Abstract

Background: Care policies emphasize deinstitutionalization and *aging in place* in response to demographic changes. Different eHealth technologies are one way to achieve this aim. However, there is a need to better understand older adults' needs for eHealth services, and thus, these health solutions require further exploration.

Objective: The purpose of this systematic literature review is to appraise, synthesize, and summarize the literature on older adults' (aged ≥60 years) eHealth learning and use in real home settings, particularly in rural and remote areas, with a focus on the social and cultural context.

Methods: A systematic search was conducted in January 2020 using 4 academic databases. The studies by means of qualitative thematic analysis to identify the barriers, enablers, and support practices involved in the domestication process were examined. In addition, we identified the various meanings attached to eHealth technologies for older adults living in rural and remote areas.

Results: In total, 31 empirical studies published between 2010 and 2020 were included in this review. A total of 17 articles included participants from rural and remote areas. The most regularly reported barriers related to older adults' learning to use and use of eHealth were health-related difficulties, such as cognitive impairment or impaired hearing. The most reported enabler was the support provided for older adults in learning and use of eHealth. Support mainly comprised older adults' own digital competences, which were distributed with their social network. It was found that eHealth technology is needed for rural and remote areas to facilitate access and reduce logistical barriers to health care services.

Conclusions: The literature review provided information and practical implications for designers, health care providers, and policy makers. On the basis of these findings, eHealth technologies should be easy to use, and adequate support should be provided to older adults for use.

Introduction

Background

The aim of this systematic literature review is to advance the understanding of older adults' (aged ≥60 years) eHealth learning and use during its domestication. The main target is older adults living in rural and remote environments, as they are far removed from traditional health care services [1-4]. According to the World Health Organization, health is understood as "a state of complete physical, mental, and social well-being and not merely the absence of disease of infirmity" [5]. As a general practice, eHealth can be seen as an umbrella concept for different health care services delivered or improved through information and communication technologies (ICTs) [6,7].

On the basis of future demographic changes, the world will face two challenges: a growing care burden per capita and

organizational changes to health care systems [8,9]. To achieve its sustainable development goals, the United Nations [8] has outlined key policy changes that deal with current and future population dynamics. Recommendations include investing in life-long learning, especially digital competences, and promoting healthy aging and long-term care systems to meet the needs of the aging population. Care policy throughout Europe has emphasized deinstitutionalization and *aging in place* to reduce paternalistic care and improve the quality of care [10,11]. Furthermore, previous research in many cultural settings has found that older adults prefer living at home for as long as possible [9].

Theoretical Framework

This study's theoretical framework is built on the concept of *distributed and situated digital competence*, *technology domestication*, and previous research on *barriers and enablers* of technology use. The European Commission's *DigComp 2.0: The Digital Competence Framework for Citizens* [12] defines digital competence as a combination of knowledge, skills, and attitudes related to the use of ICT tools. One competence is the protection of health and well-being, which means, for example, being aware of digital technologies that can be used to enhance social well-being and social inclusion. However, the framework can be criticized for being decontextualized and centered around individuals. Therefore, a socially and culturally oriented approach is followed, and digital competences are understood as the distributed and situated competences of older adults and their social networks [13,14].

The concept of domestication focuses on how technology users and nonusers adopt technologies culturally and socially in their everyday lives [15-17]. The domestication of technology includes four dimensions: appropriation, objectification, incorporation, and conversion. The process starts with appropriation, which does or does not create a relationship with the new technology, and continues to objectification, which is when the technology is given a place at home. Incorporation focuses on the technology's place in and influence over the user's everyday routines. Finally, the technology becomes familiar, and conversion is achieved [15-21]. Central to domestication are the public and personal meanings attached to the technology, which actively transform during the process [19]. Meanings are understood as individuals' thoughts and feelings regarding the technology and how it is seen as part of his or her own cultural context [22,23].

Research into health-related barriers has found that the key reasons older adults avoid ICT adoption are the accessibility of support, their health status, lack of need or interest, functionality, added value, cost, and concerns regarding privacy and trust [24,25]. In the present review, barriers were not understood as insurmountable obstacles but rather as challenges that can be solved. Conversely, the following key enablers influence older adults' use of eHealth: motivation, support, and feedback [26]. In addition, meaningful function and aesthetics are important when older adults adopt technology [27].

Objective

Recent international literature reviews on eHealth and older adults focus on a variety of topics: eHealth access and use from a health equity perspective [28], the facilitators of and barriers to eHealth use [24,26,29], and user involvement in technology design, including eHealth technologies [30,31]. In addition, Cheng et al [32] published a systematic review of eHealth interventions targeted at socially disadvantaged groups, including older adults. However, we still lack a review that examines older adults' eHealth learning and use in real home settings and in a rural context from users' perspectives. The purpose of the present review is to fill this gap by focusing on studies that report barriers and enablers that older adults face when learning to use and while using eHealth technology and how older adults are supported during the process. In addition, what eHealth technology means to older adults in rural and remote areas was examined. In reviewing relevant studies, this research seeks to answer the following questions:

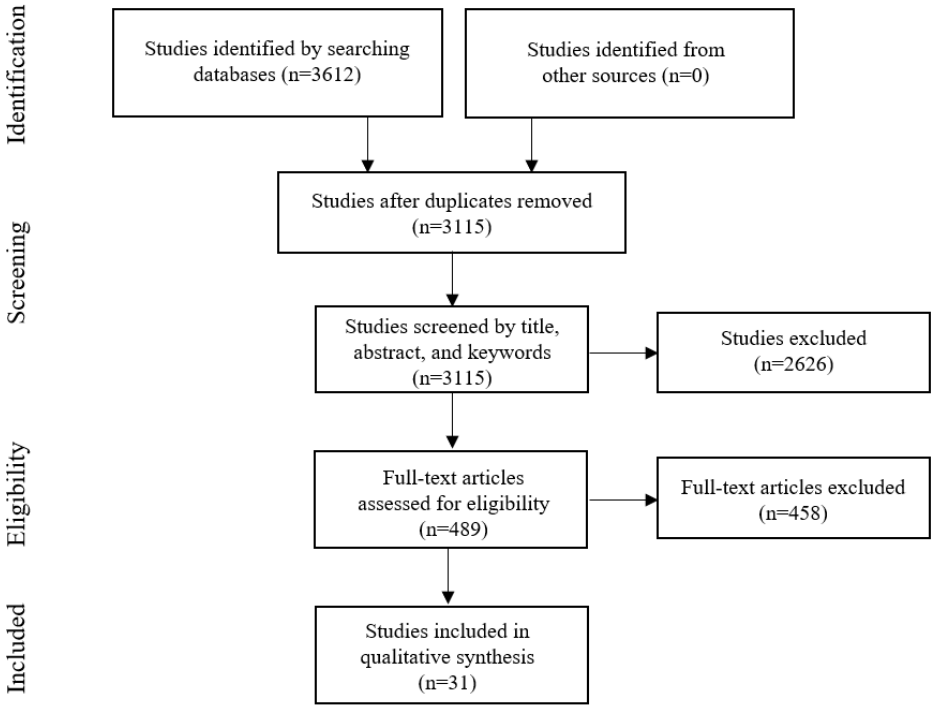
1. What barriers and enablers are related to the learning and use of eHealth technologies in domestication processes among older adults living at home?
2. How are older adults living at home supported in their domestication of eHealth technologies?
3. What are the meanings attached to eHealth technologies for older adults living in rural and remote areas?

Methods

Overview

The methodology follows the standard PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for studies that evaluate health care research [33]. PRISMA includes a 27-item checklist (Multimedia Appendix 1 [33]) and a 4-phase diagram (Figure 1) to help authors ensure clarity and transparency. A systematic literature review was selected "to appraise, synthesize, and summarize" [34] the literature and determine whether further primary research in the area is needed. The entire review process was undertaken by 1 author, and there were no additional authors.

Figure 1. Flow of information through the different phases of the systematic review.



Search Strategy

To begin the search process, the author consulted an information specialist at her university library regarding search phrases and relevant databases. A literature search was conducted in January 2020 and included the following international web-based databases: ProQuest (ERIC—Education Collection, Social Science Database, Applied Social Sciences Index and Abstracts, Sociological Abstracts, and Sociology Database), Ebsco (AgeLine, Academic Search Elite, and CINAHL Complete), Web of Science (Arts and Humanities Citation Index, Social Sciences Citation Index, Science Citation Index Expanded, and Emerging Sources Citation Index), and Scopus (Elsevier). Relevant articles were found using the search terms specified in Textbox 1 and their combinations. An example search string used to search Scopus (Elsevier) can be found in Multimedia Appendix 2. The search was applied to the field title, abstract, and keywords. Although the conversions around eHealth began at the turn of the millennium [6], the review's start date of 2010 was chosen as there has been a lot of change in health technologies over the past decade [35]. The initial database search yielded 3612 papers (n=393, 10.88% from ProQuest, n=394, 10.91% from Ebsco, n=2767, 76.61% from Web of Science, and n=58, 1.61% from Scopus). No articles were included that were identified from sources other than the abovementioned databases.

Textbox 1. Content and search terms of literature search. During the search, some terms were truncated using "*" so the search considers all the results including the first part of the word. For example, by searching learn*, the search also considers terms learner and learning.

Content and search terms

- Older people: *older, senior, elderly, aged people, old age user, elder*
- Rural: *rural, remote, sparsely populated area*
- Use: *education, learn*, competence, digital skill, geragogy, use, reject, active aging, adoption, acceptance, barrier, enabler, facilitator*
- Digital technology: *online, ICT, information, computer, internet, electronic, techolog*, digital, smart, management tool, virtual, mobile, robot, tele*, monitoring, assist*, gerontechology, compliance, reminder, dispens*, video, application, device*
- Health: *health, care, wellbeing, physical, mental, social*
- Home: *aging in place, independent, home, everyday life, living, daily life, domestication*

Study Selection

Figure 1 shows a flowchart depicting how PRISMA was used to select the studies. All articles were exported to Refworks (ProQuest), a reference management system that automatically discards duplicate papers. Of the 3612 papers, the removal reduced the number of papers to 3115 (86.24%). The remaining articles were screened for title, abstract, and keywords to select studies relevant to the research topic. Following the screening of the 3115 articles, a total of 489 (15.7%) articles were obtained. The remaining articles were exported to NVivo 12 (QSR International), a qualitative data analysis software, and the remaining duplicates were manually discarded. Full-text

articles were then assessed for eligibility based on the preliminary inclusion and exclusion criteria.

Finally, full-text articles (31/489, 6.3%) that met the following criteria (Textbox 2) were accepted: published in a peer-reviewed scientific journal; written in English; published between January 1, 2010, and January 22, 2020; had an empirical study design aimed at supporting older adults' use of eHealth technology in real home settings at the user's home; completely or partially focused on technology users' perspectives; had participants with a mean age of 60 years; and included participants who were older adults with or without health conditions. Initially, the aim was to select studies that included only older adults aged >65 years, which is a common age limit for older adults in research [36]; however, because of the low number of studies, the age range was extended to a mean of 60 years. In addition, living in rural or remote areas was a planned inclusion criterion; however, it was modified to living in any area, as not enough studies met the original criterion. However, one research question focused only on studies conducted in rural and remote areas.

Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- Academic paper published in a peer-reviewed scientific journal
- Written in English
- Published between 2010 and 2020
- Had an empirical study design aimed at supporting older adults' eHealth use
- Was located in real home settings at the user's home
- Had participants with a mean age of 60 years
- Completely or partially focused on users' perspectives

Exclusion criteria

- Did not include older adult participants
- Was not conducted in real home settings
- Was conducted in a laboratory or included no user experience with eHealth
- Was a review or theoretical study
- Only had a biomedical or technical perspective

Data Exclusion and Analysis

For the final set of full-text articles, a data extraction sheet was developed (Multimedia Appendix 3 [37-65]). The gathered data included information on article titles, authors, journals, publication years, methods, eHealth technologies, target groups, total number of participants, participant genders and ages, participants' area of residence (eg, rural or remote), and countries of residence. The included articles were analyzed in NVivo 12 using a qualitative thematic approach guided by the concepts of domestication and digital competence. In addition, previous research on the barriers to and enablers of technology use was used. The author thoroughly read and reread the articles and identified 154 subcategories that described significant sentences and phrases concerning the research questions. The obtained subcategories were clustered into 8 upper-level categories to produce a more nuanced understanding.

Results

Study Characteristics

The selected 31 articles were published in 29 different journals representing multidisciplinary research. Of the 31 papers, 16 (52%) were quantitative, 4 (13%) were qualitative, and 11 (35%) were mixed methods studies. Most studies used >1 method; only 16% (5/31) used just one method. The most common qualitative data collection methods were surveys and questionnaires (20/31, 65%) and technical logs (12/31, 39%). The most common qualitative data collection methods were interviews (9/31, 29%) and focus groups (5/31, 16%). The studies were conducted in the following 12 countries: the United States (9/31, 29%), Canada (2/31, 6%), Italy (2/31, 6%), Spain (2/31, 6%), Sweden (2/31, 6%), the United Kingdom (2/31, 6%), France (1/31, 3%), Germany (1/31, 3%), Ireland (1/31, 3%), Lebanon (1/31, 3%), Norway (1/31, 3%), and Switzerland (1/31, 3%). In 19% (6/31) of studies, the country was not identified.

The number of participants ranged from 1 to 4380, although not all were older adults. In all articles, either the mean or median age and SD or the age range was defined. However, in studies in which only the SD and mean or median age were given, it was not possible to strictly count the age of the youngest and oldest participants. In 90% (28/31) of articles, the mean or median age of the technology users was ≥60 years, and in 39% (12/31) of articles, the minimum age was >60 years. Some articles (6/31, 19%) included technology users aged<50 years, and it was possible to separate them from the older adults in the findings. This means that the findings were still based on participants who were aged >60 years or whose mean or median age was ≥60 years. In 42% (13/31) of articles, most participants were women, and in 35% (11/31) of articles, most participants

were men. In 6% (2/31) of papers, female and male participants were equally represented, and in 16% (5/31) of papers, gender was not defined.

All participants used eHealth technologies in real home settings. The eHealth technologies that occurred most frequently were mobile apps (18/31, 58%), monitoring systems (12/31, 39%), web-based platforms (11/31, 35%), assistive technologies (2/31, 6%), and ambient awareness technology (1/31, 3%). No eHealth robots were included in this study. Most technologies were targeted at older adults with different noncommunicable diseases. Of those, the largest target groups were cardiac disease (5/31, 16%), diabetes (3/31, 10%), and cancer (3/31, 10%). In total, 2 technologies were used for older adults with polypharmacy issues and 2 for those in palliative care. In 16% (5/31) of studies, eHealth technologies were aimed at isolated older adults, and in 13% (4/31) of studies, the technology was for older adults with depression, anxiety, or apathetic qualities. In total, 1 eHealth technology was only for healthy older adults, and 5 were for older adults or adults of any age group in general. In some studies, the participants were veterans (4/31, 13%), and in others, they were older family caregivers (4/31, 13%).

Barriers and Enablers in the Domestication Process

Overview

The first research question focused on the barriers and enablers related to the learning and use of eHealth technologies in the domestication process among older adults living at home. Thematic analysis produced 111 subcategories related to these barriers and enablers. The subcategories were clustered into 4 dimensions of the domestication process [15,17]: appropriation (40/111, 36%), objectification (10/111, 9%), incorporation (27/111, 24.3%), and conversion (34/111, 30.6%). A summary of these findings is presented in Tables 1 and 2.

Table 1. Summary of the findings concerning the barriers to learning and use of eHealth technologies among older adults (N=31).

Dimension of domestication and barriers	Papers, n (%)
Appropriation	
eHealth technology	
Lack of connectivity	9 (29)
Technical problems	8 (26)
Difficult to use	6 (19)
Unclear instructions	5 (16)
Cost	4 (13)
Technical limitations	4 (13)
Difficult to learn to use	3 (10)
No feedback	2 (6)
Lack of effectiveness	1 (3)
Lack of technical device	1 (3)
Technology was unexpected	1 (3)
Old age user	
Health-related difficulties	17 (55)
Lack of previous experience	5 (16)
Uncertain with the technology	5 (16)
Irritation or frustration	4 (13)
Lack of motivation or interest	2 (6)
Personal factors	2 (6)

Being female	2 (6)
User feels like an active citizen	1 (3)
Being considered *cool*	1 (3)
Educated or employed	1 (3)
Older age	1 (3)

Appropriation

Of the 31 articles, 30 (97%) reported barriers and enablers in the appropriation phase of the domestication process; this dimension had more barriers than the others. Older users' *health-related difficulties* was the most common barrier in the appropriation phase and the whole domestication process (17/31, 55%). For example, difficulties included cognitive impairment or dementia [37-39] and impaired hearing or vision [40,41]. The most common barriers related to the eHealth technologies themselves were *a lack of connectivity* (eg, a lack of access to fast enough internet connections), which was reported in 29% (9/31) of articles [42,43] and other *technical problems*, which were reported in 26% (8/31) of articles [44,45]. *The usability* of eHealth technology, which included ease of use, was the ruling enabler and was reported in 58% (18/31) of studies [46,47]. *Satisfaction* was also seen as a significant enabler in the domestication process and was reported in 45% (14/31) of studies [53,66]. In addition, *personalization or flexibility* of eHealth technology was reported as an enabler in 42% (13/31) of studies [48,49]. That the technology o*ffered a personal challenge* was reported as an enabler in 3% (1/31) of article [37]; the article reported that if the tasks proposed in a mental training system are slightly above users' capabilities, users' motivation is increased and training outcomes are improved. That the *technology was unexpected* was reported as a barrier in 3% (1/31) of articles [51], and this refers to users feeling they

had received a remote monitoring system unexpectedly without a choice and without knowing what the system was.

Objectification

Objectification was the least-coded dimension, and there was not a big difference between the different subcategories. The *design* of the eHealth technology and its placement in the home were reported as barriers and enablers. As a barrier, design referred to the look of a computer [50] and the weight and size of a remote monitoring system [51]. As an enabler, it was connected to the range of soundscapes provided to the users in an interaction radio [52]. In 3% (1/31) of articles [50], it was found that if a technology is placed *out of the way*, the placement can be a barrier to its use; however, if it is placed where the user spends time, it is used more often. In the Ottenberg et al [51] study, in addition to the weight and size of the system, wiring configurations challenged its placement. Furthermore, *ergonomic challenges*, such as typing or using a mouse, were reported as barriers in 3% (1/31) of articles [40], and this was in the context of a web-based pain management program designed for older adults with chronic pain. The objectification dimension also included barriers and enablers related to data protection and security. Here, the most common barriers were *concerns about security or privacy* [39,51,53,54]. The leading enablers were *technology security or safety* [38,51] and *user privacy* [45,50].

Incorporation

Of the 31 articles, 24 (77%) reported barriers and enablers during the incorporation phase. As reported in 32% (10/31) of articles, the most common enabler was that the eHealth technology was *suitable for everyday life* of older adults. For example, this was evident in how users did not actively think they used the technology [52], were able to use it in a self-selected environment [38,53], and found that it matched their needs [55,56]. A total of 2 equally common barriers, each reported in 10% (3/31) of articles, were that the technology was *unsuitable for everyday life* and that there were *time constraints or power dynamics* in using it, which means, for example, that users had scheduling conflicts [38], were busy [41,53], or expected faster replies via the technology [53]. The reasons the technology was not suitable for users' daily lives were that the users had to change or constrain their behaviors when using it [52], were busy or on holiday [53], and had experienced a stressful life event that caused them to disengage with the service [56].

Conversion

The conversion dimension had more enablers than the other dimensions. The most common enabler in the conversion phase and the entire domestication process was *support practices*, which was reported in 87% (27/31) of articles. The findings are presented in detail in *the Support Practices During Domestication* section below. Regarding social interactions, *social connectedness and belonging* were mentioned as enablers in the learning and use of eHealth technology in 32% (10/31) of studies [44,57]. The common barriers related to social interactions were that older adults had a *need for face-to-face contact* [39,51] and felt a *lack of support* while using the technology [44,51,58].

Regarding society and culture, *cost-effectiveness* was the most common enabler in the conversion phase, as reported in 26% (8/31) of articles. However, it was almost never reported from a user's perspective and was more society driven, providing "huge savings in clinical costs" [59], "significant saves in the health budgets" [60], and "suggesting a cost reduction for the health care system" [46]. In addition, in 13% (4/31) of articles, *cultural relevance* was noted as an enabler, which means, for example, that the users could incorporate their religious or spiritual perspectives into the service [48] or that televisions were used as devices, as they were best integrated into the older adults' lives [37,59].

In addition, o*lder age* and *being female* were reported as enablers and barriers in different articles. For example, 3% (1/31) of articles [60] reported that women needed more assistance using a mobile health app than men, and in 6% (2/31) of articles [53,67], women were more active eHealth technology users than men. Older age was mainly seen as a barrier in cases where older adults needed more help using the technology [60] or used it less than younger people [60-62,67]. However, in 3% (1/31) of articles [60], older patients reported greater improvements in several measures than younger patients. In 3% (1/31) of articles [62], it was reported that *a lower social class* reduced the prevalence of eHealth technology use.

Support Practices During Domestication

To understand how older adults were supported while domesticating eHealth technologies, the thematic analysis produced 25 subcategories related to their learning to use and the use of technology. The subcategories were clustered into two upper-level categories: social network support (22/31, 71%) and nonsocial support (3/31, 10%). Of the 31 articles, 27 (87%) reported that support was provided to users during the domestication process [15,17].

Social Network Support

Social network support was provided in 87% (27/31) of articles. During the learning process at the beginning of domestication, *face-to-face support* was more common than long-distance support. Face-to-face support was provided to users in 45% (14/31) of articles and long-distance support in 13% (4/31) of articles. The most common way to teach older adults was *a training session*, which was used in 42% (13/31) of articles. Training sessions were used to introduce the users to the use of the technology, and it could happen either at users' homes [45,47] or in a clinical setting [38,47]. The training was usually given by technical staff [59], health care professionals [49,63], or the researcher of the study [53]. *Long-distance support* was more common than face-to-face support after initial training. Long-distance support was provided to users in 39% (12/31) of articles and face-to-face support in 10% (3/31) of articles. Long-distance support was mostly provided *via phone*, and it was mainly related to technical issues [59] or questions related to the study [61], although it also took the form of consultation with a health care professional [42] or communication with a peer [38]. In some articles, it was not possible to identify

whether social network support was face-to-face or long-distance.

During the domestication process, eHealth technology users distributed their digital competence [13,14] with the following members of social networks: *spouses, grandchildren, other family members and relatives, family caregivers, peers, friends, health care professionals, coaches, researchers, technical staff,* and *proctors*. Social networks expanded as the domestication process went further. Digital competences were most commonly distributed among health care professionals, such as nurses, therapists, and social workers. This was reported in 48% (15/31) of articles [42,44]. Second, technical staff was mentioned in 23% (7/31) of studies [39,63].

Nonsocial Support

Nonsocial support practices in the learning process were *written instructions* [37,47,49,57,63], *video instructions* [53], and *diaries* [52]. Users owned their diaries before engaging in the study, and their use to support learning was not planned beforehand. Nonsocial support practices were not defined after users passed the introduction phase; however, in 3% (1/31) of articles, users were encouraged to "access the video at any time during the trial" [53]. None of the articles reported the provision of only nonsocial support. Nonsocial support was always connected to social network support.

Meanings of eHealth in Rural and Remote Areas

Overview

The focus of the third research question was on the meanings attached to eHealth technologies for older adults living in rural and remote areas. The terms *rural*, *remote*, and *sparsely populated area* were used to search the databases (Textbox 1) for this literature review. However, in only 55% (17/31) of articles, every participant (12/17, 71%) or part of the participants (5/17, 29%) lived in rural or remote areas. The minimum amount of rural or remote participants per selected article was 13.29%. The thematic analysis produced 17 subcategories of meanings attached to eHealth technologies for older adults living in rural and remote areas. The subcategories were clustered into 2 upper-level categories: needed for rural and remote areas (13/17, 76%) and source of inconvenience and concern (4/17, 24%). The articles defined rural and remote areas as underserved areas with limited access to health care.

Needed for Rural and Remote Area

Of the 17 articles, 14 (82%) reported that different eHealth technologies, such as home telehealth monitoring and videoconferencing for consultation, were needed in rural and remote areas. A total of 2 meanings clearly stood out: first, 71% (12/17) of articles [40,56] reported that eHealth technologies *facilitate access to health care services* for older rural adults; second, 65% (11/17) of articles [48,64] reported that there are *no logistical barriers* to health care services when older rural adults use eHealth technology at home. Other, less commonly reported meanings were *no temporal barriers* [61], *no financial barriers* [48], *supports relationship with care provider* [64], *no physical or physiological stress* [39], *ability to support rural caregivers* [42], *reduces boundaries of home* [50], *reduces feelings of isolation* [44], *ensures equal access to health care services* [41], *increases feelings of security* [44], *no weather-related barriers* [39], and *permits religious or spiritual inclusion* [48].

Source of Inconvenience and Concern

Although eHealth technology was principally seen as needed for rural and remote areas, 24% (4/17) of articles identified sources of inconvenience and concern. Here, the most commonly coded meanings are related to internet connectivity and use. Approximately 18% (3/17) of studies reported that rural areas *lack access to high-speed internet* [40,42,61]. Approximately 12% (2/17) of studies [42,61] noted *cultural differences regarding internet use* in rural areas compared with urban areas. Older adults in rural areas are still uncomfortable using the internet. Approximately 6% (1/17) of studies [45] reported that living in rural areas required *additional equipment*, such as "protectors to protect equipment," and rural participants had to *learn how to reset* the technology "to decrease the need for providers to make a home visit specific to technical support." The latter was the only meaning assigned to learning to use eHealth technology in rural areas.

Discussion

Principal Findings

To advance the understanding of older adults' (aged ≥60 years) eHealth learning and use during its domestication, a systematic literature review of 31 empirical studies published between 2010 and January 2020 was conducted. The aim was to summarize the literature on the barriers and enablers that older adults encounter when learning to use and using eHealth technology and how they are supported in real home settings. The main targets were rural and remote older adults. The key findings of this review confirmed that social networks supporting older adults are important enablers for learning how to use and using eHealth technology. In addition, this review revealed that health-related difficulties often prevent older adults from domesticating eHealth technologies. Various eHealth technologies have been reported as necessary for older adults in rural and remote areas, although some sources of inconvenience and concern related to internet connectivity and use were found.

One of the goals of this review was to find out which barriers and enablers are related to learning how to use and using eHealth technologies in the domestication processes among older adults living at home. The findings were divided into 4 dimensions (appropriation, objectification, incorporation, and conversion) of the domestication process [15,17]. The barriers and enablers are in line with previous similar systematic reviews [24,26]. The accessibility of support and training, usability of the technology, and its suitability for daily life were also stressed in the present review. However, for example, concerns regarding the cost or importance of motivation to use eHealth technologies were not key factors in this review. There was a significant difference between the number of reported barriers (n=48) and enablers (n=63), with enablers being more common. This may be because of a desire to highlight the benefits of eHealth technology in a study, even if unintentionally. The appropriation

dimension had the most barriers, which suggests that the first phase of domestication is critical. Previous research [68,69] has expressed that access and support for older adults using technology, especially in the early weeks of its domestication, may be the most important factor in successful technology adoption. Overall, the studies focused less on the learning process than on the use of technology.

In addition, this systematic review asked how older adults living at home are supported during the domestication of eHealth technology. In most cases, older adults distributed their digital competences with their social networks, which supported the domestication of eHealth technology. The social network included *warm experts* who are "nonprofessional persons who help inexperienced users come to terms with digital devices" [70], such as family members and peers. The network also included formal personnel, such as health care professionals and technical staff. Previous qualitative research related to eHealth learning and use [71] has underlined that there is a need to clarify the role of peer-to-peer support in the domestication of technology. This study revealed that peer-to-peer support has its place in the digital health technology context [38,44,52] as well as in other settings [14]. However, health care professionals were found to be the ones with whom digital competences were most often distributed; therefore, this review argues that digital competences related to eHealth learning and use are not only technical skills but also knowledge and skills related to health care, which is why health care professionals are also needed to support eHealth technology users.

This review's final aim was to better understand the meanings attached to eHealth technologies for older adults living in rural and remote areas. Although the literature includes few studies set in rural and remote areas, this review confirms that eHealth technologies are needed in rural and remote areas for several reasons. eHealth technology is seen as solving many problems related to limited access to health care services, such as logistical, temporal, financial, and weather-related barriers. In addition, eHealth technologies can foster a sense of belonging in older rural residents by reducing feelings of isolation and by connecting them with peers or care providers. Previous research has also shown that ICT services can reduce social isolation and promote social connectivity in older adults experiencing physical and cognitive decline or living in remote areas [3,72,73]. However, the use of eHealth technology in rural and remote areas is hampered by the lack of high-speed internet connections and older adults' lack of comfort in using ICTs. These issues are targets for future development. The findings of this systematic review confirm that the use and nonuse of eHealth technology are related to its fit in older adults' technology-related cultural understanding and the context in which people act and live [13,14].

This review reveals several gaps that suggest directions for future research. First, a stronger focus on older adults' learning processes is required in research on the domestication of eHealth technology. In the literature search, numerous articles focused only on older adults and the use of eHealth technology from a biomedical [74] or technical perspective [75]. They were excluded from the review as they did not focus on the user's point of view. Burholt and Dobbs [2] also found that research on rural aging is dominated by a biomedical perspective. Second, as this review confirmed, eHealth technology is needed in rural and remote areas. Therefore, more studies in these settings are required to better understand the processes of domesticating eHealth technology among older rural residents. Third, research efforts in eHealth technology studies in real home settings are limited. Several studies were excluded from this review as they focused on a communal dwelling [76] or nursing home [77], although the aim of the care policies is aging in place [10], which may be because it is easier to reach older adults and conduct research in organized environments. Finally, methodologically, studies on the domestication of technology were mostly qualitative, and mixed methods studies were most common [18,78]. However, the studies reviewed here were mainly quantitative. Therefore, future qualitative studies on this topic should include the voices of older adults. Furthermore, by the time this review is published, new papers relevant to this topic will have also been published. Therefore, new systematic literature reviews should be regularly conducted on the topic of eHealth knowledge and use among older adults living at home in rural and remote areas.

Limitations

This review has several limitations. First, as there was only 1 reviewer involved, this review's quality and reliability were somewhat weakened. Additional reviewers would have challenged the decisions made by the author. Second, although the selected studies were conducted in 12 countries, Western countries and English-speaking countries dominated, and studies not written in English were excluded. As noted in earlier reviews [30], this may create a bias by, for example, basing the findings mainly on reports from Western cultures. Furthermore, despite this review's intent, not all the studies were set in rural and remote areas, and therefore, its findings cannot be directly adopted in rural and remote contexts, with the exception of those of the third research question. The search included a comprehensive variation of health- and technology-related search terms (Textbox 1). The search terms did not include common abbreviations, such as *eHealth* and *mHealth.* However, these absences did not likely have a significant effect on the results. In addition, health technologies develop rapidly [35]; therefore, this review's start date of 2010 may seem distant. However, a 10-year period is commonly used in qualitative reviews of eHealth technology [14,29]. As noted by Vuojärvi [79], "although technologies change rapidly, people and the ways technologies are used in everyday lives, and particularly in the learning process, do not necessarily do so."

Conclusions

This literature review provides information and practical implications for designers, health care providers, and policy makers. eHealth technology targeted at older adults should be easy to use, and adequate support and training should be provided to users [25,80]. There are plenty of barriers that prevent older adults from ably and independently using eHealth technologies at home. Special attention should be paid to the most common barriers to learning how to use and using eHealth technologies: health-related difficulties, lack of internet connectivity, and other technical problems. We would like to

emphasize the importance of considering older adults' social and cultural practices when designing and implementing eHealth technologies. Social network support and technology integration into everyday life in rural areas contribute to a successful domestication process.

Acknowledgments

This study was part of a larger research project called HARVEST—eHealth and Aging in Rural Areas: Transforming Everyday Life, Digital Competences, and Technology (2018-2021). The project is nationally supported by the Academy of Finland (318835) as part of the international JPI MYBL (Joint Programming Initiative More Years, Better Lives) call. JPI MYBL is supported by the J-AgeII. J-AgeII is funded by Horizon 2020, the EU Framework Program for Research and Innovation, under grant agreement 643850, the JPI MYBL.

Abstract

Background: Across eHealth intervention studies involving children, adolescents, and their parents, researchers have measured user experience to assist with intervention development, refinement, and evaluation. To date, no widely accepted definitions or measures of *user experience* exist to support a standardized approach for evaluation and comparison within or across interventions.

Objective: We conduct a scoping review with subsequent Delphi consultation to identify how user experience is defined and measured in eHealth research studies, characterize the measurement tools used, and establish working definitions for domains of user experience that could be used in future eHealth evaluations.

Methods: We systematically searched electronic databases for published and gray literature available from January 1, 2005, to April 11, 2019. We included studies assessing an eHealth intervention that targeted any health condition and was designed for use by children, adolescents, and their parents. eHealth interventions needed to be web-, computer-, or mobile-based, mediated by the internet with some degree of interactivity. We required studies to report the measurement of *user experience* as first-person experiences, involving cognitive and behavioral factors reported by intervention users. We appraised the quality of user experience measures in included studies using published criteria: *well-established*, *approaching well-established*, *promising*, or *not yet established*. We conducted a descriptive analysis of how user experience was defined and measured in each study. Review findings subsequently informed the survey questions used in the Delphi consultations with eHealth researchers and adolescent users for how user experience should be defined and measured.

Results: Of the 8634 articles screened for eligibility, 129 articles and 1 erratum were included in the review. A total of 30 eHealth researchers and 27 adolescents participated in the Delphi consultations. On the basis of the literature and consultations, we proposed working definitions for 6 main user experience domains: acceptability, satisfaction, credibility, usability, user-reported adherence, and perceived impact. Although most studies incorporated a study-specific measure, we identified 10 well-established measures to quantify 5 of the 6 domains of user experience (all except for self-reported adherence). Our adolescent and researcher participants ranked perceived impact as one of the most important domains of user experience and usability as one of the least important domains. Rankings between adolescents and researchers diverged for other domains.

Conclusions: Findings highlight the various ways in which user experience has been defined and measured across studies and what aspects are most valued by researchers and adolescent users. We propose incorporating the working definitions and available measures of user experience to support consistent evaluation and reporting of outcomes across studies. Future studies can refine

the definitions and measurement of user experience, explore how user experience relates to other eHealth outcomes, and inform the design and use of human-centered eHealth interventions.

Introduction

Background

Over the past 15 years, the number of eHealth interventions available for use by children, adolescents, and their parents has grown considerably. A commonly used approach to eHealth intervention development involves human-centered design (also known as patient- or user-centered design) [1,2]. This approach includes the active participation of intervention users—children, adolescents, and parents—in the intervention design and development process. By including user perspectives and input into intervention design, the likelihood that an intervention will be easy to use and be compatible with the user and their individual context, and therefore deemed useful, is improved [3-5]. More recently, the importance of users' involvement in intervention evaluation has been recognized, with measures of *user experience* included in evaluations to identify whether and how an eHealth intervention meets the preferences and needs of the users. Understanding user experience can more or less reflect the quality of human-centered design principles associated with an intervention.

The term *user experience* initially arose in the field of human-computer interaction and technology design and was broadly defined as, "a person's perception and responses that result from the use or anticipated use of a product, system or service" [6]. To date, across eHealth studies, a wide range of definitions and concepts have been used to evaluate user experience, such as satisfaction, acceptability, adherence, engagement, and usability, with an eHealth intervention [7-14]. Similarly, user experience data collection methods have also varied, such as with the use of self-report questionnaires, in-person or telephone-based interview guides, or different types of automatic data capture of users' interactions with an intervention [15]. These variations suggest that user experience may be a multidimensional concept with several important constructs to define and measure within an eHealth intervention, and a consensus among researchers is yet to be reached. Similar to how the need to define, standardize, and measure adherence has been mounting in recent years [16,17], a need to converge on a common understanding of user experience is also becoming more apparent. A set of accepted domains, definitions, and evaluation measures used in eHealth intervention development and evaluation would benefit children, adolescents, and parents by allowing them to compare user experiences between multiple interventions and inform decisions about their own eHealth intervention use. These accepted approaches would also provide guidance to researchers in the eHealth field and allow for continued advancement and improvement of the study of user experience and other eHealth outcomes (eg, intervention effectiveness, user safety, and user empowerment), intervention design components (eg, content and technological features), and factors that can influence the intervention experience of users (eg, context of use and user expectations).

This Study

This study involves two phases: a scoping review and Delphi consultations. Our decision to conduct a review plus consultation reflects a hermeneutic position that user experience cannot be fully understood without examining it in its current context (existing literature) and the meanings attributed to it (Delphi consultations). The scoping review includes diverse literature to identify how user experience has been defined and measured in eHealth research studies of children, adolescents, and parents. These findings subsequently informed the development of surveys used in the Delphi consultations with eHealth researchers and adolescent users of an eHealth intervention, which focused on establishing a working definition of user experience (and the domains that it may encompass) and developing recommendations for measuring user experience in future evaluations of eHealth interventions.

Methods

Study Design

We followed the scoping review framework proposed by Arksey and O'Malley [18] with a Delphi consultation recommended by Levac et al [19]. Reporting of the review adheres to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) Extension for Scoping Reviews checklist [20]. The consultation exercise followed synthesis of findings from the literature. Approvals from the Health Research Ethics Board at the University of Alberta and Human Research Ethics Committee at the University of Southern Queensland were received for the Delphi consultation. The approved study protocol is available upon request.

Development of the Search Strategy

The search strategy (Multimedia Appendix 1) was developed using an iterative process. First, we developed a list of search terms using key concepts and terms from a convenience sample of indexed studies published in various years that examined user experience with an eHealth intervention. A research librarian provided input on appropriate filters, such as Medical Subject Headings terms, and modified these terms to comply with different databases. For this review, we were interested in identifying both published and unpublished English language studies of user experiences, and we sought to include studies made available between January 1, 2005, and April 11, 2019. We included the literature published since 2005 to focus on contemporary studies of eHealth technologies (eg, mobile apps, desktop-based, and multisession or single-session interventions).

The search terms and parameters were tested for sensitivity, determined by whether the search strategy successfully filtered the 63 citations that were manually selected a priori (see Multimedia Appendix 2 for the list of test citations). We then conducted 2 rounds of preliminary screening to further refine the strategy. The finalized search strategy was peer-reviewed before implementation.

Search Strategy

We identified studies from the following databases: Ovid MEDLINE, PsycINFO, CINAHL, EBM Reviews (Cochrane Database of Systematic Reviews, ACP Journal Club, Database of Abstracts of Reviews of Effects, Cochrane Central Register of Controlled Trials, Cochrane Methodology Register, Health Technology Assessment, and NHS Economic Evaluation Database), Cochrane Central Register of controlled trials, and ClinicalTrials.gov. We searched Google Scholar from January 2005 to April 2019 and conference proceedings of the International Society for Research on Internet Interventions from January 2016 to April 2019, as there are no archives of International Society for Research on Internet Interventions previous to 2016. We reviewed the reference lists from reviews (systematic, narrative, etc) to identify additional, potentially relevant studies.

Criteria for Considering Studies for the Scoping Review

We included studies of any design that assessed user experience with an eHealth treatment or prevention intervention designed for children or adolescents (aged ≤19 years). Studies with a sample that contained young adults could be included in the review if the mean age of participants was reported to be ≤19 years. eHealth interventions could target any health condition but needed to be web-, computer-, or mobile-based, mediated by the internet and include some degree of interactivity. Studies of telehealth interventions were not included. Studies could assess the eHealth user experience of children, adolescents, or parents. Given the wide range of pre-existing definitions and measurement approaches used to evaluate eHealth intervention user experience, multiple domains could be included in the user experience evaluation, such as cognitive factors (ie, beliefs, attitudes, and intention; such as satisfaction and acceptability of the intervention) or behavioral factors (ie, how the intervention was used, such as self-reported adherence to and engagement with the intervention) related to the use of an eHealth intervention. To be included, studies needed to report the measurement of *user experience* as first-person experiences reported by eHealth intervention users (parents, children, and adolescents). Studies that only reported indirect user data (ie, proxy report by a parent whose child used a program and intervention metadata [number of sessions completed]), which do not reflect the user's subjective experience, were excluded. Studies also needed to detail the evaluation measures (eg, tool, instrument, or interview questions) used to collect user experience data so that we could identify how user experience was defined and measured. Studies that did not detail evaluation questions but referenced an original publication of the evaluation measure were included if we could obtain the referenced publication to extract information.

Screening for Article Eligibility

We organized and screened identified studies using EndNote (Clarivate Analytics) bibliographic management software. In pairs, 3 reviewers (authors NDG and AKR and review contributor Marcus O'Neill) independently screened the title and abstract of articles, classifying each as *relevant*, *irrelevant*, or *unclear* using the predetermined inclusion and exclusion criteria. To assess the clarity of the criteria for each reviewer during screening, we calculated the interrater agreement for screening outcomes for the first 100 articles using the κ statistic [21]. The agreement was *substantial* (κ=0.61). We wanted interrater agreement to be ≥0.80, indicating an *almost perfect* agreement [22], so reviewers met to review the screening criteria alongside the articles for which they disagreed and sought consensus on the screening outcome for each article. Agreement increased to *almost perfect* (κ=0.81) for the next set of 100 articles and therefore the screening progressed. At this point, reviewers divided the remaining articles to be screened. Articles screened as relevant or unclear underwent independent screening and discussion by each reviewer pair to determine study inclusion or exclusion. The reviewers contacted the primary authors of 9 articles when additional information was needed to determine eligibility. The reviewers documented the articles that were excluded after full-text review to ensure transparency and replicability.

Data Extraction

Process

Data were extracted into a standardized spreadsheet. The spreadsheet underwent pilot testing with 3 independent reviewers (authors NDG and AKR and review contributor MO) who extracted data from the first 5 included studies to ensure that the spreadsheet was adequate in scope and that consensus was achieved on data categorization. Subsequently, each reviewer extracted data from one-third of the remaining included studies. Each reviewer verified the accuracy and completeness of the other reviewers' respective thirds. Data extraction discrepancies were resolved through consensus and third-party consultation (author ASN). Corresponding authors were contacted when reporting was unclear or details were lacking in the article.

Data Extracted for Analysis

We extracted the following information from the studies:

1. General information on participants (age [range] and intervention [user or respondent]) and the eHealth intervention (name, mode of delivery, target population or health condition and duration or frequency).

2. How first-person user experience was defined in studies, which included looking for definitions and terms of user-reported experiences as well as extracting individual questions used to measure user experience. We then compared author-reported user experience definitions to a priori definitions and the identified measures were categorized into 6 domains: satisfaction, acceptability, credibility, impact, adherence, and use. The domains were based on a preliminary literature review of user experiences in eHealth studies that was conducted by

one of the authors [23]. All tools fit into one or more of the 6 domains. The original working definitions for the 6 domains are presented in Multimedia Appendix 3.

3. Major characteristics of the evaluation measures used to assess user experience, including its purpose and scope, delivery time points, type of respondent (child, adolescent, or parent), administration approach (web-, telephone-, or paper-based or face-to-face interview), the number of items and item-response format (eg, Likert scale or open-ended questions), and any notations by study authors regarding limitations of the evaluation measures and recommendations for future measurement or evaluation.

4. Information on the measure's psychometrics was extracted, if available, including information on measure validity (face, content, construct, or criterion), reliability (internal consistency, interrater, or test-retest), and findings from a factor analysis. In studies where an evaluation measure was referenced, the original reference was reviewed and psychometric data were extracted, if available.

Quality Assessment

Two independent reviewers (NDG and AKR) assessed the quality of the evaluation measures reported in the studies and met to resolve discrepancies through consensus. The reviewers used 3 criteria developed by the Society for Pediatric Psychology Assessment Task Force [24]. The first criterion was the availability of details on the instrument or measure to allow evaluation and replication. This involved the reviewers confirming whether a measure was available for review in published or gray literature; study authors could have also included their measure as supplementary material to their publication. The second criterion concerned the availability of reliability and validity data for the instrument or measure. This could include psychometric data (eg, for surveys or rating scales) and data from pilot testing (eg, face and content validity or interview guide reliability for author-developed interviews). The third criterion, use of the instrument or measure by multiple, independent investigative teams as described in peer-reviewed articles, necessitated the measure or tool (including a qualitative interview guide) to have been used by more than one group.

Using the abovementioned criteria, measures were classified into 4 categories: *well-established*, *approaching well-established*, *promising*, or *not yet established*. We rated a measure as *well-established* if we could identify 2 peer-reviewed articles with very good detail of the measures and good to strong or excellent published information on both validity and reliability. We rated a measure as *approaching well-established* if we could identify 2 peer-reviewed articles with very good detail of the measure and with published information on validity *or* reliability either missing or presented in vague or poor to moderate values. We rated a measure as *promising* if we could identify 1 peer-reviewed article with sufficient detail of the measure (eg, some, but not all of the questions present) and with published information on validity *or* reliability either missing or presented in vague or poor to moderate values. Although not included in the original task force rating scheme, we rated a measure as *not yet established* if we could identify 1 peer-reviewed article with sufficient detail of the measure but with published validity or reliability information not available. The quality of validity and reliability data were interpreted using a guide presented by Phillips et al [25] (Multimedia Appendix 4).

Data Analysis

Evidence tables and a bar graph were developed to aggregate findings into descriptive and thematic summaries [5]. Descriptive summaries include information on study, participant, and eHealth intervention characteristics, user experience measures, and related psychometric statistics. Thematic summaries include grouping measures according to the quality assessment categories used to define the measures: *well-established*, *approaching well-established*, *promising*, or *not yet established*.

Delphi Consultation Process

The Delphi consultation phase of the scoping review was a stepwise process involving multiple, structured rounds of surveys to gain consensus [26-28] on how user experience should be defined and measured.

Participants

We sought input from 2 groups of individuals: researchers of the studies included in our review who had published eHealth intervention user experience evaluations and adolescents (aged 16-18 years) currently using an eHealth intervention.

We identified and contacted researcher participants using the published email contact information of lead or corresponding authors of studies included in the scoping review. We used snowball sampling so that contacted authors could also recommend colleagues with relevant expertise who may be interested in participating [26]. Each potential participant received an email invitation to participate along with an information sheet describing the Delphi consultation; those who completed the survey were considered to have given implied consent. The Delphi consultation with researchers was held over 7 months between September 2019 and March 2020.

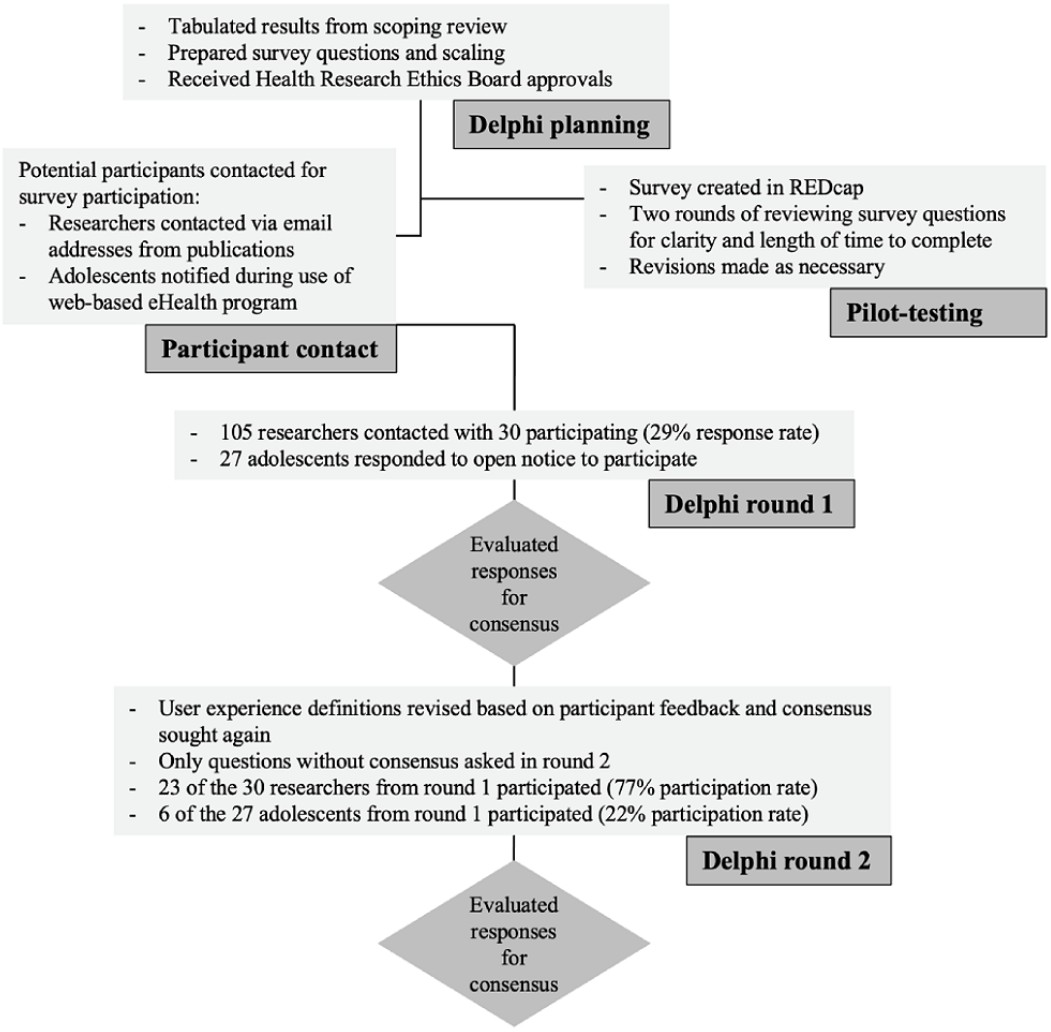
For practical and feasibility reasons, we recruited adolescent participants among current users of an evidence-based eHealth intervention, the web-based BRAVE Self-Help program [12,29], who had previously consented to be contacted for future research studies. Recruitment involved a pop-up invitation that appeared when users logged into the BRAVE Self-Help program throughout a 6-month period from June 7, 2019, to December 10, 2019. Interested participants were directed to an external site and invited to read a separate information sheet regarding the study and provide informed consent to participate in the Delphi consultation. After providing consent on the web, participants completed a survey that was used for the Delphi consultation.

Process

The process that we followed with each participant group along with the response and participation rates is presented in Figure 1. Broadly, each survey included questions that sought consensus on participants' opinions on the importance of the user experience domains and definitions used in the scoping review (Multimedia Appendix 3), additional domains for

consideration, and the appropriateness of measures used across eHealth studies of user experience. Consensus on responses to each survey question was defined as having ≥80% agreement [26].

Figure 1. Delphi consultation process. REDCap: Research Electronic Data Capture.



Survey Development and Scaling

Our team pilot-tested the surveys used in round 1 for both participant groups. We reviewed each survey for face validity, clarity, cohesiveness, flow, and completion time and made changes as needed (eg, modifying the wording of questions and changing the order of questions).

Researcher participants were first asked questions regarding their demography (age, gender, professional position, country of residence, and experience in developing and measuring user experience) followed by a series of questions on their level of agreement with the preliminary definitions of the proposed user experience domains (satisfaction, acceptability, credibility, impact, adherence, and use); initial definitions were based on a preliminary literature review that informed this scoping review as having accepted definitions or domains for measuring user experience. In round 1, an open text box for respondents to provide text supporting their answers was included. We originally wanted to survey participants for their opinions regarding the appropriateness of the user experience measures used across eHealth as well as findings from the review itself. We used a 6-point Likert scale ranging from *strongly agree* to *strongly disagree* to measure participants' level of agreement. In round 1, we also included an open text box for suggestions and comments regarding proposed definitions of identified domains and for those domains not identified in the survey. For proposed domains that could be measured at multiple time points, we also asked participants to indicate their preferred timing of measurement (before, during, or after the intervention). Researcher participants were then asked to rank the importance of the domains relative to one another using a 6-point Likert scale ranging from *most important* to *least important* when measuring user experience. Participants were also asked in both rounds to indicate the importance of studies to measure user experience; however, we realized that definitions would need to be determined before this could occur.

Adolescent participants were asked questions regarding their demography (age, gender, and frequency of using web-based health interventions) followed by questions on their level of

agreement with how important it is for researchers to ask them about each of the 6 user experience domains when using an eHealth intervention. Given the complexity and technical nature of the domains presented, adolescents were provided with lay descriptions of each of the domains and asked to rate how important they felt each domain was rather than commenting on the definition (as we did with the expert researcher sample). In this way, adolescents were able to provide input into the domains that were most important from their perspective. We used a 6-point Likert scale ranging from *extremely important* to *not at all important* to measure participants' level of agreement and also included an open text box in round 1 so that participants could identify reasons for why they felt a particular domain was important or not. Adolescent participants were then asked to rank the importance of the domains relative to one another from *most important* to *least important*. In round 1, an open text box was available for adolescents to add any other comments they had on the presented domains and any other aspects of user experience they thought were important or missing.

Consultation Rounds

We conducted independent Delphi consultations with each participant group—2 rounds with researcher participants and 2 rounds with adolescent participants—using a survey tailored to each group. The same participants participated in both rounds as the intent was to gain consensus (agreement) within the 2 participant groups. Given the nature of the questions being asked, we felt that 2 rounds were sufficient to capture participants' opinions. In round 2, we presented the summary of responses for survey questions where consensus was not achieved in round 1 or where comments and feedback for a survey question necessitated further clarification. This approach allowed each participant in round 2 to express their opinion after observing and reflecting on the opinions of other researchers or adolescents. The purpose of this approach was to decrease the degree of dispersion or increase the degree of consensus in participants' answers. The consultation exercise concluded after 2 rounds irrespective of whether consensus was reached on all survey items.

We used REDCap (Research Electronic Data Capture), a secure web-based platform [30], to administer the electronic surveys to researcher participants and the University of Southern Queensland Survey Tool based on Lime Survey and hosted on secure University of Southern Queensland servers for adolescent participants. Participants spent 15-30 minutes (researchers) or 10-15 minutes (adolescents) to complete the survey in each round. To maximize the response rate for each round, nonrespondents were sent an email reminder about the survey after every 7 days until 3 contact attempts had been made. Participants answered questions anonymously so that individual opinions did not influence other participants' opinions [26]. Adolescent participants who completed the surveys were given the opportunity to enter a draw to win one of the 10 vouchers valued at Aus $40 (US $28.92) to be drawn at completion of the study. Researchers who completed the surveys were given the opportunity to enter a draw to win a CAD $150 (US $118.14) electronic gift card.

