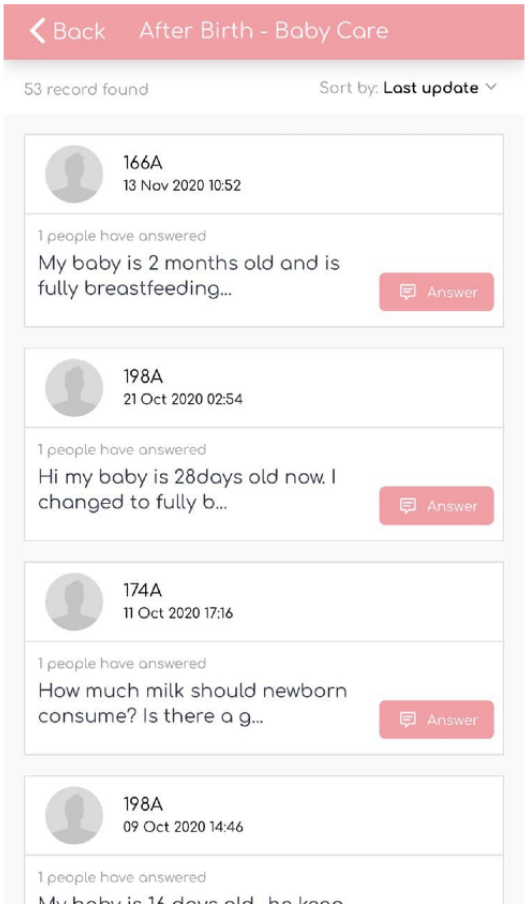
Figure 6. Discussion forum in the Supportive Parenting App.



FAQ and Expert Advice

Further informational support by health care professionals was provided through an FAQ section. If the existing information was insufficient to answer the parents' queries, parents were able to post their questions and upload supporting photos. A screenshot of the FAQ and expert advice section is shown in Figure 7. This feature allowed individualized professional help without parents having to make unnecessary visits to the physician. Expert advice from the maternity unit nurse or midwife was available from pregnancy until 1 month after childbirth. Because of the busy work schedules of the maternity unit nurse and midwife, replies were posted once a day.

Figure 7. Frequently asked questions and experts' advice page.



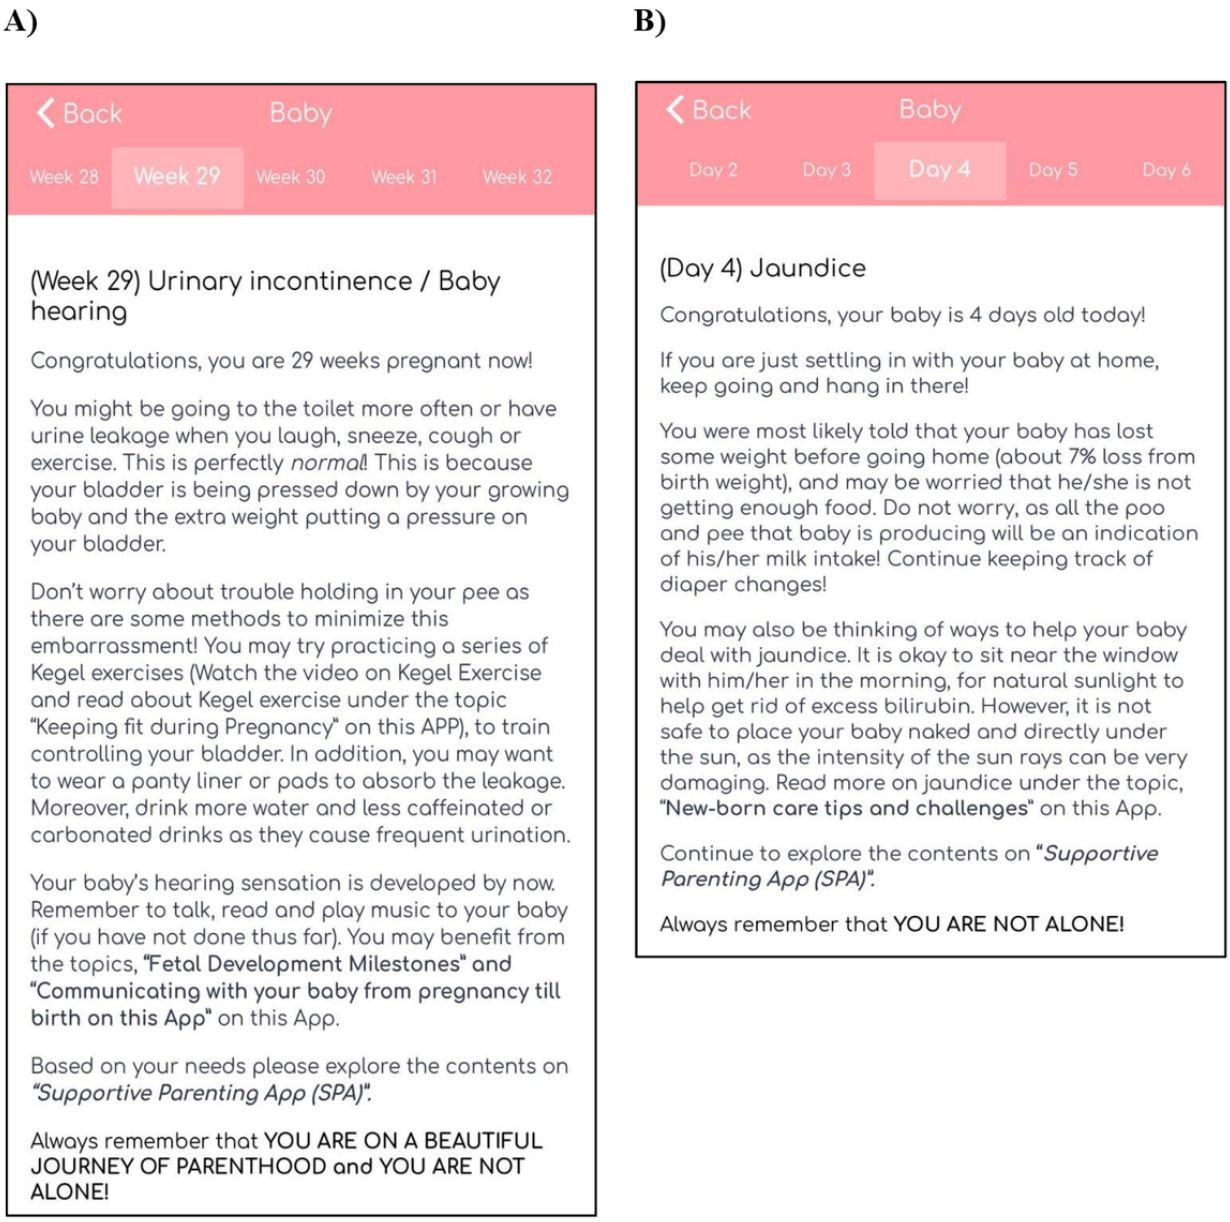
Chat Groups With Peer Volunteers

Mothers were matched for variables not limited to ethnicity and number of children and then assigned to peer volunteers. They were able to seek informational and emotional support from peer volunteers and other mothers or have a private chat with their assigned peer volunteer in the chat groups. Peer volunteers were experienced mothers who had developed and recovered from postpartum depression previously. These peer volunteers were specially trained by a psychiatrist on how to provide adequate support and be a listening ear to needy mothers, as well as on how to navigate the SPA. To ensure fidelity, an electronic training manual was provided to all peer volunteers before the start of a 3-hour web-based training session, and skills acquisition was assessed by the psychologist through web-based role-playing. After the training, each peer volunteer was assigned to approximately five couples (fathers and mothers) who were added to a group chat. Peer volunteers were encouraged to check up on the participants regularly through the group chat and to encourage mothers to interact and share their experiences. Parents who were uncomfortable with expressing themselves in a group setting had the choice to send private messages to their peer volunteer. Overall, the role of the peer volunteer was to provide emotional support to needy mothers, help foster peer support, and develop a close-knit community among parents in the chat group.

Push Notifications

Finally, push notifications were sent on a weekly basis during pregnancy, daily during the first month of the postpartum period, and biweekly thereafter until 6 months after childbirth. These notifications provided individualized information to parents, according to the specific week of their pregnancy and the age of their newborn after childbirth. The push notifications during pregnancy helped to track the pregnancy stages and provided information specific to the mother's pregnancy stage, such as common physical experiences (eg, Braxton Hicks contraction), ways to manage physical symptoms, relevant informational material that parents could refer to in the SPA, and words of encouragement. Push notifications that were sent after childbirth kept both parents updated on the infant's developmental milestones, informed parents on common physical occurrences and changes in the mother (eg, vaginal bleeding) and the infant (eg, weight loss), presented ways to care for both mother and infant, provided supportive tips for fathers, guided parents to relevant information in the SPA, and included words of encouragement. Parents were also advised to look out for required information from the knowledge-based content and informational videos and audio clips according to their individualized needs and not to switch off the notifications because this could interfere with the intervention. Examples of push notifications delivered during pregnancy and after childbirth are presented in Figure 8.

Figure 8. Examples of push notifications delivered (A) during pregnancy and (B) after childbirth.



Design Cycle: Evaluation

Pilot Test

To assess the SPA's features, functionality, usability, and content accuracy, a pilot test for the mobile app and administrator webpage was conducted among users (N=10) who were new parents and research team members (ie, app developers, clinicians, and research assistants). Feedback was gathered qualitatively and discussed among team members at a web-based meeting to further refine the app and optimize the user experience. This process was repeated multiple times and ceased when all the research team members arrived at a mutual agreement and were satisfied with the finalized version of the app. The mobile app was then made available to participants in the iOS and Android app stores.

System Compatibility

During the initial piloting, there were issues regarding the viewer compatibility of the cloud-based admin portal on different web browsers. The admin portal was not accessible on Internet Explorer and could only be viewed using Google Chrome, Mozilla Firefox, or Microsoft Edge. This was subsequently made known to all system admin users. Similarly, the SPA was initially incompatible with the older Android OS versions, but updates were made by the developer to support the older OS versions.

Restricted Admin Functions and Data Analytics

In addition, the admin portal did not allow for a full overview of and access to the SPA's contents, especially in terms of group chat details. System admin users could only view peer volunteer group chat conversations using the mobile app. In addition, the initial data analytics function on the admin portal only displayed aggregated data on user frequency. However, individual user

frequency data were deemed more informative for future research purposes. As subsequent requests for collating individual user data by the research team resulted in extra development charges and time, no enhancement was made to the data analytics.

App Notifications

The first testing of the SPA revealed that mothers did not receive group chat notifications. This was quickly fixed by the app developers so that mothers could receive a pop-up notification whenever somebody posted in the group chat. However, the problem persisted in the second round of user testing. Group chat notifications were not received when the app was not constantly updated, and parents did not receive any prompt to update the app. This situation was later rectified by sending reminders to update the app. Similarly, team members in charge of the expert advice section made a request for pop-up notifications to enable them to respond to parents' queries promptly. However, this was not implemented because of the project's tight budget. After the first user testing, educational contents (PDF files and videos) were not linked to the push notifications as expected. This issue was then rectified by the app developers for parents' convenience.

Search Function

The research team also highlighted issues with the search function of the knowledge-based content. Initially, the search engine was only able to detect specific keywords in the title but not in the text. The function for in-text search required the additional purchase of plug-ins and further development of codes that involved time and cost that the team did not take into account initially.

Discussion

Principal Findings

The development process of the SPA, which included requirement identification, the use of theories and past artifacts, the design of artifacts, and user testing, was well documented using the ISR framework. Although the ISR framework was able to capture the design technicalities and rigor of the project, it failed to highlight interpersonal and real-life challenges. Apart from technical and user issues, the design cycle faced prominent issues such as logistical limitations and also in terms of teamwork and communication because of the effects of the COVID-19 outbreak, which affected the process timeline.

Challenges in the Design Cycle: Logistics Limitations

With respect to the FAQ and expert advice section, the research team ideally wanted to provide a readily available hotline or personalized help for parents in need. However, because of limited resources and other work commitments, it was not feasible for the research team to be on constant standby to respond to parents' queries immediately. Hence, a decision was made to have a maternity unit nurse or midwife to check and respond to queries posted in the FAQ section once a day and respond within 24 hours of the queries raised by the parents. Parents with urgent queries were recommended to call the hospital or visit the physician immediately. Despite the team's best efforts to provide parents with a personalized, fast, trusted, and reliable information source, the strain on logistics and manpower led the research team to consider the future incorporation of live chatbots in the mobile app. The use of chatbots or conversational agents in the health care setting has been on the rise, especially with smartphone apps, in the areas of patient treatment and monitoring, health care service support, and patient education [47]. Given the novelty of the use of chatbots, there is a paucity of randomized controlled trials evaluating their efficacy in providing knowledge-based information to parents in the perinatal period. However, promising user test results from a few development and usability studies [48-50] indicate the viability of chatbots, thus paving the way for future research.

Second, the recruitment and training of peer volunteers posed a challenge because peer volunteers were also mothers who had work and family commitments; hence, it was difficult to recruit dedicated peer volunteers to take on this yearlong project. In addition, the conflicting schedules of peer volunteers resulted in a few postponements of face-to-face training sessions until the COVID-19 outbreak led to their conversion to web-based sessions instead. Team members in charge of conducting the sessions had to rapidly adapt to the situation and convert the face-to-face training to a web-based session. Research has shown that the efficacy of web-based interpersonal skills (ie, communication, counseling, and interview) training on skills acquisition is on par with face-to-face training [51-53]. Furthermore, participants have also commended web-based courses for their better accessibility and the ease of remote learning [54,55]; thus, a web-based session may better cater to volunteers who are working mothers. However, Doo [56] has argued that cognitive understanding of interpersonal skills does not translate into successful skills execution and interpersonal skills can only be acquired through real-life practice, which is difficult in web-based learning environments. Although web-based training may not be as beneficial as in-person training in terms of building rapport among peer volunteers and conducting role-plays, this was the optimal resolution in times of a COVID-19 outbreak. We are waiting to interview the peer volunteers at the completion of this project about their perceptions of receiving the web-based training. The interviews may provide true evaluation and recommendations on enhancing such web-based training in the future.

Challenges in the Design Cycle: Teamwork and Communication

As this was intended to be a multisite study, extensive collaboration among health care professionals from various institutions was required. However, a key challenge faced during the Tuckman model's forming phase of team development [38] was the assembling and scheduling of face-to-face meetings with different experts from various health care institutions, given their hectic schedules. As face-to-face meetings were crucial at the initial stage for the research team to get acquainted and share their expertise and viewpoints, meeting dates were scheduled when there was a likelihood of the highest possible attendance. Team members who were unable to attend received the meeting materials and minutes, and any further feedback was communicated through email. After the delegation of the

main roles and responsibilities, subsequent follow-up meetings, updates, and discussions were conducted through web-based meetings with respective parties. At the storming phase, given each team member's field of expertise and the dearth of essential information, it was difficult for the team to agree on the finalized topics and knowledge-based content to be included in the app. However, the team managed to ascend to the norming phase through resolution by constructive negotiation and eventual mutual agreement to include less essential information in the FAQ section than in the knowledge-based content section. During the performing phase, the team managed to work together effectively and cohesively and successfully rolled out the SPA for user acceptability testing. Overall, the Tuckman model of team development highlighted key characteristics and conflict resolution strategies that enabled optimal team development, which future mobile app developmental studies can use.

Another prominent issue concerned the communication between the app developers and the health care research team. Although the research team comprised experts in content development, they were unfamiliar with technical programming terms and were unable to communicate effectively with the app developers on their app preferences such as cloud hosting, data analytics function, and security mechanisms of the app. This communication difficulty resulted in different expectations for the app and led to last-minute enhancements that incurred additional costs that were not initially considered. Therefore, both parties should be careful with the use of technical jargon to avoid confusion and to constantly clarify any uncertainty or details. Alternatively, visual diagrams (eg, mind maps, drawings, and sample screenshots) could be useful in visualizing and conveying expectations of specific mobile app features.

Implications for Future Studies

Much can be learned from the intervention development process of the SPA based on the aforementioned challenges. A major setback was the sudden COVID-19 outbreak, which interrupted the development of the intervention and delayed the project. The flexibility and quick adaptability of the team in finding solutions was crucial in ensuring the continuity of the project. Although face-to-face meetings were impossible, the team was able to conduct meetings through web-based video calls and follow-up emails. Face-to-face training for peer volunteers was also revised and conducted on the web. Team cohesiveness and adaptability were crucial in effectively managing unforeseen circumstances.

Team cohesion is dependent on open and clear communication among team members to ensure that everyone's expectations are aligned, uncertainties are clarified, and there is transparency for group decision-making. This is especially crucial between the research team and the app developers because their areas of expertise differ and miscommunication in expectations could lead to unfavorable outcomes. However, the interdisciplinary, team-based approach ensured the success of the app development in this study. In addition, a structured and effective workflow was implemented through strict planning of timelines, delegation of responsibilities to team members, close updates and timely feedback among team members, and the charting of project milestones using the Gantt chart. The physical visualization of the project timeline kept everyone in check and allowed better handling of delays.

Another critical lesson learned was to ensure sufficient financial and time budgeting for last-minute enhancements of the intervention. Because of project delays during the COVID-19 pandemic, the team could not spend more time and money for potential feature enhancements that may influence the detailed data analytics. As the basic infrastructure for the parenting app has already been established and the team members have acquired sufficient experience, incorporating future improvements such as adding additional features to the platform would require much less time than that needed for the initial project. Future studies developed as part of this SPA project could assess actual app use, cost-effectiveness, impacts on longitudinal parental and infant outcomes, and qualitative user experience. The use of chatbots to answer parental queries on a timely basis could also be incorporated and evaluated in future research on supportive apps for parents.

Conclusions

This study presents a multistage iterative development process of an mHealth SPA using the ISR framework. Rooted in social cognitive theory and attachment theory, the SPA offers parents a holistic means of obtaining informational and emotional support from knowledge-based content, parents with similar backgrounds, trained peer volunteers, and health care professionals. However, the development process had its challenges because the design cycle involved other logistical and team communication issues that were not taken into consideration in the ISR framework. These issues can potentially be resolved with adequate time and financial budgeting and by developing team cohesion.

Acknowledgments

This study was funded by the Ministry of Health (HSRGHP18may-0001). The authors would like to thank the National University Health System Research Support Unit for their assistance in the language editing of this manuscript.

Abstract

Background: Today, academic social network sites' role in improving the quality of education and how investigators conduct their research has become more critical.

Objective: This study aimed to investigate Iranian health researchers' requirements for academic social network sites from a low-income country perspective.

Methods: This qualitative study with a phenomenological approach was done in 2020. In this study, 23 researchers in the health system were selected by purposive sampling. Semistructured interviews were used to collect data. Data were analyzed by MaxQDA-10 software and the content analysis method.

Results: We identified 2 categories of functional and technical characteristics in the study participants' expectations. Functional characteristics included facilitating communication and team activities, managing scientific publications, enhancing the process of conducting research, being informative, and sharing and trading laboratory materials and equipment. Technical characteristics of an academic social network include user management capabilities, high security and privacy, being user-friendly, and other technical features.

Conclusions: Health researchers emphasized 2 functional and technical characteristics required to meet academic social network sites' expectations.

research; social network; academic social network; research network; academic; researcher; literature; qualitative; content analysis

Introduction

Nonacademic social networking sites such as Facebook are prevalent, and researchers can use them. However, studies show challenges and restrictions for academic users on these sites [1-4]. Today, academic social network sites (ASNSs) have become an integral part of researcher work [5,6]. An ASNS is a type of internet service that facilitates communication between researchers [7], shares scientific resources (news, reports, articles, and data sets), exchanges research opinions, and informs about the current research trend [8]. In addition to publishing researchers' work and facilitating personal exchanges, ASNSs

are tools for describing organizational information and researcher interests [9].

Ijad Madisch, one of the creators of Research Gate, acknowledges that ASNS promotes transparency in the research process and ultimately leads to the strengthening of scientific research [10]. In May 2017, Alexa.com ranked globally Research Gate and Academia.edu 321st and 577th, respectively, indicating increased use of ASNSs [11]. Based on Dong [12], ASNSs have a positive impact on the performance of academics. However, Salvation's study [13] in Malaysia found hidden weaknesses of ASNS.

Every ASNSs is customized for one or more specific purposes; for example, Research Gate is primarily for contacting colleagues and counseling. Mendeley offers the opportunity to receive new articles [14].

Along with researchers from other countries, Iranian health researchers use different ASNSs to conduct their research activities [15]. However, 61% of Iranian researchers do not trust this social network [16]. Ghazimirsaeed [17] examined the use of the academic social networks in Iran and showed 83% (44/53) of Iranian medical science universities were present in the ASNS in 2017. On average, 180 researchers from each university and 1161 departments of the medical universities were members of these ASNSs [17].

ASNSs are created professionally and with a specific purpose, and each of them has its particular users [18]. Investigating the needs and expects of researchers from ASNSs can increase the use of these social networks and make them successful. This study aimed to investigate health researchers' requirements from ASNS in Iran, as a low-income country. In addition to being used in the design of ASNS, this study's results can strengthen them.

Methods

Study Design

This qualitative study to identify Iranian researchers' expectations from ASNS was done in 2020. This article is excerpted from a doctoral dissertation entitled “Designing and Implementing a Social Network for Laboratory Researchers in Health” [19]. We chose the qualitative method to highlight participants' experiences, knowledge, and silent information [20,21]. We selected the phenomenological approach due to the lack of a complete theory of the expectations of Iranian researchers from ASNS [22].

Participants and Setting

The study environment was a research center affiliated with medical colleges. Research managers, faculty members, postdoctoral researchers, and PhD students participated in this study. The inclusion criteria were the membership in 2 or more academic social networks and updating their user profile on academic social networks at least once a month. Participants were selected by the purposive sampling method. Individuals with good information and who provided their information appropriately were chosen as participants in this method [23-25].

The interviews with participants continued until information saturation was achieved, and researchers felt that new information on new participants was not available; this step was achieved with 23 participants. After the study's initiation and interviews, we used theoretical sampling to identify people who could provide rich and beneficial information for researchers.

We attempted to have a diversity of age, employment status, work experience, degree, and job position in our study sample.

Data Collection

Semistructured interviews in the Persian language have been done conveniently for participants. The interview questions were developed by using literature reviews and expert opinions and comprised of five questions. The interviewee was initially asked to introduce themselves and explain their recent research activities. In the second question, the researcher was asked which academic social networks they use and why; and which features are interesting to them.

The next question was about the advantages and disadvantages of these social networks. In that question, participants were asked to compare 2 or more academic social networks they have used. The fourth question asked how academic social networks could accelerate the research process and improve their quality, and the final question queried which features would be considered if the researcher were to design an ASNS.

We used S-recorder software (version 20.1.186.12; Samsung) to record the interviews alongside note-taking. Each interview lasted between 30 and 42 minutes.

Qualitative Analysis

The respondents' answers were immediately typed, summarized, and reviewed several times by listening to and reading the primary information.

Conventional content-method and MaxQDA-10 software (version 10; VERBI) were used for data analysis. The conventional content method is very useful for identifying, analyzing, and reporting the patterns (themes) in qualitative studies [26-28]. Respondent validity and immersed expert and peer checks were used for data portability, rigor, and reliability.

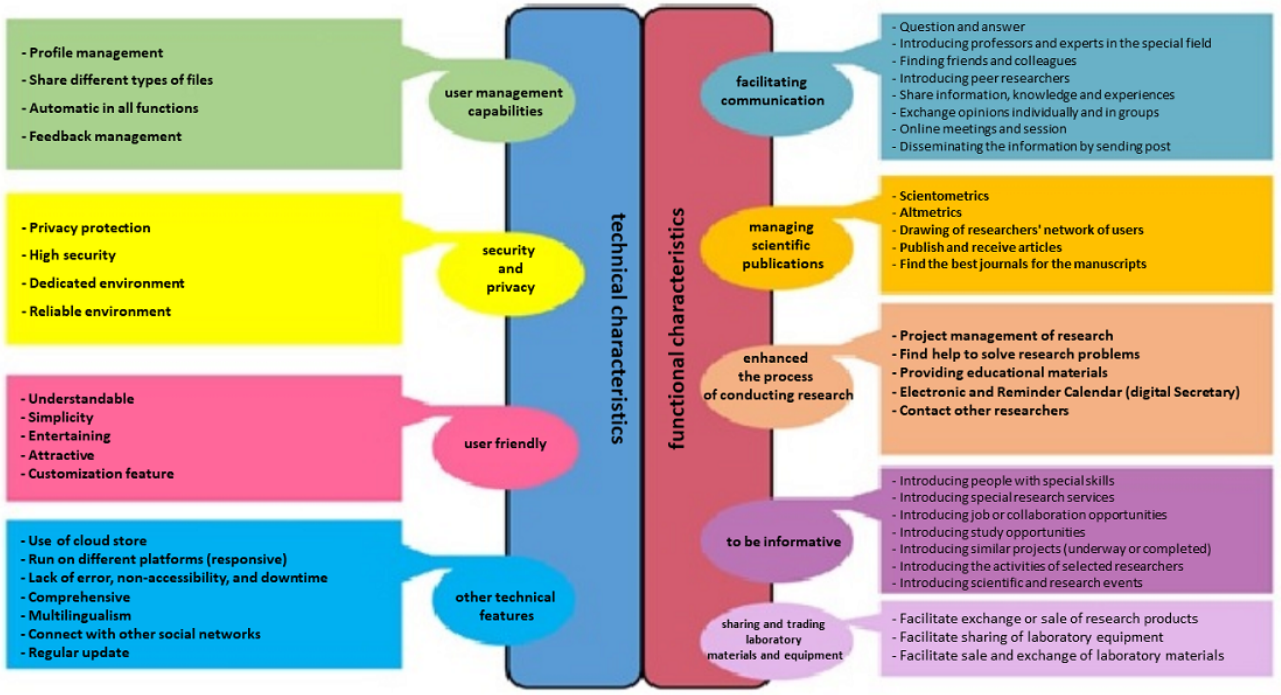
Following informed consent procedures, the research participants are provided with a brief verbal explanation of the study and told that they could leave the study at any time. The participant code and their job were used to report their statements to keep the information confidential. The ethics committee at Tabriz University of Medical Sciences approved this study (IR.TBZEDMED.REC.1398.184).

Results

Overview

Study participants included 7 research managers, 6 faculty members, 4 postdoctoral researchers, and 6 PhD students. Based on the interviews, the researchers' expectations from the ASNSs were divided into 2 general categories: the system's functional and technical characteristics (Figure 1).

Figure 1. Health researchers' expectations for academic social network sites.



Functional Characteristics

Functional characteristics included facilitating communication and team activities, managing scientific publications, enhancing the process of conducting research, being informative, and sharing and trading laboratory materials and equipment. Functional characteristics have 5 main themes and 29 subthemes. Based on the number of repetitions of the subtheme in the interviews, health researchers' most important expectation from ASNSs was to contact other researchers. Finding help to solve research problems, contacting other researchers, and introducing the activities of selected researchers are essential ASNS expectations for PhD students (Table 1).

According to the participants' scientific rank, the four columns of Tables 1 and 2 specify how many people have mentioned the relevant theme in their speeches. Moreover, the total number of people who have mentioned a particular theme is specified in the last column of the tables.

Table 1. Functional expectations of health researchers from academic social network sites.

Theme and subthemes	Description	PhD student (n=6)	Postdoctoral researcher (n=4)	Faculty member (n=6)	Research manager (n=7)	All (n=23)
Facilitating communication and team activities						
Question and answer	Health researchers need to receive advice from experts through ASNS to solve their problems.	3	2	3	1	9
Introducing professors and experts in the special field	Health researchers would like to get acquainted with the best professors and experts in their research field using ASNS.	2	1	4	0	8
Finding friends and colleagues	ASNS must allow its users to be notified of their colleagues' membership in the social network based on their email or phone contact list.	4	1	4	2	11
Introducing peer researchers with the same background	ASNS should introduce researchers with similar research backgrounds to each other based on information entered by users.	1	3	4	2	9
Share information, knowledge, and experiences	The sharing of knowledge and experiences of researchers by the ASNS is critical and considered a requirement for the ASNS's success.	0	2	5	3	10
Exchange opinions individually and in groups	Dissemination of health researchers' in-network opinions and posts to individuals and groups will improve the quality of research.	0	0	5	3	8
Online meetings and session	Although there are several specialized software for online meetings, it seems that the integration and access to more features, such as online meetings, can increase researchers' desire to use ASNSs.	3	1	3	4	11
Disseminating the information by sending posts	Health researchers tended to publish their advertisements, comments, requests, and requirements by sending a post.	3	2	3	4	12
Managing scientific publications						
Scientometrics	Researchers like to use this ASNS to monitor their citations.	2	3	5	4	14
Altmetrics	This network feature shows how many times a document has been downloaded or read, And this can show how important and practical it is.	2	3	5	4	14
Drawing of researchers' network	Showing researcher followers and followers has many advantages for other users. This allows them to get to know another person working in a common field.	2	1	2	1	6
Publish and receive articles	The possibility of publishing and receiving articles is one of the essential parts of ASNS based on health researchers' views.	3	4	5	3	15
Find the best journals for the manuscripts	The ASNS can introduce appropriate journals to users based on user profile data.	3	0	0	1	4
Enhanced the process of conducting research						
Projects management of research	In some cases, health researchers have several responsibilities other than research, including education, patient care, and executive activities. Therefore, providing services via ASNS to manage research projects is very helpful.	0	1	2	3	6
Find help to solve research problems	Various challenges, such as financial, administrative, property rights, laws, and access to protocols, are treated by health researchers during the research stage. As a facilitator, ASNS can play an essential role in solving these problems.	5	2	4	4	15

Theme and subthemes	Description	PhD student (n=6)	Postdoctoral researcher (n=4)	Faculty member (n=6)	Research manager (n=7)	All (n=23)
Providing educational materials	Given that the research is based on innovations and problem solving, new research techniques and methods can be made available to researchers through the ASNS.	3	2	1	1	7
Electronic and reminder calendar (digital Secretary)	Time management is one of the basic principles of research success; ASNS can play an essential role in managing researchers' time by providing tools such as electronic calendars and reminders.	0	1	1	0	2
Contact other researchers	Creating different communication platforms by the network and facilitating communication between researchers promotes cooperation.	5	3	5	4	17
To be informative						
Introducing people with special skills	When a researcher needs an expert with unique skills, the ASNS should support them with search tools.	4	2	3	1	10
Introducing special research services	Researchers have different knowledge and skills. Sometimes they need laboratory services that are not available in their work environment. The research manager can inform you about the services available in a laboratory and share them with other researchers using an ASNS.	1	0	0	4	5
Introducing job or collaboration opportunities	Health researchers can use ASNS to find jobs or collaboration opportunities in research projects.	1	3	4	0	8
Introducing study opportunities	Providing study opportunities on ASNS and creating transparency can lead to a better selection of candidates.	0	2	4	3	9
Introducing ongoing or completed similar projects	Searching for similar research projects and preventing duplicate works can provide good opportunities for collaboration between researchers.	0	3	5	1	9
Introducing the activities of selected researchers	The following possibility of the researcher's activities allows users to obtain information about the latest scientific achievements.	5	2	4	3	14
Introducing scientific and research events	Health researchers can use ASNSs to find out the news related to scientific and research events.	1	3	5	4	13
Sharing and trading laboratory materials and equipment						
Facilitate to exchange or sale of research products	Researchers can share, exchange, or sell their research products on ASNSs.	1	2	2	5	10
Facilitate to sharing of laboratory equipment	By creating the necessary content for sharing laboratory equipment, the ASNS can increase this laboratory equipment's efficiency and provide the opportunity for cooperation between research centers.	4	3	4	5	16
Facilitate to sale and exchange of laboratory materials	In addition to reducing research costs, the exchange of laboratory materials among researchers accelerates research processes.	4	3	3	4	15

Table 2. Technical expectations of health researchers from academic social network sites.

Theme and subthemes	Description	PhD student (n=6)	Postdoctoral researcher (n=4)	Faculty member (n=6)	Research manager (n=7)	All (n=23)
User management capabilities						
Profile management	Creating a user profile is the main feature of academic social networks.	5	3	5	6	19
Share different types of files	Due to the production of knowledge in various formats by health researchers and the communication between them, sharing files in different formats is one of the essential features of the ASNS.	4	4	5	3	16
Automatic in all functions	The automation of ASNS in different functions, such as informing and introducing colleagues, is one of these networks' main strategies to attract researchers.	2	1	1	3	7
Feedbacks management	Posting comments on the ASNS about the researcher's activities in various forms such as text, confirm, and like can improve the researcher's activities. However, the user must manage the type and content of this feedback.	1	0	0	2	3
High security and privacy						
Privacy protection	The most critical concern for health researchers in using ASNS is to protect their privacy.	2	4	5	5	16
High security	Health researchers have become more sensitive to academic and social networks' security.	2	4	4	6	16
Dedicated environment	ASNS' environment should be dedicated to researchers.	0	1	0	3	4
Reliable environment	Researchers need a reliable social media environment to share scientific discussions and share their social media views.	0	2	2	3	7
User friendly						
Understandable	The use of abstract and incomprehensible words in ASNS makes the social network unacceptable for researchers.	2	1	5	3	11
Simplicity	Researchers should simply be able to use ASNS.	2	2	3	1	7
Entertaining	The art of embedding gamification in the academic social network makes researchers more inclined to use this in their daily activities.	3	1	1	1	6
Attractive	Observance of clarity and transparency, visual appeal, color selection, and visuals are criteria for making the ASNS more attractive.	3	2	2	4	11
Customization feature	ASNS does not have wholly fixed characteristics, but a number of its features should be changeable based on the choice and needs of the researcher.	1	2	5	3	11
Other technical features						
Use of cloud store	Today, cloud storage has become an essential requirement for researchers.	2	1	1	1	5
Run on different platforms (responsive)	In the design process of a social network, all pages must be visible on all devices with similar content, design, and performance.	4	3	4	5	16
Lack of error, nonaccessibility, and downtime	The high rate of unavailability of the ASNS can reduce its users.	0	1	1	2	4
Comprehensive	The comprehensiveness and non-allocation of the site to a group of researchers lead to researchers' rapid growth.	1	1	0	0	2

Theme and subthemes	Description	PhD student (n=6)	Postdoctoral researcher (n=4)	Faculty member (n=6)	Research manager (n=7)	All (n=23)
Multilingualism	The multilingual aspect of ASNSs, in addition to understanding, can make a social network more trustworthy and more inclusive.	4	1	1	2	8
Connect with other social networks	Communicating and retrieving information from other academic social networks, in addition to saving time, can make social networks more attractive.	1	2	5	5	13
Regular update	In addition to updating security and information technology, ASNS should create new academic social network functions.	3	1	2	1	7

Technical Features

The technical features are related to the social network's design, language, and the databases and infrastructure used to implement the social network. Based on the views of the study, participants' technical features consist of 4 main themes and 20 subthemes. However, the most important subtheme based on participant study views was profile management, but their concerns about security and privacy were considerable (Table 2).

Discussion

Principal Findings

This study aimed to identify Iranian health researchers' expectations for ASNS from the perspective of a low-income country.

One of the most important expectations of ASNSs was to create a platform for communication and to strengthen researchers' team activities. In line with this study's results, Salahshour [29] showed that 54% of researchers use ASNSs to find colleagues, and 75% of them use ASNS to communicate. Krause [7] argued that in addition to creating intraorganizational communication, ASNSs should facilitate communication and the sharing of resources between scientists. Manca [30] also considers the most important task of ASNSs as establishing a relationship between researchers in the same field. Given that the study participants were researchers from a low-income country, they may have felt a greater need to connect and collaborate with other researchers in high-income countries.

Another functional expectation from ASNSs was the management of publication researchers' work. In line with the results of this study, several studies confirm that publishing management is an essential duty of ASNSs [31-33]. Salahshour [29] also found that 67 percent of users use ASNSs to improve citations and scientific advances. Weber [34] attributes researchers uploading the research results to ASNSs due to increased citations and establishing cooperation and communication between researchers [34]. However, Bonaiuti [9] attributes this behavior to the possibility of receiving feedback and the ease of loading articles in the ASNSs [9]. Because scientometric and altimetric indicators are among the main criteria for evaluating and ranking researchers, health researchers use ASNSs as a tool to display their articles. They try to improve the desired indicators by making their works available. Completing the profile correctly and updating the uploaded items plays a vital role in the researcher being seen by other colleagues. In addition to upgrading the altimetric rankings, ASNSs can improve the number of citations by creating communication capacities and collaborating with traditional metrics.

The researchers' third functional feature involved in the study was to help facilitate research and solve research projects by ASNSs. In a prior study, 56 percent of researchers said their goal for being a member of an ASNS was to improve research quality and learning [29]. In this regard, Espinoza [35] acknowledges that by creating communication, collaboration, and networking platforms, ASNSs support researchers and academics. Various studies have shown that ASNSs, in addition to their tools for communication, collaboration, question and answer, specialized discussion groups, and ability to introduce researchers with the same background, can support researchers and improve research quality [9,34,36]. The advantages of cooperation between researchers include reducing researchers' workload, regulating the activities of researchers based on expertise and skills, increasing the credibility and quality of research, increasing the number of studies, and increasing the productivity and efficiency of researchers. By creating a platform for communication and cooperation on the one hand and maintaining individuals' privacy, on the other hand, ASNSs provide the foundation for the cooperation and facilitation of research. One of the future challenges of ASNSs seems to be managing collaborations between researchers, managing collaboration requests, and protecting researchers' privacy.

Being informative is an essential expectation for ASNSs. Researchers believe, given their interest, an ASNS should automatically inform them of study opportunities, suitable jobs, and cooperation suggestions. Findings from Dermentzi [37] show that one of the purposes of using the search tool in ASNSs is to obtain information. He acknowledges that these sites must collect and process the information required by their users. Another study emphasizes that the researcher should use the ASNS to identify the researchers and create a cooperation network [38]. Meishar [33] stated in addition to finding information, researchers can use these sites to identify new research trends from leading researchers in various fields. The capacity to be informative via different avenues is one of the advantages of ASNS; however, the entry of newly requested and unrelated information by the ASNS into the email and the researcher's account can be considered a weakness for the ASNS and cause the user to leave the ASNS. Customization,

artificial intelligence algorithms, and user engagement in information acquisition can prevent this challenge and improve the quality of ASNS-related information.

The fifth practical feature considered by Iranian health researchers participating in the study was the possibility of facilitating the sharing and trading of laboratory materials and equipment amongst researchers. Bonaiuti [9] acknowledges that researchers can meet their needs using public posts on social media or specialized groups, which helps users of that social network find or share research resources. In the Salahshour study [29], 73% of researchers used ASNS to find material related to their research [29]. The existence of specialized groups in the ASNSs can be an effective solution for sharing laboratory materials and equipment and bolstering effective communication [9]. Given the situation in Iran and the sanctions imposed on the one hand [39] and poor economic conditions, on the other hand, this user expectation seems reasonable. Users can share the features of their laboratory materials and equipment and share their resources with other researchers. In addition to economic savings, this practice can increase research centers' efficiency and strengthen cooperation between researchers.

Conclusions

This study aimed to identify the expectations of health researchers from ASNSs. These expectations were divided into functional and technical characteristics. Functional characteristics were related to different research processes, and researchers used these features to increase the speed and quality of their research. In this category, they expected ASNSs to facilitate communication and inform them about various research fields. Moreover, some researchers expected ASNSs to enhance the process of conducting research and help in sharing and trading laboratory materials and equipment. Managing scientific publications is a functional characteristic that includes improving and managing scientometrics and altmetrics, introducing related journals, publishing the researcher's work, raising awareness regarding the scientific ranking of other researchers, and presenting a cooperative network.

Participants' expectations of ASNSs regarding technical characteristics included user management capabilities, high security and privacy, user-friendly, and other technical features. In addition to not meeting the user's expectations of ASNS, it is abandoned by researchers in some cases due to the lack of attention by programmers to users' opinions in the design of ASNS.

Acknowledgments

Thanks to the Vice-Chancellor for Research and Technology of Tabriz University of Medical Sciences. All participants in this study are also sincerely appreciated.

Authors' Contributions

RF, MD, and SA contributed to the study design. MD and RF completed the data collection. MK, SA, and MD conducted the data analysis. RF, SA, and BM supervised the study. MK, MD, and BM were involved in the manuscript writing. All authors contributed critical revisions for important intellectual content.

Abstract

Background: Although social networking services (SNSs) have become popular among young people, problematic SNS use has also increased. However, little is known about SNS addiction and its association with SNS use patterns and mental health status.

Objective: This study aims to test the mediating role of SNS addiction between SNS use patterns and mental health status among Chinese university students in Hong Kong (HK).

Methods: An online cross-sectional survey was conducted using a convenience sampling method. In total, 533 university students (323 [66.9%] female, mean age [SD]=20.87 [2.68] years) were recruited from February to March 2019. Multiple linear regression was used to assess the association between SNS use and SNS addiction. Structural equation modeling (SEM) was performed to examine the pathways and associations among SNS use, SNS addiction, psychosocial status, and mental health status (including anxiety and depressive symptoms).

Results: A longer time spent on SNSs per day (>3 h), a longer time spent on each SNS access (≥31 min), a higher frequency of SNS access (≤every 30 min), a longer duration of SNS use before sleeping (≥61 min), and a shorter duration from waking to first SNS use (≤5 min) were significantly associated with a higher level of SNS addiction (adjusted beta [aβ]=6.03, 95% CI 4.66-7.40; aβ=4.99, 95% CI 3.14-6.83; aβ=5.89, 95% CI 4.14-7.64; aβ=5.92, 95% CI 4.19-7.65; and aβ=3.27, 95% CI 1.73-4.82, respectively). SEM showed a significant mediating effect of SNS addiction in the relationship between SNS use and psychosocial status, and mental health status, including an indirect effect (β=0.63, 95% CI 0.37-0.93) and the total effect (β=0.44, 95% CI 0.19-0.72), while the direct effect was insignificant (β=–0.19, 95% CI –0.49 to 0.08).

Conclusions: SNS use patterns were associated with SNS addiction, and SNS addiction mediated the associations between SNS use, psychosocial status, and mental health status of Chinese university students in HK. The findings suggest that screening for and addressing excessive SNS use are needed to prevent SNS addiction and mental distress among young people.

KEYWORDS

social networking service; SNS; addiction; depression; anxiety; psychosocial status; youth; mental health

Introduction

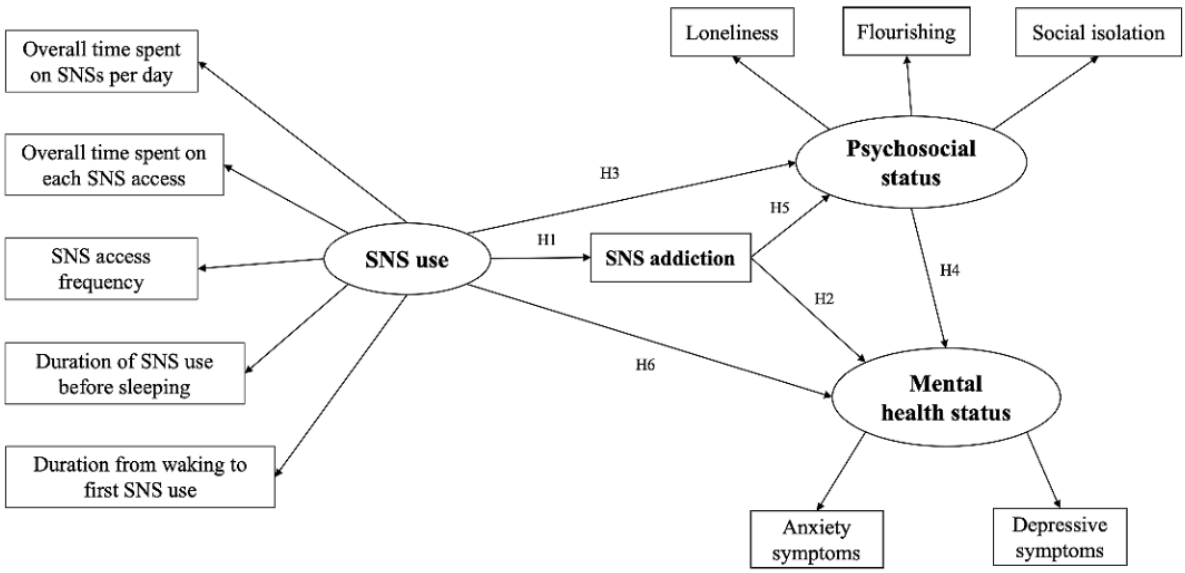
More than 1 billion people worldwide regularly use social networking services (SNSs), such as Facebook, Twitter, and Instagram, which are virtual communities where users interact and build online and real-life relationships [1-3]. Similar to the global trend, the number of SNS users has substantially increased from 68% in 2014 to 83% in 2018 in Hong Kong (HK) [4] which has 1 of the highest penetration rates of the internet and e-devices [5,6]. Compared with other age groups, younger age groups more popularly use SNSs, and 95% of young people in HK, aged from 10 to 24 years, used SNSs for an average of 17.7 h/week (the longest SNS use than other age groups) in 2018 [4]. As SNS use has gained popularity, problematic SNS use, such as excessive SNS use, which is a relatively long duration or frequent use of SNSs [7], has also increased among young people [8,9]. Evidence has shown that excessive SNS use has a negative impact on young people's physical health (eg, headache, postural pain, and eye strain) [7,10], real-life social relationships [11], and academic performance [12,13]. Moreover, although SNS platforms provide more pervasive environments for individuals to share their feelings and follow other interesting friends, previous studies have reported that excessive SNS use shows a strong association with psychological distress, including depression and anxiety [13-16], such as feeling frustrated or isolated from their real life [17] and feeling vulnerable to the perceptions of others [18].

Excessive SNS use has shown significant association with addictive behaviors [19,20], including feeling constantly anxious or uneasy about one's SNS accounts and having strong urges to use SNSs. SNS addiction is thus defined as the excessive use of SNSs that affects one's daily activities, interpersonal relationships, and mental health [21]. Although SNS addiction has not been specifically identified by the *Diagnostic and Statistical Manual 5th Edition* (DSM-5) or the *International Classification of Diseases 11th Revision* (ICD-11), SNS addiction can be considered as 1 form of behavior addiction, reflecting excessive and compulsive symptoms [22,23], similar to internet gaming disorder. However, SNS addiction can be differentiated from other behavior addictions as users focus on interpersonal networking through SNSs. According to gratification theory, users who gain enjoyment and happiness through SNS platforms would continue to spend even more time using SNSs in pursuit of more positive gratification [24]. Therefore, SNS addiction may result from gratification attained through online surfing and through virtual and real-life interpersonal relationships. Meanwhile, recent studies have found that 29% of university students have SNS addiction and that SNS addiction is associated with anxiety, depression, and mania symptoms, similar to prior studies that investigated excessive SNS use [25,26].

Although recent studies have identified associations between excessive SNS use, SNS addiction, and mental health status, it remains unknown whether there is a clear pathway from excessive SNS use to SNS addiction, thus influencing users' mental health (ie, pathway). As SNS use patterns can be differentiated by their social contexts (eg, different cultural values in interpersonal relationships on SNSs [27]), excessive SNS use and SNS addiction can be influenced by the users' psychosocial status (ie, the influence of social factors on one's mind [28]), such as the influence of social isolation and loneliness precipitating SNS use [29-31], while conversely influencing their mental health. Moreover, the possible mediating effect of SNS addiction on the pathway has been deduced as SNS addiction is also associated with SNS use patterns, psychosocial status, and mental health status [32-34]. Therefore, this study aimed to develop a structural equation modeling (SEM) approach to testing a hypothetical model and the potential mediating role of SNS addiction among Chinese university students in HK.

Based on the existing literature and knowledge gap, we developed the following hypotheses for this study and a hypothetical model (Figure 1):

Figure 1. Conceptual model and hypotheses. Ovals represent unobserved latent variables. Rectangles represent observed measured variables. SNS: social networking service.



- Hypothesis 1 (H1): SNS use is positively associated with SNS addiction.
- Hypothesis 2 (H2): SNS addiction is negatively associated with mental health status.
- Hypothesis 3 (H3): SNS use is negatively associated with psychosocial status.
- Hypothesis 4 (H4): Psychological factors are positively associated with mental health status.
- Hypothesis 5 (H5): SNS addiction is negatively associated with psychosocial status.
- Hypothesis 6 (H6): SNS use is negatively associated with mental health status.

Methods

Study Design and Sampling

A cross-sectional study design was adopted. An online survey link (Google Form) and a QR code printed on survey invitation flyers were distributed in busy public areas (eg, the entrance of library and cafeteria) within 2 major public university campuses in HK from February to March 2019. The online survey website included the study aim, respondents' rights, and participation incentive (50 respondents were randomly selected through a lucky draw for a HK $25 [around US $3.2] cash voucher). The respondents were also invited to freely share the survey link with their peers from any HK university (ie, convenience and snowball sampling). The inclusion criteria were enrolled university students residing in HK with at least 1 SNS account. Exchange students from outside HK and respondents who did not answer more than 10 survey questions were excluded. To prevent multiple responses and confirm their identity as university students, each respondent's mobile phone number and university email address were collected.

Measurements

Demographics and SNS Use

Demographic characteristics, including sex, age, university, degree pursued, and academic performance, were investigated. The respondents' patterns of SNS use (eg, overall time spent on SNS per day, time spent on each SNS access, SNS access frequency, and SNS use duration before sleeping and after waking) were surveyed.

SNS Addiction

SNS addiction was measured using a revised version of the Bergen Facebook Addiction Scale (BFAS), which consists of 6 questions [35,36]. The BFAS presented 0.83 internal consistency and reported convergent validity [35]. The overall score of the BFAS ranged from 6 to 30, with higher scores indicating a higher level of SNS addiction. The term "Facebook" in each item was changed to "SNSs" to include a wider range of SNSs, similar to Andreassen et al [36]. The internal consistency (Cronbach α) of the BFAS in this study was also 0.83.

Mental Health Status

The Patient Health Questionnaire-4 (PHQ-4) was used to screen for psychological symptoms among the respondents. The PHQ-4 consists of 2 domains (ie, depression and anxiety), and each domain has 2 questions [37]. The total score in each domain ranges from 0 to 6. Higher scores in the 2 domains refer to higher levels of depressive and anxiety symptoms, respectively. The internal consistency of the 2 domains was 0.82 and 0.81, respectively, in the original study [37] and 0.79 and 0.86, respectively, in this study.

Psychosocial Status

The respondents' psychosocial status was measured according to their psychological well-being, social isolation, and loneliness. First, the Flourishing Scale was adopted to measure the respondents' subjective psychological well-being [38]. The scale consists of 8 questions with an overall score range from 8 to 56, and higher scores represent higher subjective psychological well-being. The Flourishing Scale showed an internal consistency as 0.87 and convergent validity [38]. The internal consistency in this study was 0.92. Second, we adopted the Lubben Social Network Scale (LSNS-6) consisting of 6 questions to investigate the respondents' social isolation level [39]. The overall score ranges from 0 to 30, and higher scores indicate lower levels of social isolation [39]. The internal consistency of the LSNS-6 was 0.83 in the original study and 0.75 in this study. Lastly, a brief loneliness scale [40] was also adopted to measure the respondents' feelings of loneliness. The scale consists of 3 questions, and the total score ranges from 3 to 9. The internal consistency of the loneliness scale in the original research [40] and this study was 0.72 and 0.89, respectively.

Statistical Analysis

Descriptive analysis was conducted to detail the respondents' information about demographic characteristics, SNS use and addiction, and psychological profile. For continuous variables, the mean and SD were used, and for categorical variables, the frequency and percentage were used for analysis. Multiple linear regression was performed to assess the association between SNS use and SNS addiction. Structural equation modeling (SEM) was performed to examine the pathways from SNS use to mental health status. Multiple imputation was performed for missing data. Total, direct, and indirect effects in the hypothesized model were estimated using the maximum likelihood and bias-corrected (BC) 95% CI by the bootstrapping method with 2000 replications. Fitness indices of the SEM were considered, including the root-mean-square error of approximation (RMSEA; suggested close to or smaller than 0.06), the comparative fit index (CFI; suggested close to or larger than 0.95), the Tucker-Lewis index (TLI; suggested close to or larger than 0.95), and the standardized root-mean-square residual (SRMR; suggested close to or smaller than 0.08) [41,42]. IBM SPSS 24.0 and Amos 26.0 were used for all analyses at a .05 significance level.

Results

Respondents' Characteristics

Of the 533 respondents, 483 (90.6%) who met the eligible criteria were included in this study. The mean age was 20.87 years (SD 2.68), and 66.9% (n=323) of the respondents were female. The majority (459/483, 95.0%) were from University

Grants Committee (UGC)-funded universities (ie, large public universities) and undertook higher diploma or undergraduate courses (466/483, 96.5%). With regard to SNS use, 33.7% (163/483), 42.2% (225/483), and 31.0% (165/483) of the respondents used SNSs for over 1-2 h/day, 6-15 min each time, and every 31-60 min, respectively. In addition, 46.9% (250/483) and 36.0% (192/483) of them used SNSs for 31-60 min before sleeping and within 5 min or less after waking up. The mean scores for anxiety symptoms, depressive symptoms, flourishing, social isolation, and loneliness were 2.86 (SD 1.62), 2.70 (SD 1.58), 38.87 (SD 7.42), 16.90 (SD 5.06), and 5.55 (SD 1.79), respectively. The mean score for SNS addiction was 16.4 (SD 5.03); see Table 1.

UGC-funded universities in HK including the University of Hong Kong (350/459, 76.3%), the Chinese University of Hong Kong (14/459, 3.1%), the Hong Kong University of Science and Technology (3/459, 0.6%), the Hong Kong Polytechnic University (81/459, 17.6%), the Education University of Hong Kong (0), the City University of Hong Kong (7/459, 1.5%), the Hong Kong Baptist University (3/459, 0.6%), and Lingnan University (1/459, 0.2%).

Associations of SNS Addiction With SNS Use

SNS addiction was significantly associated with SNS use patterns (Table 2). A longer amount of time on SNSs per day (ie, >3 h), a longer amount of time on SNSs each access (ie, ≥31 min), and a higher frequency of SNS access (ie, less than every 30 min) were associated with a higher level of SNS addiction (adjusted beta [aβ]=6.03, 95% CI 4.66-7.40; aβ=4.99, 95% CI 3.14-6.83; and aβ=5.89, 95% CI 4.14-7.64, respectively). A longer duration of SNS use before sleeping (ie, ≥61 min) and a shorter duration from waking to first SNS use (ie, ≤5 min) were significantly associated with a higher level of SNS addiction (aβ=5.92, 95% CI 4.19-7.65 and aβ=3.27, 95% CI 1.73-4.82, respectively).

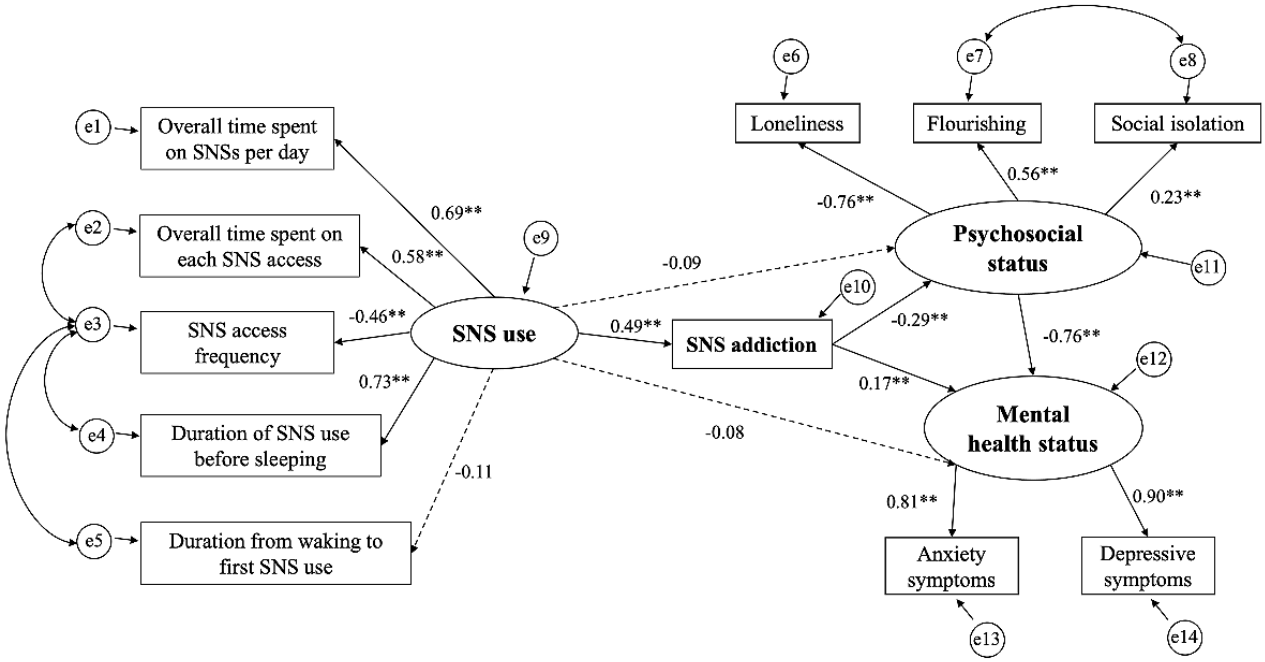
Mediating Effects of SNS Addiction Between SNS Use and Mental Health Status

The hypothesized model showed good fitness indices, with X^2/df=2.16, RMSEA=0.05, CFI=0.97, TLI=0.95, and SRMR=0.04. Results from bootstrapping showed that SNS addiction has a significant mediating effect on the relationship between SNS use and psychosocial status, and mental health status (Figure 2).

Figure 2. Standardized regression coefficient (β) of all variables in the hypothesized model. Ovals represent unobserved latent variables. Rectangles represent observed measured variables. Values are standardized path coefficients. ***P*<.01. SNS: social networking service.



H1 (SNS use and SNS addiction; β=0.49, 95% CI 0.39-0.58), H2 (SNS addiction and mental health status; β=0.17, 95% CI 0.06-0.27), H4 (psychosocial status and mental health status; β=–0.76, 95% CI –0.88 to –0.64), and H5 (SNS addiction and psychosocial status; β=–0.29, 95% CI –0.42 to –0.16) were supported. In contrast, H3 (SNS use and psychosocial status; β=–0.09, 95% CI –0.24 to 0.06) and H6 (SNS use and mental health status; β=–0.08, 95% CI –0.21 to 0.03) were not supported (Table 3).

Table 3. Standardized coefficients of raised hypotheses in the hypothesized model.

Hypothesis	β	BC[a] 95% CI	*P* value
H1: SNS[b] use → SNS addiction	0.49	0.39-0.58	.001
H2: SNS addiction → mental health status	0.17	0.06-0.27	.004
H3: SNS use → psychosocial status	–0.09	–0.24 to 0.06	.21
H4: Psychosocial status → mental health status	–0.76	–0.88 to –0.64	.002
H5: SNS addiction → psychosocial status	–0.29	–0.42 to –0.16	.001
H6: SNS use → mental health status	–0.08	–0.21 to 0.03	.16

[a]BC: bias-corrected.

[b]SNS: social networking service.

Three indirect pathways between SNS use and mental health status in SEM were investigated (Tables 4 and 5). The indirect effect of SNS addiction was significant on the pathway of SNS use to mental health status (β=0.20, 95% CI 0.08-0.34), but the indirect effect of psychosocial status was insignificant on the pathway (β=0.17, 95% CI –0.10 to 0.47). The indirect effect mediated by SNS addiction and psychosocial status in the pathway also showed a significant impact (β=0.26, 95% CI 0.14-0.44), and this pathway showed a stronger correlation than the pathway with SNS addiction alone as the mediator. The total indirect effect between SNS use and mental health status was significant (β=0.63, 95% CI 0.37-0.93). The direct effect of SNS addiction and psychosocial status on mental health status was insignificant (β=–0.19, 95% CI –0.49 to 0.08). Furthermore, the total effect of SNS addiction and psychosocial status that mediated the path from SNS use to mental health status was significant (β=0.44, 95% CI 0.19-0.72).

Discussion

Principal Findings

This study found that longer and more frequent use of SNSs is significantly associated with SNS addiction. This study also identified that SNS addiction and psychosocial status significantly and positively mediate the relationship between SNS use and mental health status (anxiety and depressive symptoms) in Chinese university students in HK.

SNS Addiction–Related Factors

SNS addiction significantly differed across the respondents' demographics in this study. We found that females have a higher level of SNS addiction than males, corresponding with another study from HK [43]. In contrast, several studies from Europe have reported that males have a higher SNS (Twitter) addiction level and SNS obsession than females [44-46]. Although there are limited studies investigating the sex differences in SNS addiction, the distinct findings in the HK studies may be due to sociocultural influences on SNS use and addiction. Chinese females who are influenced by a collectivism-dominant culture tend to be introverted and gravitate toward indirect communication styles [47]. Accordingly, they prefer to use SNSs as a way to make emotional connections and maintain their existing interpersonal relationships [48]. They also tend to spend more time on SNSs than males [47,48]; thus they are more exposed to the risk of SNS addiction. An in-depth qualitative study and meta-analysis would be helpful to uncover the extent of sociocultural influences on SNS addiction.

We also found that SNS addiction is significantly higher among undergraduate students and those with poor academic performance, consistent with previous findings on academic performance [49,50] and undergraduate studies [51]. As time spent on SNSs for entertainment is a negative predictor of time spent studying [52] and academic performance, such as grade point averages [51], excessive and addictive SNS use for entertainment would decrease the time on education, resulting in low academic performance [44]. Although the associations of SNS use patterns with SNS addiction are little known, the associations between problematic uses of smartphones or the internet, and addictive behaviors have been identified in the literature. Excessive use or habitual checking of the smartphone can lead to smartphone addiction [53-55]. Similarly, long durations of time spent on the internet are a significant indicator of internet addiction [56]. Moreover, previous studies have reported that young adults with internet and smartphone addiction mainly spend time on the use of SNS websites and applications [57,58]. Given that SNSs can be used over the internet through smartphones and other electronic devices, and that internet and smartphone addiction results in similar user behaviors, our findings on SNS addiction can be comparable to studies investigating internet use on smartphones or internet addiction. Moreover, shorter durations from waking to first SNS use and longer durations before sleeping are strong indicators of SNS addiction [53,59]. These findings from previous studies resembled our findings regarding the association of excessive SNS use patterns with SNS addiction. We also further found the effect of the SNS use patterns on SNS addiction, namely that excessive SNS use can cause SNS addiction.

Although excessive SNS use can cause SNS addiction behaviors, young people are poor at recognizing their own SNS use as excessive. In 1 study that surveyed the effects of Facebook use on the social life and behaviors of 1000 university students in Pakistan, nearly 70% of those who showed addictive Facebook use did not discern themselves as having Facebook addiction [60]. Similarly, another study that collected SNS information on 804 adolescents in India revealed that only 4% perceived their SNS use to be highly problematic [61]. Opportunities exist for health professionals to guide young people to recognize their own excessive SNS use that can cause SNS addictive behaviors. Practical screening for SNS addiction can be assessed as a daily routine in the community when dealing with young people who show problematic and excessive SNS use. This may be the first

step in recognizing potential cases before they develop further into SNS addiction. Concerning previous treatment for internet addiction [62], interventions conducted through a cognitive behavioral approach may also be helpful for users with SNS addiction in order to reconstruct their thoughts and behaviors and mitigate mental distress stemming from SNS addiction.

Impact of SNS Addiction on Mental Health Status

We found that SNS addition significantly influences mental health status (ie, anxiety and depressive symptoms), while the effect of SNS use patterns on mental health status is not significant. It should be noted that the difference between SNS use and SNS addiction is that the latter reflects more problematic behaviors and can lead to more severe outcomes that are associated with SNSs [7]. General SNS use may not be a potential factor; instead, it is the excessive use of SNSs that influences addictive behavior and mental distress [63]. Similar to our results, previous studies have reported that SNS addiction is associated with negative mental health outcomes, including depression, anxiety, and affective disorder [26,64,65]. However, these studies have mainly focused on the bivariate association between SNS addiction and mental health, while the effect of SNS addiction on mental health remains uncertain; that is, whether mental problems lead to SNS addiction or vice versa.

Furthermore, we identified that SNS addiction plays a mediating role in the pathway from SNS use to mental health status. This finding resonates with 1 study that identified that Instagram (an SNS) use predicts depression [25]. However, the mediating role of SNS addiction was not significant in that study, in contrast with our findings. SNS use in that study was only measured by 1 item (ie, the time spent on Instagram) [25], while we included diverse SNS use patterns (ie, 4 durations and 1 frequency measurement of SNS use). We also included all types of SNS use, but the aforementioned study only included Instagram use, although the use of different SNSs would be differently associated with SNS addiction and depression [25]. Therefore, the findings from our study offer more holistic and integrative viewpoints on the pathway from SNS use to mental health status via SNS addiction.

Of note, SNS use in moderation can positively affect users' mental health status. SNS use can reinforce a user's online relationships and solidify their offline connections, and this may, in turn, reduce their negative feelings and emotions (eg, anxiety, depression), positively influencing their mental health status [66,67]. Unfortunately, when SNS use becomes excessive, it conversely has an adverse effect on users. Although excessive SNS use is a popular concept in SNS studies and is known as a predictor of SNS addiction [68,69], there is ambiguity in the cut-off between non-excessive and excessive use, making excessive SNS use difficult to define. Therefore, SNS addiction would be more suitable than excessive SNS use to objectively determine that a user's SNS use is problematic and to understand its influence on health outcomes [61,69]. Moreover, the sense of belongingness (feeling of being accepted in groups) is high among young people, particularly from East Asian countries that have collectivism-dominant societies. The sense of belongingness is positively associated with social and psychological functioning [70,71]. The characteristics of young people and the social environment in HK (ie, a high sense of belongingness that we measured in this study using social well-being, loneliness, and isolation scales) likely mediate SNS use, SNS addiction, and mental health status.

As an indispensable element of today's leisure culture, absolute abstinence from accessing SNSs is not an appropriate treatment for SNS addiction and mental distress. Restricting the excessive use of SNSs, addressing the importance of SNS addiction control to improve psychosocial and mental health status and preventing relapse by encouraging self-reflection on SNS use may be possible solutions for designing educational programs. Particularly, during the COVID-19 pandemic, which hinders face-to-face intervention delivery, internet-delivered interventions (eg, internet-delivered cognitive behavioral therapy) can be also considered to address SNS addiction. Future studies on determining the appropriate duration of SNS use with findings transferable to practice guidelines would be needed.

Limitations

This study had some limitations. Cross-sectional data in this study could not provide the causality between SNS addiction and mental health status. Discussions of the magnitude of the relationship between 2 elements (SNS addiction and mental health status) were inconclusive, with different opinions that this relationship can be bidirectional [72,73]. Therefore, more studies with longitudinal designs are needed to explore the direction and mechanism of causality for the relationship between SNS addiction and mental health status in the future. Additionally, as most of our participants were ethnic Chinese in HK, replication of our study for young adults in other sociocultural settings is recommended to reveal a more comprehensive relationship that was discovered through this study. Lastly, the participants responded to an online survey. Self-reported data may result in recall bias.

Conclusion

This study provided novel information about the patterns of SNS use and its association with SNS addiction among university students. Findings from SEM also addressed that there is a significant mediating effect of SNS addiction between SNS use and mental health status, including anxiety and depressive symptoms. Further studies are suggested to demonstrate causal relationships with longitudinal data. This study helps to provide preliminary solutions for reducing SNS addiction and mental problems by conducting interventions using cognitive-behavioral approaches.

Acknowledgments

The authors would like to thank all students who assisted with the study design and participant recruitment for this study: Mr Kwong Ming Hong Bernard, Mr Lee Tsan Ho, Ms Chan Hue Yuet Kalfanie, Ms To Yi Yan Jenny, Mr Or Ego, Ms Cheung Tsz

Ching, Ms Ng Yeuk Tung, Ms Leung Ka Yan, Ms Mak Hoi Yin Tiffany, and Mr Man Anthony Gar-Ta from the University of Hong Kong.

Authors' Contributions

TW and JJL undertook the data analysis. TW drafted the manuscript. JJL conceived the study design. ACYL designed the survey and helped recruit the participants. JYHW, MPW, and SSK supported the study supervision. JJL, JYHW, MPW, and SSK revised the manuscript. All the authors approved the final manuscript.

Abstract

Background: The internet is one of the most popular health information resources, and the Chinese constitute one-fifth of the online users worldwide. As internet penetration continues to rise, more details on the Chinese population seeking online health information need to be known based on the current literature.

Objective: This study aims to explore the sociodemographic differences in online health information seeking (OHIS), including the frequency of OHIS and the types of online health information sought among the general Chinese population in mainland China.

Methods: A cross-sectional study for assessing the residents' health care needs with self-administered questionnaires was implemented in 4 counties and districts in China from July 2018 to August 2018. Pearson's chi-square test was used to identify the sociodemographic differences between infrequent and frequent online health information seekers. We also performed binary logistic regression for the 4 types of online health information as the dependent variables and the sociodemographic factors as the independent variables.

Results: Compared with infrequent online health information seekers, frequent seekers were more likely to be female (infrequent: 1654/3318; 49.85%; frequent: 1015/1831, 55.43%), older (over 60 years old; infrequent: 454/3318, 13.68%; frequent: 282/1831, 15.40%), married (infrequent: 2649/3318, 79.84%; frequent: 1537/1831, 83.94%), and better educated (bachelor's or above; infrequent: 834/3318, 25.14%; frequent: 566/1831, 30.91%). They were also more likely to earn a higher income (over RMB ¥50k [RMB ¥1=US $0.15641]; infrequent: 1139/3318, 34.33%; frequent: 710/1831, 34.78%), have commercial health insurance (infrequent: 628/3318, 18.93%; frequent: 470/1831, 25.67%), and have reported illness in the past 12 months (infrequent: 659/3318, 19.86%; frequent: 415/1831, 22.67%). Among the 4 health information types, health science popularization was the most searched for information by Chinese online health information seekers (3654/5149, 70.79%), followed by healthy behaviors (3567/5149, 69.28%), traditional Chinese medicine (1931/5149, 37.50%), and medical concerns (1703/5149, 33.07%). The binary logistic regression models showed that males were less likely to seek information on healthy behaviors (adjusted odds ratio [AOR] 0.69, 95% CI 0.61-0.78) and traditional Chinese medicine (AOR 0.64, 95% CI 0.57-0.73), and respondents who had at least 1 chronic disease were more likely to seek information on medical concerns (AOR 1.27, 95% CI 1.07-1.51) and traditional Chinese medicine (AOR 1.26, 95% CI 1.06-1.49).

Conclusions: Sociodemographic factors were associated with the frequency of OHIS and types of information sought among the general Chinese population. The results remind providers of online health information to consider the needs of specific population groups when tailoring and presenting health information to the target population.

Introduction

Given its rapid development, the internet has become an essential source of health information worldwide. According to Internet World Stats, the number of internet users has reached 5 billion, accounting for more than 60% of the world population [1]. The internet has the highest usage rate among health information sources [2-4]. Although certain groups still rely on traditional media for health information [5], the internet is increasingly growing in popularity as a source of health information.

The advantages of online health information seeking (OHIS) manifest in various aspects. Turning to the internet before seeking a professional diagnosis has the potential to improve the relationship between patients and their physicians, and patients are more inclined to trust in their physicians' advice by discussing their findings online with these professionals [6-8]. The likelihood of individuals changing their health behavior rises as the frequency of using the internet to retrieve health information increases [9]. For people who live with chronic diseases, the internet may improve their skills in managing their condition [10,11]. However, seeking health information online can be a mixed blessing. Studies have shown that online health information can be inadequate and inaccurate [12-14]. The information may be of questionable quality, leading to hasty, ill-informed, and dangerous health choices [15]. Compared with that available in Western countries, the low-quality online health information seems to be particularly serious in Asian countries [16].

Previous studies have explored how sociodemographic factors influence OHIS behavior. The frequency of OHIS is higher among individuals who are female, younger, better educated, or have a higher household income [9,17,18]. A study that analyzed 2 Pew data sets collected in 2002 and 2012 showed that the sociodemographic factors of gender and education strongly predicted OHIS in both years; meanwhile, age and income were significant predictors in 2012 but not in 2002 [19]. Internet access and OHIS behavior have been shown to vary by race and ethnicity [20-24]. Other factors, such as health status [17] and employment status [24], were also found to be statistically significant in OHIS. A meta-analysis on OHIS revealed that age, gender, education, income, race, and experience were social determinants of OHIS [25]. In summary, most related studies indicate that the crucial characteristics of online health information seekers are age, level of education, income, and ethnicity [26]. Several studies have consistently focused on the predictors of OHIS; however, most of them aimed at identifying determinants that discriminate between online health information seekers and nonseekers [4,20,24,27-29], and elements associated with OHIS among those who have used the internet for health information should also be examined.

Seekers of online health information seek various health topics. Some studies reported information about disease to be the most common topic sought by online health information seekers [19,30]. Other frequently searched topics include symptoms, medication, treatment, exercise and fitness, and nutrition or diet [8,10,30,31]. However, there is no official or agreed upon classification for these common health topics. By reviewing previous studies, these topics can be mainly grouped into 2 types: (1) healthy behaviors, including information related to nutrition or diet, exercise, and body maintenance; (2) and medical concerns, including information related to disease, medications, and treatments [19,32]. Of these 2 types, information on medical concerns is more likely to be sought by people with more health risks [8,31,32]. For instance, compared with the population with no chronic disease, people with chronic conditions are more likely to search about medicines [10]. Overall, evidence shows that medical information seems to be the most popular health information on the internet. However, different population groups have different preferences for health information, and how individuals who seek this information may vary by their characteristics remains obscure.

According to the 47th Statistical Report on China's internet Development [33], as of December 2020, 9.89 million Chinese had access to the internet, and the penetration rate in China reached 70.4%, a rate higher than the average level in Asia (62.6%) [1]. The Chinese population constitutes one-fifth of the world's internet users, and easy access to specialized information, such as medical and health care information, accounts for 29.8% of the factors facilitating China's nonnetizens' access to the internet [33]. However, academic research on OHIS has mostly collected evidence from Western countries, especially the United States [5,10,21], or has focused on certain groups, such as women [23,34], adolescents [28,35], and patients with chronic disease [10,11]. Studies on the general Chinese population, particularly the Mainland population, are still limited.

According to the literature review, OHIS has not only positive but also negative influences on individuals. With the rise of the internet penetration rate, an increasing number of people will have access to online health information. New health information is difficult to effectively categorize when individuals are overwhelmed by diverse or mixed health information, and an overabundance of health information on the internet can make individuals feel confused and become more anxious about

their conditions [36,37]. To ensure that online health information can be effectively used and to understand how individuals can best avoid the negative influence of OHIS, it is crucial to understand the characteristics and preferences of online health information seekers so that practical information can be tailored and presented to the target population. As a result, we aimed to answer 3 questions: (1) Which groups of people are frequent online health information seekers? (2) Which types of online health information do people usually search for? (3) What are the preferences for types of online health information among different population groups? Given that sociodemographic factors have provided an increasingly significant explanation of the variance in OHIS [19], our study aimed to explore sociodemographic differences in OHIS behavior among the general Chinese population, including frequency of OHIS and types of health information sought.

This study used the data of a household survey conducted in 4 counties and districts in Mainland China, which may additionally contribute to the current research. As inaccurate information and the inability to find information may discourage people from retrieving professional information [38], our findings may offer additional knowledge to online health information providers so that appropriate health information content can be tailored and presented. Therefore, we believe this study can significantly contribute to online health information management and promotion in China.

Methods

Study Design

From July 2018 to August 2018, the Research Center for Rural Health Services carried out a study to assess residents' health care needs. Based on the assessment of socioeconomic development and geographic distribution and suggestions from experts [39], 4 counties and districts across China were purposely selected as the survey areas, including 2 districts in urban China (Xiling in central China, Futian in eastern China) and 2 counties in rural China (Dangyang in central China, Sinan in western China) [40].

A multistage stratified random sampling was implemented to select representative samples of the districts' and counties' populations. In the sample size calculation, the design effect was set at 2.5, and the allowable error at the significance level of .05; the chronic disease prevalence was 21.338% according to the 2013 National Health Service Survey [41], and thus the minimum sample size in each survey area was calculated to be 3584 individuals. Given that a family in China has an average of 2.9 members [41], at least 1235 families in every study site needed to be investigated. In the 2 counties (Dangyang and Sinan), 5 towns in each county were randomly selected according to the distance to the county hospitals. Meanwhile, 6 villages in each town were randomly selected according to the distance to the township hospitals. In the 2 districts (Xiling and Futian), 5 streets in each district were randomly selected according to the distance to the medical centers. To ensure that at least 248 families in each town or street were effectively interviewed, 1 other town or street in each county or district was selected as a backup in case of refusal, closed household, or removal of defective questionnaires. We resampled and surveyed until the final sample size met the estimated requirement. The surveyed families were systematically sampled in the rosters of residents from the village or street councils. Under the guidance of well-trained interviewers, face-to-face interviews were conducted, and self-administrated questionnaires were used on all the members of the sampled families. Finally, data from 15,126 respondents in 5547 families were collected in total: 3310 individuals in 1360 families in 30 villages in Dangyang, 3983 individuals in 1355 families in 30 villages in Sinan, 4386 individuals in 1513 families in 6 streets in Futian, and 3447 individuals in 1319 families in 5 streets in Xiling. A total of 12,646 individuals above 15 years of age needed to answer the questions related to OHIS, and 5354 respondents (5354/12,646, 42.34%) reported using the internet to seek health information. Among the online health information seekers, those who failed to provide information for all variables queried in this study were excluded, and 5149 individuals were finally included in the analysis.

Ethical approval was obtained from the Ethics Committee of Tongji Medical College, Huazhong University of Science and Technology (#IORG0003571).

Variables

Sociodemographic Factors

The survey questionnaires were divided into several parts, including basic family information, individual information, health status, health care use, and health promotion need. Sociodemographic factors, including gender, age, marital status, area of residence, education level, annual household income per capita, employment, health insurance, having at least 1 chronic disease, and reported illness in the past 12 months, were considered to be independent variables. The coding of independent variables is shown in Table 1.

Table 1. Coding of independent variables.

Variables	Assignment
Gender	Female=0; male=1
Age (years)	15-45=1; 46-60=2; >60=3
Marital status[a]	Single=0; married=1
Area	Rural=0; urban=1
Education level	Junior high school or below=1; senior high school =2; 3-year college=3; bachelor's or above=4
Annual household income per capita (RMB ¥[b])	<10k=1; 10k-30k=2; 30k-50k=3; >50k=4
Employment[c]	Unemployed=0; employed=1
Types of primary health insurance	Urban employee basic medical insurance=1; urban-rural resident basic medical insurance=2; others[d]=3
Having commercial health insurance	No=0; yes=1
Having at least 1 chronic disease	No=0; yes=1
Reported illness in the past 12 months	No=0; yes=1

[a]Marital status was divided into 2 categories: single (unmarried, divorced, or widowed) and married (married).

[b]RMB ¥1=US $0.15641.

[c]Employment was recoded as 2 groups: unemployed (unemployed, students, and retired) and employed (employed).

[d]Others included no primary health insurance and health insurance outside mainland China.

Frequency of OHIS

Most frequency response scales use subjective terms as scale labels, such as the 3-point frequency scale (usually, sometimes or partially, never) and 4-point frequency scale (never, seldom/hardly ever, sometimes, often) [9,42,43]. In this study, the measurement of the frequency of OHIS was adapted from previous studies, which were based on respondents' subjective ratings. Respondents were asked to rate the frequency of OHIS on a 3-point frequency scale (frequent, infrequent, never), and those who selected "Frequent" and "Infrequent" were classified as frequent and infrequent online health information seekers, respectively. Given that our study participants were those who had used online health information, respondents who selected "Never" were excluded.

Types of Online Health Information

In the original survey, respondents were asked whether they had searched for the following health-related contents: sports and fitness, health science popularization, traditional Chinese medicine (TCM), women's health, nutrition and diet, medication guidance, disease consultation, health status monitoring, and others. In this study, 6 items were selected and then grouped into 4 types to be analyzed: (1) healthy behaviors, including sport and fitness, and nutrition and diet; (2) medical concerns, including medication guidance and disease consulting; (3) TCM, which may particularly be sought by Chinese users [31,44]; and (4) health science popularization, an emerging type of health information that aims at improving people's health literacy, which the National Health Commission of China has strongly supported in recent years. According to the National Health Commission of China, information on health science popularization mainly includes scientific knowledge about health technologies, ideas, methods, and skills, which is particularly disseminated in a way that is easy to understand, accept, and participate in [45]. Of the 4 types of online health information, the first 2 contain the common health topics frequently sought by the general population worldwide, and the analysis of the latter 2 may be helpful to better understanding the OHIS behavior of the general population in the setting of Mainland China. Each type as a dependent variable was dichotomized (yes or no).

Statistical Analysis

First, Pearson's chi-square test was used to compare sociodemographic differences between infrequent and frequent online health information seekers. Second, descriptive analysis was applied to show the prevalence of different types of online health information. Finally, binary logistic regression was conducted on each type of online health information to identify the sociodemographic differences in searches for health information types, and the adjusted odds ratio (AOR) and 95% CI were reported. The significance level was set at a *P* value of .05.

Results

Sociodemographic Information of the Respondents

Table 2 shows an overview of the main sociodemographic characteristics of the study population and differences in the frequency of OHIS. Online health information seekers comprised more females (2669/5149, 51.84), and most of them lived in urban China (3993/5149, 77.55%). Almost two-thirds (3318/5149, 64.44%) of respondents reported infrequently using the internet to seek health information. Among people who were frequent seekers of online health information, more than half (1015/1831, 55.43%) were female. The comparison between the 2 groups revealed that differences in terms of gender

(P<.001), age (P=.01), marital status (P<.001), education level (P<.001), annual household income per capita (P<.001), possession of commercial insurance (P<.001), and reported illness in the past 12 months (P=.02) were statistically significant. In contrast, area (P=.12), employment (P=.79), types of primary health insurance (P=.57), and having at least 1 chronic disease (P=.14) were not significantly different. Compared with infrequent online health information seekers, frequent seekers were more likely to be females (infrequent: 1654/3318, 49.85%; frequent: 1015/1831, 55.43%), were older (over 60 years old; infrequent: 454/3318, 13.68%; frequent: 282/1831, 15.40%), were more likely to be married (infrequent: 2649/3318, 79.84%; frequent: 1537/1831, 83.94%), were better educated (bachelor's or above; infrequent: 834/3318, 25.14%; frequent: 566/1831, 30.91%), earned a higher income (over RMB ¥50k [RMB ¥1=US $0.15641; frequent: 1139/3318, 34.33%; frequent: 710/1831, 34.78%), were more likely to have commercial health insurance (infrequent: 628/3318, 18.93%; frequent: 470/1831, 25.67%), and were more likely to have reported illness in the past 12 months (infrequent: 659/3318, 19.86%; frequent: 415/1831, 22.67%).

Table 2. Sociodemographic characteristics of the respondents by frequency of OHIS (online health information seeking).

Sociodemographic characteristics	Overall (N=5149), n (%)	Infrequent (N=3318), n (%)	Frequent (N=1831), n (%)	*P* value

[c]URBMI: urban-rural resident basic medical insurance.

Types of Online Health Information Searched

Respondents reported 1 or more different types of health information they sought online. A majority of the respondents (3654/5149, 70.79%) had used the internet to seek health science popularization information, which was followed in popularity by healthy behaviors (3567/5149, 69.28%), TCM, and medical concerns (1703/5149, 33.07%). The prevalence of the searches for the 4 types of online health information is shown in Table 3.

Table 3. Prevalence of types of online health information sought by the study participants.

Types of online health information	Prevalence (N=5149), n (%)
Healthy behaviors	3567 (69.28)
Medical concerns	1703 (33.07)
Traditional Chinese medicine	1931 (37.50)
Health science popularization	3645 (70.79)

Sociodemographic Factors Associated With the Types of OHIS

The results of the binary logistic regression models illustrated sociodemographic differences in seeking the 4 types of online health information (Table 4). Being male was significantly associated with a lower possibility of seeking healthy behaviors (AOR 0.69, 95% CI 0.61-0.78) and TCM (AOR 0.64, 95% CI 0.57-0.73). Compared with individuals aged between 15 and 45 years, middle-aged individuals were more likely to seek TCM (AOR 1.86, 95% CI 1.61-2.15) and health science popularization (AOR 1.20, 95% CI 1.02-1.40), while older adults were more likely to seek information for medical concerns (AOR 1.40, 95% CI 1.12-1.76) and TCM (AOR 2.16, 95% CI 1.72-2.70). Compared with single respondents, married respondents were more likely to seek TCM (AOR 1.22, 95% CI 1.03-1.44) and health science popularization (AOR 1.20, 95% CI 1.02-1.41) but were less likely to seek healthy behaviors (AOR 0.67, 95% CI 0.56-0.80). Living in urban China was associated with increased odds of seeking TCM (AOR 1.23, 95% CI 1.01-1.52). Higher education attainment was correlated with a higher possibility of seeking healthy behaviors (3-year college: AOR 1.56, 95% CI 1.26-1.95; bachelor's or above: AOR 1.33, 95% CI 1.10-1.62), medical concerns (senior high school: AOR 1.19, 95% CI 1.01-1.39; bachelor's or above: AOR 1.46, 95% CI 1.20-1.77), and health science popularization (bachelor's or above: AOR 1.50, 95% CI 1.23-1.83). Lower annual household income per capita was associated with increased odds of seeking healthy behaviors (RMB ¥10k-30: AOR 1.21, 95% CI 1.02-1.44) but decreased odds of seeking TCM (<RMB ¥10k: AOR 0.70, 95% CI 0.54-0.91; RMB ¥10k-30k: AOR 0.76, 95% CI 0.64-0.89). Respondents with urban-rural resident basic medical insurance were less likely to seek health science popularization than those with urban employee basic medical insurance (AOR 0.86, 95% CI 0.74-1.00). Having commercial health insurance was associated with a higher possibility to seek healthy behaviors (AOR 1.55, 95% CI 1.32-1.83) and TCM (AOR 1.27, 95% CI 1.10-1.47) but a lower possibility to seek medical concerns (AOR 0.82, 95% CI 0.70-0.95) and health science popularization (AOR 0.83, 95% CI 0.71-0.96). Individuals who had at least 1 chronic disease were more likely to seek medical concerns (AOR 1.27, 95% CI 1.07-1.51) and TCM (AOR 1.26, 95% CI 1.06-1.49). Similarly, those who reported illness during the past 12 months were also more likely to seek medical concerns (AOR 1.41, 95% CI 1.21-1.65) and TCM (AOR 1.17, 95% CI 1.00-1.38).

Table 4. Binary logistic regression models for AORs and 95% CIs of reporting the search for each type of online health information.

Sociodemographic Characteristics	Healthy behaviors, AOR[a] (95% CI)	Medical concerns, AOR (95% CI)	Traditional Chinese medicine, AOR (95% CI)	Health science popularization, AOR (95% CI)

Discussion

Principal Findings and Comparison With Prior Work

In this population-based study, we examined the sociodemographic differences in frequency of OHIS and types of online health information sought among the general population in China. This study corroborated the findings of a great deal of previous work in that individuals who were female, better educated, and had a higher household income were positively associated with OHIS [17,18,20,23]. The differences in frequency of OHIS among socioeconomically defined groups implied that inequality in health communication might also exist in China, which was consistent with findings of a previous study from Hong Kong [29]. We also found that living areas had no significant difference between infrequent and frequent online health information seekers, while this difference might exist between seekers and nonseekers [20]. In addition, the sociodemographic characteristics included in the analysis were not consistently associated with the types of online health information sought among the Chinese population.

One unanticipated finding is that respondents who frequently sought online health information were more likely to be middle-aged or older adults. This result deviated from the bulk of previous studies, which showed that younger age groups preferred the internet as a source of health information [17,20,23]. Regardless of sources, however, individuals with older age are more likely to search for health information [4,29]. Moreover, a study from Hong Kong found that older adults were more frequently exposed to health information from instant messaging such as WeChat [42]. Given that our study participants were those who had already searched on the internet for health information, a possible reason for this discrepancy is that once older adults have obtained access to online health information, they are likely to seek it more frequently than are younger individuals, thus suggesting the strong demand for health information among middle-aged or older adults in China. However, additional research effort is needed to verify this hypothesis further. As the population ages in China, the health department of the government and other health organizations should take the internet into account as an effective resource to intervene with the older adults' health behaviors. Given that digital health is not reaching all seniors equally and that this disparity probably results in differences in health outcomes [23], the skills and knowledge of older adults should be reinforced so that more of them can use and benefit from online health information. We also found that the married group had a higher proportion of frequent seekers of online health information, suggesting that married respondents might also seek health information for their family members. A study among German older adults found that internet users were more likely to be married or with a partner [46]. Another study revealed that middle-aged adults were most likely to use the internet to search for information about a condition of a loved one [47]. The association between marital status and the frequency of OHIS may coincide with the association between age and the frequency of OHIS, which may also mean that older people seek out health information for themselves as well as for their partners [47]. Therefore, meeting the health information needs of older adults (eg, information on medical concerns and TCM) is beneficial not only for themselves but also for their partners.

Health science popularization was the most searched for type of online health information among Chinese respondents, and medical concerns was the least searched for type of information. Conversely, earlier literature mostly reported that medical information was the most searched for type of online information [19,30]. This discrepancy may have several causes. On the one hand, the cultural differences between China and other countries, especially Western countries, might have played a role. In recent years, the National Health Commission of China has encouraged the dissemination of health science popularization information in various ways [45]. The increasing popularity of social media and the ever-growing number of official accounts of health science popularization might have attracted many Chinese netizens to follow such information. For instance, by comparing Americans and Hong Kongers, one study revealed that the latter were more likely to trust and use information from social websites [48]. On the other hand, only a minority of respondents in our study had a chronic disease (995/5149, 19.32%) or reported illness in the past 12 months (1074/5149, 20.86%), but they were found more likely to seek information about medical concerns. In addition, the results also showed that respondents over 60 years of age were more likely to seek information about medical concerns, but only 14.29% (736/5149) of the study participants were over 60 years old.

Consistent with previous studies, our study confirmed that people facing health challenges preferred medical information rather than information on healthy behaviors [10,32], which indicated that individuals with more health risks were more eager to improve their current health status. Therefore, people's preferences for health information may be influenced by distinct motivations [49]. More research needs to be conducted to understand Chinese people's motivation in searching for OHIS. Information on healthy behaviors was found to be more likely to be sought by female or better-educated respondents, which was broadly in line with previous studies [50-52]. Our study also found that single respondents were more likely to seek information on healthy behaviors. The sociodemographic differences in preferences for online health information highlight the importance of distinguishing online health information seekers when tailoring and presenting needed information to targeted users.

Information on TCM was more likely to attract attention from older adults, especially older women with chronic diseases. A cross-sectional study focused on older adults in Shanghai indicated that females were more likely to trust and use TCM [53]. Another study showed that having chronic lung disease

was significantly associated with higher TCM practitioner utilization [54]. Indeed, having a chronic condition was identified as one of the main factors that induced people to use TCM in China [55]. As the significant factors found in our study were consistent with those in several previous studies, the preference for online health information about TCM might partly reflect the preference for the use of TCM. Our findings also showed that 37.5% of the respondents had sought TCM information, while a study investigating OHIS behavior of Chinese college students reported that only 15.6% sought TCM information online [44]. Given that TCM is widely accepted and used among the middle-aged and older Chinese population [55], along with the advantages of online health information mentioned before, we believe the provision of TCM-related information on the internet may promote the use of TCM and improve the management of chronic disease in China.

Limitations

Our study has several limitations. First, the content about the motivation for OHIS (eg, for self-care, treating families, and improving lifestyles) and health information sources on the internet (eg, social media and professional websites) were not surveyed, thus resulting in fewer details on the OHIS behavior of Chinese internet users. Second, differences in online health information type classification made our results difficult to compare with those of previous studies. Finally, the research from which this study originated was implemented in 2018. The degree and diversity of internet use has grown since the beginning of the COVID-19 epidemic in 2020. As internet hospitals [56,57], health quick response codes, and antiepidemic science popularization online have been developed and used during the pandemic, the penetration rate of online health information users, especially online medical service users, continues to increase [33]. In addition, the status quo of OHIS in China needs to be further investigated in future research.

Conclusions

This study enriches the current research on the OHIS behavior of the Chinese population. Furthermore, it presents additional knowledge that providers of online health information, government health departments, and other organizations can use. The significant factors found in our study highlight the necessity of identifying the characteristics of the typical online health information users in China, especially age, gender, education level, marital status, and health status, when targeting and developing health interventions by offering health information on the internet. Those who provide health information online should be aware of the needs of specific population groups so that targeted strategies to promote health are presented appropriately.

Acknowledgments

This study was funded by the National Natural Science Foundation of China (#71734003 and #72074087). The funder had no role in the study design; collection, analysis, and interpretation of data; writing of the manuscript; decision to publish; or preparation of the paper.

Authors' Contributions

ZHX, YT, and ZL designed this study; ZL coordinated with the local government and organized the process of data collection; LZ assisted ZL to complete the data entry and quality control; ZHX analyzed the data and drafted the manuscript; YT, ZY, and WCX helped to interpret the results and modified the manuscript, LZ critically revised the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The onset of the COVID-19 pandemic and the consequent "infodemic" increased concerns about Twitter's role in advancing antivaccination messages, even before a vaccine became available to the public. New computational methods allow for analysis of cross-platform use by tracking links to websites shared over Twitter, which, in turn, can uncover some of the content and dynamics of information sources and agenda-setting processes. Such understanding can advance theory and efforts to reduce misinformation.

Objective: Informed by agenda-setting theory, this study aimed to identify the content and temporal patterns of websites shared in vaccine-related tweets posted to COVID-19 conversations on Twitter between February and June 2020.

Methods: We used triangulation of data analysis methods. Data mining consisted of the screening of around 5 million tweets posted to COVID-19 conversations to identify tweets that related to vaccination and including links to websites shared within these tweets. We further analyzed the content the 20 most-shared external websites using a mixed methods approach.

Results: Of 841,896 vaccination-related tweets identified, 185,994 (22.1%) contained links to specific websites. A wide range of websites were shared, with the 20 most-tweeted websites constituting 14.5% (27,060/185,994) of the shared websites and typically being shared for only 2 to 3 days. Traditional media constituted the majority of these 20 websites, along with other social media and governmental sources. We identified markers of inauthentic propagation for some of these links.

Conclusions: The topic of vaccination was prevalent in tweets about COVID-19 early in the pandemic. Sharing websites was a common communication strategy, and its "bursty" pattern and inauthentic propagation strategies pose challenges for health promotion efforts. Future studies should consider cross-platform use in dissemination of health information and in counteracting misinformation.

KEYWORDS

COVID-19; agenda setting; antivaccination; cross-platform; data mining of social media; misinformation; social media; Twitter; vaccinations; vaccine hesitancy

Introduction

Misinformation over social media contributes to the global growth in vaccine hesitancy. The World Health Organization (WHO) defined vaccine hesitancy as the "delay in acceptance or refusal of vaccines despite availability of vaccine services" [1] and declared it as one of the top 10 global health challenges in 2019, just before the outbreak of COVID-19 [2]. The "infodemic" that ensued as a response to the pandemic enhanced concerns about the rise of vaccine hesitancy in the 21st century [3] and about the key role that social media play in dissemination of vaccine-related misinformation [3]. Vaccine hesitancy discourse on social media does not represent just individual behavior. These messages are often part of concentrated disinformation efforts, intentionally promoted by nationalist right-wing politicians [4] and specific antivaccination leaders and "celebrities" [5,6]. Researchers also documented the efforts of foreign governments aiming to destabilize democratic processes by eroding the public trust in social institutions, including public health sources and the mainstream media [7-9]. With the COVID-19 pandemic, an increase was documented in the volume of misinformation on social media, including antivaccination propaganda [3,10-14]. Early in the pandemic, public health officials were concerned that the pandemic and the response to it led to worries about a global decrease in access to and acceptance of childhood and other vaccinations. In addition, public health efforts centered on developing a vaccine as a central strategy for ending the pandemic. Therefore, public trust in the safety and efficacy of vaccinations was considered paramount. Examining discourse on vaccination on social media is key to understanding public sentiments and to identifying the specific strategies used by different users, including antivaccination advocates, to erode trust in vaccinations.

Twitter has documented importance in setting the public and political players' agendas [15], including in vaccinations [16,17]. According to agenda-setting theory [18], issues that are presented in the media frequently and prominently gain perceived salience by audiences. This salience is important as it impacts political agenda and policy making. According to Langer and Gruber (page 314) [19], "Unless an issue gets into the political agenda, it will not be discussed, debated in the legislature or acted upon by the government...news coverage is an important factor in making policy change more likely." The theory was created to describe processes of *traditional media*, and specifically of legacy news. Traditional media, or *old media*, refer to the centralized mass media institutions that predated the information age, including print, television, radio broadcasting, studio-produced movies, and large advertising firms, among others [20,21]. In contrast to traditional media communication that was based on one-way technologies, new media are based on interactive and largely decentralized computer technologies [22], with the internet as the delineating telecommunication network [23].

Contrary to predictions about the death of traditional media in the age of the internet, and particularly following the rise of social media, studies indicate that they remain important. Traditional media have documented synergy with social media that amplify their mutual impact on the agenda in intermediate agenda-setting processes [19]. Research on the role of mass media during pandemics is fragmented, but a recent study that used computational methods in exploring the role of the media in covering pandemics revealed limited coverage of governmental health sources and frameworks [24]. This media coverage is important in influencing community behaviors. For instance, a study of COVID-19 coverage and behavior in Italy showed that the frames used by the news media influenced changes in community mobility significantly more than the effect of the number of daily death reports [25]. Moreover, whereas the most common source type for COVID-19 information seeking online was media outlets followed by governmental sources, governmental sources were the most likely to meet medical benchmark criteria for quality [26].

Studies on Twitter's role in political agenda setting revealed an intermediate effect, in which the agendas of traditional media and Twitter were dissimilar, but exerted mutual influences [15]. However, past studies did not examine such processes in the context of vaccination-related tweets. Due to Twitter's role in spreading health information and misinformation [27], understanding vaccination-related content and agenda-setting processes on this social platform can advance public health research and knowledge and inform future interventions.

Studies that used surveys to examine individual beliefs and intentions yielded important information on how audiences make sense of novel vaccines in the face of emerging pandemics, including their use of mental frameworks from previously known vaccines [28]. However, surveys are limited due to human recall and by access to participants. It is, therefore, pertinent to analyze the content and dynamics of social media that individuals create, share, and consume. New computational approaches to analyzing big data allow for analysis of communication about vaccination over social media in unprecedented ways [29-33].

Several studies documented the role of Twitter in disseminating vaccine-related misinformation prior to the current pandemic [8,34-38]. However, few studies examined patterns of this discourse. Notably, Twitter discourse about vaccination was reported as featuring heterogeneous conversations that were not dominated by particular subjects, sources, or users. Information sources that were tweeted frequently included health-specific sites, national media, medical organizations, and digital news aggregators [16]. A more recent COVID-19–related study [13] revealed that the largest single topic of Twitter conversations included comparisons between COVID-19 and influenza. Propagation of misinformation was observed in both previously known and new vaccine-opposing sources [13]. The study established that known sources of vaccine communication

continued to engage in the topic early in the pandemic. However, it was limited to analysis of tweets that were tweeted over the course of one day. To get a more holistic picture of these conversations, it is important to examine communication about vaccination as part of Twitter's COVID-19 discourse over extended time frames.

An additional lacuna in research on vaccine-related communication on social media involves its focus on single social media platforms. Research documented that most social media users use multiple media sources and social media platforms [39], and often go back and forth between different platforms [40]. It is, therefore, important to explore cross-platform use. Analysis of links to websites and the website domains that are shared on tweets can provide information about such cross-platform use and spread of information sources. Specifically, including a URL in a tweet allows readers to link to the website. For instance, most tweets that responded to misinformation with cross-platform links during Hurricanes Harvey and Irma focused on debunking misinformation and used news source URLs in their response [41]. Hence, such cross-platform use can serve to share information during a time of crisis. Examination of website sharing in COVID-19 conversations documented both the importance of traditional news sources and the propensity for virality of low-quality sources. Whereas low-quality information sources were tweeted at higher rates compared to high-quality health sources, traditional news sources were shared at a much higher rate than other sources [42]. Moreover, shared websites within COVID-19 Twitter conversations revealed users' political stance [43], thus lending more support to the close links between health and political debates during the pandemic.

These previous studies underscored the potential importance of cross-platform information sharing on Twitter. Analyzing both the URLs and the domains shared as external content on Twitter can provide insights into the type of specific content and information sources included in social media messages about vaccination. Despite this importance, vaccine-related cross-platform use over Twitter received limited scholarly attention. Examination of links to websites shared within vaccination-related tweets early in the COVID-19 pandemic can enrich knowledge by gaining a broader understanding of this communication. Empirical implications of this knowledge include informing strategies for evidence-based vaccine-related message dissemination over social media. Moreover, it can shed light on the role of traditional media in the era of social media, as well as on how social media are used in cahoots with vaccine-related communication and their dynamics over time. Finally, in view of the documented role of inauthentic propagation of vaccine-related content on Twitter [8,37] and in COVID-19–related discussions [44], studies should go beyond typologies of vaccine-related content [45] and understand strategies employed in the spread of this content. New social cybersecurity methods [46] can aid in such examinations.

The goal in this study was to examine website sharing in vaccine-related tweets posted to COVID-19 conversations in the 20 weeks following the declaration of the pandemic. Specifically, we analyzed tweets that were posted from February 1 (two days after the WHO declared the outbreak of COVID-19 to be a Public Health Emergency of International Concern) through June 23, 2020, and sought to examine the magnitude, temporal patterns, and content of websites shared within these tweets. This study will provide unique contributions to theory and practice. Our examined time frame took place prior to the development of the vaccine and the implementation of COVID-19 vaccination campaigns. Therefore, tweets posted during that period can indicate the degree to which vaccinations were included in COVID-19–related discourse from its inception. It will also reveal the information sources that were promoted through cross-platform link sharing. These findings have the potential to indicate the effectiveness of official health sources in leading the agenda as health information providers and the prominence of vaccine-opposing sources. It can also uncover some of the tactics of the vaccination-opposing movement over time and in response to this new, unexpected, global health threat. This understanding is important for advancing theories about the role of social media in public health crises, as well as for informing future policies, interventions, and dissemination of health information to address audiences' informational and emotional needs.

Given the importance of vaccination-related discourse and website sharing within COVID-19 Twitter conversations, including an understanding of the sources of vaccination-related information and their spread, we posed the following research questions.

First, as this is, to our knowledge, the first study to examine external content sharing in the context of vaccination in early COVID-19 conversations, we were interested in understanding the magnitude of external content, the degree to which vaccinations were featured in conversations about COVID-19 early in the pandemic, and the prevalence and dynamics of website sharing within these tweets.

Therefore, we posed the first research question: What are the prevalence and dynamics of vaccination-related tweets, including website sharing, posted between February 1 and June 23, 2020, as part of COVID-19 conversations, as evident in the number of these tweets over time?

We were further interested in learning about agenda-setting processes that are demonstrated in this relatively new social media strategy of information source promotion. As websites' domains, such as television networks, vlogs, or individual social media accounts, represent specific information sources, we aimed to learn about these sources and their characteristics. Specifically, in view of the importance of information sources in public health communication, we sought to identify the sources of the websites that were shared most prominently in the early months of the pandemic in tweets about vaccination that were posted to COVID-19 Twitter conversations.

Therefore, the second research question was posed: What are the characteristics of the 20 most-shared website domains?

In addition to the information sources, we were interested in exploring the content of the most-shared information, as evident in the 20 most-tweeted websites in our data set. The prominence of these websites can stem from users being activated by the content and their desire to share it. However, specific spread

strategies and coordinated efforts might also drive this prominence. Therefore, we wanted to examine both the content of the websites and the specific information that was shared in this cross-platform modality, as well as their propagation.

Therefore, the third research question was posed: What characterizes the content and spread of the 20 most-shared websites?

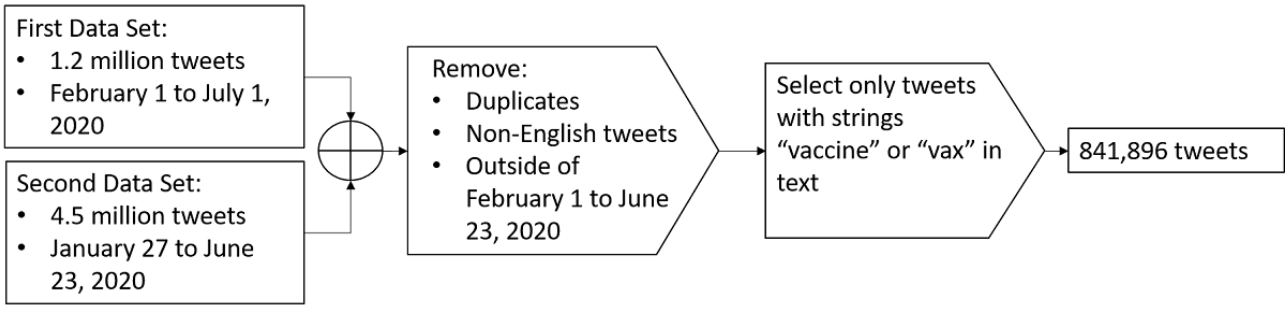
Methods

Data

The analysis encompassed two different data sets of COVID-19–related tweets. The first data set was based on a collection of tweet IDs gathered using general COVID-19–related keywords, such as "coronavirus" and "Wuhancoronavirus" [47]. We used "hydration" [48], a process of gathering all the pertinent information about each tweet into the JSON format file [49] via the Twitter search application programming interface (API) [50], on all of these tweet IDs. This process only populated data from tweets that were available on Twitter at the time of hydration and would exclude banned users or deleted tweets. This data set had around 1 million tweets. The second data set included approximately 4.5 million COVID-19–related tweets collected from January 29 to June 23, 2020, using Twitter's streaming API [51,52]. Since these tweets were collected in a streaming fashion, as they were tweeted, it allowed for analysis of some tweets that were otherwise no longer available on Twitter.

Both data sets were then filtered to include only the dates of overlap (February 1 to June 23, 2020) and to remove any duplicated tweets across the data sets. We then filtered the data to include only English-language tweets. Given our interest in tweets about vaccination, each data set was filtered using the substrings "vax" and "vaccin." This process ensured that the tweets included in our analysis referred to vaccinations. The resulting data set contained 841,896 English-language tweets. Since our focus was on analyzing content available to users rather than the identity of users, we did not attempt to distinguish between human users and machine accounts (ie, bots) [53]. Figure 1 displays a graphical flowchart for the data selection and exclusion process.

Figure 1. Data set combination, filtering, and exclusion process.



URL Extraction

We first extracted the website URLs from the JSON "entities" object of each tweet in order to get the original URL rather than the version automatically shortened by Twitter. URLs that were still shortened were unshortened to their original form using an API [54]. To preprocess the URLs for analysis, we then removed all URL query terms from all domains.

Content Analysis

In addition to computational methods, mixed methods content analysis was conducted in analyzing the 20 most-tweeted websites to identify the source of the websites and their content. First, the sources of the 20 most-tweeted URLs and the dates they were posted were recorded. The content of the 20 most-tweeted URLs was coded using inductive qualitative methods using the constant comparative method [55-57]. This design, which prioritized quantitative methods, is consistent with an *explanatory sequential* design. This design involves implementing quantitative research methods first, followed by qualitative methods, with the aim of explaining the quantitative methods [58]. Mixed methods research is particularly appropriate in studying complex social phenomena, and this approach was appropriate, as the quantitative approach was not deemed sufficient [58-60]. The qualitative research approach is suitable for exploratory studies when researchers are unable to use theory to produce hypotheses or theoretical-driven prediction [61].

The qualitative analysis followed a multistep iterative process. A coauthor with expertise in mixed methods research created initial codes and recorded memos. The initial coding involved line-by-line detailed reading of the data, aimed at understanding the different views and actions described in the different URLs and approaching coding in an inductive manner while remaining open to different potential theoretical directions emerging from the data [62]. During the second phase of the analysis, focused coding was conducted. The focused coding entailed coding of the significant and frequent themes that emerged during the initial coding. Focused coding was helpful in synthesizing and conceptualizing the data and the research [62], while also remaining cognizant of the different sources generating the content. Comparisons of statements and incidents were noted within and across the different URLs. At the second stage, previous research and categorizations were considered in addition to the texts at hand, and these informed the categories of the URLs' framing. The first category included content that overtly advanced doubts about at least one of the following: vaccines' efficacy, vaccines' safety, and the motives of those who fund, develop, and/or test them (ie, vaccine-opposed). Conversely, the second category captured content that featured the efficacy and/or safety of COVID-19 vaccines. The third

category included content that focused on advances in development of vaccines, including news on the development of specific vaccines and related scientific breakthroughs. In this third theme, coders also annotated whether the advancements that were reported were based on meaningful developments or whether they reflected anecdotal information and unfounded claims. The fourth category related to content that highlighted political aspects of vaccination, including portraying political processes as influencing vaccine development and availability to the public. This political content was further coded to capture whether vaccination was, in fact, the focus of the overall content. In addition, the coders noted whether content in any category could have increased distrust in vaccination by using implicit cues that casted doubts on the integrity of the process, those developing vaccines, or decisions and decision makers. For instance, a news story that announced that a COVID-19 vaccine was developed in 3 hours was coded as including "vaccine-opposing" sentiment, as it was judged to be increasing concerns about a vaccine that was developed so rapidly and, therefore, likely to reduce trust in its safety and efficacy.

In the third stage of the qualitative analysis, the overall theme of "politicizing vaccination" emerged. A graduate student with training in qualitative research followed this process independently by coding each of the 20 URLs using inductive coding first and then coding by the previous categories. They then provided a quotation from each URL to support the coding. As a final check on consistency of results, we evaluated the intercoder agreement for all of the URLs between the initial coding and the third stage of qualitative analysis. The use of constant comparative analysis [62] helped us develop our analytical categories, including attention to contradictions.

Twitter Spread Analysis

To examine the particular Twitter spread strategies that were used to propagate the most-tweeted websites, we have applied social cybersecurity methods to identify coordinated link sharing and flooding (or spamming) of the websites by tweeters [46,63]. Specifically, we analyzed all the tweets that shared the top 20 most-tweeted websites. First, we excluded retweets and removed the following text from the remaining original tweets: mentions, URLs, trailing white space, and formatting characters (ie, "\n"). Then, we recorded the number of tweets that included a URL to each website, unique users that tweeted the website, unique texts across all of the tweets that contained the website, tweets that featured a website that were tweeted within an hour of the first tweet of that same website, and nonreply mentions, as well as the range of days between the first and last tweet that included the website.

Results

Overview

Our aims were to understand the magnitude, dynamics over time, content, sources, and spread of websites shared within vaccine-related tweets as part of COVID-19 Twitter conversations. The first research question centered on the prevalence and dynamics of vaccination-related tweets, as well as website sharing posted as part of COVID-19 conversations over time. The analysis revealed that these conversations demonstrated an overall growth in tweets that related to vaccination. It also showed that website sharing had distinct patterns compared to overall tweets about vaccination. As mentioned above, our data set contained a total of 841,896 tweets. As seen in Figure 2, tweets about vaccination spiked in March and again in June. A corresponding spike in tweets that were retweeted was observed in March. In contrast, a more modest increase was observed in March in website sharing, followed by a leveling in April. In addition, sharing websites and the diversity in unique websites shared increased over time, indicating that Twitter users spread more external content from a greater number of sources as the scope and scale of the pandemic increased in the early months of the pandemic.

Our analysis revealed that 1 in 5 of the 841,896 tweets (n=185,994, 22.1%) contained at least one website. A total of 1 in 4 of the 524,998 users (n=128,408, 24.5%) tweeted at least one website. In comparison, only 19.4% (n=163,743) of all tweets contained at least one hashtag, and 23.0% (n=120,699) of users tweeted at least one hashtag. Additionally, 85.2% (n=717,150) of all tweets contained a mention of another user's account (ie, using the "@" symbol to refer to another Twitter account), and 87.4% (n=459,038) of users tweeted at least one mention in a tweet. Of the mentions, only 12.1% (n=87,097) were replies (ie, when a user was directly replying back to the tweet of another user). Figure 3 displays the rates of usage for these different social media artifacts.

A total of 1 out of 5 of the tweets that mentioned vaccination (185,994/841,896, 22.1%) included links to websites. These websites included 11,311 unique website domains. Most domains (n=6962, 61.6%) were tweeted with only one unique website tweeted.

Figure 2. Counts of unique tweets, users, and website domains for all of the vaccination tweets.

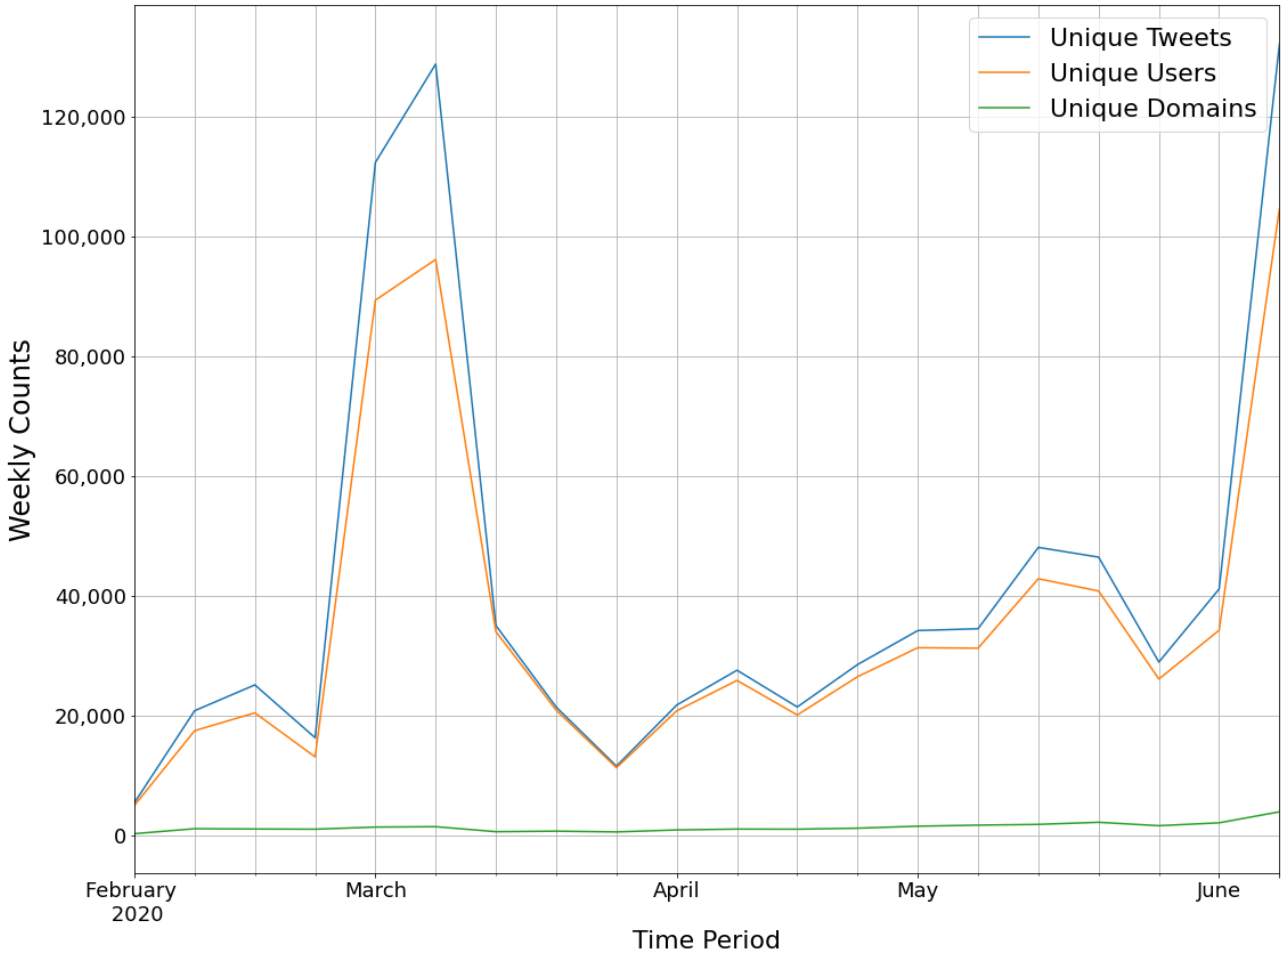


Figure 3. Rates of retweets, hashtags, mentions, and website sharing in all of the vaccination tweets.

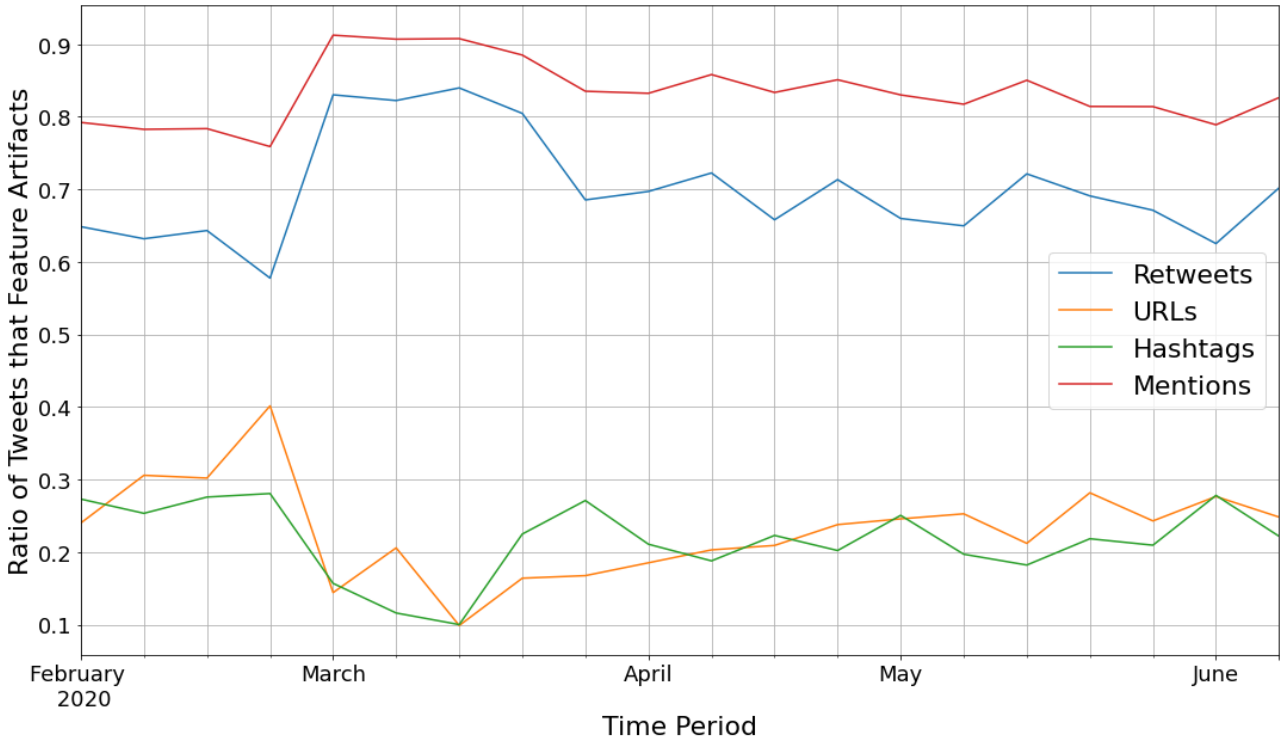


Analysis of Website Domains

Research question 2 explored the 20 most-shared website domains, with a focus on the role of legacy media, social media, and public health sources. As displayed in Table 1 [64-83], the majority (n=14, 70%) of the 20 most-tweeted website domains consisted of traditional news media, including news organizations, newspapers, and television networks. However, the most-tweeted website domain was Raw Story, a US online tabloid that is classified as progressive. Another tabloid, the New York Post, was ranked as the 19th most-tweeted website domain. The only social media platform included was YouTube, which was the third most-tweeted domain. Similarly, the only official governmental and/or health source was the US Centers for Disease Control and Prevention (CDC), which was ranked as the 20th most-tweeted website domain.

Websites associated with these 20 domains constituted 8.25% (n=6244) of all of the 75,642 websites tweeted. Two of the most-tweeted website domains—Raw Story and The Jerusalem Post—had most of their tweets from just one news story each. Notably, the top two most–individually tweeted websites were in this category, indicating that "viral" tweets can increase a domain's popularity.

On average, each domain had 4.26 (SD 24.4) websites per domain, with a mode of 1 website, indicating that many of the domains only ever had one website associated with them. In total, 62.7% (n=6963) of all domains in the data had only one unique website associated with that domain. An exception was YouTube, which had the greatest number of unique websites of any domain, followed by the CDC website.

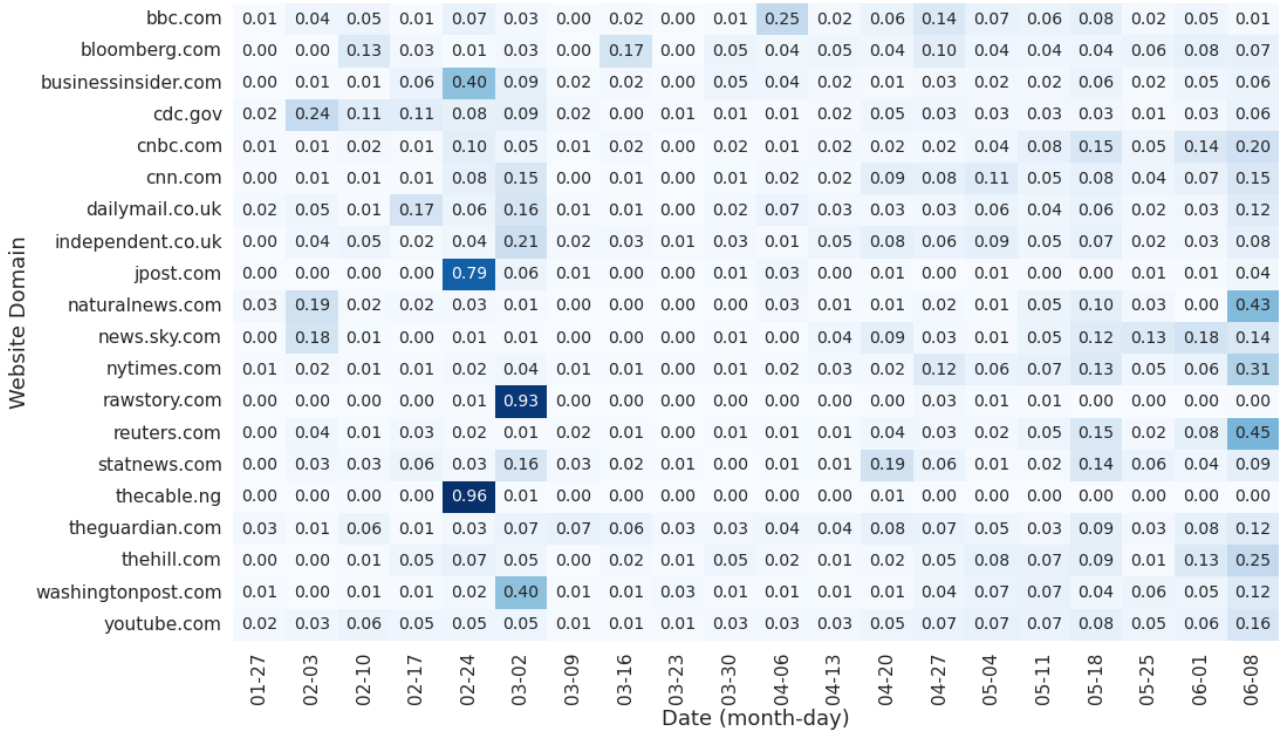
Table 1. Top 20 most-tweeted website domains.

Website domain	Tweets, n	Percentage of all tweets with website URLs that originate from website domain, %	Unique websites per domain[a], n	Type of domain and country of origin
Raw Story [64]	13,261	7.1	101	US online tabloid
Reuters [65]	4347	2.3	577	International news organization
YouTube [66]	4106	2.2	2013	International, US-based social media platform
The Guardian [67]	3167	1.7	364	UK newspaper
The Jerusalem Post [68]	3140	1.7	92	Israeli newspaper
Bloomberg [69]	2374	1.3	173	International, US-based news agency
CNBC [70]	2161	1.2	282	US television channel
The Daily Mail [71]	2102	1.1	291	UK newspaper
CNN [72]	1888	1.0	302	Multinational, US-based television channel
The New York Times [73]	1716	0.9	332	US newspaper
The Cable [74]	1642	0.9	19	Nigerian digital newspaper
STAT [75]	1552	0.8	122	Health-oriented US news website
Business Insider [76]	1447	0.8	203	US financial news website
The Washington Post [77]	1348	0.7	209	US newspaper
BBC [78]	1320	0.7	106	UK public service broadcast organization
Sky News [79]	1301	0.7	147	UK television news channel
The Independent [80]	1280	0.7	172	UK newspaper
The Hill [81]	1270	0.7	152	US newspaper
New York Post [82]	1148	0.6	152	US conservative-leaning tabloid
Centers for Disease Control and Prevention [83]	1139	0.6	435	US government health organization

[a]This is the number of unique websites that originate from the higher-level domain. For example, a news website can have several unique websites representing different news stories that all come from the same single news website domain.