Data Analysis

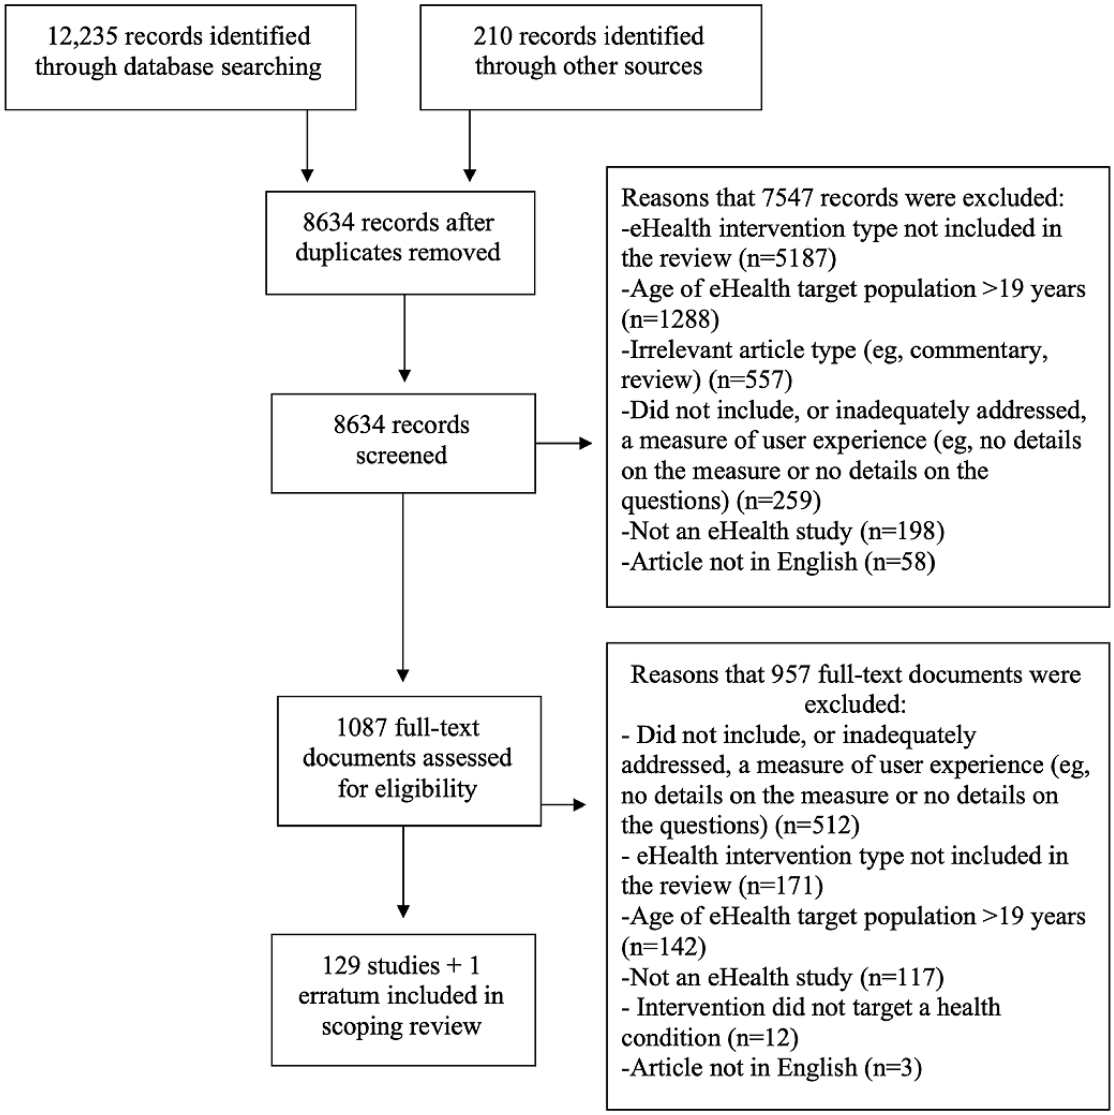
In round 1, we calculated the response rate for researcher participants only, as we were not able to determine the number of adolescent invitees from the open invitation to participate. In round 2, we calculated the participation rate for both researchers and adolescents using the denominator from round 1. For both rounds, we generated descriptive statistics (frequencies and percentages) to determine the level of agreement (consensus) among participants for each survey question. This involved grouping the responses at each end of the Likert scales (eg, grouping *strongly agree* with *agree* and *disagree* with *strongly disagree*). We also reviewed the responses to middle Likert categories (eg, *agree*/*disagree* and *slightly agree*/*slightly disagree*) to identify the range of opinions. Among researcher participants, following round 1, we collated the open-text answers or feedback on definitions and used this text to revise the definitions for the domains of user experience. We revised each domain definition using suggestions from participants irrespective of whether consensus was reached on the definition in round 1. The rationale was that the suggestions added critical details and improvements to each definition. The revised definitions were then presented for consensus in round 2 during which participants were asked to indicate their level of agreement with the revised definitions. We used IBM SPSS (version 26) for all analyses.

Results

Literature Search and Selection

The search strategy identified 8634 unique citations. Of these citations, 1087 were considered potentially relevant based on their title and abstract (Figure 2). After full-text review, 129 articles and 1 erratum met inclusion criteria and were included in the review.

Figure 2. Literature search flow diagram.



Description of Included Studies

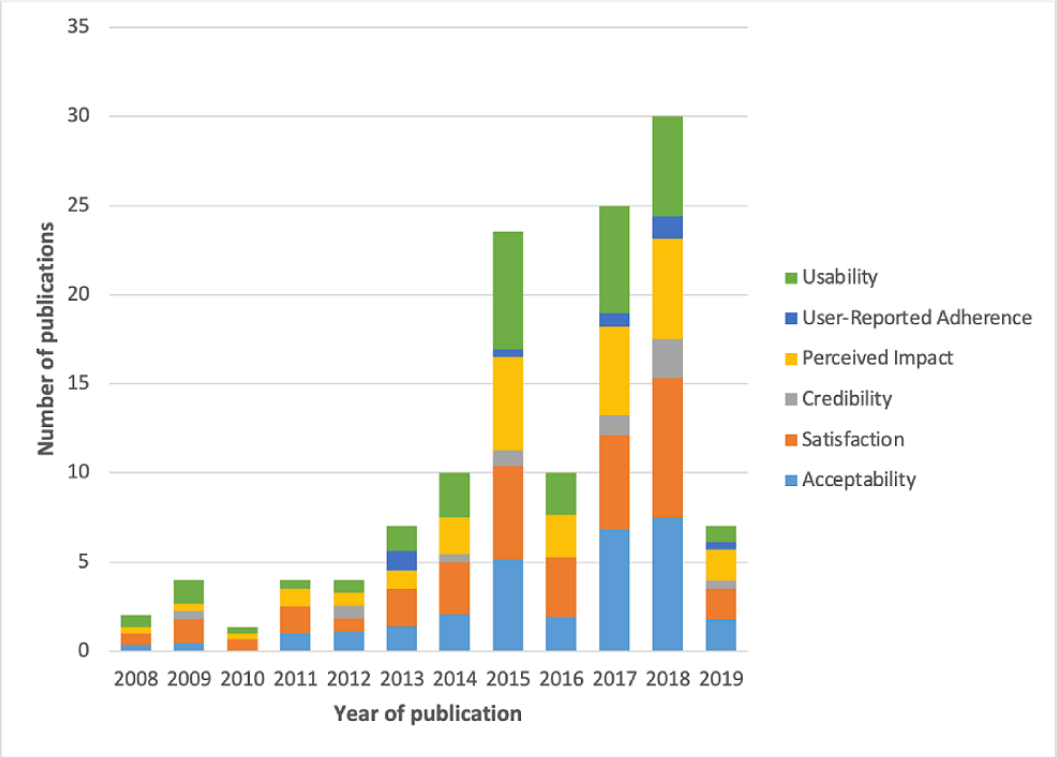
A summary of the general characteristics of 129 eHealth studies that evaluated user experience is presented in Table 1. Most studies were published in 2018 (30/129, 23.3%), 2017 (25/129, 19.4%), and 2015 (24/129, 18.6%). The most commonly measured user experience domains were acceptability, usability, and satisfaction; this trend occurred across years of publication (Figure 3). Additional details for each study are presented in Multimedia Appendix 5 [7-14,31-152], grouped by year of publication to examine trends in the domains measured over time.

Table 1. Summary of the eHealth studies that measured user experience (N=129).

Characteristics	Studies within scoping review, n (%)
eHealth user[a]	
Children aged ≤9 years	26 (20.2)
Adolescents aged 10-19 years	118 (91.5)
Young adults up to 24 years	25 (19.4)
Parents	33 (25.6)
Type of eHealth intervention	
Web-based	85 (65.9)
Mobile-based	44 (34.1)
Tablet-based	11 (8.5)
User experience domain that was measured	
Satisfaction	86 (66.7)
Acceptability	77 (59.7)
Credibility	17 (13.2)
Perceived impact	66 (51.2)
User-reported adherence	11 (8.5)
Usability	74 (57.4)

[a]Age categories defined using World Health Organization definitions [153].

Figure 3. The type and frequency of user experience domains measured across eHealth studies over time. The domains named in this figure reflect the agreed-on terminology that resulted from the Delphi consultation with researchers.



User Experience Measures

Research teams used 128 unique user experience evaluation measures in the 129 published studies included in this review. Details of the quality assessment outcomes using the Society for Pediatric Psychology Assessment Task Force [24] criteria are provided in Multimedia Appendix 6 [7-14,31-111,113-121,123-152,154,155]. Of the 128 measures,

10 (7.8%) were assessed to be *well-established* measures (Table 2) and 5 (3.9%) were assessed to be *approaching well-established* (Table 3). These measures were used in research studies to primarily capture user experiences related to satisfaction with and acceptability of eHealth interventions and program usability and perceived impact of an intervention. Evaluation measures used in research studies that were assessed to be *promising* (13/129, 10.1%) are presented in Multimedia Appendix 7 [75,90,97,99,107,109,132,136,139,152]. The remaining 100 measures identified were assessed as *not yet established* and primarily represented studies in which author-developed evaluation questions were used. Information on evaluation measures used in research studies that were assessed to be *not yet established* is available upon request to the corresponding author.

Table 2. Well-established evaluation measures of user experience.

Measure name and targeted user experience domain	Format and administration features	Psychometric properties		eHealth study
		Validity	Reliability	
SUS[a]; usability	10 items; 4- and 5-point Likert scales; administration: paper- and web-based and telephonic	Two-factor scale [156]; usable (8 items), α=.91; learnable (2 items), α=.70; overall α=.92	Internal consistency; 10 years of SUS samples: α=.91 [157]; eHealth study sample: α=.86 [31], α=.95 [32]	[14,31-39]
SUS (Portuguese version); usability	10 items; 5-point Likert scale; administration: paper-based	Construct validity with PSSUQ[b] [158]: *r*=0.70	Interrater reliability; Portuguese validation sample [158]: intraclass correlation coefficient=0.36 with modest agreement between ratings (76.67%)	[40]
Client Satisfaction Questionnaire 8; acceptability, satisfaction, and usability	8 items; 4-point Likert scale; administration: paper- and web-based	Criterion-related validity; other measures of satisfaction [159]: *r*=0.60-0.80	Internal consistency across 9 studies [159]: α=.83-.93; eHealth study sample: α=.92 [41]	[41-44]
CEQ[c]; credibility and perceived impact satisfaction	6 items; 9-point Likert scale and 0%-100% scale; administration: not reported	Two-factor scale [160]: expectancy (3 items), eigenvalue=3.42; credibility (3 items), eigenvalue=1.53; 2 factors accounted for 82.46% of the total variance	Internal consistency; CEQ validation across 3 studies [160]: expectancy, α=.79-.90; credibility, α=.81-.86; overall, α=.84-.85; test-retest reliability, CEQ validation across 3 studies [160]: expectancy, α=.82; credibility, α=.75	[41]
GEQ[d]; acceptability and satisfaction	33 items; 5-point Likert scale; administration: web-based	Five-factor scale; GEQ validation study [161]: factor 1 (5 items); factor 2 (7 items); factor 3 (4 items); factor 4 (5 items); factor 5 (4 items); all correlation coefficients >0.30	Internal consistency; GEQ development sample [162]: α=.81	[7,10]
PSSUQ also known as the Computer Systems Usability Questionnaire[e]; acceptability, perceived impact, satisfaction, and usability	19 items; 7-point Likert scale; administration: web-based	Three-factor scale; correlation coefficients on 5 years of PSSUQ samples [154]: system usefulness and informational quality, *r*=0.70; system usefulness and interface quality, *r*=0.70; informational quality and interface quality, *r*=0.60; factors scores shared 36% to 50% of the variance	Internal consistency; 5 years of PSSUQ samples [154]: system usefulness, α=.96; informational quality, α=.92; interface quality, α=.83; overall, α=.96	[45,46]
SSS[f]; satisfaction	5 items; 4-point Likert scale and open ended; administration: telephonic	One-factor scale factor loadings[g] [163]: Youth version, α=.77-.90; Parent version, α=.71-.83	Internal consistency; SSS development samples [163]: youth α=.86; parent α=.85; eHealth study sample across different time points [47]: α=.77-.95	[47]
TEI-SF[h]; acceptability and perceived impact satisfaction	9 items; 5-point Likert scale; administration: paper-based	2 factor scale [164]: acceptability (8 items), α=.49-.93, 57% of total item variance; discomfort (1 item), α=.82, 12% of total item variance	Internal consistency; TEI-SF development samples: α=.94 [165], α=.85 [164]	[48]
USE[i] questionnaire; acceptability, satisfaction, and usability	19 items (4 subscales); 7-point Likert scale; administration: web-based	Criterion-related validity [166]; compared with SUS (2 evaluations); usefulness: r_1=0.60, r_2=0.69; ease of learning: r_1=0.71, r_2=0.78; ease of use: r_1=0.78, r_2=0.81; satisfaction: r_1=0.66, r_2=0.71	Internal consistency; USE development sample [166]: α=.98; eHealth study sample [32]: usefulness, α=.90; ease of learning, α=.98; ease of use, α=.95; satisfaction, α=.96	[32]
WAI-SR[j]; credibility and perceived impact	12 items; 5-point Likert scale; administration: web-based	Three-factor scale; correlation with WAI-SR within 2 samples (S1 and S2) [167]: goal (4 items), α=.89 (S1), α=.87 (S2); task (4 items), α=.87 (S1), α=.90 (S2); bond (4 items), α=.86 (S1), α=.84 (S2); overall, α=.95 (S1), α=.94 (S2)	Internal consistency; WAI-SR development within 2 samples [167]: goal, α=.87 (S1), α=.85 (S2); task, α=.85 (S1), α=.87 (S2); bond, α=.90 (S1), α=.85 (S2); overall, α=.91 (S1), α=.92 (S2); eHealth study sample [41]: α=.95	[41,49]

[a]SUS: System Usability Scale.

[b]PSSUQ: Poststudy System Usability Questionnaire.

[c]CEQ: Credibility Expectancy Questionnaire.

[d]GEQ: Game Experience Questionnaire.

[e]The Computer Systems Usability Questionnaire and PSSUQ are the same questionnaire; the only difference is that the Computer Systems Usability Questionnaire wording is appropriate for use in field settings or surveys rather than in a scenario-based usability evaluation [154,155].

Delphi Consultation

Overview

In round 1, 30 researchers and 27 adolescents participated. In round 2, the number of participants decreased to 23 researchers (23/30, 77% participation rate) and 6 adolescents (6/27, 22% participation rate; Figure 1). The demographic characteristics of researcher and adolescent participants are presented in Table 4. Researcher participants were mainly women and employed in academic positions, and all participants had used a measure of user experience in their work. In addition, most adolescent participants were female participants, and most had limited experience in using eHealth interventions (despite being currently enrolled in an eHealth intervention for anxiety).

Table 4. Demographic information about the participants.

Characteristics	Round 1	Round 2
Researcher participants, n (%)	30 (100)	23 (77)
Age (years), mean (SD)	42.6 (1.4)	43.7 (1.7)
Sex, n (%)		
Female	26 (86.7)	20 (87)
Male	4 (13.3)	3 (13)
Primary role or position, n (%)		
Academic (professor and lecturer)	19 (63.3)	13 (56.5)
Scientist (researcher and research fellow)	5 (16.7)	5 (21.7)
Clinician	4 (13.3)	4 (17.4)
Trainee (PhD candidate and postdoctoral fellow)	2 (6.7)	1 (4.3)
Country, n (%)		
Australia	4 (12.9)	3 (13)
Canada	3 (9.7)	2 (8.7)
Finland	1 (3.2)	1 (4.3)
Ireland	2 (6.5)	1 (4.3)
Italy	1 (3.2)	1 (4.3)
Korea	1 (3.2)	1 (4.3)
New Zealand	4 (12.9)	3 (13)
Sweden	2 (6.5)	2 (8.7)
United Kingdom	1 (3.2)	1 (4.3)
United States	11 (35.5)	8 (34.8)
Has measured user experience, n (%)	30 (100)	23 (100)
Has developed a user experience measure, n (%)	7 (23.3)	6 (26.1)
Adolescent participants, n (%)	27 (100)	6 (22)
Age (years), mean (SD)	16.44 (0.6)	N/A[a,b]
Sex, n (%)		
Female	20 (74.1)	N/A
Male	5 (18.5)	N/A
Other	2 (7.4)	N/A
Use of eHealth programs, n (%)		
Never used until the day of the survey	14 (51.9)	N/A
<once per week	7 (25.9)	N/A
1-2 times per week	4 (14.8)	N/A
3-4 times per week	0 (0)	N/A
5-6 times per week	1 (3.7)	N/A
≥7 times per week	1 (3.7)	N/A

[a]N/A: not applicable.

[b]Demographics for adolescent participants in round 2 were not collected to ensure anonymity as per the research ethics board's requirements.

Researcher Participants

Over 2 rounds of consultation, researcher participants made several suggestions for refining the original definition of each user experience domain. The revised definitions achieved by round 2 are presented in Table 5 along with the consensus scores for the definition (the percentage of participants who *strongly agreed* or *agreed* with the definition). Researchers met or surpassed the threshold for agreement on all definitions except the definition for perceived impact. Regarding the importance

of each of the domains to the overall assessment of user experience in round 1, researchers achieved consensus in their ranking of credibility as less important to measure relative to the other 5 domains (80%; Table 6); no other rankings achieved consensus in this round. Perceived impact was ranked in both rounds as more important than the other domains, but consensus (≥80% agreement) was not achieved. Regarding when assessment of user experience should be conducted, the responses differed across domains. By round 2, researchers agreed that eHealth intervention acceptability (87% consensus) and satisfaction (97% consensus) should be measured after intervention completion. Researchers were divided on when credibility should be measured, with equal proportions of researchers indicating credibility should be measured at all 3 time points (before the intervention: 61%; during the intervention: 65%; and after the intervention: 61%).

Table 5. Working definitions of user experience domains developed with researcher participants.[a]

Domain	User experience definition	Definition consensus (%)
Acceptability	Acceptability refers to whether the intervention *content, features, and delivery* meet user *expectations* (eg, relevance, convenience, accessibility, feasibility, appropriateness, *appeal [fun, interesting, and likable], value, engaging, and privacy*). *These aspects may be different depending on the user (ie, child, adolescent, or parent).*	100
Satisfaction	Satisfaction refers to *the user's overall impression of the* intervention *and whether it meets their needs* (eg, global satisfaction rating, *value for money or time, helpful, whether they would they use it again or recommend it to a friend, and ratio between expectations and results*).	96
Credibility	Credibility refers to the extent to which the user perceives the intervention to be trustworthy and *has the potential to work* (eg, perceived accuracy and quality of information *in the intervention and/or evidence base supporting the intervention*).	96
Usability[b]	Usability refers to the user's perceived ease of use *of the intervention based on technical factors (eg, interface/equipment/reminder features or problems)* and environmental/personal factors (eg, content, time, and *competing priorities*) *that impact* the individual's use of the intervention (eg, *frequency*).	87
User-reported adherence[c]	User-reported adherence refers to how and why the user *did or did not follow* the intervention or research protocol (eg, completing outcome measures and content) as recommended.[d]	83
Perceived impact	Perceived impact refers to the extent to which the user *perceives the effect of the intervention's impacts (eg, impressions of* change in symptom levels and skills and *perception* of overall effectiveness).	78

[a]Italics represent additions or changes to the original definition. Domains are listed in descending order of consensus.

[b]Usability should also be measured in conjunction with objective measures of use (ie, intervention metadata).

[c]User-reported adherence should also be measured in conjunction with objective measures of adherence (ie, intervention metadata) and clinician expectations and adherence to the protocol (if relevant).

[d]Content removed from the definition.

Table 6. The relative rankings among researcher participants for the importance of the user experience domains across 2 rounds of consultation.

Domain	Round 1 (%)		Round 2 (%)	
	More important	Less important	More important	Less important
Acceptability	73	27	48	52
Satisfaction	43	57	30	70
Credibility	20	80	—[a]	—
Usability	47	53	26	74
User-reported adherence	47	53	26	74
Perceived impact	70	30	65	35

[a]Round 2 not conducted as consensus was achieved in round 1.

Researcher participants' opinions varied greatly on whether a universal measure of user experience was needed to enable direct comparisons between studies of eHealth interventions. By round 2, a total of 70% (16/23) stated that a universal measure was extremely or quite important, 22% (5/23) stated that it was slightly important, and 9% (2/23) stated it was slightly unimportant. In round 1, a total of 37% (11/30) of the participants also provided comments. Most stated that although a universal measure may be impractical given variability across users' developmental stage, technology types, and language, a core set of user experience items would be a valuable addition to the eHealth field. Participants suggested that other measures could be added to this core set to obtain intervention-specific feedback as needed. Moreover, 1 participant pointed out that

accepted definitions of user experience domains are also important to ensure that the domains are not used differently from study to study even if different measures are used to assess them.

Adolescent Participants

Adolescents were asked to indicate which user experience domains were important for a researcher to ask them about. In round 1, adolescents reached consensus that acceptability was more important for a researcher to ask about compared with other domains (81% consensus); satisfaction and perceived impact were indicated as important, but adolescents did not reach consensus in round 1 (78% consensus for both). After the second round, adolescents achieved consensus with satisfaction, credibility, and perceived impact (100% consensus) and usability (83% consensus) identified as important domains for researchers to ask about when measuring adolescents' user experience. After the 2 survey rounds, adolescents remained divided on the importance of measuring user-reported adherence, with 50% (3/6) of the participants rating it more important and 50% (3/6) rating it as less important

When asked to rank the domains in order of importance to one another (ie, which domains were more important than the other domains), perceived impact was considered the most important domain to measure (83% consensus) based on 2 rounds of consultation. Credibility and acceptability were also ranked highly and were considered more important than the other domains, but they did not meet or surpass the 80% threshold to achieve consensus. User-reported adherence was ranked the least important domain relative to the others (83% consensus). Usability (76%) and satisfaction (67%) were also ranked as less important to measure, although consensus was not reached for these 2 domains either.

Discussion

Summary of Principal Findings

To our knowledge, this is the first study to review how eHealth intervention studies have defined and measured user experience, consult with experts (researchers) as to how user experience could be defined and measured, and consult with users (adolescents) as to which domains they considered important for examining their user experience. In the scoping review, we made 2 important discoveries: several well-established measures are available to quantify user experiences and a large proportion of published eHealth studies did not involve the use of a well-established measure, with authors having developed user experience questions specific to their eHealth intervention. Key findings from our Delphi consultation are the alignment between researcher and adolescent relative rankings of user experience domains and the refinement of definitions for the 6 proposed domains of user experience.

Discussion of Principal Findings

We identified 10 well-established measures available in the current literature to quantify 5 of the 6 proposed domains of user experience (satisfaction, acceptability, credibility, perceived impact, and usability). Therefore, we recommend that eHealth researchers use an available, well-established measure instead of developing their own measure to assess these 5 user experience domains. This approach will allow for between-study comparisons of user experiences, including whether and how experiences with similar eHealth interventions are considered the same or different among users. Not only could such comparisons help inform parents and their children with their decisions for which eHealth intervention to use but also findings across studies could be used by researchers to identify and understand the relationship between user experience and other eHealth outcomes (ie, intervention effectiveness and program adoption or use).

To date, no well-established measure exists for studying user-reported adherence. This is not surprising, as adherence is typically measured using intervention metadata, such as the number of sessions completed and time spent per session. We propose that in addition to such objective metrics, researchers measure how and why a user *did or did not follow* the intervention or research protocol (eg, completing outcome measures and content) as recommended or as encouraged by intervention design. This subjective information can expand the understanding of metadata—for example, why did the user complete the number of sessions or outcome measures that they did. These data could be collected using a set of open-ended questions designed to be used across studies and tailored, when needed, to specific interventions, studies, or user profiles.

Definitions of the 6 domains of user experience that resulted from our international consultation with eHealth researchers offer a guidepost for new studies of user experience. Although the proposed definitions may continue to be refined over time as the eHealth field advances, we see them as an important cornerstone to user experience measurement. A set of commonly accepted domains, similar to the efforts to define, standardize, and measure eHealth adherence [16,17] and engagement [170,171], can introduce a taxonomy that can be applied across eHealth studies even if different populations, interventions, and measures are used. However, it remains unclear, as to whether a universal measure of user experience would be useful for researchers. Although 16 of the 23 of the researchers in this study responded that it is important to use a universal measure, several concerns were brought forward regarding the challenge to implementing such an approach. As a follow-up to the results we reported here, further investigation of the utility and feasibility of a core set of items and what this core set should be is needed. It is possible that consideration needs to be given to how measures can be adapted for different respondents (eg, parents, adolescents, and clinicians) or different intervention contexts (eg, open access vs therapist supported). For example, the findings of this study showed that perceived impact was rated as important by both the researchers and adolescents; however, it is entirely possible that each would describe the desired impact of the intervention in different ways. Further investigation is necessary to examine how these constructs can be best assessed using different respondents and contexts.

The Delphi consultations we conducted provide insight into the value that researchers and adolescents place on the different domains of a user's experience with an eHealth intervention. Both adolescent and researcher respondents ranked perceived impact as one of the most important aspects of a user's eHealth

experience, indicating that whether the user perceives the intervention to have had an impact on their health is a central component of user experience. There were also divergent perspectives, with one the most divergent being researchers' ranking of satisfaction among the most important domains compared with adolescents' ranking of it as less important. At the core of the definition of satisfaction is an emphasis on whether an intervention meets a user's expectations and needs. From the adolescent point of view, the definition of perceived impact, which focuses on the *impressions of change in symptom levels and skills or the perception of overall effectiveness*, may have been a more meaningful way to identify whether their needs would be met, as perceived impact directly links to an observable or tangible change in their symptoms or behavior because of the eHealth program. The ranking of credibility also differed between researchers (lower ranking) and adolescents (higher ranking). With the choice of eHealth interventions increasing, as consumers, it is not surprising that adolescents would place greater priority on credibility as an important aspect to the selection and use of an eHealth intervention. This prioritization should be considered by researchers when developing and marketing their interventions for use.

Usability was considered one of the least important domains of user experience from the perspective of both adolescent and researcher respondents. This ranking may reflect the discrepancy between the more commonly used definitions of usability and the one proposed in our Delphi consultation. Originating from the field of computer science, usability is considered a main design component (design heuristic), similar to aesthetics, user safety, or data privacy, meaning that a certain degree of (technical or functional) usability is fundamental to or expected with the use of an eHealth intervention. Although an intervention may be usable, it does not mean that it will be *used* or perceived as *useful* by adolescents [172]. Therefore, if usability is currently understood as a measure of the technical ease of use or the functionality of an intervention, then examining it may add little *richness* to the understanding of what and how users describe their user experience with eHealth intervention to be like. However, if usability comes to be associated with the conditions (barriers or constraints, facilitators, and context) of use and reasons for usefulness (meets the needs and preferences of users), then usability may be considered an important indicator of the user experience.

Future Directions

This scoping review with Delphi consultations has provided a broad overview of the current state of user experience measurement in the eHealth field along with expert (researcher) and user (adolescent) input into how user experience could be defined and measured with an eHealth intervention. An extension of this work may include investigating whether a core set of items used to measure the various domains of user experience would add value to the field and could be feasibly applied across different interventions and user populations [23]. Future research could benefit from qualitative investigations with adolescents to further define their understanding and definitions of the user experience domains within different eHealth contexts and test the feasibility of core assessment items for these domains from their perspective. It would then be beneficial to validate their definition of user experience (and the associated domains) and test the feasibility of core measurement item sets across large numbers of adolescent users of eHealth interventions internationally. With greater awareness and emphasis on patient-oriented research and improving outcomes important to patients, assessment of user experience can become an important part of patient-centered treatment planning.

Further attention could also be directed toward the definition and measurement of self-reported adherence. In our study, although a definition of self-reported adherence was achieved through consensus, its importance in measurement was not established among researcher or adolescent participants. Although a wealth of measurement studies exists for understanding adherence from an objective standpoint [16,173,174], few explanatory studies have been conducted to explore how and why the user did or did not follow the intervention and research protocol as recommended [23]. This *why* component is critical for meaningful improvement of eHealth interventions to increase program adherence and therefore achieve related health benefits [175].

Future studies may also look at how to apply both objective and subjective intervention outcomes or user experience measures to improve the validity of eHealth evaluations. For example, adolescents and researchers in our study reported perceived impact to be an important aspect of the user experience. Objective measures of intervention impact, such as changes in diagnostic severity, global functioning, symptom checklists [176], or self-reported minimal clinically important difference [177], could reinforce or complement the findings generated by more subjective measures [23]. In this way, we could better understand how various measures converge or diverge on similar user experience concepts, begin to develop more psychometrically and theoretically robust assessment measures, and establish indicators of clinically meaningful outcomes based on users' perspectives.

Limitations

Although this scoping review and associated Delphi consultations were conducted according to published guidelines, this study is not without limitations. First, our study focus was placed on eHealth interventions that were web-, computer-, or mobile-based and mediated by the internet; we excluded studies that did not primarily include these features and therefore, our results will not be representative of all technologies for which user experience may be measured. In addition, eHealth interventions being used and evaluated in health care systems that have not been scientifically investigated and reported in the published or gray literature were not included in our review. Our scoping review focus also required studies to describe the measure or measures used to collect user experience data. This requirement resulted in the exclusion of 512 studies. Given that this was a review of definition and measurement of user experience, such details were essential to understanding the current state of the eHealth field. This approach was systematic in that we applied the same working definitions to each study; however, it may have resulted in the classification of a domain of user experience that differed from what study investigators

intended. The challenge in grouping some of the studies confirms that agreement regarding definitions of user experience domains would be of value to the eHealth field. The proposed domains and definitions are not intended to be static, and we expect that they will be refined to reflect advances in the eHealth field. Finally, although we present the results from the first international Delphi consultations, our sample size was limited; particularly in representation from adolescent users.

Conclusions

eHealth interventions are now widely available for use by children, adolescents, and parents, and positive user experiences are generally reported across individual studies. The outcomes of this review and Delphi process highlight the various ways in which user experience has been defined and measured across studies, with a large proportion of research studies using study-specific, nonstandardized instruments. Through the conduct of this study, we propose definitions for 6 user experience domains: acceptability, satisfaction, credibility, usability, user-reported adherence, and perceived impact, as informed by empirical literature and agreed upon by eHealth researchers and adolescent users. Findings revealed 10 well-established measures that assess 5 of the 6 user experience domains (satisfaction, acceptability, credibility, perceived impact, and usability), and we recommend that eHealth researchers use an available, well-established measure over developing their own to assess these domains. The proposed working definitions and importance rankings from researcher and adolescent participants can be used to inform eHealth user experience research in the future and encourage consistency in reporting and to guide the development of measurement tools. Future studies should examine whether a core set of items used to measure the various domains of user experience would add value to the field and be feasibly applied across different interventions and user populations. Closing these gaps has the potential to enable comparisons across the user experience literature and better understand how user experience relates to other outcomes, such as effectiveness or objective measures of adherence, in eHealth interventions.

Acknowledgments

This work was supported by the Alberta Strategy for Support for People and Patient-Oriented Research and Trials (SUPPORT) Unit Knowledge Translation Platform, which is funded by Alberta Innovates and the Canadian Institutes of Health Research. The authors would like to acknowledge the contributions of Robin Featherstone, MLIS, who developed and conducted the initial search strategy; Tara Landry, MLIS, who peer-reviewed the search strategy and conducted an updated search; and Marcus O'Neill who assisted with article screening for eligibility and data abstraction.

Conflicts of Interest

Although SM does not own the BRAVE Program, it is possible that at some point in the future, she may receive royalties from future commercialization of the program.

Abstract

Background: Health systems and providers across America are increasingly employing telehealth technologies to better serve medically underserved low-income, minority, and rural populations at the highest risk for health disparities. The Patient-Centered Outcomes Research Institute (PCORI) has invested US $386 million in comparative effectiveness research in telehealth, yet little is known about the key early lessons garnered from this research regarding the best practices in using telehealth to address disparities.

Objective: This paper describes preliminary lessons from the body of research using study findings and case studies drawn from PCORI seminal patient-centered outcomes research (PCOR) initiatives. The primary purpose was to identify common barriers and facilitators to implementing telehealth technologies in populations at risk for disparities.

Methods: A systematic scoping review of telehealth studies addressing disparities was performed. It was guided by the Arksey and O'Malley Scoping Review Framework and focused on PCORI's active portfolio of telehealth studies and key PCOR identified by study investigators. We drew on this broad literature using illustrative examples from early PCOR experience and published literature to assess barriers and facilitators to implementing telehealth in populations at risk for disparities, using the active

implementation framework to extract data. Major themes regarding how telehealth interventions can overcome barriers to telehealth adoption and implementation were identified through this review using an iterative Delphi process to achieve consensus among the PCORI investigators participating in the study.

Results: PCORI has funded 89 comparative effectiveness studies in telehealth, of which 41 assessed the use of telehealth to improve outcomes for populations at risk for health disparities. These 41 studies employed various overlapping modalities including mobile devices (29/41, 71%), web-based interventions (30/41, 73%), real-time videoconferencing (15/41, 37%), remote patient monitoring (8/41, 20%), and store-and-forward (ie, asynchronous electronic transmission) interventions (4/41, 10%). The studies targeted one or more of PCORI's priority populations, including racial and ethnic minorities (31/41, 41%), people living in rural areas, and those with low income/low socioeconomic status, low health literacy, or disabilities. Major themes identified across these studies included the importance of patient-centered design, cultural tailoring of telehealth solutions, delivering telehealth through trusted intermediaries, partnering with payers to expand telehealth reimbursement, and ensuring confidential sharing of private information.

Conclusions: Early PCOR evidence suggests that the most effective health system- and provider-level telehealth implementation solutions to address disparities employ patient-centered and culturally tailored telehealth solutions whose development is actively guided by the patients themselves to meet the needs of specific communities and populations. Further, this evidence shows that the best practices in telehealth implementation include delivery of telehealth through trusted intermediaries, close partnership with payers to facilitate reimbursement and sustainability, and safeguards to ensure patient-guided confidential sharing of personal health information.

Introduction

Background

People living in medically underserved, low-income, or rural areas; those from racial and ethnic minorities; members of the lesbian, gay, bisexual, and transgender (LGBT) community; and those with limited English proficiency or disabilities often face substantial barriers to accessing needed health care and are at high risk for health disparities [1,2]. About one-quarter of the US population experiences geographic and/or economic disparities. For example, 34 million Americans (10.5%) live in poverty [3] and some 46 million Americans (15%) live in rural areas [4]. These populations are more likely to report issues with access to primary and specialty care, longer travel time to providers, lower rates of insurance coverage, and higher rates of chronic conditions than urban resident [2,5-7]. Racial and ethnic disparities are also common and are strongly linked to social determinants of health [1,5,8].

Other populations at particularly high risk for disparities include low-income African Americans in medically underserved urban and rural areas of the South [9-11], American Indian populations in rural areas [8,12,13], the mostly Alaskan Native residents of Alaska [14], and Latinx Americans, who face language, insurance, and other barriers to access to care [8]. Additional groups identified by the Patient-Centered Outcomes Research Institute (PCORI) as priority populations include LGBT persons, those with low health literacy/numeracy and limited English proficiency, and those with disabilities [15-21]. All these populations face barriers related to the social determinants of health that prevent adequate access to care [13,19-23], resulting in poor health outcomes across a multitude of domains.

Potential for Using Telehealth to Address Disparities

Telehealth modalities have great potential to help overcome geographic, socioeconomic, cultural, and language barriers related to the social determinants of health and enhance access to essential health services for high-risk populations [24,25]. Telehealth has traditionally been a way to provide health care access in rural communities, and its adoption has accelerated for these populations during the COVID-19 pandemic [26,27]. While the potential for telehealth to address disparities, such as transportation and availability of providers, is high, preliminary data during the COVID-19 pandemic suggest that differences in internet and telehealth access may actually compound disparities in chronic disease outcomes [28]. Telehealth can be used for multiple purposes, including direct delivery of care to patients and their caregivers, remote monitoring of health outcomes, education of patients and caregivers, support for self-care and health behavior change, assistance with health care decision-making, and communication of test results [29]. Likewise, telehealth can employ multiple communication modalities, including telephone, video teleconference, text messaging, mobile apps, and wearable monitors, that allow providers to remotely communicate, monitor, and share information with patients [30-32]. Previous research has documented the effectiveness of these telehealth modalities in reaching rural populations to provide care, prescreening evaluations, and patient education [25,33,34], yet data on the effectiveness of telehealth in other populations is more limited [29-32]. Moreover, while many health care delivery systems have implemented telehealth solutions to address barriers to access and better serve populations at risk for disparities, outcomes and sustainability have been variable [24,25,35].

Study Aims

The primary purpose of this scoping review was to identify key barriers to telehealth implementation and describe how barriers can be addressed in populations at risk for disparities. PCORI has invested US $386 million in comparative effectiveness research in telehealth, yet little is known about the key early lessons of this research for using telehealth to address disparities. This review describes preliminary lessons from early patient-centered outcomes research (PCOR) experience and literature, using study findings and illustrative case studies drawn from these seminal PCOR initiatives and literature.

Methods

Overview

A systematic scoping review of telehealth studies addressing disparities was performed and was guided by the Arksey and O'Malley Scoping Review Framework [36], with a focus on PCORI's active portfolio of telehealth studies and key supporting PCOR identified by several of the investigators.

Identifying the Research Question

The purpose of this scoping review was to describe barriers and facilitators to implementing telehealth or remote interventions in populations at risk of health disparities (eg, racial and ethnic minority groups or people living in rural areas) within comparative effectiveness research projects funded by PCORI. The specific question addressed was as follows: "How have PCORI-funded investigators overcome barriers to implementing telehealth interventions in populations at risk for disparities?"

Identifying Relevant Studies

Between December 2012 and March 2019, PCORI funded 84 comparative effective research projects, in which at least one of the study's comparison arms used telehealth to improve health outcomes. PCORI defines telehealth as the delivery of health services via remote telecommunication modalities, such as telephonic communication, remote monitoring devices, real-time videoconferencing, and mobile devices. For this scoping review, PCORI staff first reviewed the telehealth portfolio to identify studies aiming to improve health outcomes for populations at risk of or facing disparities. Studies included those that targeted at least one of the following PCORI priority populations at risk for disparities: people living in medically underserved, low-income, or rural areas; those representing racial and ethnic minorities; members of the LGBT community; those with low health literacy/numeracy and limited English proficiency; and those with disabilities [37]. Other PCORI populations of interest, including older adults, women, children, individuals with multiple chronic diseases, individuals with rare diseases, individuals whose genetic makeup affects their medical outcomes, veterans, and members of the armed forces and their families, were not specifically included in this scoping review.

Of the 84 PCORI-funded studies in this portfolio, PCORI staff identified 41 studies focused on improving health outcomes for populations at risk of or facing disparities by confirming the target population for each study. Qualifying studies were further reviewed by PCORI staff to determine if any barriers to implementation of the planned telehealth intervention were experienced and whether the investigators were able to mitigate these barriers to successfully implement the study telehealth intervention. A convenience sample of 8 studies was selected based on their representativeness (ie, to ensure that all major targeted populations at risk for disparities were included), study phase (ie, studies either completed or nearing completion), and perceived principal investigator availability to provide illustrative examples of successful approaches for working through obstacles in implementing telehealth interventions for diverse populations.

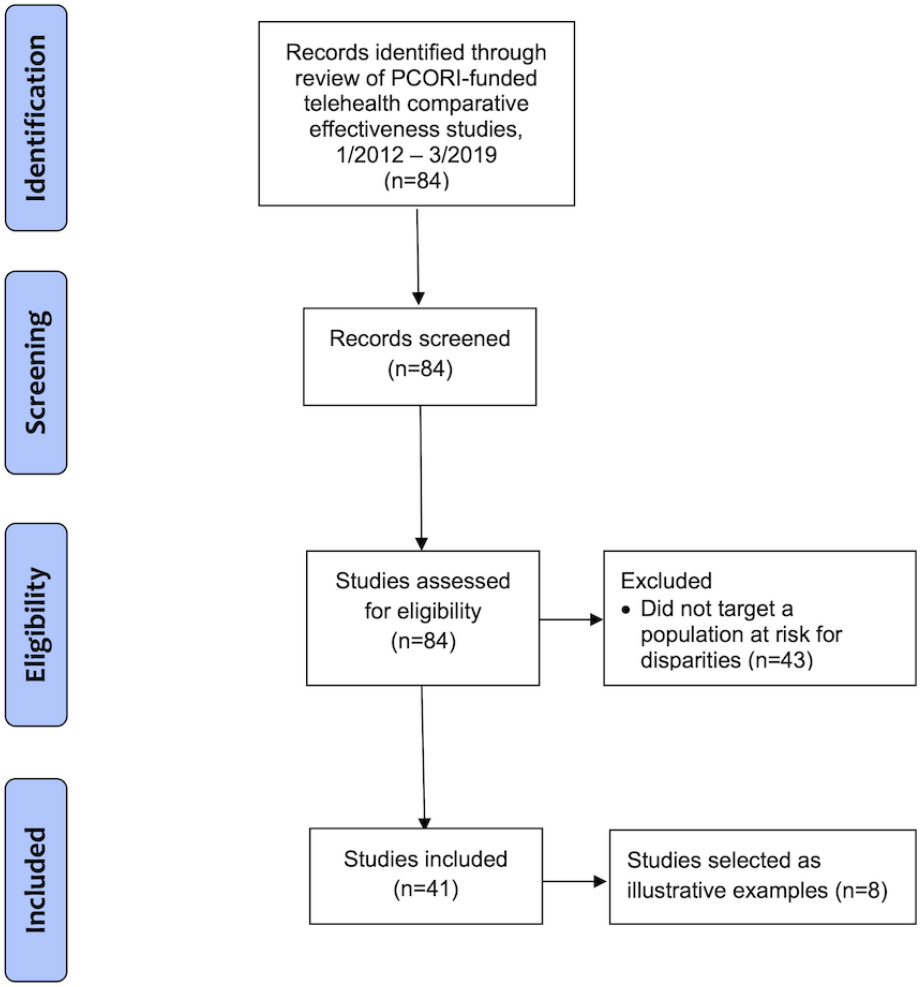
Identifying Barriers and Facilitators

We drew on these 8 illustrative examples from early PCOR experience and evidence from the literature to assess barriers and facilitators to implementing telehealth in populations at risk for disparities [25]. Key informant interviews of principal investigators were conducted for the convenience sample of 8 PCORI studies to identify common challenges in the implementation of telehealth in populations at risk for disparities. Among the 8 studies in the convenience sample, 6 principal investigators were contacted for phone interviews and 4 interviews were completed. PCORI then hosted a webinar attended by investigators from all 8 of the studies to facilitate discussion about the study challenges investigators faced and the solutions they identified and implemented. After the initial information gathering from the interviews and webinar, PCORI staff invited investigators to participate in this scoping review and share the lessons learned.

Extracting the Data

Following identification of all PCORI studies meeting the criteria for the scoping review (n=41), PCORI staff extracted descriptive data for all these studies, including telehealth purpose and modality, population, health condition, budget amount, principal investigator, and institution, using published project descriptions and study papers. PCORI staff and study investigators then extracted additional data from these same sources and interim progress reports (where available) in order to categorize documented barriers and facilitators using a published framework of identified barriers (eg, limitations) and facilitators (eg, solutions) to telehealth [25]. We then used prespecified data definitions from the Fixsen active implementation framework to further categorize barriers and facilitators to implementing telehealth within 3 major domains, including competency drivers (ie, participant selection, training, and supervision), organizational drivers (ie, decision support, administrative support, and system intervention), and leadership drivers [38,39]. The reporting process used the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) extension for scoping reviews (Figure 1) [40,41].

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) extension for scoping reviews flow diagram of the study selection process. PCORI: Patient-Centered Outcomes Research Institute.



Collating, Summarizing, and Reporting the Data

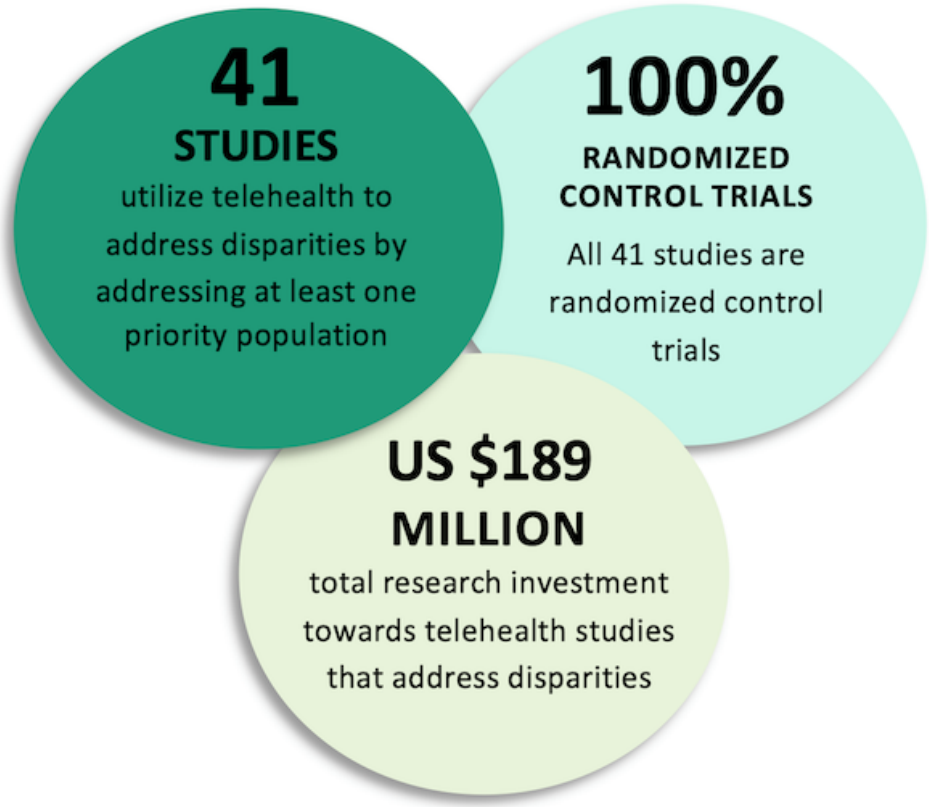
A table including the core descriptive data regarding all PCORI-funded telehealth studies addressing populations at risk for disparities was created. In addition, figures and charts were created to summarize project details about this subset of studies. An assessment of the quality of studies included in this review was not performed. A table was created summarizing the barriers and facilitators identified within each major implementation domain. Finally, major themes regarding how telehealth interventions can overcome barriers to telehealth adoption and implementation were identified through review of both the extracted data and illustrative examples using an iterative Delphi process among the 8 PCORI principal investigators participating in the study to achieve consensus. The Delphi process was facilitated by PCORI staff and a lead principal investigator for the scoping review, and was conducted through teleconference and email communication. PCORI staff and the lead principal investigator initially categorized extracted data and illustrative examples by barrier and facilitator types based on previously published categories [25]. Studies were then recategorized and category labels were revised based on feedback from participating investigators until consensus on the barrier and facilitator types was achieved.

Results

Identifying Relevant Studies

As shown in Figure 2, 41 PCORI-funded studies were identified that assessed the use of telehealth to improve outcomes for populations at risk for health or health care disparities in this analysis. Of note, all 41 studies employed a randomized controlled trial methodology, and all were pragmatic or "real-world" comparative effectiveness studies rather than efficacy studies.

Figure 2. Patient-Centered Outcomes Research Institute comparative effectiveness studies assessing telehealth solutions to address disparities.

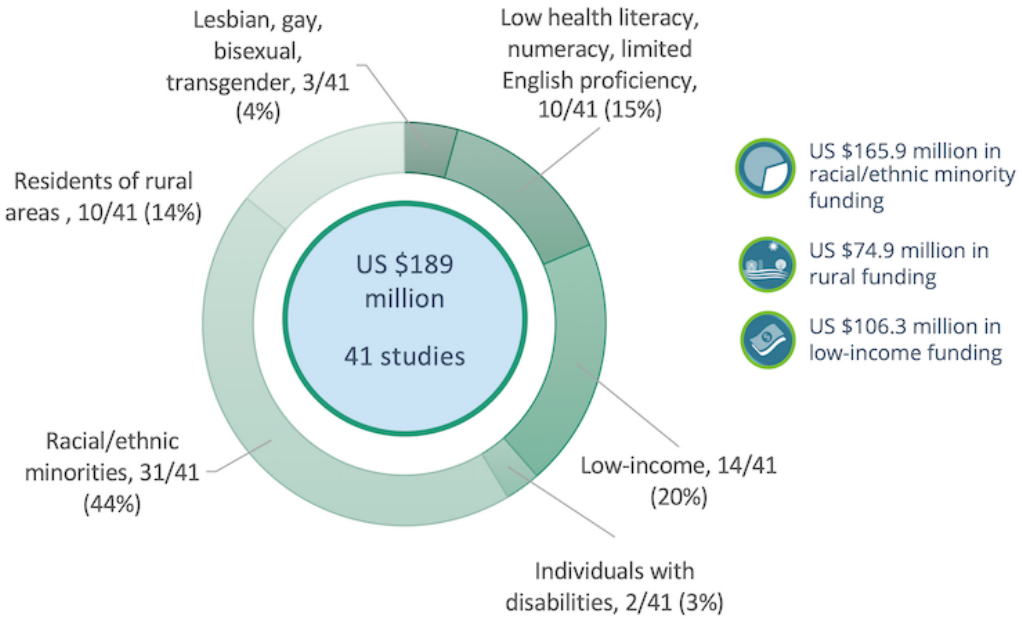


Study Characteristics

The descriptions, study goals, telehealth interventions studied, settings, number of participants, and targeted study populations for these 41 PCORI-funded studies are detailed in Multimedia Appendix 1 [42-96]. The studies ranged in size from 59 to 84,828 participants; all were conducted in ambulatory settings; and the majority (33/41, 80.5%) were conducted in primary care and/or community settings.

As shown in Figure 3, all 41 studies targeted at least one of PCORI's priority populations, including racial and ethnic minorities, people living in rural areas, people with low income or low socioeconomic status, people with low health literacy, members of the LGBT community, and people with disabilities.

Figure 3. Populations at risk of disparities targeted by Patient-Centered Outcomes Institute comparative effectiveness studies in telehealth.



PCORI-funded studies employed multiple telehealth modalities. The majority of these 41 studies used a mobile device (n=29, 71%) or were web-based (n=30, 73%). Fewer studies used real-time videoconferencing (n=15, 37%), remote patient monitoring (n=8, 20%), or store-and-forward capability (ie, asynchronous electronic transmission; n=4, 10%). It is important to note that a similar telehealth modality does not indicate similar studies. For example, studies employing mobile device interventions were diverse and included web-based interventions requiring full internet access, as well as lower-tech interventions that only employed SMS or simple text messaging. All the web-based interventions referenced below required reliable broadband internet access. Real-time videoconferencing was used in 15 studies, and 11 of these studies utilized telehealth to improve access to primary or specialty care. Health conditions involving videoconferencing were cardiovascular diseases (n=2), kidney diseases (n=2), mental/behavioral health (n=4), nutritional and metabolic disorders (n=3), allergies and immune disorders, multiple chronic conditions, neurological disorders, respiratory diseases, and trauma/injury. Remote patient monitoring (eg, blood pressure or blood glucose levels) was used in 8 studies. Remote monitoring varied from a wearable device (eg, Fitbit) to mobile app monitoring to an in-home device (eg, scale, blood pressure monitor, or video monitoring). Health conditions incorporating remote monitoring included cardiovascular diseases (n=3), mental/behavioral health (n=2), nutritional and metabolic disorders, and respiratory diseases. Store-and-forward technology was employed in 5 studies that included the following conditions: functional limitations and disabilities, mental/behavioral health, rare diseases, hearing loss, and skin diseases.

Furthermore, the purpose of the 41 PCORI telehealth interventions also varied substantially, with 8 (20%) focused on enabling health monitoring, 20 (49%) focused on improving access to specialty care, 22 (54%) focused on health education, and 27 (66%) focused on promoting chronic condition self-management. The spectrum of chronic conditions studied also varied substantially. The largest proportion of studies focused on behavioral health (n=9, 22%), and nutritional and metabolic disorders (n=6, 15%), including obesity and diabetes. In addition, PCORI has funded telehealth projects addressing disparities focused on cardiovascular conditions (n=3), chronic kidney disease (CKD; n=2), neurological conditions (n=2), reproductive and perinatal health (n=2), rare diseases (n=2), allergies and immune disorders (n=1), cancer (n=1), hearing loss and ear diseases (n=1), functional limitations and disabilities (n=1), infectious diseases (n=1), multiple chronic conditions (n=1), trauma (n=1), and skin diseases (n=1). Although only 1 study focused on patients with multiple chronic conditions, most of the studies included patients with multiple chronic conditions and some additional studies used such presence as an inclusion criterion.

Identifying Barriers and Facilitators

Barriers and facilitators of telehealth implementation in PCORI-funded studies using telehealth to address disparities are detailed in Tables 1 and 2. Barriers and facilitators are described for only 35 of the 41 studies as 6 were in the early stages of implementation and lacked sufficient data for evaluation. Review of this data revealed that 20 (57%) studies actively engaged patients to assist investigators in building patient-centered design with active patient participation in each development phase, 13 (37%) studies culturally tailored their telehealth intervention, 4 (11%) studies employed partnership with payers to expand telehealth reimbursement, and 11 (31%) studies delivered telehealth care through or with the assistance of trusted intermediaries. Of the 11 studies, 5 (14%) had clinical support team members available to support their telehealth interventions with a human interaction component.

Table 1. Barriers to telehealth adoption identified in Patient Centered Outcomes Research Institute–funded studies using telehealth to address disparities.

Barriers (ie, limitations or challenges)	Barriers identified, n	Example
Competency drivers		
Participant engagement barriers (eg, social determinants of health presenting barriers to telehealth adoption)		
Inadequate access to telecommunication technology	9	Patients with many competing social needs and low levels of social support and resources that may have prevented individuals who would otherwise be eligible and/or interested in study participation (eg, inadequate access to technology). This barrier was removed by adding "access to a phone or iPad" to the inclusion criteria.
Patient and stakeholder feedback	1	Patient and stakeholder partners were integrated into studies to provide feedback on the usability and feasibility of technology.
Staff training barriers	3	Providers and health care staff may not receive training on technology use or telehealth etiquette. Inadequate communication among patients, multiple providers, primary care providers, and specialists exacerbates the technology divide.
Inadequate program supervision/management	3	Lack of personnel structure to oversee administrators of technology platforms.
Organizational drivers		
Inadequate decision support		
Technology problems	0	Not reported.
Inadequate administrative support		
Insufficient administrative support staff to deliver or support telehealth solutions	5	Lack of support staff available to help access and utilize the different app platforms.
Health systems workflow	1	Poor integration of telehealth intervention and existing clinical care workflows.
Inadequate clinical support		
Insufficient staff to deliver telehealth solutions	5	Lack of clinical support, such as providers or lay health workers, available to assist with the delivery of telehealth platforms.
System-level barriers		
Legal (eg, inadequate safeguards to ensure patient-guided confidential protected health information sharing, state licensure laws, need for credentialing at multiple sites, and liability concerns)	2	Lack of protection for study participants, specifically those who were undocumented immigrants.
Financial (eg, limited insurance coverage for telehealth)	5	Inconsistent reimbursement coverage for providers. State-based licensure laws exist.
Leadership drivers		
Inadequate administrative leadership	0	Not reported.
Inadequate clinical leadership (eg, concerns regarding lower quality patient–physician relationship or poor physician buy-in)	0	Not reported.
Partnership	1	Partnership with national organizations to help design and implement the intervention.

Table 2. Facilitators to telehealth adoption identified in Patient Centered Outcomes Research Institute–funded studies using telehealth to address disparities.

Facilitators (ie, solutions or improvements)	Facilitators identified, n	Example
Competency drivers		
Improvements in participant engagement (eg, approaches to address social needs and facilitate telehealth adoption)		
Provision of access to telecommunication technology	4	Case managers assisted patients with addressing telehealth access barriers.
Patient-centered design (eg, telehealth solutions) actively guided by patients to meet community needs	20	Most studies engaged patients in the design of the intervention and obtained feedback from the target population.
Cultural tailoring of telehealth solutions to meet the needs of specific communities and populations	13	Culturally tailored interventions for target populations.
Improvements in staff training (eg, training in patient empowerment techniques such as motivational interviewing to facilitate telehealth adoption)	4	Technology training for providers and community health workers. Help solving workflow issues.
Organizational drivers		
Decision support solutions		
Technology solutions	0	Not reported.
Administrative solutions		
Strengthening of administrative support staff to support telehealth solution	11	Support staff to provide ongoing support and engagement for technical issues.
Process evaluation	1	Feasibility assessments to determine the fidelity of the technology.
Clinical support team solutions		
Strengthening clinical support staff to deliver or support telehealth solutions (eg, delivering telehealth through trusted intermediaries)	5	Support staff, such as nurses, providers, and lay health workers, are available to provide human interaction, which strengthens trust with technology.
System-level improvements		
Legal (eg, safeguards to ensure patient-guided confidential sharing of protected health information)	2	Reassurance for securing data using appropriate computer technology.
Financial (eg, partnering with payers to expand insurance coverage for telehealth and telehealth reimbursement)	4	Working with communities to provide coverage for community health aides to help implement technology and to better understand telehealth insurance claims.
Legislative policies	1	Experience working with state legislature/licensure to help lower barriers to telehealth.
Leadership drivers		
Improvements in administrative leadership	0	Not reported.
Improvements in clinical leadership (eg, engagement of strong physician champions to lead change)	0	Not reported.

Major themes identified across these studies included the importance of patient-centered design, cultural tailoring of telehealth solutions, delivering telehealth through trusted intermediaries, partnering with payers to expand telehealth reimbursement, and ensuring confidential sharing of private information.

Illustrative examples of these key themes are reviewed in the sections below, and key system- and policy-level changes needed to address barriers to telehealth adoption and implementation are identified.

Patient-Centered Design

Patient engagement is a core component of PCORI studies. Some studies go beyond incorporating patient input and feedback on the research and actively engage patients into the study design and overall design of the intervention.

The VIGoROUS (Video Game Rehabilitation for Outpatient Stroke) study illustrates how user-friendly consumer-driven design serves as a critical component of sustainable telehealth initiatives [70,71]. It employed a video gaming system to deliver therapeutic exercises and track adherence/progress remotely for individuals with motor disability. The gaming system was co-designed by therapists and people with motor disability. Artificial intelligence automatically adjusted the difficulty of

the exercises to match the ability of the patient, allowing for a simple user interface and less than 1-minute setup.

Similarly, the study by Williams et al comparing high-touch and high-tech care in patients with complex care needs utilized a smartphone-based remote care management platform and digital health innovations to support self-directed care management [85,97]. While the participant technology comfort level was assessed prerandomization and was expected to be variable among the study population, the study team found that participants often requested assistance in understanding basic phone functionality. Thus, the investigators worked to devise a modality flexible enough to support all levels of technical knowledge, which was easy to access, was user friendly, and addressed a broad range of skills from simple to difficult. The investigators developed a high-tech care strategy user guide with input from the stakeholder partners, patients, and providers. The need for more tailored technical support also resulted in concierge-style in-person technical visits to perform functional assessments that could not be completed over the phone, leading to a new workforce supporting additional technical initiatives across the care delivery continuum.

Cultural Tailoring of Telehealth Solutions

When developing telehealth interventions, it is particularly important to consider the need for culturally competent care, defined as care that respects the diverse characteristics and values of the patients, which can ultimately affect their overall health and health care [98]. This review of PCORI-funded studies showed that patient study engagement improved with the use of culturally competent messaging delivered via telehealth interventions.

The MODEL (Management of Diabetes in Everyday Life) study assessed the effectiveness of tailored motivational text messaging for improving diabetes self-care activities in medically underserved African American adults in the Mid-South, and illustrated the importance of cultural tailoring of telehealth solutions [44,45]. This study incorporated feedback from a patient advisory council into the message development process to more competently culturally tailor message content to the target population, an approach that has demonstrated positive impacts in other populations with diabetes [44,45]. The MODEL study's registry-based text message system employed electronic medical record and survey data, as well as ongoing message input from patients themselves to personalize and deliver culturally tailored content to patients with uncontrolled diabetes [45]. Preliminary program results indicated high satisfaction with the MODEL text message program, with greater than 90% participant retention in this group of the study.

Similarly, the Health-E You/SaludiTu study demonstrated how cultural tailoring of telehealth interventions can improve their acceptance by populations at risk of disparities [91,92]. This study aimed to assess the effectiveness of a patient-centered computer-based clinical intervention to reduce health disparities in unintended pregnancies among Latina adolescent girls in 18 school-based health centers in Los Angeles, California. Latina adolescents and local community representatives were key stakeholders in the design and implementation of this app, which may have helped the adoption and implementation of this intervention into clinic workflows at the school-based health centers. The culturally tailored tool was available in English and Spanish, and adapted language that resonated with Latina adolescents (eg, the use of the more colloquial term *condones* versus *preservativos* to refer to condoms). Preliminary findings showed that both providers and study participants reported high satisfaction with the app, as it was easily integrated into the clinic flow, and more importantly, participants showed an increase in knowledge of contraceptive use from baseline to their 6-month follow-up.

Likewise, early implementation experience from a PCORI-funded study of underserved Asian Americans having chronic hepatitis B suggested that culturally and linguistically competent interventions improve participant retention [72]. This study employed patient-designed culturally tailored text messaging along with patient navigator–led educational sessions to improve adherence to medication therapy for hepatitis B. Patient partners and community stakeholder groups provided extensive input on the appropriateness and framing of the messages. These messages were delivered in Chinese, Vietnamese, or Korean. Early implementation findings showed evidence that this culturally and linguistically appropriate intervention was effective in improving follow-up in patients living with hepatitis B.

Delivering Telehealth Through Trusted Intermediaries

Many of the studied PCORI telehealth projects successfully employed trusted intermediaries to deliver telehealth solutions and help support people at high risk for health disparities in crossing the digital divide. These projects provided confirmatory evidence to extensive literature suggesting that lay health worker and paraprofessional intermediaries can help build trust among patients and providers in new telehealth modalities. New technologies, including telehealth, that enable the delivery of interventions and diagnostics remotely are emerging, but patients commonly struggle to use these technologies. Patients struggle with both simple technical issues, such as neglecting to ensure that an electronic system is plugged in, and more complex barriers related to social determinants of health (eg, poverty, unpredictable work schedules, unreliable transportation, and lack of internet access) when using advanced technologies such as secure videoconferencing.

PCORI telehealth projects consistently demonstrate high patient acceptance of telehealth modalities that connect them to trusted providers, but even with careful attention to patient-centered design, investigators commonly found availability of in-person technological support to be essential. For example, when 1 participant in the aforementioned VIGoROUS video gaming intervention reported that her gaming system would not turn on, a support call revealed that she had not plugged it into an electrical outlet [70,71]. This early experience suggested that widescale implementation of telehealth technologies requires funding of responsive technical support infrastructure to avoid technology abandonment by patients in greatest need.

Similarly, a study of Native Americans addressing gaps in self-management through home-based CKD care found that continuous care coordination using trained and trusted tribal community health representatives (CHRs) was essential to

effective program implementation [86-88]. This program used videoconferencing with patients via internet-connected portable tablets using Verizon wireless Jetpack mobile hotspots. The program worked with other local health and wellness programs (eg, Indian Health Services and other programs operating within tribal communities) and conducted community-wide health fairs. Telehealth adoption was also encouraged through distribution of culturally sensitive newsletters and brochures to all these health programs and individual community members. The secondary data analysis of the study demonstrated that behavioral and lifestyle educational reinforcement through motivational text messaging and alternate weekly home visits by the CHRs with quarterly group sessions was an effective means of providing care to patients with type 2 diabetes mellitus and CKD who may otherwise avoid diagnosis and treatment due to stigmatization. The CHR-led home-based care model provided the additional care necessary to bolster patient levels of disease-specific knowledge, self-efficacy, and diabetes and CKD self-management, enabling patients to more effectively carry out the recommendations that they received during the home visits, as compared to patients who received clinic-based usual care [99].

A study addressing childhood hearing loss in an Alaska Native population similarly found that using trusted lay health workers based in the communities served was essential to telehealth program deployment [100-103]. In the remote rural communities served by this program, health care is provided by community health aides/practitioners who are commonly from the community they serve and are selected by their community to receive training. This care is supported by specialist triage using the statewide telemedicine network. As a result, ear and hearing problems in isolated communities are routinely managed remotely by audiologists and surgeons through telemedicine, including provision of local care (such as for ear infections), preoperative planning, and postoperative follow-up [102,103]. This requires community health aides/practitioners performing telemedicine consults to be proficient with telemedicine equipment, including basic testing, such as tympanometry, to assess eardrum movement and digital otoscopy for photos of the eardrum. Training with telemedicine equipment is built into each session of the standardized community health aide/practitioner program and includes continued on-the-job training and direct observation of practical skills. Expanding the use of telemedicine equipment for prevention, such as follow-up for referred school hearing screenings, utilizes community health aide/practitioner knowledge and training on the telemedicine infrastructure already in place. However, Emmett et al also provided additional training on the expedited telemedicine consult form to facilitate the application of modified workflows for school hearing screening referrals [68,69].

Partnering With Payers to Expand Telehealth Reimbursement

Reimbursement for telehealth encounters is increasing. However, lack of adequate reimbursement continues to present a major challenge to telehealth adoption, implementation, and sustainability. Reimbursement barriers to telehealth were acknowledged by nearly all the PCORI-funded study investigators who participated in this study. Despite recent expansions in telehealth reimbursement during the COVID-19 pandemic, variable state and federal reimbursement policies and low levels of reimbursement for services delivered via telehealth continue to challenge telehealth implementation efforts. In response to these challenges, many studies found it essential to partner with payers to expand their support and/or reimbursement for telehealth services.

For example, the TEAM UP (Treatment Efforts Addressing Child Weight Management by Unifying Patients, Parents, and Providers) study assembled a Payer Advisory Board that explored how military medical sites use telehealth for services such as teleradiology and telebehavioral health [96]. The Board noted how telehealth could facilitate access to qualified and trained health care professionals in rural areas, as well as foster treatment engagement and reduce program attrition by increasing flexibility for patients with challenging schedules. The Payer Advisory Board stressed the viability of telehealth and the need for these types of visits to be considered billable encounters to help overcome the challenges facing populations with barriers to care.

In the rural Alaska study addressing childhood hearing loss, the research team developed a streamlined telemedicine consultation process in order to make it financially sustainable in the school setting [68,69,104]. Translating a clinically oriented technology to a preventive service raises inherent logistical challenges [69]. The team shortened the telemedicine consult time from 60-90 minutes to 10-15 minutes, making it feasible to perform 10 to 15 telemedicine referrals for school hearing screening in a single day. This process took several iterations, with feedback sought from multiple stakeholders including community health aides/practitioners. Maintaining the integrity of billing requirements, while shortening the telemedicine consultation process, allowed the preventive service to remain reimbursable and financially sustainable after the conclusion of the randomized trial.

Similarly, in the Mid-South MODEL study, investigators worked with regional health systems to provide long-term support for a regional registry-based tailored text message system that can assist both large health systems and small independent primary care practices in sending regular motivational messages to interested patients [44,45].

Ensuring Confidential Sharing of Private Information

Early implementation experience from numerous PCORI telehealth studies demonstrates the importance of ensuring confidential sharing of private information in all telehealth interventions considered. The application of telehealth often involves paperless collection and transmission of data at each touch point with participants and with communication between staff at the regional and local levels. This requires careful attention to compliance with local, regional, and federal legal requirements for protection of privacy.

For example, the TEAM UP study of alternative childhood obesity treatments for Medicaid-insured individuals employed a secure Health Insurance Portability and Accountability Act (HIPAA)-compliant videoconferencing system to enable remote

communication with children and families that protected privacy [96]. Working with a low-income population presents an inherent set of barriers, including unpredictable schedules and unreliable transportation, both of which could negatively impact the fidelity of family-based behavioral treatment delivery. In anticipation of these potential barriers, the study team contracted with a fully HIPAA-compliant videoconferencing system to allow for telehealth delivery of family-based behavioral treatment sessions as needed. Secure video was found to be an ideal technology solution since it is accessible on virtually all devices, including cell phones, and provides necessary flexibility to support adherence with demanding treatment schedules. Use of secure HIPAA-compliant videoconferencing ensured the confidentiality and security of participants' protected health information in compliance with part 11 of Title 21 of the Code of Federal Regulations pertaining to Electronic Records and Electronic Signatures (21 CFR Part 11) [96]. Likewise, the study employed an electronic consent process that allows for the use of alternative consent forms for each participating site.

The VIGoROUS study also had to address challenges related to information security [70]. First, it was necessary to find a HIPAA-compliant videoconferencing platform for secure video chat between participants and providers. While there are numerous platforms available, some of which are free, the lead site's hospital system was relatively unfamiliar with telehealth and thus required new technology platforms to undergo an extensive information security vetting process (eg, conducting risk assessments and obtaining administrative approvals), a process that ultimately spanned 3 years. To proceed with the study, investigators were able to identify and pivot to a user-friendly videoconferencing platform (Bluejeans) that had already been vetted by the university health system. The second challenge was how to make large amounts of remote-monitoring data (adherence data, quality of movement data generated continuously during rehabilitation, and behavioral assessment data) accessible to a clinician providing care remotely. This was addressed by streaming deidentified data to a secure cloud server. The data were stored under a unique machine identifier that could only be obtained through physically accessing the rehabilitation gaming system (located within participants' homes). During video consultations with a therapist, the participant provided the therapist with the machine identifier to enable the therapist to track his/her progress [70].

Discussion

Principal Findings

This scoping review of early PCOR evidence suggests that the most effective health system- and provider-level telehealth implementation solutions to address disparities employ patient-centered and culturally tailored telehealth solutions. We found that the development of the most effective telehealth solutions was actively guided by patients themselves in order to meet the needs of specific communities and populations. Early PCOR evidence demonstrates that the best practices in telehealth implementation include delivering telehealth through trusted intermediaries, close partnership with payers to facilitate reimbursement and sustainability, and safeguards to ensure patient-guided confidential sharing of personal health information.

The COVID-19 pandemic has given new urgency to these questions regarding telehealth adoption among people at the highest risk for disparities, including those living in medically underserved, low-income, or rural areas; those from racial and ethnic minorities; LGBT persons; and those with limited English proficiency or disabilities. Telehealth modalities have great potential to help overcome these geographic, socioeconomic, cultural, and language barriers and to give populations at risk of disparities enhanced access to essential health services. Although many PCORI-funded studies had to put their research on hold and transfer their institution's focus on the needs of patients experiencing COVID-19 [105], the pandemic generally helped to accelerate telehealth adoption for vulnerable populations [26,28]. However, since early evidence indicates that differences in internet and telehealth access may worsen disparities in chronic disease and COVID-19 outcomes [106], it is clear that telehealth solutions must deliberately target and prioritize populations at the highest risk for disparities.

Toward that end, this review places strong emphasis on the importance of deploying patient-centered and culturally tailored telehealth solutions that address the social determinants of health faced by populations at risk for disparities [19-21]. Even though low-income, minority, and rural populations face heightened barriers to effective self-care related to the social determinants of health, most telehealth behavioral interventions for chronic conditions are tailored for individuals with higher incomes. Thus, low-income, minority, and rural groups need specific culturally tailored solutions that specifically address the social determinants of health they face [69,104]. Preliminary evidence from PCORI-funded studies consistently demonstrates that intensive personalization and cultural tailoring of intervention components [70] can help enable vulnerable patients to address critical social determinants of health [71]. Effective telehealth interventions need to address the key social determinants of health at the root of entrenched health behaviors in systematic ways [72]. Most of the reviewed PCOR initiatives employed component interventions that were extensively culturally tailored during the initial program planning phases and on an ongoing basis to ensure that they were culturally congruent and appropriate based on the subjective culture (ie, norms and attitudes), behavioral preferences, and cultural values and expectations of the population served [71,73]. Thus, although cultural tailoring alone is not sufficient, the early PCOR literature indicates that it is an essential component of effective telehealth solutions to address health disparities.

Furthermore, this review revealed that telehealth solutions can take advantage of and expand on existing technological capacities accessible to low-income and other populations at risk for health disparities, and can often be deployed at low cost. The existing PCORI-funded telehealth research suggests that low-cost strategies that employ existing telehealth capacities using standard mobile phones and smartphones may be particularly effective in reaching patients where they are and engaging them in needed care. Although more than 90% of Americans overall carry cell phones and 80% have smartphones [107], among people with household incomes less than US

$30,000, only 71% own a smartphone, 54% own some type of computer, and 56% have home broadband [106]. As demonstrated by several of our case studies above, early evidence indicates that text messaging and other culturally tailored mobile health (mHealth) interventions can provide effective low-cost approaches for engaging patients in self-care [108-112]. Some systematic reviews have identified text messaging as among the most effective low-cost technological strategies for engaging patients in behavior change and have highlighted the importance of such technology-supported behavioral interventions [113-115]. Thus, health systems seeking to target telehealth solutions to address disparities should actively seek to employ existing technologies and devices like traditional cell phones to which populations at risk for disparities already have access.

This review also emphasizes the importance of telehealth solutions that work through existing trusted care networks and providers, and that employ trusted lay health worker and paraprofessional intermediaries to introduce and support the use of these technologies by people from the community. Many of the most effective PCORI telehealth initiatives considered in this paper focused their interventions around engaging, training, and deploying trusted intermediaries from the community and/or the population at risk for disparities to be served. This evidence also suggests that personalized human interaction is essential. For example, text messaging interactions were found to be most effective when delivered in real-time, tailored to participant interests and needs, and originated from a trusted known source. The PCORI-funded telehealth projects reviewed suggested that face-to-face videoconferencing and telephone interventions with trusted caregivers are particularly effective.

Our review further suggests that substantive reimbursement and regulatory changes are immediately needed to enable low-cost and efficient telehealth solutions. We found that the best practices in telehealth implementation include close partnership with payers to facilitate reimbursement and sustainability. However, ultimately, experience from the existing portfolio of PCORI telehealth projects indicates that permanent changes are needed in national reimbursement policies and regulations to facilitate broader telehealth adoption and implementation. Policies and reimbursement for telehealth were rapidly put into place to allow health care to continue during the severe restrictions early in the COVID-19 public health emergency after March 2020, in order to allow care to continue during the COVID-19 pandemic. However, these changes clearly need to be extended. Needed regulatory changes include expanded reimbursement as well as relaxations of regulations around where the patient or practitioner is located, licensure, and reciprocity across states. For example, since populations at risk for disparities generally have less access to the internet and technology, regulatory solutions need to facilitate and enable the use of existing lower-cost technologies, such as telephone visits using traditional cell phones, rather than requiring video teleconferencing for medical billing. As the pandemic eases, it will be essential to carefully think about how to preserve the progress that was made in expanding telehealth in ways that improve patient care at the federal (eg, Medicare), state, and individual insurance company levels [116-118].

Strengths and Limitations

The existing PCORI telehealth research targeting populations at risk for health disparities is of very high quality and has high applicability to real-world clinical and community settings. Of note, 100% of the PCORI-funded studies in this category employed a randomized controlled trial design and 100% were pragmatic rather than being conducted in highly controlled university settings among highly selected patients. This is a major strength of both the research reviewed in this scoping review and the scoping review itself. Furthermore, the studies included in this scoping review are also notable for their generalizability, given their pragmatic real-world approach. Rather than excluding patients with multiple chronic conditions as is often done in randomized clinical trials, many of the PCORI-funded studies specifically included patients with multiple morbidities given their representativeness of patients most commonly seen in real-world clinical settings.

This review is limited by the small numbers of studies that were considered, and its main findings are subject to numerous potential biases. First, since PCORI staff chose studies for an in-depth review based on their perception regarding which study teams overcame notable obstacles to telehealth, selection bias could have occurred. Our expectation is that this bias would most likely lead to the overemphasis of facilitators and solutions as opposed to barriers and challenges. Second, because PCORI staff and investigators comprised the study team, it is possible that there was some bias toward reporting of positive study findings. However, the study team and methods actively sought to address this potential limitation by identifying and categorizing barriers first prior to the discussion of solutions. In addition, some of the telehealth services provided in these studies may be difficult to consistently replicate outside of structured evaluations.

The review is also limited because final study results are not available for many of the included studies, and even fewer have detailed analyses of implementation factors and lessons learned available in the peer-reviewed literature. However, the review was facilitated by the detailed project knowledge of PCORI staff and the investigators themselves.

Future Directions

Over the past 5 years, PCORI has supported many comparative effectiveness studies of adopting virtual care solutions to manage health outcomes across a wide range of populations at risk for disparities. Through these research initiatives, health care delivery systems are learning to leverage low-cost telehealth solutions to promote better health outcomes by increasing access to care, making care more effective, and continuously engaging patients. PCORI-funded comparative effectiveness research is demonstrating how we can reduce health disparities across the spectrum of disease conditions and populations through low-cost telehealth solutions. This research is identifying key barriers and limitations to implementing telehealth in vulnerable populations and ways to overcome these barriers to help improve health and health care outcomes.

In this new era of the COVID-19 pandemic, there has been rapid growth in the use of technology across all industries, but it is proving to be particularly important in the areas of health and health care. Future efforts should focus on fostering collaborations between researchers, payers, and administrators to facilitate widespread adoption of new treatment models that have already demonstrated success through definitive clinical trials. Our review indicates that key system- and policy-level changes are desperately needed to address barriers to telehealth reimbursement. Moreover, further pragmatic research is needed to demonstrate the best approaches for disseminating and scaling these early telehealth findings in broader community practice to promote population health.

Conclusions

This scoping review gives strong guidance to health systems seeking to target evidence-based telehealth modalities for health disparities. Results from the studies demonstrate that systems can do so in innovative ways, and in fact, some of the studies identify methods for systems to effectively reach underserved populations in their own communities. These case studies also highlight the critical importance of both supportive infrastructure, and regulatory and reimbursement policies to facilitate telehealth modalities and make them sustainable.

However, despite growing evidence that telehealth can deliver care to people at risk for disparities, many major obstacles exist for its implementation. Early PCOR evidence demonstrates that the most effective health system- and provider-level solutions for at-risk populations use patient-centered and culturally tailored telehealth solutions whose development is actively guided by the patients themselves.

Acknowledgments

The authors gratefully acknowledge the many Patient-Centered Outcomes Research Institute (PCORI) study participant patient advisors who contributed their substantial expertise on patient experience to this scoping review. Without their participation and insights, this study would not have been possible. We are also very thankful for the contributions of the numerous PCORI-funded investigators and teams whose studies are cited in this scoping review. Lastly, we specifically acknowledge the editorial contributions of James Schuster, MD, at the University of Pittsburgh Medical Center, who also serves on the Board of Governors of the PCORI.

Conflicts of Interest

All listed authors are either investigators associated with Patient-Centered Outcomes Research Institute (PCORI)-funded studies in its specific telehealth portfolio, PCORI employees, or PCORI contractors/consultants. All statements in this report, including its findings and conclusions, are solely those of the authors and do not necessarily represent the views of PCORI, or its Board of Governors or Methodology Committee.

Multimedia Appendix 1
Patient-Centered Outcomes Research Institute–funded studies assessing the use of telehealth to improve outcomes for populations at risk for health or health care disparities.

Abstract

Background: Cognitive behavioral therapy (CBT) is the gold standard of psychotherapy for psychiatric disorders. However, the format of delivering CBT in person limits access to the intervention. The advancements in information and communication technology, especially the internet, present an opportunity for cognitive behavioral therapists to service patients or clients in remote areas through videoconferencing. Although many randomized controlled trials of videoconference-delivered cognitive behavioral therapy (VCBT) have already been conducted, the overall estimated effect size of VCBT for psychiatric disorders has not been examined by systematic reviews and meta-analyses.

Objective: This study attempts to evaluate the effectiveness of VCBT for psychiatric disorders through a systematic and meta-analytic review.

Methods: A systematic review and meta-analysis of studies in which VCBT was directly compared to control groups (such as treatment as usual, attention control, wait-list control, and other minimal supports) was carried out. To identify previous studies that meet our study objective, 2 independent reviewers undertook a systematic search through seven databases: MEDLINE (via PubMed), Web of Science, Science Direct, PsycINFO, CINAHL, LILACS, and SciELO. Other databases (ClinicalTrials.gov and Cochrane Central Resister of Controlled Trials) were also checked. All studies included in the review were assessed using the quality criteria of the Cochrane Collaboration. Statistical analysis was performed by using Cochrane Review Manager (RevMan, version 5.4.0). Standardized mean difference was used in major meta-analyses where a *P* value of .05 or less was the threshold for statistical significance. A heterogeneity test and the chi-square test were performed to assess the presence and extent of statistical heterogeneity with significance set at $P<.10$. Funnel plots were visually inspected to assess the risk of bias. Subgroup analyses were conducted for each disorder to estimate intervention effects.

Results: The systematic search resulted in 16 studies (total N=1745) that met the criteria for this study and were included in the review. There were 10 studies on depressive symptoms, 3 on chronic pain, 1 on generalized anxiety disorder, 1 on obsessive-compulsive disorder, and 1 on hypochondriasis. The quality and risk of bias was also assessed. Results showed a pooled effect size (Hedge *g*) post treatment of −0.49 (95% CI –0.68 to –0.29), indicating that VCBT is effective for clients with psychiatric disorders. Study quality did not affect outcomes.

Conclusions: While the overall results indicate the effectiveness of VCBT, there are still only a limited number of studies on specific psychiatric and somatic conditions. Therefore, more randomized controlled trials are needed to establish the effectiveness of VCBT for different disorders.

Introduction

Background

The incidence of mental health disorders has significant socioeconomic implications for public health and human rights globally. Depression, for example, is a leading cause of disability, affecting an estimated 264 million people worldwide [1]. It has been shown that cognitive behavioral therapy (CBT) is an effective treatment for a variety of mental disorders [2,3]. Cognitive behavioral therapists analyze the effects of their patients' cognition and behavior on psychiatric symptoms [4,5], and work toward developing adaptive cognitive-behavioral techniques with their client [6,7]. Evidence suggests that CBT is effective not only for psychiatric disorders [8] but also for somatic disorders [9]. It is considered the gold standard in the treatment of mental health disorders because it is substantiated by theory and research [10]. Further, evidence suggests that CBT is superior to other modalities, such as interpersonal psychotherapy [11]. The World Health Organization (2019) has also recognized its effectiveness and stated that access to CBT is important [12]. Face-to-face therapy is the most common format for providing treatment for mental health issues. However, this can restrict access to CBT for patients living in remote areas. Considering the widespread use of the internet and telecommunications equipment [13], there is a window of opportunity to provide access to CBT to patients living in remote areas [14]. Most remote CBT is delivered with the help of websites/webpages, under the guidance of a therapist. This format is called internet-based cognitive behavioral therapy (ICBT) or simply "internet intervention." According to Olthuis et al [15], "to be considered an Internet intervention, CBT must have been delivered over the Internet through the use of web pages or e-mail, or both." Two systematic reviews including meta-analyses have suggested that in terms of effectiveness, ICBT is equivalent to face-to-face CBT [16,17].

Videoconference-Delivered CBT

Another approach to improve accessibility to CBT for individuals residing in remote areas is to utilize a videoconferencing system [18-20]. In comparison to ICBT, videoconference-delivered CBT (VCBT) has the advantage of enabling remote treatment through interactive real-time communication between the therapist and the patient, which makes it similar to face-to-face CBT. At the same time, VCBT differs from face-to-face CBT because there is a "physical separation" between the therapist and patient, which may create limitations in clinical practice. For example, when dealing with a patient with obsessive-compulsive disorder, the patient cannot directly touch the stimulus/subject provided by the therapist. The patient must work on the subject at home on their own. Time lags and poor eye contact during video calls may affect the quality of interaction between the therapist and patient, creating obstructions for cognitive reconstruction and the creation of cognitive models.

Despite these concerns, results from previous clinical trials investigating the feasibility and efficacy of VCBT were generally promising [18-21]. The results from prospective and rigorous clinical trials (RCTs) have suggested that VCBT is not inferior to face-to-face CBT for the treatment of depression and posttraumatic stress disorder [22-25]. An existing literature review summarized previous findings [26] but did not conduct a meta-analysis of the results of RCTs drawing direct comparison to controls such as conventional treatment. A network meta-analysis that examined the most effective CBT format for the treatment of acute depression also did not compare for VCBT [27]. Several systematic reviews to assess the effectiveness of videoconference-delivered psychotherapy for the treatment of depression [28] and anxiety disorders [29] suggest that VCBT is an acceptable form of remote therapy for such patients, and clinical symptoms can be expected to improve. However, these reviews did not perform a meta-analysis owing to a lack of RCTs. Therefore, the estimate effect size of VCBT could not be gauged.

Study Objective

As of December 2020, results from new RCTs to validate the effectiveness of VCBT for people with depressive symptoms [30-35], chronic pain, and hypochondriasis [36,37] have emerged. Therefore, there is a need for a systematic review and meta-analysis focusing on VCBT. The objective of this study is to examine the effectiveness of VCBT as a treatment option for psychiatric and somatic disorders in comparison to control conditions. The population of this review targeted both clinical and community samples. To increase the credibility of the results by reviewing high-evidence studies [38], this review included only RCTs. This study's protocol was registered with PROSERO (CRD42021224832) [39]. The protocol planned to include RCTs targeting children and adolescents. However, owing to a small number of RCTs with children and adolescents as participants [40,41], the selection criteria for this review focused on studies with adult participants. This review was in accordance with the

Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) 2020 statement [42], see the PRISMA checklist provided in Multimedia Appendix 1.

Methods

Eligibility Criteria

The eligibility criteria for the original studies to be a part of review were as follows: (1) subjects of the study were adults (age>18 years); (2) the intervention was VCBT; (3) the intervention group was compared to attention training (AT), treatment as usual (TAU), wait-list control (WLC), or other active control (AC) conditions; (4) the outcome was the effect of VCBT on the management of the symptoms of psychiatric or somatic disorders (primary outcome measures); (5) used a randomized control study design; and (6) were written in English. Exclusion criteria were studies in which the intervention was not based on cognitive-behavioral techniques, participants were children or adolescents, and the necessary data were inaccessible.

Information Sources and Search Strategy

To identify previous studies that met our study objective, systematic searches were conducted on MEDLINE (via PubMed), Web of Science, Science Direct, PsycINFO, CINAHL, LILACS, and SciELO using the following terms related to psychiatric and somatic disorders: “depression,” “panic disorder,” “social phobia,” “social anxiety disorder,” “generalized anxiety disorder,” “obsessive-compulsive disorder,” “post-traumatic stress disorder,” “specific phobia,” “hypochondriasis,” “bulimia,” “tinnitus,” “erectile dysfunction,” “chronic pain,” or “fatigue.” To determine the intervention approach, these search terms were combined with “videoconference,” “video conference,” “videoconferencing,” “tele,” “teleconference,” “tele conference,” or “teleconferencing,” and the search filter “randomized controlled trial” was used. The search did not include unpublished studies. Searches were last updated on December 25, 2020. Other databases were also checked (ClinicalTrials.gov and Cochrane Central Resister of Controlled Trials), along with the references of the previous systematic reviews [28,29]. For more information on the full search strategies, see the complete search strategy provided in Multimedia Appendix 2.

Process of Selection and Data Collection

A total of 2 reviewers (KM and SH) independently made decisions on whether they met the selection criteria in accordance with the aforementioned search strategy. If the selected studies did not match, the decision was made by a joint discussion among the research team, including a third party (ES). The selected studies were managed using EndNote.

Data Items

Participants were those who received VCBT without restrictions, including clinical samples, community members, and students. We set the clinical symptoms as outcomes before and after the intervention. For example, if satisfaction or acceptance of the intervention was the primary outcome, a secondary outcome to measure the severity of the target disorder was adopted. The intervention was conditional on the inclusion of having sessions with the therapist via a videoconferencing system and cognitive behavioral techniques such as behavioral activation, cognitive restructuring, exposure, and mindfulness, among others.

Study Risk of Bias Assessment

The first and second authors (KM and SH) read the abstracts independently. In case of any disagreement regarding the inclusion of a particular study, the article was discussed among all researchers. All studies included in the review were assessed using the revised Cochrane risk-of-bias tool for randomized trials (RoB 2) [43,44]. The included studies were rated on each of the aforementioned dimensions as low risk, some concern, or high risk.

Statistical Analysis

Effect Measures

The standardized mean difference (SMD) was used in major meta-analyses because the studies included in this review used different symptom evaluation scales for the primary outcomes. The value of SMD depends on the effect size (difference in mean) and SD of the outcome (unique variation between participants). In the event of a missing summary statistic, we contacted the authors. If there was no reply, it was excluded from this review because there were no data that can be handled.

Synthesis Methods

Statistical analysis was performed by using Cochrane Review Manager (RevMan; version 5.4.0) [43]. First, standardization was achieved by dividing the mean difference (the change from baseline to the end of the study or the value at the end of the study) by the SD of the control group in the study. Next, in a meta-analysis, the standardized mean values from individual studies were integrated to calculate the SMD. The data reflecting intention-to-treat took precedence over the per-protocol data in the meta-analysis. Intervention effects were assessed with random-effect meta-analyses, assuming variation in true effects and accounting for the hypothesized effect distribution [45,46]. A P value of ≤.05 was considered the threshold for statistical significance. According to the power calculation by Borenstein et al [45], a power of 80% to detect a small effect size required that each group has an average of 25 participants and studies be 14 or more in number (if the probability of rejecting the null hypothesis is 5%). Subgroup analyses to the estimation of intervention effects were conducted for each disorder.

The heterogeneity test and the chi-square test were performed. Significant heterogeneity of >40% suggests the presence of heterogeneity [47]. The presence and quantity of statistical heterogeneity was assessed using the I^2 statistic, with significance set at P<.10 [48].

Sensitivity analysis was performed to compare studies that were judged to have a low risk of bias and to determine the quality of the affected outcomes.

Reporting Bias

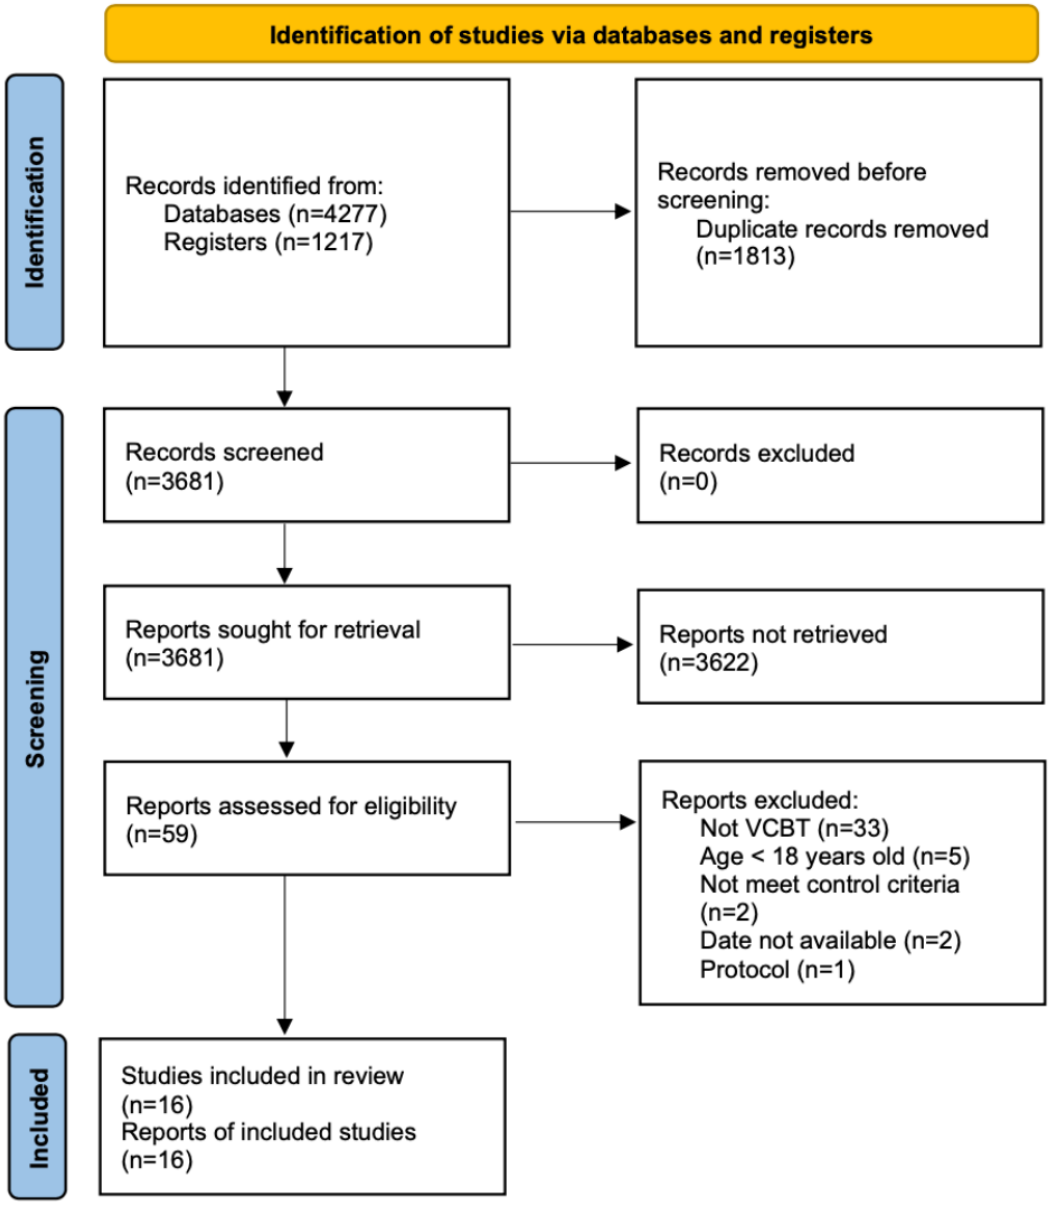
The funnel plots were visually inspected to assess the risk of bias.

Results

Studies Included in the Review

Of the 3684 screened studies, 16 (N=1745) met all selection criteria and were included in the analysis. Figure 1 shows the inclusion process based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram [49]. There was a 3-arm RCT [33]; 2 arms of those intervention groups were behavioral activation and problem-solving. In terms of participants' conditions, 10 studies targeted depressive symptoms [30,32-35,50-54], 3 focused on chronic pain [31,37,55], 1 on obsessive-compulsive disorder [21], 1 on general anxiety disorder [56], and 1 on hypochondriasis [36]. The total number of participants from whom posttreatment data were collected was 768 in VCBT and 718 in the control conditions. Studies that reported 2 RCTs were excluded because no data were available [57,58].

Figure 1. The inclusion process. VCBT: Videoconference-Delivered Cognitive Behavioral Therapy.



Characteristics of the Selected Studies

The RCTs included in this review were conducted by 13 independent research teams. Of them, 11 were performed in the United States, 2 in the United Kingdom, 2 in Canada, and 1 in Norway. The smallest study had 27 participants and the largest had 343 participants. All studies were published between 2008 and 2020. One RCT was configured with 2 VCBT intervention arms [33], the sample size of the control group set to half when the effect size was estimated in the meta-analysis. Table 1 presents the characteristics of each included study (see Multimedia Appendix 2 for details).

Table 1. Characteristics of the selected studies.

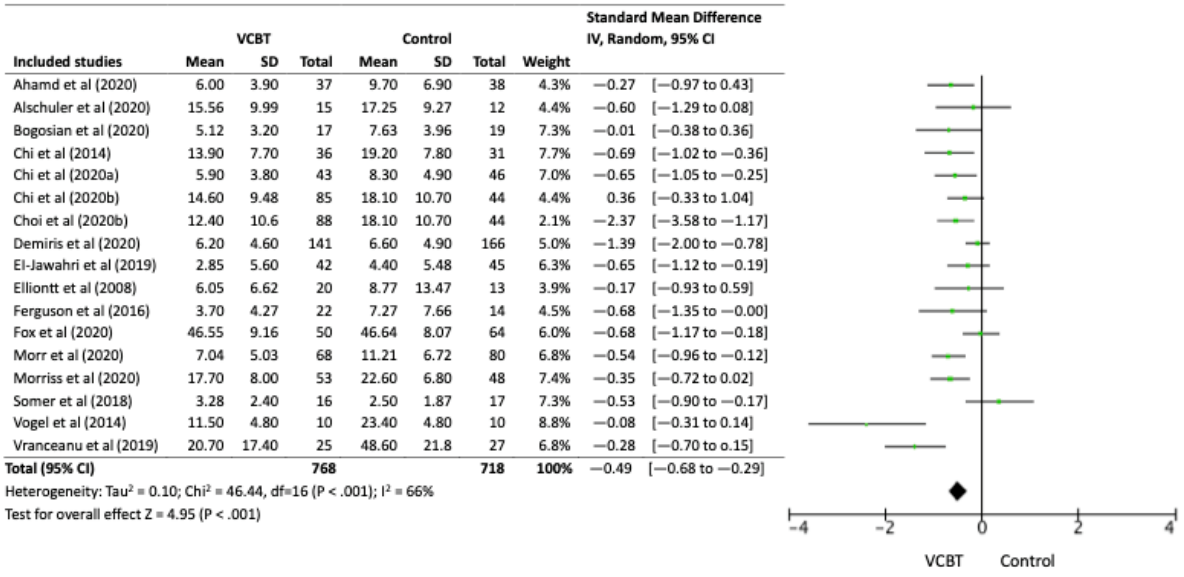
Risk of Bias in Studies

Evaluation of the quality of the studies included in this review shows that 4 RCTs (5 comparisons) are at a lower risk of bias [30,33,35,50], 10 RCTs are of some concern [31,32,34,36,37,51-55], and 2 RCTs are at a high risk of bias (see Multimedia Appendix 2 for details) [21,56].

Results of Syntheses

Figure 2, a forest plot, shows the effect size (Hedge *g*) of each study and the overall effect size integrated by the meta-analysis. An effect size estimated below 0 favors guided VCBT. In all 16 studies (17 intervention arms), the pooled between-group effect size (Hedge *g*) was −0.49 (95% CI −0.68 to −0.29, *P*<.001), showing that VCBT was significantly more effective than the control conditions.

Figure 2. Forest plot. VCBT: videoconference-delivered cognitive behavioral therapy.



In the 10 studies (11 comparing) focused on depressive symptoms, the effect size (Hedge *g*) was medium, at −0.46 (95% CI −0.60 to −0.32, *P*<.001). In 3 studies targeting chronic pain, the effect size (Hedge *g*) was −0.41 (95% CI −1.49 to 0.67, *P*=.46), showing the effectiveness of VCBT, but was not significant. In the study targeting generalized anxiety disorder, the effect size (Hedge *g*) was −0.08 (95% CI −0.31 to 0.14, *P*=.46). In the study targeting obsessive-compulsive disorder, the effect size (Hedge *g*) was −2.37 (95% CI −3.58 to −1.17, *P*<.001). In the study targeting hypochondriasis, the effect size (Hedge *g*) was −0.65 (95% CI −1.05 to −0.25, *P*=.001).

Results of the Heterogeneity Test

Tests of heterogeneity demonstrated significant differences in effects across treatments (τ^2=0.10; χ^2_{16}=46.40; I^2=66%; P<.001). The heterogeneity was largely driven by a study conducted on exposure response prevention for obsessive-compulsive disorder [21], and 2 studies that conducted unique interventions [37,55]. If those studies were excluded, the I^2 decreased from 66% to 27%: heterogeneity was not significant (τ^2=0.02; χ^2_{13}=17.87; P=.16). The pooled effect size across all studies changed marginally from Hedge g=−0.47 (95% CI −0.69 to −0.23) to Hedge g=−0.44 (95% CI −0.59 to −0.29), if those studies were excluded from the analysis. In the 10 studies (11 comparing) on depressive symptoms, tests of heterogeneity demonstrated no differences in effects across treatments (τ^2=0.01; χ^2_{10}=11.09; I^2=10%; P=.35).

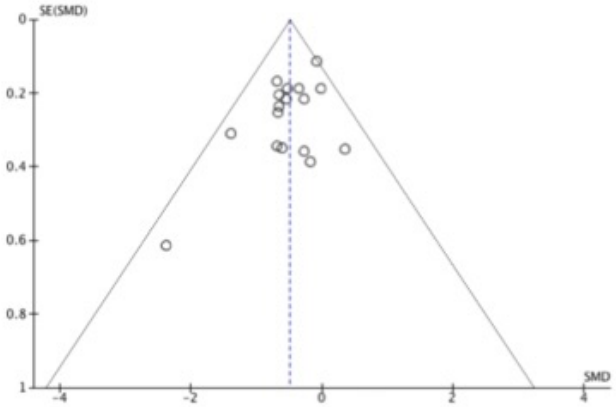
Results of Sensitivity Analysis

Subgroup analysis was conducted to verify an association between the studies' quality and intervention effects. In the 4 studies (5 comparisons) judged to have a low risk of bias, the estimated pooled effect size (Hedge g) was −0.56 (95% CI −0.74 to −0.38, P<.001; τ^2<0.001, χ^2_4=2.13, P=.71; I^2=0%) and −0.42 (95% CI −0.69 to −0.16, P=.002; τ^2=0.15, χ^2_{12}=42.01, P<.001; I^2=71%) for the other 11 studies. Thus, our results suggest that study quality did not significantly affect intervention effects.

Publication Bias

Figure 3 displays a funnel plot. Effect sizes were not evenly distributed around the averaged effect. The lower-right section of the funnel plot is devoid of studies, which suggests that there was bias in the pooled effect estimate owing to unpublished studies.

Figure 3. Funnel plot. SMD: standardized mean difference.



Discussion

Principal Findings

The objective of this systematic review was to investigate the effectiveness of VCBT as an intervention strategy as compared to control conditions such as AC, AT, TAU, and WLC using meta-analysis. Taken together, the results of this meta-analysis suggest that the pooled effect size of the primary outcomes of each disorder is medium, indicating that VCBT is especially effective for depressive symptoms. The novelty of this meta-analytic review lies in integrating the effectiveness of VCBT for psychiatric and somatic disorders, extending current knowledge into the field of remote psychotherapy [28,29,59]. However, most of the RCTs included in this review targeted depression. Therefore, further RCTs should be performed to accurately estimate the effectiveness of VCBT for generalized anxiety disorder, obsessive-compulsive disorder, chronic pain, and hypochondriasis. The quality of the study in the 16 RCTs (17 comparisons) was evaluated using RoB [43]: only 4 studies (5 comparisons) showed a low risk of bias, 10 showed some concern, and 2 showed a high risk of bias. Meta-analysis with the 4 studies (low risk of bias) revealed a moderate effect size and no heterogeneity for the effectiveness of VCBT. This result was also similar to those of a meta-analysis of 11 studies in which other judgments were made for all 16 RCTs (17 comparisons) and other bias risks. Therefore, the findings of this systematic and meta-analysis suggest evidence that VCBT is also effective for diseases for which face-to-face and guided ICBT have been demonstrated [8,16,17].

Strengths of the Review

This meta-analysis has several strengths. The results of this systematic review and meta-analysis for psychiatric disorders extend support in favor of VCBT as an effective mode of intervention. Prior systematic reviews of CBT utilizing videoconferencing systems did not include meta-analysis [28,29]. Furthermore, this study has integrated the results of RCTs that directly compared the effectiveness of VCBT for typical psychiatric disorders with minimal intervention. Our results provide useful information for clinicians and policy makers to take the practicality of VCBT into account, especially in response to the COVID-19 pandemic [60].

Limitations

This study also has some limitations. First, the analyzed studies were highly heterogeneous. Second, this study adopted a broad definition of CBT. CBT is a broad concept that includes treatment methods such as cognitive therapy, behavioral therapy, acceptance and commitment therapy, behavioral activation, problem-solving techniques, and prolonged exposure therapy. Therefore, the effect size should ideally be estimated for each therapeutic technique in the future, as was performed in a previous review of cognitive therapy for depression [61].

However, the effectiveness of each cognitive behavioral technique could not be calculated in this study, owing to the small number of pre-existing studies to analyze intervention categories and subcategories. Furthermore, owing to the inconsistent control criteria in this review, it is not possible to assess the exact effectiveness of VCBT. The gold-standard design for estimating the effect of treatment is RCT with psychological or the pill placebo group [62]. These control conditions can be standardized to control the impact of patient expectations on outcomes. Therefore, to estimate the effectiveness of VCBT accurately, it is necessary to perform a meta-analysis at the stage when RCT with psychological or pill placebo group is sufficiently accumulated. Further, this review only included studies that used adult participants owing to the low number of RCTs for children and adolescents. In future, RCTs to evaluate the effectiveness of VCBT should also be conducted on samples of children and adolescents. Since we only included articles written in English, we need to examine studies reported in more diverse languages in the future. Finally, long-term effectiveness of VCBT was not analyzed. Since this study succeeded in demonstrating the short-term effectiveness of VCBT for adult psychiatric disorders and somatic symptom disorders, the results of long-term effectiveness in the future RCTs should also be integrated.

Comparison With Prior Work

Our results, indicating that VCBT is effective for somatic disorders, extend support to those of Liu et al [9], who compared VCBT and face-to-face CBT. Additionally, the overall effect size estimated in this meta-analysis is very similar to previous results on face-to-face CBT and computerized CBT for treatment of depression and anxiety, compared to primary care TAU [61,63]. Furthermore, the effect size (Hedge g=0.46, medium effect size) of VCBT for depressive symptoms is consistent with previous results (Hedge g=0.71, large effect size) of a bias-adjusted meta-analysis [64]. Therefore, our findings demonstrate the effectiveness of VCBT as a treatment option for adults with psychiatric disorders.

This review did not include exposure techniques except for an RCT by Vogle et al [21]. Real-time interventions that utilize videoconferencing systems have the advantage of exposing the home environment of the patient [65]. At the same time, it is difficult to match up to the interpersonal experience of working with a therapist to resolve the issues, especially in the treatment for disorders that require exposure therapy such as obsessive-compulsive disorder and panic disorder. In case of obsessive-compulsive disorder, patients are afraid of things such as hospital floors, rags, and toilet paper. In case of panic disorder, the task of working with the therapist to climb stairs and exercise may be difficult to perform. Therefore, it would be premature to determine the effectiveness of VCBT for patients with anxiety disorders from the effect sizes shown in this review. The results of clinical studies that were not RCTs show that VCBT is sufficient to improve symptoms of obsessive-compulsive disorder and panic disorder [18,21,65], where exposure is an important therapeutic component [66,67]. In the future, tightly controlled RCTs are expected to be implemented, and this review should be updated with regard to the calculation of integrated estimated effect sizes for those disorders.

The number of studies included in the analysis corresponding to each condition was small, except for depressive symptoms. However, the total number of studies and participants made it possible to detect significant differences between VCBT and control conditions. However, the high degree of heterogeneity indicates the need for careful interpretation of our results. While the risk of bias detected in the quality assessment appeared to have an overall minor impact, there may be publication bias, as no negative results were reported. Namely, the funnel plot in this study suggests that there was bias in the pooled effect estimate owing to unpublished studies. Positive findings are thrice more likely to be published than negative findings [68]; hence, careful interpretation of our results is required.

Conclusions

This study attempted to provide evidence in favor of the effectiveness of VCBT as a feasible alternative approach to service patients with poor access to face-to-face CBT. VCBT, has the advantage of facilitating real-time communication between patients and therapists. This has important implications for clinicians and policy makers because it is a well-accepted approach that has demonstrated a high degree of satisfaction [19]. Although more studies are needed to draw firm conclusions, findings such as those from our meta-analysis show that VCBT is a promising treatment for future use [69].

Abstract

Background: Pediatric drug calculators (PDCs) intended for clinical use qualify as medical devices under the Medical Device Directive and the Medical Device Regulation. The extent to which they comply with European standards on quality and safety is unknown.