The temporal analysis of the patterns of the 20 most-tweeted domains documented three distinct peaks of domain usage, as presented in Figure 4. The peaks included The Jerusalem Post and The Cable from February 20 to 24 and Raw Story on March 4. These spikes in domain usage were the result of tweeting a particular website from that domain. Specific stories that became "viral" underlined domain activity. Tweeted domains were typically shared over one week, or even one day. This pattern can, therefore, be characterized as "bursty," as opposed to having different websites associated with specific domains tweeted consistently across longer periods of time.

Figure 4. The 20 most-used domains overall by the number of tweets featuring each domain. Counts are normalized within each time period (week).



In contrast to the majority of the domains that were characterized by "bursty" activity, some domains, such as YouTube and The Guardian, had consistent usage over time. The 20 most–persistently tweeted domains are summarized in Table 2 [65-67,69-73,75-78,80,82-88].

As Table 2 shows, YouTube was the most–persistently tweeted domain. Out of the 20 domains, the 12 (60%) that were tweeted most persistently over time were news organizations, and 2 (10%) included official US federal health organizations. Both the CDC and the National Institutes of Health (NIH) were included in this list, indicating the persistent sharing of content of these domains. Similarly, in addition to YouTube, Instagram was a second social media platform that made the list, as well as Google.

Table 2. The 20 most–persistently tweeted website domains.

Home domain	Type of domain	Days that a website from the domain was tweeted at least once, %
YouTube [66]	Social media platform	77
The Guardian [67]	UK newspaper	76
The Daily Mail [71]	UK newspaper	72
Centers for Disease Control and Prevention [83]	US federal health organization	71
CNBC [70]	US television news channel	71
The New York Times [73]	US newspaper	70
Reuters [65]	International news agency	70
Bloomberg [69]	US business newspaper	67
STAT [75]	Health-oriented US news website	66
Business Insider [76]	US financial news website	65
Instagram [84]	Social media platform	65

Analysis of Websites

The third research question explored the content and dynamics of spread of the 20 most-tweeted websites. Table 3 [89-108] displays the 20 most-tweeted individual websites within the data.

The 20 most-tweeted websites comprised around 13% of all the tweets containing websites (n=185,994) in the data set. The most-tweeted website, which was by Raw Story, accounted for almost half of these, with 6.6% (n=12,201) of the overall number of tweets containing websites. As Table 3 indicates, the majority (n=11, 55%) of the 20 most-tweeted websites were tweeted by traditional media sources or news organizations, and the sources of 6 other websites (30%) were tabloid and digital-only newspapers and websites. One fake news website, a petition website for right-wing causes, and another domain were the sources of three more websites. The latter two were the only nonnews sources among the top 20 most-tweeted websites.

As an overarching theme, the qualitative analysis indicated that the content of these websites demonstrated politicization of vaccination. The single most-tweeted website was by the digital tabloid Raw Story, which described Republicans blocking the COVID-19 bill to avoid posing limits on pharmaceutical companies' charges for the vaccine. This politicization of vaccination was evident in other websites. As seen in Table 3, 9 out of 20 (45%) websites (#1, #4-6, #8, #9, #15, #17, and #20) focused on political aspects of the vaccine and its development. In 2 of them (#6 and #15), vaccines were mentioned merely as a minor issue. Moreover, 2 of these featured cues that could increase, or were related to, distrust in vaccination. These included a Fox Business story (#14) claiming that a vaccine was developed in 3 hours in collaboration with China and was funded by the Gates Foundation, and a BBC News story (#18) that reported on comments by a top health official in France that called to test the COVID-19 vaccine in Africa. Although the WHO was cited as denying these comments, the story, overall, featured distrust in vaccine development, provided direct citations of celebrities that responded to the possibility of testing in Africa, and referred to controversial testing of HIV medications on prostitutes in Africa. Similarly, the STAT story (#20) that covered Dr Rick Bright's departure from directing the Biomedical Advanced Research and Development Authority, without stating a reason for his departure, could have led audiences to have reduced trust given their portrayals of plots that left much to the imagination. Other frames included criticism of then-President Trump's competence in combating the pandemic following comments or decisions that he made, including suggesting using a flu vaccine to prevent COVID-19 (#8 and #15) and pulling out of a national effort to speed vaccine development (#17).

Table 3. The 20 most-tweeted websites.

Rank	Title of webpage	Source; type	Topic	Coding	Tweets, n	Date in 2020
1	GOP blocking coronavirus bill — because it limits how much drugmakers can charge for a vaccine: Report [89]	Raw Story; US progressive-leaning tabloid	Republicans block coronavirus bill because it limits how much pharmaceutical companies can charge	4. Political focus: the main focus is on the political processes and motives related to vaccination	12,201	March 3
2	Israeli scientists: 'In a few weeks, we will have coronavirus vaccine' [90]	The Jerusalem Post; Israeli newspaper	Israeli scientists are close to developing a COVID-19 vaccine	3b. News on vaccine development that proved unfounded	2780	April 13

[a]WHO: World Health Organization.

Of the 9 (45%) websites that covered news about advances in vaccine development, only 2 of the developments that were covered proved founded (#7 and #16 covered AstraZeneca and Moderna, respectively). TIME reported on the rollout of Moderna vaccine clinical trials (#16), stood out as the only website that provided medical framing of the content, and included explanations regarding the vaccine's mechanism of using messenger RNA (mRNA). In contrast, 7 (35%) stories covered advancements that, at the time of analysis, were unfounded or did not come to fruition (#2, #3, #11-14, and #17). Notably, 3 of these included news on development of an Israeli vaccine that allegedly was 3 days away from the finish line and 90 days from approval. This information came from the Israeli Science and Technology Minister, and the sources were an Israeli newspaper in English and a Nigerian digital newspaper. Of the coverage of vaccine development that did not reach the market, only the report about the Novavax vaccine (#11) included information about the phase of the trial. The report on Greffex (#12) included some scientific information on the technology of the vaccine and a timeline that emphasized the lengthy process.

Only 1 (5%) website expressed explicit opposition to vaccination (#10). It consisted of a petition to block mandatory vaccination, which was included in a website domain that promoted petitions for conservative, right-wing causes. Similarly, only 1 (5%) website (#19), by Business Insider, a US online media company, provided provaccination framing by positioning vaccines as the way to end the pandemic.

The Twitter propagation statistics of some of the websites show attempts at spreading the websites through inauthentic means. Specifically, a high percentage of the tweets that included links to The Cable website (#3) and to the STAT website (#20) had a high percentage of retweets only, an indicator of spreading by flooding or spamming of a website on a social media platform in an effort to get the website artificially trending and, consequently, to give more exposure to other social media users. In addition, the text of over half of the tweets that included the 20th most-tweeted website, STAT, was identical, which is indicative of coordinated, inauthentic link sharing. Evidence of such coordinated inauthentic link sharing was also present in tweets that included links to the Life Petitions website (#10), which also had relatively few unique tweet texts compared to the number of tweets of the website and the number of unique users that tweeted that website.

Discussion

Principal Findings

This study is the first to examine the prevalence, dynamics, and content of websites shared in vaccination-related tweets. We focused on tweets that were part of COVID-19 conversations over 20 weeks, following the WHO's announcement of COVID-19 as a pandemic until June 23, 2020. The main finding of this study is the use of a cross-platform strategy for promoting politicization of COVID-19 vaccination well before the rollout of these vaccines. This politicization of content, promotion of unfounded "advancements" in vaccine development, and coverage of unsettling political plots that left much unexplained are likely, in turn, to contribute to a decrease both in the public's knowledge of the science behind vaccine development and effectiveness and its trust in vaccination. Future studies should investigate the impact of exposure to this coverage.

Whereas previous research on the topic typically focused on the degree to which Twitter discussions reflected specific vaccine sentiments, our study indicates the politicization of the topic, which was shared by both progressive-leaning sources and content (eg, the Raw Story online tabloid) and legacy media (eg, The Washington Post) as well as by right wing–leaning sources, including legacy media (eg, The Jerusalem Post) and fake news sources (eg, True Pundit).

The websites that were tweeted represented diverse communication sources, with traditional news media making the top shared domains. Both the prominence of legacy news media in websites shared and the emergence of nontraditional media outlets, such as tabloids, vlogs, and other social media, exemplify processes of intermediate agenda setting in the new media environment. These processes were previously documented in political content [15], and this study extends them to this health context. Along with "rehashing" legacy news content, as was evident in the majority of the sources shared, Twitter has also given rise to nontraditional, digital-only content. These nontraditional sources typically reached salience in terms of website sharing when a story they published became viral. For instance, Raw Story, a digital tabloid [109], featured the most-tweeted website in its story of Republicans blocking a bill in order to protect pharmaceutical companies from limitations on vaccine-related profits. The salience of nontraditional sources demonstrates an intermedia agenda-setting process that provides a platform for individuals who were previously blocked from entering the elite spaces to disseminate their messages [15,110]. Twitter "has become an important platform for eloquent and media-savvy people outside the traditional political, economic, or academic elites" [15]. Our study extends this line of research to intermedia agenda setting in vaccine-related conversations. The content of the URLs shared over Twitter represented, to a great degree, an alternative agenda. In this agenda, stories that advanced political motives that went beyond the issue of vaccination were featured prominently. They represented both opposition to Trump's US presidential administration at the time of data collection and right-wing populist views, including vaccine-opposed content. Similarly, while some of the news coverage about vaccine development stood the test of time, a

few stories that reported on vaccine advancement were inaccurate, such as the Israeli development of a vaccine. This type of coverage is likely to increase public doubt regarding news in general and scientific news in particular. Agenda setting by non-legacy media sources has both theoretical and practical implications for public health efforts. Unfortunately, in this context, these sources are also used by Twitter users associated with misinformation, conspiracy theories, and vaccine opposing messages.

In this new media environment, official health sources like the CDC and the NIH have had some success in disseminating their information, indicated by their inclusion in the lists of the most-tweeted domains (ie, CDC) and the most–consistently shared domains (ie, CDC and NIH). This is important, as governmental sources have been shown to provide credible, high-quality information compared to other sources, including the media [42]. However, producing the most-tweeted unique websites, in other words, "becoming viral," proved more challenging, at least in the context of cross-platform sharing. The importance of trustworthy sources that provide scientifically sound information to the public is heightened at a time of a pandemic. Our findings revealed that the CDC had a salient role in the vaccine conversation on Twitter as the 20th most-tweeted website domain in our sample. The CDC was also second only to YouTube in providing a large number of different websites, which indicated that it provided diverse information that was deemed important by Twitter users who felt the need to share this information over Twitter. In comparison, no NIH-specific unique link to a website was included in the top 20 most-tweeted websites, but its domain was one of the 20 most–consistently tweeted domains. Although it is also possible that the CDC, NIH, and other public health sources exuded additional influence via links to traditional media shared over Twitter, such influence was not evident in the 20 most-tweeted websites.

Given the prominence of traditional media with their established gatekeeping, checks, and balances, it is not surprising that most stories shared in websites did not include obvious vaccine-opposing content. This finding is consistent with previous content analyses of tweets, reporting that vaccine-opposing content comprised a minority of the overall discussions on Twitter [16,111,112]. While this is encouraging from a public health perspective, it is important to remember that the impact of misinformation might still be significant, particularly in view of the social network nature of Twitter that often broadcasts to specific groups [36] and the need for herd immunity in maximizing the effects of vaccinations [112].

Our findings also point at the salience of international content. In addition to large, global media institutions like Reuters or CNN, and US-based newspapers and tabloids, some British newspapers, most notably The Guardian, were heavily tweeted in our data. Moreover, both the Israeli newspaper, The Jerusalem Post, and the Nigerian digital newspaper, The Cable, were included in list of the most-shared websites thanks to the viral story about an alleged Israeli COVID-19 vaccine. Similar to other smaller media organizations that were heavily tweeted, these two foreign, small newspapers demonstrated the opportunity of small players to advance their agenda in this new media environment by becoming "viral" through provision of sensational narratives. In the case of the Nigerian newspaper, inauthentic targeted attempts to spread this story contributed to its popularity, demonstrating the importance of deliberate manipulation in the new social media environment. It is likely that this rapidly changing environment, characterized by a "bursty" pattern of website sharing and the need to continuously provide new and sensational narratives as well as information and inauthentic spread strategies, poses unique challenges for governmental and official health sources. In addition, social media cross-platform sharing was evident in the prominence of YouTube as the third most-shared domain, as well as the most–consistently shared website over time. Future studies should further explore the content included in the different platforms, as well as users' interpretation of this content and their motivation to engage in sharing it.

Finally, these findings are important in revealing patterns of propagation of this external content and these links. Despite the known presence of bots and other inauthentic propagation strategies of vaccination-related content on Twitter [8,37], and regarding COVID-19 [44], previous studies typically focused on analyzing the content of tweets in attempts to identify misinformation [45]. Such studies are important in advancing the knowledge and theories concerning the content to which users are exposed. However, the propagation strategies of this content should also be understood and considered. For instance, interventions to block such content should consider the propagation strategies. Given silos in current studies, social cybersecurity methods, to our knowledge, were not previously applied to vaccination-related discourse. Our study, therefore, is important in providing an opportunity to explore propagation of vaccine-related content over Twitter by spread of external content.

These results have important implications that can inform interventions, policies, and future research. At the most basic level, our findings indicate that sharing links to websites is a common strategy in Twitter conversations on the topic. In fact, shared websites were more common than hashtags, which have become synonymous with Twitter. Hashtags are frequently researched due to their use in creating discussion communities on social media [113,114]. It is, therefore, significant that in the context of the vaccine discussions we examined, external websites were featured as frequently as hashtags.

Our analysis also revealed that websites were tweeted in a "bursty" pattern, indicating heterogeneity of a large number of sources, stories, and topics shared. The results regarding the increased number and diversity of external links shared at the time of data collection are consistent with other studies that documented the ebbs and flows of the "infodemic." A recent study suggested that this increase was motivated by both uncertainty and state-sponsored propaganda [115]. COVID-19 is used as vector to propagate misinformation and disinformation by foreign governments. In addition, it provides a highly uncertain information environment in which fact-checking is difficult. The authors emphasized the importance of constant, reliable medical information provided by governmental sources. While we concur with this suggestion, it is important to note that our findings also point at the challenges of such public

health response. Given the numbers, diversity of sources, and dynamics of the topic that are constantly evolving, such response would require significant efforts and resources [115].

Strengths and Limitations

The strengths of this study stem from its analysis of a large data set that was collected at a historically important period. Moreover, we employed a triangulation of computational methods and human coding to study a previously unexplored communication strategy within vaccine discourse on Twitter. However, this study is not without limitations. First, our tweets were collected by searching common vaccine-related keywords and hashtags. While these keywords and hashtags were identified following an extensive literature review and analysis of tweets by multiple research teams, it is possible that some emerging keywords and hashtags were not included. Future studies could apply additional computational methods, such as the Analysis of Topic Model Networks [116].

Additional limitations are grounded in our focus on tweets in English and on a specific time frame. Future studies should expand research to include additional languages and time frames, particularly during and following the rollout of the COVID-19 vaccine. In addition, some vaccine-related tweets, particularly those advancing vaccine-opposing messages, were deleted by Twitter by the time of analysis. Hence, the actual number of antivaccination tweets shared might be higher than what we were able to report, and their content might be somewhat different from what was collected. Moreover, we have focused on vaccine-related tweets that were part of the COVID-19 Twitter conversations. Although our data set is unique in including all related tweets rather than a sample, our findings do not apply to vaccine-related discourse on Twitter that was not part of the pandemic discourse. Moreover, our study focused on the first 20 weeks of the pandemic. Future studies should compare our findings regarding website sharing with similar content following the implementation of the COVID-19 vaccination campaigns globally. In addition, we focused on the content and propagation of the 20 most-tweeted websites and domains, and these findings might not apply to other links shared in this data set.

Conclusions

These findings are important in advancing understanding of website sharing in vaccine-related tweets, its use, and its dynamics. The analysis revealed that Twitter users share websites as part of their vaccine messages in COVID-19 conversations and that some of this sharing revealed inauthentic, deliberate attempts to spread this content. Our data included tweets that were posted in the first 5 months of the pandemic and showed that vaccine-related tweets were prominent in the pandemic-related Twitter discourse from its inception. Future research should examine the following months, as it is likely that with the advances in vaccine development, these conversations have increased in frequency and perhaps included different information sources.

The findings of this study pave the way for future studies that would answer additional questions. First and foremost, future research should expand the scope of this study by examining websites shared after June 2020, especially as new COVID-19 vaccines were approved and disseminated, and as information became available about their safety and efficacy. Given that our findings encompass the period prior to the approval and dissemination of the specific COVID-19 vaccines, they shed light on early communication on the topic rather than the specific risks and benefits of these vaccines.

In view of the global importance of the pandemic and vaccinations, future studies should also expand the scope of analysis to include additional languages other than English. In addition, it is important to consider, measure, and analyze additional aspects and implications of our work. For instance, to date, studies did not explore the impact of visual content on vaccine-related messages over social media. Future studies should expand the scope of this study's analysis by exploring the visual content of vaccine-related tweets, websites, and of YouTube videos on the topic and the visual impact on propagation of the content over social networks. Similarly, future studies should explore the content and propagation of additional URLs in addition to the 20 most-tweeted websites explored in this study.

Finally, we call for hypothesis-driven communication interventions that would not only measure how and why antivaccination messages propagate over social media [117] and attempt to correct misinformation [118], but would also attempt to prevent this propagation and advance scientifically accurate content instead. Such future interventions should not focus on one social media platform, but should instead consider and integrate cross-platform use for message sharing.

Acknowledgments

This research was, in part, funded by the Omar N Bradley Foundation through a General Omar N Bradley Research Fellowship in Mathematics Grant (IC) and was conducted with support from the University of New Mexico Women in STEM Faculty Development Fund (TG). We would like to thank Melanie Catron, Zohar Griffith, Kenneth Hafer, Paulina Majewska, and Rachel Taylor for their help in coding the data.

Abstract

Background: US president Joe Biden signed an executive action directing federal agencies to combat hate crimes and racism against Asians, which have percolated during the COVID-19 pandemic. This is one of the first known empirical studies to dynamically test whether global societal sentiments toward Asians have become more negative during the COVID-19 pandemic.

Objective: This study aimed to investigate whether global societal sentiments toward Asians across 20 countries have become more negative, month by month, from before the pandemic (October 2019) to May 2020, along with the pandemic (incidence and mortality rates) and cultural (Hofstede's cultural dimensions) predictors of this trend.

Methods: We leveraged a 12-billion-word web-based media database, with over 30 million newspaper and magazine articles taken from over 7000 sites across 20 countries, and identified 6 synonyms of "Asian" that are related to the coronavirus. We compiled their most frequently used descriptors (collocates) from October 2019 to May 2020 across 20 countries, culminating in 85,827 collocates that were rated by 2 independent researchers to provide a Cumulative Asian Sentiment Score (CASS) per month. This allowed us to track significant shifts in societal sentiments toward Asians from a baseline period (October to December 2019) to the onset of the pandemic (January to May 2020). We tested the competing predictors of this trend: pandemic variables of incidence and mortality rates measured monthly for all 20 countries taken from the Oxford COVID-19 Government Response Tracker, and Hofstede's Cultural Dimensions of Individualism, Power Distance, Uncertainty Avoidance, and Masculinity for the 20 countries.

Results: Before the pandemic in December 2019, Jamaica and New Zealand evidenced the most negative societal sentiments toward Asians; when news about the coronavirus was released in January 2020, the United States and Nigeria evidenced the most negative sentiments toward Asians among 20 countries. Globally, sentiments of Asians became more negative—a significant linear decline during the COVID-19 pandemic. CASS trended neutral before the pandemic during the baseline period of October to November 2019 and then plummeted in February 2020. CASS were, ironically, not predicted by COVID-19's incidence and mortality rates, but rather by Hofstede's cultural dimensions: individualism, power distance, and uncertainty avoidance—as shown by mixed models (N=28,494). Specifically, higher power distance, individualism, and uncertainty avoidance were associated with negative societal sentiments toward Asians.

Conclusions: Racism, in the form of Anti-Asian sentiments, are deep-seated, and predicated on structural undercurrents of culture. The COVID-19 pandemic may have indirectly and inadvertently exacerbated societal tendencies for racism. Our study lays the important groundwork to design interventions and policy communications to ameliorate Anti-Asian racism, which are culturally nuanced and contextually appropriate.

Introduction

The COVID-19 crisis has brought with it a disconcerting increase in racism against the Asian community. In the early phase of the pandemic (March 2020), a Singaporean international student in the United Kingdom was physically assaulted in central London [1]. This was an unprovoked attack that the perpetrators justified by saying "we do not want your coronavirus in our country." Similarly, a Vietnamese curator in London was dropped from an art exhibition, having been told that her presence alone would increase anxiety to those attending the event. She was told that her Asian ethnicity meant that she would be perceived as a carrier of the coronavirus [2].

In the web space, there has been a rise in vitriol and hate speech toward Asians: L1ght found a 900% growth in hate speech towards Asians on Twitter [3]. In the political realm, barbed appellations—"Chinese Virus" and "kung flu" [4]—from government leaders have equated a *whole* ethnicity with the deadly virus and disparaged them, consequently drawing out a fear of Asians. Moreover, the Pew Research Centre found that 58% of Asian Americans reported that it has become more common for people to express racist or racially insensitive views about Asians than before the coronavirus outbreak [5]. Three in 10 Asian American adults have been subject to slurs or jokes because of their race or ethnicity since the outbreak began. In view of the alarming increase in anti-Asian racism, US president Joe Biden signed an executive order on January 26, 2021, directing federal agencies to combat xenophobia toward the Asian American community in the hope of reversing the 2-fold issue of increasing unemployment and hate crimes [6].

Apart from several cross-sectional studies and numerous commentaries [7-10], there are few empirical studies that have assessed the development of anti-Asian sentiments across the pandemic. Our study is one of the first to track anti-Asian sentiments, month by month, from before the pandemic (October 2019) to during the pandemic (May 2020) across 20 countries. We investigated whether global societal sentiments toward Asians across 20 countries have become more negative month by month from before the pandemic (October 2019) to May 2020, as well as the pandemic (incidence and mortality rates) and cultural (Hofstede's cultural dimensions) predictors of this trend.

We selected Hofstede's dimensions [11] as they are one of the most widely used measures of cultural values, and are relevant to this study for 3 reasons. First, they provide multiple dimensions from which a culture can be understood. Second, they are widely recognized and understood, demonstrating our study's comparability and contribution to prior literature. Third, they are based on a national-level understanding of culture, which has been shown to differ from individual-level culture [12], and therefore compatible with the scope of our study as we observe racial sentiments at the national level across 20 countries.

Hofstede's cultural dimensions [13] are as follows: *individualism* is "the degree to which individuals are supposed to look after themselves or remain integrated into groups, usually around the family"; *masculinity* is "the distribution of emotional roles between the genders (…); it opposes 'tough' masculine to 'tender' feminine societies"; *uncertainty avoidance* is "the extent to which a culture programs its members to feel either uncomfortable or comfortable in unstructured situations"; *power distance* is "the extent to which the less powerful members of organizations and institutions accept and expect that power is distributed unequally."

Our study is significant in 3 ways. Conceptually, we contribute to race relations research by analyzing how an extraordinary event, such as the COVID-19 pandemic, may dynamically influence societal sentiments toward an ethnic group. Second, we extend the field of cultural studies by examining the impact of culture on anti-Asian sentiments across 20 countries during a pandemic. Practically, understanding the cultural underpinnings lays the groundwork for designing policy interventions to reduce it, as studies show the malleability of cultural frames [14]—our study provides the cultural considerations to do this effectively.

We hypothesize that societal sentiments toward Asians have become more negative as the pandemic unfolded from October 2019 to May 2020 (hypothesis 1). Second, we tested the factors associated with the hypothesized rise in anti-Asian sentiments during the pandemic. Most opinion-editorials posited that the prevalence of new cases and incidence of new deaths have been associated with increasingly negative racial sentiments (pandemic hypothesis). However, we argue that racism is more deep-seated and is influenced by culture, history, and exclusionary policies such as the Chinese Exclusion Act of 1882 [15]. Discernibly, sociological scholarship reported that cultural factors such as masculine ideals and individualistic traits are associated with racism [16]. Against this background, we hypothesize that both pandemic variables (COVID-19 prevalence and mortality rates) and cultural variables—measured with Hofstede's cultural dimensions—are associated with negative ethnic sentiments during the pandemic (Hypothesis 2).

Methods

Study Design

Data Set

We used the news on the web corpus [17], the largest cross-cultural database with 12 billion words ingested from over 30 million articles—found in over 7000 web-based newspapers and magazines—across 20 countries in six continents: North America (United States and Canada), Asia (Bangladesh, Hong Kong, India, Malaysia, Pakistan, Philippines, Singapore, Sri Lanka), Africa (Ghana, Kenya, Nigeria, South Africa, and Tanzania), the Caribbean islands (Jamaica), Europe (Ireland

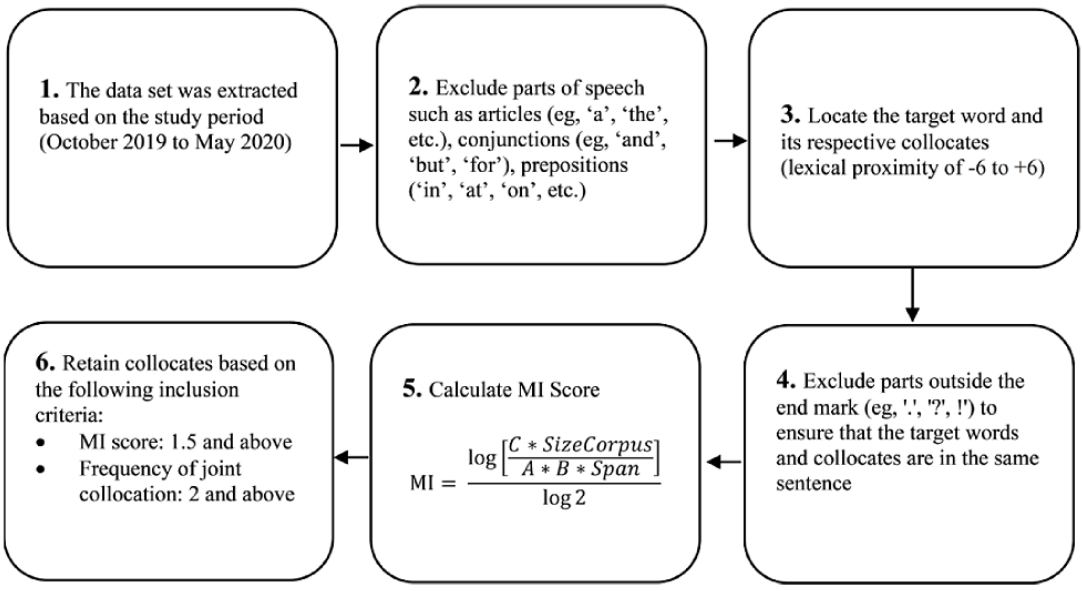
and the United Kingdom), and Oceania (Australia and New Zealand). This data set was created with funding from the National Science Foundation (NSF) and the National Endowment for the Humanities (NEH) to study contemporary language usage in countries where English is mainly and widely used. The dynamic nature of the corpus—with 200 million new words, from 300,000 new articles, added every month—makes it appropriate to study month-by-month change in societal sentiments toward Asians across 8 months, from before the pandemic (October 2019) to during the pandemic (May 2020). Within this study's timeframe, our corpus consists of 1.5 billion words. This data set is appropriate as Cultivation Theory [18] suggests that the large representation of web-based media within the corpus reflects societal perceptions across 20 countries and provides an extraordinary platform to study the global sentiments of Asians. This unprecedented data set further circumvents the ecological fallacy that limits most survey studies that mistakenly draw country-level conclusions from individual-level surveys.

Data Preprocessing

The data set was preprocessed through a 6-step process that aimed at identifying a list of 7 relevant target nouns (*Asian*, *Asians*, *Asia*, *Chinese*, *China*, *Wuhan*, and *Hubei*) and their descriptors (collocates) for sentiment analysis. Figure 1 shows a flowchart for data preprocessing. We generated collocates (ie, words that co-occurred most frequently with each target noun) every month, between October 2019 and May 2020 for each of the 20 countries with the following inclusion criteria: (1) lexical proximity: collocates present within 6 words prior and after the target noun (step 3, Figure 1). Articles such as "the" and "a" were not included in the 6-word lexical span. If the target noun was the first word of a sentence, the collocates from the prior sentence were excluded. (2) Mutual Information (MI) score of 3 and above: collocates had a stronger association with the target noun than with other nouns in the corpus for that country, indicating semantic bonding (step 4, Figure 1) [19]. The MI score estimates word association norms directly from the corpus. It is calculated via sentiment analysis, which shows the MI between collocates and target words. The higher the MI value, the closer the relationship between the collocate and target word. The MI value is calculated using the formula:

where *A* indicates the possibility of the target word *A* appearing, which is calculated by the frequency of the target word. *B* indicates the possibility of the collocate *B* appearing, which is calculated by the frequency of word *B*. *C* indicates the possibility of *A* and *B* appearing together, which is calculated by the frequency of collocate *B* appearing near the target word *A*. "SizeCorpus" refers to the size of corpus or the number of words. Span is the span of words (eg, if there are 6 words to the left and 6 words to the right of the target word, span=12) [log (2)=0.30103]. This is a well-established application of computational linguistics to study stereotypes in other studies [20-28]. The rigorous process culminated in 85,827 collocates over eight months, across 20 countries.

Figure 1. Preprocessing steps to identify collocates of target nouns for sentiment analysis. MI: Mutual Information.



Measurement of Societal Sentiments of Asians Across 20 Countries

After data preprocessing, each collocate was rated on a scale from 1 (very negative) to 5 (very positive) by 2 independent raters with a high interrater reliability (Cronbach α) of .916 (95% CI 0.874-0.958). For instance, *dirty*, *dangerous*, and *suspicious* were rated 1 (very negative); *employee*, *resident*, and *transportation* were rated 3 (neutral); *empowering*, *hero*, and *venerable* were rated 5 (very positive). Table 1 provides sample descriptors associated with narratives on Asians. We calculated a Cumulative Asian Sentiment Score (CASS) per month by taking the respective mean ratings globally to test Hypothesis 1, and by country, to test hypothesis 2. CASS is mathematically defined as follows:

where Y_{kt} is the CASS for country K during month t. For country k, during month t, S_i is the score of the word (i), while h_{ikt} is the count of the word (i).

Table 1. Examples of negative, neutral, and positive descriptors of Asians in the media during the COVID-19 pandemic.

Negative	Neutral	Positive
sin	commerce	benefit
weakness	secretary	leading
vile	domestic	calm
protest	affair	rejuvenated
vilify	demand	intelligence
denounce	military	good
deface	philosopher	peaceful
anti-china	deal	intellectual
anger	navy	groundbreaking
punishment	culture	successfully
crisis	market	sophisticated
chaos	country	greatest
agitation	establish	charm
meddling	influence	admiration
discord	rule	improving

Pandemic Variables

The monthly prevalence of new cases and incidences of new deaths across 20 countries were derived from the Oxford COVID-19 Government Response Tracker [29].

Hofstede's Cultural Dimensions

Calculations of the country dimension scores have been reported by Hofstede and Minkov [30], which were based on original cross-national surveys of IBM employees, and subsequent studies (eg, Hofstede Insights, 2020). The country score for each of Hofstede's dimensions was calculated using this method: First, individual survey responses to each question were calculated at the national level. For questions that were answered on a 5-point Likert scale, the national mean of the responses was calculated. For questions requiring a yes/no or multiple-choice answer, the national percentage of each answer, or a combination of answers (eg, "Option A OR Option C") was calculated. Next, these national-level scores were combined using a weighted formula to yield a country dimension score based on 3-8 survey questions, resulting in final scores that ranged from 0 to 100.

Analytical Strategy

Hypothesis 1, positing that societal sentiments toward Asians (as measured with the CASS) have become more negative across 8 months from October 2019 to May 2020, was tested using a trend model to show a significant linear decline in racial sentiments. The linear regression model can be expressed as the following:

$$y = a + bX$$

Where a represents the intercept, b represents the slope and X represents the week.

Hypothesis 2, positing that pandemic variables (COVID-19 incidence and mortality rates) and cultural variables (Hofstede's cultural dimensions) are associated with the CASS, was tested using a linear mixed model. CASS was the independent variable while the pandemic and cultural variables were the dependent variables. The model can be expressed as the following:

$$y = X\beta + Zb + \varepsilon$$

Where $b \sim N(0, \varphi_\theta)$ and $\sim N(0, \gamma_\theta)$, X and Z represent model matrices for the fixed effects—pandemic and cultural dimensions—(β) and random effects—time—(b), respectively. All data preprocessing, text analytics, and statistical analyses were conducted using Python (version 3.7) and OriginPro 2019b.

Data Accessibility

Data are publicly available at English-Corpora.org.

Results

CASS Across 20 Countries During the COVID-19 Pandemic

Globally, we observed a significant negative linear trend in CASS toward Asians (β=–.03, P=.018), supporting hypothesis 1 (Figure 2). Other trends such as quadratic and cubic were nonsignificant. Societal sentiments of Asians, measured with the CASS, were trending neutral before the pandemic (October to December 2019) and reached the lowest point in February 2020 during the pandemic. Before the pandemic in December 2019, Jamaica and New Zealand evidenced the most negative

societal sentiments toward Asians. In January 2020, when news of the novel coronavirus was released, the United States and Nigeria evidenced the most negative societal sentiments of Asians among 20 countries. The CASS for each of the 20 countries are presented in Figures 3 and 4.

Figure 2. Global Cumulative Asian Sentiment Scores (CASS) across 20 countries from October 2019 to May 2020. Globally, societal sentiments of Asians became more negative across 20 countries—a significant linear decline during the COVID-19 pandemic. CASS were trending neutral before the pandemic (October to November 2019), and plummeted in February 2020. Thereafter, CASS increased gradually, although it has not recovered to prepandemic levels.

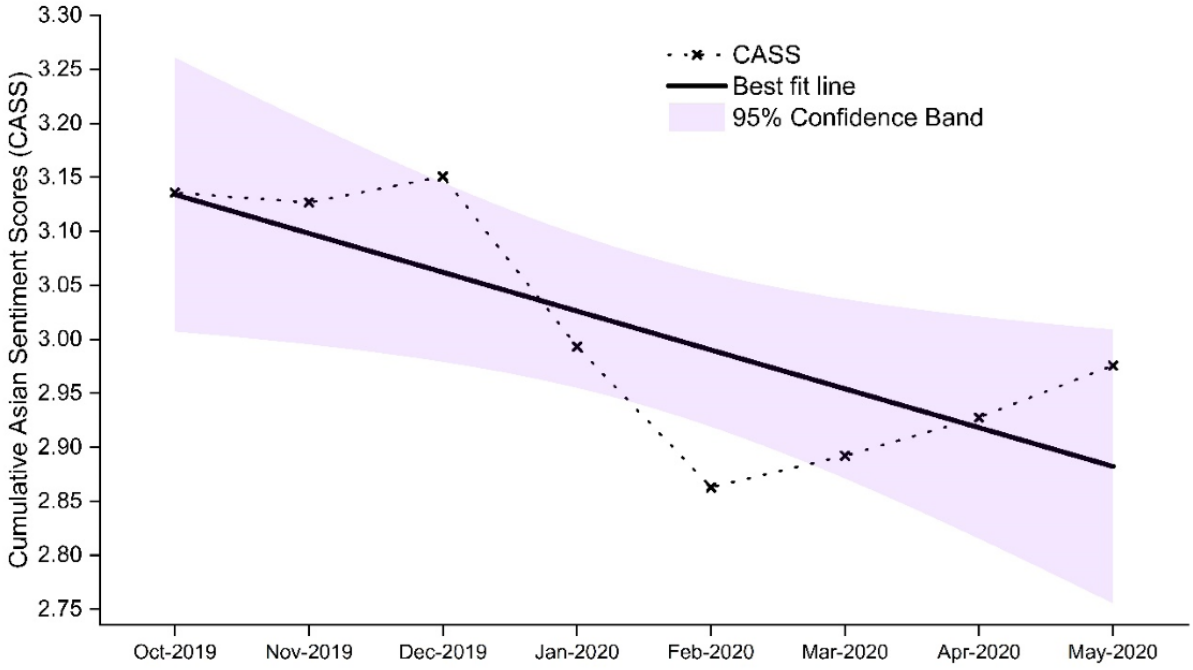


Figure 3. Cumulative Asian Sentiment Scores (CASS) across 10 countries (Australia, Bangladesh, Ghana, Hong Kong, Jamaica, Kenya, Nigeria, New Zealand, Singapore, and Tanzania) from October 2019 to May 2020. There was a significant negative linear trend in CASS across the various countries as the pandemic progressed.

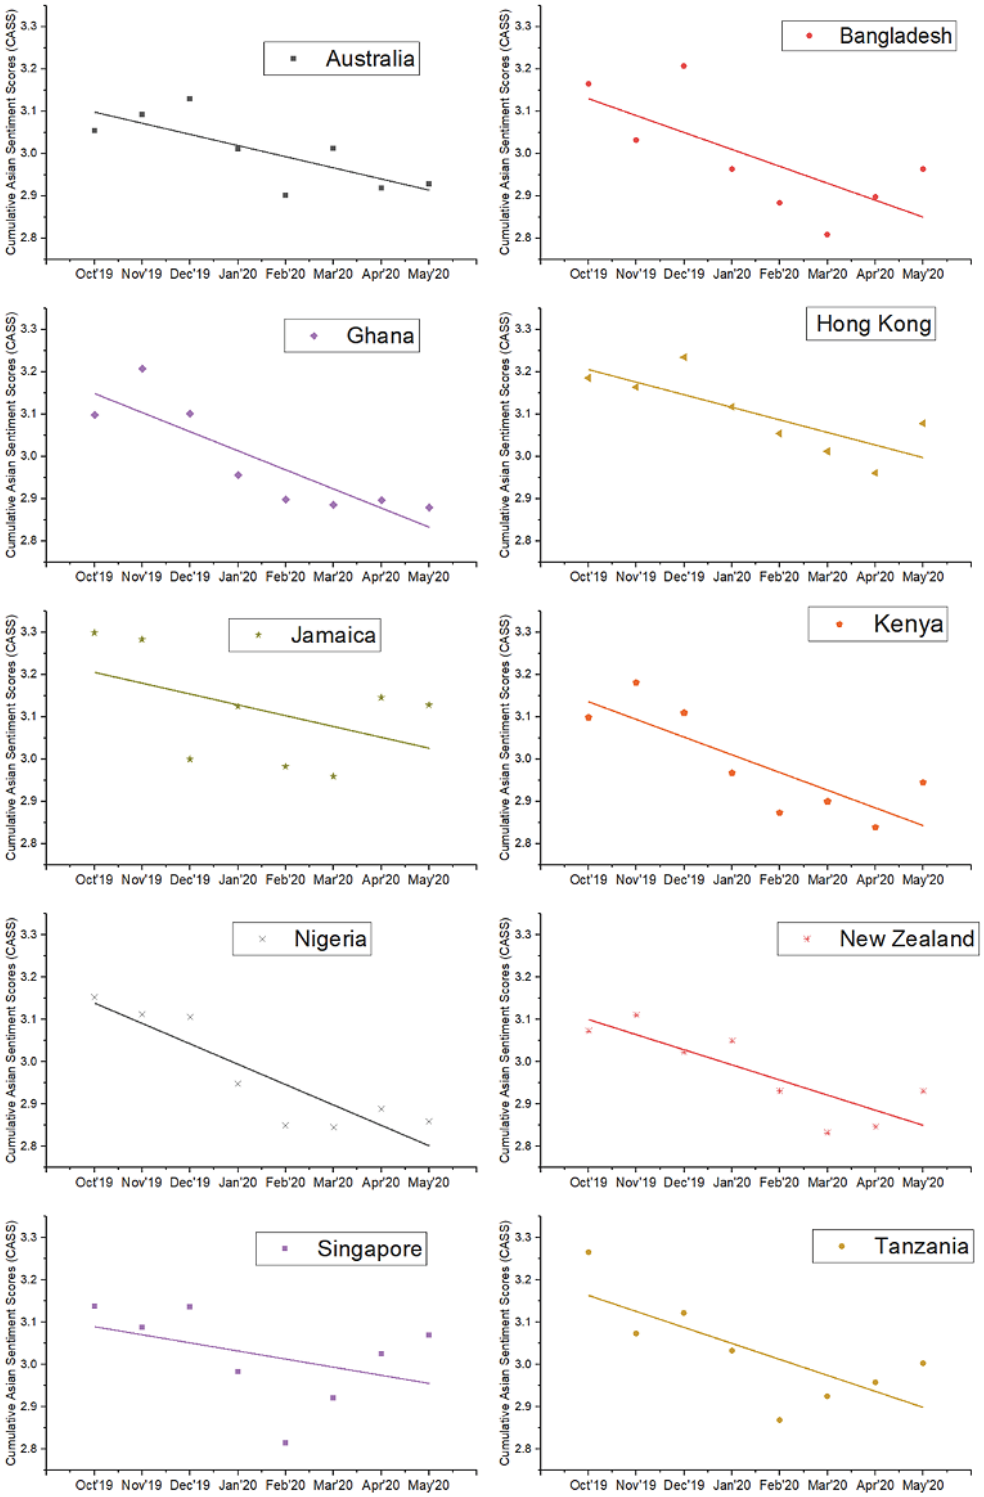

Figure 4. Cumulative Asian Sentiment Scores (CASS) across 10 countries (Canada, the United Kingdom, Ireland, India, Sri Lanka, Malaysia, Philippines, Pakistan, the United States, and South Africa) from October 2019 to May 2020. There was a significant negative linear trend in CASS across the various countries as the pandemic progressed.

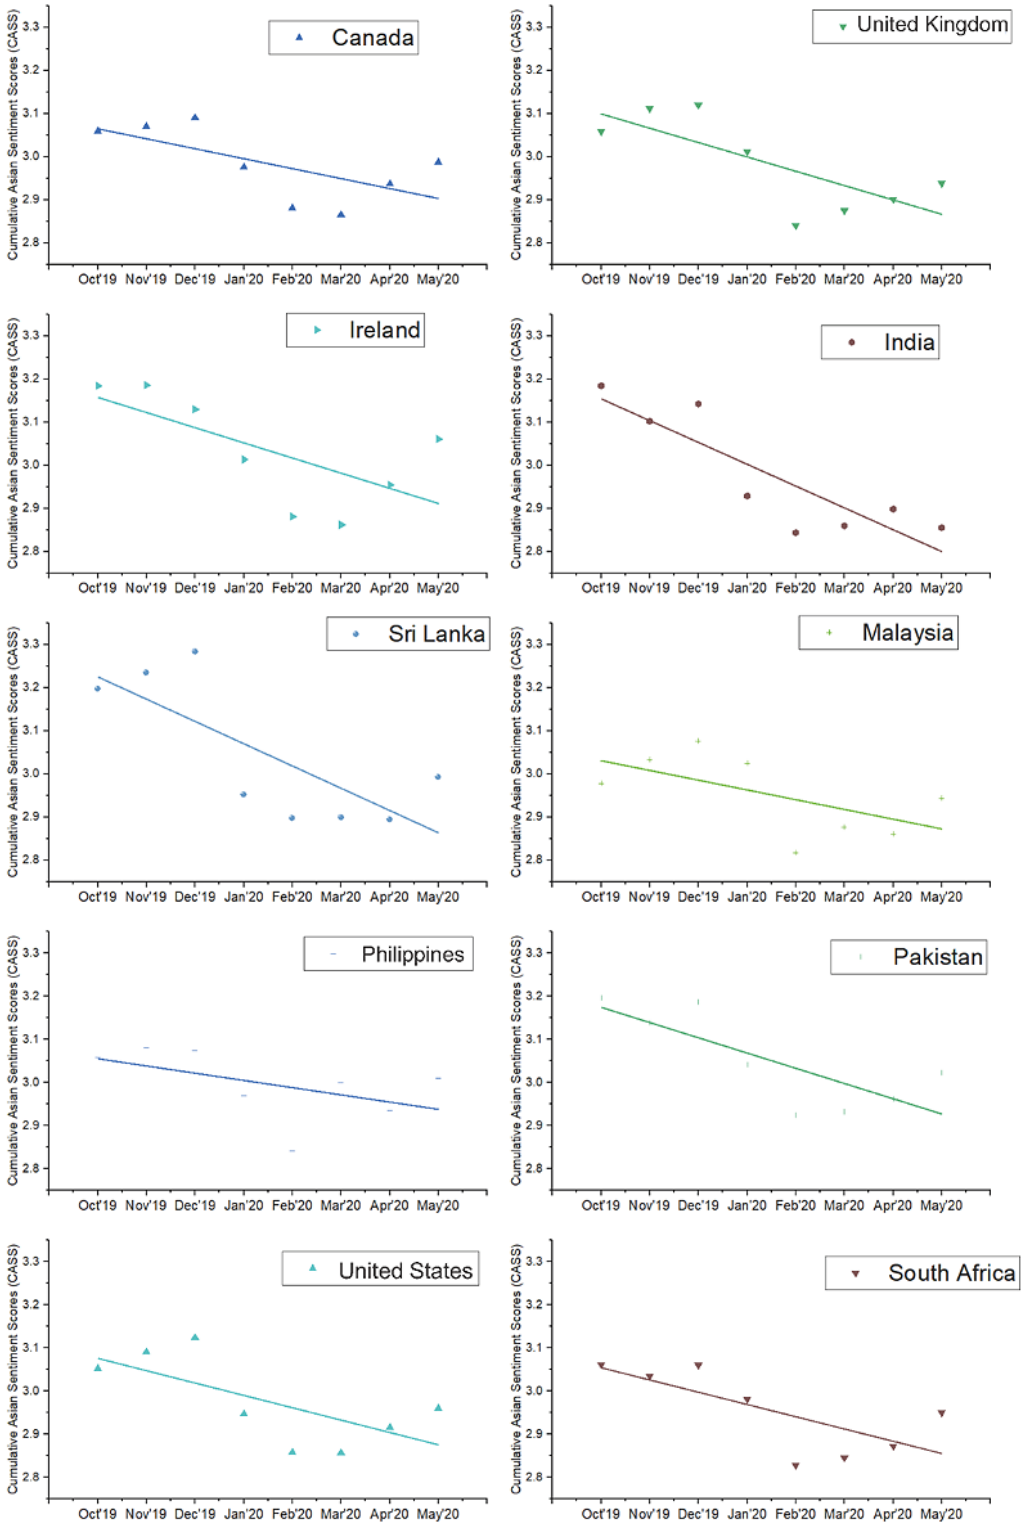

Predictors of Racial Sentiment Trends During the COVID-19 Pandemic

We tested hypothesis 2 using a mixed model, with pandemic variables (monthly prevalence of new cases and incidence of new deaths for 20 countries) and cultural dimensions as fixed variables, and time as the random variable (Table 2). The pandemic variables of prevalence and mortality rates did not reach significance, while 3 of 4 cultural dimensions were significant: higher power distance (β=–.002, *P*<.001), individualism (β=–.002, *P*<.001), and uncertainty avoidance (β=–.001, *P*<.001) were associated with negativity of societal sentiments toward Asians, holding other covariates constant; this provides support for hypothesis 2.

Table 2. Pandemic and cultural predictors of societal sentiments toward Asians across 20 countries during the COVID-19 pandemic (N=28,494): Model 1.[a] Higher power distance, individualism and uncertainty avoidance were associated with negative sentiments toward Asians; the pandemic variables of prevalence and mortality rates did not reach statistical significance.

Predictor	Value (SE)
Prevalence of new cases[b]	0.000 (0.000)
Incidence of new deaths[c]	0.000 (0.000)
Individualism	–0.002[d] (0.000)
Power distance	–0.002[d] (0.000)
Uncertainty avoidance	–0.001[d] (0.000)
Masculinity	–0.001 (0.000)

[a]R^2=0.737; adjusted R^2=0.723.

[b]Respective monthly COVID-19 incidence rates from October 2019 to May 2020.

[c]Respective monthly COVID-19 mortality rates from October 2019 to May 2020.

[d]P<.001.

Discussion

This is one of the first known empirical studies to dynamically test whether global societal sentiments toward Asians have become more negative month by month from before the pandemic (October 2019) to during the pandemic (May 2020). Our findings show that societal sentiments toward Asians became more negative across the 20 countries over time. This study contributes to the existing literature in 2 ways. First, it contributes to research on race relations by showing how pandemics may have severe repercussions on discourse surrounding certain ethnic groups. Second, by providing insight into the cultural factors associated with anti-Asian sentiments, this study lays the groundwork for more effective cultural communication strategies concerning public health issues.

Historically, incidences of xenophobia have accompanied the onset of global pandemics. With such catastrophic outbreaks, fear often drives those at risk to pin the blame on some group external to their own national, religious, or ethnic identity—in a bid to attribute their troubles to some known entity while reinforcing an “us against them” mentality [31]. As sickness cultivates fear, it can in turn incite moral panic and promote bias. Consequently, minority groups have often found themselves erroneously blamed for being contagious, as others perceive them to be “dirty” [32]. This blame culture could be a driving force for the negativity of societal sentiments toward Asians during the pandemic, as shown in our study.

Delving further, we argue that the negative rhetoric against Asians promoted “otherness” [32-34]. In times of crises such as the current pandemic, it is common for individuals with similar attributes to be categorized as the ingroup, and those who are “different” as the outgroup. The differentiation accentuates the similarities and homogeneity of ingroup members, while juxtaposing the differences of the outgroup members who have been accused of spreading the virus. This reinforces ingroup notions of “normality,” and positions those who are different—the Asians in this context—as deviant, through a process of othering and social exclusion [34]. A consequence of this othering could be prejudice, unfavorable treatment, and discrimination against Asians—possibly leading to heightened racial tensions and frayed social fabric in multiracial communities.

In addition, metaphors are ubiquitous in forming our world view [35]. The adjective “Chinese” in “Chinese virus” is particularly problematic as it metaphorizes the devastation of the pandemic with an ethnicity. Connecting group identities with explicitly negative medical language (ie, virus) serves to categorize those group identities as others. Such “othering” rhetoric only serves to typify stigmatized groups, devaluing them as those in society who possess undesirable characteristics that are outside normal expectations [36].

In relation to hypothesis 2, our results show how anti-Asian sentiments during the COVID-19 pandemic were strongly associated with cultural norms in society and not with the pandemic variables. Three of 4 cultural dimensions [37-42]—individualism, power distance, and uncertainty avoidance—were associated with increasing negativity of racial sentiments. This is one of the first known studies to link cultural dimensions and race relations during the COVID-19 pandemic, and this study attempted to explain these links.

First, we found that increased individualism was associated with negative societal sentiments toward Asians. In societies where tenets of individualism thrive, self-interests and outward expressions of intense emotions such as anger and antagonism [11] are more common, with less importance placed on avoiding confrontation and social harmony. We postulate that high levels of individualism in some societies could have encouraged people to speak their minds and outwardly display of anger and blame toward Asians, resulting in an outpouring of more pernicious sentiments. Moreover, in high-individualism societies, epitomized by a desire for an autonomous identity defined by personal choices and achievements [11], feelings of intrusion and encroachment into these pursuits—inflicted by the virus and those deemed to be “associated” with it—might have also ignited the spark for such confrontational anti-Asian sentiments. We argue that the widespread fear of contracting the disease and thus being precluded from pursuing one’s goals freely engenders prejudice against the outgroup that might be deemed

responsible for this, positioning them as effective scapegoats for both the virus and hampering one's personal individualistic identity.

Second, high power distance was associated with negative societal sentiments toward Asians. In essence, power distance represents the amount of respect and deference between people from different levels of the social hierarchy. Cultures high in power distance advocate a social hierarchy based on institutionalized status differentials, where members from the lower status groups are disadvantaged in terms of resource allocation, are expected to treat their high-status counterparts with deference and respect [11]. We argue that such demarcations of inequality allow for a perpetuation of social dichotomies and an increase in xenophobic sentiments toward those deemed undeserving of respect owing to their perceived "lower" status.

Third, high uncertainty avoidance was associated with negative societal sentiments toward Asians. We suggest that the uncomfortable threat and dangers from stemming those "associated" with the virus, and the pressing need to actively dispel the anxiety of its looming impact, has led to the prevalence of such negative narratives toward Asians. Labeling others on the basis of a variety of stigmas and associating an entire race with the virus not only aids in the identification of "negative" traits that are synonymous with risk, but also reinforces the lack of tolerance for ambiguities and uncertainty associated with particular groups of people who have been deemed to possess deviant behaviors [43]. Such stigmatizing sentiments serve as the cognitive basis of social grouping, helping individuals categorize and cautiously avoid people of particular social groups by displacing the threat of the unknown onto them. We thus argue that uncertainty avoidance is linked to stereotyping, distrusting, and dehumanizing outgroups through harsh sentiments owing to the perceived unpredictability of outgroup members possibly "spreading" the disease and jeopardizing them.

Hofstede's cultural dimensions have proven to be a useful framework to explore how anti-Asian sentiments have evolved over the course of the COVID-19 pandemic. It is evident that deep-seated cultural norms—individualism, power distance, and uncertainty avoidance—are a driving force in stigmatizing behavior against outgroups and revealed apertures in societal relations that arise during global crises such the COVID-19 pandemic. Future studies should explore the associations between cultural dimensions and racism. In addition, our study limitations could provide ideas for future studies. A key shortcoming is the lack of data from social media in the corpus. The diversity of social media usage across multiple platforms renders data collation challenging, and most social media platforms such as Facebook are closed for public access—they have also become increasingly monetized, selling selected data sets that may not be representative. Though our methodology allows for dynamic social sensing, compared to traditional methods [44-54], this is a significant drawback that we intend to overcome in future studies upon augmenting our database.

The COVID-19 pandemic has deepened fissures in racial relations as posited by numerous commentaries, and now shown empirically by the negativity of societal sentiments of Asians, across 20 countries, over 8 months, from October 2019 to May 2020. It is critical that governments and policy makers consider the cultural underpinnings linked to anti-Asian sentiments when designing appropriate messages for risk communication. In particular, societies high in power distance, individualism and uncertainty avoidance must be prioritized. Confronting the specific cultural factors fueling anti-Asian sentiment will achieve a multiplier effect, eventually forming the basis for solidarity.

Abstract

Background: Many people suffer from insomnia, a sleep disorder characterized by difficulty falling and staying asleep during the night. As social media have become a ubiquitous platform to share users' thoughts, opinions, activities, and preferences with their friends and acquaintances, the shared content across these platforms can be used to diagnose different health problems, including insomnia. Only a few recent studies have examined the prediction of insomnia from Twitter data, and we found research gaps in predicting insomnia from word usage patterns and correlations between users' insomnia and their Big 5 personality traits as derived from social media interactions.

Objective: The purpose of this study is to build an insomnia prediction model from users' psycholinguistic patterns, including the elements of word usage, semantics, and their Big 5 personality traits as derived from tweets.

Methods: In this paper, we exploited both psycholinguistic and personality traits derived from tweets to identify insomnia patients. First, we built psycholinguistic profiles of the users from their word choices and the semantic relationships between the words of their tweets. We then determined the relationship between a users' personality traits and insomnia. Finally, we built a double-weighted ensemble classification model to predict insomnia from both psycholinguistic and personality traits as derived from user tweets.

Results: Our classification model showed strong prediction potential (78.8%) to predict insomnia from tweets. As insomniacs are generally ill-tempered and feel more stress and mental exhaustion, we observed significant correlations of certain word usage patterns among them. They tend to use negative words (eg, "no," "not," "never"). Some people frequently use swear words (eg, "damn," "piss," "fuck") with strong temperament. They also use anxious (eg, "worried," "fearful," "nervous") and sad (eg, "crying," "grief," "sad") words in their tweets. We also found that the users with high neuroticism and conscientiousness scores for the Big 5 personality traits likely have strong correlations with insomnia. Additionally, we observed that users with high conscientiousness scores have strong correlations with insomnia patterns, while negative correlation between extraversion and insomnia was also found.

Conclusions: Our model can help predict insomnia from users' social media interactions. Thus, incorporating our model into a software system can help family members detect insomnia problems in individuals before they become worse. The software system can also help doctors to diagnose possible insomnia in patients.

insomnia; Twitter; word embedding; Big 5 personality traits; classification; social media; prediction model; psycholinguistics

Introduction

Background

Insomnia, a type of sleep disorder, is the inability to fall asleep or stay asleep at night. It is one of the most prevalent mental health symptoms globally [1]. One study [2] suggests that approximately 30% of adults worldwide exhibit insomnia symptoms, like difficulty initiating and maintaining sleep and waking up too early. People with insomnia might also experience other problems, such as depression, anxiety, and excessive alcohol consumption [3].

With the unprecedented growth of smartphone and internet technologies, social media has now become a ubiquitous platform that reflects users' daily activities, preferences, and beliefs. These social media platforms have become a means to share health information [4-9] for many users. For example, Paul et al [10] have stated that Twitter has become a common place to discuss a wide range of health information, including insomnia and other mental health conditions such as depression, stress, and anxiety. Several other studies [10-12] also report that Twitter is used as a platform to share symptoms [11], seek help, and exchange advice [12].

As insomnia is a mental health disorder, the illness might have a strong connection with human personality attributes. In fact, prior studies [13-15] suggest that insomnia has links with certain personality traits. Therefore, in this study, we attempted to derive personality traits from users' social media interactions and use these traits along with users' word usage patterns to predict insomnia. To the best of our knowledge, our study is the first to investigate from social media interactions whether personality traits have an association with insomnia. Predicting insomnia by analyzing users' tweets has a number of real-life applications. For example, friends and parents can identify problems in their loved ones, while health care providers can use the system to diagnose insomnia and can build an automated early warning system.

Insomnia and the Big 5 Personality Traits

Many adults experience short-term (acute) insomnia, which lasts for days or weeks. Acute insomnia is common and often brought on by situations such as stress at work, family pressures, or a traumatic event. Some adults have long-term (chronic) insomnia that lasts for several months or years [16]. In most cases, chronic insomnia may be a side effect of other problems [16]. Insomnia not only reduces individuals' energy levels but also degrades their health, work performance, and quality of life. There are several causes of insomnia [16-18], including mental health disorders, such as posttraumatic stress disorder. Antidepressants, asthma medications, and blood pressure medications can also lead to sleep disorders. Medical conditions such as chronic pain, cancer, diabetes, heart disease, asthma, gastroesophageal reflux disease, overactive thyroid, Parkinson disease, and Alzheimer disease can also cause insomnia. High consumption of caffeine, nicotine, or alcohol may also prevent sleep and lead to insomnia [16].

Personality differentiates individuals in their patterns of thinking, feeling, and behaving [19]. The Big 5 personality scale is a common scale for measuring personality [19,20]. The Big 5 model has 5 different personality traits: openness, conscientiousness, extroversion, agreeableness, and neuroticism. People with a high level of openness have a tendency to reflect on ideas, innovate, and appreciate values. People with high conscientiousness are cautious and meticulous and tend to seek achievement. People with high extroversion have a tendency to seek excitement and show positive emotions. People with high agreeableness tend to be sympathetic, trusted, and merciful to others. Neurotic individuals show negative emotions, such as anxiety, inhibition, anger, and depression. Personality traits are important factors that are associated with disorders [21]. For example, prior research has found that conscientiousness and neuroticism are related to insomnia [22,23]. Personality is also the key factor for dropout and treatment resistance in cognitive behavioral therapy for insomnia [24].

Social Media and Insomniac Patterns

A few studies have been conducted to predict insomnia by analyzing the content of social media. Michael et al [10] described a method that uses Twitter for public health research. They exploited the Ailment Topic Aspect Model to create structured disease information from tweets that they used for public health metrics. These authors [25] also reported that early detection of disease outbreaks, medication safety, health behaviors, and individual well-being can be investigated through social media data, and applied traditional natural language processing tools to analyze social media content. Rice et al [26] found that young people may be at risk of negative consequences from new technologies and online media. Therefore, social media platforms are important for measuring young people's mental health states. Andrew et al [27] conducted a study to identify common mental health topics from popular social media platforms and identified common mental health topics such as anxiety, depression, and sleep problems. Jamison-Powell et al [9] completed a study on discussions of insomnia on Twitter. Through an analysis of 18,901 tweets, they discovered that when the word "insomnia" appears in users' tweets, they are likely to convey strong negative health information. These authors mainly conducted their analysis over 2 different themes: coping with insomnia and describing experiences with insomnia. For the first theme, users share symptoms and coping strategies on Twitter, while for the second theme, users share frustration. However, the authors did not build a prediction model and did not explore the association between users' personality and insomnia. McIver et al [28] examined how 2 groups of Twitter users—sleep and nonsleep groups—were active on social media. They found that the nonsleep group showed negative sentiment over social media. Suarez et al [29] conducted a study on the real-time streaming of Spanish tweets for insomnia prediction by analyzing 54,432 tweets and built a classifier whenever insomnia phrases appeared. They used term frequency-inverse document frequency to find features of n-grams and then applied different classifiers including support vector machines and k-nearest neighbors.

It is clear that prior studies suffer from the following deficits in research: prior studies largely built classifiers based on explicit insomnia phrases (eg, "insomnia," "sleepless") rather than the linguistic cues and relationships between the words,

the authors did not build any novel machine learning models, and, to the best of our knowledge, no study predicted insomnia based on users' personalities from social media interactions. The aim of this paper was thus to address these research gaps.

Research Objectives

The main objective of this study is to predict insomnia by analyzing users' psycholinguistic characteristics (eg, word usage patterns) and Big 5 personality traits as derived from their tweets. In this study, we built a rigorous classification model to predict users' insomnia from their interactions on Twitter. We collected a total of 4,198,683 tweets from 1574 users and classified our training data set into 2 classes: individuals who suffer from insomnia and individuals who do not suffer from insomnia. We then conducted psycholinguistic-based analyses of users' tweets by using 2 popular tools: Empath [30] and Linguistic Inquiry and Word Count (LIWC) [31]. We also analyzed users' tweets by using the bidirectional encoder representations from transformers (BERT) [32] word embedding technique to investigate semantic relationships between words. We carefully conducted both psycholinguistic- and word embedding–based analyses to find insights into users' tweets. We then integrated users' personalities with the psycholinguistic models. Finally, we built double-weighted, ensemble-based classification models by combining psycholinguistic-, word embedding–, and personality-based models.

In summary, our study provides the following contributions: a large insomnia data set consisting of 1574 users from different geographical locations; novel insomnia classification models comprising psycholinguistic, word embedding, and Big 5 personality attributes as derived from users' tweets; and a novel and rigorous double-weighted, ensemble-based classification model to predict insomnia.

Methods

In this paper, we performed the 5 following steps to predict insomnia by analyzing users' word use patterns in tweets: (1) user selection—first, we found a total of 1574 users by using Twitter's advanced search technique [33] and divided the users into 2 groups, users with sleep disorders and users with no sleep disorder; (2) linguistic analysis—we performed 2 different types of linguistic analyses, psycholinguistic-based analysis and word embedding–based analysis; (3) correlation analysis—we found correlations between users' psycholinguistic patterns and sleep disorders by using Fisher's latent Dirichlet allocation (LDA) [34]; (4) model building—we built 3 different machine learning models by using psycholinguistic features, word embedding attributes, and the Big 5 personality traits; and (5) ensemble of the models—finally, we built a double-weighted ensemble model by integrating the previous models. These steps are further detailed in the subsequent subsections.

Data Collection

We collected tweets from a total of 1574 users. We searched phrases such as "insomnia" and "sleepless" by using Twitter's advanced search technique. We divided the users into 2 groups: Insomnia Yes and Insomnia No. We then manually annotated the files of the users' tweets with the Insomnia Yes and Insomnia No labels.

We confirmed that randomly selected users were neither organizational nor celebrity profiles. We manually checked whether Insomnia Yes users disclosed their own sleep disorders. We found users' tweets and their locations. The following are a few sample tweets shared by insomniac users on Twitter: "I wish insomnia wasn't a part of my life" and "my insomnia is officially the worst I got into bed at 12, slept for 2 hours, and am still wide awake at 6:30 AM." These tweets indicated that these users suffered from insomnia. If we found several such tweets (28.60 times on average) in the newsfeed or tweets of a user, we labeled that user as Insomnia Yes.

For Insomnia No users, we randomly selected users who did not have these search phrases in their tweets. We also manually checked whether these users shared any sleeping-related issues, and if they did, we discarded them from the list. After labeling Insomnia Yes or No on the users' csv files containing the tweets, we removed text such as "insomnia" and "sleepless" from the users' tweets. By removing these phrases, we created a bias-free data set that contained cues regarding users' insomnia without explicitly mentioning these phrases. Users who used contractions tend to have higher levels of fluency in their pronunciation, while users who do not use contractions are largely nonnative speakers. People may contract many words every day but mainly focus on the word "not" during contraction [35]. For the above reasons, we kept contracted words in our tweets to indicate a difference between the patterns of writing between native and nonnative speakers. Later, we conducted our full analysis again.

It is important to note that we only focused on users who express their insomnia on Twitter. If they are actually suffering from insomnia, then their word usage pattern could be insightful. We collected users' tweets, and multiple referees labeled these users after investigating their writing, their geographic locations, and the irregular timestamps of the tweets. In this way, we could be confident that a given user was suffering from insomnia. We emphasized a users' concern from their tweet content to make decisions about their behavior. It is likely that when users encounter a grave issue, they frequently express their problem to others. Thus, we labeled a user as Insomnia Yes if we found a high frequency (average 28.60) of mentions of the problem. We also found the maximum, minimum, and SD of users' number of posted tweets regarding the aforementioned problem to be 363, 8, and 24.57, respectively. These numbers revealed that some users suffering from extreme insomnia-related problems continue to tweet at nighttime about their sleeplessness.

There might be another group of users who have insomnia but do not disclose the problem in their tweets. We did not consider those users in our study. We also found a large number of users who were noninsomniacs. We again manually checked the users' data and tweet times based on geographic location to confirm that these users were noninsomniacs. If we had users who were noninsomniacs but tweeted in different time patterns to regular users, then we discarded their tweets from our study. As the number of insomniac users is lower in comparison to

noninsomniac users, we took less data of noninsomniac users to make a balanced data set.

It is important to note that there might have been users who had insomnia but do not disclose it in their tweets. However, we argue that they are not in large numbers, as previous studies show that in social media people reveal their actual behavior without idealization [36] and share private traits [37].

Next, we identified the genders of Twitter users based on various attributes to investigate correlations between users' gender and insomniac behavior. First, we manually checked profile pictures and biographies to identify gender, but many users do not share their photos in their profiles. Thus, we observed their writing and the replies of other users to determine their gender from third person pronouns (ie, "he," "she," "him," and "her"). If we could not identify the gender from Twitter, we then checked the other social network accounts of that particular user by conducting a manual search based on their names and usernames. For instance, we could identify the genders of Twitter users based on their pictures on their Instagram or Facebook profiles. If all the above methods failed to ascertain the gender, we discarded the user from our list.

We searched for users from those countries that have English as their first language and were either native or nonnative speakers. We collected users' tweets from a total of 6 different countries: Australia, Canada, Ireland, New Zealand, the USA, and the UK. Table 1 shows the number of users from both groups (Insomnia Yes and Insomnia No) collected from different geographical locations.

Table 2 displays the statistics describing the tweets of our data set.

Table 1. Twitter users' statistics by location.

Countries	Total, n (N=1574)	Insomnia Yes users, n (n=820)	Insomnia No users, n (n=754)
UK	212	108	104
Australia	62	31	31
Canada	334	181	153
USA	919	473	446
New Zealand	32	18	14
Ireland	15	9	6

Table 2. Tweet statistics.

Statistic	Insomnia Yes	Insomnia No
Tweets, n	1,998,683	1,810,567
Maximum number of tweets of a user, n	3247	3250
Minimum number of tweets of a user, n	26	26
Average number of tweets of a user, mean (SD)	2437.42 (1035.42)	2401.28 (1156.65)
Maximum word count of a user, n	67,427	65,660
Minimum word count of a user, n	195	191

For raw data preprocessing, we discarded the username and mentions. We kept the retweets of users because the act of retweeting could indicate the personality traits of users. We removed hashtags (eg, "#insomnia,") and converted them into text (eg, "insomnia"). We also removed URLs and http links because these text data cannot be analyzed by lexical methods. These texts also do not produce any sensible numeric vector for the word embedding method. We did not remove stop words because some word embedding techniques, like BERT, show that prepositions facilitate a better understanding of the context. We removed emojis by using the Python demoji package [38]. For example, we replaced the fire symbol emoji with the word "fire." We used the LIWC2015 dictionary for removing emoticons according to the suggestion of Seabrook et al [39].

Model Building

We built the classification models from 3 different techniques: (1) a psycholinguistic-based model (ie, LIWC and Empath), (2) a word embedding–based model (ie, BERT), and (3) a Big 5 personality–based model. First, we describe the performance of predicting Insomnia Yes and Insomnia No for each of the independent models. We then describe the process of building our novel ensemble model from these 3 independent models. Since we used word-embedding techniques for deep learning–based models, we did not need a feature selection method for this classification category. We carefully selected important features for the other 2 approaches because irrelevant features can weaken the accuracy of a model [40].

Feature Selection

In our data set, our independent variables consisted of analysis scores from users' tweets as generated by psycholinguistic tools (ie, LIWC and Empath), word-embedding methods (ie, BERT), and the Big 5 personality traits. Our dependent variable was Insomnia Yes and Insomnia No. As our independent variables were continuous while the dependent variable was categorical, we applied Fisher' linear discriminant analysis [34] for our feature selection method.

As mentioned earlier, we used 2 different psycholinguistic techniques, LIWC and Empath, to analyze users' tweets. Initially, we used the LIWC-based approach using LIWC2015, which classifies approximately 90 different features from texts into 7 different categories, where each category contains hundreds of words [41]. These categories include summary language variables (analytical thinking, clout, authenticity, and emotional tone), general descriptor categories (words per sentence, percent of target words captured by the dictionary, etc), standard linguistic dimensions (articles, auxiliary verbs, etc), word categories tapping psychological constructs (affect, cognition, etc), personal concern categories (work, home, leisure activities, etc), informal language markers (assents, fillers, swear words, netspeak), and punctuation categories (periods, commas, etc).

We first considered LIWC scores to be independent variables and Insomnia Yes and Insomnia No as dependent variables. We applied Fisher's linear discriminant analysis by using SPSS statistical software (IBM Corp) to find the relevant features. Table 3 shows the correlation coefficient between users' LIWC scores and Insomnia Yes and Insomnia No according to Fisher's linear discriminant analysis. The predictors with larger (>1.0) scores are better predictors. Therefore, these scores are helpful in deciding which variables have more effect when building the classification models [42].

Table 3. Fisher's correlation coefficient between LIWC[a] categories and insomnia categories.

LIWC category	Insomnia Yes	Insomnia No
i	48.117	47.838
negate	123.587	123.253
swear	74.714	74.521
health	18.731	18.466
drives	–31.599	–31.479
focuspresent	17.453	17.342
SemiC	16.856	16.157
cogproc	–38.140	–38.057
sad	19.972	20.991
affiliation	37.245	37.323
anx	17.692	18.524
death	22.654	23.873
social	83.284	83.246
Analytic	–17.013	–16.901

[a]LIWC: Linguistic Inquiry and Word Count.

Second, we used an Empath-based approach to address the shortcomings of the LIWC-based approach. LIWC can only analyze a total of 6400 dictionary words. A dynamic deep learning–based approach was used to analyze these words with Empath. We analyzed the text with Empath by using the empath-client Python implementation package [43]. Empath draws connotations between words and phrases by using deep learning–based neural embedding across more than 1.8 billion words of modern fiction. Given a small set of seed words that characterize a category, Empath uses its neural embedding to discover new, related terms and then validates the category with a crowd-powered filter. Empath analyzed text across 200 built-in, prevalidated categories we generated from common topics in our data set, like neglect, government, and social media. We analyzed the tweets of each user by using Empath and considered the outcome of the tweets as our independent variables; meanwhile, Insomnia Yes or Insomnia No was taken as the dependent variable. Although LIWC and Empath are highly correlated (r=0.906), we found no correlation between Empath and our insomnia classification categories. LIWC has a total of 93 psycholinguistic categories, whereas Empath has a total of 200 word categories. When these 93 LIWC word categories were divided between 200 Empath word categories, which might not have been evenly distributed across the categories, Empath showed weak correlation coefficients. Therefore, we ultimately did not integrate the Empath word categories with our combined model.

Third, to find correlations of users' sleeping patterns with the Big 5 personality traits, we initially computed users' personality scores. We computed the Big 5 personality traits [20] of the users from their tweets by using the IBM Watson Personality Insight API (application programming interface) [44]. Arnoux et al [8] have shown that the IBM Watson Personality Insight API performs well in comparison to other techniques. Other prior studies [45,46] have also used the API and demonstrated reasonable performance. We found that the majority of the traits had a high score of 1.00 and low score of 0.01. We also observed that insomniac users had average openness, conscientiousness, extraversion, agreeableness, and neuroticism scores of 0.61, 0.29, 0.52, 0.56, and 0.83, respectively.

Building Classifiers

After feature selection of all the techniques was completed, we first built a classification model with LIWC. To build the

classification model, we considered 14 different LIWC categories of words as initial features. Table 3 shows the features for the LIWC-based approach. The features are i, negate, swear, health, drives, focuspresent, SemiC, cogproc, sad, affiliation, anx, death, social, and Analytic. A potential problem can arise when collinearity is present among the features. To remove collinearity among independent LIWC features, we computed the correlation among the features by using the R regression subset selection package "leaps" [47]. We found that the following features were collinear: drives, sad, SemiC, focuspresent, and affiliation. We discarded these collinear features from our feature list. Finally, we conducted classification with the relevant features using a 10-fold cross-validation with 10 iterations. We built our classification model with several classifiers that included Naive Bayes, AdaBoost, random forest, support vector machine, and Gaussian process.

After this, we used a linguistic model that is capable of finding contextual relationships between words in a sentence. To this end, we use the BERT [32] model which is pretrained on a large corpus of sentences. The model learns to produce a powerful internal representation of words as embeddings. We used the sentence-transformers [48] library to generate BERT vectors by using a pretrained model. We grouped 2 sets of preprocessed data sets, one without applying lemmatization and punctuation marks and the other after applying all the preprocessing techniques.

We used the BERT vector as input for our convolutional neural network (CNN)–based deep learning model [49]. As CNN is a nonlinear machine learning model and the BERT embedding vector has a large input feature (768 × 1), we trained our model with this deep learning–based architecture. The CNN model contains 2 hidden layers. In the first hidden layer, we added the leaky ReLU (rectified linear unit) [50] activation function. In the next hidden layer, we added a dropout for regularization of the model with a tanh activation function. Finally, we added a dense layer with a softmax activation function [51] and used the Adam optimizer with binary cross-entropy loss. We split the training and test data sets by 70% and 30%, respectively, and built the classification model using a 10-fold cross-validation with 10 iterations. With this configuration, the accuracy was 67% and 58% for the training and test data sets, respectively.

Next, we built our classification model by using the Big 5 personality traits. Based on the date summarized in Table 4, we selected 3 relevant Big 5 traits: conscientiousness, neuroticism, and agreeableness. We built the classification model with the relevant traits using a 10-fold cross-validation with 10 iterations. We built our classification model with several classifiers that included Naive Bayes, AdaBoost, random forest, support vector machine, and Gaussian process by again splitting the training and test data sets by 70% and 30%, respectively.

Table 4. Fisher's correlation coefficient between personality traits and Insomnia Yes and Insomnia No.

Personality trait	Insomnia Yes (Fisher's score)	Insomnia No (Fisher's score)
Conscientiousness	31.885	29.227
Neuroticism	28.168	17.336
Openness	–19.137	–20.785
Extraversion	–1.93	–1.61
Agreeable	2.175	3.132

Building Weighted Ensemble Classifiers

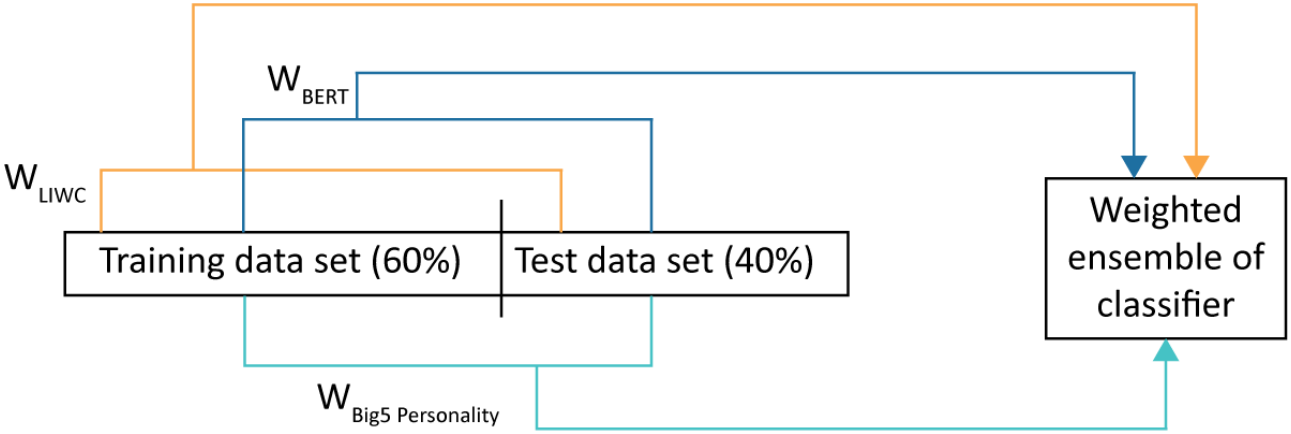
We finally combined the previous classification models to increase the strength of our prediction model. To determine a unified final insomnia label, we combined all the independent models, including, LIWC, BERT, and the Big 5 personality traits. It was necessary to prioritize the approaches based on their performance. We ordered the approaches by assigning weights to each model. We used these weights to build our final ensemble model. To build our ensemble model, we performed the following 2 steps: computing weights of each approach from both the training and test data sets and combining the models with a double-weighted linear ensemble technique.

We then determined the weights of each approach (ie, W_{LIWC}, W_{BERT}, and W_{Big5} personality traits) from both the training and test data sets. We occasionally observed that a model showed better strength with the training data set while the model performed weakly for the test data set. Therefore, we paid close attention to the performance of our models in both the training and test data sets. This way, we could bring greater diversity to the weights to build our ensemble model. To this end, we first ran the classification model over the training data set of 944 Twitter users (944/1574, 60.0% of the total data set). We ran the classification models by using LIWC, BERT, and the Big 5 personality traits. We used both linear (eg, random forest, Naive Bayes) and nonlinear (ie, CNN) models during training. We ranked the strength of these classification models by checking their root mean square error (RMSE) scores. The lower the RMSE score, the higher the weight of a model (linear or nonlinear). To compute the weight, we subtracted the RMSE score from 1 (W=1–RMSE).

We again ran the classification models over the test data set of 630 Twitter users (630/1574, 40.0% of the total data set). We also applied both linear and nonlinear techniques by using LIWC, BERT, and the Big 5 personality trait approaches. We then ranked the weights (1–RMSE for the test data set) of these approaches. Figure 1 shows the detailed process of producing weights from both the training (60%) and test (40%) data sets. In the figure, we indicate weight as W, which indicates that we subtracted RMSE from 1 for the model. In our double-weighted

method, we combined the weights of each type by using convex combination techniques [52] for both the training and test data sets. For the training data set, we obtained weights of 0.52, 0.47, and 0.50 from LIWC, BERT, and the Big 5 traits, respectively. In contrast, for the test data, we achieved weights of 0.38, 0.50, and 0.36 from LIWC, BERT, and the Big 5 traits, respectively. These weights were generated from linear and nonlinear classification models of LIWC, BERT, and the Big 5 personality traits.

Figure 1. Weight computation and building ensemble model for predicting insomnia. BERT: bidirectional encoder representations from transformers; LIWC: Linguistic Inquiry and Word Count.



Finally, we combined the weights that we found from the double-weighted method by using the convex combination method. Equation 1 presents the final insomnia ensemble classification result (I_{Final}) from the previous 3 different models.

where Y_{LIWC}, Y_{BERT}, and Y_{Big5} refer to insomnia prediction results through use of LIWC, BERT, and the Big 5 personality traits, respectively; and W_{LIWC}, W_{BERT}, and W_{Big5} denote the weights generated from LIWC, BERT, and the Big 5 personality traits, respectively, from both the training and test data sets through use of the convex combination technique.

Results

Overview

Our study is the first study to build a novel ensemble learning model to predict insomnia by analyzing a large number of tweets. Prior studies [28,29] investigated the pattern of insomniac behavior by using only a limited number of tweets. Furthermore, the authors explicitly considered phrases such as "insomnia" and "sleepless" in their data sets. In contrast, in our study, we discarded these explicit phrases when predicting users' sleeping issues, which makes our study different and more robust than the previous studies. In this section, we report the performance of our independent and final ensemble-based classifiers, discuss the incorporation of the emotional variability among the insomniac and noninsomniac users from their tweets, and present the distribution of insomniac users and the variability of their Big 5 personality scores. Finally, the correlation between users' genders and their insomniac behavior is discussed.

Performance of Independent and Ensemble Classifiers

First, we investigated the performance of our independent and ensemble-based classifiers. Table 5 shows the performance of the classifiers. We found that the Gaussian process classifier had the best average performance (area under the curve [AUC] 75.3%) in predicting users' insomnia.

Table 5. Strength of the classification model for predicting insomnia by LIWC categories and the Big 5 personality traits.

Classifier, insomnia class	LIWC[a]			Big 5 personality traits		
	TPR[b]	FPR[c]	AUC[d]	TPR	FPR	AUC

[a]LIWC: Linguistic Inquiry and Word Count.

[b]TPR: true-positive rate.

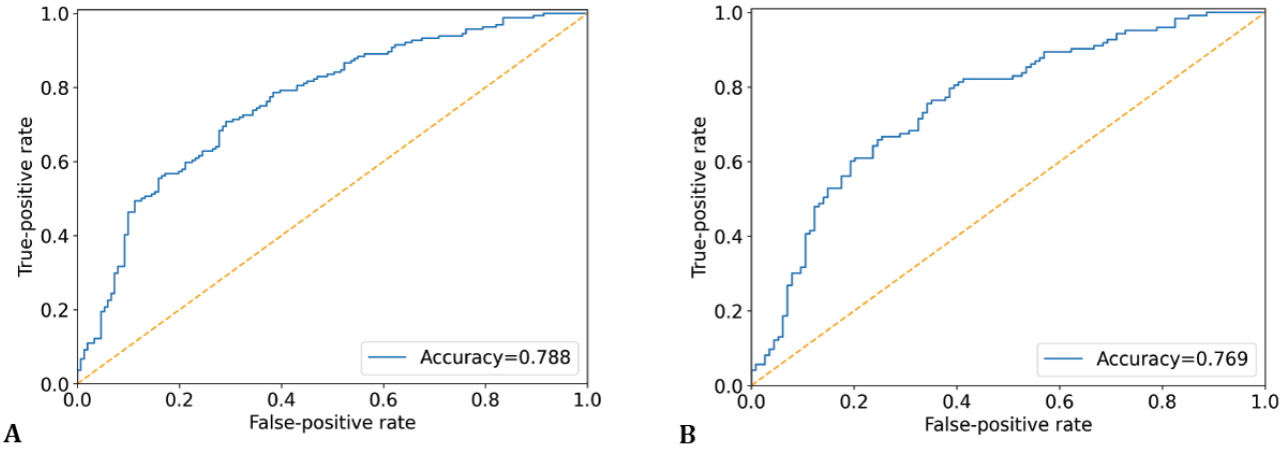
[c]FPR: false-positive rate.

[d]AUC: area under the curve.

[e]SVM: support vector machine.

Our final ensemble classification model for insomnia, I_{Final}, achieved an AUC of 78.8% and 76.91% from the training and test data sets, respectively, outperforming the previous independent models. When observing the performance of the ensemble-based classifiers on the training and test data sets, we found that the performances in the test set were similar to those of the training data set. The receiver operating characteristic curves for the training and test data sets on our ensemble-based classifiers are displayed in Figure 2.

Figure 2. Receiver operating characteristic curves for insomnia classification for the (A) training set and (B) test set.

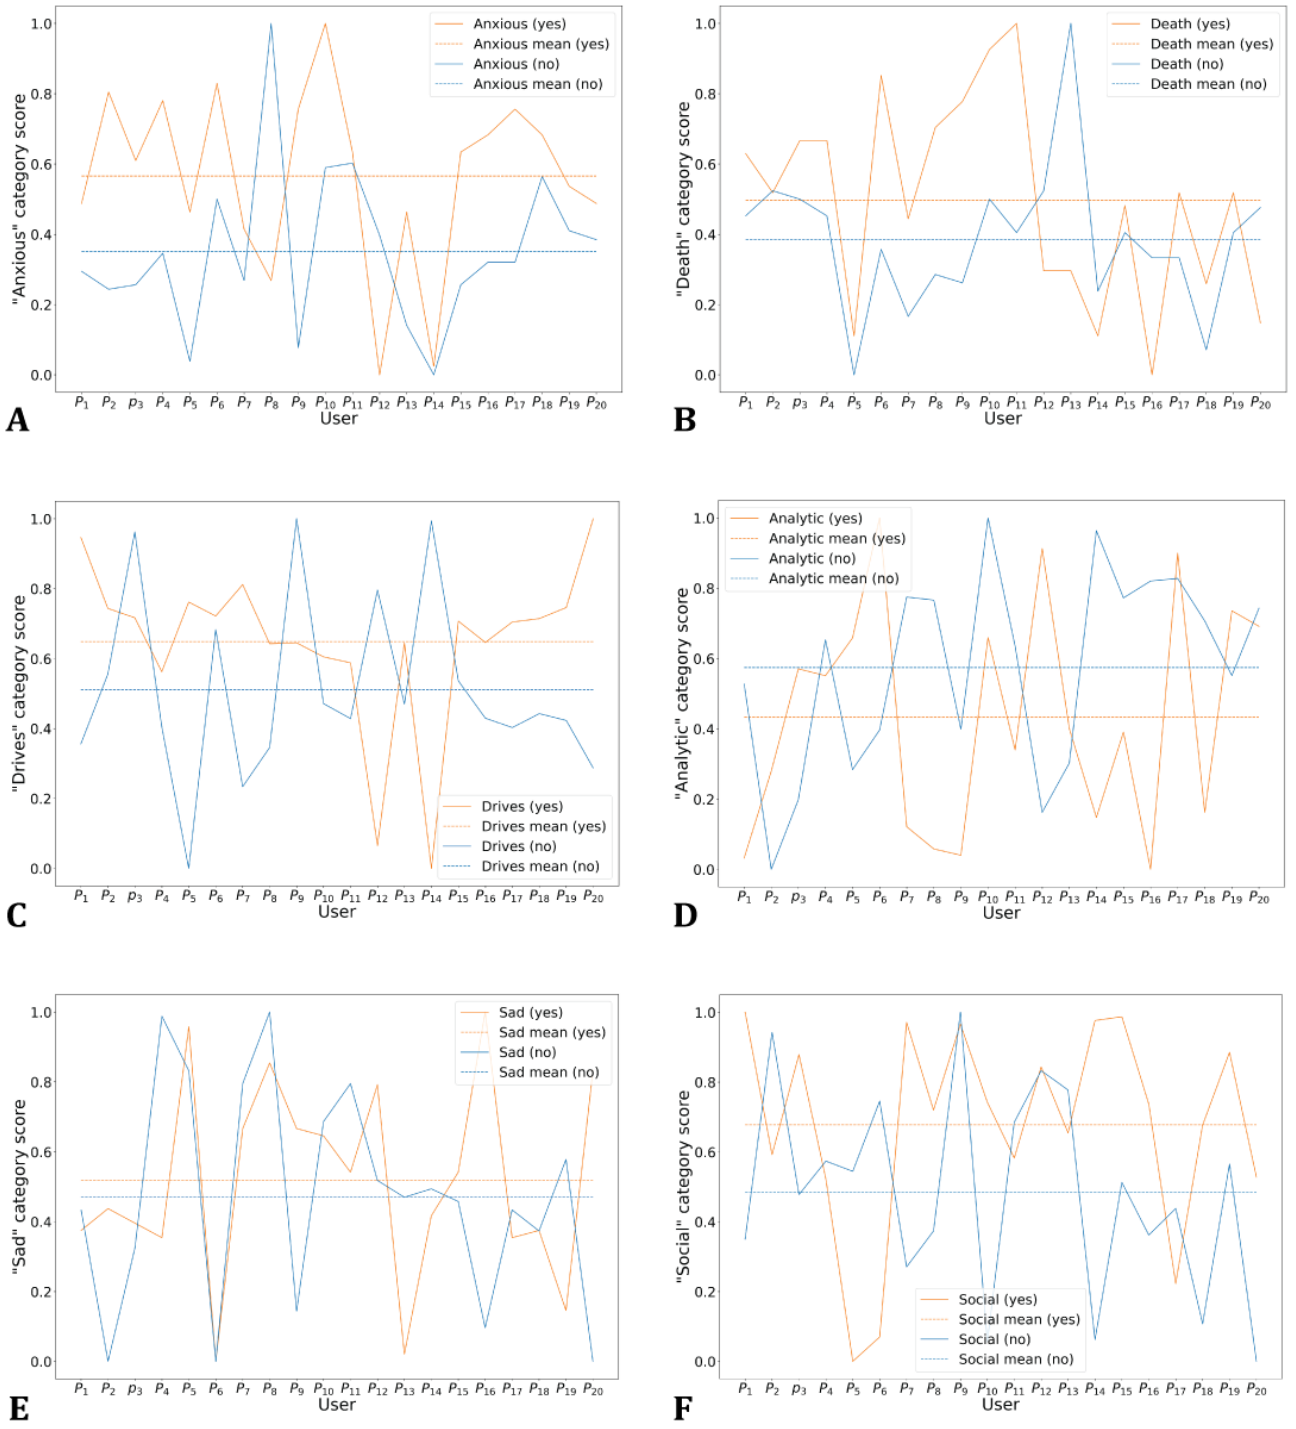


Emotional Variability Among Insomniac and Noninsomniac Users

Our study investigated whether emotional variability exists between insomniac and noninsomniac users based on their tweets. From our observation, we found that users' insomniac behavior and their psycholinguistic categories were correlated. We randomly selected 20 insomniac and 20 noninsomniac users. We extracted users' anxiety-related words, (eg, "worried," "fearful," "nervous," "tense") and converted their scores into a range from 0 to 1 by using the max-min normalization technique. Figure 3 presents the variability in the use of these words

between the insomniac and noninsomniac users. We also observed that on average, insomniac users exploited anxiety-related words 10% more than did the noninsomniac users. Carrera et al [53] showed in their study of 200 college students that a significant association can be found between difficulty sleeping and fear of death. In our study, we also found that insomniac users are likely to post death-related words in their tweets. We observed that insomniac users write more "social words." These users tend to spend more time socializing with others when they face difficulty sleeping. Our study also showed that insomniac users tend to display a lack of analytical thinking.

Figure 3. Usage of words, (A) "Anxious," (B) "Death," (C) "Drives," (D) "Analytic," (E) "Sad," and (F) "Social," related to the LIWC category and their mean scores between insomniac and noninsomniac users. LIWC: Linguistic Inquiry and Word Count.



Visualization of the Correlation Between Big 5 Personality Traits and Insomniac Users

Users' Big 5 personality traits and insomniac behavior showed correlations. Table 6 shows the distributions indicating that agreeableness might have a weak correlation with insomniac behavior. However, conscientiousness had a strong correlation with insomniac behavior (Fisher's score 31.88). The users who had high insomnia were more likely to be more conscientious. In contrast, Wissar et al [54] reported that lower

conscientiousness is associated with greater insomnia severity. We also find that users who had high neuroticism scores were more likely to have severe insomnia. Table 6 shows that insomniac users have moderate scores in agreeableness, are likely to be high in conscientiousness, and are highly neurotic.

Table 6. The distribution of correlated Big 5 personality trait scores among insomniac users.

Traits by range	Percentage, n (%) (N=820)
Agreeableness	
0.0–0.2	77 (9.4)
0.2–0.4	164 (20.0)
0.4–0.6	188 (22.9)
0.6–0.8	214 (26.1)
0.8–1.0	177 (21.6)
Conscientiousness	
0.0–0.2	111 (13.5)
0.2–0.4	213 (26.0)
0.4–0.6	376 (45.9)
0.6–0.8	88 (10.7)
0.8–1.0	32 (3.9)
Neuroticism	
0.0–0.2	9 (1.1)
0.2–0.4	38 (4.6)
0.4–0.6	79 (9.6)
0.6–0.8	125 (15.2)
0.8–1.0	569 (69.4)

Insomnia and Gender Correlation

Seabrook et al [39] showed that gender might have an association with mental health problems, such as depression. Reasoning that insomnia is a mental health problem [55] and motivated by previous studies [39,56], we also investigated the association between users' gender and their insomnia-related problems. We discovered that the number of insomniac and noninsomniac male users was 309 and 363, respectively. We further observed that the number of insomniac and noninsomniac female users was 511 and 391, respectively. From our data set, we conducted chi-square (P<.001) tests based on gender and insomnia where the degrees of freedom ([number of rows–1] × [number of columns–1]) in the contingency table were 1. Our result showed that gender and insomnia were correlated.

After careful observation, we found that among 511 of all female users 6.8% (n=35 users) were suffering from pregnancy- or postpartum-induced insomnia. These users' tweets contain words related to "pregnant," "postpartum," and "cosleep." Later, we applied LDA [57] over the tweets from these users' pregnancy or postpartum times. LDA is a topic modeling technique that automatically organizes a large corpus to discover hidden themes. From users' patterns of tweeting, we could estimate the possible time frame for their pregnancies. Table 7 presents the extracted 5 major topics from their tweets: sleep, night, tired, child, and weird.

Table 7. Distribution of major topics, including (A) sleep, (B) child, (C) night, (D) tired, and (E) weird, extracted from a group of insomniac users' tweets during their pregnancy or postpartum periods.

Discussion

Emotional Linguistic and Insomniac Behavior

As discussed earlier, users' linguistic patterns and Insomnia Yes or Insomnia No indications were strongly correlated. Insomniacs tended to use negative categories of LIWC words (eg, "no," "not," "never"). Some people with strong temperament frequently use swear words (eg, "damn," "piss"). In Bonnet et al's [55] study, insomniacs showed hyperarousal (an abnormal state of responsiveness) due to increased secretion of corticosteroids and adrenaline and an elevated metabolic rate. In another study, Bonnet et al [58] showed that insomniacs experience mood alternation and chronic psychological activation. The following is a sample tweet from an Insomnia Yes user that endorses our finding: "It sucks when you realize that the people closest to you are the most toxic." They also use anxious (eg, worried, fearful, nervous) and sad (eg, crying, grief, sad) categories of LIWC words in their tweets. Freeman et al [59] showed that insomnia has a connection with anxiety, depression, and being worried, and these people are likely to use death-related words (eg, "bury," "coffin," "kill"). Harrison et al [60] reported that insomniacs generally exhibit fear of death and show anxiety about the uncertain (eg, "maybe," "perhaps," "guess"). The following tweet is an example this: "I feel dead and I hate everybody." Our study also adds to these findings by analyzing the correlation between LIWC categories of words found in the users' tweets and their sleeping patterns. Hiller et al [61] showed that cognitive processes (eg, the psychobiological inhibition model) play an important role in understanding and treating insomnia. We obtained a few correlations, such as focuspresent and SemiC, which cannot be intuitively explained.

We did not find a correlation between Empath categories of words and users' sleeping patterns. It is interesting to observe that none of these categories showed any significant correlation between Empath word categories and users' sleeping habits. Fast et al [62] reported that LIWC and Empath word categories are correlated (r=0.906). LIWC has a total of 93 word categories that are distributed across a total of 200 word categories in Empath. When a word category subsumes a greater number of individual words, then the chance of 2 features being correlated, such as LIWC and insomnia class labels, increases. In contrast, when the number of words decreases in a category, such as in Empath, then the possibility of being correlated decreases. In our study, we observed that although LIWC and Empath were correlated, this correlation might not have been sustained in a transitive case. For example, although Empath $\rightarrow$ LIWC and LIWC $\rightarrow$ $Feature_x$ are true, Empath $\rightarrow$ $Feature_x$ does not exist in our data set.

The Big 5 Personality Traits and Insomniac Behavior

We discovered that users' personalities and their sleeping patterns have strong correlations and that users with high neuroticism are more likely to have insomnia. They tend to go through depression, social introversion, repression, and intolerance in terms of somatic health problems. The following is a sample tweet supporting this finding: "Ralph Northam needs to fucking RESIGN already. I have zero tolerance for him." A prior study [63] also reported similar observations related to the correlation between neuroticism and insomnia. Assessing neuroticism may allow for the early detection of catastrophic situations of insomnia. We also observed that users with high conscientiousness scores had strong correlations with insomniac patterns. The following tweet from our data set exemplifies this finding: "I cannot control others actions but I can control mine and my reactions." Larsgaard et al [64] noticed that conscientiousness in people might be correlated with reduced sleeping behavior due to their self-inhibition and the meticulousness in their daily activities.

In our study, we also found a correlation, albeit a weak one, between users' agreeableness and insomnia. The following tweet from an Insomnia Yes user is an example of this: "understand people who talk crap about others thru social media. Listen Linda, why aren't you handling it like an adult?" Dekker et al [65] found that neuroticism, agreeableness, and openness are

directly associated with the insomnia severity index. In our study, we discovered that openness is negatively correlated with users' sleeping patterns. Tsaousis et al [66] also demonstrated that openness and insomnia are negatively correlated with each other. However, several studies [67-70] have demonstrated that openness is unrelated to sleep quality.

In our study, there was negative correlation between extraversion and insomnia. Gray et al [69] found there to be no correlation between users' extraversion and insomniac patterns. Our observations of the relationship between the Big 5 traits and insomnia largely overlap with prior findings [63-65,67-70], which suggest that investigating users' insomnia patterns through social media can leverage our manual effort without asking an individual directly about their sleeping issue. Furthermore, understanding and inspecting one's personality traits may provide clues to underlying causes of vulnerability to developing insomnia.

Pregnancy and Insomniac Behavior

According to our finding, users share their depression during their pregnancies and share their experiences during their postpartum periods. We observed that the major supporting topics were night, suffer, problem, and birth, among others. We also found a few topics that described parents' postpartum-related anxiety. Important topics that we found from users' tweets were birth, breast, tired, suffer, and random, among others. Previous studies also support our findings [71,72].

Conclusions

In this study, we investigated the associations between the psycholinguistic and personality traits of users' with insomnia. We captured both the word usage and semantics of users' tweets through the LIWC and BERT linguistic models and developed 2 models to predict insomnia from LIWC features and BERT word embedding. We then built our third machine learning model that used derived personality traits to predict insomnia from tweets. Finally, we built a rigorous ensemble model by combining the 3 separate models. Our ensemble classifier showed strong prediction potential (AUC 78.8%). The classifier was built by using a novel, double-weighted ensemble technique that outperformed the independent classifiers. We plan to improve our classifier by integrating more data from social networks, such as friend lists, time of tweets, gender, workplace, time spent on activities, etc. We also plan to analyze tweets in different languages.

Abstract

Background: The rapidly evolving digital environment of the social media era has increased the reach of both quality health information and misinformation. Platforms such as YouTube enable easy sharing of attractive, if not always evidence-based, videos with large personal networks and the public. Although much research has focused on characterizing health misinformation on the internet, it has not sufficiently focused on describing and measuring individuals' information competencies that build resilience.

Objective: This study aims to assess individuals' willingness to share a non–evidence-based YouTube video about strengthening the immune system; to describe types of evidence that individuals view as supportive of the claim by the video; and to relate information-sharing behavior to several information competencies, namely, information literacy, science literacy, knowledge of the immune system, interpersonal trust, and trust in health authority.

Methods: A web-based survey methodology with 150 individuals across the United States was used. Participants were asked to watch a YouTube excerpt from a morning TV show featuring a wellness pharmacy representative promoting an immunity-boosting dietary supplement produced by his company; answer questions about the video and report whether they would share it with a cousin who was frequently sick; and complete instruments pertaining to the information competencies outlined in the objectives.

Results: Most participants (105/150, 70%) said that they would share the video with their cousins. Their confidence in the supplement would be further boosted by a friend's recommendations, positive reviews on a crowdsourcing website, and statements of uncited effectiveness studies on the producer's website. Although all information literacy competencies analyzed in this study had a statistically significant relationship with the outcome, each competency was also highly correlated with the others. Information literacy and interpersonal trust independently predicted the largest amount of variance in the intention to share the video (17% and 16%, respectively). Interpersonal trust was negatively related to the willingness to share the video. Science literacy explained 7% of the variance.

Conclusions: People are vulnerable to web-based misinformation and are likely to propagate it on the internet. Information literacy and science literacy are associated with less vulnerability to misinformation and a lower propensity to spread it. Of the two, information literacy holds a greater promise as an intervention target. Understanding the role of different kinds of trust in information sharing merits further research.

KEYWORDS

misinformation; information literacy; science literacy; webcasts as topic; YouTube

Introduction

Introducing the Concern

When it comes to digital consumer health information, web-based resources can provide both valuable information and misinformation [1]. Concerns regarding the quality of health information and individuals' susceptibility to misinformation are as old as health information websites that target consumers. The changing digital ecosystem of the social media era has increased the potential for and the speed of spread of misinformation, making these concerns more urgent. At present, web-based health information exists in many different formats, often with videos and interactive features. Entire networks, such as YouTube, enable the sharing of videos in an easy manner accessible to a broad public. Social networks allow consumers to spread links to sources that promise quick and easy remedies and promote wellness approaches that are not supported by evidence.

A common theme in non–evidence-based consumer health information is strengthening the immune system and developing natural immunity against infectious diseases. This topic relates to many important public health concerns, from vaccination compliance to individual behavior during epidemics. The COVID-19 pandemic and the need for pandemic-curbing measures underscore the importance of understanding how the public evaluates and shares information about non–evidence-based remedies. We are writing this paper approximately a year after the pandemic reached the United States, and the word *infodemic* is often used to characterize the accompanying epidemic of unreliable information about the virus and the disease [2].

An extensive body of research suggests that individuals often lack the information skills required for navigating effectively through a multitude of health information sources of varying formats and quality [3]. To the best of our knowledge, no studies to date have attempted to characterize the relationship between an individual's tendency to share or recommend a video with non–evidence-based health advice and multiple cognitive and social factors. Understanding how such factors may affect information sharing is essential to curtail the spread of misinformation. This study is concerned with the types of statements that individuals view as convincing support of health claims, as well as the relationship between several factors—information literacy, science literacy, knowledge of the immune system, interpersonal trust, and trust in health authority—and inclination to share a non–evidence-based claim.

A Word on Misinformation

This study focuses on a YouTube video that promotes a dietary supplement, making strong claims about this supplement's ability to *boost* the immune system. Research into how vitamins, minerals, enzymes, and other substances may modulate the immune system is highly complex. However, the claims made by the video are simple and confident. While discussing these claims, we use the term *misinformation*, hence not making any assumptions about the intent of the supplement's producers and promoters.

Misinformation has been defined as *objectively incorrect information that is not supported by scientific evidence and expert opinion* [4]. Although the 2016 US presidential election brought intense attention to the phenomenon, Molina et al [5] analogized it to a much older problem—*yellow journalism*—dating from the Spanish-American War of 1896. It differs from disinformation in that disinformation connotes "an intentional, deliberate, or purposeful effort to mislead, deceive, or confuse."

Wardle and Derakhshan [6] considered information problems for journalists and outlined 7 types of misinformation and disinformation. In this taxonomy, problematic content is contrasted with genuine content:

1. Misleading content (misleading use of information)
2. Satire or parody (without intention to harm)
3. Fabricated content (false content intended to deceive)
4. Imposter content (impersonation of genuine sources)
5. Manipulated content (manipulation of genuine sources to deceive)
6. False context (attached to genuine content)
7. False connection (mismatch of headline to content with intent to deceive).

Clearly, some of these problematic content types are more malicious than others. However, whether intentional or not, misinformation can cause harm. This paper focuses on health information that makes unsubstantiated and exaggerated claims, purposefully or not, with the ultimate objective being to promote and sell a product.

Health Misinformation on the Internet

The prevalence of health misinformation is an ongoing concern. Keselman et al [7] analyzed 24 type 2 diabetes top result pages, obtained from a Google search on *diabetes*, *reversal*, and *natural*. Most of the sites either promised or implied full recovery, most commonly achieved by taking dietary supplements, making claims that opposed the evidence-based perspective of the American Diabetes Association.

Research into behavior on the internet shows that people are susceptible to misinformation and are willing to share it. Web-based health misinformation has been investigated in various places, including web-based health communities [6], social media [8,9], Google Trends [10,11], Amazon's web-based bookstore [12], and smart assistants such as Apple Siri and Amazon Echo [13].

Most research into how people spread misinformation in web-based social networks has been conducted in the domains of vaccines and infectious diseases [14]. For example, Basch et al [15] analyzed the most viewed vaccine-related videos on YouTube. The most popular videos were antivaccine (65.5%). They were commonly posted by laypeople and most often focused on the causal links between vaccines and autism. This and other such studies [16,17] not only illustrate the prevalence of misinformation but also underscore its potential impact. Krishna found that "knowledge-deficient, vaccine-negative individuals" were more active in spreading messages on the internet about vaccines [18]. The messages they spread were aligned with their attitudes.

In a study that focused on social media spread, Chen et al [19] analyzed 2691 tweets on Weibo (a Chinese equivalent of Twitter) related to breast and cervical cancers. They found that about 30% of the tweets contained misinformation, and that treatment-related tweets were more likely to contain misinformation than prevention-related tweets.

Sommariva et al [8] investigated stories circulating in social networking services about the Zika virus and found that half of the *top 10* were either misinformation or rumors. Studies are now beginning to emerge, focusing on the exchange of COVID-19 misinformation. Two-thirds of Korean adults surveyed by Lee et al [20] reported encountering myths and misinformation about COVID-19. Scientific discoveries, especially when they are of focal public interest and rapidly disseminated, beget misinformation; COVID-19 vaccines are being developed so fast that acquiring enough information about them to make decisions is a difficult task. In the United States, in May 2020, 73% of Republicans and 82% of Democrats surveyed called COVID-19 misinformation "a major problem," and almost 70% of those surveyed identified social media as the principal source of such misinformation [9].

Information Competencies

Overview

Researchers have been looking for effective approaches to promote accurate information in impactful ways and for factors that may reduce individual vulnerability. One of the most researched factors is health literacy, sometimes defined as "the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions." [21]. Other cognitive factors, while emerging as important theoretical constructs, have been studied less often in an empirical context. Sometimes these constructs are merged with the concept of health literacy (for a review of the conceptual underpinnings and research gaps in health literacy [22,23]). Three of these constructs—information literacy, science literacy, and trust—were considered in this study.

Information Literacy

Pinto et al reviewed the evolution of information literacy as a term and concept [24]. One useful definition is that information literacy is "a set of aptitudes to locate, handle, evaluate and use information efficiently for a wide variety of purposes, generating competent citizens who are better able to perform their activities in the new society" [24].

Information literacy instruction originated in libraries, in the practice known as *bibliographic instruction*. For this reason, both instruction and evaluation techniques were developed for *static, primarily print, sources* [24] and not the information content encountered by today's social media users. For this reason, the assessment of information literacy is typically conducted by academic librarians engaged in the instruction of a specific community of learners—from kindergarten through college—to determine that those learners are meeting the goals of a specific library instruction program. Instruments are developed by librarians and for libraries to fit their institutional missions. Information literacy is an *essential learning outcome* according to the Association of American Colleges and Universities [25].

Information literacy skills apply to any domain of information, including but not limited to health. An information-literate person is one who has "learned how to learn" [26]. That person can find appropriate information resources to meet their specific needs, can search those information resources effectively to find information, and distinguish between different types of resources based on characteristics that include quality markers. Health literacy, in contrast, relates specifically to outcomes affecting the health of the individual, for example, the ability to function in the health care environment (Berkman et al [27] presents a review of health literacy definitions).

Research assessing the effectiveness of information literacy is difficult to find, in part, because there are *very few* measures of the application of real-world learning [28]. However, the importance of information literacy for effectively navigating information and avoiding misinformation is in the very definition of the concept of information literacy.

Science Literacy

Researchers in the field of science education describe scientific literacy as comprising 3 components: (1) knowledge of science, (2) knowledge about science, and (3) attitudes toward science [29].

Knowledge of science refers to understanding specific scientific concepts, for example, being able to explain how antibodies bind to antigens. Research into the impact of knowledge of science on daily life has been very limited, and the few existing studies have produced mixed results. Layton et al [30] studied how people make decisions in situations where science has a potential bearing, for example, the older adults planning their heating budgets. They found that people rarely framed their problems as scientific ones, attending more to social and emotional aspects (eg, the pleasure of a glowing heater). In contrast, Keselman et al [31] found that the depth of biological knowledge contributed to adolescents' ability to reject myths about HIV. Overall, there is no convincing evidence that the knowledge of science is a ubiquitous and powerful aid in real-life situations. In part, the uncertain role of knowledge may be attributed to the depth of knowledge required. More recently, Keselman et al [7] evaluated websites promoting remedies for type 2 diabetes and found that the treatment mechanisms described on these sites referred to concepts well beyond high school biology.

Knowledge about science refers to understanding what constitutes a scientific question, how science may go about deriving the answer, and the checks and balances that exist to minimize bias and reduce errors [29]. Knowledge about science is a potentially promising competency that may be related to evaluating health information on the internet. Individuals with this competency may be skeptical about conspiracy claims and promises of simple solutions for complex problems and attentive to egregious research design flaws. Although science education recognizes the importance of knowledge about science [32,33], empirical investigations are complicated by the absence of operational definitions and assessment tools. Few instruments

isolate this component from general science literacy; the one instrument we found (and used as a basis for this study) targets students in college-level science classes [34].

The third component, attitude toward science, incorporates the view that science is valuable as an advantageous way to derive knowledge about the natural world: understanding the importance of the scientific process and trusting science as an enterprise. Trust in science can undeniably influence individuals' beliefs, consequential to matters of health. Agley and Xiao conducted a cross-sectional survey on the believability of 5 COVID-19 narratives, ranging from *scientific consensus* to *conspiratorial* [35]. Trust in science was the only significant predictor of the acceptance of more scientifically grounded narratives. Jennings et al [36] also found that trust played a role in the willingness to get vaccinated and the rejection of conspiracies.

While discussing science literacy throughout the rest of this paper, we use the term to refer to the *knowledge about science* component, as a generalizable aspect of science literacy that can be addressed through science education. When we write about knowledge of science, we refer to knowledge of the immune system, as the area of science knowledge that is directly applicable to the subject of our study.

In everyday situations that require weighing evidence, science literacy may be overridden by other factors. One factor is sociocultural. The cultural cognition thesis [37] proposes that individual perceptions of societal risks cohere with values characteristic of groups with which they identify. People process information in a manner adjusted to preserve identity-consistent rather than factually correct beliefs [36]. In a large-scale study evaluating views on climate change, Kahan et al [38] found that participants with the most sharply polarized cultural views, not those with high scientific literacy, were most concerned about climate change.

Pennycook et al [39,40] put forth a different kind of argument. They draw on dual-process theory [41] to distinguish System 1 thinking—fast, intuitive, and effortless—from System 2 thinking—analytic and effortful. Pennycook et al [42] argue that lazy System 1 thinking, more than strong partisan belief, predisposes individuals to believe in fake news. People tend to share false health claims from social media partly because they fail to sufficiently consider whether the content is accurate [42]. Moreover, different information presentation formats tend to trigger different systems, with film, compared with graphs and formulas, being more likely to activate analytical reasoning [43].

Trust

In social science literature, the concept of interpersonal trust is a measure of social capital that reflects the goodwill and sense of community that members of a society feel toward one another [44]. Higher general trust is a sign of well-functioning democratic societies and cohesive communities [45]. Multiple studies have found that trust is positively correlated with self-reported health and happiness [45]; trust is viewed as a positive, desirable characteristic of individuals in societies. Generalized trust also correlates with institutional trust in the government and its foundational institutions. Rotter distinguished between *trust* and *gullibility* by defining trust as "believing others in the absence of a clear-cut reasons to disbelieve" [46]. However, to the best of our knowledge, no study has investigated the relationship between interpersonal trust and web-based information behavior. In developing this study, we were interested in understanding the relationship among interpersonal trust, trust in health authorities (eg, leading biomedical research organizations, public health authorities, health care providers) and susceptibility to web-based health misinformation.

Objectives

The study described in this paper has 3 specific objectives:

1. Assess individuals' willingness to share a non–evidence-based YouTube video about strengthening the immune system and characterize types of evidence that positively or negatively affect the opinion of a non–evidence-based remedy.
2. Describe levels of information literacy, science literacy, knowledge of the immune system, and trust among the participants.
3. Characterize the relationship between information literacy, science literacy, knowledge of the immune system, trust, and the likelihood of recommending a YouTube video about a supplement with an immunity-boosting claim.

Methods

Participants

Participants (N=150) were recruited via Regional Medical Libraries (RMLs) of the National Network of the Libraries of Medicine (NNLM). NNLM is a diverse network of 7186 academic health sciences libraries, other special biomedical libraries, public libraries, information centers, and community-based organizations. RMLs coordinate the Network's operations in their regions, supporting and coordinating regional and national programs focused on health information. One coauthor emailed the 8 RML Associate and Executive Directors in late November of 2020 and requested permission to send out the study recruitment announcement to public libraries and community organizations using the listservs in their networks. Listserv members—employees of NNLM member organizations—were asked to promote the survey link among their patrons or clients via means appropriate to their environment. We hoped that this recruitment method would increase the likelihood of the geographic and cultural diversity of the participants. The announcement specified that participants needed to be proficient in English and comfortable using the internet. Professional librarians were excluded from the study.

The initial objective was to recruit 100 participants. Although we did not have previous data that could serve as the basis for power analysis to estimate the needed sample size, past experience suggested that this number would provide a sufficiently large sample size to answer our inferential questions; however, it would also be small enough for a thorough review of open-ended questions that would enrich the study. The first

response was received on December 2. On December 3, the survey was closed because the target number had been reached.

Participants came from 34 US states, including Alaska and Hawaii, and from the District of Columbia. Demographic characteristics of the participants are presented in Table 1.

Upon completing the survey, participants received a US $50 Amazon e-gift card. The study protocol was exempted from Institutional Review Board's review by the National Institutes of Health Office of Human Subjects Research.

Table 1. Demographic characteristics of the participants (N=149)[a].

Demographic characteristics	Participants, n (%)
Age (years)	
18-29	35 (23.5)
30-49	87 (58.4)
50-64	24 (16.1)
65+	3 (2)
Education	
High school or less	12 (8.1)
Some college	28 (18.8)
College graduate	83 (55.7)
Postgraduate degree	26 (17.4)
Gender	
Female	70 (47)
Male	79 (53)
Race and ethnicity	
White	89 (59.7)
Black or African American	21 (14.1)
Hispanic or Latino	17 (11.4)
Asian	5 (3.4)
American Indian or Alaska Native	10 (6.7)
Native Hawaiian or Other Pacific Islander	2 (1.3)
Declined to answer	7 (4.7)
Residential setting	
Urban	102 (68.5)
Rural	11 (7.4)
Suburban	36 (24.2)

[a]One participant did not complete the demographic section.

Instruments

Participants completed a web-based survey comprising the following components (Multimedia Appendix 1).

Web-Based Health Information Evaluation Task

For this task, participants viewed a 5-minute YouTube video, promoting a dietary supplement to strengthen the immune system [47].

Participants received the following prompt:

> *Your cousin had a bad case of the flu last year and did not fully recover for several weeks. In recent years, your cousin has frequently suffered from cold and occasionally flu. A friend told you about how certain supplements can help rev up your immune system. That friend recommends the following video: (link to the video).*

The video is an excerpt from the 2019 TMJ4-TV News episode of *The Morning Blend* TV show, in which 2 anchors talk to a Welltopia Pharmacy pharmacist about a cold and flu-fighting dietary supplement Viracid, which is claimed to "boost your immune system like no other." The episode is sponsored by Welltopia Pharmacy, and the sponsorship is clearly indicated in the video caption. The studio table contains multiple bottles of Viracid. On the close-up, viewers can see the price tag of US $37.50 on a bottle with 60 capsules. The pharmacist recommends taking one capsule of the supplement every hour at the onset of cold and flu symptoms. The pharmacist claims

that the ingredients are "very pure," "in concentrated form," and "the best immune booster" on the market. The video offers a 10% discount when buying the supplement.

After viewing the video, the participants answered several questions. The first asked them how likely they were to recommend the video to their cousin. The 4-point Likert score answers ranged from *Very unlikely* to *Very likely*. Participants were also asked to explain their decision and comment in free text on the convincing and concern-raising aspects of the video. Next, they were presented with several hypothetical pieces of evidence and asked how likely that evidence was to affect their opinion about the supplement. The answer options were *Very likely, negatively*; *Somewhat likely, negatively*; *No effect*; *Somewhat likely, positively*; and *Very likely, positively*. The hypothetical pieces of evidence are as follows:

- A friend taking this supplement for the past 2 years had not had a cold.
- The supplement's rating on a crowdsourced review site is 4.5/5.
- The supplement's rating on a crowdsourced review site is 2.3/5.
- A survey of consumers of the product reported that 85% did not have the flu within a year.
- Positive reviews on the supplement producer's website.
- The explanation of the supplement's biochemical mechanism of action on the company's website.
- Knowledge that the supplement has not been evaluated in a clinical trial.
- The National Institute of Allergy and Infectious Diseases (NIAID) review finding inconclusive evidence about the effectiveness of the supplement.
- NIAID review finding evidence of the effectiveness of the supplement in reducing the frequency and severity of respiratory infections.

Participants had the opportunity to explain their ratings.

Demographic Survey

The demographic survey included questions about participants' gender, age, race and ethnicity, highest level of education achieved, and place of residence.

Information Literacy Survey

The information literacy survey, developed by the authors, comprised 6 multiple-choice questions. The questions were modeled on skill domains and questions presented in 2 existing instruments: *Test of Scientific Literacy Skills* (TOSLS) [34] (refer to the *Science Literacy Survey* section) and *Parenting Plus Skills Index* [48]. The *Parenting Plus Skills Index* was validated in 3 samples of 500 Australian adults, ages 20-44 years. In addition, McKenzie's checklist for evaluating health information [49], which is not an instrument but a decision aid intended for health educators to share with consumers, was used to further support the choice of particular domains of skills to test. The internal consistency of the survey, measured by Cronbach α, was 0.62 considered acceptable [50].

Science Literacy (Knowledge About Science) Survey

This survey, which comprised 12 multiple-choice questions, was developed based on TOSLS, with a number of modifications. TOSLS, which measures the scientific literacy skills of students in undergraduate biology classes, includes questions that assess competency in 9 scientific literacy skills. Of these 9, we adopted 2, *identifying a valid scientific argument* and *understand elements of research design and how they impact scientific findings or conclusions*, as highly relevant to evaluating the content of web-based health claims. We excluded skills that pertained to conducting first-order research inquiry and analyzing and presenting quantitative data (*solve problems using quantitative skills, including probability and statistics*), as we saw these as more relevant to performance in undergraduate biology classes than to consumer health tasks. We also excluded *evaluate the validity of sources*, viewing this as a key information literacy competency, measured by our information literacy test. Finally, we excluded questions that involved judging the appropriateness of the *use of science by government, industry, and media*.

To develop our measure, we adopted the structure and content of some questions and answer options by Gormally et al [34], while simplifying the language (as our primary audience was not a college class) and editing the content to make it applicable to the health domain. We also wrote several additional health-specific questions and answer options that pertained to the 2 scientific literacy skills relevant to our task. The resulting measure comprised 12 questions, 5 assessing the ability to identify a valid scientific argument, and 7 assessing understanding of research design and how it pertains to scientific findings.

TOSLS was developed through an iterative process using built-in validation procedures. According to Gormally et al [34]:

> *...measures of validity included correspondence between items and scientific literacy goals of the National Research Council and Project 2061, findings from a survey of biology faculty, expert biology educator reviews, student interviews, and statistical analyses.*

Although TOSLS validity data do not extend to our measure, TOSLS provides a theoretical foundation for our conceptualization of scientific literacy as it pertains to evaluating web-based health information. The items were developed through several iterative review and discussion rounds by the 4 authors. The internal consistency of our science literacy survey, measured by Cronbach α, was 0.6, which is considered acceptable [50].

Immune System Knowledge Survey

We devised a five-question immunology knowledge assessment test to measure the basic knowledge of the immune system. The questions were developed with the expectation that anyone who had taken a middle or high school biology course could answer them correctly. The issue is whether someone with basic knowledge of the immune system would assess the claims expressed in the video from a more critical vantage point.

Immunology is an immensely complex topic that addresses issues well beyond the scope of our study.

Interpersonal Trust Survey

This survey assessed interpersonal trust and included one question commonly used in interpersonal trust surveys [51]. The question asked, "Generally speaking, would you say that most people can be trusted or that you cannot be too careful in dealing with people?" The answers required choosing a number on the scale from 1 to 5, where 1 meant *you can't be too careful* and 5 *most people can be trusted*.

Trust in Health Authority Survey

This survey, developed by the researchers, assessed participants' trust in 5 established authoritative health information sources: the Centers for Disease Control and Prevention, National Institutes of Health, major research universities, national voluntary health associations (the survey included American Diabetes Association as an example), and responders' primary health care providers. The answer options ranged on a 5-point Likert scale, from *don't trust at all* to *trust completely*. The questions were developed based on a literature review of trust in health care and biomedicine [52]. The internal consistency of the health authority trust items, measured by Cronbach α, was 0.64 and considered acceptable [50].

Data Collection and Preparation

The survey data were collected using Qualtrics XM, a widely used survey software. As a quality control measure, we removed responses that were submitted multiple times (those containing near-identical narrative answers) and responses that were completed in less than 20 minutes. The cutoff was determined empirically by the authors by completing the task as rapidly as possible while viewing the entire video and giving meaningful answers. The resulting data set included 150 responses. One of the participants completed the main information evaluation task only; another completed all the tasks except for the scientific literacy survey, which the participant left partially incomplete. The remaining 148 responses were complete. Missing data for the 2 partial responses were imputed from the means of the corresponding variables.

Data Analysis

For quantitative analysis, we used multiple-choice data that did not require coding. Scores for each survey were obtained as a simple count of the correct answers. Open-ended responses were reviewed carefully and used to provide illustrations and outline the narrative context of the quantitative data. SPSS (IBM) was used for quantitative data analysis. All subsections of the Results section, except for the last one, titled "Relationship between willingness to share the video and information competencies," report descriptive statistics illustrated by narrative examples. The last subsection reports the results of the inferential analysis using the statistical methodology described in this subsection.

Results

Willingness to Share the Video and Conceptualization of Evidence

Overall, the participants found the video worth sharing. Of the 150 participants, 70% (105/150) were *very likely* (47/150, 31.3%) or *somewhat likely* (58/150, 38.7%) to recommend the video to their respective cousin, whereas only 11.3% (17/150) were *very unlikely* to do that. Those likely to recommend the video put forward several reasons why they found it worth forwarding. Some had to do with their previous beliefs about the effectiveness of dietary supplements and the particular ingredients in the advertised supplement to enhance the immune system.

For example, one participant stated:

> *I am a firm believer in supplements.*

and another wrote:

> *With ingredients like Zinc and Elderberry, I feel more confident in this pill, as I bombarded myself with elderberry last flu season and it seemed to stop my cold.*

Other reasons had to do with the confidence in the wisdom of the crowd and the quality control afforded by the visibility of public opinion in the internet era, "If the quality is not good, many people [would] have complained." Some expressed trust in the channel or TV show on which the video aired, and with which they had prior familiarity. A number felt that there was no harm in trying something that may potentially be of help (eg, "Since [he] hasn't recovered for a few weeks, try all of them, maybe it works"). However, many others provided statements that did not include justifications (eg, "It's a good choice and I think it will work").

The participants who were unlikely to recommend the video also provided different justifications. Some mentioned the absence of *evidence* of the supplement's effectiveness or the lack of Food and Drug Administration's approval. Many were taken aback by the proposed schedule of taking the supplement every hour. Typically, regardless of their willingness to share the video, participants did not provide multiple reasons and did not weigh *pro* and *con* arguments against one another.

Participants were also presented with a number of hypothetical statements that could be viewed as evidence and asked whether these would affect their opinion about the supplement, either positively or negatively (Table 2 contains statements and the results). The large majority responded that their opinion about the supplement would be positively influenced by factors that do not meet the criteria of valid scientific evidence. These included a friend's account of a positive experience with the supplement (124/150, 82.7% of individuals), high customer ratings on a website of crowdsourced reviews (108/150, 72% of individuals), a survey of supplements consumers done without controls (99/150, 66% of individuals), and a statement on the supplement producer's site that 9 out of 10 people found the product beneficial (98/150, 65.3% of individuals).

Table 2. Likelihood of the following things affecting the opinion about the supplement (N=150).