Objective: This study determines the number of PDCs available as mobile apps for use in the Netherlands that bear a CE mark, and explore the factors influencing the CE marking of such devices among app developers.

Methods: A scoping review of Google Play Store and Apple App Store was conducted to identify PDCs available for download in the Netherlands. CE accreditation of the sampled apps was determined by consulting the app landing pages on app stores, by screening the United Kingdom Medicines and Healthcare products Regulatory Agency's online registry of medical devices, and by surveying app developers. The barriers to CE accreditation were also explored through a survey of app developers.

Results: Of 632 screened apps, 74 were eligible, including 60 pediatric drug dosage calculators and 14 infusion rate calculators. One app was CE marked. Of the 20 (34%) respondents to the survey, 8 considered their apps not to be medical devices based on their intent of use or functionality. Three developers had not aimed to make their app available for use in Europe. Other barriers that may explain the limited CE accreditation of sampled PDC apps included poor awareness of European regulations among developers and a lack of restrictions when placing PDCs in app stores.

Conclusions: The compliance of PDCs with European standards on medical devices is poor. This puts clinicians and their patients at risk of medical errors resulting from the largely unrestricted use of these apps.

Introduction

The use of mobile health (mHealth) apps among clinicians is growing [1,2]. In 2015, 60% of medical doctors in the Netherlands used at least 1 mHealth app [3]. The widespread use of mHealth apps creates new risks for patient safety [4,5]. These risks include both technical malfunctions and misuse, either of which may lead to life-threatening medical errors [4].

To mitigate these risks, the European Union (EU)'s 2007 Medical Device Directive (93/42/ECC) (MDD) qualifies "any…software…intended by the manufacturer to be used…for the purpose of diagnosis…or treatment…of disease" as a medical device [6]. The MDD categorizes medical devices into 4 classes of risk (Classes I, IIa, IIb, and III) based on their technical characteristics, invasiveness, and potential for harm. Each class of risk determines a specific conformity assessment procedure for legally entering the European market. The higher the class of risk, the more stringent the conformity assessment procedure, with the overall objective being to provide adequate safeguards for users to be able to safely use the device. For example, for a Class II medical device, conformity assessment entails an evaluation of the device's technical documentation as well as its quality management system [6]. Depending on the device classification, conformity assessment is performed by either the manufacturer (Class I) or a European Notified Body (Class IIa and above). Once the conformity assessment is complete, medical devices obtain a CE mark, indicating their conformity with European health and safety standards, allowing them to be made available to the public within the extended single market of the European Economic Area (EEA) [7].

In May 2017, the MDD was replaced by the Medical Device Regulation (2017/745) (MDR) [8]. Among other changes, the MDR addresses software as a distinct item and establishes more stringent classification rules for software apps under Rule 11 [8,9]. By May 2021, all new devices placed on the European market were required to comply with the MDR. Devices already certified under the MDD may continue to be placed on the European market until May 2024, with the exception of Class I devices receiving a higher class under the MDR [10,11].

Despite increasingly binding European regulations, poor compliance of mHealth apps with EU certification requirements has been found. An examination of a sample of health apps freely available on several app stores by the Dutch Royal Institute for Public Health and the Environment reported that less than half are CE marked, as appropriate [12].

Pediatric drug calculators (PDCs) are tools designed to help clinicians overcome the complexities of dosing calculations in pediatrics and are increasingly used in clinical care [13]. By allowing clinicians to calculate drug doses to be administered to children based on patient characteristics, most often their weight, PDCs constitute 1 example of medical apps potentially associated with new risks for patients [14,15]. PDCs have received little scrutiny with regard to their conformity to European standards [12,16]. In this study, we perform a scoping review of Google Play Store and Apple App Store to identify PDCs available for download in the Netherlands and determine their CE accreditation status. Barriers to CE accreditation are explored through developer surveys and interviews.

Methods

Definitions

In this study, a PDC was defined as a mobile app that allows clinicians to enter information about an individual child's weight or age in order to calculate a recommended drug dosage for that child. Programs designed to determine an infusion rate or dilution volume for a given drug dosage were also defined as PDCs.

Because PDCs perform transformation of data intended to inform treatment decisions for individual patients, they would qualify as medical devices under the MDD and the MDR [6,8,17,18]. According to the MDD, PDCs would be classified as Class I medical devices [6]. In line with Rule 11 of the MDR, any software "intended to provide information…used to take decisions with…therapeutic purposes" falls under Class IIa. When such decisions can cause "a serious deterioration of a person's state of health…," the software falls under Class IIb [8]. If the decision has the potential to "cause death or an irreversible deterioration of a person's state of health," the software receives a class III classification [8]. PDCs intended for clinical use would therefore be classified as Class IIa or above under the MDR.

The terms "application provider," "manufacturer," and "developer" have been used interchangeably in this study.

Search Strategy and Screening

A scoping review of PDCs available on app stores was performed using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology [19]. Apps were searched for on Google Play Store (Android system, desktop version) and Apple App Store (iOS system, mobile version) between April 8 and April 19, 2020. Separate searches were performed in both app stores using the following search terms: "pediatric drug," "pediatric drug calculator," "neonatal drug," and "neonatal drug calculator." Sample searches for the terms "pediatric drug" and "pediatric drug calculator" were also conducted in both app stores. They produced identical results to the ones obtained for the previous search terms and were hence not completed. All sampled apps were deduplicated and screened by an individual reviewer (author CK). The availability of each app on Google Play Store and Apple App Store was verified independently of the initial search results.

Eligibility criteria were defined a priori. Apps were required to appear to be designed for health care professionals, including medical students, doctors, nurses, and paramedics. A PDC was required to be the main functionality or 1 of several functionalities of each app. The drug dosage calculator should have been developed for a pediatric population, with users able to calculate a drug dose for a specific weight, age, or body surface area. PDCs for oral or intravenous drugs were eligible if they covered more than 1 drug. Infusion dilution and infusion rate calculators were also included. Apps solely performing calculations for parenteral nutrition, maintenance fluids, electrolytes, or chemotherapy were excluded.

PDCs were screened based on their name, description, and screenshots available in each app store. Only apps that were freely available were downloaded.

Data Extraction and Qualitative Analysis

The name, manufacturer, and country of manufacture of each PDC were collected. Information about the type of calculations performed (drug dosage or infusion dilution or rate), the intended location of use (within or outside the EEA), and the number of downloads on Google Play Store were captured. To determine the CE marking status, we searched the PDC description and screenshots in app stores, any documentation provided on the app website, and relevant pages of the downloaded app (License, Disclaimer, About, or Terms and Conditions).

All PDC manufacturers with identifiable contact information were contacted through email (see Multimedia Appendix 1). Developers were invited to provide information about the type of calculations performed and the intended location of use of their PDC. They were asked whether their apps were CE marked and were invited to describe their considerations in choosing whether to pursue CE marking. They were additionally asked to report any barriers encountered in the CE accreditation process. When their responses called for clarification, they were recontacted. App providers were interviewed through video calls whenever they accepted to do so.

Data obtained from PDC manufacturers were anonymized through the attribution of a numeric code and access restricted to the first author. Responses from developers were manually analyzed. Separate considerations and barriers to CE accreditation were identified from their responses and categorized through thematic inductive analysis by 1 reviewer (CK). Developers' responses were coded against the identified themes. The coded list of barriers and considerations was discussed with 2 additional authors (JC and NA), and discrepancies were resolved through consensus.

When relevant information about CE accreditation could not be obtained from the aforementioned sources, registration of the app on the United Kingdom Medicines and Healthcare products Regulatory Agency (MHRA) was searched using the MHRA website's search function with the app manufacturer name [18]. At the time of data collection, the MHRA website constituted the only available repository of information related to the CE accreditation of medical devices in the EU.

Both app stores were contacted through their online contact pages to inquire about their review process for medical apps and the extent of their collaboration with European regulatory authorities.

Ethics

According to the Dutch Medical Research Involving Human Subjects Act, formal ethical review was not needed. Interviewees provided informed consent through email to collect and store their anonymized responses and for these to be published. Patient consent was not applicable.

Data Sharing

All data that informed this study are contained within the article and its supplementary files.

Public and Patient Involvement

Patients and the public were not involved in the design, conduct, reporting, dissemination plans of this research.

Transparency

The lead author affirms that this manuscript is an honest, accurate, and transparent account of the study being reported; that no important aspects of the study have been omitted; and that any discrepancies from the study, as planned, have been explained.

Results

Inclusion and Classification of Apps

A total of 632 PDCs were included for screening after deduplication (see Figure 1 and Multimedia Appendix 2). Of these, 74 (11.7%) PDCs met the inclusion criteria: 66 of the 74 (89.2%) apps were available on Google Play Store and 8 (10.8%) on Apple App Store (see Table 1); 20 (27%) apps were available on both stores. In addition, 18 of 74 (24.3%) apps were developed in EEA countries, 60 (81.1%) included a drug dosage calculator, and 14 (18.9%) incorporated an infusion rate or infusion dilution calculator without a drug dosage calculator. The number of installations per app on Google Play Store varied from 10-100 to over 100,000; 13 of 74 (17.6%) apps had been installed over 100,000 times. Of the 74 screened PDCs, only 1 (1.4%) app was CE marked.

Qualitative Analysis

App Developers

Of 61 app developers, 59 (96.7%) for whom contact information was available were contacted through email; 1 (1.6%) developer was additionally contacted through a video call. Responses were obtained from 20 of 59 (33.9%) providers that developed 21 apps (see Table 2). Of the 20 developers, 3 (15%) were based in the EEA. None of the apps developed by the respondents were CE marked. In addition, 2 of the 20 developers (10%) indicated that they understood that their apps qualified as Class I medical devices under the MDD but were not CE marked (developers 4 and 8), while 2 (10%) had attempted to get their apps CE marked but were unsuccessful (developers 5 and 18).

The most frequent reason for not pursuing CE accreditation provided by developers was that in their view, their apps did not qualify as medical devices (8/20, 40%). Various arguments informed this assessment. Of the 20 developers, 2 (10%) referred to the intended use of their apps, stating that the apps were designed as a *reference* or an *educational* tool for clinicians as opposed to a clinical decision-making aid (developers 11 and 15). This disclaimer was also frequently provided in the end-user licenses of sampled apps. Other developers referred to their apps' functionality, describing them as *digital documents* (developer 1) or *books* (developer 14), which did not entail manipulation of data. In both cases, the functionality of the apps involved transformation of data. Arguments pertaining to functionality also examined the nature of the information being input into and delivered by a given app, and the weight of the result in determining the process of care. Developer 18 highlighted a difference between drug dosage calculators that could be seen as medical devices owing to their recommending a specific drug dose based on an individual patient's characteristics, and the infusion rate or dilution calculators performing simple conversion operations on pre-established drug prescriptions. According to developers 8 and 13, the level of transparency and complexity of the computations performed

by an app constituted key factors when determining whether it qualified as a medical device. Developer 13 suggested that if the calculations performed by an app are simple enough to be immediately replicable by users, then the app would not qualify as a medical device. Developer 8 suggested that even for more complex calculations, if the calculations are linked to user-accessible formulae and bibliographic support, the app should not be classified as a medical device.

Other reasons put forward by developers as justification for not CE-marking their apps included a lack of knowledge of European legislation on medical devices (3/20, 15%), the fact that their apps were not devised for use in EEA countries (3/20, 15%), and the fact that no certification was required for access to Google Play or Apple App Store (4/20, 20%). Several manufacturers described app stores as implicit arbiters for matters of regulatory compliance or safety ("My app was evaluated in the…store by the public user" or "It was very easy to place on the…store."). Of the 20 providers, 3 (15%) indicated that Apple App Store was more restrictive than Google Play Store when granting access for PDCs; 1 (5%) developer outside the EEA argued that his app did not require testing or accreditation according to the regulations of his country (developer 15).

Several barriers to CE marking were outlined by developers. Of the 20 manufacturers, 2 (10%) indicated that the process was too complex (developers 4 and 18), and 1 (5%) said it was too costly to take on as an individual developer or a small enterprise (developer 18). This appeared more generally relevant across the sample, with multiple developers stating that they were clinicians with programming skills who developed a PDC "as a hobby" (developer 6) or "for their own use" (developer 16). An added barrier in this view concerned the lack of institutional support received by app manufacturers seeking to obtain a CE marking that were also affiliated to a hospital or a university. After receiving confirmation from national regulatory authorities that his app qualified as a Class I medical device under the MDD, developer 4 asked the relevant national health care institution for its support in the CE accreditation process. He did not obtain this support due to the institution's concerns over the costs and associated legal liability. He shared that "developers are often left unsupported by their associated institutions...I think mostly because of a lack of experience and knowledge regarding the governance and legal implications, many institutions feel vulnerable and unwilling to engage with regulatory bodies." Overall, this "had an unfortunate regressive effect" on the dissemination of his app. Independently of CE accreditation, 5 of 20 (25%) developers had sought alternative forms of clinical validation for their apps, for example, by national experts.

App Stores

Neither store provided information about its review process and collaboration with European regulatory authorities. Apple App Store's guidance states that "drug dosage calculators must come from the drug manufacturer, a hospital, university, health insurance company, pharmacy or other approved entity, or receive approval by the FDA or 1 of its international

counterparts" [20]. No such clause was found in the Google Play Store guidance [21].

Discussion

Principal Findings

We systematically reviewed the CE accreditation of PDCs available on 2 mobile app stores in the Netherlands. Of 74 sampled PDCs, 1 (1.4%) had the appropriate CE marking in conformity with the MDD. At a time when European regulatory authorities are seeking to enhance their scrutiny of medical apps, for example, through the MDR, this study sheds a new light on several barriers to CE accreditation for eligible mHealth apps.

This study delivered several new insights. It revealed that almost all PDCs available for download in the Netherlands fail to comply with European regulations on medical devices. The only app that is certified under the MDD (Neomate; see Table 1) will likely require additional assessment due to the more stringent classification requirements of the MDR [3,8,22]. The status quo with regard to CE accreditation for PDCs available on app stores is concerning, especially considering the fact that these apps are widely used by clinicians and have the potential to cause harm. Of the 74 PDCs identified on the screened stores, 13 (17.6%) had been downloaded over 100,000 times. Our findings thus echoed those of earlier studies highlighting the widespread use of mHealth apps among clinicians, including pediatricians [1,3].

Multiple reasons were identified for PDC manufacturers' poor compliance with European regulations. First, PDC developers appeared to have varying levels of awareness of the existence of such regulations. For those manufacturers that knew about these regulations, European rule interpretation was ambivalent. Several developers argued that their apps do not qualify as medical devices according to the relevant European standards. This was true despite the clear statement by the MDD, the MDR, and associated European and European member state guidance that any software involving manipulation of data intended to be used for diagnostic or treatment purposes in individual patients qualify as a medical device [3,6,8,17,22]. The concept of *intent of use* seemed especially prone to a variety of interpretations by manufacturers. Many of those interviewed, as well as the end-user licenses of multiple sampled apps, indicated that their PDCs were for reference or educational purposes only. This claim, however may be in conflict with the *actual* use of such apps by their users, given their functionality. Although data on PDC usage by clinicians is scarce, anecdotal evidence suggests that the advice generated by such apps is frequently used to inform real patient care.

Reflecting on the functionality of their apps, some developers highlighted a difference between pediatric drug dosage calculators and calculators of infusion volumes or rates [23]. The difference, they contended, pertained to the type of information being input into the app and the data delivered by it, as well as the complexity and transparency of the computations it ran. Although drug dosage calculators generated medication advice based on individual patient characteristics, this was not the case for infusion rate calculators that performed conversion calculations on a pre-established drug dosage. This distinction, however, does not align with MDD guidance nor with the MDR, which take the stance that any app involving transformation of data subsequently informing the treatment of an individual patient qualifies as a medical device, irrespective of the complexity of the transformation [6,7,17].

In addition to disagreements on the substance of European law, another barrier hampering broader CE accreditation of eligible apps concerned the technical nature and potential costs associated with this process. According to the MDD and the MDR [6,8], the onus of certification falls on providers that may lack the capacity to take on the associated liability and costs [24,25]. The challenging nature of the conformity assessment process will only increase under the MDR, given the up-classification of software apps, leading to additional evaluation requirements, including the appointment of a notified body [8,9]. In this context, a general lack of institutional support for developers seeking CE accreditation for their apps may become even more discouraging.

Another factor likely to undermine the compliance of PDC manufacturers with European standards on medical devices concerns the lack of an established process for enforcing these rules at a premarket stage. As with other European legislations, the enforcement of the MDD and the MDR is incumbent upon each EU member state [26]. Although the Dutch Decision on Medical Devices states that the distribution and use of apps that fail to obtain a CE mark is forbidden [27], it does not provide any enforcement means before such apps become available on app stores. Restrictive measures are unlikely to be taken unless a medical error resulting from the use of software occurs, especially if the latter leads to litigation. In this case, the responsibility for the medical error falls on both app users and the app developer [3]. Although the MDR tightens the requirements for CE accreditation and enhances postmarket surveillance [28], it does not fundamentally change the principle by which software manufacturers are themselves responsible for initiating the CE marking process [8]. Effectively, the EU's reliance on this framework in the absence of institutional support for developers and of control mechanisms at a premarket stage may have contributed to making other actors, for example, app stores, informally responsible for restricting European market access. It also implies that clinicians (or their institutions) wishing to use a PDC should themselves assess whether an app is properly accredited despite their lack of expertise in such matters [5].

Among other measures, these findings speak to the need for making CE marking information more readily available to PDC users. This may be achieved through the planned extension of the European Database on Medical Devices (EUDAMED), scheduled to become publicly accessible in May 2022 [29,30], and through the introduction of unique device identifiers for medical devices across the EEA, expected by 2024 [31]. EEA member states may also choose to build on existing online registries of certified or evidence-based apps [16,32]. European authorities could seek to formally engage app stores as partners in the enforcement of the European MDR. At this stage, it appears that the initiative for restricting access to app stores resides with the app stores themselves, as illustrated by the

various levels of restrictions described in the guidance documents of Apple App Store and Google Play Store. The finding that more PDCs were available on Google Play Store (66/74, 89.2%) than on Apple App Store (28/74, 10.8%) may suggest that differences in the stringency of requirements contributed to developers' decisions on where to make their apps available.

Limitations

This work had several limitations. Web-based PDCs that did not have a mobile interface, for example, the Dutch Paediatric Formulary calculator, which was developed in conformity with the requirements of the MDD [33,34], were excluded. The restricted search functions of app stores limited the comprehensiveness of the search possible, for example, excluding paid-for apps. As a result, the list of PDCs included from those stores may not be exhaustive and may only apply to apps available for download in the Netherlands. Eight apps that were only available for purchase were excluded. Considering the potential differences between freely available apps and apps that were available for purchase and whose manufacturers may thus rely on additional finances to recover the costs associated with obtaining a CE marking, this could have led to selection bias. Despite the existence of MDD guidance stating that CE accreditation should be clearly displayed on app landing pages in the relevant stores [17] and our cross-referencing of multiple sources, it is possible that 1 or more CE-marked PDCs were misclassified. In the absence of a mandatory statement on CE accreditation on the app stores, PDC developers were contacted directly. Additionally, 2 of the 61 (3.3%) developers could not be contacted due to missing contact information, and only 20 of the 59 (33.9%) developers contacted provided responses. This relatively low response rate was likely to introduce response bias into the qualitative component of the study. We expect therefore that those developers who responded may represent those who wish to be accessible to those with questions about their apps, and as such their responses may not be representative of all app developers.

Conclusion

This study demonstrates that almost no PDC currently available on two app stores accessed in the Netherlands adheres to European regulations on CE marking. In addition to the limited awareness of these norms among PDC developers, this compliance gap can be related to incorrect rule interpretation by some app manufacturers, the lack of mechanisms for verifying mHealth apps' compliance with European medical device rules before market access, and the technical nature of the CE accreditation process for developers often lacking institutional support.

Although limited to a single category of apps, it is likely that these findings apply to a broader set of mobile devices being used in clinical settings. This lack of regulatory compliance puts both clinicians and patients at risk of medical errors resulting from the use of uncertified and, in some cases, potentially unsafe PDCs. This practice therefore undermines the potential impact of the MDD and the MDR, which strive to create a technologically safer European medical landscape, while supporting clinicians' trust in the devices they use.

Abstract

Background: Disrupted social connections may negatively affect youth mental health. In contrast, sustained quality social connections (QSCs) can improve mental health outcomes. However, few studies have examined how these quality connections affect depression and anxiety outcomes within digital interventions, and conceptualization is limited.

Objective: The aim of this study is to conceptualize, appraise, and synthesize evidence on QSC within digital interventions (D-QSC) and the impact on depression and anxiety outcomes for young people aged 14-24 years.

Methods: A systematic scoping review and meta-analysis was conducted using the Joanna Briggs Institute methodological frameworks and guided by experts with lived experience. Reporting was guided by the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses). The MEDLINE, Embase, PsycINFO, and CINAHL databases were searched against a comprehensive combination of key concepts on June 24, 2020. The search concepts included young people, digital intervention, depression, anxiety, and social connection. Google was also searched. A reviewer independently screened abstracts and titles and full text, and 9.99% (388/3882) of these were screened by a second reviewer. A narrative synthesis was used to structure the findings on indicators of D-QSC and mechanisms that facilitate the connection. Indicators of D-QSC from the included studies were synthesized to produce a conceptual framework.

Results: Of the 5715 publications identified, 42 (0.73%) were included. Among the included studies, there were 23,319 participants. Indicators that D-QSC was present varied and included relatedness, having a sense of belonging, and connecting to similar people. However, despite the variation, most of the indicators were associated with improved outcomes for depression and anxiety. Negative interactions, loneliness, and feeling ignored indicated that D-QSC was not present. In 24% (10/42) of the applicable studies, a meta-analysis showed a significant decrease in depression (–25.6%, 95% CI –0.352 to –0.160; $P<.001$) and anxiety (–15.1%, 95% CI –0.251 to –0.051; $P=.003$) after a D-QSC. Digital mechanisms that helped create a quality connection included anonymity, confidentiality, and peer support. In contrast, mechanisms that hindered the connection included disconnection from the real world and inability to see body language. Data synthesis also identified a 5-component conceptual framework of D-QSC that included rapport, identity and commonality, valued interpersonal dynamic, engagement, and responded to and accepted.

Conclusions: D-QSC is an important and underconsidered component for youth depression and anxiety outcomes. Researchers and developers should consider targeting improved QSC between clinicians and young people within digital interventions for

depression. Future research should build on our framework to further examine relationships among individual attributes of QSC, various digital interventions, and different populations.

Introduction

Background

Enforced lockdowns and physical distancing measures introduced to slow the COVID-19 infection rate have resulted in disrupted face-to-face connections. Ordinarily, a lack of meaningful social connections through social isolation is associated with poor health outcomes such as sleep problems, loneliness, depression, and anxiety, leading in some cases to suicide. Young people are particularly vulnerable to mental health difficulties such as depression and anxiety because onset usually occurs before the age of 24 years [1], and they are often comorbid globally [2]. Although disrupted social connections and loneliness can have a negative effect on mental health [3,4], feeling socially connected is one of the strongest protective factors for depression [5] and can decrease symptoms of anxiety [6].

Social connection as a concept is multifaceted. It can be described as the quantity of connections, the opposite of loneliness, or as having social support. In our context, social connection is the perceived value of attributes of a meaningful interaction among 2 or more people or a *quality* social connection (QSC). Such valued attributes can include, for example, feeling listened to, understood, and a sense of belonging. Similarly, a cooperative relationship between client and therapist, comprising a close bond, shared goals, and tasks, is defined as a *therapeutic alliance* in face-to-face therapy [7]. A therapeutic alliance has been shown to significantly modulate treatment outcomes [8], including in digital settings [9]. Similarly, *social prescribing* to improve social connection has decreased loneliness and improved health outcomes [10]. However, studies have only subjectively demonstrated the value of strong social networks and social relationships for both physical and mental health [11] and longevity [12]. This suggests a need for well-defined indicators of social connection to enable objective measurement of these effects.

The COVID-19 pandemic has accelerated a rapid shift to digital provision of formal and informal mental health support [13]. Indeed, mental health care is often seen as the best candidate for a *digital revolution* because prevention and treatment, including talking therapies, are amenable to delivery over screens and remotely [14]. Social media, video consultations, texting, and virtual reality are interventions that can enable social connections [13]. They represent an important intervention for young people with mental health difficulties to strengthen new and existing relationships and facilitate peer-to-peer and formal mental health support [15]. However, digital interventions such as social media use are also associated with negative consequences such as cyberbullying, viewing harmful content, and a greater sense of isolation [16]. This contradiction requires further investigation to identify the ways in which digital interventions may help or hinder QSC.

Young people are the most digitally fluent and most in need of mental health support. However, QSC within digital interventions (D-QSC) has received little attention in relation to outcomes for depression and anxiety in young people. A recent review produced a conceptual framework for *social connectedness* but positioned it as a solution to loneliness and not as an *active ingredient* (best bet) for the prevention and treatment of depression and anxiety [17]. It also did not consider digital interventions or young people. A systematic review is needed to help produce a conceptual framework for indicators of D-QSC that can be applied to examine its influence on depression and anxiety outcomes across contexts. Our study aims are to (1) identify indicators of D-QSC and their ability to improve or worsen outcomes for depression and anxiety in young people across contexts, (2) identify digital intervention mechanisms that facilitate QSC, and (3) produce a conceptual framework for indicators of D-QSC.

Research Questions

The research questions are:

1. What indicates the presence of QSC in nondigital and digital interventions?
2. How does D-QSC improve or worsen outcomes for depression and anxiety in young people?
3. What digital intervention mechanisms facilitate QSC when preventing or treating depression and anxiety in young people?
4. Whom does D-QSC help or hinder across different contexts, user preferences, and levels of engagement?

Methods

Design

Overview

This systematic scoping review was conducted using the Joanna Briggs Institute methodological framework for scoping reviews. Reporting was guided by the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses; Multimedia Appendix 1) guidelines to ensure clear structure, reproducibility, and rigor.

Defining Objectives and Questions and Developing Inclusion Criteria

The research questions were considered, refined, and then finalized with all team members. The Population, Intervention, Comparison, Outcomes, and Study Design Tool was used to

produce our inclusion and exclusion criteria (Table 1). Notably, *young people* (population) as a definition is heterogeneous. However, we have chosen the age group of 14-24 years because it captures key points of vulnerability to developing anxiety and depression between midadolescence and emerging adulthood.

Table 1. Selection criteria.

Category	Inclusion criteria	Exclusion criteria
Population	• Young people aged 14-24 years • Young people aged 14-24 years and additionally 1 year either side of this range (eg, young people aged 13-16 years would be included, whereas those aged 16-26 years would be excluded)	• Nonhuman subjects • Adults aged ≥25 years if unable to easily separate results from those of younger group
Intervention	• Explores QSC[a] (ie, mentions relevant attributes such as empathy, feeling listened to, understood by another person) • Use of a digital intervention, software, or internet-delivered services (eg, smartphone app, virtual reality packages, internet-based treatment, and chat room)	• No mention of QSC (eg, focuses only on quantity of connections) • No mention of digital intervention (eg, based on a face-to-face situation only)
Comparator	• N/A[b]	• N/A
Outcome	• Scope of depression and anxiety spanned all forms, including major, bipolar, psychotic, perinatal, postpartum, PMDD[c], and manic depression, as well as social, generalized, OCD[d], panic, PTSD[e], and anxiety disorders • Influence on existing symptoms of depression or anxiety (eg, mood and self-esteem through self-report questionnaire or clinical interview) • Prevention of onset of depression or anxiety (eg, measuring mental well-being through self-report questionnaire or clinical interview)	• No mention of depression or anxiety • No mention of the influence on existing symptoms of depression or anxiety • No mention of the influence on depression or anxiety prevention
Study design	• All study designs	• N/A
Dates	• From earliest date to June 24, 2020	• Outside date remit

[a]QSC: quality social connection.

[b]N/A: not applicable.

[c]PMDD: premenstrual dysphoric disorder.

[d]OCD: obsessive-compulsive disorder.

[e]PTSD: posttraumatic stress disorder.

Searching for the Evidence

The MEDLINE, Embase, PsycINFO, and CINAHL databases were searched on June 24, 2020. The search strategy was developed and verified by 3 team members (LD, EL, and HA) and an institutional librarian and tailored to each database (Multimedia Appendix 2 [18-59]). In all, 4 facets made up the strategy, including young people (eg, *youth* and *teens*), social connection (*social connect** and *sociali?ation*), digital intervention (eg, *online* and *digital*), and depression and anxiety (*depress** and *anx**). The World Health Organization International Clinical Trials Registry Platform, ClinicalTrials.gov, and the *Journal of Medical Internet Research* were searched on July 14, 2020. The first 100 Google search hits were also systematically searched by 2 reviewers (LR and EBH) using key words across the 4 facets (eg, young people, social connect*, anxiety and depression, and digital) as a further check (Multimedia Appendix 2). The included papers' reference lists were also reviewed and added to the search if appropriate.

Selecting the Evidence

Titles and abstracts were independently screened by 1 reviewer (LR) and excluded if they did not match the selection criteria (Table 1). Studies that met the inclusion criteria were retrieved in full by the primary reviewer (LR) and reassessed against the selection criteria in detail. A second reviewer (EBH) independently screened a random 9.99% (388/3882) of the titles, abstracts, and full-text manuscripts to ensure reliability in study selection. A predefined interreliability agreement (≥0.70) was agreed upon and calculated. Another random 9.99% (388/3882) would have been screened until agreement was achieved. Disagreements were resolved with a third reviewer (LD).

Extracting and Charting the Evidence

The data-charting process documented indicators of QSC, prevention and treatment categorization, digital intervention mechanisms that facilitate QSC, and participant characteristics. An initial 20% (8/42) of the studies were extracted independently by 2 reviewers (LR and EBH) and reviewed to ensure accuracy before 1 reviewer (LR) continued with the remaining extraction. All included studies were also appraised using the Hawker checklist [60], which is designed specifically for cross-comparison across heterogeneous designs (quantitative, qualitative, and mixed methods). A total of 9 domains were appraised: (1) abstract and title, (2) introduction and aims, (3) methods and data, (4) sampling, (5) data analysis, (6) ethics and bias, (7) results, (8) transferability and generalizability, and (9) implications and usefulness. Quality scores were assigned to

each domain, from 1 point (very poor) to 4 points (good), summed and assigned as high quality (30-36 points), medium quality (24-29 points), or low quality (9-23 points).

Analysis of the Evidence, Presentation of the Results, and Summarizing the Evidence

Meta-analyses were performed where appropriate to examine the effect of D-QSC on outcomes. Overall and specific categories of depression, anxiety, and well-being outcomes were analyzed by calculating the ratio of means within each study. We substituted median for mean in studies where only the median was reported. The inverse-variance, random-effects model of DerSimonian and Laird [61] was used for analysis of both continuous and categorical variables in Stata software (version 15; StataCorp) [62]. The I^2 statistic was used to estimate the degree of heterogeneity among studies, where larger values indicated increasing heterogeneity. The scoping nature of the review meant that a narrative approach was appropriate. All indicators of the development and presence of D-QSC were first collated and synthesized using a deductive approach. The initial relationship between these indicators and the outcomes was explored. Potential themes were identified, discussed, and agreed upon by 3 reviewers (LD, LR, and EL).

To produce a conceptual framework for indicators of D-QSC there were 4 main stages. At the first stage, all indicators identified in the literature synthesis or by experts with lived experience (see the *Patient and Public Involvement* section) were added as cards in Miro (ie, participative visual platform). Indicators that directly described *social connection* (eg, social connectedness) were repeated and those that were not an attribute of D-QSC were excluded. Second, the remaining indicators were either grouped with similar indicators or stood alone. Third, the indicators were then mapped onto a preexisting framework of the components of social connectedness in mental disorders (closeness, identity and common bond, valued relationships, involvement, and cared for and accepted [CIVIC] framework) [17]. Indicators that did not map onto the preexisting framework were kept together and merged under a new component name. This resulted in preliminary components of D-QSC. Finally, young experts with lived experience critically reflected on the preliminary framework and answered a series of questions at a web-based meeting and through email. For example, “Is any indicator missing?” and “Do the indicators link together well or should they be moved?” This discussion was unstructured to allow independent and novel thought. As a result, changes were made to either component or indicator wording and indicators were added or merged. All team members and the young experts agreed on the final conceptual framework for D-QSC.

Patient and Public Involvement

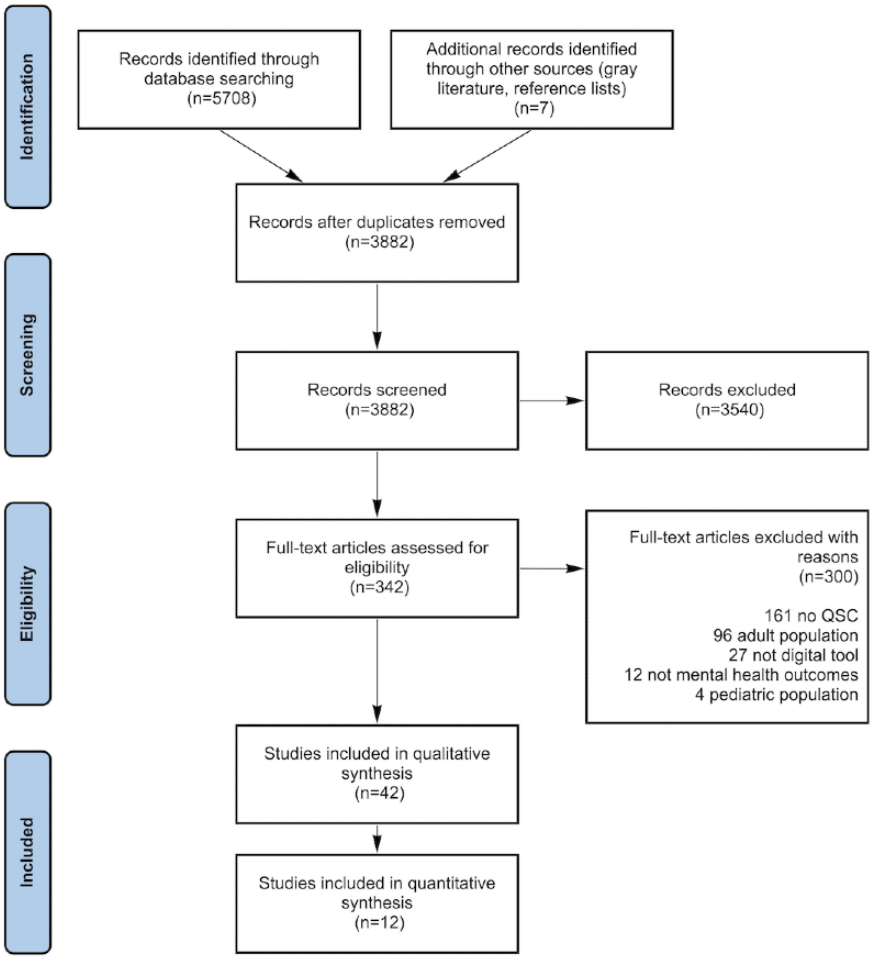
We advertised for young people aged 14-24 years with experience of depression or anxiety and digital interventions for mental health to work on a review about social connection in the digital world through The McPin Foundation newsletter, email distribution lists, Twitter, and Instagram. A total of 9 people applied using a simple form, and all joined the Young Persons Advisory Group (YPAG). They represented different genders, ethnicities, ages, and UK locations. We held an initial web-based workshop to help define QSC and D-QSC, inform search terms, and review the protocol. At this stage, we approached the Lancet Commission for Global Mental Health Young Leaders and experts with professional experience (ie, delivery of digital interventions) to ensure a diverse range of experiences, cultural contexts (ie, low- and high-resource settings), and experience of youth interventions for depression or anxiety. We had separate discussions with each group on the web (eg, Zoom). Subsequent changes were made to our definition of D-QSC, selection criteria, and protocol. On the basis of definitions of quality [63] and therapeutic alliance [7] and input from team members (EL, LD, and LR) and experts, QSC was then operationally defined as *theperceived value of the attributes of an interaction between two or more people*. Key attributes (ie, indicators) of D-QSC that made up the definition were logged across the 3 expert groups and amalgamated with the literature indicators as described previously. Others were changed (eg, changed to plain English) or merged after the YPAG and the Lancet Commission for Global Mental Health Young Leaders were shown the findings and conceptualization framework. A YPAG member (EBH) also screened, extracted, and quality-assessed literature. All were given appropriate support and paid in line with guidance [64].

Results

Overview

A total of 5715 records were identified (Figure 1). Of the 5715 articles, 1833 (32.07%) were duplicates and were removed. Substantial agreements were achieved in the screening of the random 9.99% (388/3882) abstracts and titles as well as full-text subsamples (K=0.80 and K=0.70, respectively). Papers were then excluded if they did not match the selection criteria; of the 3882 publications remaining after duplicates were removed, 42 (1.08%) were included (Figure 1). Of these 42 studies, 28 (67%) were of high quality, 13 (31%) were of medium quality, and 1 (2%) was of low quality. High-quality studies largely demonstrated good explanation of aims, methods, and sampling to enable replicability. Medium-quality studies included most of the good study criteria but were lacking in some areas, which reduced their scores. The low-quality study did not provide enough detail across most domains (eg, it did not report ethical considerations, the results were unclear, and the methods were not replicable).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart. QSC: quality social connection.



Study and Participant Characteristics

Of the 42 included studies, 25 (60%) were quantitative [18-42], 11 (26%) were qualitative [43-53], and 6 (14%) were mixed methods studies [54-59] (Table 2; Multimedia Appendix 3 [18-59]). The studies mainly used uncontrolled or cross-sectional designs and had questionnaires as their main data collection method (22/42, 52%). All studies took place in high-income countries: the United States [23-28,36,38,40,42,44,47,49,50,53], Australia [22,29-31,43,46,55-58], Ireland [18,45,54], Israel [19,32,48], Taiwan [20,35], Sweden [21,41], the Netherlands [33], Turkey [39], Austria [34], Belgium [37], Canada [59], Cyprus [52], and the United Kingdom [51]. There were 23,319 participants in total (12,825/23,319, 55%, were women; of the 42 studies, 2 (5%) did not report participant gender). Of the 42 studies, 21 (50%) focused on both prevention and treatment [18,20,21,23-29,36-39,41-44,48,50,57], 12 (29%) focused on treatment [22,30,31,45,49,51-56,58], and 9 (21%) focused on prevention [19,32-35,40,46,47,59]. Digital mental health–related intervention types included mental health social networking tools, smartphone apps, self-help cognitive behavioral therapy, telepsychiatry, one-to-one peer mentor support, video gaming, avatars, and internet use for mental health support. Nonspecific informal digital interventions included general social networking and social media (eg, Facebook, Twitter, Tumblr, Snapchat, and Reddit) and general internet use and web browsing. Intervention duration was reported in 48% (20/42) of the studies and ranged from 8 weeks to 1 year.

Table 2. Data extraction and quality assessment of included studies (N=42).

Author, year, country, quality	Study design	Setting and participants	Digital intervention	Outcomes and measures
Alvarez-Jimenez et al [58], 2013, Australia, high quality	Quantitative and qualitative, uncontrolled single-group, observation, questionnaire, and semistructured interview	Setting: early psychosis prevention and intervention center; sample: 20 patients (50% female; aged 15-25 years; 45% Anglo-Australian, 25% Asian, 10% biracial, and 5% African); presenting condition: first episode psychosis	Peer-to-peer web-based social networking, individually tailored web-based psychosocial interventions, and expert moderation: HORYZONS	Outcomes: depression and anxiety reduced; measures: BPRS[a], CDRS[b], and BAI[c]
Alvarez-Jimenez et al [30], 2018, Australia, medium quality	Quantitative, uncontrolled single-group, observation, and semistructured interview	Setting: PACE[d] clinic for ultrahigh-risk psychosis; sample: 14 patients (79% female; aged 15-25 years; ethnicity unknown; all Australia-born); presenting condition: ultra-high risk for psychosis	Web-based social networking, peer-to-peer and professional moderation: MOMENTUM	Outcomes: depression reduced and psychological well-being improved; measures: SWLS[e], MADRS[f], and PSSS[g]
Bailey et al [22], 2020, Australia, high quality	Quantitative, uncontrolled single-group pre- and posttest, observation, and semistructured interview	Setting: tertiary-level mental health service; sample: 20 patients (55% female; aged 16-25 years; ethnicity unknown; country of birth: 75% Australia, 20% Asia, and 5% United Kingdom); presenting condition: suicidal ideation	Enhanced web-based social networking intervention: Affinity	Outcome: depression reduced; measure: PHQ-9[h]
Bhuvaneswar and Gutheil [49], 2008, United States, high quality	Qualitative, retrospective case study, and observation	Setting: psychodynamic psychotherapy clinic; sample: 1 patient (female; aged 17 years; ethnicity unknown); presenting condition: depression	Instant messenger	Outcome: psychological well-being worsened; measure: self-report
Blackwell et al [24], 2012, United States, high quality	Quantitative, randomized controlled trial, and questionnaire	Setting: general; sample: 100 adolescents (62% female; mean age 15.69 years, SD 2.91 years; 57% White, 16% Hispanic, 9% African American, and 18% ethnicity unknown); presenting condition: cystic fibrosis	Web-based social networking peer support program: CFfone.com	Outcomes: Depression and anxiety reduced; measure: HADS[i]
Campbell et al [55], 2019, Australia, medium quality	Qualitative and quantitative, participatory action research design, observation, and questionnaire	Setting: Kids Helpline family discord service; sample: 105 callers to helpline (82% female; aged 13-25 years; ethnicity unknown); presenting condition: mild to moderate depression or anxiety (not high risk)	Social networking site for peer-to-peer and counsellor-to-peer group support	Outcomes: depression and anxiety—data quality too low to assess; measures: CES-D[j] and RCMAS[k]
Canady [25], 2018, United States, high quality	Quantitative, cross-sectional study, questionnaire, and interview	Setting: general; sample: 1300 adolescents (gender unknown; aged 14-22 years; ethnicity unknown); presenting condition: none in particular	Web-based health information and digital health tools in general, including peer-to-peer health exchange networks	Outcomes: Depression and anxiety reduced; measures: PHQ-9 and self-report
Chyzzy et al [59], 2020, Canada, high quality	Qualitative and quantitative, uncontrolled single-group design, questionnaire, and semistructured interview	Setting: MPPS[l] intervention group; sample: 21 mothers (100% female; aged 17-24 years, mean age 21.3, SD 1.8, years; ethnicity unknown; country of birth: 66.7% Canada), presenting condition: generally healthy, 14.3% with prior history of depression	Individualized peer mentor support through telephone call and SMS text messaging: MPPS intervention	Outcomes: depression and anxiety reduced; measure: self-report
Clarke [45], 2018, Ireland, high quality	Qualitative, retrospective case study, and observation	Setting: clinical; sample: 1 patient (male; aged 16 years; ethnicity unknown); presenting condition: Asperger syndrome with comorbid depression	Telepsychiatry	Outcome: depression treatment engagement improved; measure: observation

Author, year, country, quality	Study design	Setting and participants	Digital intervention	Outcomes and measures
Colder Carras et al [28], 2017, United States, medium quality	Quantitative, cross-sectional study, and questionnaire	Setting: 30 US schools; sample: 9733 students (51% female; aged 13-16 years, average age 14.1 years; 82.1% Dutch); presenting condition: none in particular	Web-based video gaming	Outcomes: depression and social anxiety reduced for *social engaged gamers* compared with *problematic*, *at-risk*, or *extensive* gamers; measures: depressive mood list and SASC-R[m]
Cole et al [36], 2017, United States, —[n]	Quantitative, uncontrolled single-group design, and questionnaire	Setting: private university; sample: 231 undergraduate students (72% female; average age 19.28, SD 1.15, years; 67.1% White, 23.4% Asian American, 10.4% African American, 5.2% Hispanic or Latino, and 0.4% Other); presenting condition: none in particular	Web-based social networks in general	Outcomes: depression worsened; measures: DASS[o], CTI[p], and BDI-II[q]
Dhesi [51], 2019, United Kingdom, high quality	Qualitative, cross-sectional, and web-based semistructured interviews	Setting: Kooth digital mental health care service; sample: 13 Kooth users (69% female; aged 14-18 years; 69.2% White British, 15.4% White and Asian, and 15.4% Other); presenting condition: none in particular	Web-based counseling (text)	Outcomes: anxiety reduced; measure: thematic analysis of interviews
Dolev-Cohen and Barak [48], 2013, Israel, high quality	Qualitative, case-control design, questionnaire, textual analysis, and observation	Setting: general; sample: 150 instant messaging users (63% female; aged 14-18 years; ethnicity unknown); presenting condition: distressed vs nondistressed groups of participants	Regular use of instant messaging	Outcome: psychological well-being improved; measure: PANAS[r]
Ellis et al [56], 2011, Australia, —	Qualitative and quantitative, comparative randomized controlled trial, and questionnaire	Setting: university students not receiving mental health treatment; sample: 39 students (77% female; aged 18-25 years, mean age 19.67, SD 1.66, years; ethnicity unknown); presenting condition: anxiety or depression but none severe	Web-based cognitive behavior therapy self-help program (MoodGYM) compared with web-based support group (MoodGarden)	Outcomes: depression and anxiety reduced; measures: DASS and ATQ[s]
Feinstein et al [26], 2012, United States, high quality	Quantitative, short-term prospective cohort study, and questionnaire	Setting: undergraduate university students; sample: 301 students (62% female; mean age 19.44, SD 2.05, years; 41% Asian or Pacific Islander, 41% White, 6% Latino, 6% African American, and 6% Other); presenting condition: some participants had raised depression, anxiety, or social anxiety at baseline	Social networking in general	Outcome: depression resulted in poor-quality social connections, which in turn worsened depression and anxiety; measures: DASS and BFNE[t]
Felnhofer et al [34], 2018, Austria, —	Quantitative, randomized controlled trial, and questionnaire	Setting: public university; sample: 95 students (87% female; mean age 23.34, SD 2.727, years; ethnicity unknown); presenting condition: none in particular	Avatars (virtual entities controlled by another human being) and agents (virtual entities controlled by a computer)	Outcome: social interaction anxiety unchanged; measure: SIAS[u]
Frison and Eggermont [37], 2016, Belgium, medium quality	Quantitative, uncontrolled cross-sectional, and questionnaire	Setting: 18 randomly selected high schools in Flanders, Belgium; sample: 910 students with Facebook account (52% female; average age 15.44, SD 1.71, years; ethnicity unknown; country of birth: 96.1% Belgium, 1.8% Europe, and 2.1% non-European country); presenting condition: none in particular	Facebook	Outcome: depression reduced; measure: CES-DC[v]

Author, year, country, quality	Study design	Setting and participants	Digital intervention	Outcomes and measures
Garrido et al [43], 2019, Australia, medium quality	Qualitative and focus groups	Setting: high schools and universities in Western Australia; sample: 23 students (65% female; aged 13-25 years; ethnicity unknown); presenting condition: DASS score <15 (severely depressed excluded)	A total of 6 currently available smartphone apps for mental health (Mood Mission, Music eScape, Pacifica, Mindshift, Headspace, and What's Up)	Outcome: helpful and unhelpful aspects of smartphone apps for mental health; measure: thematic analysis of focus group content
Horgan et al [54], 2013, Ireland, medium quality	Qualitative and quantitative, pre- and posttest and qualitative descriptive designs, extraction of posts from website, and questionnaire for CES-D scores	Setting: University of Cork; sample: 118 students (36% female; aged 18-24 years; 98.3% White and 1.7% Asian or Asian Irish); presenting condition: depression	Depression support website with peer support forum	Outcome: depression reduced; measure: CES-D
Horgan and Sweeney [18], 2010, Ireland, medium quality	Quantitative, descriptive study, and questionnaire	Setting: university; sample: 922 students (62% female; aged 18-24 years; ethnicity unknown); presenting condition: none in particular	Internet use for mental health support	Outcome: reasons for use of internet-based mental health support; measure: self-developed questionnaire
Lim et al [57], 2019, Australia, high quality	Qualitative and quantitative, descriptive design, pre- and posttest questionnaires, mood tracker, and semistructured interview	Setting: local youth health service (participants with social anxiety disorder) and Australian university (participants without social anxiety disorder); sample: 20 participants (45% female; aged 18-23 years; 91% White and 9% multiracial or other); presenting disorder: with or without social anxiety disorder	+Connect, a digital smartphone app with video material	Outcomes: depression and anxiety reduced; measures: CES-D and SIAS
Liu and Yu [35], 2013, Taiwan, medium quality	Quantitative, cross-sectional study, and questionnaire	Setting: college; sample: 330 Facebook-using students (63% female; aged 18-23 years; ethnicity unknown); presenting condition: none in particular	Facebook	Outcome: psychological well-being improved; measure: Ryff scales of psychological well-being
McCloskey et al [23], 2015, United States, medium quality	Quantitative, uncontrolled single-group design, and questionnaire	Setting: university; sample: 633 undergraduate students with Facebook page (70% female; aged ≥18 years, median age 21 years; 64.8% White); presenting condition: none in particular; participants on average had mild levels of depression at baseline	Facebook	Outcome: depression reduced; measure: PHQ-9
Mikami [38], 2010, United States, high quality	Quantitative, longitudinal, observation, and questionnaire	Setting: public middle school; sample: 92 social networking site users (58% female; mean age 20.92, SD 1.11, years; 58% White, 29% African American, and 13% Other or Mixed); presenting condition: none in particular	Web-based social networking	Outcome: depression—no outcomes reported; measure: CDI[w]
Ozcan and Buzlu [39], 2007, Turkey, high quality	Quantitative, uncontrolled single-group design, and questionnaire	Setting: university; sample: 730 undergraduate students who use the internet (53% female; mean age 20.84, SD 1.95, years; ethnicity unknown); presenting condition: none in particular	Internet use in general	Outcome: depression reduced; measure: BDI
Poppelaars [33], 2018, The Netherlands, medium quality	Quantitative, randomized controlled trial, and questionnaire	Setting: university; sample: 146 undergraduate students who play video games (71% female; mean age 20.2, SD 1.74, years; ethnicity unknown; nationality: 76% Dutch, 23% German, and 1% Other); presenting condition: none in particular; some with higher depressive symptoms at outset	Video game that included cooperation with other players and with mental health messaging vs video game without mental health messaging	Outcome: psychological well-being improved, with larger improvement for those higher in depressive symptoms; measures: BDI-II, SAM[x], and International PANAS short form

Author, year, country, quality	Study design	Setting and participants	Digital intervention	Outcomes and measures
Radovic [44], 2017, United States, United States, high quality	Qualitative, randomized controlled trial, semistructured interviews, think aloud, advisory boards, and focus groups	Setting: academic adolescent medicine clinic and specialty psychiatry clinic; sample: 23 patients (78% female; aged 13-20 years, mean age 16, SD 2.3, years); presenting condition: depression	Social media website for depressed adolescents	Outcome: adolescent-informed design of social media website for depression; measure: thematic analysis from semistructured interviews
Radovic [53], 2017, United States, medium quality	Qualitative, uncontrolled cross-sectional study, and semistructured interview	Setting: academic adolescent medicine clinic and specialty psychiatry clinic; sample: 23 patients (78% female; aged 13-20 years, mean age 16, SD 2.3, years; 87% White); presenting condition: depression	Social media	Outcomes: depressive symptoms either made participants reach for social media as a distraction or avoid it to avoid bringing down others. Psychological well-being improved; measure: thematic analysis from semistructured interviews
Rice et al [29], 2018, Australia, medium quality	Quantitative, uncontrolled single-group pilot, structured clinical interview, and questionnaire	Setting: mental health clinic; sample: 42 patients (50% female; aged 15-25 years, mean age 18.5, SD 2.1, years; ethnicity unknown; country of birth: 95.2% Australia); presenting condition: previous depression sufferers	Novel, moderated web-based social therapy intervention: Rebound	Outcomes: depression reduced and anxiety unchanged; measures: MADRS and DASS
Rice et al [31], 2020, Australia, high quality	Quantitative, single-group uncontrolled pre-post design, and questionnaire	Setting: 4 Headspace early intervention centers in northwestern Melbourne; sample: 89 patients (47% female; aged 14-25 years; ethnicity unknown); presenting condition: social anxiety	Social networking platform for socially anxious young people (Entourage): a *wall* function allows posting and commenting publicly	Outcomes: depression and social anxiety reduced and psychological well-being improved; measures: PHQ-9, MDRS-22[y], LSAS[z], BFNE, SIAS, and SWEMWBS[aa]
Santesteban-Echarri et al [46], 2017, Australia, medium quality	Qualitative, uncontrolled single-group pilot, semistructured interview, and focus group data	Setting: mental health clinic; sample: 42 patients (50% female; aged 15-25 years, mean age 18.5, SD 2.1, years; ethnicity unknown; country of birth: 95.2% Australia); presenting condition: previous depression sufferers	Novel, moderated web-based social therapy intervention: Rebound	Outcome: efficacy and usability evaluation of web-based social therapy intervention; measure: thematic analysis from semistructured interviews
Saulsberry et al [40], 2013, United States, medium quality	Quantitative, randomized controlled trial, and telephone interview	Setting: 12 primary care sites across southern and midwestern United States; sample: 58 patients (57% female; mean age 17.26, SD 1.85, years; 61% White, 24% Black, 6% Asian, 5% Hispanic, and 4% Other); presenting condition: depression	Primary care provider motivational interview+CATCH-IT internet program vs primary care provider brief advice+CATCH-IT internet program	Outcome: depression reduced; measures: CES-D-10, DSM-IV-TR[ab], and PHQ-A[ac]
Selkie et al [47], 2020, United States, high quality	Qualitative, uncontrolled single-group design, and semistructured interviews	Setting: pediatric gender clinic; sample: 25 transgender adolescents with social media profile (44% trans-feminine; aged 15-18 years, mean age 16 years; 80% White non-Hispanic, 4% African American, 8% American Indian, and 8% Asian); presenting condition: none in particular	Social media platforms, including YouTube, Instagram, Facebook, Twitter, and Tumblr	Outcomes: positive and negative outcomes of using social media for mental health support; measure: —
Sharabi and Margalit [32], 2011, Israel, medium quality	Quantitative, cross-sectional crossover, and questionnaire	Setting: middle to high socioeconomic families vs those who failed in school (mostly from low socioeconomic families); sample: 716 students (48% female; aged 16-18 years; ethnicity unknown); presenting condition: with or without learning disabilities	Internet communication	Outcomes: psychological well-being negatively correlated with loneliness. Loneliness reduced by internet communication with people known offline; measure: Hebrew adaptation of Mood Scale

Author, year, country, quality	Study design	Setting and participants	Digital intervention	Outcomes and measures
Sharabi and Margalit [19], 2011, Israel, medium quality	Quantitative and cross-sectional case-control	Setting: 3 high schools in urban Israel; sample: 887 students grades 10-12 (50% female; aged 16-18 years; ethnicity unknown); presenting condition: with (n=213) or without (n=674) learning disabilities	Internet communication	Outcome: psychological well-being reduced; measure: Hebrew adaptation of Affect Scale
Siriaraya et al [52], 2011, Cyprus, medium quality	Qualitative, cross-sectional study, and content analysis	Setting: general; sample: 400 messages from teenagers using web-based discussion forum (gender unknown; age range unknown; ethnicity unknown); presenting condition: none in particular	Web-based anonymous discussion forum	Outcome: level of support provided among adolescents; measure: Content analysis of web-based forum messages
Stockdale and Coyne [27], 2020, United States, high quality	Quantitative, longitudinal, and questionnaire	Setting: longitudinal study of intrafamily life participants; sample: 385 participants who use smartphones (53% female; aged 17-19 years; 70% European-American, 10% African American, 12% Multiethnic, 5% Asian American, and 2% Other); presenting condition: none in particular	Social media use	Outcomes: depression unchanged and anxiety worsened; measures: CES-DC and SCAS[ad]
van Rensburg et al [50], 2015, United States, high quality	Qualitative, uncontrolled single-group design, and semistructured interviews	Setting: Yale Psychiatric Hospital Intensive Outpatient Program; sample: 20 patients (75% female; aged 14-19 years; 80% White, 15% Hispanic, and 5% Mixed); presenting condition: combination of ADHD[ae], mood disorder NOS[af], MDD[ag], anxiety, PTSD[ah], psychosis, and ODD[ai]	Social media for patient-provider interactions	Outcomes: positive (including safety) and negative (including anxiety) outcomes of patient-provider interactions through social media; measure: thematic analysis of semistructured interviews
van Zalk et al [41], 2011, Sweden, high quality	Quantitative, uncontrolled single-arm longitudinal study, and questionnaire	Setting: university in Utrecht; sample: 197 psychology freshmen (78% female; mean age 18.9, SD 1.6, years; ethnicity unknown; 92% Dutch origin); presenting condition: none in particular	Web-based chatting with friends through web-based social networking site	Outcome: depression unchanged; measure: BDI Dutch short version
Van Zalk and Tillfors [21], 2017, Sweden, high quality	Quantitative, longitudinal study, and questionnaire	Setting: Swedish school; sample: 526 students from grades 7-9 (68% female; aged 13-15 years; ethnicity unknown; 12.1% first-generation immigrants); presenting condition: none in particular	Web-based chatting with friends through web-based social networking site	Outcome: Reduced depression among those with higher, but not lower, social anxiety; measures: CES-D and SPSQ-C[aj]
Wright et al [42], 2013, United States, medium quality	Quantitative, cross-sectional observational study, and questionnaire	Setting: undergraduate university; sample: 361 students who use Facebook (53% female; mean age 20.26, SD 2.72, years; 77% White, 8.6% Native American, 4.4% Latino, 3.6% Asian American, 3.3% African American, and 3.3% Other); presenting condition: none in particular	Facebook use	Outcome: depression reduced; measure: CES-D

Author, year, country, quality	Study design	Setting and participants	Digital intervention	Outcomes and measures
Yeh et al [20], 2008, Taiwan, medium quality	Quantitative, cross-sectional, and questionnaire	Setting: project of mental health survey; sample: 3477 college students (55% female; mean age 22.45, SD 1.56, years; ethnicity unknown); presenting condition: none in particular	Social support on the web	Outcome: depression worsened by higher web-based and lower actual social support; measure: Ko Depression Inventory

Indicators That QSC Is Present in Digital Interventions

Indicators and measures used to quantitatively assess D-QSC presence were heterogeneous (Tables 3 and 4). The most common indicator for D-QSC was social support (14/42, 33%; Table 3). Among the 31 quantitative studies assessed, there were 20 different standardized questionnaires used to measure QSC (Tables 3 and 4), with only 4 (13%) studies using the same measure (Multidimensional Scale of Perceived Social Support). Nonstandardized questionnaires were also used in some studies, including single questions (eg, "I hope to gain support through meeting people going through similar experiences, Y/N"). The remaining indicators of QSC were identified from qualitative analysis within 17 studies [43-59].