Statement	Participants, n (%)		
	Positive effect[a]	No effect	Negative effect[a]
You speak to another friend, and she says that she has been taking this product for the past 2 years and has never caught a cold.[b]	124 (82.6)	21 (14)	5 (3.3)
A crowdsourcing review website focused on supplements found that almost every reviewer had positive things to say about the supplement (its average rating being 4.5 out of 5 stars).[b]	108 (72)	29 (19.3)	13 (8.6)
A crowdsourcing review website focused on supplements found that many people were dissatisfied with the supplement (its average rating being 2.3 out of 5 stars).[c]	24 (16)	40 (26.6)	86 (57.3)
A survey of consumers who had been using the product for the last year indicates that 85% of them did not get the flu last year and 15% got the flu.[b]	99 (66)	47 (31.3)	4 (2.6)
On the supplements company's website, they state that a study found that 9 out of 10 people found the product to be beneficial.[b]	98 (65.3)	48 (32)	4 (2.6)
On the supplements company's website, a video explains the benefits of the supplement in terms of the biochemistry of how it boosts the immune system.[b]	92 (61.3)	52 (34.6)	6 (4)
This supplement has never been tested in a controlled clinical trial.[c]	20 (13.3)	31 (20.6)	99 (66)
A year later, a review by scientists from the National Institute of Allergy and Infectious Diseases concludes that scientific evidence about the effectiveness of this supplement is inconclusive.[c]	40 (26.6)	37 (24.6)	73 (48.6)
Another year later, a new review by scientists from the National Institute of Allergy and Infectious Diseases concludes that scientific evidence supports the claim that this supplement reduces frequency (how often) and severity (how bad) of respiratory (breathing-related) infections.[b]	127 (84.6)	18 (12)	5 (3.3)

[a]Combines *very likely* and *somewhat likely*.

[b]May be perceived as *in favor* evidence.

[c]May be perceived as *against* evidence.

In explaining their responsiveness to potential influences, many participants stressed the value of their friends' personal experiences. They described relationships with friends as built on trust, which translated into the information being seen as trustworthy. For example, one participant said, "Personal experience from a trusted person is persuasive." The term *trust*, mentioned frequently, was described as an assurance of accuracy and objectivity:

> *I trust what my friends say. So her experience would make me believe in the product's efficacy more than the information from the morning show guest. I perceive the guest to have a pecuniary interest in sales of the product.*

Many respondents also had positive views of reviews on crowdsourcing sites. Although some mentioned possible reasons for skepticism, such as the number of reviews or reviews by bots, many felt reassured by the absence of negative reviews. For example, one respondent wrote, "So many people use it and the effect is very good, so I believe this product has good quality." However, others preferred to obtain recommendations from their doctors.

In considering a survey that found that 85% of the product's users did not get the flu in a year, most felt reassured by the number, stating that, in their experience, the number was high enough to suggest that the product was effective. There were also some doubts voiced by participants; for example, "I have a feeling that people who seek out and spend money on supplements like these tend to be healthier in many areas of their lives, so are less likely to get the flu in general." Responses to testimonies and claims of effectiveness on the company's site also included a mix of positivity and skepticism. They ranged from "They did research and the results are good, so I think the product quality is good" to "The credibility of research done by his own company is not guaranteed."

Participants also reacted to the hypothetical scientific evidence. A total of 73 (48.6%) participants said their opinion of the supplement would be negatively affected if a study by the NIAID deemed the evidence of the supplement's effectiveness inconclusive. Overall, 99 (66%) participants reacted to "This supplement has never been tested in a controlled clinical trial" by stating that this would affect their opinion *very* or *somewhat* negatively. Had a NIAID study found evidence of the supplement's effectiveness, 127 (84.6%) respondents' opinions would be positively affected. Overall, many participants expressed a view of science as an important foundation of health-related knowledge. They referred to scientists as having "authority" and "credibility." One person stated, "Dr. Fauci and the National Institute of Allergy and Infectious Diseases conduct research in a scientific manner and this is very good." Many expressed trust in NIAID and "national institutions," "public health agencies," and "government agencies." Skeptical voices also existed: "I would still be skeptical, and would want to know about who funded the study, what they found, how much the supplement actually reduced frequency, severity, etc." Yet others explicitly preferred their own conclusions and experience.

Information Competencies

Information Literacy

For the information literacy measure with a possible range of scores from 0 to 6, participants' mean score, or the number of correct responses to the multiple-choice questions, was 3.23 (SD 1.72). Table 3 shows the distribution of information literacy scores.

Responses to individual information literacy questions are summarized in Table 4. In evaluating the reliability of information sources, most participants recognized the value of dot-gov and, to a lesser extent, dot-edu domains. For example, in choosing among 3 possible websites in search of "unbiased information" about food to support a child's immune system, 72.4% (108/149) responders chose a dot-gov site that was "checked by health professionals." In deciding which site was most likely to provide accurate health information, 59.7% (89/149) chose "an institute run by the US government," followed by "a support group for patients living with a particular illness" (46/149, 30.9%). In choosing the most reliable site between Harvard Health Publishing website, Healthline website, Medlinx website, and BBC website, a little over half (77/149, 51.7% of respondents) wrote that the Harvard site was the most reliable. When it came to evaluating author credentials as markers of their authority and qualification to write about the immune system, a little over half (76/149, 51%) participants chose an allergist (a physician specializing in immune deficiency disorders) over a food chemist (28/149, 18.8%), a naturopath (27/149, 18.1%), or a health blogger (18/149, 12.1%).

Table 3. Distribution of participants' information literacy scores (N=149).

Score	Participants, n (%)
0	6 (4)
1	19 (12.8)
2	28 (18.8)
3	39 (26.2)
4	18 (12.1)
5	16 (10.7)
6	23 (15.4)

Table 4. Information literacy, correct responses (N=149).

Question	Answer options[a]	Correct responses, n (%)
Lisa has a toddler and is looking for a website with unbiased information about food to support her daughter's immune system. She finds 3 websites. Which of the sites is the best option for Lisa?	• The 3 options differ in domains (dot-com, *dot-gov*, dot-info, recency, and background of authors)	108 (72.5)
Which of the following sources' websites is most likely to provide accurate health information?	• Four options ranging from a *US federal institution* to a social media company selling a health app	89 (59.7)
You want to find more information about making your immune system stronger. You type *boost immune system* into Google. From the results of that search, which website is likely the most reliable information source?	• *www.health.harvard.edu* • www.healthline.com • www.medlinx.com • www.bbc.com	77 (51.7)
Which of the following authors would be the best qualified to write an article about the immune system?	• a food chemist, PhD • a naturopath, NMD • a food blogger, MA • *an allergist, MD*	76 (51)
You go to the mercola.com website, which features health news and articles. The website states that "The entire contents of this website are based upon the opinions of Dr. Mercola, unless otherwise noted." Does this mean the content has been reviewed by independent medical professionals (eg, qualified doctors, nurses, or other health care providers?)	• Yes, definitely • *No, not necessarily*	72 (48.3)
The developers of a drink called BoostRx claim that their product increases the effectiveness of the immune system. Which of the additional information below would provide the strongest evidence supporting this claim?	• Four options that include *published independent studies*, studies by the developer, advertisements, and purchasers' reviews	60 (40.3)

[a]Correct answers in italics.

Another information literacy question asked participants to determine whether the content of a health information site was verified by independent reviewers. Despite the explicit statement in the question that "the entire contents" were based on the opinions of the site's owner, Dr. Mercola, fewer than half (72/149, 48.3%) of the participants chose *no, not necessarily*, whereas the majority (77/149, 51.7%) believed that the site was *probably* verified by independent medical professionals.

The most difficult information literacy question turned out to be the one asking participants to choose a piece of information that would provide the strongest evidence for the claim that a drink called BoostRx increased the effectiveness of the immune system. Only 40.3% (60/149) of respondents correctly chose links to published studies that did not involve developers. A total of 31.2% (47/149) chose reviews by satisfied purchasers, 24.9% (37/149) preferred articles written by one of the developers, and 5 selected advertisements on the developer's site.

Immune System Knowledge

For the measure of immune system knowledge, with possible scores ranging from 0 to 5, the mean score was 2.38 (SD 1.34). The distribution of scores is presented in Table 5.

The question answered correctly by most of the participants was "What do vaccines do?" The majority, 70.5% (105/149), selected "Stimulate the immune system to produce antibodies." The majority (100/149, 67.1% of participants) also recognized that white blood cells produced antibodies. A little fewer than half (72/149, 48.3%) were able to answer what constituted the first line of defense against microbes (skin). About a third, approximately 36.2% (54/149) correctly selected the answer that described the relationship between antibodies and antigens. Finally, only 16.1% (24/149) recognized that all 3 organs, cells, and chemicals were components of the immune system.

Table 5. Distribution of participants' immune system knowledge scores (N=149).

Score	Participants, n (%)
0	12 (8.1)
1	29 (19.5)
2	38 (25.5)
3	43 (28.9)
4	17 (11.4)
5	11 (7.4)

Science Literacy

For the measure of science literacy, with possible scores ranging from 0 to 12, the mean score was 6.57 (SD 2.40). The distribution of the scores is shown in Table 6.

Table 6. Distribution of participants' science literacy scores (N=148).

Score	Participants, n (%)
0	0 (0)
1	0 (0)
2	0 (0)
3	10 (6.8)
4	23 (15.5)
5	29 (19.6)
6	17 (11.5)
7	22 (14.9)
8	13 (8.8)
9	8 (5.4)
10	14 (9.5)
11	11 (7.4)
12	1 (0.7)

The questionnaire included 2 question formats. The first presented an accurate or faulty reasoning statement and asked, "Is this a good scientific argument?" The other format described the design of a study, either well-designed or problematic, and

a conclusion, and asked whether, based on the presented information only, any other factors could explain the difference (Table 7). In both cases, participants were less likely to recognize faulty reasoning or design than they were to doubt good logic and well-designed experiments. The most difficult questions turned out to be those that required recognizing potential confounding factors in the research design. Considering base rates and sample sizes also proved challenging (see Table 7 for examples).

Table 7. Selected questions requiring recognizing potential confounds in research design (N=148).

Question	Answer[a]	Correct, n (%)
Researchers want to study how noise affects task performance. They randomly put participants into 2 groups. Females make up 35% of the first group and 75% of the second group. Participants in the first group complete a moderately difficult task in a quiet room. Participants in the other group do the same task in a noisy room. Researchers say that any differences in performance between the groups will be because of the noise. Based on this information only, do you see any other factors that may explain the difference?	• *Yes* • No	47 (31.8)
This year, there were 100,000 more cases of adolescent depression diagnosed in the US than last year. Thus, adolescent depression in the US is on the rise. Is this a good scientific argument?	• Yes • *No*	63 (42.6)
Researchers in a cancer clinic test a new drug in 12 patients with a rare cancer. None of the patients experience any dangerous side effects. The researchers concluded that the drug is safe. Based on this information only, do you see any factors in the design that make you less confident about the researchers' interpretation of their findings?	• *Yes* • No	58 (39.2)
Many people who take multi-vitamins do not catch colds frequently. Thus, taking multi-vitamins prevents colds. Is this a good scientific argument?	• Yes • *No*	77 (52)

[a]Correct answers in italics.

Trust

On the measure of interpersonal trust, deciding whether *most people can be trusted* where 1 meant *you can't be too careful* and 5 *most people can be trusted*, the majority of respondents leaned toward trusting people. Although most participants trusted major biomedical research and policy organizations and the health care establishment, a not so small minority was skeptical of them (Table 8). The mean health authority trust score was 20.08 (SD 2.81) out of 25.

Table 8. Trust in health authority (N=149).

	Participants, n (%)				
	1 (do not trust at all)	2	3	4	5 (trust completely)

[a]For this question, answer options are 1=cannot be too careful and 5=can be trusted.

Relationship Between Willingness to Share the Video and Information Competencies

For the inferential analysis, we were interested in the impact of information literacy, science literacy, knowledge of the immune system, interpersonal trust, and trust in health authority on the likelihood of recommending the video.

As a first step in the analysis, we looked at pairwise correlations among the independent variables of interest. The variables were highly correlated (Table 9).

Table 9. Correlations among independent variables (with significance level; N=150).

Independent variable	Information literacy	Science literacy	Immune system knowledge	Interpersonal trust	Health authority trust
Information literacy					
r	1.000	0.505[a]	0.286[a]	−0.390[a]	0.143
P value	N/A[b]	<.001	<.001	<.001	.08
Science literacy					
r	0.505[a]	1.000	0.357[a]	−0.228[a]	0.175[c]
P value	<.001	N/A	<.001	.005	.03
Immune system knowledge					
r	0.286[a]	0.357[a]	1.000	−0.157	0.112
P value	<.001	<.001	N/A	.06	.17
Interpersonal trust					
r	−0.390[a]	−0.228[a]	−0.157	1.000	0.235[a]
P value	<.001	.005	.06	N/A	.004
Health authority trust					
r	0.143	0.175[c]	0.112	0.235[a]	1.000
P value	.08	.03	.17	.004	N/A

[a]Significant at the .001 level (2-tailed).

[b]Not applicable.

[c]Significant at the .05 level (2-tailed).

As interventions often target a single variable, we wanted to compare effect sizes of single predictor models. To do this, we conducted 5 single-predictor regression analyses of the independent variables on the 4-level *likelihood of recommending the video*. To correct for multiple hypotheses, the significance of the models was assessed at $P<.01$. The data are summarized in Table 10.

Table 10. Comparing single predictor models.

Independent variable	F test (*df*)	*P* value	Adjusted R^{2a}	Standardized coefficient β	Unstandardized coefficient *B* (CI; SE)	*t* test (*df*)	*P* value
Information literacy	31.24 (1,148)	<.001[b]	0.17	−0.417	−0.236 (−0.320 to −0.153; 0.042)	−5.59 (148)	<.001[b]
Interpersonal trust	29.04 (1,148)	<.001[b]	0.16	0.405	0.393 (0.249 to 0.538; 0.073)	5.38 (148)	<.001[b]
Science literacy	11.65 (1,148)	<.001[b]	0.07	−0.270	−0.110 (−0.174 to −0.046; 0.032)	−3.41 (148)	<.001[b]
Immune system knowledge	6.17 (1,148)	.01[c]	0.03	−0.200	−0.146 (−0.262 to −0.030; 0.059)	−2.48 (148)	.01[c]
Health authority trust	2.40 (1,148)	.12	0.01	0.126	0.044 (−0.012 to −0.101; 0.029)	1.55 (148)	.12

[a]Reflects proportion of variance accounted by the model.

[b]Statistically significant at $P<.01$.

[c]Approaches significance at $P<.01$.

The analysis shows that, as single predictors, information literacy had the largest effect size, predicting the largest amount of variance in the dependent variable (17%). Although only 22% (5/23) of the participants with the highest possible information literacy score of 6 said they would share the video, 95% (18/19) with a score of 1 would share it. The percentage of participants wishing to share the video increased sharply at the information literacy score of 5 (11/16, 69%) and continued to increase (41/57, 72% at the scores of 4 and 3, 25/28, 89% at the score of 2).

The effect size of information literacy was closely followed by that of interpersonal trust (accounting for 16% of the variance). Science literacy as a single predictor accounted for 7% of the variance in the dependent variable and immune system

knowledge for 3%. Trust in health authority had no significant effect as a single predictor.

To compare the strength of associations, we calculated correlations of each predictor with the dependent variable and then used the Fisher r-to-z transformation. The analysis revealed that the top 3 predictors, namely information literacy, interpersonal trust, and science literacy, were not statistically different in the magnitude of their association with the likelihood of sharing the video.

The effects of the variables were in the expected directions: higher information literacy, science literacy, and immune system knowledge scores were associated with a lower likelihood of recommending the video. Higher interpersonal trust was associated with a greater likelihood of recommending the video.

Due to multiple correlations leading to expectation of shared variance, we also performed a linear regression with all 5 independent variables in the single model. Multicollinearity diagnostic tests were performed and did not raise concerns about violations of assumptions for regression (all VIFs≤1.48). The model was statistically significant, $F_{1,144}$=10.60; P<.001, and accounted for 24% of the variance in the likelihood of recommending the video. In the final model with all the predictors entered, information literacy (2-tailed t_{149}=−3.26; P=.001) and interpersonal trust (t_{149}=2.85; P=.005) were statistically significant; trust in health authority approached significance (t_{149}=1.72; P=.09); immune system knowledge and science literacy were not significant with the other factors in the model.

The overall analysis suggests that information literacy, science literacy, immune system knowledge, and interpersonal trust were related to participants' willingness to share the video; the impact of trust in health authority was marginal. Moreover, the correlation among the predictors and different significance of the variables in the single predictor and multiple predictor models suggest the possibility of mediation. For example, it is possible that information literacy mediated the impact of scientific literacy variables, with science literacy variables influencing judgment not directly, but by affecting information literacy.

Discussion

Overview

This study confirms that people are vulnerable to web-based misinformation and are likely to propagate it by sharing it with others [8-19]. In evaluating claims, they are often influenced by the information that science and information professionals within the normative health care paradigm do not consider supporting evidence. Examples include hearsay, majority opinions, or statements by those with conflicts of interest. The study also shows that information literacy, science literacy, and health domain knowledge are challenging competencies. None of this is surprising.

Theoretical and Practical Contributions

The study's major theoretical and practical contribution to the field is in demonstrating that greater information literacy and science literacy are associated with lesser vulnerability to misinformation and lesser propensity to share it. Although the field of eHealth recognizes these literacies, they have received little attention in empirical research [53]. Although the relationship is complex, and vulnerability to misinformation is affected by a host of interacting factors, programs that target information literacy and understanding of science hold promise for helping individuals and communities. Of these 2 factors, information literacy is easier to address in informal educational settings, such as libraries, community organizations, and health clinics. Science literacy, on the other hand, is primarily developed over a period of years in a science classroom. Still, the two correlate and likely influence one another, pointing to the value of a collaborative conversation among school science educators, information professionals, and health professionals.

Another contribution of this study to the field is providing a starting point for building instruments for assessing information literacy and science literacy as they pertain to health information and information behaviors. The instruments developed for this study build on existing tools developed for related purposes. Although developing robust psychometric instruments requires multiple rounds of item testing and adjustment that are beyond the scope of this study, the internal consistencies of our initial instruments pose them as a feasible foundation. Further work is needed to sharpen and validate them for use in consumer health information contexts.

Finally, unlike much research into the public's reaction to web-based health information [8,10,14], this study focuses on a YouTube video, rather than web text. YouTube videos as an information source pose a unique challenge to consumers: their authorship and ownership are often harder to establish, whereas auditory information and the absence of hyperlinks make verifying authority and fact checking more challenging. In addition, existing web-based information evaluation criteria have not been optimized for assessing the quality of videos [54,55]. At the same time, videos are an attractive format to watch and easy to share, and studying consumer behavior in sharing online health videos is important.

The Issue of Trust

This discussion would be incomplete without addressing the issue of trust and the need for further research into the relationship between trust and vulnerability to health misinformation. One important area of trust that merits further investigation is trust in science [52]. In designing our science literacy instrument, we chose to focus on knowledge about science (eg, understanding scientific methods and argumentation), rather than on trust in science as an enterprise. In evaluating potential supporting evidence for the claims made in the video, our participants made many positive claims about science. For example, clinical trials of the effectiveness of the supplement were the type of evidence that raised confidence in the supplement for the greatest number of participants. In future research, we intend to explore trust in science more closely.

The 2 kinds of trust that were investigated in this study, interpersonal trust and trust in health authority, also merit further investigation. It was unexpected that trust in health authority was only marginally associated with vulnerability to misinformation and in only one of the models. This may be due to the specific health information domain addressed by the study, dietary supplements for strengthening the immune system. Scientific data addressing the impact of supplements on health are very complex and do not easily translate into evidence-based public health messaging. In other areas, such as attitudes toward vaccination, trust in health authority and vulnerability to misinformation may have a stronger association.

Interpersonal trust's association with vulnerability to health misinformation posits a philosophical challenge. In a way, it is not surprising that people who are less trusting in general are also more skeptical of overgeneralized, inflated promises of cures, unsupported by research evidence. At the same time, social science research does not equate trust with gullibility [46] and generally views higher interpersonal trust as a characteristic of healthy functional societies. Institutional trust also positively correlates with trust in societal institutions [45] and should be expected to correlate with trust in science and health care establishments. To the best of our knowledge, no studies have conducted an in-depth investigation of different types of trust related to the spread of misinformation on the internet. The topic, however, is important, especially as it relates to misinformation around COVID-19 infodemic, and merits further studies.

Implications for Education and Consumer Health Informatics

Efforts to help the public navigate and share health information in the era of social media can be of 2 kinds. The first kind involves programs, activities, and materials that target individuals' information competencies. Such programs can occur in a variety of settings, focusing on helping individuals analyze the characteristics of information sources, presentation, and content. Our study suggests that such interventions have promise. At the same time, information and science literacy develop over time, growing with many educational and personal experiences, so easy fixes are unlikely. Moreover, these competencies do not tell the full story when it comes to predicting information behavior. As an illustration, in our sample, many participants with high competencies scores expressed an intent to share the video. The science literacy background section of this paper discusses how people often make choices that appear inconsistent with their scientific knowledge, driven by considerations of group identity [38] or fast reactive responses [40].

The second kind of approach to supporting the public involves leveraging technologies. Examples of technologies can vary, from fact-checking sites to machine learning misinformation detection tools [56]. The development of such tools is important because it alleviates the burden of being vigilant for consumers and also reduces the cognitive load while processing complex information. This entails less time commitment than educational efforts.

However, technology alone will not solve the problem of misinformation. The challenge of evaluating information authority applies to a fact-checking tool as much as it applies to a YouTube video selling dietary supplements. Moreover, trust in information and information providers is critical for the acceptance of any information technology. Helping individuals recognize web-based health misinformation is a complex, multifaceted enterprise that should involve the collaborative efforts of researchers, technology developers, librarians, educators, and community outreach specialists.

Limitations and Directions for Future Research

As this study was conducted with a small nonrepresentative sample, it does not provide information on the general picture of the propensity to share health misinformation on the internet, as well as related literacies, in the population. Moreover, the study used a hypothetical scenario and could not draw on the complex social factors that affect decisions to share information in real life (eg, approval and status seeking). Supplementing this study with research into real-world health information sharing decision making will provide more nuanced data for future understanding of the issue.

Furthermore, no validated psychometric instruments exist currently for assessing information literacy and science literacy in the context of web-based health information behavior. Although our research instruments were designed with care, the formal process of designing, testing, adjusting, and validated psychometric tools was outside the scope of our study. Although the internal consistency data of our instruments were acceptable, a higher reliability is expected of formal instruments. We hope that as attention to information literacy, science literacy, and trust grows, such robust instruments will emerge. At present, our results should be interpreted with the understanding that they are affected by our specific selection of questions and answer options in our instruments. As the lower internal consistency of instruments makes the effects more difficult to detect, the sizes of the effects found here may be greater in future studies.

Finally, our study involved a survey methodology with a primarily quantitative focus, an approach that works better for establishing relationships than for describing them in depth. An interview study probing participants' reasoning would provide a nuanced richness of information on this important topic.

Acknowledgments

This work was supported in part by the intramural research program at the National Library of Medicine, National Institutes of Health. The authors thank Yulia Chentsova Dutton for sharing her invaluable statistical expertise. The authors are also thankful to the Network of the National Library of Medicine for helping with inviting participants to the study.

Abstract

Background: In the absence of official clinical trial information, data from social networks can be used by public health and medical researchers to assess public claims about loosely regulated substances such as cannabidiol (CBD). For example, this can be achieved by comparing the medical conditions targeted by those selling CBD against the medical conditions patients commonly treat with CBD.

Objective: The objective of this study was to provide a framework for public health and medical researchers to use for identifying and analyzing the consumption and marketing of unregulated substances. Specifically, we examined CBD, which is a substance that is often presented to the public as medication despite complete evidence of efficacy and safety.

Methods: We collected 567,850 tweets by searching Twitter with the Tweepy Python package using the terms “CBD” and “cannabidiol.” We trained two binary text classifiers to create two corpora of 167,755 personal use and 143,322 commercial/sales tweets. Using medical, standard, and slang dictionaries, we identified and compared the most frequently occurring medical conditions, symptoms, side effects, body parts, and other substances referenced in both corpora. In addition, to assess popular claims about the efficacy of CBD as a medical treatment circulating on Twitter, we performed sentiment analysis via the VADER (Valence Aware Dictionary for Sentiment Reasoning) model on the personal CBD tweets.

Results: We found references to medically relevant terms that were unique to either personal or commercial CBD tweet classes, as well as medically relevant terms that were common to both classes. When we calculated the average sentiment scores for both personal and commercial CBD tweets referencing at least one of 17 medical conditions/symptoms terms, an overall positive sentiment was observed in both personal and commercial CBD tweets. We observed instances of negative sentiment conveyed in personal CBD tweets referencing autism, whereas CBD was also marketed multiple times as a treatment for autism within commercial tweets.

Conclusions: Our proposed framework provides a tool for public health and medical researchers to analyze the consumption and marketing of unregulated substances on social networks. Our analysis showed that most users of CBD are satisfied with it in regard to the condition that it is being advertised for, with the exception of autism.

KEYWORDS

social media; social networks; text mining; CBD; cannabidiol; cannabis; public health; drug regulation; Twitter; sentiment analysis; unregulated substances

Introduction

Although the cannabis plant has been used as a medication for centuries, the use of cannabis was criminalized in the United States in 1937. However, beginning in the 1990s, a few states began allowing the medical use of cannabis even as the plant remained illegal at the federal level [1]. As more states introduced laxer cannabis policies, public interest in the medicinal properties of cannabis evolved to embrace cannabidiol (CBD). CBD is an active chemical found in variants of the cannabis plant that does not have the psychoactive side effects of the tetrahydrocannabinol (THC) components of the cannabis plant [2].

In recent years, the utility of medical cannabis has grown as a major point of discussion in public policy, and especially in online social media discourse [3,4]. In particular, consumers have reported using CBD to treat various conditions, including epilepsy and other neurological disorders, insomnia, and some mental illnesses. CBD remains unregulated by the Food and Drug Administration (FDA) and has not been subjected to the same conclusive trials as most medications pertaining to its many specific uses. In fact, the FDA has only approved one cannabis-derived medication and three cannabis-related drugs to date—all of which require a prescription—and it has not approved marketing cannabis as a safe and effective drug for treating any disease [5]. Palmieri et al [6] reported promising results of CBD as a treatment for inflamed skin conditions and scars. There have also been many studies performed on CBD as a treatment for anxiety and sleep disorders [7-10], as a pain reliever [11-13], and as a treatment for cancer and cancer side effects [13-15].

Although most CBD-based medications and nutritional supplements have not demonstrated safety and efficacy for the numerous indications for which they are used, there are nevertheless many claims in public circulation regarding the effectiveness of CBD for a wide spectrum of ailments.

Social media serves as a primary location for viral CBD marketing and individuals sharing their experiences of personal use. Twitter, in particular, is a useful platform for understanding how cannabis, including CBD, is marketed to consumers and how individuals are using cannabis, as it provides a large corpus of both personal and commercial tweets [3]. Additionally, sentiment analysis can be used on personal and commercial CBD tweets to gauge user satisfaction for CBD treatment of particular medical conditions.

Thus, we propose a framework for the use of text mining in social networks that can help public health experts understand the landscape of personal and commercial claims and sentiments about unregulated substances such as CBD. There are two practical advantages to this framework. First, the data are readily available, easy to access, and inexpensive to use compared to administering surveys or utilizing data from governments and health providers. Second, public health researchers have already shown that sentiment analysis is an effective tool for understanding the public perception of drugs, diseases, and medical services as well as for detecting certain forms of depression [16-19].

To demonstrate the usefulness of this framework, we distinguished between tweets reflecting personal CBD use and tweets reflecting the sales, promotion, and commercialization of CBD. The two resulting corpora of tweets were analyzed for medical-related terms such as conditions, side effects, anatomical terminology, and use of other substances mentioned. This approach allowed us to identify terms that are being used in online CBD marketing in relation to the terms referenced by individuals taking CBD. In addition, we performed sentiment analysis on personal CBD tweets to gauge public opinion on the effectiveness of CBD in treating certain conditions. We were also able to use the Valence Aware Dictionary for Sentiment Reasoning (VADER) model to compute the sentiment of the personal and commercial CBD tweets making reference to specific medical conditions. The VADER sentiment model was used as it was specifically developed for analyzing sentiment on posts made on social network sites such as Twitter [20]. Since its development, VADER has been used to gauge sentiment on digital assistants among Twitter users, political tweets, as well as course evaluations [21-24]

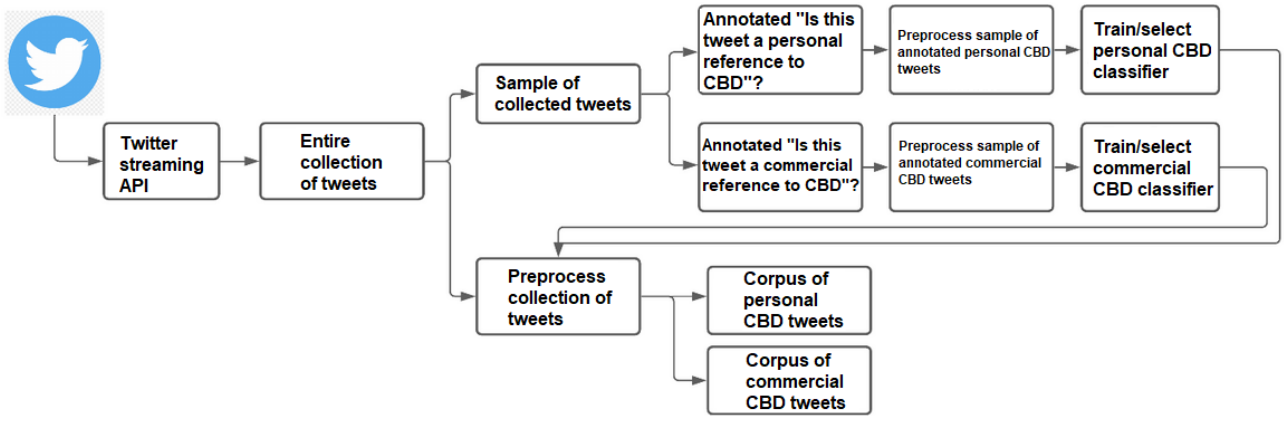
Findings from this study will provide important information on public perceptions of CBD and how CBD is marketed through a social media platform. Misinformation has increased with the rise of social media. Recently, researchers have used social networks to analyze these concepts with regard to medical misinformation [25-28], which can contribute to negative health outcomes. For this reason, unverified claims overstating, exaggerating, and lying about CBD's medical benefits have circulated freely on the internet, leading many to wonder how to assess the actual benefits (if any) of using CBD in medical contexts. Some of the conditions referenced in these claims include ear pain in infants, autism, attention deficit and hyperactivity disorder, Parkinson disease, and Alzheimer disease [29]. By analyzing personal and commercial tweets about CBD using the adaptable and generalizable framework developed for this study, public health and medical professionals can more readily identify viral misinformation pertaining to CBD claims.

Methods

Framework Development

To build this framework, we collected tweets that make reference to "CBD" or "cannabidiol." We then took a random sample of these tweets and labeled them as a personal CBD reference (true/false) or commercial CBD reference (true/false). Using these annotated tweets, we trained two binary text classifiers to separate the personal and commercial CBD tweets from the larger collection of tweets. Using these two corpora of tweets, we identified the most frequently occurring medically relevant terms (terms related to diseases, conditions, symptoms, body parts, other substances, cannabis, etc) and compared these term frequencies between the two corpora. Figure 1 provides a visual description of our framework from data collection through classification. We then computed the sentiment of the personal CBD tweets containing specific terms using the VADER model to assess the satisfaction of CBD for treating those conditions.

Figure 1. Workflow of Tweet collection and classification. API: application programming interface; CBD: cannabidiol.



Data Collection

We collected tweets from the Twitter public stream using the Tweepy Python package as an interface to the live Twitter stream, which provides access to approximately 1% of the public tweets as they are created. Our data collection ran from October 7, 2019, to January 26, 2020, and used the search terms "CBD" and "cannabidiol." We selected this period as it represents the time when CBD had become popular. We restricted our collection to an approximate 3.5-month period so that we could collect a sufficient amount of tweets within a window of time to avoid potential concept drift within the data. We also set filters to collect tweets that were written in English and were original (ie, no retweets). We did not want to include retweets as the actual contents of these tweets are linked to another author and are nearly identical in text to an existing tweet. For each tweet collected, we kept the full-length tweet text, the ID of the tweet, the time the tweet was created, and the Twitter user that authored the tweet. The resulting collection consisted of a data set of 567,850 tweets.

Tweet Annotation

To identify the personal and commercial-related CBD tweets from our collection of 567,850 tweets, we built two binary classifiers trained on a sample of 5496 tweets. This sample of tweets was obtained by taking a 6000-tweet sample from our collection and removing entries with verbatim duplicate tweets. The process of annotating the personal CBD tweets consisted of evaluating each tweet in the sample as to whether or not it was posted from an individual (ie, not a "bot") discussing the past, current, and/or future use of CBD. The process of annotating the commercial CBD tweets consisted of evaluating each tweet in the sample as to whether or not it was posted from an actual (ie, not a "bot") nonnews entity selling, advertising, or promoting CBD. These classifiers were used to distinguish between personal and commercial CBD-related tweets. To train these classifiers, all tweets in the sample were manually labeled as either a personal CBD-related tweet or a nonpersonal CBD-related tweet, and either a commercial CBD-related tweet or a noncommercial CBD-related tweet, according to the content in their full text, which consisted of a maximum of 280 characters. Textbox 1 provides some examples of the personal and commercial CBD-related tweets, and Textbox 2 provides some examples of the types of tweets referencing CBD that we encountered that were considered erroneous for both the personal and commercial CBD classes.

Textbox 1. Examples of personal and commercial cannabidiol (CBD)-related tweets (paraphrased slightly for anonymity). CBC: cannabichromene.

Personal CBD-related tweets.

CBD products are so good for anxiety, and they don't make you high

I've used CBD for anxiety. It is WAY healthier than taking benzodiazepines…I also use CBC for pain. You know what else is bad for your liver? Tylenol and Ibuprofen

Take some painkillers with sleeping aid like Tylenol or Advil PM or something…any CBD or weed maybe try that too

CBD gummies will not give you the high, but for me personally CBD oil edibles helped with anxiety and menstrual cramps

Commercial CBD-related tweets

Go Away!!!!Pain! We have a variety of CBD products for your needs.... Make sure to ask about our selection your next visit. URL

Over time, poor sleep can leave you feeling wrecked...Could CBD help? URL #cbd #cbdoil #hemp #cannabis #sleep #insomnia

Chronic Fatigue...Cannabis CBD THC oil – URL

Our CBD cream combines the relief potential of arnica and natural menthol oil with cocoa butter and the scents of eucalyptus & lavender

Textbox 2. Examples of erroneous tweets (paraphrased slightly for anonymity). CBC: cannabichromene; CBD: cannabidiol; FDA: Food and Drug Administration; THC: tetrahydrocannabinol.

- If you live where medical marijuana is legal, get paid $3k a month to critique weed, CBD, edibles and more URL
- The FDA is worried about CBD. Should you be concerned? URL
- This room is half the size of my cbd apartment...
- Flinders Street in Melbourne's CBD has been re-opened following an earlier protest....Thanks for your patience during this disruption. #victraffic

Analysis of the manually annotated tweets indicated that the classes of personal and commercial CBD-related data sets were imbalanced; the nonpersonal CBD-related tweets occurred 7.7 times more than the personal CBD-related tweets, and the noncommercial CBD-related tweets occurred 10.2 times more than the commercial CBD-related tweets. To achieve a balance of the classes in the training set, we downsampled both of the positive classes in the training set by taking a random sample equivalent in size to the negative class. Table 1 and Table 2 show the class frequencies for the personal and commercial CBD-related tweet classes, respectively, prior to and following downsampling.

Table 1. Training set for personal cannabidiol (CBD) class counts.

Class	Predownsampling, n	Postdownsampling, n
Personal CBD	631	631
Nonpersonal CBD	4865	631
Total	5496	1262

Table 2. Training set for commercial cannabidiol (CBD) class counts.

Class	Predownsampling, n	Postdownsampling, n
Commercial CBD	489	480
Noncommercial CBD	45,007	489
Total	5496	978

Classification Training

Before training the binary classifiers to sort the full data set into personal and commercial CBD-related tweets, we preprocessed the text of the tweets by normalizing all URLs to one consistent string, removing special characters and English part of speech, converting all of the text to lowercase, and lemmatization. This preprocessing was performed to reduce the noise in the data, which would potentially impact the performance of our tweet classifiers. The binary classifiers were then trained on 80% (4396 of 5496) of the annotated sample and validated on the remaining 20% (1099 of 5496) of the annotated sample. We then created a matrix of the term frequency-inverse document frequency (TF-IDF) features based on the words within tweets using a range of n-grams from 1 to 3, as well as a matrix of the TF-IDF features based on the characters within tweets using a range of n-grams from 3 to 6. The resulting matrices were stacked horizontally, which served as the input to our model for training the classifiers.

To train the two binary classifiers, we performed a 5-fold cross-validation grid search using a logistic regression model to find the optimal combination of parameters. The range of parameters is shown in Table 3. After training the binary classifiers, we applied each model to the larger CBD corpora of tweets. To compensate for the small validation set due to the balancing, we performed an additional postclassification test on a random set of 500 unbalanced tweets from our collection to confirm that our models would perform well on real-world unbalanced data. This sample was annotated with the same approach as used for the training set, with the predicted result hidden. We will discuss classification in further detail within the Results section.

Table 3. Parameters used in text classification tuning with the logistic regression model.

Parameter	Range
Penalty	{none,.l1.l2}
Regularization parameter	$x_k=10^{a+(b-a)(k-1)/(n-1)}$, k=1,…n; a=0; b=5; n=20
Solver	{newton-cg, lbfgs, liblinear, sag, saga}

Term Analysis

To track the medical terminology referenced in the sorted commercial and personal CBD tweets, we computed the term frequencies of the top 1000 words in both corpora of tweets. We then confirmed whether these terms were related to relevant medical conditions, medical symptoms, body parts, and/or other

medications/substances by referencing standard English, medical (Systemized Nomenclature of Medicine-Clinical Terms [SNOMED CT]), and slang dictionaries. We categorized the terms into three groups: health/medical, cannabis-related terms, and other substances. Within the health/medical group, we included terms related to diseases, aliments, symptoms, and body parts. We applied the same logic to the terms that appeared to be hashtags by examining the individual words that formed the hashtag for relevancy. We grouped cannabis-related terms together and separated them from the other substances group since there seemed to be an overlap of CBD- and THC-related tweets, both of which referenced the broader cannabis plant; we included cannabis-related slang terms as well as foods that are commonly associated with cannabis infusion (eg, gummies, honey). The other substances group included terms that refer to any other drug or medication. There were a few instances of words being included in multiple groups. For instance, "high" is a side effect of cannabis but is a term commonly used in both cannabis and CBD tweets. Additionally, we considered terms that may represent side effects caused by taking a substance, especially terms commonly associated with cannabis. Finally, we compared the overall frequency of the top occurring terms relative to their frequency in either the personal or commercial class of tweets, and produced a visualization of relevant term frequencies. We used the Scattertext Python package to generate a graphical representation of the frequencies within the personal and commercial CBD classes for each of the three term groups [30].

Sentiment Analysis

We used the VADER model to compute the sentiment of the personal and commercial CBD tweets that reference specific medical conditions. Since this sentiment model incorporates punctuation and text capitalization into computing sentiment, we used the raw tweet text as an input for the model. The VADER model produced a normalized score between –1 and +1 for each tweet based on the summation of the valence scores of each word in the tweet. We converted each tweet's score into a 3-level categorical variable based on the threshold recommended by Hutto and Gilbert [20]: (1) positive sentiment, compound score≥0.05; (2) neutral sentiment, compound score>–0.05 and compound score<0.05; and (3) negative sentiment, compound score ≤–0.05.

We then analyzed the distribution of the compound scores and sentiment class (positive, negative, neutral) in tweets containing terms related to specifically defined conditions and symptoms. Since the VADER model is partially based on a dictionary score and since many terms related to illness may influence the overall sentiment of a tweet (eg, pain, stress, cancer), as part of our analysis, we computed the VADER sentiment scores both with and without medical terms of interest, and compared the mean VADER scores using a *t* test to determine whether any individual term of interest biased the overall sentiment assigned to a tweet. The purpose of the *t* tests was to determine if there was a statistically significant difference in the sentiment conveyed in commercial CBD tweets containing certain terms versus the sentiment conveyed in personal CBD tweets referencing the same terms. For instance, the VADER sentiment score of "CBD really helps my pain" was –0.171 versus a VADER sentiment score of 0.4391 for "CBD really helps my," where the word "pain" holds such a negative VADER sentiment score on its own that it is influencing the overall sentiment score of the tweet.

Ethics

This study leverages publicly available data and is registered as approved by the University of Louisville Institutional Review Board (approved protocol 20.1122).

Results

Classification

We trained the binary classification algorithms for the personal and commercial CBD tweets independently. In both the optimal personal CBD classifier (logistic regression: C=3.36, penalty=none, solver="newton-cg") and commercial CBD classifier (logistic regression=428.13, penalty="l1", solver="saga"), we observed a decrease in classification performance between the smaller validation set derived from balanced data from the unbalanced sample. Despite this decrease in classification performance on the unbalanced data, both the personal and commercial CBD classification models were able to achieve area under receiver operating characteristic curve scores above 0.80. Table 4 and Table 5 show the performance of the personal and commercial CBD binary classifiers, respectively. When the personal CBD binary classifier was applied to the collection of tweets, it classified 167,755 tweets as personal CBD-related tweets. When the commercial CBD binary classifier was applied to the collection of tweets, it classified 143,322 tweets as commercial CBD-related tweets.

Table 4. Personal cannabidiol (CBD) logistic regression classifier performance metrics.

Classification	Precision	Recall	F1	Support	Accuracy	AUC[a]
Balanced sample					0.85	0.86
Nonpersonal CBD	0.93	0.79	0.85	138		
Personal CBD	0.79	0.93	0.85	115		
Unbalanced sample					0.89	0.87
Nonpersonal CBD	0.94	0.91	0.93	367		
Personal CBD	0.78	0.83	0.81	133		

[a]AUC: area under the receiver operating characteristic curve.

Table 5. Commercial cannabidiol (CBD) logistic regression classifier performance metrics.

Classifier	Precision	Recall	F1	Support	Accuracy	AUC[a]
Balanced sample					0.89	0.89
Noncommercial CBD	0.92	0.85	0.89	95		
Commercial CBD	0.87	0.93	0.90	101		
Unbalanced sample					0.87	0.82
Noncommercial CBD	0.90	0.93	0.91	367		
Commercial CBD	0.79	0.70	0.74	133		

[a]AUC: area under the receiver operating characteristic curve.

Term Analysis

We generated unigram frequencies for both the personal and commercial corpora of tweets. We looked at the top 1000 occurring terms (excluding common English stop words) and manually checked if the terms were relevant to health; wellness; diseases; side effects; conditions; body parts; and/or references to other substances against standard English, medical, and slang dictionaries.

In other tweets making cannabis references (Figure 2), it seemed that THC-related terms were mentioned in both the personal and commercial corpora of tweets, with hashtags containing these references more frequently found in the commercial CBD tweets. The terms drink, melatonin, and pills were mentioned in the other substances group (Figure 3) in both the personal and commercial CBD tweets. Kratom and medium-chain triglyceride (MCT) were mentioned more frequently within the commercial CBD tweets and less frequently in the personal CBD tweets. References to alcohol occurred slightly more than average within the personal CBD tweets and below average in the commercial CBD tweets. Opioids were mentioned but only infrequently in both the personal and commercial CBD tweet classes. In the health and wellness group (Figure 4), pain, sleep, and anxiety occurred frequently in both the personal and commercial CBD classes. Terms related to fitness and nutrition were found more frequently in the commercial CBD tweets. Tweets referencing posttraumatic stress disorder (PTSD) occurred at the same average within both classes. Finally, CBD tweets referencing autism occurred more frequently than average in personal tweets, but infrequently in commercial tweets. This is despite the US FDA sending out warning letters to CBD sellers for disseminating misinformation by promoting CBD as a treatment for a variety of medical conditions, including autism [29].

Figure 2. Cannabis-related term frequency per class.

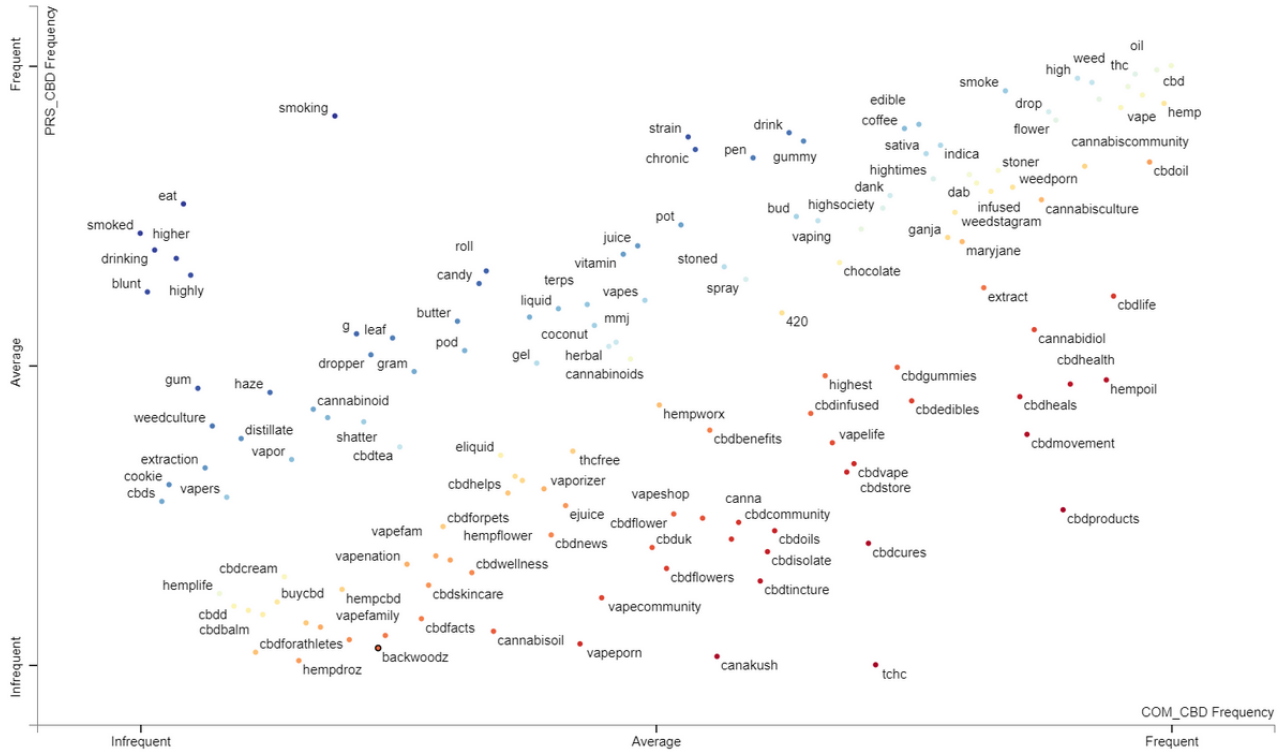


Figure 3. Other substances term frequency per class.

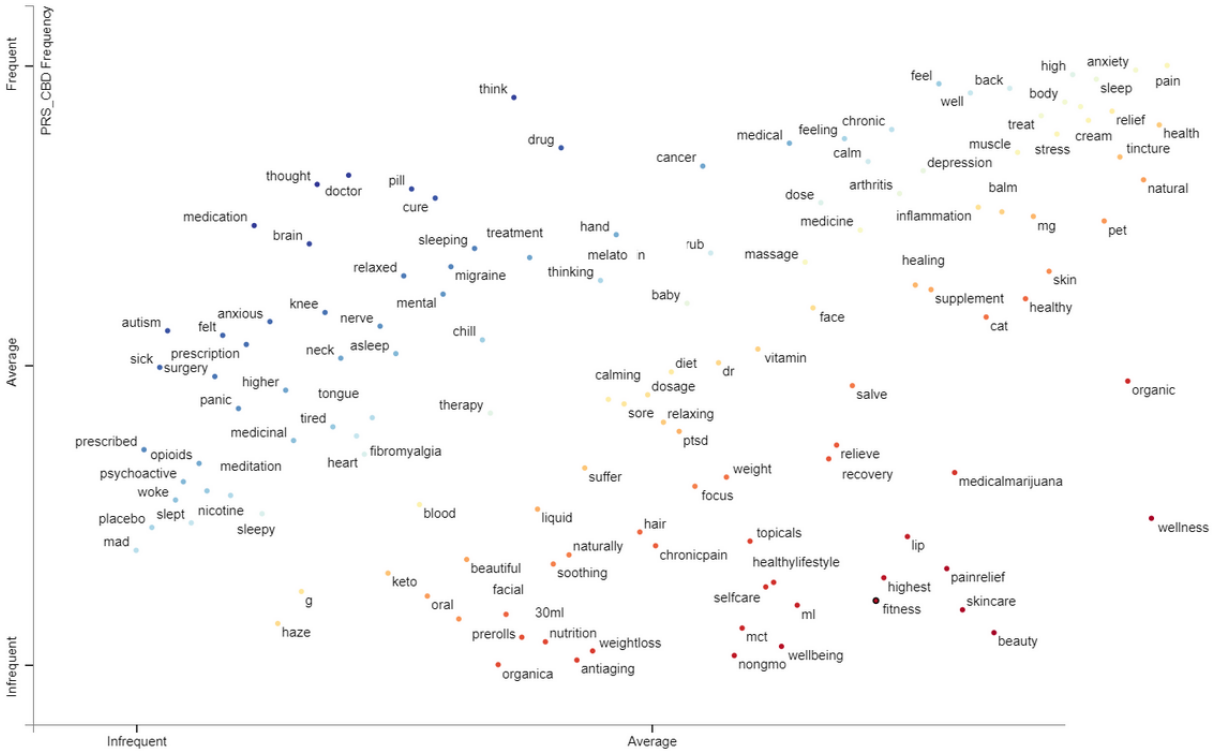
Figure 4. Medical/health/wellness-related term frequency per class.



Sentiment Analysis

We computed sentiment scores for both the commercial and personal CBD tweets that referenced any of the following 17 terms: *anxiety*, *anxious*, *autism*, *calm*, *calming*, *cancer*, *depression*, *energy*, *fitness*, *pain*, *pains*, *PTSD*, *skin*, *sleep*, *stress*, *weight loss*, and *wellness*. We also computed the term-level sentiment for each of these individual terms. Table 6 contains a list of the terms related to nonneutral sentiment and where the VADER score of the individual term might impact the sentiment score of the entire tweet. We calculated the sentiment for each personal and commercial CBD tweet referencing any of the 17 terms of interest, both in the original tweet text and with the term of interest removed. Using a *t* test to gauge any statistically significant difference in the mean sentient scores allowed us to

assess how sentiments about the condition itself might affect the sentiment score.

Table 6. Medical-related terms with nonneutral sentiment.

Term	VADER[a] compound score
anxiety	–0.1779
anxious	0.25
calm	0.3182
calming	0.4019
cancer	–0.6597
depression	–0.5719
energy	0.2732
pain	–0.5106
pains	–0.4215
stress	–0.4215

[a]VADER: Valence Aware Dictionary for Sentiment Reasoning.

Tables 7-9 demonstrate a significant difference in the mean sentiment score in the personal CBD tweets with the term of interest versus that obtained without the term of interest for 11 of the 17 terms examined. There was a significant difference in the mean sentiment score in the commercial CBD tweets with the term of interest versus that obtained without the term of interest for 12 of the 17 terms examined. There was also a significant difference in the mean sentiment score in the commercial CBD tweets compared to that of the commercial CBD tweets with the term of interest for 11 of the 17 terms examined, both with and without the term of interest included. Table 8 indicates that although the sentiment was overall positive, in the instances where there was a significant difference in the sentiment scores between the personal and commercial CBD tweets, the mean sentiment score of the commercial CBD scores was higher than that of the personal CBD scores. Figure 5 and Figure 6 provide examples of how the distribution of the sentiment score changed when the term of interest (“pain”) was removed from the tweet.

Table 7. Personal and commercial cannabidiol (CBD) sentiment categorical counts.

Term	Personal tweets							Commercial tweets

[a]ptsd: posttraumatic stress disorder.

Figure 5. Distribution of sentiment scores of personal tweets referencing the term “pain.”.

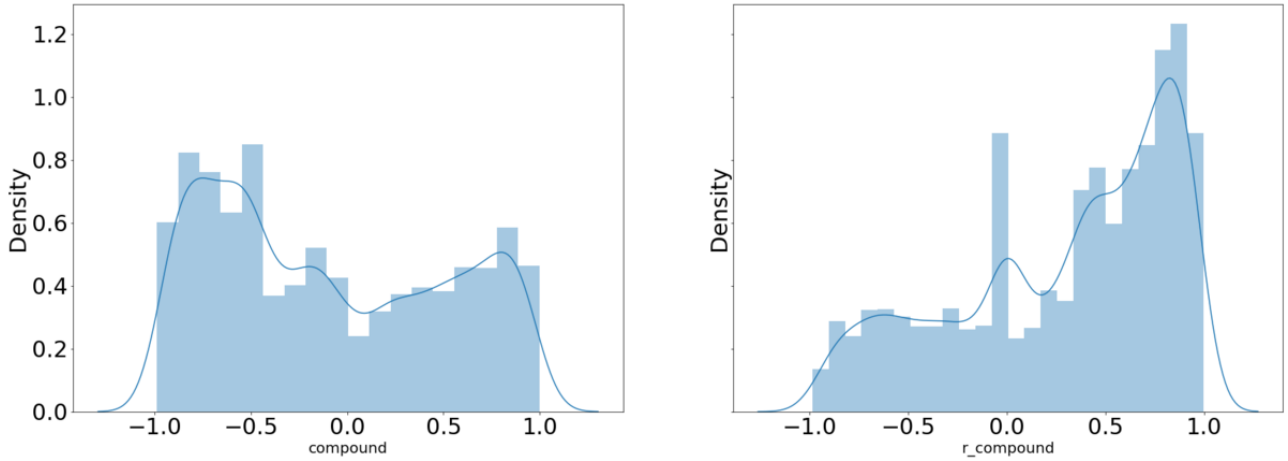

Figure 6. Distribution of sentiment scores of commercial tweets referencing the term “pain.”.

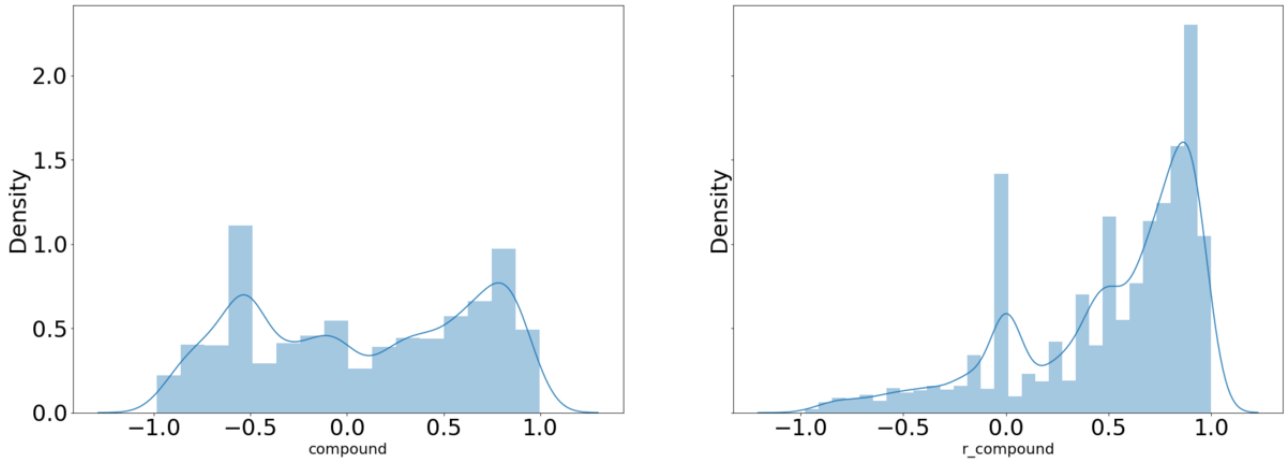
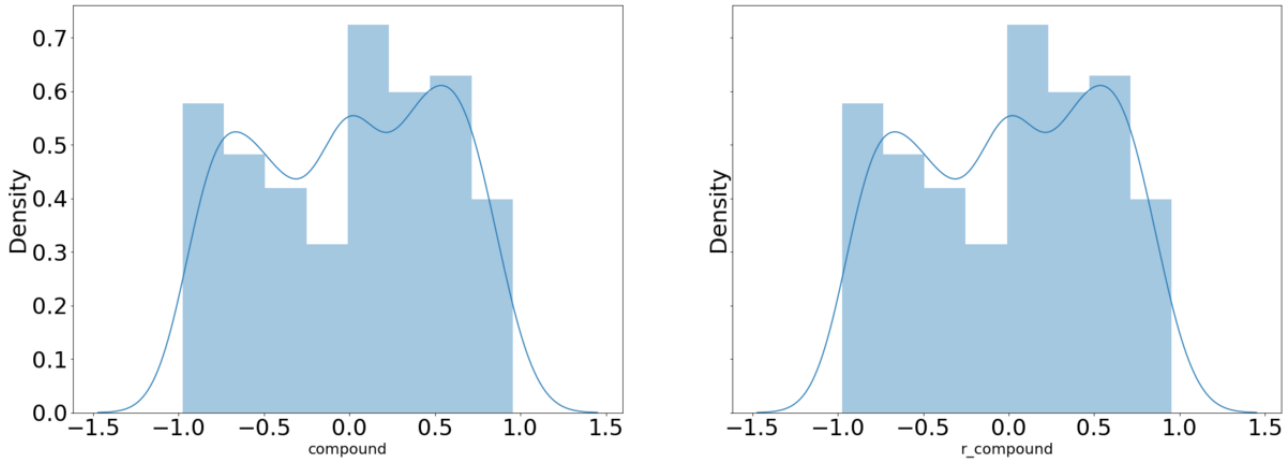


There were instances of CBD tweets that offered a mix of both positive and negative sentiments within the personal tweets, such as in tweets referencing CBD’s relationship with autism. Figure 7 shows a more negative sentiment in the personal CBD tweets referencing autism. However, the sentiment of the personal tweets did not change when the term “autism” was removed. Despite being negative, the mean sentiment score of these tweets was –0.042, which is considered neutral by the authors of the VADER model. We observed a large amount of personal CBD tweets referencing the term “autism,” with 42.5% (168/395) of personal CBD tweets referencing autism classified as negative versus 45.6% (180/395) being classified as positive and 11.9% (47/395) classified as neutral.

Figure 7. Sentiment distribution of personal cannabidiol-related tweets referencing autism.



Textbox 3 shows tweets that our classifiers identified to be CBD-related that contained the word “autism.” These personal CBD tweets sometimes favored and sometimes disfavored CBD as a treatment for autism. In the commercial CBD tweets referencing autism, we observed both implicit and explicit claims regarding CBD’s ability to treat autism.

Our framework thus works well in contexts where the efficacy claims of medications and supplements are both validated and refuted.

Textbox 3. Examples of personal and commercial tweets referencing cannabidiol (CBD) and autism (paraphrased slightly for anonymity).

Personal autism CBD tweets

@user @user He's...on a thc/cbd tincture. It's helped his autism beautifully

@user I use CBD for my C-PTSD [posttraumatic stress disorder] and the overstimulation that comes from Autism...it's kinda hard to function...It works better than any antipsychotic I've ever been on.

I see a lot of ppl on my timeline...claiming CBD can "cure" autism is bad and so is anyone knowingly peddling the idea what is wrong with you people URL

@user @user @user if you work somewhere that lies about curing autism with cbd oil you should feel bad

Commercial autism CBD tweets

Discussion

Principal Findings

Text classification of tweets provides a means to segment tweets into defined groups at a large scale. We have demonstrated that we can do this with tweets related to CBD by using text classification to identify tweets that reflect personal usage of CBD and tweets that reflect the sales and/or commercialization of CBD. This classification of public social media data is useful because CBD has not been subjected to the same tests and clinical trials as modern medications, yet is currently being used to treat a variety of conditions without proof of safety or efficacy. Our analysis provided a methodology to identify the terms of interest that are frequently referenced in the commercial and personal corpora of CBD tweets, as well as a comparison of these term frequencies in relation to the document class (commercial or personal CBD). This allowed us to identify the medical conditions commonly referenced in both document classes at high frequencies, as well as terms that occur more frequently in one document class over the other. We also used the VADER model to analyze the sentiment of personal CBD tweets referencing certain medical conditions and symptoms. Despite the US FDA's warnings regarding the marketing and promotion of CBD as treatment of autism and Alzheimer disease, while certainly not the most frequent conditions referenced, we did observe multiple instances of these tactics.

These methods and results speak to the recent efforts of researchers to use social networks to analyze the concept of misinformation in ways that are directly related to the potential problem of CBD misinformation. Ferrand et al [25] analyzed responses to queries from common digital assistants such as Siri, Alexa, and Google for misinformation regarding vaccines. Chen et al [26] collected social network posts from Weibo related to cancer and observed that 30% of posts contained misinformation. Ahmed et al [27] collected tweets referencing COVID-19 and 5G, and performed graph analysis to identify and analyze how misinformation was being disseminated online. Allem et al [3] observed unsubstantiated health claims related to cannabis on Twitter. More recently, Rovetta and Bhagavathula [28] also observed an abundance of COVID-19 misinformation in their analysis of tweets.

To address potential social media misinformation in the area of CBD, it is important to develop methods for gathering and classifying text corpora. Previous studies using the internet and social media have described the personal and commercial discourses about CBD. Narayanan et al [15] made use of internet-based data sources to examine CBD trends by examining Google searches, demonstrating that interest in CBD oil increased significantly from 2014 to 2018. Tran and Kavuluru [31] used CBD-related posts from Reddit and comments submitted to the FDA regarding these posts to examine the conditions that are commonly being treated by CBD. The researchers in this study examined both corpora of texts for medical conditions and methods of use in posts and comments using the term "CBD," along with any indication of therapy implied in the two corpora.

There have also been nonmachine learning approaches to researching marijuana sentiment on Twitter, such as the work done by Nguyen et al [32]. Their study collected marijuana-related tweets, disregarded the tweets that were authored by less influential posters, manually annotated the marijuana tweets on a Likert scale via crowdsourcing, and segmented them by demographics applied to the data set through a proprietary service. The researchers observed more promarijuana attitudes among African Americans and youth/younger adults. In another example of a research approach that did not rely primarily on machine learning, Krauss et al [33] based their marijuana sentiment analysis on crowdsourced tweets. The researchers aimed to examine the preferences between marijuana and alcohol on Twitter. They collected tweets containing alcohol and marijuana references, and then annotated the tweets via crowdsourcing. The results showed that 54% of

the tweets normalized marijuana and alcohol, 24% showed a preference for marijuana over alcohol, 2% showed a preference for alcohol over marijuana, 7% showed negative sentiment toward both alcohol and marijuana, and 13% demonstrated no sentiment toward either substance.

Our proposed framework extends the existing CBD research by further examining the perceptions of CBD in online discussions through a comparison of the terms and sentiment of tweets that reflect the personal use of CBD and tweets that reflect the sales and/or promotion of CBD. No other studies have attempted this type of comparative work, and this approach helped to examine which terms are being used proportionally or disproportionally, and to compare the sentiment of personal and commercial CBD tweets. Our methods can be applied to other types of research aimed at analyzing trends in the consumption and advertising of unregulated substances.

Conclusion and Future Work

The strengths of our framework are the ability to identify personal and commercial CBD tweets, associated conditions, and sentiment. However, some limitations should be noted. First, we limited our search to tweets referencing "CBD" and "cannabidiol." Our preliminary research did not indicate that the topic of CBD is as subjected to slang terms as other forms of cannabis (eg, THC) and did not indicate that it was necessary to include additional related terms in the search [34]. Additionally, we limited our collection to tweets as Twitter is one of the world's largest social networks that provides the ability to collect a large volume of data quickly. Second, our data were collected over an approximate 3-month period. Although the data collection period was relatively small, we were able to identify trends in personal and commercial CBD tweets that will be useful for future studies. Another limitation is the use of the dictionaries (standard, slang, and SNOMED-CT) for finding associated medical conditions. This step was based on checking high-frequency terms against dictionaries to determine medical relevancy. Future research could use deep neural network models to extract medical-related named entities from the tweets to automate and to possibly obtain context in which the medically related term is being used [35]. Finally, although we did not explicitly identify and remove social bots from our collection, as discussed by Himelein-Wachowiak et al [36], we did remove bots during the annotation process, as tweets that were possibly machine-generated were not considered personal or commercial CBD tweets.

We successfully used text classification to identify tweets making personal or commercial CBD references. When we applied two classifiers to the collection of tweets, we identified multiple medical conditions, body parts, symptoms, other substances, and cannabis references that were mentioned at high frequencies in both the personal and commercial CBD corpora, as well as conditions that were mentioned disproportionately in one corpora over the other. This suggests that CBD is being used and marketed for consistent types of ailments. Our sentiment analysis showed that the term of interest can indeed influence the sentiment score; when controlling for the term, 15 of 17 terms tested showed a positive sentiment within the personal CBD tweets and all 17 terms showed a positive sentiment within the commercial CBD tweets. This suggests that CBD, on the whole, is well-regarded in terms of its medical applications and that the commercial claims are not gross distortions of popular sentiment; however, we observed evidence where claims may have been exaggerated. We encourage future research to investigate the patterns in sentiment, usage, and sales of CBD as well as other forms of cannabis over time. Additionally, we recommend extending this proposed framework by further using text mining and machine learning methods to identify the dissemination of misinformation as it relates to CBD's health and medical benefits.

Abstract

Background: Expanding access to and use of medication for opioid use disorder (MOUD) is a key component of overdose prevention. An important barrier to the uptake of MOUD is exposure to inaccurate and potentially harmful health misinformation on social media or web-based forums where individuals commonly seek information. There is a significant need to devise computational techniques to describe the prevalence of web-based health misinformation related to MOUD to facilitate mitigation efforts.

Objective: By adopting a multidisciplinary, mixed methods strategy, this paper aims to present machine learning and natural language analysis approaches to identify the characteristics and prevalence of web-based misinformation related to MOUD to inform future prevention, treatment, and response efforts.

Methods: The team harnessed public social media posts and comments in the English language from Twitter (6,365,245 posts), YouTube (99,386 posts), Reddit (13,483,419 posts), and Drugs-Forum (5549 posts). Leveraging public health expert annotations on a sample of 2400 of these social media posts that were found to be semantically most similar to a variety of prevailing opioid use disorder–related myths based on representational learning, the team developed a supervised machine learning classifier. This classifier identified whether a post's language promoted one of the leading myths challenging addiction treatment: that the use of agonist therapy for MOUD is simply replacing one drug with another. Platform-level prevalence was calculated thereafter by machine labeling all unannotated posts with the classifier and noting the proportion of myth-indicative posts over all posts.

Results: Our results demonstrate promise in identifying social media postings that center on treatment myths about opioid use disorder with an accuracy of 91% and an area under the curve of 0.9, including how these discussions vary across platforms in terms of prevalence and linguistic characteristics, with the lowest prevalence on web-based health communities such as Reddit and Drugs-Forum and the highest on Twitter. Specifically, the prevalence of the stated MOUD myth ranged from 0.4% on web-based health communities to 0.9% on Twitter.

Conclusions: This work provides one of the first large-scale assessments of a key MOUD-related myth across multiple social media platforms and highlights the feasibility and importance of ongoing assessment of health misinformation related to addiction treatment.

opioid use disorder; substance use; addiction treatment; misinformation; social media; machine learning; natural language processing

Introduction

Background

In the United States, opioid overdose continues to be a leading cause of death [1]. The Centers for Disease Control and Prevention estimates that the total economic burden of prescription opioid misuse in the country alone is US $78.5 billion a year, including the costs of health care, lost productivity, treatment, and criminal justice involvement [2]. Alarmingly, opioid overdoses increased by 30% from July 2016 to September 2017 in 52 areas in 45 US states [3]. Consequently, in 2017, the Department of Health and Human Services declared it as a public health emergency [4]. Central to addressing the opioid crisis is expanding access to medication treatment for opioid use disorder (MOUD) [5]. MOUD increases treatment retention and reduces opioid use, risk behaviors that transmit blood-borne pathogens, and overdose mortality [6]. However, despite its well-documented effectiveness, studies have found that MOUD is underused due in part to stigma and misperceptions about treatment [7].

In recent years, many individuals have been seeking both conventional and nonconventional ways to recover from substance use, including using web-based resources [8]. For these conditions, as well as opioid use disorder (OUD), research has shown that individuals turn to the web for promoting and discovering recovery strategies, for example, appropriating the Forum77 forum for prescription drug use recovery [9] and participating in 12-step programs such as Narcotics Anonymous [10,11]. Social support is another motivation behind individuals with substance use disorders turning to social media; Rubya and Yarosh [12] examined peer support for substance use disorder recovery meetings through video chat, discovering that video chat support groups not only provide immediacy and convenience in meeting needs but can also be places of obtaining emotional and informational support. More recently, researchers have examined patterns of anonymity in web-based recovery communities [13]. Specific to OUD, previous studies have investigated the different types of web-based discourse associated with opioid use, including personal use, whether it is associated with legitimate use or abuse of opioids [14], or whether it involves the promotion of clinically unverified treatments [15]. Abuse discourse on social media platforms has been further broken down into stand-alone use and co-use of opioids with other opioids, illicit drugs, and alcohol [16]. In addition, a prior study analyzed the web-based discourse surrounding the perception of opioids [17]. The perception of opioids included commentary on the opioid crisis, opioids in general, and interaction with news surrounding the opioid crisis or medical use of opioids [17]. Researchers in the past have also harnessed social media data as unobtrusive sensors to identify individuals who might benefit from or be receptive to treatment and recovery interventions [18]. Others have computationally examined and compared web-based discussion communities to discover the intent to contribute to web-based mental health communities [19]. In general, social media platforms have been found to allow increased self-disclosure for users to discuss otherwise sensitive and stigmatizing topics such as OUD [20]. Apart from self-disclosure, social media data provide unique opportunities for understanding the users' sentiments and opinions [21], which may be insightful from the perspective of addiction treatment.

Despite the positive benefits of social media, existing attempts of individuals with OUD are often challenged because of the pervasiveness of inaccurate and potentially harmful health misinformation on social media platforms [15]. Health misinformation is defined as a health-related claim of a fact that is currently false because of a lack of scientific evidence [22]. In general, misinformation is usually attributed to misconceptions and is not intended to cause harm. Disinformation is false information that is created deliberately to cause harm, with motivations that are often social, political, or financial. Although misinformation and disinformation are inherently false, malinformation is usually based on real information that is taken completely out of or without context to inflict harm [23]. Fake news is defined as fabricated information that mimics news media content in form but not in organizational process or intent [24,25]. Molina et al [24] have outlined key indicators of fake news such as content that is not fact-checked, is emotionally charged, is written in narrative style, has unverified sources, or comes from an unknown source. In this study, we focused on the language of false claims surrounding MOUDs regardless of intent; therefore, it might be the case that we captured a few instances of disinformation, possibly on web-based platforms that lack constant domain-specific moderation. Thus, we use the term *health misinformation* as we assume that the spread of these claims is not intentional.

From the discourse on infectious disease outbreaks and global epidemics to alternative therapies to tackle behavioral health problems, web-based misinformation can have adverse effects on public health, including negatively influencing people's health literacy, attitudes, beliefs, and health-related decision-making [22]. For example, antivaccine-promoting social media posts legitimize debate about vaccine safety, contribute to reductions in vaccination rates, and increase vaccine-preventable diseases such as measles [26]. In the context of public health crises, social media rumors circulating during the Ebola outbreak in 2014 were found to create hostility toward health workers, which posed challenges in controlling the epidemic [27]. Most recently, the novel COVID-19 pandemic has come to be defined by a tsunami of persistent misinformation to the public on everything from the utility of masks and the effectiveness of social distancing to even the promise of vaccines, together contributing to an increased

COVID-19 pandemic burden [28]. At-risk populations are known to be particularly vulnerable to misinformation [22,29] because of a lack of reliable information outside of formal clinical or rehabilitation contexts [30,31]. In fact, studies show that because of exposure to such misinformation, people worry that they will be ostracized by their community if their substance use is revealed to others, thus delaying treatment [32].

Given the limited uptake of MOUD, the potential contribution of health misinformation to this public health problem, and the fact that information about barriers to MOUD is challenging to ascertain from other data sources, exploring digital health-seeking behavior through *passive sensing* of misinformation related to MOUD provides an important avenue for addressing this problem. Thus, *infodemiology*, which refers to the science of studying the distribution and determinants of information and user-generated content in an electronic medium such as the web in general and social media in particular [33], has the opportunity to shape MOUD-related health promotion strategies and policies. Given the potential impact of misinformation in the midst of the ongoing overdose crisis, there is a critical need to better understand misinformation-related social media posts on OUD treatment. In fact, in recent years, approaches in infodemiology have been noted to be important in mitigating public health problems stemming from *infodemics* [34,35], a portmanteau of *information* and *epidemic* that typically refers to a rapid and far-reaching spread of both accurate and inaccurate information about a disease.

Objective

In this study, we focus on one particular myth (and its language variants) related to MOUD: *agonist therapy or medication-assisted treatment (MAT) is simply replacing one drug with another*. For example, someone might express this myth by saying "You are not really in recovery if you are on Suboxone." This myth is believed to be one of the major reasons cited for individual hesitancy to initiate MOUD; it has been discussed extensively in clinical literature [29,36,37] and has been discredited by evidence that MOUDs facilitate recovery and that multiple other chronic health conditions such as diabetes and asthma necessitate reliance on daily medication to maintain health.

By adopting a multidisciplinary, mixed methods strategy, this paper aims to present the first work that investigates the characteristics and prevalence of web-based misinformation related to MOUD across 3 types of web-based social platforms to inform future prevention, treatment, and response efforts. Our contributions include a set of machine learning (ML) models that classify whether a post revolves around conversations surrounding a specific MOUD as replacing one drug with another or explorations of lexical variations characterizing web-based conversations relating to this myth.

Methods

Data Set Curation

We first identified and curated a set of clinically grounded and publicly prevalent myths that surround OUD treatment and developed a lexicon of opioid-related keywords associated with different aspects of OUD. We captured different types of opioids, such as natural opiates, semisynthetic opioids, and synthetic opioids, and included opioids that were over-the-counter, prescription based, or illicit. For each generic name, we also included trade and combination product names in consultation with the substance use literature and the public health coauthors. This resulted in a total of 152 keywords curated in the lexicon. We then curated a diverse data set from Twitter, YouTube, and the web-based health communities Reddit and Drugs-Forum. These platforms were selected as (1) they are adopted pervasively by Americans and (2) there are well-established means and infrastructures for collecting meaningful data sets by leveraging app programming interfaces to query them and access public posts on these platforms. According to the Pew Research Center, in 2021, 18% of US adults use Reddit, 23% use Twitter, and 81% use YouTube [38]. In addition, these platforms have been mined in prior substance abuse literature for abuse monitoring and digital epidemiology purposes [39-41]. For all the platforms we investigated, we focused on public posts and messages created between January 1, 2018, and December 31, 2019.

Our data set collection methodology for Twitter comprised querying for all tweets that included 1 of the words in our lexicon. This process yielded a total of 6,365,245 tweets. For YouTube, owing to limitations in the number of comments that can be accessed, we restricted the 152 keywords to 11 OUD treatment keywords such as *buprenorphine* and *naltrexone*. We used the YouTube app programming interface to identify 552 YouTube videos that contained 1 of the 11 keywords in the title and then collected all of the associated comments (99,386 comments). We relied on expert domain knowledge to identify subforums pertinent to OUD for Reddit and Drugs-Forum and used the full set of 152 keywords for these sites. For Reddit, we used data from 22 opioid-specific subreddits: *r/Carfentanil*, *r/opiates*, *r/fentanyl*, *r/opiatesmemorial*, *r/modquittingkratom*, *r/Methadone*, *r/suboxone*, *r/kratom*, *r/heroin*, *r/quittingkratom*, *r/Tianeptine*, *r/loperamide*, *r/naltrexone*, *r/oxycodone*, *r/OpiatesRecovery*, *r/Opiatewithdrawal*, *r/lean*, *r/heroinaddiction*, *r/HeroinHeroines*, *r/OpiateChurch*, *r/suboxone*, and *r/OurOverUsedVeins*. This resulted in a total of 1,189,590 posts and 12,293,829 comments. In addition, we collected all 5549 messages posted under the *Opiates and Opioids* subforums on Drugs-Forum [42]. Throughout the paper, we have combined Reddit and Drugs-Forum content under the category of web-based health communities, as both have similar structure, format, and affordances.

ML Approach Using Expert Involvement

Web-based discourse surrounding OUD is semantically rich; that is, there are different words and combinations of words that people use to convey meaning. Previous literature has quantitatively and qualitatively investigated various categories of language pertaining to OUD, including OUD use (own use, use by others, abuse, legitimate use, and co-use), OUD perception (commentary on opioid crisis or opioids in general), and OUD advertisements [14,16,17]. In light of such linguistic richness and prior investigations, we adopted an ML and natural

language analysis methodology to identify posts relevant to the myth under investigation in the huge search space.

We first leveraged representation learning techniques, which are a set of techniques that allow a system to automatically discover the representations needed for feature detection or classification from raw data [43] to construct document-level embeddings (consisting of 4096 dimensions) of the myth statement noted earlier. For this, we used a bidirectional long short-term memory (LSTM) sentence encoder model universally trained on a natural language inference task [44]. LSTM was a suitable choice here as it allowed us to learn long-term dependencies among words in sentence structures. We then used this model to encode all the collected posts. Following this step, we obtained the k-nearest neighbor (KNN), where k=200, for semantically most similar posts per platform for the MOUD-related seed myth under investigation. Second, using a mixed methods approach, our models then harnessed qualitative content analysis in the form of public health expert annotations to label a total of 800 posts (200 KNNs per platform) and annotate whether each post was relevant to the myth (ie, whether the post discussed MOUD and described MOUD as using one drug to replace another). Hence, we modeled this problem as a binary classification task where the positive class denoted a post discussing the aforementioned piece of misinformation and the negative class represented any post that was not relevant to the myth. Each myth KNN post was annotated by the same expert public health annotator to provide consistent annotations within the linguistic domain of a given myth.

Leveraging these annotations as training data, we finally built and evaluated a series of supervised ML models, ranging from logistic regression (LR) and support vector machines to feedforward neural networks and LSTM networks. Our feature set included lexical features such as n-grams (n=1, 2, 3), term frequency–inverse document frequency (TF–IDF) weights, and representation learning features, including sentence-based embeddings (semantic) and transformer-based embeddings, such as bidirectional encoder representations from transformers [45] and bidirectional encoder representations from transformers for biomedical text mining [46]. We used all annotations belonging to our myth and considered all the samples from other myths as negative training samples. On the basis of this process, we obtained 171 positive samples and 2229 negative samples. Owing to this large imbalance, we leveraged an oversampling technique from the rare class, called the synthetic minority oversampling technique [47]. We then split the data set into training and test samples with an 80% to 20% split, respectively. We leveraged 2 techniques for cross-validation: k-fold cross-validation (for LR and support vector machine models) and an independent validation sample to tune a model's hyperparameters (for the LSTM model).

Results

Table 1 and Figure 1 show the best-performing ML models in terms of their area under the curve, precision, recall, and F_1 scores. Our best-performing model was a combination of TF-IDF features and an LR classifier, achieving a precision of 0.85, a recall of 0.91, an F_1 score of 0.88, and an area under the curve of 0.9. By applying our best-performing model to machine label all posts in our data sets, we were able to estimate the prevalence of posts related to the myth under investigation on each platform. The prevalence of posts among our sampled comments that were related to the myth that the use of MOUD does not constitute true recovery was 0.4%, 0.9%, and 0.58% for web-based health communities, Twitter, and YouTube, respectively. For additional context and interpretability in terms of how our best-performing models operated per platform, 2 examples of posts that were classified correctly by our classifier are provided in Table 2, along with the top words used by the classifier to attain a relevancy decision for each post on each platform. Here we observed some consistencies in the discussions of the myth across platforms. For example, we noted that our model was able to pick up on the use of verbs synonymous with *replac*, such as *switch*, which was not originally included in the myth phrasing. In addition, the verb *go* was used in multiple contexts, such as going to Alcoholics Anonymous meetings instead of relying on MATs and going through withdrawals from MAT. We also noted the presence of multiple drug names such as *Ativan*, *buprenorphine*, *methadone*, and *suboxone*.

Table 1. Macroperformance metrics of the opioid use disorder treatment myth classifiers[a].

The top 10 features (terms) associated with our best-performing model (LR+TF-IDF) for identifying relevant posts and their TF-IDF values are shown in Table 3. These terms include *mat*, *assist*, *treatment*, *replac*, *therapi*, *rehab*, *methadon*, *behavior*, *habit*, and *substitut*. Furthermore, to provide additional insight into words used by the ML model to identify myth-related posts, for each of the top 10 terms, we display the 15 words with the closest semantic proximity (based on training a Word2Vec embedding model [48]) as measured by cosine similarity. Qualitative assessment of the identified words revealed excellent identification of synonymous terms and phrases, including those that were unlikely to be readily suggested or identified by human readers, such as *ost* (opioid substitution therapy).

[a]Data from 112,281 opioid-related posts identified by our best-performing model from Twitter, web-based health communities, and YouTube. The first column depicts the features and their term frequency-inverse document frequency scores. The nearest neighbors column also depicts the cosine similarity between each word and the corresponding feature. Words in posts are stemmed before being fed to models (eg, recovery is stemmed to its root *recoveri*). Web-based health communities refer to Reddit and Drugs-Forum.

Discussion

Principal Findings

Harms propagated by misinformation are aplenty on the web and come at both financial and societal costs. People often accept what they read as true, especially if it comes from a reasonably reputable source, and do not question the information, no matter how astounding or alarming. In fact, people even repeat the more remarkable information regardless of how accurate it is. In the context of MOUD, it can lead to grave consequences, including overdose deaths [29]. To the best of our knowledge, this is the first study to examine MOUD-related misinformation on a large scale, harnessing conversations happening on the web.

Closely related to our work is the study by Jamison et al [49], which leverages a collection of tweets to quantify vaccine misinformation. Similar to our work, Jamison et al [49] coded tweets into thematic categories based on vaccine sentiment (positive, negative, or neutral). However, our work leveraged thematic categories (relevant and not relevant to the myth) to design ML-based models that are able to identify misinformation in the context of MOUDs. Heimer et al [29] discussed prevalent misconceptions about OUDs in the United States through 3 crises (1865-1913, 1960-1975, and 1995-today). Similar to our focus, the authors acknowledged opioid *abstinence-based* recovery models as a prevailing misconception and promoted the large-scale expansion of MAT. Our work complements their work by investigating this misconception quantitatively through the lens of social media. Chenworth et al [50] investigated the perception of the general public toward methadone and buprenorphine-naloxone on Twitter. The authors identified that a common barrier to treatment with these medications was the idea of opioid substitution—the exchange of one opioid addiction for another [50]. Our work investigates this barrier at a deeper level by building models that are able to recognize this type of discourse on social media.

Our results have important public health implications. Across multiple platforms, we detected that the prevalence of posts about a single myth related to medication treatment for OUD in our sample ranged from 4 per 1000 posts on web-based health communities to 9 per 1000 posts on Twitter. This is notable, as, at any time, there are likely multiple myths being discussed on the web, suggesting that the total volume of misinformation content related to opioids may be a substantial proportion of the total posts. The prevalence of such information has not been

previously quantified, and this study offers important insights into the potential scope of this health information issue.

Although we cannot speculate on the exact reason why Twitter presented more misinformation in the case of OUD-related misinformation as that requires causal inference analysis, which is beyond the scope of this paper, prior literature has pointed out the lack of active expert or clinical-based moderation on Twitter [51]. Although web-based health communities are also not immune to bad behavior and antisocial activities such as trolling, spamming, and harassment, these communities are often guided by strict norms against such behavior and moderated to ensure the quality and credibility of the content being shared [52]. Prior studies on different types of web-based health communities have demonstrated that adequate active moderation increases the engagement of members and consequently also increases the beneficial outcomes for members in a web-based community [53]. In fact, the moderators themselves regard their moderation style as important for the regulation and stimulation of membership engagement [54,55]. We suspect that, because of these established moderation norms, we observed a relatively lesser prevalence of MOUD misinformation in the web-based communities we studied. We noted that Twitter does implement some broad governance rules that allow for certain types of information to stay on the platform, whereas others are removed (eg, graphic violence and adult content [56]). The platform also has provisions to tackle the widespread presence of hate speech and abusive content [57]. However, to the best of our knowledge, Twitter does not implement policies toward the moderation of MOUD misinformation. Our conjecture is that, because of this existing practice, our study revealed a greater prevalence of this misinformation on the platform. Nevertheless, in light of the ongoing COVID-19 pandemic, Twitter has broadened its definition of harm to address "content that goes directly against guidance from authoritative sources of global and local public health information" [58]. We hope that the findings of this study can motivate social media platforms to consider moderation approaches toward substance misuse information as well.

Given the significant prevalence of myths around OUD treatment, as shown in this study, a possible approach to counter web-based misinformation could be to perform targeted, expert fact-checking of social media posts. This could mirror and harness guidelines adopted by public health organizations to debunk unverified information about OUD treatment. For instance, substance use experts can be identified and asked to review the content of social media posts to determine their accuracy. These experts could critically appraise a post and produce a response comprising a lay summary of the evidence in addition to a detailed, referenced evidence review. This review could be directly linked to the original post through appropriate platform affordances to provide users with quick access to fact-checked information. Specific fact-checking processes could also be tailored to individual social media platforms, given the differences we observed both in terms of prevalence and the linguistic characteristics of the myth discussions. Qualitative exploration of the characteristics of the statements identified by the ML approach revealed linguistic and topical diversity. Some statements explicitly referenced the main concept we queried for—that MOUD represents replacing one drug with another. However, related statements were identified in which alternative treatments such as kratom entered into the discussion. Rationales for hesitancy toward MOUD also became apparent, including concerns about the addictiveness of MOUD, the nature of withdrawal symptoms from MOUD, and concerns about industry or governmental motivations for recommending MOUD. Understanding these concerns is directly relevant to providing health information, understanding the role of digital information ecosystems as a supplant or adjuvant resource in substance misuse treatment, and addressing treatment hesitancy.

In addition to fact-checking efforts, public health engagement campaigns could also be used to address specific cases of misinformation. Recent research suggests that information campaigns led by trusted community members and health partners can help address health misinformation on social platforms [59]. Accordingly, alliances can be forged with social media influencers and key opinion leaders to run targeted health promotion campaigns. Interventions such as those with positive messaging can also be tailored to the preferences, perceptions, and cultures of different platforms. Educational interventions that improve literacy around OUD treatment and reduce the stigma that precludes seeking help, as well as ecologically sensitive interventions that open up avenues to access social support, could also empower individuals to be better equipped to deal with OUD treatment myths on the web. In short, although the literature on strategies to effectively counter health misinformation is still emerging, at minimum, this work highlights the importance of ongoing assessment and awareness of what health information is being prominently discussed on the web to guide both the provision of effective health care and public health prevention activities.

We note some limitations of this work. Although our analysis included large data sets from diverse web-based platforms, MOUD-related discussions happen on a wide variety of social platforms, and the prevalence of misinformation across a broader set of web-based environments needs characterization. For one platform, YouTube, limitations in the number of comments that can be accessed required restriction of the keyword list, which may have affected the prevalence of misinformation, although the estimate from YouTube was comparable with the other platforms. Furthermore, this research did not examine the nature of conversations surrounding the OUD treatment myth we focused on in this paper, such as whether a conversation might be reinforcing or countering the myth or discussing other previously known myths. Future work may unpack these characteristics of web-based discussions while also investigating additional myths about OUD misuse that surface on web-based platforms. Finally, geospatial-temporal studies on MOUD misinformation that originates and spreads via social media platforms can be a promising and significant direction for future research; they can influence interventions such as targeted location-based misinformation-countering campaigns as well as help clinicians respond to patients' false beliefs or misperceptions.

Conclusions

Using ML and natural language analysis, our research demonstrated promise in identifying social media posts that centered on treatment myths about OUD, including how these discussions varied across platforms in terms of prevalence. As the overdose epidemic continues to evolve, attention from health professionals to health information on the web that drives patient decision-making will continue to be a critical element of prevention.

Acknowledgments

This research was supported through a contract by the Centers for Disease Control and Prevention (CDC; via the Department of Health and Human Services) to the Georgia Institute of Technology (principal investigator: MDC). CDC investigators participated in the design and conduction of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication. ME and MDC had full access to all the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis. ME conducted this research while being affiliated to the Georgia Institute of Technology. The authors thank Kenneth Kannampully for his help with the Drugs-Forum.com data collection. The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the CDC.

Abstract

Background: Worldwide, social media traffic increased following the onset of the COVID-19 pandemic. Although the spread of COVID-19 content has been described for several social media platforms (eg, Twitter and Facebook), little is known about how such content is spread via private messaging platforms, such as WhatsApp (WhatsApp LLC).

Objective: In this study, we documented (1) how WhatsApp is used to transmit COVID-19 content, (2) the characteristics of WhatsApp users based on their usage patterns, and (3) how usage patterns link to COVID-19 concerns.

Methods: We used the experience sampling method to track day-to-day WhatsApp usage during the COVID-19 pandemic. For 1 week, participants reported each day the extent to which they had received, forwarded, or discussed COVID-19 content. The final data set comprised 924 data points, which were collected from 151 participants.

Results: During the weeklong monitoring process, most participants (143/151, 94.7%) reported at least 1 COVID-19–related use of WhatsApp. When a taxonomy was generated based on usage patterns, around 1 in 10 participants (21/151, 13.9%) were found to have received and shared a high volume of forwarded COVID-19 content, akin to super-spreaders identified on other social media platforms. Finally, those who engaged with more COVID-19 content in their personal chats were more likely to report having COVID-19–related thoughts throughout the day.

Conclusions: Our findings provide a rare window into discourse on private messaging platforms. Such data can be used to inform risk communication strategies during the pandemic.

Introduction

WhatsApp (WhatsApp LLC) is the most commonly used messaging app worldwide; it has 1.5 billion users across 180 countries [1]. On account of its large user base and near-instant message transmission capabilities, the platform has played a critical role in risk communication during the COVID-19 pandemic.

WhatsApp has been co-opted by government agencies and the World Health Organization to disseminate official COVID-19 updates [2]. However, while this showcases the platform's ability to reach a large sector of the population, this feature has also made it a vessel for misinformation. For example, at the beginning of the pandemic, WhatsApp noted a 40% surge in usage [3]. This was paired with a high volume of message forwarding activity that was widely believed to support misinformation. As a result, the platform restricted the number of individuals to whom a message could be forwarded simultaneously [4,5].

Despite these restrictions, a survey in India found that 1 in 2 participants had received COVID-19 misinformation through WhatsApp or Facebook [6]. Likewise, WhatsApp was identified by Hong Kong residents as the foremost source for COVID-19–related rumors [7]. As misinformation can jeopardize public health strategies, these findings underscore the need for infodemiological studies that document how COVID-19 content spreads through WhatsApp.

To date however, the bulk of infodemiology studies have focused on social media platforms in which content is publicly accessible (eg, Twitter and Facebook) [8,9]. In contrast, research on WhatsApp has proven to be elusive because of the platform's private nature; its end-to-end encryption software ensures that only senders and recipients have access to messages sent through the platform. Nonetheless, WhatsApp research remains a priority; aside from its popularity and role in disseminating crisis-related misinformation [10,11], insights from public posts are also unlikely to generalize to WhatsApp's private messages [12]. It thus remains unclear as to who sends COVID-19–related messages, who receives such messages, and what manner such messages are sent.

To address these gaps in the literature, we designed a study to (1) describe the base rate of COVID-19 content dissemination, (2) understand WhatsApp users, and (3) examine correlates of usage patterns. Specifically, we used the experience sampling method to track WhatsApp usage amid everyday routines across 1 week [13,14]. We asked participants to report each day their frequency of receiving, forwarding, or discussing COVID-19–related content. Through this method, we generated a taxonomy of participants based on their usage patterns and examined whether day-to-day variations in WhatsApp usage predicted COVID-19–related concerns.

Methods

Recruitment

From March 17 to May 7, 2020, participants were recruited from the general community via advertisements placed in Facebook and WhatsApp community groups (eg, residential groups, workplace groups, and university groups), posts on popular web-based forums, and paid Facebook advertisements targeting Singapore-based users. All study activities took place on the web-based survey platform Qualtrics (Qualtrics International Inc), and participants were reimbursed with SGD $5 (US $3.65) upon study completion. The study protocol was approved by the Yale-NUS (National University of Singapore) College Ethics Review Committee (protocol record: 2020-CERC-001) and was preregistered at ClinicalTrials.gov (trial number: NCT04367363).

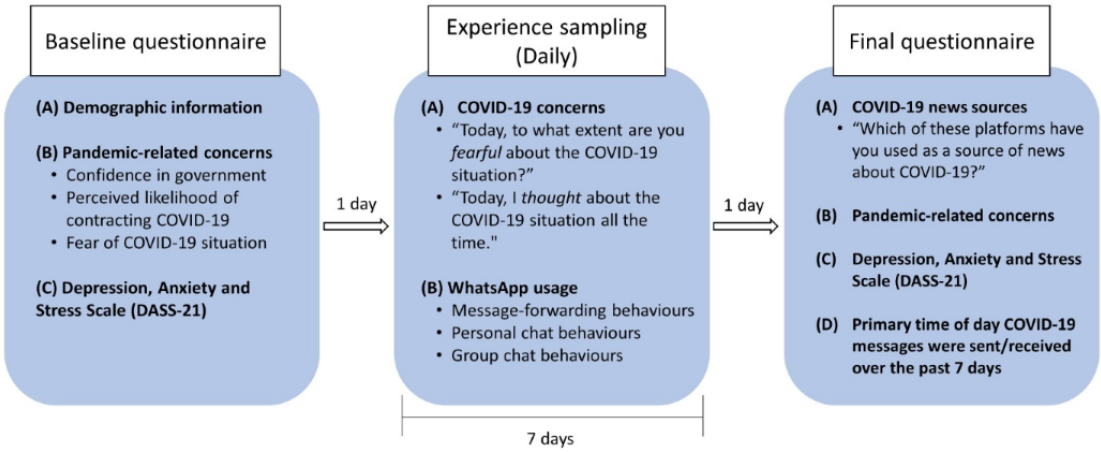
Participants

The participants were 151 adults who met the following inclusion criteria: (1) aged 21 years or older, (2) had lived in Singapore for at least 2 years, and (3) had a WhatsApp account.

Measures

Following the provision of informed consent, participants completed (1) a baseline questionnaire, (2) experience sampling responses daily for 7 days, and (3) a final questionnaire (Figure 1).

Figure 1. Schematic of study procedures. All participants completed a baseline questionnaire. This was followed by 7 days of experience sampling, during which participants addressed questions about COVID-19 concerns and WhatsApp usage daily. Participants completed a final questionnaire 1 day after the experience sampling procedure ended. DASS-21: 21-item Depression, Anxiety and Stress Scale.



Experience Sampling

As the primary form of data collection, we used the experience sampling method to capture COVID-19 chatter on WhatsApp. Through this method, we collected 924 data points across 151 participants (compliance rate: 924/1057, 87.4%).

For 7 days, participants accessed a web-based survey each evening (at 9:30 PM) to report their WhatsApp usage for the

day. Participants indicated whether they had forwarded messages related to COVID-19 (“yes” or “no”). We focused on message forwarding as a proxy indicator for high-risk content, since (1) large Twitter studies have observed that misinformation is more likely to be shared than posts that are true [15] and (2) WhatsApp developers had previously linked forwarded messages to misinformation [4,5]. If participants had forwarded COVID-19 content, they were then asked about (1) the number of unique COVID-19 messages they had forwarded and (2) the number of unique groups and individuals to which they had forwarded messages.

Participants were also asked about their personal chats (ie, their one-to-one chats on WhatsApp). They indicated whether COVID-19 messages had been forwarded to them in personal chats (“yes” or “no”). If so, they were asked about (1) the number of unique messages they had received and (2) the number of different people from which they had received messages. Thereafter, participants recounted whether they had discussed COVID-19 in conversations where either they or the other party generated messages related to COVID-19 (“yes” or “no”). If so, they were asked about how many unique chats were involved.

Finally, for group chats, participants were asked if COVID-19 had been mentioned in any of their WhatsApp groups by at least 1 other person (not including themselves; “yes” or “no”). This could have occurred either through others forwarding messages or through others generating their own comments. Affirmative responses were followed with a question on how many WhatsApp groups had done so.

Aside from WhatsApp metrics, participants also reported their COVID-19 concerns for the day; they were asked about (1) how afraid they felt about the COVID-19 situation (4-point scale: 1=“Not scared at all”; 4=“Very scared”) and (2) whether they thought about the COVID-19 situation all the time (5-point scale: 1=“Not at all true”; 5=“Very true”).

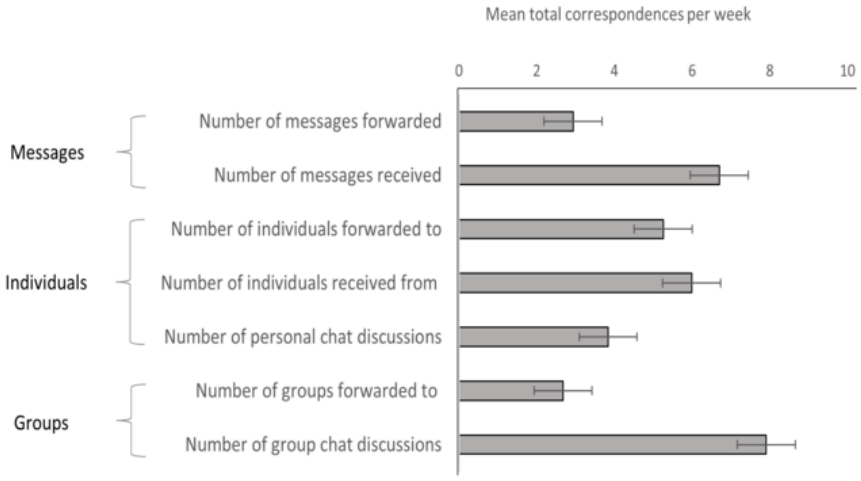
Baseline and Final Questionnaires

To characterize the participants, we included baseline and final questionnaires in which participants reported demographics (age, gender, religion, ethnicity, marital status, education, house type, household size, citizenship, country of birth, and number of years in Singapore), the time of day when they read and sent COVID-19 messages on WhatsApp (mostly in the morning, afternoon, evening, or late night or throughout the day), and sources through which they obtained COVID-19 news (eg, printed newspapers, radio, WhatsApp, and YouTube). Additionally, participants completed the 21-item Depression, Anxiety and Stress Scale (DASS-21) [16] to evaluate their mental health during the pandemic. Participants were also asked about their responses to the pandemic [2,17], that is, (1) how confident they were that the government could control the nationwide spread of COVID-19 (1=“Not confident at all; 4=“Very confident”), (2) their perceptions on how likely that they or someone in their immediate household would contract COVID-19 (1=“Not at all likely”; 4=“Very likely”), and (3) how fearful they were about the situation in the country (1=“Not scared at all”; 4=“Very scared”).

Statistical Analysis

First, we summarized the data as counts with percentages or as means with SDs, focusing on the following seven quantitative WhatsApp usage variables (Figure 2): the number of (1) COVID-19 messages that participants forwarded, (2) groups to whom messages were forwarded, (3) individuals to whom messages were forwarded, (4) forwarded messages received, (5) individuals from whom messages were received, (6) personal chats involving COVID-19–related conversations, and (7) group chats discussing COVID-19. Multimedia Appendix 1 shows the pattern of correlations across these variables.

Figure 2. Distribution of COVID-19–related behaviors on WhatsApp. In a weeklong experience sampling procedure, participants reported the extent to which they engaged in COVID-19–related behaviors on WhatsApp (either by forwarding or receiving messages or in conversations). Horizontal bars represent the total amount of each activity captured (averaged across all participants). Horizontal lines represent the 95% CIs for the means.



Second, to understand WhatsApp user profiles, we performed a latent profile analysis to create a taxonomy of participants based on their WhatsApp usage (R package *mclust* [18]). Latent profile analysis is a bottom-up statistical clustering method for defining classes of people based on common characteristics. By using all observations of a continuous dependent variable, classes are created such that within each class, indicator variables are statistically uncorrelated [19]. We thus used this

technique to cluster participants based on their responses to the seven WhatsApp usage variables; values were obtained by aggregating the reported frequency of each variable over the week. To uncover clusters, we used Gaussian mixture models and assigned participants to clusters by using Bayesian probabilities. The final number of clusters was determined by using the Bayesian information criterion, the integrated completed likelihood criterion, and a bootstrap likelihood test.

Finally, we examined whether day-to-day variations in COVID-19 WhatsApp chatter could be tracked based on variations in COVID-19 concerns. We quantified COVID-19 chatter on personal and group chats, so that such chatter could be used as predictors. For personal chats, the following variables were summed for each day and for each participant: the number of (1) individuals to whom COVID-19 messages were forwarded, (2) individuals from whom forwarded messages were received, and (3) personal conversations discussing COVID-19. For group chats, the following variables were summed: the number of (1) groups participants to whom COVID-19 messages were forwarded and (2) groups where COVID-19 messages were mentioned. Scores were grand-mean centered by subtracting the mean number of chats across subjects and time points from each score (number of chats: mean 2.47 and mean 1.29, respectively). In addition, we created between- and within-subject versions of each predictor [20]. The final analyses involved linear mixed-effects models for each outcome measure (fear of and thoughts about COVID-19). The following were entered as fixed effects: time (centered such that 0 referred to the middle of the week), daily personal chats (between subjects), daily personal chats (within subjects), daily group chats (between subjects), and daily group chats (within subjects). Random intercepts accounted for correlated data resulting from repeated measures.

Across all analyses, the type 1 decision-wise error rate was controlled at an α of .05. All statistical analyses were conducted in R 3.5.0 (R Foundation for Statistical Computing) and SPSS 25 (IBM Corporation).

Results

Baseline Participant Characteristics

As shown in Table 1, 68.9% (104/151) of participants were female, and their mean age was 36.35 (SD 14.7) years. Participants were predominantly of Asian ethnicity (Chinese: 140/151, 92.7%) and had at least a postsecondary education (133/151, 88.1%). Further, 39.7% (60/151) of participants were married, and the majority (105/151, 69.5%) belonged to households of at least 4 members.

[a]HDB: housing and development.

Base Rate of COVID-19 WhatsApp Usage

Participants' self-reports revealed that WhatsApp was the second most common source for COVID-19 news after news websites or apps (Figure 3). By quantifying this through 1 week of experience sampling, we found that nearly all participants (143/151, 94.7%; 95% CI 90-98%) reported at least 1 COVID-19 related use of WhatsApp. Namely, around 1 in 2 participants (79/151, 52.3%; 95% CI 44%-60%) forwarded at least 1 COVID-19 message (to either individuals or groups), 78.1% (118/151; 95% CI 71%-84%) received at least 1 forwarded message in personal chats, 66.2% (100/151; 95% CI 58%-74%) engaged in personal chat conversations about COVID-19, and 88.1% (133/151; 95% CI 82%-93%) had been in groups where COVID-19 was mentioned.

Figure 3. Sources of COVID-19 news. In a questionnaire, participants self-reported the sources from which they received COVID-19 news.

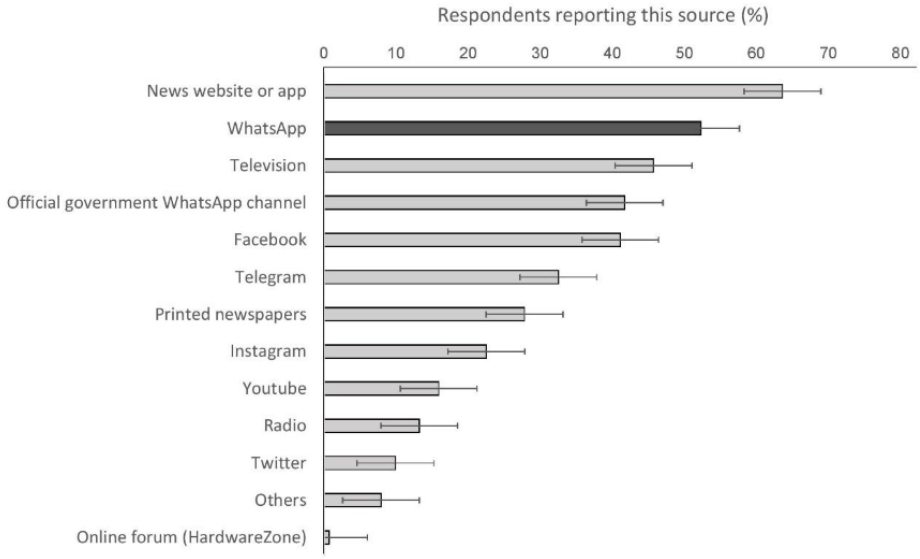

Figure 2 shows the extent to which participants engaged in each of these activities. On average, participants (1) received 2.3 times more messages than they forwarded and (2) were more likely to forward messages to individuals than to groups (average of 5.3 messages per week vs 2.7 messages per week, respectively). Beyond passive engagement, participants also took part in an average of 3.8 one-to-one conversations about COVID-19 during the week; however, these interactions occurred less frequently than the sending or receiving of forwarded messages in group chats.

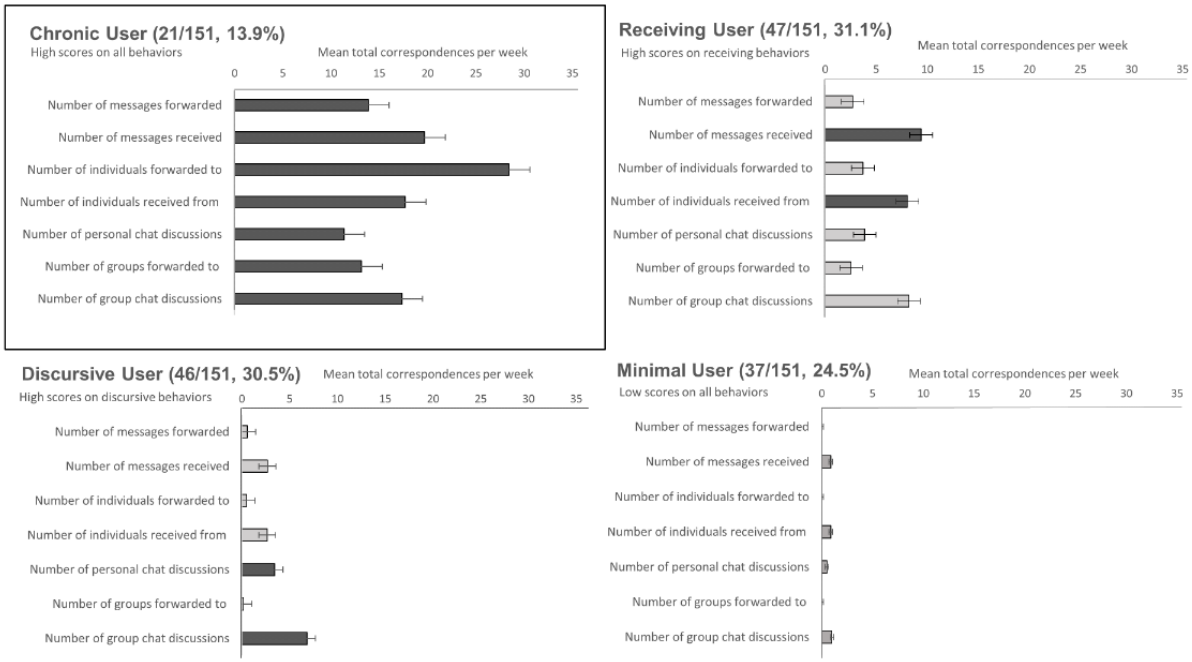
Characterizing Participants Based on COVID-19 WhatsApp Usage

Latent Profile Analysis: Generating a Taxonomy of WhatsApp Usage

Although most participants (143/151, 94.7%) received and shared COVID-19 content on WhatsApp, there were individual differences in usage patterns (Figure 4). Correspondingly, we conducted a latent profile analysis to understand how usage patterns clustered.

Figure 4. Taxonomy of COVID-19–related WhatsApp usage. By using latent profile analysis, we classified participants based on how they had used WhatsApp to engage with COVID-19 content during 1 week of monitoring. The figure depicts the WhatsApp usage activities of chronic users (top left), receiving users (top right), discursive users (bottom left), and minimal users (bottom right). Horizontal lines represent the 95% CIs for the means.



A 4-cluster solution yielded the lowest absolute Bayesian information criterion values (Multimedia Appendix 2), resulting in the following taxonomy (Figure 4). First, 13.9% (21/151) of participants were chronic users, who exhibited high levels of activity with regard to each of the WhatsApp usage variables. Correspondingly, this group of participants was responsible for receiving and transmitting a large volume of forwarded COVID-19 messages; they sent the messages both to individual

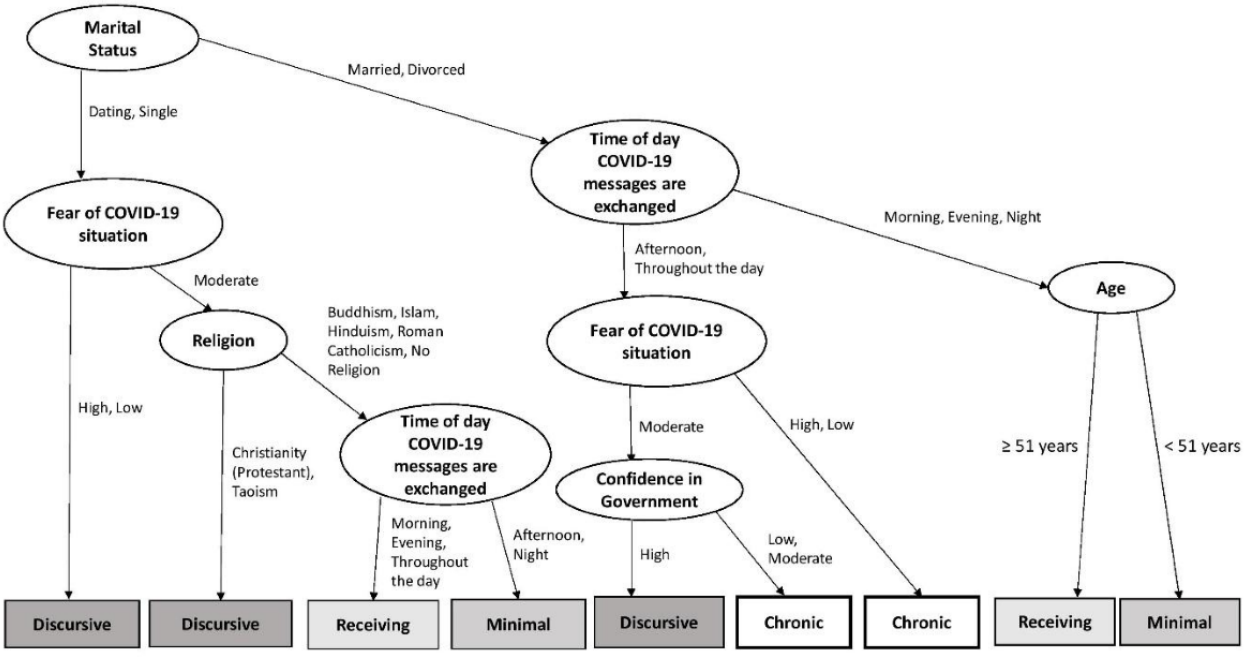
contacts and to groups. Second, 31.1% (47/151) of participants were receiving users, who were distinguished by their receipt of multiple forwarded COVID-19 messages. Although this group discussed COVID-19 frequently in group chats, they rarely passed along the forwarded COVID-19 messages that they had received. A third group – discursive users (46/151, 30.5%) – had low exposure to forwarded COVID-19 messages and primarily engaged with COVID-19 content through personal and group chats. Finally, 24.5% (37/151) of participants were minimal users, who had low levels of engagement with COVID-19 content overall.

Understanding User Characteristics

As an exploratory analysis, we performed a classification tree analysis to predict WhatsApp user types based on demographics, COVID-19 concerns, depression and anxiety scores (DASS-21), and the time of day when participants used WhatsApp. We performed recursive partitioning (*rpart*)—a machine learning technique that allows multiple variables to be analyzed simultaneously and supports the modeling of complex, nonlinear relations among predictors [21]. To avoid overfitting, the final tree was pruned by selecting the tree size with the lowest cross-validation error, which, for our data set, was a tree size of 8.

As shown in Figure 5, chronic users were more likely to be married or divorced and more likely to send messages either throughout the day or in the afternoon. In terms of responses to the COVID-19 pandemic, chronic users either (1) had extreme fears of the COVID-19 situation (low or high levels of fear) or (2) had moderate fears paired with low confidence in the government's response (low or moderate confidence in government).

Figure 5. Classification tree analysis. Recursive partitioning was used to predict which of the four WhatsApp usage profiles (chronic, receiving, discursive, or minimal) participants belonged to based on baseline questionnaire measures (demographics; COVID-19 concerns; scores on the 21-item Depression, Anxiety and Stress Scale; and time of WhatsApp usage). The final tree model is presented as a flowchart; factors are chosen at each level to categorize the maximal number of participants. Marital status, the time of WhatsApp usage, and age emerged as the primary predictors (model classification accuracy: 64.2%; above the chance level of 25%).



Discursive users were more likely to be single or be dating and had either (1) extreme levels of COVID-19–related fears (either high or low levels of fear) or (2) moderate fear levels alongside Christian or Taoist affiliations. A subgroup of discursive users were, like chronic users, married or divorced and had moderate levels of COVID-19–related fears. However, they were distinguished from chronic users based on their high confidence in the government (chronic users had lower confidence in the government).

Finally, receiving, and minimal users had similar profiles. If they were single or were dating, both sets of users tended to have moderate levels of COVID-19–related fears, had a wide range of religious backgrounds, and were distinguished based on the time of day when they received COVID-19–related messages (receiving users: in the morning, in the evening, and throughout the day; minimal users: in the afternoon and at night). If they were married or divorced, both sets of users tended to send messages at only 1 time of the day (morning, evening, or night) and were distinguished based on age (receiving users: aged ≥51 years; minimal users: aged <51 years). Table 1 describes the demographic characteristics of the four user profiles.

Does WhatsApp Usage Relate to COVID-19 Concerns?

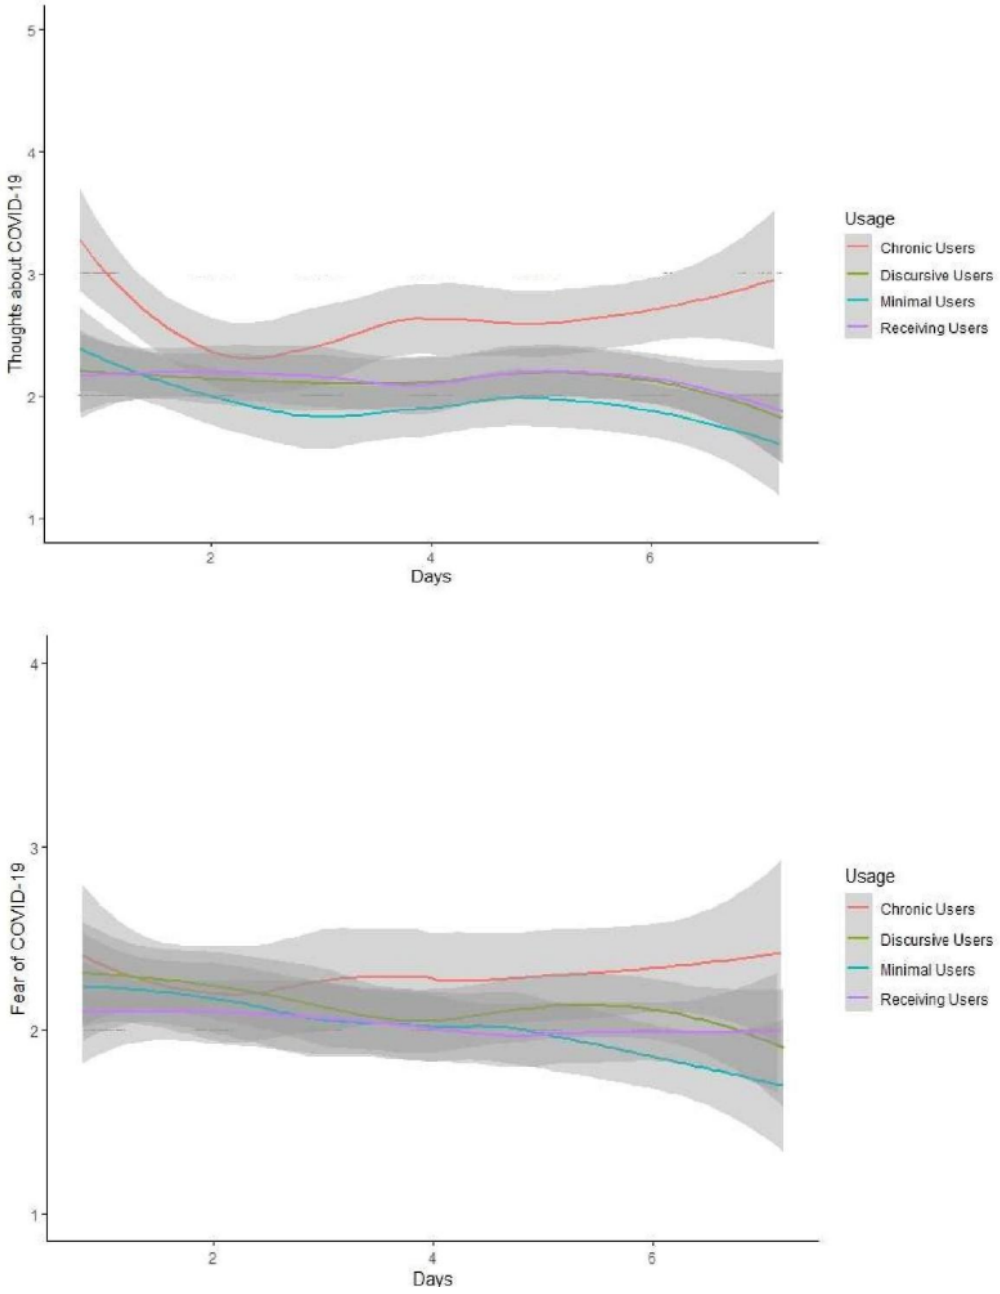
Finally, we conducted linear mixed-effects models to examine whether WhatsApp usage was related to COVID-19 concerns (Table 2). As shown in Figure 6, day-to-day COVID-19–related fears and thoughts fluctuated (fears: $t_{249.13}=-3.72$; $P<.001$; thoughts: $t_{297.02}=-2.36$; $P=.02$).

Table 2. Parameter estimates for the multi-level model of thoughts about COVID-19 (model 1) and the fear of COVID-19 (model 2) as a function of participants' daily WhatsApp use (personal chats and group chats).

Model and effects	Estimate, β (SE; 95% CI)	*t* test[a]*(df)* or *Z*	*P* value
Model 1 outcome: thoughts about COVID-19			
Fixed effects			
Intercept	2.18 (0.07; 2.05 to 2.31)	32.81 (135.68)	<.001
Time (centered)	−.03 (.01; −.05 to 0)	−2.36 (297.02)	.02
Daily personal chat usage (between subjects)	.04 (.02; 0 to .07)	2.36 (164.48)	.02
Daily personal chat usage (within subjects)	0 (.01; −.01 to .02)	0.42 (17.63)	.68
Daily group chat usage (between subjects)	.05 (.06; −.06 to .17)	0.89 (141.17)	.37
Daily group chat usage (within subjects)	0 (.03; −.06 to .05)	−0.08 (14.09)	.93
Random effects			
Intercept (between subjects)	.56 (.08; .42 to .75)	6.89	<.001
Residual (within subjects)	.37 (.02; .33 to .43)	14.90	<.001
Autocorrelation (within subjects)	.24 (.05; .14 to .33)	4.97	<.001
Model 2 outcome: fear of COVID-19			
Fixed effects			
Intercept	2.10 (0.06; 1.98 to 2.21)	36.37 (144.90)	<.001
Time (centered)	−.03 (.01; −.05 to −.02)	−3.72 (249.13)	<.001
Daily personal chat usage (between subjects)	.01 (.01; −.02 to .04)	0.85 (155.44)	.39
Daily personal chat usage (within subjects)	.01 (.01; −.01 to .02)	1.22 (24.97)	.24
Daily group chat usage (between subjects)	.02 (.05; −.07 to .12)	0.49 (128.59)	.62
Daily group chat usage (within subjects)	−.03 (.02; −.06 to .01)	−1.42 (28.88)	.17
Random effects			
Intercept (between subjects)	.44 (.06; .34 to .58)	7.47	<.001
Residual (within subjects)	.21 (.01; .18 to .23)	13.83	<.001
Autocorrelation (within subjects)	.26 (.05; to .16 to .35)	5.16	<.001

[a]The *t* test was 2-tailed.

Figure 6. COVID-19–related thoughts and fears over 1 week. Day-to-day variations in COVID-19–related thought (top) and fear levels (bottom) as a function of WhatsApp user profiles. The shaded grey areas represent 95% CIs.



For thoughts about COVID-19, there was a significant effect in WhatsApp personal chat usage at a between-subjects level ($t_{164.48}$=2.36; *P*=.02), that is, participants who handled larger amounts of COVID-19 content in their personal chats reported having more thoughts about COVID-19 (relative to participants who handled smaller amounts of COVID-19 content). However, the corresponding effect for group chats was not significant ($t_{141.17}$=0.89; *P*=.37). At the within-subjects level, neither day-to-day fluctuations in personal chat activities nor those in group chat activities significantly predicted thoughts about COVID-19 (smallest *P*=.68).

For COVID-19–related fears, we found no significant effects in any of the WhatsApp usage variables (smallest *P*=.17). For sensitivity analyses, we repeated both models and used group membership as a fixed factor in place of personal and group chat usage, and our primary conclusions did not change (Multimedia Appendix 3).

Discussion

Principal Findings

The ongoing pandemic has drawn attention to the role of social media in public health. Against this backdrop, we present the first infodemiological study to document the spread of COVID-19 content through WhatsApp. By tracking daily WhatsApp usage for 1 week, we found that (1) nearly every participant engaged in COVID-19 chatter and (2) participants were more likely to share or receive forwarded messages than to engage in conversations about COVID-19.

The volume of forwarded messages that we observed raises concern. On other social media platforms, forwarding behaviors have been linked to the spread of misinformation. For example, a study of 4.5 million Twitter posts found that misinformation was 70% more likely to be shared than posts that were true; correspondingly, any single retweet had a higher probability of containing false news rather than truthful news [15]. Although analogous research has not been conducted on WhatsApp, the app's developers have likewise deemed forwarded messages as a high-risk source of misinformation [4,5].

With regard to the extent that forwarded messages carry misinformation [1,2], our latent profile analyses revealed that around 1 in 10 (21/151, 13.9%) participants were chronic users who received and shared a large volume of such messages. Notably, chronic users disseminated an average of 14 forwarded messages during the week, which is approximately 5 times the number of messages that were sent by all participants in this study. This is reminiscent of research on other social media platforms (eg, Twitter) where a small group of super sharers and super consumers are responsible for the bulk of shared misinformation [22]. Given the potential influence of this group, further research is needed to understand (1) the profile of chronic users, (2) the reasons why they forward messages, and (3) how their forwarding activities may influence outcomes during health crises.

Aside from chronic users, our study also found that around 1 in 3 (47/151, 31.1%) participants were receiving users who had high exposure to forwarded COVID-19 content. Receiving users tended to be older (in line with misinformation studies on Facebook [23]) but were otherwise moderate in terms of their profiles, that is, in terms of COVID-19–related fears or religion (they came from a diverse religious background). Although this group did not spread forwarded messages themselves, their high exposure may nonetheless leave them susceptible to false beliefs. Correspondingly, we urge researchers to conduct further research to understand how WhatsApp use among receiving users influences health behaviors.

Finally, we also found that WhatsApp users who discussed COVID-19 in their personal chats were more likely to think about COVID-19 throughout the day. As similar forms of rumination (involving frequent and persistent thoughts) have been linked to clinical depression [24], this finding may implicate COVID-19 chatter as a risk factor for poorer well-being [25]. Future studies should thus explore this possibility and the potential mechanisms involved.

Implications

Taken together, our findings on WhatsApp message transmission have several implications for public health responses during a crisis. First, our taxonomy of user profiles provides a basis for targeted risk communication. Our findings suggest that public health agencies may need to reach out proactively to chronic and receiving users, who handle the bulk of forwarded COVID-19 content on WhatsApp. One possible intervention may be encouraging these users to subscribe to official WhatsApp channels for updates (eg, updates from the World Health Organization) [2] to capitalize on their pre-existing readiness to use the platform.

Tracking WhatsApp chatter may also result in new opportunities for detecting disease outbreaks. The nascent field of digital epidemiology seeks to model how diseases spread by monitoring digital data sources (eg, through Google search data and Twitter posts) [26]. Although the content of private WhatsApp messages is difficult to track, the volume or nature of messages (eg, forwarded messages) may provide information that can be used to support disease surveillance. To this end, further research is needed to explore the predictive utility of message transmission dynamics on WhatsApp.

Limitations

In reporting these findings, we noted several limitations. First, we opted to study WhatsApp—the most widely used messaging app. At this juncture, it is unclear whether our results generalize to other messaging apps (eg, Facebook Messenger and Telegram).

Second, our recruitment strategy was limited by the nature of the pandemic. Owing to infectious disease protocols and the short time period when the amount of crisis-related communication was high [27], our data collection process was restricted in terms of the recruitment strategy (web-based sampling), sample size (151 participants), and time frame (1 week per participant). Further research is needed to examine whether our findings generalize to the broader population.

Finally, although the experience sampling method captured WhatsApp usage in participants' naturalistic settings, the method nonetheless required self-reports. By extending our findings, future studies will benefit from having objective metrics of WhatsApp usage.

Conclusions

In conclusion, we used the experience sampling method to capture COVID-19 chatter on WhatsApp for the first time. In total, we tracked 924 days' worth of chatter in situ, revealing (1) the sheer prevalence of WhatsApp usage, (2) a typology of WhatsApp users, and (3) a link between usage patterns and constant thoughts about the pandemic. These findings have implications for health communication and disease surveillance, bringing the field 1 step closer to characterizing WhatsApp usage and using these data to gain insights on individual and societal concerns.

Acknowledgments

This research was funded by a grant awarded to JCJL from the NUS (National University of Singapore) Centre for Trusted Internet and Community (grant CTIC-RP-20-09). The first author's (EYQT) involvement was funded by a center grant awarded to the Centre for Sleep and Cognition.

Authors' Contributions

RREW, KJQH, and JWEC contributed to the study design and collected the data. EYQT and YES analyzed the data and wrote the first draft of the manuscript. JCJL and EMWT conceived the study, had oversight of the overall project, and supervised both the data analyses and manuscript preparation. All authors provided feedback on the final version of the manuscript.

Abstract

Background: Low back pain (LBP) remains the leading cause of disability worldwide. A better understanding of the beliefs regarding LBP and impact of LBP on the individual is important in order to improve outcomes. Although personal experiences of LBP have traditionally been explored through qualitative studies, social media allows access to data from a large, heterogonous, and geographically distributed population, which is not possible using traditional qualitative or quantitative methods. As data on social media sites are collected in an unsolicited manner, individuals are more likely to express their views and emotions freely and in an unconstrained manner as compared to traditional data collection methods. Thus, content analysis of social media provides a novel approach to understanding how problems such as LBP are perceived by those who experience it and its impact.

Objective: The objective of this study was to identify contextual variables of the LBP experience from a first-person perspective to provide insights into individuals' beliefs and perceptions.

Methods: We analyzed 896,867 cleaned tweets about LBP between January 1, 2014, and December 31, 2018. We tested and compared latent Dirichlet allocation (LDA), Dirichlet multinomial mixture (DMM), GPU-DMM, biterm topic model, and nonnegative matrix factorization for identifying topics associated with tweets. A coherence score was determined to identify the best model. Two domain experts independently performed qualitative content analysis of the topics with the strongest coherence score and grouped them into contextual categories. The experts met and reconciled any differences and developed the final labels.

Results: LDA outperformed all other algorithms, resulting in the highest coherence score. The best model was LDA with 60 topics, with a coherence score of 0.562. The 60 topics were grouped into 19 contextual categories. "Emotion and beliefs" had the largest proportion of total tweets (157,563/896,867, 17.6%), followed by "physical activity" (124,251/896,867, 13.85%) and "daily life" (80,730/896,867, 9%), while "food and drink," "weather," and "not being understood" had the smallest proportions (11,551/896,867, 1.29%; 10,109/896,867, 1.13%; and 9180/896,867, 1.02%, respectively). Of the 11 topics within "emotion and beliefs," 113,562/157,563 (72%) had negative sentiment.

Conclusions: The content analysis of tweets in the area of LBP identified common themes that are consistent with findings from conventional qualitative studies but provide a more granular view of individuals' perspectives related to LBP. This understanding has the potential to assist with developing more effective and personalized models of care to improve outcomes in those with LBP.

low back pain; Twitter; content analysis; social media; topic modeling; patient-centered approach; pain experience; context of pain

Introduction

Low back pain (LBP) is the leading cause of disability worldwide [1,2]. Approximately 50%-80% of adults experience LBP at least once in their lives [3] and it is a leading cause of work absence and limits physical activities, posing a large economic burden [1,4]. In the United States, the total cost associated with LBP exceeds US $100 billion per year [5,6]. It is also a significant contributor to the current global epidemic of narcotic prescriptions [7].

Optimizing management of conditions such as LBP requires consumers to be engaged in their care. To enable this, health care providers need to have an understanding of the full context of the condition from the consumer perspective. “Contextual variables” here refer to any type of useful information about the context of an individual’s pain experience, such as physical, emotional, social, and/or occupational variables [8]. A better understanding of the contextual variables of individuals with LBP could provide clinicians and health providers with an alternative insight into patients’ concerns, beliefs, and expectations, and has the potential to improve outcomes in LBP [9]. Although there have been many studies examining individuals’ beliefs about LBP, patients’ perspectives remain inadequately understood [10]. Although qualitative studies—including systematic scoping reviews—investigating patients' needs and expectations have been conducted, these have largely focused on a single topic, such as health care, with the findings extrapolated from heterogeneous studies that are of poor quality [11-13]. A further limitation of current approaches is that most traditional data collection methods use predefined frameworks that have the potential to constrain responses. For instance, validated questionnaires that provide statements about back pain and its consequences (such as “back pain must be rested”) and require the respondent to indicate their level of agreement on a scale are commonly used [12,13]. Moreover, for logistical and methodological reasons, many studies restrict the selection of populations to be studied.

With the current advances in online and web technologies, social media has emerged as a new and rich source of first-person health care data [14-16]. Social media platforms provide an opportunity to rapidly collect data from a larger and more diverse population in a cost-efficient manner. Health-related topics are commonly discussed on Twitter [17-19], a microblogging social media site [20]. A systematic review conducted by Sinnenberg et al [21] found six main uses of Twitter in health research: content analysis, surveillance, engagement, recruitment, intervention, and network analysis. Aggregation and analysis of large volumes of health-related data from social media sites could provide valuable information from a first-person point of view [14,22]. In the area of LBP, this approach could be used to investigate individuals’ perspectives and the context around the LBP experience [15,23]. We hypothesize that the detected topics identify specific contexts around the LBP experience in individuals. Thus, the aim of this study was to identify contextual variables of the LBP experience from a first-person perspective using a topic modeling approach of Twitter data to provide useful insights into individuals’ beliefs and perceptions. This has the potential to inform more effective patient-centered approaches to the management of LBP.

Methods

Study Approach

Our study approach was to undertake content analysis of Twitter data by applying topic modeling. Content analysis is a widely used technique for qualitative research [24] that enables studying patient experience in depth by deriving topics of interest from text documents [14,25].

Twitter Data

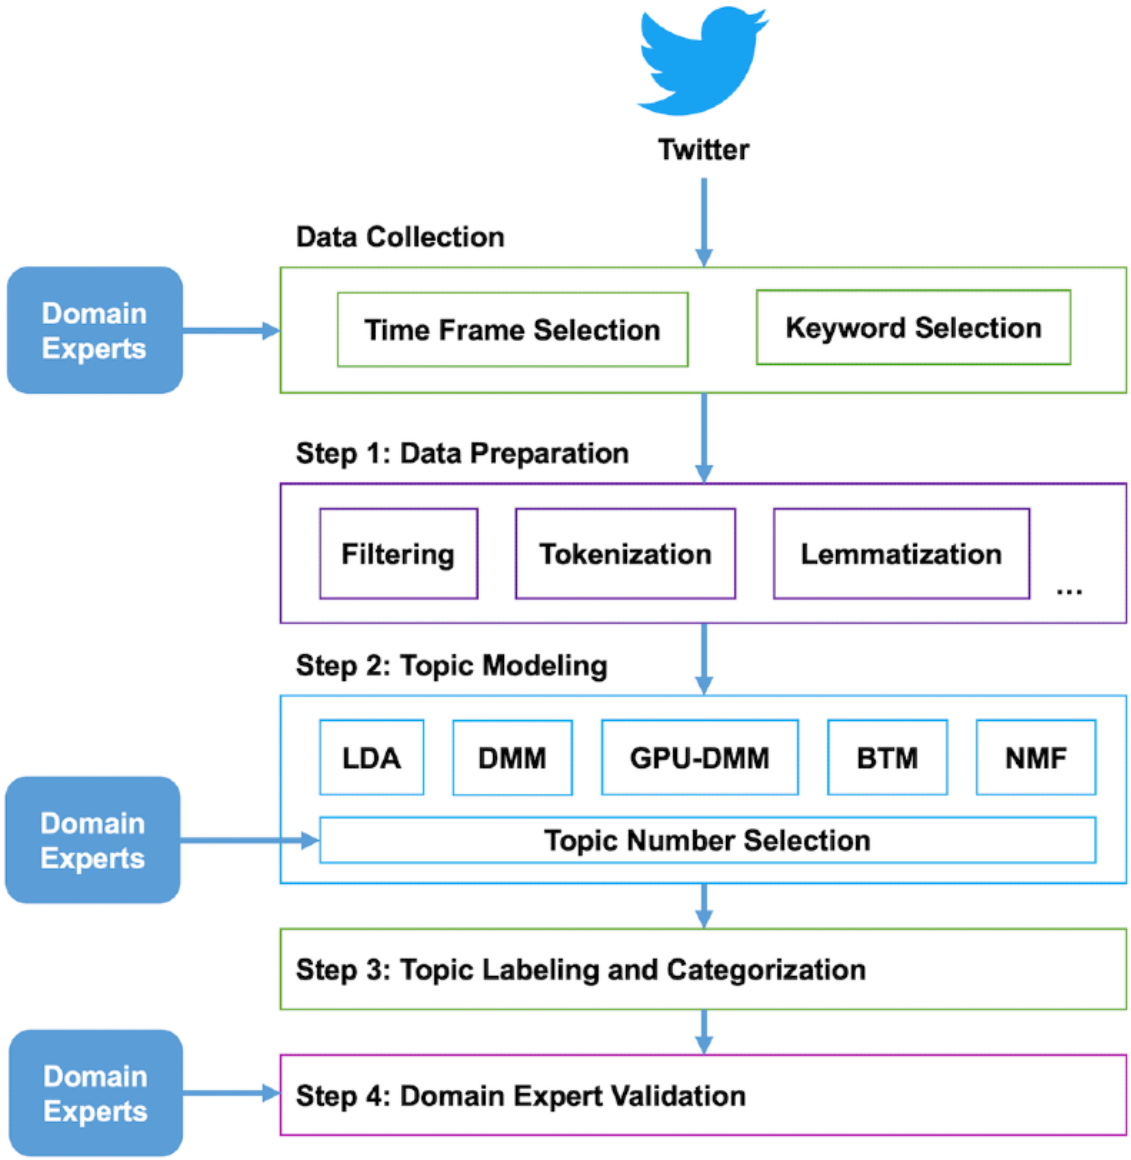
Twitter was used as the data source rather than other social media platforms, blog posts, or news articles because individuals use this platform for expressing and sharing their feelings and opinions on health-related topics by posting short messages that can be easily collected through application programming interfaces (APIs) or other open sources [14-17,26]. We used an open-source Twitter scraping tool called Twint [27] for collecting tweets related to LBP that were written in English. Twint enables the collecting of Twitter data without using Twitter's API through its publicly available library in the Python programming language [27,28]. We collected tweets posted between January 1, 2014, and December 31, 2018 (inclusive). The time frame of 5 years was selected to provide us with sufficient data to examine the patterns in emerging topics and the number of tweets over time. Since the number of active users on the social media platform increased in recent years and we needed a large volume of data for topic modeling, we did not consider tweets posted before 2014. We selected the search keywords based on 3 studies on back pain [15,29,30]. These are detailed in Table 1. Search keywords were verified by our domain experts (FC, a rheumatologist; DU, a physiotherapist) who have extensive research and clinical expertise in the area of LBP. Selecting search keywords and an appropriate time frame are important considerations in the data collection process. The Monash University Human Research Ethics Committee approved this study (project ID 19738).

Our data processing and analysis consisted of 4 steps (see Figure 1).

Table 1. Keywords used to search tweets related to low back pain.

Source	Study purpose	Keywords	Total, n
Lee et al, 2016 [15]	To quantify the risks associated with a new tweet about back pain	"painful back," "sore back," "back started hurting," "buggered my back," "hurt my back," "I've got backache," "injured my back," "my back hurts," "I've got back pain," "pain in my back," "put my back out," "my back is killing me"	12
Ahlwardt et al, 2014 [30]	To compare self-reported toothache experiences in tweets with those of backache, earache, and headache	"backache," "back ache," "back aches," "back hurt," "back hurting," "back hurts," "back killin'," "back killing," "back pain," "back sore"	10
Campbell et al, 2013 [29]	A systematic review to study the influence of employment social support in nonspecific back pain	"lumbago," "backache," "back ache," "back pain," "low back ache," "low back pain," "lower back pains"	7

Figure 1. The overall data analysis workflow. The analysis consists of four steps: (1) data preprocessing, (2) thematic analysis using topic modelling, (3) topic labeling and categorization, and (4) domain expert validation. BTM: biterm topic model; DMM: Dirichlet multinomial mixture; GPU-DMM: General Pólya Urn Dirichlet Multinomial Mixture; LDA: latent Dirichlet allocation; NMF: nonnegative matrix factorization.



Step 1: Data Preprocessing

We removed duplicates, retweets, URLs, and tweets related to marketing and advertisements, which reduced the data set from 7,892,210 to 2,825,645. We filtered the data further by removing tweets that did not contain first person pronouns [15]. As a result, the remaining data set size was 2,010,295.

We replaced contractions with their expanded forms (eg, "didn't" to "did not"). We converted the HTML characters to ASCII characters and removed hashtags, Unicode strings (eg, "\u2026"), numbers, and punctuation. We replaced abbreviations, elongated words (eg, "gooood" to "good"), and emoticons and emojis with their equivalent English expressions. We then performed spelling correction, lowercasing, tokenization, and lemmatization, created n-grams, removed stop words (eg, common terms such as "the" and "is"). We again removed the duplicates and the remaining data set was 1,249,576 tweets.

After completing the abovementioned steps, we excluded tweets with less than three words because in topic modeling, the document size is important to achieve high accuracy [31]. This reduced the data set to 896,867 tweets.

Step 2: Topic Modeling

Topic modeling is a technique used to provide a summary of a large collection of documents by extracting "topics" that represent the dominant themes [32]. It allows the uncovering of common, hidden themes from a corpus of text documents such as tweets. We tested 5 well-established topic modeling algorithms for detecting topics in a text-based corpus, namely latent Dirichlet allocation (LDA) [33], Dirichlet multinomial mixture (DMM) [34], GPU-DMM [35], biterm topic model (BTM) [36], and nonnegative matrix factorization (NMF) [37].

LDA is a generative probabilistic model that assumes each document can be represented by distribution over topics and each topic by distribution over words [33,38]. DMM is also a generative model but it assumes that each document is associated with one single topic [34,39]. GPU-DMM is an extended method of DMM that considers semantic similarity between words to provide semantic understanding of text documents and improve topic inference [35,40]. BTM uncovers topics by modeling the word co-occurrence patterns (ie, biterms) rather than using the document-level word co-occurrences [36,41]. NMF is able to learn the latent features in data using a nonnegative representation and improve latent semantic topic identification [37,42,43].

To use these models (except for NMF), we used a Java-based open-source library for short text topic modeling algorithms called STTM (version 1.8) [44], whereas for NMF we used the sklearn [45] library. For each approach, we performed a series of experiments ranging from 5 topics to 200 topics. We applied the 5 algorithms to the 896,867 tweets to determine the best model and the optimal number of topics.

Choosing the right number of topics is a crucial step in topic modeling because it can affect the accuracy of results. The quantitative approach computes the coherence score and perplexity, which helps in determining the optimal number of topics [46]. The coherence score measures the sum of the pairwise word-similarity scores of the words in the topic, using the pointwise mutual information (PMI) score [47]. Best collocation pairs usually have a high PMI. On the other hand, the qualitative approach requires humans and domain experts to examine the topics. Human judgment is extremely important because topic modeling uses a form of unsupervised learning.

As a quantitative approach, we calculated the coherence score of each model on different numbers of topics ranging from 5 to 200, based on the PMI score [47,48]. The coherence score was used to evaluate the quality of the topic-word distribution. LDA outperformed other approaches (ie, DMM, GPU-DMM, BTM, and NMF).

Additionally, we used a qualitative approach to select the most representative topics. We manually examined the topics, their top 20 terms, and a random sample of tweets in each topic. We also created a word cloud for each topic and evaluated word clouds and their sample tweets. We identified the number of topics that provided us with distinct and meaningful topics; if we exceeded this number of topics, we started to notice an increase in duplicates and overlapping topics. We used both quantitative and qualitative approaches to select the optimal number of topics.

Step 3: Topic Labeling and Categorization

Topic labeling is a process of representing the meaning of a topic by assigning each topic a descriptive word or phrase [49]. Although automatic labeling approaches can reduce costs and time required, they are not able to achieve high semantic validity and accuracy [50,51]. In our study, we used the "eyeballing" method, which refers to reading and inspecting the top words in a topic and manually assigning a label [50]. We made sure that the results met the requirements of a "good" label: (1) semantically relevant, (2) meaningful, (3) representative, (4) adequate, and (5) understandable [34,49].

LDA assumes that each document (tweet) is a mix of topics with different proportions [33]. We were interested to examine tweets based on their dominant topic to gain a better understanding of the frequency of topics across all tweets. Therefore, we performed further analysis, and used the label of the dominant topic to represent each tweet, and then calculated the total number of tweets per topic.

To improve the results of thematic analysis, low-order topics can be grouped under broad, higher-order categories [52]. Higher-level categories can provide a better overview of the key topics discussed by individuals. To this end, after manual topic labeling, we performed topic categorization and assigned a category label to the topics that represented common themes. To identify the important and widely discussed categories, we then calculated the percentage of all tweets that corresponded to each individual category.

Step 4: Domain Expert Validation

Two domain experts (FC, a rheumatologist; DU, a physiotherapist), actively working clinically and researchers in the area of LBP, independently examined the selected topics from the previous step where each topic included the top 20

words to determine face validity. As previously described, in topic modeling, the top words of each topic provide the description of that topic, thereby assisting the domain experts with inferring its meaning [49]. The experts then met to reconcile any differences and develop the final labels.

Results

Overview

The total number of collected tweets about LBP was 7,892,210 from 2,420,258 unique users from 2014 to 2018. The average number of words in each tweet increased from 2017 onward (Multimedia Appendix 1), in line with Twitter doubling the character limit of tweets from 140 to 280 characters as of November 2017 [53].

Step 1: Data Preprocessing

After performing comprehensive data preprocessing, the final number of retained tweets was 896,867, which represents 11% (896,867/7,892,210) of the original raw data we collected, with a vocabulary size of 29,539. The minimum length of tweets was 4 words and the maximum length was 20 words.

Step 2: Topic Modeling

After testing 5 topic modeling algorithms and the number of topics based on the coherence score and our manual examination, we selected the best model that included 60 topics, detected from 896,867 self-reported tweets about LBP. Multimedia Appendix 2 shows the coherence score of different models with a different number of topics ranging from 5 to 200. The best model was the LDA model with 60 topics, which had a coherence score of 0.562. Multimedia Appendix 3 shows the best model selected with 60 topics and their top 20 terms.

Step 3: Topic Labeling and Categorization

The 60 topics were examined and manually given a topic label. The common and duplicate labels were then grouped into higher-order categories. Word clouds for the two categories of “pain regions” and “sleep” after combining the related topics are provided in Multimedia Appendix 4. The prevalence of the 60 manually labeled topics is presented in Multimedia Appendix 5.

Step 4: Domain Expert Validation

Independent examination of selected topics by two domain experts and reconciliation of any differences resulted in 19 contextual categories, with details presented in Multimedia Appendix 6. The total number of tweets within each of 19 contextual categories is presented in Figure 2, with more details in Multimedia Appendix 7. The “emotion and beliefs” category had the largest proportion of the total tweets, followed by “physical activity” and “daily life.” The lowest proportion of tweets belonged to the categories of “food and drink,” “weather,” and “not being understood.”

The proportion of tweets for each higher-level category over the years showed that all 19 categories had been discussed by individuals with relatively similar frequency every year (see Figure 3). However, the proportion of “emotion and beliefs” decreased from 2014 to 2018. The number of tweets about other categories, such as “aggravating factors” and “symptoms,” increased over that time period. An example of a tweet for each category is presented in Table 2 to illustrate the type of personal point of view related to each category.

Figure 2. The 19 categories and their proportions based on all tweets posted from 2014 to 2018.

Figure 3. The proportions of 19 categories based on the dominant topic per year.

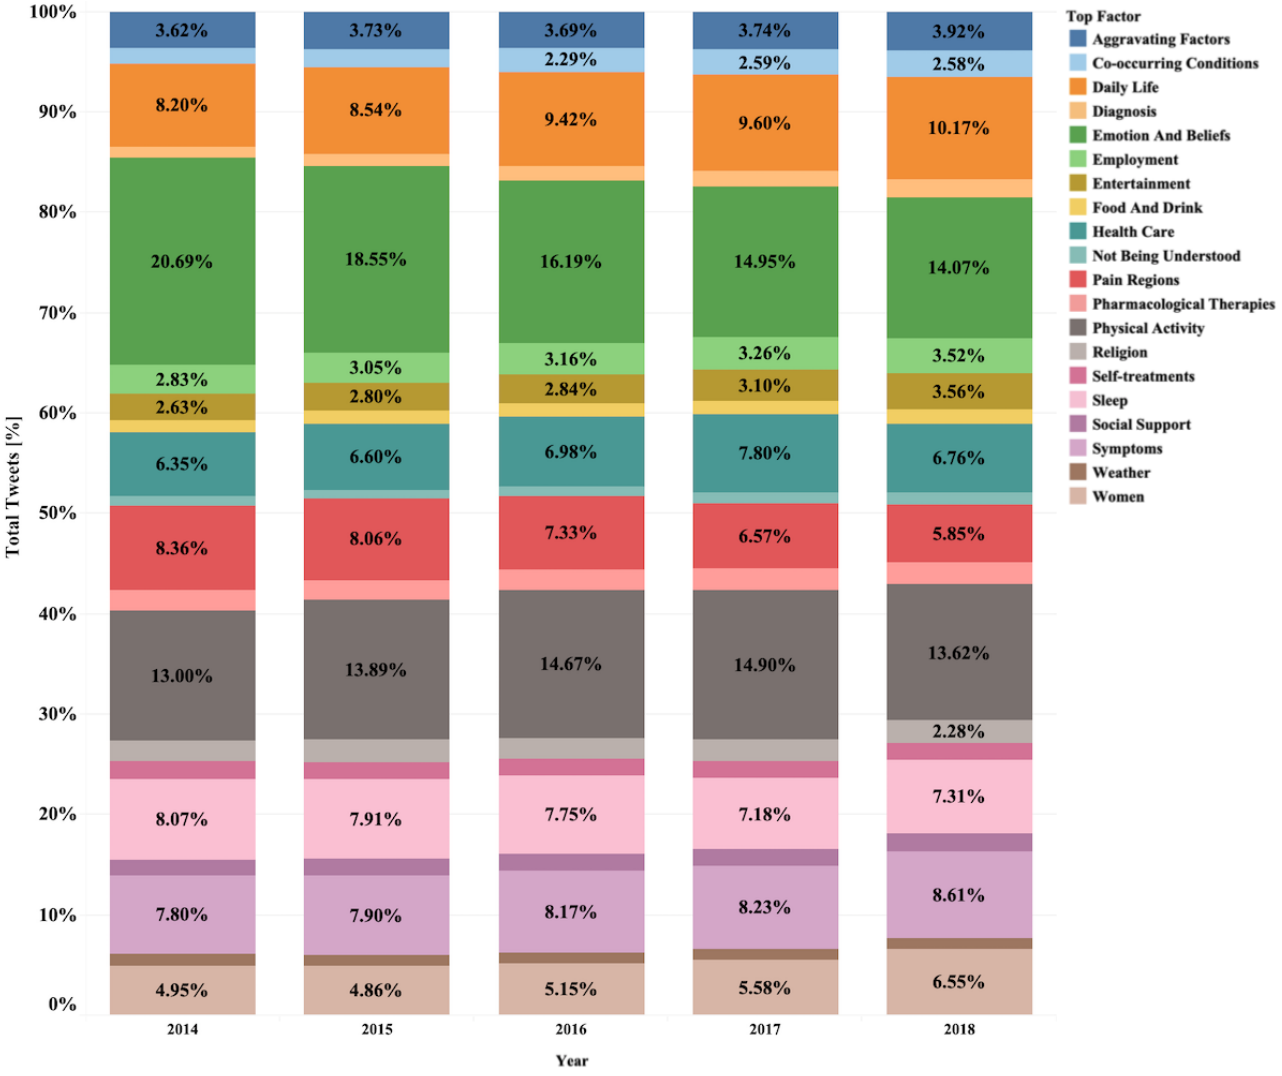


Table 2. An example of tweets for each contextual category.

Categories	Examples of tweets
Emotion and beliefs	• My back hurts, feeling sad because I wanna get up and do something ! I hate staying in bed :(
Physical activity	• I did 6 miles on my exercise bike yesterday, felt really pleased with myself, and ate healthy. My back hurts today
Daily life symptoms	• So my back hurts like hell and I can hardly sit here and do my hair. • I hate it when my lower back hurts and sends shooting pains down my legs, making them ache and throb. Ugh.
Sleep	• Every time I sleep in my sis guest bedroom my back hurts, that bed is not comfortable. I"d prolly be better off sleeping on the floor
Pain regions	• today is not a good day. my back hurts, my shoulder hurts, my elbow is tingly, a little numb down to my hand and to top it off now my left knee hurts a little.
Health care	• So I have found one good physio and one good chiropracter, both same price, who would you see if you had lower back pain?
Women	• Being pregnant is literally taking everything out of me. I'm exhausted, my back is killing me and I stay moody…
Aggravating factors	• Yesterday I tried doing a back flip on my trampoline. Now, every time I walk my back hurts. When I did the back flip I landed on my head.
Employment	• Hurt my back at work yesterday and I'm working a full 12 hours tomorrow without getting paid. Lovin life right now.
Entertainment	• Watching Cirque Du Soleil: Michael Jackson my back hurts just from watching it
Religion	• Testimony Time! i want to give God the glory for healing me from a severe back pain
Co-occurring conditions	• I don't know if my back pain is causing depression or my depression is causing back pain…
Pharmacological therapies	• I just took my very first Oxycodone for lower back pain. I think I'm in love. It didn't just kill the pain. It assassinated it.
Self-treatments	• Coconut oil epsom salt & vapor bath oil just soothed my back pain away
Social support	• Told mom my back hurts she offered to rub my feet an back I have the best mom ever
Food and drink	• my back is killing me cant get out ov bed but need coffee
Weather	• I love cold weather but it's really not helping with my back pain. Where is that warm summer weather atttttttt.
Not being understood	• OMG no one understands the pain I'm in right now. My back is killing me.

Discussion

Principal Results

In this study, we identified 60 specific topics from 896,867 tweets about LBP and grouped them into 19 categories that relate to contextual variables of LBP. The top category was "emotion and beliefs," with 157,563/896,867 tweets (17.6%), followed by "physical activity" (124,251/896,867, 13.85%) and "daily life" (80,730/896,867, 9%), while "food and drink," "weather," and "not being understood" had the lowest proportions of tweets (11,551/896,867, 1.29%; 10,109/896,867, 1.13%; and 9180/896,867, 1.02%, respectively). There were 11 topics within the category of "emotion and beliefs"; of 157,563 tweets in this category, 113,562 (72%) expressed negative sentiment. Our results were consistent with the general findings from traditional study methods in the area of LBP but provided more in-depth detail on the context of LBP from the individual perspective.

Comparison With Prior Work

Our study examined contextual variables to provide a novel insight into first-person perspectives of the LBP experience and confirmed the broad areas that have previously been identified using more traditional data collection methods from qualitative and quantitative studies. For example, psychosocial factors have an important role in LBP [54] and, from our analysis of tweets, "emotion and beliefs" was the most common topic we identified, with 157,563 of 896,867 tweets. This is consistent with LBP being widely recognized as a biopsychosocial condition, and growing evidence to show that psychological factors, such as beliefs and emotions, play an important role [55]. For instance, systematic reviews have highlighted that beliefs about back

pain and negative consequences resulting from these beliefs are common across different countries and populations [56], and affect both treatment efficacy and prognosis [57]. Moreover, mass media campaigns that target negative beliefs have been implemented in an effort to influence how people manage their back pain on a population level [58]. Our study has also provided novel findings with respect to emotions. Although we found a range of emotions, from positive emotions (such as happy, love, or fun) to negative emotions (including hell, bad, or disgusting), the majority were found to be of negative affect. Although several studies have examined the role of specific emotions, such as anger [59,60], in LBP research, our understanding of the array of emotions experienced by individuals with back pain, specifically negative emotions, is limited.

Our study also highlighted areas related to the pain experience in individuals that have not been adequately explored in the literature but that play an important role in the effectiveness of LBP interventions and self-management behaviors, such as the "not being understood," "religion," and "food and drink" categories. We found that although the category of "not being understood" had the smallest proportion of tweets with a total of 9180 tweets, it had the top five words: "make," "people," "stop," "thing," and "complain." This is consistent with a previous systematic scoping review that examined what patients want from their medical care, which reported that patients felt misunderstood and wanted legitimation of their LBP [11]. Patients with LBP report negative social stereotyping from health care professionals, family and friends, and the community [61] and that they are dissatisfied with the inadequate advice they receive from medical practitioners and have identified an unmet need for care providers that show more understanding and empathy [11].

The category of "food and drink" is novel and interesting. The tweets included words relating to the type of food (eg, pizza, chocolate, cookies and cream), mealtimes (such as breakfast and lunch), and the process of bringing or making food. Although they reflect important daily habits of eating and drinking, they may also highlight issues around pain affecting an individual's capacity to eat and drink and/or problems associated with weight and in particular obesity [62], which is a major public health issue [63].

There are well-described sex differences in the prevalence of back pain [64]. Analysis of tweets identified 3 topics under the "women" category including "motherhood," "large breasts problem," and "female health complaints." LBP has been reported in more than two-thirds of pregnant women [65]. Improving psychological well-being, physical fitness, and general well-being may reduce LBP in women [65-67]. The topics identified in tweets may provide more direction in relation to the personal topics that warrant further examination (eg, the potential effect of "large breasts problem" and whether this is a cause of LBP or a potential confounding variable). Identifying possible mechanisms for the association with topics such as "motherhood" or "female health complaints" could also help with understanding whether these associations are due to psychosocial factors or biomechanical factors such as the lifting and carrying of children. Understanding the context of LBP could offer valuable insights into how people with LBP view and experience their condition; this could lead to the identification of new areas of research in exploring the causes of LBP, as well as the opportunity to identify areas of potential misinformation that need to be addressed.

Limitations

There are some limitations to our study. Although the keywords were taken from existing studies about LBP and approved by domain experts, some keywords, such as "back hurt" and "back pain," were very broad. Therefore, the data collected might not have been specific to LBP. Selection of the right keywords in Twitter data analysis is very important to avoid unrelated data that could reduce the accuracy of results. Filtering and cleaning of Twitter data is also crucial for achieving high accuracy of results. In our study, we performed vigorous data cleaning, but our manual examination showed that there was a group of tweets that contained a few lines from the lyrics of a famous hip-hop song (Bad and Boujee) by Migos. These lines included "…So my money makin' my back ache." One of our search keywords was "back ache." Although there are many tools and methods available to automatically perform data cleaning, it is always necessary to manually inspect the results.

Twitter users tend to be younger and might not represent the general population; therefore, the results must be carefully interpreted [68]. Similar to other social media studies in health care, we cannot verify that individuals who tweeted about LBP were actually real patients [15]. However, the filtering based on first-person pronouns (eg, I, my, or mine) that we performed is likely to have reduced this.

To determine the optimal number of topics, we used the coherence score, a widely used method, and then manually examined and compared the models. This process can be further improved by using other measures such as heuristic approaches [69] or perplexity measures [70].

We also recognize that manual labeling of topics can be subjective. Two domain experts with extensive knowledge were involved in the labeling and examination of selected topics but future work in this area could involve a greater number of and more diverse domain experts to further reduce this subjectivity.

Conclusions

Our findings provided useful insights into individuals' beliefs and perspectives regarding their needs and concerns related to LBP that complement the information available in the literature. Considering the contextual factors identified in this study rather than simply focusing on a biomedical model of LBP could address the needs of patients more holistically, help with improving LBP outcomes, and increase patient satisfaction. These findings have the potential to assist health care providers and clinicians with developing more effective, personalized therapies for LBP. There is also the potential to use social media to identify any major changes in community beliefs and needs regarding LBP that can be addressed in a timelier manner.

Acknowledgments

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. DU was supported by a National Health and Medical Research Council Career Development Fellowship (Level 2; 1142809).

Authors' Contributions

PDH, FB, DU, and FC contributed to study concept and design. R contributed to data collection and topic modeling. PDH, DU, and FC contributed to topic labeling and clustering. PDH, FB, DU, and FC contributed to interpretation of data. R and PDH contributed to drafting of the initial manuscript. PDH, FB, DU, and FC contributed to critical revision of the manuscript for important intellectual content. R and PDH provided administrative, technical, or material support. All authors approved the final version of the manuscript.

Abstract

Background: Given the permeation of social media throughout society, rumors spread faster than ever before, which significantly complicates government responses to public health emergencies such as the COVID-19 pandemic.

Objective: We aimed to examine the characteristics and propagation of rumors during the early months of the COVID-19 pandemic in China and evaluated the effectiveness of health authorities' release of correction announcements.

Methods: We retrieved rumors widely circulating on social media in China during the early stages of the COVID-19 pandemic and assessed the effectiveness of official government clarifications and popular science articles refuting those rumors.

Results: We show that the number of rumors related to the COVID-19 pandemic fluctuated widely in China between December 1, 2019 and April 15, 2020. Rumors mainly occurred in 3 provinces: Hubei, Zhejiang, and Guangxi. Personal social media accounts constituted the major source of media reports of the 4 most widely distributed rumors (the novel coronavirus can be prevented with "Shuanghuanglian": 7648/10,664, 71.7%; the novel coronavirus is the SARS coronavirus: 14,696/15,902, 92.4%; medical supplies intended for assisting Hubei were detained by the local government: 3911/3943, 99.2%; asymptomatically infected persons were regarded as diagnosed COVID-19 patients with symptoms in official counts: 322/323, 99.7%). The number of rumors circulating was positively associated with the severity of the COVID-19 epidemic (ρ=0.88, 95% CI 0.81-0.93). The release of correction articles was associated with a substantial decrease in the proportion of rumor reports compared to accurate reports. The proportions of negative sentiments appearing among comments by citizens in response to media articles disseminating rumors and disseminating correct information differ insignificantly (both correct reports: χ_1^2=0.315, *P*=.58; both rumors: χ_1^2=0.025, *P*=.88; first rumor and last correct report: χ_1^2=1.287, *P*=.26; first correct report and last rumor: χ_1^2=0.033, *P*=.86).

Conclusions: Our results highlight the importance and urgency of monitoring and correcting false or misleading reports on websites and personal social media accounts. The circulation of rumors can influence public health, and government bodies should establish guidelines to monitor and mitigate the negative impact of such rumors.

Introduction

Accurate, timely, and publicly accessible information is critical to effectively control serious public health emergencies such as the COVID-19 pandemic [1]. Unfortunately, necessary information is sometimes unavailable to the public, and some news reports are misleading or inaccurate. The absence of proper information offers fertile ground for the emergence and propagation of rumors (also called *fake news*). If rumors appear convincing and are not effectively refuted, they can create serious consequences such as poor health-related decisions and distrust of public health agencies by the public.

Over the past few decades, rumor-debunking strategies such as fact checking, corrections, and retractions (eg, deleting social media posts) have been implemented as postevent responses to counteract the impact of rumors [2-4]. The effectiveness of these strategies has not been assessed systematically; previous research focuses on strategies to mitigate public belief of the rumors [5-7] but not on the role of strategies in reducing the proportion of rumor reports and alleviating negative sentiments among the public. Partly due to lack of solid research evidence, the World Health Organization (WHO) concluded that health-related rumors were poorly managed in nearly all major public health emergency events during the 21st century [1].

During the COVID-19 pandemic, rumors have emerged and propagated in nearly every country [8]. The rapid development and widespread use of the internet, social media, and mobile phone technology facilitate the emergence and propagation of rumors, making prevention and control of rumors more challenging than they were even a decade ago. In fact, widespread fake news rumors, such as “COVID-19 is just a version of seasonal influenza” and “Hydroxychloroquine is an effective drug to treat COVID-19,” significantly compromised COVID-19 prevention and control efforts and influenced social stability in highly populated countries such as the United States and Brazil [9].

China began facing large waves of pandemic-related rumors early in 2020. Between February and May 2020, the Chinese government actively released multiple clarification and correction announcements to reduce the influence of those rumors [10]. No empirical research has examined the characteristics of the COVID-19–related rumors or the effectiveness of the counteractive measures taken by Chinese health authorities. Knowledge of these characteristics would be helpful, both for countries across the globe that continue to face COVID-19–related rumors and public health challenges as well as to handle rumor patterns that emerge from future public health emergencies.

This study was designed to examine the characteristics and propagation of rumors during the early months of the COVID-19 pandemic in China and to evaluate the effectiveness of health authorities’ correction announcements. We considered the following research questions: What were the contents of rumors about COVID-19 in the early months of the pandemic in China, and what was the source of those rumors? Was the release of correction announcements by health authorities effective in mitigating the impact of major rumors?

Methods

Classification of the COVID-19 Rumors

Rumors were defined as reports that disseminate false information—information that is inconsistent with existing scientific evidence. In this study, all COVID-19 rumors were confirmed to be incorrect based on current scientific evidence by health authorities. In 3 rounds of discussions, we categorized the rumors that we identified into 8 groups: (1) prevention, (2) diagnosis/treatment/assistance, (3) origin and spread of COVID-19, (4) consequences of COVID-19, (5) disease statistics, (6) return to work or back to school, (7) imported cases, and (8) all others. We arranged a trained researcher to categorize each rumor into 1 of the 8 categories. One-third of the rumors were randomly extracted for a second evaluation by 3 other independent researchers. Consistency between both sets of evaluations was excellent (κ=0.96, P<.001).

Data Sources

Data sources were derived through 4 steps. First, based on preliminary search results, we identified 20 prominent and publicly accessible web-based platforms available in China to search for COVID-19–related rumors. These platforms included 9 websites, 5 official Sina Microblog accounts, and 6 WeChat public accounts (Table S1 in Multimedia Appendix 1).

Second, we retrieved all media reports regarding 4 major rumors and classified the media reports into 3 categories: those disseminating rumors, those providing correct information, and those with ambiguous information. We conducted this classification using the ZhongQing HuaYun web-based public service platform (CYYUN), a free public database platform licensed by the Central Committee of the Communist Youth League. CYYUN automatically retrieves media reports from WeChat accounts officially certified by governmental or business entities, Microblog accounts, public forums, news websites, print media, blog accounts, videos, news apps, major overseas media sources, and other mainstream national news sources. CYYUN data are updated approximately every 5 minutes.

Third, Sina Microblog Topic was used to gather readers’ comments in response to media reports of the rumor event with the most public comments. Sina Microblog Topic is a webpage that summarizes personal microblogs with a tag (“#topics-related keywords#”), allowing readers to post personal comments below the microblogs. Comment data from Sina Microblog Topic are freely accessible in China.

Last, the number of daily confirmed COVID-19 cases at the national and provincial levels were derived from the official website of the National Health Commission of China.

Data Collection

COVID-19 Rumor Reports

Given the pattern of the COVID-19 epidemic period in China, we limited the study time period from December 1, 2019 to April 15, 2020. We used Python (version 3.7) to develop a web crawler algorithm to automatically retrieve all media reports related to COVID-19 rumors from the 20 selected web-based platforms. Duplicate and irrelevant reports were removed by manually reviewing article titles and full-text articles.

Stages of the Early COVID-19 Epidemic in China

As defined by a previous study [11], the early phase of the COVID-19 pandemic in China was divided into 6 stages: (1) an early stage without any significant interventions (December 30, 2019-January 9, 2020); (2) massive population migration before the Spring Festival but no strong interventions were implemented (January 10, 2020-January 22, 2020); (3) city lockdowns, traffic suspension, and home quarantine (January 23, 2020-February 1, 2020); (4) centralized quarantine and treatment in designated hospitals or facilities, with improved medical resources (February 2, 2020-February 16, 2020); (5) centralized quarantine and whole-community symptom survey administered concerning COVID-19 symptoms, such as fever and respiratory symptoms (February 17, 2020-March 10, 2020); and (6) a focus on preventing imported cases (March 11, 2020-April 15, 2020).

Media Reports Related to Major COVID-19 Rumors

The number of relevant media reports obtained from CYYUN was used to estimate the social influence of rumors. We selected 1 rumor that was most socially influential from each of the 6 epidemic stages based on the number of relevant media reports. We retained 4 rumors for analysis; we excluded 2 rumors that attributed false quotes to Professor Nanshan Zhong, a famous Chinese scientist. The rationale of this exclusion is that the high social status of Professor Zhong rather than (or along with) the contents of these quotes might have fueled the spread of the 2 rumors, potentially leading to bias in our analysis of the impact of the contents of rumors.

We used CYYUN to collect all media reports related to the propagation of the 4 retained rumors: Case A, the novel coronavirus can be prevented with "Shuanghuanglian," a traditional Chinese medicine; Case B, the novel coronavirus is the SARS coronavirus; Case C, medical supplies intended for assisting Hubei were detained by the local government; and Case D, asymptomatically infected persons were regarded as diagnosed COVID-19 patients with symptoms in official counts. (Note that Case D is a rumor because the WHO and all major countries do not count asymptomatically infected persons as diagnosed COVID-19 cases in their official data counts [12]).

All media reports related to the 4 major rumors were gathered and processed. Based on official statements from the government regarding each rumor, trained researchers manually divided each media report into 3 categories: (1) the report disseminated or perpetuated the rumor, (2) the report disseminated correct information to refute the rumor, or (3) the report disseminated ambiguous information that did not clearly support or refute the rumor. To assure the consistency of the classifications, we randomly selected 500 media reports for each of the 4 major rumors and asked an independent researcher to categorize them into the 3 categories. Consistency between both sets of researchers was acceptable (Case A: κ=0.87, P<.001; Case B: κ=0.87, P<.001; Case C: κ=0.90, P<.001; Case D: κ=0.87, P<.001).

Microblog Readers' Comments

We used a Python crawler algorithm to retrieve reader comments concerning Microblog articles for the most discussed rumor (Case A) on Sina Microblog Topic, "The novel coronavirus can be prevented with "Shuanghuanglian." We selected Case A for this analysis because it was sustained for a longer time period than the other rumors. It also stimulated more media reports and readers' comments compared to the other 3 cases. Using the sentiment orientation analysis application programming interface from Baidu [13], we grouped reader comments into positive (expressing agreement, support, or optimistic attitudes, eg, "the situation will surely become better"); neutral (showing neither clear support and optimism, nor disagreement and pessimism, eg, "thanks for interacting with us"); or negative (expressing disagreement or worried, pessimistic, and ironic attitudes, eg, "I feel like swearing") categories.

Data Analysis

We implemented 2 strategies to assess the effectiveness of authorities' refutation of rumors.

We compared the distribution of the 2 types of media reports (those perpetuating the rumor and those correcting the rumor) before and after the rumor was formally refuted in the media. Because there is no standard criterion to determine the launch time of a formal rumor-refuting effort, we studied the temporal distributions of the number of correct reports and the number of rumor reports per hour for all 4 cases (Figure S1 in Multimedia Appendix 1). Based on these empirical distributions, we found that the number correct reports per hour generally increased substantially in subsequent hours once it reached over 50 reports. Thus, we considered the refutation as formally launched from the first hour in which more than 50 reports refuting the rumor were posted. We considered 3 phases for our analysis: prerefutation, refuting the rumor, and postrefutation.

We examined differences in the distribution of positive, neutral, or negative emotions in comments responding to reports disseminating the rumor and in reports correcting the rumor. We focused this analysis on case A, the rumor that received the most reader comments and was sustained the longest, thus having the largest social impact among all COVID-19 rumors during the early stages of the pandemic in China. To conduct the analysis, we examined both the frequency of reader comments and the time intervals between the first and last comments from the same readers when more than 2 comments were posted.

Based on publicly accessible Microblog users' unique identity accounts, we compared the distribution of comments in response to case A from readers who posted 2 comments or more. For each user, the first and last comments during the study period were considered, and the pairs were divided into 4 groups:

Group A, both comments occurred in response to reports disseminating correct information; Group B, both comments occurred in response to reports disseminating rumors; Group C, the first comment occurred in response to a report disseminating a rumor, and the last in response to correct information; and Group D, the first comment occurred in response to a report disseminating correct information and the last in response to a rumor. This grouping allowed us to examine the potential effect of the order of reading media reports (first reading reports disseminating rumors and then reading correct reports or vice versa).

All statistical analyses were performed using the R software package (version 4.0.0). Proportions and Spearman rank correlation coefficient with 95% confidence intervals were calculated. The chi-square test was used to test the difference in the proportion of rumor reports and correct reports between prerefutation and postrefutation. All tests were 2 tailed, and $P<.05$ was considered statistically significant.

Ethics Concerns

This study was approved by the ethics committee of Xiangya School of Public Health (XYGW-2020-43). This study used open-access social media data and excluded all personal information. The ethics committee determined that this study was exempt from requiring informed consent.

Results

Characteristic of Rumors

After screening 19,683 recorded rumors on 20 websites and social media accounts, we obtained 1829 unique COVID-19–related rumors in China that appeared from December 1, 2019 to April 15, 2020 (Figure S2 in Multimedia Appendix 1).

The frequency of rumors began with a quiescent period (<6 rumors per day before January 20, 2020), but then rose rapidly to reach an initial peak on January 25, 2020 (n=75). After a second peak on February 7, 2020 (n=82), the frequency started to decrease gradually (Figure 1a). “Pneumonia,” “WeChat,” and “spread” were the most commonly occurring words, with high-frequency words varying across the 6 stages of the COVID-19 epidemic (Table S2 and Figure S3 in Multimedia Appendix 1).

Figure 1b shows the large variation in the number of rumors across different provinces during the study period. Of the 1829 rumors, 399 (21.8%) rumors involved more than 1 province, but the majority (1430 rumors) involved a single province. The largest number occurred in Hubei (n=186), followed by Zhejiang (n=137) and Guangxi (n=121). Ningxia, Tibet, Xinjiang, Qinghai, Hainan, and Taiwan each had fewer than 10 rumors.

The content of the rumors evolved greatly across the 6 stages of the COVID-19 epidemic in China (Figure 1c). Rumors related to prevention and disease statistics were most common, accounting for 72.2% (39/54), 73.3% (335/457), and 64.8% (414/639) of all rumors in stages 2, 3, and 4, respectively. The percentage of rumors involving the categories *diagnosis/treatment/assistance* ($\chi_1^2=6.352$, $P=.01$), *return to work or back to school* ($\chi_1^2=148.094$, $P<.001$), and *imported cases* ($\chi_1^2=126.04$, $P<.001$) significantly increased during stages 5 and 6.

We considered in greater detail the 4 most widespread rumor cases (case A, the novel coronavirus can be prevented with “Shuanghuanglian”; case B, the novel coronavirus is the SARS coronavirus; case C, medical supplies intended for assisting Hubei were detained by the local government; and case D, asymptomatically infected persons were regarded as diagnosed COVID-19 patients with symptoms in official counts). Most reports were from personal social media accounts for case A (33,870/53,798, 63.0%), case B (21,234/24,436, 86.9%), and case C (6411/7101, 90.3%). For case D, most reports were from websites and social media accounts of news agencies (1850/3436, 53.8%) (Figure 2). Personal social media accounts were the major source of rumor reports (case A: 7648/10,664, 71.7%; case B: 14,696/15,902, 92.4%; case C: 3911/3943, 99.2%; case D: 322/323, 99.7%) and ambiguous reports (case A: 3116/4968, 62.7%; case B: 2582/2592, 99.6%; case C: 382/383, 99.7%; case D: 156/156, 100.0%).

In addition, there was a strong correlation between the frequency of rumors and the daily number of newly confirmed COVID-19 cases at the national level from December 30, 2019 to April 15, 2020 ($\rho=0.88$, 95% CI 0.81-0.93, $P<.001$). A spatial correlation between the frequency of rumors and the cumulative number of confirmed cases up to April 15, 2020 also emerged at the provincial level ($\rho=0.83$, 95% CI 0.61-0.94, $P<.001$) (Figure S4 in Multimedia Appendix 1).

Figure 1. Number of rumors related to the COVID-19 epidemic in China from December 30, 2019 to April 15, 2020 (a. time trend; b. provincial variations; c. contents by stage).

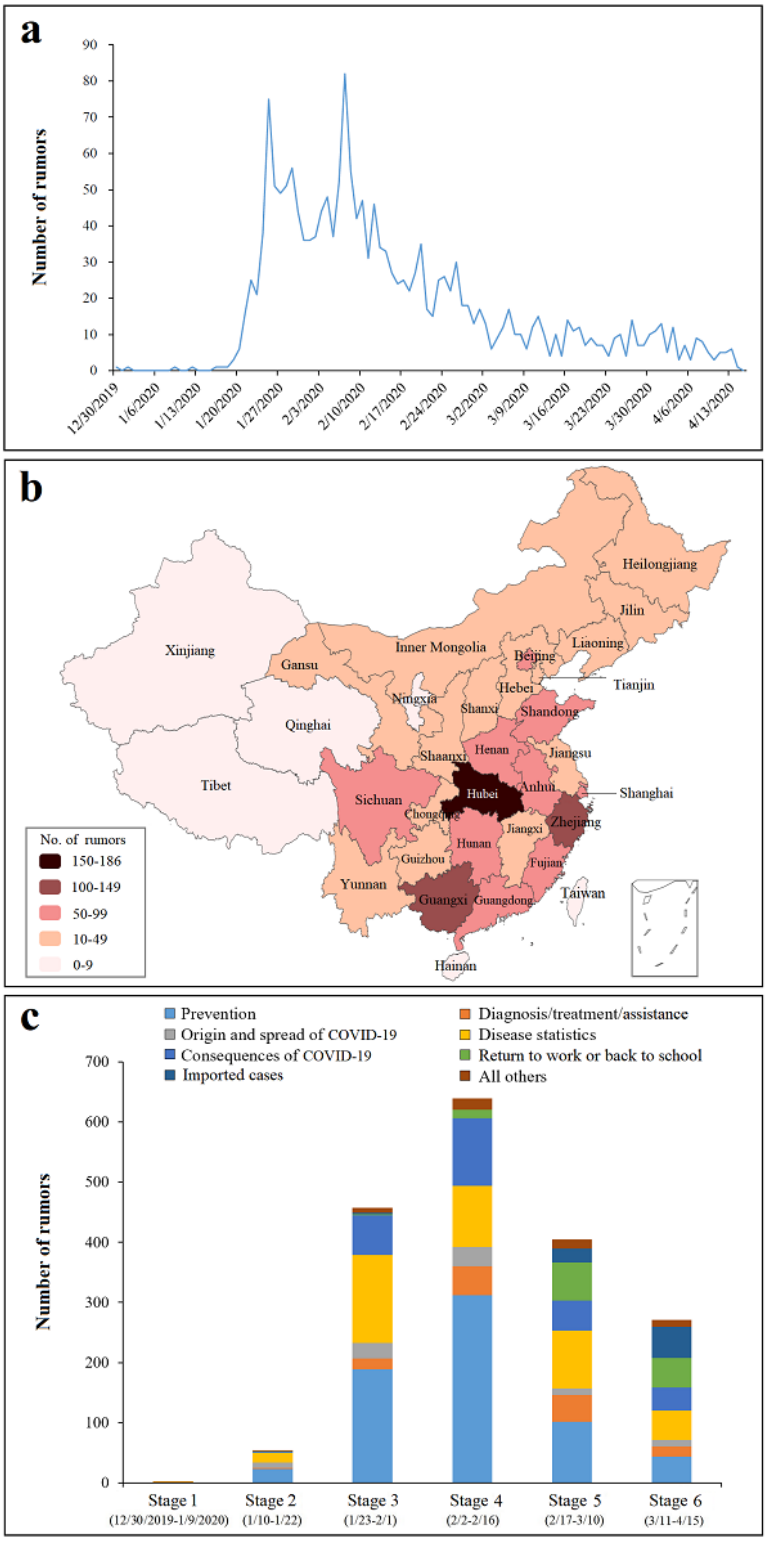

Figure 2. Source of media reports for 4 major rumors related to the COVID-19 epidemic in China.

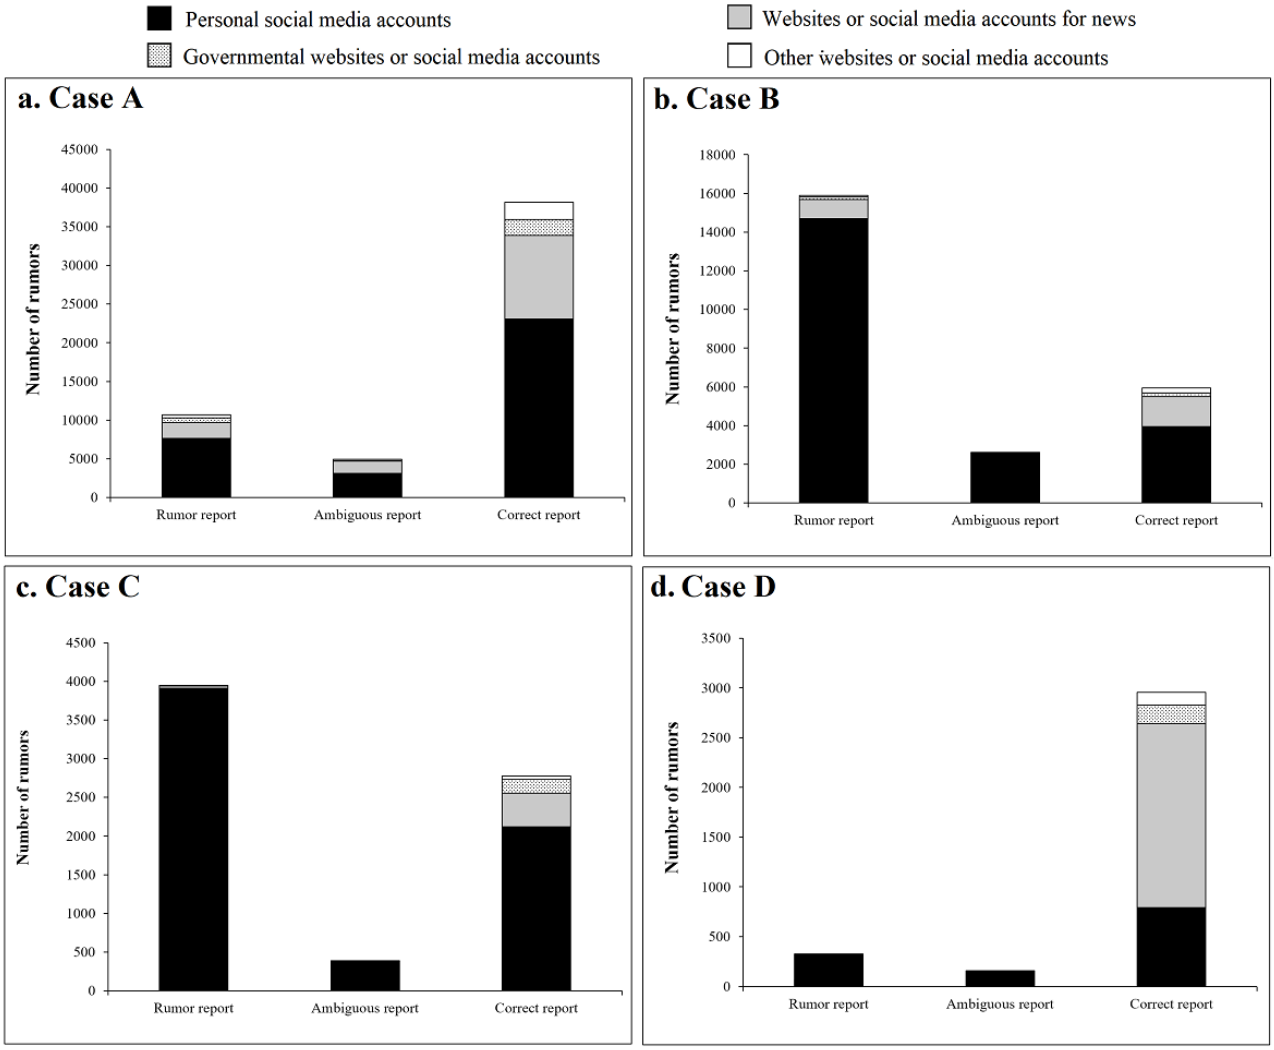


Effectiveness of Releasing Correct Information

Totals of 53,798 media reports (case A), 24,436 media reports (case B), 7101 media reports (case C), and 3436 media reports (case D) were obtained after eliminating duplicates (n=3788) and irrelevant reports (n=4036) (Figure S2b in Multimedia Appendix 1).

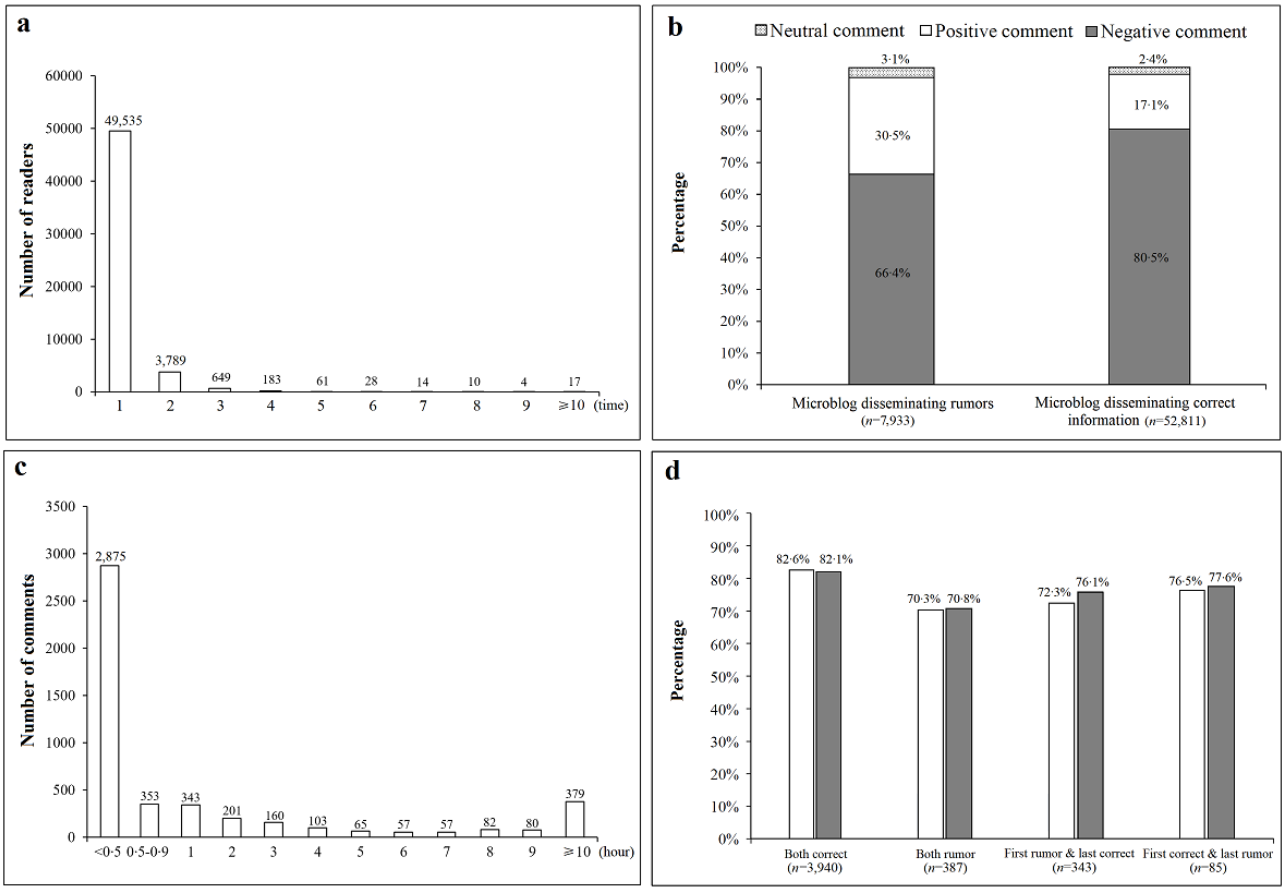
The proportion of rumor reports significantly decreased after the rumors were refuted by health authorities for case A (before: 534/666, 80.2%; after: 5685/45,657, 12.5%), case C (before: 1978/2101, 94.1%; after: 908/3796, 23.9%), and case D (before: 120/860, 14.0%; after: 192/2431, 7.9%) (P<.001) (Table 1); however, the proportion of rumor reports increased from 10.8% (50/463) to 60.5% (12,004/19,846) for case B after the official clarification with correction information was released (P<.001).

For case A (the novel coronavirus can be prevented with "Shuanghuanglian"), we identified a total of 60,744 comments posted by 54,290 microblog readers in response to 42 articles disseminating rumors and 78 articles refuting rumors and providing accurate information. Most readers posted once (49,535/54,290, 91.2%) or twice (3789/54,290, 7.0%) (Figure 3a), and most readers' comments expressed emotions with a negative connotation (eg, anger, anxiety, fear) in response to both types of microblog articles. However, the proportion of comments with negative emotions for articles disseminating correct information was significantly higher than the proportion for articles disseminating rumors (correct: 42,485/52,811, 80.5%; rumor: 5271/7933, 66.4%, χ_1^2=804.55, P<.001) (Figure 3b). Among readers who posted multiple comments, 60.5% (2875/4755) posted their first and last comments within half an hour (Figure 3c), and the proportion of negative comments posted by those readers did not change significantly when comparing their first versus last posts, no matter what type of article they read (both correct: χ_1^2=0.315, P=.58; both rumors: χ_1^2=0.025, P=.88; first rumor and last correct: χ_1^2=1.287, P=.26; first correct and last rumor: χ_1^2=0.033, P=.86) (Figure 3d).

Table 1. Media reports related to 4 most influential rumor cases before and after refuting the rumor.

Case and time period	Rumor report, n (%)	Correct report, n (%)	*P* value
Case A: The novel coronavirus can be prevented with "Shuanghuanglian"			<.001
Prerefutation	534 (80.2)	81 (12.2)	
Refuting the rumor (January 31, 11 PM to midnight)	4445 (59.5)	2079 (27.8)	
Postrefutation	5685 (12.5)	36006 (78.9)	
Case B: The novel coronavirus is the SARS coronavirus			<.001
Prerefutation	50 (10.8)	412 (89.0)	
Refuting the rumor (February 9, 9 PM to 10 PM)	3848 (93.2)	86 (2.1)	
Postrefutation	12004 (60.5)	5444 (27.4)	
Case C: Medical supplies intended for assisting Hubei were detained by the local government			<.001
Prerefutation	1978 (94.1)	3 (0.1)	
Ongoing (February 10, 11 PM to midnight)	1057 (87.8)	51 (4.2)	
Postrefutation	908 (23.9)	2721 (71.7)	
Case D: Asymptomatically infected persons were regarded as diagnosed COVID-19 patients with symptoms in official counts			<.001
Prerefutation	120 (14.0)	660 (76.7)	
Refuting the rumor (March 22, 7 AM to 8 AM)	11 (7.6)	126 (86.9)	
Postrefutation	192 (7.9)	2171 (89.3)	

Figure 3. Readers' comments in response to microblog articles for the case A rumor, "the novel coronavirus can be prevented with 'Shuanghuanglian'": (a) frequency of comments, (b) comment distribution by type of article, (c) time interval between the first and last comment for the same readers, and (d) proportion of negative comments in the first and last comments by type of article.



Discussion

Principal Findings

This study yielded 3 key findings. First, the contents and the number of rumors were strongly associated with the development of the COVID-19 epidemic in China, both temporally and geographically, and reports from personal social media accounts accounted for 71.7% (7648/10,664), 92.4% (14,696/15,902), 99.2% (3911/3943), and 99.7% (322/323) for cases A, B, C, and D, respectively, of all rumor reports. Second, releasing news to correct rumors decreased the dissemination of media articles for 3 of the 4 selected rumors (cases A, C, and D) but did not reduce news disseminations for case B. Third, the likelihood that readers posted negative comments in response to rumor reports and to reports disseminating correct information differed insignificantly (both correct reports: χ_1^2=0.315, *P*=.58; both rumors: χ_1^2=0.025, *P*=.88; first rumor and last correct report: χ_1^2=1.287, *P*=.26; first correct report and last rumor: χ_1^2=0.033, *P*=.86).

Interpretation of Findings

The findings of previous studies, regarding fluctuations in the number of rumors reported on a daily basis, the geographic variations for those reports across China [14], and major topics of the COVID-19 rumors [14,15], were generally concordant with our findings. The strong and positive correlation between reported rumors and the development of the COVID-19 epidemic likely reflects extreme tension, fear, and anxiety about the novel contagious disease among the population, especially residents of the regions most affected by the epidemic [16], such as Hubei, Zhejiang, and Guangxi. The likely reason for this was that the rapidly growing epidemic provoked emotional responses among inhabitants, leading them to scramble for any information they could find to alleviate their anxieties and fears. When the residents in those regions were unable to obtain timely official answers about major public concerns related to the COVID-19 epidemic, rumors emerged and were disseminated quickly [17]. For example, during the early stages of the COVID-19 epidemic in China, the question of how to dispose of used face masks emerged as a major public health concern. The question aroused 2031 microblog posts, but only 10 official Sina Microblog accounts released authoritative information on the issue before January 23, 2020 [18]. As a result, a total of 14 versions of misleading rumors emerged immediately on this topic, and 4740 articles disseminated improper strategies to dispose of discarded masks, such as heating them in the oven, scrubbing them with water, or cutting them into pieces [18].

This study presents a unique finding that personal social media accounts were the dominant source of rumor reports. This may reflect the combined effect of flourishing personal social media accounts [19], an inability for average citizens to detect misinformation [20], and amplification effects through (ie, an "echo chamber"—people are susceptible to peer influences when engaging in a homogeneous online cluster with others who share similar interests) [21].

Unexpectedly, we found that websites or news-based social media accounts were the second most common source of rumor reports. This may be a result of inadequate fact-checking of contents by the news industry or deliberate reports designed to attract public attention to these news media outlets [22,23]. As an example, the most widely spread rumor (Case A, the novel coronavirus can be prevented with "Shuanghuanglian," a traditional Chinese medicine used to treat the common cold) was first released by Weibo of Xinhua, an official news platform with nearly 100 million subscribers [24]. That release quickly led to a Sina Microblog topic titled "The novel coronavirus can be prevented with Shuanghuanglian," attracting 1.55 billion readings and 423,000 reader comments [25] and leading to panic buying of Shuanghuanglian.

The release of news to correct rumors was successful in reducing the spread of rumors in cases A, C, and D. This confirms that it is possible to mitigate the spread of rumors through authoritative releases of correct information in a timely manner [26]. Case B did not follow the same pattern, probably due to an unintentional slip of tongue by a government spokesperson at the 19th press conference in Hubei province on February 9, 2020 [27]. The spokesperson unintentionally and incorrectly confirmed the rumor, leading to a rapid increase in the number of rumor reports concerning Case B (from 41 to 15,767; Figure S5 in Multimedia Appendix 1) within 3 hours of the start of the press conference.

Strikingly, most reader comments in response to articles were negative, whether the articles reported rumors or correct information, and the proportions of negative comments were similar between both types of articles. These results match those of previous reports [28,29] and may reflect the fact that official correction news tends to disseminate correct information but largely overlooks any attempt to provide emotional support or empathy to affected people. Such factual presentation without empathy leads to unproductive dialogue with the emotional public, who release their negative sentiments in writing [29].

Implications

Our findings have 3 major implications. First, they underscore the importance of releasing scientifically accurate information in response to major public health concerns in a timely manner. Such releases help prevent the spread of rumors. To be effective, they require close cooperation between government officials, scientists, and the media.

In emerging health crises, such as the COVID-19 pandemic, public concerns inevitably arise that cannot always be answered immediately with accurate scientific evidence. In the absence of guidelines to satisfy public angst and curiosity for critical public health information while science progresses, basic guidance might be established by the WHO or academic experts to direct the release of available information through multiple channels, including government websites, news websites, and official and personal social media accounts. Such releases might reduce tension and anxiety among the public.

Second, the official release of correction articles tended to reduce rumor reports in China, suggesting similar effects could be expected in other countries. Success with this strategy would

require a real-time web-based monitoring system to detect rumor reports and close cooperation between government, media companies, and public health experts to release authoritative correction articles that refute rumors, with the caveat that such a strategy may not work well in countries where government and public health experts provide conflicting advice, such as in the United States for much of the situation with COVID-19 in 2020 [30].

Last, our findings suggest rigorous public health research is needed to generate solutions to unsolved questions, including how to effectively detect rumor reports as early as possible, which solutions might be best for releasing and disseminating correction articles, and how to effectively alleviate negative sentiments held by the public. In addition, the effectiveness of alternative postrumor approaches such as fact-checking and retractions (eg, deleting posts) should be evaluated.

Limitations

This study has limitations. First, our data collection approach likely underestimated the number of COVID-19 rumors, by missing some comments in response to Sina Microblog topics, since some were likely quickly detected and deleted by platform providers as part of efforts to control rumors [31]. Second, the lack of detailed data limited our ability to explore why most reader comments in response to media articles that disseminated correct information were negative and how to alleviate such negative sentiments to promote public support on fighting the COVID-19 pandemic. Further research is needed to address this critical public health matter. Third, we could not determine if any rumors we studied were published artificially by robots. As readers generally do not know who posted the reports, the role of robots is unlikely to influence our findings substantially. However, future studies may collect data on readers' responses to rumors spread by robots versus those spread by humans to quantify potential differences in their social impact and to develop specific interventions to deal with them separately.

Conclusion

The number of rumors about COVID-19 fluctuated greatly in China during the early months of the pandemic. The frequency of rumors was highly correlated with the magnitude of the epidemic. Rumor-disseminating reports emerged primarily from personal social media accounts, and releasing rumor-correcting news substantially reduced the spread of rumor reports. Reader comments in response to media articles disseminating rumors and to articles disseminating correct information expressed nearly the same percentage of negative emotions.

Individual governments and relevant international organizations such as the WHO should take immediate actions to develop regulations or guidelines to help social media companies and users of social media prepare and release reports properly and efficiently to prevent and control rumors, especially when scientific knowledge is limited during a health crisis such as the COVID-19 pandemic. In the meantime, our results suggest refutation reports were generally successful in reducing spread of rumors, and governments should encourage timely release of correct information to minimize the impact of rumors.

Acknowledgments

This work was funded by the Major Program of the National Social Science Foundation of China (20&ZD120). The sponsors had no role in the design and conduct of the study; analysis, report, or interpretation of the data; preparation, review, or approval of the manuscript; or the decision to submit the manuscript for publication.

Authors' Contributions

GH conceptualized and designed the study, supervised the implementation of this study, and finalized the manuscript. JL and MZ collected and verified the underlying data. PC and JL carried out data analyses. PN and PC developed the manuscript. JL, PL, ML, and ZZ contributed to finding interpretation and revised the manuscript. Abstract

Background: Examining public perception of tobacco products is critical for effective tobacco policy making and public education outreach. While the link between traditional tobacco products and lung cancer is well established, it is not known how the public perceives the association between electronic cigarettes (e-cigarettes) and lung cancer. In addition, it is unclear how members of the public interact with official messages during cancer campaigns on tobacco consumption and lung cancer.

Objective: In this study, we aimed to analyze e-cigarette and smoking tweets in the context of lung cancer during National Cancer Prevention Month in 2018 and examine how e-cigarette and traditional tobacco product discussions relate to implementation of tobacco control policies across different states in the United States.

Methods: We mined tweets that contained the term “lung cancer” on Twitter from February to March 2018. The data set contained 13,946 publicly available tweets that occurred during National Cancer Prevention Month (February 2018), and 10,153 tweets that occurred during March 2018. E-cigarette–related and smoking-related tweets were retrieved, using topic modeling and geospatial analysis.

Results: Debates on harmfulness (454/915, 49.7%), personal experiences (316/915, 34.5%), and e-cigarette risks (145/915, 15.8%) were the major themes of e-cigarette tweets related to lung cancer. Policy discussions (2251/3870, 58.1%), smoking risks (843/3870, 21.8%), and personal experiences (776/3870, 20.1%) were the major themes of smoking tweets related to lung cancer. Geospatial analysis showed that discussion on e-cigarette risks was positively correlated with the number of state-level smoke-free policies enacted for e-cigarettes. In particular, the number of indoor and on campus smoke-free policies was related to the number of tweets on e-cigarette risks (smoke-free indoor, $r49=0.33$, $P=.02$; smoke-free campus, $r49=0.32$, $P=.02$). The total number of e-cigarette policies was also positively related to the number of tweets on e-cigarette risks ($r49=0.32$, $P=.02$). In contrast, the number of smoking policies was not significantly associated with any of the smoking themes in the lung cancer discourse ($P>.13$).

Conclusions: Though people recognized the importance of traditional tobacco control policies in reducing lung cancer incidences, their views on e-cigarette risks were divided, and discussions on the importance of e-cigarette policy control were missing from public discourse. Findings suggest the need for health organizations to continuously engage the public in discussions on the potential health risks of e-cigarettes and raise awareness of the insidious lobbying efforts from the tobacco industry.

Introduction

Background

Tobacco control has been identified as a global public health priority by the World Health Organization [1]. Tobacco use is one of the leading causes of preventable deaths globally, and it is responsible for 7 million deaths worldwide [2]. In the United States, the Centers for Disease Control and Prevention (CDC) reported that tobacco use accounted for 1 in 5 deaths, leading to more than 480,000 deaths annually [3]. As such, for tobacco control, understanding public perception of tobacco products and their severe health risks, such as lung cancer, is essential to inform educational campaigns and tobacco control policies.

Particularly, health education campaigns and control policies should pay attention to tobacco consumption trends. In terms of traditional tobacco use, the CDC reported that smoking among adults had declined from 20.9% in 2005 to 13.7% in 2018, and the proportion of smokers who reported quitting had increased [4]. But, the popularity of emerging tobacco products such as electronic cigarettes (e-cigarettes) has been rising steadily since 2010. E-cigarettes are electronic devices that are used to deliver nicotine and other chemicals to users through inhalable aerosols. The US Surgeon General declared that e-cigarette use was an epidemic among youth in 2018, given that 21% of high school seniors in the United States reported using e-cigarettes in the preceding 30 days in the same year [5]. In particular, Juul captured and dominated 73% of the e-cigarette market through its product promotion featuring youth culture and lifestyle on different social media platforms [6].

The overwhelming popularity of e-cigarettes may be due to conflicting messages in the public. Some argue that e-cigarettes could help with smoking cessation as they appear to pose fewer health risks than traditional cigarettes [7-9]. Meanwhile, others cautioned against e-cigarette consumption as they contain nicotine, a highly addictive drug, that can lead to the use of other tobacco products [10-12]. Even though there is no established connection between e-cigarette use and severe diseases such as lung cancer, there is evidence of lung injuries associated with its use [13-15]. Notably, the CDC declared an outbreak of lung injuries associated with e-cigarette use in 2019 [16].

Related Work

Survey studies have investigated the perceived associations of smoking traditional tobacco products and e-cigarettes with health diseases such as lung cancer. Smoking is recognized as a major risk factor for lung cancer by the public [17]. In contrast, the public may not view e-cigarettes as a likely cause of lung cancer [18,19] but, instead, may view e-cigarettes as a safe alternative to combustible cigarettes [20,21]. There are very few studies that have compared public perceptions of both smoking and vaping in relation to severe health consequences using social media data. Currently, a growing body of social media studies [22,23] on e-cigarettes and smoking show that e-cigarettes are often presented as a positive and healthier alternative to smoking, despite controversies surrounding their effectiveness in smoking cessation and the likelihood of initiating adolescents to consuming other tobacco products. Nevertheless, there is limited evidence about the extent that the public perceives lung cancer to be a health consequence of both smoking and vaping [24-26]. Such comparisons are critical as they can highlight contextual, psychological, and behavioral factors specific to the reasons for which individuals consume different tobacco products. This knowledge is valuable as it can inform strategic messaging and educational programs to facilitate behavioral changes in reducing tobacco consumption [27].

Furthermore, to the best of our knowledge, none of the existing social media studies has investigated spatial patterns of tobacco conversations on social media in relation to implementation of health policies. For example, it has been found that the number of obesity-related policies in certain geographic regions were associated with an increase in obesity prevention discussions on Twitter within the same area [28]. This likely suggests that the number of health policies, or the policy environment in general, have a reciprocal relationship with consumers' health awareness. Putting this in the context of tobacco control, the number of state-level tobacco policies in the United States may be a reflection of the risk perception of tobacco products and e-cigarettes, and this heightened awareness of risk on a societal level may be impetus for policy makers to enact more laws to rein in tobacco consumption. Therefore, it is crucial to study how tobacco policies of the various states are associated with public perceptions and discussions of health effects of tobacco products on social media.

Tobacco Discourse During US National Cancer Prevention Month

While the majority of social media studies largely examine public discourse of e-cigarette and smoking in general, this study examined tobacco discourse in the context of US National Cancer Prevention Month, which is an annual campaign led by the American Institute for Cancer Research in the month of February that aims to foster cancer knowledge and promote cancer prevention practices [29]. Particularly, lung cancer, which is a deadly disease that is caused by tobacco consumption [30], is one of prominent cancer topics during the campaign. Past research has shown that month-long cancer campaigns, such as National Cancer Prevention Month, are the key to increasing awareness of cancer and its associated risk factors [31]. As such, National Cancer Prevention Month offer opportunities to examine e-cigarette and smoking discourse related to lung cancer.

Past research has shown that public discourse during cancer campaigns may be different from that during other months. Cancer campaigns raise public awareness by promoting cancer conversations about risk factors and preventions on Twitter [32]. Also, public discourse during cancer campaigns is often driven by health organizations, advocacy groups, and influential personalities such as celebrities [32,33]. The agenda of cancer campaigns typically involves disseminating cancer education messages, advocating prevention engagement, and sharing affective stories of survivors [33,34]. In addition to these messages, Twitter users could respond and selectively follow and express their own opinions on lung cancer. As such, public discourse during campaigns would likely reflect how the public

interact with official messages on tobacco consumption and lung cancer. This knowledge can be important for public health officials in identifying gaps in health education.

Objective

First, we aimed to examine if National Cancer Prevention Month plays a role in promoting conversations on the link of e-cigarettes and smoking with lung cancer. Second, we aimed to examine and compare public discourse in the United States on smoking and e-cigarette in the context of lung cancer on Twitter during National Cancer Prevention Month. Third, we aimed to examine if there were spatial patterns of smoking and e-cigarette's themes in the United States during National Cancer Prevention Month. Fourth, we explored the relationship between e-cigarette and smoking discussions on Twitter during National Cancer Prevention Month with implementation of tobacco control policies. As such, we put forth 4 research questions: (1) Does national cancer prevention month promote e-cigarette and smoking conversation related to lung cancer? (2) What are the key themes in e-cigarette and smoking tweets within the broader context of lung cancer discussion during National Cancer Prevention Month? (3) Are there geospatial differences in how e-cigarette and smoking tweets were distributed across the United States during National Cancer Prevention Month? (4) What is the relationship between the number of tobacco control policies in states and themes of e-cigarette and smoking tweets?

Methods

Data Collection

Data were retrieved from an existing data set of US English-based lung cancer tweets that contained the term "lung cancer" purchased from Twitter. A list of 28 keywords, such as "e-cigarette," "vape," and "juul" [35,36], and another list of 21 keywords, such as "cigarette" and "smoking" [37], were developed and used to extract e-cigarette and smoking tweets from the data set, respectively (Table 1). Tweets that contained both sets of keywords were excluded from further analysis to obtain a proper comparison.

Table 1. Search keywords for data collection.

Topic	Keywords
E-cigarette	electronic cigarette; vap*; e-cig*; ecig*; e cig; e-pen; epen; e pen; e-juice; ejuice; e juice; e-liquid; eliquid; e liquid; esmoke; e-smoke; e smoke; e-hookah; ehookah; e hookah; e-pipe; epipe; e pipe; atomizer; juul; njoy; v2 cig; joye510
Smoking	cig*; tobacco; waterpipe; water pipe; hooka; smok*; chew; nicotine; shisha; sheesha; bidi; beedi; kretek; narghile; argileh; cheroot; snuff; snus; betel; gutkha; toombak

Data Processing and Analysis

R statistical software (The R Project) was used for textual analyses. Data were preprocessed and cleaned before advanced textual analysis. Texts were formatted to lower case. Different forms of phrases that had the same meaning were transformed into a common format to facilitate future text processing, such that "e cig," "e-cig," "ecig," and "electronic cigarette" were reformatted into "ecigarette." Common English stop words, such as "the" and "of," special characters, and punctuations were removed. The remaining texts were tokenized and lemmatized to further avoid inflected words. The word "lung cancer" was also removed from the analysis.

Topic Modeling

Topic modeling, using latent Dirichlet allocation, was employed to understand the differences between themes of e-cigarette and smoking in the context of lung cancer discourse. Latent Dirichlet allocation is a popular and widely used algorithm for topic modeling, by which documents are modeled as mixtures over topics and a topic is characterized as a distribution of words [38]. R software (topicmodels package [39]) was used.

The latent Dirichlet allocation algorithm requires a predefined number, *k*, of topics, which we determined with the perplexity and log-likelihood indices. Both indices have been conventionally used to evaluate the model [38,40]. A lower perplexity score and a higher log-likelihood score indicate better generalization performance. We trained topic models from k=2 to k=20. To maximize the diversity of discussion while at the same time minimize topic overlaps, we selected the k model when the $k+1$ model did not improve [27,38]. After the topics were generated, we named each topic by examining keywords and posts that were representative of those topics. Topics deemed to have similar themes were combined to facilitate discussions.

To evaluate the prevalence of topics, we used methods described in [27] to determine the topic of each tweet. The output of topic modeling included estimates of the proportion of each topic present in each tweet. Based on this output, we assigned each tweet the topic that had the highest predicted proportion. For example, the tweet "February 7, 2018. The day everyone who juuls simultaneously got lung cancer" was estimated to be 1.1% similar to other tweets under the topic *affective reasoning*, 1.1% similar to other tweets under the topic *personal experiences*, 95.6% similar to other tweets under the topic *sarcasm*, 1.1% similar to other tweets under the topic *cognitive reasoning*, and 1.1% similar to other tweets under the topic *e-cigarette risk* and was, therefore, classified under the topic *sarcasm*.

We compared the temporal distribution of e-cigarette and smoking tweets using chi-square analysis.

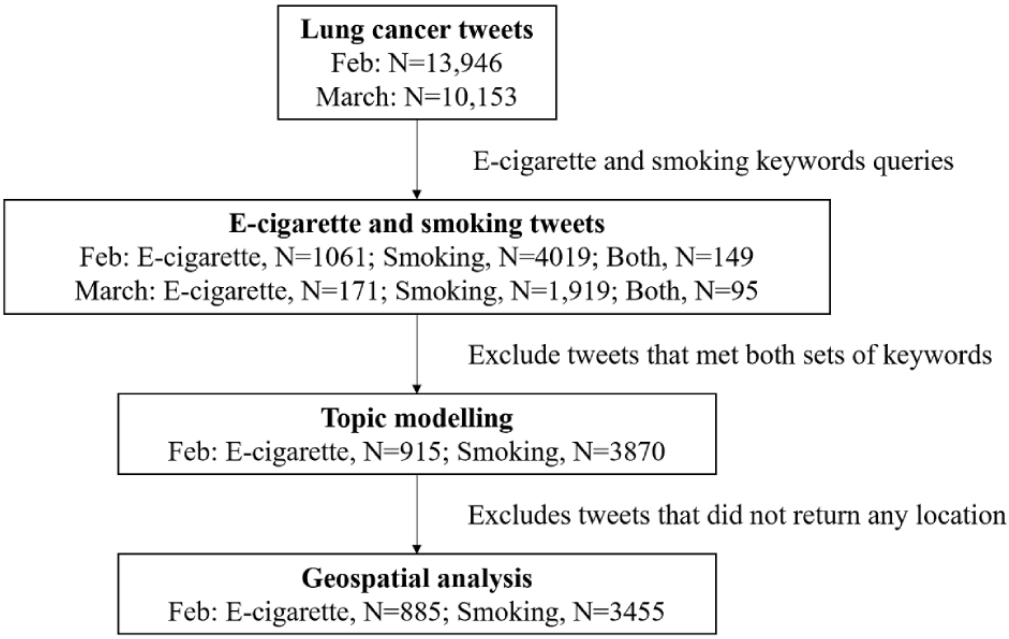
Geospatial Analysis

The geolocation of a tweet was determined by the self-reported location in the profile of the relevant Twitter user. We imported the location strings into the Google Maps geocoordinates application programming interface (API) to obtain the geocoordinates and the corresponding states in the United States. Then, we manually checked to ensure the state information is correct for each tweet. Tweets that did not have a user-reported location or whose reported location string did not return any results were excluded from the geospatial analysis. To further

understand the spatial distribution of themes, ratio values were calculated for each state by dividing the number of tweets in each theme by the total number of tweets in each state. We plotted the ratio values by state to visualize the spatial distribution patterns.

To further understand how state policies might affect twitter discussions of e-cigarette and smoking, we compared the number of tweets with the number of state policies (existing, introduced, or recently enacted in the first quarter of 2018) related to e-cigarettes and smoking. State policies were obtained from the tobacco use data portal from the US CDC [41]. For e-cigarettes, the data included policies related to the sale of e-cigarettes to youth, retail licenses to sell e-cigarette, smoke-free indoor, smoke-free on campus, taxes on e-cigarette products, and preemption. For smoking, the data included all policies similar to those for e-cigarettes and additional policies on fire safety. We conducted bivariate correlation analysis (Pearson correlation) of the total number of tweets and the total number of state policies, as well as between the themes of tweets and types of tobacco control policies.

Figure 1. Study flowchart.



Results

Temporal Distribution of E-cigarette and Smoking Tweets

The data set had 13,946 publicly available tweets obtained during National Cancer Prevention Month (ie, February) and 10,153 tweets obtained during March in 2018 in the United States. The keyword queries returned 1061 e-cigarette tweets and 4019 smoking tweets during National Cancer Prevention Month, and 171 e-cigarette tweets and 1919 smoking tweets during March (Figure 1). Of these, 149 tweets during National Cancer Prevention Month and 95 tweets during March contained both sets of keywords and were removed. This yielded 6.56% (915/13,946) e-cigarette tweets and 27.7% (3870/13,946) general smoking tweets made by 839 and 3501 unique users during National Cancer Prevention Month, and 0.75% (76/10,153) e-cigarette tweets and 18.0% (1824/10,153) general smoking tweets made by 57 and 1643 unique users during March.

There was a significant difference between the temporal distributions for e-cigarette and smoking tweets (χ^2=256.85, P<.001). This suggests that National Cancer Prevention Month did promote lung cancer discussion associated with e-cigarette and smoking.

E-cigarette and Smoking Tweets Themes

During National Cancer Prevention Month, 3 major e-cigarette themes—comprising 5 topics—emerged (Table 2). The topics *affective reasoning*, *cognitive reasoning*, and *sarcasm* were categorized under the overarching theme *e-cigarette debate*. First, Twitter users made the link between e-cigarettes and lung cancer based on emotional evaluation of their experiences or anecdotal stories they have heard. Second, there were those who discussed and cognitively processed e-cigarette information presented to them. For instance, one of the tweets highlighted that lung cancer could take years to develop and simply "juuling" for a short period may not be enough to develop lung cancer. Third, some of the Twitter users expressed sarcasm when discussing e-cigarettes, pushing back on the idea of "juuling" and lung cancer. These 3 topics accounted for half of all tweets (454/915, 49.7%). The second major theme was *e-cigarette risks* (145/915, 15.8%), where many tweets discussed scientific evidence on the risks of e-cigarette on lung diseases. The third major theme was *personal experience*s, which constituted approximately one-third of the tweets (316/915, 34.5%). Many tweets in this category encouraged others to stop vaping, with users citing stories they had heard about someone who contracted lung cancer by consuming e-cigarettes.

Table 2. E-cigarette themes from tweets (based on latent Dirichlet allocation algorithm).

Theme	Words	Examples	Tweets (n= 915), n (%)
E-cigarette debates			454 (49.7)
Affective reasoning	Juul, hit, kid, people, rumor, cause, shit, really, report, untrue	Drop your juuls like deadass. Have heard of three people my age who have been diagnosed with lung cancer from juuls. Feel like we all saw this coming	158 (17.3)
Cognitive reasoning	Juul, year, cause, cancer, develop, know, take, use, lung, say	When people think that juuls give you lung cancer but lung cancer takes years to develop	127 (13.9)
Sarcasm	Juul, everyone, day, February, simultaneously, friend, today, people, college, think	February 7, 2018. The day everyone who juuls simultaneously got lung cancer.	169 (18.5)
Personal experiences	Friend, cousin, stop, girl, good, sister, neighbor, immediately, son, sorority	STOP JUULING IMMEDIATELY, My best friends neighbors girl friend's sorority sister's cousin's step son got lung cancer from a single hit of juul. Drop these cancer sticks.	316 (34.5)
E-cigarette risks	Juul, link, lung, kid, disease, ecigarette, severe, flavoring, hit, addict	ecigarette Flavorings linked to Severe LUNG disease https://t.co/2VhStSkI0s #lungdisease #lungcancer #ecigarettes #cancer #ecigaretteflavoring #severlungdisease #howbadareecigarettes	145 (15.8)

Unlike themes expressed in e-cigarette tweets, which showed that users were divided over the association of e-cigarettes with lung cancer, those expressed in smoking tweets (Table 3) showed that users were largely unanimous in perceiving the link between smoking and lung cancer. More than half of tweets (2251/3870, 58.1%) were classified under the theme *policy discussion*, which equated the importance of tobacco control policies with that of gun control policies. Furthermore, more than 20% of tweets (843/3870) focused on the theme *smoking risks*—tweets promoted smoking cessation by mentioning scientific facts of smoking and its relation to lung cancer. Another major theme was *personal experiences*, with 20% of the tweets (776/3870) having stories of how users or their families suffered lung cancer because of smoking.

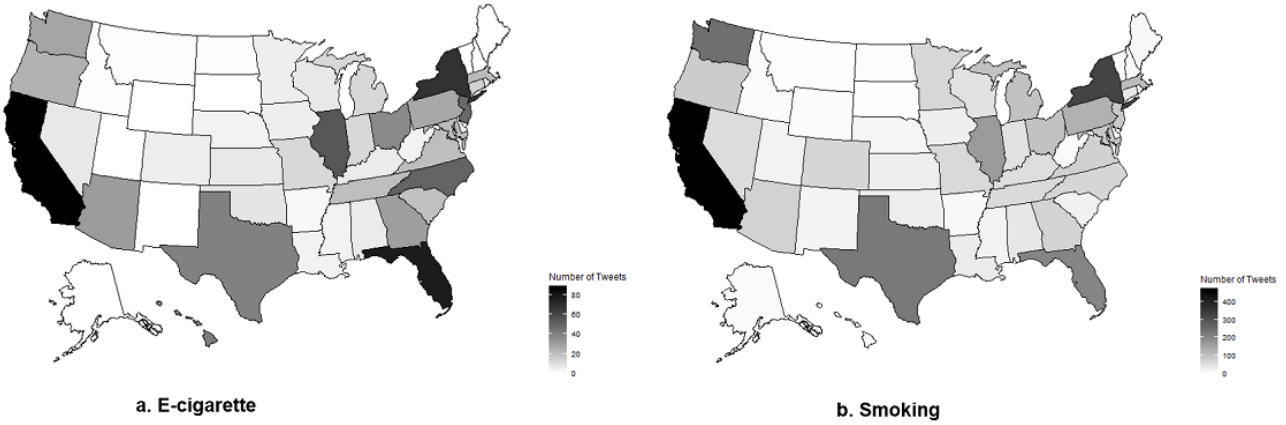
Table 3. Smoking themes (based on latent Dirichlet allocation) from tweets.

Theme	Words	Examples	Tweets (n= 3870), n (%)
Policy discussion			2251 (58.1)
Tobacco lobbying	Tobacco, kid, one, lose, prevent, explain, love, lobbyist, invite, this	This is like inviting tobacco lobbyists to explain to kids who have lost loved ones to lung cancer how we can prevent smoking deaths. Lobbyists don't deserve a seat at this table.	1831 (47.3)
Smoking control policy	Smoker, cigarette, gun, smoke, cause, blame, tobacco, gum, chew, death	Higher prices / taxes on cigarettes=less deaths due to lung cancer. Seat belts / stricter regulations on vehicle safety=less auto deaths	420 (10.8)
Smoking risks	Smoke, cancer, smoker, lung, non, die, people, risk, quit, cigarette	433 Americans die daily from #lungcancer. The majority of people living with lung cancer r nonsmokers or have quit smoking. Anyone, smoker or nonsmoker, can get lung cancer. While smoking greatly increases the risk of #lungcancer , NO ONE DESERVES CANCER. @theNCI #LCSM https://t.co/9CtilnJLzm	843 (21.8)
Personal experiences	Smoke, get, cigarette, people, die, tobacco, cause, someone, kill, make	Great! My big brother was smoking for the last fifty years Lung cancer finally killed him. Small pain under the arm one sunny morning. Two years later a 3cm tumor killed him.	776 (20.1)

Spatial Distributions of E-cigarette and Smoking Tweets and Themes

The geospatial analysis included 96.7% (885/915) of the e-cigarette tweets and 89.3% (3455/3870) of the smoking tweets during National Cancer Prevention Month. Overall, discussions of e-cigarettes and smoking in relation to lung cancer occurred mostly in the coastal areas and the eastern part of the country (Figure 2). California, New York, Florida, Texas, and Illinois had the most tweets about e-cigarettes and smoking. We focused our analysis on states that had more than 20 tweets in order to draw meaningful distribution patterns (Figures S1 and S2 in Multimedia Appendix 1).

Figure 2. The spatial distribution of e-cigarette and smoking tweets mentioning lung cancer during US national cancer prevention month (February 2018).



a. E-cigarette

b. Smoking

For e-cigarette tweets, California, Arizona, Pennsylvania, Illinois, and Virginia had more tweets debating e-cigarettes than tweets containing the other two themes. Oregon, Texas, Tennessee, and North Carolina had more tweets asking people to stop vaping based on personal stories. Hawaii and the Washington state had more tweets on scientific evidence showing the link between e-cigarettes and lung diseases.

For smoking tweets, most states predominantly had tweets about policy discussions regarding smoke control and how tobacco control policies were important to reign in tobacco companies, equivalent to how gun control policies would restrict gun lobbyists. Nevada and Kentucky had more tweets about the scientific evidence of smoking risks than those about the other two themes.

Association With State-Level Tobacco Control Policies

The number of tweets under the theme *e-cigarette risks* was positively associated with the number of both indoor arena and on campus smoke-free policies (smoke-free indoor: r_{49}=0.33, *P*=.02; smoke-free campus: r_{49}=.32, *P*=.02). Likewise, the number of tweets under the theme *e-cigarette risks* was positively associated with the total number of e-cigarette policies, r_{49}=.32, *P*=.02). There were no statistically significant associations between the 3 smoking themes and the number of smoking policies in the context of lung cancer (*P*>.13) (Tables S1 and S2 in Multimedia Appendix 2).

Discussion

Principal Findings

We examined the prevailing topics and distributions of discussions in Twitter about e-cigarettes and traditional tobacco consumption during the National Cancer Prevention Month in 2018 within the broader context of lung cancer to offer key insights on how the public perceives health risks of both e-cigarettes and smoking and potentially help public health organizations to be more strategic in their messaging and tobacco control efforts by targeting different tobacco products.

First, the findings of temporal distributions of e-cigarette and smoking tweets suggest that National Cancer Prevention Month promoted both e-cigarette and smoking conversations related to lung cancer. What we found notable was that National Cancer Prevention Month promoted e-cigarette conversations more than smoking conversations in the context of lung cancer. Without the cancer campaigns, lung cancer discourse on Twitter were rarely about e-cigarettes (76/10,153, 0.75%) and mostly revolved around the harms of smoking (1824/10,153, 18.0%). This is likely for a few reasons. In February 2018, the American Cancer Society [42] first released an official statement that discouraged youths or young adults from using any tobacco products including e-cigarettes. As such, it might have generated additional attention to the harms of e-cigarettes in relation to lung cancer during National Cancer Prevention Month. Second, 2018 National Youth Tobacco Survey data raised concerns about the vaping epidemic by showing an alarming surge in e-cigarette use among youths from 2017 to 2018; there was a 78% increase in e-cigarette use among high school students and a 48% increase among middle school students [43]. In addition, the nature of National Cancer Prevention Month itself, as a cancer awareness campaign, did indeed promote public debate and concerns about e-cigarettes on Twitter as demonstrated by our data.

Second, the findings of our thematic analysis suggest that Twitter users were aware of the risks of lung cancer from smoking but were split over the potential health effects of vaping. While some of the Twitter users evaluated the link between e-cigarettes and lung cancer based on personal experiences or anecdotal stories they have heard, others processed e-cigarette information in a more cerebral manner and were convinced of the health risks of e-cigarettes. This split in attitude toward e-cigarettes may be the result of mixed communication messaging from public health organizations. For instance, while the CDC has acknowledged the risks of e-cigarettes, particularly for young people due to the presence of nicotine, the long-term health effects of e-cigarettes have been debated [44]. And the National Academies of Sciences, Engineering, and Medicine [10] released a report concluding that e-cigarette use could not be strictly categorized as harmful or beneficial because it would require more long-term studies on the health effects of vaping.

Another significant finding was that themes of political lobbying and policy making were absent from e-cigarette tweets, but not from those about traditional tobacco consumption, during the

cancer campaign. When discussing smoking, Twitter users were mindful of the political lobbying by tobacco industries (and equated it to that of gun lobbyists), but this particular theme was missing from e-cigarette tweets. This is crucial, as it suggests that the political lobbying efforts by e-cigarette companies may not be as visible or prominent as those of the traditional tobacco industry. This is a cause for concern. After all, the tobacco industry is very much involved in the e-cigarette industry, as shown by the acquisition of Juul by Altria (formerly known as Philip Morris) for US $12.8 billion in 2018 [45]. Moreover, in recent years, e-cigarette companies have increased efforts in boosting scientific legitimacy in the context of health effects from consumption of their vaping products. For instance, Juul established the JLI Science lab, to fund scientific research on the effects of vaping products—a move that resembled the tobacco industries' use of research for political lobbying efforts in the 1980s [46]. In terms of policy actions, public debate on the need for tighter regulations over e-cigarettes is critical. Research has shown that supply-side restrictions—such as limiting tobacco retail outlet density—are effective in reducing tobacco consumption [47]. If there are any indications that the current ban on flavored e-cigarettes by the United States and other countries has an effect on the tobacco industry, Altria will revise terms of investments in Juul [48].

Third, this study demonstrated geospatial differences in e-cigarette and smoking discussions on Twitter during National Cancer Prevention Month. In terms of discussing e-cigarette risks, results showed that only 2 states—Hawaii and Washington—had more discussions than those of the others. In the state of Washington, 30% of 12th grade students used e-cigarettes [49], compared to the use of other tobacco products such as smokeless tobacco (4%) or cigars (7%). In the state of Hawaii, high school teenagers vaped twice as much as the national average [50]. To curb the vaping epidemic, Hawaii was one of the first states to raise the legal age of sales for tobacco from 18 years to 21 years, in an effort to prevent young people from nicotine addiction and the harms of tobacco use [51].

There was a positive correlation between discussion of e-cigarette risks and the number of smoke-free policies at the state level. While the findings cannot be used to make any causal claims, it is worth nothing that there may be a reciprocal relationship between public awareness of e-cigarette risks and the passing of smoke-free policies. In other words, when the public becomes aware of the risks of e-cigarettes, they may encourage local representatives to push for more smoke-free policies. At the same time, the passing of smoke-free policies may further increase awareness of e-cigarette risks in the general public.

Though discussion of tobacco risks and the number of smoke-free policies were not correlated, as discussed, people still mentioned the importance of smoking control policies in their tweets. The data suggest that policy engagement and public awareness and discussion of tobacco risks are symbiotic. When the risk awareness of a tobacco product is low, especially for emerging tobacco products such as e-cigarettes, public policy engagement motivated by the community leaders or public health organizations may heighten risk awareness. Once the public are adequately educated on the health risks of a tobacco product (eg, combustible cigarettes), this risk awareness may, in turn, fuel discussions on the need for stringent tobacco control policies, as well as strategically address tactics of political lobbying and messaging by the tobacco industry. In other words, the findings of our study suggest that public health organizations should focus on both improving risk awareness of tobacco products, as well as engaging and educating the public on the importance of tobacco control policies, because these strategies complement and reinforce one another.

We believe that our findings will be useful to help health communication scholars understand public perception and attitudes toward e-cigarettes and smoking. Future studies should (1) test potential reciprocal relationship between policy engagement and risk awareness of tobacco products; (2) investigate the underlying mechanisms, specifically examine how National Cancer Prevention Month or other cancer awareness months could promote e-cigarette discussions with randomized controlled trials, and identify the best strategies in educating the public about the harms of vaping; and (3) replicate our study by examining how cancer awareness months drive conversations about other cancers (eg, breast cancer, prostate cancer) compared with other noncancer awareness months and how various health policies (eg, health insurance) across different states are associated with cancer discussion.

Limitations

First, while social media sources, such as Twitter, can be used to gauge public opinion and sentiments toward smoking and e-cigarette, we are mindful that they may not be representative, and as such, there are constraints on the generalizability of the results. For example, our data came from publicly available posts, and thus, we were not able to capture themes and sentiments toward smoking and e-cigarettes in private posts. Also, because not all users reported their locations in their profiles, there may be potential selection biases in the geospatial analysis. In addition, we are cognizant that there potentially could be a spill-over effect because our data were collected from consecutive months in February and March. However, we are confident that this was not a major issue of concern given that the number of e-cigarette tweets in February (n=1061) during National Cancer Prevention Month was much greater than the number of e-cigarette tweets in March (n=171). Finally, we excluded tweets with both sets of keywords that might introduce bias and ran the same analyses; we found that the results did not substantially differ; therefore, we are confident that our results are robust.

Conclusion

The public is aware of smoking and lung cancer risks, but people were generally divided over the risks of e-cigarettes in relation to lung cancer. Public health organizations should invest in strategic messaging efforts over social media to address any misinformation about e-cigarettes because there is a reciprocal relationship between public awareness and discussion on tobacco products on social media and the implementation of tobacco control policies.

Abstract

Background: There is growing evidence of the need to consider cultural factors in the design and implementation of digital health interventions. However, there is still inadequate knowledge pertaining to the aspects of the Saudi Arabian culture that need to be considered in the design and implementation of digital health programs, especially in the context of home health care services for patients who are chronically and terminally ill.

Objective: This study aims to explore the specific cultural factors related to patients and their caregivers from the perspective of physicians, nurses, and trainers that have influenced the pilot implementation of Remotely Accessible Healthcare At Home, a connected health program in the Home Health Care department at King Saud University Medical City, Riyadh, Saudi Arabia.

Methods: A qualitative study design was adopted to conduct a focus group discussion in July 2019 using a semistructured interview guide with 3 female and 4 male participants working as nurses, family physicians, and information technologists. Qualitative data obtained were analyzed using a thematic framework analysis.

Results: A total of 2 categories emerged from the focus group discussion that influenced the experiences of digital health program intervention: first, culture-related factors including language and communication, cultural views on using cameras during consultation, nonadherence to web-based consultations, and family role and commitment and second, caregiver characteristics in telemedicine that includes their skills and education and electronic literacy. Participants of this study revealed that indirect contact with patients and their family members may work as a barrier to proper communication through the Remotely Accessible Healthcare At Home program.

Conclusions: We recommend exploring the use of interpreters in digital health, creating awareness among the local population regarding privacy in digital health, and actively involving direct family members with the health care providers.

Introduction

Background

Digital health technology (including telemedicine, telehealth, remote patient monitoring, and connected health) that supports patient-centered care is a rapidly evolving field and is gaining popularity as a means of driving quality improvements and accessibility in health care [1]. Digital health is assumed to enhance the provision of health care services outside conventional hospital settings [2,3], thereby strengthening the development of home health care (HHC) services. Numerous benefits related to the implementation of digital health have been suggested, including improved quality of care, patient safety, accessibility, and cost minimization [4,5]. Their use is also linked with enhanced clinical outcomes, such as a decline in mortality and emergency room admission rates [6]. During the 2019 COVID-19 global pandemic, telemedicine and telehealth have provided opportunities for delivering health care remotely and have underpinned the beneficial role of digital health in the future [7].

Owing to these beneficial uses of technology in health care worldwide, there has been a dramatic growth in the number of digital health pilot programs [8]. However, a critical issue in this domain is that a considerable number of these pilot programs have been unsuccessful in progressing toward full-scale implementation and widespread adoption [9-11]. The reasons underlying the failure of these pilot programs have received substantial interest in the literature [12,13]. One of the key barriers identified in numerous studies pertains to cultural factors and influences [14-16]. Culture refers to “a system of knowledge, beliefs, patterns of behavior, artifacts, and institutions that are created, learned, and shared by a group of people” [17]. Culturally appropriate health-related interventions have been reported to improve clinical outcomes [18]. Likewise, cultural sensitivity is a key element for honoring patient-centered health care [19], and it has been identified as one of the significant factors needed to extend telemedicine projects to mainstream health care [20].

Being the cradle of the Islamic faith, Saudi Arabia is home to a predominantly Muslim population, and this shapes cultural and social life. In general, some characteristics of the Arab-Muslim culture that influence health include health beliefs, family relationships, health providers, diet and medications, life stages, views on death and dying, preventive health, gender issues, space, time, and communication [21]. Specific to Saudi Arabia, the language barrier between patients and providers has been well documented to adversely affect the quality of health care in Saudi Arabia [22,23].

The influence of culture on digital health practices in Saudi Arabia is the focus of a study by Kaliyadan et al [24], which included 166 patients and evaluated the application of a 4G smartphone for teledermatology. The study found that 14% of the mostly female patients refused photography of their skin lesions, citing social and cultural reasons [24]. In addition, a review article by Alkhalifah and Aldhalaan [25] that examined the use of telehealth services to support families with children diagnosed with autism spectrum disorder in rural areas of Saudi Arabia recognized that telehealth interventions developed in the West were culturally unsuitable in the local context, thus acting as a barrier to extensive adoption [25]. Hence, the provision of culturally appropriate digital health is crucial for delivering high-quality health care in Saudi Arabia.

Research Gap

There is still inadequate knowledge pertaining to the aspects of Saudi Arabian culture that need to be considered closely in the design and implementation of digital and connected health programs. This is especially relevant in the context of HHC services for vulnerable groups such as patients who are chronically and terminally ill that require longstanding treatment and management and often have complex unmet health care needs [26]. Information regarding the unique cultural factors of the patients and caregivers that influence the successful application and adoption of health technology will enable program managers and health care providers to design and deliver culturally sensitive digital health interventions for use in the local context [27]. This is especially vital in light of Saudi Arabia’s Vision 2030 National Transformation Program (2018-2020) that has reinforced the role of patient-centered telemedicine and digital health technology as a means of driving major developments in the health care sector and improving health care outreach [28]. Its vitality is also relevant in light of Saudi Arabia’s active digital health response to the COVID-19 pandemic [29].

Thus, through our study, we aim to explore the culture-specific observations relating to patients and their caregivers through the perspective of physicians, nurses, and trainers during the pilot implementation of a connected health program named Remotely Accessible Healthcare At Home (RAHAH) in the HHC department at King Saud University Medical City (KSUMC), Riyadh, Saudi Arabia.

Methods

Study Design

This is a phenomenological qualitative study using focus group discussions (FGDs) to explore experiences and opinions of health care workers (HCWs) and program trainers who have been using telehealth for HHC in the Saudi Arabian cultural context. FGD was used as the technique, and it reflects the process through which meaning was constructed collectively and can be regarded as naturalistic.

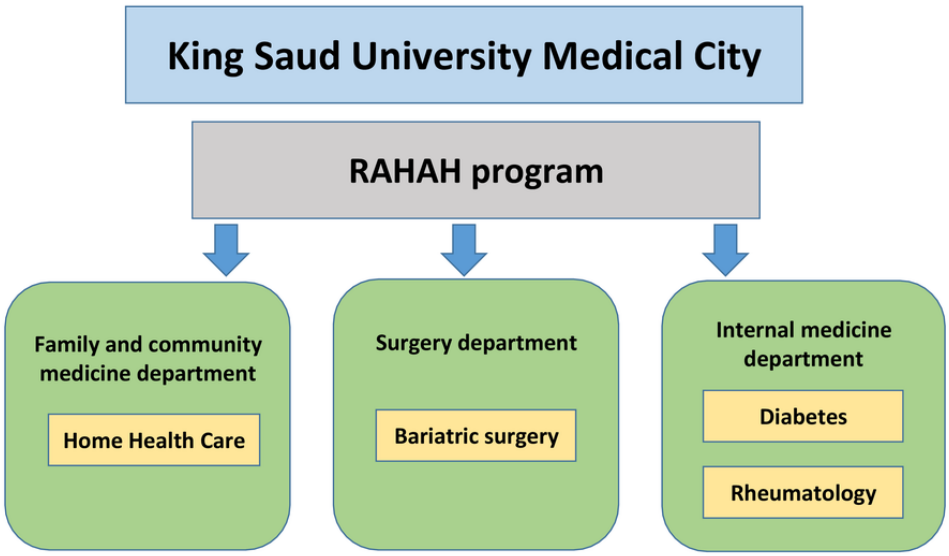
Some of the researchers (AAA, AMA, ZA, and FRQ) held an emic perspective as they worked in close contact with the RAHAH team. This assisted in bringing more knowledge, as they were more familiar with the expressions and ways of communicating and establishing trust between the researchers and participants. The others held an etic perspective (MMH and NAA), as they were only involved for the purpose of conducting the study. This allowed them to look at the participants experiences without a preconceived assumption.

Study Setting

KSUMC is a tertiary care hospital in the capital city of Riyadh. It is a leader in medical specialties, subspecialties, and

technologies. A connected health program called *RAHAH* was developed by Prince Naif Bin AbdulAziz Health Research Center at KSUMC. RAHAH uses a wide array of digital-based health tools on its platform, including patient health records, portals, mobile apps, remote monitoring devices (such as glucometers, blood pressure monitors, oximeters, and thermometers), teleconsultation, and e-response centers (through messaging and chat). In 2018, the HHC department at KSUMC embarked on piloting the RAHAH program in its department (Figure 1). This pilot program is being conducted in a phased approach, with geriatric patients constituting the first phase. There were 40 geriatric patients with chronic conditions such as diabetes mellitus and hypertension who were enrolled in this program when the study was conducted.

Figure 1. Different departments piloted by Remotely Accessible Healthcare At Home program including the Home Health Care department. RAHAH: Remotely Accessible Healthcare At Home.



Sampling and Recruitment

This research project was conducted at the HHC department, KSUMC where 6 HCWs were dedicated to piloting the RAHAH program. RAHAH provides technical liaisons to different departments at KSUMC to implement the RAHAH program. These liaisons also train patients, caregivers, physicians, nurses, and allied health staff on how to use the service, observe and curate feedback from users, and help in cases of technical hurdles. They provide valuable insight into the audience of interest (the HHC team and patients or caregivers) because of their close and frequent contact with them. For the HHC department at the time of this study, there were 2 RAHAH technical liaisons. This project's research team comprises administrative researcher physician figures from the HHC department and RAHAH program (AAA, AMA, and ZA), 2 qualitative research public health physicians from community medicine units (MMH and NAA), and a RAHAH researcher (FRQ).

The criteria for participant selection included those working on the RAHAH project in the HHC department at KSUMC. Those who were not directly involved in the HHC department at KSUMC were excluded. The total number of team members working on the RAHAH pilot in the HHC department was 8 (6/8, 75% HCWs and 2/8, 25% technical liaisons). They were all invited by researchers MMH and FRQ (who are not associated with HHC) via email to participate in the focus group. It was explained to all participants that their decision to participate would not have any implication on their jobs. An invitee declined (1 of the 2 RAHAH technical liaisons), and the remainder accepted by responding to the email. Thus, a total of 7 participants attended the FGD. Reminders for the invitation date and time were sent out via SMS text messages and emails with no prior knowledge of the actual number that will be attending the focus group. The focus group time was voided from the HHC team schedule to provide an opportunity to those who wanted to participate in the research.

Data Collection

The discussion guide was developed in English based on the study objectives, previous studies [15,21,30-33], professionals' experiences [34], and personal familiarity and clinical experiences with the Saudi Arabian culture (Multimedia Appendix 1). It followed a semistructured format with open-ended questions that facilitated the development of emergent themes during the discussion.

The discussion guide was tested with 1 RAHAH trainer who was not invited to the FGD. A researcher tested the guide for ease of understanding and checked whether the answers met the requirements of the question. Consequently, some of the guide questions were rephrased, and the definition of *culture* was added to the introduction.

The FGD was conducted on July 28, 2019, for 2 hours by 2 researchers, MMH and FRQ. MMH led the discussion, as she is bilingual in Arabic and English, whereas FRQ took notes of the discussion and kept track of the time. The discussion was conducted in a quiet meeting room at KSUMC on July 28, 2019, and lasted for an hour.

The discussion was in English, which is the main language spoken by workers in KSUMC. However, to enhance the credibility of the findings, participants were given the option

to use Arabic. For each question, the focus group facilitator gave ample time for all participants to share their thoughts and at times used prompters to further explore the answers. The facilitator would move on to the next question when she reached saturation with the answers.

The discussion was audiotaped and transcribed verbatim by a transcription service. The transcript had time stamps on speaker change, and MMH and FRQ filled in unintelligible and Arabic audio, deidentified the participants and names, crosschecked the text with audio, and refined and finalized the transcript for analysis.

Having different perspectives among the authors, using probing questions, using ≥1 coder, and having transparency in reporting the results added to the trustworthiness of the study. A focus group method was chosen as it is the best technique to elicit shared experiences, permitting participants to raise topics that they deem to be important and allowing people to probe each other's reasons for holding certain views. All of the above enriched the data and supported the credibility of the study.

Data Analysis

We conducted a thematic framework analysis as described by Ritchie and Spencer [35]. A holistic overview of the data set and familiarization with the range, depth, and diversity of the participants' responses was performed by NAA and MMH. Similar codes were developed by both authors, and an agreement on an initial coding frame was achieved with the flexibility to enable other codes to be added and discussed regularly. Key themes were developed, and quotations were used to support the provided evidence. NVivo software (version 11.4.2; QSR International) [36] was used to manage the data.

Ethical Considerations

Ethical approval was obtained from the institutional review board of King Saud University College of Medicine in June 2019 (project number E-18-3914) based on the Declaration of Helsinki. Participation in the study was voluntary, maintaining the right of the participants to withdraw at any time. The participants were fully informed regarding the study aims, objectives, methods, and how the interview material would be recorded and protected. All the information provided by the participants was kept confidential, the participants' names were coded, and possible identifiers were omitted from the final transcript. As the head of the HHC department and RAHAH program managers are researchers in this study, they were not involved in the facilitation or transcription of this focus group to avoid the power effect of the relationship between managers and employees to influence the latter's responses.

Results

Overview

A total of 7 participants were included in the focus group (Table 1), and 2 categories emerged from the FGD. These were (1) culture-related factors, including language and communication, cultural views on using cameras during consultation, nonadherence to web-based consultations, and family role and commitment and (2) caregiver characteristics in telemedicine, including their skills, education, and electronic literacy (Textbox 1).

Table 1. Demographic data of the study participants.

Participant number	Nationality	Gender	Time working in home care and telemedicine	Specialty
1	Saudi Arabia	Female	3 years	Information technology
2	South Asia	Male	3 years	Family physician
3	South Asia	Male	1 year	Family physician
4	Southeast Asia	Male	4 years	Nurse
5	Southeast Asia	Male	3 years	Nurse
6	South Asia	Female	3 years	Nurse
7	Saudi Arabia	Female	3 months	Nurse

Textbox 1. Emerging themes in the experiences of health care workers.

Culture-related factors

- Language and communication
- Communicating with the caregiver
- Behavior and media used in urgent communication
- Bilingualism
- Cultural views on using the camera
- Nonadherence to web-based consultations
- Family role and commitment

Caregiver characteristics

- Skills and education
- Electronic literacy

Culture-Related Factors

A total of 4 themes emerged from this category: language and communication, cultural views on using the camera, nonadherence to web-based consultations, and family role and commitment.

Language and Communication

Communicating With the Caregiver

The participants acknowledged that dealing with the caregivers rather than directly with patients is inevitable, as almost all patients who are registered in the RAHAH program at the HHC department are diagnosed with cognitive impairment. This is evident in the response of participant 2:

> *Most of the patients are not able to express themselves...they are demented, and they cannot express themselves.*

As family members are usually busy during the day, they assign a housemaid or sometimes a nurse to escort the patient. A participant explained the following: "We are communicating with the attendants who are hired ones, not the real relatives of the patient" [participant 2].

Another participant added the following: "Very few, uh, family members are communicating with us" [participant 1].

Caregivers were seen by the participants as an essential link between the patients and the health care team. According to them, they train all caregivers to assist in patient care: "We train them on feeding, giving medications, vital signs recording" [participant 2].

They correspondingly acknowledged that if the caregiver was sincere, good patient outcomes could be observed. A participant explained as follows:

> *Dedication is very important for the caregiver because we have some patients with bed sores...So, if she is dedicated [you can see] good progress and good healing of the wound...But if they are not dedicated and they are not concerned, it will linger on.* [participant 3]

Furthermore, discrepancies in the information shared by patients and caregivers were noted. A participant explained the following:

> *Even when their caregivers told us that she [the patient] was having pain in her knees, she was not eating, she—didn't go to the toilet for like three, four days and I asked her, "Mama, how are you? Are you okay?" "Yeah, everything is good."* [participant 7]

Moreover, handover of care between caregivers and family members was described as *poor,* as they do not involve the health care team in the process of care transition to family members. A participant stated the following: "They [caregivers] will not even tell us when they are travelling" [participant 7].

Behavior and Media Used in Urgent Communication

According to the participants, phone calls to their offices or messages on WhatsApp were the modes of communication in case of emergencies. A participant explained the following:

> *We are not watching RAHAH all the time...They [patients] call our office. If there is some urgent problem...they send the pictures, messages on WhatsApp and immediately we connect and then call them and see what the problem is.* [participant 2]

Participants felt comfortable providing their personal cell phone contacts, as they believed that some patients might need immediate attention:

> *If the nasogastric tube is out...So, they communicate with us because our patients need to be fed...or if the catheter is pulled out, they need to be relieved.* [participant 3]

A participant expressed his inconvenience in dealing remotely with some caregivers in the case of an emergency. He believed that caregivers' expressed stress could be exaggerated, and the situation could be misinterpreted by the HCW:

> *You directly see they are very hysterical, especially ladies, and shouting "the patient is dying! The patient is dying!" or "there's blood coming out" or "please, we cannot give medicine anymore." So, once they are*

> *hysterical...They do create a hysterical situation for the treatment team.* [participant 2]

Bilingualism

The participants denied language as a barrier to communication. They noticed that their caregivers or relatives spoke both Arabic and English, which made it easier for them to communicate. Participant 3 explained it as follows: "If you go back years and years, most people were speaking Arabic, but now I have noticed most of the people there speak English fluently too."

In contrast, another participant noted the following:

> *Sometimes they do not know how to use the system because the RAHAH system is an English based system...Others [caregivers] from African countries do not speak English, so they do not communicate with us directly and they just work under the supervision of some ladies of the house.* [participant 2]

The problem of caregivers with limited knowledge of the English language contributes to difficulties in communication with health care providers and eventually influences the level of care provided to the patient. Those who are fluent in English would be able to operate the telehealth program effectively and understand the treatment team instructions better compared with those who do not speak English:

> *Some female foreigner caregivers can speak English and they can operate the telehealth system. They are the most helpful to us, taking pictures, and sending us messages.* [participant 2]

> *Others are housemaids who are not trained in the English language and do not communicate well with us; they just work under the supervision of family members. They are trained to clean the patient's bed, bedsheets, and things, and they are not trained to take care of medical problems. They are also not able to use the telemedicine system.* [participant 2]

Cultural Views on Using the Camera

Participants commented on the acceptance of camera use by patients during web-based consultations. A participant noted the following:

> *Even if I ask them to show me the patient, they are reluctant. They say "I will tell you everything instead."* [participant 2]

Some participants believed that this is rooted in a religious viewpoint, acknowledging that Saudi Arabian culture is shaped by the Islamic religious background. A participant remarked the following: "Some might think that showing themselves on camera is Haram [religiously prohibited]" [participant 1].

Participants also speculated that most female patients were uncomfortable showing themselves on camera, as they covered their faces from male strangers. A participant further opined that the patients or caregivers feared using the camera and technology during communication with their health care provider and expressed concerns regarding their privacy:

> *They do not want to use the camera...because it could be recorded. They are afraid that technology is so advanced, and cameras can record their (face)...stalking...taking photos.* [participant 2]

The participants showed full acceptance of the patients' preferences. Moreover, most of them preferred not to ask female patients to show themselves on camera anymore, as they knew this might not be acceptable to them and only tried to see parts of the body when necessary. Male patients, on the other hand, do not generally have reservations in this regard. A participant noted the following:

> *We do not request any exposure on camera. For females, we do not request to examine them on the telemedicine system...or to show parts of their body unless absolutely necessary. But in males...it is okay.* [participant 3]

Nonadherence to Web-Based Consultations

Participants perceived that patients' attitudes toward attending their web-based appointments were different from face-to-face hospital appointments. Some patients do not take their web-based appointments seriously. A participant explained the following:

> *They are not particular about this appointment and whether to attend it or not...In out-patient clinics, people are careful because if they do not show up then they will not get another appointment for three months. Here, there is no such problem. They can get another one soon.* [participant 2]

Family Role and Commitment

Most participants acknowledged the key role of family members in facilitating the implementation of the RAHAH program in HHC and communicating with health care providers. Moreover, their role in reaching an optimum state of health care outcomes was highlighted. The participants mentioned the following:

> *The main role is the family's.* [participant 3]

> *If the family is proactive, we can expect that the patient has no acute conditions...their health status is optimum and meet expectations.* [participant 5]

However, the participants conveyed that family members were unavailable, most of the time, to take care of the patients:

> *...because family members are working outside the home, and they are busy.* [participant 3]

> *Men generally are not at home...Even ladies are working, such as teachers.* [participant 2]

Consequently, physicians generally rely on a hired nonnational caregiver to provide them with health-related information about the patient, and sometimes, the team may find it difficult to communicate with family members when the caregiver is unavailable. A participant noted the following:

> *They [the family member] will be updated by the caregiver, usually a housemaid. And whenever we ask more questions, they need to call the caregiver for more clarification. This may create a problem with telling the truth.* [participant 7]

The participants further acknowledged that the commitment of families varied regarding their involvement in patient care. A participant reported a few incidents that highlighted the lack of commitment by some family members:

> *Do you remember what happened last week with us? The patient who had not taken medicine...he used to take medicine at 9 or 10 AM. Why? Because the caregiver was traveling. The lady of the house was there at home, and she said, "I don't know how to give the medications. I told the caregiver that before she leaves, she should hand over the care."* [participant 3]

A participant reported that some families hindered the successful implementation of the telehealth program and recounted an instance in which the family did not provide the Wi-Fi password to the caregiver in their absence:

> *I have encountered two caregivers who want to use RAHAH, but the problem is they do not have Wi-Fi. I mean the family do not give the password to the caregivers.* [participant 4]

In short, the quality of the telehealth experience is affected by specific culture-related factors, including language and mode of communication, religious views of the patients or caregivers, and family role and commitment to patients' care.

Caregiver Characteristics

As caregivers are the main link between patients and health care providers, under this category, caregiver characteristics that were commonly observed by the participants were classified into the following themes: skills and education and electronic literacy of the caregiver.

Skills and Education

The participants highlighted several individual skills of the caregivers that influenced the care provided to patients. For example, a participant noted the following:

> *We see all types and all categories of caregivers. Some are trained nurses, some are nursing assistants, and some are only housemaids.* [participant 3]

Educated caregivers prove to be valuable in driving an effective telehealth consultation, as they are able to identify dangerous signs and symptoms in the patient and inform the treating team in a timely manner. A participant described incidents where an educated caregiver was able to use the telehealth program to connect with the health care team and alert them regarding unusual symptoms such as blood in the stool and discoloration of the patient's leg, which subsequently saved the life of the patient:

> *So, an educated attendant is the main person who is helping us in telemedicine...remember that lady? She sent out the photos of the blood in the stool. Therefore, we immediately contacted her and then we went there to see the patient, and found out that he had colon cancer...There was a blood clot in the leg that we recognized from picture that she sent.* [participant 2]

Electronic Literacy

According to the participants, some caregivers had limited electronic literacy and found it difficult to deal with the technology necessary to conduct a telehealth consultation:

> *Yeah, um, few times I faced difficulties in leading the caregiver to just sign up to Gmail...even the application...sometimes they have difficulties with that.* [participant 1]

In addition, some patients and caregivers showed low self-confidence in using the technology. A participant explained the following:

> *One patient said "I do not know how to use the application. I do not know how to use technology. I am not good with phones."* [participant 7]

Discussion

Principal Findings

The RAHAH program applies a user-centered design approach to its development process. The program team is in constant communication with the health care providers piloting it, as well as patients and caregivers receiving care through the program. The program team also conducts frequent surveys and observation visits to better understand the user experience and enhance it. This qualitative study aligns with this approach of adopting the bottom-up design of the program for better acceptability, usability, and satisfaction. The pathway of communication in the RAHAH program is depicted in Figure 2, where the HCWs communicate with the caregiver, as most patients have difficulties in verbal communication, who in turn communicate with the family members. HCWs communicate with family members only when needed or in emergency cases.