Table 3. Indicators of the presence of quality social connection within digital interventions in the included studies (N=42).

Indicator	Description and measurement example	Values, n (%)	Improved depression outcomes, n (%)	Improved anxiety outcomes, n (%)
Social support[a]	Level of support received from others. Multidimensional Scale of Perceived Social Support: "There is a special person who is around when I am in need"	14 (33) [20,23,24,30,35-39,41,42,46,53,56]	9 (64) [23,24,30,36,37,39,41,42,56]	2 (14) [24,56]
Social connectedness[a]	A sense of feeling connected to others. Social Connectedness Scale Revised: "I feel understood by the people I know"	10 (24) [22,27-29,31,43,52,56-58]	6 (60) [22,28,29,31,57,58]	5 (50) [28,31,52,57,58]
Relatedness	Bonding through shared experience or understanding. Open-ended survey questions to determine best and worst aspects of intervention	5 (12) [33,43,46,55,56]	1 (20) [56]	1 (20) [56]
Connecting with similar people	Communicating with those who have similar experiences and feelings. Content analysis and thematic coding of qualitative questions	4 (10) [18,25,47,53]	1 (25) [25]	1 (25) [25]
Feeling accepted	Having a sense that people are okay with, and accepting of, oneself. Likert-scale response to statement "I felt that the [forum] moderators accepted me"	3 (7) [29,53,59]	2 (67) [29,59]	1 (33) [59]
Being able to share	Feeling able to disclose one's thoughts and feelings to others. Friendship Quality Questionnaire: "I would tell him or her what upsets me"	4 (10) [21,51,52,54]	2 (50) [21,54]	1 (25) [52]
Feeling normalized	Someone making it clear that what one is feeling is normal. Peer Support Evaluation Inventory subscale item: "Helped me feel that what I was going through was 'normal'"	3 (7) [47,52,59]	1 (33) [59]	2 (67) [52,59]
Feeling close to a peer	A sense of intimacy or connection with another person. Peer Support Evaluation Inventory subscale item: "I felt close to my peer"	2 (5) [57,59]	2 (100) [57,59]	2 (100) [57,59]
Less alone in one's feelings	Knowing that others are experiencing similar feelings. Content analysis and thematic coding of qualitative interview questions	3 (7) [25,54,55]	2 (67) [25,54]	1 (33) [25]
Sense of belonging	Feeling that one is part of a group. Interpersonal Needs Questionnaire: "I don't fit in"	2 (5) [22,31]	2 (100) [22,31]	1 (50) [31]
Emotional connection	A bond created among 2 or more people by sharing feelings. Text-based ethnographic study of instant messaging conversations	2 (5) [48,50]	—[b]	—
Empathy	Understanding and sharing feelings of another person. Networked Minds Measure of Social Presence Empathy subscale: "When the other was happy, I was happy"	2 (5) [27,34]	—	—

Indicator	Description and measurement example	Values, n (%)	Improved depression outcomes, n (%)	Improved anxiety outcomes, n (%)
Feeling you are not a burden	Sense that one is not bothering or troubling others. Interpersonal Needs Questionnaire low score for items such as "These days I think I make things worse for the people in my life"	2 (5) [22,31]	2 (100) [22,31]	1 (50) [31]
Rapport	Trust and understanding established between the provider and patient. Provider-reported from ethnography	1 (2) [45]	—	—
Feeling validated	Having acceptance or approval from others of one's thoughts and feelings. Content analysis and thematic coding of qualitative questions, categorized as *Appraisal support*	1 (2) [47]	—	—
Shared understanding	Another person knowing how one is feeling through their own similar experience. Content analysis and thematic coding of forum posts	1 (2) [54]	1 (100) [54]	—
Trust	Ability to rely on someone. Peer Support Evaluation Inventory: "My peer was trustworthy"	1 (2) [59]	1 (100) [59]	1 (100) [59]

[a]Directly encapsulates the definition of quality social connection.

[b]Not available.

Table 4. Indicators of the absence of quality social connection within digital interventions in the included studies (N=42).

Indicator	Description and measurement example	Values, n (%)	Improved depression outcomes, n (%)	Improved anxiety outcomes, n (%)
Negative interactions	Harm being inflicted through digital interventions, resulting in negative feelings such as loneliness or hurt. Social Networking Survey: "How positive (or negative) are your interactions with people on FB[a] and MS[b]?"	6 (14) [26,43,47,49,51,53]	—[c]	—
Loneliness	A sense of isolation as a result of being disconnected from other people. University of California, Los Angeles, Loneliness Scale: "I lack companionship"	7 (17) [19,30-32,40,47,59]	4 (57) [30,31,40,59] (Reduced loneliness)	2 (29) [31,59] (Reduced loneliness)
Feeling ignored	Not being responded to. Content analysis and thematic coding of semistructured interviews exploring engagement with therapist through social networks and its efficacy	2 (5) [49,51]	—	—

[a]FB: Facebook.

[b]MS: Myspace.

[c]Not available.

Associations Between D-QSC and Outcomes

The relationship between D-QSC indicators and outcomes was mixed. Of the 42 studies, 10 (24%) reported a change in depression symptoms over time after participants experienced a D-QSC, and a pooled analysis demonstrated a significant weighted mean decrease in depression by 25.6% (–0.256, 95% CI –0.352 to –0.160; P<.001), with high heterogeneity (I^2= 90.8%; Figure 2) [20,23,24,26,30,36,37,39,41,42]. Of the 42 studies, 5 (12%) reported change over time in anxiety symptoms; there was also a decrease, but it was smaller (15%; –0.151, 95% CI –0.251 to –0.051; P=.003), with high heterogeneity (I^2= 83.1%; Figure 3) [29,31,56-58].

The indicators of D-QSC associated with improved depression or anxiety symptoms included social support [23,24,30,36,37,39,41,42,56], social connectedness [22,28,29,31,52,57,58], loneliness (reduced) [30,31,40,54,59],

relatedness [56], sense of belonging [22,31], being able to share [21,52,54], less alone in one's feelings [25,54], feeling normalized [52,59], feeling close to peer [57,59], feeling you are not a burden [22,31], feeling accepted [29,59], shared understanding [54], and trust [59] (Table 3). For example, depression outcomes improved after good social support for those abused on the web [36] and for adolescents with high social anxiety [21]. In contrast, negative interactions [20,26], negative experiences of social support [49,51,52], and frequent social media use [27] were associated with worsened outcomes (Table 4). For example, young people aged 17-19 years using social media (eg, Facebook, Instagram, and Twitter) to connect with others were more likely to have anxiety but not depression at 3 years' follow-up [27]. A similar but older study found a worsening of depression outcomes with social networking interactions (ie, Facebook, Myspace, and texting) [26]. This relationship between negative interactions on social media and worsened outcomes was evident in both men and women, particularly in those also receiving low face-to-face social support [20]. Additional indicators of D-QSC that did not explicitly indicate effect on depression or anxiety were feeling validated [47], rapport [45], empathy [27,34], and emotional connection [48,50]. The indicators also improved well-being outcomes (Multimedia Appendix 4 [19,30-33,35,48,49,53]).

Figure 2. Forest plot showing the effect of social connection within digital interventions on depression outcomes. ES: effect size.

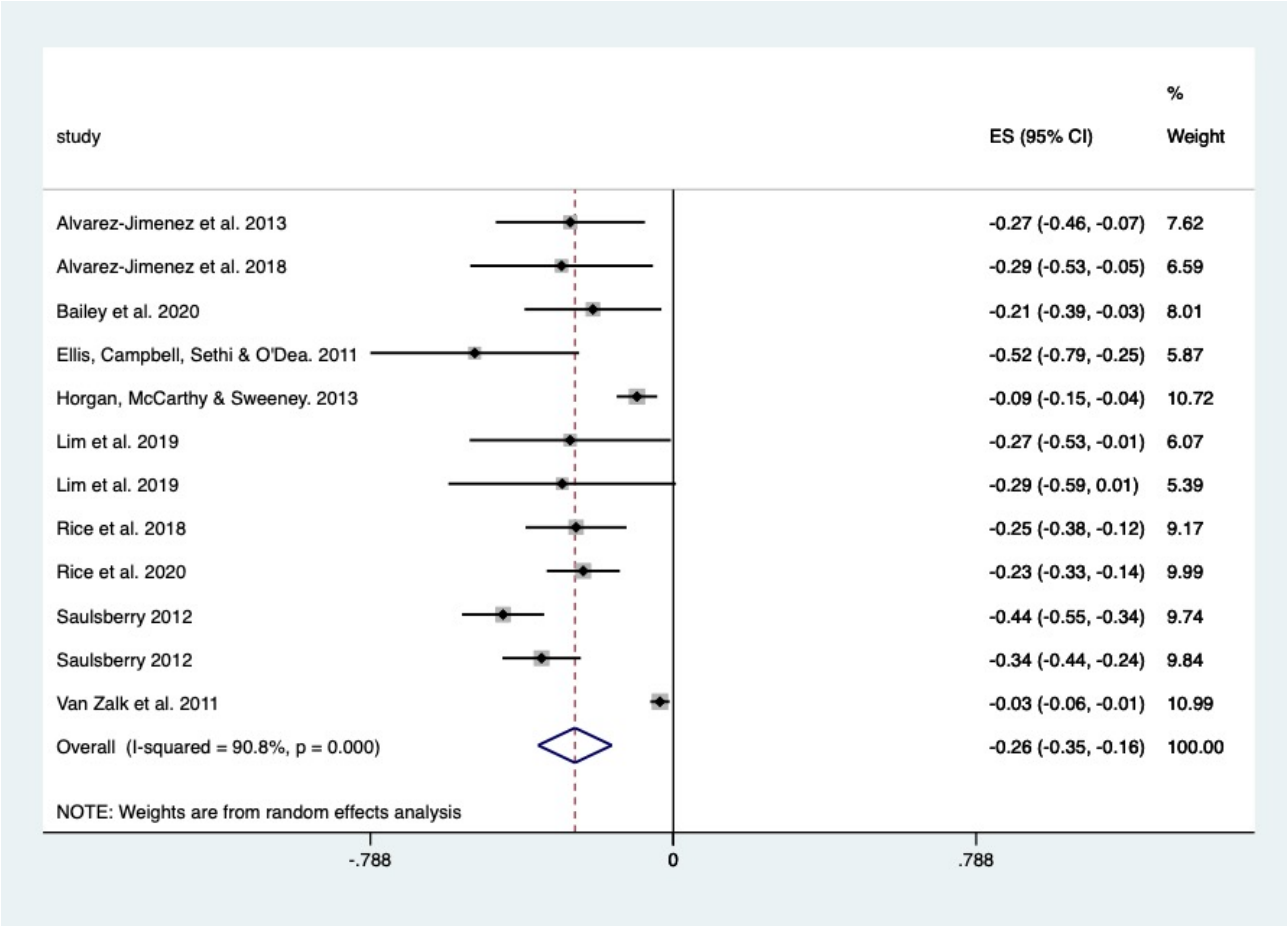

Figure 3. Forest plot showing the effect of social connection within digital interventions on anxiety outcomes. ES: effect size.

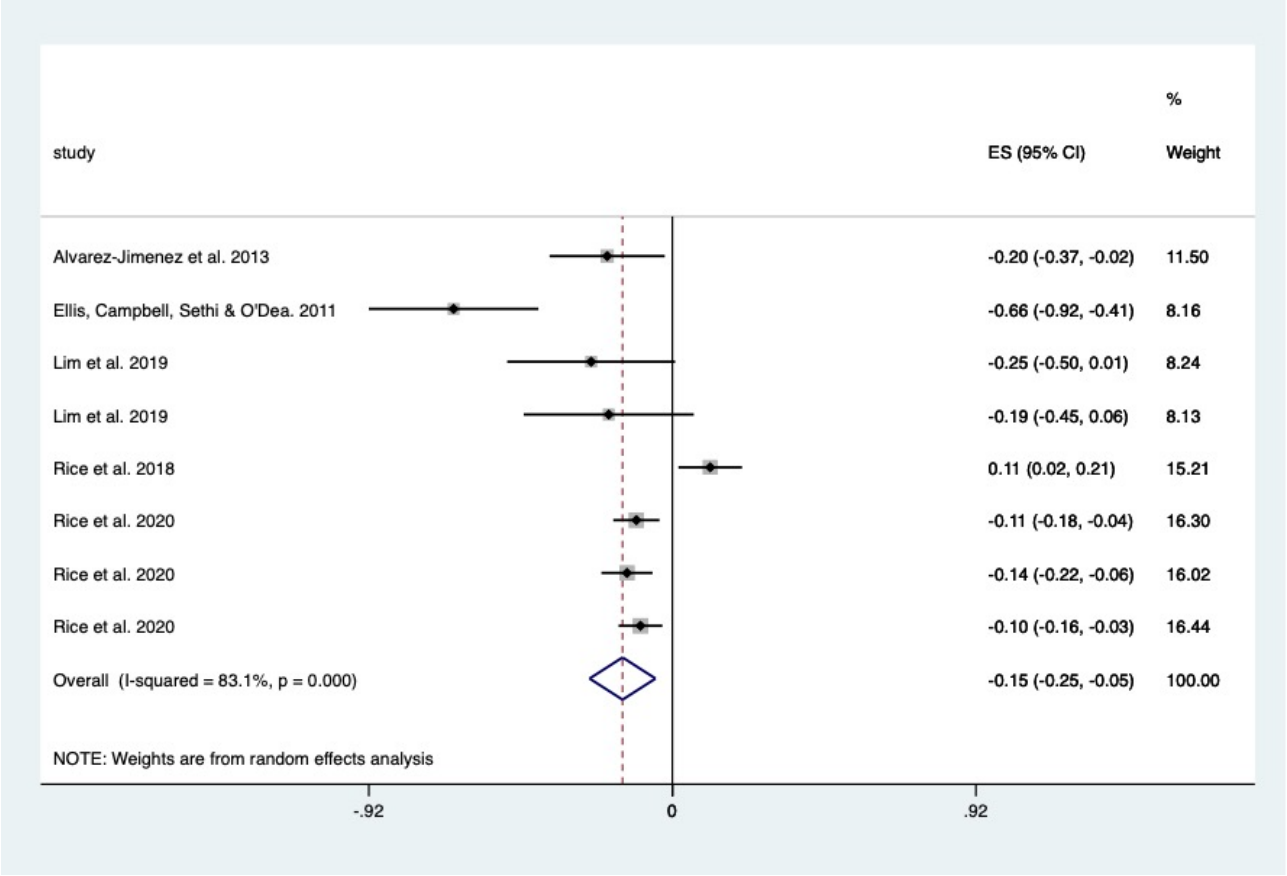


Digital Intervention Mechanisms That Facilitate QSC

Digital intervention mechanisms mainly helped facilitate QSC [18,20,25,30,35,43,44,46,50,51,55,56,58,59]. Forum moderation, confidentiality, ease of access, and anonymity supported by digital interventions were cited as valuable [18,43,50,56,58,59], facilitated open sharing in digital environments, and could lower inhibitions compared with face-to-face engagement [50,51]. The usual signals received during face-to-face interactions, such as body language or facial expression, were lost during digital interactions [52] and could impair the quality of interactions [26].

D-QSC was deemed more valuable when digital interactions were blended with face-to-face interactions [20,35,43]. For example, digital interactions were convenient and accessible, whereas face-to-face meetings helped maintain the connection. Higher levels of web-based social support were associated with increased symptoms of depression, specifically in both men and women and those who had little in-person social support [20]. One study found that participants were disconnected from the *real world* through high levels of web-based engagement [43]. Indeed, disconnection can have an impact on the interaction between peers and family and result in increased loneliness [19,32]. Other studies indicated that participants felt ignored [51], misunderstood [51], and had hurt feelings [43,49].

Participants also valued opportunities to support others [41,55], to connect with peers, and compare similar mental health experiences [25,54]. Some participants considered the networking component as the most helpful aspect of a moderated web-based social therapy tool, more helpful than the therapy itself [46]. Harassment was also identified as occurring frequently on the web. For example, a study reported this frequently among transgender adolescents [32].

Individual and Contextual Factors Influencing Mechanisms

Demographic and Personality Factors

The effect of D-QSC on depression outcomes differed across genders and personality variables. Social support from active Facebook use predicted a reduction in depression symptoms in girls but not in boys [37]. In another study, increased social support on the web and decreased offline social support was associated with increased depression symptoms across both genders [20]. Demographic (eg, personality type) and dynamic (eg, vulnerability level) characteristics were also reported to modulate the influence of D-QSC on depression and anxiety outcomes. Personality differences were only discussed in 5% (2/42) of the studies [41,48]. Chatting exclusively on the web predicted significantly improved depression [41] or psychological well-being [48] outcomes only in participants with more introverted personality traits.

Anxiety Versus Depression

D-QSC was more important for depression than for anxiety outcomes. For example, both web-based self-help cognitive behavioral therapy and peer support effectively reduced anxiety, but peer support was more effective in improving outcomes of depression [56]. Moreover, those with higher social anxiety had lower depression symptoms after corumination with a web-based

best friend [21]. In contrast, symptoms of depression predicted negative social networking interactions, which in turn resulted in higher symptoms of depression and anxiety [26]. An app designed to strengthen relationships and increase social connections for individuals with social anxiety disorder also improved symptoms of depression [57]. This effect lasted longer in participants without existing social anxiety disorder.

Offline–Web-Based Engagement

A cross-sectional study reported improved mood only for participants chatting with friends on the web who were also known offline; they were not web-exclusive friends [32]. Social web-based gamers who had lower depression and social anxiety on the web had higher QSC with friends offline [28].

Adapted Conceptual Framework

Stage 1

A total of 55 indicators were found from professionals (19/55, 35%), young people (19/55, 35%), and the literature (17/55, 30%; Multimedia Appendix 5). Social connectedness and social support were excluded because they directly described social connection and were not *attributes* of D-QSC (indicators). Of the 55 indicators, 5 (9%) were direct repeats and 5 (9%) were deemed not attributes of D-QSC.

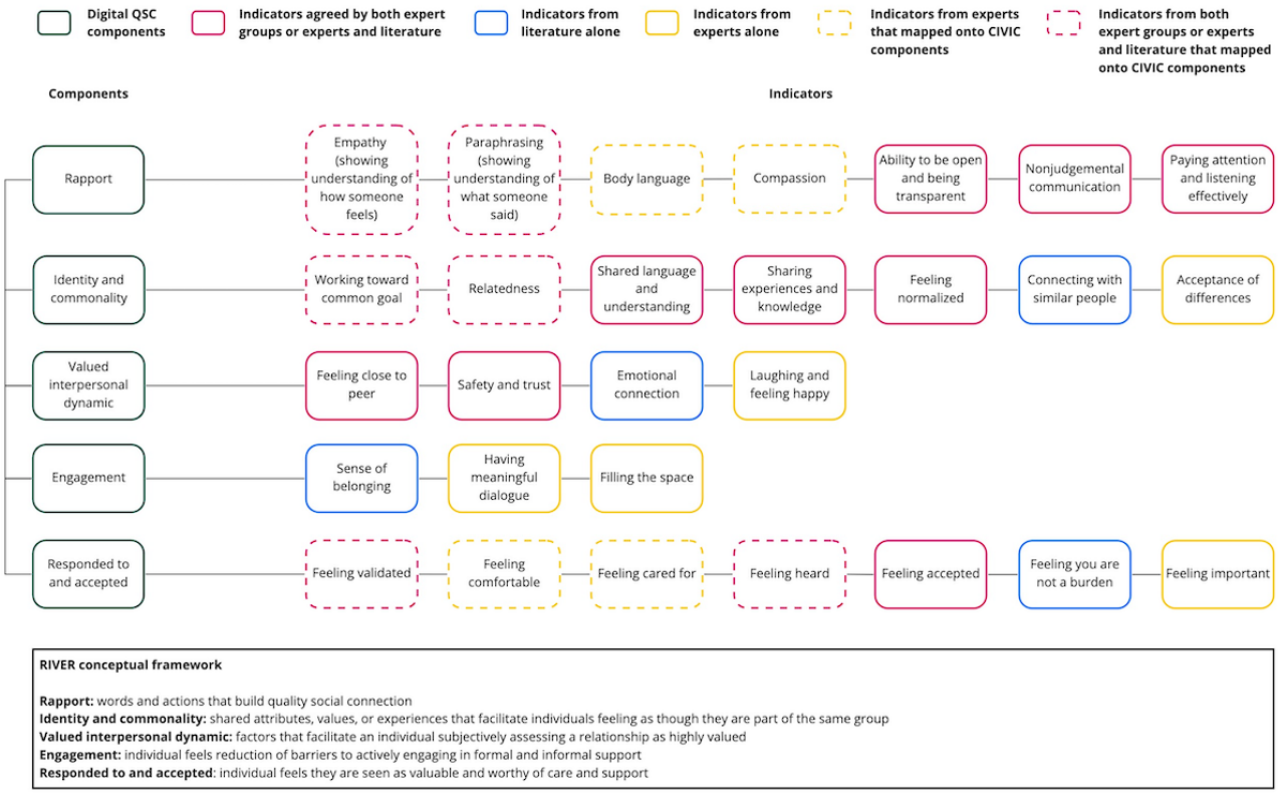
Stage 2

The remaining 45 indicators were grouped if conceptually similar or stood alone. For example, *Trust established* and *Trust*, as well as *Nonjudgmental* and *Not feeling judged*, were grouped, respectively. After the grouping, 30 indicators remained.

Stage 3

Of the 30 D-QSC indicators, 10 (33%) were initially mapped directly onto the preexisting CIVIC framework components (Figure 4). The remaining 67% (20/30) of indicators that did not map on directly were either merged with indicators that naturally went together, such as *Safety* and *trust*, or remained standalone indicators. Merged indicators (eg, *Safety and trust*, *Feeling close to peer*, and *Laughing and feeling happy*) and standalone indicators (eg, *Emotional connection*) were then loosely grouped and given new provisional component names (eg, Valued interpersonal dynamic) that suited the indicators' collective meaning.

Figure 4. Adapted RIVER (rapport, identity and commonality, valued interpersonal dynamic, engagement, and responded to and accepted) conceptual framework for quality social connection within digital interventions. CIVIC: Closeness, Identity and common bond, Valued relationships, Involvement, and Cared for and accepted; QSC: quality social connection.



Stage 4

Young experts reviewed the preliminary framework and identified 2 extra indicators that were deemed important (ie, *Feeling important* and *Acceptance of differences*) and added to the framework. Experts also helped to refine the wording or further merge indicators and components. For example, the *Identity and common bond* component was changed to *Identity and commonality*. There were 28 indicators across 5 components: rapport, identity and commonality, valued interpersonal dynamic, engagement, and responded to and accepted, given the acronym RIVER (Figure 4).

Discussion

Principal Findings

To our knowledge, this is the first systematic scoping review with meta-analysis to examine D-QSC as an *active ingredient* for depression and anxiety outcomes in young people. Usually conflated with quantity of social connections, QSC has now been comprehensively examined for its relevance to the mental health outcomes of digital interventions. We coproduced a conceptual framework of D-QSC for young people experiencing depression or anxiety that summarizes current understanding of component attributes or indicators. The RIVER framework comprises indicators relevant for establishing and assessing the presence of D-QSC. This can be characterized across 5 components. These components are interconnected and may not be exhaustive, but they provide a foundation for further work in this field to establish appropriate metrics for D-QSC.

D-QSC seems to help improve depression outcomes across most digital interventions. However, there is weaker evidence that D-QSC improves anxiety and well-being. There was also limited evidence of gaming, which was surprising considering that the participative nature with other users is at its core. D-QSC also worsened depression and anxiety outcomes in some instances, but this was often a result of negative interactions through social networking sites, which could be construed as a poor D-QSC. Few studies examined individual factors, contextual factors, or digital mechanisms that may modulate the impact of digital QSC on mental health outcomes. However, in the few studies that did report on mechanisms, a face-to-face connection before web-based support was an important consideration for improving outcomes. Furthermore, the impact of web-based support was modulated by the strength of offline connections.

Comparison With Prior Work

Reviews assessing the efficacy of digital mental health interventions for young people have found digital interventions to be as efficacious as, or sometimes more efficacious than, similar interventions delivered in person [65]. The strongest review to date that most closely relates to QSC collated measures of *social connectedness* to produce a conceptual framework of social connectedness in mental disorders (CIVIC) [17]. However, the review positioned social connectedness as the solution to loneliness and not as an *active ingredient* for the prevention and treatment of mental disorders (ie, depression and anxiety). Our work extended this framework to ensure that QSC was considered for digital interventions, for young people, and across different contexts. This process substantially expanded the elements indicating the development or presence of D-QSC and required redefining the CIVIC framework components to form the *RIVER framework of D-QSC indicators for young people*. Interestingly, the component of the CIVIC framework found to be most frequently assessed in current QSC metrics was *Identity and common bond*; this was the only component of our adapted framework not selected as a top priority in the context of digital interventions for anxiety and depression during review of the framework by 9 young people. This highlighted the need to develop improved metrics that are uniformly applied.

Strengths and Limitations

Young people with lived experience were involved at all review stages, including screening and interpretation. Dual independent review of the literature with people with direct experience of the review area helped us to overcome some limitations inherent in the current literature to gain better understanding of QSC and ensure accuracy of the screening. The insight from the young people during the data synthesis and interpretation stages helped to retain the data integrity. We have subsequently added to the limited evidence base for the impact of patient and public involvement throughout all stages of systematic and scoping reviews. Our adapted RIVER framework provides the foundation for future work to develop measures that would enable a developer, evaluator, or practitioner using digital interventions for mental health to assess the presence and degree of the QSC established.

The main limitation was that the studies did not control for a previous established connection offline before the D-QSC. Of the 42 studies, only 12 (29%) could be included in the meta-analysis because of a lack of measured effect sizes in previous work and heterogeneity across approaches, suggesting that the results should be interpreted with caution. Because of the scoping nature of the review, there was also statistical and methodological variability in the meta-analysis. Only manuscripts that were in English were included, which enables cultural bias. However, this was mitigated to an extent by working with young people and professionals from a variety of countries and cultural contexts to interpret the findings.

Clinical and Research Implications

QSC should be considered in the development and application of most digital interventions, particularly for depression. However, more research is needed to examine its impact within gaming platforms. In general, digital interventions mostly helped facilitate QSC; therefore, developers should consider factors such as user preference, anonymity, delivery medium, and content moderation. Initially, they should consider whether D-QSC is appropriate, depending on the target audience, and whether it will be important for engagement, or efficacy, or both. Further research is required to establish which individuals, conditions, and therapeutic mechanisms respond most strongly to D-QSC and what format is most appropriate. Clinical trials of any new digital intervention for mental health should control for previous face-to-face connections.

Future research should build upon our RIVER framework to further examine relationships among individual indicators of QSC, variations across different digital interventions, and the impact on outcomes across different user groups, particularly those in low- and middle-income countries. Factors that may mediate any causative relationships between QSC and mental health outcomes also deserve further attention. This work will inform the creation of standardized measures for D-QSC to evaluate its presence across different social settings. New measures should be developed to assess (1) attributes of a digital intervention that help or hinder good QSC and (2) the perceived value of a particular QSC for an individual and its relationship to outcomes within digital interventions. This work has value for development, regulation, and evaluation of digital mental

health interventions, as well as delineating helpful and harmful web-based interactions for young people, including social media. It will be vital to expand digital mental health care provision during the COVID-19 pandemic.

As the COVID-19 pandemic accelerates the shift to digital delivery of traditional therapy [13], clinicians should be trained in how to incorporate techniques for developing or maintaining D-QSC. Guidelines should be developed to ensure that moving face-to-face therapies to web-based spaces does not affect the QSC in the practitioner-patient dyad, and they should include strategies to improve connection on the web. Further clinical recommendations include a prioritization of video communication for web-based therapy to allow body language to be observed. However, anonymity can be beneficial to some users when first divulging sensitive mental health information. Blended care should enable patients to first meet their therapist in person, if desired, to facilitate QSC that can be translated to digital follow-ups.

Conclusions

In conclusion, D-QSC is important and an underconsidered component supporting engagement and efficacy for young people with depression and anxiety. In the wake of the COVID-19 pandemic, our work holds relevance as mental health needs rise and support will increasingly be provided on the web.

Acknowledgments

This work was funded by a Wellcome Trust Mental Health Priority Area *Active Ingredients* commission awarded to LD at Imperial College London.

The authors would like to thank Clara Nolan, Daniella Mallory, Emily Morse, Nathan Jackson, Nusaybah Choudhury, Ryan Vaughan, Tom Sharpe, Yasamin Neisi, and the other members of our UK Young Persons Advisory Group for all their excellent guidance and feedback throughout the project. The authors would also like to thank the Lancet Commission for Global Mental Health Young Leaders for their useful feedback from different global perspectives. Additional thanks go to the professional experts: Nicky Forsythe, Oliver Harrison, Heleen Riper, Victoria Hornby, Ariele Nobel, Anabelle Zhuang, Theresa Nguyen, Aliza Werner-Seidler, Tom Insel, Chris Martin, Jonny Benjamin, Peter Fonagy, and Peter Fuggle. Special thanks also go to Anna Lawrence-Jones and Catherine Kilkenny for their advice and guidance regarding patient and public involvement.

Authors' Contributions

LD and EL are joint first authors, led on conceptualization, and have contributed equally to writing this paper. LD led on patient and public involvement, synthesis, project management, and finalizing the paper. EL led on professional involvement. LR led on the scoping review, data extraction, and synthesis. EBH was involved in data screening, extraction, and quality assessment stages of the review. HA conducted the meta-analysis and advised on the review process. PA and GF provided project guidance. All authors reviewed and signed off the final paper.

Conflicts of Interest

HA is Chief Scientific Officer, Preemptive Medicine and Health Security at Flagship Pioneering. PA is a nonexecutive of West London NHS Trust, a mental health and community care provider.

Abstract

Background: Smoking tobacco, poor nutrition, risky alcohol use, and physical inactivity (SNAP) behaviors tend to cluster together. Health benefits may be maximized if interventions targeted multiple health risk behaviors together rather than addressing single behaviors. The internet has wide reach and is a sustainable mode for delivery of interventions for multiple health behaviors. However, no systematic reviews have examined the long-term effectiveness of internet-based interventions on any combination of or all SNAP behaviors in adults aged 18 years or older.

Objective: This systematic review examined, among adults (aged ≥18 years), the effectiveness of internet-based interventions on SNAP behaviors collectively in the long term compared with a control condition.

Methods: The electronic databases Medline, PsycINFO, Embase, CINAHL, and Scopus were searched to retrieve studies describing the effectiveness of internet-based interventions on ≥2 SNAP behaviors published by November 18, 2019. The reference lists of retrieved articles were also checked to identify eligible publications. The inclusion criteria were randomized controlled trials or cluster randomized controlled trials with adults examining an internet-based intervention measuring the effect on ≥2 SNAP behaviors at least 6 months postrecruitment and published in English in a peer-reviewed journal. Two reviewers independently extracted data from included studies and assessed methodological quality using the Quality Assessment Tool for Quantitative Studies. A robust variance estimation meta-analysis was performed to examine the long-term effectiveness of internet-based interventions on all 4 SNAP risk behavior outcomes. All SNAP outcomes were coded so they were in the same direction, with higher scores equating to worse health risk behaviors.

Results: The inclusion criteria were met by 11 studies: 7 studies measured the effect of an internet-based intervention on nutrition and physical activity; 1 study measured the effect on smoking, nutrition, and physical activity; and 3 studies measured the effect on all SNAP behaviors. Compared with the control group, internet-based interventions achieved an overall significant improvement across all SNAP behaviors in the long term (standardized mean difference –0.12 [improvement as higher scores = worse health risk outcomes], 95% CI –0.19 to –0.05; I^2=1.5%, *P*=.01). The global methodological quality rating was “moderate” for 1 study, while the remaining 10 studies were rated as “weak.”

Conclusions: Internet-based interventions were found to produce an overall significant improvement across all SNAP behaviors collectively in the long term. Internet-based interventions targeting multiple SNAP behaviors have the potential to maximize long-term improvements to preventive health outcomes.

KEYWORDS

internet; multiple health behaviors; tobacco; nutrition; alcohol; physical activity

Introduction

Smoking tobacco, poor nutrition, risky alcohol use, and physical inactivity (SNAP) are modifiable risk factors for chronic diseases such as heart disease, stroke, cancer, and diabetes [1]. Individuals who engage in all 4 SNAP behaviors, compared with 0, have an increased risk of mortality, equivalent to 14 years of aging [2]. Evidence has shown that SNAP behaviors tend to cluster together [3-5], suggesting a holistic approach for interventions to modify multiple health behaviors collectively rather than single behaviors individually may be beneficial. Multiple health behavior interventions target 2 or more health behaviors either sequentially or simultaneously [6]. Advantages of improving multiple health behaviors include maximizing health benefits [7], greater reduction in medical costs [8], and successfully modifying one behavior may increase confidence or motivation to change other health behaviors [7,9].

The internet is accessible globally and is a sustainable mode for the delivery of interventions for multiple health behaviors [10]. There are more than 4 billion internet users worldwide [10]; therefore, internet-based interventions have the potential to reach large numbers of people. Other advantages of internet-based interventions include that users can access information any time [11,12] as well as a low-cost modality for information delivery [11,12] and allowing for privacy, confidentiality [11], and long-term use [12,13]. Internet-based interventions may be interactive [11-13] and incorporate behavior change techniques such as individually tailored information [11,13], goal setting [12-14], self-monitoring [12-14], personalized and normative feedback [11,12,14], and progress tracking [12,13]. Internet-based interventions may also reduce health inequalities by improving access to services, for example among individuals who live in rural and remote areas or have significant mobility issues [13,15].

Existing systematic reviews have examined the effectiveness of behavioral interventions on multiple health risk behaviors [16,17]. A systematic review of nonpharmacologic interventions on multiple health risk behaviors found modest improvements in fruit and vegetable intake, physical activity, reduced fat intake, and reduced smoking [16]. Furthermore, another systematic review examining the efficacy of apps in children, adolescents, and adults reported that 41% of multiple health behavior interventions showed significant between-group improvements in behaviors [17]. However, only 2 systematic reviews have specifically examined the effectiveness of internet-based interventions on 2 or more SNAP behaviors in adult populations [18,19]. The review by Norman et al [18] focused on interventions for nutrition and physical activity but not tobacco use and alcohol intake. Of the 17 studies targeting multiple behaviors, 6 studies favored an internet-based intervention for increasing physical activity, and 6 studies favored an internet-based intervention for changing nutrition behaviors [18]. However, this systematic review was not restricted to adult populations, and findings from children and adolescents were included in the synthesis of findings [18]. Furthermore, short-term follow-up assessments were contained within this systematic review, and many studies did not report the effect of the internet-based intervention on nutrition and physical activity in the long term [18]. In the second systematic review, Oosterveen and colleagues [19] examined the effectiveness of internet-based interventions on combinations of all SNAP behaviors but included young adults aged 18 years to 35 years only. This systematic review identified only 2 studies with young adults targeting nutrition and physical activity behaviors that included a long-term follow-up (ie, 6 months or longer) [19]. To our knowledge, there is no systematic review that has examined the long-term effectiveness of internet-based interventions on any combination of or all SNAP behaviors in adults aged 18 years or older. Further critical review of the evidence is therefore needed to understand whether internet-based interventions are effective in improving multiple SNAP behaviors in the long term.

This systematic review aimed to examine the effectiveness of internet-based interventions on multiple SNAP health risk behaviors in the long term compared with a control condition.

Methods

Search Strategy and Selection Criteria

The electronic databases Medline, PsycINFO, Embase, CINAHL, and Scopus were searched to retrieve studies describing the effectiveness of internet-based interventions on 2 or more SNAP behaviors published by November 18, 2019. The following combinations of keywords were used: (multiple health behavio* or multiple behavio* or multiple risk* or multiple health* or smok* or tobacco or alcohol or diet* or nutrition or exercise or physical activity or fruit* or vegetable*) AND (internet or web* or online or on-line) AND (trial* or RCT* or random*). The reference lists of retrieved articles were also checked to identify any additional eligible publications.

The inclusion criteria were studies (1) that reported randomized controlled trials (RCTs) or cluster RCTs of internet-based interventions for ≥2 SNAP behaviors as either the sole intervention or an adjunct to written materials, (2) with adults aged 18 years or older, (3) that reported outcomes for ≥2 SNAP behaviors at least 6 months postrecruitment, (4) that had a no-intervention control group or the control group received information either in hard copy or information unrelated to

SNAP via a website, and (5) in the English language in a peer-reviewed journal.

Publications were excluded if (1) they did not report the outcomes of an RCT or cluster RCT (eg, systematic reviews, commentaries); (2) they examined only 1 SNAP health behavior; (3) they included special populations only such as people with chronic conditions (eg, cancer, diabetes) or pregnant women (this criterion was chosen because people with chronic conditions may differ in their motivation and capacity to change behaviors compared with those without chronic conditions and is consistent with the criterion set in another systematic review that examined multiple health risk behaviors [16]); (4) were conducted with people under 18 years of age; (5) outcome measures were not related to SNAP (eg, blood pressure); (6) the internet-based intervention was part of a multicomponent approach that included other modes of support (eg, face-to-face, telephone); (7) there was no control arm, and instead, comparisons were made with other interventions (eg, face-to-face support); and (8) SNAP outcomes were measured before 6 months postrecruitment.

Selection of Eligible Studies

This systematic review was conducted in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [20]. All records identified in each electronic database were imported into Endnote, and duplicates were removed. Titles, abstracts, and full texts of each reference were independently screened in duplicate by 2 reviewers (LW and FT or AM or EB) to determine if eligibility criteria were met. Full-text articles were retrieved when eligibility could not be determined from the title and abstract screening.

Study and Sample Characteristics

Data were independently extracted from the included studies by 2 authors (AM and AH or LW). A third author (FT) resolved any inconsistencies in data extraction. The study and sample characteristics extracted from eligible publications included authors and year of publication, country, years that data were collected, setting, sample characteristics (eg, mean age, gender, education, employment status), recruitment method, eligibility criteria, treatment conditions (relevant arms only; ie, internet-based intervention and control arms), internet-based intervention received (eg, duration, number of modules), retention rate at follow-up, SNAP measures, SNAP outcomes at 6 months of follow-up or later, and costs.

The outcomes extracted for each health behavior were any measure of (1) tobacco smoking (eg, current tobacco smoking, point prevalence abstinence, or prolonged abstinence), (2) nutrition (eg, number of daily serves of fruit and vegetables, dietary score), (3) alcohol consumption (eg, number of alcoholic drinks per day), and (4) physical activity (eg, moderate to vigorous physical activity, metabolic equivalent of task [MET] minutes per week).

Methodological Quality Assessment

The Quality Assessment Tool for Quantitative Studies developed by the Effective Public Health Practice Project was used to assess methodological quality [21]. This tool was chosen because it has demonstrated content validity, construct validity, and test-retest reliability [22] and has been shown to have higher interrater reliability than the Cochrane Collaboration Risk of Bias Tool [23]. The Quality Assessment Tool for Quantitative Studies allows randomized trials to be rated on 6 components: (1) selection bias, (2) study design, (3) confounders, (4) blinding, (5) data collection methods, and (6) withdrawals and dropouts. Each study was rated as "strong," "moderate," or "weak" for each component. An overall global rating was then assigned to each study, with studies classified as "strong" (no weak ratings), "moderate" (1 weak rating), or "weak" (2 or more weak ratings). The Quality Assessment Tool for Quantitative Studies Dictionary was used to make judgments about each of the 6 components [24].

The methodological quality of included studies was rated by 2 authors (FT and AM). Any discrepancies were discussed between these authors until consensus was reached. When rating the data collection methods, the measures for "all" SNAP outcomes needed to be shown to be valid and reliable for the data collection methods to be rated as strong. For instance, if smoking cessation was measured via biochemical validation and physical activity assessed via pedometers, the data collection methods were rated as strong. However, if smoking cessation was measured via a self-reported measure with no information about its psychometric properties and pedometers were used to assess physical activity, the data collection methods were rated as weak because "all" SNAP measures were not shown to be reliable and valid.

Robust Variance Estimation Meta-analysis

A robust variance estimation meta-analysis was performed using the R package *robumeta*. All SNAP behaviors were coded so they were in the same direction, with higher scores equating to worse health risk outcomes. Where a study measured the outcome at multiple time points (eg, 6 months and 12 months), data from the longer-term follow-up was included in the meta-analysis. The SNAP outcomes from each study were converted into Cohen d (standardized mean differences [SMDs]) and the corresponding variance [25]. Robust variance estimation meta-analysis was then performed on the SMDs (and variances), using the R package *robumeta*. A common within-study correlation (rho) of 0.8 was assumed, and sensitivity analyses were performed to determine the sensitivity of the results to this assumption (by looking at the results across various rho equal to 0, 0.2, 0.4, 0.6, or 1.0). Heterogeneity was measured using the I^2 statistic [26].

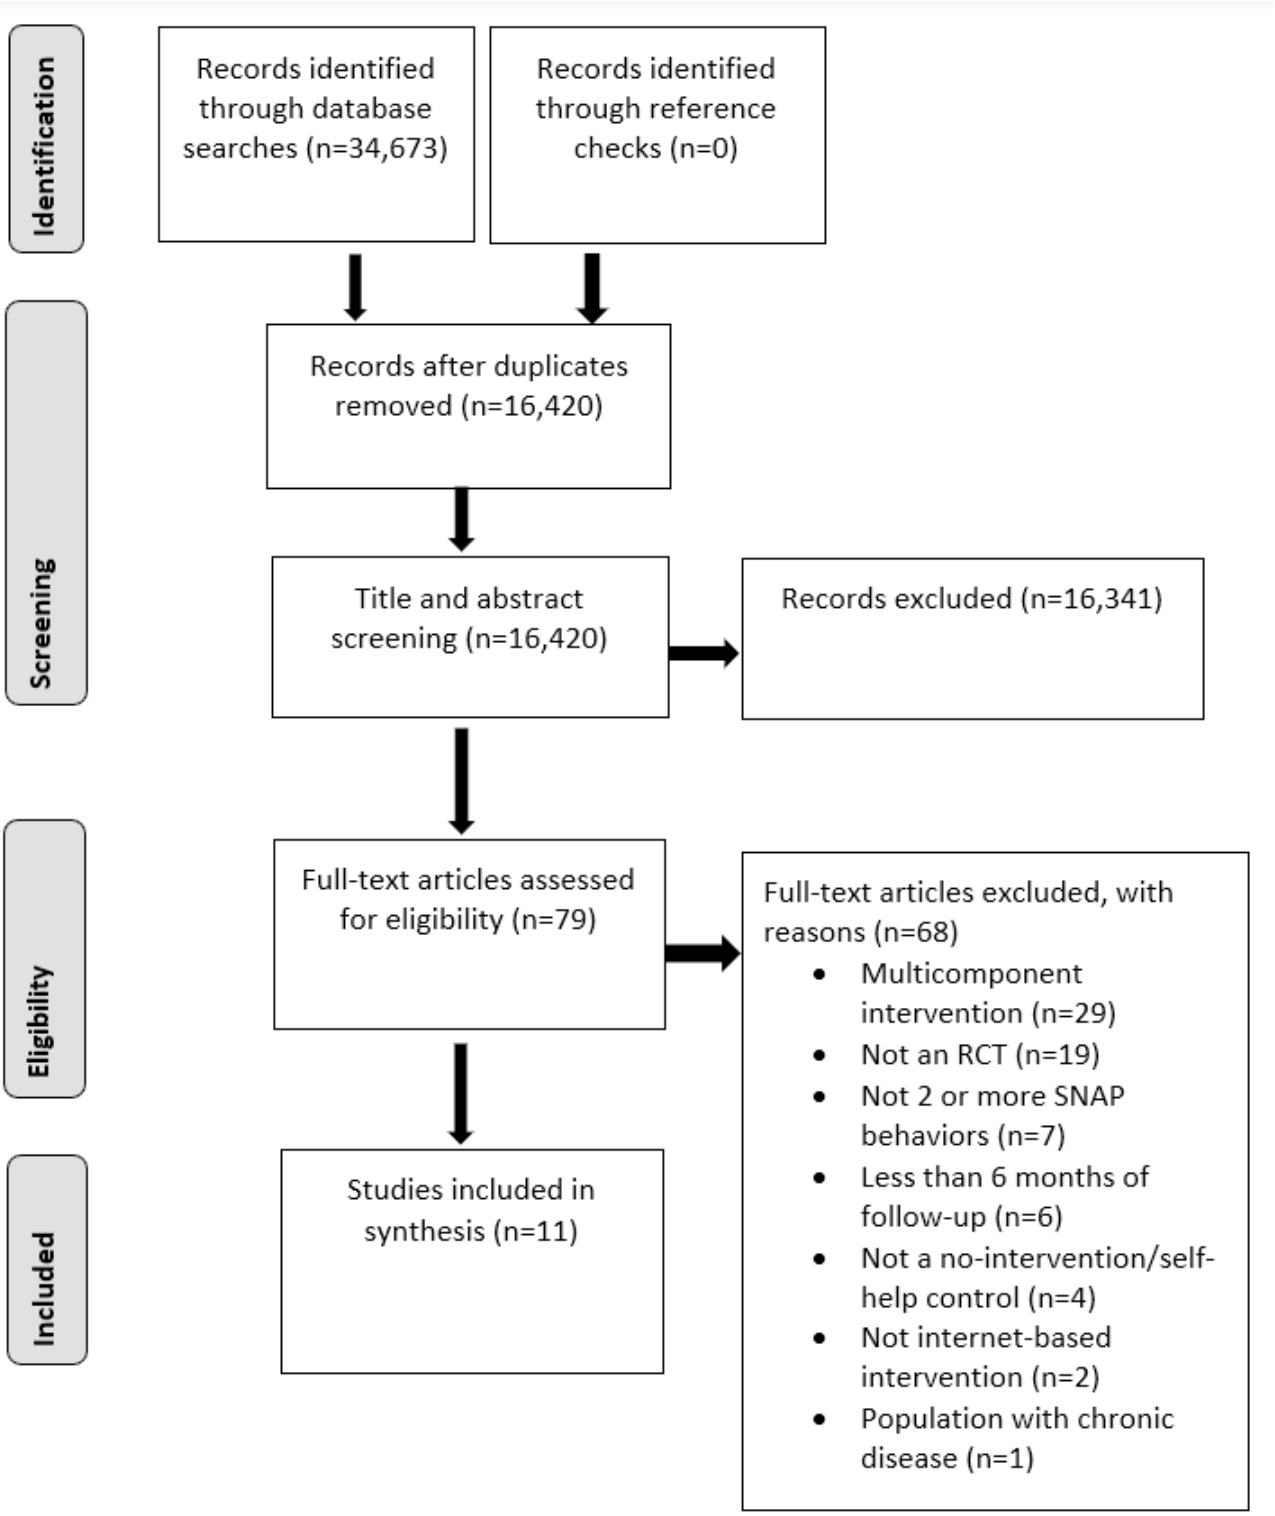
Results

Search Results

The PRISMA flow diagram outlining the study selection process is presented in Figure 1. A total of 34,673 records were identified from the electronic database searches. After the removal of duplicates, 16,420 records had their title and/or abstract screened, and 16,341 did not meet the inclusion criteria. The full texts of the remaining 79 articles were retrieved for further review, and 68 articles were excluded for the following

reasons: multicomponent intervention (n=29), not an RCT (n=19), did not measure 2 or more SNAP behaviors (n=7), less than 6 months of follow-up (n=6), did not include a no-intervention or self-help control group (n=4), not an internet-based intervention (n=2), and population with chronic disease (n=1). The inclusion criteria for this review were met by 11 studies.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram of the screening and selection process. RCT: randomized controlled trial.



Study Characteristics of Internet-Based Interventions for Multiple Health Risk Behaviors

Studies That Examined Nutrition and Physical Activity

As shown in Multimedia Appendix 1, the effectiveness of an internet-based intervention on nutrition and physical activity was examined by 7 studies [27-33]; 5 studies were conducted in the United States [27,29,30,32,33], and 1 study each was conducted in the United Kingdom [31] and Australia [28]. Recruitment occurred from the community in 3 studies [28,32,33], from health care settings in 2 studies [27,31], and from universities in 2 studies [29,30]. In 6 studies, participants were recruited via various advertisements (eg, website, emails, newspaper, flyers, posters, radio) [27,28,30-33], while 2 studies used sign-up tables at universities [29,30]. The sample size ranged from 121 [27] to 1071 [33]. Only men were included in 2 studies [28,32], and only women were included in 1 study [27]. The percentage of women ranged from 56.3% (268/476) to 77% (171/221) in the remaining studies [29-31,33].

The interventions included web-based learning activities, modules, or tutorials [27,30,32,33]; self-monitoring [28,32]; educational materials [28,29,31]; social support [28]; tailored information [27,30-33]; feedback [32]; and goal setting [32,34]. The duration of engagement with the internet-based interventions ranged from 2 sessions [29] to a 12-month trial period [31]. Nutrition and physical activity were measured via self-reported measures in 6 studies [27-32], while 1 study used self-reported measures for nutrition and pedometers for physical activity [33]. Nutrition and physical activity were assessed at 6 months in 4 studies (range of retention of 291/441, 66.0% to 105/121, 86.8% [27,29,31,32]), 7 months in 1 study (retention: 950/1071, 88.7% [33]), 9 months in 1 study (retention: 148/317, 46.7% [28]), 12 months in 2 studies (retention: 131/221, 59.3% and 309/441, 70.1% [31,32]), 15 months in 1 study (retention: 1126/1689, 66.7% [30]), and 16 months in 1 study (retention: 935/1071, 87.3% [33]).

Studies That Examined Smoking, Nutrition, and Physical Activity

Multimedia Appendix 2 describes the study characteristics of the US study examining the effectiveness of an internet-based intervention on smoking, nutrition, and physical activity [34]. This study recruited 423 university staff (female: 347/423, 82%; mean age 51 years) via announcements on staff listservs, targeted emails, recruitment tables at events, and flyers [34]. The RealAge internet program generated individual risk profiles and allowed users to select behaviors to change and create plans to meet behavioral goals [34]. Self-reported measures assessed smoking cessation, nutrition, and physical activity at 6-month (retention: 360/423, 85.1%) and 12-month (retention: 367/423, 86.8%) follow-ups [34].