Our findings show that HCWs communicate directly with caregivers who are characterized by some features that may hinder proper telemedicine-based communication and hence affect the quality of care provided by the health care team. This finding aligns well with previous studies that suggested cultural influences impede the full-fledged implementation and adoption of digital health systems [10-12]. Moreover, although HCWs using telemedicine believe that better health outcomes are associated with family involvement, their direct communication with the family members of the patients is lacking. This can be explained by the changing social culture in Saudi Arabia in terms of more women joining the workforce [37] and the breakdown of the extended family structure [38].

Although language was not explicitly reflected as a significant barrier by the participants, this aspect must be considered because the probability of challenges related to language and communication is high in Saudi Arabia, as many of the caregivers are expatriates and do not speak Arabic [22,23]. This is a matter of concern, as poor patient–provider communication is linked to poor diagnosis, treatment, and medication instructions and a significantly higher risk of serious medical events [39-43]. Bilingual providers are preferred to bridge the patient–provider gap. In this regard, researchers suggest that professionally trained interpreters can provide a high-quality, culturally competent language in the absence of the services of

bilingual clinicians [44]. However, a scarcity of interpreters has been reported previously [45], and in Saudi Arabia, a systematic review suggested that the cultural and language training currently provided to expatriate nurses is not fulfilling its purpose [46].

The findings of this study are consistent with earlier studies that highlight the cultural beliefs affecting camera use in teleconsultations, especially among women [24,47-49]. The culture-religious belief that inhibits women from showing themselves on camera is deeply rooted in decades-old *Fatwas* (scholarly religious decisions) that forbade photography in all its forms and the revealing of any part of a female's body to men, even in medical situations. These *Fatwas* have been amended to accommodate the modern-day context but remain a deterrent in the consciousness of some patients. It was clearly important for the participants of this study to be culturally sensitive when delivering their services using RAHAH. However, they may hinder a successful telehealth experience by refraining from asking female patients to appear on camera or to show some body parts.

Figure 2. Pathway of health communication using telemedicine in Remotely Accessible Healthcare At Home program in the Home Health Care department.

Studies have largely reported technology-learning barriers in telemedicine [50-52]. Our findings contrast with previously published studies in which a positive attitude toward telemedicine was evident in patients with cancer [53], as well as in those with lung diseases [54]. In their large survey study, Edwards et al [55] found that patients with depression and those with a high risk of cerebrovascular disease have a moderate interest in phone-, email-, and internet-based services, whereas interest in social media–based services was lower. In Saudi Arabia, it was found that several barriers hinder decision-makers of health care facilities from adopting and implementing telemedicine in their health care facilities. These barriers were the availability of adequate, sustainable funding and financial support for operations; the reimbursement for telemedicine services; the quality of information; the cost-effectiveness of telemedicine; and cultural and social constraints [56]. Another local study highlighted factors such as privacy, equipment cost, lack of training, information, and communication technology issues as significant barriers to the adoption of telemedicine in hospitals [57]. However, the latter studies focused on patients or HCWs mediating the consultation in the absence of caregivers.

Regarding the recurring *no show* behavior, it could be curbed with punitive procedures and communicated to caregivers when onboarding the program. The cost-effectiveness of the implemented telehealth program should be assessed with regard to nonadherence to web-based consultations [58]. The *no show* behavior in the served population in this study could be explained by proximity to the hospital premises. In this case, telehealth was not the only option for patients. Telehealth services for individuals living in rural areas have observed different behavior [25,59].

Overall, it is important to empower patients and caregivers in the context of digital health care. Our study can be looked at as a piece of a whole. The whole picture includes patients, caregivers, and HCWs. The findings of this study can be compared against perspectives on the experience of the primary audience of the RAHAH program later on to improve the overall communication process.

Study Limitations

Potential information recall bias among participants must be considered in similar studies in the future. This study would have benefited from triangulation with the primary audience (patients and caregivers). In this study, patients were not interviewed because of their health conditions, whereas caregivers spoke different languages, which required unavailable resources for translation to conduct the interviews and transcribe them. Future projects could triangulate with other departments' findings and RAHAH's user analytics and should capture the experiences of patients or their family members. The study team dedicated effort to concealing the participants' identities by not involving research team members who are also HHC or RAHAH administrative figures in the focus group or analysis phases.

Conclusions

The study results illustrate the importance of improving awareness among the public and health care teams to reassure the patients and caregivers that their privacy and preferences with respect to the socioreligious culture are vital. HCWs should remind caregivers of the importance of following a proper handover of care, should the need arise. Furthermore, because caregivers are not always professionally trained in nursing and personal characteristics affect their capabilities, it is crucial that HCWs communicate directly with family members, providing a summary of the teleconsultation conducted in their absence. More research could focus on the feasibility of using interpreters to improve the care provided via telehealth.

Acknowledgments

This study was supported by the Deanship of Scientific Research, Research Chair for Evidence-Based Healthcare and Knowledge Translation, King Saud University, Riyadh, Saudi Arabia.

Abstract

Background: Early in 2020, mental health services had to rapidly shift from face-to-face models of care to delivering the majority of treatments remotely (by video or phone call or occasionally messaging) due to the COVID-19 pandemic. This resulted in several challenges for staff and patients, but also in benefits such as convenience or increased access for people with impaired mobility or in rural areas. There is a need to understand the extent and impacts of telemental health implementation, and barriers and facilitators to its effective and acceptable use. This is relevant both to future emergency adoption of telemental health and to debates on its future use in routine mental health care.

Objective: To investigate the adoption and impacts of telemental health approaches during the COVID-19 pandemic, and facilitators and barriers to optimal implementation.

Methods: Four databases (PubMed, PsycINFO, CINAHL, and Web of Science) were searched for primary research relating to remote working, mental health care, and the COVID-19 pandemic. Preprint servers were also searched. Results of studies were synthesized using framework synthesis.

Results: A total of 77 papers met our inclusion criteria. In most studies, the majority of contacts could be transferred to a remote form during the pandemic, and good acceptability to service users and clinicians tended to be reported, at least where the alternative

to remote contacts was interrupting care. However, a range of impediments to dealing optimal care by this means were also identified.

Conclusions: Implementation of telemental health allowed some continuing support to the majority of service users during the COVID-19 pandemic and has value in an emergency situation. However, not all service users can be reached by this means, and better evidence is now needed on long-term impacts on therapeutic relationships and quality of care, and on impacts on groups at risk of digital exclusion and how to mitigate these.

KEYWORDS

telemental health; COVID-19; remote care; telemedicine; mental health; systematic review, implementation science

Introduction

Since the onset of the COVID-19 pandemic in the first few months of 2020, most countries have experienced a severe disruption of mental health service delivery in its usual forms [1]. Community-based outpatient, day and home treatment programs, prevention and mental health promotion programs, and services for specific age groups, such as older adults, children, and adolescents and people with substance misuse problems, have been among those severely affected at a time of potentially increased demand due to the adverse mental health consequences of the pandemic [2,3].

Mental health care providers around the world responded to the disruption of services in many ways, including the significant and widely documented shift to remote delivery of mental health services to replace in-person consultations [1,4,5]. Telemental health, defined as "the provision of behavioral and/or mental health care services using technological modalities in lieu of, or in addition to, traditional face-to-face methods" [6], including video conferencing, telephone, email or text messaging, has been central to continuing assessment and support in the community. Additionally, technological innovations are helping to address isolation and service disruption in hospital and residential settings [4,7].

Multiple research studies conducted both before and during the pandemic have reported evidence of the effectiveness of telemental health in reducing treatment gaps and improving access to care for a range of service users [8-10]. Findings from studies, often of telemental health programs established for purposes of research, have suggested that, overall, synchronous modalities such as video conferencing are comparable to face-to-face delivery in terms of quality of care, reliability of clinical assessments, and treatment outcomes and adherence [11-15]. Good levels of service user acceptance and satisfaction with telemental health services have also been reported [10]. Successful adoption of telemental health has been described across a wide range of populations (adult, child and adolescent, older people, ethnic minorities), settings (hospital, primary care, community), and conditions [11,13,16]. For certain populations, including some with autism and severe anxiety disorders, and those with physical disabilities or geographical barriers to accessing services, telemental health can be preferable for some service users [6,17], although individuals experiencing significant social disadvantage or severe mental health problems, such as psychosis, have been found to benefit less [18]. Research suggests that telemental health can also work for group interventions [19]. The attitudes of clinicians who have delivered care via synchronous telemental health appear to be largely positive, with professionals finding it both effective and acceptable [20] and recognizing its potential to enhance communication within and between mental health teams [4,7]. There is also some positive health economic evidence, with several studies suggesting telemental health is no more expensive than face-to-face delivery and tends to be more cost-effective [12]. This approach also appears to be a viable and inexpensive treatment option where access to emergency services is limited, and associations have been found with reduced psychiatric admissions [10].

However, despite this evidence base, integration of telemental health approaches into routine mental health care or the widespread adoption of remote working across whole systems has rarely been reported. Even during the pandemic, adoption of such technologies has been piecemeal, with utilization varying substantially both between and within countries [1,7]. Technological barriers to the wider adoption of telemental health include (1) the risk of digital exclusion of some service users, such as those facing significant social disadvantage or with limited technological access and expertise, and (2) the lack of technological infrastructure and clear protocols within services, impeding the integration of telemental health with face-to-face care [4,21,22]. Other barriers include difficulty in establishing and maintaining therapeutic relationships and in conducting high-quality assessments; service users who lack private space or find participating in sometimes intimate and distressing discussions from home intrusive [4,11,12,18,21-23]. A range of other ethical, regulatory, technological, cultural, and organizational barriers have also been identified, both before and during the pandemic [12,24-27].

The widespread emergency adoption of telemental health since the onset of the pandemic has generated a substantial literature. Numerous commentaries, service evaluations and reports of telemental health innovations, and service user, carer and staff experiences, in addition to a growing number of research studies addressing effectiveness and implementation issues [28-31] have been published internationally. Clinical guidelines have been rapidly produced in a number of countries [32].

A synthesis of the relevant empirical evidence gathered during the pandemic is therefore timely and informative for planning by generating evidence of effects of adopting telemental health across whole populations and service systems rather than in the context of relatively small-scale research studies involving volunteer participants. Capturing the learning and experiences gained through the rapid shift to telemental health will help optimize remote health care in a population that presents unique relational challenges associated with mental distress. It will also help to understand and overcome implementation barriers and inform strategies for improving the flexibility, effectiveness, and efficiency of mental health services through the sustained integration into routine care of telemental health approaches, to ensure that it brings the greatest benefits for patients, carers, and staff.

The aim of this review is to synthesize the international literature specific to remote working in mental health services (as a replacement for or in conjunction with face-to-face service delivery) in the context of early stages of the COVID-19 pandemic. The paper complements our previous umbrella review (systematic review of reviews) of literature on telemental health prior to the COVID-19 pandemic [15]: focusing on the literature from the pandemic period allows us to identify specified learning from the very wide implementation that occurred during this period. Our research questions are as follows:

1. What evidence has been obtained during the COVID-19 pandemic regarding the effectiveness and cost-effectiveness of telemental health and regarding its safety (including adverse events due to breaches of privacy and safety)?
2. What coverage has been achieved through telemental health adoption in the pandemic (including extent of adoption by services and reach among clinical populations in which it is adopted); in which groups and for which service settings is telemental health more or less likely to be implemented successfully; what are potential risks associated with digital exclusion for those not reached; and what barriers and facilitators influence success in implementation?
3. How acceptable are telemental health approaches to service users, carers, and staff as applied during the pandemic, including perceived impacts on therapeutic relationships, communication, and privacy?
4. What innovations and improvements have been introduced to make clinical care via telemental health more effective and acceptable, achieve greater coverage, and address barriers to delivering care in this way? (This includes descriptions and evaluations of specific strategies designed to make telemental health work better than usual delivery, and of adaptations of telemental health to specific settings, such as inpatient wards and crisis services).

Methods

A systematic review was conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement [33]. The protocol for this review was registered with PROSPERO (CRD42021211025).

Search Strategy

Four electronic databases (PubMed, PsycINFO, CINAHL, and Web of Science), preprint servers medRxiv, PsyArXiv, Wellcome Open Research, and JMIR were searched for research relating to COVID-19, mental illness, and remote working from January 1 to December 9, 2020. An example search strategy can be found in Multimedia Appendix 1.

This search was supplemented by searching the references listed in included studies for any additional studies that met our inclusion criteria.

Screening

The resulting list of articles was deduplicated using Endnote [34] and all references were imported into Rayyan [35] for title and abstract screening. Full texts were sourced for articles deemed relevant for inclusion, and these were screened against the full review eligibility criteria. To establish consistency in study selection, title and abstract screening was conducted by 4 reviewers (MS, ZH, JH-S, and LSR), with 100% of included and 25% of excluded references checked by another reviewer (RA). Full texts were screened by 3 reviewers (RA, MB, and MS), with 100% of included and 25% of excluded papers checked by another reviewer (task divided between LG, HJ, JW, PB, and LSR). Any disagreements were resolved through team discussion.

Inclusion Criteria

Participants

Staff working within the field of mental health, people receiving organized mental health care for any condition (including addictions, dementia, and intellectual disability), family members or carers of people receiving mental health care (regarding their views on the impact of remote working on the service user, and interventions aimed at reducing carer distress). There are no age restrictions on participants in this review.

Interventions

Any form of spoken or written communication carried out between mental health professionals or between mental health professionals and service users/family members/unpaid carers or peer support communications using the internet, the telephone, text messaging platforms, or hybrid approaches combining different platforms.

Comparator(s)/Control

Any mental health communication delivered face-to-face, digitally or remotely, waitlist control, or placebo. Studies comparing different modes of delivery during the pandemic, and those comparing care delivery and outcomes during the pandemic with those before the pandemic were included. Relevant studies with no comparator were also included.

Outcomes

Qualitative and quantitative outcomes describing implementation effectiveness (including process evaluations) and barriers and facilitators to digital engagement, clinical effectiveness, cost-effectiveness, acceptability (including service user, carer, and staff satisfaction), impacts on communication and

therapeutic relationships, coverage and impacts of digital exclusion, interventions to improve quality or coverage, improvements in quality of life, and economic impacts.

Design

Any papers that present qualitative or quantitative data from study designs of any type (including relevant service evaluations and case series). If the focus of the study was not solely remote working but the results section contained substantial data relevant to our research questions, these were also included. Any relevant reviews identified in the searches were checked for included research which met our inclusion criteria.

Exclusion Criteria

We excluded studies that were (1) not specific to the pandemic response; (2) reporting on interventions with patients with primary sleep disorders; (3) reporting on those with subclinical symptoms (unless combined with another included mental health problem); (4) focused on digital interventions such as apps, websites, and virtual reality tools, except where the sole purpose of the digital intervention was to facilitate direct spoken or written communication; (5) focused on interventions aimed at improving the mental health or well-being of health care professionals; and (6) editorials, opinion pieces, guidance documents, protocols, conference abstracts, and letters, with the exception of editorials or letters which contained primary research findings.

No language or location restrictions were applied in this review.

Data Extraction

Data extraction was supported by well-established implementation science frameworks. A data extraction form was developed based on a brief version of the Consolidated Framework for Implementation Research (CFIR) [36] and the taxonomy of implementation outcomes [37]. We used the higher-level CFIR constructs (see Table 2 in section *Barriers and Facilitators to Telemental Health* for a brief definition of each one of the implementation facets that CFIR constructs capture) to extract data on factors influencing implementation success [38], and the taxonomy of implementation outcomes including acceptability, adoption, and feasibility. We also extracted information deemed relevant based on previous studies conducted by the research team, including an umbrella review of pre-COVID-19 systematic reviews on telemental health and a qualitative study [15,21]. Data extracted consisted of study details, including design and focus of study; gender, ethnicity, age; diagnosis of participants; details of staff occupation; setting and context of study; intervention details, implementation outcomes (including acceptability, adoption, appropriateness, feasibility, fidelity, cost effectiveness, penetration, and sustainability); barriers and facilitators to implementation; and clinical and safety outcomes. The full data extraction form can be viewed in Multimedia Appendix 1.

Data extraction was completed by 9 reviewers (AP, JW, MS, ER, RA, MT, JM, SS, HJ, approximately 8 studies each) using EPPI-Reviewer 4 [39]. All reviewers were trained on how to extract data to ensure consistency, and extracted data were checked by a second reviewer (RA & NVSJ). The extraction form was first piloted on 9/77 (12%) of included studies to assess usability and content, with amendments made before completing extraction for the whole data set.

Quality Appraisal

Given the diversity of the included article types and methods, 2 quality appraisal tools were used. Primary research studies were assessed with the Mixed Methods Appraisal Tool (MMAT) [40]. Commentaries and service evaluations were assessed using AACODS (authority, accuracy, coverage, objectivity, date, significance) tool, which appraises the veracity, clarity, acknowledgement of bias, and relevance of the contribution to the field [41]. Study quality was assessed by RA and verified by NVSJ. Disagreements were resolved through discussion.

Evidence Synthesis

We conducted a framework synthesis of study characteristics and outputs. Study outcomes were tabulated by applying existing implementation science frameworks, that is, the CFIR framework [36], Proctor et al's [37] taxonomy of implementation outcomes; and also by relevant topics/themes that emerged during data extraction. This table-based synthesis of the study outcomes combined a deductive and inductive approach to data analysis by using existing frameworks, while identifying emerging themes. Results reported in this paper include a narrative synthesis of the study characteristics and quantitative study outputs [42] and the tabulated results.

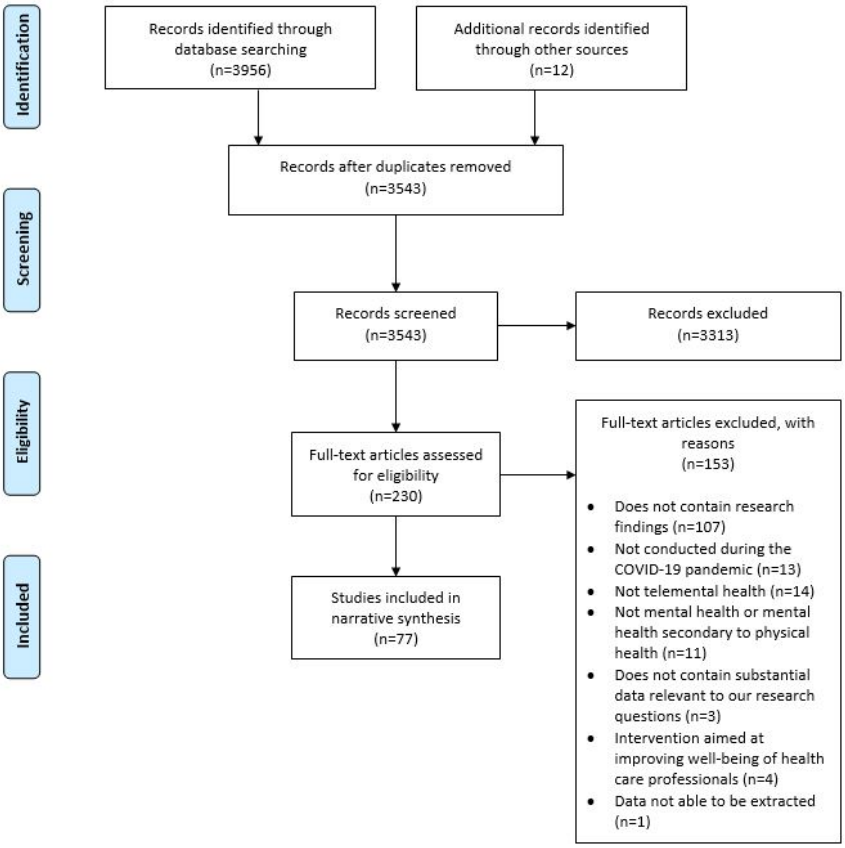
Results

Study Selection

A total of 3956 references were identified through searching databases of published papers. medRxiv was the only preprint database where included papers were found (n=10); 1 more relevant paper was identified by a member of the research team and a further paper was found through reference searching of included studies.

A PRISMA flow diagram [33] of the screening and selection process is presented in Figure 1.

Figure 1. PRISMA diagram showing screening and included studies.



Quality of Included Studies

The quality of included primary research studies was moderate to high: 23 out of 48 studies appraised using the MMAT met above 80% of quality criteria, whereas 21 out of 48 met between 50% and 79%. The quality of included service evaluations or audits was generally high: 27 out of 29 studies appraised using the AACODS met at least 4 out of the 6 quality criteria assessed. These include being written by recognized experts; including reference lists; having a clear aim; stating details such as date, location, and limitations; and making a meaningful contribution to the research literature.

Study Characteristics

Of the 77 studies which were eligible for inclusion in the review (Table 1), 45 were primary research studies, 24 were service evaluations or audits, and 8 were editorials or letters that included data. Thirty-three were conducted in the United States, 9 in the United Kingdom, and 5 each in Australia, Canada, and Spain. Five were conducted across more than 1 country.

Of the 45 primary research studies, 32 involved staff and 9 involved service users. The remaining 4 analyzed service use data (3 evaluated contacts with hotlines and 1 evaluated service use in 1 UK National Health Service [NHS] service provider).

Most studies were conducted in services that worked with people with mixed psychiatric diagnoses (n=30), although we also found studies conducted with groups with a single diagnosis (eg, dementia or eating disorders). Studies could include more than 1 service type, the most commonly studied being community mental health teams (CMHTs) or outpatient settings (n=39), followed by psychology or psychotherapy services (n=17). Inpatient or residential services were included in 15 studies, while 12 included general hospitals. Eight studies included private hospitals or clinics, while 4 explored telemental health use in helplines, voluntary sector services, crisis teams, or veterans' health services, respectively. Five studies did not report any specific setting.

The aims of most studies were either a description of changes made due to the pandemic, new services set up because of the pandemic, or an evaluation of the impact of the pandemic on either staff or service users. The descriptions of changes either focused specifically on the move to telemental health or were wider descriptions of changes to services including the use of telemental health. The characteristics of each of the included studies are shown in Table 1, with a more detailed summary in Multimedia Appendix 2.

Table 1. Study characteristics.

Study	Aim of study	Modality used	Mental health problem/diagnosis	Participants (sample size)
Aafjes-van Doorn et al [43]	Survey of therapists' experiences of video therapy during the pandemic	V[a]	Not stated	Staff (n=144)

Data Synthesis

Barriers and Facilitators to Telemental Health

Implementation barriers and facilitators were categorized using a condensed version of the CFIR framework (see Table 2, where definitions of the CFIR constructs are also provided). The key findings are summarized below.

Table 2. Implementation barriers and drivers for telemental health grouped according to condensed CFIR[a] domains.

CFIR domain	Findings	Example references
Intervention characteristics: Whether the intervention was internally/externally developed, evidence supporting the intervention, advantages compared with other methods of delivery, adaptability, trialability, and complexity	• Remote care had advantages over face-to-face, for example, making therapy more accessible for certain groups such as service users in remote locations; saving users money on travel; helping therapists get a better idea about the service users' home environment; some users benefitted from the distance, found it easier to communicate openly, and became more independent. • The main barriers for clinicians to deliver quality therapy were picking up on nonverbal cues, assessing mental health symptoms, keeping service users engaged. • Video and phone calls were the most common modalities; however, studies also reported the use of emails, instant messaging services, apps, videos, and forums. • Duration of telemental health appointments were shorter than face-to-face; clinicians reported it required more concentration and was more tiring. • In some cases, studies have reported using shorter but more frequent appointments to deal with challenges in remote working (eg, some service users struggling to stay focused). This was also used as a method to increase flexibility. • Frequent contacts between sessions helped to build the therapeutic relationship.	[43,51,56,86,108,109]
Outer setting: Information on whether the organization is networked with others, peer pressure to implement intervention, and external policies and incentives	• Implementation was commonly due to "stay at home" orders or national lockdowns, or a high level of COVID-19 cases in that area resulting in social distancing requirements. • In the United States, health insurers did not always cover telemental health care, whereas in some European countries, insurance cover for telemental health terminated at the end of the first wave of infections. • Telehealth service delivery was eased by the relaxation of policy and billing reimbursements during this time. • Professional bodies facilitated transition to telehealth by posting guidelines on their websites to assist clinicians. • Platform developers worked rapidly to increase capacity. • Clinicians identified the need for a video tool that adheres to privacy standards and links with a technical helpdesk. • There were also concerns over the reduction in services to support the physical health needs of mental health service users.	[29,56,57,75]
Inner setting: Information on the structural characteristics, networks and culture of an organization, as well as the implementation climate (eg, capacity for change)	• Overall, all settings had sufficient capacity to shift to some delivery of telemental health in a short period.	[76,100,102,105]
Staff characteristics: Information on the following psychological attributes and also on any effects of staff demographic and professional backgrounds	• There was some variation in acceptability of remote ways of working for staff depending on their therapeutic approaches. • Telemental health take-up was dependent on perceived experience of patient (positive or negative), comfort with online platform, previous clinical experience. • Some staff felt less confident about professional skills during online compared with in-person consultations, especially those with less clinical experience and those who perceived their patients disliked remote care.	[43,52,111]
Process: Training provided and any processes put in place to support telemental health intervention, planning, and feedback on progress of implementation	• The transition to telemental health occurred usually over a short period. • Training staff to use platforms was mentioned frequently, as was phoning service users to let them know about the transition to telemental health and how care would be provided going forward. • Methods of staff training included courses, shadowing or observing senior colleagues, discussion within clinical teams, facility-level telehealth coordinators, clinical champions providing training, and webinars. • Sources of information for staff: colleagues, government guidelines, prepared consent forms, posts on listservs, American Psychological Association, and other official guidelines. • New workflows had to be developed to allow staff to access patient records remotely. • Despite some training, staff reported lack of support and identified training needs across several studies regarding how to use online platforms and meeting privacy regulations.	[7,28,44,45,50,59,61,62,74,105,112,115]

CFIR domain	Findings	Example references
Service user needs/resources: Statements demonstrating awareness of the needs and resources of those served by the organization (eg, barriers and facilitators and feedback)	• A commonly reported issue was access to technology, particularly among service users with diagnoses such as schizophrenia, service users with a lower socioeconomic status, and older adults (one study mentioned that older adults often lacked access to video software, so preferred phone calls). • Concerns around privacy and confidentiality, and forming a therapeutic relationship may be more difficult when using remote care. • Difficulties for service users to concentrate within a digital environment. • Several studies mention the need for an agreed "Zoom etiquette" for service users, including attire, audio/visual setup, and reducing background distractions. • Stable internet connection was a problem for some service users. • Some clients benefitted from the distance created by online treatment, as they became less inhibited and less dependent on therapist.	[50,62,77,86,98,116]

[a]CFIR: Consolidated Framework for Implementation Research.

Intervention Characteristics

Video and phone calls were the most common modalities used for remote care; studies also reported the use of emails, instant messaging services, apps, prerecorded videos and forums (further details about the modality used in each study can be found in Table 1).

When comparing remote care with traditional face-to-face settings, studies identified advantages for both methods. Benefits for remote care included being more convenient (for both staff and service users), making care more accessible to groups who may previously have been excluded, reducing travel (resulting in both time and cost savings), and helping clinicians understand more about the service user, as they had more insight into their home lives. A further benefit is that more family members were readily able to attend family therapy or family education sessions since care was moved online (eg, [43]). However, clinicians reported difficulties in picking up on nonverbal cues in remote compared with face-to-face care, and that remote care could sometimes require more concentration.

Outer Setting

Services commonly implemented remote methods of working due to "stay at home" orders or national lockdowns, or due to a high level of cases in their local area. Overall, all settings described in papers had sufficient capacity to make a rapid shift to remote forms of care. Several studies in the United States in particular mentioned the impact of health insurance regarding uptake of telemental health (eg, [56]), as not all insurance providers covered remote care. However, this did change during the course of the pandemic as telemental health delivery was eased by the relaxation of policy and billing reimbursements [56,75]. The change from face-to-face to remote delivery of care was also facilitated by professional societies who posted guidelines on their websites to assist clinicians.

Staff Characteristics

Enablers for clinician uptake included supporting clinicians by ensuring supervision, supportive leadership, clear communication, keeping track of clinicians' needs, optimizing physical space for comfort and privacy (eg, using headphones or ergonomic seating), and arranging times away from the computer.

However, staff in several studies reported a lack of initial training for telemental health, and therefore identified training needs regarding the use of online platforms and meeting privacy regulations in particular. In some studies, having no previous experience with telemental health was also found to be associated with higher anxiety [43] and lower uptake [52] of remote care. However, others found that previous experience did not impact clinicians' views of telemental health during the pandemic [47].

Process

As telemental health was not commonly used in most services before COVID-19, staff had to rapidly adjust to a new way of working. Several studies discussed the training which was put in place for staff, which included training courses, shadowing, or observing senior colleagues; discussion within clinical teams' facility-level telehealth coordinators and clinical champions providing training; webinars; and checking official guidelines. New workflows also had to be developed to allow staff to access patient records remotely, and service users had to be informed about the transition to telemental health.

Service User Needs/Resources

In addition to the needs of staff, service users also identified certain needs and resources to enable them to effectively transition to telemental health care. A commonly reported issue was access to technology, particularly among service users with diagnoses such as schizophrenia (eg, [116]), older adults (eg, [50]), and service users from lower socioeconomic backgrounds (eg, [78]). Service users also reported problems having a stable internet connection to allow for uninterrupted communication, which could negatively impact the therapeutic relationship. Concerns were also raised by both clinicians and service users regarding privacy and confidentiality, and in some cases service users had difficulties concentrating on remote care. Several studies (eg, [86,98]) mentioned the need for an agreed "Zoom etiquette" for service users, including attire, audio/visual set up, and background distractions.

Implementation Outcomes

Outcomes of the implementation of telemental health have been summarized below using Proctor et al's [37] taxonomy of implementation outcomes. Further information can be found in Table 3.

Table 3. Implementation outcomes summary findings for telemental health.

Implementation outcome	Findings	Example studies
Acceptability	• Remote methods of care are acceptable to most service users and "exceeded expectations" in terms of satisfaction, but are not viewed as a substitute for face-to-face care. • Clinicians and service users consider the intimacy and connection of face-to-face care are not reproducible on virtual platforms, especially for treatments involving nonverbal communication. • Beyond the pandemic: further data are needed about longer-term acceptability, observance, quality of care, and satisfaction. • Clinician burnout due to more appointments per day and requiring more concentration.	[7,45,60,64,70,74,76,78,87,91,94,96,97,100,104]
Adoption	• Remote working was generally well adopted (most service users switched to remote working). • A few studies also mentioned lower levels of cancellations/no shows, likely due to not having to travel to the service and the removal of other barriers (eg, difficulty fitting care around school or work). • Remote working also had the potential to result in reduced waiting times. • Productivity was generally maintained, or in some cases even increased. • Some studies showed no decrease, just change in modality and need to modify psychological treatment.	[7,50,52,54,56,58,61,75,79,81,82,113,114]
Appropriateness	• Difficulties managing medication prescription during online consultations. • Concerns around user engagement and assessing new patients. • Harder to assess mental status markers such as hygiene or eye contact, or physical symptoms (eg, of opioid withdrawal). Although it allows to know more about home environment and behavior outside of clinic. • Does not capture the richness of in-person interaction. • Online felt safer for clinicians providing care to service users at risk for violence and behavioral dysregulation. • Not appropriate for patients with auditory or visual impairments, or with conditions such as migraines.	[56,60,78,82,99,100,112]
Feasibility	• Links with service user and staff needs and resources, in particular problems accessing technology/private space/stable internet connection. • All studies reported good feasibility at least for the short-term emergency response during the pandemic. • However, it was not possible to use for specific therapies that require physical presence (role play, collaborative models). Telemental health was less suitable for treating trauma, for clients with severe anxiety, children, and clients with cognitive impairment. • Insurance coverage and legal aspects affected feasibility of implementation in some countries. However, most health insurances caught up and started covering costs.	[7,56,58,62,64,73,74,78,82,94,96,104]
Fidelity	• No studies explored this area.	
Implementation cost	• Limited information about cost of intervention, suggested to be "cost effective" without any presentation of costs. • Reduced travel costs.	[59,70,87,103]
Penetration	• Prior to the pandemic, few services used telemental health and for those that did, uptake was low. After the first few weeks, most or all of services were conducted remotely.	[7,54,105]

Implementation outcome	Findings	Example studies
Sustainability	• Rates of telemental health use fell as COVID-19 rates declined in the summer of 2020. Links with findings that not all staff and service users would want to continue using remote methods of care after the pandemic ends. • Flexibility is a key advantage of telemental health versus face-to-face care. • There are some aspects of remote working that services would like to keep, as they provide benefits such as being more efficient and enabling access for certain groups. • Some barriers to remote working (such as lack of experience with online methods of care) have been reduced, making it more likely telemental health will continue to some extent.	[43,64,85,93,95,104]

Acceptability

Remote care was seen as satisfactory by the majority of clinicians and service users in most studies in the context of the pandemic. A number of studies also reported that telemental health enabled some groups to access care who found it difficult to engage with face-to-face support (eg, [7]). Some clinicians reported that they would also be willing to continue with some aspects of remote care in the future (eg, [43,77]). However, it is important to note that while acceptability was high overall, this was not the case for all groups; for example, Grover et al [71] reported acceptability rates of around 45% for both clinicians and service users using services in a range of settings in India. Further details of satisfaction and acceptability outcomes are presented in Table 4.

Telemental health services were acceptable to people during the pandemic as a way of continuing their treatment; however, findings from several studies also indicated that participants wanted at least some appointments to be face-to-face once restrictions on in-person contact had loosened.

Table 4. Levels of acceptability of telemental health during the COVID-19 pandemic.

Author	Type of service	Service location	Acceptability data
Aafjes-van Doorn et al [43]	Psychology/psychotherapy/counseling service	United States, Canada, Europe (Hungary, Italy, United Kingdom, Germany, Norway, Sweden, Switzerland, Latvia, Ireland)	• Clinician views: Mainly positive attitudes toward video therapy were reported (mean 3.42 [SD 0.50]; range: 2.31-4.69). Views on video therapy had become more positive since the pandemic (t140=2.06, *P*<.05); video therapy was still viewed as somewhat less effective compared with in-person therapy (mean 2.19 [SD 0.65]; range: 1.00-4.00). • Service user and carer views (reported by clinicians): Only 7% (n=10) thought their patients experienced video therapy negatively. The majority perceived patient experience as either positive (N=88, 63.8%) or neutral (N=40, 28.4%).
Békés et al [46]	Psychology/psychotherapy/counseling service; private hospital/clinic; CMHT[a] and outpatient services	Canada, United States, Europe (countries not stated)	• Service user and carer views (reported by clinicians): Psychotherapists reported that their patients had an extremely positive (N=20, 13.8%), positive (N=71, 49%), or neutral (N=40, 27.6%) experience with online psychotherapy. About 7.6% of the psychotherapists thought that their patients experienced online psychotherapy somewhat negatively and none of the psychotherapists reported an extremely negative patient experience.
Békés et al [47]	CMHT and outpatient services; psychology/psychotherapy/counseling service; private hospital/clinic	Canada, United States, Europe (countries not stated)	• Clinician views: Challenges included technical/internet problems (64.7%), patients not having a private space (46.8%), risk of patient (44.7%) or therapist (26.3%) getting distracted, difficulty feeling connected to patients (29.5%) or reading their emotions (27.4%), difficulty keeping professional boundaries (23.2%), and confidentiality concerns (16.3%). About 64.2% (n=122) reported their relationships with service users felt as authentic to before COVID-19, 46% felt as emotionally connected, and 64% reported no change to the therapeutic relationship. • Service user and carer views (reported by clinicians): Most therapists reported a positive (n=101, 53.2%) or neutral (n=55, 28.9%) patient experience, with only 34 reporting a somewhat negative online therapy experience for their patients (25.8%).
Benaque et al [48]	Voluntary sector/nonprofit	Spain	• Clinician views: 81% of clinical staff considered the quality of telemedicine consultations to be either good or excellent; 75% viewed telemedicine visits as equal or better than face-to-face consultations.
Colle et al [58]	CMHT and outpatient services	France	• Clinician views: 94.1% of psychiatrists were satisfied with teleconsultations in this context. • Service user and carer views: 89.5% of patients were satisfied and 73.3% of patients spontaneously expressed their gratefulness for remote care.
Dores et al [60]	Psychology/psychotherapy/counseling service	Portugal	• Clinician views: 21 (out of 71) psychologists (29.6%) considered their experiences to be neither negative nor positive. Most of the respondents considered their experience with digital technologies to be either positive (n=37, 52.1%) or very positive (n=13; 18.3%). None reported their experiences as negative.
Grover et al [69]	CMHT and outpatient services	India	• Service user and carer views: 75.5% of patients and family members were satisfied they could remain in touch with the treating doctor. A quarter of patients had difficulty in procuring clozapine, with clozapine not being available in their locality in 15% of cases and 3.4% having to switch their brand. 25% were able to get the absolute neutrophil count done in the previous month.

Author	Type of service	Service location	Acceptability data
Grover et al [70]	CMHT and outpatient services; inpatient mental health service; private hospital/clinic	India	• Service user and carer views (as reported by clinicians): 21% reported that non-HCWs[b] in quarantine were dissatisfied, 19.9% reported that HCWs in quarantine were dissatisfied, and 13.5% reported that HCWs working with patients with COVID-19 were dissatisfied. • Clinician views: Participants rated their satisfaction with the services they were currently providing to their patients with a mean of 45.8% (SD 28.6) on a Likert scale from 0 to 100.
Grover et al [71]	Medical colleges, government-funded institutes, general hospital psychiatry units	India	• Clinician views: Overall satisfaction with the mental health services being catered; the participants rated their mean level of satisfaction as 46.6% (SD 27.6).
Haxhihamza et al [72]	Day hospital	Macedonia	• Service user and carer views: 20/28 strongly agreed/agreed that the medical care received was just about perfect; 4 patients agreed that they were dissatisfied with some things about their medical care (1 strongly agreed and 3 agreed); 20 (strongly) agreed that they can get medical care whenever they need it; 20 (strongly) agreed that they have easy access to medical specialists; 4 (strongly) agreed that the wait for emergency treatment was too long.
He et al [73]	Helplines; online media programs	China	• Service user and carer views: Feedback from clients demonstrated that more than 50% felt their negative emotions, such as anxiety and depression, were relieved.
Hom et al [74]	Private hospital/clinic	United States	• Service user and carer views: Patients who have been discharged thus far (n=10) have also expressed confidence in their aftercare plans; 2 patients who completed the exit survey reported very positive experiences and both rated their care as 9/10.
Izakova et al [77]	CMHT and outpatient services; inpatient mental health service	Slovakia	• Clinician views: 69.4% of them have considered it as an adequate form for diagnostics and therapy in the common clinical practice; 51.6% want to use it at a limited level with the defined guidelines in future.
Johnson et al [7]	All service settings, including inpatient, CMHTs, voluntary sector	United Kingdom	• Clinician views: A majority (n=818, 74.0% of respondents) agreed/strongly agreed that video calls were suitable to assess progress of existing service users, but only 39.8% (n=442) agreed/strongly agreed that they were suitable for making the initial assessments. A majority (n=725, 65.8%) agreed/strongly agreed that use of remote care had resulted in not having contact with some service users who had not engaged with remote appointments.
Lakeman and Crighton [82]	Psychology/psychotherapy/counseling service	Australia	• Clinician views: 32% (n=7) stated they were not confident at all in delivering online DBT[c], 50% (n=11) reported being "a little" confident and 4 reported feeling confident doing so; 14 respondents identified limited access to the internet, appropriate devices, or internet blackspots as being significant obstacles to engagement.
Lynch et al [86]	CMHT and outpatient services	United States	• Service user and carer views: The telehealth acceptance rates of the CP[d] subsample indicated that 90% (n=18) enrolled at the time of conversion agreed to telehealth sessions within 10 days of the service transition.
Olwill et al [90]	CMHT and outpatient services	Ireland	• Clinician views: 92% of respondents (n=24) (and 100% consultants [n=12]) reported lower confidence in making a diagnosis. 96% (n=25) agreed that the lack of visual cues affected their assessment of the patient; 70% agreed that they found it more difficult to consider discharging a patient; 88% agreed they found it more difficult to establish a therapeutic alliance with new patients.

Author	Type of service	Service location	Acceptability data
Sheehan et al [105]	CMHT and outpatient services	United Kingdom	• Clinician views: 53.3% reported concerns of having to adapt too quickly to new ways of working; 37.9% reported having to learn new technologies too quickly or without sufficient training or support; 45.3% raised concerns around engaging patients with learning difficulties or autism; 23.7% had concerns around safeguarding or risk management; 27.9% reported greater workload than usual.
Wang et al [111]	Not stated/unclear	United States and China	• Clinician views: Before COVID-19, 25% of US psychoanalytic practitioners felt mainly negative about teletherapy and 36% felt mainly positive, as compared with only about 9% and 47% of CAPA[e] practitioners, respectively; during the pandemic about 23% of US psychoanalytic practitioners felt mainly negative about teletherapy and about 37% felt mainly positive, compared with about 2% and about 58% of CAPA practitioners, respectively.
Wilson et al [112]	CMHT and outpatient services; crisis and emergency mental health services; inpatient mental health service	United Kingdom	• Clinician views: Staff reported feeling less able to assess women attending the perinatal mental health service using telemedicine, particularly their relationship with their baby (43.3%, 90/208), and to mobilize safeguarding procedures (29.4%, 62/211).

[a]CMHT: community mental health team.

[b]HCW: health care worker.

[c]DBT: dialectical behavior therapy

[d]CP: complex psychosis

[e]CAPA: China American Psychoanalytic Alliance.

Adoption

Adoption rates were relatively high across studies, with most services or clinicians moving their appointments to remote methods. Rates of adoption of telemental health for service users who were already receiving care at the start of the pandemic ranged from 48% [89] to 100% [44,67,110]. Some studies reported face-to-face appointments still took place if necessary, for example, for initial assessments or for medication reviews (eg, [116]). Most studies that examined impact on attendance reported no adverse effects on attendance rates after introducing telemental health: there was either no difference in missed appointments when comparing remote with face-to-face care [45,86], or nonattendance after adoption of telemental health decreased [79,91,103]. Further details about adoption of telemental health across studies can be found in Table 5.

While most studies reported high adoption rates, a few studies reported a decrease in attendance: for example, Erekson et al [61] (though possibly because of the university setting) and Dores et al [60] identified challenges in retention due to low client adherence, lack of privacy, interruptions at home, lack of appropriate technology, or simply preference for face-to-face contact.

There was also evidence to indicate that adoption rates of telemental health fell as COVID-19 cases decreased (eg, [84,85]).

Table 5. Levels of adoption and coverage of telemental health during the COVID-19 pandemic.

Author	Type of service	Service location	Adoption/coverage data
Anton et al [44]	General hospital/physical health service	United States	77% (n=20) of those approached via telephone enrolled in the program, higher than the observed in-person rates of 61%. 80% of patients who were contacted by phone in the hospital agreed to be enrolled, lower than the 98% success rate when staff approaches patients in person at the bedside. 100% of patients who received in person care and 100% on the waitlist (n=5) transitioned to telepsychotherapy.
Barney et al [45]	CMHT[a] and outpatient services	United States	The percentage of provider telemedicine visits increased from 0% to 97%. The number of overall clinic visits did not decline when compared with that a year before (337 visits in March 2019 vs. 332 visits in March 2020), No-show rates were comparable between remote and face-to-face care.
Békés et al [47]	CMHT and outpatient services; psychology/psychotherapy/counseling service; private hospital/clinic	Canada, United States, Europe (countries not stated)	Before COVID-19 an average of 23 sessions (SD 10.58) per week were conducted in person, 3 sessions (SD 2.28) by phone, and 1 session (SD 2.84) online via videoconferencing. During COVID-19 an average of 7 (SD 7.91) of the in-person sessions changed to sessions by phone, and 15 (SD 10.33) to online sessions.
Benaque et al [48]	Voluntary sector/nonprofit organization	Spain	Initially, average weekly visits dropped from 657 to 254 in the first week after the state of alarm was declared. This drop was of 44% for follow-up visits and 40% for on-demand consultations. By week 16 the total number of visits (n=514; 78%) was almost up to prepandemic levels.
Boldrini et al [52]	CMHT and outpatient services; psychology/psychotherapy/counseling service; private hospital/clinic	Italy	42.1% (SD 28.9) of their psychotherapy treatments were interrupted during the lockdown. The remainder of their treatments was primarily delivered via online video (63.7% [SD 38.3]) or telephone (29.1% [SD 25.3]). 7.2% (SD 15.1) of their treatments were delivered face-to-face.
Carpiniello et al [54]	CMHT and outpatient services; inpatient mental health service	Italy	75% of appointments were switched to remote. Telehealth modalities used were mainly phone calls (100% of the Italian Departments of Mental Health), videocalls (67%), or emails (19%), with 41% of units adopting all these means of contact.
Chen et al [56]	General hospital/physical health service	United States	The outpatient psychiatry division switched from under 5% virtual visits in March 2019 to over 97% in March 2020. Productivity was maintained at about 95% of previous levels, with 9206 virtual visits in March 2020. Between March 30 and April 24, 2020, 30% of the virtual visits were conducted via phone.
Childs et al [57]	CMHT and outpatient services	United States	Before COVID-19, 100% of care was delivered in person. In the first week after shutdown, telehealth comprised 65.45% of visits (100% over the telephone). In the second week, 91.6% of visits were conducted using telehealth (83.49% over the telephone and 15.6% video). By the third week 99% of appointments used telehealth (30% using video). The percentage of appointments using video increased weekly, peaking at 69.9%
Colle et al [58]	CMHT and outpatient services	France	After 2 weeks of teleconsultations, 376 (91.0%) out of the 413 previously planned appointments were performed.
Connolly et al [29]	CMHT and outpatient services; Veterans Affairs service	United States	Daily TMH-V[b] encounters rose from 1739 on March 11 to 11,406 on April 22 (556% growth, 222,349 total encounters). Between March 11 and April 22, 114,714 patients were seen via TMH-V. A total of 88,908 (77.5%) were first-time TMH-V users. A total of 12,342 mental health providers completed a TMH-V appointment between March 11 and April 22; 4281 (34.7%) were first-time TMH-V users. Daily telephone encounters rose from 6348 on March 11 to 34,396 on April 22 (442% growth). Daily in-person encounters fell from 57,296 on March 11 to 10,931 on April 22 (81% decrease).

Author	Type of service	Service location	Adoption/coverage data
Dores et al [60]	Psychology/psychotherapy/counseling service	Portugal	During the lockdown period, 17 (15.7%) of the 108 psychologists discontinued therapy and counseling; 53 (58.2%) continued to provide services to most or all of their clients; 23 psychologists (25.3%) decreased the number of clients they saw to a range of between 0% and 25%, and for another 15 psychologists (16.5%) that number diminished to a range of between 26% and 50%.
Erekson et al [61]	Psychology/psychotherapy/counseling service	United States	Attendance rates for individual therapy temporarily dropped by about 35% but climbed to previous levels within 2 weeks. Group therapy attendance dropped by about 30% but did not fully recover, remaining about 15% lower after 2 weeks. The number of clients receiving individual therapy in 2020 dropped by 43%. Between March 22 and April 4, 2020, the service had fewer than half the intakes of any other recent year.
Gaddy et al [65]	Music therapy service	United States	Of the 869 respondents indicating current contact hours, 70.54% reported that they were providing alternative services, including telehealth services (54.81%), virtual music lessons (17.01%), prerecorded songs/playlists (16.98%), and prerecorded video sessions (16.00%). Individual services increased (mean 61.58% [SD 41.26], whereas group services decreased (mean 24.97% [SD 37.56]).
Gomet et al [67]	General hospital: addiction service	France	100% of service users took part in remote care
Graell et al [68]	CMHT and outpatient services; inpatient mental health service	Spain	During the study period, a total of 1818 outpatient consultations were carried out: 1329 (73.10%) by telephone or videoconferencing and 489 (26.9%) face-to-face.
Grover et al [69]	CMHT and outpatient services	India	The majority of the patients reported that they were in touch with their treating doctor (81.5%), with contact initiated by the treating team in 79% of patients.
Grover et al [70]	CMHT and outpatient services; inpatient mental health service; private hospital/clinic	India	Use of teleservices almost doubled during the lockdown period: 206 (52%) participants provided telecommunication services during the lockdown period, 186 (47%) provided free tele-consultation to the general public, and 269 (67.9%) provided free tele-consultation to their patients; 132 (33.3%) were using both voice and video calls (combination of free and paid services), 31 (7.8%) were using only voice calls (combination of free and paid services), and 31 (7.8%) were using only voice calls (combination of free and paid services).
Grover et al [71]	Medical colleges, government-funded institutes mental hospital setting, general hospital psychiatry units	India	Around 25% of institutes began offering telemental health services; 45.9% of institutes reported that telecommunication services continued during lockdown. Mental health services were being provided to people in quarantine (66.1%) and those with COVID-19 infection (59.6%), family members of patients with COVID-19, and those in quarantine (40.4%).
Humer et al [75]	Psychology/psychotherapy/counseling service	Czech Republic, Germany, Slovakia	Among all countries, the combined (personal contact + telephone + internet) number of patients treated on average per week during COVID-19 (mean 18.32 [SD 12.86]) did not differ from the combined (personal contact + telephone + internet) number of patients treated on average per week in the months before the COVID-19 situation (mean 19.35 [SD 13.73]), $t_{337}=-1.506$; $P=.133$.
Humer et al [75]	Psychology/psychotherapy/counseling service	Austria	During the COVID-19 pandemic, face-to-face psychotherapy remained the most abundant treatment modality.
Khanna et al [79]	CMHT and outpatient services	Australia	There was a 3% increase in appointment bookings compared with the same period in 2019. Cancellation/nonattendance rate dropped from an average of 19% last year to 12% for 2020
Kopec et al [80]	CMHT and outpatient services	United States	Prior to COVID-19, Network180 served an average of 2390 patients/month, which decreased to an average of 1921 patients/month during the pandemic. This decrease was noted most significantly in crisis services (averaging 822 patients/month before COVID-19 and 640 patients/month during COVID-19). Telehealth increased from 5% of all services prior to COVID-19 to 84% of all services during COVID-19. The majority of services provided via telehealth were audio only (versus audiovisual), with a ratio of 1.9:1 for crisis services and 4:1 for noncrisis services.

Author	Type of service	Service location	Adoption/coverage data
Looi et al [84]	Psychiatrist telehealth service	Australia	Percentage of consultations conducted using telemental health—ACT: 62% (April), 58% (May); NT: 53% (April), 51% (May); SA: 69% (April), 58% (May); Tasmania: 38% (April), 40% (May)
Looi et al [85]	Psychiatrist telehealth service	Australia	The majority of private practice was conducted by telehealth in April but was lower in May as new COVID-19 case rates fell. Percentage of consultations conducted using telemental health—NSW: 56% (April), 52% (May); QLD: 63% (April), 53% (May); VIC: 61% (April), 59% (May); WA: 51% (April), 36% (May)
Lynch et al [86]	CMHT and outpatient services	United States	The service continued providing all services except community-based coaching via telehealth. 90% of patients with complex psychosis accepted telehealth sessions and maintained their specific treatment plans. 2 opted out of telemental health. Mean comparisons between session attendance and cancellations/no-shows during the 6-week period before and after telehealth conversion showed no significant differences in service utilization.
Medalia et al [88]	CMHT and outpatient services	United States	Tracking the number of RS enrollees with active participation indicated that in the week before telehealth conversion, when shelter-in-place recommendations commenced, participation dropped from 94% to 52%; after telehealth conversion, participation rose from 67% in the first 4 days to 79% after 1 week and to 84% after 2 weeks.
Miu et al [89]	CMHT and outpatient services	United States	A total of 816 participants comprised the analytic sample. A total of 400 converted to telehealth and of those 64 were SMI[c]. The conversion rates from in-person psychotherapy to teletherapy were similar for SMI (n=64, 51.6%) and non-SMI (n=334, 48.3%) groups. The rate at which the SMI group converted from in-person therapy to teletherapy (52%) was not statistically different from that of the non-SMI group (48%) during COVID-19.
Patel et al [91]	All National Health Service Trust services	United Kingdom	From March 2020, in - person contacts reduced substantially from around 9000 per week to 3000 per week in early April 2020. Over the same period there was an increase in remote contacts from around 2500 per week in early March 2020 to around 8000 per week by the end of April 2020. Total clinical contacts per week dropped from around 12,500 in mid - March to around 10,000 in mid - April 2020. The number of unattended appointments was temporarily reduced in April, May, June, and September 2020.
Pierce et al [93]	Variety of MH service settings	United States	Psychologists estimated that telepsychology comprised 85.53% of their clinical work during the pandemic, compared with the prepandemic context when only 7.07% of their clinical work was conducted remotely.
Probst et al [94]	Psychology/psychotherapy/counseling service	Austria	Face-to-face psychotherapies in personal contact were reduced and remote psychotherapies (via telephone or internet) were increased in the early weeks of the COVID-19 lockdown as compared with the months before. Although average increases in psychotherapies via telephone (979%) or via internet (1561%) were dramatic, there was an undersupply of psychotherapy in Austria in the early weeks of the COVID-19 lockdown as the total number of patients treated on average per week was lower in COVID-19 lockdown than in the months before.
Reilly et al [95]	Various service types	United States	There was uptake of telemental health by approximately 80% of respondents by late March or early April 2020. All but 2.11% (19/903) of providers in this study made practice adjustments (transition to telemental health).
Rosen et al [98]	VHA[d] mental health services	United States	VHA provided nearly 1.2 million telephone and video encounters to veterans in April 2020 and reduced in-person visits by approximately 80% when compared with the October 2019 to February 2020 period before the pandemic. By June 2020, VHA had an 11-fold increase in encounters using direct-to-home video and a fivefold increase in telephone contacts relative to before the pandemic. VHA reduced in-person visits by approximately 80% when compared with the October 2019 to February 2020 period before the pandemic.

Author	Type of service	Service location	Adoption/coverage data
Scharff et al [100]	Community-based training clinic providing therapy	United States	The Psychological Services Centre saw an initial retention rate of 82% in the first week of teletherapy, with more clients resuming services in the weeks that followed.
Schlegl et al [101]	Inpatient mental health service	Germany	More than 80% of patients with bulimia nervosa received face-to-face therapy before the COVID-19 pandemic (81.8%) compared with 36.4% during the pandemic (ie, a decrease by 55.5%). Use of videoconference-based therapy increased from 3.6% to 21.8% and use of telephone contacts from 18.2% to 38.2%, whereas the use of additional online interventions decreased from 3.6% to 0%. Face-to-face psychotherapy decreased by 56% but videoconferencing therapy was only used by 22% of patients.
Sciarrino et al [102]	Veterans Healthcare Administration	United States	Approximately 76% of veterans engaged in posttraumatic stress disorder treatment chose to continue despite the COVID-19 pandemic via telehealth.
Sequeira et al [103]	Residential services	United States	After transition to teletherapy, the average daily virtual program census from March 19, 2020, to April 18, 2020, was 3.3 intensive outpatient program patients and 22.4 outpatients. These numbers indicate a slight decrease in intensive outpatient program patients (−0.3/per day) and an increase in outpatients seen per day (+2.7/per day). There was an increase in the outpatient sessions retained and a decrease in the appointments cancelled.
Severe et al [104]	CMHT and outpatient services	United States	Take up for remote care was over 95%; 82.8% (n=202) initially chose to receive psychiatric care through video visits, whereas 13.5% (n=33) chose telephone visits; 1.2% (n=3) decided to postpone care until in-person visit availability.
Sharma et al [28]	General hospital/physical health service	United States	By March 20, 2020, 67% of all outpatient appointments were conducted at home. Most of these appointments were conducted by phone with some TMH sessions. By March 27, 2020, 90% of all outpatient appointments were done at home, predominantly by phone (59%) but increasingly by HB-TMH[e] (31%). One week later (April 3, 2020), these rates were 48% versus 45%, respectively. By March 31, 2020, 98% of faculty completed expedited training and obtained departmental approval for HB-TMH services during the COVID-19 crisis. By April 10, 2020, HB-TMH was offered to all established outpatients for individual visits. Only the crisis clinic continued a regular in-clinic presence.
Sheehan et al [105]	CMHT and outpatient services	United Kingdom	64% were spending at least some time working from their workplace (either solely or in combination with home working); 33.9% were working from home only. Just over a third were at the workplace (n=178, 35.1%) and the remainder (n=147, 28.9%) worked from both home and at the workplace.
Termorshuizen et al [107]	CMHT and outpatient services	The Netherlands and United States	Most transitioned to telehealth care (United States 45%; Netherlands 42%), with fewer still receiving face - to - face care (United States 3%; Netherlands 6%), or not having been able to engage with their provider at all (United States 6%; Netherlands 5%).
Uscher-Pines et al [108]	CMHT and outpatient services and private hospital/clinic	United States	Most of the psychiatrists had transitioned to fully virtual practices. Only a quarter of the participants were seeing any patients in person.
Uscher-Pines et al [109]	CMHT and outpatient services; private hospital/clinic; general hospital/physical health service	United States	Telemedicine use: None (in-person only), 1 (5.6%); phone only, 2 (16.7%); video only, 0 (0.0%); combination of video and phone, 15 (83.3%).
van Dijk et al [110]	CMHT and outpatient services; psychology/psychotherapy/counseling service	The Netherlands	Treatment adherence was 100%.
Yellowlees et al [115]	General hospital/physical health service	United States	By the second day after shutdown, only 8% (n=52) of our appointments were in-person clinic visits, compared with our baseline average of 98%. By the third business day, 100% (n=73) of appointments were conducted virtually, with 92% (n=67) via videoconference and 8% (n=6) by phone.

Author	Type of service	Service location	Adoption/coverage data
Zulfic et al [116]	CMHT and outpatient services	Australia	Some patients still required regular face-to-face reviews, including the 91 patients (29%) who are treated with depot medications and 71 (23%) taking clozapine.

[a]CMHT: community mental health team.

[b]TMH-V: telemental health: video.

[c]SMI: serious mental illness.

[d]VHA: Veterans Health Administration.

[e]HB-TMH: home-based telemental health.

Appropriateness

There were some concerns raised over the appropriateness of remote care, for example, studies reported difficulties managing medication (eg, [45,108,109]) and concerns around engaging and assessing new patients (eg, [78]). Clinicians also found it harder to assess some physical indicators of mental health status (eg, hygiene, eye contact, physical symptoms of opioid withdrawal) without being able to see the service user in person. However, by contrast, remote methods of working felt safer for clinicians who worked with service users at risk for violence and behavioral dysregulation (eg, [56]). Online care was also not necessarily appropriate for patients with auditory or visual impairments, or with conditions such as migraines.

Staff reported concerns around the management of risk and safeguarding of service users when using remote methods of care (eg, [79,93]). Some helpful features of platforms which were thought to improve safety were using the waiting room function, being able to remove call participants, renaming participants (to protect anonymity), and using the private chat function.

Feasibility

In general, all studies reported good feasibility, at least for the short-term emergency response during the pandemic. However, some studies reported that telemental health is not suitable for all types of therapy, for example, those that require a physical presence (exposure therapy, role play, collaborative models; eg, [106]). Telemental health may also be less suitable for treating trauma [62,102]; clients with severe anxiety [62], learning difficulties or autism [105]; children [62]; and clients with cognitive impairment [62,90].

Cost-Effectiveness

There was limited information about costs of implementation of remote care in the included studies and no actual costs of telemental health were reported in the papers. However, initial evidence suggests remote care is not a costly intervention, with 1 paper stating that telemental health is “cost-effective” [69], while another mentions the use of “low-cost technologies” by clinicians [72].

Penetration

There was widespread penetration (the extent to which telemental health was integrated into mental health services) of remote methods of care delivery due to the COVID-19 pandemic, despite few services utilizing telemental health previously. Services were able to rapidly adapt to this new way of working, with the majority of appointments conducted remotely after the first few weeks of “stay at home” orders.

Sustainability

The sustainability of telemental health cannot be completely determined from the included studies, as they present data mostly from the early stages of the COVID-19 pandemic. However, there was some indication that although remote working was widely accepted as a necessity, once restrictions loosened, rates of telemental health use declined (corresponding with the drop in cases in Europe in summer 2020). This correlates with findings that not all staff and service users would want to continue using remote methods of care after the pandemic ends. However, there are some aspects of remote working that both clinicians and service users would like to keep in the future in combination with face-to-face care (eg, [93,104]), as this approach has benefits such as being more efficient, flexible, and enabling access for certain groups (eg, [7,60,62]).

Clinical Outcomes

Comparing the clinical outcomes of face-to-face and remote care using quantitative measures indicated that telemental health approaches could be as effective as face-to-face care (eg, [55,103]), although it should be noted that most studies were on a small scale. Several studies also reported no psychiatric decompensations after switching to remote care (eg, [86,88]). However, it is important to note that clinical outcomes for telemental health were not comparable for all service users; for example, Dores et al [60] found that a quarter of psychiatrists reported poorer clinical outcomes after switching to remote care. Another study also indicated that only one-third of clinicians felt as though telemental health consultations were comparable to prepandemic sessions [114]. A full presentation of the clinical outcomes reported in included studies is shown in Table 6.

Although the quality of therapeutic relationships reported by studies was generally good, clinicians reported problems reading patients’ emotions (eg, [43]) or feeling less connected to the service user compared with face-to-face sessions (eg, [56]). Clinicians also reported difficulties regarding feeling and expressing empathy remotely. Other challenges to therapeutic relationships when using remote care included a lack of client engagement, possible misunderstandings due to lack of nonverbal signals, common context, or not having a clear idea of patients’ physical state (alongside reduced privacy).

Table 6. Studies which reported clinical outcomes of telemental health.

Item	Type of service	Country	Clinical outcomes
Cheli et al [55]	Psychology/psychotherapy/counseling service	Italy	• 5/6 patients reported a reliable change index (≥1.96) in the primary outcome (Symptoms Checklist 90 [SCL-90] total score), and 1 reported a stable symptomatology. • All the patients reported a significant decreasing trend in the Depression, Anxiety and Stress Scale (DASS-21) total score (secondary outcome), as determined by Kendall τ (P<.001).
Dores et al [60]	Psychology/psychotherapy/counseling service	Portugal	• Comparing remote to in-person care (psychologists): 65 (71.6%) considered the results to be more of less the same, 4 (4.4%) reported obtaining better results with at-distance sessions, and 22 (24.2%) considered that at-distance sessions have yielded worse results than in-presence sessions. • Comparing remote with in-person care (service users): Remote and in-person sessions were more or less the same (n=71; 78.0%). Six (6.6%) of the respondents reported receiving better feedback (ie, the clients preferred the online sessions), and 1 (1.1%) received much better feedback. Even so, 13 (14.3%) psychologists received worse feedback from their clients about this type of intervention.
Erekson et al [61]	Psychology/psychotherapy/counseling service	United States	• Comparing current students (who received telemental health) with those in previous years (who received face-to-face care) found that students in previous years were not significantly different in their achievement of reliable improvement compared with those in 2020 (χ23=10.43, P=.015). • However, students in previous years were significantly more likely to deteriorate than those in 2020 (χ23=8.48, P=.04).
Gomet et al [67]	General hospital/physical health service (addictions service)	France	• 13 out of the 16 patients did not relapse during the data collection period.
Lai et al [81]	Day center (dementia service)	Hong Kong	*Patient outcomes* • The MoCA[a] scores in the intervention group (who received additional services using video conference, rather than telephone only) remained largely stable, whereas the MoCA scores for the control group fell after the 4-week study period ($F_{1,58}$=17.97, P<.001, ηp^2=0.24). • Quality of life scores were higher for the intervention group by the end of the study period ($F_{1,58}$=5.54, P<.05, np^2=0.49). • Scores on behavioral and psychological problems remained stable for both groups. *Caregiver outcomes* • Improvement in both physical and mental status of the caregivers was identified—($F_{1,58}$=60.30, P<.001, np^2=0.51) and ($F_{1,58}$=49.13, P<.001, np^2=0.46), respectively—a reduction in perceived burden ($F_{1,58}$=19.04, P<.001, np^2=0.25), and an increase in self-efficacy ($F_{1,58}$=17.30, P<.001, ηp^2=0.23).
Lynch et al [86]	CMHT[b] and outpatient services	United States	• During the 12-week study timeframe, the subsample of participants with complex psychosis remained psychiatrically stable; there were no psychiatric decompensations or referrals to a higher level of care.
Medalia et al [88]	CMHT and outpatient services	United States	• There were no psychiatric decompensations after conversion to telehealth.
Sequeira et al [103]	Residential services (obsessive compulsive disorder)	United States	• There were overall trends in reductions of scores of the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS), The Centre for Epidemiologic Studies Depression Scale (CES-D), The 7-item General Anxiety Disorder-7 (GAD-7), and Distress Intolerance Index (DII) across all patients, indicating that the telemental health program was effective in reducing symptoms of obsessive compulsive disorder, anxiety, and depression.

Item	Type of service	Country	Clinical outcomes
Wyler et al [114]	Mental health team and outpatient services	Switzerland	• For about 1 in 3 cases, therapists reported that they felt the sessions were at least fairly comparable to pre-COVID-19 sessions or that the restrictions were not particularly problematic.

[a]MoCA: Montreal Cognitive Assessment.

[b]CMHT: community mental health team.

Social Outcomes

One study [81] compared social outcomes in a trial comparing telephone-only care with caregivers of older adults with neurocognitive disorder, with supplementary video care to both carers and service users. Findings indicated that those who received both telephone and video support had greater resilience, better cognitive functioning, and a higher quality of life.

Organizational and Care Delivery Outcomes

Improved communication was noted between staff when using telemental health when compared with traditional face-to-face care, as the use of online file sharing or discussion platforms facilitated communication between staff (eg, [74,105]). The use of online methods also facilitated staff training and some staff reported that remote working resulted in a better work–life balance (eg, [59]).

Discussion

Summary of Findings

This review collated evidence regarding the implementation and outcomes of remote working in mental health services in the context of the COVID-19 pandemic. Most studies indicate a relatively high level of activity, suggesting that at least in the services studied in higher-income countries, much mental health care can be shifted to telemental health in a crisis. Services mainly reported using a mixture of phone and video calls, with both service users and clinicians varying in their preference for these modalities. There were some indicators of reduced numbers of missed appointments, potentially due to the greater convenience of remote care, which may make access to services easier for some service users.

There was reasonable acceptability across the studies, at least in conditions where the alternative may have been no contact with services at all. However, there were situations where telemental health may be less acceptable, including for new patients, physical health aspects of care, and for service users without a private space at home to use for therapy. Telemental health also may not be as feasible for certain types of support, including support which needs a physical presence such as exposure therapy or role play. This finding reflects those in a systematic review by Turgoose et al [117], which found that service users had concerns around managing emotions during exposure tasks without the physical presence of a clinician. There was also evidence that telemental health may not be feasible for some clinical presentations, including some service users with psychosis, learning difficulties, or autism. Clinicians also reported a decrease in their ability to develop and maintain a strong therapeutic relationship with service users, due to being unable to pick up on nonverbal cues and a lack of connectedness, something which was also identified in a review conducted prior to the pandemic [118]. The acceptability levels found in this study are not dissimilar to previous studies (eg, [15]), even though the participants in the current studies are less likely to be volunteering to pilot a new type of care and more likely to be using telemental health because they have no alternative.

Few formal investigations of how to improve implementation were identified in this review, which may reflect the rapid nature of research conducted during the pandemic. However, some strategies for improving adoption/penetration/acceptability may include staff training, the use of telemental health champions, strategies for introducing service users to technology, and providing some simple guidance on how to use it best, identifying situations or populations when telemental health is not a good idea and those where it might be better. There was also a lack of fidelity assessments when therapies had to be adapted to fit telemental health delivery formats; therefore, little is known about the consequences of these adaptations.

Our interpretation of this pattern of findings is that the successful delivery in a pandemic of telemental health should not necessarily be seen as confirmation that people are happy with this mode of delivery long-term, as some of the identified problems may become more serious over time, and reports of being satisfied may have reflected awareness that at the time of the study, it was difficult to offer care by any other means. The longevity of these changes will ultimately turn not only on information technology, safety, and quality, but also on whether policy changes will support the reimbursements and regulatory adjustments implemented during the current crisis [29,57].

Implications for Future Research

There was a lack of reporting in included studies of trying to identify and reach those patients who are at increased risk of digital exclusion (Textbox 1). The needs of those at risk of digital exclusion are still largely underreported in both pre-COVID-19 [15] and COVID-19–specific literature and should be made a priority for future research. Studies also included little information regarding the cost-effectiveness of telemental health implementation. Further research is needed to explore the differences in cost (both to the service and to the service user) between face-to-face and telemental health care. Further research can also formally compare (rather than simply observe) different delivery support strategies that can improve the implementation and potentially also the clinical effectiveness of telemental health, including for specific conditions and service user groups.

Textbox 1. Lived experience perspective commentary.

Lived experience commentary by Karen Machin and Raza Griffiths, members of the NIHR Mental Health Policy Unit's Lived Experience Working Group.

Systematic reviews aim to give an overview of research findings around a particular topic, although, as in this review, they may find that many of the primary studies are of moderate to low quality. At times of intense pressure, such as those presented by the COVID pandemic, overviews may be welcomed, and researchers may feel a need to respond promptly. This urgency creates a potential for gaps to be overlooked.

The main concern for us is around service user involvement, which has been acknowledged as key to good quality research, but has still not become the default for research teams. Participatory approaches are largely absent from the reviewed studies, with service user and carer views "reported by clinicians" ignoring the likelihood of misunderstandings and service user views being skewed by unequal power dynamics. There is no statement about the involvement of lived experience researchers in the review itself either. While some researchers may not wish to expose their personal experiences, it is important to be clear about the level of involvement within all studies.

Service users can shine a spotlight on aspects of mental health support of importance to people who rely on services which may otherwise be missed. Their lack of involvement in this review may be one reason why only one out of 41 primary research studies reviewed looks at the voluntary sector, and none at peer support or social care. It is unclear if this is a result of the review process itself or a lack of evidence. Had service users been involved, this fundamental gap might have been explored at an earlier stage.

The review does identify some factors that can help determine how useful or accessible telemental health is for different groups of people. However, an analysis linking these factors to broader underlying factors such as poverty would be more helpful.

Further research is needed to ensure future service planning can more accurately assess which elements of telemental health work well, why, and for whom, and to have service user involvement integral to the whole process from beginning to end.

Finally, there is scope to conduct big data studies to identify who is not accessing remote care or those at risk of disengaging, and potential comparisons for matched groups to try to compare effectiveness across a range of settings, as this could be done more quickly than in clinical trials while respecting patient preference.

Strengths and Limitations

The studies included in this review identified outcomes across different settings and health care systems, which may help findings generalize to different settings. This review also captured recent findings on the use of telemental health during the COVID-19 pandemic, allowing findings to be used to improve both existing and future models of remote mental health care.

However, it is also important to take some limitations into account when interpreting the findings from this review. First, the results from quality assessment indicated that while around half of primary research studies and the majority of the service evaluations were high quality, around half of primary research studies were scored as moderate to low. This reflects the short nature of studies and often quick turnaround from data collection to publication. Some studies were also published in preprint form and therefore had not undergone peer review. The majority of studies used cross-sectional data, rather than more rigorous methods. Second, there was a lack of high-quality quantitative evidence for the clinical effectiveness of telemental health care. Clinical effectiveness outcomes were only reported in 9/77 included studies, with some of these findings only based on qualitative evidence or a small number of service users. It is also important to note that the voices of those who dropped out of care may not be included.

The short time scale for data collection and assessment of changes in practice in included studies could also be viewed as a limitation of this research, as it is not clear if changes will be sustained over time or in other contexts (eg, lower-income countries). We also recognize that the search dates do not cover the whole of the pandemic to date; however, as plans for the medium- to long-term adoption of telemental health are currently being made in several countries, we think it best to make the findings from this research available promptly. Research was also not inclusive of those not accessing or using remote technologies, meaning there is a risk of those at risk of digital exclusion being forgotten when taking the findings of this review into consideration.

We also designed this review to be conducted rapidly to ensure results would be relevant and quickly available, therefore we chose to search 4 databases and not all studies were independently double screened by blinded researchers. Although quality assessment was conducted by 2 reviewers independently, they were also not blinded to the previous decision. However, we are confident that the rigor of our searches and inclusion of preprint servers meant that the papers included are representative of the literature on this topic.

Conclusion

Telemental health was a largely effective method to enable continuation of mental health support during the COVID-19 pandemic. While most reported outcomes were positive, telemental health was not feasible for all types of support and may not be acceptable to all service user groups. A blended approach combining face-to-face and telemental health care may be the most desirable service model for future care. The need remains for higher-quality evidence regarding the clinical effectiveness of telemental health and how uptake can be improved for groups at risk of digital exclusion.

Abstract

Background: Chronic obstructive pulmonary disease (COPD) and chronic heart failure (CHF) are characterized by severe symptom burden and common acute worsening episodes that often require hospitalization and affect prognosis. Although many studies have shown that person-centered care (PCC) increases self-efficacy in patients with chronic conditions, studies on patients with COPD and CHF treated in primary care and the effects of PCC on the risk of hospitalization in these patients are scarce.

Objective: The aim of this study is to evaluate the effects of PCC through a combined digital platform and telephone support for people with COPD and CHF.

Methods: A multicenter randomized trial was conducted from 2018 to 2020. A total of 222 patients were recruited from 9 primary care centers. Patients diagnosed with COPD, CHF, or both and with internet access were eligible. Participants were randomized into either usual care (112/222, 50.5%) or PCC combined with usual care (110/222, 49.5%). The intervention's main component was a personal health plan cocreated by the participants and assigned health care professionals. The health care professionals called the participants in the intervention group and encouraged narration to establish a partnership using PCC communication skills. A digital platform was used as a communication tool. The primary end point, divided into 2 categories (improved and deteriorated or unchanged), was a composite score of change in general self-efficacy and hospitalization or death 6 months after randomization. Data from the intention-to-treat group at 3- and 6-month follow-ups were analyzed. In addition, a per-protocol analysis was conducted on the participants who used the intervention.

Results: No significant differences were found in composite scores between the groups at the 3- and 6-month follow-ups. However, the per-protocol analysis of the 3-month follow-up revealed a significant difference in composite scores between the

study groups (*P*=.047), although it was not maintained until the end of the 6-month follow-up (*P*=.24). This effect was driven by a change in general self-efficacy from baseline.

Conclusions: PCC using a combined digital platform and structured telephone support seems to be an option to increase the short-term self-efficacy of people with COPD and CHF. This study adds to the knowledge of conceptual innovations in primary care to support patients with COPD and CHF.

Introduction

Background

Chronic obstructive pulmonary disease (COPD) and chronic heart failure (CHF) are known for their high mortality and severe impact on daily living activities [1-3]. Although pharmacological therapy has dramatically improved outcomes over the past decade, patients still perceive a high symptom burden and acute worsening of events. Therefore, self-management strategies that enhance self-efficacy are crucial to optimize [4] and strengthen preventive approaches in primary care [5]. Digital solutions have been suggested as a safe option for addressing health care challenges and promoting self-management of chronic conditions such as COPD and CHF [6-8]. However, most digital solutions lack user involvement in the development of the platform [9].

Person-centered care (PCC) is an approach based on ethical principles by which a contractual agreement is formed involving the patient as an active partner in the care and decision-making process [10]. To support the operationalization of person-centered ethics in clinical practice, a framework was developed by the Gothenburg Centre for Person-Centred Care. This Gothenburg Centre for Person-Centered Care framework underlines the importance of cocreated care between patients and health care professionals (HCPs; eg, registered nurses and a physiotherapist) based on the patient's narrative, which identifies personal resources and potential barriers together with medical status [10,11]. A central concept of PCC is self-efficacy, that is, a person's conviction in his or her ability to manage challenges and complete a task successfully [12]. Enhanced self-efficacy has been shown to improve disease management and clinical outcomes, including health status in patients with chronic diseases [13], physical functioning in patients with COPD and CHF [14], and daily living in patients with COPD [15]. Thus, HCPs need to target patients' self-efficacy beliefs to perform desired activities and support them in taking responsibility for engaging in their care [16]. Previous research has shown that PCC increases the self-efficacy of patients [17-19]. PCC via telephone is also thought to mitigate worsening self-efficacy in COPD and CHF, indicating that a partnership could be established between patients and HCPs without face-to-face contact [20].

Several studies have used telemedicine and digital interventions for people with COPD and CHF [21,22]; however, PCC was not part of their design, and the results were mixed [23].

Objective

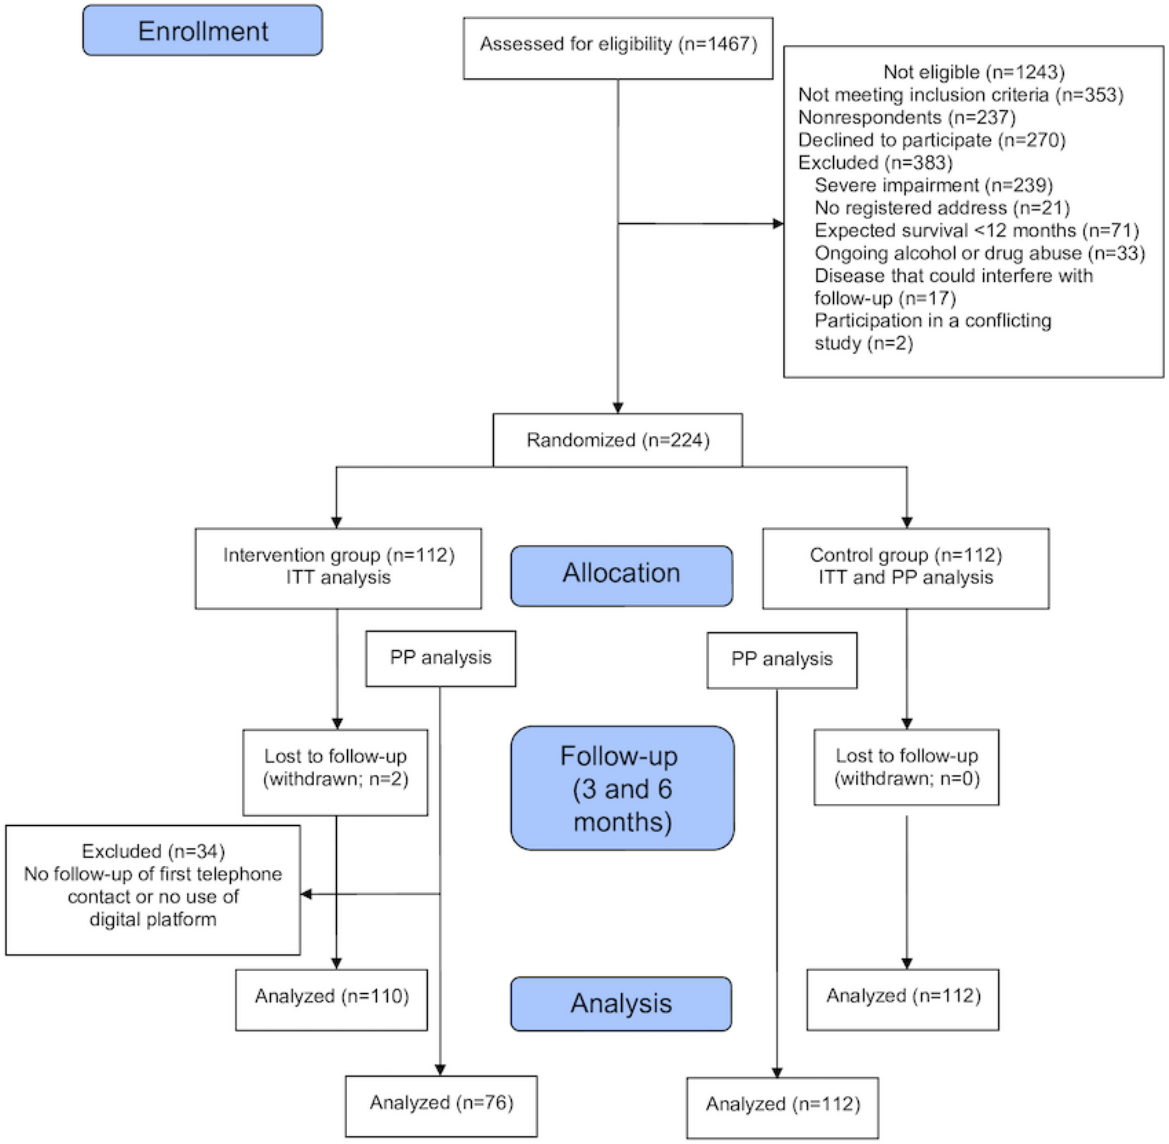
We hypothesize that PCC principles that include a digital platform and structured telephone support for people with COPD and CHF would reduce the need for primary care and hospital admission and improve self-efficacy through collaboration in the care process. Therefore, the aim of this study is to evaluate the effects of PCC through a combined digital platform and telephone support for people with COPD and CHF.

Methods

Design, Participants, and Setting

Study participants were recruited from 9 primary health care centers in Gothenburg from August 2017 to June 2019. The study, including consent forms for participants, was approved by the regional ethics board in Gothenburg (Dnr 063-17 and T613-18). The inclusion criteria were a diagnosis of COPD (J43.0, J44.0-J44.9) or CHF (I50.0-I50.9), being listed at one of the participating primary health care centers, understanding written and spoken Swedish, and having access to a device with an internet connection. The exclusion criteria were severe impairment (cognitive or other) that prevented the individual from using eHealth support, no registered address (follow-up questionnaires were sent by mail), expected survival of <12 months, ongoing documented diagnosis of alcohol or drug abuse, diseases that could interfere with follow-up (ie, multimorbidity), and participation in a conflicting study. A flowchart of the study participants is given in Figure 1.

Figure 1. CONSORT flowchart. ITT: intention-to-treat; PP: per-protocol.



Enrollment and Randomization

Designated HCPs screened medical records at the 9 participating centers for potential patients diagnosed with COPD, CHF, or both. Eligible participants were sent an information letter about the study with an invitation to contact the HCPs for more information. If the participants did not contact an HCP within 2 weeks after the information letter had been sent out, they were contacted by phone for further details and asked to participate. Patients who accepted the invitation to participate were sent a consent form together with a prepaid return envelope by mail. Upon receipt of the signed consent form, patients were randomized into either standard care or PCC in addition to standard care. Randomization was based on a computer-generated list created by a third party and stratified by age (<65 or ≥65 years) and diagnostic group (COPD, CHF, or COPD and CHF). All participants were informed of their allocation by phone, a call not included as part of the intervention.

Usual Care

Usual care was managed as per the physician's judgment based on current guidelines, for example, medicine adjustments [24,25]. The usual care group had no follow-up phone conversations.

Intervention

The intervention, comprising PCC using a combined digital platform and structured telephone support system, was provided in addition to usual care for 6 months. The structured telephone support program comprised an optional number of phone calls that included a health plan cocreated and followed up by patients and HCPs, which is consistent with person-centered principles. The digital platform was aimed at supporting communication between phone calls and providing access to shared documentation (health plans and self-ratings) and reliable information sources. The digital platform was developed using a participatory design with user involvement. The method draws on the user's *tacit knowledge*, that is, their implicit or unarticulated knowledge learned and transmitted through experience and apprenticeship, for example, by taking part in

this project. The researchers had workshops together with the HCPs, patient partners, and experts in which the platform and intervention were discussed and developed [26].

HCPs assisted participants in the intervention group in creating a log-in to the digital platform that they could access during the study period and described its features. In the first telephone conversations, the HCPs encouraged narration. They established a partnership using communication skills such as listening to the participants' narratives about daily life events and how they were affected by their condition. The next step entailed cocreating a health plan based on patient narratives through discussion and agreement, including patient goals, resources, and needs. Usually, the health plan contained information about what the participants had talked about, how they felt, what goals they had, and what they wanted to accomplish. The health plan also included information on the participants' capabilities and resources that could be used to help them reach their respective health goals. The health plan was written jointly at the initiative of the HCPs or the patients and uploaded to the digital platform by either the HCPs or the patients.

The HCPs and patients jointly scheduled the date of the follow-up meetings based on the preferences of the patients. The health plan served as a point of departure for the impending conversations and communication via the platform. The participants and HCPs had access to the platform during the 6-month study period. The health plan was considered and revised during each follow-up phone call and when needed (eg, if the participants spontaneously contacted the HCPs). The fidelity of the intervention was ensured by meetings and seminars on a regular basis, constructive discussions and education on PCC, and person-centered communication and monitoring of the HCPs by researchers and experts in their respective fields. The review group comprised senior and junior researchers and patient representatives. In addition, the HCPs reviewed some of each other's telephone calls and health plans. A total of 5 HCPs were involved in the intervention: 3 (60%) registered nurses, 1 (20%) occupational therapist, and 1 (20%) physiotherapist. Years of work experience ranged from 6 to 26 years for the HCPs.

The platform contained functionalities for 2-way communication through private messages; the possibility to rate daily symptoms, such as shortness of breath and tiredness, to be visualized as trend graphs; and an archive of the health plans. The participants could invite and give customized access to the platform to any person they wanted, such as informal carers, family, or friends. They could also access links to relevant websites containing information on COPD and CHF provided by patient organizations (eg, the Heart and Lung Association) and the Swedish national support guide to an online peer-to-peer support group. A detailed description of the intervention has been published elsewhere [27].

Collection of Data and Outcome Measures

Data were collected through questionnaires and from medical records at inclusion and 3 and 6 months later. Questionnaires were mailed to all participants together with a prepaid return envelope. If the questionnaires were not returned within 2 weeks, reminders were given by phone. New questionnaires and return envelopes were sent out if needed. Approximately 6.8% (15/222) of participants (11/110, 10% in the intervention group and 4/112, 3.6% in the control group) did not return their questionnaires at the 3-month follow-up. At the 6-month follow-up, 8.6% (19/222) of participants (13/110, 11.8% in the intervention group and 6/112, 5.4% in the control group) did not return their questionnaires despite being reminded.

The primary end point was a composite score of general self-efficacy (GSE) changes and hospitalization or death 6 months after randomization into each group.

A patient was classified as improved if GSE increased by ≥5 units, the patient was not hospitalized because of COPD or CHF, and the patient did not die. A patient was classified as deteriorated if GSE decreased by ≥5 units, the patient was admitted for unscheduled reasons because of COPD or CHF, or the patient died because of any cause.

Those who neither improved nor deteriorated were considered unchanged. GSE was assessed using the GSE scale, a 10-item scale designed to measure a sense of personal competence in dealing with stressful situations (eg, handling unforeseen situations and finding possible solutions to problems). The GSE scale has been widely tested and used internationally; the Swedish version has shown high internal consistency (Cronbach α=.90) [28]. The 10 items are rated on a 4-point scale, with total scores ranging from 10 to 40 [29]. An increase of 5 units has been suggested as a threshold for minimal clinically meaningful change [18,20].

Statistical Methods

A sample size of at least 91 participants in each group was needed to achieve a power of 80% based on a *P* value of .05 (2-tailed) to detect an increase in the composite score from 20% in the control group to 40% in the intervention group.

Descriptive and comparative statistics were used to characterize the study groups. Group differences were calculated using the Pearson chi-square test for categorical variables, the Fisher exact test for dichotomous variables, and the independent 2-tailed Student *t* test for continuous variables. Between-group differences in the composite score were tested using the Fisher exact test for the dichotomous version and the Mantel-Haenszel chi-square test for the ordered categorical version. Binary logistic regression was used to calculate odds ratios with 95% CIs for the dichotomous version of the composite score. The Student *t* test was used to compare the mean change in GSE scores between groups. Between-group differences in improvement of ≥5 points on the GSE scale were calculated in the same way as the dichotomous version of the composite score. Bivariate correlations were computed using Pearson *r*. Missing outcome data for the 3- and 6-month follow-ups were imputed using the last value carried forward. Sensitivity analyses were conducted to assess robustness. Both intention-to-treat (ITT) and per-protocol (PP) analyses were conducted. The PP group included participants with at least one PCC phone call and at least one health plan who logged into the platform and used at least one of its functions. The significance level was set at $P<.05$ (2-sided).

Results

Overview

In total, 224 participants were randomly assigned to either the control or the intervention group, of which 2 participants withdrew consent, leaving 222 participants (112/222, 50.5% in the control group and 110/222, 49.5% in the intervention group). The baseline characteristics are presented in Table 1. The study population was 53.6% (119/222) men and 46.4% (103/222) women, with a mean age of 70.8 (SD 9.4) years. Approximately 51.8% (115/222) participants had COPD, 38.3% (85/222) had CHF, and 9.9% (22/222) had both. Of the 222 participants, 32 (14.4%) were current smokers. The treatment and control groups were similar at baseline, except that significantly more participants in the control group were married or living with a partner than in the intervention group (P=.01). However, this difference did not remain when comparing the control and PP groups (P=.07). There were no significant differences between the groups in medical histories (eg, diagnosis, previous cardiovascular disease, or stages of COPD; Table 1).

[v]n=33.
[w]n=21.

During the 6-month intervention, the ITT group had a median of 4 (range 0-11) telephone conversations with the HCPs. Of those, a median of 3 (range 0-7) was within 90 days of randomization. The PP group had a median of 4 (range 1-11) telephone conversations during the study period, with a median of 3 (range 1-7) within 90 days of randomization. No statistically significant correlations were detected between the number of calls and changes in GSE.

Effects

No significant differences in composite scores (improved vs deteriorated or unchanged) at the 3- or 6-month follow-ups were observed between the groups. However, a significant difference in the PP analysis was noted at the 3-month follow-up (*P*=.047). The analysis confirmed this result using the composite score (improved, unchanged, or deteriorated; *P*=.04). However, none of these differences could be sustained at the 6-month follow-up (*P*=.24 and *P*=.50; Table 2). We found no differences in composite scores between patients with COPD, CHF, or COPD and CHF. During the 6-month intervention, there were 4 recorded hospitalizations: 3 (75%) in the intervention group and 1 (25%) in the control group. There were no participant deaths during the intervention.

Table 2. Composite scores at the 3- and 6-month follow-up.

Time and composite score	Control (n=112)	Intention-to-treat (n=110)[a]			Per-protocol (n=76)[a]		
		Value	OR[b] (95% CI)	*P* value	Value	OR (95% CI)	*P* value
3 months							
Composite score 1[c], n (%)							
Improved	10 (8.9)	15 (14)	1.663 (0.712-3.884)	.24	14 (19.2)	2.420 (1.011-5.792)	.047[d]
Deteriorated or unchanged	102 (91.1)	92 (86)	1.663 (0.712-3.884)	.24	59 (80.8)	2.420 (1.011-5.792)	.047[d]
Composite score 2[e], n (%)			—[f]	—		—	
Improved	10 (8.9)	15 (14)			14 (19.2)		.04[d]
Unchanged	89 (79.5)	83 (77.6)			54 (74)		.04[d]
Deteriorated	13 (11.6)	9 (8.4)			5 (6.8)		.04[d]
6 months							
Composite score 1[c], n (%)							
Improved	13 (11.6)	16 (15)	1.339 (0.611-2.936)	.47	13 (17.8)	1.650 (0.717-3.795)	.24
Deteriorated or unchanged	99 (88.4)	91 (85)	1.339 (0.611-2.936)	.47	60 (82.2)	1.650 (0.717-3.795)	.24
Composite score 2[e], n (%)			—	—		—	
Improved	13 (11.6)	16 (15)			13 (17.8)		.50
Unchanged	83 (74.1)	74 (69.2)			49 (67.1)		.50
Deteriorated	16 (14.3)	17 (15.9)			11 (15.1)		.50

[a]3 missing values (no general self-efficacy score at baseline).

[b]OR: odds ratio.

[c]Composite score dichotomized into improved vs deteriorated or unchanged.

[d]Significant at $P<.05$.

[e]Composite score improved vs unchanged vs deteriorated.

[f]The statistical test used (Mantel-Haenszel chi-square test) does not generate odds ratio or 95% CI.

Differences between the groups at 3 months were driven mainly by changes in the GSE scale. The PP group had a mean improvement of 0.941 (SD 4.4) points, whereas the control group had a mean reduction of 0.568 points (SD 4.6; $P=.03$). At the 3-month follow-up, 19.2% (14/76) of the participants in the PP group versus 8.9% (10/112) of those in the control group had an improvement of ≥5 points on the GSE scale, indicating that the PP group was more than twice as likely to have a clinically meaningful improvement in GSE compared with the control group (Table 3).

Table 3. Change in general self-efficacy (GSE) from baseline and at the 3- and 6-month follow-ups.

Follow-up	Control (n=112)	ITT[a] (n=110)[b]			PP[c] (n=76)[d]		
		Value	OR[e] (95% CI)	*P* value	Value	OR (95% CI)	*P* value
3 months							
Change in GSE score, mean (SD)	−0.568 (4.6)	0.544 (4.0)	2.261 to 0.038[d]	.06	0.941 (4.4)	−2.842 to −0.174[d]	.03[f]
Improvement ≥5 points, n (%)	10 (8.9)	15 (14)	1.663 (0.712 to 3.884)	.24	14 (19.2)	2.420 (1.011 to 5.792)	.047[f]
6 months							
Change in GSE score, mean (SD)	−0.397 (4.5)	0.127 (4.3)	−1.689 to 0.642[d]	.38	0.384 (4.4)	−2.103 to 0.542[d]	.25
Improvement ≥5 points, n (%)	13 (11.6)	16 (15)	1.339 (0.611 to 2.936)	.47	13 (17.8)	1.650 (0.717 to 3.795)	.24

[a]ITT: intention-to-treat.

[b]3 missing values (no general self-efficacy score at baseline).

[c]PP: per-protocol.

[d]Only 95% CI shown as the statistical test (Student *t* test) does not generate odds ratio.

[e]OR: odds ratio.

[f]Significant at $P<.05$.

Discussion

Principal Findings

This study shows that a 6-month intervention with PCC using a combined digital platform and structured telephone support system does not improve outcome as assessed by a composite end point of change on the GSE score and absence of hospitalization or death. However, the PP analysis, which only included those who used the intervention, showed a difference in composite scores at 3 months. However, this difference did not hold at the 6-month follow-up. The difference at 3 months was primarily because of an improvement in the GSE scale score. PP analyses are usually data-driven and thus, of lower evidence than prespecified analyses but are important to explore the mechanisms behind the effects of treatment and care interventions [30].

Several explanations have been proposed to account for why the ITT analysis showed no significant differences and why the PP analysis only showed differences at the 3-month follow-up. The participants had a relatively stable disease, as illustrated by the few disease-related hospitalizations and the high self-reported GSE at baseline (mean score 31.1; Table 1). In contrast, population studies have reported a mean GSE score of 29 [29]. A previous study from our group targeting patients with more severe forms of COPD and CHF demonstrated more pronounced positive results from a similar intervention. In that study, the participants had lower GSE (mean score of 28) at baseline and therefore, had more margin for improvement [20]. Previous studies have highlighted the difficulties in showing the significance of an intervention when the participants' score on outcome measurements at baseline (ie, ceiling effects) was high [31].

The intervention's timing might have played a role in the lack of significant differences between the groups. The intervention sought to reach out with a preventive tool to support self-management and, therefore, recruited participants from primary care centers. Thus, unlike our previous interventions that mainly recruited participants during an unplanned hospitalization, in this intervention, patients were targeted in their everyday lives. In those interventions, hospitalization was an exact starting point, and many were eager to recover their health after a period of deterioration [18,20]. That the intervention's timing is important for its meaningfulness was also confirmed by the findings from the participant interviews [32]. Moreover, previous research has pointed out the importance of including participants in need of an intervention to achieve favorable outcomes [31]. In this study, screening was not performed to determine which participants might be most suitable for the intervention.

The intervention showed an effect after 3 months in the PP analysis but not after 6 months. This result is likely because of the participants' initial high degree of communication with the HCPs and the fact that the increase in GSE caused by the intervention attenuated over time. At least two phone meetings were initially made, one occurring when the patients were contacted and asked to participate and the other during the health plan's joint formulation. As the median number of calls was 4, many of the participants had few conversations with HCPs after the first 2 calls. The intervention did not include mandatory follow-up or booster calls. If this had been done, the effect of the intervention might have been maintained. Nevertheless, no statistically significant associations were found between the number of calls and changes in the GSE. Associations might have been present; however, the study was underpowered to detect them. There may also be other explanations for the lack of effect after 6 months, such as lack of motivation and

worsening of COPD and CHF; however, these variables were not collected.

Another possibility for the ITT analysis not detecting any differences is that the participants did not use the digital platform to its fullest extent. A reason for this lack of difference may be that the participants did not feel the need to use the digital platform when feeling stable [32]. Even if used, the digital platform might not have added enough support to improve GSE. These possibilities are important to explore further to find the best technique for future digital communication between HCPs and participants. It can be speculated that this essential partnership may not be established without face-to-face meetings. However, a process evaluation of the trial using grounded theory has shown that it is possible to establish partnerships without face-to-face meetings [32]. Although the intervention might not suit all people with COPD and CHF, those who used the platform and structured telephone support (ie, the PP group) showed a significant improvement in GSE. In addition, an increase of ≥5 on the GSE scale, which was considered a clinically meaningful improvement, was equivalent to almost 1 SD in our sample. In general, 0.5 SD is viewed as the cutoff for a clinically significant difference [33]. Previous research has shown that GSE improvement is associated with better food choices [34], improved exercise endurance in people with COPD [35], and functional fitness among older adults [36]. These findings indicate that GSE increment may support people with chronic illnesses to improve and maintain health. This study shows that PCC using a combined digital platform and structured telephone support system is one way to support people with COPD and CHF. However, this type of intervention must target those who would benefit the most from it. An important finding for HCPs is that when using self-care tools for home monitoring, our patients with CHF emphasized that they did not want to read or be reminded of CHF. This may be a way for people with CHF to cope with everyday life [8]. It also highlights the need for HCPs to listen to their patients' concerns and individualize care accordingly.

To our knowledge, this is the first randomized trial in which the effects of PCC using a combined digital platform and structured telephone support system for people with COPD and CHF treated in primary care were evaluated. This study adds knowledge on which factors (eg, timing of the intervention and sustainability of interventional effects) are essential when designing interventions targeting self-care. In general, most self-care interventions are time intensive and require effort from the interventionist. Information on the sustainability of the effects after the end of the intervention is often not reported. Nonetheless, telehealth self-management interventions do not seem to report any adverse effects, which could suggest that such interventions are a suitable option to support people with chronic conditions [6].

Strengths and Limitations

This study has several limitations worth noting. First, there is no information on the disease severity of CHF in the background information of the participants, as this was not consequently reported in medical records. Second, few hospitalization events indicate that another outcome measure might have been more suitable for this study population. Furthermore, the participants had a high mean GSE score at baseline, leaving little margin for improvement. The results might have been different if another outcome measure had been evaluated. Fourth, the design of the intervention might not have been ideal for all of the included participants. More participants might have been identified and benefited from the intervention if the study had used more rigorous screening criteria. Fifth, this manuscript only focuses on the effects of the intervention and might have been strengthened by adding a process evaluation; however, those data are, unfortunately, not currently available.

This study also has some strengths. First, the intervention improved GSE at the 3-month follow-up for the participants who used it. In addition, the use of telehealth made it more accessible and reduced the need for patients to travel to and from health care centers.

Conclusions

By combining a digital platform with structured telephone support, PCC seems to be an option to increase the short-term self-efficacy of people with COPD and CHF. This study adds to the knowledge of conceptual innovations in the primary care setting to support patients with COPD and CHF. Further research is needed to explore which patient at what point in the natural history of the disease would benefit the most and tailor different digital interventions and PCC components to each patient's unique needs.

Acknowledgments

The authors want to thank all the participants for sharing their experiences and the professional health care workers Eva-Lena Andersson, Paula Johansson Tunås, Emma Vasell, and Dr Joanne Fuller. The authors also gratefully acknowledge the contribution of the participating primary care centers, their managers, and particularly area manager Cathrine Thanner for their support and assistance in conducting the study.

This work was supported by The Swedish Heart and Lung Foundation (DNr.20180183), the Swedish Research Council (Dnr 2017-01230), and the Centre for Person-Centred Care at the University of Gothenburg, Sweden. The funders had no role in the analysis or preparation of the manuscript.

Abstract

Background: Chronic headache causing severe headache-related disability for those affected by the disease is under- or misdiagnosed in many cases and therefore requires easy access to a specialist for optimal health care management.

Objective: The goal of the research is to determine whether video consultations are noninferior to face-to-face consultations in treating chronic headache patients referred to a specialist in Northern Norway.

Methods: Patients included in the study were recruited from general practice referrals to a specialist at a neurological department in Northern Norway (Tromsø) and diagnosed according to the International Headache Society classification system. In a randomized controlled design, the 1-year remission rate of chronic headache (change from ≥15 to <15 headache days per month during the last 3 months), patient satisfaction with a specialist consultation, and need for follow-up consultations by general practitioners were compared between groups consulted by video and face-to-face in a post hoc analysis. Data were collected by interview (baseline) and questionnaire (follow-up).

Results: From a baseline cohort of 402 headache patients consecutively referred from general practice to a specialist over 2.5 years, 58.0% (233/402) were classified as chronic headache and included in this study. Response rates were 71.7% (86/120) in the video group and 67.3% (76/113) in the face-to-face group. One-year remission from chronic headache was achieved in 43.0% (37/86) in the video group and 39.5% (30/76) in the face-to-face group (P=.38). Patient satisfaction with consultations were 86.5% (32/37; video) and 93.3% (28/30; face-to-face; P=.25). A total of 30% (11/37) in the video group and 53% (16/30) in the face-to-face group consulted general practitioners during the follow-up period (P=.03), and median number of consultations was 1 (IQR 0-13) and 1.5 (IQR 0-15), respectively (P=.19).

Conclusions: One-year remission rate from chronic headache was about 40% regardless of consultation form. Likewise, patient satisfaction with consultation and need for follow-up visits in general practice post consultation was similar. Treating chronic headache patients by using video consultations is not inferior to face-to-face consultations and may be used in clinical neurological practice.

Trial Registration: ClinicalTrials.gov NCT02270177; https://clinicaltrials.gov/ct2/show/NCT02270177

Introduction

Background

Chronic headache is a condition that transforms from primary headaches and is mainly identified as chronic migraine and chronic tension-type headache affecting about 1% to 2% and 2% of the population, respectively [1-3]. Lack of diagnostic biomarkers is a major challenge, and the chronic headache diagnosis (presence of headache 15 or more days per month for the last 3 months) is made by using a structured interview that relies on a validated diagnostic classification system [4]. Headache burden in the population is high and has not improved at the population level over time [5,6]. Preferably, headache should be correctly classified and treated at earliest to minimize risk of becoming chronic and development of associated conditions such as psychiatric symptoms [7], comorbid pain [8], increased costs for patients and the society [9], and impaired work performance [10], which are some known consequences that may burden chronic headache patients further. Depression, anxiety, sleep problems, stress, medication overuse, and low degree of headache self-management were associated with poorer prognosis of chronic headache in randomized controlled trials (RCTs) and prospective cohorts as summarized in an American review [11]. It has long been known that headache syndromes are underdiagnosed and undertreated, especially migraine [12,13]. There are many possible reasons for that. Professional headache care needs to be better coordinated with general health practice [14,15] and is further challenged by variable access to headache specialists [16]. In a group of 1254 chronic migraine sufferers, 40% had consulted a headache specialist, but only 4.5% reported that they additionally received correct diagnosis and treatment [13]. Knowledge about how alternative specialist consultations using information and communication technology may be used to treat patients with difficult headache is limited. In less populated areas where a secondary health service such as a general neurological department is the only alternative to primary health care, telemedicine might be effective. The main hypothesis of this study was that treating chronic headache patients referred to a neurological department by using video consultations is not inferior to traditional face-to-face consultations.

Methods

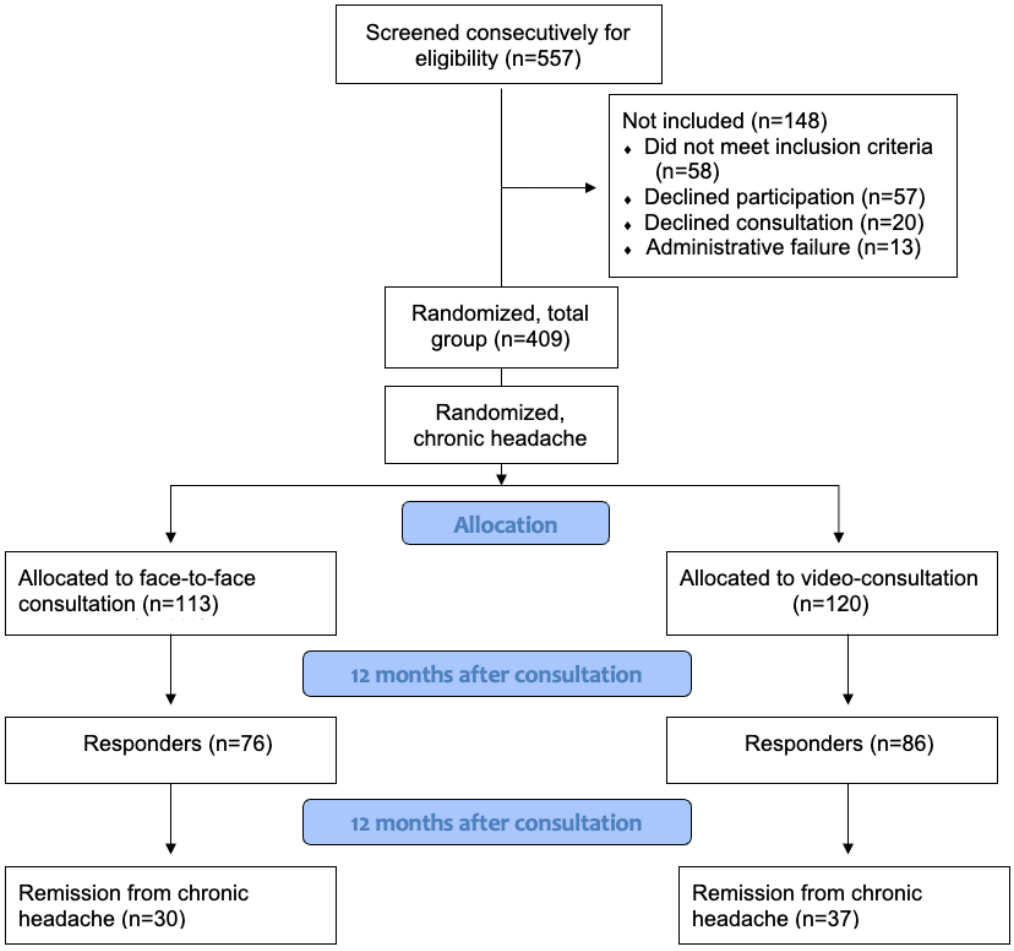
Study Design and Hypotheses

The results from this study are based on post hoc analyses from a previous open-label randomized clinical trial where a larger group (n=409) of heterogeneous headache patients referred from general practitioners (GPs) to specialists were assigned to either video or face-to-face (in-office) consultations to study cost, feasibility, and clinical aspects [17]. The trial was registered at ClinicalTrials.gov [NCT02270177]. The group of patients with chronic headache from that cohort were selected for this study to test the following primary hypothesis: providing treatment to chronic headache patients by specialist video consultations is noninferior to face-to-face specialist consultations with respect to 1-year remission rate of chronic headache (change from ≥15 to <15 headache days per month during the last 3 months). Secondary hypotheses were (1) patient satisfaction with specialist consultation, (2) frequency of chronic headache patients visiting GP for headache in the 12 months postconsultation, and (3) median number of headache-related consultations at GPs in the 12 months posttreatment, all end points postulated to be indifferent between the groups. The CONSORT-eHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online TeleHealth) was used as a guide in describing the scientific study method [18].

Study Population and Randomization

Patients were consecutively identified, screened, randomized, and consulted for 2.5 years (September 30, 2012, to March 30, 2015). Of the included patients, 58.0% (233/402) of patients were classified to have chronic headache and included in the study (Figure 1).

Figure 1. Flowchart of patients with chronic headache referred to neurologists from general practitioners for headache fulfilling the study inclusion criteria.



Selection criteria were as follows: (1) patients referred from GP to neurologist for headache, (2) fulfilling the classification criteria for chronic headache without evidence of secondary headache (ie, headaches classified as primary headache without specific causes [4] except patients with suspected medication overuse headache), (3) Norwegian speaking men and women aged 16 to 65 years, (4) not having visited a neurologist for headache within 2 years prior to consultation, and (5) waiting time from referral to consultation 4 months or less.

A nurse welcomed the participants at the entrance of the neurological department at the Tromsø University Hospital, checked the patient's self-administered prefilled forms and participation consent and called the randomization administrator at the hospital (Centre for Quality Improvement and Development). Participants were block-randomized by using an Rnd function in Access (Microsoft Corp), and thereafter guided to an examination room for face-to-face consultation (traditional group) or to the video conference room located next to the department (video group). Video consultations were performed by using a video conference system including a C40 Integrator package (Cisco Systems Inc) with dual display option and Touch Control Device for C Series, C40 Integrator Multisite (Cisco Systems Inc), Precision HD 1080*P* 12× camera (Cisco Systems Inc), X551S 55" LED (Sharp NEC Display Solutions of America Inc) monitor, ceiling microphones (Audio-Technica Inc), and JBL LSR2325P (Harman International Industries) active speakers installed in the video conference room providing 2-way video and audio communication between patient and specialist. The neurologists consulted the patients from 2 other offices via a EX60 unit (Cisco Systems Inc) with an in-touch panel. Traditional face-to-face consultations were performed in the same offices. The study nurse confirmed that the visual and audio devices worked and informed the patients about the location of the web camera and microphone and where to sit. The nurse also provided a short training and assured optimal communication with the specialist. Two experienced neurologists (KIM and SIB) performed clinical consultations without neurological examinations but with additional checklists for inclusion criteria, diagnostic classification, and a standardized interview which were developed before the trial without further development during the trial. Further details are published elsewhere [19].

Data Collection and End Points

Data were obtained by structured interview at baseline and via questionnaire at 1-year follow-up. The prefilled forms included a Headache Impact Test–6 (HIT-6) measuring 6 items of headache impact (pain, social, role and cognitive functioning, vitality, and psychological distress). Every question was answered by never, rarely, sometimes, very often, or always, and each answer scored 6, 8, 10, 11, or 13 points, respectively [20]. Pain intensity using a horizontal visual analog scale (VAS)

ranging from 0 to 10 (0 = no pain, 10 = worst possible pain) was used in conjunction with HIT-6 [21]. Clinical and headache characteristics including comorbidity and diagnosis according to International Classification of Headache Disorders–2 [4] were recorded. Also, inaccurate headache diagnosis (ie, diagnostic disagreement between specialist and diagnoses reported in the electronic referral letter) were registered. The follow-up questionnaire recording demographics, clinical and headache characteristics, and end point variables was sent to the patients (with a reminder 2 weeks later to the nonresponders) either through an online survey service (Questback) or by postal letter. To classify chronic headache, the patients responded to number of headache days per month for the last 3 months.

Secondary end points were recorded from the patients' registration form as follows: "Where you satisfied with the consultation?" (yes or no), "Have you consulted your GP for headache after the specialist consultation?" (yes or no), and "Number of headache consultations with GP after the specialist consultation." Also, use of painkillers, triptans, and preventive headache drugs used in the last month were recorded.

Ethics

Oral and written consent were obtained from all participants before study entrance. The Norwegian National Committee for Medical and Health Research Ethics approved the study (number 2009/1430/REK).

Statistical Analyses

Data were analyzed with SPSS (version 27, IBM Corp). Descriptive variables are compared between the randomized groups and presented as mean and standard deviation or median and interquartile range in skewed distributed data (number of GP consultations). Consequently, comparisons between groups were analyzed by independent Student *t* test or Mann-Whitney *U* test, respectively; all 2-sided with $P<.05$ selected as level of statistical significance. Categorical variables were presented as numbers and percentages while groups were compared by using chi-square tests.

Results

Patients' characteristics were similar for both video and traditional consultations in all aspects including education and headache characteristics except for younger age in the video group (Table 1). A majority (174/233, 74.7%) had migraine as primary headache, and about one-third (79/233, 33.9%) used analgesic drugs and/or triptans or other headache-specific medication (Table 1). Consultation duration was shorter in the video group (Table 1). Inaccurate headache diagnosis (diagnostic disagreement between specialist and diagnoses reported in the electronic referral letter) are presented in Table 2. Comparisons between the video group and the face-to-face group were insignificant with respect to renewed headache diagnosis and preventive treatment given by the specialist (Table 2). The specialist prescribed preventive medication to 50% to 70% of the patients, and the group with chronic headache remission was treated similarly regardless of consultation form in that respect (Table 2). The main outcome was 43.0% (37/86) 1-year chronic headache remission rate in the video group compared to 39.5% (30/76) in the traditional group ($P=.38$; Table 3). Number and frequency of patients satisfied with consultations were 86.5% (32/37; video) and 93.3% (28/30; face-to-face; $P=.25$; Table 3). GP consultations (numbers and frequencies of patients and median numbers of consultations) are presented in Table 3. More patients treated traditionally (16/30, 53.3%) reported that they had consulted a GP for headache in the follow-up period (Table 3). No end points were otherwise statistically significantly different between the 2 groups. Neither were there any differences in changes in the HIT-6 and VAS scores from baseline to 1-year assessment between the 2 groups (Table 2).

Table 1. Clinical characteristics in randomized groups of patients referred to specialist for chronic headache consulted by video or traditionally.

Characteristic	Chronic headache at baseline			Remission from chronic headache at 12 months		
	Video (n=120)	Face-to-face (n=113)	*P* value	Video (n=37)	Face-to-face (n=30)	*P* value
One-year response, n (%)	86 (71.7)	76 (67.3)	.52	__[a]	—	—

Medication ≥15 days/month[g], n (%)	27 (55.1)	23 (50.0)	.48	8 (21.6)	3 (10.0)	—

[a]CH: chronic headache.

[b]Calculated by using response rates (per protocol analyses) as reference.

[c]Not applicable.

[d]GP: general practitioner.

[e]HIT: headache impact test.

[f]VAS: visual analog scale.

[g]Use of painkillers and/or triptans ≥15 days per month last 3 months.

When taken data from the groups together (pooled data), the comparisons between baseline and status after 12 months were as follows: remission rate from chronic headache was 41.4% (67/162) and numbers visiting GPs were 30.2% (49/162) of those with persisting chronic headache and 40.3% (27/67) in the chronic headache remission group (*P*=.41). Median numbers of GP consultations were 1.0 (IQR 0-15) and 2.0 (IQR 0-11), respectively (*P*=.25). The rate of participants using analgesic medication or triptans ≥15 days per month declined from 52.6% (50/95) to 16.4% (11/67) 1-year post consultation.

Discussion

Principal Findings

By managing new referred chronic headache patients at a secondary neurological center, the 1-year results from this post hoc RCT showed that consulting a neurological specialist by using video were equivalent to face-to-face consultations. Thus, we found no significant differences in remission rate from chronic headache, patient satisfaction with consultation, or GP visits due to headache conducted in the 1-year follow-up period. This study provides evidence to support specialist video consultations as a good alternative to face-to-face consultations in treating patients with chronic headache.

Comparison With Prior Work

There are no previous studies comparing consultation forms in treating chronic headache by a specialist, but in an earlier RCT the group of chronic headache patients randomized to an internet-delivered self-managing relaxation program (n=39) improved by 47% on measures of self-reported headache symptoms compared to an equivalent control group recruited from the waiting list with symptom monitoring only [22]. That study documents the usefulness of communicating via electronic devices as an alternative to face-to-face consultations in treating difficult headache such as chronic headache in line with this study. Likewise, the 1-year treatment response is comparable between the studies (47% vs 43%) despite different treatment methods and outcomes [22]. A smaller RCT by Friedman et al [23] randomized 18 patients with severe migraine to video consultations and 12 to in-office visits in a tertiary headache center. Improvement in headache burden and number of headache days were not different between the groups, and the authors concluded that video consultations were as effective as in-office visits. Furthermore, the consultation time was shorter in the telemedicine cohort as in this study (Table 1) indicating that telemedicine is effective for physicians in treating difficult headache [23].

In our study, approximately 40% of the chronic headache patients had remitted 1-year postconsultation while about 60% persisted with chronic headache. This rate of remission is somewhat lower than a previous longitudinal study that showed a 40% persistent rate at 1 year and 25% at 2-year follow-up [24]. Medication overuse was associated with chronicity in that study, which is also indicated here, as the rate of participants using analgesic medication or triptans ≥15 days per month declined from 52.6% to 16.4%. Similar findings are also demonstrated in population-based studies [25]. RCTs as a method to investigate different neurological outpatient management are in general few [26,27], but use of telemedicine was equivalent to face-to-face consultations with specialist as far as number of consultations [28]. Teleneurology is nevertheless widely used in clinical practice [29-31] with favorable results from the patient perspective (time- and money-saving, communication, perceiving good care, and future preference) [31,32]. From a specialist point of view (n=135 specialists), headache and follow-up consultations were well suited for telemedicine [33].

In general, RCTs in eHealth are few despite occurrence of the COVID-19 pandemic situation, which has demonstrated a need for more evidence-based knowledge about the use of digital health technology in evaluating treatment effect, safety, and other aspects of patient management [34-37]. Patient education programs [38,39]; evaluation of psychological distress using teletechnology in diabetes [40]; use of mobile in suboptimal health [41], surgery care, and follow-up [42-44]; aphasia [44]; HIV consultations [38]; cancer symptom monitoring [45]; motor and cognitive function in stroke [46]; and COVID-19 follow-up [47] are areas where RCTs are used. Moreover, this study agrees with previous telemedicine RCTs in the same area reporting positive outcomes in treating diabetic foot ulcer [48] and in a follow-up study of orthopedic patients [49]. Thus, the RCT design is the main advantage of this study, especially since it is the first one to compare consultation forms with specialist in chronic headache where one treatment arm is based on teletechnology.

Limitations

This post hoc study containing a 53% sample of the original cohort of headache sufferers may be prone to statistical type 2 failure due to risk of underpowered sample size, although the video and traditional consultation groups were similar with respect to group sizes and most of the social and clinical characteristics reflecting a design resistant to selection bias. Moreover, such a study lacks a placebo group and blinding, which would have optimized the evidence further. Awareness of the fact that this study compares different consultation forms and not specific treatment options should be emphasized. Interim analyses comparing additional clinical information between patient groups within the 1-year follow-up period might extend the knowledge about patient experiences with video consultations and should be performed in future studies. Additionally, consecutively including patients from clinical practice and a relatively low dropout rate accounts for acceptable generalizability.

Conclusions

This RCT of video consultations for new referrals of chronic headache patients demonstrated that chronic headache remission rate, patient satisfaction with specialist consultation, and GP consultations for headache performed during follow-up were equivalent between the video group and the face-to-face group. This study adds to the documentation of eHealth in consulting headache patients by specialist.

Abstract

Background: The McIsaac criteria are a validated scoring system used to determine the likelihood of an acute sore throat being caused by group A streptococcus (GAS) to stratify patients who need strep testing.

Objective: We aim to compare McIsaac criteria obtained during face-to-face (f2f) and non-f2f encounters.

Methods: This retrospective study compared the percentage of positive GAS tests by McIsaac score for scores calculated during nurse protocol phone encounters, e-visits (electronic visits), and in person f2f clinic visits.

Results: There was no difference in percentages of positive strep tests between encounter types for any of the McIsaac scores. There were significantly more phone and e-visit encounters with any missing score components compared with f2f visits. For individual score components, there were significantly fewer e-visits missing fever and cough information compared with phone encounters and f2f encounters. F2f encounters were significantly less likely to be missing descriptions of tonsils and lymphadenopathy compared with phone and e-visit encounters. McIsaac scores of 4 had positive GAS rates of 55% to 68% across encounter types. There were 4 encounters not missing any score components with a McIsaac score of 0. None of these 4 encounters had a positive GAS test.

Conclusions: McIsaac scores of 4 collected during non-f2f care could be used to consider empiric treatment for GAS without testing if significant barriers to testing exist such as the COVID-19 pandemic or geographic barriers. Future studies should evaluate further whether non-f2f encounters with McIsaac scores of 0 can be safely excluded from GAS testing.

Introduction

The McIsaac (modified Centor) scoring system is a validated tool used to determine the likelihood of an acute sore throat being from group A streptococcus (GAS) [1-3]. Criterion include patient age, absence of cough, fever, tonsillar swelling or exudates, and the presence of anterior cervical lymphadenopathy, with the last 2 criteria requiring a physical

examination [1]. Even with 4 of the criteria present, the likelihood of an infection with strep is around 60% [4], so best practice dictates patients should be swabbed for GAS prior to initiating treatment with an antibiotic. Current guidelines also suggest against GAS testing in patients with a McIsaac score of less than 3 [5,6]. The most recent Infectious Diseases Society of America guidelines recommend considering testing unless other features strongly suggest a viral etiology [7].

The McIsaac criteria were based on clinician assessment and were not intended to be based on patient/caregiver report. The ability of patients and parents to assess tonsils and lymph nodes is not well studied. Minimal evidence exists in the literature related to use of the McIsaac criteria being calculated based on patient/caregiver report in a non–face-to-face (non-f2f) encounter. A previous study showed that adult patients may over- or underreport physical exam findings compared with clinicians [8]. Another study comparing patients or caregivers to physicians showed moderate to substantial agreement for 3 of 4 key pharyngitis signs and symptoms [9].

In 2017, our institution began using the McIsaac scoring criteria for non-f2f nurse phone triage and e-visit encounters. This scoring system was chosen due to it being validated and having relatively few components needing a response from patients/caregivers. Both phone triage and e-visit encounters relied on patients/caregivers to report on historical symptoms of cough and fever as well as physical exam findings of enlarged tonsils, tonsillar exudate, and anterior cervical lymphadenopathy. Both phone triage encounters and e-visits also allowed patients/caregivers to respond with “I don’t know” for any of the McIsaac criteria with the exception of e-visits not allowing an “I don’t know” response for cough. e-Visits were text-based asynchronous visits that did not require photo or video capability. To complete an e-visit, patients/caregivers completed an online questionnaire via a secure patient portal which was then reviewed by family medicine nurse practitioners and physician assistants. Both e-visit and phone triage end points recommended reporting for strep testing if the McIsaac score was 3 or higher. However, some patients were also referred for a f2f visit or strep testing with scores less than 3 either by clinician judgement or, at times, due to patient/caregiver desire. Additionally, triage nurses sent patients for strep testing if the patient or caregiver was not able to assess any components of the score.

The primary aim of this study was to evaluate and compare use of the McIsaac criteria to predict positive GAS tests in e-visits, phone triage, and f2f visits. We hypothesized that there would not be a significant difference in positive GAS results by McIsaac score between the different encounter types.

Methods

This retrospective, observational study evaluated patients, ages 3 to 75 years, who had a nurse triage phone encounter, submitted an e-visit, or had a f2f visit for acute sore throat between February 23, 2017, and May 4, 2018, and had subsequent GAS testing done on the same day as the encounter. GAS testing was done using a polymerase chain reaction test. During the study time period, there were 211 e-visits with same day strep tests. All 211 e-visit encounters and a randomly selected sample of 211 records for both phone and f2f encounters were manually reviewed to determine the McIsaac score by patient/caregiver self-assessment during non-f2f encounters (nurse phone triage and e-visits) and by clinicians at f2f encounters. For f2f encounters, a score of 1 for fever was given if the provider included in their history that the patient reported a fever or the vital signs for the visit included a temperature greater than 38 °C. F2f visits without a fever at the time of the visit and with no mention in the note of the patient/caregiver reporting presence or absence of fever were counted as missing data for fever. Scores for each encounter type were compared with GAS results. We also calculated receiver operating characteristic (ROC) curves and area under the curve (AUC) for the McIsaac score for each encounter type. Patients were excluded if they had previous treatment for GAS within 30 days prior to the encounter, were currently on antibiotics for acute infection, or were younger than age 3 years or older than age 75 years. Statistical methods used are listed in the result tables. JMP PRO (version 14.1.0, SAS Institute Inc) was used to perform statistical analysis. This study was approved by the Mayo Clinic institutional review board.

Results

There was no difference in average patient age or percentage of positive strep tests between encounter types (Table 1).

There was a significantly higher percentage of patients aged 15 to 44 years and a lower percentage of patients aged 45 years and older with e-visits compared to phone call and f2f encounters. There were significantly more phone and e-visit encounters with missing score components compared with f2f visits. For individual score components, there were significantly less e-visits missing fever and cough information compared with phone call and f2f encounters. F2f encounters were significantly less likely to be missing descriptions of tonsils and lymphadenopathy compared with phone and e-visit encounters.

Percentages of positive strep tests for each McIsaac score by encounter type are shown in Table 2. There were no significant differences in percentages of positive strep tests between encounter types for any of the McIsaac scores.