Studies That Examined Smoking, Nutrition, Alcohol, and Physical Activity

As outlined in Multimedia Appendix 3, the effectiveness of internet-based interventions on smoking, nutrition, alcohol, and physical activity was assessed by 3 studies [35-37]. All studies were conducted in the United Kingdom [35-37]; 2 studies were undertaken in the university setting [35,36], and 1 study was conducted in the community [37]. In 2 studies, incoming undergraduate students were recruited via an email invitation [35,36], while online and print advertisements were used to recruit participants in the community study [37]. Across the 3 studies, the sample size ranged from 100 [37] to 2621 [35]. Most participants were women in all the studies (range: 1447/2614, 55.4% to 82/100, 82% [35-37]), and the mean age ranged from 18.8 years [35] to 39 years [37]. The U@Uni [36] and U@Uni:LifeGuide [35] internet-based interventions included a profile page containing self-affirmation manipulation, theory-based messages for each SNAP behavior, and a planner to form implementation intentions. The HealthyValues Healthy Eating program targeted motivation, volition, and maintenance and included weekly tasks for 24 weeks [37]. All studies measured SNAP outcomes via self-reported measures at a 6-month follow-up [35-37]. The retention rates at 6 months were 41.2% (1079/2621) [35], 63.2% (913/1445) [36], and 95% (95/100) [37], respectively.

Long-Term Effectiveness of Internet-Based Interventions Across SNAP Risk Behaviors

The robust variance estimation meta-analysis found that, compared with the control group, internet-based interventions achieved an overall significant improvement across all SNAP behaviors in the long-term (SMD –0.12 [improvement as higher scores = worse health risk outcomes], 95% CI –0.19 to –0.05; I^2=1.5%, *P*=.01) [27,29,30,32,34-37]. Heterogeneity was low (I^2=1.5%), and the tau-square (the extent of variation due to between-study variance) was low, at <0.001. The sensitivity analysis showed that the model results did not vary greatly across different values of within-study correlation (rho).

Methodological Quality Assessment

Table 1 presents the methodological quality ratings for the 6 components and the global rating as assessed via the Quality Assessment Tool for Quantitative Studies [21]. In terms of selection bias, all studies were rated "weak," as 9 of these studies recruited volunteers who responded to advertisements or sign-up tables [27-34,37], and 2 studies sent emails to all incoming undergraduate students but recruited less than half of those approached [35,36]. All included studies were RCTs or cluster RCTs and were rated as "strong" in terms of study design [27-37]. With regards to confounders, 8 studies were rated as "strong" because there were no between-group differences at baseline [31,32,34,35,37] or adjustments for baseline characteristics were made during analysis [27,29,36], while 1 study was rated as "moderate," as stratification attempted to balance baseline characteristics across groups [33], and 2 studies were rated as "weak," as no adjustments were made during analysis for baseline characteristics that differed between the groups [28,30]. For blinding, 9 studies were rated as "weak" because the assessors and participants were not blinded [28,31,34] or there was no information about blinding [27,29,30,33,35,36], while 2 studies were rated as "moderate" because only the assessors were blinded to the condition [32,37]. For data collection methods, 8 studies were rated as "weak," as all relevant SNAP measures were not shown to be valid or reliable (either via the use of an objective measure or demonstration of acceptable psychometric properties of a

self-reported measure) [27,30,31,33-37], while 3 studies were classified as "strong," as all SNAP measures used were valid and reliable [28,29,32]. In relation to withdrawals and dropouts, 4 studies were rated as "strong," with retention rates ≥80% (105/121; 935/1071; 367/423; 95/100) [27,33,34,37]; 4 studies were rated as "moderate," with retention rates between 60% and 79% (422/606; 1126/1689; 309/441; 913/1445) [29,30,32,36]; and 3 studies were rated as "weak," with retention rates <60% (148/317; 131/221; 1079/2621) [28,31,35]. In terms of the global rating, 1 study was rated as "moderate" [32], and the remaining 10 studies were rated as "weak" [27-31,33-37].

Discussion

Principal Findings

This is the first systematic review to examine the long-term effectiveness of internet-based interventions on SNAP behaviors collectively in adults aged 18 years or older. This systematic review focused on internet-based interventions to increase the homogeneity of included studies. This is similar to other systematic reviews that have focused on a specific digital technology [38,39]. More broadly, however, digital technologies can also include text messaging, email, mobile applications, video conferencing [40], and just-in-time feedback interventions [41]. The studies included in this systematic review most commonly examined effectiveness on 2 SNAP behaviors, namely nutrition and physical activity [27-33]. Only 3 studies examined the effectiveness of internet-based interventions on all 4 SNAP behaviors [35-37], whereas 1 study measured the effect on 3 behaviors (ie, tobacco smoking, nutrition, physical activity) [34].

The robust variance estimation meta-analysis findings reported that internet-based interventions achieved an overall significant improvement across all SNAP behaviors in the long term. This suggests that internet-based interventions that adopt a holistic approach to behavior change by addressing multiple SNAP behaviors improve these behaviors collectively and consequently may lead to better health outcomes and reduced health care costs. Given no previous systematic reviews have examined the long-term effectiveness of internet-based interventions on multiple SNAP behaviors nor provided an overall effect size across all SNAP behaviors, we cannot compare our findings to previous reviews. To advance the field, further research is needed on the long-term effectiveness of internet-based interventions on multiple SNAP behaviors.

The studies in this systematic review recruited participants from a variety of settings, including universities [29,30,34-36], the community [28,32,33,37], and health care [27,31]. Among the 5 studies conducted in universities, only 1 study reported a significant treatment effect on both nutrition and physical activity [30], while another study found the intervention reduced

current smoking but had no effect on nutrition, alcohol, and physical activity [36]. Of 4 studies conducted in the community, 2 studies reported a significant treatment effect of the internet-based intervention on nutrition and some physical activity outcomes [32] or on some nutrition outcomes but not physical activity [33]. The trials that recruited participants from health care settings found no significant differences between the internet-based intervention and the control condition [27,31]. Additional research is needed across a variety of settings to expand the evidence base examining the long-term effectiveness of internet-based interventions on combinations of 2 or more SNAP behaviors.

In terms of methodological quality, 10 of 11 studies had a global rating of "weak" [27-31,33-37], with only 1 study rated as "moderate" [32]. Improvements to methodological rigor are particularly needed for selection bias, blinding, and data collection methods. Selection bias could be reduced by using recruitment methods that aim to enroll a representative sample (eg, random selection of potential participants) while data collection methods could be improved via objective measures (eg, pedometers for physical activity, biochemical validation for smoking cessation) for all SNAP behaviors assessed. Given the nature of behavioral interventions, blinding is often difficult; however, future studies should attempt to blind assessors and participants where possible.

Limitations

This systematic review had some limitations. First, although we were able to pool the studies to undertake a robust variance estimation meta-analysis to examine the long-term effectiveness of internet-based interventions across all SNAP behaviors, additional analyses examining potential moderators (eg, country) were not possible due to the relatively small number of studies in this systematic review. Second, the methodological quality assessments were based on the information contained in the articles, and missing details from these articles may have had an impact on the ratings. Finally, all the studies were conducted in high-income countries, which may limit the generalizability of this systematic review's findings to low- and middle-income countries. In addition to expanding the research in the settings and populations included in this review, future research should assess the long-term effectiveness of internet-based interventions on multiple SNAP behaviors in additional populations (eg, culturally and linguistically diverse groups, Indigenous), settings (eg, vocational education settings, rural and remote locations), and countries (eg, low- and middle-income) to strengthen the evidence base and improve the generalizability of the findings.

Conclusions

Internet-based interventions were found to produce an overall significant improvement across all SNAP behaviors in the long term. Given the promising findings on the long-term effectiveness of internet-based interventions across all SNAP behaviors collectively, such interventions may maximize improvements to health and prevent chronic diseases.

Acknowledgments

The School of Medicine and Public Health at the University of Newcastle, Hunter New England Population Health, and the Hunter Medical Research Institute provided infrastructure support. FT was supported by a Heart Foundation Postdoctoral Fellowship (100128), followed by a National Health and Medical Research Council (NHMRC) Career Development Fellowship (APP1143269). The sponsors had no role in study design; in the collection, analyses, and interpretation of data; in the writing of the manuscript; and in the decision to submit the article for publication.

Abstract

Background: Virtual assistants can be used to deliver innovative health programs that provide appealing, personalized, and convenient health advice and support at scale and low cost. Design characteristics that influence the look and feel of the virtual assistant, such as visual appearance or language features, may significantly influence users' experience and engagement with the assistant.

Objective: This scoping review aims to provide an overview of the experimental research examining how design characteristics of virtual health assistants affect user experience, summarize research findings of experimental research examining how design characteristics of virtual health assistants affect user experience, and provide recommendations for the design of virtual health assistants if sufficient evidence exists.

Methods: We searched 5 electronic databases (Web of Science, MEDLINE, Embase, PsycINFO, and ACM Digital Library) to identify the studies that used an experimental design to compare the effects of design characteristics between 2 or more versions of an interactive virtual health assistant on user experience among adults. Data were synthesized descriptively. Health domains, design characteristics, and outcomes were categorized, and descriptive statistics were used to summarize the body of research. Results for each study were categorized as positive, negative, or no effect, and a matrix of the design characteristics and outcome categories was constructed to summarize the findings.

Results: The database searches identified 6879 articles after the removal of duplicates. We included 48 articles representing 45 unique studies in the review. The most common health domains were mental health and physical activity. Studies most commonly examined design characteristics in the categories of visual design or conversational style and relational behavior and assessed outcomes in the categories of personality, satisfaction, relationship, or use intention. Over half of the design characteristics were examined by only 1 study. Results suggest that empathy and relational behavior and self-disclosure are related to more positive user experience. Results also suggest that if a human-like avatar is used, realistic rendering and medical attire may potentially be related to more positive user experience; however, more research is needed to confirm this.

Conclusions: There is a growing body of scientific evidence examining the impact of virtual health assistants' design characteristics on user experience. Taken together, data suggest that the look and feel of a virtual health assistant does affect user experience. Virtual health assistants that show empathy, display nonverbal relational behaviors, and disclose personal information about themselves achieve better user experience. At present, the evidence base is broad, and the studies are typically small in scale and highly heterogeneous. Further research, particularly using longitudinal research designs with repeated user interactions, is needed to inform the optimal design of virtual health assistants.

Introduction

Background

Advancements in machine learning and artificial intelligence offer promise for delivering automated, tailored, convenient health assistance with an unprecedented level of sophistication and personalization and are already contributing to the transformation of health care [1]. Virtual assistants can be broadly defined as digital services designed to simulate human conversation and provide personalized responses based on input from the user. They can be programmed with structured conversations or to answer the user's questions. Capabilities range from simple menu or multiple choice–based assistants to more sophisticated virtual assistants with natural language processing that recognize free speech or text. At present, virtual assistants are widely deployed in web-based banking and service settings, reducing reliance on staff by being available to answer consumers' questions about products and services *on demand*. Virtual assistants are also increasingly being designed for various health applications, such as delivering cognitive behavior therapy for depression and anxiety [2], improving diet and physical activity [3], and conducting remote patient monitoring [4]. Despite the exciting potential for using virtual assistants for health purposes, the use of virtual assistants in health could be ineffective or even have unintended negative consequences if the technology does not meet the user's needs and preferences.

The user experience of a virtual health assistant can be defined as the user's perceptions and responses (eg, emotions, beliefs, preferences, and behaviors) that result from its use or anticipated use [5]. User experience is influenced by a range of factors, including presentation, functionality, and interactive behavior [5]. It is important to optimize the design of virtual assistants to provide a positive user experience and promote engagement. A growing body of evidence suggests that design characteristics that influence the *look and feel* of the virtual assistant, such as visual appearance, communication method, and language features, are an important consideration for design, as such design characteristics can significantly influence users' psychological and emotional responses and engagement with technology-based applications [6,7]. In addition, although some design decisions may not affect the cost (eg, whether an avatar should be male or female), other decisions may have a major impact on the cost of designing a virtual health assistant (eg, whether an avatar should be animated with facial expressions). Understanding how such design characteristics influence user experience will assist in using finite health software development budgets most effectively.

Previous literature has proposed general guidelines for designing voice user interfaces [8] and accessible conversational user interfaces for different disability groups [9], as well as virtual assistants for specific purposes such as teaching [10] and in-vehicle assistance [11]. Optimal design techniques are likely to depend on the purpose of the virtual assistant [12,13]; therefore, recommendations specifically in the context of health are needed. Although research has examined methods of assessing the usability of virtual assistants in the health domain [14], clear guidelines on maximizing the user experience of virtual health assistants are lacking.

An important first step toward constructing guidelines for the development of virtual health assistants was achieved by the literature review conducted by ter Stal et al [15] in 2018, which aimed to identify the researched design characteristics for embodied conversational agents (virtual assistants that have an animated avatar) in health. The review provided a comprehensive overview of the existing literature, with results suggesting that speech and/or textual output and facial and gaze expressions were the most commonly researched design characteristics. The secondary aims of ter Stal et al [15] were to identify the outcome variables used in the research and the effects of the design characteristics. The authors concluded that, based on the immature body of evidence at the time, there was no consensus on the optimal design characteristics for embodied conversational agents in health. Results highlighted key avenues for future research, including the fact that more research is needed on all design characteristics to advance the field. Notably, the review by ter Stal et al [15] included studies using any research design and studies where participants viewed stimuli but did not necessarily interact with a virtual assistant.

Objectives

The evidence base for the use of interactive virtual health assistants is rapidly growing in both size and quality. In particular, experimental research designs with interactive virtual assistants are being reported increasingly, which should provide clearer evidence of the influence of design characteristics on user experience. A scoping review methodology offers an explicit, systematic means to overview this large and diverse body of literature using rigorous methods to minimize bias [16]. In this study, we seek to undertake the first scoping review of design characteristics of virtual health assistants, with a view to bring together the strongest evidence available regarding the effects of design characteristics on the user experience of interactive virtual health assistants. In particular, the aims of our scoping review are as follows:

1. Provide an overview of all the experimental research examining how design characteristics of virtual health assistants affect user experience
2. Summarize research findings of experimental research examining how design characteristics of virtual health assistants affect user experience
3. Identify whether research supports making recommendations for the design of virtual health assistants

Bringing together the available evidence on how design characteristics affect the user experience of virtual health assistants will assist researchers and software developers in making decisions about the look and feel of their software and developing the most user-friendly and effective virtual health assistants.

Methods

This review is reported according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist [17].

Eligibility Criteria

Eligibility criteria were designed using the population, intervention, comparator, and outcome framework (population: adults; intervention: virtual health assistant; comparator: design characteristics; and outcome: user experience) [18]. Original research articles in peer-reviewed journals and full-length conference papers were included.

Population

Studies with adult samples (aged ≥18 years) were included.

Intervention

Studies examining virtual health assistants were included. For this review, we considered virtual health assistants to be any virtual assistant aimed at the health consumer (general population or patient) relating to the prevention, management, or treatment of any physical or mental health condition, as well as clinical research. Virtual health assistants were included if they functioned on any electronic device (eg, smartphone, computer, and headset). *Wizard of Oz* virtual assistants (where the user believes they are interacting with a computer-automated virtual assistant, but the virtual assistant is operated by a human [19]) were included.

Comparator

Studies comparing design characteristics between ≥2 versions of a virtual health assistant were included. For this review, we defined design characteristics as characteristics of the virtual assistant that influence its *look and feel* without affecting its core content, purpose, or function. Examples of design characteristics include visual cues such as whether the virtual health assistant has an avatar (ie, an image that represents the virtual assistant), language style, and interaction modality (ie, text or speech). Between- and within-subject experimental designs were included.

Outcome

Studies evaluating user experience outcomes were included. For this review, we defined user experience to include self-reported evaluations of the virtual assistant or the user's interaction with the virtual assistant that indicated a more positive or negative experience (eg, trustworthiness, likeability, enjoyment, and ease of use), affect, intentions to continue using the virtual assistant, and objective measures of user engagement (eg, frequency, duration, or nature of the interaction with the virtual health assistant). Only quantitative data were included.

Exclusion Criteria

Dissertations, review articles, conference abstracts, and studies with children were excluded. Virtual assistants used for training or educating medical professionals, as well as robots with a physical body, were excluded. Studies were excluded if participants did not interact with the virtual health assistant; that is, they did not provide any input into the system. Studies were also excluded if the virtual health assistant was not the main component of the health program. Studies were excluded if they evaluated only 1 version of a virtual assistant (ie, nonexperimental research design with no comparator) or if they compared a virtual assistant to a human. Dependent variables that were not associated with a more positive or negative user experience—for example, those used as *manipulation checks* (eg, where participants were asked to confirm whether a realistic-looking assistant was indeed more realistic looking than a cartoon-style assistant)—were excluded.

Information Sources and Search Strategy

A cross-disciplinary search of the literature was conducted on June 4, 2020, and included 5 electronic databases across the fields of health and information technology: Web of Science, MEDLINE, Embase, PsycINFO, and ACM Digital Library. Search terms for virtual assistant AND design characteristics were included in the search strategy (Table 1). Eligibility specifying the virtual assistant related to *health*, user experience outcomes, and experimental study design was assessed at screening. Searches were limited to the English language with no limit on publication date. Reference lists of the included studies and other key papers in the field were searched to identify further studies (pearling).

Table 1. Search terms.

Search category	Search terms
Virtual assistant	*"conversational agent*"* OR *"conversational system*"* OR *"dialog system*"* OR *"dialogue system*"* OR *"assistance technolog*"* OR *"relational agent*"* OR *"virtual agent*"* OR *"virtual assistant*"* OR *"embodied agent*"* OR *chatbot**
Design characteristics	*anthropomorphi** OR *humanness* OR *personality* OR *emotion** OR *empathy* OR *sympathy* OR *humour* OR *humor* OR *language* OR *linguistic** OR *communication* OR *"conversational tone"* OR *voice* OR *speech* OR *avatar* OR *"profile picture"* OR *face* OR *facial* OR *graphic** OR *appearance* OR *"visual design"* OR *animation* OR *interface* OR *button** OR *menu** OR *emoji** OR *emoticon** OR *"human factors"*

Evidence Selection and Data Charting

Search results from each database were imported into EndNote (Clarivate) [20], in which duplicates were removed. Studies were screened based on title and abstract. Studies that met the eligibility criteria progressed to full-text screening. The full texts of the studies were then screened to determine final eligibility. Articles were screened by 1 of 2 raters. Raters screened a randomly generated selection of 20 articles in duplicate, and the agreement was 100%. A custom form was developed and used for data charting (Multimedia Appendix 1). Extracted data included population, sample size, age, gender, study country, cultural background, health domain, purpose of the virtual assistant, name of the virtual assistant, *Wizard of Oz*

design, device used, animated character, output modality, input modality, whether the interaction was scripted (whether participants were told what to say), duration of interaction, experimental design, and study results. If articles included multiple studies, data extraction was completed only for studies meeting the eligibility criteria. Where multiple eligible studies were included in an article, data were extracted separately. Where relevant outcomes were measured but not compared statistically between experimental conditions, authors were contacted to provide additional information.

Data Synthesis

Study characteristics were compiled for all the studies included in the review. Where a study was reported in multiple articles, articles were compiled as 1 study with a primary reference indicated, as well as an indication of additional references. To facilitate data synthesis across diverse research designs, overarching categories were constructed to describe the health domains, design characteristics, and outcomes. Retrospective thematic analysis was used to identify similar health domains, design characteristics, and outcomes to construct the relevant categories. After data extraction was completed, lists of all reported health domains, design characteristics, and outcomes were compiled. After familiarization with the data, the first author sorted them into similar categories using an inductive approach (ie, directed by the data with no preconceived categories). These categories were reviewed with the senior author, refined, and named.

Data were synthesized descriptively. Descriptive statistics were used to summarize the body of research. A matrix of the design characteristics and outcome categories was constructed to summarize the research findings. Results in the matrix were based on statistical results reported in the articles. Where interactions were examined (eg, in factorial designs or examining interactions with participant characteristics), main effects were included in the matrix. Studies could report results for 1 or multiple outcomes within a particular outcome category. Results were categorized as positive, negative, or no effect. Where studies reported multiple results in a single outcome category, they were categorized as positive if all multiple outcomes showed positive effects, mixed positive if multiple outcomes were reported with both positive and nonsignificant effects, negative if all multiple outcomes showed negative effects, mixed negative if multiple outcomes were reported with both negative and nonsignificant effects, and no effect if multiple outcomes showed no significant effects.

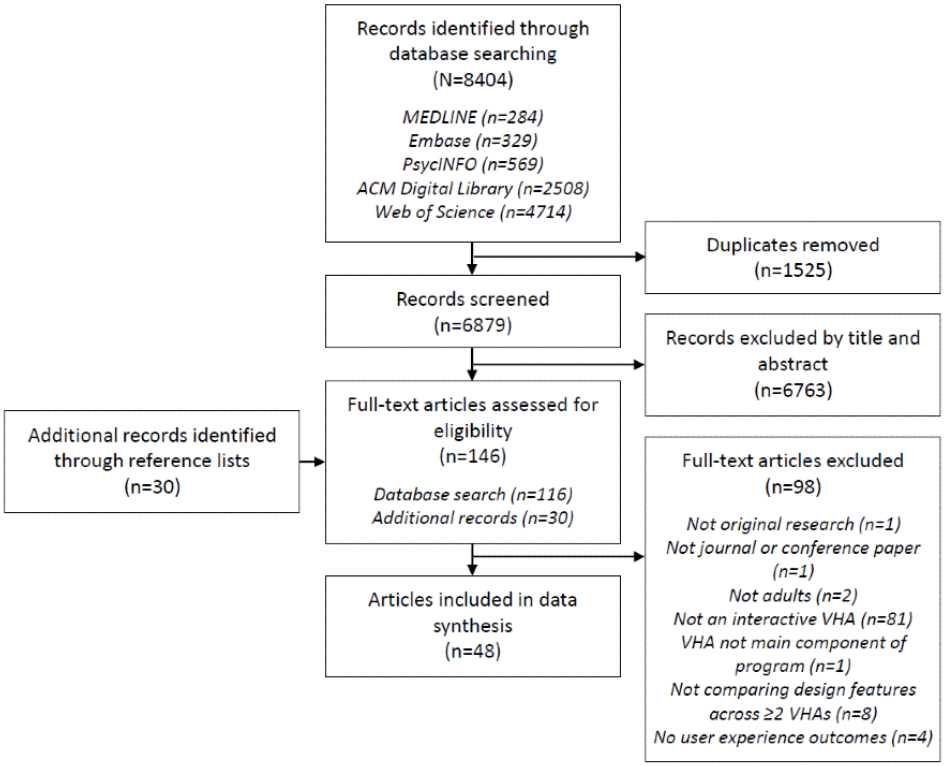
Authors from 2 studies provided additional data on measures that were not compared between experimental groups. Independent sample *t* tests (2-tailed) were conducted, and the results were included in the matrix. In total, 4 studies did not present a statistical analysis comparing relevant experimental conditions; therefore, these studies are included only in the text description.

Results

Overview

The search identified 6879 articles after duplicates were removed. Of the 6879 articles, 6763 (98.31%) were deemed ineligible based on title and abstract screening. We identified 30 additional records through reference lists. In total, 146 articles (116/6879, 1.69% from the database search plus 30 from reference lists) were screened at full text. Of the 146 articles, 98 (67.1%) were deemed ineligible; 81 (55.5%) did not examine an interactive virtual health assistant, 8 (5.5%) did not compare design features between ≥2 virtual health assistants, 4 (2.7%) did not report user experience outcomes, 2 (1.4%) were not adult samples, 1 (0.7%) did not report original research, 1 (0.7%) was not a journal of conference paper, and 1 (0.7%) did not have the virtual health assistant as a main component of the program. Of the 146 articles, a final 48 (32.9%) articles were included in the scoping review (Figure 1). From the 48 articles, 45 unique studies were identified (5 studies were reported in multiple articles, whereas 3 articles contained multiple studies).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart. VHA: virtual health assistant.



Multimedia Appendix 2 [21-68] provides an overview of the participant characteristics and study designs for all studies included in the review. Table 2 summarizes the characteristics of the body of research. The virtual assistants used in the research were categorized into 8 health domains: physical activity (aimed to increase exercise), nutrition (aimed to improve diet), alcohol consumption (aimed to reduce alcohol consumption), mental health (eg, aimed to improve mood), medical information or treatment (eg, discussed colorectal cancer screening), sexual health (eg, provided advice about sexually transmitted infections), multiple health behaviors (eg, aimed to improve both exercise and diet), and other (eg, aimed to prevent carpal tunnel). A total of 27 design characteristics were examined in the literature. These were categorized into 5 categories: visual design (eg, realism, age, and body shape of an animated avatar), interface design (eg, input modality), conversational style and relational behavior (eg, empathy and relational behavior and personality), combined visual and conversational design (eg, variability in language and background scene assessed simultaneously), and cultural and organizational affiliation (eg, culturally tailored argumentation and appearance; see Table 3 for the full list of design characteristics). We identified 140 outcome variables, which were categorized into nine categories: virtual assistant personality traits (eg, credible and intelligent), relationship (eg, intimacy and relationship closeness), ease of use (eg, cognitive load and ease of use), satisfaction (eg, enjoyment, satisfaction, and usefulness), emotion (eg, positive and negative affect), use intention (eg, intention to keep using the virtual assistant), engagement (eg, interaction duration), and disclosure (eg, self-disclosure detail and intimacy; see Multimedia Appendix 3 for a full list of outcomes by category). Outcome assessment most frequently used Likert scales, with server logs and conversation transcripts used to assess engagement and disclosure.

Most studies were conducted in the United States, with a greater number of studies conducted during more recent years (ie, between 2017 and 2020). Several authors led multiple studies (ie, Bickmore [25-27,29,31], Creed [34,35], Olaffsson, [53,54], Ring [56-58], and Zhou [67,68]). Most studies examined conversational style and relational behavior or visual design and assessed outcomes in the categories of personality, satisfaction, relationship, and use intention. Virtual assistants most frequently related to mental health and physical activity. Those addressing multiple health behaviors frequently examined physical health and nutrition together. Most virtual assistants had an animated avatar and used speech output and multiple-choice input. Most virtual assistants were automated (did not use a *WizardofOz* design), and participant input was not scripted. Studies were most frequently conducted with between 21 and 100 participants in a single session using a between-subjects design, where participants were allocated to evaluate 1 version of the virtual assistant. Participants were most frequently from the general population, with a larger proportion of females than males. Studies were most often published in conference proceedings in fields related to interdisciplinary research on intelligent virtual agents and human–computer interactions, with fewer published in health-related fields.

Participant control of facial and vocal expression (vs none)	1 (2)	—	—	No significant effect [26]	Mixed positive [26]	—	—	—	—

Design characteristics	Values, n (%)	Outcomes (effect)							
		Personality	Relationship	Ease of use	Satisfaction	Emotion	Use intention	Engagement	Disclosure
Constrained to positive user response options (vs negative responses allowed)	1 (2)	No significant effect [54]	No significant effect [54]	—	Mixed negative [54]	—	No significant effect [54]	—	—
Combined visual and conversational design									
Personification (name, static avatar, and conversational language vs none)	1 (2)	—	—	—	—	—	—	—	Mixed negative [59]
Variability in dialog structure, language, and scene (vs no variability)	1 (2)	Positive [29]	—	—	—	—	Positive [29]	Positive [29]	—
Cultural and organizational affiliation									
Culturally tailored argumentation (vs not)	2 (5)	No significant effect [65]	—	—	Positive [50]	—	—	—	—
Culturally tailored appearance (vs not)	3 (7)	No significant effect [65,67]	Negative [67]	No significant effect [67]	No significant effect [50,67]	—	No significant effect [67]	—	—
Culturally tailored argumentation and scene combined (vs not)	1 (2)	No significant effect [68]	No significant effect [68]	No significant effect [68]	No significant effect [68]	—	No significant effect [68]	—	—
Patient assistant (vs researcher or government employee)	1 (2)	Mixed positive [66]	—	—	Mixed positive [66]	—	Positive [66]	—	—

[a]Results indicated for nonempathetic avatar only (empathetic avatar had additional dialog to the no avatar condition).

[b]No study examined the combination of design characteristic and outcome.

[c]Multiple studies were reported in the article with similar results.

[d]Similar results were additionally reported at a different time point in the study [39].

[e]Similar results were additionally reported at a different time point in the study [46].

[f]Indicates any effects of personality (no consistent comparator).

Table 3 summarizes research findings grouped according to the design characteristic examined and the categories of outcomes measured. Where identical outcomes of a study were reported in multiple articles, the primary reference listed in Multimedia Appendix 2 was used. Additional references were used for outcomes that were not reported in the primary study. In total, 4 studies did not present a statistical analysis comparing the relevant experimental conditions; therefore, these studies are not included in Table 3.

The following paragraphs highlight key results from the studies presented in Table 3 and include a narrative synthesis of studies that were not presented in Table 3.

Visual Design

Approximately 7% (3/41) of studies examined whether user experience differed using a virtual assistant with an animated avatar compared with using a text- or speech-only virtual assistant with no visual representation [48,51,62]. Findings were generally nonsignificant [48,51,62], with some mixed negative effects of using an animated avatar [48,62]. An additional study not included in Table 3 concluded that virtual assistants with an animated avatar were preferred over voice-only assistants; however, the analyses included both real and virtual assistants [45].

Approximately 22% (9/41) of studies examined the appearance of the animated avatar, and 10% (4/41) of studies examined whether user experience differed using a virtual assistant with a more realistic human avatar compared with a more cartoon human avatar [57,62,64]. Although some positive and mixed positive effects of using a more realistic avatar were found [64], more effects were nonsignificant [57,62,64], and 1 was negative [57]. The species of the avatar was examined by 2% (1/41) of studies, which found mixed negative effects of using a human avatar compared with using a robot avatar [62]. Age was examined by 2% (1/41) of studies, which found mixed positive effects of using an avatar with a younger appearance compared with using one with an older appearance on satisfaction but no significant effects on other outcomes [64]. Body shape was examined by 2% (1/41) of studies, which found a positive effect of a fat avatar compared with a slim avatar on personality traits but nonsignificant effects on other outcomes [63]. The familiarity of the avatar was examined by 2% (1/41) of studies, which found mixed negative and nonsignificant effects of using an avatar that looked like a health coach that participants met at the beginning of the session compared with using an unfamiliar avatar [64]. The avatar's attire was examined by 2% (1/41) of studies, which found consistently positive effects of medical professional attire compared with casual attire [55].

The background scene behind the avatar was examined by 2% (1/41) of studies, which found mixed positive effects of representing a medical office compared with representing an empty room on personality but no significant effects on other measured outcomes [55]. Approximately 7% (3/41) of studies (all reported in 1 paper) examined whether variability in the *camera* position, distance, and focus was associated with user experience and found mostly nonsignificant effects [58].

Interface Design

Approximately 7% (3/41) of studies examined the effects of input modality—whether the user communicates using speech, text, or multiple choice—on user experience and found a combination of positive, mixed negative, and nonsignificant effects of speech input compared with other modalities [32,33,52]. A menu-based virtual assistant was examined by 1 further study not included in Table 3, and it concluded that there were no differences in usability between speech and phone key press user input [42].

How the conversation between the virtual assistant and user was initiated was examined by 2% (1/41) of studies, which found positive and nonsignificant effects of automated motion initiation compared with user initiation [56]. The type of ringtone used to initiate a conversation with the user was examined by 2% (1/41) of studies, which found positive effects of more polite tones compared with less polite tones [25].

Conversational Style and Relational Behavior

Approximately 17% (7/41) of studies examined empathy and relational behavior—empathetic verbal feedback and nonverbal behavior such as facial expressions and gestures [27,31,39,40,48,49,51]. Although some effects were nonsignificant [27,40,48,49,51], more effects were positive or mixed positive, with 71% (5/7) of studies showing at least some positive effect [27,31,39,48,51]. Approximately 7% (3/41) of studies examined emotional expression—the use of facial expression and voice to express emotion—and found some mixed positive effects [34,43] but more nonsignificant effects [34,35,43]. Approximately 7% (3/41) of studies examined self-disclosure—whether the virtual assistant tells the user information about themselves—and found mostly positive effects [29,44,47]. Approximately 7% (3/41) of studies examined personality [36,60,61]. Although some positive and mixed positive effects were found [60,61], most effects were nonsignificant [36,60].

Approximately 5% (2/41) of studies examined conversation memory—whether the virtual assistant remembered information from earlier conversation—and found some mixed positive effects [36] but mostly nonsignificant effects [23,36]. An additional study not included in Table 3 compared users' first interactions when the virtual assistant did not recall their previous session and when the virtual assistant did recall their previous session [38]. The authors concluded that users were more positive when the virtual assistant recalled their session; however, the conversations were less personal.

Humor was examined by 2% (1/41) of studies, which found mostly nonsignificant effects of including humor compared with not including humor [36]. Using emojis was examined by 2% (1/41) of studies, which found no significant effects of using emojis compared with not using emojis [37]. Rap was examined by 2% (1/41) of studies, which found a combination of mixed positive, mixed negative, and nonsignificant effects of including rap compared with not including rap [53]. Allowing participants to control the virtual assistant's facial and vocal expression was examined by 2% (1/41) of studies, which found nonsignificant and mixed positive effects compared with not allowing such control [26]. Approximately 2% (1/41) of studies examined constraining users to respond only positively to questions about their confidence and motivation compared with also presenting negative multiple-choice response options [54]. It found a combination of mixed negative and neutral effects of constraining users to positive responses. A further study not included in Table 3 examined whether user evaluations were more positive for a virtual assistant that changed behavior based on the user's eye contact compared with a virtual assistant that always appeared attentive or always bored or that changed behavior randomly [41]. The authors concluded that changing based on the user's eye contact seemed more normal than changing behavior randomly but did not confirm the hypothesis

that changing behavior is more normal than unchanging behavior.

Combined Visual and Conversational Design

Personification—the use of a name, static avatar, and conversational language—was examined by 2% (1/41) of studies, which found negative effects of personification on users' disclosure [59]. Variability in dialog structure (the order of the conversation and the utterances used) and background scene was examined by 2% (1/41) of studies, which found consistently positive effects of variability compared with no variability [29].

Organizational and Cultural Affiliation

Approximately 10% (4/41) of studies examined cultural tailoring—matching the culture of the virtual assistant to that of the user [50,65,67,68]. Approximately 5% (2/41) of studies examined cultural tailoring of the virtual assistant's argumentation (eg, discussed culturally relevant topics) [50,65], and 50% (1/2) of those found a positive effect [50]. Approximately 7% (3/41) of studies examined cultural tailoring of the virtual assistant's appearance and the household setting and found predominantly nonsignificant effects [50,65,67]. Culturally tailored background scene and argumentation combined were examined by 2% (1/41) of studies, which found no significant effects [68]. The organizational affiliation of the virtual assistant—who the virtual assistant claimed to be and the context provided in the background scene—was examined by 2% (1/41) of studies, which found positive effects of the virtual assistant being a patient assistant compared with the virtual assistant being either a member of the medical team conducting the research or a government employee [66].

Discussion

Principal Findings

This study aimed to provide an overview of experimental research examining how design characteristics of virtual health assistants affect user experience. This is a growing area of scientific endeavor with studies, taken together, examining highly diverse health domains, design characteristics, and outcomes. The most common health domains were physical activity and mental health, with relatively few virtual assistants related to specific health conditions. Approximately half of the studies were categorized as examining the design of conversational style and relational behavior, with the most common design characteristic researched being empathy and relational behavior. The most commonly measured outcomes were in the categories of personality traits, satisfaction, relationship, and use intention.

This study also aimed to summarize the research findings of experimental research examining how design characteristics of virtual health assistants affect user experience. Generally, research has been piecemeal, with few design characteristics having a sufficient body of evidence to draw conclusions about their effects on user experience. The 2 design characteristics that defy this are virtual assistants' empathy and relational behavior and self-disclosure, which have been the focus of a good number of studies. Research suggests that all 3 (ie, empathy, relational behavior, and self-disclosure) are related to more positive user experience. Other design characteristics with emerging levels of evidence are having a more realistic human representation for an avatar and having medical attire for the avatar, both of which may potentially be related to more positive user experience. Finally, evidence to date suggests that using an animated avatar (compared with no avatar) and cultural tailoring may not affect user experience; however, more research is needed to explore these findings.

One of the clearest findings of this study was that the use of empathy and relational behavior in virtual health assistants appears to have positive effects on user experience. Empathy may help to build trust and rapport with the virtual assistant. The finding that empathy was associated with user satisfaction is in line with research indicating a positive association between empathy in real health care providers and patient satisfaction [69,70]. Results were not consistently positive; however, this may be related to differences between the virtual assistants. For example, for the outcome category personality traits, of the 5 studies examining empathy and relational behavior, 3 (60%) studies showing positive effects used animated avatars, including nonverbal relational behaviors [31,48,51]. In contrast, 40% (2/5) of studies showing no effects were text-only assistants [40,49]. It may be that users do not expect text-only assistants to show empathy; therefore, the presence or absence of empathy has no impact on the ratings of the virtual assistant. Alternatively, the effects of empathy may be diminished when nonverbal relational behaviors such as expression and gestures are not present.

Research suggests that virtual health assistants that use self-disclosure (ie, provide information about themselves) elicit a more positive user experience. Results were similar whether the autobiographical information was framed as being about the virtual assistant's experience as a computer agent [44] or included human experiences that could not actually be true [29,47]. Self-disclosure is important for the formation of relationships [71], although research suggests that self-disclosure by a real counselor can have either positive or detrimental effects on a client's perceptions of the counselor [72]. The finding that users respond positively to the autobiographical stories of a virtual health assistant supports the *computers are social actors* paradigm, where users display social responses to computers, although they know they are not human [73,74].

Research examining the realism of the animated avatar showed some positive effects; however, more were nonsignificant. The *uncanny valley* theory suggests that robots that appear almost but not quite human may elicit a negative emotional response and be less likable than those that are clearly nonhuman [75]. However, in this review, the study that used a photo-realistic representation in the realistic experimental condition [64] showed positive effects. More research is needed to examine how the realism of the avatar affects the user experience of virtual health assistants.

Results from 1 study suggest that dressing the avatar in medical attire results in a more positive user experience [55]. Although more research is needed to confirm this finding, this was a large study (n=308) with consistent results across all outcomes measures. Interestingly, the background setting for the avatar

(medical office or empty room) had a mixed positive effect on only 1 out of 3 outcomes categories [55].

Research suggests that including an animated avatar has no effect or, in some cases, a negative effect on user experience. However, upon closer inspection, this may be because of the nature of the avatars used in the research and may also be affected by interactions between the animation and other virtual assistant characteristics. For example, Lisetti et al [48] showed that an animated avatar with a neutral facial expression and no empathetic dialog led to poorer user experience than a text-only virtual assistant, whereas an expressive and empathetic virtual assistant led to a better user experience than the text-only virtual assistant. Nguyen and Masthoff [51] reported similar findings; a nonempathetic animated virtual assistant and a nonempathetic text-only virtual assistant led to a similar user experience; however, an empathetic animated virtual assistant led to better user experience than an empathetic text-only virtual assistant. Taken together, it appears that users may expect a virtual assistant with a human-like representation to have empathy and human-like relational behaviors and have a poorer user experience when this expectation is not met.

Overall, the research did not show cultural tailoring to improve the user experience of virtual health assistants. Notably, although 75% (3/4) of studies included participants who were born overseas (in China [68], India [50], or a Spanish-speaking Latin-American country [65]), participants in all the studies lived in the United States. This may suggest that cultural tailoring is not required for different cultures living in the United States who have had exposure to Anglo-American culture, although more research could confirm this finding. Additional research is also needed to determine whether cultural tailoring affects user experience in other cultural contexts.

Strengths and Limitations

This scoping review is the most rigorous attempt at synthesizing the literature regarding the effects of design characteristics on the user experience of virtual health assistants. It followed the PRISMA-ScR guidelines for scoping reviews and searched a large number of databases. It examined a broad range of design characteristics using the highest level of evidence—experimental research using only interactive virtual health assistants where participants were able to input into the system. However, we acknowledge that the use of specific search terms to capture virtual assistants and design characteristics could have omitted some results. It is also possible that other literary sources may have been available in other databases. In addition, qualitative data were excluded. This enabled a structured approach to synthesizing the data based on statistical significance but may have omitted some important views on user experience.

Although the breadth of the review is a major strength, the heterogeneity of the included studies makes it difficult to synthesize and interpret the results. There was considerable heterogeneity in the purpose of the virtual assistants studied. Optimal design techniques may differ among different health domains. For example, although no overall effect of using emojis was found, the difference in ratings of confidence between using text-only and text with emojis depended on whether the virtual assistant was discussing physical or mental well-being [37]. In addition, some health conditions were not represented in the studies, for example, neurocognitive impairments such as dementia. There was also significant heterogeneity in the outcomes measured. The most commonly measured outcomes were in the categories of personality, satisfaction, relationship, and use intention. Few studies examined the ease of use, engagement, or disclosure. Although interface design may play a key role in determining the ease of use, other design characteristics such as the visual appearance of an avatar may not be expected to affect the ease of use. More research examining how users interact with the virtual assistant (engagement and disclosure), particularly using objective measures, may complement subjective ratings of the virtual assistant and interaction.

An additional limitation of the literature is that some studies combined a set of similar characteristics into 1 condition, making it difficult to ascertain which characteristic might be responsible for the effects on user experience. For example, research on empathy and relational behavior frequently included verbal empathy with nonverbal relational behaviors. In addition, in most studies, participants evaluated the virtual assistant after interacting during a single session. Programs that aim to promote health behavior change or provide support for a health condition are often designed for ongoing use. Additional research should examine how design characteristics affect user experience over time. Most virtual assistants had animated avatars and speech output; however, over half constrained user input to selecting from predefined response options. Constraining user input requires simpler programming and removes the risk of errors occurring when the virtual assistant misinterprets the user's input or cannot formulate a response to a query that is outside the bounds of its programmed knowledge [76]. Natural language processing enables users to communicate using unconstrained text or speech and enables more natural user-directed communication. Virtual assistants using natural language processing have been commonly used in health care [77] and, with rapid advancements in artificial intelligence, are likely to become increasingly sophisticated. More research should examine the design and user experience of these types of virtual health assistants.

Recommendations

Research demonstrates that design characteristics affect the user experience of virtual health assistants; therefore, researchers and software developers should carefully consider the look and feel of a virtual health assistant during development and testing. On the basis of the results of this scoping review, the following recommendations for designing virtual health assistants and advancing the field of research may be useful for health researchers and software developers:

1. Design virtual health assistants to express verbal empathy, for example, understanding of the user's feelings
2. Design virtual health assistants to disclose personal information about themselves to the user, for example, information about their past and personal preferences
3. Consider designing a human avatar to be more realistic with medical professional attire

4. If designing an animated virtual health assistant, it should display nonverbal relational behaviors, for example, emotional facial expressions, gestures, and mutual gaze
5. If empathy and relational behaviors are unable to be incorporated, consider that an animated avatar may not be beneficial or cost-effective
6. Engage in formative research with the target audience and adopt a user-centered design approach to ensure that the software meets the needs and preferences of the user
7. Conduct further systematic research to replicate and extend previous findings, particularly with longitudinal research designs with repeated user interactions, objective engagement outcomes, and virtual assistants with natural language processing capabilities

Conclusions

Virtual health assistants can provide health information and support on demand and may be applied in the future to a wide variety of purposes such as providing public health information, health education, supporting patients with chronic health conditions, and assisting with healthy lifestyle behavior change. This scoping review examined experimental research assessing how design characteristics of virtual health assistants affect user experience. This is a rapidly growing field of research but is difficult to synthesize and interpret because of the heterogeneity of studies. Nonetheless, certain design characteristics have emerged as important for improving user experience. Preliminary recommendations suggest that programming virtual health assistants to show empathy, display nonverbal relational behaviors, and disclose personal information about themselves may result in a more positive user experience. The decision to include an animated avatar should consider whether the avatar can display empathy and nonverbal relational behaviors. Future research is required to improve our understanding of the relationship between design characteristics and user experience of virtual health assistants, particularly with longitudinal research designs with repeated user interactions.

Acknowledgments

CAM is supported by a Medical Research Future Fund Emerging Leader Grant (GNT1193862). HTB is supported by an Australian Government Research Training Program Scholarship. The funders had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Authors' Contributions

RGC and CAM conceived and designed the study. RGC conducted database searches. RGC and BB conducted screening, and RGC, BB, TF, CN, HTB, and RV conducted data extraction. RGC analyzed the data and wrote the manuscript. All authors revised the manuscript and reviewed and approved the final version.

Abstract

Background: Parental health literacy is associated with child health outcomes. Parents are increasingly turning to the internet to obtain health information. In response, health care providers are using digital interventions to communicate information to assist parents in managing their child's health conditions. Despite the emergence of interventions to improve parental health literacy, to date, no systematic evaluation of the effectiveness of the interventions has been undertaken.

Objective: The aim of this review is to examine the effect of digital health interventions on health literacy among parents of children aged 0-12 years with a health condition. This includes evaluating parents' engagement (use and satisfaction) with digital health interventions, the effect of these interventions on parental health knowledge and health behavior, and the subsequent impact on child health outcomes.

Methods: This systematic review was registered a priori on PROSPERO (International Prospective Register of Systematic Reviews) and developed according to the Joanna Briggs Institute methodology for systematic reviews. The databases CINAHL, MEDLINE, and PsycINFO were searched for relevant literature published between January 2010 and April 2021. Studies were included if they were written in English. A total of 2 authors independently assessed the search results and performed a critical appraisal of the studies.

Results: Following the review of 1351 abstracts, 31 (2.29%) studies were selected for full-text review. Of the 31 studies, 6 (19%) studies met the inclusion criteria. Of the 6 studies, 1 (17%) was excluded following the critical appraisal, and the 5 (83%) remaining studies were quantitative in design and included digital health interventions using web-based portals to improve parents' health knowledge and health behavior. Owing to heterogeneity in the reported outcomes, meta-analysis was not possible, and the findings were presented in narrative form. Of the 5 studies, satisfaction was measured in 3 (60%) studies, and all the studies reported high satisfaction with the digital intervention. All the studies reported improvement in parental health literacy at postintervention as either increase in disease-specific knowledge or changes in health behavior. Of the 5 studies, only 1 (20%) study included child health outcomes, and this study reported significant improvements related to increased parental health knowledge.

Conclusions: In response to a pandemic such as COVID-19, there is an increased need for evidence-based digital health interventions for families of children living with health conditions. This review has shown the potential of digital health interventions to improve health knowledge and behavior among parents of young children with a health condition. However, few digital health

interventions have been developed and evaluated for this population. Future studies with robust research designs are needed and should include the potential benefits of increased parent health literacy for the child.

Introduction

Background

Parents of young children are responsible for the health and well-being of their children and are the advocates and primary caregivers of their children [1]. Parents are expected to interact with health services in the delivery of health care [2] and learn about their child's health condition and potential interventions and procedures involved in treatment [3,4]. To interact effectively with health services, parents of children with health conditions need a level of health literacy. Health literacy increases the parents' capacity to take responsibility and be involved in making decisions related to their child's health [2].

Health literacy is commonly described as knowledge, motivation, and competence to assess, understand, appraise, and apply health information. Health literacy enables people to make decisions on health care, disease prevention, and health promotion throughout their life course [5]. A parent's level of health literacy influences 3 aspects of health behavior: access and use of health services, patient-provider interactions, and self-management [5].

Low parental health literacy has been linked to poor health knowledge and child health status [6-9]. Limited health literacy has been associated with various concerns, including delayed diagnoses, misunderstanding of medication labels [10,11], poor adherence to treatment regimens, and increased use of emergency care [12]. Limited parental health literacy may also result in poor child health outcomes, including depressive symptoms, persistent asthma [8,13-16], and less than optimal glycemic control in children with diabetes [17].

Parents' need for health information can remain unmet [18]. Moreover, parents of children with health conditions are often affected by stress [19] and poor sleep, which may hinder their ability to receive and process new information and learn about their child's condition to provide them with optimal care [20,21]. Information about a child's health condition needs to be delivered at a time that is appropriate for the family and offered as many times as needed, which can be challenging for both the parents and the health service [22,23]. A way to enhance the delivery of information is through digital technology (eg, mobile phones and tablets), as this can be accessed at a time, place, and pace that best suits the parent. Thus, digital health interventions (eg, information videos, web-based platforms, and mobile apps) can be used in the home settings where most care is provided [3]. Internet and mobile phone use are high among parents worldwide, with most parents using the internet and mobile phones to access information multiple times a day [24,25]. Parents are heavy users of web-based child health-related information [25]. Between 70% and 80% of parents have searched on the web for health information, with most parents seeking parenting advice, health information, or social support [26].

Health care providers increasingly use digital technologies to communicate information to address health needs and deliver health care interventions [27]. Despite minimal evidence for the effectiveness of digital health interventions, these have significantly increased because of the restrictions related to COVID-19 [28].

Considerable challenges exist related to how digital health technologies can best be used and integrated to support and facilitate user engagement and provide individualized health information and care [29]. A level of engagement is required to affect a change in health behaviors [30]. Engagement is measured by the extent of use of the intervention (initial log-in and number of activities completed) and the subjective user experience, which is often measured by user satisfaction [31,32].

Objectives

Despite the growth in the use of the internet among parents to obtain health information and the emergence of digital health interventions to support parents, systematic evaluation of parental engagement with and effectiveness of digital interventions to improve health literacy has not been conducted. The objective of this review is to examine the effect of digital health interventions on health literacy among parents of children aged 0-12 years with a health condition. In this study, health literacy includes the evaluation of parental engagement (use and satisfaction) with digital health interventions, the effect of these interventions on parental health knowledge and health behavior, and the subsequent impact on child health outcomes.

Methods

This review followed the Joanna Briggs Institute (JBI) methodology for systematic reviews [33] and was conducted according to the registered a priori PROSPERO (International Prospective Register of Systematic Reviews) protocol CRD42020192386. Qualitative and quantitative studies were included as a broad search was required to address the complex health system–related questions [34].

Inclusion Criteria

Participants

This review considered studies that included parents or primary caregivers of children aged 0-12 years with a health condition. Health conditions could be an acute or a chronic disease, diagnosis, or condition. Studies involving children aged ≥12 years were excluded, as children aged ≥12 years are more likely and encouraged to take more responsibility for their health care. Studies were also excluded if health-related information was directed to the child, if the child was healthy, or if the primary users of the digital health intervention were health professionals such as medical staff, nursing staff, health care management, and administrators or researchers. Studies focusing on health promotion or disease prevention (eg, increased knowledge of obesity, physical activity, and smoking) were excluded.

Intervention

This review considered studies that examined any digital health intervention that aimed to improve health literacy among parents. Interventions could focus on communication (eg, web-based platforms, mobile apps, videoconferencing, and SMS text messaging), education (eg, videos, web-based platforms, mobile apps, and interactive training), or a combination of communication and education interventions. Interventions that targeted the child or clinician or were delivered directly (eg, face to face by health care professionals) to the parent were excluded.

Context

This review considered studies that examined the use of digital health interventions in both the home and hospital setting.

Outcomes

This review considered studies that included an increase or decrease in health literacy defined by health knowledge or health behavior [5,30]. The review also considered the following outcomes: changes in the child's health outcome and engagement with the digital health intervention, including (1) use, that is, *logging into* the web-based platform, *continued use of* the digital health intervention, amount and duration of access, and type of information accessed; or (2) satisfaction with the digital health intervention measured, for example, by attention, interest, usefulness, and perceived benefits through survey items [31,32].

Search Strategy

The following databases were searched for existing systematic reviews on this topic: CINAHL, MEDLINE, PROSPERO, JBI Database of Systematic Reviews and Implementation Reports, and Cochrane Library Database of Systematic Reviews, and no reviews were located on the specific topic. The base search strategy was developed in CINAHL, and additional adapted searches were run on CINAHL, MEDLINE, and PsycINFO and hand searched in Google Scholar. The search strategy was developed in collaboration with a research librarian to identify articles examining the health literacy of parents of children with a health condition. The key terms were *health literacy* or *health behavior* or *health education* or *health information* and *digital health* or *mobile health* or *electronic health*. The initial search was undertaken in June 2020 and updated in April 2021. The search was limited to papers published in English between January 2010 and April 2021, as there have been constant developments and improvements in digital health technology over the past 10 years. The complete search strategy is shown in Multimedia Appendix 1. The reference list of all the included studies was reviewed to identify any relevant papers not found in the electronic search. Gray literature sources including OpenGrey, ProQuest Dissertation and Theses, Google, and Google Scholar were also searched to identify unpublished studies.

Screening of Articles

After removing duplicates using Endnote (Clarivate), the web-based tool Rayyan (Rayyan Systems Inc) was used to screen the articles [35]. Titles and abstracts were reviewed independently by 2 authors (EM and SR) to determine if they met the inclusion criteria. Any disagreement regarding eligibility was resolved through discussion with a third author (DA). The selected articles were reviewed in full text by the same authors.

Assessment of Methodological Quality

The quality of the screened studies was critically appraised independently by 2 reviewers (EM and SR) using the Mixed Methods Appraisal Tool (MMAT) version 2018 [36]. The MMAT was selected in preference to the JBI critical appraisal tool as the MMAT was developed to appraise studies that combine qualitative, quantitative, and mixed methods studies.

Data Extraction

Data extraction was undertaken by the second author (SR) and reviewed by the first author (EM) and modeled on the standardized data extraction tool from the JBI [33]. The extracted data included specific details about the study setting and context; phenomena of interest (health literacy); study design; sampling of participants, sample size, and characteristics of the study sample; specific details about the interventions; and outcomes of significance to the review question. All data were extracted following a thorough, complete reading of the text to identify qualitative and quantitative findings relevant to the objectives and questions of the review.

Data Synthesis

Owing to differences in reported quantitative data and the small number of studies, meta-analysis was not possible. The findings are presented in a narrative form [37], including tables and figures to aid in data presentation.