We also reviewed encounters that had all components to document a McIsaac score (ie, no missing criteria). There were 342 encounters with no missing score elements (101 phone encounters, 83 e-visits and 158 f2f visits). Of these encounters, 52.1% (178/342) had a positive strep test. There were no significant differences between encounter types for percentage positive strep tests for all McIsaac scores (Table 3).

ROC AUC for e-visits was 0.62, for f2f was 0.69, and for phone encounters was 0.62.

Discussion

Principal Findings

The use of nursing protocols and e-visits in today's outpatient settings has improved access for patients and proven to be a patient satisfier [10-14]. Patients today want health care that fits their schedules with tests and treatments accomplished with minimal waiting [15,16]. The ability to access a triage nurse 24/7 or complete an e-visit with a response within a few hours has improved the care of outpatients and allowed more access for patients who need to be seen by a provider [10,13-15,17].

In addition, the cost of such care is greatly reduced from the usual clinic visit [11,13,14,18,19].

The validation of non-f2f visits for sore throats is important when determining the safety of this type of care. Potential ramifications of not treating GAS infections include the possibility of rheumatic fever leading to rheumatic heart disease, invasive GAS diseases, and acute glomerulonephritis [5,20-22]. GAS tonsillitis can also lead to significant discomfort [23]. Knowledge that a sore throat is due to a strep infection versus a viral cause could help reduce complications and get patients back to work or school after antibiotic treatment or home care for an upper respiratory viral infection.

Our study showed no significant difference in the percentage of positive strep tests for each McIsaac score when compared across f2f and non-f2f encounter types. Additionally, ROC AUC values were very similar for the McIsaac score across encounter types. These findings support the use of McIsaac criteria in non-f2f encounters as being comparable to use in f2f encounters. However, our study showed a high rate of positive strep tests for low McIsaac scores in all encounter types (including f2f visits) compared with the literature. Specifically, our rates of 0% to 21% positive strep tests for McIsaac scores of 0 are higher than the published values of 1% to 2.5% [1,4,24]. Similarly, for McIsaac scores of 1 our findings of a positive strep test of 26% to 35% across encounter types appears higher than the published literature of 5% to 10% [1,4,24]. This could be a result of our methodology of including patients who did not have complete data to calculate a McIsaac score and choosing to count missing data (either due to not being recorded in encounters or being answered as “I don’t know” in non-f2f encounters) as contributing 0 points to the total McIsaac score. We attempted to correct for this limitation by further analyzing only encounters with no missing data to compute a score. There were only 4 encounter types with all score components with McIsaac scores of 0, and none of these encounters had a positive strep test. There were only 26 encounters with no missing data and McIsaac scores of 1 with a positive strep rate of 22% to 50%. Another consideration for the higher percentage of positive strep tests is the presence of a carrier state since as many as 12% to 32% of children may be pharyngeal carriers of GAS [25,26]. A throat swab would be unable to differentiate whether the pharyngitis is due to acute GAS infection or viral illness in a GAS carrier [25-27].

In contrast to the above findings, the percentage of positive strep tests for McIsaac scores of 4 appears comparable to rates listed in the published literature for all encounter types (both for those not missing any score components and those with missing score components). Some previous guidelines have recommended consideration of empiric treatment for strep throat for patients with McIsaac scores of 4 or higher [24]. Our study lends support to empiric treatment of patients with McIsaac scores of 4 in non-f2f encounters, as the percentage of positive strep tests is high in this group without any significant differences between encounter types and is consistent with the published literature. This finding may be helpful in scenarios where f2f visits are challenging due to geographical barriers, reduced access to appointments in the clinics during influenza season, or even care barriers such as our current COVID-19 pandemic. Provider visits were more complete in documenting the McIsaac criteria than the phone triage or e-visits. In particular, presence or absence of tonsillar enlargement/exudate and cervical lymphadenopathy were more consistently noted in f2f visits then in non-f2f visits. However, e-visits were significantly less likely to be missing information on fever. No e-visits were missing data on the presence or absence of cough; however, this was due to the e-visit process not allowing an answer of “I don’t know” for cough. The e-visit consists of a series of questions to which the patient can answer yes, no, or “I don’t know” (for most answers), making the criteria easier to document. F2f clinic visits were not as likely as e-visits to document fever and cough. The clinic visits do not have a template for the McIsaac criteria, which most likely explains this difference in documentation.

There were no differences between encounter types in the average age of patients evaluated. Interestingly, however, patients aged 15 to 44 years more often used e-visits as their method of seeking care for a sore throat. This age group consistently uses the digital platform for health care at our institution more often than any other group. This reliance on electronic portals for health care has been the newest method to improve clinic access, reduce waiting time for patients seeking answers to health questions, and improve time spent on renewing prescriptions and allowing patients to access their health records anytime of the day or night. As this younger group ages, more electronic access to health care will need to be available.

Limitations

Prima facie, our study showed a surprisingly high percentage of positive strep tests in the lower McIsaac scores as well as an overall high rate of positive GAS tests (49%). The high percentage of positive GAS tests in our study (both for low McIsaac scores and overall) is very likely due to the retrospective methodology used. In prospective studies of the McIsaac criteria, all patients have GAS testing done regardless of their McIsaac score or other risk factors for a positive GAS test [4,28]. Due to the retrospective nature of this study, only patients who had GAS testing recommended and done as part of their clinical care were included. This methodology means there are likely many patients with low McIsaac scores who were not represented in our dataset as they would have been had this been a prospective trial. Not including these patients with low McIsaac scores in our study (as they did not have GAS testing done) likely elevated the positive rate for the low McIsaac scores and thus the overall positive rate of tests as, in a prospective trial, these patients would have had GAS tests that would be more likely to have been negative. Specifically, we anticipate that patients with low McIsaac scores who were included in our study are likely to have had a higher pretest probability of having a positive GAS test compared with patients with low scores who were not recommended for testing. This higher pretest probability is likely since these patients were recommended to have GAS testing done despite a low McIsaac score. Reasons other than a high McIsaac score that could increase the pretest probability of having a positive test (and thus leading to these patients being tested) could include a history of positive GAS tests (either due to recurrent strep

infections or carrier status) or a known strep contact. These factors would not be reflected in the McIsaac score but would lead to a higher pretest probability of testing positive for GAS and may have led to recommendations for these low McIsaac score patients to be tested, thus increasing the percentage of low McIsaac score patients with a positive GAS test. This would, in turn, elevate the overall positive GAS rate in our study. This supposition is further supported by the fact that our study has a lower percentage of patients with McIsaac scores of 0 and 1 (14% of our study population) when compared with a prospective multisite nationwide McIsaac validating study by Fine et al [4], which had 41% of their study population in the McIsaac 0 and 1 categories. A better comparison to validated studies would be comparing higher McIsaac scores of 3 or 4 where strep testing is routinely recommended. Our study found positive GAS rates of 54% and 63%, respectively, for these scores. This is closer to, although still somewhat higher than, the prospective study by Fine et al [4], where rates were 38% and 57%, respectively. Although somewhat higher, our study also included a significantly younger population (average 22.2 years) versus 34 years of age for Fine et al [4]. Given that younger patients have a higher pretest probability of a positive GAS test, this partially helps to explain the remaining discrepancy in the positivity rate [29].

Conclusions

Measures to combat the above limitations could be a prospective trial performing GAS testing in all patients (including all patients with low McIsaac scores). Methods to improve non-f2f assessment of physical exam findings could include options for patients to send in photos of their tonsils for the e-visit and phone encounters for a provider to review and provide that component of the score. Additionally, photos with examples of various degrees of tonsillar hypertrophy and exudate could be included for patients to choose which appeared similar to their own exam findings. Descriptions (and diagrams with location) of cervical lymph node enlargement could also be included in e-visits to improve patient and caregiver assessment of this score component. Both changes have in fact been instituted in new processes at our institution.

There is no difference in the percentage of positive GAS tests for each McIsaac score when comparing f2f and non-f2f care. Our study is supportive that patients with a McIsaac score of 0 and no missing score components might be candidates to safely exclude from strep testing as none of these patients in our study had a positive strep test; however, as our numbers for this category are small this should be further evaluated in future studies. Additionally, McIsaac scores of 4 or higher calculated during non-f2f care could be considered for empiric treatment of GAS pharyngitis without confirmatory testing, especially when there are significant barriers to obtaining testing.

Abstract

Background: The use of smart speakers to improve well-being had been trialed in social care by others; however, we were not aware of their implementation in most care homes across a region in the Southwest of the United Kingdom. For the widespread adoption of new technology, it must be locally demonstrable and become normalized.

Objective: The aim of this study was to install smart speakers in care homes in a rural and coastal region and to explore if and how the devices were being used, the barriers to their implementation, and their potential benefits.

Methods: Email, workshops, drop-in sessions, phone, and cold calling was used to contact all 230 care homes, offering a free smart speaker and some advisory support. Care homes accepting the devices were asked to complete a feedback diary. Nonresponse rate for diary completion was high and was thus supplemented with a telephone survey.

Results: Over the course of 7 months, we installed 156 devices in 92 care homes for older people, 50 devices for people with physical or mental health needs, and 8 for others. The devices were used mainly for music but also for poetry, recipes, light controls, jokes, and video calls. Care home managers reported the benefits for the residents, including enhanced engagement with home activities, enjoyment, calming effects, and the acquisition of new skills. Implementation problems included internet connectivity, staff capacity, and skills.

Conclusions: Affordable consumer devices such as smart speakers should be installed in all care homes to benefit residents. Voice-activated technologies are easy to use and promote interaction. This study indicates that implementation in care homes was possible and that smart speakers had multifaceted benefits for residents and staff. Most care homes in this region now use smart speakers for their residents, thereby normalizing this practice.

Introduction

The United Kingdom currently has 425,000 people requiring some form of residential care in over 11,000 care homes [1]. In Cornwall, two-thirds of care homes are for older people and one-third for people requiring physical and mental health care. Care homes are under pressure from an ageing population, an underresourced workforce [2], and currently from the impact of COVID-19.

Both the Social Care Institute for Excellence and the Care Quality Commission recognize the importance of technology in providing high quality care services [3,4]. For example, technology can help address loneliness through internet training and video call interventions [5].

Many projects have focused on cutting edge technologies still under development [6] rather than commercially available products that may improve quality of life now in residential care. Exceptions include the use of affordable companion robots [7]. Implementing technology use such as Skype (Microsoft Inc) in care homes has not always been straightforward [8]. Studies of smart home technology have identified desired features such as emergency help, health monitoring, and environmental control [9,10]; however, their implementation may be prevented due to cost [11].

The literature has numerous examples of "pilots" and small-scale studies and national programmes, such as the United Kingdom "delivering assisted living lifestyles at scale" project [12,13], which were set up to try to address implementation at scale conceptual frameworks on technology implementation such as Greenhalgh's Non-adoption, Abandonment, Scale-up, Spread, Sustatinability framework [14], May and Mair's Normalization Process Theory (NPT) [15], the longer standing Technology Acceptance Model [16] and the Unified Theory of Acceptance and Use of Technolgy [17], and the original work of Roger [18] all include the idea of demonstrability at scale and reaching critical mass [19]. Although the Unified Theory of Acceptance and Use of Technology 2 framework has previously been used to examine the adoption of voice-activated digital assistants with community-dwelling older adults [20], we find the NPT framework to be more appropriate for assessing and enhancing the implementation of complex interventions into routine practice, the process known as normalization. The 4 NPT components for the successful integration of interventions are coherence, cognitive participation, collective action, and reflexive monitoring.

Smart speakers became commercially available in 2014 [21] and have seen a rapid uptake with 20% of households now owning one [22]. In 2018, those aged 55 or older comprised 33% of smart speaker ownership, while 14- to 18-year-olds comprised only 10% [23]. Smart speakers are currently available from providers such as Amazon, Google, and Apple, and vary in shape, size, and cost, with some models having screens and cameras. For example, the Amazon Echo also contains a "drop-in" capability where devices, even if in different locations, can be linked and act as an intercom. Most also have the added capability of controlling appliances such as light bulbs, smart doorbells, and heating systems to create a "smart home." Popular uses for speakers include music, information seeking, and entertainment [24,25], but they may extend to companionship, health care support, and better sleep [26]. Speech input and output provide increased accessibility for all users, but particularly for those with limited mobility and vision.

Hampshire and Oxfordshire County councils implemented Alexa devices for 60 people requiring support from social care [27,28]. Both pilot studies found improvements in service users' ability to remain independent and feel less isolated. In Wales, the Innovate Trust investigated how smart speakers could meet the needs of adults with learning differences and reduce staff workload, thus saving money [29]. They estimated a potential saving of £20,000 (US $26,434) per year across two assisted living sites. There are an increasing number of studies examining the use of smart speakers among community-dwelling older adults [30], with qualitative feedback demonstrating commands on first interaction, which included asking for health care-related questions [31]. Although the results of a survey showed that half of care home staff think artificial intelligence in devices such as smart speakers should be in use to help care for residents [32], we found no evidence of the previous implementation of smart speakers in care homes at the majority of sites across the region under study.

The eHealth Productivity and Innovation in Cornwall and the Isles of Scilly (EPIC) project aims to develop the eHealth sector working with both the demand—improving the capability and capacity for using digital technologies—and the supply through supporting small companies producing new products and services. Early workshops identified loneliness as a major health problem and lack of skills in using technology in care homes as a barrier [33]. Voice technology was identified as an area where local expertise could be expanded, but it was clear that its use needed to be normalized [34], and a large user base would provide the incentive of a local market.

This study aimed therefore to address the loneliness and mental well-being of care home residents and at the same time to stimulate the improved uptake of technology in the care home sector, raising awareness and normalizing the use of video calls and voice-activated technologies among care home staff. We aimed to create an expectation of use across the sector.

We aimed to give at least one smart speaker device to 150 (65.2%) of 230 Cornish residential care homes and to explore if and how the devices were used, the barriers to their implementation, and their potential benefits.

Methods

Study Design

This mixed methods implementation study used care home staff diaries and telephone surveys to assess the use and impact of smart speakers. We took an eclectic approach to theory, with a lexicon borrowing ideas of "local demonstrability" [18], "technology acceptability" [16,17], implementation "at scale" [13,14], and "normalization" [15]. This eclectic conceptual framework drew mostly from NPT. The 4 NPT components were considered in our aim to understand if the devices were set up and used (cognitive participation), what they were used

for (coherence), what barriers were experienced (collective action), and any potential benefits to residents and staff (reflexive monitoring). Ethical approval was granted by the Faculty of Health Ethics Committee (reference 18/19-1054).

Choice of Smart Speakers

We aimed to implement devices that offered the possibility of video calls through a screen. In December 2018, the most appropriate device on the market was the Amazon Echo Spot (Figure 1; Multimedia Appendix 1). At Amazon's suggestion, the Amazon Kindle Fire (Multimedia Appendix 1) was trialed in some homes. Early feedback indicated that Echo Spot devices were more physically robust, and Kindle Fires looked more like "regular tablets," which some homes owned and had limited use for. With this feedback, Echo Spots were distributed until October 2019, when they were discontinued. Subsequently, we offered homes the Echo Show 5 (Multimedia Appendix 1).

Figure 1. Amazon Echo Spot.

Care Homes

Using published lists [35] updated through local knowledge, 230 homes were identified. All homes were approached at least once, using a combination of the recruitment methods.

Recruitment and Device Distribution

Initially, care homes were invited to 2 workshops, in West and East Cornwall. The participants were presented with project information and received written information, and those who agreed to participate were provided with a device. In total, 18 homes attended the 2 workshops, and 17 agreed to take part. Moreover, 4 further drop-in sessions were held over 5 months to enable care home staff to speak to researchers about the project. Those agreeing to participate were provided with a smart speaker. Drop-in sessions were advertised via postal and email campaigns and targeted telephone calling. Attendance at local drop-in sessions was low (6 people at 4 sessions from over 200 invited). However, all 6 agreed to participate. A substantial effort was also made via face-to-face recruitment with research assistants "cold calling" approximately 150 homes to explain the project and offer the opportunity to take a device. Cornwall Council also emailed all homes advertising the project resulting in 20 responses.

Support Offered to Care Homes in Using the Smart Speaker

Ongoing support was offered to care homes by two methods. First, the core EPIC team, who had made the initial approach and supplied the device. A monthly email newsletter was circulated with suggestions on different ways to use the device. Second, Digital Health Champions were recruited via undergraduate nursing and occupational therapy programs and students aged 16 or more, from 2 secondary schools. Digital Health Champions were asked to support care home staff in using smart speakers. EPIC team members supported Digital Health Champions with guidance on how to use the device and monthly group Skype sessions as a group.

Data Collection

Care homes were supplied with a short user guide and a diary to keep track of how and how often they were using the device, any barriers and how they were overcome, and any factors that enabled use of the device. Only 18 homes returned completed diaries; therefore, the remaining homes were contacted in early 2020 to take part in a short telephone survey to gain feedback on their device usage, their reason (if they were not using the device), and where it was located. We also asked for short descriptive accounts of their experiences including what the device was being used for and if they had experienced any problems. The responses were documented verbatim directly during the telephone call. Most (142, 95%) homes provided feedback either via diary or by telephone.

Data Analysis

Survey data were analyzed using descriptive statistics. Descriptive experiences of the device usage, gathered from diaries and telephone survey, were qualitatively analyzed using

thematic analysis. We followed the 6-step guide outlined by Braun and Clarke [36].

Results

Care Homes That Took 1 or More Devices

Of the 230 homes invited, 156 (68% initial uptake) homes took at least 1 device (Figure 2). Six homes returned their speaker, leaving 150 (65.2%) with devices (Figure 2). Dividing Cornwall into 5 areas (Figure 3) aggregating primary care networks, uptake was lower in East (44/79, 56%) and West Cornwall (12/23, 52%) compared with the other 3 areas (67%-78%; X^2=10, 4 *df*; *P*=.04). The 150 homes with devices comprised 92 for older people (estimated resident population 2099 [24]) and 50 for those with physical or mental health needs (resident population 1097). Moreover, 10 homes received a Kindle Fire, 141 an Echo Spot, and 5 an Echo Show 5.

Figure 2. Flowchart of recruitment, interventions, and data collection.

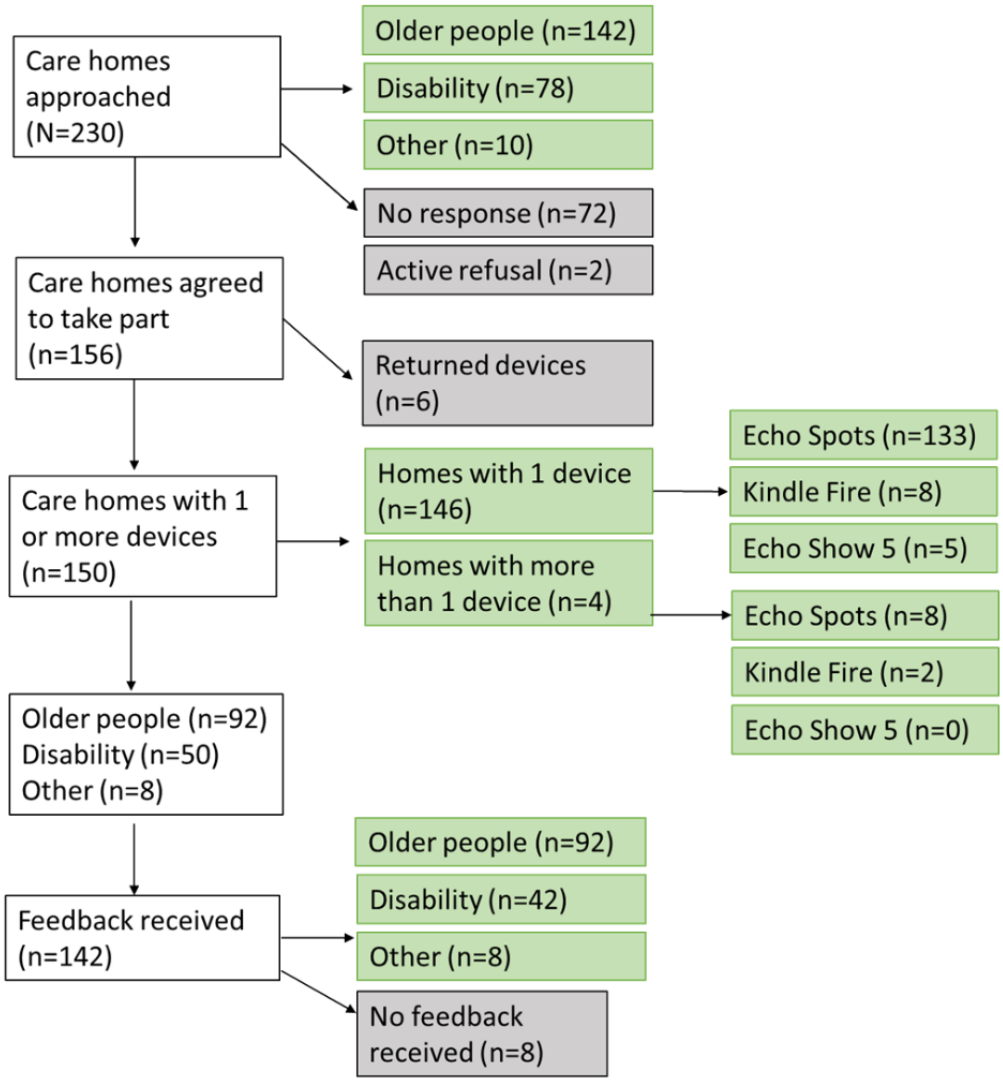

Figure 3. Location of 230 care homes in Cornwall and the Isles of Scilly showing 150 that accepted a smart speaker device and 80 that did not by primary care network areas. PCN: primary care network.

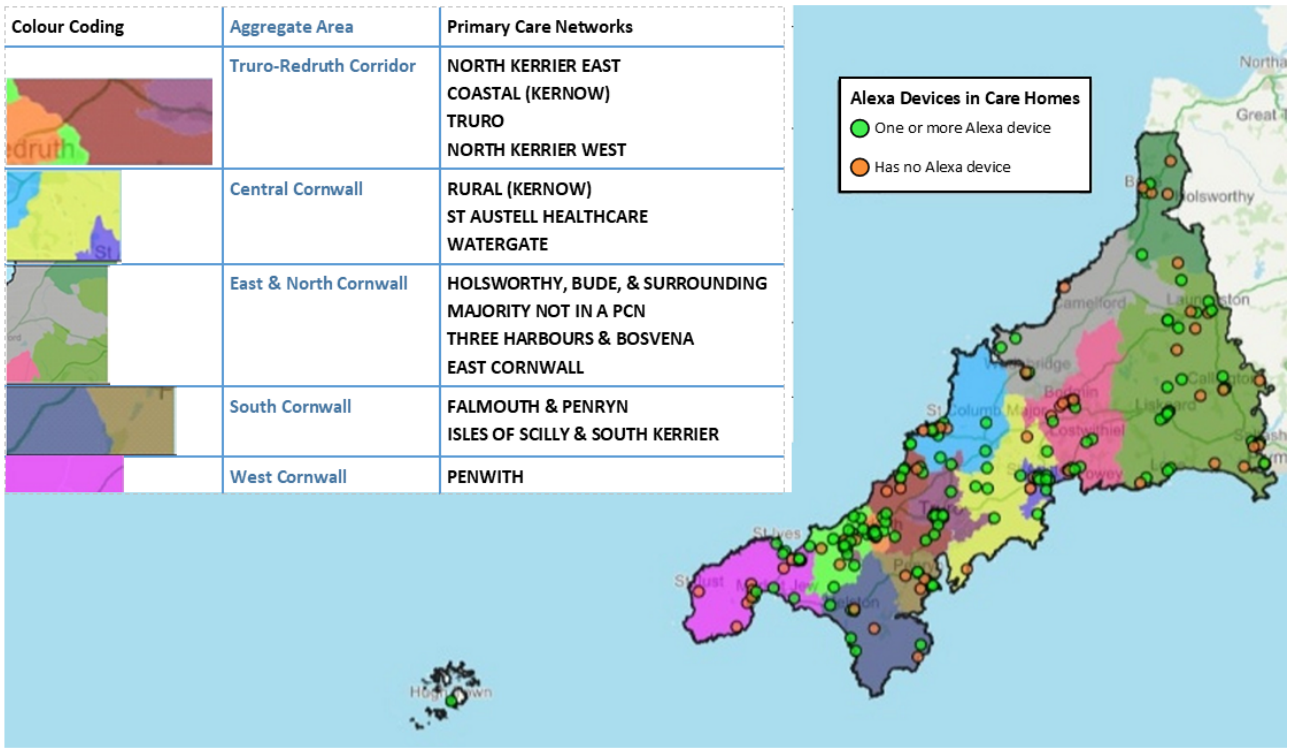

Care Homes That Returned or Did Not Take a Device

The reasons for the 6 returned devices were as follows: (1) management concerns about access to confidential information; (2) staff thinking it was inappropriate for their clients; and (3) lack of internet access. Of the 72 homes (resident population 1740), not taking devices, 3 "positively" declined but 69 did not respond.

Device Usage

Most (142, 95%) care homes provided feedback (Figure 2), of which three-quarters (107/142, 75%) were currently using the device (Table 1). More homes caring for older people were using the device than homes for people with physical and mental health needs (82% vs 61%; X^2=7.1, 2 *df*; *P*=.03). Most homes (70/107, 65%) placed the device in communal areas such as living or dining rooms. Homes caring for older people were more likely to move the device around (26/75, 35%) compared with homes for people with physical or mental health needs (2/27, 7%) (Table 1).

Table 1. Care homes using one or more devices at follow-up, by care home type.

Home type and location of use	Homes, n (%)	Homes using the device, n (%)	Homes not using the device, n (%)	Total, n
Older people		75 (82)	16 (18)	91
Moveable	26 (35)			
Communal	44 (59)			
Other	5 (7)			
Physical or mental health needs		27 (61)	17 (39)	44
Moveable	2 (7)			
Communal	22 (81)			
Other	3 (11)			
Other		5 (71)	2 (29)	7

Communal	4 (80)			
Other	1 (2)			
Total	N/A[a]	107 (75)	35 (25)	142

[a]N/A: not applicable.

Thematic Analysis

We identified 5 themes and 26 subthemes, which can be seen in Multimedia Appendix 2.

Usage

Virtually all (103/107, 96%) homes used devices for music and audio including listening to the radio, creating playlists, listening to Christmas carols, background music, and audiobooks (Multimedia Appendix 2). More than half (62/107, 58%) used it for information seeking, asking the speaker for the news, weather, and checking tide times when arranging walks. A third (35, 33%) used it for quizzes and games, 18 (17%) for jokes and comedy, and 4 (4%) for reminders. Eleven homes (10%) reported "general engagement" with residents talking to and engaging with the smart speaker. One manager reported "We have a resident who just loves to shout at Alexa, she gets in the neck but because she's compliant, the resident loves it!" Video calling was reported by only 6 (6%) homes, although some homes expressed a desire to use it but had not yet tried. However, 2 (2%) homes were using screens as part of other activities (including watching videos), 8 (7%) in sing-along sessions, and 3 (3%) using the "drop-in" feature. One (1%) found the screen useful when running quizzes or adding enjoyment to listening to music.

Moreover, 4 (4%) homes reported "advanced use" such as connecting multiple devices to create a "call bell" for one bedbound resident; "We use it as a makeshift call button, which is linked to all the other devices; when the person presses the button, a song plays across the whole house, and we know he needs support." One (1%) used the device to integrate with other smart technology.

Benefits Associated With Use

In most homes (83/107, 78%) all residents had access to the device, 10 (9%) reported 75%-90% access, and 14 (13%) with more limited access. In diaries and telephone surveys, staff relayed benefits of using the speakers despite not being directly asked. These benefits were grouped into 5 themes (Multimedia Appendix 2). The most frequently reported benefit was resident enjoyment (36/107, 34%). For example, one reported, "the person we support has started to really enjoy music and will dance, relax, or feel vibrations on the echo spots speaker," and another, "this has brought great joy and laughter to the home. Lots of dancing and singing currently taking place."

Relaxation and calming were reported by 11 (10%) homes; for example, "when a client is suffering from agitation we asked for thunderstorms and the results where amazing relaxed the client almost within minutes and he slept peacefully." Seven (7%) homes reported that the device offered companionship, one saying "Alexa is the resident's companion that never sleeps, she is always there if a resident can't sleep and wants some company." Four (4%) homes reported the acquisition of a new skill set for residents as a benefit. One said "our resident has a speech difficulty, so struggles to ask it things, but it helps her to communicate more clearly. She sees staff using it and tries to copy." The less frequently reported benefits were the time saved (2/107, 2%), increased staff engagement (3/107, 3%), and ease of use (2/107, 2%).

Barriers Associated With Nonuse

Among the 35 care homes that reported not using the device, 15 (43%) belonged to a care provider whose IT specialist raised concerns about data protection (Multimedia Appendix 2). Other reported barriers included lack of time and resource (7/35, 20%), internet connectivity (4/35, 11%), and lack of skill or confidence around technology (6/35, 17%).

Barriers Associated With Use

Most homes using their device (75/107, 70%) reported no barriers setting up and using the speaker. Homes who expressed issues most frequently reported internet connectivity problems (14/107, 13%). Nine (8%) homes reported device limitations including the smart speaker's inability to understand certain

residents because of speech difficulties or not using the "desired" language. Barriers to video calling included reluctance from family members and limitations associated with moving the device.

In 2 (2%) homes, residents had broken the device; however, both homes had repurchased devices and placed them in more secure locations. Four (4%) homes reported that the device caused confusion, or residents disliked it; however, in most cases, this was part of an adjustment period. One said, "I think originally they were a little suspicious of the speaker, but now they take it in their stride and just accept that they can ask this small 'box' questions!"

Data protection concerns were reported by 1 home with a device in use. Only 1 home reported resident inability to operate the device as a problem. A lack of skill or confidence in staff was reported by 1 home as a concern.

Support Offered and Requested

Twenty (19%) homes contacted the core EPIC team between April 2019 and February 2020. Nine (8%) homes wanted support including with setup, internet connectivity, connecting two devices, or using Skype. Four (4%) homes requested an additional device, 1 wanted a device with a bigger screen, 1 to exchange their Fire tablet with a Spot, and 5 homes requested further support from a student to use the speaker more effectively.

Moreover, 24 university and 8 secondary school students became Digital Health Champions and borrowed a device. Each university student was assigned at least 2 care homes. Of the recruited care homes, 122 (81%) were linked with a Digital Health Champions and offered support via email, phone, or occasionally face-to-face. However, only 11 homes provided the students with feedback, despite numerous attempts to contact their care homes.

Discussion

Implementation at Scale and "Normalization" of Use

We aimed to get smart speaker devices used in 65% of care homes. This proved challenging but was achieved, benefitting residents and creating a "user base" of voice-activated devices. Although at follow-up 25% (35/142) were not yet using the device, redistribution and prompting was likely to bring these devices into use. Overall, there was emerging "normalization" [34] of smart speaker use in care homes in Cornwall.

Uses and Benefits

Similar to pilot projects conducted in Oxfordshire and Hampshire [27,28], we received positive feedback on the use of smart speakers. Their use was similar to that in the general population [24,25], music and information-seeking being the most popular. While music is a basic function, its use supported opportunities for reminiscence; the speakers provided soothing music with end-of-life care, calming the residents.

Smart speakers may help reduce loneliness and increase independence [27,28]; 6 of our homes stated that the devices provided companionship for residents. Further exploration of functions that support independence, particularly for those living with physical or mental health needs, is required. For example, the "reminder" function has been shown to benefit individuals requiring support while living in their own homes [27,29,37], but only 4 of the 150 homes in our study reported spontaneous use of this function.

Similar to the findings by Pradhan et al [11], our results demonstrated unexpected uses, including 2 homes where the residents' interaction with the smart speaker provided opportunities to practice and improve expressive language skills.

Barriers to Implementation

Implementing new technology in care homes can prove challenging. Zamir et al [5] found that implementing video calls within care homes faced barriers such as staff turnover and lack of family commitment. In our study, only 6 homes reported using the devices to make video calls, suggesting that cheaper devices without screens could be used instead. However, screens were used intuitively as part of other activities including reading lyrics for sing-along sessions and displaying pictures to support information seeking. It remains to be seen how the COVID-19 pandemic has affected the use of video calls within care homes to overcome "shielding."

Studies have cited the lack of digital literacy as a barrier to smart speaker use for individuals requiring social care support at home [27]. Only 1 home in our study that used a device reported a lack of confidence or skill as a barrier; however, for those not yet using it, a lack of skill among staff was a concern. One issue experienced by homes was insufficient internet connectivity; however, outages of Wi-Fi or main power did not pose an unacceptable inconvenience, nor did they seem to inhibit continued use. Changing working methods is always difficult [29], and undertaking activities to increase digital literacy of care home staff could facilitate adoption of voice-activated technology.

As Hoy [21] also found, privacy and data protection using smart speakers was of concern for a few homes and 1 home using the device at follow-up. Such concerns therefore appeared to inhibit adoption but did not limit use once installed. Others have found patient privacy and data protection concerns where there is more specific health care use [38], yet a pilot project in Stoke-on-Trent concluded that while concerns related to privacy and accessibility cannot be ignored, smart speakers may partially solve some problems facing primary care [39]. Our research suggests that smart speaker use in communal areas of care homes for mainly entertainment purposes creates few privacy concerns. Undertaking activities to increase digital literacy including knowledge of data security of care home staff could facilitate adoption of voice-activated technology for more health-related and care-related uses.

In our study, only 1 home refused to participate based on "not liking technology." However, others may find that cultural change hinders wider adoption. Changing working methods is always difficult, as found by a Welsh project on smart speakers in supported living [29]. Undertaking activities to increase digital literacy of care home staff could facilitate adoption of voice-activated technology.

Negative Outcomes

None of the homes reported distress linked to the use of smart speakers, and only 4 homes reported temporary dislike or confusion by residents. However, confusion around the device did not typically affect enjoyment. Other reports suggest people with dementia have shown distress at having a robotic voice speaking to them [40]. How smart speakers are perceived and are of benefit to those experiencing dementia requires more in-depth exploration.

Supporting Installation of New Technology

Although all care homes had the offer of help from a Digital Health Champion student, we had few (20/150) requests for support. In some cases, Digital Health Champion students were particularly active; but overall, this aspect of the project had limited uptake as students had difficulty contacting care homes, with most requests for help being received by the core research team. This may be due to the initial personal contact made for distributing the devices.

Future Uses

As the use of smart speakers becomes normalized in care homes, one might expect an increased use for other purposes such as providing health care information or advice to staff. This extends the use beyond entertainment, and further research is needed to evaluate effective workflows [41]. Further research is also needed on designing voice user interfaces for health care, as current design training for voice interfaces is relatively limited [42].

Limitations

The feedback collected was primarily from one person, usually the manager, and therefore may only represent a single stakeholder perspective. To gain more in-depth understanding of the practical use, barriers, and facilitators of smart speakers, further research is needed from a broader stakeholder base including residents, families, and the Digital Health Champions. On collection of feedback, homes were not specifically asked to share the benefits of device usage; therefore, the benefits experienced may be understated. We had hoped that care homes would keep diaries and be able to tell us how many of their residents interacted with the smart speakers, but this data collection proved impractical. Systematic exploration of benefits and how they related to specific smart speaker "skills" and subsets of service users will be important for future research. Further exploration of the sustainability of benefits of the smart speakers is required in the longer term beyond 3-6 months.

Conclusions

This study demonstrated that most care homes are prepared to install and use smart speakers to benefit staff and residents. As an affordable and readily available commercial product, smart speakers represent a highly scalable option to facilitate technology-enabled care. Future work needs to explore how to reach the remaining care homes, deal with cybersecurity concerns, highlight beneficial "skills" for residents in the longer term, and investigate the impact on staff workload. This may lead to opportunities for smart speaker software development supported by local small and midsize enterprises.

Acknowledgments

We would like to thank Sarah Scrivener (Cornwall Council), Wo King (Hi9), Kirsty Marrs, Anita O'Connor, and other members of the EPIC project for their help and support. We would also like to thank all care homes that took part, in particular, those providing video and other feedback. Lastly, we are grateful to all University of Plymouth students who participated as Digital Health Champions and other Digital Health Champions from Scott Medical College and Pool Academy.

The hardware for this project was funded by Cornwall Council Echo Spot care home project (reference TECGS R1 8). KJE, DS, and TP were funded by the eHealth Productivity and Innovation in Cornwall and the Isles of Scilly project, a project funded in part by the European Regional Development Fund and the South West Academic Health Science Network.

Authors' Contributions

KJE recruited most care homes, distributed smart speaker devices, maintained database and data collection, called all care homes for feedback, analyzed feedback (with DS), wrote draft paper (with RBJ and DS), liaised with Cornwall Council for grant monitoring (with RBJ), and edited and approved the final paper.

RBJ had the idea for the project in response to Cornwall Council funding opportunity, carried out initial literature and informant review, successfully applied for funding and ethics permission, recruited academic colleagues to support digital health champions (with TP), bought smart speaker devices, organized initial workshops, worked with KE, DS, and TP to maintain database, carried out geographical analysis, wrote draft paper (with KJE and DS), liaised with Cornwall Council for grant monitoring (with KJE), and edited and approved the final paper.

DS worked with KJE in recruiting care homes and distributing Alexa devices, worked with KJE in gathering and analyzing feedback, wrote draft paper (with KJE and RJ), and edited and approved the final paper.

TP was coapplicant on application to Cornwall Council and University of Plymouth ethics, recruited Digital Health Champions, liaised with nursing and Occupational Therapy academics, worked with KJE, DS, and RBJ to allocate Digital Health Champions to care homes, supported Digital Health Champions (with written guides and online meetings) in trying to contact care homes, and edited and approved the final paper.

IM gave technical support in use of smart speaker devices, wrote guide and answered queries from care homes and digital health champions, and edited and approved the final paper.

TC was coapplicant on application to Cornwall Council and University of Plymouth ethics, helped with the recruitment of Digital Health Champions, and edited and approved the final paper.
HC was coapplicant on application to Cornwall Council and University of Plymouth ethics, helped with the recruitment of Digital Health Champions, and edited and approved the final paper.
AW was coapplicant on application to Cornwall Council and University of Plymouth ethics, helped recruit and manage digital health champions, and edited and approved the final paper.
FF was coapplicant on application to Cornwall Council and University of Plymouth, helped with the recruitment of Digital Health Champions, and edited and approved the final paper.
TK was coapplicant on application to Cornwall Council and University of Plymouth ethics, helped with the recruitment of Digital Health Champions, and edited and approved the final paper.
AC advised on the project and further developed links with Amazon and other stakeholders for future work using progress in this project, edited, and approved the final paper.

Abstract

Background: Inequities in access to health services are a global concern and a concern for Canadian populations living in rural areas. Rural children hospitalized at tertiary children's hospitals have higher rates of medical complexity and experience more expensive hospitalizations and more frequent readmissions. The 2 tertiary pediatric hospitals in Alberta, Canada, have already been operating above capacity, but the pediatric beds at regional hospitals are underused. Such imbalance could lead to poor patient safety and increased readmission risk at tertiary pediatric hospitals and diminish the clinical exposure of regional pediatric health care providers, erode their confidence, and compel health systems to further reduce the capacity at regional sites. A *Telemedicine Rounding and Consultation for Kids* (TRaC-K) model was proposed to enable health care providers at Alberta Children's Hospital to partner with their counterparts at Medicine Hat Regional Hospital to provide inpatient clinical care for pediatric patients who would otherwise have to travel or be transferred to the tertiary site.

Objective: The aim of this study is to identify perceived barriers and enablers to implementing the TRaC-K model.

Methods: This study was guided by the Theoretical Domains Framework (TDF) and used qualitative methods. We collected qualitative data from 42 participants from tertiary and regional hospitals through 31 semistructured interviews and 2 focus groups. These data were thematically analyzed to identify major subthemes within each TDF domain. These subthemes were further aggregated and categorized into barriers or enablers to implementing the TRaC-K model and were tabulated separately.

Results: Our study identified 31 subthemes in 14 TDF domains, ranging from administrative issues to specific clinical conditions. We were able to merge these subthemes into larger themes and categorize them into 4 barriers and 4 enablers. Our findings showed that the barriers were lack of awareness of telemedicine, skills to provide virtual clinical care, unclear processes and resources to support TRaC-K, and concerns about clear roles and responsibilities. The enablers were health care providers' motivation to provide care closer to home, supporting system resource stewardship, site and practice compatibility, and motivation to strengthen tertiary–regional relationships.

Conclusions: This systematic inquiry into the perceived barriers and enablers to the implementation of TRaC-K helped us to gain insights from various health care providers' and family members' perspectives. We will use these findings to design interventions to overcome the identified barriers and harness the enablers to encourage successful implementation of TRaC-K.

These findings will inform the implementation of telemedicine-based interventions in pediatric settings in other parts of Canada and beyond.

Introduction

Background

The World Health Organization considers "providing equitable access to people-centered care" as one of the key components of a well-functioning health system [1]. In Canada, almost one-fifth of the population (18%) lives in rural communities, but they are served by only 8% of the physicians [2]. Evidence suggests that rural children hospitalized at tertiary children's hospitals have higher rates of medical complexity and experience more expensive hospitalizations and more frequent readmissions [3]. Although inequitable access to health services is a global concern, it is paramount for provinces in Canada to efficiently allocate health resources to reduce health care spending and provide equitable access to pediatric patients in nonmetropolitan and rural communities.

Alberta Children's Hospital (ACH) and Stollery Children's Hospital are the 2 tertiary pediatric hospitals in Alberta. Several regional hospitals throughout the province also have dedicated pediatric beds. Medicine Hat Regional Hospital (MHRH) is one such regional hospital located 300 km southeast of Calgary. Alberta Health Services (AHS) is the single health authority for Alberta province and is the largest such organization in Canada. Both ACH and MHRH are part of AHS. In 2015-16, ACH operated at 95.1% of its bed capacity half of the year and at more than 100% during the rest of the year. During the same year, MHRH showed only 57% occupancy rates. Furthermore, in that same year, 28% of the total pediatric inpatient days of stay at ACH were used by 19% of the pediatric patients from the MHRH catchment area. High bed occupancy is not only associated with poor patient safety, high mortality rates, and increased readmission risk, but it also increases the stress of health care providers [4,5]. In contrast, low use of beds in regional hospitals may diminish the clinical exposure of regional pediatric health care providers, erode their confidence, and compel health systems to further reduce the capacity at regional sites, which hampers access to specialized care for rural patients [6].

Telemedicine is a way to address tertiary–rural imbalances in health care delivery. The World Health Organization defines telemedicine as "healing at a distance" through the use of information and communication technologies (ICTs) [7]. The use of telemedicine enables health care systems to connect patients with health care providers in underserved areas, save time and travel expenses for the patients and their families, increase efficiency, and improve quality of care while supporting health care providers at rural, regional, or community health care sites [8,9]. Telemedicine is an umbrella term that incorporates the use of various forms of ICTs, including but not limited to telephone, electronic messaging, SMS text messaging, mobile apps, and audiovisual tools to provide clinical care. Among these various ICT applications, audiovisual systems are the most promising because they provide an opportunity for real-time audiovisual communication between 2 sites, which facilitates better understanding of a patient's clinical condition, more accurate diagnosis and clinical management, and enhanced communication between personnel at both sites [10]. A growing body of evidence suggests that telemedicine has the potential to bridge geographical barriers to providing clinical care, ranging from diagnosis and active management to maintaining continuity of care for pediatric patients [8]. The educational applications of telemedicine lie in its ability to connect tertiary teaching hospitals with community or rural practices, allowing bidirectional flow of information [11]. Telemedicine also enhances personal relationships between rural pediatricians and subspecialists [12].

Telemedicine-Facilitated Model for Inpatient Pediatric Clinical Care

The use of telemedicine to provide outpatient clinical care is common and usually involves a single patient visit and a few health care providers. The imbalance in use of pediatric beds in Alberta warrants testing innovative solutions to provide equitable and patient- and family-centered care to pediatric patients in nonurban and rural parts of Alberta. Therefore, *Telemedicine Rounding and Consultation for Kids* (TRaC-K), a telemedicine-facilitated model for inpatient pediatric clinical care, is in development and will be piloted between ACH and MHRH. This model was jointly developed by the team of health care providers from ACH and MHRH, as well as administrators and technical experts at AHS. TRaC-K will enable health care providers at ACH to partner with their counterparts at MHRH to provide inpatient clinical care for pediatric patients from the MHRH catchment area. The model promotes regional site access to tertiary care providers and enhances collaboration and communication between care teams. The potential patients for the TRaC-K model will be those who are either admitted at MHRH and could benefit from TRaC-K to receive care at MHRH or those from the MHRH catchment area who are admitted at ACH but are stable and could benefit from TRaC-K for potential early transfer back to MHRH to complete their remaining treatment. These patients will be identified by health care providers from both sites. A telemedicine cart with capability to provide real-time audiovisual transmission will be used for TRaC-K (Figure 1). Textbox 1 lists the key features of the TRaC-K model.

Figure 1. Mobile telemedicine cart capable of real-time audiovisual transmission.

Textbox 1. Key features of Telemedicine Rounding and Consultation for Kids (TRaC-K).

TRaC-K: key features

- Daily inpatient census and patient rounds
  - Census: Monday to Friday; health care teams review patients eligible for TRaC-K at both sites
  - Patient-focused consultation or rounds regarding the care of a patient at 1 site involving teams at both sites and may occur at the bedside with the patient and family included in care planning when able and appropriate
- Telemedicine-facilitated
  - Real-time audiovisual transmission using telemedicine cart (Figure 1)
- Tertiary–regional collaboration
  - Collaboration between Alberta Children's Hospital (tertiary) and Medicine Hat Regional Hospital (regional)
- Multidisciplinary teams
  - General pediatricians, subspecialists, allied health professionals, nurses, and nurse educators (based on patient needs)

The patient-centered–care approach of the TRaC-K model will benefit patients from regional catchment areas who will be able to access tertiary hospital–level care expertise and resources within their own region without having to travel to the tertiary-level hospital. Families will also benefit by saving travel time, minimizing time away from work, and being able to stay better connected to their community support networks.

Inpatient care at both tertiary and regional sites is provided within a complex health system with many providers and occurs independently with limited communications through telephone for specialist physician consultation related to the care of patients. Therefore, it is important to apply rigorous methods to understand the potential influences on behavior in the context in which it will occur and understand the mechanisms of change

even before implementation of the intervention. There exist several models and frameworks for assessing and identifying barriers and enablers to implementation of eHealth interventions, but their focus lies on technological aspects rather than behavioral determinants at the individual level. In the TRaC-K model, technology acts as the facilitator for the clinical model through behavior change. Implementing the TRaC-K model requires change in individual and collective behaviors of all stakeholders involved (ie, physicians, nurses, allied health providers, hospital and unit managers and administrators, patients, and families). Therefore, to systematically identify the stakeholders' perceived barriers and enablers to the implementation of the proposed TRaC-K model of inpatient pediatric care, we used the Theoretical Domains Framework (TDF). The TDF provides a theoretical lens to identify barriers and enablers to change to inform implementation of an intervention in local contexts. The TDF consists of 84 theoretical constructs that are refined into 14 domains [13,14]. The TDF has been used widely to identify behavioral determinants to implementation of health care interventions [15-17].

Therefore, a study identifying perceived barriers and enablers such as health care providers' skills, their perceptions of compatibility of the TRaC-K model, and their motivations to provide virtual care would help in the implementation of TRaC-K, especially in the local context of Canada's first and largest province-wide, fully integrated health system. A paucity of evidence in the scientific literature regarding the implementation of such interventions undermines telemedicine's potential to provide high-quality, cost-effective, patient- and family-centered, and equitable clinical care [18,19]. To our knowledge, no other study has comprehensively studied barriers and enablers to such telemedicine models of inpatient pediatric clinical care.

The COVID-19 pandemic has exponentially increased the uptake of telemedicine in clinical care; however, to our knowledge, TRaC-K is the first telemedicine-facilitated model to provide inpatient clinical care for pediatric patients. Therefore, the objective of this study is to conduct a systematic and theory-informed identification of barriers and enablers to the implementation of the TRaC-K model between ACH and MHRH.

Methods

Design

This study is part of a larger multiphase project to develop, implement, and evaluate a virtual tertiary–regional telemedicine rounding and consultation model of inpatient pediatric care. This is a qualitative descriptive study guided by the TDF. The protocol of this study has been published elsewhere [20].

Ethics

Ethical approval for this study was obtained from the Conjoint Health Research Ethics Board at the University of Calgary (REB17-1435). Administrative approval for this project was also obtained from AHS.

Setting

Participants were selected from ACH and MHRH. ACH is located in Calgary; with 141 beds, it is the largest tertiary pediatric hospital in Alberta. MHRH is located in the city of Medicine Hat, Alberta. It is a 325-bed regional hospital with 10 dedicated beds for pediatric patients, excluding the neonatal intensive care unit.

Participants

We recruited a stratified purposive sample of clinical stakeholders at ACH and MHRH. In addition, we invited family caregivers of pediatric patients with a history of availing inpatient medical services at both ACH and MHRH in the last 3 years to participate in this study. At ACH, we recruited participants by sending an email describing the study, which included an invitation to participate, to unit and allied health managers as well as physician leaders to distribute among their respective teams. We also contacted administrators, including senior leaders at ACH, through email. At MHRH, we recruited participants by sending an email describing the study, which included an invitation to participate, to site pediatric managers and the physician coinvestigator of the study who also distributed it among their respective teams. At ACH, pediatricians and Family Advisory Council members suggested the names of family caregivers meeting our criteria as potential study participants; at MHRH, a single pediatrician obtained the consent to contact from family caregivers to participate in this study. We contacted these family caregivers through email. Interested participants replied to the emails, and we contacted them to set up an in-person interview or telephone interview or focus group. Participant recruitment continued until saturation. We offered a CAD $15 (US $12) gift card honorarium to all participants for their participation in the study.

Interview Topic Guide

The TDF informed the interview guide, with 2-4 questions formulated to explore each of the 14 TDF domains (Multimedia Appendix 1). Investigators with expertise in implementation science (CC and JC) provided guidance to develop the interview guide. Next, members of the research team reviewed the guide to refine it further. We used the same guide for the focus groups, but fewer key questions were asked to initiate the discussion on different TDF domains. We modified some of the questions for the interviews with family caregivers of pediatric patients.

Procedure

A single interviewer (SB), who has expertise and experience in qualitative research, conducted all the interviews and focus groups at ACH and MHRH. For the focus groups, a notetaker accompanied the interviewer to take field notes. Before each in-person interview or focus group, we reviewed the written consent form, and each participant signed it. We excluded administrators from both the focus groups to prevent the power differential from influencing group dynamics during the focus group discussions. For the telephone interviews, we emailed the consent form to the participants before the interview and obtained written consent at the beginning of the interview. In addition, all participants from ACH and MHRH, including family caregivers, completed a brief demographic form.

Individual interviews lasted 30-60 minutes, and each focus group lasted approximately 50 minutes. We audio recorded and transcribed verbatim all the interviews and focus group discussions. Subsequently, we imported all the transcripts into NVivo software (version 11; QSR International) to code, organize, and manage the data to facilitate analysis.

Data Analysis

Before analyzing all the data, 2 reviewers from the research team (SB and CC) independently coded 2 randomly selected transcripts to discuss consistency in coding and develop a codebook. Discrepancies were resolved through discussion. On the basis of this discussion, a codebook was developed, and a single reviewer (SB) coded the remaining transcripts using this codebook.

We analyzed data in 3 steps. First, a directed content analysis approach [21] was used to categorize similar belief statements into each of the 14 TDF domains. We cross-indexed similar statements in multiple domains if they were relevant to more than one domain. Second, we used an inductive coding approach [22] to group similar belief statements to form subthemes within the initial coding scheme of the 14 TDF domains. Finally, as a study team, we further examined these subthemes to aggregate and reword before categorizing them into barriers and enablers. To prepare the results, we tabulated the subthemes within each TDF domain and tabulated larger themes into barriers and enablers separately. Quotations illustrating core beliefs are used to highlight subthemes in each domain.

Results

Interviews and Focus Groups

All the interviews and focus groups were held over a 10-month period (from November 2017 to August 2018). We conducted 31 interviews and 2 focus groups. At ACH, we conducted 15 semistructured individual interviews and 1 focus group. At MHRH, we conducted 16 semistructured individual interviews and 1 focus group. A total of 29 interviews were held face to face, whereas 2 interviews were conducted by telephone because of the inability of the participants to travel to either ACH or MHRH. The ACH focus group consisted of 5 participants, whereas the MHRH focus group included 6 participants. Both focus groups included pediatricians, nurses, and other allied health professionals. Thematic saturation where no new information was achieved was reached after interviewing 42 participants (see Table 1 for characteristics of the participants).

Table 1. Characteristics of study participants (N=42).

Characteristics and category	Participants
Gender, n (%)	
Male	3 (7)
Female	39 (93)
Site, n (%)	
Alberta Children's Hospital	20 (48)
Medicine Hat Regional Hospital	17 (40)
Family members	5 (12)
Position, n (%)	
Administrator	7 (16)
General pediatrician	8 (19)
Pediatric subspecialist	2 (5)
Nurse	10 (24)
Allied health professional	10 (24)
Family member	5 (12)
Focus group participants, n (%)	
Alberta Children's Hospital	5 (45)
Medicine Hat Regional Hospital	6 (55)

During data analysis, key statements demonstrating the beliefs of participants were attributed to each TDF domain. Next, the statements in each domain were grouped to form subthemes. Multimedia Appendix 2 lists all 14 domains of the TDF, their definition, subthemes, and representative quotes for each subtheme.

Barriers and Enablers to Implementing TRaC-K

The subthemes identified in each domain (Multimedia Appendix 2) were further categorized and tabulated into barriers and enablers. This study identified 4 barriers and 4 enablers to the implementation of the TRaC-K model, which are presented in Table 2.

Table 2. Telemedicine Rounding and Consultation for Kids (TRaC-K) barriers and enablers.

Themes and subthemes	Theoretical Domains Framework domain source
Barriers	
Awareness of telemedicine	
Limited awareness about the use of telemedicine in pediatric clinical care	1
Skills to provide virtual clinical care	
Lack of skills to communicate over the screen	2
Lack of clinical assessment skills to provide care over the screen	2
Lack of technical skills	2
Processes and resources to support TRaC-K	
Unclear processes as a potential source of harm	5, 6
Considering challenging clinical circumstances	4, 6, 10, 11
Physical environment	10
Absence of dedicated personnel	14
Difficulties in scheduling	11
Paucity of professional guidelines	3
Provider roles and responsibilities	
Concerns about clear roles and responsibilities	4
Lack of workflow integration	4, 6
Increased workload and competing priorities	11, 7
Enablers	
Motivation to provide care closer to home	
Desire to provide care closer to home	3
Confidence in TRaC-K	5
High importance	8
Excitement	13
System resource stewardship	
Balancing provincial resources	3, 6
Ability to provide tertiary-level care at regional sites	4
Redistribution of patient load and resources; care closer to homes	3, 7
Site and practice compatibility	
Compatible with current practice	9
Buy-in from key stakeholders	12
Education for potential TRaC-K users	14
Motivation to strengthen tertiary–regional relationships	
Opportunity for trust building	3, 6
Opportunity for educational exchange	3, 7

Barriers

Theme 1: Awareness of Telemedicine

Overall, there was limited awareness about the use of telemedicine in pediatric clinical care. All participants were aware of telemedicine in some form such as telephone calls or Skype video meetings among health care providers or between health care providers and patients. Most respondents had heard about telemedicine in adult care or in other jurisdictions of Canada or in the United States. Participants from MHRH were aware of outreach clinics where Medicine Hat patients have direct telemedicine consults with their pediatric specialists at ACH, but MHRH pediatric unit staff are not involved in these consults. Some of the participants reported that they have used or heard of telemedicine being used to provide specific types

of care, such as transition of care or use of synchronous audiovisual telemedicine by the patient transport team.

At the time of the interviews, awareness about using synchronous audiovisual technology for rounding and consultation in inpatient pediatric care was very low. Almost all participants reported that this was the first time they were hearing about a telemedicine-based model of inpatient pediatric care.

Theme 2: Skills to Provide Virtual Clinical Care

Participants identified a number of skills that were currently lacking and would need to be developed to use TRaC-K successfully. All respondents acknowledged the difference between in-person and virtual communication; therefore, they underlined effective communication as an important skill for the TRaC-K model of care. Family members also highlighted that lack of proper communication skills would hamper developing trust and building rapport between patients and health care providers and among health care provider teams. Health care providers at both sites reported that well-organized communication with an ability to verbalize findings, being concise with the information, and framing proper questions would be essential components of communication skills required to provide care through the TRaC-K model. MHRH providers also pointed out that as health care providers at a regional site, MHRH team members would sometimes have to be assertive during the TRaC-K rounds.

In terms of using clinical skills in a virtual health environment, health care providers at ACH believed that they would have to rely on team members at MHRH for clinical observations. In addition, they would have to improve their skills to virtually assess patients over the screen. In contrast, health care providers at MHRH believed that because of TRaC-K, they would have to handle patients with higher acuity; therefore, they might have to advance their assessment skills to make decisions about a transfer to ACH. They might also have to advance their practical skills to perform new or less familiar procedures.

Finally, participants also stressed the importance of technical skills to handle the telemedicine cart and their ability to troubleshoot any technical issues during rounds.

Theme 3: Processes and Resources to Support TRaC-K

Participants identified that lack of clear processes and resources could be an important barrier to successfully use TRaC-K. Most of the participants did not think there was any harm in providing care using the TRaC-K model, but several participants identified some potential harms such as overreliance on technology and incorrect use of this mode of providing care if processes were unclear. Health care providers mentioned a need for specific processes for using TRaC-K in challenging clinical situations as well as ensuring resources to support care in these situations.

Participants highlighted the inability to perform physical examinations and potential miscommunication as sources of adverse outcomes for patients. Health care providers raised concerns about potential delay or failure in recognizing and managing patients whose condition was deteriorating because patients' conditions may change quickly. Health care providers mentioned that because of lack of resources at MHRH, their decision to directly transfer patients to ACH instead of using TRaC-K would be influenced by the need to treat patients classified as acute, especially those with life-threatening emergencies such as respiratory arrest and cardiac arrest as well as those requiring intubation. In addition, health care providers listed clinical situations when it would be difficult to provide care using TRaC-K, such as those requiring *hands-on* care by specialists as well as those involving mental health issues, palliative care, child abuse cases, patient counseling, and patients with complex care needs. Therefore, it was suggested to establish good criteria to determine the kinds of patients who are appropriate to receive care using TRaC-K and those who are not appropriate.

Health care providers also noted several family factors that could contribute to challenging situations, such as non–English-speaking patients, cultural minorities, and families with significant stressors. They highlighted the importance of acceptance of TRaC-K by patients and their families. Participants suggested that one of the ways to mitigate these issues was to educate patients and their families about the TRaC-K model by explaining the reasons for using TRaC-K when they are admitted at MHRH or ACH and addressing any concerns they might have. Other forms of support, such as the Language Line telephone interpreting service to provide care for non–English-speaking patients and billing codes for MHRH pediatricians, were also identified by a few MHRH health care providers.

Specific resources such as the setup of the physical environment and availability of personnel for coordination of TRaC-K were mentioned by many participants. According to participants, factors related to the physical environment, such as the ease of moving the TRaC-K cart among different rooms, size of the patient rooms, and privacy in these rooms, might hinder the use of TRaC-K.

According to many participants, the implementation of TRaC-K involves several logistical issues such as testing technology, scheduling, and coordinating between the 2 sites. Scheduling TRaC-K rounds as part of the workflow and background coordination were consistently highlighted as some of the major challenges. Participants stressed the importance of having support in place before providing care using the TRaC-K model, and they indicated that having dedicated TRaC-K coordinators at ACH and MHRH would address many barriers.

All participants were asked if they were aware of any practice guidelines from their professional organizations regarding telemedicine-facilitated care. Interestingly, almost all were unsure or unaware of any relevant practice guidelines. Many of them guessed that the use of telemedicine would be encouraged by their professional organization but were not able to provide any concrete information about what type of guidelines their organizations want them to adhere to while providing telemedicine-facilitated inpatient care.

Theme 4: Provider Roles and Responsibilities

Health care providers at both ACH and MHRH stressed the importance of having clear roles and responsibilities.

Considering the potential for conflict and medicolegal issues, health care providers wanted clear guidelines on who holds the primary responsibility for the patient, especially if there is disagreement among health care providers at ACH and MHRH in the presence of families.

Health care providers from ACH also raised the issue of their lack of understanding of the capabilities of regional hospitals and the staff at MHRH. The need to integrate TRaC-K workflow into current clinical structures was also highlighted by participants. Health care providers at MHRH mentioned that pediatricians there provide care at their private clinics as well as at the inpatient unit and emergency department at MHRH; therefore, finding time to schedule their TRaC-K rounds would be challenging. Similarly, health care providers at ACH and MHRH also emphasized the importance of scheduling TRaC-K rounds in advance. Health care providers at ACH also did not want to be torn between multiple sites because this may have a negative impact on the care they provide for their own patients at ACH.

Participants were asked to imagine the potential changes that would occur with the implementation of TRaC-K. Health care providers at MHRH expressed that TRaC-K would increase their workload because they would see more patients classified as acute, and because of TRaC-K, MHRH patients transferred to ACH might be transferred back to MHRH, resulting in higher use of the pediatric unit at MHRH and increasing their workload. Participants also shared their thoughts on the situation that would arise if TRaC-K was not implemented. Without TRaC-K, the status quo would continue, resulting in continuation of current practices, including calling ACH by telephone for specialist physician consultation, patients and families traveling to ACH, and imbalance in bed occupancy.

Other competing priorities were also as seen as a potential barrier. Health care providers at MHRH mentioned that they have fewer pediatricians than ACH, and most of them have their own private clinics; therefore, they have to provide care at different locations, and accordingly sometimes other competing priorities might act as a barrier to using TRaC-K.

Additional issues such as the comfort level of health care providers at MHRH to handle patients with complex care needs and non–English-speaking patients were also mentioned as some of the circumstances under which it would be difficult to use TRaC-K. Some patient-related challenges in the use of TRaC-K were also pointed out. According to a health care provider at ACH, some patients “like” to be at ACH for various nonclinical reasons such as an opportunity to shop and visit the city.

Enablers

Theme 1: Motivation to Provide Care Closer to Home

Participants at ACH and MHRH stressed the importance of providing care closer to home, especially for pediatric patients. Participants believed that pediatric patients and their parents develop their social support mechanism in their own communities; therefore, taking patients to ACH disconnects them from such social support. The long commute (3-4 hours, one way) between MHRH and ACH and the dangers associated with such long-distance travel, especially during snowy winter months, was stated as another reason for providing care closer to home.

Most of the participants showed high confidence in TRaC-K and affirmed that it would not drastically change the current practice of providing care but rather enhance it. During the focus group at ACH, a few health care providers cautioned against overvaluing TRaC-K as a total replacement for face-to-face care. Despite several potential sources of harms having been identified, participants supported TRaC-K and expressed that the benefits of using TRaC-K would outweigh potential harms or negative consequences.

Participants also felt that the TRaC-K project was of high importance. They were asked to rate the importance of providing care through the TRaC-K model on a scale of 1-10, with 10 being very important. The score given by participants ranged from 5 to 10; most rated it as 8 or 9. The reasons for giving high scores were the TRaC-K model’s ability to keep patients and families within local communities and its potential to improve the quality of care. Some of the reasons cited for lower scores were a potential increase in workload and skepticism about the TRaC-K model’s usefulness.

In general, participants were excited about the TRaC-K model mainly because they want to try something new and TRaC-K offers them a novel way to care for their patients. However, without having tried it, some participants mentioned being optimistically cautious.

Theme 2: System Resource Stewardship

Participants acknowledged the importance of telemedicine-facilitated pediatric care in promoting sustainability from a health system’s perspective. Participants were aware of overcapacity at ACH and underuse of pediatric beds at MHRH; therefore, they recognized that the TRaC-K model would help in balancing the patient load. According to participants, TRaC-K would also facilitate transition of care for patients with complex chronic conditions from ACH to MHRH. Therefore, TRaC-K was viewed as a mechanism to address this imbalance and to advocate for additional resources for regional sites such as MHRH. None of the participants mentioned any personal monetary incentives to use the TRaC-K model of inpatient clinical care. However, the potential cost saving for AHS was mentioned as a financial incentive at the system level.

Providing care at regional sites when possible was deemed important for the system and for families. All participants reiterated the important role of TRaC-K in providing patient- and family-centered care in local communities for patients from regional sites. Other key benefits such as prompt expert care, faster diagnosis and treatment, and better quality of care were also mentioned. Health care providers acknowledged that using TRaC-K would help to provide family-centered care, and if patients and families at MHRH felt that they were not at the best hospital, then joint rounds using TRaC-K in their presence would show that ACH and MHRH were working as 1 team to provide the best care for their child. Family members mentioned the potential reduction in wait times to see a specialist as an incentive for them to use the TRaC-K model.

Participants described various incentives for them to use TRaC-K from their own perspectives. The biggest incentive for health care providers was the professional satisfaction gained by providing best-quality care closer to the patient's home.

Theme 3: Site and Practice Compatibility

Participants overwhelmingly agreed that TRaC-K would be compatible with their practice because it aligns with their motivation to provide patient- and family-centered care and technology is slowly changing the way care is provided; therefore, with a few modifications, they could easily incorporate TRaC-K into their practice or adapt their practice to use TRaC-K.

Participants highlighted that buy-in from all health care providers, especially from key stakeholders such as physicians and administrators, would be essential for successful implementation of TRaC-K. A participant even considered the interviews and focus groups for this study as an educational opportunity for them to know more about TRaC-K.

Many participants alluded to the importance of educating potential users of TRaC-K, including health care providers at ACH and MHRH and patients and their families. The educational activities mentioned were creating educational material, performing hands-on trials with technology, and practicing in mock scenarios. It was suggested that to promote family-centered care, families should be engaged right from the beginning, with explanations of the TRaC-K model provided to them verbally or by using pamphlets and of what they should expect during their stay at MHRH, instead of a screen being wheeled directly into their room and placed in front of them.

Theme 4: Motivation to Strengthen Tertiary–Regional Relationships

Participants from MHRH affirmed that having access to, and frequent interactions with, the teams from ACH would help build trust between regional and tertiary health care providers. Participants at MHRH pointed out that having access to tertiary health care providers, including specialists at ACH, through TRaC-K would enhance patients' and families' trust in MHRH and encourage them to seek care at MHRH instead of traveling to ACH, especially in situations where visiting ACH was unnecessary.

During joint rounds, clinical teams from ACH would be able to disseminate knowledge about new treatment guidelines, procedures, and protocols for handling patients with complex care needs among their peers at MHRH. ACH providers would also be able to learn about the challenges and capacities of regional sites. Participants from MHRH also viewed TRaC-K as an opportunity to learn and receive more support from their colleagues at ACH. Therefore, implementation of the TRaC-K model was considered a great learning opportunity for health care providers at both ACH and MHRH, which would enable both sides to share clinical knowledge. Regular communication between regional and tertiary health care providers would also serve as additional support for newly trained clinicians moving to regional sites because they would be able to receive second opinions and have a new set of eyes looking at their patients.

Discussion

Principal Findings

Our study identified 31 major subthemes in 14 domains, ranging from administrative issues to specific clinical conditions. These subthemes were further aggregated into major themes and categorized into 4 barriers and 4 enablers. Our findings suggest that most of the barriers concern uncertainties associated with potential hands-on, day-to-day use of TRaC-K. We anticipate that some of these barriers will be mitigated once the TRaC-K model pilot begins. On the basis of these barriers, dedicated TRaC-K coordinators will be hired to address administrative issues such as scheduling, providing technical support, and streamlining the process to reduce some of the workload. Some of the barriers identified in this study, such as lack of information technology skills and paucity of professional guidelines, are consistent with those identified in a study from Australia [12]. The ongoing COVID-19 pandemic has significantly affected the delivery of health care. Travel restrictions and the burden on tertiary sites have created a unique opportunity to use telemedicine. The urgency of providing efficient clinical care during this pandemic has mitigated many barriers to using telemedicine; however, the use of telemedicine in the postpandemic era remains uncertain. Many health care systems have realized the importance of telemedicine but still struggle to use it as a long-term solution [23]. Thus, the findings of this study remain timely and relevant.

On a positive note, the enablers demonstrate the willingness of health care providers to embrace the change to provide patient- and family-centered care. The enablers were also associated with participants' desire to change the current imbalance in health care use between ACH and MHRH and a positive attitude toward TRaC-K's potential to change the status quo and probably open new opportunities for educational exchange and trust building between tertiary and regional sites. ACH and MHRH are part of AHS, a single province-wide health authority, which might have helped participants to understand the importance of rebalancing resources between tertiary and regional sites. The potential of these enablers will be harnessed to encourage health care providers to use TRaC-K.

Next, the findings from this study will be used to map potential barriers and enablers to the behavior change techniques (BCTs) from BCT Taxonomy version 1, which is a standardized list of 93 hierarchically clustered BCTs [24]. The BCT-mapping exercise will be conducted with the key stakeholders. The BCTs that are likely to change behavior will be used as ways to mitigate barriers and harness the potential of enablers. Finally, the revised TRaC-K model will be piloted between ACH and MHRH for 1 year. The results of the TRaC-K pilot study will determine its feasibility and scale-up throughout the province.

The province-wide application of the TRaC-K model may increase regional pediatric bed use at multiple regional sites, thereby having a positive impact on the current tertiary overcapacity crisis in Alberta. In addition to addressing the imbalance in the use of pediatric capacities between regional and tertiary hospitals, it is anticipated that this project will enhance tertiary–regional collaboration, thereby supporting

numerous other provincial goals such as provincial pediatric guideline implementation and pediatric workforce sustainability. AHS has created various strategic clinical networks (SCNs) as engines for research and innovation as well as to act as vehicles for translating evidence into practice to improve patient care and health system performance. This project is supported by the Maternal, Newborn, Child & Youth SCN. Therefore, the findings of this study will be disseminated as pediatric health services research–generated knowledge through the Maternal, Newborn, Child & Youth SCN to drive the pilot and scale-up of TRaC-K in Alberta.

Interventions such as the TRaC-K model could fail to achieve the expected outcomes because of the lack of a scientific approach to identify and address factors such as barriers and enablers before implementation. This study contributes a comprehensive and systematic inquiry into perceived barriers and enablers to implementing telemedicine to the body of scientific literature. The evidence generated from this study would not only benefit other health care systems interested in implementing telemedicine-facilitated interventions to provide inpatient clinical care, but also serve as a publication to guide other research teams undertaking similar research to identify barriers and enablers for similar interventions within their own contexts.

The systematic and theoretical framework–driven approach to identify potential barriers and enablers to the TRaC-K mode is a clear strength of this study. In addition, a major strength of this study was the diversity of perspectives captured through interviews and focus groups. The inclusion of families of pediatric patients who frequently travel between ACH and other regional sites provided patient- and family-centric insights regarding the TRaC-K model. However, the findings of this study must be interpreted keeping some limitations in mind. First, this study was conducted before the COVID-19 pandemic; therefore, some of the barriers and enablers might have changed. Methodologically, the TDF is a framework; hence, it only describes empirical phenomena by classifying them into sets of domains. The TDF neither describes nor provides an explanation for a phenomenon; nor does it specify a relationship among its domains. Although we excluded administrators from the focus groups to mitigate the potential power imbalance, pre-existing professional relationships might have influenced the opinions of some of the participants of these focus groups. Finally, recruitment through stratified sampling required contacting family caregivers meeting the eligibility criteria through their pediatricians, which might have resulted in selection bias.

Conclusions

This systematic inquiry into perceived barriers and enablers to the implementation of TRaC-K helped us to gain insights from health care providers' and family members' perspectives. We are optimistic that the implementation of TRaC-K will be successful based on the enablers identified through this study. Enablers such as motivation to provide care closer to pediatric patients' homes and to adjust the imbalance in health care resource use will play a key role in the implementation of TRaC-K. The association of barriers with the uncertainties concerning day-to-day use of TRaC-K will enable us to address these barriers by creating clear processes and providing support through dedicated staff. Finally, these findings will inform the development and implementation of telemedicine-based interventions in other parts of Canada and beyond.

Acknowledgments

This study was made possible by support from the Maternal, Newborn, Child & Youth Strategic Clinical Network (MNCY SCN). The authors would like to gratefully acknowledge the study participants (health care providers and patients) for their contributions to this study. The authors would also like to thank Mr Ashton Chugh for helping with notetaking during the focus groups.

The project team acknowledges funding from the Department of Pediatrics, University of Calgary, and the Health Outcomes Improvement Fund from MNCY SCN. SB received financial support in the form of a graduate studentship from MNCY SCN, Collaborative Research and Innovation Opportunities scholarship from the Ward of the 21st Century Research and Innovation Center at the University of Calgary, and Graduate Student Scholarship from the Alberta Children's Hospital Research Institute.

Authors' Contributions

JAMB, DWJ, JC, and CC contributed to the overall study rationale, design, and methods development. SB conducted all the interviews and focus groups. SB and CC analyzed the data. SB led the drafting of the manuscript. All authors contributed to the drafting of the manuscript and approved the final version.

Abstract

Background: Young adults' early adoption of new cell phone technologies have created challenges to survey recruitment but offer opportunities to combine random digit dialing (RDD) sampling with web mode data collection. The National Young Adult Health Survey was designed to test the feasibility of this methodology.

Objective: In this study, we compared response rates across the telephone mode and web mode, assessed sample representativeness, examined design effects (DEFFs), and compared cigarette smoking prevalence to a gold standard national survey.

Methods: We conducted a survey experiment where the sampling frame was randomized to single-mode telephone interviews, telephone-to-web sequential mixed mode, and single-mode web survey. A total of 831 respondents aged 18 to 34 years were recruited via RDD at baseline. A soft launch was conducted prior to main launch. We compared the web mode to the telephone modes (ie, single-mode and mixed mode) at wave 1 based on the American Association for Public Opinion Research response rate 3 for screening and extended surveys. Base-weighted demographic distributions were compared to the American Community Survey. The sample was calibrated to the US Census Bureau's American Community Survey to calculate DEFFs and to compare cigarette smoking prevalence to the National Health Interview Survey. Prevalence estimates are estimated with sampling weights and are presented with unweighted sample sizes. Consistency of estimates was judged by 95% CI.

Results: The American Association for Public Opinion Research response rate 3 was higher in the telephone mode than in the web mode (24% and 30% vs 6.1% and 12.5%, for soft launch and main launch, respectively), which was reflected in response rate 3 for screening and extended surveys. During the soft launch, the extended survey and eligibility rate were low for respondents pushed to the web mode. To boost productivity and survey completes for the web condition, the main launch used cell phone numbers from the sampling frame where the sample vendor matched the number to auxiliary data, which suggested that the number likely belonged to an adult in the target age range. This increased the eligibility rate, but the screener response rate was lower. Compared to population distribution from the US Census Bureau, the telephone mode overrepresented men (57.1% [unweighted n=412] vs 50.9%) and those enrolled in college (40.3% [unweighted n=269] vs 23.8%); it also underrepresented those with a Bachelor of Arts or Science (34.4% [unweighted n=239] vs 55%). The web mode overrepresented White, non-Latinos (70.7% [unweighted n=90] vs 54.4%) and those with some college education (30.4% [unweighted n=40] vs 7.6%); it also underrepresented Latinos (13.6% [unweighted n=20] vs 20.7%) and those with a high school or General Education Development diploma (15.3% [unweighted n=20] vs 29.3%). The DEFF measure was 1.28 (subpopulation range 0.96-1.93). The National Young Adult Health Survey cigarette smoking prevalence was consistent with the National Health Interview Survey overall (15%, CI 12.4%-18% [unweighted 149/831] vs 13.5%, CI 12.3%-14.7% [unweighted 823/5552]), with notable deviation among

18- to 24-year-olds (15.6%, CI 11.3%-22.2% [unweighted 51/337] vs 8.7%, CI 7.1%-10.6% [unweighted 167/1647]), and those with education levels lower than Bachelor of Arts or Science (24%, CI 19.3%-29.4% [unweighted 123/524] vs 17.1%, CI 15.6%-18.7% [unweighted 690/3493]).

Conclusions: RDD sampling for a web survey is not feasible for young adults due to its low response rate. However, combining this methodology with RDD telephone surveys may have a great potential for including media and collecting autophotographic data in population surveys.

Introduction

For a multitude of reasons, young adults have been a difficult and resource-demanding population on whom to conduct surveillance research using traditional sampling and data collection methods, especially for longitudinal surveys. They are highly mobile, moving at over twice the rate of other adults [1], making address-based and area-based sampling, as well as recontacting for follow-up data collection, challenging and resource-demanding. Likewise, they are much more likely than the general adult population to live in nontraditional and group housing such as military barracks or college dormitories [2]. Moreover, they are early adopters of new communication technologies that replace traditional contact modes, such as wireless substitution (eg, foregoing traditional landline telephones in favor of only owning cell phones). The combination of early adoption of wireless substitution, nontraditional housing, and high mobility has created substantial challenges to conducting both repeated cross-sectional and longitudinal telephone-based surveillance research among this important population subgroup. For example, their high and rapid rate of wireless substitution from the early 2000s through today led to a decline in participation and likely increased coverage bias in traditional random digit dialing (RDD) surveillance systems such as the Behavioral Risk Factor Surveillance System [3,4]. Likewise, their higher rate of living in institutional housing leads to greater coverage errors for many surveillance studies that use address-based or area probability sampling. Lastly, their high mobility rate means they are more difficult to locate and contact for follow-up data collection in longitudinal surveillance designs that typically rely on numerous approaches to engage participants such as mailings, keeping contact information for someone who knows the respondent (in case of difficulty recontacting), and making telephone calls. This is particularly detrimental to rapid surveillance of behaviors and health conditions that are themselves highly dynamic or occur in dynamic environments, such as tobacco use, which has seen a drastic shift in the tobacco product market with the introduction and growth of emerging products such as e-cigarettes in a historically short period of time.

Paradoxically, wireless substitution proved beneficial with respect to sampling young adults for cross-sectional telephone surveillance surveys [5]. Indeed, cell phone ownership is practically universal among young adults, and research found that cell-phone–only RDD led to a representative cross-section of the young adult population [3,6]. However, despite advances in sampling and weighting methodologies to address the wireless substitution challenges, response rates have continued to drastically decline. For example, Pew Research Center reports an average response rate of 28% in 2001 compared with only 6% in 2018 [7]. Thus, considerable challenges remain in conducting behavioral surveillance research, particularly rapid surveillance, in this population. This recent drastic decline in response rates for RDD surveys may be related to the rapid transformation of cell phone technology and, in turn, how cell phones are used, particularly among young adults who are the early adopters of this technology [8,9]. Indeed, smartphones, which have seen an incredibly rapid uptake in the population, allow users to communicate via multiple modes—voice, text, email, messaging, and through social media. People are decreasingly using the device for telephone conversations and increasingly using them to connect to the internet for communication via social media, texting, and email [9,10]. Moreover, some cell phone platforms (eg, iOS, Apple Inc) now include functions that block incoming calls that are not from telephone numbers known to the recipient [11]. Thus, RDD surveys once again are faced with major challenges related to secular shifts in technology use. However, as with wireless substitution, these challenges may create a new opportunity by providing a single device through which young adults can be sampled, recruited, and administered surveys via multiple modes for both cross-sectional and longitudinal surveillance research projects that use RDD and telephone mode. Indeed, this could save tremendous resources and lay the groundwork for the collection of new types of data if smartphones can be used for administering web surveys with data quality that is on par with telephone surveys.

We designed the National Young Adult Health Survey (NYAHS), a national longitudinal RDD survey of young adults, to compare two ways of integrating web-based data collection—sequential telephone-to-web mixed mode and single-mode web survey—against traditional single-mode telephone surveys. This paper uses the baseline data collection of the NYAHS to compare the response rates across telephone and web modes; to assess the generalizability of the sample by benchmarking the demographic distributions to population distributions; to examine the impact of sampling design and sample weighting on statistical precision; and to compare estimated cigarette smoking prevalence to the prevalence from a gold standard national survey.

Methods

Sampling and Recruitment

The NYAHS was designed to provide representative cross-sectional and longitudinal estimates of health behaviors using RDD sampling and to test the feasibility and utility of integrating web surveys in surveillance systems that use RDD sampling. Specifically, we compared three modes of data collection: (1) single-mode telephone survey, (2) sequential telephone-to-web dual mode, and (3) single-mode web survey. Single-mode telephone survey is the traditional approach for RDD surveillance systems, while sequential telephone-to-web dual mode and single-mode web surveys are experimental. The sample was purchased from Marketing Systems Group, and the initial sample of 136,000 cell phone numbers was randomized to one of the three data collection modes prior to loading to the computer-assisted telephone interviewing system. Figure 1 presents the sampling and original data collection design for the study. For each mode, a random selection of cellular phone numbers from cellular-dedicated thousand-level blocks were selected. Telephone interviewers manually dialed selected numbers and read a recruitment script that explained the purpose of the study and screened for eligibility. For single-mode telephone, recruitment and each data collection occasion were conducted entirely through telephone. For the sequential mixed mode, the baseline or wave 1 survey as well as waves 2 and 3 were conducted using telephone recruitment and data collection (identical to single-mode telephone), while brief follow-up surveys were conducted via the web. For the single-mode web survey, baseline recruitment was conducted via telephone with the web mode data collection. Following baseline, invitations to web surveys were sent via text and/or email depending on the respondents' preference.

Figure 1. NYAHS sampling and original data collection design. CATI: computer-assisted telephone interview; NYAHS: National Young Adult Health Survey; RDD: random digit dialing.

Frame		Mode	Sampling + recruitment mode	Wave 1 mode	Brief follow-up	Wave 2 mode	Brief follow-up	Wave 3 mode
Telephone numbers	Randomization	Single-mode telephone	RDD + CATI	CATI	CATI	CATI	CATI	CATI
		Sequential mixed mode	RDD + CATI	CATI	Web	CATI	Web	CATI
		Single-mode web	RDD + CATI	Web	Web	Web	Web	Web

To improve retention, a revision was made to the design to collect data via telephone for all modes following wave 2.

We worked 28,519 samples as a soft launch to identify ways to streamline data collection. To ensure adequate sample size for tobacco types with lower prevalence, "ever use" of any tobacco product (ie, having used a tobacco product at any time, hereafter "ever tobacco") was an inclusion criterion. However, in combination with lower response rates in the web condition, the ever tobacco inclusion criterion proved infeasible. Thus, for the main survey launch, the only inclusion criterion was being 18 to 34 years old. Moreover, in order to increase the likelihood that we reach eligible people in the single-mode web condition, we only used telephone numbers that were identified as having a high likelihood of belonging to young adults based on an additional preprocessing step using auxiliary data. We also made small wording changes to the recruitment script. No other changes were made to the recruitment process or data collection for either of the conditions.

Instrumentation

The survey instrument was designed to collect data to estimate annual tobacco prevalence and longitudinal tobacco use trajectories. Consequently, most items in the survey asked about the use of tobacco and nicotine products, but the survey also asked about the awareness of new and emerging tobacco products, cannabis and alcohol use, and several demographic characteristics. We used standardized measures when possible and adapted nonstandardized measures from other tobacco surveys. The English language survey was translated into Spanish by a bilingual researcher and independently reviewed by a second translator with inconsistencies adjudicated by the investigator team. New survey questions were pretested in Spanish and English using cognitive interviewing techniques, and a usability test was carried out on iOS and Android (Google Inc) devices.

Data Collection

Baseline data collection occurred between April 2018 and May 2019 via a computer-assisted telephone interviewing system and web-based survey. A screening questionnaire was used to identify eligible participants, defined as young adults between the ages of 18 and 34 years. The respondents in the single-mode telephone and sequential telephone-to-web modes were immediately transitioned to the main interview following the recruitment script and eligibility determination, while the respondents in the single-mode web group were texted a link

to a URL for the web survey. The URL led them to a consent form page after which the respondents were taken to the main survey. Interviews and web surveys were conducted in Spanish when language barriers were encountered during recruitment. The interviews took an average of 16.8 minutes to complete and were comparable in length in both English and Spanish. Invitation texts and emails were sent in Spanish for Spanish-speaking respondents. The participants were offered a conditional US $15 electronic gift card to a major online retailer as an incentive. The data collection protocol was approved by the Institutional Review Board at Rutgers Biomedical Health Sciences.

Sampling Weights

A base weight was calculated as the product of the inverse of the probability of selection for each sample member and the number of cellular telephones on which a respondent receives calls. The base weight was adjusted for a 24% oversampling of ever tobacco users due to the inclusion criterion of the soft launch. The base weight was then calibrated via iterative proportional fitting to population numbers from the 2018 American Community Survey (ACS) [12], a large-scale survey conducted by the Census Bureau to update population estimates between decennial censuses. Specifically, the base-weighted sample was calibrated along age (18-21 years, 24-29 years, and 30-34 years), sex (male and female), education (<BA vs ≥BA), and race or ethnicity (White, non-Latino; Black, non-Latino; Asian, non-Latino; Latino; and other). Population demographic distributions were generated from weighted analysis of the 664,617 participants aged 18 to 34 years in the ACS Public Use Microdata Sample. Calibration of the NYAHS was conducted using the 'survey' package in R (R Core Team) [13,14].

Statistical Analysis

The eligibility rate was calculated as the number of respondents meeting the inclusion criteria (aged 18-34 years and ever using tobacco during the soft launch; for the main launch, just ages 18-34 years) divided by the total number of respondents who were contacted and who answered the screening questions about age (and tobacco use early in the study). Second, we calculated the American Association for Public Opinion Research response rate 3 for screening, for extended surveys, and overall [15]. The screening response rate 3 is calculated as the number of completed screeners (eligibility questions) divided by the estimated number of sampled phone numbers active and used for personal calls. Importantly, it includes in the denominator an estimate of the eligible numbers among the dialed numbers where eligibility could not be determined. Since a vast number of the dialed numbers fall in this category, it is instructive to look at the overall response rates as well as the extended survey (ie, among those for whom eligibility could be established), the latter of which is also known as cooperation rate.

Sample representativeness across data collection modes was assessed by comparing the base-weighted NYAHS demographic distribution for sex (male and female), age (18-21 years, 22-24 years, 25-29 years, and 30-34 years), and race or ethnicity (White, non-Latino; Black, non-Latino; Asian, non-Latino; Latino; and other) against population distribution from the ACS. Single-mode telephone and sequential telephone-to-web mixed mode was collapsed as their protocols are identical at baseline. Because the calibration of base-weighted demographic distributions to population values is based only on point estimates, we did not present confidence intervals as a measure of precision. Rather, we used the National Center for Health Statistics Data Presentation Standards for Proportions criteria for reliability to suppress data that are not reliable [16].

The impact of sampling design and calibration on statistical precision is summarized with the sampling design effect (DEFF). DEFF is the ratio of variance under the complex sampling design to the variance under a simple random sample for a given estimate. We calculated DEFF as presented by Kish [17], who incorporates the correlation of sampling weights with the outcome, and presented it overall and by key subpopulations.

To assess bias in cigarette smoking prevalence, we compared the estimated prevalence from the NYAHS combined across data collection modes to the National Health Interview Survey (NHIS) [18]. The NHIS is an in-person interviewer-mediated national survey that uses area probability sampling. Thus, it is not subject to any bias resulting from an RDD approach or due to push-to-web survey following telephone recruitment. Cigarette smoking was selected as a comparison benchmark as its measurement has long been standardized. By contrast, newer products do not have uniform question wording across surveillance systems; thus, they lack a gold standard measurement. Current smokers were defined as individuals who have smoked at least 100 cigarettes in their lifetime and who currently smoke every day or some days. We presented point estimates with 95% CI calculated using the logit method. The NHIS and NYAHS estimates were generated using final sampling weights and are presented with unweighted numerators and denominators. Consistency of prevalence estimates were judged by comparing the point estimates and the degree of overlap of confidence intervals. The estimates were suppressed from tables and figures if they did not meet the National Center for Health Statistics Data Presentation Standards for Proportions [16]. All analyses were conducted using the survey package in R [13,14].

Results

Eligibility and response rates are presented in Table 1, for the main data collection (ie, after including the supplemental sampling frame for the single-mode web survey and implementing minor tweaks to the introductory language) and the soft launch. The eligibility rate for telephone was 12% (143/1191) for the soft launch and 17.6% (864/4909) for the main data collection, and 9.6% (51/532) and 30.3% (306/1009), respectively, for the single-mode web survey (where only cell phone numbers identified as having a higher likelihood of being in the 18-34 years age range were used). The screening response rate was 32.8% (4909/14980) and 39.8% (1191/2994) for the main and soft launch, respectively, compared to 16.1% (1009/6248) and 42.6% (532/1248) for the single-mode web survey. The extended response rate was 68.6% (593/864) and 74.8% (107/143) in the main and soft launch for the telephone survey and 37.9% (116/306) and 29.4% (15/51), respectively, for the single-mode web survey. These resulted in the overall

response rates of 24% (main) and 30% (soft launch) for telephone and 6.1% (main) and 12.5% (soft launch) for the single-mode web survey.

Table 1. Response rate by mode from the National Young Adult Health Survey.

Eligibility and response rate	Soft launch			Main		
	Phone	Mixed mode	Web	Phone	Mixed mode	Web
Eligibility rate, n/N (%)	71/588 (12.1)	72/603 (11.9)	51/532 (9.6)	448/2393 (18.7)	416/2516 (16.5)	306/1009 (30.3)
Screener response rate 3, n/N (%)	588/1496 (39.3)	603/1498 (40.3)	532/1248 (42.6)	2393/7763 (30.8)	2516/7218 (34.8)	1009/6248 (16.1)
Extended response rate 3, n/N (%)	55/71 (77.5)	52/72 (72.2)	15/51 (29.4)	306/448 (68.3)	287/416 (69)	116/306 (37.9)
Response rate 3, %	30.4	29.1	12.5	21.1	24	6.1

The base-weighted sample demographics for telephone and single-mode web survey benchmarked against the 2018 ACS are presented in Table 2. The telephone survey tracked the overall population distribution well by race or ethnicity and age. The NYAHS telephone survey slightly overrepresented men (57.1% [unweighted n=412] vs 50.9%) and those currently enrolled in college (40.3% [unweighted n=269] vs 23.8%) and underrepresented those with a Bachelor of Arts or Science (34.4% [unweighted n=239] vs 55%). The single-mode web sample closely tracked the population based on gender, but overrepresented White, non-Latinos (70.7% [unweighted n=90] vs 54.4%) and those with some college education (30.4% [unweighted n=40] vs 7.6%) and underrepresented Latinos (13.6% [unweighted n=20] vs 20.7%), and those with a high school or General Education Development diploma (15.3% [unweighted n=20] vs 29.3%).

Table 2. National Young Adult Health Survey demographic distribution (base weighted) benchmarked to the 2018 American Community Survey for 18- to 34-year-olds.

Demographics and category	Census (ACS[a])	Phone or mixed (unweighted N=700)	Web (unweighted N=131)
Gender, unweighted n (weighted %)			
Female	49.1	288 (42.9)	58 (45.4)
Male	50.9	412 (57.1)	73 (54.6)
Age (years), unweighted n (weighted %)			
18-24	40.4	309 (45.5)	28 (22.0)
25-29	30.6	188 (26.4)	49 (37.3)
30-34	29.0	203 (28.1)	54 (40.7)
Race or ethnicity, unweighted n (weighted %)			
Asian, non-Latino	6.5	55 (8.6)	N/A[b]
Black, non-Latino	14.3	80 (11.8)	11 (8.0)
Latino	20.7	148 (21.2)	20 (13.6)
Other, non-Latino	4.1	44 (6.2)	N/A
White, non-Latino	54.4	373 (52.2)	90 (70.7)
Education, unweighted n (weighted %)

[f]BS: Bachelor of Science.

Table 3 displays the DEFF overall and by subpopulations. Overall, the estimated variance of the sampling distribution was 1.28 times greater than if the same estimate had been derived from a simple random sample. This corresponds to an approximately 13% inflation of the estimated standard errors compared with simple random sampling. DEFF ranged from a low of 0.96 among those with a Bachelor of Arts or Science to 1.93 among those with Some College, corresponding to a range of 2% decrease to 39% increase in standard errors compared to simple random samples, respectively.

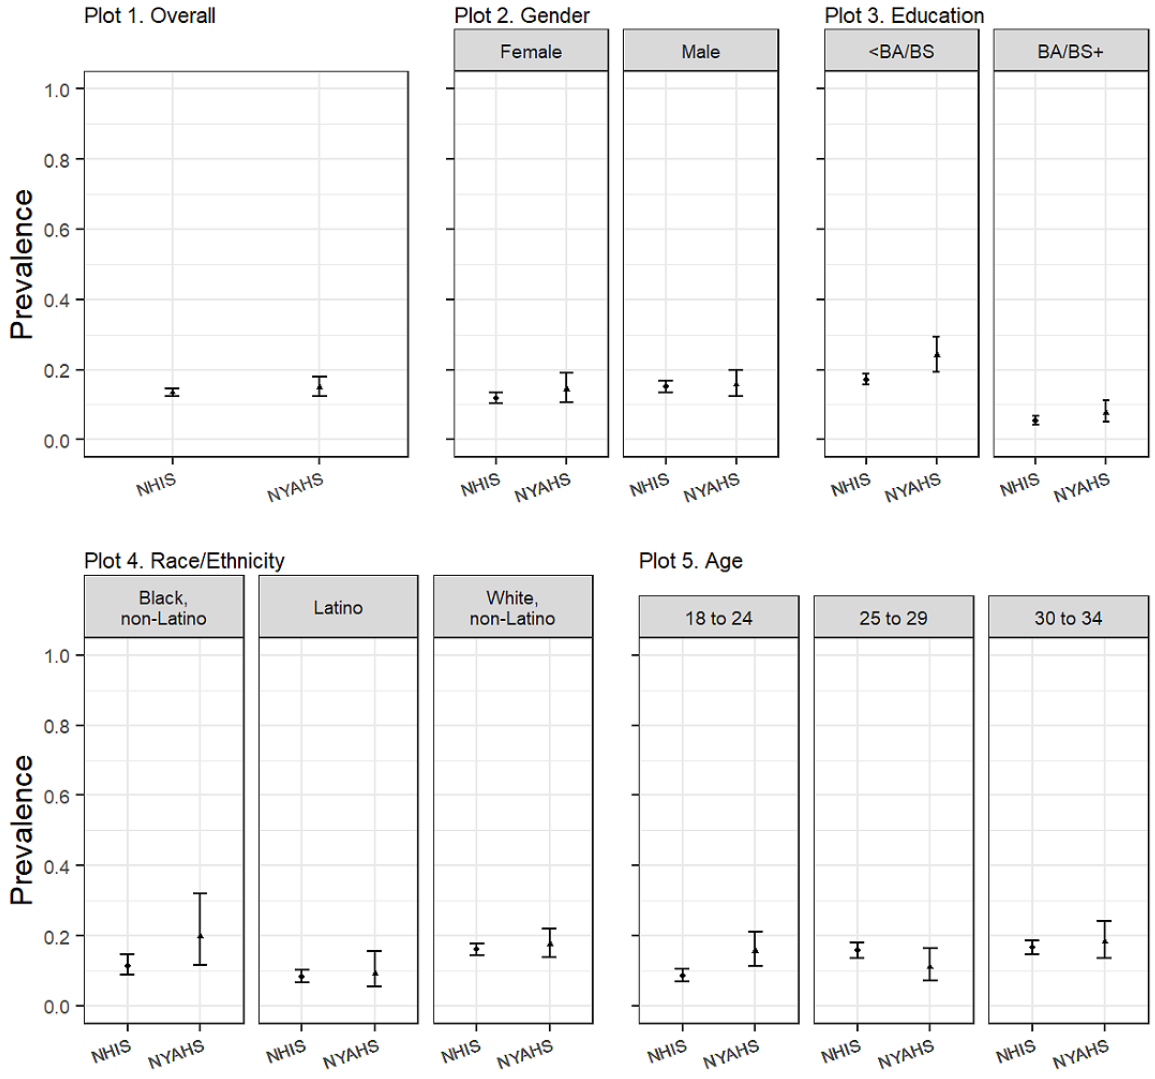
Figure 2 shows the estimated smoking prevalence for the NYAHS and NHIS overall (plot 1) and population subgroups (plots 2 through 5). The estimated prevalence was consistent overall (NYAHS: 15%, 95% CI 12.4%-18% [unweighted 149/831]; NHIS: 13.5%, 95% CI 12.3%-14.7% [unweighted 823/5552]), and for men, women, Whites, Latinos, Black, non-Latinos, 30- to 34-year-olds, among those with education levels <Bachelor of Arts or Science, and those with Bachelor of Arts or Science. There were notable differences only among 18- to 24-year-olds (NYAHS: 15.6%, CI 11.3%-22.2% [unweighted 51/337]; NHIS: 8.7%, CI 7.1%-10.6% [unweighted 167/1647]), and those with education levels <Bachelor of Arts or Science (NYAHS: 24%, CI 19.3%-29.4% [unweighted 123/524]; NHIS: 17.1%, CI 15.6%-18.7% [unweighted 690/3494]).

Figure 2. Cigarette smoking prevalence, NYAHS vs NHIS. BA: Bachelor of Arts; BS: Bachelor of Science; NHIS: National Health Interview Survey (2018); NYAHS: National Young Adult Health Survey (2018).



Estimates for Asian, non-Latino, and Other, non-Latino populations do not meet National Center for Health Statistics Data Presentation Standards for Proportions.

Discussion

Principal Findings

Our analysis demonstrated that using RDD sampling and telephone recruitment to a single-mode web survey is not feasible as a sole methodology for surveillance research, but it suggests that web surveys may have good utility using concurrent mixed mode designs (ie, concurrently conducting telephone and web surveys with different respondents) for surveillance research that use RDD sampling and telephone data collection mode. Our soft launch found that eligibility rates, including the use of tobacco as a qualifier, were so low that it proved cost prohibitive using traditional RDD sampling frames. Removing the requirement for tobacco use improved the recruitment using RDD sampling, though low response rates and the limited age eligibility range still made this a resource-intensive effort. In particular, response rates to the web survey among respondents screened as eligible were very low, though they were similar to those reported by Pew [7], which is consistent with other push-to-web research projects [19]. To increase web survey completes, the main baseline launch used an additional preprocessing step of the sampling frame to increase the likelihood of reaching a young adult. Indeed, this nearly tripled the eligibility rate.

Our methodology had good representativeness for the telephone mode and, to a lesser extent, the web mode. For the web condition, the base-weighted sampling distribution tracked the population distribution well on most characteristics, except for overrepresenting older young adults and White, non-Latinos. By contrast, the telephone sample tracked the population very well across all demographics, except college enrollment. This suggests that the preprocessed list-assisted RDD sampling frame we used for the web mode may have greater coverage error and/or differential nonresponse compared with the telephone

mode. However, deviation from population distributions is common in surveys with probability sampling designs and can be addressed via weighting adjustments such as poststratification or, as in our case, calibration methods [20]. Indeed, the pooled web and telephone surveys produced unbiased cigarette estimates following calibration. Notable exceptions were for 18- to 24-year-olds and those with less than a bachelor's degree, though this may be due to differences in the NHIS's poststratification and our sample calibration approaches. In particular, the NHIS does not poststratify on college enrollment, which is known to be associated with tobacco use [21], while the NYAHS does [22]. Moreover, our approach had DEFFs that were considerably smaller than the Behavioral Risk Factor Surveillance System's national estimates of 4.49 (although that estimate varies from year to year) [23]. This ensured reasonable precision for overall and some subpopulation estimates. However, larger sample sizes may be necessary for producing estimates with adequate statistical precision for smaller subgroups, particularly with distributions that deviate substantially from the population as larger weighting adjustments may result in increased variability of sampling weights and smaller effective sample sizes. Because the web mode had poorer representativeness, sample calibration and thus precision may be impacted by the proportion of the sample that is allocated to the web mode in concurrent mixed mode surveillance designs. In our case, approximately 16% (n=131) of the total sample came from the web survey, but future research should be carried out to identify the optimal allocation of the web mode and telephone mode in order to maximize the statistical precision relative to cost. The integration of a web mode in RDD methodology has tremendous potential to collect data not possible in traditional telephone surveys and/or conducting mobile-based research that is difficult to implement using probability-based sampling designs. For example, including web surveys in a telephone-based surveillance methodology allows researchers to embed visual and auditory media [24,25]. This can be used to test social marketing messaging on a large and geographically diverse scale, which can help inform public health workers and policy makers about the effective approaches to health promotion messaging. Similarly, it allows respondents to submit media in autophotography data collection to capture important contextual or exposure information that may not be adequately captured by closed or open-ended questions [26]. Such methodologies have traditionally been used in qualitative research [27,28], but future research should explore ways in which combining web surveys with RDD sampling may be used to collect such data in large-scale surveys that use probability sampling methods. Similarly, our methodology suggests that RDD sampling and the web mode may be combined with passive data collection from health tracking data linked to the respondents' mobile devices, which may reduce the overall data collection burden on them. To date, however, the feasibility and challenges of linking survey responses to health trackers in general population surveys are not known. Future research should evaluate the receptivity of respondents to participate in pulse surveys, link the resulting information with tracking data, and identify challenges and ways to address them.

Limitations

The limitations of this paper are that representativeness was evaluated over a relatively limited number of demographic characteristics. Ours were chosen because they are the most commonly used in poststratification or calibration and are priority groups for tobacco control. Moreover, consistency of prevalence estimates should be evaluated for other health indicators. This can be challenging because many tobacco products, particularly new and emerging tobacco products, do not have standardized measurements across surveillance systems. Thus, we would not be able to disentangle differences due to measurement versus sampling and data collection mode.

Conclusions

Our findings demonstrated that integrating the web mode into the traditional telephone mode in a concurrent mixed mode design for surveillance research is challenging, and RDD sampling for web-based surveillance methodology may not be feasible as a sole data collection methodology. However, our findings also suggested that the web mode can be integrated in an RDD telephone surveillance system by allocating a random subsample to complete the same survey on the web. This has tremendous potential to enhance data collection, particularly for testing social marketing messages and combining general population surveys with autophotographic or health tracking data.

Abstract

Background: Previous studies have shown inconsistencies in the accuracy of self-reported work hours. However, accurate documentation of work hours is fundamental for the formation of labor policies. Strict work-hour policies decrease medical errors, improve patient safety, and promote physicians' well-being.

Objective: The aim of this study was to estimate physicians' recall bias of work hours with a mobile app, and to examine the association between the recall bias and physicians' work hours.

Methods: We quantified recall bias by calculating the differences between the app-recorded and self-reported work hours of the previous week and the penultimate week. We recruited 18 physicians to install the "Staff Hours" app, which automatically recorded GPS-defined work hours for 2 months, contributing 1068 person-days. We examined the association between work hours and two recall bias indicators: (1) the difference between self-reported and app-recorded work hours and (2) the percentage of days for which work hours were not precisely recalled during interviews.

Results: App-recorded work hours highly correlated with self-reported counterparts (r=0.86-0.88, P<.001). Self-reported work hours were consistently significantly lower than app-recorded hours by –8.97 (SD 8.60) hours and –6.48 (SD 8.29) hours for the previous week and the penultimate week, respectively (both P<.001). The difference for the previous week was significantly correlated with work hours in the previous week (r=–0.410, P=.01), whereas the correlation of the difference with the hours in the penultimate week was not significant (r=–0.119, P=.48). The percentage of hours not recalled (38.6%) was significantly higher for the penultimate week (38.6%) than for the first week (16.0%), and the former was significantly correlated with work hours of the penultimate week (r=0.489, P=.002)

Conclusions: Our study identified the existence of recall bias of work hours, the extent to which the recall was biased, and the influence of work hours on recall bias.

Introduction

Excessive work hours adversely affect physicians' alertness and performance [1], increase the number of medical errors, and jeopardize patient safety [2]. The crucial effects of work-hour policies on patient safety have been widely described since 2003 when the Accreditation Council for Graduate Medical Education (ACGME) adopted restrictions on physician work hours to 80 hours a week and no more than 24 consecutive hours [2-6]. Due to similar concerns, in 2019, the work-hour restrictions in Taiwan became stricter, from a limit of 88 hours per week adopted in 2013 to 80 hours per week and 28 hours of continuous work duty.

ACGME's regulations shifted following evidence provided by trials and systematic reviews. In 2003, the ACGME allowed 24 hours of continuous work duty, which was reduced to 16 hours in 2011 and then reverted back to 24 hours in 2017 following results of a randomized controlled trial published in 2016 showing that more flexible duty-hour policies resulted in noninferior patient outcomes and physicians' self-reported well-being when compared with restrictive policies [4]. In addition, a recent study showed that residents on 16-hour or less schedules made more serious medical errors than those working shifts spanning 24 hours or more [7].

The controversial effects of eliminating extended-duration work shifts for physicians on patient safety might result from the methodological limitations of the measurement of work hours. Previous studies of work policies focused disproportionately on consecutive work hours of night shifts rather than on total work hours within a time frame, such as work hours per week. These studies were mostly limited by using work-hour measurements yielded from self-reported or medical staff–recorded logs [7] and described the fluctuating, inconsecutive nature of physician work hours with consecutive work hours. Self-reported work hours is a widely used metric in most research [3,8,9], although it is continuously shown to be unsuitable for monitoring over longitudinal time periods. Moreover, the value of self-reported work hours might be reduced by biases, especially in the estimation of total work hours. In addition, programs' compliance with ACGME regulations are usually based on medical residents' self-reports, which might be prone to the residents' biases [10]. Resident physicians, of various proportions, have admitted to not reporting duty hours accurately so as to appear compliant with regulations [6,9].

Currently, the widespread use and deep reach of smartphones in modern life enable the measurement of work hours in an affordable, reliable, and unobtrusive way. We developed an app, "Staff Hours," to automatically calculate a user's work hours via GPS background data [11]. Staff Hours is a region-restricted app, which could only be downloaded in Taiwan. Staff Hours records consecutive work hours in real time with accuracy, and enables comparisons of work hours among different hospitals, departments, and divisions with aggregate data collected from the Staff Hours database.

Using Staff Hours, we assessed physicians' estimation of work hours and found a clear bias toward underestimation. The specific aims of this study were to (1) identify recall bias indicators, including the percentage of days that work hours were not precisely recalled during interviews (NR) and the difference between self-reported and app-recorded work hours (D); and (2) examine the correlation between these two recall bias indicators and app-recorded work hours. We hypothesized that the two recall bias indicators can effectively demonstrate how work hours influence recall bias differently during the previous week and the penultimate week before assessment.

Methods

GPS-Defined Work Hours Recorded by the App

Staff Hours is a newly designed app that captures the work hours and patterns of medical staff in real time [11]. Participants installed the Staff Hours app onto their smartphones from Apple's App Store or Android's Google Play store. This app collects objective GPS location data continuously in the background and has a power-saving design. Using geofencing technology, the app automatically records the work hours one spends in the workplace. The sensitivity (94.6%) and specificity (93.9%) of app-recorded work hours were validated in our previous study [11]. The app is illustrated in Figure 1A. For example, the user's regular work hours (6:30 AM to 5:30 PM) and on-call duty (5:30 PM to 12:00 AM) were 11 hours and 6.5 hours, respectively, on November 1; the sum of the work hours, 17.5 hours, was calculated by the app. The lower part of the screenshot reveals the total work hours of each day of the previous week. The upper part of the screenshot shows the regular work hours (66 hours) and overtime work hours (19.4 hours) on the left side, and the total work hours (85.2 hours) of the past 7 days at the top-right corner of the screen. App-generated data provide real-time work hours recorded with high temporal resolution (within 10 minutes). The app saves all recorded GPS data in a log file and uploads these data to the database every day. Figure 1B shows an example of recording the daily work hours from November 1 to December 1. This user typically had longer work hours during on-call duties (night shift), including November 1-2, 7-8, 21-22, and 24-25, as well as November 30 to December 1, on which days the scheduled works hours were 16 hours (8:00 AM to 12:00 AM). There were 10 holidays within this period of time, denoted with red figures on the x-axis. On five holidays (November 3, 9, 10, 16, 23), the user was free from on-call duty, and the work hours were 0. App-recorded work hours of the previous week (WH_{APP-1}), the week before that (WH_{APP-2}), and the previous month (WH_{APP-M}, denoted by average work hours per week in 1 month), as well as the mean (SD) work hours of regular work days within a month, were obtained from app-record data. The app-recorded work hours were used as a putative gold standard to validate self-reported work hours.

Figure 1. Screenshot of the Staff Hours app user interface, with app-recorded and self-reported work hours. (A) Weekly summary of daily work hours. The light gray bar represents regular work and the dark gray bar indicates on-call duty (night shift). (B) The Staff Hours app continuously collects GPS data without active data entry by the smartphone users and provides the daily work hours. (C) Recall bias was quantified by calculating the differences between the app-recorded (orange line) and self-reported (blue line) work hours of the last week (November 25 to December 1) and the penultimate week (November 18 to 24).

Participants

A total of 18 medical doctors (11 men; median age 29 years, range 24-53 years) were recruited by randomly selecting resident physicians working at hospitals in Taipei from August 2019 to December 2019. Approval was obtained from the ethics committee in Taiwan (approval number: EC1070107-E). The inclusion criteria were resident physicians who could install the Staff Hours app on their mobile phones. There were no strict exclusion criteria. Each participant installed the app and ran it for at least 2 months. The study duration was 61 days, contributing 1098 person-days. Some of the participants failed to record their work hours for technical reasons. When this happened, their data were considered missing data. There were 30 missing days. Hence, the final data included 1098–30=1068 person-days. The participants received identical structured interviews at the first and second month after installation of the Staff Hours app. The majority (16/18, 89%) of participants were resident physicians undertaking training programs in specialized fields, including surgery, internal medicine, pediatrics, obstetrics and gynecology, emergency medicine, occupational and environmental medicine, and psychiatry. All participants were given detailed descriptions regarding the study, and individual informed consent was obtained in written form. All clinical investigations were conducted according to the principles expressed in the Declaration of Helsinki. The study was approved by the Institutional Review Board of the National Health Research Institutes.

Self-Reported Work Hours

The two authors, who are psychiatrists experienced in physicians' work-hour patterns and structured interviews, conducted structured interviews at the first and second month after the app installation blinded to the app-recorded work hours. An identical structured interview was repeated 1 month after the first interview. The interrater reliability of $WH_{self\text{-}1}$, $WH_{self\text{-}2}$, NR_1, and NR_2 between the two interviewers was 1.00 in all cases based on Pearson correlation analysis. The lengths of both interviews were documented. The interviews simulated investigations conducted by the Taiwan Ministry of Labor. The definitions of work hours and nonwork hours (eg, continuing medical education) were in line with the standard policies in hospitals in Taiwan [12]. The first interview assessed recalled work hours of the past month. In this case, the interviewers recorded the average time of arriving and leaving work on regular work days over the past month, as well as how many work days and on-call days, respectively, there had been. The total work hours of the previous month were calculated by the obtained report. The second interview assessed the recalled work hours of the previous week and the penultimate week. In this case, the interviewers recorded the specific work hours of each day (from Monday to Sunday) during the previous week and the penultimate week, as demonstrated in Figure 1C. Recall bias was quantified by calculating the differences between the app-recorded (orange line) and self-reported (blue line) work hours of the last week (November 25 to December 1) and the penultimate week (November 18 to 24). In the example shown in Figure 1C, self-reported work hours were mostly lower than the app-recorded counterparts across time, by an average of 1.19 hours and 1.01 hours every day of the last week and the penultimate week, respectively.

In addition, the percentage of days that participants were unable to recall work hours precisely (NR) was recorded. If the

participants reported they were unable to recall the work hours of a particular day, the interviewers provided cues by offering them their average time of arriving and leaving work in the last month according to the participant's report earlier during the interview. Self-reported work hours of the previous week (WH_{self-1}) and the penultimate week (WH_{self-2}) were calculated by summing the reported work hours of each day.

Recall Bias Indicators

We used two groups of indicators to quantify recall bias. The first group included the differences between self-reported and app-recorded work hours of the previous week (D_1), penultimate week (D_2), and previous month (D_M), in which D is defined as $WH_{self}–WH_{app}$. The second group included the percentage of days that participants were unable to precisely recall their work hours of the previous week (NR_1) and the penultimate week (NR_2) during interviews.

Statistical Analysis

We compared the self-reported work hours with their app-recorded counterparts with a paired *t* test, and examined their correlation with Pearson correlation coefficients. We compared the percentage of days that participants were unable to recall their work hours precisely for the previous week (NR_1) and the penultimate week (NR_2) with a paired *t* test. We also used Pearson correlation coefficients to examine the associations between work hours and the recall bias indicators D_1, D_2, NR_1, and NR_2. In addition, we examined the test-retest reliability of the recall bias indicators by intraclass correlation coefficients between the first month and the second month; $P<.05$ was considered to indicate statistical significance. Data arrangement and statistical analysis were performed using IBM SPSS Statistics 25.

Results

An average of 9.7 (SD 3.2) minutes was required to complete a participant's interview every month. The percentage of days that participants were unable to precisely recall their work hours of the penultimate week (NR_2; mean 38.6%, SD 33.9%) was significantly higher than that of the previous week (NR_1; mean 16.0%, SD 23.7%) by 18.5% ($P=.004$). The standard deviation of day-to-day work hours was 3.8 hours.

Both WH_{app-1} and WH_{app-2} presented a normal distribution according to the Kolmogorov-Smirnov test ($P=.20$ for both) and Shapiro-Wilk tests ($WH_{app-1}P=.26$, $WH_{app-2}P=.77$). These self-reported work hours were highly correlated to their app-recorded counterparts for the previous week ($r=–0.87$, $P<.001$), penultimate week ($r= 0.88$, $P<.001$), and previous month ($r=0.86$, $P<.001$). Table 1 shows that the self-reported hours were significantly lower than their app-recorded counterparts, with the greatest average differences for the previous week (D_1), followed by the penultimate week (D_2), and the smallest difference found for the previous month (D_M) (all $P<.001$).

Table 1. Comparison of self-reported and app-recorded work hours of the previous week, the penultimate week, and previous month.

Time period recorded	Self-reported work hours	App-recorded work hours	Difference, mean (SD)	*P* value
Previous week	57.30	65.63	–8.33 (8.95)	<.001
Penultimate week	58.57	65.65	–7.08 (8.74)	<.001
Previous month (weekly)	60.26	66.94	–6.68 (8.27)	<.001

Table 2 shows the correlation coefficients between the recall bias indicators (D_1, D_2, NR_1, NR_2) and the app-recorded work hours (WH_{app-1} and WH_{app-2}). WH_{app-1} was significantly negatively correlated to D_1, meaning that the longer WH_{app-1}, the more negative the difference between WH_{self-1} and WH_{app-1}, representing more underestimation of self-reported work hours. WH_{app-1} was not significantly correlated to NR_1. By contrast, WH_{app-2} was significantly correlated to NR_2, meaning that the longer WH_{app-2}, the higher percentage of days that work hours were not precisely recalled during interviews. WH_{app-2} was not correlated to D_2 and WH_{app-m} was not significantly correlated to D_M.

Table 2. Pearson correlation coefficients (r) of app-recorded work hours and recall bias indicators.

Recall bias indicator	WH_{app-1}[a]		WH_{app-2}[b]	
	r	*P* value	*r*	*P* value
Difference between self-reported and app-recorded work hours	–0.41	.01	–0.12	.48
Percentage of days that participants were unable to recall their work hours precisely	0.08	.37	–0.49	.002

[a]app-recorded work hours of the previous week.

[b]app-recorded work hours of the penultimate week.

Discussion

Principal Findings

This study demonstrated the underestimation of 11.5%-12.0% (D_1/WH_{app-1} and D_2/WH_{app-2}) work hours and the association between this recall bias and excessive work hours, with the novel app "Staff Hours" recording GPS-defined work hours. We recruited a total of 18 medical doctors (11 men; median age 29 years, range 24-53 years) as participants. As methodological strengths, this study helps to advance the field of work-hours estimation by recording work hours in efficient, precise ways and with higher temporal resolution. The app automatically recorded work hours in real time, and an average of 9.7 minutes was required to complete a participant's interview every month. We were able to collect self-reported data with structured interviews twice per participant, using psychiatrists as interviewers. An earlier study conducted in the United States in 2004 including 45 female flight attendants as participants examined work hours per month [13]. Another study conducted in Japan in 2016 included 164 male employees as participants to gather work-hour information with questionnaires [14]. Studies using self-reported questionnaires typically processed work-hour details as ordinal variables [14], such as by recording the work hours roughly (eg, 45 to <60 hours per week, 60 to <80 hours per week, and >80 hours per week) rather than as continuous variables (eg, 67 hours per month), although the latter has higher precision than using ordinal variables. In addition, the app recorded data with higher temporal resolution than obtained from self-reports. This study included 18 participants and ran over 61 work days, contributing 1068 pairs of app-recorded and self-reported data after subtracting missing data. On the basis of the high temporal resolution of the data, the standard deviation of the average day-to-day work hours was 3.8 hours, highlighting the fluctuating nature of physicians' work hours.

Our result that app-recorded work hours strongly correlated with their self-reported counterparts (r=0.86-0.88, P<.001) was consistent with previous studies [2,14]. One previous study [14] also demonstrated a high correlation between self-reported and actual work hours. Our study further extends this previous research by describing the extent of underestimation; the weekly underestimation was 6.48 to 8.97 work hours per week, which represents approximately 1.30-1.79 hours of underestimation every day considering a 5-day work week (6.48/5=1.30; 7.05/5=1.79). Differences of temporal resolution between the app-recorded work hours and participants' recall were noted, which may contribute to systematic biased recall. When participants were unable to recall the work hours of a particular day precisely, they tended to report rounded-up hours, typically to the nearest half hour (eg, reporting as having arrived at work at 6:30 AM or 7:00 AM), as well as reporting regular work hours, which were often lower than their actual work hours. The app scanned at 10-minute intervals to determine the GPS coordinates and therefore the initiation and cessation of recording work hours. Our results showed that all participants reported starting at the scheduled work time, despite actually having arrived at the workplace a few minutes earlier than their work hours according to GPS coordinates.

Previous studies [9,10] showed that when duty hour regulations were enforced, resident physicians were faced with a dilemma between violating the duty hour regulations and maintaining patient care quality. When facing such a dilemma, an option that resident physicians chose was working overtime while still reporting the duty hours within the limitations of regulations. It was estimated that up to 60% of surgical residents reported their work hours untruthfully when filling out questionnaires. The reasons resident physicians underreported their work hours might have included pressure from the system (eg, receiving punishment due to violations of regulations) and pressure from peers (eg, being viewed as "incompetent" when leaving work on time).

Besides differences in temporal resolution between app-recorded and self-reported work hours, distorted time perception resulting from long work hours may also contribute to recall bias, as demonstrated by the two recall bias indicators used in this study. Physicians whose work hours were longer during the previous week demonstrated a tendency toward more underestimation during recall (r=–0.410, P=.01), whereas participants whose work hours were longer in the penultimate week showed a diminished tendency to underestimate their work hours during recall (r=–0.119, P=.48). In addition to previous studies that simply showed the extent to which recall of work hours was impaired [2,14], our study recorded the percentage of work days that participants were unable to recall their work hours. Participants whose work hours were longer during the penultimate week showed a lower rate of recalling their work hours precisely when compared with those who worked shorter hours (r=0.489, P=.002). As a result of a higher NR, the interviewers provided cues more frequently when participants recalled their work hours of the penultimate week, thus allowing for attenuation of underestimation.

Excessive work hours may distort the time perception and memory of the extent of work hours. Our previous studies performed in 2012 involving 74 medical interns showed that physicians in Taiwan worked an average of 86.7 hours per week with up to 33.5 consecutive working hours per duty shift, and that they sometimes developed hypervigilant perceptions, phantom vibration, and ringing-ear syndrome in the absence of an external stimulus [1,15]. Excessive work hours also resulted in reduced cardiac sympathetic modulation [1,16], disrupted sleep stability [17], and increased anxiety and depression symptoms [18-20]. These psychological and physiological impacts of excessive work hours could alter time memory and time perception (ie, the ability to recall work hours), thereby increasing recall bias [21,22].

Limitations

This study has several methodological limitations that should be considered when interpreting the results. First, if the participants reported that they were unable to recall the work hours of a particular day, the interviewers provided cues by offering them their average time of arriving and leaving work in the last month. For some participants who were more unable to recall their work hours (ie, those with a larger NR), their D values were calculated based more on cues provided by the interviewers. By contrast, NR was not affected by any cues

provided by the interviewers. Therefore, NR might be a better self-defined recall bias indicator compared with D. Second, the participants were not asked to recall any work hours earlier than the penultimate week, which thus limited the studied timeframe of recall bias in this study. However, the percentage of days that participants were unable to recall work hours of the penultimate week was 38.6%. It was conceivable that reports of work hours earlier than 2 weeks prior may result in greater recall bias. Third, the sample size of this study was relatively small, which limits the generalization of the findings as well as the detection of other recall bias indicators. However, we were able to ensure participant diversity, and the 2-month length of app installation guaranteed adequate data input for analysis. Future research should investigate how a larger sample size would identify more factors associated with recall bias indicators. Future studies are also warranted to assess the underlying mechanisms of time perception and recall bias of work hours.

Conclusion

This pilot study identified the existence of recall bias of work hours, the extent to which the recall was biased (6.48-8.97 work hours per week), and the influence of work hours on recall bias. We were able to demonstrate that long work hours in the previous and the penultimate week influenced recall bias in different ways. Working overtime has long been part of the culture among Taiwanese physicians [1,15,17,19,20,23]. However, the extent to which medical staff overwork has never been systemically investigated, and hence the work-hour regulations of physicians were formed without the basis of solid work-hour studies. This study has clear public health relevance by confirming that this time-saving, easily accessible app can provide solid, precise reports of actual work hours, aid work policy formation for physicians, and promote the care quality of patients, as well as the well-being of physicians in Taiwan.

Abstract

Background: eHealth and social media could be of particular benefit to adults with hearing impairment, but it is unknown whether their use of smart devices, apps, and social media is similar to that of the general population.

Objective: Our aim is to study whether adults with normal hearing and those with impaired hearing differ in their weekly use of smart devices, apps, and social media; reasons for using social media; and benefits from using social media.

Methods: We used data from a Dutch cohort, the National Longitudinal Study on Hearing. Data were collected from September 2016 to April 2020 using a web-based questionnaire and speech-in-noise test. The results from this test were used to categorize normal hearing and hearing impairment. Outcomes were compared using (multiple) logistic regression models.

Results: Adults with impaired hearing (n=384) did not differ from normal hearing adults (n=341) in their use of a smartphone or tablet. They were less likely to make use of social media apps on a smartphone, tablet, or smartwatch (age-adjusted odds ratio [OR] 0.67, 95% CI 0.48-0.92; *P*=.02). Use of social media on all devices and use of other apps did not differ. Adults with hearing impairment were more likely to agree with using social media to stay in touch with family members (OR 1.54, 95% CI 1.16-2.07; *P*=.003) and friends (age-adjusted OR 1.35, 95% CI 1.01-1.81; *P*=.046). Furthermore, they were more likely to agree with using social media to perform their work (age-adjusted OR 1.51, 95% CI 1.04-2.18; *P*=.03). There were no differences in the experienced benefits from social media.

Conclusions: The potential for eHealth is confirmed because adults with hearing impairment are not less likely to use smart devices than their normal hearing peers. Adults with hearing impairment are less likely to use social media apps on a smart device but not less likely to use social media on all types of internet-connected devices. This warrants further research on the types of social media platforms that adults with hearing impairment use and on the type of device on which they prefer to use social media. Given that participants with hearing impairment are more likely than their normal hearing peers to use social media to perform their work, use of social media may be seen as an opportunity to enhance vocational rehabilitation services for persons with hearing impairment.

Introduction

Background

Disabling hearing loss affects 466 million people worldwide [1]. Its prevalence will double by 2050 because of increasing life expectancy. Hearing impairment is one of the most prevalent disabilities because hearing deteriorates with age. Almost one-third of people aged ≥65 years have disabling hearing loss [1]. However, because age-related hearing loss can start earlier, a large number of middle-aged adults also have hearing disabilities. In high-income countries, 15%-25% of adults between the ages of 50 and 65 years have mild to severe hearing loss [2,3]. A recent study in the Netherlands estimated that 1.2 million adults aged ≥40 years, or 13% of the population in that age bracket, have disabling hearing loss [4]. Hearing difficulties can be mitigated by the use of communication strategies, speech reading, hearing aids, and hearing assistive technology. A smaller number of people with impaired hearing, mostly those who have been deaf or hard of hearing from a young age, communicate in sign language as their native language.

Most adults in high-income countries have access to the internet, although its use is less ubiquitous in older adults [5,6]. This gives potential for digitalized hearing health care, both stand-alone and adjunct to in-person care [7-9]. Digital hearing health care facilitates patient-centered care in the comfort of one's own home. In this way, next to making hearing health care more accessible, digital care could perhaps boost the lagging uptake of communication strategies and hearing aids [10]. The current COVID-19 pandemic has sped up the shift to remote audiological care, although audiologists still have concerns about patients' access to technology and their preferences [11]. During the UK lockdown, teleaudiology was particularly used for (tinnitus) counseling [11]. The internet offers many synchronous and asynchronous communication options that support counseling, for example, email, direct messaging, social network sites and apps, and video calling. With the development of web-based hearing assessment and hearing aid fitting, these in-person services will also be offered on the web [12]. In addition to teleaudiology, internet-mediated communication could also support psychosocial health by fostering social connection. Mild to severe hearing loss makes it difficult to follow conversations in certain situations, even with the use of a hearing aid, leading to less meaningful interactions and withdrawal from social activities [13]. Loneliness, depression, and anxiety are more prevalent in adults with hearing loss than in their peers who have no hearing problems [13-16]. Communication and connection with others through the internet could replace some of the face-to-face contacts and mitigate these negative outcomes [17]. This raises the question of whether adults with hearing impairment use the internet, smart devices, apps, and social media as much and for the same reasons as their normal hearing peers and the general public. If so, it would be reasonable to move (some) services to the web, which would substantiate the opportunities for social support. Earlier research disputes the assumption of equal use.