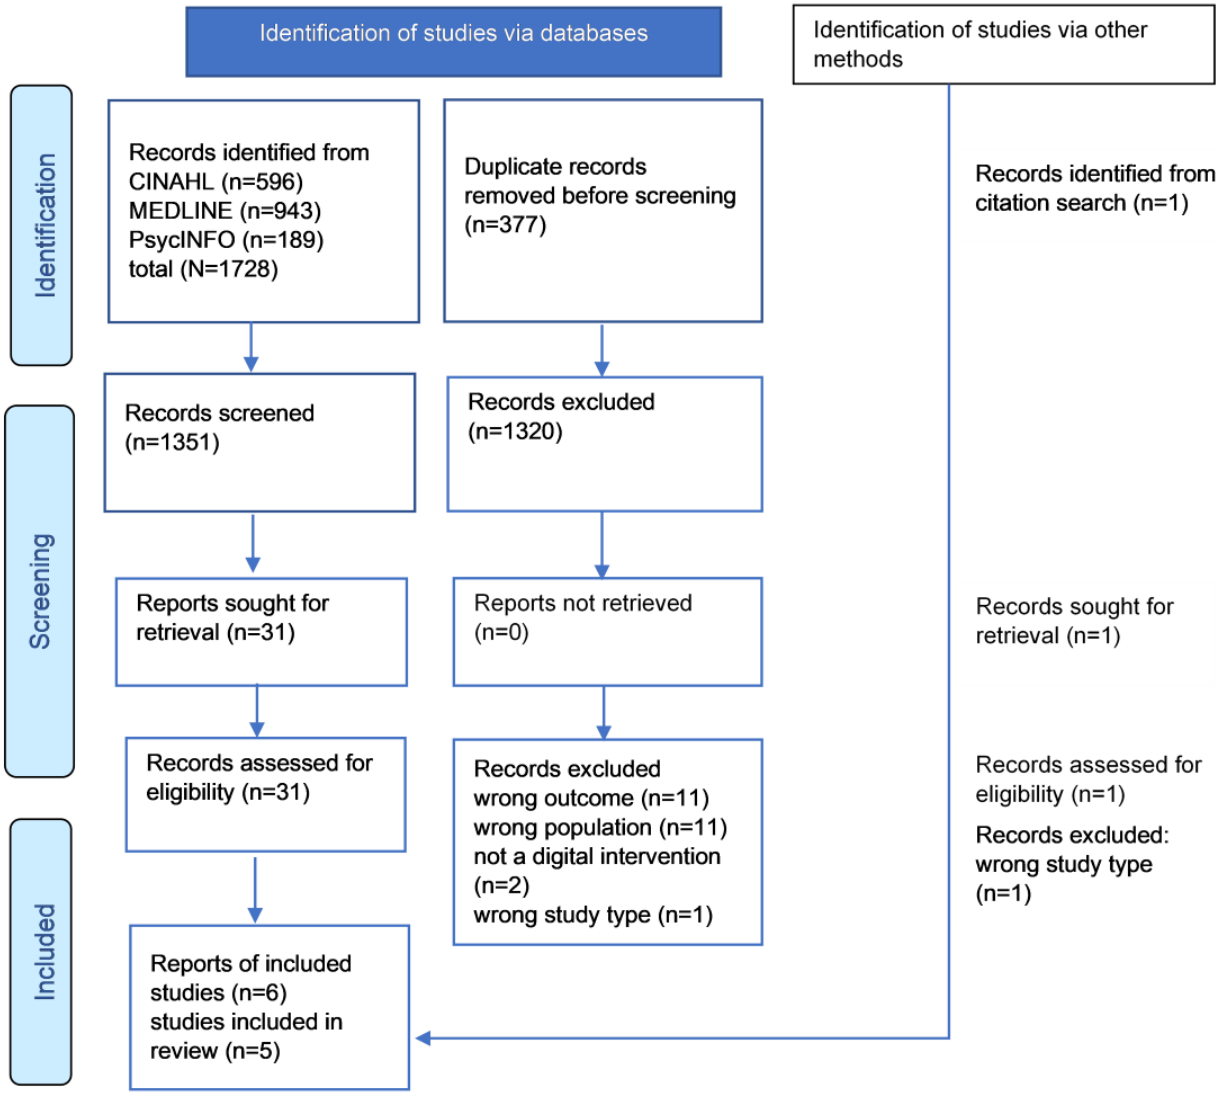
Results

Study Inclusion

In total, 1728 references were identified using the search terms. The addition of secondary searches of reference lists and searches of gray literature resulted in the identification of another reference. The exclusion of duplicates resulted in 1351 references, of which 1320 (97.71%) were excluded after the title and abstract screening. The remaining 31 references were retrieved in full text. Of the 31 papers, 25 (81%) were excluded

(Multimedia Appendix 2 [38-62]), resulting in 6 (19%) papers eligible for inclusion (Figure 1) [63-68].

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of the study selection and inclusion process.



Methodological Quality

A total of 2 authors (EM and SR) independently appraised the 6 articles that met the inclusion criteria for methodological quality. Table 1 summarizes the questions answered in the MMAT, with 1 study excluded as it did not meet the essential screening criteria questions [36,68]. The methods varied across the remaining 5 studies. Of the 5 studies, 2 (40%) studies used mixed methods [63,64] and 3 (60%) studies used a quasi-experimental design (quantitative nonrandomized) [65-67].

Table 1. Assessment of methodological quality with the Mixed Methods Appraisal Tool version 2018 [36].

Screening questions						
Are there clear research questions?	Yes	Yes	Yes	Yes	Yes	Unclear
Do the collected data allow to address the research questions?	Yes	Yes	Yes	Yes	Yes	Unclear
Quantitative descriptive						
Is the sampling strategy relevant to address the research question?	Yes	Yes	N/A[a]	N/A	N/A	N/A
Is the sample representative of the target population?	Yes	Yes	N/A	N/A	N/A	N/A
Are the measurements appropriate?	No	Yes	N/A	N/A	N/A	N/A
Is the risk of nonresponse bias low?	Yes	Yes	N/A	N/A	N/A	N/A
Is the statistical analysis appropriate to answer the research question?	Yes	Yes	N/A	N/A	N/A	N/A
Quantitative nonrandomized						
Are the participants representative of the target population?	N/A	N/A	No	No	Yes	N/A
Are measurements appropriate regarding both the outcome and intervention (or exposure)?	N/A	N/A	Yes	Yes	No	N/A
Are there complete outcome data?	N/A	N/A	Yes	No	Yes	N/A
Are the confounders accounted for in the design and analysis?	N/A	N/A	Yes	Yes	Yes	N/A
During the study period, was the intervention administered (or exposure occurred) as intended?	N/A	N/A	Yes	Yes	Yes	N/A
Quantitative score, n (%)	4 (80)	5 (100)	4 (80)	3 (60)	4 (80)	N/A
Qualitative						
Is the qualitative approach appropriate to answer the research question?	Yes	Yes	N/A	N/A	N/A	N/A
Are the qualitative data collection methods adequate to address the research question?	No	No	N/A	N/A	N/A	N/A
Are the findings adequately derived from the data?	No	No	N/A	N/A	N/A	N/A
Is the interpretation of results sufficiently substantiated by the data?	No	No	N/A	N/A	N/A	N/A
Is there coherence between qualitative data sources, collection, analysis, and interpretation?	No	No	N/A	N/A	N/A	N/A
Qualitative score, n (%)	1 (20)[b]	1 (20)[b]	N/A	N/A	N/A	N/A

[a]N/A: not applicable.

[b]Only the quantitative part was used in the review as the qualitative information provided was minimal.

The quality of the 60% (3/5) quasi-experimental studies was moderate, with a 60% to 80% score [65-67], as was the quality of the quantitative component of the mixed methods studies, which was moderate to good with an 80% to 100% score [63,64]. The quality of the qualitative component of the 40% (2/5) mixed methods studies was poor (20%) and was therefore excluded [63,64].

Although the 5 included studies met the quality criteria, biases were noted. A mixed methods study [63] and a quasi-experimental study [67] used nonvalidated measurement tools. In 67% (2/3) of the quasi-experimental studies, it was unclear if the participants were representative of the population, as a large proportion of participants were White [65] or college-educated [66]. McGarry et al [66] did not provide complete outcome data, with a high rate of participants not

completing the program and not providing a rationale for why they dropped out of the program [66]. None of the 5 studies were randomized or had an independent control group, limiting the ability to quantify the effect of the digital health intervention and limit the confounding factors. Of the 5 studies, 3 (60%) had small sample sizes, with not more than 30 participants in each study receiving the digital health intervention [63,65,66]. Of these 3 studies, 2 (67%) were pilot studies [65,66].

Characteristics of the Studies

Of the 5 studies, 2 (40%) used a descriptive longitudinal design with repeated measures [63,64] and 3 (60%) used a pretest–posttest design [65-67]. Of the 5 studies identified as meeting the selection criteria, 1 (20%) study was implemented in a hospital [63], 2 (40%) in outpatient clinics [64,65], and 2 (40%) in the community [66,67]. Of the 5 studies, 4 (80%) were conducted in the United States [63-66] and 1 (20%) study in Spain [67]. More detailed information about the study characteristics is provided in Multimedia Appendix 3 [63-67].

Description of the Participants

The sample size varied across the 5 studies, with 3 (60%) studies having <30 participants [63,65,66] and 2 (40%) studies with >200 participants [64,67]. Most participants were mothers, ranging from 73% [66] to 100% of the sample in each study [63]. The mean age of participants in each study varied; the lowest mean age was 28.6 years [63], and the highest was 37.5 years [64]. A higher percentage of male children living with health conditions was represented in the studies, ranging from 54.5% [64] to 73% [66] (Multimedia Appendix 3).

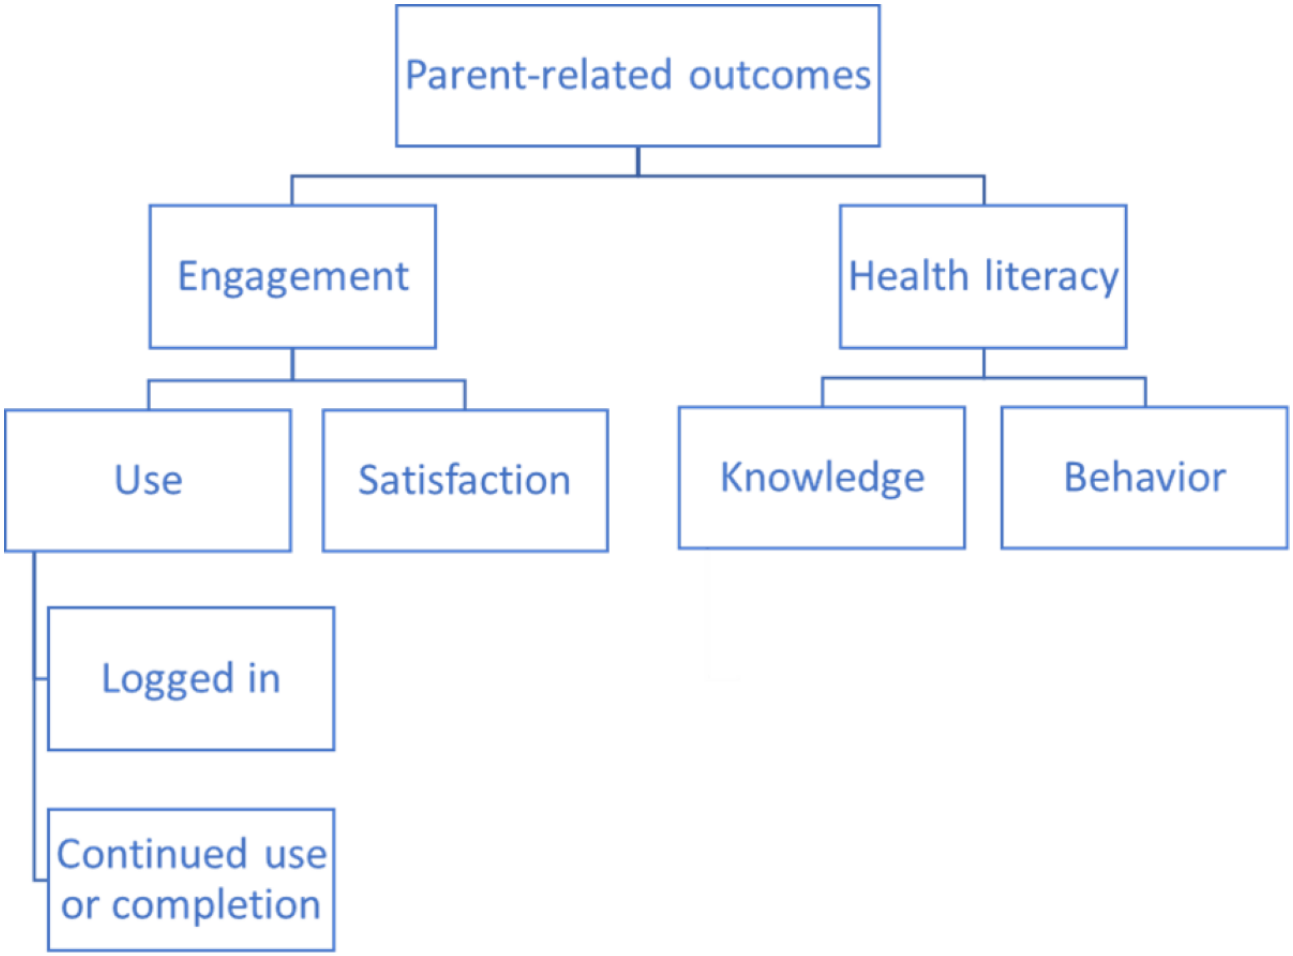
Description of the Interventions

All the 5 digital interventions used web-based portals, with access limited to the participants only (ie, access was not open to the general public). The interventions targeted a variety of health conditions: infants born preterm [63], asthma [64], autism spectrum disorder [65,66], and food allergy [67]. All 5 study interventions included an educational component, with 4 (80%) studies including additional interactive communication components (electronic recording of times and volumes of breastmilk expression, a patient portal to interact with health care providers [64], use of videos, web-based training of parents to promote the child's communication skills [66], and web-based discussion forums [67]; Multimedia Appendix 4 [63-67]).

Parent-Related Outcomes

Parent-related outcomes were extracted as engagement (use and satisfaction) and health literacy (health knowledge and health behavior; Figure 2).

Figure 2. Parent-related outcomes extracted as engagement and health literacy, including subcontent.



Engagement

All studies reported on engagement, although the definitions of engagement and levels of engagement varied across the studies. Additional details are outlined in Multimedia Appendix 4 and further described in the following sections.

Use

Approximately 80% (4/5) of the studies reported the number of parents who were invited to participate [63,64,66,67]. Invitees logging into the website ranged from 2.6% of eligible parents [64] to 100% [66] (Table 2). Most participants (67%-100%) who logged into the website accessed the digital intervention at least once [63-67]. Users who continued to use the intervention or completed the digital health intervention ranged from 37% of parents participating in the Pivotal Response Treatment (PRT) program [66] to 100% in the Lactation Log Plus website [63] and the web-based tutorial, which focused on communication with children with autism spectrum disorder [65] (Table 2).

Table 2. Number and percentage of parents approached to participate, logged into the website, and accessed the digital intervention (use).

Study	Approached to participate, N	Logged into the website, n (%)	Accessed the intervention, n (%)	Continued use or completed the intervention, n (%)
Blatz et al [63]	20	18 (90)	13 (100)	13 (100)
Fiks et al [64]	9133	237 (2.59)	237 (100)	156 (65.8)
Kobak et al [65]	—[a]	23 (—)	23 (100)	23 (100)
McGarry et al [66]	51	30 (59)	30 (100)	11 (37)
Ruiz-Baqués et al [67]	277	207 (74.5)	139 (67.1)	130 (62.8)

[a]Not provided.

Satisfaction

Of the 5 studies, 3 (60%) measured satisfaction with digital health interventions. Tools used to measure satisfaction varied, with high satisfaction identified in all 3 studies [65-67].

Kobak et al [65] used the System Usability Scale to measure satisfaction with the technical parts of the web-based version of the Enhancing Interaction Program. This is a validated 10-item scale ranging from 0 to 100. The mean score in this study was 85 (SD 17), which corresponds to a score of excellent. They also used the User Satisfaction Questionnaire to evaluate the clinical content of the web-based program. This scale ranges from 15 to 60 and has shown good internal consistency. The mean score in this study was 54.5 (SD 5.9). McGarry et al [66] used Social Validity Measures to assess parents' satisfaction with the PRT program. Parents were asked to respond to a variety of statements using a scale from 0 (strongly disagree) to 5 (strongly agree). Over 90% of the parents agreed that the course was well-written and organized. Ruiz-Baqués et al [67] used a 5-item Likert scale to assess satisfaction with the educational program. The scale ranged from 0 (not at all) to 10 (great deal) points. The mean score in this study was 8.78.

Health Literacy

All studies reported on health literacy, either as a change in health knowledge or health behavior. Additional details are outlined in Multimedia Appendix 4 and further described in the following sections.

Health Knowledge

Improvement in parental knowledge was identified in 40% (2/5) of the studies [65,67]. Kobak et al [65] used a questionnaire to measure changes in knowledge before and after a web-based intervention program for autism spectrum disorder and found an increase in the mean number of correct items from 12.6 to 20.4 (P<.001); 79% of parents scored ≥80% after taking the tutorial compared with 8% before taking the tutorial. Ruiz-Baqués et al [67] measured the changes in knowledge before and after a web-based intervention program for food allergy and found an improvement in 15 out of 30 questionnaire items and a significant improvement (P<.001) in 8 items. Improvement was more frequent in the *general knowledge and clinical aspects* domain than in the *daily life with food allergy* domain. No study reported on the time elapsed between the end of the intervention and the knowledge test.

Health Behavior

Of the 5 studies, improvement in behavior was identified in 3 (60%) studies [63,64,66]. Blatz et al [63] found that a website that included breast milk information and a milk diary helped participants pump milk and sustain milk supply. Of the 13 participants, 2 (15%) felt that the milk log website helped to pump milk a great deal, 5 (38%) felt that it somewhat helped, and 6 (46%) felt that the website log did not help them pump breast milk. Furthermore, of the 13 participants, 2 (15%) felt that the milk log website helped maintain milk supply a great deal, 3 (23%) felt that it somewhat helped, and 8 (62%) felt that the website log did not help them maintain it.

Fiks et al [64] found increased medication refills and asthma-related medical visits among parents of children with uncontrolled asthma. Of the 76 children with uncontrolled asthma after the first survey, 20 (67%) had a medication change or refill within 30 days of survey completion, and 21 (28%) had an asthma-related primary care visit within 30 days. The results represent a significant increase in medication changes or refills and asthma-related visits when compared with the same period in the prior year for each child (14% increase in medication changes, 95% CI 2%-27%, and 16% increase in visits, 95% CI 3%-28%).

McGarry et al [66] found that parents who completed the Autism PRT program were successfully able to learn and implement

the strategies. Parents submitted videos of parent-child interactions, which were coded for the fidelity of implementation and social communication behaviors. Parent's treatment fidelity improved from baseline (mean 65.34%, SD 18.04%) to week 5 (mean 90.13%, SD 7.20%; *P*<.001). At baseline, of the 11 parents, 1 (9%) met the fidelity of implementation, with ≥80% fidelity score. By the end of the program, 10 parents met the fidelity of implementation, whereas 1 parent approached fidelity with a 75% fidelity score.

Child Health Outcomes

Of the 5 studies, 1 study (20%) reported on child health outcomes. McGarry et al [66] demonstrated increased communication behavior among children with autism spectrum disorder. There was an improvement from baseline to week 5 in children's vocalization (*P*=.05), eye contact (*P*=.03), and positive affect (*P*<.001).

Discussion

Principal Findings

With only 5 intervention studies identified in this systematic review, it is clear that few digital health interventions have been developed to improve health literacy among parents of children aged 0 to 12 years living with a health condition. Of the 5 studies, 4 (80%) were published in the past 4 years, suggesting that digital health interventions to improve health literacy are an emerging area of research. The use of digital health interventions in clinical practice has also increased because of the COVID-19 pandemic [25].

The 5 studies reported parent-related outcomes, with a focus on engagement with digital health interventions. Despite the low number of studies, digital health interventions to improve health literacy appear acceptable and useful among parents. After parents logged into a website and enrolled in the digital health intervention, >60% of parents demonstrated continued engagement with the program [63-65,67], with 1 exception [66]. The study by McGarry et al [66] had the lowest rate of continued use. The reason could be a rather demanding program where the parents had to submit a video after each web-based lesson, capturing how they used their new information with the child. Submission of a video was a prerequisite for continuing with the intervention. In another study, <3% of the parents who were approached logged into the intervention platform [64]. However, in the same study, approximately 66% of the parents continued to use the portal once logged in [64], implying that parents who initiate engagement are also likely to remain engaged. A systematic review studying the factors affecting engagement and recruitment to digital health interventions suggests that people struggle to make sense of digital health interventions and recommends raising the profile for digital health products to make people more aware of them [69]. It is possible that the current pandemic, which has increased the use of digital health care, has raised the awareness of digital interventions.

Improvement in parental health literacy, including either knowledge [65,67] or behavior change [63,64,66], indicated positive results, which are important when parents are responsible for their children's health care and well-being [1]. However, none of the included studies used a validated instrument developed to measure general health literacy, such as Rapid Estimate of Adult Literacy in Medicine or Test of Functional Health Literacy in Adults [70]. Instead, both Kobak et al [65] and Ruiz-Baqués et al [67] measured specific knowledge targeting autism spectrum disorder and food allergy, respectively. Disease-specific knowledge has proved to be of greater importance in affecting health behavior change than general health literacy [71]. It is also suggested that general health literacy can be a prerequisite for disease-specific knowledge [71]. Health literacy is a complex concept in which knowledge is important and can influence health behavior and child health outcomes [5]. For parents responsible for their children's basic care and specific care related to their health condition, it is essential to have both general health literacy and disease-specific knowledge. However, few studies have evaluated the effect of digital health interventions on either parents' general health literacy or disease-specific knowledge. In times of a pandemic, when access to physical consultations with health care providers has been affected, digital health interventions to increase parents' knowledge and behavior may be of utmost importance for the child's health.

Health literacy increases the parent's capacity to engage in and take responsibility for their child's health care [2], both of which are associated with improved child health outcomes. Only 20% (1/5) of the studies reported on a change in outcomes [66]. McGarry et al [66] reported positive changes in children's communicative behavior at the same time as the parent's treatment fidelity improved significantly. These are promising results showing that increased disease-specific knowledge in parents can positively affect child health outcomes; however, more studies are necessary to prove this hypothesis. Therefore, it is essential to report on potential improvements in the child's health status in future studies to evaluate the impact of increased health literacy in parents.

No randomized controlled studies were included in this review. Of the 5 studies, 2 (40%) were presented as mixed methods studies [63,64]. Unfortunately, the qualitative part of these studies was assessed as having low methodological quality. The only qualitative study included following full-text review was subsequently excluded after critical appraisal [68]. The 3 quantitative studies that evaluated satisfaction reported high satisfaction levels with the digital health intervention [65-67]. However, these studies all used different tools to measure satisfaction, thus limiting the aggregation and synthesis of data. Qualitative studies could help to develop an understanding of why some parents decide to initiate engagement with digital health interventions and what factors contribute to their continued use.

Limitations of the Review

Although this review was systematic, the findings must be interpreted with caution. The number of studies identified was small, homogeneity among the studies was limited, and none of the included studies used a true comparison (ie, control group). Several factors may have influenced the outcome of the digital health interventions, including the implementation methodology, limited responses and participation rates,

encouragement by health care providers, and participants' characteristics. Owing to the small number of included studies and missing data on participants' characteristics, the influence of potential covariates could not be further evaluated. The variation in methodological design, including differences in outcomes and few comparators, limited the authors' ability to conduct a meta-analysis. It should also be considered that only studies published in English were included in this review. Despite these limitations, the favorable results across studies suggest that further evaluations of the benefits of digital health interventions should be undertaken.

Conclusions

This review has shown the potential of digital health interventions to improve health knowledge and health behavior among parents of children aged 0-12 years with a health condition. Of the 5 included studies, 4 (80%) were published in the past 4 years, indicating that digital health interventions aimed at improving health literacy are a developing research area. Future studies should include qualitative studies and studies with randomized samples to more fully understand the potential of digital health interventions to increase parent health literacy.

Abstract

Background: Electronic records could improve quality and efficiency of health care. National and international bodies propagate this belief worldwide. However, the evidence base concerning the effects and advantages of electronic records is questionable. The outcome of health care systems is influenced by many components, making assertions about specific types of interventions difficult. Moreover, electronic records itself constitute a complex intervention offering several functions with possibly positive as well as negative effects on the outcome of health care systems.

Objective: The aim of this review is to summarize empirical studies about the value of electronic medical records (EMRs) for hospital care published between 2010 and spring 2019.

Methods: The authors adopted their method from a series of literature reviews. The literature search was performed on MEDLINE with "Medical Record System, Computerized" as the essential keyword. The selection process comprised 2 phases looking for a consent of both authors. Starting with 1345 references, 23 were finally included in the review. The evaluation combined a scoring of the studies' quality, a description of data sources in case of secondary data analyses, and a qualitative assessment of the publications' conclusions concerning the medical record's impact on quality and efficiency of health care.

Results: The majority of the studies stemmed from the United States (19/23, 83%). Mostly, the studies used publicly available data ("secondary data studies"; 17/23, 74%). A total of 18 studies analyzed the effect of an EMR on the quality of health care (78%), 16 the effect on the efficiency of health care (70%). The primary data studies achieved a mean score of 4.3 (SD 1.37; theoretical maximum 10); the secondary data studies a mean score of 7.1 (SD 1.26; theoretical maximum 9). From the primary data studies, 2 demonstrated a reduction of costs. There was not one study that failed to demonstrate a positive effect on the quality of health care. Overall, 9/16 respective studies showed a reduction of costs (56%); 14/18 studies showed an increase of health care quality (78%); the remaining 4 studies missed explicit information about the proposed positive effect.

Conclusions: This review revealed a clear evidence about the value of EMRs. In addition to an awesome majority of economic advantages, the review also showed improvements in quality of care by all respective studies. The use of secondary data studies has prevailed over primary data studies in the meantime. Future work could focus on specific aspects of electronic records to guide their implementation and operation.

Introduction

This review is an update of 2 previous literature analyses on the benefits and costs of electronic medical records (EMRs), based on articles from 1966 to January 2004 [1] and from 2004 to 2010 [2]. Using the same method, this review explores the progress in evidence from empirical studies. The World Health Organization (WHO) has a clear position concerning the evidence for eHealth in general. Already in 2005, the WHO noted, "the potential impact that advances in information and communication technologies could have on health-care delivery..." [3]. Ten years later, the WHO put this straight by stating several advantages of electronic health records (EHRs) in the report of the third global survey on eHealth, which was produced by the Global Observatory for eHealth [4]:

- EHRs improve the quality, accuracy, and timeliness of patient information at the point of care.
- EHRs provide insights into health care costs, utilization, and outcomes.
- EHRs promote quality of care, reduce costs, support patient mobility, increase reliability of information, and provide access to patient information to multiple health care providers.
- Analyses from EHR data can highlight areas of concern and health services delivery.

The latter is emphasized in the current European digital strategy for data by creating a common European health data space that ensures interoperability of health data and in which every citizen has secure access to his or her EHR [5]. Consequently, many states adopted these visions and implemented national strategies for eHealth in general and for the EHR in particular (see [6] for an overview of Europe or [7] for country profiles from the Global Observatory for eHealth). In the United States, the meaningful use of health care information technology (IT) was fostered by the implementation of EHRs for all citizens until 2014 through the Health Information Technology for Economic and Clinical Health (HITECH) Act [8,9]. HITECH was successful, increasing the hospitals' adoption rate of a basic EHR from 9.4% in 2008 and 15.6% in 2010 to 97% in 2014 [10]. In Germany, the Patient Data Protection Act "obliges the public sickness funds to offer their clients an electronic patient record (EPR) not later than 1 January 2021" [11]. Furthermore, physician practices and hospitals are requested to support and to use the EPR based on the legal basis of an informed consent by the patients. In 2017, half of the German hospitals quoted the existence of an institutional electronic record similar to the situation in Austria [12]. Only the Swiss hospitals reported a higher proportion with 78%, a statistically significant difference to Germany.

EHRs will offer basic values by providing "the right information at the right time in the right place" [13]. This aim is achieved by improving the traditional function of patient records to store information relevant to the care. However, EHRs should additionally guide the process of clinical problem solving and should support clinical decision making [14]. In 1991, the Institute of Medicine (IOM) listed 4 ways to positively influence quality of care [14]: (1) improving quality of and access to clinical data, (2) integrating information over time and settings, (3) making knowledge available, and (4) providing decision support. Looking at costs, the IOM expected positive effects in 3 ways: (1) reducing unnecessary tests and services, (2) reducing administrative costs, and (3) increasing the productivity of health care professionals.

One might argue that a further discussion about the proposed value of an EMR is needless because of its nearly complete implementation. Nobody will vote for a fallback to paper. However, the implementation does not guarantee a positive perception by the users. In a recent survey including 208 physicians from 3 Norway hospitals [15], 72% of the physicians reported interrupted or delayed work at least once a week because the EHR hangs or crashes, and 53% of the physicians indicated that the EHR is cumbersome to use and adds to their workload. These results demonstrate a reasonable room for improvements, besides noncontroversial advantages that were reported in the study from Norway. Even if up-to-date health care cannot be imagined without an EMR, an ongoing evaluation of its advantages and disadvantages is a prerequisite for a well-considered further development and adjustment. In our sequence of literature reviews, we put the ultimate goals of health care in the middle, to provide a high level of care for reasonable costs in terms of effectiveness and efficiency [16]. Furthermore, the series of reviews allows a monitoring of the EMR's value over time by preserving the criteria for the selection and the appraisal of the included studies. The research questions were twofold. What is the effect of EMRs on the quality of inpatient care? What is the effect of EMRs on the costs for inpatient care?

Methods

Terminology of Electronic Records in Health Care

Concepts and terms denoting electronic records in health care are still not unambiguously defined [17]. Differences and similarities of "electronic medical records," "electronic patient records," and "electronic health records" are a matter of a long-lasting debate. In our reviews, we focused on electronic records used by health professionals and administrative staff for inpatient care, including, for example, physicians, nurses, radiologists, pharmacists, laboratory technicians, and radiographers [17]. Those records must not necessarily follow a patient lifelong. Therefore, we adopted the definition of an EMR by Waegemann [18]: an EMR is a "computer-stored collection of health information about a person, linked by a person identifier", with the application environment being a

hospital and including any care delivery being the full responsibility of the health care provider.

Search Strategy

The literature search was performed between March 10, 2019, and April 2, 2019, using MEDLINE. MEDLINE was accessed via PubMed [19]. The keyword "Medical Records Systems, Computerized" from the MeSH was separately combined with the MESH terms "technology assessment, biomedical", "costs and cost analysis", "health care costs", "cost savings", "cost effectiveness", "cost benefit", "cost analysis", "benefits and costs", "quality of health care", "outcome study", "outcome assessment, patient", and "critical care outcomes". Additionally, January 1, 2010, was defined as the earliest date of publication. After an exclusion of duplicates, interactive tutorials and reviews, and a restriction to the languages German and English, 1345 references remained.

Study Selection

Using titles and abstracts, both authors independently reviewed the 1345 literature references regarding the existence of an EMR, the application of an EMR in inpatient care, and an empirical analysis of benefits or costs. Explicitly excluded were studies in physician offices or about ambulatory care provided by hospitals, studies about picture archiving and communication systems, and studies about systems for computerized physician order entry (CPOE). The rating comprised the categories accept, refuse, and unclear. References rated as accept/accept and accept/unclear were qualified, references rated as refuse/refuse and refuse/unclear were rejected. References rated as accept/refuse or unclear/unclear were discussed and a final decision was reached based on a consensus. Herewith, 84 publications were qualified for the further evaluation (6.25%). From these, full texts of 79 papers could be obtained; for 5 papers, this was not possible. Textbox 1 shows the inclusion and exclusion criteria of both stages.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Acute care hospital
- Inpatient care
- Electronic medical record
- Empirical result
- Statement about costs
- Statement about benefits

Exclusion criteria

- Physician office
- Ambulatory care
- Picture archiving and communication system
- System for computerized physician order entry

Both authors again carried out the evaluation of the remaining 79 publications independently. This time, the evaluation was based on the full texts of the references. Both authors looked at concrete statements on benefits and costs, and gave a final recommendation about the inclusion into the review. References were finally included if they reached 2 or 3 positive votes from both authors (16/79 references, 20%). References were finally excluded if neither authors gave at least two positive votes (43/79 references, 54%). The remaining 20 references were discussed to reach a consensus about their inclusion for the review (25% from 79 references). Overall, the selection process produced 23 relevant studies that ultimately formed the subject of the detailed analysis, being 1.71% from the initially identified references (N=1345; Figure 1).

Interrater reliability during study selection was verified by calculating Cohen κ. In the first evaluation level based on titles and abstracts, the κ value was 0.185, indicating a slight agreement between the reviewers according to the interpretation of Landis and Koch [20] (Table 1). In the second evaluation level of full texts, the κ value was 0.428, indicating a moderate agreement. The interrater reliability was comparable to the previous reviews.

Figure 1. Selection and review process.

Table 1. Interpretation of κ values [20].

κ value	Level of agreement
<0.00	Poor
0.00-0.20	Slight
0.21-0.40	Fair
0.41-0.60	Moderate
0.61-0.80	Substantial
0.81-1.00	Almost perfect

Study Evaluation

For a semiquantitative evaluation of the studies, a catalog of criteria was drawn up focusing on the study design, the formal quality of the publication, the number of users included, the study duration, and the use of statistical tests. Each aspect of a study was rated 2, 1, or 0 points, with 2 being the best score for a study. Missing information was rated 0 points. The maximum number of points that could be achieved was therefore 10. In addition, the studies were described with regard to their origin, their application scenarios, and their target values. The approach proposed by Johnston et al [21] was adopted as basis for the evaluation method. The definition of the criteria was partly different between studies collecting primary data and studies analyzing existing, secondary data. The definition was carried out as described below.

Study Design

The assessment of the study design was based on the classification depicted in Table 2, according to Roine et al [22]. Different types of studies were ranked from 1 to 9 concerning the evidence hierarchy. The first stage, meta-analyses from randomized, controlled studies, was not a component of the inclusion criteria. The remaining study types were combined into the following 3 groups: randomized controlled studies (evidence stages 2 and 3); nonrandomized controlled studies (evidence stages 4, 5, 6, and 7); and uncontrolled clinical series, descriptive studies, consensus methods, application observations, and empirical reports (evidence stages 8 and 9). Studies in the first group received 2 points, studies in the second group 1 point, and the remaining studies 0 points. According to the proposal of Nathan and Gorman [23], all secondary data analyses were assigned to evidence stage 7 of Table 2 and were uniformly assigned 1 point. Therefore, the maximum number of points was reduced to 9 for those studies.

Table 2. Classification of study designs [22].

Evidence stage	Study design
1	Meta-analyses of randomized controlled trials
2	Large-sample randomized controlled trials
3	Small-sample randomized controlled trials
4	Nonrandomized controlled prospective studies
5	Nonrandomized controlled retrospective trials
6	Cohort studies
7	Case–control studies
8	Noncontrolled clinical series, descriptive studies, consensus methods
9	Anecdotes or case reports

Formal Quality of Publication

The publication should follow the international standard structure of scientific articles, that is, authors' names and affiliations on the title page, abstract, introduction, material and methods, results, discussion, conclusions, and references. For a publication in full compliance with this structure, 2 points were assigned; if the article provided a separate introduction and an explicit naming of authors and the medical environment, 1 point was assigned; otherwise, 0 points were given.

Number of Users

The number of EMR users can affect the reliability and the generalizability of the results. Therefore, 2 points were given for studies based on primary data with 20 or more users, 1 point for 6-19 users, and 0 points for less than 6 users or if no number of users was specified. For studies analyzing secondary data, the number of hospitals included was scored as follows: 2 points for a hospital number of 2000 and above; 1 point for a hospital number of 500 to 1999; and no points for a hospital number of 0-499 or missing information.

Implementation Duration

Primary data studies implemented for at least one year received 2 points, 1 point was given for a half to less than 1 year, and 0 points for less than a half year. For the secondary data studies, the evaluation periods were scored as follows: 2 points were awarded to a study for an evaluation period of 3 years or longer, 1 point for a period of 1 or 2 years, and no points for an implementation period of less than 1 year or in case of missing information.

Statistical Evaluation

Assessment and evaluation of scientific statements gain in evidential power with inferential statistical statements. Two points were given for studies reporting the result(s) of statistical analyses with full information concerning the level of significance, and 1 point for the description of a statistical test performed without indication of the level of significance. Otherwise, 0 point was given.

Results

Origins and Locations of the Studies

The 23 studies selected for the main evaluation [24-46] consisted of 6 primary and 17 secondary data studies (Table 3). Three (7, 18, and 23) of the 6 primary data studies were conducted in the United States (Wisconsin, North Carolina, and Massachusetts), 1 study each was conducted in China (21), Germany (3), and Japan (17). Sixteen secondary data studies originated from the United States, 1 from the Netherlands.

In the secondary data studies, 15 different data sources were used to analyze the issues of treatment quality, costs, and EMR equipment (Table 4). The most frequently used data sources stemmed from the American Hospital Association (AHA; 19 studies), the Healthcare Information and Management Systems Society (HIMSS; 11 studies), and the Centers for Medicare & Medicaid Services (CMS; 9 studies). They were followed by the Hospital Quality Alliance database (HQA), the National Database of Nursing Quality Indicators (NDNQI), and the Office of Statewide Health Planning and Development (OSHPD). The remaining sources were used only in 1 study.

Table 3. Characteristics of the included studies.

Study number	Reference	Country	Sample size	Period	Main outcomes
1	Adler-Milstein et al [24]	United States	191 hospitals	2 years	EHR[a] adoption is associated with better performance in terms of payment and length of stay in well-run institutions. EHR adoption may be associated with worse performance in poorly run institutions.
2	Adler-Milstein et al [25]	United States	2591 hospitals (2011)	4 years	Degree of EHR adoption is positively correlated with process adherence, patient satisfaction, and efficiency.
3	Castellanos et al [26]	Germany	Not indicated	6 years	Small increase in profit in the year after the introduction of the patient data management system.
4	DesRoches et al [27]	United States	3049 hospitals	6 months	Presence of clinical decision support is associated with small quality gains. No relationship between EHR level and overall risk-adjusted length of stay, risk-adjusted 30-day readmission rates, and risk-adjusted inpatient costs.
5	Elnahal et al [28]	United States	3101 hospitals	9 months	Higher rates of adoption of key EHR functions among high-quality hospitals.
6	Encinosa and Bae [29]	United States	2619 hospitals	1 year	EMRs[b] do not reduce the rate of patient safety events. In case of patient safety events, EMRs reduce deaths, readmissions, and spending.
7	Feblowitz et al [30]	United States	Not indicated	2 years	Length of stay increased after implementation of an electronic documentation. Mean time to disposition for admitted patients remained stable.
8	Furukawa et al [31]	United States	5066 hospitals	10 years	Advanced EMR applications may increase hospital costs and nurse staffing levels, as well as increase complications and decrease mortality for some conditions.
9	Furukawa et al [32]	United States	509 hospitals	5 years	Nurse-sensitive patient outcomes improved. EMR implementation may be associated with reduced demand for nurses.
10	Himmelstein et al [33]	United States	4000 hospitals	6 years	Hospital computerization has not achieved savings on clinical or administrative costs. More computerized hospitals might have a slight quality advantage for some conditions.
11	Jarvis et al [34]	United States	2988 hospitals	1 year	Most advanced EHRs have the greatest payoff in improving clinical process of care scores.
12	Jones et al [35]	United States	6057 hospitals	4 years	Availability of basic EHR is associated with a significant increase in health care quality for heart failure.
13	Joynt et al [36]	United States	1236 hospitals	4 years	Patients with stroke are more likely to receive guideline-driven components of care at hospitals with EHRs. Patients are slightly less likely to have a hospital stay longer than 4 days at hospitals with EHRs.
14	Kazley et al [37]	United States	1000 hospitals	1 year	In hospitals with advanced EHRs, patient costs are less compared with hospitals without advanced EHRs.
15	Lee et al [38]	United States	708 hospitals	8 years	Hospitals adopting EMRs experience shorter length of stay and lower 30-day mortality.
16	McCullough et al [39]	United States	3401 hospitals	4 years	Use of EHRs results in improvements in process-of-care measures for patients with heart failure or pneumonia.
17	Nakagawa et al [40]	Japan	Not indicated	7 years	EMR may decrease medical risks, but profitability does not rise more than the investments.

Study number	Reference	Country	Sample size	Period	Main outcomes
18	Schenarts et al [41]	United States	Not indicated	40 months	Implementation of the EMR is associated with an improvement in several complications and process measures.
19	Teufel et al [42]	United States	2307 hospitals	1 year	Advanced-stage EMR is associated with greater costs per case.
20	van Poelgeest et al [43]	Netherlands	67 hospitals	1 year	No statistically significant association between a hospital's EMR adoption and an overall quality or safety performance.
21	Xue et al [44]	China	251 physicians and 298,760 patient visits	5 years	Length of stay declines and mortality rate decreases with EMR. An EMR has no positive effect on patient costs.
22	Yanamadala et al [45]	United States	448,767 patients	1 year	Patients at hospitals with full EHR have the lowest rates of inpatient mortality, readmissions, and patient safety indicators.
23	Zlabek et al [46]	United States	Not indicated	Not indicated	Implementation of an inpatient EHR results in a rapid improvement in measures of cost of care.

Methodical Quality

The results of the semiqualitative assessment are presented in Table 5 and Multimedia Appendix 1. In the evaluation of the primary data studies, 2 (18 and 21) publications achieved a score of 6 points, 3 (3, 7, and 17) scored 4, and 1 (23) achieved only 2 points. No primary data study scored 0, 1, 3, 5, and 7-10 points. While in the secondary data studies 2 papers (2 and 10) achieved the maximal score of 9 points, another 4 (9, 13, 15, and 16) scored 8, 7 (4-6, 8, 11, 12, and 19) scored 7, 2 (1 and 14) scored 6, 1 (22) scored 5, and 1 (20) scored 4. No secondary data study scored 0-3 and 10 points. A total of 18 of the 23

studies scored 5 and more points (78%), while 5 remained below this score (22%). Only 2/6 (33%) primary data studies achieved 5 points or more. By contrast, 16/17 (94%) secondary data studies achieved a score of 5 points or more.

Two (1 and 19) of the primary data studies were randomized controlled trials; one (4) was a nonrandomized controlled trial; the remaining 3 belonged to a lower evidence stage. By definition, the 17 secondary studies were all assigned to evidence level 7. Fifteen (1-6, 9-11, 13-16, 19, and 20) studies followed the internationally accepted structure of scientific articles. The remaining 8 studies (7, 8, 12, 17, 18, and 21-23) lacked any formal structure.

Three (17, 18, and 21) of the 6 primary data studies had a user population of at least 20 or more. The remaining three (3, 7, and 23) did not provide any information. Five (3, 7, 17, 18, and 21) primary data studies had an implementation period of at least one year, 1 (23) less than 6 months. Eleven (2, 4-6, 8, 10-12, 16, 19, and 22) of the 17 secondary studies included at least 2000 hospitals, 4 (9, 13-15) 500 to less than 2000 hospitals, and 2 (1 and 20) less than 500 hospitals. Eight (2, 8-10, 12, 13, 15, and 16) of the secondary data studies analyzed data from at least three years, 1 (1) from 1 or 2 years, and 8 (4-6, 11, 14, 19, 20 and 22) from less than 1 year.

Nineteen (1, 2, 4-15, 18, 19, and 21-23) of the 23 studies supported the value of their results by statistical tests with full information on the level of significance. Two (16 and 20) studies stated that they had performed statistical tests but did not name them, and 2 (3 and 17) studies did not provide any information on them.

Main Subjects

A total of 5 out of the 23 studies (3, 14, 17, 19, and 23) dealt solely with economic aspects of the use of an EMR, 7 (5, 11, 12, 16, 18, 20, and 22) dealt solely with the effects on the quality of care, and 11 studies (1, 2, 4, 6-10, 13, 15, and 21) dealt with both aspects (Tables 3 and 4). Primary data studies and secondary data studies were found in all groups. While 9 (39%) of the 23 studies (1-3, 6, 9, 13-15, and 23) showed an economically positive impact, 7 (30%) (4, 7, 8, 10, 17, 19, and 21) did not reveal monetary advantages due to the use of the EMR. Eighteen studies (1, 2, 4-13, 15, 16, 18, 20-22) looked at the impact of the use of an EMR on the quality of care. All of them (18/23 studies, 78%) found a positive effect. However, 4 (4, 7, 10, and 20) did not provide specific information about it. No study indicated evidence of disadvantages in the quality of treatment from the use of an EMR. Primary data studies and secondary data studies showed similar results.

One of the striking studies, Zlabek et al [46] looked at the effects of an EMR system on selected measures of cost of care and patient safety. They demonstrated the following outcomes (means and % change):

- Laboratory tests per week per hospitalization decreased from 13.9 to 11.4 (18).
- Radiology examinations per hospitalization decreased from 2.06 to 1.93 (6.3).
- Monthly transcription costs declined from US $74,596 to US $18,938 (74.6).
- Numbers of copy paper ordered per month decreased from 1668 to 1224 (26.6).
- Medication errors per 1000 hospital days decreased from 17.9 to 15.4 (14.0), while near misses per 1000 hospital days increased from 9.0 to 12.5 (38.9), and the percentage of medication events that were medication errors decreased from 66.5% to 55.2%.

In a national study about hospital computing and the costs and quality of care, Himmelstein et al [33] analyzed whether highly computerized hospitals had lower costs of care or administration, or better quality. They acquired the following outcomes in their work:

- Higher overall computerization scores correlated weakly with better quality scores for acute myocardial infarction, but not for heart failure, pneumonia, or the 3 conditions combined. In multivariate analyses, more computerized hospitals had a slightly better quality.
- Hospitals on the “Most Wired” list performed not better than others on quality, costs, or administrative costs.
- Hospitals’ administrative costs increased slightly but steadily, from 24.4% in 2003 to 24.9% in 2007. Higher administrative costs weakly predicted higher total Medicare spending, inpatient spending, and outpatient spending.

According to the study performed by Encinosa and Bae [29], many reforms in the Patient Protection and Affordable Care Act (ACA) underlie the use of EMRs to help contain costs. In this regard, the authors found that EMRs do not reduce the rate of patient safety events. However, once an event occurs, EMRs reduce death by 34%, readmissions by 39%, and spending by US $4850 (16%), a cost offset of US $1.75 per US $1 spent on IT capital. Thus, the authors concluded that EMRs contain costs by better coordinating care, a coordination that rescues patients from medical errors once they occur.

The study by Castellanos et al [26] analyzed cost and reimbursement data from a 25-bed intensive care unit at a German university hospital in a retrospective analysis, 3 years before and 3 years after the implementation of a patient data management system (PDMS). Costs and revenues increased continuously over the years. The profit of the investigated intensive care unit was fluctuating over the years and seemingly depending on other factors as well. They found a small increase in profit in the year after the introduction of the PDMS, but not in the following years. Therefore, a clear evidence for cost savings after the introduction of PDMS was not seen.

Discussion

Principal Findings

This review is an update of 2 previous analyses on the benefits and costs of EMRs, based on articles from 1966 to January 2004 [1] and 2004 to 2010 [2]. Using the same method, this review explored the progress in evidence from empirical studies. With a total of 19 of the 23 publications selected for evaluation (83%), studies from the United States dominated. Of the remaining 4 studies, 2 were conducted in Europe. Asia was represented by 1 Chinese and Japanese study each. South America, Africa, and Australia were not represented at all. Results of our reviews over the 3 periods showed a number of significant developments (Table 6). For example, the total number of initial hits had almost doubled. While the number of studies relevant to the evaluation remained more or less the same for the first and the current review, the second review produced almost one-third fewer studies. Remarkable in the current review was the predominant use of secondary data studies compared with primary data studies. In this context, highlighting the differences between primary and secondary studies should help to better assess the conclusions drawn from the results. While the primary data studies collected new and yet unexplored data, the secondary data studies used statistical processing of already existing data. In general, secondary data studies do not reach the evidence level of meta-analyses comprising also already existing but initially primary data. The most important advantage of primary data studies is that data can be collected and statistically evaluated in a targeted and problem-oriented manner. Their disadvantage is that specific surveys of patient data are often time-consuming and expensive compared with secondary data studies. Furthermore, in case of complex interventions, as it is the case for EMRs, primary data studies are often not feasible [47]. The advantage of secondary data studies is that comparatively few resources are required to prepare them. Their disadvantage is that the data were not collected specifically to answer the research questions as part of a specifically designed study design.

The annual number of studies on EMRs showed a continuous increase over our 3 review periods (Table 6). The same was true for the annual number of finally included studies. The methodological quality of the studies changed as well. While

only 35% of the studies scored more than 5 points in the first review (7/20), 74% of the studies scored more than 5 points in the third review (17/23). Among the finally included studies in the first review, costs were analyzed in 100% of the publications (20/20), with only 20% also focusing on quality of care (4/20). In the second review, both aspects were analyzed in 71% of the publications (5/7). In this review, costs were analyzed in 70% of the publications (16/23), quality of care in 78% (18/23).

The comparison of the 3 periods revealed a twofold shift. On the one hand, the studies' focus switched from an economical one to a clinical one. The percentage of studies concerned solely with costs decreased from 80% (16/20, 1966-2004) to 14% (1/7, 2002-2010) and 22% (5/23, 2010-2019). On the other hand, the positive effects of EMRs on quality of care became apparent over time. In the first review, none of the 4 studies concerned with quality of care presented well-defined advantages. In this review, this was the case in 14 of 18 studies analyzing the effects of EMRs on quality of care. The reasons for this shift remain speculative. The focus of EMRs might have changed from an administrative one to a patient-oriented one. Technological progress could have helped to achieve the clinical benefits that were an important motivator for the introduction of EMRs even in the early years [48]. In 1997, it was reported that costs remained a significant barrier for EHRs [49]. Now, experiences concerning the introduction, implementation, and an accompanying change management might have better prepared hospitals for the harvesting of clinical benefits and simultaneously for the limiting of additional costs.

Table 6. Number of studies considered for the reviews.

Review	Years, n	Hits without duplicates, n	Hits per year, mean	First selection, n	Finally included studies, n	Finally included studies per year, mean
First (1966-2004)	38	588	15.5	117	20	0.5
Second (2004-2010)	6	578	96.3	64	7	1.2
This (2010-2019)	9	1345	149.4	84	23	2.6

Limitations

The reliability between the 2 authors in selecting the papers was slight in the first phase (κ=0.185) and moderate in the second phase (κ=0.428). Both results were nearly equal compared with the 2 previous reviews, first phase 0.26 (review 1) and 0.192 (review 2), second phase 0.36 (review 1) and 0.399 (review 2). Unfortunately, measures of interrater reliability are usually not presented in systematic reviews. We assume that our results are not inferior in comparison to comparable reviews. The agreement was high in excluding references that do not fulfill the inclusion criteria. Differences occur in the detection of appropriate studies. To avoid the exclusion of false negatives, contrary votes and unclear votes were dissolved in a consensus. However, the extraction of the papers' main conclusions was a complex process. Misunderstandings and errors in this process cannot be completely ruled out. For example, authors' conclusions summarized in a paper's abstract could differ from individual results found in the paper's main text. The results of univariate and multivariate analyses may not agree and positive effects in one medical condition could be absent in another condition. Therefore, the review's rating is a pragmatical compromise to reach a meaningful conclusion.

The authors kept the EMR as type of intervention for all 3 reviews and attached great importance to an unaltered approach. This allowed the comparison of results over the whole series of reviews. The decision to maintain the focus on the EMR might be questioned because the literature addresses many different levels of IT used in hospitals. The results are therefore neither tailorable to more detailed types of IT providing only selective functionalities as CPOE nor generalizable to lifelong EPRs or to health information and communication technology overall. Nevertheless, through the clear and persistent focus, the authors gained reliable and valid conclusions beyond transitory trends and fashions.

Furthermore, the series maintained the same set of keywords. The authors could not rule out that newer functionalities of EMRs are not appropriately covered by this set. However, even then, the striking results supporting an indisputable positive effect of EMRs would be an underestimation of the actual situation. It is unlikely that newer functionalities decline the effects of EMRs on quality of care.

The detected studies represent primarily the perspectives of the United States and developed countries. Developed countries have the economic power to implement EMRs and to realize respective evaluation studies. This will not be the case for developing countries. However, the perspective for developing countries is similar. For example, Odekunle et al [50] reported for Sub-Saharan Africa the same vision as it was uncovered in our review. EHRs will improve quality of care in Sub-Saharan Africa, but high costs of procurement and maintenance of the EHR system hindered their widespread adoption until now.

Comparison With Prior Work

In 1963 the then American President, John F. Kennedy, was pointed to the potential of health record systems: "The application of computer technology to the recording, storage, and analysis of data collected in the course of observing and treating large numbers of ill people promises to advance our understanding of the cause, course, and control of disease" [51]. Forty-five years later, another American President (in 2009) proposed a fundamental change to the use of IT in the national health care system by passing the HITECH Act [52]. Besides other regulations, each person in the United States should have an EHR by 2014 [53]. With the idea of a meaningful use, health care providers and hospitals should be rewarded for using an EHR under the Medicare and Medicaid schedule. The time gap between expectations and routine application makes it clear that the proposed advantages were neither easy to demonstrate nor easy to achieve [54]. Even a proposal in 1991 for a nationwide

implementation of electronic records in the next decade failed [14]. Whether an evaluation of a technology in one country could be transferred to another one remains questionable, considering different health care systems and different strategies implemented with regard to the digitization of health care [55].

Our result of the positive impact of EMRs on the quality of care is supported by a systematic review by Campanella et al [56]. Their meta-analysis of 47 studies revealed a reduction of documentation time, a higher guideline adherence, and a lower number of medication errors and adverse drug events in the intervention group using an EHR. However, no association with mortality was found. Different to our review, the authors included studies on CPOE and did not focus on a specific area. The effect on mortality might be too small to be statistically significant even in a meta-analysis. Therefore, the inclusion of secondary data studies in our review series was reasonable. Thompson et al [57] also did not find a positive impact of EMRs on mortality. Besides, they did not find a positive impact on length of stay and costs. Their results were similar for record systems, CPOE, clinical decision support systems (CDSSs), and surveillance systems. In contrast to our results, Thompson et al [57] concluded that there "is not enough evidence to confidently state that electronic interventions have the ability to achieve the goal of improving quality and safety". Moja et al [58] also did not find effects of CDSSs on mortality in their meta-analysis based on 16 randomized controlled trials [58]. The authors stated, "most of the studies were underpowered and too short to prove or exclude an effect on mortality, and effects as large as a 25% increase or reduction could still be possible." In this day and age, where digitization is anywhere, it could become difficult to fill this gap with randomized controlled trials about EMRs using an appropriate control group. Besides secondary data analyses, ecological analysis might be worthwhile, even though the risk of an ecological fallacy exists [59]. With regard to CPOE as another subfunctionality of an EMR, Page et al [60] analyzed the evidence concerning a positive impact of quality of care. Defining a period overlapping with our study, 2000-2016, they included 23 studies with a control group. About half of the studies reported beneficial effects. However, the authors did not clearly distinguish between the effects of medication prescribing alerts as intervention and CPOE systems as infrastructure.