So far, only 3 studies have looked at internet access and use among adults with hearing impairment in high-income countries. Of these studies, 2 [18,19] showed that older adults with hearing difficulty were less likely to use the internet, whereas the other [20] found no differences between users of hearing aids and the general population overall. However, the latter study did find a higher internet use among users of hearing aids aged ≥75 years compared with the (age-matched) general population. Thus, there is inconclusive evidence regarding whether adults with hearing loss make different use of the internet than their normal hearing peers. Moreover, these studies were performed at a time when the internet was mostly accessed through desktop computers and was less pervasive in daily life. A more recent marketing survey looked at whether ownership and use of a smartphone is different in adults with a hearing impairment [21]. This 2018 UK survey found that the rates of smartphone ownership were 53% in people with self-reported hearing impairment and 81% in people who reported having no disabilities. Furthermore, 44% of the adults with hearing impairment used their mobile device to access the internet, whereas this rate was 69% in respondents without disabilities. However, 60% of the people who reported a hearing impairment were aged >65 years compared with only 16% of the nondisabled people. The results might therefore reflect the differences in age between both groups. The same survey found that people with a hearing impairment had quite similar reasons for using the internet as the people who reported no disability. Comparable results were obtained from a 2016 US survey [22]. This survey asked people with self-reported hearing disabilities which features or functions they use on their smartphone. Use of the internet in general and of social media apps in particular seems to be a little lower in people with a hearing disability compared with the general population, but as in the UK survey, this may also reflect differences in age.

Several studies have analyzed social media use by distinct groups of adults with hearing impairment by extracting publicly available content and user data (manual and automated *web scraping*) posted on social network sites such as Facebook, Twitter, and YouTube, as well as from web-based forums and from personal blogs [23-28]. This type of research gives insight into the information that is shared, the feelings and opinions of the posters, and the nature of communication on these platforms, but there are also limitations. Content analysis studies do not give insight into either the relative frequency of social media use or its passive use (ie, reading and watching). Furthermore, the characteristics of the posters, such as age, sex, income, education level, and whether they have hearing loss and to what extent, are unknown or not verifiable. This impedes specification of who uses which type of social media and in which way and who does not. In addition, there is no (legal) access to private communication such as WhatsApp messages and private Facebook pages. Postings on social media also do not provide information about the potential benefits of using social media, for example, whether it has strengthened the social connections of the user. In conclusion, these studies do not give insight into the social media use of all adults with hearing impairment: whether they use social media for private communication, the extent of use, and their reasons for using social media; the experienced benefits from using social media; and whether all these data are comparable with those found in the general public and normal hearing adults. The latter would justify relying on

data from the general public when making decisions on using computer-mediated communication with adults with hearing impairment. We did not find studies that addressed these questions.

Research Questions

This study therefore investigated the following research questions (RQs):

- RQ1: Do adults with normal hearing and those with impaired hearing differ in the use of smart devices?
- RQ2: Do adults with normal hearing and those with impaired hearing differ in the use of different types of apps?
- RQ3: Do adults with normal hearing and those with impaired hearing differ in the use of social media?
- RQ4: Do adults with normal hearing and those with impaired hearing differ in their reasons for using social media?
- RQ5: Do adults with normal hearing and those with impaired hearing differ in the experienced benefits from using social media?

Methods

Overview

Data were available from a long-running Dutch national cohort of adults with normal hearing and those with impaired hearing, the National Longitudinal Study on Hearing (NL-SH). Demographics and use of technology, apps, and social media were collected through a web-based questionnaire. The hearing status of participants was determined by a web-based speech-in-noise test.

Details of NL-SH

Recruitment and Measurements

Initiated in 2006, the NL-SH is an ongoing, prospective cohort study in which both adults with normal hearing and those with impaired hearing participate. This cohort was set up to gain knowledge on the long-term trajectory of hearing loss and its association with psychosocial health, work outcomes, and health care use in adults of working age. The NL-SH uses convenience sampling. The major portals for recruitment are the web-based Dutch National Hearing Test (NHT) [29] and the study website [30] where the public can take the same hearing test. It offers the general public a fast and convenient way to test their own ability to recognize speech in noise (further described in the *Speech-in-Noise Test* section). After presenting the test results, they are asked if they are interested in taking part in hearing-related research. If they are interested, they are taken to the introduction page of the NL-SH on the study website [30], where the study is fully explained and they can download an information brochure. Prospective participants can then choose to enroll. At enrollment, sex, age, and contact details (email address, home address, and phone number) are asked. Age is checked against the inclusion criterion of being 18-70 years; those who do not fit this criterion cannot enroll. Other eligibility criteria are not set for the NL-SH. Those who are eligible have to take a speech-in-noise test specific to the NL-SH and are sent a link to the web-based study questionnaire.

Inclusion measurements (T0) started in 2006 and still continue. The 5-year follow-up (T1) started in 2011, and the 10-year follow-up (T2) started in 2016. For this study, only the T2 measurements were used. The invitation for the T2 measurement round was sent approximately 10 years after the T0 hearing test was performed. In all, 2 email reminders and a postal reminder were sent within a period of 3 months after the first invitation to fill out the questionnaire. In general, the T2 hearing test is performed directly after participants fill out the web-based questionnaire, but a delay of up to 3 months is possible. People who did not perform this test received a total of 3 email reminders during these 3 months. To be included in this study, both the T2 questionnaire and hearing test had to be fully completed. Data collected up to April 1, 2020, were included in the analyses.

The NL-SH study protocol has been approved by the Medical Ethics Committee of the Amsterdam Medical Center, location VUmc, in Amsterdam, the Netherlands (METC number: 2006/83; ToetsingOnline NL12015.029.06).

Questionnaire

The questionnaire consisted of questions on demographics; hearing; use of technology, apps, and social media; and reasons for using social media and benefits of this use. The questions on use of technology and apps were taken from a web-based marketing study (Sonova AG, written communication, 2019). The validity of these questions is unknown. Standardized questionnaires about use of social media, reasons for using social media, and the experienced benefits from using social media are not available. The questions on these topics were devised by the research team and pilot-tested in a group of adults with hearing impairment. Textbox 1 lists the questions other than demographics. The full questionnaire can be found in Multimedia Appendix 1.

Textbox 1. Overview of the questions on use of technology, apps, and social media, as well as reasons for using social media and benefits of social media use.

Questions and answer options used in this study

- Which of these devices do you use at least once a week?
  - Smartphone
  - Smartwatch
  - Tablet
- Which types of apps do you use at least once a week on your current smartphone, tablet, or smartwatch?
  - Weather
  - News
  - Finances (mobile banking, stock exchange, etc)
  - Navigation
  - Remote control (television, stereo system, etc)
  - Fitness
  - Communication (email, WhatsApp, WeChat, etc)
  - Medical or health
  - Social media (Facebook, Instagram, Twitter, etc)
  - Music and podcasts
- Do you use social media?
  - Yes
  - No
- To what extent do you agree with the following statements (rated on a scale of 1-10: fully disagree=1, fully agree=10)? I use social media to...
  - Stay in touch with family members
  - Stay in touch with acquaintances
  - Stay in touch with colleagues or peers
  - Share experiences, videos, or photos
  - View experiences, videos, or photos
  - Expand my work-related network
  - Perform my work
  - Gain new knowledge
  - File complaints and problems with the government or businesses
- With what frequency do you use social media?
  - Multiple times a day
  - Daily
  - Weekly
  - Monthly
  - A couple of times a year
- What have you gained from your social media use so far?
  - New acquaintances
  - New friendships
  - Closer or more intense family ties
  - Closer or more intense friendships

- Expanded work-related network
- New knowledge about health
- I have gained little or nothing from social media

Demographics concerned sex, current age, highest attained education, and first language Dutch or other. Education was divided into low (elementary school or attended high school but no degree), medium (high school graduate or having an associate's degree), and high (having a bachelor's degree, master's degree, or doctoral degree). In all, 2 hearing-related questions asked about having normal hearing or some type of hearing loss and, for those with self-reported hearing loss, whether they use a hearing aid.

Use of technology consisted of a list of devices with the question "Which of these devices do you use at least once a week?" The list included devices such as a traditional mobile phone, smartphone, traditional wristwatch, smartwatch (eg, Apple watch), fitness watch (eg, Fitbit), laptop or notebook computer, tablet, television, radio, and more. The list did not mention a PC. Participants could tick the box for all devices that applied. For this study, the use of only mobile devices on which an app can be installed (ie, a smartphone, a tablet, or a smartwatch), further referred to as a smart device, was analyzed.

Next, participants who indicated that they used a smart device were asked what types of apps they used at least once a week. The options to tick were as follows: weather, news, finances (mobile banking, stock exchange, etc), navigation, remote control (television, stereo system, etc), fitness, communication (email, WhatsApp, WeChat, etc), medical or health, social media (Facebook, Instagram, Twitter, etc), music or podcasts, and other. The category *other* was not included in the analyses.

Participants were then asked if they use social media, for example, Facebook, LinkedIn, Skype, WhatsApp, Twitter, and Instagram. If they said "yes" or if they had a missing answer on this question, they were asked about frequency of use (1 answer possible): multiple times a day, daily, weekly, monthly, or a couple of times a year. In the analyses, monthly and a couple of times a year were collapsed into 1 category. Those who used social media were asked how much they agreed with several statements about reasons for using social media. The reasons provided were as follows: to stay in touch with family; to stay in touch with friends; to stay in touch with acquaintances; to stay in touch with colleagues or peers; to share experiences, videos, or photos; to view experiences, videos, or photos; to expand work-related network; to perform work; to gain new knowledge; and to file complaints. These questions could be answered on a scale from 0 to 10 (an 11-point Likert scale), with 0=*fully disagree* (coded as 1), 5=*do not agree, do not disagree* (coded as 6), and 10=*fully agree* (coded as 11), resulting in scores of 1-11, to be handled as a continuous outcome.

Finally, social media users were asked what they had gained from social media use so far. They could choose any of the following answers: new acquaintances, new friendships, closer or more intense family ties, closer or more intense friendships, expanded work-related network, new knowledge about health, gained little or nothing, and other. The category *other* was not used in the analyses.

At the end of the questionnaire, a personal link was provided to the web-based speech-in-noise test.

Speech-in-Noise Test

The ability to recognize speech in noise is salient for measuring the disabling effects of hearing impairment because one of the first and major complaints of adults with hearing impairment is difficulty in understanding what is said when there is background noise [31]. To measure speech-in-noise recognition, the procedures of the NHT were followed. First developed for use by phone, the internet version of the NHT was launched in 2005. To ensure comparability to the earlier measurements, the procedures of this original version are still used in the NL-SH measurements. Participants are instructed to perform the test in a quiet room. Users of hearing aids are instructed to perform the test without their hearing aids. All participants are asked to use headphones for the test, but speakers are also allowed. Participants have to indicate which transducer they used. The test is binaural (ie, diotic), and the results are mainly representative of the better ear. A total of 23 digit triplets (eg, 6-2-5) are presented against a background of masking noise in an adaptive manner: the noise level is fixed in the test, and the speech level varies. After each incorrect response, the subsequent triplet is presented at a level higher by 2 dB, increasing the signal-to-noise ratio (SNR) a level higher of 2 dB. If the participant provides a correct response, the subsequent triplet is presented at a level lower by 2 dB. The speech-reception threshold in noise (SRTn) is calculated by taking the average SNR of the last 20 presentations, corresponding to a score of 50% of the presented triplets understood correctly. Because of the design of the test, the SRTn values range from –13.4 dB SNR to a ceiling level of 4 dB SNR.

Validation of the original NHT version showed a high correlation (ρ=0.866) with SRTns derived from the standard test in the Netherlands that uses sentences in stationary speech-shaped noise. The measurement error (SE of measurement) is estimated to be <1 dB [32]. Compared with the standard sentence-in-noise test, the NHT phone version has a sensitivity of 0.91 and a specificity of 0.93 at a cutoff of –4.1 dB for hearing impairment [32]. Because of the benefit of listening with 2 ears, the cutoff of the internet version was adjusted with 1.4 dB [33]. This gives a cutoff of –5.5 dB to divide the group into adults with normal hearing ability to recognize speech in noise (further indicated as normal hearing) and those with impaired hearing. It should be taken into account that diotic speech understanding in noise is less compromised in conductive and mixed hearing losses. This means that participants with these types of hearing loss, even those normally using a hearing aid, may be classified as normal hearing.

Participants using speakers may perform slightly worse in the test than if they had used headphones, resulting in misclassification to the group with hearing impairment for some of the participants with normal hearing.

Statistical Analysis

Normally distributed continuous data are described with means and SDs, whereas nonnormally distributed continuous data are described with medians and IQRs. For nominal and ordinal data, frequencies are reported.

Adults with impaired hearing and normal hearing adults were compared using multiple logistic regression analysis. Age, sex, and education level were considered potential confounders. They were included in the model if (1) the potential confounder had influence (P<.10) on both the outcome and the independent variable and (2) the regression coefficient of the influencing factor changed by ≥10% after adding the potential confounder to the model.

Answers to the items that were scored on an 11-point Likert scale (fully disagree-fully agree) were not normally distributed and had to be categorized. To prevent uneven numbers in the categories, they were categorized into 3 groups based on approximate 1/3 divisions with increasing levels of agreement. Multiple ordinal logistic regression analysis was used to analyze whether the distribution of these answers and answers about the frequency of social media use (several times a day, daily, weekly, monthly, or a couple of times a year) differed between adults with normal hearing and those with hearing impairment. Assumptions of logistic analysis were tested in all analyses. For the ordinal results where the assumption of proportional odds was not met, multinomial logistic regression analysis was used. The results were considered statistically significant if P<.05. Analyses were conducted using SPSS software (base edition with custom tables and advanced statistics add-on; version 26.0; IBM Corporation).

Results

Overview

A total of 885 study participants responded to the T2 measurement round between September 15, 2016, and April 1, 2020. Of the 885 participants, 837 (94.6%) fully filled out the questionnaire. Of these 837 participants, 725 (86.6%) also performed the speech-in-noise test. Of the 112 participants who did not perform the speech-in-noise test, 68 (60.7%) reported in the questionnaire that they had hearing loss.

Of the 725 participants with complete data, 619 (85.3%) participated from September 2016 to December 2017. Most of the participants were women (442/725, 61%). The participants' mean age was 57.7 (SD 11.4) years, and 60% (435/725) had a high level of education (Table 1).

Of the total group, 53% (384/725) had a hearing test score ≥–5.5 dB SNR and were subsequently classified as having a hearing impairment. Table 1 shows the characteristics of these participants and of the normal hearing participants separately.

Table 1. Overview of characteristics and categorical outcomes for the total group, a group with normal hearing, and a group with hearing impairment (N=725).

Characteristics	Total group (N=725)	Normal hearing (n=341)	Hearing impairment (n=384)

[d]n=384.

RQ1: Weekly Use of Smart Devices

Most of the participants made weekly use of a smartphone: 87.4% (298/341) of the normal hearing group and 81.8% (314/384) of the group with impaired hearing (Table 1). Logistic regression analysis, which had to be adjusted for age, revealed that there was no statistically significant difference between the 2 groups in the weekly use of a smartphone (odds ratio [OR] 0.82, 95% CI 0.53-1.25; *P*=.35; Table 2).

Table 2. Odds ratios (ORs) for smart device use, social media use, and experienced benefits from social media use for adults with hearing impairment compared with normal hearing adults; results from (multiple) logistic regression analysis.

Outcome	Crude model		Age-adjusted model[a]

[a]Age in quartiles: Q1: 29-49 years; Q2: 50-59 years; Q3: 60-66 years; and Q4: 67-81 years.
[b]N/A: not applicable; no age adjustment necessary.
[c]Use of an app on a smartphone, tablet, or smartwatch.

The rates of weekly use of a tablet were 57.5% (196/341) in the normal hearing group and 58.3% (224/384) in the group with hearing impairment. Logistic regression analysis showed that these percentages did not differ between the groups (OR 1.3, 95% CI 0.77-1.4; *P*=.82; Table 2).

Because of the small number of people using a smartwatch, we did not test for differences in the use of this device.

RQ2: Weekly Use of Different Types of Apps

Of the 725 participants, 660 (91%) reported using one or more smart devices on which an app could be installed (ie, a smartphone, tablet, or smartwatch). Their weekly use of these apps is shown in Table 1. Use of communication apps such as an email app or WhatsApp was common in the total sample: 83.5% (551/660). Social media apps such as Facebook, Instagram, and Twitter were used weekly by little more than half of the total sample: 56.7% (374/660). Of the normal hearing participants, 63.3% (198/313) made weekly use of social media

apps compared with 50.7% (176/347) of the adults with hearing impairment. After adjustment for age, a statistically significant difference was found between the groups, with adults with hearing impairment 33% less likely to use social media apps (OR 0.67, 95% CI 0.48-0.92; *P*=.02; Table 2). This was the only type of app for which statistically significant differences in weekly use were found.

RQ3: Use of Social Media

Of 722 participants, 625 (86.6%) reported using social media. Use of social media did not differ between adults with normal hearing and those with hearing impairment (age-adjusted OR 0.90, 95% CI 0.57-1.4; *P*=.65; Table 2).

We also looked at the frequency with which social media was used. Most of the participants (551/627, 87.9%) used social media daily or multiple times a day. Of note, of the 627 participants, 2 (0.3%) had a missing score on use of social media, but they answered the question about frequency. The age-adjusted cumulative OR for frequency of use of social media for adults with hearing impairment compared with normal hearing adults was 0.91 (95% CI 0.67-1.2; *P*=.56), showing that there was no statistically significant difference in the frequency of social media use between the groups.

RQ4: Reasons for Using Social Media

Table 3 shows the distribution of the answers for agreements with reasons for using social media. Most of the participants agreed with the statements that they use social media to stay in touch with family members (213/624, 34.1%, score=10-11; 193/624, 30.9%, score=8-9) and with friends (199/625, 31.8%, score=10-11; 227/624, 36.4%, score=8-9). The statement that they use social media to stay in touch with acquaintances was also agreed with by most of the participants, with 31.8% (199/625) scoring 10-11 and 43.4% (271/625) scoring 7-9. Use of social media to expand their work-related network, perform their work, or file complaints and problems was fully disagreed with by most of the participants; 42.1% (257/611), 45.9% (281/611), and 43.5% (263/605), respectively, scored 1 on this question.

Table 3. Reasons to use social media: descriptive outcomes for the answers given on an 11-point Likert scale, divided over 3 percentile groups representing the lowest, middle, and highest levels of agreement for that statement in approximate tertiles.[a]

I use social media to...	Lowest-level agreement		Middle-level agreement		Highest-level agreement	
	Value, n (%)	Value, mean (SD; range)	Value, n (%)	Value, mean (SD; range)	Value, n (%)	Value, mean (SD; range)
Stay in touch with family members	218 (35.9)	4.1 (2.4; 1-7)	193 (31.8)	8.6 (0.5; 8-9)	213 (35.1)	10.8 (0.4; 10-11)
Stay in touch with friends	199 (31.8)	4.6 (2.3; 1-7)	227 (36.3)	8.6 (0.5; 8-9)	199 (31.8)	10.7 (0.5; 10-11)
Stay in touch with acquaintances	186 (30.5)	4.2 (2.1; 1-6)	271 (44.4)	8.3 (0.8; 7-9)	153 (25.1)	10.7 (0.5; 10-11)
Stay in touch with colleagues or peers	202 (33.2)	1.6 (1.0; 1-4)	169 (27.8)	6.2 (0.6; 5-7)	237 (39)	9.2 (1.1; 8-11)
Share experiences, videos, or photos	173 (28)	2.2 (1.3; 1-5)	251 (40.7)	7.0 (0.8; 6-8)	193 (31.1)	9.8 (0.9; 9-11)
View experiences, videos, or photos	207 (33.6)	3.8 (2.1; 1-6)	173 (28.1)	7.6 (0.5; 7-8)	236 (38.3)	9.8 (0.9; 9-11)
Expand my work-related network	257 (42.1)	1.0 (0.0; 1-1)	130 (21.3)	3.1 (1.2; 2-5)	224 (36.7)	7.7 (1.6; 6-11)
Perform my work	281 (46)	1.0 (0.0; 1-1)	112 (18.3)	3.2 (1.1; 2-5)	218 (35.7)	7.8 (1.8; 6-11)
Gain new knowledge	204 (33.7)	1.6 (1.0; 1-4)	234 (38.6)	6.9 (1.0; 5-8)	168 (27.7)	9.7 (0.8; 9-11)
File complaints and problems with the government or businesses	263 (43.5)	1.0 (0.0; 1-1)	142 (23.5)	3.1 (1.1; 2-5)	200 (33.1)	7.5 (1.6; 6-11)

[a]The numbers in each percentile group can be dissimilar because the group cannot be broken up within a specific Likert score. The groups are therefore an approximation of percentile groups based on thirds of the sample.

The analyses of differences between participants with normal hearing and those with impaired hearing showed 3 statistically significant results (Table 4). Ordinal regression analysis revealed that participants with hearing impairment were more likely to score a higher level of agreement, compared with the lowest level, with the statement that they use social media to stay in touch with family members (OR 1.5, 95% CI 1.2-2.1; *P*=.003) and, after correcting for age, to stay in touch with friends (OR 1.4, 95% CI 1.0-1.8; *P*=.046). Multinomial regression analysis, in which ORs are estimated separately for the levels of agreement, showed that participants with hearing impairment were also more likely to have the highest level of agreement (score 6-11 on the agreement scale) with using social media to perform their work (age-adjusted OR 1.5, 95% CI 1.04-2.2; *P*=.03). However, the comparison for the middle level of agreement (score 2-5) did not show a statistically significant relationship (age-adjusted OR 0.98, 95% CI 0.62-1.5; *P*=.93), meaning that normal hearing participants and those with impaired hearing were equally likely to score 2-5 on this statement compared with scoring 1.

Table 4. Cumulative odds ratios (ORs) for being in a higher percentile of agreeing with reasons for using social media for adults with hearing impairment compared with normal hearing adults; results from (multiple) ordinal logistic regression analysis.

I use social media to...	Crude model		Age-adjusted model[a]

[c]Multinomial logistic regression analysis.

RQ5: Experienced Benefits From Using Social Media

Table 1 shows the benefits that participants experienced from using social media. Almost a third (202/628, 32.2%) of the whole group agreed that using social media had given them closer or more intense family ties. Approximately 1 in 4 (161/628, 25.6%) had gained closer or more intense friendships from using social media. New friendships were found by only 11.5% (72/628) of the whole group, and gaining acquaintances was agreed with at a slightly higher rate (114/628, 18.2%). There was also a substantial percentage of participants who had gained little or nothing from social media: 29.3% (184/628).

Logistic regression analysis showed no differences between adults with hearing impairment and those with normal hearing for the experienced benefits from social media use (Table 2).

Discussion

Principal Findings

Adults with hearing impairment and normal hearing adults did not differ in either weekly use of a smartphone or weekly use of a tablet. Adults with hearing impairment were less likely to make weekly use of social media apps on a smartphone, tablet, or smartwatch, but they were not less likely to use social media on all types of devices (including a desktop computer or laptop). Compared with normal hearing adults, adults with hearing impairment were more likely to agree with the statements that they use social media to stay in touch with family members and to stay in touch with their friends. Furthermore, participants with hearing impairment were more likely to be in the group that very much agrees with the statement that they use social media to perform their work. The experienced benefits from social media did not differ between adults with hearing impairment and those with normal hearing.

RQ1: Weekly Use of a Smart Device

Among all NL-SH participants, 84.4% (612/725) made weekly use of a smartphone. This percentage is comparable with the 85% of households in the Netherlands that owned a smartphone in 2017 [34], although it should be noted that our study concerned use of a device and not ownership. After correction for age, we found no differences between adults with normal hearing and those with hearing impairment. Our results therefore are not consistent with those of a 2018 UK survey [21]. This survey found that the rates of smartphone ownership were 53% in people with self-reported hearing impairment and 81% in people who reported having no disabilities. However, 60% of the survey respondents with a self-reported hearing impairment were aged >65 years compared with only 16% of the nondisabled respondents. Although older adults in the United Kingdom are catching up on smartphone use, in 2018 they were still behind younger groups [35]. The results of the UK survey therefore likely reflect the differences in age between both groups.

A tablet is used on a weekly basis by 57.9% (420/725) of all NL-SH participants. In 2017, 66% of Dutch households owned a tablet, which is somewhat higher than in our sample [34]. We found no differences in the use of these devices between adults with normal hearing and those with hearing impairment. No comparisons can be made with other literature because this difference has not been studied before.

RQ2: Weekly Use of Different Types of Apps

Of the 91% (660/725) of the NL-SH participants who use a smart device, 83.5% (551/660) make weekly use of a

communication app such as an email app or WhatsApp. Statistics Netherlands found that 80% of the Dutch general population aged ≥12 years used direct messaging (mostly WhatsApp) in 2017 [34]. This proportion is comparable with the one we found for the weekly use of a communication app. In contrast, Ipsos found a slightly lower percentage for Dutch smartphone users aged 18-64 years [36]. They reported that 68% had used an app to communicate with people in the previous 30 days (data collected in 2017). Use of the following types of apps can be compared with the Ipsos results: weather: NL-SH 69.1% (456/660), Ipsos 54%; news: NL-SH 68.6% (423/660), Ipsos 44%; financial: NL-SH 33.6% (222/660), Ipsos 51%; music and podcasts: NL-SH 26.5% (175/660), Ipsos (listen to music) 37%; and fitness (tracking): NL-SH 8.9% (59/660), Ipsos 20%. Overall, the percentages from the Ipsos report deviate from the ones we found, likely due to differences in the composition of the samples. The mean age of the Ipsos Dutch sample was 40.4 (SD not reported) years (NL-SH 57.7, SD 11.4 years), with 50% of the participants being women (NL-SH: 442/725, 61%) and 78% reporting to be working (NL-SH: 331/725, 45.7%).

We found the rate of overall weekly use of medical and health apps, other than fitness tracking apps, to be 12.4% (82/660). Overall use of these apps among the Dutch population is not known, but in February 2019 the most used nonfitness apps were diet-tracking apps (10.8%), first-aid apps (9.2%), and sleep-tracking apps (8.1%) [37]. These percentages seem to be somewhat higher than those in the NL-SH sample, but this could also be because most of our measurements were performed in 2017. It was only for use of social media apps that we found a difference between adults with normal hearing and those with hearing impairment. After adjustment for age, the adults with hearing impairment had a 33% (OR 0.67, 95% CI 0.48-0.92) lower odds of using social media apps. Another study looked at the use of apps by adults with hearing impairment. A 2016 US survey asked people with self-reported hearing disabilities which features or functions they use on their smartphone and mirrored this with results for all American adults [22]. In the survey, the use of social media apps seems to be lower in people with a self-reported hearing disability (64% vs 75% of all American adults), but no statistical testing was done, nor was an adjustment made for potential age differences. Therefore, it is uncertain if these results agree with those of our study.

It therefore seems that, apart from the use of social media apps, no notable differences exist in the type of apps that adults with hearing impairment use compared with normal hearing adults, but other research should confirm these results.

RQ3: Use of Social Media

Of the NL-SH participants, 86.6% (625/722) used social media on any type of device. Again, this is comparable with the general Dutch population: 85% used social media in 2017 [34]. Most of the NL-SH participants who use social media do this daily or multiple times a day (551/627, 87.9%). This outcome is not available for the general Dutch population, but there is a marketing report describing 72% of WhatsApp users (WhatsApp is the most frequently used social media app in the Netherlands) using this app on a daily basis in 2017 [38]. This is lower than the 87.9% (551/627) we find for social media overall, but this difference is likely caused by this percentage only covering a single social media platform that is also primarily used on a smart device.

Despite the lower weekly use of social media apps by adults with hearing impairment, overall social media use did not differ between adults with normal hearing and those with hearing impairment. A reason for this could be that, in the question on the use of apps, we made a distinction between communication apps (email and direct messaging apps such as WhatsApp) and social media apps (eg, Facebook, Instagram, and Twitter; Textbox 1). The latter addresses use of social networking sites. In the question about overall social media use, direct messaging and social networking sites were taken together. The addition of direct messaging to this question may have obfuscated the difference in use of social networking sites. Another explanation could lie in device preferences. Many social media platforms also run in a web browser. Perhaps adults with hearing impairment have a preference for approaching these social media through a web browser on a laptop or PC because of their larger screens. It is also possible that they prefer to use these devices because they can easily be set up with a speaker. From the hearing test results we know that 71.9% (276/384) of the participants with hearing impairment performed this test with speakers as opposed to using a headphone, whereas this rate was 37.9% (129/340; the type of transducer used was missing for 1 participant) in normal hearing participants. It should also be taken into account that different social media platforms attract users with different characteristics [39]. As we did not ask about distinct social media platforms, we could not compare their specific use. The results could therefore also imply that adults with hearing impairment make less use of social media platforms that are mainly used as an app, for example, Instagram. A final reason for the divergence could be that the use of apps concerned weekly use, whereas use of social media did not specify frequency of use.

We also did not find differences in the frequency of overall social media use. The sparse literature on the latter outcome shows contradictory results and focuses on young people who were born deaf or hard of hearing or became deaf or hard of hearing at a young age [40]. This group is not representative of the participants with hearing impairment in the NL-SH, most of whom have age-related hearing loss. There are important differences in proficiency in reading and writing and in their self-identification between these groups that will likely affect their social media use.

RQ4: Reasons for Using Social Media

A comprehensive theoretical framework on what people do on social media and why they use social media has not been established. Several motivations [41] and theories [42] have been put forward. The activities we asked about in our reasons for using social media mostly fall within the motivations summed up previously [41]. In line with the literature [41,43] and marketing research [44], we found considerable agreement with using social media to keep in touch with people, especially those in the private social network [44]. This is also confirmed by the fact that 80% of the Dutch people aged ≥12 years use

social media for direct messaging. There was also agreement with using social media to connect with colleagues and to create content and consume content, but this was less pronounced. These reasons also concern relationships with other people but are probably less important because the first reason pertains to professional contacts and the latter 2 concern less direct ways of connecting with others. Although 30% of the population of the Netherlands were said to use a professional social network in 2017 [34], daily use of LinkedIn is limited [38]. This confirms the disagreement we found with the statements about social media and work. NL-SH participants also do not agree with filing complaints and problems (with businesses and organizations) using social media. Marketing research in 2017 shows similar outcomes: 9% of Dutch people contacted customer services through WhatsApp, and only 12% of them had a preference for this [45]. There is a major preference for traditional contact through phone and email. Agreement with using social media to gain new knowledge was fairly evenly divided across the participants. The literature also mentions this as a motivation for using social media but gives no clues about its relative importance for using social media [41].

In the comparison between the 2 groups, we found that participants with hearing impairment are more likely to agree with using social media to stay in touch with family members and friends. They were also more likely to have the highest level of agreement with using social media to perform their work compared with the lowest level of agreement. The results of research among young people who are deaf and hard of hearing show that the most frequent motive to use social media is to maintain social contact, although no comparisons were made with normal hearing people [40].

No other studies could be found on use of social media for work purposes among adults with hearing impairment. Thus, we are the first to report that agreement with using social media to keep in contact with family and friends and to perform work is higher among adults with hearing impairment than among normal hearing peers.

RQ5: Experienced Benefits From Using Social Media

Gains or benefits experienced from using social media are conflated with the reasons to use social media. The finding that almost a third (202/628, 32.2%) of the whole group agreed that using social media had given them closer or more intense family ties and that 25.6% (161/628) had gained closer or more intense friendships ties in with many participants using social media to stay in touch with people close to them. Research in adolescents shows that social media can have a positive effect on their social connectedness and sense of belonging [46]. Positive results on social well-being are also found in adults but only when there is low emotional investment [47].

We found no differences between adults with hearing impairment and those with normal hearing for the experienced benefits from social media use. This suggests that despite our previous finding that participants with hearing impairment are more likely to use social media to stay in touch with family members and friends and to perform their work, they derive benefits from this similar to those derived by normal hearing adults.

Implications for Clinical Practice and Research

The broad use of smart devices in our sample shows the potential for digitalized hearing health care through specific apps. However, it should be noted that 9% (65/725) of the NL-SH participants did not use a smart device and that this was more prominent in older adults. Of all study participants aged >65 years, 15.7% (182/216) did not use a smart device (results not shown). As most of the people with hearing impairment are aged >65 years, this means that a substantial number of people with hearing impairment access the internet by other means. To ensure equal access, digital hearing health care should not be restricted to apps; it should also be available on desktop computers and laptops. This ties in with the possibility that adults with hearing impairment have a preference to use these latter devices to access social media.

The use of medical and health apps appears low in our sample because only 12.4% (82/660) reported using these apps and their use is apparently higher in the general public. This does not imply that adults with hearing impairment have little interest in apps for hearing health care; rather, it means that more research is needed into their needs and wants. A variety of solutions may be necessary, as was shown in previous research on eHealth alongside the customer journey of older people with hearing loss [48].

We speculated that communication through the internet could be specifically attractive to adults with hearing impairment. Indeed, adults with hearing impairment were more likely to use social media to stay in touch with family members and friends than normal hearing adults. Nonetheless, they were not more likely to report closer or more intense family ties or friendships from using social media. This shows that internet-mediated communication does not have more salience for adults with hearing impairment than other modes of communication. More research is needed on the type of social media that adults with hearing impairment use to stay in touch with close family members and friends and whether the higher use mitigates mental health outcomes as we have put forward.

Finally, participants with hearing impairment were more likely to use social media to perform their work. Work can be challenging for people with hearing loss because of the difficulties in spoken communication. This can result in increased levels of fatigue, stress, loss of productivity, and job loss [49,50]. It would be of interest to study how adults with hearing impairment use social media to perform their work and whether social media use can help to mitigate these adverse effects. Consideration could also be given to using social media for audiological rehabilitation purposes, for instance, providing the option to consult vocational rehabilitation services through direct messaging, but this needs further investigation.

Strengths and Limitations

The strengths of this study include the large sample, its diversity in age, the comparison between adults with normal hearing and those with hearing impairment, the correction for confounders, and the functional measurement of hearing ability. As all measurements were performed through a questionnaire and a hearing test that ran in a web browser, the study was likely to

attract adults who are fairly comfortable with using the internet through a web browser. Nevertheless, the total sample seems representative of the general Dutch population in their use of technology and social media.

Our study includes several limitations. We used existing questionnaires that are used for marketing purposes. We were not able to find any documents showing validity of these questionnaires. Nevertheless, given that they are used in marketing research, we assume that they were developed according to accepted standards and hence valid, although a scientific report on their validity has not been published. We assume that the questions on use of technology and different types of apps were valid. The questions we devised on several aspects of social media use were not tested for validity either. This needs further investigation. In addition, all data were self-reported and could therefore suffer from recall bias, particularly the questions that included frequency of use, as well as from social desirability bias. The actual use of apps and social media on smart devices can be measured by individually tracking their use with software that collects these data and sends them to a research database [51], but this was not feasible in this study. Given that we did not ask about controversial topics with respect to using the internet and social media as well as the rather anonymous nature of filling out a web-based questionnaire, we believe that social desirability bias is of minimal importance in our study. Another limitation is the use of convenience sampling. The NL-SH sample is more highly educated than the general Dutch population, which could hamper generalization. However, the comparisons between adults with hearing impairment and those with normal hearing are still valid because they were performed within this sample and no influence of education level was found on the associations. All analyses were cross-sectional, which does not allow for inferences on causal relationships. Finally, we performed a very large number of statistical tests. The probability of a type 1 error, finding a statistically significant difference when in reality there is no difference, increases with multiple testing. We did not correct for this because we considered our study to be exploratory in nature. The results should be interpreted accordingly.

Conclusions

The potential for digitalized hearing health care is confirmed. Adults with impaired hearing are not less likely to use smart devices than their normal hearing peers. More research is needed into the needs and wants of adults with hearing impairment for the type of hearing health care solutions they seek.

Adults with hearing impairment agreed more with using social media to stay in touch with family members and friends than normal hearing adults, but this did not result in closer or more intense family ties or friendships. Research is needed on the type of social media that adults with hearing loss use to stay in touch with close family members and friends and to determine whether the higher use of social media mitigates mental health outcomes as we have put forward. Given that participants with hearing impairment are more likely than their normal hearing peers to use social media to perform their work, it would be of interest to study whether and how vocational rehabilitation services for workers with hearing impairment could be implemented on social media platforms as an alternative or supplementary to standard hearing health care. Adults with hearing impairment are less likely to make weekly use of social media apps on a smartphone, tablet, or smartwatch but not less likely to use social media on all types of internet-connected devices. This warrants further research on the types of social media platforms that adults with hearing impairment use and on the type of device on which they prefer to use social media.

Acknowledgments

The authors thank the participants of the Netherlands Longitudinal Study on Hearing. Funding for data collection of the 10-year measurement round came from the EMGO+ Institute for Health and Care Research, the Netherlands, and Sonova AG, Switzerland. This study was supported with monetary and nonmonetary means (ie, personnel time) by Sonova AG, Switzerland.

Abstract

Background: Technology-based innovations that are created collaboratively by local technology specialists and health experts can optimize the addressing of priority needs for disease prevention and control. An EpiHack is a distinct, collaborative approach to developing solutions that combines the science of epidemiology with the format of a hackathon. Since 2013, a total of 12 EpiHacks have collectively brought together over 500 technology and health professionals from 29 countries.

Objective: We aimed to define the EpiHack process and summarize the impacts of the technology-based innovations that have been created through this approach.

Methods: The key components and timeline of an EpiHack were described in detail. The focus areas, outputs, and impacts of the twelve EpiHacks that were conducted between 2013 and 2021 were summarized.

Results: EpiHack solutions have served to improve surveillance for influenza, dengue, and mass gatherings, as well as laboratory sample tracking and One Health surveillance, in rural and urban communities. Several EpiHack tools were scaled during the COVID-19 pandemic to support local governments in conducting active surveillance. All tools were designed to be open source to allow for easy replication and adaptation by other governments or parties.

Conclusions: EpiHacks provide an efficient, flexible, and replicable new approach to generating relevant and timely innovations that are locally developed and owned, are scalable, and are sustainable.

Introduction

Technology can play an important role in the prevention and control of infectious disease. Historically, developing technical solutions has required substantial financial resources, human capacity, and time. All too often, innovative technologies that are introduced as pilot projects or research endeavors are terminated prematurely due to a lack of sustained funding or a lack of a postresearch plan. Third-party technologies that are created for governments are often discarded when vendors change or fail to create long-term plans for sustainability and scaling. In other cases, misalignment with current contexts and capabilities has often resulted in technologies being unsuccessful despite the best intentions. In short, technology solutions that are created *for* low- and middle-income countries to address local challenges, rather than those created *by* such countries, are quickly becoming a thing of the past.

Creating scalable and sustainable innovations for disease prevention and control requires local technologists to work

together with health experts to optimize the desired results when creating technology-based innovations. Conducting an EpiHack is one way to optimize such results. EpiHacks provide a unique process for combining the science of epidemiology with elements of a hackathon to cocreate solutions that address existing and future needs through a highly collaborative and intensive event.

Engaging local technologists and health experts from idea inception to prototype development can ensure that the appropriate contexts, such as language, culturally relevant imagery, and social norms, are duly considered when creating any solution to identified challenges. Additionally, innovative solutions that are generated through the use of existing infrastructures and widely available technologies are more likely to be widely adopted and affordable.

In an EpiHack, design thinking is the principal approach that is used to identify needs and guide the development of tools and systems to meet those needs. Design thinking is a process for solving problems by prioritizing end users' needs through observing how people interact with their environments and by using an iterative, hands-on approach to creating innovative solutions [1]. The focus of an EpiHack can be specifically on disease, situations, or improved data analysis and visualization. EEpiHack solutions have served to improve surveillance for influenza, dengue, and mass gatherings, as well as laboratory sample tracking and One Health surveillance, in rural and urban communities. As of January 2021, a total of 12 EpiHacks have been executed across 5 continents, resulting in open-source technologies positively impacting disease prevention and control. This paper defines the EpiHack process and summarizes the impacts of the technology-based innovations that have been created through this approach.

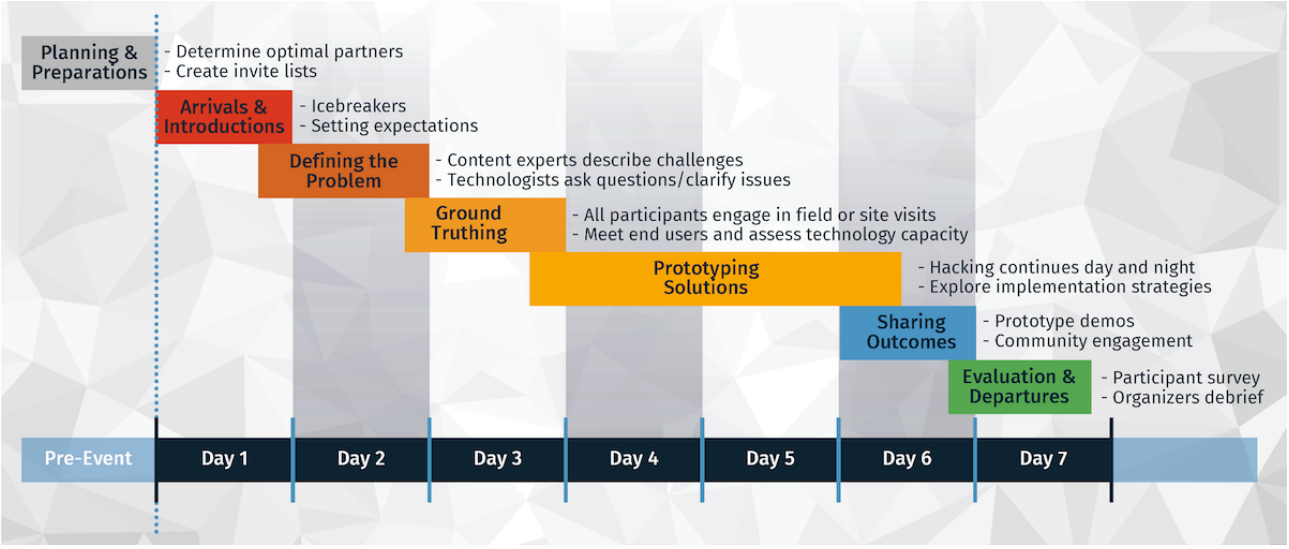
Methods

EpiHack elements and the timeline of an EpiHack were described. The twelve EpiHacks conducted between 2013 and 2021 were reviewed to document the focus areas, outputs, and impacts.

EpiHack Components and Timeline

Each EpiHack prioritized the needs of the host country or organization to solve real-world problems efficiently and effectively through a highly interactive and collaborative process. EpiHacks are immersive, residential programs in which developers and health experts work side by side on-site until the desired outcomes are achieved. EpiHacks generally occur over the period of 1 week but can be adapted according to the complexity of the problem(s) to be solved (Figure 1). In theory, it may be possible to host a web-based EpiHack, although this approach has not yet been tested. Participants do not compete for prizes or awards; rather, they collaborate to achieve common goals and maximize the desired impact.

Figure 1. EpiHack components and timeline. EpiHacks are ideally conducted over a 1-week period to provide optimum time for defining the problems, exploring solutions, and arriving at prototypes by the conclusion of the event.



Planning and Preparation

An EpiHack requires rigorous advanced planning, including securing a location for hosting an immersive, potentially weeklong event with extended hours each day. A good deal of time and effort goes into identifying participants, which include key stakeholders from the government, the private sector, and the community along with technologists and facilitators, who are critical to ensuring the successful outcomes of the event. It is imperative that various levels of government be brought into the planning process at the earliest stage, given their critical roles and responsibilities in national and local disease prevention and control.

The host organization is typically an in-country partner who is eager to improve local disease prevention and control capacities and fill existing gaps. Host organizations have included government agencies, universities, and not-for-profit organizations. The host must oversee all planning and the execution of the event and ensure that the right mix of health and technology participants will be in attendance. An appropriate balance of subject matter expertise and technology development

skills is crucial to inspiring unbridled creativity. A developer to health expert ratio of 3:1 is recommended.

Given that 3 in 4 emerging infectious diseases have their origins in animals, it is imperative that technology-enabled solutions for disease prevention and control engage both the human and animal sectors [2]. EpiHacks therefore require the active engagement of subject matter experts across the human and animal health sectors, including epidemiologists, veterinarians, and health care specialists. They also engage diverse end users, such as farmers, market workers, community health volunteers, district health officers, and lab technicians. EpiHacks also require the participation of a diverse set of local technology professionals who are familiar with front-end development (user interfaces and web design), back-end development (servers and databases), and data science elements (data management and analytics). Local technology expertise promotes mindfulness toward how proposed innovations can manifest into readily usable technologies.

Ensuring that strategic governmental partners, potential funders, and key community organizations are engaged in the planning of an EpiHack also improves the likelihood of successful outcomes. This also allows for the longer-term engagement of stakeholders from key implementing organizations, who are necessary for fully deploying the tools and systems that are created during an EpiHack.

In some cases, hosts may work with stakeholders in advance to frame the challenges that will be addressed during an EpiHack before the start of the event. In most instances however, the true nuances of these challenges come to light only after an EpiHack begins. Many aspects of an EpiHack are intentionally made to be unconfined to provide participants with the freedom to arrive at the most creative and appropriate solutions. Part of the initial planning includes arrangements for "field trips" or site visits to explore technical capabilities and to meet the potential end users of the innovations to be created during an EpiHack.

Most EpiHack attendees—both technology and health expert participants—reside in the host country. This ensures that participants are aware of the local contexts and challenges related to developing compelling prototypes that resonate with the targeted end users. Attracting and identifying the right local technology partners often require posting about the upcoming EpiHack on various media outlets and recruiting them from both the private and public sectors. Health expert attendees are generally invited based on their area of expertise or role within the government with regard to disease prevention and control.

Arrivals and Introductions

Given that many EpiHack participants do not know each other or have not attended a prior EpiHack, it is important to provide adequate time for getting acquainted through icebreakers, providing an introduction to the process of an EpiHack, and setting expectations for the days of the EpiHack. Often, the human and animal health experts, even if they are from the same country, do not know each other well and appreciate the opportunity to socialize before the intensive EpiHack process ensues. Building mutual trust and respect between the health experts and the technologists is essential, given the rapid pace of the event.

Defining the Problem

In most EpiHacks, participants begin their substantive work by defining the problem or clarifying the challenges to be addressed over the course of the week. This focus at the start provides the opportunity for content experts to explain existing challenges and allows for technology participants to ask questions to the health experts and vice versa. In cases where the problem to be addressed is determined through pre-event work, the EpiHack starts off with the host organization updating the participants on the desired goals.

Ground Truthing

Once the challenges have been defined, the participants travel to the "field" to visit relevant sites, so that they can better understand the needs of end users. During these visits, participants interact directly with multiple end users of the proposed technology solution(s) and explore their operating environments. This may include visits to government facilities, community health clinics, hospitals, or live animal markets to examine the existing workflows and current infrastructures with which the proposed tools will operate. These visits might entail engaging with farmers in rural villages or observing community health workers in their catchment areas to understand firsthand the challenges to be resolved. EpiHack solutions must be capable of integration and interoperation with existing systems and use the pervasive technologies in a given country or region. These solutions must also account for issues, such as those related to internet connectivity and ease of use.

Prototyping Solutions

An important part of an EpiHack is hacking, and this takes place over the several days of the so-called *hacking stage*. Participants work collaboratively to iterate on ideas, test concepts by developing mock-ups, and begin to create functional prototypes. During this time, technology experts work closely with their health counterparts to resolve issues related to design, testing, and strategies for implementation. Although hacking is the primary function of the technologists, the health experts use this time to further develop plans for pilot tests, end-user engagement, and the scaling of the solutions. Often, the participants divide themselves into smaller teams to concentrate on building a specific tool or to allow for intense focus on a particular issue.

All tools, prototypes, and systems that are developed in EpiHacks are open source, meaning that the software for original source codes is made freely available and may be modified. This allows others to replicate or adapt the tools for their own purposes. Participants are asked to sign an open-source agreement to this effect, waiving any intellectual property rights for the ideas or tools that are developed during EpiHack events. The designs, prototypes, and tools that are created during an EpiHack are typically further developed into fully deployed systems that serve the host country or organization following the event. In many cases, the collaborations among the technologists and health experts that occur during an EpiHack continue well after the week's end.

Sharing Outcomes

The penultimate event of the week is the showcasing of the solutions and prototypes developed during the EpiHack among the participants and key stakeholders. Community members are also invited to this event to broaden engagement and further facilitate the uptake of the solutions. Private sector participation can often help with devising strategies and creating necessary partnerships for financing and scaling tools. Such partnerships are especially useful when large-scale health emergencies require the rapid adoption and widespread use of solutions.

Evaluation and Departures

The work of an EpiHack does not end after participants share the outcomes. Often before leaving, participants make commitments to certain outcomes and align their roles with those of other stakeholders to ensure the completion and sustainability of the proposed solutions. Many times, participants create a mailing list or a WhatsApp group to update each other on the progress of tool development post-EpiHack and to share opportunities for further engagement. At the conclusion of each EpiHack event, participants complete a survey, and organizers hold an after-action debrief to evaluate the impact of the EpiHack and identify areas for improvement.

Research Ethics Statement

This study did not receive or require ethics approval, as it did not involve human or animal subjects.

Results

Since 2013, a total of 12 EpiHacks have been conducted, and each event resulted in 1 or more prototypes of tools or systems for enhanced disease prevention and control (Table 1).

EpiHack solutions have included national hotlines, One Health participatory surveillance systems, health monitoring tools for mass gatherings, and systems for mosquito vector control. EpiHack Phnom Penh, for example, laid the groundwork for the 115 Hotline—an interactive voice response system that allows Cambodians nationwide to report on suspected health threats in their community as well as access a menu of health education messages [3,4]. During the COVID-19 response, this free national hotline became the primary means for reporting COVID-19 suspect cases, initiating contact tracing efforts, and sharing COVID-19–related health information to the community. The hotline received an average of 18,000 calls per day at the peak of the COVID-19 pandemic and an average of 600 calls per day before the pandemic [5].

EpiHack Chiang Mai resulted in the Participatory One Health Disease Detection (PODD) system in Thailand, which uses smartphone apps and web applications to empower trained village volunteers to report unusual disease events in livestock, wild animals, and humans. By using this system, reports are triaged by PODD analysts and result in a response from local public health and livestock offices when warranted [6,7]. To date, over 19,000 volunteers have been trained to use the PODD system, and the project has expanded to approximately 400 subdistricts across 27 provinces in Thailand. In addition, community members used the PODD system to track the health of nonresidents who entered their village during the government-instituted COVID-19 lockdowns. Among 340 applications from 61 countries, the PODD system was the grand prize winner of the Trinity Challenge—an initiative that was created by a coalition of companies, foundations, and universities to recognize innovations in data-driven research and analytics for global health emergencies [8].

EpiHack Arusha participants created digital prototypes that resulted in the AfyaData mobile app for One Health surveillance in Tanzania. The system is used by trained volunteers in the Morogoro and Ngorongoro districts in Tanzania and allows for the real-time collection of data on human and animal health. AfyaData collects information at both the community and health facility levels and returns information on potential health intervention strategies to the reporters [9]. During the COVID-19 pandemic, AfyaData was shared with Mozambique for the cross-border tracking of COVID-19.

Due to the successful use of participatory surveillance for the first time at a mass gathering during the 2014 World Cup in Brazil, EpiHack Rio de Janeiro hosted a diverse set of international participants in 2015 to replicate this surveillance approach and enable the early identification of disease clusters during the Rio Olympic and Paralympic Games [10,11]. Members from India attended this EpiHack and incorporated their learnings from mass gathering disease surveillance during religious events in India [12]. The participatory surveillance tool in Brazil has since been adapted to monitor symptom reports from the public in Brazil and to capture data on COVID-19 symptom reporting in Brazil, Chile, and Peru.

Table 1. Summary of the EpiHacks conducted between 2013 and 2018.

Date	Location	Participants, n	Hosts	Focus area	Output and impact
August 2013	Phnom Penh, Cambodia	55	Royal University of Phnom Penh and Cambodia Ministry of Health	Participatory surveillance	The 115 national reporting hotline was created and deployed nationwide for disease reporting by the community and relaying health alerts. Averaging 600 calls per day, the hotline scaled during the COVID-19 pandemic to 18,000 calls per day and captured over 90% of the initial COVID-19 suspect cases [5].
March 2014	Chiang Mai, Thailand	49	Chiang Mai University College of Veterinary Medicine and Chiang Mai Provincial Public Health & Livestock Offices	One Health participatory surveillance	PODD[a] mobile apps and web-based applications were created. The PODD tool expanded from a single province and was adopted by >400 local governments across 27 provinces in Thailand with >19,000 trained volunteers [5]. During the COVID-19 pandemic, the PODD tool was adapted for tracking suspected COVID-19 cases.
June 2014	Lao People's Democratic Republic	62	Mekong Basin Disease Surveillance Network and Lao People's Democratic Republic Ministry of Health	Dengue surveillance	A dengue larvae survey tool was developed to allow for active community engagement in reducing the number of larvae breeding sites to improve dengue prevention and control.
December 2014	Arusha, Tanzania	74	Southern Africa Center for Infectious Disease Surveillance, Ministry of Health, and Ministry of Livestock and Fisheries	One Health participatory surveillance	The AfyaData One Health surveillance tool was developed, and it collected over 12,000 reports of abnormal health events in humans and animals over first 5 years of operation. The timeliness of local reporting to authorities improved from an average of 10 days to an average of 3 days [9]. During the COVID-19 pandemic, AfyaData was shared with Mozambique for cross-border reporting.
July 2015	Rio de Janeiro, Brazil	49	Brazil Ministry of Health	Mass gathering surveillance	The Guardians of Health surveillance tool was created, and it demonstrated the utility of participatory surveillance for monitoring health events during mass gatherings [10,11]. The tool has been used for COVID-19 surveillance among subpopulations in Brazil, Chile, and Peru.
September 2015	Minneapolis, United States of America	30	University of Minnesota Food Protection and Defense Institute and National Association of City and County Health Officials	Influenza surveillance	A Flu Near You (influenza-like illness symptom reporting system) data dashboard was created to improve data visualization, and it enhanced data analytics for use by local health departments.
April 2016	Saranda, Albania	41	Southeast European Center for Surveillance and Control of Infectious Diseases, Ministry of Health, Institute of Public Health, and Ministry of Animal Health	One Health surveillance systems	A digital data dashboard for One Health surveillance was built based on the learnings from the Thailand and Tanzania EpiHacks.
April 2016	Yangon, Myanmar	44	Myanmar Ministry of Health	Participatory surveillance	A hotline for citizen volunteers to report on health issues was developed for direct community reporting on health issues.
September 2016	Denver, United States of America	25	Council of State and Territorial Epidemiologists	Influenza surveillance	A Flu Near You data validation toolkit and data dashboard enhancements were developed for local health departments to better interpret Flu Near You data [13].
October 2017	Hanoi, Vietnam	31	Vietnam Ministry of Health General Department of Preventive Medicine	Participatory surveillance	A community outbreak reporting hotline was created by replicating the 115 Hotline model from Cambodia for use in Vietnam [14].

Date	Location	Participants, n	Hosts	Focus area	Output and impact
November 2017	Colombo, Sri Lanka	90	Colombo Municipal Council and Nanyang Technology University	Vector-borne disease surveillance	The Mo-Buzz dengue surveillance app was enhanced to improve the user interface, digitize paper forms, and improve data analytics and the visualization of breeding sites that were indicated as high-risk areas [15].
April 2018	Kampala, Uganda	44	Uganda Ministry of Health	Emergency Operations Center	A contact tracing prototype and laboratory sample tracking system were created.

[a]PODD: Participatory One Health Disease Detection.

EpiHacks have also contributed to building a community of practice around innovations in surveillance. In several instances, members who have attended an EpiHack apply their learnings to subsequent EpiHacks and new tool development. For example, health experts and developers from Tanzania attended EpiHack Chiang Mai (conducted in March 2014) to learn about the EpiHack process. Subsequently, they applied their learnings to the EpiHack in Tanzania (conducted in December 2014). Conversely, participants from EpiHack Chiang Mai attended the EpiHack in Tanzania to help guide the event. Furthermore, learnings from the Tanzania EpiHack informed the Albania EpiHack, which resulted in the development of the Albania One Health surveillance system.

EpiHack participants' evaluations uncovered key thematic areas, including the value of dedicating time to networking, the utility of the "field trips," and the desire for ongoing engagement with coparticipants. As noted in the evaluations, the provision of adequate time during each EpiHack for networking is prioritized. Additionally, up to 1 whole day is dedicated to the "field trip," so that all participants can experience the realities that are relevant to their solutions. Finally, given the interest of participants in continuing their engagement after EpiHack events, email listservs and WhatsApp groups are created by the organizers to facilitate ongoing communication among participants.

Discussion

EpiHacks provide an efficient and effective approach for generating relevant and timely innovations in disease prevention and control that are locally developed and owned. EpiHacks are well suited for tackling challenges that require creativity, consensus among stakeholders, and cross-sectoral collaboration. Political support and buy-ins from local leadership are foundational for a successful EpiHack. Although not all EpiHack hosts are government agencies, their participation is important for fostering the necessary buy-ins for the development of prototypes and sustainability.

EpiHacks offer opportunities for new collaborations and networking among participants at the national level and on a global scale. Most EpiHack participants are chosen by organizers from the host nation in keeping with a focus on local and sustainable solutions. Engaging EpiHack alumni, who understand the process due to their previous experiences, is highly beneficial. Those who are interested in hosting a future EpiHack might attend an event to experience this approach prior to hosting their own convening.

EpiHacks have been used primarily in the context of innovations for the prevention and control of infectious disease. This approach however could serve as a model for the advancement of solutions to other global health challenges. Web-based training on the EpiHack approach is free, and the health community is encouraged to consider this efficient method for advancing technology solutions to challenges in a variety of contexts [16]. The lessons gained from EpiHacks to date are that no community is too hard to reach, no country is too resource poor to innovate, and curiosity outshines fear around the globe when people are given the opportunity to create local solutions to pressing problems.

Acknowledgments

EpiHacks were conceived by Ending Pandemics—a San Francisco–based nonprofit—to support the locally led development of tools for rapidly detecting, verifying, reporting, and containing disease outbreaks across the One Health spectrum. Ending Pandemics would like to acknowledge everyone who participated in, facilitated, and organized EpiHacks, with a special thanks to the public health officials in Albania, Brazil, Cambodia, Laos, Myanmar, Sri Lanka, Tanzania, Thailand, Uganda, the United States of America, and Vietnam who engaged in this novel process for improving disease surveillance. We would also like to acknowledge the critical contributions of our former colleagues—Dr Jennifer Olsen, who facilitated several of the EpiHacks, and Adam Crawley, who assembled material for an early draft of the manuscript and Table 1. We are equally indebted to our partners from Opendream and InSTEDD (Innovative Support to Emergencies Diseases and Disasters) for designing and hosting numerous EpiHack events. Specifically, we would like to acknowledge Mr Patipat "Keng" Susumpow for coining the term *EpiHack* and Ms Prapapan "Bunny" Phetra and Mr Polawat "Pok" Phetra for their roles in developing the EpiHack web-based training resources and their invaluable contributions as EpiHack lead facilitators at events across the globe.

Authors' Contributions

ND was involved in the drafting, revision, and final review of the manuscript. MS conceptualized the EpiHack methodology. He was integrally involved in the drafting, revision, and final review of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Many people use the internet to access health care information to support health care decisions, and hospital websites can be the first point of contact to provide health care information services for consumers. However, little is known about the current information services provided by the websites of large Chinese hospitals.

Objective: The aim of this study is to evaluate and compare the information services of the websites of large hospitals in China and the United States. We hope that our findings will benefit hospital managers worldwide in providing service information on the web.

Methods: This study adopted a cross-sectional analytical approach to evaluate the websites of large hospitals in China and the United States in 2020. A total of 300 large hospitals were randomly selected, of which half were in China and half were in the United States. Based on the 7Ps marketing mix, we identified 39 items that represent typical hospital website information services, covering the following seven dimensions: product, price, place, propagation, people, process, and physical evidence.

Results: Most of the items (34/39, 87%) related to information services offered by hospital websites were less covered in China than in the United States; however, 5 items (appointments by a third-party platform, mobile payment, hospital value, hospital environment display, and physicians' profiles) had higher coverage in China. The average scores for hospital websites in China and the United States were 13.25 (SD 2.99) points and 23.16 (SD 2.76) points, respectively. Generally, high scores were given to the south areas of China and north areas of the United States.

Conclusions: Hospital websites in China lagged behind those in the United States with regard to information services offered. We recommend that hospital managers in China place more emphasis on the people, product, and propagation dimensions of the 7Ps marketing mix in the construction of information services on hospital websites. Through the comparison of the websites of large hospitals in China and the United States, our study findings can provide suggestions for forming standard hospital website construction guidelines worldwide.

Introduction

The internet has become ubiquitous in people's lives. As of October 2020, almost 5 billion people had direct access to the internet worldwide [1]. According to a report by the China Internet Network Information Center, as of March 2020, the penetration rate of internet users in China was 64.5%, which represents an increase of 4.9% when compared to this penetration rate in 2018 [2]. Most adults use the internet to access health care information to support health care decisions [3,4], and a hospital's home page can serve as the first point of contact to provide health care information services for consumers. Thus, in the internet era, the hospital website has become an important window connecting various departments of a hospital with patients and society, as well as a fairly new marketing tool to current and potential customers [5]. Customers' decision-making processes are often influenced by their perceptions and evaluations of a hospital's website [6]. It is important for hospital websites to meet their expectations by providing useful and accessible information [7]. Therefore, the evaluation of hospital websites has become inevitable.

The subject of hospital website evaluation has been heavily researched in different studies, such as an analysis of private hospital websites promoting medical tourism in India, Malaysia, and Thailand [8]; an evaluation of the quality of private hospital websites in Turkey; an evaluation of top academic hospitals for finding endocrine surgeons [7]; an evaluation of website information provided by pediatric surgery centers in Australia and New Zealand [4]; and a ranking of children's hospital websites in the United States [9]. However, previous studies have not fully examined the evaluation of websites of general or large hospitals. Various models or frameworks have been proposed to evaluate hospital websites, mainly focusing on the quality of the websites [10-12] or evaluating their accessibility [13]. Network engagement for hospitals is a skill that exists at the intersection of marketing and technical capability [6], and a well-designed hospital website that shows considerable service information could influence patients to take the first step into a facility. There is much less evidence of evaluating hospital websites from the perspective of information service.

Affected by the "Internet Plus Healthcare" strategy of the Chinese government (which proposes that internet technologies should be used to offer medical and public health services, promote family physician practices, improve drug supply and medical bill settlement, conduct medical education, and provide artificial intelligence services) [14], the overall construction level of hospital websites in China has improved significantly with time [15]. Furthermore, there is a substantial difference between past and modern hospital service concepts, especially in terms of offering user-oriented services and information. It is imperative to improve the information services provided by Chinese hospitals, especially those provided by large hospitals that offer intensive health care services. Therefore, it has become necessary to determine the current state of hospital websites in China. In addition, as shown in research that compared hospital websites from different countries [16], there is no study about the difference between hospital websites in China and other countries. The United States, where the internet emerged, was ranked third among countries with the most internet users after China, which had the highest number of internet users [17]. It would be interesting and meaningful to compare two powerful countries such as China and the United States, which have the largest economies in the world and represent a limited-income country and high-income country, respectively. There are 615,000 hospitals in the United States and 3,435,000 hospitals in China with a very large medical service market [18,19]. These hospitals could provide valuable information for global health care services when facing the increasing demand of the internet market.

This study aims to compare the information services of large hospital websites in China and the United States, based on the 7Ps marketing mix, and examine the problems that exist in Chinese hospital websites. We hope that our findings will benefit hospital managers not only in China and the United States but also around the world, especially in providing web-based service information.

Methods

Evaluation Framework Development

To the best of our knowledge, this study is the first to adopt the 7Ps marketing mix to form a logical evaluation framework for the sake of comparison, as this study focuses on the information services offered by hospital websites. The 7Ps marketing mix is a service marketing theory that was developed by Booms and Bitner [20] in 1981 by adding 3 new elements (people, process, and physical evidence) to the traditional marketing theory of 4Ps (product, price, place, and promotion). People, process, and physical evidence embody the characteristics of service marketing. Through a combination of production and consumption processes, this model allows customers to perceive high-quality service with the purpose of establishing, maintaining, and strengthening good long-term relationships with customers. According to the general definition and components of the 7Ps marketing mix, the corresponding definitions and components in relation to service information from hospital websites are presented in Multimedia Appendix 1. This evaluation framework consists of 7 dimensions and 39 items (components) for evaluating the service information of hospital websites. We consulted 10 hospital management or marketing experts to reach a consensus on determining and classifying the 39 items (components).

Sampling

A large cross-sectional analysis approach was adopted to evaluate hospital websites in China and the United States. We randomly selected 150 large Chinese hospitals and 150 large American hospitals (a total of 300 hospitals) to conduct a survey of their website information services. Because it is very difficult and time-consuming to extract information from websites, we decided to randomly take 3 and 5 hospitals in each state and province to obtain 150 samples from the United States and China, respectively, after consulting with a statistician. All eligible hospitals (over 500 beds) from each administrative region of the two countries were included initially, and then a random sampling procedure was conducted. We focused on large hospitals because they usually serve more patients on

average and their websites are visited by more users. Furthermore, large hospitals are more likely to represent the medical service capacity of a country. According to the current classification standards of Chinese hospitals, the definition of "large" refers to a Chinese hospital with at least 500 beds. Correspondingly, the same criterion was applied to the selection of American hospitals to map with the Chinese group. The number of beds for the selected hospitals in the United States was over 500 as well. The final sample of hospitals covered 31 provincial administrative regions in China (excluding Taiwan, Hong Kong, and Macao) and 45 states in the United States (excluding the states of Alaska, Montana, New Hampshire, Vermont, and Wyoming). Hospitals in Taiwan, Hong Kong, and Macao were excluded from the list of Chinese hospitals because their development and management systems are run differently from those in other regions of China for several historical reasons. Additionally, the population of these regions is too small to be included for explaining the general situation of China. We excluded 5 US states in our study because we failed to find hospitals with over 500 beds in these regions. Detailed information about the samples is provided in Multimedia Appendix 2.

Data Collection

From February to June 2020, two independent reviewers identified the websites of the sampled hospitals using the Baidu and Google search engines. Each website was comprehensively assessed based on the 39 items of the previously developed evaluation framework to check if the corresponding information was available.

Statistical Analysis

To create summarized scores of website service performance, the analytic method involved scoring the content according to 30 items, and each item was valued 1 point. The total score for each hospital website was reported in a range from 0 to 30, with a higher score on any given scale representing better comparative performance. The higher the score, the richer the information offered.

The 9 items that were not included in the scoring system were website accessibility, mobile payment, web account payment, appointment by telephone, appointment by official website, appointment by official app, appointment by a third-party platform, independent web page for hospital culture expressions, and patient-centered value. Website accessibility was not included in the scoring system because the information services and total scores for the websites could not be identified. Methods of making appointments and payments were excluded because there were no criteria showing which method was better. Independent web pages for hospital culture expressions and patient-centered value were not related to the availability of the service information offered but were related to how such information was offered by hospital websites; therefore, they were also left out of the scoring system.

Categorical variables were expressed as proportions and were tested using the chi-square test. Continuous variables were expressed as means and SDs and were tested by *t* test (if the sample observations followed a normal distribution and had homogeneity of variance) or Wilcoxon rank sum test (if the sample observations followed an abnormal distribution and had heterogeneity of variance). All analyses were conducted using Stata, version 12.0 (StataCorp LLC). All *P* values quoted below are 2-tailed and were considered significant when <.05.

Results

Of the sampled hospitals, a total of 143 Chinese and 150 American hospital websites were included, because 7 Chinese hospitals had no website on the internet or the site could not be accessed during our research.

All of the Chinese provinces/municipalities in this survey scored below 20 points, and more than 90% (29/31, 94%) scored in the range of 10 to 20 points. All of the studied American states scored above 20 points. As shown in Figure 1, there was a large gap between the two countries. It is interesting to note that the highest scores were generally given to the southern areas of China and northern areas of the United States. In terms of states or provinces/municipalities, the American hospital websites in Colorado, Delaware, and Rhode Island achieved the best scores (28 points); in China, the websites in Beijing, the capital city, obtained the highest score (17.2 points), followed closely by those in Zhejiang Province (17 points), Guangdong Province (15.43 points), and Shanghai Municipality (15.4 points). In the United States, hospitals in the state of California were rated the lowest (21.43 points); however, Sinkiang hospitals had the lowest score (5.4 points) in China.

The comparative results of 39 items representing the information services available on the websites between China and the United States are shown in Table 1. Overall, the information services offered by hospital websites in China were less covered than those offered in the United States, except for the following five items: appointment by a third-party platform, mobile payment, hospital value, hospital environment display (pictures/videos), and physicians' profiles. The item with the highest availability on websites in China and the United States was the medical services list (139/143, 97.2%) and appointment services (150/150, 100%), respectively. There were no information services about 2 items—web account payment and patient and family advisory council—on the Chinese hospital websites, and no appointment service by a third-party platform was available on American hospital websites. The data in Figure 2 are derived from the proportion of American hospital websites minus that of Chinese hospital websites for each information service item. Among the items in which Chinese hospital websites lagged behind, the five with the largest gaps were web account payment, patient privacy protection statement, volunteer services, COVID-19 information/policies, and social donation (Figure 2). The differences were all statistically significant (*P*<.001; Table 1).

[a]N/A: not applicable.

Figure 2. Differences in proportions of information service items on American and Chinese hospital websites. The proportion difference equals the percentage of accessibility of an item on American hospital websites minus the percentage of accessibility of an item on Chinese hospital websites.

Table 2 indicates the scoring results of information services available on hospital websites in China and the United States. The average scores for the 143 hospital websites in China and the 150 hospital websites in the United States were 13.25 (SD 2.99) points and 23.16 (SD 2.76) points, respectively. The scores of American hospital websites on 6 dimensions (product, price, place, propagation, people, and process) were all higher than those of Chinese hospital websites, and the differences were all statistically significant (*P*<.001). For the physical evidence dimension, namely, hospital environment display (pictures/videos), the score of the Chinese hospital websites was higher than that of the hospitals in the United States, and the difference was statistically significant (*z*=–2.37; *P*=.02). In addition, it can be seen from Table 2 that the largest gap existed in the people dimension, with a difference of more than 2 times in the average scores.

Table 2. Scoring results based on the 7Ps marketing mix for Chinese and American hospital websites.

Criterion	China (n=143)		United States (n=150)		*z* score	*P* value
	Score, mean (SD)	Score, P_{50} (P_{25}, P_{75})[a]	Score, mean (SD)	Score, P_{50} (P_{25}, P_{75})[a]

Discussion

Principal Findings

This is the first study to evaluate the website information services provided by large Chinese and American hospitals based on the 7Ps marketing mix. Overall, the hospital websites in the United States offer more information services compared to those in China, which suggests that US hospital managers consider this to be an important method of reaching their customers. According to the scores of the hospital websites, it can be clearly seen that the higher scores were mainly concentrated in the south and east regions of China, which have higher gross domestic products than those of other regions. This could be explained by the fact that these regions have more income and resources. It may also be the case that hospitals in these regions are more concerned about competition and have implemented a website as part of their strategy for attracting patients [21].

Specifically, the results suggest that large hospitals in China are largely lagging behind in offering user-oriented information services on their websites. Our findings revealed that the Chinese hospital websites focused primarily on basic services and information, such as the medical service list, appointment services, and physicians' profiles, rather than paying more attention to the people dimension and involving the participation of and communication with the public, including patients, patients' families, volunteers, social donors, and website users. Taking the item of the patient privacy protection statement as an example, the proportion difference between Chinese and American hospital websites was ranked first among the 30 comparable scoring items. This finding is consistent with a previous study, in which only 22% websites of leading Chinese general hospitals included a privacy and security policy or terms of use [22]. Similarly, a comparable study revealed that hospital websites in Kuwait focus primarily on promoting services provided by the hospital rather than on engaging and communicating with patients [23]; moreover, hospital websites in Italy function more as sources of information on admissions and services than as a means of communication between users and the hospital [24]. As for the product dimension, Chinese hospital websites are less thoughtful in caring about people with special needs, such as patients with disabilities or language communication barriers or people who require referral services or living guides.

For the propagation dimension, the function of disseminating public health information on websites is underused by large hospitals in China. At present, the COVID-19 pandemic is still active around the world; with the resumption of school and work, the Chinese government is implementing normalized epidemic prevention and control measures for a long-term fight against the disease. Hospitals in mainland China responded to the outbreak of COVID-19 positively by using information technology–enabled services [25]. Nonetheless, the number of hospital websites with COVID-19 prevention information and policies in the United States is approximately 10 times that of such websites in China. Additionally, the relatively low percentages we found for the items of vision, mission, and independent web pages for hospital culture expressions and patient-centered value on Chinese hospital websites indicate that there is significant potential for Chinese hospitals to promote their culture development.

Conversely, compared to the United States, our study shows that more Chinese hospital websites contain the following information services: appointment by a third-party platform, mobile payment, physicians' profiles, hospital value, and environment display.

Two factors can be mainly attributed to the differences in appointments by third-party platforms and mobile payments between the two countries. First, the payment method for medical expenses in a country is closely related to the country's medical insurance system. In the United States, large hospitals are often tied to (large) employers, such as Kaiser Permanente. Patients do not have the choice to "shop" for hospitals and may not wish to do so. This is also true of payment. Employees are often insured "for free" in the United States, as their employer provides them with insurance. People who are unemployed and have a low income are not insured, and they may have no money and no possibility to make mobile payments. In China, more

than 95% of people are covered by basic health insurance [26]. Chinese people are usually free to make choices when seeking care and making payments.

Second, with the continuous development of mobile information technology, some basic functions performed by hospital websites in the past have been gradually transferred to mobile terminals, and the proportion of mobile medical services used in the process of patient medical treatment is increasing in China [27]. Chinese people, especially the younger generation, are more accustomed to using phones to make mobile payments—usually the consultation fee, which is a relatively small amount—to immediately confirm their appointments on the web. Mobile payment in China has become a life habit for Chinese people; this is not only reflected in the payment of medical expenses but also in all aspects of life because of its convenience and popularity. Chinese hospitals, under the influence of the "Internet Plus Healthcare" strategy, which is the application of internet technology in the medical industry and has been promoted by the Chinese government since its initiation in 2015, are also willing to cooperate with some large-scale application platforms, such as WeChat and Alipay, to implement these functions conveniently.

Therefore, Chinese users can easily obtain what they need without visiting hospital websites. In contrast, the relatively high rate of appointments on official websites and web account payments by American hospital websites has firmly locked American users into using them, and these websites have become the main source for Americans to obtain health information and services. With regard to the hospital values and environment display, as well as physicians' profiles, we found in this study that incorporating hospital values, pictures of the hospital environment, and physicians' profiles into the hospital's introduction and home pages has almost become a fixed practice in most hospitals in China, which may partly explain the higher percentages of these services on Chinese hospital websites.

Strengths and Weaknesses of This Study

By referring to the 7Ps marketing mix, we examined the websites' information services in terms of the aspects of product, price, place, propagation, people, process, and physical evidence. To the best of our knowledge, no previous study has built evaluation items and thoroughly examined the information services of hospital websites based on the 7Ps marketing mix. In addition, this is the largest cross-sectional survey to date, assessing and comparing 150 hospital websites in China and 150 hospital websites in the United States.

This study may have several limitations that are important to note. On the one hand, we aimed to study the information services provided by hospital websites, which are different from traditional services; therefore, the classical 7Ps marketing mix may not be fully applicable to this study. However, we have adapted it to the websites' information service features to perform a rational evaluation. On the other hand, we simply assigned 1 point to each item to build the scoring system for evaluating the information services of Chinese and American hospital websites; this approach may be unreasonable, as it does not take into account the weight of each item. Finally, there were 119 private (79.3%) and 31 public (20.7%) hospitals among the sample of 150 American hospitals. All 150 Chinese hospitals in the sample were public. We did not take the matter of public and private hospitals into account; moreover, the differences in social, political, legal, cultural, and other environmental factors between China and the United States were not considered, which could have affected the results.

Potential Implications for Hospital Leaders

For hospital leaders, the findings of our study may have some potential implications based on the analysis of the product, price, place, propagation, people, process, and physical evidence dimensions of the 7Ps marketing mix.

Product Dimensions

It is necessary for hospital leaders to establish a user-friendly hospital website based on users' actual needs. A study by Hakim and Deswindi [28] showed that the functional aspects of hospital websites are the most significant dimension because customers want to obtain in-depth information about a hospital's organization, facilities, and list of services. Overall, it is necessary to reduce or categorize the information that has little relevance for website users; unfortunately, this problem is commonly found on the home pages of Chinese hospital websites. For example, Chinese hospital websites usually provide medical service information in the form of listings of departments; in contrast, most American hospital websites provide more detailed information about medical services, such as diseases, symptoms, departments, surgical operations, and other related services. This information is more helpful to web users who know little about their diseases or are not familiar with the related medical knowledge. For information services, it is important to strengthen the function of guidance rather than focusing on display only.

Price and Place Dimensions

With the development of mobile information technology, some important information services, such as payment and appointment methods, have been gradually transferred from websites to mobile terminals (eg, hospital apps and WeChat) in China. Therefore, customers no longer find it necessary to access a website to obtain required health information services. Mobile information technology has brought great convenience to people's lives, and its use has become an inevitable trend. Compared to hospital websites in China, it was found that in the United States, a better balance is reached between the use of mobile devices and official websites. How to take advantage of mobile technology while also building a website that is valuable to visit has become an important issue that is worthy of consideration by Chinese hospital leaders.

Propagation Dimension

Culture development in an organization is a complicated and long-term process; however, one important measure is to clearly establish the mission of the organization, and this is especially urgent for Chinese hospital leaders given our findings. Furthermore, Chinese hospitals should make full use of the propagation function of their website platforms, whether to provide information on how to fight the pandemic or to disseminate public health knowledge. Another notable fact is that American hospital websites often use patient stories to build

a positive image of their hospitals. This can readily enhance a customer's feelings of trust toward a hospital. However, Chinese hospitals usually propagate information about the hospitals from the perspectives of medical staff skills or medical specialty strengths. As a result, because of information asymmetry between providers and patients, it is inevitable that certain obstacles in understanding will be created for ordinary users and will keep them at a distance.

People Dimension

The largest difference between Chinese and American hospitals lies in the people dimension, in which Chinese hospitals require much improvement to reach the level of US hospitals. According to our findings, Chinese hospitals should enhance their interactions on their websites with users and attach sufficient importance to social participation from individuals and other organizations. In detail, Chinese hospitals need to work more on feedback regarding hospital services and website visit experiences, develop volunteer services and social donation channels on their websites, show more respect to patients by emphasizing patient privacy protection statements, and attempt to learn more about patient and family advisory councils to determine if these organizations could work at Chinese hospitals.

Process Dimension

In the context of this research, the process dimension refers to the information or functions that are provided by a website to help users obtain the required information services. We investigated the situation of interface classification by users, site searches, and frequently asked questions pages of hospital websites between China and the United States, and we found that all of them were less covered on Chinese hospital websites. Therefore, more attention should be paid to the process dimension, as it directly reflects user-oriented ideas and is beneficial for improving website browsing experiences.

Physical Evidence Dimension

Vivid pictures or videos can be used to make websites more appealing to potential customers, so that they will spend more time on the websites. Although a few more Chinese hospitals displayed pictures or videos of the hospital environment according to our research, it was found that hospital websites in the United States as a whole are more aesthetic in terms of their visual design, which is worthy of learning by Chinese hospital administrators.

Unanswered Questions and Future Research

In this paper, we studied the availability of information services on Chinese and American hospital websites; however, we did not investigate which factors could affect the performance of such websites. It would be interesting to know if there are certain correlations among some additional factors, such as the economic development level and population size of different regions in China and the United States, development level of informatization, and competition of medical services. This is worthy of analysis and discussion in further studies.

Conclusions

Overall, hospital websites in China lagged behind their counterparts in the United States in providing user-oriented services and information. Most Chinese hospital websites focused primarily on basic services and information rather than involving the participation of and communication with the public. Additionally, culture development and the dissemination of public health knowledge need to be strengthened on Chinese hospital websites. Notably, we found that the transfer of basic services and information to mobile terminals has reduced the number of visits to hospital websites and may create obstacles to their further development. Hospital administrators can use the recommendations with respect to the product, price, place, propagation, people, process, and physical evidence dimensions to improve their hospitals' websites. On the basis of the comparison of the large hospital websites in China and the United States, it is critical to develop standard website construction guidelines for hospitals worldwide.

Abstract

Background: The predominant implementation paradigm of electronic health record (EHR) systems in low- and middle-income countries (LMICs) relies on standalone system installations at facilities. This implementation approach exacerbates the digital divide, with facilities in areas with inadequate electrical and network infrastructure often left behind. Mobile health (mHealth) technologies have been implemented to extend the reach of digital health, but these systems largely add to the problem of siloed patient data, with few seamlessly interoperating with the EHR systems that are now scaled nationally in many LMICs. Robust mHealth applications that effectively extend EHR systems are needed to improve access, improve quality of care, and ameliorate the digital divide.

Objective: We report on the development and scaled implementation of *mUzima*, an mHealth extension of the most broadly deployed EHR system in LMICs (OpenMRS).

Methods: The "Guidelines for reporting of health interventions using mobile phones: mobile (mHealth) evidence reporting assessment (mERA)" checklist was employed to report on the *mUzima* application. The World Health Organization (WHO) Principles for Digital Development framework was used as a secondary reference framework. Details of *mUzima*'s architecture, core features, functionalities, and its implementation status are provided to highlight elements that can be adapted in other systems.

Results: *mUzima* is an open-source, highly configurable Android application with robust features including offline management, deduplication, relationship management, security, cohort management, and error resolution, among many others. *mUzima* allows providers with lower-end Android smartphones (version 4.4 and above) who work remotely to access historical patient data, collect new data, view media, leverage decision support, conduct store-and-forward teleconsultation, and geolocate clients. The application is supported by an active community of developers and users, with feature priorities vetted by the community. *mUzima* has been implemented nationally in Kenya, is widely used in Rwanda, and is gaining scale in Uganda and Mozambique. It is disease-agnostic, with current use cases in HIV, cancer, chronic disease, and COVID-19 management, among other conditions. *mUzima* meets all WHO's Principles of Digital Development, and its scaled implementation success has led to its recognition as a digital global public good and its listing in the WHO Digital Health Atlas.

Conclusions: Greater emphasis should be placed on mHealth applications that robustly extend reach of EHR systems within resource-limited settings, as opposed to siloed mHealth applications. This is particularly important given that health information exchange infrastructure is yet to mature in many LMICs. The *mUzima* application demonstrates how this can be done at scale, as evidenced by its adoption across multiple countries and for numerous care domains.

KEYWORDS

mobile health; electronic medical records; developing countries; digital divide; digital health; global health

Introduction

Background

Low- and middle-income countries (LMICs) have, over the last decade, seen an exponential increase in the adoption of digital health solutions. Among the systems being actively implemented in these settings are electronic health record (EHR) systems. These are deployed to largely replace or supplement existing paper-based records, with the aims of improving quality of patient care and supporting the monitoring and evaluation of programs [1-3]. Several LMICs have gone beyond initial pilot EHR system implementations to large-scale rollout of these systems in government-run public facilities. Countries like Kenya, Uganda, Nigeria, and Mozambique now run nationally endorsed EHR systems that are deployed in hundreds to thousands of public health facilities across each country [4-7].

In most LMICs, national-level EHR system initiatives have largely been driven by the need to support HIV care and treatment, with significant funding coming from donor organizations such as the U.S. President's Emergency Plan for AIDS Relief. EHR systems targeting HIV care largely focus on the HIV care continuum, which emphasizes (1) finding patients who are HIV-positive (through active screening approaches), (2) linking HIV-positive patients to care, (3) ensuring that patients are on appropriate treatment, and (4) actively following patients to retain them in care [8-10]. The continuum of care paradigm is widely applicable for numerous other chronic diseases and is employed within other EHR systems to support longitudinal care in LMICs.

Approaches and Gaps in HIV EHR System Implementations Within LMICs

There are several core functionalities needed within EHR systems to support longitudinal care, key among them being the abilities to register patients, review historical patient information, and collect new data on patients. Features such as computerized decision support, order entry capabilities, and electronic prescribing are often incorporated at varying levels [11]. In many settings, retrospective entry of data is still employed, though efforts are underway to increase use of EHR systems at the point of care [12]. Point-of-care EHR systems still face the challenges of inadequate infrastructure, unreliable system uptime, cost, busy care settings, and provider discomfort with real-time entry of data while caring for patients.

The most widely employed modality of EHR system implementation in LMICs involves standalone EHR system implementations at individual facilities [13]. This implementation model entails installation of a local server, local area network, and end user terminals. The model relies on a dependable electrical supply and readily available information technology personnel [14]. Unfortunately, these infrastructure and personnel requirements are prohibitive in many LMIC settings, particularly in remote areas—exacerbating the "digital divide." Facilities in areas with limited power, internet connectivity, and technical support are thus less likely to implement EHR systems [15]. Further, population health programs and community-based care services occurring outside of care facilities, such home-based HIV screening, testing, and patient tracing, are often poorly supported when access to EHR systems is limited to facilities.

To address some of the challenges and gaps with tethered EHRS that can only be accessed from within facilities, mobile health (mHealth) solutions are increasingly being adopted in LMICs [16,17]. Ideally, these mHealth systems should exchange data with the predominant EHR system, but a majority do not [18]. Instead, most mHealth systems often collect and transmit data to their own independent repositories that are separate from facility-based EHR systems—adding to the problem of siloed information for patients spread across multiple systems [19]. In the absence of interoperability with facility-based EHR systems, mHealth solutions cannot receive and display comprehensive historical patient and treatment information that are stored in the separate EHR systems, adversely affecting quality of care. Even when mHealth systems are able to share data with facility-based EHR systems, there is often lack of robust deduplication approaches for patient data, causing further challenges. Other common challenges observed with attempts to synergize mHealth solutions with facility-based EHR systems include (1) a lack of robust mechanisms to generate subsets of patients from EHR systems to be availed on mobile devices that have limited data storage capacities; (2) inefficient data synchronization, with mHealth applications requiring a complete wiping of existing data prior to new updates, resulting in increased expenses from use of paid internet data known as data bundles; (3) suboptimal mechanisms for updating or adding new forms, with some mHealth solutions requiring a new version of the application to be installed every time new forms are deployed; and (4) inability to handle forgotten log-in credentials that are aligned with EHR system credentials when providers are off-site.

With renewed emphasis on reaching the "last digital mile" while ensuring health information exchange with existing EHR systems, mHealth solutions are needed that can seamlessly interoperate with existing EHR systems in LMICs. This exchange is needed even in settings where health information exchange infrastructure is yet to mature [20]. In this paper, we present one such mobile application, *mUzima* [21], a UNICEF-recognized digital global public good [22], as a demonstration of a successful extension of existing national-level EHR systems in several LMICs, with the aim of increasing access and reach of digital technologies for providers and patients. We report on *mUzima*'s features and functionality, guided by the mHealth Evidence Reporting and Assessment (mERA) guidelines [23] and referencing the World Health Organization (WHO) Principles for Digital Development framework [24] where relevant. We also provide real-world examples of how the *mUzima* application has been scaled to support care across several countries and disease domains.

Methods

The "Guidelines for reporting of health interventions using mobile phones: mobile (mHealth) evidence reporting assessment (mERA)" checklist was developed by the WHO mHealth Technical Evidence Review group to improve comprehensiveness and standardization of reporting of mHealth interventions [23]. The guidelines ensure that the reporting covers the (1) content of the mHealth intervention, (2) context within which the mHealth intervention is implemented, and (3) technical features of the intervention. These 3 components are encapsulated in the *mERA* checklist of 16 elements, namely (1) infrastructure (population level), (2) technology platform, (3) interoperability/health information system (HIS) context, (4) intervention delivery, (5) intervention content, (6) usability/content testing, (7) user feedback, (8) access of individual participants, (9) cost assessment, (10) adoption inputs/program entry, (11) limitations for delivery at scale, (12) contextual adaptability, (13) replicability, (14) data security, (15) compliance with national guidelines or regulatory statutes, and (16) fidelity of the intervention.

This paper describes in detail each element of the mERA checklist as relevant to the *mUzima* application. Special emphasis is placed on the technology platform (item #2) to highlight choices made and features of the application that can serve as a technical reference for readers. As the *mUzima* application is developed for a global context, additional considerations need to be given to its applicability in LMICs. To this end, we also integrate components of the Principles of Digital Development by the WHO, using this framework to further elucidate the various items in the mERA checklist [24]. The Principles are "designed to help integrate best practices into technology-enabled programs...and are derived from lessons learned through the use of information and communication technologies (ICTs) in development projects" [24]. The 9 principles include (1) design with the user; (2) understand the existing ecosystem; (3) design for scale; (4) build for sustainability; (5) be data driven; (6) use open standards, open data, open source, and open innovation; (7) reuse and improve; (8) address privacy and security; and (9) be collaborative. Reference to these principles extends the relevance of the reported work to the larger LMIC and global context.

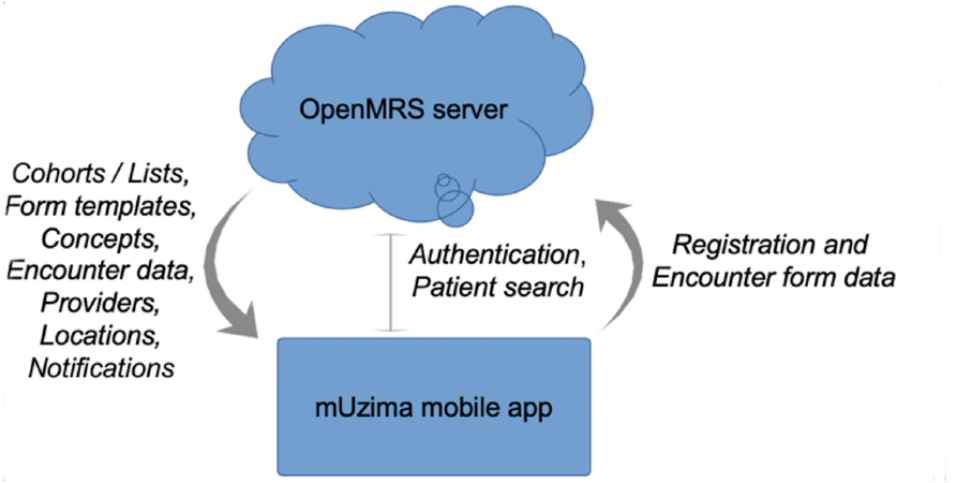
Results

'*Uzima*' is a Swahili word that means "life"—hence *mUzima's* slogan "Mobile for Life" [21]. It is a provider-facing mHealth application for use by health care workers for direct patient care. *mUzima* has particular relevance to providers working outside of care facilities and those with unreliable connection to the EHR system. In the following sections, we provide details of the *mUzima* application in line with 16 mERA checklist items.

Item 1: Infrastructure

mUzima is a robust and adaptable Android-based mHealth platform that can seamlessly interoperate with the OpenMRS EHR system (Figure 1) [25,26]. The OpenMRS EHR system was chosen for the mHealth extension, as it is the most widely endorsed EHR system for national use by Ministries of Health (MoHs) across numerous LMICs. OpenMRS is currently in use in over 40 countries, with national deployments for HIV and tuberculosis care in Kenya, Mozambique, Nigeria, and Uganda, among others [27]. The hardware requirements for *mUzima* include an Android smartphone device and an OpenMRS EHR system instance. In Africa, over 85% of smartphones use the Android operating system [28]. *mUzima* was developed to work with Android versions 4.4 and above, as low-end Android smartphones predominate in LMICs. *mUzima* has robust offline functionality to address limited internet connectivity in many LMICs, allowing for health providers using *mUzima* to care for patients even when disconnected from the EHR system server. These infrastructure considerations align with the Digital Development Principles of "Understanding the Existing Ecosystem" by recognizing that power and internet connectivity challenges exist in the LMIC settings where *mUzima* is intended for use and that low-end Android smartphones predominate in these settings.

Figure 1. Interaction between *mUzima* and the OpenMRS electronic health record (EHR) system.

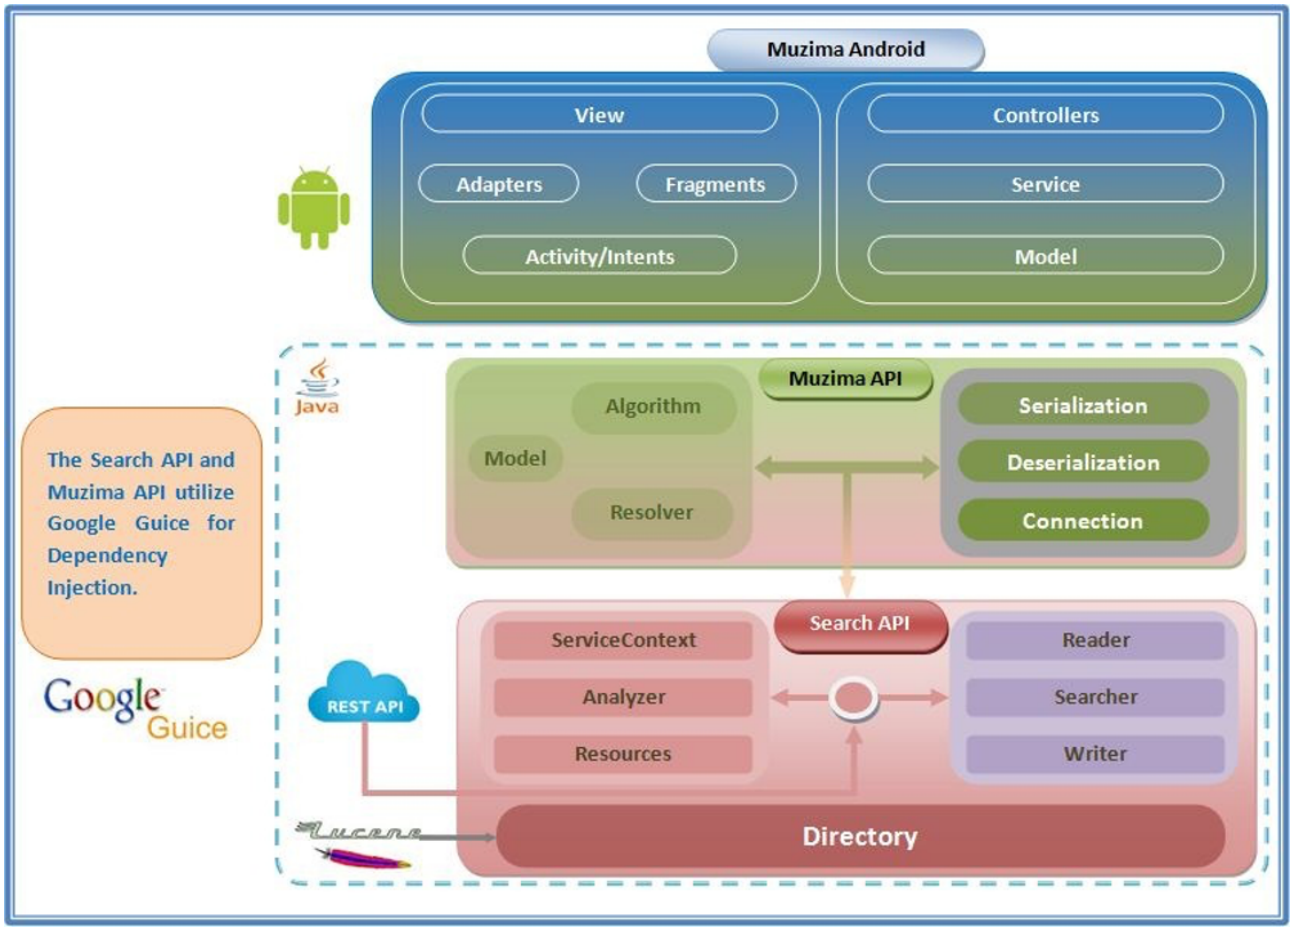


Item 2: Technology Platform

Overview

mUzima was developed as an open-source application under the Mozilla Public License 2.0 license [29]. The application has a modular architecture that lends it a strength of simplicity while ensuring full functionalities of the installed modules. *mUzima* uses a stacked framework consisting largely of 3 layers (Figure 2), namely the (1) Search Application Programming Interface (API), (2) *mUzima* API, and (3) *mUzima* Android.

Figure 2. Architecture of the *mUzima* mobile health (mHealth) application. API: application programming interface; REST: representational state transfer.



The Search API provides encrypted data storage based on a robust and flexible data model. This API utilizes Lucene, a Java-based, open-source, searching engine library, for indexing and searching [30]. Within the Search API are the service layer and a dependency injection layer using Guice [31] and the Indexer document repository [32]. Connection between *mUzima* and the EHR system server occurs using a representational state transfer (REST) API [33].

The *mUzima* API includes the business logic layer of the platform, exposing the underlying Lucene repository to a robust front-end application (*mUzima* Android) while hiding the complexity of the underlying repository to the developer. This layer can be easily used to expose the *mUzima* data model to any system integrating with *mUzima*.

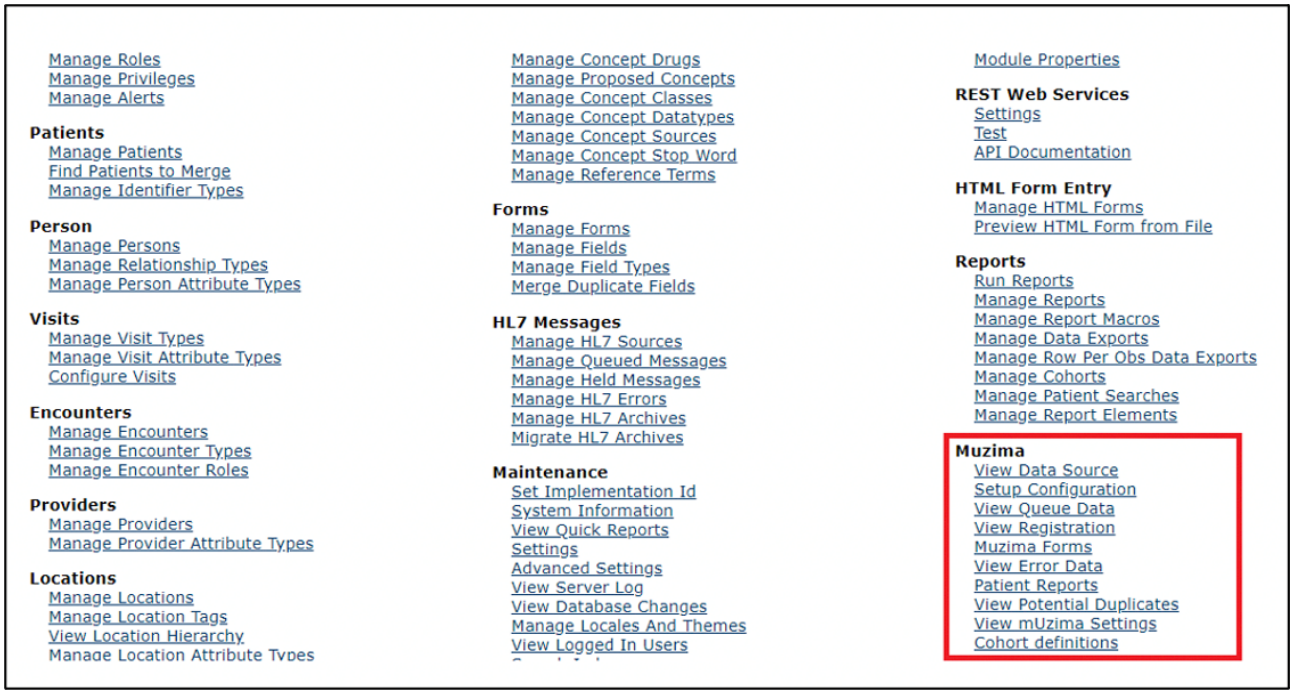
mUzima Android is the Android application package (APK) with which users interact, oblivious of the other 2 underlying stack layers. *mUzima* Android supports user interface activities and uses the underlying *mUzima* API to store and retrieve data resources from the phone's local repository and to upload and download data from the remote EHR system server. The APK is structured into the following main components: (1) models comprised of objects that encapsulate data and logic for resources specific to Android. Some of the objects extend *mUzima* API models and add logic specific to usage in the Android application and (2) controllers for each type of resource. The controllers act as coordinators within the Android app and between the Android app and *mUzima* API. Controllers are commonly used to request various actions related to objects, such as sending to storage, retrieval from storage, searching, counting, uploading, and downloading; (3) services, which are components used to handle requests for repetitive and potentially long-running operations; and (4) views, which are the implementation of the *mUzima* user interface.

mUzima Server-Side Module

mUzima has a server-side module created within the OpenMRS EHR system that has REST endpoints enabling linkage of OpenMRS instances to the *mUzima* mobile application (Figure 3 and Multimedia Appendix 1). Key features of the *mUzima* server-side module include (1) the set-up configuration and (2) error resolution mechanisms. The server-side setup configuration features are used to define care programs. To this end, the setup configuration has provisions for defining patient lists or cohorts,

forms, historical data, providers, and locations to be included in each care program (Multimedia Appendix 1). The server side also offers the ability to define multiple settings that will be applied onto all *mUzima* instances on mobile devices, removing the labor-intensive need of having to configure individual settings within each mobile device. The error resolution mechanism on the server side allows nondevelopers to manage forms submitted to the server that are identified as having errors (Multimedia Appendix 2). Errors are typically encountered when information on clients registered offline are synchronized onto the server and are found to be duplicates once patient-matching is run on the server. The ability to resolve errors on submitted data without the need for programming expertise or access to the server's backend makes *mUzima* highly usable and scalable in remote facilities, which often lack personnel to offer advanced technical support. The error resolution module also handles queuing and processing of data submitted into OpenMRS from *mUzima*.

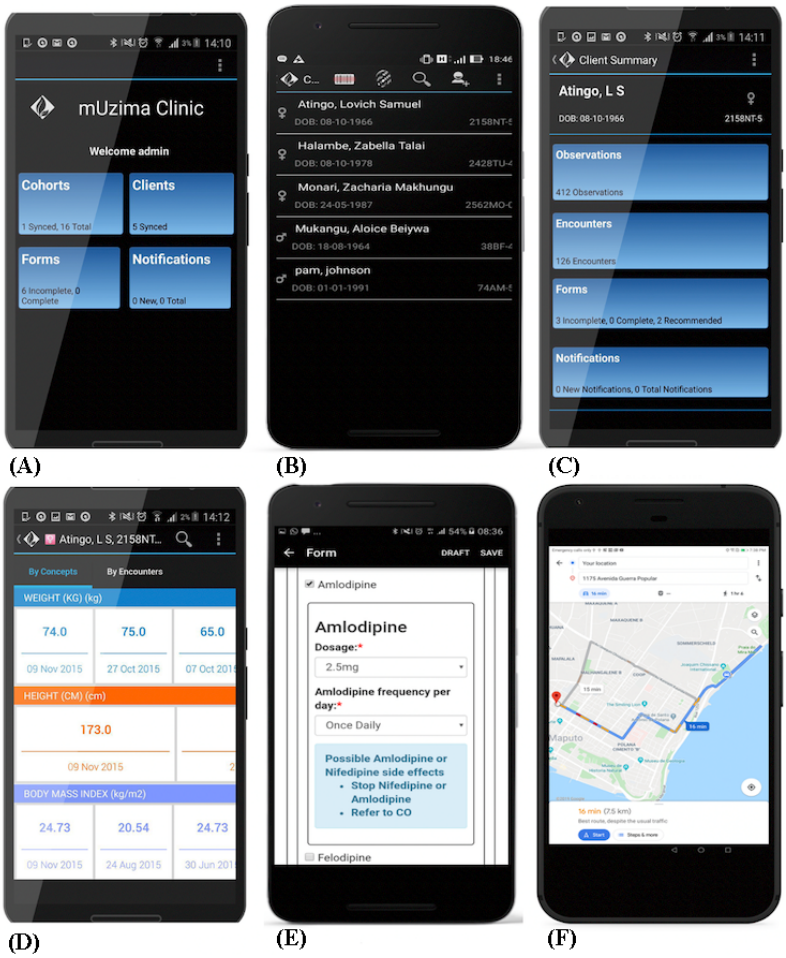
Figure 3. Components of the *mUzima* server-side module.



mUzima Mobile Application

Access to the *mUzima* mobile application requires a username and password, which are initially authenticated against the EHR system. This access times out automatically if the user is idle for a predefined period of time. Once logged in, users have access to the *mUzima* mHealth application landing page, which can be defaulted to display key menu options of cohorts, forms, clients, and notifications (Figure 4A). Alternatively, the landing page can be configured to display lists of clients available on the device (Figure 4B). *mUzima* users are able to find clients by scrolling through the client list, by searching via names and IDs, or by using the barcode scanning feature. Partial matching of names is available against both the local Lucene-based database that provides fast search capabilities [28] and the linked OpenMRS instance via its RESTful API. Further details of specific *mUzima* features are outlined in the Item 4 and Item 5 sections that follow.

Figure 4. *mUzima* features: (A) menu options, (B) client list, (C) options under client, (D) historical data, (E) form entry with decision support, (F) geolocation.



Item 3: Interoperability and Health Information System (HIS) Context

mUzima serves as an HIS for collecting primary health data, which are then exchanged with the associated EHR system. Health information exchange between *mUzima* and OpenMRS is achieved through use of the same concept dictionary terms, locations, providers, and patient identifiers that are common between the 2 systems. The REST API is used to connect *mUzima* to OpenMRS for bidirectional data exchange (Figure 1) [33]. This multifaceted approach for direct system-to-system exchange has been adopted to overcome the lagging implementation of robust health information exchange mediators and mechanisms in many LMICs. To facilitate future integration and health information exchange with other systems, several fast health care interoperability resources (FHIR) such as patient, provider, and observation FHIR are being developed for *mUzima* [34].

Item 4: Intervention Delivery

The WHO, in its "Recommendations on digital interventions for health system strengthening," strongly advocates that "recommended interventions should be accessible via mobile devices at a minimum" [35]. *mUzima* is primarily for use by health providers through smartphones that are often owned by the care program. Access to *mUzima* is on-demand when the provider logs in with the relevant credentials. The providers use *mUzima* to access cohorts and historical data on patients under their care, as well as to capture new data on patients. Significant time and effort were expended to ensure that *mUzima* can auto-update changes in cohort membership, forms, and historical data elements (ie, managing delta), without the need to re-download data that had previously been downloaded onto the mobile device. This allows for seamless update of content to the mobile device through *mUzima's* synchronization mechanism with OpenMRS.

Item 5: Intervention Content

Over half of the recommended digital interventions by the WHO pertain to mobile-based EHR solutions and include "digital tracking of clients' health status combined with decision support; targeted client communication; digital provision of educational and training content to health workers; provider-to-provider telemedicine; and client-to-provider telemedicine" [35]. *mUzima* satisfies all of the WHO mobile-based EHR system recommendations. Core features currently available within the *mUzima* application are described in the following sections.

Cohort Management

Given limitations on storage size within mobile devices, approaches are needed that limit the amount of data downloaded onto devices. This means downloading only the relevant subset of patients and their corresponding data to the mobile device. *mUzima* features the ability to define cohorts of patients using

SQL. Cohorts can be as simple as a list of individuals with a particular disease (eg, diabetes) or can be more complicated, such as "diabetic patients with kidney disease plus poorly controlled blood sugar and who are noncompliant with their medications." *mUzima* has functionality that allows for membership within a cohort to remain "static" (ie, never change after the initial run) or to be dynamic (allowing for automatic addition or removal of members over time, based on whether they still meet the cohort criteria).

Programs

A program within *mUzima* is used to consolidate all features in the mHealth application that are needed to take care of a group of patients. Programs can be disease-specific or based on cohorts. *mUzima* provides the ability to configure all details for programs using the set-up configuration feature on the server side (see the *mUzima* Server-Side Module section). Programs contain (1) lists of clients from one or more cohorts, (2) details of relevant historical data elements to be downloaded onto the device for these clients, (3) program-specific forms to be completed for clients, (4) an optional list of locations and providers that serve the program, and (5) settings that can be predefined for end users. Program functionality enables *mUzima* to be highly configurable and disease-agnostic, allowing the application to serve multiple clinical scenarios and domains. Further, programs integrate workflow features, such as sequential filling of forms, to support care processes. The ability to easily configure elements for programs ensures needed optimization of mobile device setup and also reduces the cost and time of data transmission and downloads.

Historical Data

Through its connection with an EHR system, *mUzima* has the ability to download a subset of historical data on patients that are predefined as part of a program. Beyond program-defined historical data to be downloaded, users of the *mUzima* application have the option to include additional historical data or remove any or all of the predefined historical data, based on their individual preferences. The historical data downloaded through *mUzima* can come from any source that saves data to the EHR system, including laboratory and pharmacy systems, ensuring that providers using *mUzima* have the complete clinical picture of a patient's data. This contrasts with numerous mHealth applications that only display historical data originally collected through that application and not from any other sources or those that are used as simple data collection tools, with no ability to display any historical information. Within *mUzima*, the historical data can be viewed by data type, date, or clinical encounter type (Figure 4D).

Data Capture Mechanisms

mUzima allows flexibility in data collection, with forms created to capture elements based on the same concept dictionary terms and other patient attributes (eg, demographics) shared with the EHR system. HTML5 is used to describe each form, enabling form development with little programming experience. *mUzima* forms can accommodate all data types, such as text, numeric, float, Boolean, and dates, and can support numerous media types. The application can also capture individual data elements (eg, individual test results), without relying on a form. As needed, *mUzima* forms can incorporate data validation, branching logic, rule-based decision support, and multimedia items (Figure 4E). Data captured within forms can be saved as complete or as draft for future completion. A configurable autosave feature also exists to ensure that data collected in forms are not inadvertently lost.

Forms are automatically downloaded into the mobile application based on their inclusion within a program, but mobile device users can easily add or remove individual forms as per the user's preferences. With *mUzima*, there is no need to install a new version of the application every time new forms or form updates are available. Further, the *mUzima* form update mechanism is optimized to ensure that no data collected in older forms within the mobile application are lost during the form update process.

Registration and Patient Matching

Registration forms within *mUzima* rely on the form features. Prior to registering any new client, the application runs a probabilistic patient-matching algorithm to ensure that duplicate patients are not created. When no patient matches are found on the mobile device, *mUzima* runs a match against the server if there is connectivity. In settings where the device is offline and new individuals still need to be registered offline, the *mUzima* server-side module provides functionality to first match the new registration against existing EHR records once the registration information is uploaded to the server. If duplicates are found, functionality exists to merge the patient's records.

Geolocation Services

Patient tracing is a core component of community-based care, especially in areas without reliable address systems. Geolocation functionality within *mUzima* can help in finding patients within communities (Figure 4G). *mUzima* provides the ability to add and edit the GPS locations for individuals and employs navigation functionality to help locate patients. Functionality also exists to automatically capture the location where a clinical form is completed, should the program decide to enable this feature.

Relationship Support

The relationships feature captures the nature of relationships of various individuals with the reference client. Relationships are particularly relevant for contact tracing in the age of COVID-19 and for HIV index case testing services. In both cases, individuals related to or who have contact with the index case need to be traced for testing and follow-up. *mUzima* supports capturing information on the nature of the relationship between 2 individuals and collection of data on the related individual (Multimedia Appendix 3).

Table 1 summarizes key features within the *mUzima* application, highlighting often-overlooked elements in developing configurable and scalable mHealth applications for use in LMICs [36].

Table 1. *mUzima* features.

Feature	Description
EHR[a] system compatibility	*mUzima* was designed to be the mHealth[b] extension to a largely deployed EHR system (OpenMRS) to prevent siloed data collected within *mUzima*. OpenMRS is deployed nationally in several countries.
Security	Security features in *mUzima* include password-based log-in, data encryption, secure data transmission, timed user logouts, and a password-changing mechanism within limited connectivity settings.
Multiple use cases	*mUzima* is easily customizable to support any clinical use case, both within and outside of clinical facilities.
Data collection tools	*mUzima* uses easy-to-develop, web-based forms to collect data (including by providers off-site) that are securely transmitted and stored in an EHR system, as opposed to a siloed server
Offline capabilities	*mUzima* functions smoothly in both online and offline modes. This allows for data collection and review, even when the mobile device is offline.
Error resolution	*mUzima* prevents duplicate form data entry on mobile devices and resolves errors in the EHR system during data processing.
Form management	*mUzima* enables easy download and update of new forms onto the app without the need to re-install or restart the app. Form default text sizes are configurable, with the ability to magnify forms during use.
Cohort management	*mUzima* allows for the management of different patient or client groups on a mobile device.
Multiple languages	*mUzima* provides localization support for use in various languages. The full application is also currently available in 6 languages: English, Portuguese, French, Swahili, Gujarati, and Hindi.
Multiple themes	*mUzima* is shipped on 2 themes as of v2.5.0, including a dark theme (white on black) and light theme (black on white)
Relationships	In the health care space, a relationship is used to pair or associate 2 people whose care may be interlinked. *mUzima* supports recording of relationships (Multimedia Appendix 3).
Geomapping	*mUzima* can easily capture and record patient GPS coordinates and provides navigation services to support tracing of clients (Multimedia Appendix 4).
Clinical summary or abstracts	*mUzima* utilizes the OpenMRS Reporting Module to design and generate HTML reports that are then rendered on the app, providing comprehensive abstracts for each patient (Multimedia Appendix 4).

[a]EHR: electronic health record.

[b]mHealth: mobile health.

Items 6: Usability and Content Testing

In line with the Digital Development Principles of "Building for Sustainability" and "Be Collaborative," *mUzima* relies on a community of developers and implementers for content and user acceptance testing. As of February 2021, the *mUzima* community had 112 members, with a total of 31 unique contributors to the *mUzima* codebase. This community has made over 3800 contributions or commits to the codebase. Over 250 individuals have used, contributed, or reviewed *mUzima* documentation through *mUzima*'s Wiki platform [37], and more than 190 have contributed in the *mUzima* discussion forums [38]. The community is made up of stakeholders supported through various funded projects and agencies.

User testing for *mUzima* is conducted by a core team, as well as by community members prior to any *mUzima* release. Each feature in an *mUzima* release is documented as a JIRA ticket [39,40]. These tickets are used to track testing findings, with changes made based on feedback received. Final acceptance testing is conducted prior to deploying a new version of the application. Multimedia Appendix 5 provides a screenshot of release testing for a ticket in *mUzima* version 2.7.0, with details of testing status for each ticket in this version shared in a publicly available release plan [40].

Item 7: User Feedback

A user-centered design approach is employed in developing core *mUzima* functionality and features and in adapting the application for various use cases. An engaged Implementer Community provides suggestions for features, as well as feedback on developed application components and content. This feedback is primarily gathered via weekly community calls and through the *mUzima* forum [38]. Additional user inputs are gathered through reviews of the application using the feedback mechanism in Google Play Store, where *mUzima* has thousands of downloads and a 5-star rating [41].

Item 8: Access by Individual Participants

mUzima increases access to clinical data for providers who work outside of care facilities and in settings disconnected from the EHR system server. It is a provider-facing application and not available for direct use by patients. The application can leverage both WiFi-based or phone-based data bundles for data transmission. As an Android application, *mUzima* is not available to health providers who do not have Android smartphones and has limited utility to providers who are illiterate or unfamiliar with using smartphones. To use *mUzima*, providers need to have credentials to access an OpenMRS EHR instance, and this will limit utility of *mUzima* for those without such access or those using other EHR systems.

Item 9: Cost Assessment

A formal cost assessment has yet to be done on *mUzima*. Although *mUzima* is available free of charge to users, there are still several associated costs to implement it. Key costs include customization costs that involve creating relevant forms for a program; development of queries that define cohorts of patients; smartphone purchase; costs associated with hosting an OpenMRS instance (if one does not exist); connectivity costs to the server through WiFi or Internet; and costs of personnel to support users, maintain infrastructure, and conduct training. Comparatively, in instances where care is conducted outside of facilities, *mUzima* implementation should be cheaper than using laptops equipped with OpenMRS—given the higher cost associated with laptops and managing multiple OpenMRS instances. Although paper-based systems have historically been used to support care in LMICs, they have recurrent costs given that pieces of paper can only be used once to record data, and there are personnel costs associated with retrospective entry of data collected on paper into the EHR system [42]

Item 10: Adoption Inputs and Program Entry

mUzima is freely available on the Google Play Store [41], with all changes and enhancements in any new version shared broadly via multiple channels, as well as fully documented in the collaborative wiki space [37]. Within the wiki space are documents on setting up the system, as well as training materials. Multiple introductory and educational videos on *mUzima* are also available through the *mUzima* YouTube channel [43]. *mUzima* training often involves technical personnel as well as training of end user providers. Technical team members, comprised of developers and implementing information technology personnel, often need to understand how to customize *mUzima* and to set up the server and smartphone devices for use. The technical team training is largely hands-on, with the *mUzima* community forums and weekly meetings available for answering questions from community members. End users are often trained by the technical team members from their organization. These trainings typically cover core *mUzima* features and also the customized elements relevant to that program. For most end users, training on *mUzima* typically takes 1 to 2 days. Refresher trainings are available especially when there are upgrades to the application.

Item 11: Limitations for Delivery at Scale

The Digital Development Principle "Design for scale" is highly relevant to *mUzima*. Scalability was considered at the outset, allowing for the system to support any type of clinical condition, various workflows, and multiple versions of both OpenMRS and Android. Load testing is a core part of all *mUzima* version releases to ensure that *mUzima* works with larger patient populations and data needs. *mUzima's* ability to scale is evidenced by its successful large-scale adoption across multiple clinical settings and countries (Table 2). As a testament of its scalability and implementation success, *mUzima* has been recognized as a digital global public good since 2019 [22] and is listed as a global project in the WHO "Digital Health Atlas" [44].

Despite having scaled to national levels, further expansion of *mUzima* is limited by the fact that it only currently extends 1 EHR system, OpenMRS. *mUzima's* FHIR resources are under development to allow seamless health information exchange with other FHIR-compliant systems [34]. Customization of *mUzima* requires knowledge of form programming using HTML and basic knowledge on creating cohorts and queries within OpenMRS—both of which can limit scaling of *mUzima* implementations. Further, as a native Android application, *mUzima* will not work with smartphones that run on different operating systems.

Table 2. Large-scale *mUzima* implementations.

Type of implementation	Description
HIV care	*mUzima* is nationally endorsed and implemented by the Kenya Ministry of Health (MoH) to support HIV testing and screening (HTS) [45]. In Kenya, the application is in use at over 220 public facilities, with more than 1000 providers using it on any given workday. To date, over 500,000 HTS visits have been conducted in Kenya using *mUzima*. In addition, *mUzima* is in use in Zambezia province in Mozambique for defaulter and lost-to-follow-up tracing and for preventative visits (Multimedia Appendix 6). The application has also been adapted for national rollout in support of HIV patient tracing activities in Uganda.
Cancer care	Partners in Health Rwanda, working closely with the Rwanda MoH and the Clinton Health Access Initiative, are using *mUzima* for cervical and breast cancer screening and referral. Currently implemented in 3 districts, the *mUzima* application has already been used to support data collection during screening of more than 4000 patients for breast and cervical cancer at 39 facilities. The goal is to extend *mUzima* application use to 15 districts in Rwanda.
Chronic disease management (CDM)	*mUzima* is in use at more than 70 facilities in Kenya as part of a task-shifting program to support CDM, including hypertension and diabetes care. Unlike other implementations that use *mUzima* in communities, these CDM implementations use *mUzima* at dispensaries and within other facilities across 6 counties (Uasin Gishu, Bungoma, Trans-Nzoia, Nandi, Kisumu, and Busia). To date, over 350 providers have used *mUzima* to record CDM encounters in more than 100,000 visits. The CDM program incorporates robust decision support features based on alerts and reminders, as well as educational media with a personalized display based on patient-specific data (Figure 4E).
COVID-19	At the request of Kenya's MoH, *mUzima* was adapted to support COVID-19 care, including screening, contact tracing, testing, and symptom monitoring. The COVID-19 forms used are based on guidelines provided by the World Health Organization (WHO) and use standard terms based on the Columbia International eHealth Laboratory (CIEL) dictionary [46]. The *mUzima* COVID-19 application leverages relationship and geomapping features for contact tracing and is available for adaptation beyond Kenya (Multimedia Appendix 7). *mUzima* is also in use by the MoH in Rwanda for COVID-19 management.

Item 12: Contextual Adaptability

mUzima has been used across various health domains (Table 2), with most use in primary contexts that have limited internet connectivity, especially in Sub-Saharan Africa. *mUzima* provides localization support for use in various languages and is currently available in 6 languages, namely English, Portuguese, French, Swahili, Gujarati, and Hindi. The application comes with multiple configurable settings that are not hard coded into the application. Examples of configurable settings include whether to capture GPS location of activity, default font size, auto-synchronization feature, time setting for automatic time-outs, form auto-save time interval, among other features. Forms, cohorts, and clinical observations within the application can be customized without any need for reprogramming.

Item 13: Replicability

Content related to *mUzima* is organized in the application's website that highlights key application features and provides a demonstration instance for those interested in exploring the application [21]. This website provides links to all other *mUzima*-related resources and documentation. Detailed documentation on *mUzima* is available on the wiki page and includes user guides, technical documentation, and implementation guides, among others [37]. Multimedia content such as demonstration videos is also available on the *mUzima* YouTube channel [43]. *mUzima* code is shared via GitHub [47], and as of February 2021, there had been 650 pull requests and over 120 forks to the *mUzima* code.

Item 14: Data Security

mUzima is developed to enable the primary clinical implementing partners to remain full custodians of all data collected and transmitted to OpenMRS through *mUzima*. As such, identifiable patient information is only accessible to those given access through the EHR system. In line with the Principle for Digital Development to "Address privacy and security," the *mUzima* application has incorporated several security features. Access to the *mUzima* is done through a username and password validated initially with the EHR system. Users who forget their password have to be re-authenticated within the EHR system by an administrator. *mUzima* contains a feature for automatic time-outs where users are logged out after a program-defined period of inactivity. Bidirectional exchange of data between *mUzima* and the EHR system is secured through use of an https protocol. All *mUzima*-related data are stored in an encrypted format in the mobile device.

Item 15: Compliance With National Guidelines or Regulatory Statutes

Implementations using *mUzima* have full control of locations of servers where patient data from *mUzima* are stored. It is advocated that these implementations comply with data residency guidelines and laws for the country of operation. Organizations that opt to use *mUzima* are advised to contact relevant statutory bodies within countries that oversee mHealth applications. *mUzima* allows users to configure forms, patient identifiers, and concept dictionary terms to be used in each implementation. Compliance with national guidelines for these items is thus at the discretion of the implementers but is highly advocated. Forms and data elements can be easily developed to align with approved forms in countries and using any national dictionary should one be available. As an example, implementations in Kenya leverage the standards-based Columbia International eHealth Laboratory (CIEL) concept dictionary [46].

Item 16: Fidelity of the Intervention

Performance of the *mUzima* application is gathered using the Firebase Crashlystics plugin [48]. These performance metrics indicate that it takes <5 seconds for the application to launch and <1 second to upload each completed form payload to the OpenMRS EHR system from within *mUzima*. Over the most recent 3-month period (December 2020 to February 2021), the percentage of *mUzima* users without crashes in any of their usage sessions was 92.88%. *mUzima* also uses Firebase Crashlystics to monitor locations where *mUzima* has been used over a period of time, as well as high-level details of the users, broken down by user-provided gender and age (Multimedia Appendix 8). For individualized and detailed usage statistics, *mUzima* has also been programmed to collect paradata through logs of key components of the application while it is in use. Although performance and workflow analytics can be conducted on the logged paradata, there is a need to create a user-friendly and personalized dashboard highlighting a user's work performance on *mUzima* that can be availed to support decision making around work patterns.

Discussion

Although EHR and mHealth solutions have been widely embraced in LMICs, there is often lack of seamless data exchange between widely deployed EHR systems and these mHealth solutions. To our knowledge, this is one of the only descriptions of a robust extension of a widely used EHR system in LMICs. Most other widely deployed mHealth applications primarily save data to their own servers and have challenges integrating with existing EHR systems. It will be several years before all LMICs have effective interoperability and health information exchange infrastructure [49,50]. In the meantime, a paradigm that advocates for comprehensive mobile extensions to existing EHR systems will help to reduce the widening digital divide that adversely impacts resource-limited settings.

For mHealth applications to be effective and scalable within resource-limited settings, they have to build on lessons learned in implementation and development over the years [16,19,35]. Integration of mHealth applications with EHR systems uncovers new challenges that deserve attention. In particular, challenges emerge around best approaches to manage user credentials across 2 systems and in disconnected settings, appropriate delivery of subsets of EHR system data to mobile devices that have limited storage, management of ever-changing cohort sizes and patient-level data while ensuring data transmission costs are contained, and development of tethered mHealth solutions that can adapt to multiple use cases without the need to reprogram the application.

The *mUzima* team is currently broadening its support for implementations within various countries to ensure responsiveness to needs. As countries mature with regard to health information exchange, the *mUzima* team has started implementing FHIR, starting with patient, person, encounter, and observation FHIR [34]. The application user interface is undergoing redesign and revamping with input from users. The aim is primarily to enhance the user experience and to ensure that key features are more easily accessible to users through the interface. The *mUzima* team is in the process of adding secure messaging and communication features and incorporating a more robust teleconsultation feature, beyond the store-and-forward teleconsultation functionality already incorporated in the application. Finally, the application's modularization feature is being revamped to enable easier incorporation of additional plug-ins to *mUzima*. The *mUzima* data analytics team is also working on reusable paradata analytics and visualization to provide needed information on provider work performance and engagement with the application [51].

Evaluation is important for any health information system. Usability and feasibility of *mUzima* have previously been assessed in an implementation to support nurses in managing hypertensive patients [52]. Ongoing *mUzima* evaluations include (1) evaluation of patient-specific, phone-generated reminders through *mUzima* for hypertension care in Kenya; (2) evaluating use of *mUzima*-facilitated monitoring of health worker performance in Western Kenya using logged paradata; and (3) evaluation of the *mUzima* mobile application for patient tracing and preventive visits in Mozambique. Priorities for future evaluations should include comprehensive assessment of costs and benefits of using the *mUzima* application.

In conclusion, greater emphasis needs to be placed on mHealth applications that extend reach of EHR systems within resource-limited settings to reduce the digital divide that has emerged with use of standalone EHR systems or mHealth applications. *mUzima* demonstrates how this can be done at scale, with evident adoption across countries and for various types of care programs.

Acknowledgments

This work was made possible by the support of the American people through the United States Agency for International Development (USAID; grant number 7200AA18CA00019), Norwegian Agencies for Development Cooperation under the Norwegian Programme for Capacity Development in Higher Education and Research for Development (NORHED) program (Norad: Project QZA-0484), and Medtronics Foundation. The contents are solely the responsibility of the authors and do not necessarily represent the official views of USAID, NORHED, the United States Government, or Medtronics Foundation. The authors thank the *mUzima* developer and implementer community members and numerous other contributors to this project.

Authors' Contributions

MCW conceptualized the study, acquired funding, was the project administrator, supervised the study, wrote the original draft of the manuscript, and edited the manuscript. SS, BM, SM, and NR were the core *mUzima* development and implementation team and contributed the writing, review, and editing of the manuscript. PC provided critical input on the manuscript and contributed to its writing and revision. AY conducted *mUzima* project management, performed quality assurance, and contributed to the manuscript writing, review, and editing.

Conflicts of Interest

This paper describes an application that has the development team primarily as the leaders in its writing.

Abstract

Background: The short form, 17-item version of the Pediatric Symptom Checklist-Youth Self-Report (PSC-17-Y) is a validated measure that assesses psychosocial problems overall (OVR) and in 3 major psychopathological domains (internalizing, externalizing, and attention-deficit/hyperactivity disorder), taking 5-10 min to complete. Prior research has established sound psychometric properties of the PSC-17-Y for English speakers.

Objective: This study extends psychometric evidence for the acceptability of the PSC-17-Y in a large sample of Spanish adolescents, providing proof of its reliability and structure, convergent and discriminant validity, and longitudinal and gender invariance.

Methods: Data were collected on 5430 adolescents, aged 12-18 years, who filled out the PSC-17-Y twice during 2018-2019 (7-month interval). We calculated the Cronbach alpha and the McDonald omega coefficients to test reliability, the Pearson correlation for convergent (distress) and criterion validity (well-being, quality of life, and socioemotional skills), confirmatory factor analysis (CFA) for structure validity, and multigroup and longitudinal measurement invariance analysis for longitudinal and gender stability.

Results: Within structural analysis for the PSC-17-Y, CFA supported a correlated 3-factor solution, which was also invariant longitudinally and across gender. All 3 subscales showed evidence of reliability, with coefficients near or above .70. Moreover, scores of PSC-17-Y subscales were positively related with convergent measures and negatively related with criterion measures. Normative data for the PSC-17-Y are presented in the form of percentiles (75th and 90th).

Conclusions: This work provides the first evidence of the reliability and validity of the Spanish version of the PSC-17-Y administered over the internet to assess mental health problems among adolescents, maintaining the same domains as the long version.

Introduction

According to Polanczyk et al [1], the most common mental health disorders among children and adolescents include anxiety or depression, behavioral disorders, and attention-deficit/hyperactivity disorder (ADHD). Emotional and behavioral symptoms at the subclinical level raise the risk of subsequent development of mental disorders [2]. Moreover, the COVID-19 pandemic has provoked a considerable increase in mental health problems among children and adolescents [3-5].

National and international policies and strategies globally recommend that young people attending primary care should be routinely screened for psychosocial problems [6]. Despite this, such screening occurs in less than 50% of primary care visits of adolescents, meaning that more than half of adolescent mental health problems go undetected [7,8]. Although several screening tools exist for psychosocial problems in young people, most cover a single domain [9] and can be time consuming to administer and interpret [10]. Primary care clinicians can often be unsure of which screening tools are appropriate for their clinical context. In addition, many tools rely on the provider having the skills, knowledge, expertise, and experience to initiate screening, interpret results, and provide appropriate interventions [8]. Providers often describe a lack of resources in terms of the availability of time, appropriate tools, training, and experience in youth health [11].

A recent review of "Self-Report Rating Scales to Guide Measurement-Based Care in Child and Adolescent Psychiatry" [12] highlights that the Pediatric Symptom Checklist (PSC) is 1 of the most widely used measures to screen psychosocial problems in primary care units and school settings. This statement is supported for all parent and youth reports and for long and short forms (parent- and youth-reported long form [PSC-35]; parent- and youth-reported short form [PSC-17]) [13-23].

The short form, 17-item version of the PSC-Y (PSC-17-Y) [16] is used to assess self-reported general psychosocial functioning among youth above 11 years old, taking only 5-10 min to be completed, and is statistically equivalent to the short form of the parent version (PSC-17) [16] and to the longer youth report form (PSC-35-Y [19-21]).

Three studies of the parent report PSC-17 (Gardner et al [16,17] and Murphy et al [18]) have confirmed the existence of the 3 original subscales for internalizing (INT) symptoms, externalizing (EXT) symptoms, and ADHD symptoms (ATT) and provided evidence of the reliability of the overall (OVR) scale. Two studies with the youth-reported short form have been published. On the one hand, Bergman et al [22] found that the PSC-17-Y is equivalent to the parent-reported form of the PSC-17, indicating that a 3-factor short form with 17 items meets the criteria for scalar invariance across gender. On the other hand, Parker et al [23] examined the screening validity of the PSC-17-Y in a child welfare population. Youth with any lifetime mental health diagnosis scored significantly higher on the PSC ATT and INT subscales. The ATT, INT, and OVR subscale scores were significantly correlated with psychosis, depression, and anxiety disorder scores. ADHD was associated with ATT, OVR, and EXT scores. Only bipolar disorder was weakly associated with PSC subscale scores (EXT and OVR). This study provides support for the convergent and discriminant validity of the PSC-17-Y.

Despite PSC-17-Y's potential, however, there is limited evidence of some of its relevant psychometric properties (eg, longitudinal measurement invariance and other reliability coefficients different from the Cronbach alpha [α]), and to the best of our knowledge from the scientific literature review, none of these psychometric analyses are in languages other than English (ie, none on Spanish populations).

Thus, this work aimed to extend the psychometric evidence for the acceptability of the PSC-17-Y in a large sample of Spanish adolescents, providing different sources of reliability and validity. This research could facilitate the use of the PSC -17-Y in more contexts and for more possible applications in youth mental health settings. Overall, we expected that the PSC-17-Y would show that it is a valid and reliable ultrabrief screening measure that can be administered over the internet to detect mental health problems in Spanish adolescents.

Methods

Sample

The final sample consisted of 5430 adolescents (2769 [51%] females) at time 0 and 2117 (1109 [52.4%] females) at time 1 (approximately 7 months later). The participants were enrolled in Spanish secondary education grades, equivalent to US middle and high school, from grades 7 (12-13 years) to 12 (17-18 years). The average age of the sample at time 0 was 14.17 years (SD 1.50) and of the sample that participated at time 0 and time 1 was 13.99 years (SD 1.39).

Measures

PSC-17-Y

The PSC-17-Y [16] consists of 17 items and 3 factors to assess 3 types of problems: INT symptoms (ie, depression and anxiety), EXT symptoms (ie, disruptive behavior), and ATT, as well as an OVR score. The Spanish version of the PSC-17-Y was developed in accordance with the guidelines of the International Test Commission [24], using an iterative translation method that began with several independent translations. The item translations were then reviewed by a joint committee comprising translators with knowledge of the Spanish language and culture and specialists in the field of assessment who analyzed the adequacy of the adapted version. To be sure that adolescents properly understood all items, interviews asking about the comprehension of the items were conducted. In addition, in 2018, we had conversations with colleagues who had worked

on the translation of the PSC for parents in Chile [25,26] in order to obtain an adequate cross-cultural adaptation into the European Spanish language of the PSC-17-Y.

Social-Emotional Distress Survey-Secondary

The Social-Emotional Distress Survey-Secondary (SEDS-S) [27] is a 10-item behavioral screening questionnaire designed to measure INT distress. The reliability of the 1-factor total scale was α=.91. In their study, Dowdy et al [27] found a significant positive association of the SEDS-S distress factor with symptoms of anxiety and depression and a significant negative association with life satisfaction and strength scores.

Mental Health Continuum-Short Form

The Mental Health Continuum-Short Form (MHC-SF) [28] is the reduced version of the MHC Long Form. This measure provides self-reported well-being, divided into 3 subfactors: psychological (6 items), emotional (3 items) and social well-being (5 items). In this study, we used the Spanish version of the MHC-SF recently adapted by our team. The MHC-SF has received psychometric support for use with adolescents across many different countries, including Spain [29,30], showing excellent internal consistency (Cronbach α>.80) and discriminant validity in adolescents.

KIDSCREEN-10 Index

The KIDSCREEN-10 Index [30] is a unidimensional scale that measures health-related quality of life (HRQoL) in healthy and chronically ill children and adolescents. It was developed to specifically identify children at risk in terms of subjective health and suggest appropriate early interventions. The instrument provides an overall HRQoL index covering the physical, psychological, and social facets of the HRQoL. Internal consistency values (Cronbach α) reach .82, and test-retest reliability within 2 weeks reaches .55 [31].

Social-Emotional Health Survey-Secondary

The Social-Emotional Health Survey-Secondary (SEHS-S) [32] was developed to measure the components of the covitality latent construct among youth. We used the Spanish version of the SEHS-S, which is appropriate for adolescents aged 12-18 years [33]. The SEHS-S includes 36 items for the assessment of core psychosocial assets based on a higher-order model comprising 12 first-order, grouped into 4 second-order, latent traits (3 each) and a higher-order general factor (covitality). The first domain, called belief-in-self, measures self-efficacy, self-awareness, and persistence. The domain belief-in-others comprises school support, peer support, and family support. The domain emotional competence considers emotion regulation, empathy, and behavioral self-control. Engaged living, which is the final domain, comprises 3 subscales: gratitude, zest, and optimism.

Procedure

This research used a non-experimental, transversal/longitudinal, quantitative, and descriptive-correlational design [34,35]. The UMH Project Evaluation Committee approved the study (reference no. DPS.JPR.02.17). Once the project was approved, quota sampling was carried out in 2 areas of southeastern Spain: the province of Alicante (PA) belonging to the Valencian Community, and the Autonomous Community of the Region of Murcia (RM), making a random selection of secondary schools based on ownership (public/nonpublic schools) and regional geographical areas (9 areas in PA and 21 in RM). After 100 schools were contacted, 13 from PA and 21 from RM agreed to participate, resulting in a total of 34 secondary schools (22 [65.2%] public and 12 [34.8%] nonpublic schools; 30 [87%] secular and 4 [13%] catholic schools).

Once the schools agreed to participate, signed informed consent was requested in writing from the parents/legal guardians of the adolescent participants and from the adolescents themselves, accepting participation in the research. The data collection was carried out in the schools and supervised by the research staff in person. The self-reporting assessment protocol was individually applied through the online survey tool LimeSurvey (LimeSurvey GmbH, Hamburg, Germany). Participation was voluntary, and the adolescents did not receive any incentive for their collaboration, while each school received a feedback report, including results by class group.

Data Analysis

All analyses were conducted using IBM SPSS Statistics version 25 and Mplus 8.4 (Muthén & Muthén). Confirmatory factor analysis (CFA) was conducted to test the structural validity. Figure 1 represents the correlated 3-factor solution tested. We used a diagonally weighted least squares means and variance adjusted (WLSMV) model estimator due to a number of alternative responses and the nonnormality distribution [36]. We tested the model's goodness of fit using the comparative fit index (CFI), the Tucker-Lewis index (TLI), and the root-mean-square error of approximation (RMSEA). A CFI of >0.90 and a TLI of >0.95 indicate an acceptable and an optimal fit, respectively [37], and RMSEA values of ≤0.10 indicate an acceptable fit [38].

Later, we tested whether the PSC-17-Y exhibits an invariant structure across gender and across time through longitudinal and multigroup measurement invariance analysis. In particular, 3 levels of invariance were tested: (1) *configural* (test whether all items load on the proposed factor), (2) *metric* (test whether item-factor loadings are similar across groups), and (3) *scalar* (test whether unstandardized item thresholds are similar across groups). In addition, within longitudinal measurement, invariance residuals covariances between the same item over time (eg, time 0 with time 1) were included. Thus, to indicate a significant decrement in fit when testing for measurement invariance, we used model comparison criteria of ΔCFI/ΔTFI ≥ 0.01 (ie, a decrease indicating the worst fit) [39] and ΔRMSEA ≥ 0.015 (ie, an increase indicating the worst fit) [40].

When there is scalar measurement invariance, the comparison of factor means across groups is permissible [41]. Consequently, we calculated gender differences. We also estimated the Cohen d index (standardized mean difference), which allows evaluating the effect size (ES) of the obtained differences [42].

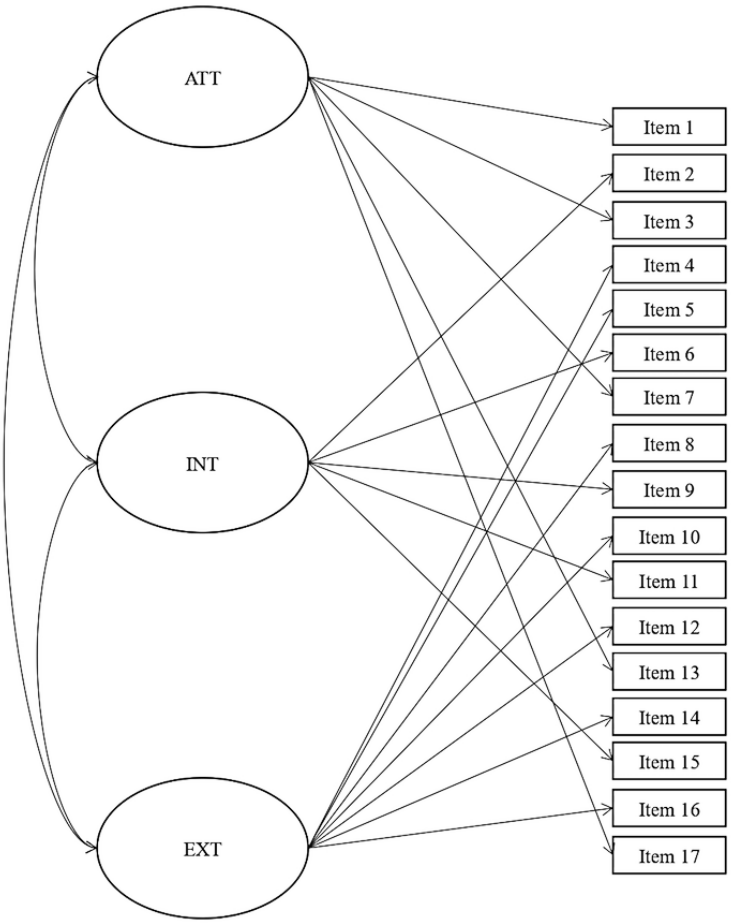
The Cronbach α and the McDonald omega (ω) [43] were used to estimate the internal consistency of the PSC-17-Y since the McDonald ω is a better estimator of reliability than the Cronbach α [44].

Convergent and criterion validity was evaluated by calculating the correlation coefficients between the scores on the PSC-17-Y and different, well-established measures. Specifically, we tested the convergent validity with measures of distress (SEDS-S) and criterion validity with measures of well-being, QoL, and socioemotional skills (MHC-SF, KIDSCREEN-10 Index, SEHS-S). The Cohen criteria were used to estimate the ES of the correlations [42,45].

Finally, normative data for the PSC-17-Y were presented in the form of percentiles (75th and 90th). We also calculated the cut-off point of 15 for OVR, 5 for INT symptoms, 7 for EXT symptoms, and 7 for ATT, as proposed by Gardner et al [16,17], because these scores have not received evidence-based support in Spanish adolescents.

As the sample size determination for psychometric validation studies lacks clear recommendations [46], we determined the required sample size by allocating several observations 5-10 times greater than the variables [47]. Accordingly, the sample size needed ranged between 85 and 170 participants based on the number of items in the PSC-17-Y. Furthermore, according to the subject-to-item ratio method, a sample size of ≥1000 to perform exploratory factor analysis (EFA) or CFA would be excellent [46].

Figure 1. Visual representation of the 17-item, 3-factor solution of the PSC-17-Y. ATT: attention-deficit/hyperactivity disorder symptoms; EXT: externalizing; INT: internalizing; PSC-17-Y: Pediatric Symptom Checklist-Youth Self-Report.



Results

Confirmatory Factor Analysis and Measurement Invariance

Findings of CFA and measurement invariance over time and across gender groups are summarized in Table 1. Since item 13 (“Me cuesta mucho cansarme”/“Acts as if driven by a motor”) had a low loading at the ATT subscale (0.127), we also tested the 16-item model, which slightly improved the fit. An optimal fit index was observed for both the 17- and 16-item models, with loadings from 0.348 (item 5) to 0.858 (item 6) and from 0.346 (item 5) to 0.859 (item 6), respectively. Longitudinal and multigroup measurement invariance was found for the 17- and 16-item models, which means that the structure, loadings, and intercepts of the PSC-17-Y were invariant over time and across gender groups. Although the 16-item version was slightly stronger than the 17-item version, we concluded that the minimal improvement in accuracy was less important than being able to use the 17-item model, which is the internationally recognized version and facilitates comparisons with other studies. For this reason, subsequent analyses were performed with a 17-item version.

Table 1. Goodness of fit for baseline models and measurement invariance of the 3-factor solution.

[b]CFI: comparative fit index.

[c]TLI: Tucker-Lewis index.

[d]RMSEA: root-mean-square error of approximation.

[e]Not applicable.

The correlation matrix of the items can be seen in Table 2.

As can be seen in Tables 3 and 4, the reliability coefficients for all measures ranged from .64 to .76 (McDonald ω). Regarding gender differences among total scores, females showed significantly higher scores on general social-emotional distress (d=0.34) and INT (d=0.42) scales than males, with a small-to-medium ES. Concerning the differences in the EXT scale, males showed more symptoms of EXT problems than females, with a small ES (d=0.12). Although the scores for well-being and socioemotional competencies were lower in females than in males, the ESs were low (d ranged from 0.08 to 0.15). Finally, males showed higher HRQoL levels than females, with an ES of 0.35.

According to Table 5, the intercorrelation between the PSC-17-Y subscales was moderate, indicating that this measure is composed of 3 differentiated and mutually associated factors. Regarding the relationship between PSC-17-Y subscales and the remaining measures, the highest positive correlations were between the INT subscale and the measure of distress (large ES), while the association of the ATT and EXT subscales with distress was medium. Similarly, the correlation was higher (and negative) between the INT subscale and the HRQoL (large ES) than between different types of well-being and socioemotional competencies (moderate to large). However, the correlation between ATT and measures of well-being, socioemotional competencies, and the HRQoL was significant and negative, with a small-to-medium magnitude. Finally, the EXT subscale presented a small-to-medium association with the different positive measures.

[g]$P<.001$.

Concerning normative information for PSC-17-Y subscales, each subscale is scored by the sum of its items. The adolescent's score on the scale can then be used to obtain the corresponding percentile score. The normative information for each of the 3 PSC-17-Y subscales and total scores for the whole sample are shown in Table 6. We also included percentile scores for PSC-17-Y OVR scores to facilitate international comparisons.

The values obtained in our study using the international cut-off point of 15 for OVR, 7 for ATT, 5 for INT symptoms, and 7 for EXT symptoms, as proposed by Gardner et al [24], were 20.7%, 15.1%, 29.7%, and 5.1%, respectively. The 90th percentile indicated that 11.6% of the sample scored above this cut-off point of 17 for OVR on the PSC-17-Y, 26.3% of the participants exceeded the 75th percentile for the PSC-17-Y total score. Regarding specific symptoms, 15.1%, 10.2%, and 10.6% of the participants scored above the 90th percentile on ATT, INT symptoms, and EXT symptoms, respectively. The data at the 75th percentile or quartile 1 indicated that 29.1%, 28.7%, and 32.0% of the participants exceeded the cut-off points for ATT, INT symptoms, and EXT symptoms, respectively.

Discussion

Principal Findings

This study aimed to delineate the psychometric properties of the PSC-17-Y in Spanish adolescents. As expected, this study found evidence of a 3-factor solution, as in the original English version, and also gave evidence of reliability and validity (structural, convergent, and criterion) to assess several psychopathology symptoms among adolescents. However, item 13 showed a lower loading (0.127) than the remaining items. This finding is consistent with Bergmann et al. [22], who validated the PSC-17-Y in English and reported a relatively low factor loading (0.233) for this item. Following the same logic as these authors, we maintained item 13 in the final set of items for the PSC-17-Y in Spanish, since it is important to keep the measure as simple as possible for respondents and clinicians to complete, score, and interpret and since the parent- and youth-reported short forms were identical except for this 1 item. We found that the inclusion of item 13 had a negligible impact on the psychometric properties of the PSC-17-Y in Spanish. As a result, we elected to add item 13 to the 16-item model and recommend a 17-item short form of the PSC-Y that uses the same 17 items on the same 3 subscales as the parent-reported PSC-17. Furthermore, we hypothesized that the problem with this item could be the wording and that future studies might review it to improve the saturation in the factor. The PSC-17-Y also showed an invariant structure across both genders, again consistent with Bergman et al [22].

Additionally, our study provided the first evidence, as far we know, for longitudinal invariance, indicating that the PSC-17-Y in Spanish adolescents is stable over time. This finding implies that it is reasonable to conclude that growth or development in observed scores over time can be attributed to actual development or changes in the construct under investigation, not measurement problems [48]. Further studies that replicate our study over more extended periods are, of course, needed.

Once gender and longitudinal invariance were tested, this study provided new evidence on gender-attributable differences in the PSC-Y scales. The gender differences found in this study were consistent with the overwhelming prior research establishing that females are more likely to express INT

symptoms and males are more likely to express EXT symptoms [49-51]. Furthermore, the small ES found in these gender differences is also consistent with other ones, which highlighted the small magnitude of gender differences in INT problems among children and adolescents [52]. These findings suggest that gender differences should be considered when pediatric and mental health professionals interpret PSC-17-Y results. Furthermore, gender is a crucial variable in the relationship between INT symptoms and suicide among adolescents, increasing this risk in females [53].

Regarding reliability evidence, our study showed McDonald ω values between .64 and .76, which are slightly lower than those shown by previous studies. Gardner et al [16] reported high internal consistency (.79 for INT symptoms, .83 for EXT symptoms, and .83 for ATT), and in the same order, Bergmann et al [22], with 16 items, found consistency values of .81, .74, and .69, respectively. The lowest internal consistency value was ATT (.65 and .64 for females and males, respectively). The removal of item 13 could improve the internal consistency of the ATT subscale slightly to values of .70 and .71 for females and males, respectively but at the cost of losing the original 17-item structure of the questionnaire.

Concerning other sources of convergent and criterion validity evidence of the PSC-17-Y, all 3 subscales correlated positively with the measure of distress and negatively with well-being, HRQoL, and social-emotional competencies, indicating a higher correlation between PSC-17-Y INT problems and the remaining convergent and criterion validity measures. This finding is consistent with previous studies on the PSC-17-Y, such as Parker et al [23], who reported screening validity of the PSC-17-Y in terms of higher scores on the PSC ATT and INT subscales among youth with any lifetime mental health diagnosis, as well as that ATT and INT subscale scores (but not EXT) are significantly correlated with psychosis, depression, and anxiety disorders. Thus, both our study and Parker et al's [23] provide support for the convergent and discriminant validity of the PSC-17-Y.

Finally, regarding percentile scores, score distributions showed a positive asymmetric distribution, but these normative data can help locate specific and general psychopathological problems among adolescents. Our rates would be suggestive of adolescents presenting scores compatible with mental health symptoms likely being in the clinical range. These data are equivalent to those reported in previous studies using different versions and cut-off scores for the PSC, PSC-17, and PSC-17-Y: 5%-25% of children were screened positive [15,16,54-56]. For example, a study using the 90th percentile score on the PSC found that 10.4% of children had problems on the OVR scale [54]. Additionally, the prevalence rates found in our study are consistent with wide international reviews on estimates of mental health prevalence among adolescents [1].

Limitations

The absence of an equivalent, well-established measure of INT, EXT, and ADHD measures; the absence of data on the area under the curve at optimal cut-off points in this study; and the sample's representativeness because we recruited the sample from the southeast of Spain exclusively were limitations of this study. In addition, there were only 2 waves of assessment in a short period of time (7 months), so it is recommended that future studies replicate the longitudinal invariance findings over longer intervals.

Conclusion

This study showed that the PSC-17-Y is a useful, reliable, and valid ultrabrief screening measure for detecting mental health problems in adolescents and can be administered over the internet. More specifically, this study provided evidence of the reliability and validity (structural and convergent-discriminant) of the Spanish version of the PSC-17-Y for adolescents.

Finally, these findings are significant for the scientific community. Therefore, this work has allowed us to extend the evidence of the validity of the PSC-17-Y to another language and country (Spain) in a large sample of adolescents, where scores were invariant over time irrespective of gender. This is a requirement that few instruments meet or for which evidence has been provided. All of this supports the reliability of the PSC-17-Y's assessments and its use in clinical contexts, such as monitoring the development of symptomatology. The fact that the PSC-17-Y is a tool that is easy to administer is another support for its use in clinical contexts.

Having instruments such as the PSC-17-Y with established reliability meets an especially important need during COVID-19 times, which have been characterized by an increase in mental health problems among children and adolescents [3-5] and a possibly greater need for case identification and outcome measurement.

Lastly, the results also support the use of the PSC-17-Y in longitudinal research, for example, for the study of the temporal trajectories of psychopathology in children, facilitating, among other things, reliability in the evaluation of the effectiveness of treatments. In addition to its usefulness in research, the PSC-17-Y is an instrument with applicability in the clinical setting, specifically in both primary care and specialty mental health units, as a screening tool for mental health problems in children and adolescents that is valid for monitoring changes in functioning over time.

Acknowledgments

We would like to thank collaboration and support by the Dirección General de Atención a la Diversidad y Calidad Educativa de la Consejería de Educación, Juventud y Deportes de la Región de Murcia (General Department for Attention to Diversity and Educational Quality of the Regional Ministry of Education, Youth and Sports of the Region of Murcia, Spain) and the Secretaría Autonómica de Educación e Investigación de la Conselleria de Educación, Investigación, Cultura y Deporte de la Generalitat Valenciana (Regional Secretariat of Education and Research of the Regional Ministry of Education, Research, Culture and Sport

of the Generalitat Valenciana, Spain), as well as to the educational centers, the authorization of parents and legal guardians, and especially the students, in the completion of the psychological assessment protocol, which made this study possible. We would also like to thank Javier Guzman (University of Desarrollo, Chile) for his assistance in adapting the PSC-17-Y into European Spanish.

This research was supported by a grant for I+D+i projects under award number PSI2017-88280-R (AEI/FEDER, UE) and 2 grants for Research Networks (PSI2015-70943-REDT and PSI2017-90650-REDT) from the Ministry of Economy, Industry and Competitiveness of the Spanish Government, as well as 3 predoctoral fellowships cofinanced by the European Social Fund and the Regional Ministry of Education, Research, Culture and Sport from the Generalitat Valenciana (RF: ACIF/2019/052; BM-A: ACIF/2019/055). VV-A is supported by a scholarship from the Universitat Jaume I (PREDOC/18/12); JMH and MM receive salary support from the Fuss Family Fund.

Authors' Contributions

JAP is principal investigator 1 of the funded project. He participated in the design of the psychological assessment protocol, collaborated in the conceptualization of this study by providing theoretical knowledge and professional and research background, and drafted the initial manuscript. VV-A participated in the conceptualization of the study by providing an analytical-methodological perspective, undertook the analysis of the data that made up the results of the study, and carried out a review of the statistical content. RF participated in the conceptualization of the study and in the design of the assessment protocol, coordinated and supervised the data collection, managed the database, reviewed the contents and terminology of the manuscript, and adapted its presentation format to the formatting requirements. BM-A participated in the design of the assessment protocol, coordinated and supervised the data collection, managed the online survey, collaborated in the selection and adaptation of the instruments, assisted in literature review tasks, and carried out a general review of contents. JCM is principal investigator 2 of the funded project. He participated in the design of the psychological assessment protocol, in the review and editing of the theoretical-methodological content, and in the adaptation of the manuscript to the formatting requirements. JH collaborated in the review of English editing and the final version of the manuscript. MM is the cocreator of the Pediatric Symptom Checklist (PSC). He consulted on the adaptation of the PSC into European Spanish and reviewed the final revision of the manuscript. All the authors approved the final manuscript, as submitted, and agree to be accountable for all aspects of the work.

Abstract

Background: Cognitive impairment (CI) is one of the most prevalent symptoms of multiple sclerosis (MS). However, it is difficult to include cognitive assessment as part of MS standard care since the comprehensive neuropsychological examinations are usually time-consuming and extensive.

Objective: To improve access to CI assessment, we evaluated the feasibility and potential assessment sensitivity of a tablet-based cognitive battery in patients with MS.

Methods: In total, 53 participants with MS (24 [45%] with CI and 29 [55%] without CI) and 24 non-MS participants were assessed with a tablet-based cognitive battery (Adaptive Cognitive Evaluation [ACE]) and standard cognitive measures, including the Symbol Digit Modalities Test (SDMT) and the Paced Auditory Serial Addition Test (PASAT). Associations between performance in ACE and the SDMT/PASAT were explored, with group comparisons to evaluate whether ACE modules can capture group-level differences.

Results: Correlations between performance in ACE and the SDMT (R=–0.57, *P*<.001), as well as PASAT (R=–0.39, *P*=.01), were observed. Compared to non-MS and non-CI MS groups, the CI MS group showed a slower reaction time (CI MS vs non-MS: *P*<.001; CI MS vs non-CI MS: *P*=.004) and a higher attention cost (CI MS vs non-MS: *P*=.02; CI MS vs non-CI MS: *P*<.001).

Conclusions: These results provide preliminary evidence that ACE, a tablet-based cognitive assessment battery, provides modules that could potentially serve as a digital cognitive assessment for people with MS.

Introduction

Background

Multiple sclerosis (MS) is a chronic inflammatory and neurodegenerative disorder, and it is the leading cause of major disability in young adults. Cognitive impairment (CI) occurs in 30%-70% of patients with MS [1,2], even in the absence of physical impairment [1,3,4]. CI is one of the most debilitating manifestations of MS and can have a profound influence on a patient's personal independence and quality of life, interfering with social functioning and employment. Since 2014, CI assessment has been one of the measure specifications of the American Academy of Neurology's MS Quality Measurement Set [5]. Ideally, patients with MS should undergo a complete cognitive assessment and routinely repeat the examination to detect cognitive changes overtime and to start timely treatment, if needed. However, to date, cognitive assessment in MS relies on a comprehensive neuropsychological examination, which is time-consuming and extensive; therefore, it makes it difficult to include cognitive assessment/monitoring as part of MS standard care.

Cognitive Assessment with Digital Tools

Integrating digital tools into clinical settings can reduce the time and cost associated with cognitive examination and further allows repeated assessments, which provide more precise monitoring of cognitive performance and longitudinal changes. One more feature of digital tools is the capability of remote and self-administration, which can relieve the burden of travel to the clinic, due to deficits in mobility or cognition for many patients. Moreover, with remote administration features, data collection can be performed in a nonclinical, real-life setting, which allows sampling of cognitive performance more closely reflecting real-world cognitive function [6]. The self-administered feature also reduces common stressors for patients who get nervous during structured testing in clinical settings.

With advanced technology, remote, computerized platforms for cognitive assessment and treatment, using personalizing features, including adaptive staircase algorithms for populations with cognitive deficits [7-14], have been developed. In Alzheimer's disease–related dementias, digital cognitive assessment tools have shown reliability in measuring longitudinal cognitive changes in individuals with no CI, mild CI, and dementia [15,16] and have exhibited cross-sectional sensitivity to cerebrospinal fluid amyloid-ß levels [17]. In schizophrenia, digital assessments have also shown effectiveness in identifying deficits across different cognitive domains [18,19]. Moreover, tablet-based cognitive assessment has been validated to differentiate cognitive control ability between children with and without 16p11.2 deletion, a genetic variation implicated in attention deficit/hyperactivity disorder and autism [8]. Although the development and validation of digital cognitive assessment tools have been growing, the investigations of remote, digital CI assessments in MS have been scarce [20-23]; therefore, there is a need to deepen the exploration of digital cognitive evaluation for improving access to CI assessments in order to thereby navigate problems related to cognitive issues and further reduce the impact of CI on patients' lives.

Aims and Overview of the Study

The goal of this study was to evaluate the feasibility and potential assessment sensitivity of a tablet-based cognitive assessment battery in patients with MS, focusing on the most commonly affected cognitive domains in MS: processing speed, attention, executive function, and memory [1,2]. To accomplish this, a tablet-based cognitive assessment battery (Adaptive Cognitive Evaluation [ACE]; see the Methods section) that measures different aspects of high-order cognitive function (eg, attention, working memory, speed of information processing, and executive function) [24], was tested in 53 participants with MS and 24 participants without MS. ACE was developed by Neuroscape at the University of California, San Francisco (UCSF) [24]. It has a user-friendly interface as well as adaptive algorithms, which modulate the challenge level of a task on a trial-by-trial basis based on individual performance. In this study, 3 modules (Boxed, Sustained Attention ACE Task [SAAT], Spatial Span) assessing different aspects of cognitive control ability and 1 module (Basic Reaction Time [BRT]) measuring the basic response speed were included (see the Methods section) for a preliminary examination of the construct validity of the ACE battery. The Symbol Digit Modalities Test (SDMT), a test considered the most sensitive measurement for the evaluation of cognitive involvement and information processing speed in the early MS course [25,26], was also administered. Given that information processing speed has been shown to account for impairments in high-level cognitive functions in MS [27-30], the relationship between performance in the SDMT and ACE modules was investigated. To further delineate whether ACE modules can differentiate different levels of cognitive function, performance differences among participants with MS with and without CI, as well as participants without MS, were examined.

We hypothesized that there would be a correlation between the SDMT score and ACE performance in accordance with the relative consequence theory of information processing speed [30-32], in which impaired processing speed is considered the key deficit underlying CI in MS [27-30]. In addition, as a tool for cognitive assessment in MS, ACE would reveal group-level differences between participants with MS with and without CI, as well as participants without MS.

Methods

Participants

In total, 53 adults with clinically definite MS [33], mean age 51.8 (1.7) years, were recruited from the University of California, San Francisco Multiple Sclerosis and Neuroinflammation Center between April 2018 and January 2019 with the following inclusion criteria: internet connection available at home or in the work environment and free of relapses or steroid use in the past month. Patients with severe visual, cognitive, or motor impairment that would preclude the use of a tablet-based tool were excluded. A group of 24 adults without MS (non-MS), mean age 46.0 (3.7) years, with no chronic autoimmune diseases were also recruited from the UCSF

staff, willing family members of patients in the clinic, and other eligible and willing volunteers.

Standard Approval, Registration, and Patient Consent

All procedures performed in the study involving human participants were approved by the Committee for Human Research at the UCSF. Written informed consent was obtained from each participant. The trial is registered with clinicaltrials.gov (NCT03569618).

Study Design

To evaluate ACE, both ACE and the SDMT were administered to all participants, including 53 adults with MS and 24 adults without MS (non-MS). All participants with MS were recruited as part of studies to determine the feasibility [20] and preliminary efficacy [34] of a digital cognitive treatment, as previously described [34]. As part of a published study in which another tablet-based assessment (ie, EVO Monitor) was investigated [35], this study contains data that have not been analyzed or published in a larger trial (clinicaltrials.gov NCT03569618). The analysis of this study was based on baseline performance data (ie, before any cognitive intervention) of our feasibility [20] and efficacy [34] trials, where participants underwent cognitive testing, including ACE and the SDMT. The 2-hour baseline session began with standard measures (SDMT, the Paced Auditory Serial Addition Test [PASAT], the California Verbal Learning Test Second Edition, and the Brief Visuospatial Memory Test Revised), followed by digital cognitive assessment with ACE (BRT, Boxed, SAAT, Spatial Span) and EVO Monitor (data presented in [35]). Standard measures were administered by a study coordinator. Digital tool assessment was self-guided; however, a study coordinator sat in with the participants to answer questions and clarify aspects of the directions, if needed. The baseline session did not include any predetermined break, while participants were informed at the beginning of the visit that they could take a break at any time, if needed. Task order was predetermined (as described above) and remained consistent through the whole study. Only the SDMT and PASAT were included in the analysis of this study, given that they are the most widely used standard measures for people with MS and the cognitive domains being evaluated by these tests are close to cognitive aspects that ACE is designed to test for (ie, attention, working memory, speed of information processing, and executive function).

Cognitive Measures

Standard Measures: SDMT and PASAT

SDMT is a widely used measure of selective attention and information processing speed in MS [25,26], which requires the participant to substitute geometric symbols for numbers while scanning a response key. The participants were presented with a page headed by a key that pairs 9 symbols with the single digits 1-9. Rows below showed only symbols, and the task was to write the correct number in the spaces below based on the key row. After finishing the first 10 items with guidance, correct responses being made within 90 seconds were counted as the SDMT score.

Since PASAT has also been used extensively to test information processing speed, attention, and working memory in MS [36], we included it as a standard measure for participants with MS recruited in this study. The participants were instructed to listen to numbers presented every 3 seconds and add the number they hear to the number they heard before (rather than giving a running total). The PASAT score was defined as the total number of correct answers out of 60 possible answers.

Digital Cognitive Assessment Battery: ACE

Tasks within ACE (Figure 1) followed a similar schematic: across modules, the probe or target (as specified in the individual module description below) was displayed either until a response was made or until the maximum reaction time (RT) limit was reached. After each trial, the trial-level feedback, either a green (correct response was made within the RT limit), yellow (correct response was made outside of the RT limit), or red (incorrect response) centralized fixation cross was displayed for 200 ms, followed by a standard 1000 ms intertrial interval.

The *BRT* task was designed to index the basic response speed of participants on a simple task with minimal loading on executive function skills [37]. Participants were instructed to press a button at the bottom of the screen as fast as they could when they detected a symbol (target) that appeared in the center of the screen. The target always appeared without distraction. The BRTs were measured for both index fingers. Participants first completed 5 practice trials for each of their right and left index fingers, followed by 20 experimental trials per index finger. This task started with a maximum RT limit of 500 ms and a response window of 500 ms that adapted for each participant according to trialwise performance. An average RT was measured for each hand. Only data from the dominant hand were included as each participant's BRT in the following analyses.

The *Boxed* task was designed to measure visual search performance across different types and number of distractors [38]. Participants were presented with an array of either 4 or 12 Landolt squares (ie, squares with gaps) with an opening on 1 side until participants located the target (a green box with a gap on the top or bottom) and indicated the location of the gap (top or bottom) by tapping with their dominant hand on a button with either "top" or "bottom." Two distinct search modes were included: a feature search, where red Landolt squares were present in addition to the single green target, allowing the target to be located based solely on object color, and a conjunction search, where distractor boxes were green and red, with all green distractor boxes having gaps on either side and red distractor boxes having gaps on the top and bottom, similar to the green target box. As such, participants had to search the array for the target square based on a conjunction of features: both color and position of the opening. In addition to the 2 search types (feature and conjunction), there were 2 distractor load conditions: a low load with 1 target and 3 distractors and a high load with 1 target and 11 distractors. Participants completed 8 practice trials of each condition (32 total) before moving on to the experimental task with 25 trials per condition (100 total). This task started with a maximum RT limit of 1500 ms and a response window of 1000 ms that adapted for each participant according to

trialwise performance. Only correct responses made within the participants' adaptive response window were included in analysis. Task performance was assessed by examining the mean RT to correct responses for all trial types, including 4- and 12-item trials collapsed across both feature and conjunction search modes. The RT cost between target identification for feature and conjunction trials across each set size was measured as distraction cost = 12-item (conjunction and feature) – 4-item (conjunction and feature).

Figure 1. Screenshot of ACE. ACE: adaptive cognitive evaluation.

SAAT was developed based on the Tests of Variables of Attention (TOVA) [39] and was designed to include blocks that separately measure sustained attention (to an infrequent target) and inhibitory control (inhibiting a prepotent response to salient distractors). During a trial, a symbol (target) appeared at the top or bottom of the screen. Participants were instructed to press a button with the index finger of only their dominant hand when the target appeared at the top of the screen and to ignore the symbol and withhold a response when it appeared at the bottom. This task proceeded in 2 blocks. In the inhibitory control block, targets appeared on 27 of 40 (67%) of trials and required participants to withhold a (highly primed) response when a distractor appeared. In the sustained attention block, the target appeared on only 13 of 40 (33%) of trials, requiring participants to maintain attention to avoid missing an infrequent target. Participants completed 10 practice trials (6 target and 4 nontarget trials) and then 80 experimental trials, 40 in each block. This task started with a maximum RT limit of 600 ms and a response window of 600 ms that adapted for each participant according to trialwise performance. However, to avoid creating an artificially low response window, correct rejections did not affect the response window. Trials where no response was given (when a response was expected) or that were anticipatory (RT < 150 ms) were excluded from analyses. All remaining trials were evaluated for accuracy regardless of whether the response was within the response window. Thus, trials were only considered incorrect if an incorrect response was made (and not if they were correct but late). The mean RT to correct responses collapsed across block types were measured as task performance.

The *Spatial Span Task* is a computerized version of the Corsi Block-Tapping Test [40], which has frequently been used to assess visuospatial working memory capacity. On each trial, participants viewed a test array of 20 black circles that were cued sequentially in line with the typical administration of the Corsi Block-Tapping Task stimuli. Cued circles were lit in green, one at a time, sequentially. After the sequence of circles was complete and no longer displayed, participants were instructed to recall the location of each cued circle in the order they were shown and indicate the location and sequence by tapping each cued location in the cued order. Participants started with between 2 and 4 practice trials with 3-location sequences (ie, 3 cued circles). Participants practiced until 2 consecutive trials were answered incorrectly. Regardless of practice performance, participants then began the experimental task with a 3-location sequence. Once the participant completed 2 consecutive trials of the previous level without an error, they would advance to the next level that included an additional cued

circle, increasing the difficulty level. Participants completed as many levels as possible until 2 consecutive incorrect trials, at which point the task ended. Participants had unlimited time to respond for this task. Participants needed to have successfully completed at least 2 3-location sequence trials to be included in analysis. The highest level (ie, maximum number of items in a sequence) of the successful trial for each participant was defined as the spatial span, the measurement of working memory capacity.

Statistical Analysis

All numerical data are presented as the mean (SE). To evaluate the digital cognitive assessment battery (ie, ACE), Pearson correlation analyses were conducted to scrutinize the relationship between performance in the SDMT/PASAT and ACE modules. Partial correlation analyses with age, sex, years of education, and the BRT as covariates were applied, when appropriate. To examine whether the selected ACE modules can differentiate CI and non-CI participants with MS, participants with MS were divided into 2 subgroups (ie, CI and non-CI) according to their baseline SDMT z scores. Participants with an SDMT z score of <–1 based on published normative data [41] were characterized as CI. Differences between CI and non-CI participants with MS, as well as non-MS participants in terms of ACE performance, were examined by one-way ANOVA, with the BRT as a covariate to control for potential motor speed deficit in participants with MS. Two-tailed Student *t* tests were carried out for post hoc comparisons, when appropriate. The statistical significance threshold was set as $P \leqq .05$.

Results

Participants

A total of 53 participants with MS (mean age 51.8 [1.7] years) and 24 participants without MS (mean age 46.0 [3.7] years) completed the assessments; their demographic and clinical characteristics are summarized in Table 1. One-way ANOVA revealed no age differences between the groups ($F(2,76)=1.42$, $P=.24$). For categorical variables (ie, sex and race), chi-square tests showed no statistically significant association between groups and sex ($X^2(2)=5.31$, $P=.07$) as well as race ($X^2(4)=2.90$, $P=.59$). For analysis purposes, the 53 participants with MS were divided into CI (n=24 [45%]) and non-CI (n=29 [55%]) subgroups based on to their baseline SDMT z score. Figure 2 details the task completion rate.

Correlation Between Standard Measures and ACE

To delineate associations between performance in standard measures (ie, SDMT and PASAT scores) and the tested digital cognitive platform (ie, ACE), Pearson correlation analyses were performed. The SDMT showed significant correlations with several ACE measures (Boxed RT: R=–0.57, *P*<.001; Boxed distraction cost: R=–0.28, *P*=.02; SAAT RT: R=–0.36, *P*=.001; Spatial Span: R=0.34, *P*=.003; Figure 3). Since the Boxed RT showed the strongest correlation with the SDMT, we further

performed an exploratory linear regression analysis to examine to what extent the Boxed RT value can be used to predict the SDMT score. The analysis revealed a moderate R-squared value of 0.333 with the regression equation SDMT = 82.55 – 0.038 × Boxed RT; 33% of the total variation in the SDMT score can be explained by the Boxed RT.

When controlling for age, sex, years of education, and the BRT with partial correlations, similar results were observed (Boxed RT: R=–0.44, *P*<.001; Boxed distraction cost: R=–0.28, *P*=.01; SAAT RT: R=–0.17, *P*=.15; Spatial Span: R=0.18, *P*=.12; Table 2). When we restricted the analyses to only participants with MS, SDMT correlations with the Boxed RT and Boxed distraction cost remained statistically significant (Boxed RT: R=–0.50, *P*<.001; Boxed distraction cost: R=–0.34, *P*=.01; SAAT RT: R=–0.22, *P*=.10; Spatial Span: R=0.24, *P*=.07). Again, in adjusted correlation analyses, we saw similar results (Boxed RT: R=–0.43, *P*=.002; Boxed distraction cost: R=–0.38, *P*=.01; SAAT RT: R=–0.16, *P*=.26; Spatial Span: R=0.18, *P*=.21; Table 2).

PASAT, which has also been extensively used to test cognitive function in MS, was tested in the participants with MS and also showed significant correlations with the Boxed RT (R=–0.39, *P*=.01) and Spatial Span (R=0.29, *P*=.03; Figure 4 and Table 3). These correlations remained significant after accounting for age, sex, years of education, and the BRT as covariates (Boxed RT: R=–0.40, *P*=.01; Spatial Span: R=0.34, *P*=.02). These results support the hypothesis that there is a correlational association between standard MS information processing measures and ACE measures.

Group Differences in ACE

We then determined whether ACE modules can differentiate participants with MS with CI (SDMT z score<–1) and without CI (SDMT z score≥–1), as well as non-MS participants. To accomplish this, we conducted one-way ANOVA with the participant category as the independent variable for the Boxed RT, Boxed distraction cost, SAAT RT, and Spatial Span. We included age, sex, and years of education as covariates. The BRT was also included as a covariate since there was a significant difference in the BRT among the 3 groups ($F_{(2,71)}=3.96$, $P=.02$), where the non-MS group showed a faster BRT (311.81 [14.50] ms) compared to both CI (362.86 [13.56] ms, $P=.02$) and non-CI (357.27 [12.34] ms, $P=.02$) participants with MS.

Significant group differences in the Boxed RT (F (2,66)=9.73, *P*<.001) and Boxed distraction cost (F (2,66)=7.40, *P*=.001) were revealed. Post hoc comparisons indicated a slower Boxed RT in CI (1072.72 [28.14] ms) compared to non-CI (959.89 [25.48] ms; *P*=.004) participants with MS as well as non-MS participants (904.86 [31.68] ms, *P*<.001). For Boxed distraction cost, CI participants showed a higher attention cost (274.35 [20.47] ms) when compared to non-CI participants (170.12 [18.53] ms, *P*<.001) and non-MS (203.84 [23.04] ms, *P*=.02) participants (Figure 5). Although no statistical differences in Boxed distraction cost were found between the non-CI and non-MS groups (*P*=.20), numerically, the distraction cost in the non-CI group was slightly lower than in the non-MS group. A lower RT cost may be attributed to 2 combinations of task performance: First, the same level of performance for the more challenging task condition but a worse performance in the easier task, and second, the same level of task performance for the easier task and a less performance drop in the more challenging task, indicating better cognitive ability as the performance is not affected much when the task becomes more difficult. Here, the numerical difference in Boxed distraction cost between non-CI and non-MS groups was more likely to be a result of worse performance in the easier task in the non-CI group (ie, slower RT in the 4-item condition) rather than a less performance change in the more challenging task (ie, faster RT in the 12-item condition). To understand this, we investigated RTs in 12-item and 4-item conditions in both groups. As expected, the 2 groups showed the same level of RT in the 12-item condition (non-CI vs non-MS: 1030.22 [24.09] ms vs 1022.23 [30.66] ms, *P*=0.84), but a slower RT was found in the non-CI group in the 4-item condition (non-CI vs non-MS: 854.37 [19.42] ms vs 814.89 [23.87] ms, *P*=0.23). The slower RT in the 4-item condition, to some extent, explained the numerically lower Boxed distraction cost in the non-CI group. No significant difference between the 3 groups was discovered for the SAAT RT (F (2,66)=0.42, *P*=.65) or Spatial Span (F (2,66)=0.62, *P*=.54). The results suggest that the ACE Boxed module can identify group-level differences between CI participants with MS, non-CI participants with MS, and non-MS participants.

Discussion

Principal Findings

In this study, we aimed to determine whether a digital cognitive assessment battery (ie, ACE) could be used to evaluate cognitive function in adults with MS with and without CI. We found a significant correlational association between ACE metrics and standard cognitive measures. When age, sex, years of education, and the BRT were considered as covariates, only correlations between the SDMT score and the Boxed RT as well as the Boxed distraction cost remained significant. Specifically, the ACE Boxed module, a task measuring visual search performance and attention [38], showed the strongest correlation with the SDMT and could identify group-level differences between adults with MS with and without CI, as well as adults without MS. Altogether, these results provide preliminary evidence that ACE, a tablet-based cognitive assessment battery, provides modules that could potentially serve as an unsupervised cognitive assessment for people with MS.

Correlational links between standard measures and ACE measures were discovered. Specifically, we noted significant correlations between higher SDMT scores and faster Boxed and SAAT RTs, lower Boxed distraction costs, and higher Spatial Span. The significant correlations between SDMT and Boxed measures in all participants (including both non-MS and MS) indicate that this ACE module is a potential cognitive assessment tool, and the results stand alone when only participants with MS are considered. Moreover, an exploratory simple linear regression analysis revealed a moderate R-squared value of 0.33, indicated that 33% of the total variation in the SDMT score can be explained by the Boxed RT. These findings partially support relative consequence theory [30-32], which postulates that a change in the information processing speed is a key deficit underlying cognitive dysfunction in MS [27-30]. However, a clear causal relationship between information processing speed and high-level cognitive performance cannot be concluded with the current results. Of note, when age, sex, years of education, and the BRT were considered as covariates, only correlations between the SDMT score and the Boxed RT and Boxed distraction cost remained significant. Boxed is a visual search task that requires participants to search for a specific target, filter out distractors, and provide a response. To some extent, the task structure and the domains of cognitive function being challenged are similar to those of the SDMT, in which participants are asked to substitute geometric symbols for numbers (make a response) while scanning a response key (search and filter out distractors). The similarity of the cognitive function subserving the 2 tasks may explain the consistent correlation between SDMT scores and Boxed performance. In contrast, the cognitive domains mainly being challenged in SAAT and Spatial Span are attention control and working memory, respectively, which are less similar to what is being challenged during an SDMT test. These different cognitive domains could have been affected differently by factors such as age, sex, and years of education, which could explain the marginally significant correlation revealed between the SDMT and performance in SAAT and Spatial Span when controlling for these factors.

Participants with MS with a higher PASAT score demonstrated a faster Boxed RT and better Spatial Span. PASAT is a test involving information processing, attention, and short-term maintenance and manipulation of information [36]. These associations were expected, as the Boxed module is designed to assess attention and information processing speed, and Spatial Span mainly contains the cognitive component of holding information in mind.

In addition to showing the correlational association between a subset of modules of ACE and standard cognitive measures, we further demonstrated that ACE could differentiate CI in adults with and without MS, as indicated by a significantly slower Boxed RT and the higher attention cost in CI compared to both non-CI participants with MS and non-MS participants. Of note, performance on SAAT and Spatial Span was not significantly different among the 3 groups. Compared to SAAT and Spatial Span, which only challenge 1 or 2 cognitive domains, Boxed is a task that is more complicated and requires more underlying cognitive resources to reach the task goal. Since there is large interindividual variability in the pattern of CI in MS [42,43], it is possible that a complex task requires more executive control and may be a more sensitive tool to capture cognitive dysfunction in participants with MS compared to tasks that challenge only 1 or 2 aspects of cognitive function. These results support our hypotheses that there are correlational links between performance in standard cognitive measures for MS and ACE modules. In addition, as a digital tool in assessing cognitive function in MS, at least 1 ACE module has the capacity to differentiate group-level differences among CI and non-CI MS participants and non-MS participants.

With the advances in digital technology, the assessment and treatment for people with MS have adopted digital platforms [44], which when used in the home can substantially improve accessibility to cognitive remediation programs. Recently, we demonstrated that in-game navigation features of an unsupervised, digital video game–based digital therapeutic could represent a novel and sensitive way to perform cognitive evaluations in MS [34]. The current results further support the use of a digital platform for cognitive assessment in MS. The built-in adaptive algorithms, which modulate task difficulty based on individual performance, reduce interindividual variability, which is usually a concern for cognitive assessments [45,46]. Since ACE is a self-guided digital assessment tool, it has the potential to be used in different settings (eg, at home or in the clinic). Future studies evaluating how ACE performance fluctuates during a day and whether the results would be affected by different testing environments are warranted. Moreover, since each ACE module is designed to challenge specific cognitive components, baseline ACE subtest scores could be useful to inform personalized cognitive training targets. For instance, for a participant with a low-grade score in Spatial Span and a high score in SAAT, the prescribed cognitive training approaches may place great emphasis on working memory rather than attentional control. Studies with a larger sample size or administering ACE as an outcome measure to capture the effect of a cognitive intervention are also needed to provide more information about how the ACE battery can reflect the patient's and the caregiver's real-life experience and to better translate the subtest scores to a meaningful treatment target.

Limitations

Among the limitations of this study, the relatively small sample size and lack of multiple points of data collection at baseline made it difficult to draw a definitive conclusion with respect to the test validity and test-retest reliability of the ACE battery in people with MS. Related to this, given the predominately White participants in the study, particularly those with CI, the potential influence of racial and ethnicity on the results could not be fully excluded. Participants with severe CI were excluded from the study. Although the severity of CI can vary from mild to quite severe in MS patients, it has been reported that the majority (771/1014, 76.03%) of patients experience mild (340/771, 33.7%) to moderate (431/771, 42.7%) cognitive disturbance [47]. Since the application of the ACE program in clinical settings is still at an early stage, we planned to start with patients without severe CI to reduce the heterogeneity of the sample. Future studies with a broader range of CI are needed to investigate how the ACE tool performs when applied to

participants with severe CI. Furthermore, the results of the exploratory simple linear regression analysis should be taken with caution, given the sample size does not have adequate power to provide a rigorous predictive model. Future studies with a larger sample size are warranted for a better predictive model development. Finally, experience with using digital tools may be confounding factors that can impact the results where participants with more experience in using digital tools may have performed better in this study. Future studies investigating digital assessments should control for participants' skills in using digital devices.

Conclusion

In summary, this study suggests that a tablet-based adaptive cognitive battery could be used to perform cognitive assessments in MS. As noted previously [20,34], the high adherence rate indicated that this remote, home-based health care strategy is well accepted by patients with MS, who may have limited access to cognitive assessment or treatment. Since CI poses major limitations to patients with MS, the current findings open up new paths to deploying digital cognitive tests for MS.

Abstract

Background: Massive open online course (MOOC) research is an emerging field; to date, most research in this area has focused on participant engagement.

Objective: The aim of this study is to evaluate both participant engagement and measures of satisfaction, appropriateness, and burden for a MOOC entitled Understanding Multiple Sclerosis (MS) among a cohort of 3518 international course participants.

Methods: We assessed the association of key outcomes with participant education level, MS status, caregiver status, sex, and age using summary statistics, and 2-tailed *t* tests, and chi-square tests.

Results: Of the 3518 study participants, 928 (26.37%) were people living with MS. Among the 2590 participants not living with MS, 862 (33.28%) identified as formal or informal caregivers. Our key findings were as follows: the course completion rate among study participants was 67.17% (2363/3518); the course was well received, with 96.97% (1502/1549) of participants satisfied, with an appropriate pitch and low burden (a mean of 2.2 hours engagement per week); people living with MS were less likely than those not living with MS to complete the course; and people with a recent diagnosis of MS, caregivers, and participants without a university education were more likely to apply the material by course completion.

Conclusions: The Understanding MS MOOC is fit for purpose; it presents information in a way that is readily understood by course participants and is applicable in their lives.

Introduction

Background

Massive open online course (MOOC) research is an emerging field [1,2]. The work done to date has focused on participant engagement, particularly course completion [3], which has presented a challenge for MOOCs because MOOCs have a mean 5% to 15% completion rate [4]. Few studies have evaluated course material appropriateness, participant satisfaction, and reasons for noncompletion. Here, we contribute to this ongoing conversation by evaluating the impact of education level, multiple sclerosis (MS) status, caregiver status, sex, and age on completion, satisfaction, perceived appropriateness, and burden of a MOOC on MS.

MOOCs emerged internationally into the knowledge economy in 2012, where they were heralded as a revolution that would democratize education by offering high-quality courses for free to anyone with access to an internet connection [5]. Since then,

the number of MOOCs has rapidly increased; Class Central, the largest MOOC aggregator website, listed more than 13,000 MOOCs from more than 900 universities in 2019 [6]. However, despite the increased availability of MOOCS, these courses have struggled to reach and retain underserved students in the same numbers as their more privileged peers. As students from more affluent areas are more likely to participate in and complete MOOCs [7,8], MOOCs may exacerbate educational inequalities by offering additional resources to populations that also have access to a range of other educational opportunities.

Health and medicine MOOCs may encounter an additional challenge because they are often developed for use by people living with a health condition and their caregivers to address information asymmetry between the medical profession (as the suppliers) and people with health conditions and their caregivers (as consumers) [9-11]. However, because health status is related to socioeconomic status and education [12,13], people affected by a health condition may be less likely to enroll and complete a MOOC than those who are unaffected. Fortunately, previous studies suggest that these challenges can be addressed successfully. The Wicking Dementia Research and Education Centre (WDREC) has developed a MOOC on dementia that demonstrably improves knowledge of dementia in participants with a wide range of educational attainment [14,15], indicating that appropriately designed MOOCs can overcome some of these barriers.

Using the WDREC MOOCs as a successful model of knowledge dissemination, we have developed a free 6-week MOOC about MS [16] to increase awareness and understanding of MS in the MS community and interested laypeople. MS is a chronic autoimmune disorder where the immune system attacks and damages the central nervous system [17]. MS-related symptoms, such as mobility impairment and fatigue, may make it difficult for people living with MS to access traditional educational offerings [18]. After a year of development in collaboration with the MS community (eg, people with MS, carers, service providers, health care providers, and researchers), the Understanding MS MOOC was released in 2019 and had 2 open enrollments in that year. It was well received by participants, ranking first among the >2400 MOOCs released in 2019 based on participant reviews [6,19].

Objective

In this study, we assessed the impact of the course on information asymmetry in the MS community. In health care (particularly in health services and health economics), information asymmetry (or asymmetry of information) relates to the difference in the information known by the consumer (eg, the patient or a member of the public) and that known by the producer or supplier, a health care professional [20]. In the information age, the gap creating information asymmetry could close if consumers can access appropriately pitched, validated, and targeted information sources [21]. Therefore, to assess the potential impact of the course on information asymmetry, we explored the overall course completion rate, participant satisfaction, perceived appropriateness and burden, and the association between these outcomes and demographic and health factors.

Methods

Overview

The data for this study were collected during the 2 enrollments of the Understanding MS MOOC administered in 2019. The course is free and available in English internationally on any internet-connected device (eg, computer or smartphone; [22]). Course content is presented in videos (transcripts are available for all videos), text, images, and animations. The content is presented in 6 modules over 6 weeks, and course participants can access the material for a total of 8 weeks. Each module contains at least 1 optional activity and discussion prompt. At the end of each module is a summary of the module content and a 10-question multiple-choice quiz. Participants can take the quiz as many times as they like but must achieve a score of 70% or higher to move on to the next module. The course covers topics ranging from the underlying pathology of MS to its impact on everyday life and includes both academic content and lived experience videos from a range of MS community members (for a more detailed description, refer to the study by Claflin et al [16]).

An optional feedback survey was accessible in the completion section during the 2- to 3-week period that the section was open before course closure. Therefore, the survey was only available to the participants who completed the course. We chose to place the feedback survey in the completion section to ensure that all survey respondents had completed the full intervention. An analysis of reasons for noncompletion is underway in a separate study. The feedback survey was adapted from a similar tool used to assess a WDREC MOOC about dementia [14] and queried participants' overall satisfaction with the course and various aspects of the course. With a few exceptions, the questions in this survey were presented on a 5-point Likert scale, ranging from very dissatisfied to very satisfied, or strongly disagree to strongly agree and example survey questions are available in the study by Claflin et al [16].

Small changes to the web-based content were made between the 2 enrollments based on feedback from the first enrollment. We added 3 short videos (<3 minutes each): 1 on exercise physiology, 1 on physical therapy, and 1 on comorbidities. We added a couple of paragraphs of text about disease-modifying therapies and more clearly identified the activities in each module. We also added 2 small interactive features to help participants navigate through a series of short videos on symptoms and risk factors.

The course was advertised widely through social media, particularly through Facebook ads. Advertising targeted anglophone countries. Information about the course was also disseminated through the Menzies Institute network, as well as that of our project partners, Multiple Sclerosis Limited and WDREC, and other related organizations.

Participants in this study gave informed consent for their course-collected data, including their course feedback survey, to be used for research purposes in the introduction or orientation section of the course before they had access to any course content. This study was approved by the University of

Tasmania Social Science Human Research Ethics Committee (H0017892).

Demographic and Health Status Characteristics

This study evaluated 3 primary predictor variables for course completion and course satisfaction: MS status, caregiver status, and education level. These variables were of primary importance, as education has been shown to affect course completion in many MOOCs, and as a course intended for the MS community and interested laypeople, the course can only be considered fit for purpose if it is appropriate for people with MS and their caregivers.

Participants self-reported demographic and health status characteristics during course enrollment and in the feedback survey. This includes self-identification with various roles in the MS community. We categorized all participants into 2 MS status groups, as people with MS or those not living with MS, based on this information. We categorized people not living with MS into 2 caregiver status groups: not caregivers and caregivers, defined as anyone who identified as either a family or friend of a person with MS or a caregiver, thereby incorporating both formal and informal caregivers into a single group.

Similarly, participants self-reported their education level as grade 12 or below, occupational certificate or diploma, undergraduate degree, or postgraduate degree. We then categorized all participants into 2 education-level groups: no university education (grade 12 or below and occupational certificate or diploma) and university education (undergraduate or postgraduate degree), following the methodology of Goldberg et al [14].

Our secondary predictors were MS disease duration, sex, and age, which were self-reported during course enrollment. We calculated age from self-reported year of birth and calculated MS disease duration from self-reported year of diagnosis.

Outcome Measures

Completion

We evaluated participant completion using course-collected data and compared the completion rate with the average for MOOCs, which is 5% to 15% [4]. We determined the course completion and final course module using quiz attempts. Any attempt to complete a quiz (whether or not the score was sufficient to move on to the next module) was considered an indication that the participant had completed the module. All module 6 (final module) quiz attempts were considered an indication of course completion. We assessed the association between completion rate and demographic and health status characteristics (MS status, caregiver status, education level, sex, age, and disease duration).

Satisfaction, Perceived Appropriateness, and Burden

We evaluated satisfaction, perceived appropriateness, and burden among course completers using data from the course feedback survey.

Satisfaction was determined using 2 questions. The first was a 5-point Likert scale that asked about overall satisfaction with the course. We categorized responses into 2 groups: satisfied (satisfied or very satisfied) or not satisfied (neutral, dissatisfied, or very dissatisfied). The second was a 6-point Likert scale that asked about the overall course quality. We categorized responses into 2 groups: average or below (average, poor, very poor), or above average (good, very good, and excellent).

We evaluated the appropriateness and burden of the course with questions querying (1) self-reported agreement that the participant could understand the content, (2) that the language was too technical, (3) that there was too much or too little material, (4) that the course improved their understanding, (5) that the material could improve care or quality of life for people with MS, (6) that they would recommend the course, and (7) that they had already applied course material in their lives. Responses were categorized into 2 groups: agree (agree or strongly agree) and disagree (neutral, disagree, or strongly disagree). We also assessed the burden by comparing the self-reported average time spent on a single course module between groups.

Analysis

We cleaned the data set by removing any staff accounts and removing the second attempts of any participant who took part in both enrollments. During data cleaning, we designated ages (based on self-reported year of birth) of <10 years or >95 years as no data, as these values were deemed implausible. Similarly, we excluded impossible or uninterpretable years of diagnosis (eg, 1 or 1900).

As this data set was overpowered, there were many statistically significant differences that were not of interest because they were not reflective of materially significant differences between groups. To account for this, we set a threshold of material significance for comparisons between categorical variables, which required a 5% difference between groups. We report the results of these materially significant differences (all of which are statistically significant). As age and disease duration were continuous variables, we evaluated their effects on all outcomes of interest. To determine whether the enrollments could be evaluated together, we compared the outcomes of interest to assess if there were any materially significant differences (>5%).

We assessed the demographics of study participants using the sample size and percentage of the cohort for categorical variables and mean and SD for continuous variables. We assessed the association between the predictor variables on the responses of interest and the relationships between the predictor variables using 2-tailed chi-square and *t* tests. As disease duration was not normally distributed, we evaluated its association with the outcomes of interest using the Mann-Whitney rank-sum tests of equal medians. We used Pearson correlation to evaluate the association between the average time taken to complete a module and participant age and disease duration. In all analyses, statistical significance was set at $P<.05$. All analyses were conducted using STATA (version 16.0, StataCorp).

Results

Participant Characteristics

In total, 8324 people enrolled in the first 2 enrollments of the Understanding MS MOOC, 3912 (46.99%) of whom completed the course. After removing 52 second attempts, 3518 unique participants across the 2 course enrollments gave permission for their data to be used in research; 1549 consenting course completers also completed a feedback survey (Figure 1).

Participant characteristics are presented in Table 1. Differences between enrollments were <5% for the outcomes of interest. Therefore, data from both enrollments were assessed together.

The majority of the participants were women and had an undergraduate degree or higher education level (course data in Table 1). Nearly two-thirds of the participants resided in Australia, with other large anglophone countries with high MS prevalence comprising the other most well-represented nations in the sample (eg, Canada and New Zealand). Nearly a third of the participants were people with MS. Of the 2096 course participants not living with MS, 862 (41.12%) identified as formal or informal (family or friends of people with MS) caregivers.

Completion

Of the 3518 course participants who gave permission for their course-collected data to be used in research, 2363 (67.17%) completed the course. There were significant differences in the completion rate between MS status groups (χ^2_1=36.8; *P*<.001; Table 2). People with MS were less likely to complete the course than those not living with MS (539/928, 58.08% compared with 1455/2096, 69.42%). People with MS completed an average of 3.9 modules while those not living with MS completed an average of 4.5. This association was consistent across all course modules, with people with MS less likely to complete module 1 (χ^2_1=26.7; *P*<.001), module 2 (χ^2_1=22.2; *P*<.001), module 3 (χ^2_1=26.03; *P*<.001), module 4 (χ^2_1=28.8; *P*<.001), and module 5 (χ^2_1=27.9; *P*<.001).

Table 2. The percentage of participants completing the course, satisfied with the course, or agreeing with various statements about the course in the course feedback survey in different participant groups, and the absolute difference between groups. Italicized values indicate materially significant (>5%) differences between groups.

[c]MS: multiple sclerosis.

To further explore this, we evaluated the completion rate among participants who completed module 1 and found that the difference between those living with MS and those not living with MS shrank to about 6% (539/707, 76.24% compared with 1455/1762, 82.58%). This difference was maintained among those who completed module 2. Among module 3 completers, the difference between people with MS and those not living with MS dropped below the threshold for material significance and continued to decline in the remaining module completion groups. There were no materially significant differences in completion based on caregiver status, sex, or education level, but age was significantly associated with completion. Course completers were more likely to be older than noncompleters (Table 3). However, the effect size was not large; the mean age of completers was 45 years compared with 42 years for noncompleters. Similarly, among people with MS, participants with more recent diagnoses were less likely to complete the course than those who had been living with MS for longer periods (Table 3). However, the effect size was small (median disease duration of 1 year compared with 2 years).

Table 3. Results of *t* tests, Mann-Whitney rank-sum tests of equal medians, and Pearson correlations evaluating the association between age and disease duration, and all outcome variables.

Satisfaction, Perceived Appropriateness, and Burden

Overall, course completers were satisfied with the course, with 96.97% (1502/1549) of those completing the feedback survey reporting that they were satisfied or very satisfied (Multimedia Appendix 2). They also rated the quality of the course highly, with 98.38% (1519/1544) rating it above average (good, very good, or excellent). The pitch of the course appears appropriate, with nearly all participants agreeing that they could understand the information, that the course improved their understanding, and that they would recommend the course.

Participants also found the material helpful, with 63.42% (945/1490) reporting that they had applied information from the course at course completion, and nearly all) agreed that the information could improve care (1407/1516, 92.81%) or quality of life (1357/1509, 89.93%) for people with MS. In addition, the burden was low (average of 2.2 hours to complete a module). Only 5.02% (76/1513) agreed that there was too much material, whereas 14.6% (221/1514) agreed that there was too little material.

There were few materially significant differences in the responses of the demographic and health status groups (Table 2). People with MS were less likely to report improved understanding because of the course material (χ^2_1=26.2; *P*<.001) and were less likely to agree that the course material could improve care (χ^2_1=12.6; *P*<.001). Among people not living with MS, caregivers were more likely to report applying the course material by course completion than noncaregivers (χ^2_1=60.0; *P*<.001).

University education was also associated with applying the course material; participants with a university education were less likely to report applying the course material at course completion than those without one (χ^2_1=5.2; *P*=.02). Sex was significantly associated with agreement that the language in the course was too technical (χ^2_1=8.4; *P*=.004) and that there was too much material (χ^2_1=11.7; *P*<.001). Male participants were more likely to agree with these statements than female participants. However, there was no difference in the average time spent per module between males and females.

Age was associated with several outcomes of interest (Table 3). Participants who agreed that there was too much material in the course were more likely to be older (mean age of 47 years compared with 40 years). Correspondingly, those who agreed that there was not enough material were more likely to be

younger. Participants who agreed that the language was too technical were also more likely to be older. However, the effect sizes for the latter 2 associations were small, with differences in mean age between 2.5 and 3.5 in the 2 groups. Similarly, increasing age was associated with a greater average number of hours taken to complete a module, but the effect size was small (coefficient=0.02; Table 3).

Among people with MS, disease duration was also associated with several outcomes of interest (Table 3). People with MS who agreed that the course had improved their understanding were more likely to have a shorter disease duration than those who did not (median disease duration of 1 year compared with 4 years). A total of 93.5% (172/184) of participants with disease durations of ≤4 years reported improved understanding, compared with 86.2% (181/210) of those with disease durations of >4 years. Similarly, participants who reported that they had applied information from the course by course completion were more likely to be recently diagnosed (median of 1 year compared with 3 years). A total of 73.9% (136/184) participants with a disease duration of ≤4 years reported applying the course material, compared with 58.9% (46/78) of the participants with a disease duration >4 years.

Participants with more recent diagnoses were also more likely to report that there was not enough material in the course than those with older diagnoses (median disease duration of 1 year compared with 2 years) and that the content of the course could improve care for people with MS (median of 1 year compared with 2 years), although the effect sizes of these comparisons were small (1 year).

Associations Between Demographic and Health Status Characteristics

Among course completers, education level was associated with MS status, caregiver status, and sex (Table 4). People with MS were less likely than participants not living with MS (230/437, 52.63% compared with 724/1112, 65.11%) to have a university education. Among those not living with MS, caregivers were less likely than noncaregivers (215/422, 50.95% compared with 509/690, 73.77%) to have a university education. Males were more likely than females to have university education (158/227, 69.6%) compared with 61.01% (723/1185).

Age was significantly associated with caregiver status and education level (Table 4). Participants who were caregivers were more likely to be older than noncaregivers (mean age 50 years compared with 44 years). Similarly, participants without a university education were more likely to be older than those with a university education (mean of 50 years compared with 45 years). Among people with MS, MS disease duration was not associated with sex or education level but was strongly associated with age (Table 4).

Discussion

Principal Findings

To our knowledge, the Understanding MS web-based course is the largest MS-related web-based course in the world. To date, more than 13,000 people from 128 countries have enrolled in the course, and it was ranked first among the >2400 courses released in 2019 based on participant reviews. Correspondingly, we found that overall, the Understanding MS MOOC had a completion rate that was more than 3 times higher than the average for MOOCs and very high participant satisfaction. However, there were materially significant differences in participant experience among the different participant groups. People with MS were less likely than those not living with MS to complete the course. Although 63.42% (945/1490) of all course completers reported applying the course material, caregivers and those without a university education were more likely to apply it. Overall, the Understanding MS MOOC is fit for purpose, with an appropriate pitch and burden level, and presents information that is relevant to participants' lives. By disseminating relevant content directly to information consumers (people with MS, caregivers, and those without a university education), the course addresses information asymmetry in the MS community.

Completion

The first 2 open enrollments of the Understanding MS MOOC had an average completion rate of 47% (data not presented here). However, among study participants (the subset of all course participants who consented to take part in this research), there was a 67.17% (2363/3518) completion rate. This is 3-9 times higher than the average for all MOOCs, which fluctuates between 5% and 15% [4]. Course completion was about 11% higher among those not living with MS (539/928, 58.08%) than among those with MS (1455/2096, 69.42%), driven by noncompletion early in the course, particularly in module 1. This may be because of the additional challenges faced by people with MS that may interfere with their ability to complete the course, including complications arising from MS-related symptoms such as fatigue and cognitive impairment.

In addition, course completion was about 4% higher among participants with a university education (1162/1707, 68.07%) than among those without (744/1169, 63.64%). Although this difference is not materially significant, it is larger than other similar courses, such as the Understanding Dementia MOOC developed by WDREC [4], who observed a difference of 0.44% between groups. This discrepancy may be because of the underlying differences in the course participants. The Understanding Dementia MOOC is intended primarily for dementia carers rather than those living with dementia, whereas the Understanding MS MOOC is aimed at a broad audience, including people with the condition; 30.69% (928/3024) of this sample comprised people with MS. People with MS were both less likely to have completed university and less likely to complete the Understanding MS MOOC. The difference in completion between education levels may reflect the difference in completion rate associated with MS status. The data support the possibility that education level and health status interactively affect completion. Among the study participants, people with MS without a university education had the lowest completion rate (250/450, 55.56%) of any MS status or education level group. Conversely, people not living with MS who had a university education had the highest completion rate (904/1278, 70.74%).

Satisfaction, Perceived Appropriateness, and Burden

Among course completers, satisfaction and perceived appropriateness were high in all demographic and health status groups, with >98% satisfied and ≥95% agreeing that they could understand the course material. This agrees with previous work on health and medicine MOOCs, which found >80% participant satisfaction among allied health professionals (Harvey et al 2014 [13]) and members of the community (Tieman et al 2018 [23]). The course also presents a low burden for participants, with participants reporting that the material took an average of 2.2 hours per week to complete. This is far lower than the average 4.2 hours per week required by health and medicine MOOCs [24].

Almost two-thirds of the course completers reported applying course material by completion. However, there were significant differences in the application of course materials between the participant groups. People with MS who were newly diagnosed, caregivers, and those without a university education were more likely to report that they had applied the course material. Newly diagnosed people with MS, who were also more likely to report that the course improved their understanding, were well positioned to apply the course material immediately. Among people not living with MS, caregivers may be better positioned to apply the material immediately. Again, the association between caregiver status and education level, with caregivers less likely to have a university education than noncaregivers, may in part drive the observed association between education level and application of course material. The data support this; caregivers without a university education were the most likely to report applying information by completion (140/201, 69.65%) of any caregiver or education level group. Noncaregivers with university education were least likely to report applying it (279/483, 57.76%). However, this result also agrees with the large body of work demonstrating that higher education levels are associated with higher health literacy and better health outcomes [13,25]. Participants with lower education levels may have lower baseline health literacy and MS-related knowledge, and therefore, learn more from the course.

Knowledge Dissemination to Address Information Asymmetry

Health information is a valuable commodity. High-value health care relies on effective information exchange [11], and better information dissemination is needed to close the gap between health information providers and information consumers [10]. This study demonstrates that participation in the Understanding MS MOOC helps to address information asymmetry among course completers. By course completion, participants successfully translated information by applying it to their lives. This is particularly clear among newly diagnosed people with MS (disease duration of 0-4 years) and caregivers, who are the most likely to apply the course material by completion (136/182, 74.73% and 276/407, 67.81%) reported applying course material by completion, respectively). Recent research suggests that services intended for caregivers need to be sensitive to the fluctuating demands placed upon caregivers and be flexible in their support [23]. This study shows that the Understanding MS MOOC accommodates the needs of health information consumers, such as newly diagnosed and caregivers, and can help to address information asymmetry in the MS community.

Strengths, Limitations, and Future Directions

The main strength of this study is the large and diverse course evaluation cohort. The study participants comprised an international cohort of MS community members and interested laypeople with a range of educational attainment. This study had 2 main limitations. First, the analysis grouped formal and informal carers. These groups may have different needs and characteristics that we were unable to parse in this study. Second, the course evaluation survey was only presented to course completers, making the group vulnerable to selection bias. Although we cannot control for this bias, we have presented our results accordingly. Future research should explore the impact of MS status on the reasons for noncompletion.

Conclusions

The Understanding MS MOOC is an accessible health education intervention with a pitch and burden that is appropriate for course participants. It presents information relevant to the lives of the participants and can be immediately applied. Because a large proportion of course participants identify with MS community roles that are traditional consumers of information, the results of this study suggest that the Understanding MS courses can help to address information asymmetry.

Acknowledgments

The authors would like to thank the Understanding Multiple Sclerosis massive open online course participants who participated in this study and Multiple Sclerosis Limited for supporting the course.

Abstract

Background: Unwarranted variability in clinical practice is a challenging problem in practice today, leading to poor outcomes for patients and low-value care for providers, payers, and patients.

Objective: In this study, we introduced a novel tool, QualityIQ, and determined the extent to which it helps primary care physicians to align care decisions with the latest best practices included in the Merit-Based Incentive Payment System (MIPS).

Methods: We developed the fully automated QualityIQ patient simulation platform with real-time evidence-based feedback and gamified peer benchmarking. Each case included workup, diagnosis, and management questions with explicit evidence-based scoring criteria. We recruited practicing primary care physicians across the United States into the study via the web and conducted a cross-sectional study of clinical decisions among a national sample of primary care physicians, randomized to continuing medical education (CME) and non-CME study arms. Physicians "cared" for 8 weekly cases that covered typical primary care scenarios. We measured participation rates, changes in quality scores (including MIPS scores), self-reported practice change, and physician satisfaction with the tool. The primary outcomes for this study were evidence-based care scores within each case, adherence to MIPS measures, and variation in clinical decision-making among the primary care providers caring for the same patient.

Results: We found strong, scalable engagement with the tool, with 75% of participants (61 non-CME and 59 CME) completing at least 6 of 8 total cases. We saw significant improvement in evidence-based clinical decisions across multiple conditions, such as diabetes (+8.3%, $P<.001$) and osteoarthritis (+7.6%, $P=.003$) and with MIPS-related quality measures, such as diabetes eye examinations (+22%, $P<.001$), depression screening (+11%, $P<.001$), and asthma medications (+33%, $P<.001$). Although the CME availability did not increase enrollment in the study, participants who were offered CME credits were more likely to complete at least 6 of the 8 cases.

Conclusions: Although CME availability did not prove to be important, the short, clinically detailed case simulations with real-time feedback and gamified peer benchmarking did lead to significant improvements in evidence-based care decisions among all practicing physicians.

Introduction

Clinical practice variation is recognized as one of the most challenging problems in current practice [1,2]. Unwarranted variability in clinical practice has multiple root causes, starting with the uneven recognition and application of medical knowledge [3,4]. The sheer volume of new research, including nearly 1.4 million papers (or 1 paper every 23 seconds) posted to the National Library of Medicine's PubMed database in 2019, also makes it virtually impossible for busy practicing physicians to keep their practice up to date [5]. Our own research shows that even after case mix adjustment, practice variation within the same practice is a significant problem, characterized by standard deviations of approximately 10% [6-8]. The good news is that when knowledge and practice gaps are closed, variability declines, adoption of best practices accelerates, and patient outcomes improve [9,10]. Conversely, failing to recognize and address unwarranted variation has deleterious impacts on quality, outcomes, and value [11-16].

The challenge of reducing unwarranted clinical variation has been widely documented across care settings, clinical specialties, Merit-Based Incentive Payment System (MIPS) measures, and geographies. Easy solutions have been tried, including Continuing Medical Education (CME) and maintenance of certification (MOC), performance dashboards, and reminders; however, success has been limited [17]. For example, the most common forms of CME activities, ranging from printed information to didactic presentations and formal conferences, have shown relatively little impact on physician performance [18]. Other engagement strategies, such as multimedia approaches, multiple instructional techniques, repeated exposures, and direct feedback on care decisions, have shown better effectiveness but are difficult to scale and time-intensive for participating physicians [19].

Research using a newer approach—timely feedback on case-based decisions using validated case simulations—has been shown to lead to significant changes in actual practice in randomized controlled trials [6,20,21]. Another research stream has used the motivational aspects of gaming, real-time scoring, digital feedback, leaderboards, and serial competition, which suggests that the gaming approach provides an opportunity to enhance medical education [22-25].

The engagement tool created for this study builds on over 20 years of research using Clinical Performance and Value (CPV) patient simulations [26]. We adapted those lessons to develop a novel web-based patient-simulation platform, known as QualityIQ, which is focused on primary care providers (PCPs) and leverages the serial engagement of case-based learning in CPVs with immediate personalized evidence-based feedback and gamified peer benchmarking. QualityIQ is distinct from the standard gamification approach in that QualityIQ leverages iterative measurement, feedback, and remeasurement over multiple rounds of engagement using the CPV approach. We introduced the QualityIQ tool to PCPs to determine if serial measurement and feedback improved evidence-aligned practice decisions overall and whether it improved specific quality measures included in MIPS. After completing their cases, we determined whether receiving CME credits increased participation in this quality improvement initiative. Finally, we asked the participants directly if they expected to make changes in their actual practice setting after participating in this gamified learning approach.

Methods

Study Design

From January through March 2019, we conducted a randomized controlled study of clinical care decisions made by a national sample of PCPs managing typical primary care patients. We asked United States–based, board-certified internal medicine and family medicine physicians to care for four different types of routine primary care cases (diabetes, osteoarthritis [OA], asthma, and musculoskeletal pain). We used the novel web-based QualityIQ patient simulation tool to serially measure provider care decisions for these cases. Physicians were given real-time feedback when they completed their cases to determine the extent to which their care decisions aligned with the latest guidelines. We measured the care decisions judged to be the most critical to high-quality care, namely the workup (laboratory and imaging), diagnosis, and treatment. Gaming elements included a leaderboard for all participants and gift cards for top scores. We took advantage of the prospective design and used a coin flip methodology to randomly assign half of the participants to receive CME and the other half to not receive CME to observe whether this augmented the participation, learning, or standardization effects of serial measurement and feedback.

Physician Recruitment

From a list of over 10,000 US-based PCPs, we sent out 2000 emails to randomly selected addresses. From this group, we screened potential participants using the following enrollment criteria: (1) is board-certified in internal medicine or family medicine, (2) practices exclusively in primary care, (3) has an active panel of over 1500 patients, and (4) has 2 to 30 years of postresidency experience. In total, 202 providers were eligible, and of these, 141 agreed to participate. The 141 participants were further randomized into 1 of 2 study arms, with 68 in the non-CME control group and 73 in the intervention group that received CME with their participation. Of the 141 physicians who completed the questionnaire and enrolled in the study, 21 began the first week but did not complete their case and were subsequently dropped from the study, leaving 120 enrolled providers who completed at least one week of cases (see Table 1).

QualityIQ Patient Simulation Cases

We created 8 fully automated QualityIQ case simulations and uploaded these cases onto the Qualtrics platform [27]. Each case included evidence-based feedback delivered in real time as physicians progressed through various workup, diagnosis, and treatment decisions. Each case was designed to be completed on a smartphone, tablet, or computer in less than 10 minutes. Each week, all participants cared for the same case.

The 8 cases were developed as pairs of typical cases seen by PCPs in four areas: diabetes, OA, asthma, and pain management (see Table S1 in Multimedia Appendix 1). While each case was unique and required different treatment decisions based on each patient's presenting symptoms and risk factors, many care decisions were featured in multiple cases (see Table S2 in Multimedia Appendix 2). For example, we included decisions directly related to Medicare 2019 MIPS measures, such as addressing poor hemoglobin A_{1c} control (>9%). We also included general measures that cut across multiple conditions, such as zoster vaccination. By having multiple related scoring items in multiple cases, we were able to track changes over time.

QualityIQ Scoring and Gamification

The PCPs completed 1 case per week, with weekly email reminders to notify them when the next case opened. Each weekly case consisted of 8 to 10 multiple choice questions covering workup, diagnosis, management, and follow-up decisions, and each question had explicit evidence-based scoring criteria. After each question, physicians received real-time feedback on their care decisions, including the appropriateness of their decision, recommended alternative decisions, and supporting evidence-based references for the preferred care path.

At the end of each week, participants received a detailed score report that included a summary of key evidence-based recommendations for their case, their personal score in the case, and how their care compared to that of their peers. At the start of the study, all participants chose a pseudonym so they could track their scores relative to their peers on a leaderboard that was updated weekly. The top scores in each weekly case were awarded a US $20 electronic gift card from Amazon. The study was completed after the close of the final case.

Statistical Analysis

The primary outcomes were to measure evidence-based care scores within each case, adherence to MIPS measures, and practice variability among the PCPs caring for the same patient. We were especially keen to determine if the physicians improved their scores on these measures after serial measurements. We also investigated if the availability of CME credit had any effect on participation or performance. Lastly, we asked the participants for their appraisal of the usefulness of the tool in their practice.

For descriptive comparisons between the 2 study arms, we used the chi-square test for significance. To determine significance across cases, we normalized the scores to percentages; a score of 100% indicated that the PCP made all the correct evidence-based decisions without any incorrect decisions, with a possible score of less than 0% if the PCP made more incorrect than correct decisions. We compared these normalized quality-of-care scores across the cases using either multivariate linear regression or the Student *t* test to measure improvements in overall and domain quality of care scores. We also performed an equality of variances test to test for homogeneity of the overall scores. All analyses were conducted in Stata 14.2 (StataCorp LLC).

Ethics Approval and Consent to Participate

This study was conducted in accordance with ethical standards, approved by the Advarra Institutional Review Board, Columbia, Maryland, and listed on ClinicalTrials.gov (NCT03800901). Informed consent was obtained through electronic signatures from all participants.

Results

Physician Demographics

Of the 120 participants in the study, more than two-thirds were male, and 72 (60%) were board certified in internal medicine. Among the demographics and practice characteristics listed in Table 1, we found no significant differences between the two groups except that the CME group had a higher percentage of providers who were employed by their practice (86.4% vs 68.9%; *P*=.03).

All 120 participants cared for one QualityIQ patient in the first week of the project. In the second week, 91 (76%) of the 120 participants completed their second case. After week 2, participation stabilized, with only modest decreases from weeks 3 to 8. Of the 91 participants who completed at least 2 cases, 68 (75%) went on to complete at least 6 of the 8 weekly cases. 58 (48%) physicians completed all 8 cases, and 79 (66%) participated in at least half (n=4) of the cases. When we compared the first week scores between providers who completed 8 weeks of the study to those who only completed the first week of the study, we found no significant difference in their scores (*P*=.37).

The ability to earn CME did not affect recruitment rates. However, once enrolled, those eligible for CME credits completed an average of 1.6 more cases in the project than their non-CME peers (*P*=.003) and were more likely to participate in at least 6 of the weekly rounds (40 of 61, 66.1%, vs 28 of 59, 47.5%; *P*=.045).

In aggregate, female physicians performed significantly better than their male counterparts (+3.1%, *P*=.02), and family medicine diplomates performed better than internal medicine providers (+3.2%, *P*=.008) (see Table 2). We saw no significant difference in overall scores by age, with providers aged over 55 years scoring a nonsignificant 0.7% lower than their younger counterparts (*P*=.56). In our study, those practicing in multispecialty group practices (+6.5%) and those practicing in the Midwest region (+8.1%) scored significantly higher (*P*<.001 for both). PCPs who participated in 6 or more weeks of QualityIQ cases had higher average quality scores than those who participated in 5 or fewer weeks (+5.2%, *P*=.04). However, providers who were randomized into the CME arm of the study did not perform better than those in the non-CME arm (+0.5%, *P*=.84).

Table 2. Multivariate linear regression analysis of total QualityIQ scores (as percentages of the maximum score).

Characteristic	Coefficient	*P* value
Male sex	–3.1	.02
Internal medicine physician	–3.2	.008
Age >55 years	–0.7	.56
US-trained physician	–0.1	.97
Midwest region	8.1	<.001
Suburban locale	2.0	.12
Multispecialty group practice	6.5	<.001
Academic practice	4.9	.01
Received quality bonus	0.8	.50
Case type[a]		
Osteoarthritis	–10.1	<.001
Asthma	–6.9	<.001
Pain	–8.4	<.001
Second case of type	6.4	<.001

CME[b]	0.5	.84
Participation ≥6 rounds * CME	–0.6	.84
Constant	74.7	<.001

[a]Reference case type: diabetes.

[b]CME: Continuing Medical Education.

Reduction in Variability of Care

Overall, we found a 9.2% reduction in variation between the first and second cases for each case type (*P*=.07). There were different levels of reduction by case type. For example, the relative standard deviation decreased by 37.0% (*P*<.001) in the diabetes cases. When we disaggregated this further, the decreased variation was split fairly evenly between the treatment domain, where the standard deviation decreased by 34.1% (*P*<.001), and a 33.1% reduction was observed in the diagnostic domain (*P*<.001). Variation decreased between the OA and asthma case pairs, but not between the pain cases. In the OA cases, we found a 12.5% relative decrease in variation (*P*=.14), and in the asthma cases, we saw a 15.9% decrease (*P*=.08).

Quality of Care Improvement Overall and by Case

In the first week of the project, the average score was 77%. When we compared changes in scores among the different case pairs over time (ie, diabetes, OA, asthma, and pain; see Table 3), we found that providers performed 1 to 10 percentage points better in the second case compared to the first. These improvements were statistically significant for patients with diabetes, OA, and asthma but not for the pain case pair. When we looked at the mean scores for the OA and asthma case pairs, we saw a significant increase in the mean scores (Table 3), with the OA case scores improving by 7.6% (*P*=.003) and the asthma scores improving by 10.7% (*P*<.001).

Table 3. Summary of QualityIQ results.

Case type and week	Maximum total score	All providers			*P* value
		n	Mean total score	Percentage of maximum score, mean (SD)	
Diabetes mellitus					<.001
1	350	120	272	77.6 (14.6)	
7	350	74	301	85.9 (9.2)	
Osteoarthritis					.003
2	270	85	185	68.5 (16.5)	
4	330	76	251	76.1 (14.6)	
Asthma					<.001
3	260	81	184	70.8 (15.1)	
6	350	65	285	81.5 (12.7)	
Pain					.73
5	320	72	236	73.7 (12.8)	
8	310	65	231	74.5 (15.9)	

Improvement in MIPS-Related Measures

We found that baseline performance on the specific MIPS-related scoring items ranged from 21% for screening and brief counseling for unhealthy alcohol use to 100% for prescribing high blood pressure medication (Table 4). In comparing the two study arms, as well as family medicine versus internal medicine providers, we found no overall differences between the two groups. There were instances of significance, which might be expected with a subanalysis; for example, the CME arm was more than twice as likely (odds ratio [OR] 2.2, 95% CI 1.2-3.8) to order pneumococcal immunization than the non-CME arm, and internal medicine providers were half as likely (OR 0.5, 95% CI 0.3-0.8) to screen for depression.

Not surprisingly, measures with baseline performance above 80% showed minimal improvement in subsequent cases. These high-performing measures appeared to be well-established items in primary care practice, such as influenza immunization, colorectal cancer screening, and statin therapy. By contrast, MIPS-related scoring items with baseline performance <80% demonstrated strong and statistically significant improvements through serial measurement and feedback. Notable examples include a 22% increase in diabetic eye examination referrals (P<.001), an 11% increase in depression screening (P<.001), a 19% increase in appropriate identification of blood pressure goals (P=.04), and a 33% increase in evidence-based asthma medication recommendations (P<.001). Pneumococcal vaccination for older adults was the lone exception; it started at 72% in the baseline case but did not demonstrate a significant improvement (P=.34) in the 3 subsequent cases that included this care decision.

Physician Survey Results

After the 8 weeks of the project were complete, we asked the physicians about the usefulness of this approach. Of the 120 participants, 62 responded (a 52% response rate). 89% rated the overall quality of the material as good or excellent; 76% reported that they plan to do something in differently in their practice based on what they learned in the cases and the feedback. In addition, participants rated their satisfaction with the gamified weekly leaderboard at 4.1 out of 5.0 on a Likert scale. Importantly, the participants gave the project a net promoter score (NPS) of 59, indicating a strong preference that they would recommend the program to their primary care colleagues.

Discussion

Principal Results

Finding effective tools that reduce the variation in clinical practice has been challenging. Traditional CME tools have not shown knowledge retention, and scalable engagement has proven difficult to implement [17,18]. Recent studies have shown that active case-based learning and more interactive techniques, gamification, and deliberate practice show promise in boosting physician engagement, enhancing mastery learning, and improving clinical care quality [23,28-30]. Reducing practice variation and increasing the quality of care patients receive may be most urgently needed in primary care, where the high volume of patients and large breadth of conditions managed are particularly manifest.

This study, which introduced the QualityIQ tool to reduce practice variation, had a few notable findings. Participation rates were high over multiple exposures, with 66% of participants

completing at least half of the weekly cases. This is significant because participation was voluntary and offered without any emoluments beyond gamification and recognition on an anonymous leaderboard. The findings also suggest that physicians are interested in efficient and engaging tools that help providers stay abreast of the latest guidelines. Interestingly, the availability of CME and MOC credits had no impact on recruitment into the activity or on performance in the cases, although once a participant joined, they were more likely to complete more cases if they were randomized to CME. We believe that the proliferation of web-based CME opportunities means that fewer physicians need to seek out CME opportunities.

The most significant finding from our study is that iterative measurement, feedback, and remeasurement over multiple rounds of engagement led to significant reductions in care variation (variation reduction by case type: asthma: –15.9%, P=.08; osteoarthritis: –12.5%, P=.14; diabetes: –37.0%, P<.001). There were also broad-based improvements in care decisions from one case to the other (by case type: asthma: +15.1%, P<.001; osteoarthritis: +11.1%, P=.003; diabetes: +10.7%, P<.001). There was no decreased variation or improvement in the pain management cases, which we attribute to two factors: (1) the pain case pairs were too clinically dissimilar (headache and low back pain), and (2) the established clinical guidelines for pain management are less robust that for the other case types. This lack of findings in the pain case type is a strong indicator that the improvements seen in the other case pairs was not simply a "learning effect" bias, wherein participants simply became accustomed to the format.

The specific MIPS-measured care decisions were assessed across multiple cases and also showed improvements with multiple exposures. These improvements extended across preventive and treatment clinical areas, and the measures with the lowest baseline performance showed the strongest improvements. MIPS measures that were adhered to less than 80% of the time at baseline specifically improved between 11% and 33% (P<.05). These may be especially important for commonly overlooked items (eg, depression screening) and new items where the guidelines have changed recently (eg, zoster vaccination). Pneumococcal immunization was the outlier, not improving over time from its baseline performance of approximately 70%. This may reflect disagreements with the guideline-based recommendations, which were subsequently updated by the US Centers for Disease Control and Prevention Advisory Committee on Immunization Practices in June 2019, after completion of our data collection [31].

Practice improvement tools only have impact if they are welcome and adopted. Accompanying these improvements, we found corroborating self-reports of practice change among the physician participants and enthusiastic reception of the tool, with an NPS of 59. The NPS is indicative of a user or client's experience. Users are first asked to rate how likely they are to recommend a service to others. The NPS is then determined by determining the difference between the percentage of promoters (satisfied clients who give a score of 9-10) and the percentage of detractors (dissatisfied clients who gave a score of 0-6). A score above zero can be considered a good score, meaning there are more promoters than detractors, and a score above 50 is considered excellent [32]. In addition, the gamified leaderboard allowing peer-to-peer comparisons using pseudonyms was well received by participants. Another noteworthy finding, given concerns that web-based or digital tools may not reach older physicians, is that physicians over the age of 55 years performed as well as other providers, suggesting that the approach may be broadly applicable to practicing PCPs at various stages of their career.

Limitations

There are limitations to this validation study that are worth noting. Although an impressive 76% of participants reported making changes to their practice based on their participation in the QualityIQ cases and feedback, the study was not designed to interrogate practice or patient-level records to validate these improvements. This important work will be left to future studies. In addition, this 8-week curriculum covered a number of cases typically seen in primary care, but it did not include an exhaustive range of high-priority topics. This could be addressed through longer-term studies, potentially in partnership with health systems or physician groups. The project was designed to simulate actual practice decisions through simulations rather than create a fully validated examination. As such, questions formulated around areas of clinical relevance were tied to typical practice patterns. Psychometric validation of the questions was not performed but could be a priority for future academic research applications of the tool. In addition, although PCPs play a critically important role in quality improvement, there are significant opportunities to improve care quality among specialist physicians, medical trainees, nurses, and other health care professionals. Future work will elucidate the impact of this engagement model in these other settings.

Conclusions

In recognition of the vital role of primary care, multiple programs from government and nongovernment agencies have prioritized primary care practice improvement as essential to care transformation efforts to improve care quality and value. In this study, we have shown that short case simulations delivering real-time personalized feedback and gamified peer benchmarking are very well received by practicing primary care physicians and lead to significant improvements in evidence-based care decisions. Importantly, as the QualityIQ scores increased, the unwarranted variation between providers decreased, which is a "holy grail" in efforts to build high-quality, high-reliability primary care networks. As a web-based, scalable engagement tool, this model may be of interest to health systems, payers, policy makers, patient advocacy groups, and life science companies looking to collaborate with providers in practice change efforts to improve the quality, value, and consistency of care.

Abstract

Background: The COVID-19 pandemic restricted everyday life during 2020-2021 for many people worldwide. It also affected alcohol consumption patterns and leisure activities, including the use of social media.

Objective: The aim of this study was to analyze whether social media use predicts increased risky drinking over time and during the COVID-19 pandemic restrictions in particular.

Methods: This 5-wave longitudinal survey study, based on a nationwide sample of workers, was conducted in Finland in 2019-2021. A total of 840 respondents (male: 473/840, 56.31%; age range 18-64 years; mean age 43.90, SD 11.14 years) participated in all 5 waves of the study. The outcome variable was risky drinking, measured using the 3-item Alcohol Use Disorders Identification Test (AUDIT-C). Multilevel linear hybrid modeling enabled the investigation of both within-person and between-person effects. Predictors included social media use and communication, involvement in social media identity bubbles, psychological distress, and remote working. Controls included sociodemographic factors and the Big Five personality traits.

Results: Increased involvement in social media identity bubbles was associated with an increase in risky drinking behavior. Of all social media platforms examined, online dating app use was associated with riskier use of alcohol over time during the COVID-19 crisis. Daily social media communication with colleagues about nonwork topics was associated with risky drinking. Female gender, younger age, university education, nonindustrial occupational field, conscientiousness, agreeableness, and neuroticism were associated with lower levels of risky drinking.

Conclusions: Social media use during a pandemic carries some risks for alcohol consumption. Involvement in social media identity bubbles and online dating are risk factors for excessive drinking during the COVID-19 pandemic.

Introduction

The COVID-19 pandemic has remarkably changed everyday life for people worldwide. Restrictions placed on social gatherings, public events, bars, and restaurants are likely to affect peoples' drinking habits [1,2]. Researchers have argued that the COVID-19 crisis has put home drinking in focus more than ever before [3,4]. Recent studies have reported increased drinking during the COVID-19 pandemic [5-8]; however, few cross-sectional studies have reported both a decrease as well as no change in drinking [9-11]. Thus far, only a few studies have been based on longitudinal samples [1,6,7,12,13]. Additionally, it seems that individuals react to the COVID-19 crisis differently, and those facing emotional worry and distress are

especially at risk for increased drinking [1,9,14-18]. There might be specific risk factors associated with increased drinking during the COVID-19 pandemic, and the role of social media in drinking, in particular, calls for attention.

Different forms of social media have become a central part of communication and interaction among people across the world [19-21]. Social media has evolved through a transformation from Web 1.0 society to Web 2.0 society, with web-based global services enabling individuals, communities, and organizations to engage, produce, co-create, modify, and share individualized user-generated content, as well as interact, collaborate, and manage their social networks on the internet [21,22]. Social media has numerous advantages, such as quick transmission of information and fostering social connectedness [23,24]. However, social media use also has downsides, and previous research has established a relationship between social media use and higher alcohol consumption [25,26], which has been investigated particularly among young users and college students [27-33]. Furthermore, it seems that some social media apps are more popular among risk drinkers. For example, studies on Tinder users have shown that they drink more than nonusers do [34-36]. Dating app users are also more likely to engage in hookups involving alcohol use [37,38].

The underlying mechanisms between social media use and related alcohol use are not entirely known, although previous studies suggest that perceived drinking norms and exposure to alcohol content and marketing might be possible factors [25,39-41]. A meta-analysis showed that exposure to and engagement with alcohol-related content on social media were associated with higher self-reported drinking and alcohol problems among adolescents and young adults [42]. Individuals' attitudes and positive alcohol-related cognitions are motivational determinants of alcohol use [39]. Moreover, social media has been argued to be a source for social influence altering peer-drinking norms [32]. Drinking-related content on social media has become common for some users during the pandemic, and it has potential to lead to increased drinking [43].

Research on social media identity bubbles (ie, social cliques) shows that people are drawn toward similar-minded individuals with whom they identify strongly and share information [21,44,45]. Thus far, identity bubbles based on drinking during the COVID-19 pandemic have not been investigated. It is likely that in the absence of regular social activities and places to drink, people engage in drinking while interacting with their friends and colleagues on the internet. Social media is known to induce the development and duration of web-based social drinking events for normal and risky drinkers, enabling large gatherings of groups regardless of their location and prior familiarity [25]. Social media apps may promote users to find other similar-minded individuals to drink with at private parties, although this practice is not encouraged by health officials during the pandemic [46].

There are likely to be major differences in drinking during the COVID-19 pandemic at the individual level. Although the ongoing pandemic has been reported to have a negative impact on the mental well-being of people in Europe [47,48], it seems that mental health of the Finnish working population did not decline dramatically during the COVID-19 crisis, probably due to the relatively mild course of the pandemic in Finland [49]. Nevertheless, previous studies have shown that, for many people, lockdowns and changes in work conditions, with the expansion of remote work, have been associated with increased psychological distress [1,24,50,51]. In turn, psychological distress has been linked to an upsurge in alcohol use [1,52,53].

According to pre-pandemic studies, younger people and men are more likely to be risky drinkers [54-56]. Some studies have found similar connections during the COVID-19 pandemic for men [8,12,17,57] and people under 30 years of age [1]. However, female gender and younger age have been associated with both an increase and decrease in drinking [5,8,9,17,58]. The rise in drinking also varies across industries; for example, business, communication, and technology sector employees, as well as public administration employees, have reported increased drinking [1]. Higher education has been linked with increased drinking [58]. Poor financial situation has been associated with increased drinking [16,59], but also with reduced drinking [9]. A European study found that changes in drinking patterns were associated with financial stress, particularly among high-income groups—a decrease in drinking was observed among those reporting no financial stress and an increase in drinking was noted among those reporting financial distress [10]. People with conscientious personality characteristics were less likely to increase drinking during the COVID-19 crisis [1].

This longitudinal study focused on analyzing risky drinking behaviors before and during the COVID-19 pandemic restrictions in Finland. The first COVID-19 case in Finland was reported in January 2020, and the country reacted to the rising worldwide crisis in March 2020 by placing several restrictions: large public events were cancelled and recommendations for remote work were implemented [60]. On March 16, 2020, a national state of emergency was declared. Following the new emergency legislation, bars and nightclubs were forced to close, and restaurants were only allowed to sell food and low-alcohol beverages (eg, beer) to go. Finland does not allow alcohol to be delivered to homes, but monopoly stores and supermarkets were open as usual. The state of emergency was lifted in mid-June 2020; however, new restrictions were implemented again in October 2020. These restrictions concerned large public events, limiting the amount of people allowed to gather and the hours of operation of bars, nightclubs, and restaurants. The emergence of the new Delta variant of SARS-CoV-2 presented challenges to the existing guidelines. Subsequently, a state of emergency was declared again in the beginning of March 2021, leading to the closure of bars and nightclubs, and restaurants were only allowed to sell food and low-alcohol beverages to go. The second state of emergency lasted until April 27, 2021. The restrictions for bars, nightclubs, restaurants, and cultural events were gradually eased up during summer and autumn 2021. The recommendation for remote work was in place until October 15, 2021.

This longitudinal study aimed to analyze risky drinking behaviors before and during the COVID-19 pandemic restrictions in Finland. The research questions were (1) How did alcohol use change during the COVID-19 pandemic restrictions? (2) Do social media–related factors predict alcohol

use over time? (3) Are psychological and social factors, such as psychological distress, remote working, and personality, associated with drinking?

Methods

Participants

The longitudinal *Social Media at Work in Finland Survey* study started in Finland in mid-March 2019, and data were collected at 6-month intervals. A total of 5 waves were collected from Finnish employees. The baseline survey data collection commenced in mid-March 2019 (time point 1 [T1]; N=1817), with a response rate of 28.3%. The same participants were contacted for the follow-up surveys in mid-September 2019 (T2; n=1318), mid-March 2020 (T3; n=1081), mid-September 2020 (T4; n=1152), and mid-March 2021 (n=1018). The third survey was sent only to those who had responded to the second survey, whereas the fourth and fifth surveys were sent to all original respondents. Of the original 1817 survey respondents, 840 (46.23%) participated in all 5 surveys.

The survey was designed to represent the Finnish working population. The survey was conducted in Finnish, and responses were collected from all areas of mainland Finland. All participants were working at T1, and they were from various major occupational fields (see Multimedia Appendix 1 for details). Comparison of T1 participants to official statistics on Finnish workers provided by Statistics Finland showed that data collection was successful. We found no major deviations in sociodemographic factors, including age, gender, and geographical area [61-63]. The sample was similar to the official census data in other ways as well. Although official census figures are not available for the working population only, the proportion of excessive drinking in our sample was close to national statistics data for the 20-64 age group (ie, 30.35% male and 19.59% female participants in our sample vs 39% men and 24% women in the national population) [64]. Among the Finnish population of the 16-89 years age group, 58% used Facebook (vs 79.31% in our T1 sample), 39% used Instagram (vs 52.01% in our T1 sample), and 13% used Twitter (24.49% in our T1 sample) [65]. These differences are explained by the fact that our T1 sample included only workers aged 18 to 65 years.

Nonresponse analysis between those who responded to all 5 study waves (n=840) and those who responded only to some waves (n=977) showed that the final sample included slightly older respondents and more male participants. However, we found no differences in other variables included in this study, such as risk drinking, between those who had participated in all 5 surveys and others. In other words, dropout from the survey is not associated with our main points of interest. Our final sample is very close to the official census figures provided by Statistics Finland in terms of mean age (43.90 years in our sample vs 41.81 years in the Finnish population), gender (56.31% male participants in our sample vs 51.85% in the Finnish population), and university-level education (47.74% in our sample vs 42.46% in the Finnish population) [62,63].

The study protocol was reviewed and accepted by the Academic Ethics Committee of the Tampere region (decision 90/2018). All participants agreed to voluntarily participate in the web-based surveys, and they were informed about the purpose of the study and data processing procedures. Data collection was carried out in collaboration with Norstat, a data solutions provider.

Measures

Drinking

We used the 3-item Alcohol Use Disorders Identification Test (AUDIT-C) to measure risky drinking. AUDIT-C is a widely used screening tool for excessive drinking [66-68]. AUDIT-C is considered to perform almost as well as the full 8-item AUDIT as a screening tool for risky drinking [68]. Three items measure frequency of drinking, units of alcohol per drinking occasion, and the frequency of heavy drinking. Each question has multiple response options, with risk points from 0 to 4, and the scale ranges from 0 to 12. A higher score indicates a higher level of risk drinking. The scale showed good internal consistency among time points (T1: α=.75, T2: α=.73, T3: α=.76, T4: α=.76, and T5: α=.77; see Table 1 for details). Our models used AUDIT-C as a continuous variable. We also report the proportion of excess users, using a cutoff of ≥6 points for men and ≥5 points for women [64].

Table 1. Descriptive statistics of the main study variables.

Outcome variable	T1	T2	T3	T4	T5
Risky drinking, AUDIT-C score (range 0-12), mean (SD)	3.83 (2.50)	3.80 (2.44)	3.75 (2.51)	3.73 (2.47)	3.59 (2.51)
Continuous predictors (range 0-1), mean (SD)					
Psychological distress	0.36 (0.17)	0.34 (0.16)	0.34 (0.15)	0.34 (.15)	0.34 (0.16)
Social media identity bubble	0.45 (0.17)	0.46 (0.17)	0.46 (0.17)	0.47 (.16)	0.46 (0.17)
Categorical predictors (code 0/1), %					
Online dating app use (eg, Tinder)	10.12	9.17	9.88	8.81	9.76
Daily social media communication with colleagues about nonwork topics	10.95	9.40	11.31	9.64	9.52
Social media use several times a day	35.00	34.29	38.69	38.57	39.64
Remote work (≥3 days a week)	5.00	4.88	10.48	22.62	30.71

Psychological Distress

We used the 12-item General Health Questionnaire (GHQ-12) to measure psychological distress [69-72]. All 12 items concerning general mood and psychological strain have 4 answer options, rated on a Likert scale, ranging from very positive (0) to negative (3). The total scale ranged from 0 to 36, where higher scores indicate higher psychological distress. This scale was transformed to a scale of 0 to 1. The internal consistency of the scale was *excellent* at all time points (T1: α=.92, T2: α=.90, T3: α=.90, T4: α=.91, and T5: α=.92).

Social Media Identity Bubble

We measured involvement in social media identity bubbles using the 6-item Identity Bubble Reinforcement Scale (IBRS-6) [44]. Involvement in identity bubbles concerns strong social identification, homophily, and reliance on information from others on social media. Respondents were asked to respond to statements such as "On social media, I prefer interacting with people who share similar interests with me," with response options ranging from 1 (*does not describe me at all*) to 7 (*describes me completely*). The original scale ranged from 6 to 42, but we transformed it to a scale of 0 to 1. The internal consistency of the scale was *good* at all time points (T1: α=.84, T2: α=.83, T3: α=.83, T4: α=.83, and T5: α=.85).

Use of Social Media Platforms

The use of different social media platforms and apps was determined by asking the study participants questions about their general use of social media ("How often do you use the following social media platforms?") and their use of social media for work purposes ("How often do you use the following social media platforms for work purposes?"). Both questions were followed by separate items for different social media apps and internet services, such as Facebook, Instagram, Twitter, YouTube, LinkedIn, Microsoft Teams, and "Dating apps" (eg, Tinder). Answer options included "I don't use it," "less than weekly," "weekly," "daily," and "many times a day." All commonly used apps were first analyzed separately by using dummy variables for weekly users. In the final models, we used a dummy variable for use of online dating apps (0=no use and 1=at least sometimes). Sensitivity analyses were performed for weekly and daily users of online dating apps. The models also included a variable for general social media use. This variable was combined from the most used social media platforms (Facebook, Instagram, Twitter, or YouTube), and the dummy variable was created on the basis of social media use several times a day (0=less often than several times a day and 1=several times a day).

Daily Social Media Communication With Colleagues About Nonwork Topics

We used a single-item measure for daily social media communication with colleagues about nonwork topics: "How often do you use social media to keep in touch with your colleagues or work community regarding nonwork-related matters?" Answer options included "I don't use it," "less than weekly," "weekly," "daily," and "many times a day." A dummy variable was created indicating those communicating with their colleagues informally at least once a day. The measure was previously validated with two Finnish cross-sectional samples [23,24].

Remote Work

We measured remote work with a question on whether respondents were working remotely. Those respondents who indicated that they were working remotely at least 3 days a week were considered remote workers in this study.

Control Variables

Control variables included gender, age, education (MA degree or higher), and occupational area (industrial sector vs others). Gender included options for male, female, and other gender. Very few participants selected *other gender*, and none were among those who had participated in all waves (n=840). Hence, gender was used as a dummy variable (0=male, 56.31%; 1=female, 43.69%). Information on participants' education was obtained via a question including 7 categories (see Multimedia Appendix 1 for details). A dummy variable was created to indicate those who have a master's degree or higher from a university (0=no, 75%; 1=yes, 25%). For occupational field, we used the list of International Standard Industrial Classification of All Economic Activities (see details about the 7 broader categories in Multimedia Appendix 1). We used a dummy variable indicating the industrial area of workers (0=no, 70%; 1=yes, 30%) as a control in our analysis.

We used the 15-item Big Five Inventory for personality [73]. All items had responses ranging from 1 to 7, leading to 5 scales ranging from 3 to 21. These were transformed to a scale of 0 to 1 for the models: openness (mean 0.70, SD 0.16), conscientiousness (mean 0.75, SD 0.15), extroversion (mean 0.64, SD 0.21), agreeableness (mean 0.69, SD 0.14), and neuroticism (mean 0.56, SD 0.17). Internal consistency of the traits varied from acceptable (openness: α=.69; conscientiousness α=.67; agreeableness: α=.56; and neuroticism: α=.71) to good (extroversion: α=.87).

Statistical Analyses

Descriptive results of the study are reported in Table 1 and the text. We provide information about general changes in risky drinking during 2019-2021. The main analyses focus on longitudinal predictors of risky drinking using linear multilevel hybrid models. With hybrid models, it is possible to estimate the within-person effect of time-variant variables, while simultaneously considering the between-person effects. Hybrid models combine the strengths of random-effects and fixed-effects approaches and address their shortcomings [74,75]. We ran the hybrid models with the xthybrid command in Stata (version 16.1; StataCorp) [75].

In our models, all main time-varying variables had both within-person and between-person effects. Within-person effects show how changes in predictors over time are associated with the change in the outcome variable. Between-person variables show group differences between individuals. The models also included several between-person control variables.

We first focused on analyzing within-person and between-person effects of social media app use on risky drinking. We performed analyses on the use of such apps, as well as on weekly and daily

use, when possible. The full model reporting our main findings included only those social media apps that were found relevant during this analysis. Different sensitivity analyses were performed, and we also checked interactions with COVID-19 time points (T3-T5) to determine whether some effects were stronger or different during the pandemic.

Results

Descriptive results showed changes in risky drinking measured were relatively small during the COVID-19 time points examined (T3-T5) compared to the pre-pandemic time points (T1-T2). Drinking decreased slightly, especially at T5 (see Table 1). The proportion of excessive drinkers (AUDIT-C score ≥6 for men and AUDIT-C score ≥5 for women) decreased slightly, from 25.24% (212/840) at T1 to 23.57% (198/840) at T5. Among male participants, no change was reported at all between T1 and T5, with 30.87% (146/473) reporting excessive drinking at both time points. However, excessive drinking among women declined from 17.98% (66/367) at T1 to 14.17% (52/367) at T5.

Our results showed that the most used social media apps were not strongly associated with risky drinking (see Multimedia Appendix 2 for details). Weekly use of Yammer had a small within-person effect (B=0.22; SD 0.11; 95% CI 0.01, 0.46; *P*=.04). Use of online dating apps (eg, Tinder) was strongly associated with risky drinking in all models. In particular, between-person effects were strong for users in general (B=1.52; SD 0.34; 95% CI 0.85, 2.19; *P*<.001), weekly users (B=1.85; SD 0.49; 95% CI 0.88, 2.81; *P*<.001), and daily users (B=2.06; SD 0.80; 95% CI 0.50, 3.62; *P*=.02) in models adjusting for age and gender. Therefore, of all the different social media apps, online dating app use was included in our final model.

Analysis based on the full hybrid model showed that of the within-person predictors, only involvement in social media identity bubbles was significantly associated with risky drinking (B=0.32; *P*=.04; see Table 2 for details). We found robust effects on some between-person variables. Online dating app users were more engaged in risky drinking than nonusers were (B=1.33; *P*<.001). Additionally, those respondents who had daily social media communication with colleagues about nonwork topics drank more than others did (B=0.96; *P*=.005). Women (B=−1.35; *P*<.001) and those with an MA degree or higher from university drank less than others did (B=–0.41; *P*=.02). Older age was associated with higher risky drinking (B=0.02; *P*=.01). Workers in the industrial sector drank more than others did (B=0.40; *P*=.02). Lower conscientiousness (B=−1.41; *P*=.01), lower agreeableness (B=−1.55; *P*=.005), and lower neuroticism (B=−1.17; *P*=.04) were associated with higher drinking. In addition, the full model shows that participants drank less during the COVID-19 era than they previously did (B=–0.13; *P*<.001).

The last part of our analysis aimed at reviewing whether these within-person and between-person effects were stronger during the pandemic. This analysis showed that the within-person effect of Tinder use was observed during the pandemic (B=0.29; SD 0.12; 95% CI 0.05, 0.53; *P*=.02). Other relevant interactions with time were not observed.

Table 2. Multilevel linear hybrid regression model showing within-person and between-person effects on drinking.

	B	Robust SE (B)	95% CI	*P* value
Within-person variables				
Psychological distress	−0.02	0.17	−0.35 to 0.32	.92
Social media identity bubble	0.32	0.15	0.02 to 0.62	.04
Use of a dating app (eg, Tinder)	0.16	0.09	−0.02 to 0.34	.08
Use of social media several times a day	−0.01	0.05	−0.12 to 0.09	.82
Daily social media communication with colleagues about nonwork topics	−0.01	0.06	−0.13 to 0.11	.88
Remote work	−0.11	0.05	−0.21 to 0.00	.04
Between-person variables				
Psychological distress	0.56	0.71	−0.83 to 1.95	.43
Social media identity bubble	−0.28	0.65	−1.54 to 0.99	.67
Use of a dating app (eg, Tinder)	1.33	0.33	0.68 to 1.99	<.001
Use of social media several times a day	0.16	0.20	–0.23 to 0.56	.42
Daily social media communication with colleagues about nonwork topics	0.96	0.34	0.29 to 1.64	.005
Remote work (≥3 days a week)	−0.19	0.33	−0.83 to 0.45	.57
Controls				
Female	−1.35	0.16	−1.66 to −1.03	<.001
Age	0.02	0.01	0.00 to 0.03	.02
MA degree or higher	−0.41	0.17	−0.74 to –0.08	.02
Industrial sector	0.40	0.17	0.05 to 0.74	.02
Openness	0.00	0.52	–1.01 to 1.02	>.99
Conscientiousness	−1.41	0.57	−2.53 to −0.29	.01
Extroversion	0.73	0.45	–0.15 to 1.61	.10
Agreeableness	−1.55	0.55	−2.62 to −0.47	.005
Neuroticism	−1.17	0.56	−2.26 to −0.08	.04

Discussion

Principal Results

This longitudinal, 5-wave study investigated changes in risky drinking in 2019-2021. Longitudinal analysis showed that stronger involvement in social media identity bubbles was associated with higher risky drinking over time. A within-person effect of online dating app use (eg, Tinder) was also found, but only during the COVID-19 pandemic. This finding suggests that unusual circumstances have perhaps led to unusual and risky drinking habits. Online dating app users also drank more than others. Moreover, we found that daily social media communication with colleagues about nonwork topics was associated with risky drinking. Altogether, our results suggest that people engaged in drinking as part of involvement in web-based social bubbles. Furthermore, as dating in bars, clubs, and restaurants was not possible during the COVID-19 pandemic, dating apps such as Tinder were considered an alternative. These dating activities were found to be associated with risky drinking, despite the closure of bars.

Comparison With Prior Work

Previous cross-sectional studies conducted during the COVID-19 pandemic have reported decreased drinking, especially in Europe [10], but increased drinking has also been reported [5-8]. Our results indicating a slight decrease in risky drinking are not surprising, because during spring of 2020 and 2021, there were severe restrictions on bars and restaurants, limiting the possibilities for social drinking. Previous longitudinal studies have shown that drinking less is related to lower access to typical drinking locations [10,12,58].

Our finding on the within-person effect of involvement in social media identity bubbles offers an interesting contribution to the literature. Previous studies have especially considered social media postings as motivational determinants of alcohol use [39] and generally discussed exposure to drinking cues on social media websites [25,42]. Our findings expand this notion by considering the potential effect of engaging with similar-minded individuals. We further noted that individuals communicating with colleagues about nonwork-related issues tended to drink more. As our models controlled for personality, we believe these findings reveal something interesting about the role of social

media in the context of drinking during the COVID-19 pandemic.

We discovered that increased use of dating apps was associated with increased risky drinking during the pandemic. Our longitudinal evidence supports previously noted findings that dating app users drink more than nonusers, and this pattern increases during their dates [34-36]. It is likely that alcohol is consumed during the dates, despite bars being closed. Our study contributes to the growing number of studies on risks and risky behavior related to dating apps [76,77].

Our findings further showed that female gender, younger age, university education, nonindustrial occupational field, conscientiousness, agreeableness, and neuroticism were associated with lower levels of drinking. These results reflect the findings of previous studies [1,58].

We found no longitudinal evidence on the effect of psychological distress on risky drinking during the COVID-19 pandemic. This finding contrasts previous findings on the role of psychological distress and mental well-being in drinking during the pandemic [9,14-18]. One potential reason for this might be that in global comparisons, the COVID-19 situation was manageable in Finland during 2020 and spring 2021. For example, a report by *Der Spiegel* indicated that Finland had coped the best with COVID-19 in comparison with 154 other countries [78]. It is feasible that spring 2020 only presented a major stress for people, reflecting increased drinking among those who were distressed [1]. It is, however, quite early to estimate potential long-lasting effects of the COVID-19 pandemic on drinking levels, as the crisis is still ongoing.

Limitations and Strengths

Our study was limited to Finland and its working population. Hence, some risk drinking groups, including full-time students and retired elderly people, were not part of the study. The results only cover the timeframe of 2019-2021, and it is too early to estimate how the crisis and drinking will further develop. Our results are limited to self-reported information on drinking. Despite these limitations, a major strength of our study is the use of multi-wave, longitudinal data. Data collection started before the COVID-19 crisis, enhancing estimation of the effects of the pandemic on drinking. Our data are particularly strong on social media measures, and the response rate for surveys was high. Our modelling strategy used within-between person hybrid models that provide an advanced way of estimating longitudinal effects of independent variables.

Conclusions

This longitudinal study of workers in Finland showed a decrease in risky drinking during the COVID-19 crisis. The main risk factors for increased risky drinking were found to be related to social media use. Involvement in social media identity bubbles was associated with risky drinking over time. Dating app users were more likely to drink more during the pandemic. Moreover, daily social media communication with colleagues about nonwork topics was associated with higher risky drinking. Our results provide significant evidence of the power of social media during unusual times.

The role of social media in drinking should be considered by social media companies such as Tinder to monitor and regulate alcohol-related postings and advertising on their services and promote more healthy ways of social interaction. This is especially essential during a crisis like the COVID-19 pandemic, when social media services present virtually the only possibilities for forming new social relationships due to lockdowns and restrictions on movement. The connection between social media use, involvement in social media identity bubbles, and increase in alcohol consumption are important findings for organizations and policy makers alike. Education and prevention efforts should consider these risk factors and, possibly, be targeted to at-risk groups.

Acknowledgments

This research has received funding from the Finnish Work Environment Fund (Professional Social Media Use and Work Engagement Among Young Adults Project; project number 118055; principal investigator: Atte Oksanen). Data collection was also partly funded by the Faculty of Social Sciences at the Tampere University, Finland. RO is funded by the Finnish Cultural Foundation.