In summary, the impact of EMR subfunctionalities remains unclear in the literature. At a level beyond electronic records, the impact of health information exchange (HIE) as "the electronic transfer of patient data and health information between health care providers" is discussed [61]. Having EMRs as the condition, the exchange of data via HIE might bring the breakthrough in terms of quality of care and cost reduction. In their recent review, Sadoughi et al [62] considered 32 studies published between 2005 and 2016 that analyzed the financial or clinical impact of HIE. In that review, studies on EMRs were explicitly excluded. The majority of the studies were conducted in the United States (28/32), which is similar to our results. Furthermore, 19 studies were labeled as cohort studies, supporting our observation of a rather small number of controlled trials. Nearly all studies analyzing an improvement of quality showed a positive impact (16/17, 94%); 15/19 (79%) respective studies showed a positive effect on cost-effectiveness. With a similar span, these results from Sadoughi et al [62] match our review, with 78% of studies demonstrating an increase in quality of care and 56% demonstrating a reduction of costs. Contrary to a review including studies between 2003 and 2014 [63], Sadoughi et al [62] revealed a considerable progress in the use of HIE.

However, the advantages of EMRs have to be balanced with risks that are linked to IT not necessarily considered in evaluation studies. The relationship between the level of digitization and effects on quality and costs of care must not be linear. Higher levels of digitization might be correlated with higher risks that could lead to a reversion of the effect, as indicated by a study about the HITECH Act [64]. Therefore, it might be worthwhile to focus on the appropriate level of health IT instead of looking for global effects. Furthermore, the type of technology might not make the difference but rather the usability of the technology. For example, Roman et al [65] analyzed navigation-related issues in the field of EHRs. A lack in usability could induce risks for health care that lower the provided level of care. Finally, one should not forget that software, hardware, or electrical power supply can fail or can be a target for criminal attacks [66]. An overall perspective on the value of EMRs must therefore include a broader definition of assets and drawbacks.

Conclusions

Our literature review revealed a clear evidence about the value of EMRs. Only some primary data studies failed to demonstrate a reduction of costs after the implementation of an EMR. Quality of care improved in all respective studies. In comparison with our first review covering the period between 1996 and 2004, the picture changed completely. At that point, only 4 of 20 studies published benefits for the quality of care and 19 reported a reduction of costs. In parallel with the appearance of the first secondary data studies, the proportions turned around in the second review from 2004 to 2010. Interestingly, the positive effects on costs could not be completely confirmed by primary data studies now. To promote an extended use of EMRs, there must be a financial refund of additional costs, given the current scientific evidence. The switch from interventional studies to observational studies using publicly available data might have induced a bias in confirming everyday perceptions about electronic records in health care. Broader and better designed studies are needed to establish better scientific evidence regarding benefits of EMRs in hospital care. Nevertheless, further studies could focus on specific aspects of electronic records to guide their implementation and operation.

Abstract

Background: Patient and public involvement (PPI) in research aims to increase the quality and relevance of research by incorporating the perspective of those ultimately affected by the research. Despite these potential benefits, PPI is rarely included in epidemiology protocols.

Objective: The aim of this study is to provide an overview of methods used for PPI and offer practical recommendations for its efficient implementation in epidemiological research.

Methods: We conducted a review on PPI methods. We mirrored it with a patient advocate's viewpoint about PPI. We then identified key steps to optimize PPI in epidemiological research based on our review and the viewpoint of the patient advocate, taking into account the identification of barriers to, and facilitators of, PPI. From these, we provided practical recommendations to launch a patient-centered cohort study. We used the implementation of a new digital cohort study as an exemplary use case.

Results: We analyzed data from 97 studies, of which 58 (60%) were performed in the United Kingdom. The most common methods were workshops (47/97, 48%); surveys (33/97, 34%); meetings, events, or conferences (28/97, 29%); focus groups (25/97, 26%); interviews (23/97, 24%); consensus techniques (8/97, 8%); James Lind Alliance consensus technique (7/97, 7%); social media analysis (6/97, 6%); and experience-based co-design (3/97, 3%). The viewpoint of a patient advocate showed a strong interest in participating in research. The most usual PPI modalities were research ideas (60/97, 62%), co-design (42/97, 43%), defining priorities (31/97, 32%), and participation in data analysis (25/97, 26%). We identified 9 general recommendations and 32 key PPI-related steps that can serve as guidelines to increase the relevance of epidemiological studies.

Conclusions: PPI is a project within a project that contributes to improving knowledge and increasing the relevance of research. PPI methods are mainly used for idea generation. On the basis of our review and case study, we recommend that PPI be included

at an early stage and throughout the research cycle and that methods be combined for generation of new ideas. For e-cohorts, the use of digital tools is essential to scale up PPI. We encourage investigators to rely on our practical recommendations to extend PPI in future epidemiological studies.

Introduction

Background

Patient and public involvement (PPI) in research is defined as "research being carried out 'with' or 'by' members of the public rather than 'to,' 'about,' or 'for' them" [1]. PPI means that patients or the public are actively involved in the research process rather than being included only as participants. Public engagement is the 2-way process of engagement activities that benefits both the researcher and the public [2].

Research that involves patients and the public can reduce the mismatch between what matters to patients and what is actually being done in the research [3]. A waste of research resources can be generated when the needs of those likely to use the research results, such as patients and caregivers, are not taken into account [4]. PPI can contribute to the identification and selection of high-priority research questions, planning and performing of more focused research, and improvement of participants' enrollment in clinical trials [5]. Ultimately, this can result in a higher societal benefit through better use of resources for research. PPI improves the quality of the study and makes research more relevant [6].

Involve, a UK-funded program, aims to improve the quality of research through the integration of PPI throughout the research cycle (identification and prioritization, commissioning, design and management, implementation, dissemination, implementation, and evaluation). Involve has published a report with guidelines to help researchers start new projects when they intend to include PPI in their projects [7].

Digital epidemiology has the same objectives as epidemiology, which are the observation of disease patterns, their evolution, and the causes of these patterns to improve population health and prevent diseases, but digital epidemiology uses digital data [8]. A digital or e-cohort study can integrate data that were not generated for the research (social media and registries) or were generated with digital tools (wearables, sensors, smartphone technologies, and e-questionnaires through web platforms) [9]. Before starting any epidemiological, clinical, or population-based study, researchers need to choose the best methodology to incorporate PPI throughout the project [10]. However, although there are approaches to integrate PPI in a research project, we think that there are no clear recommendations of which methods are the most appropriate, in particular with respect to the launch of cohort studies with digital sources of data.

Although PPI is recommended in research projects, this involvement is often not described or is incompletely reported [11]. A reason for underreporting may be to avoid describing an unsuccessful PPI attempt or that there was no involvement [12]. In addition, there is some evidence that PPI is seldom used in many countries [13]. In the case of cohort studies and, in particular, e-cohorts, we believe that this insufficient involvement may be due to a lack of knowledge of the methods, barriers, or facilitators to apply PPI. In addition, we think that there is a need to have concrete and clear examples for applying PPI in this type of study.

Objectives

The aims of this study are to (1) review methodologies used to include PPI in research, (2) provide the viewpoint of a final user of research results, and (3) provide practical guidelines and recommendations about how to initiate and run an e-cohort study with PPI based on the review and the point of view of a patient advocate.

Methods

This work entails 3 parts: a narrative review about methodology and description of PPI, a viewpoint of a patient advocate, and a case study with practical guidelines and recommendations, illustrated by the implementation of a digital cohort study.

Review

Data for this review were identified by searches of PubMed, Google Scholar, targeted websites about PPI, reports, and existing PPI guidelines, as well as Google Search and references from relevant studies. We used the following search terms: "patient and public participation," "patient engagement," "patient involvement," "consumer involvement," "community involvement," "participatory health research," "community based research," "research ideas," "co-writing," "coproduction," "co-design," "cohort study," "e-cohort," and "longitudinal study." We included original studies describing PPI methods using the Involve definition with at least one type of PPI in the study. We included information on studies published in English from 2000 to the present.

Viewpoint of a Patient Advocate

We used relevant definitions from the European Patients' Academy on Therapeutic Innovation for patients. We defined patients as individuals with personal experience of the disease, caregivers as individuals supporting a patient, and patient advocates as individuals representing large numbers of patients with a specific disease [14].

We invited a patient advocate to present her perspective and expectations regarding PPI in the context of diabetes research

and the use of digital tools and, in particular, the use of social media.

Recommendations

We integrated the results of the review and the patient advocate's viewpoint to identify practical guidelines on how to increase PPI in future epidemiological studies. We used the implementation of a digital cohort study as an exemplary case for testing and illustrating established guidelines for PPI [15]. In addition, we integrated in our recommendations the revised version of Guidance for Reporting Involvement of Patients and the Public (GRIPP2) checklist as an instrument to improve the quality of PPI reporting [16].

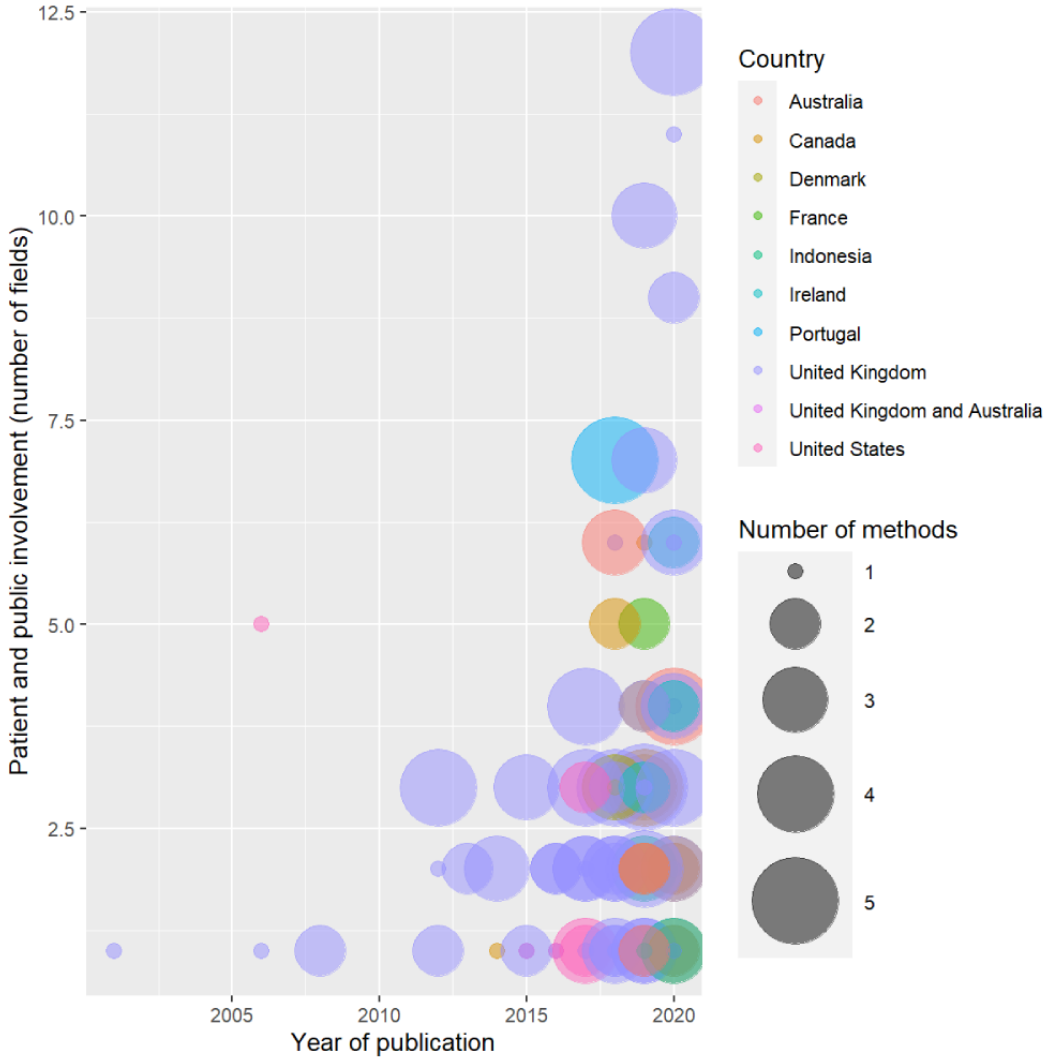
This study was based on a collaboration of patients and researchers. A patient advocate (RS), patient researchers (TS and TB), and researchers (GAA, CG, AF, VTT, PR, LH, and GF) were involved in the preparation of the manuscript (cowriting, editing, and critical review).

Results

Review of PPI Methods

We analyzed data from 97 studies published from 2000 to 2020. The studies were performed in 9 countries: the United Kingdom (58/97, 60%), Canada (13/97, 13%), the United States (8/97, 8%), Australia (6/97, 6%), Ireland (6/97, 6%), Denmark (2/97, 2%), France (1/97, 1%), Portugal (1/97, 1%), Indonesia (1/97, 1%), and the United Kingdom and Australia (1/97, 1%). The most frequent methods of PPI were workshops (47/97, 48%); surveys (33/97, 34%); meetings, events, or conferences (28/97, 29%); focus groups (25/97, 26%); interviews (23/97, 24%); consensus techniques (8/97, 8%); James Lind Alliance consensus technique (7/97, 7%); social media analysis (6/97, 6%); and experience-based co-design (3/97, 3%). Of the 97 studies, 34 (35%) used only 1 method, whereas 30 (31%), 22 (23%), 8 (8%), and 3 (3%) used 2, 3, 4, and 5 methods, respectively. The use of ≥3 methods together was observed from 2017 onwards (Figure 1 and Multimedia Appendix 1 [17-114]).

Figure 1. Number of fields or areas (ie, 1 field=involved in research ideas and 2 fields=research ideas and co-design) in which patients, carers, or the public were involved (y-axis); number of methods (circles); and countries (colors) where the studies were performed from 2000 to 2020 (x-axis). Patient and public involvement increases over time and at different stages of involvement. The size of each circle represents the number of methods used for patient and public involvement. Circles representing a combination of methods are very common in recently published studies. The most represented country is the United Kingdom.



Format of Involvement

Broad Definition of PPI Used

When considering methods of approaching PPI, 2 situations should be distinguished. The first situation is where patients or the public provide data on ideas or research priorities. The second situation is where patients or the public are actively involved in decisions about the research and perform or collaborate in the design, data analysis, data interpretation, writing, or diffusion of results. For this review, we used a broad definition of PPI that includes both situations: patients or the public involved in generating research ideas and patients or the public actively involved in the research cycle [115].

Workshops

We found that the most frequent method for approaching PPI was a workshop. Workshops are group activities where participants discuss a defined topic and decide actions. There are different ways of organizing a workshop. The first way is to organize it always in the same place and at the same hour. Morris et al [116] emphasized the importance of having enough space and time for the discussion. In addition, the number of participants by workshop or by discussion group may be limited. Mackintosh et al [17] proposed separate groups of users and service providers of 3-4 people. In contrast, Kelemen et al [18] organized full-day workshops with 20 to 25 participants of different origins and ages and divided into 2 groups randomly assigned. Patients prefer places with quiet rooms and parking lots, with meeting and meal times that allow them to participate and manage their medications [19]. An alternative to a workshop held at a specific location is to organize mobile workshops to facilitate the participation of people with busy schedules or mobility issues. Eccles et al [20] organized this type of workshop with a maximum of 10 participants and a short duration (30 minutes). These workshops were usually offered on the sites of existing organizations, which improved the success rate [20]. When face-to-face workshops are not possible, a workshop by videoconference can be organized [21]. Workshops can also be organized as consensus meetings [15,22], with a second-round workshop [117] or by applying other techniques to improve explicit involvement, such as experience-based co-design [23]. Workshops are usually analyzed with qualitative research methods such as thematic analysis [118] (Multimedia Appendix 1).

Surveys

Surveys aim to obtain information in an easy, individual, and feasible way. They can include open-ended questions. For example, a citizen science study asked participants the *magic wand* question ("If you had a magic wand, what would you change in your healthcare?") [24]. Surveys can also include closed-ended questions. Little et al [25] performed a study to identify patients' preferences for a patient-centered consultation using Likert scale questions that were previously tested and validated in a pilot study. To respond to a survey, patients and the public could be contacted in person [25], through a web-based survey [119], or by telephone [120]. Several studies included a second round of questions for improving ideas or establishing priorities [26,121].

Focus Groups

Focus groups are group activities, a form of qualitative research that includes people with certain similarities such as a therapeutic area or illness or demographic or socioeconomic group to discuss their opinions and beliefs about a topic familiar to the participants [27]. An advantage of focus groups is the potential to obtain multiple opinions and different understandings of the same question, which can enrich explanations for a certain issue. A disadvantage is that focus groups require a trained interviewer to conduct them, and interaction among participants can influence the outcome [122].

Meetings

Meetings are group activities where patients, carers, caregivers, and researchers participate in the project discussing and co-organizing activities for PPI [15]. They are complementary to workshops or focus groups and are also used to prepare these activities and to debrief methods or actions for PPI [28]. Meetings can be organized as festivals and public events, conferences [29], or web-based activities [30].

Semistructured Interviews

Semistructured interviews are a qualitative research method where the researcher discusses a defined topic individually and informally with the participant [123]. Using this method, nonresponse or direct behavioral observations, individual reflections on a specific research question, can be incorporated as outcomes; the advantage is that the participant is not influenced by other persons [124,125].

Consensus Techniques

Consensus techniques analyze a project's chances of success by bringing together a group of experts at a workshop, meeting, or conference to discuss solutions and reach agreements [31]. James Lind Alliance is a consensus technique bringing clinicians, patients, carers, and the public together to achieve the convergence of opinions for establishing research priorities. The process starts with a web-based survey to collect research ideas from the public. Next, only unanswered research questions are selected. With a second web-based survey, the public prioritizes the selected questions. At the end of the process, the steering committee chooses the top 10 research priorities [126].

Persona-Scenario

Persona-scenario is a method for co-design in PPI where a fictitious user (persona) is created to communicate in a committed manner. Next, a scenario is proposed based on a story with an actor (the persona), a framework, a goal, actions to reach this goal, and obstacles. Participants can be asked to evaluate the extent to which they agree with the choice of the persona or what they would do if they were in the situation of the persona. This distancing—giving advice about someone else's choice rather than answering for yourself—can help address sensitive themes [23,32].

Experience-Based Co-design

Experience-based co-design is a technique using narratives, usually video recorded, that allows patients and researchers to work in partnership to co-design new services and technology

with the objective of improving the quality of health services. This technique has been applied with success for fostering PPI [33-36].

Digital Methods to Promote PPI

Digital methods can be enablers of PPI, and the public can help modulate and develop digital technology [127]. Dedicated websites can enhance PPI not only by providing information, but also by organizing PPI itself. An example is the use of a webpage to organize a patient-led research hub. This is an initiative aimed at making patients and the public leaders of their own research projects. The researchers assist and support the patients and the public who proposed projects [37].

Crowdsourcing is a method by which many people are engaged on the web for a common goal such as obtaining new ideas and analyzing data. The main advantage is that it is possible to have a large number of contributors in a very short time [128]. However, because crowdsourcing participants are generally younger than participants from traditional nonweb-based procedures, these participants are not always representative of the target population [129].

Social media analysis is the use of digital data from social networks for epidemiological purposes. This information increases knowledge about epidemiological trends and may be very different from information obtained by traditional methods [130]. Social network data sources can be used, for example, to obtain information about the patient's research priorities [38]. This often generates large quantities of data and can offer the opportunity to use special techniques such as natural language processing for the analysis [131].

Web-based platforms are internet services where the public and innovators meet and can be created for allowing coworking [132]. Vasilica et al [39] reported creating a web-based network to co-design a social media–based platform with the aim of generating information to improve disease outcomes [39]. In addition, web-based platforms through a web-based voting system have been used for establishing research priorities [133].

Fields of Involvement

We found that many studies (60/97, 62%) involved patients and the public for generation of new ideas. Patients or the public contributed also in coproduction, co-design, or study scope (42/97, 43%) and in establishing research priorities (31/97, 32%). Other forms of PPI included participation in data analysis (25/97, 26%), as coauthors of a scientific article (17/97, 18%), as members of a steering committee or advisory group (16/97, 16%), reviewing or writing protocols (14/97, 14%), in the interpretation of results (12/97, 12%), in the dissemination of results and advocacy (11/97, 11%), in the data collection (9/97, 9%), in the development of the recruitment strategy (7/97, 7%), as a project manager (4/97, 4%), and being coinvestigator or having patient- or public-led projects (2/97, 2%). We found only 1 study where patients were involved in the co-design of mobile health tools (1/97, 1%). Finally, recent studies reported an early PPI in at least three different stages or fields of involvement and throughout the life of the research project (Table 1 and Figure 1).

Table 1. Fields of involvement in the included studies (N=97).

Type of involvement	Frequency, n (%)	References
Generation of new ideas	60 (62)	[18,20,22-27,30,32-36,38-82,134]
Coproduction, co-design, or study scope	42 (43)	[17,19,23,30,32-37,39,41,49,54,55,59,60,65-69,74,75,78,81,83-98]
Establishing research priorities	31 (32)	[24,26,29,30,34,35,41-43,46-48,53,54,57,60,62-64,66,72,75,77,81,83,89,90,99-102]
Participation in data analysis	25 (26)	[24,30,31,34,51,60,61,66,69-71,78,81,87,90,91,94,96,103-109]
As coauthors of a scientific article	17 (18)	[24,30,31,57,60,61,68,69,73,83,86,94-96,105,110,111]
As members of a steering committee or advisory group	16 (16)	[26,28,30,31,35,42,43,53,62,76,78,84,91,106,110,112]
Reviewing or writing protocols	14 (14)	[30,49,51,59,60,68,73,74,78,83,91,95,111,113]
Interpretation of results	12 (12)	[24,30,41,49,60,66,69,78,91,94,96,104]
Dissemination of results and advocacy	11 (11)	[30,39,41,49,57,60,70,78,86,94,104]
Data collection	9 (9)	[54,60,66,70,88,91,94,96,114]
Development of the recruitment strategy	7 (7)	[41,60,66,68,91,104,111]
Project management	4 (4)	[30,37,78,94]
Coinvestigator or having patient- or public-led projects	2 (2)	[37,94]
Co-design of mobile health tools	1 (1)	[135]
At least three different stages or fields of involvement and throughout the life of the research project	39 (40)	[24,26,28,30,31,34,35,39,41-43,49,51,53,54,57,59-61,66,68-70,73-75,78,81,83,86,89-91,94-96,104,110,111]

To develop a successful PPI project, patients or the public and researchers must have, or develop, certain skills. For example, researchers need to become familiar with PPI as a research approach, know how to manage a PPI project, and how to deal with conflict. As for the patients and the public, they must understand the research process and develop capacities for

management and conflict management. However, it is not mandatory that patients have specific vocational or educational training [136].

PPI in Epidemiology: Trials and Cohort Studies

Web-based trials are more and more frequently described in the literature. Price et al [137] performed a systematic review of web-based trials and found that PPI was only reported in 24% (10/41) of the trials included in the review. Face-to-face meetings and email contact were the most common ways of interaction [137].

Taylor et al [97] performed a cohort study in patients with cancer that involved the patients in the creation and choice of a brand for the cohort. With a 1-day workshop, patients and researchers co-designed the brand. The results showed higher acceptance and retention of the study than expected. An ongoing cohort study used social media (Facebook) for PPI by creating a closed group of patients and families to bring new ideas to the project [80]. Meetings with a family advisory committee were organized regularly.

Morris et al [116], in the context of an epidemiological study, investigated PPI with surveys and postevent interviews and wrote recommendations. Before an event, they suggest sending a detailed document with the topics to be discussed. During the event, they suggest having enough space between tables to allow all participants to be heard, providing materials to facilitate note taking, taking a whole day for the meeting, and arranging a facilitator for each table. Finally, after the event, they recommend a follow-up by sending the notes to the participants [116].

Barriers to PPI

Domecq et al [138] in a systematic review described some barriers to PPI. They highlighted 2 barriers: the excessive time taken for training activities and attendance and the risk of a tokenistic involvement. Another barrier reported in participants who were frail was frustration because of discontinuity in the involvement [139]. Barriers reported by researchers were concerns about the quality of research, ethical issues, lack of funding, failure of the PPI in the past, and not being convinced of the real need for PPI in the cohort [140]. Maccarthy et al [113] described communication issues as a key barrier to PPI. Researchers fear not being able to explain the project and not being able to engage patients and the public in the project; they also feel discomfort speaking about their experiences with patients and the public and fear having misunderstandings.

Facilitators of PPI

Creating a safe and welcoming environment where each contributor feels empowered and confident facilitates PPI [94]. The coproduction process can give participants the self-confidence to take responsibility for the entire duration of a project [78]. In addition, an iterative process of PPI evaluation during the entire research cycle has been proposed to ensure success in PPI [113]. Mathie et al [141] reported that feedback for patients, when provided, motivated them to continue their collaboration with researchers. Concerns for well-being, trust, mutual respect, and flexibility in time and methods were facilitators of PPI [139]. Chambers et al [142] found key areas that may facilitate or hinder the development of PPI. These key areas were the following: good role definition, recognition of difficulties, integration through organizations, training, developing networking, considering different perspectives, improving communication, and recognizing the relevance of emotional impact. Finally, concerning digital interventions and PPI, O'Connor et al [143] recommend investing in raising awareness of the usefulness of digital tools, improving health literacy, and using optimal tool design.

A Patient Advocate's Viewpoint of PPI in Diabetes Research

When writing this review, it was natural to allow a potential representative of study participants to express how they see PPI so far in research and what they are expecting from researchers to increase the participation of people with diabetes in research (Textbox 1, written by RS).

Textbox 1. Involving people with diabetes in research: a patient advocate's viewpoint.

Viewpoint of a patient advocate

- On November 14 each year, World Diabetes Day is celebrated across the globe. The International Diabetes Federation with the World Health Organization created this awareness campaign in 1991 to respond to the growing numbers of people with diabetes worldwide. In 2006, World Diabetes Day was deemed an official United Nations Day with a special resolution, becoming only the second health condition so recognized.
- Why November 14? That date marks the birthday of Sir Frederick Banting, who, along with Charles Best, is credited with the discovery of insulin. The day is acknowledged by diabetes organizations, health care professionals, researchers, and governments. Most importantly, people with diabetes have embraced the day to acknowledge, commemorate, and also celebrate life with diabetes as we gratefully signpost the man whose research is responsible for our very lives.
- People with diabetes are interested in research. We know that the developments we see each and every year that advance how we live with diabetes are the result of research. We are interested in the different branches of research—clinical, educational, social, and behavioral—because we know better than anyone that living with diabetes is a multi-pronged existence that affects every part of our lives.
- However, despite how much we appreciate the work of researchers and how keen we are to learn more, sometimes it is difficult to engage with us and involve us as participants. Let us explore how we can address this gap and consider some changes that can be made to encourage people with diabetes to take more interest in research.

Tell the story

- The story of Banting and Best is folklore for those of us living with diabetes. It is a compelling story, but so are many other research tales. Unfortunately, the narrative is not always told especially effectively. It is difficult to make research sound relevant to people living each day with diabetes when research involves cells in a petri dish or stem cells in a temperature-controlled laboratory. What is the difference this work will make to our day-to-day lives?
- It is exhausting for us to hear how mice are cured of diabetes (once again), especially when we know that our cure is still as elusive as ever.
- However, these stories—the cells and the mice—are links in a long chain that lead to significant developments that do directly affect us. At the moment, explaining that seems lost in translation, and researchers need to think about how to decode in basic language how the work they are doing has the potential to make significant changes to the everyday life of people with diabetes and that participating in relevant research gets us to that goal.
- Even those researchers whose work is more practical based are not always especially successful in describing the impact of their work on those of us with diabetes. Plain language statements are a start, but looking for even more nuanced and targeted ways to communicate is important.

Tell it in a tweet!

- With 280 characters on offer, Twitter is the perfect platform for researchers to hone their short story–telling skills. Practice the elevator pitch of your research by narrowing down the key points and benefit to people with diabetes, and share it on the web to encourage interest. (Twitter threads allow for linking a number of tweets together, so if you need more than 280 characters, you can take a couple of tweets. But do keep it brief!)

What is involved?

- When recruiting people for your research, be very clear about what they will need to do. How much time is involved? Where will they need to go? Will there be any invasive procedures and how uncomfortable are they likely to be? (Be honest!)
- Follow-up is critically important. A complaint we hear from people participating in research is that once their involvement is over, they never again hear from the research team. This can be especially frustrating if people have invested a lot of time and energy in a trial. Regular updates through a newsletter or social media page keep people informed and linked in with your work. This is especially important if you are planning to recruit people for future phases of your study.

Participants, not subjects #LanguageMatters

- The words you use when communicating to, and about, people with diabetes are critically important. Refer to language position statements developed by diabetes organizations to ensure that your language is supportive, empowering, positive, and encouraging. We people with diabetes are more inclined to be involved if we see a study that treats us with respect.

The 2 camps—and how to bridge them

- There seem to be 2 main camps when it comes to diabetes research. Some believe that the focus should be primarily on finding a cure for diabetes. This seems to be especially prevalent in the type 1 diabetes space, with much of this thinking led by parents of children living with diabetes. In 1970, it was these parents who founded the leading diabetes research organization, the Juvenile Diabetes Foundation (renamed the Juvenile Diabetes Research Foundation), now known as JDRF. The original organization's mission was very clear: to find a cure for diabetes. In recent years, however, the research funded by JDRF has branched out to include studies looking at improving management through technology and drugs.
- However, it is important to acknowledge the importance of research that looks at better management. Without this research, there would be no treatment for diabetes-related complications and we would not have technology such as home blood glucose meters, insulin pumps, continuous and flash glucose monitors, algorithms to automate insulin delivery...and we would still be using the same insulin from dogs that Banting and Best had used.

- Just as important is the growing body of work and researchers dedicated to researching the social, psychosocial, behavioral, and emotional aspects of living with diabetes. As anyone living with diabetes will tell you, this condition is never just about metrics. It is very much about our *headspace* and how we feel about living with diabetes.

Involve us

- When is the best time to start to involve people with diabetes in your research? It is probably already too late! Have you consulted us when you were establishing your study design? And back up a little more...is the research really something that is going to be of interest or benefit to people with diabetes. Is the problem you are looking to solve really a problem for us?

Patient advisory committees

- Many research bodies now require patient advisory committees to be established as part of the overall study. Done well, these groups can provide invaluable input for projects. Done badly, they are nothing more than a tick-the-box exercise. Ensure that there is funding available for travel, accommodation, and other expenses. Be clear about what you expect the patient advisory committee members to do and which aspects of the project they will be involved in. Remember that patient advisory committee members will most likely be volunteering their time. Their expertise and time should be reimbursed by honoraria or hourly payments.

Not enough money in the pot

- Research dollars are never enough, and each year, there are more researchers contending for elusive grants. When the results from grant rounds are shared, it seems that diabetes is repeatedly the *poor cousin* of health conditions, regularly being awarded significantly less money (with fewer successful grants) than conditions such as cancer and cardiovascular disease. In recent grant announcements from the National Health and Medical Research Council in Australia, only 16 diabetes grants worth Aus $13.5 million (US $9.6 million) were awarded compared with 69 grants worth Aus $52.9 million (US $37.8 million) awarded for cancer research.
- People with diabetes can help to advance the cause of diabetes grant applications by telling their stories. Perhaps one of the reasons that diabetes receives comparatively little of the research bucket is because we have not been all that successful in telling our stories. Instead, we have created a false image of diabetes as a hugely preventable, self-inflicted condition, resulting in government and other research bodies considering diabetes a less worthy condition to fund.
- Researchers are encouraged to work closely with people with diabetes to help tell the story of why their own research is important and how it has the potential to help in the lives of people affected by, or at risk for, diabetes. Humanizing the story is important—all too often, diabetes is presented in the media as a headless overweight body, which only adds to the stigma and image problem of the condition.

The story of hope

- Research is selling an important feature: hope. People with diabetes trade on hope; we look for it in research because we know that is what holds the key to improving outcomes, reducing burden, and making our diabetes lives easier. We want to be part of those discoveries that promise a better life, and we want to be involved in your research that will help us get there.

Illustration of PPI in a Digital Cohort Study

Digital cohort studies are longitudinal studies in which the data come either totally (e-cohort) or partially (hybrid: e-cohort and traditional cohort) from digital sources. Modern cohort studies increasingly incorporate digital tools such as data generated on the web and connected devices that allow much wider use of data generated for multiple projects [9].

We elaborated a strategy of PPI for a digital cohort study. Tables 2 and 3 show recommendations for PPI at all stages of research. This participation was defined in 2 categories: *Recommended participation activities*, in which patients and the public participate more passively, helping to generate research ideas and prioritize those ideas by participating in surveys, and *Recommended involvement activities*, in which patients actively participate in collaborative work with researchers on an equal footing. Examples of these activities are events, meetings, workshops, and focus groups. The chosen strategies for the digital cohort study are detailed in 32 actions in total for participation as well as participation and involvement, corresponding to the different steps of the research process, and are based on the current recommendations of Involve [7], our review results, and the viewpoint of a patient advocate (Textbox 1). In addition, for the realization of certain activities, we suggest a recommended duration of the activity based on our review of the literature and the point of view of the patient advocate.

Table 2. Recommendations for the promotion of patient and public involvement (PPI) projects: concrete examples for a digital cohort study. Steps to be taken before starting the cohort study.

Stages (Involve list)	Suggested actions	
	Recommended participation activities	Recommended involvement activities
Identifying and prioritizing research axes	• Web-based survey through social media: identification of research questions. Duration of the activity: 15 minutes	• Videoconference meeting: establishing an international scientific steering committee with researchers and patients as members. Duration of the activity: 1 hour. Preparation: read agenda that should be sent 1 day before the meeting • Meeting: identification of, and invitation to, a group of patients interested to be involved as patient partners (eg, through patient associations). Duration of the activity: 3 hours. Preparation: not needed. Venue: local patient association • Videoconference meeting and use of web-based collaboration tools: cowriting PPI plan for the cohort and submission to an ethics committee. Duration of the activity: 2 hours. Preparation: read the proposal draft sent and written by researchers 1 week before
Designing	• Web-based survey through smartphone app: identification of research questions, web-based survey with open-ended questions. Duration of the activity: 10 minutes • Web-based survey: ranking research questions (through smartphone app, web-based survey using persona-scenario technique) with closed-ended questions. Duration of the activity: 15 minutes	• Web-based or mobile workshops: coproduction by giving feedback on study design and chosen questionnaires and research tools (such as mock-ups of app, user experience and user interface). Duration of the activity: 3 hours • Web-based training: language matters. Searching, choosing, and checking the most appropriate use of language for communication with the public and patients. Duration of the activity: 2 hours • Mobile focus group and survey (Multimedia Appendices 2 and 3): assessment of the beta version of smartphone app and flyers, as well as assessment of the wording and visual of the website, flyer, study objectives, and PPI expectations. Duration of the activity: 4 hours. Meeting place: comfortable, with catering and parking lot available
Drafting grant protocol	—[a]	• Web-based meeting: cowriting study protocol, involvement of patient associations as partners in grants. Duration of the activity: 1 hour. Preparation: read agenda that should be sent 1 day before the meeting
Testing and scaling up	• Surveys through smartphone app: testing of pilot study by limited number of potential study participants. Duration of the activity: 30 minutes	• Web-based meeting: co-designing pilot study on smartphone app. Duration of the activity: 1 hour. Preparation: read agenda that should be sent 1 day before the meeting • Web-based meeting: co-design of generalization phase and recruitment. Duration of the activity: 1 hour. Preparation: read agenda that should be sent 1 day before the meeting • Web-based meeting: advertise through social media and press for patients and the public to participate in the study

[a]No specific recommendations.

Table 3. Recommendations for the promotion of patient and public involvement (PPI) projects: concrete examples for a digital cohort study. Steps to be taken during the cohort study.

Stages (Involve list)	Suggested actions	
	Recommended participation activities	Recommended involvement activities
Analyzing and interpreting	—[a]	• Web-based meeting using web-based collaboration tools: cowriting of annual reports • Webpage, web-based workshops, meetings, and web-based collaboration tools: coproduction of research projects through a patient-led research hub. Webpage with a dedicated section for submission of projects by patient. Projects assessed by the scientific steering committee • Web-based workshops, meetings, and web-based collaboration tools: data analysis and interpretation of results • Meetings and web-based collaboration tools: writing of manuscripts cowritten by scientists and patients
Disseminating	—	• Social media: dissemination of publications coauthored by scientists and patients • Web-based meetings, workshops, and web-based collaboration tools: participation at conferences as author or coauthor • Focus groups and workshops: communication of research results (plain language, infographic, and dissemination)
Implementing	—	• Web-based meetings and workshops: implementation of some results from the study at hospitals and consultations facilitated by patients
Monitoring and evaluating	• Smartphone app: improving participants' retention by reminders • Email newsletter and social media announcement: follow-up of the project by researchers (once a month) • One-day general public event: follow-up of the project by researchers (once a year) • Web-based survey through social media and smartphone app: monitoring evolution of the research protocol (adding or deleting research questions)	• Web-based meetings: checking of data collection and data quality by patients • Web-based meetings and web-based collaboration tools: review of research projects by patient representatives • Social media: improving participants' retention by involved patients • One-day general public event: follow-up of the project by patients and public (once a year). Remuneration or facilities for attending should be budgeted for members of the scientific committee • Workshop: evaluation of PPI by researcher and contributors (use GRIPP2[b] checklist). Duration of the activity: 1 day. Meeting place: comfortable with catering and available parking places • Meetings and workshops: Monitoring evolution of the research protocol (adding or deleting research questions) by scientific steering committee (scientists and patient members)

[a]No specific recommendations.

[b]GRIPP2: revised version of Guidance for Reporting Involvement of Patients and the Public.

The advantage of a digital cohort study is that digital tools can be used to promote PPI at each stage as a primary method or as a complementary or alternative method. A digital cohort can facilitate PPI, allowing participation from remote locations, using a smartphone app with web-based questionnaires, organizing most of the meetings through videoconferences, and using web-based tools for coworking. However, we think that face-to-face activities are also recommended and these 2 approaches may be complementary.

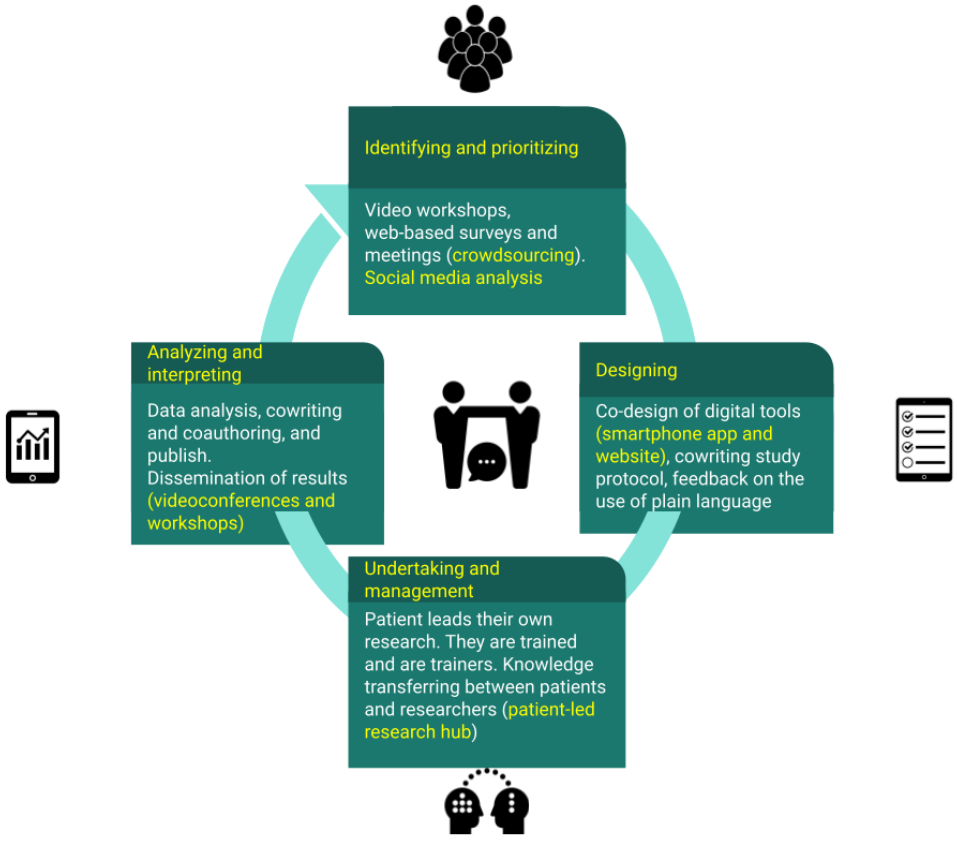
The recommendations are as follows:

- Recommendation 1: Identify patients and the public who might be interested in participating as members of the patient advisory steering committee. This contact can be achieved through social media and patients' organizations. Use digital tools to identify people. For example, contact organizations that are active on forums or social media.
- Recommendation 2: Write a PPI protocol in the digital cohort protocol describing all planned activities and include funding for patients. The patients who are part of the steering committee should be actively involved in this activity.
- Recommendation 3: Identify patients and the public who might be interested in participating in focus groups, semistructured interviews, or workshops by being involved actively in the design of the app, website, research ideas, and project evaluation.
- Recommendation 4: Organize focus groups as an important activity to obtain information about how PPI can be integrated in a digital cohort study. We present an example guide for this activity in Multimedia Appendix 2. A passionate and enthusiast moderator is needed. Sometimes it is not possible to find a place and a time that works for everyone. In such cases, mobile or web-based focus groups can be organized.

- Recommendation 5: Involve patients in the design of the smartphone app or other digital tools. For working on the design of a smartphone app, we encourage the use of an evaluation grid to assess the app with direct observation of how patients and the public use it. We present an example of an evaluation grid in Multimedia Appendix 3. Patients and the public can also assess a smartphone app using a validated scale. We suggest the application of the user version of the Mobile Application Rating Scale [144].
- Recommendation 6: Involve patients in the generation of new research ideas and research priorities. Using a smartphone app or through a website, we recommend that during the study, participants be invited to propose research questions at any time and as often as they wish. The patient advisory steering committee is involved in all the discussions about research priorities and follow-up of the project.
- Recommendation 7: Give feedback to patients and the public through web-based newsletters and social media. Evaluate regularly satisfaction with PPI. To assess the impact of PPI among active participants and to define roles and changes in the project, we advise that annual workshops should be organized. At these annual workshops, PPI can also be assessed by contributors (researchers, patients, and the public) using the GRIPP2 checklist [16].
- Recommendation 8: Establish a patient-researcher partnership. On the cohort's website and in the smartphone app, we encourage the creation of a *patient- or public-led research hub* space. This space can receive applications from patients or the public to develop research projects. The scientific steering committee assesses applications concerning scientific content and feasibility. The research team helps patients and the public to carry out their own projects by providing methodological support.
- Recommendation 9: Finally, we recommend inviting patient advocates, patients, or caregivers to become *study ambassadors*. They are volunteers actively involved in the study and social networks. The role of the study ambassadors will be to actively disseminate the results of the study and invite their networks to join the project.

Figure 2 shows our vision of integrating PPI in a digital cohort study in the whole research cycle.

Figure 2. Patient and public involvement in the research cycle of a digital cohort study. Digital tools are integrated at each stage of the research cycle, and some examples of digital tools are shown in the figure.



Discussion

Principal Findings

We observed that the most popular methods for PPI are workshops, focus groups, interviews, and surveys. The appropriate method must be carefully chosen to fit the research objective. For example, workshops and focus groups can be a rich source of information in the prestudy phase; they can be adapted to the context of the participants; and they allow direct observation of, and interaction among, participants. The downside is that they are highly dependent on the capacity of the moderators.

We have also described digital tools to collect information from the patients and the public for research, such as social media

listening and a particular web-based crowdsourcing survey with the *magic wand*–like question [24]. We think that digital tools may not only facilitate patient engagement in research, but can also stimulate a continuous and long-term participation and involvement of patients and the public.

Overall, none of these methods can address all relevant questions for scientists and patients or the public related to a research project. Therefore, we recommend a mix of methods to obtain optimal and meaningful information for the research project at stake. Different methods can be applied at different times of the project depending on the objective. Regarding the timing of introducing PPI, we recommend that PPI be included from the beginning (eg, co-design and research plan) to the end (publication and dissemination), followed by a PPI assessment.

We suggest pragmatic steps to integrate PPI in future epidemiological studies. These recommendations are as generic as possible but may not be applicable in all cases. They are based on current guidelines for PPI with concrete examples for a digital cohort study [14,15]. These recommendations should be understood as modular, meaning that they must be adapted to the study design, population, available budget, duration of the project, and local context. For PPI report and assessment, we recommend using the GRIPP2 checklist, a dedicated PPI reporting checklist [16].

Comparison With Prior Work

Domecq et al [138], in a systematic review, identified barriers to, and facilitators of, PPI. They found no evidence indicating which method was best for PPI. In our review, we found that a combination of methods is more common with greater involvement (patients included in many areas or across the research cycle). We integrated the barriers and facilitators described by Domecq et al [138] in our recommendations.

Liabo et al [145] performed a systematic review of good PPI practices. They compared the results of the systematic review with 3 involvement groups and found that the priorities were similar. However, the involvement groups found additional values that were not described in the literature, such as the enthusiasm of the participants and the choice of welcoming venues for the meetings. We integrated these reflections in our recommendations.

Nunn et al [146] reviewed reports of 96 human genomic research projects and found that only 33% (32/96) declared PPI. From these, most of the PPI activities were organized in formal groups (20/32, 63%), with 22% (7/32) using web-based tools (website, social media, and web-based communities). We found similar results with social media reporting in 6% (6/97) of the studies with PPI. We think that there is room for more PPI using digital tools.

Miah et al [147] conducted a scoping review of PPI in dementia research and found 19 studies from the United Kingdom and 1 from the Netherlands. Biddle et al [13] found an uneven distribution of PPI in Europe. They attributed this to a lack of infrastructure, support, and guidance. An example of support is that research-funding institutions in the United Kingdom require PPI in project applications. However, funding agencies in many countries do not have this requirement. We found similar results with most of the studies on PPI from the United Kingdom. We believe that PPI is still underreported or not performed in many countries.

Few epidemiological or clinical studies report PPI in the research process [11,146]. Studies that include patients and the public most often involve them only at the stage of idea generation, but not in the whole research cycle. This suggests that PPI is symbolically added or very limited.

Individual interviews are useful for tackling sensitive questions because participants do not feel dominated or influenced by the opinion of other participants. Surveys (web-based, telephone-based, or paper-based) are a pragmatic method of obtaining large-scale information from many people quickly. Differently, a survey can be very useful for generating new ideas and for refining and improving them when a new survey containing the generated ideas is launched for another sample of people.

PPI is a *project in the project*, creating its own challenges such as completing appropriate regulatory tasks and obtaining approval from an ethics committee. In the informed consent, the nature of participation must be specified, with clear and fair terms and conditions. This includes whether remuneration, cost coverage for the patient organization, and travel costs of patients or the public are provided and whether there are other benefits for the patients, such as nonfinancial compensation for the time allocated to project participation [14].

Several reasons for a lack of, or delay in, PPI have been mentioned in the literature. Some researchers do not include patients or the public in the research, arguing that the patient or public point of view is too subjective [148]. Furthermore, researchers may consider PPI only as a requirement of funding agencies for the project to be approved; therefore, PPI arrives late in the process and is treated as an afterthought [149]. We believe that obstacles can be overcome when they are identified and taken into account in the plan and recommendations.

When PPI is considered, there is the risk of selective PPI, which means that only those within the community who agreed with the research objectives are included. In addition, this may have the risk of hearing only the opinion of the most active patients or public, which may not reflect the opinion of most of the other patients and can therefore lead to research designs that still do not research the questions that interest most patients. We recommend nonselective PPI, meaning that the aim should be to involve a diverse selection of participants in the PPI process, including patient organizations, patient advocates who are legitimately speaking on behalf of a patient community, and individual patients, to ensure that the opinions and views of the participants are representative of most patients with the same condition [47].

Researchers should make a greater effort to minimize the burden of participation for patients and maximize the benefits for participants at the same time. A lack of participation is more likely to occur when there is poor or 1-way communication, resulting in poorly organized protocols and demanding follow-ups that lead to noninformed, noninvolved, and nonmotivated participants. Nevertheless, when done properly,

patients can associate their participation with feelings such as usefulness, empowerment, and consideration [150].

Limitations

This study includes certain limitations. Our search was limited to studies in English. In addition, a part of what is happening in PPI is described in the gray literature and has therefore been excluded from the review. Our review may give the impression that early involvement in setting research priorities is the norm, but this may not be true because of a potential publication bias. For example, the results of studies with PPI are often not intended to show improvements in efficacy in clinical studies; therefore, they are less likely to be accepted by publishers for publication or publication may be delayed because of negative or statistically insignificant results.

Conclusions

There are, and rightly so, many expectations on the part of patients and the public to be actively involved in research and not only by providing data, but also as research partners. PPI can contribute to patient empowerment by increasing disease awareness and according recognition as actors of their own condition [151]. However, PPI is uneven among countries and research institutions, and even now many patients and the public are not yet involved in research [13] and ignore or do not have access to research protocols [152]. Digital tools such as websites, social media, and connected devices have been increasingly incorporated into cohort studies and could be leveraged to increase PPI [153]. Digital tools can facilitate PPI by providing an opportunity for remote access and therefore easier participation. In addition, digital tools can facilitate PPI by enabling feedback and interaction between researchers and patient collaborators [154].

PPI can be a powerful approach to increase the relevance of research projects. We have shown that PPI must be planned in the initial phases of the development of a new epidemiological study and then be considered throughout the life of the research project. Combining different approaches of PPI seems to be the most effective strategy for improving the quality of research.

Some techniques such as *persona-scenario* are very powerful for idea generation and can be combined with digital tools. In addition, web-based surveys are easy to implement and allow involving many participants (crowdsourcing).

Digital methods such as social media listening or web-based *magic wand*–like questions can also offer useful complementary channels of interaction and help to identify key information such as research gaps at large scale with a limited cost directly from the target population. As such, we recommend that these methods be also integrated in the PPI process. With the example of a new digital cohort study, we offer practical guidelines to implement and run a patient- or public-centered research study. We therefore encourage investigators to rely on our practical recommendations to increase PPI in future epidemiological studies.

Acknowledgments

This study was funded by the Ministry of Higher Education and Research of Luxembourg and the Luxembourg Institute of Health. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

The authors thank Ms Sandrine Lavalle for her support for this work.

Authors' Contributions

GAA reviewed the literature, selected the studies, extracted and analyzed data, and wrote the first draft. RS wrote Textbox 1 and contributed to the review and editing of the manuscript. CG, AF, TS, VTT, PR, TB, and LH contributed to the writing and editing of the manuscript. GF designed the study, selected and analyzed the data, and contributed to the writing and editing of the manuscript. All authors agreed on the final version of the manuscript.

Abstract

Background: The emergence of genetic and genomic sequencing approaches for pediatric patients has raised questions about the genomic health literacy levels, attitudes toward receiving genomic information, and use of this information to inform treatment decisions by pediatric patients and their parents. However, the methods to educate pediatric patients and their parents about genomic concepts through digital health interventions have not been well-established.

Objective: The primary objective of this scoping review is to investigate the current levels of genomic health literacy and the attitudes toward receiving genomic information among pediatric patients and their parents. The secondary aim is to investigate patient education interventions that aim to measure and increase genomic health literacy among pediatric patients and their parents. The findings from this review will be used to inform future digital health interventions for patient education.

Methods: A scoping review using PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines and protocols was completed using the following databases: MEDLINE, Embase, CINAHL, and Scopus. Our search strategy included genomic information inclusive of all genetic and genomic terms, pediatrics, and patient education. Inclusion criteria included the following: the study included genetic, genomic, or a combination of genetic and genomic information; the study population was pediatric (children and adolescents <18 years) and parents of patients with pediatric illnesses or only parents of patients with pediatric illnesses; the study included an assessment of the knowledge, attitudes,

and intervention regarding genomic information; the study was conducted in the last 12 years between 2008 and 2020; and the study was in the English language. Descriptive data regarding study design, methodology, disease population, and key findings were extracted. All the findings were collated, categorized, and reported thematically.

Results: Of the 4618 studies, 14 studies (n=6, 43% qualitative, n=6, 43% mixed methods, and n=2, 14% quantitative) were included. Key findings were based on the following 6 themes: knowledge of genomic concepts, use of the internet and social media for genomic information, use of genomic information for decision-making, hopes and attitudes toward receiving genomic information, experiences with genetic counseling, and interventions to improve genomic knowledge.

Conclusions: This review identified that older age is related to the capacity of understanding genomic concepts, increased genomic health literacy levels, and the perceived ability to participate in decision-making related to genomic information. In addition, internet-searching plays a major role in obtaining genomic information and filling gaps in communication with health care providers. However, little is known about the capacity of pediatric patients and their parents to understand genomic information and make informed decisions based on the genomic information obtained. More research is required to inform digital health interventions and to leverage the leading best practices to educate these genomic concepts.

(J Med Internet Res 2021;23(12):e26684) doi:10.2196/26684

Introduction

Background

Recent scientific breakthroughs and technological advancements in personalized and precision medicine are changing the way we diagnose and treat diseases, leading to more precise, predictable, and powerful health care that is customized for the individual patient [1]. However, individualized diagnostic and treatment pathway development is expensive and introduces new aspects of patient engagement into the more traditional medical practice. Personalized and precision medicine and genome sequencing have gone hand in hand and become more widely available and incorporated into clinical pediatric and adolescent care, either in the context of routine patient care or research [2,3]. However, genetic counselors have indicated that they lack the relevant knowledge, confidence, and practical techniques to educate adolescents about genomic concepts [4]; some health professionals have also expressed uncertainty about the cognitive abilities of adolescents to understand genomic concepts [5].

Genomic health literacy is defined as the basic knowledge of genetic and genomic concepts and the capacity to obtain, process, understand, and use genomic information for health-related decision-making [6]. Studies have shown that children and adolescents have the desire to learn more about the genetic factors related to their illness and to be more involved in the decision-making process of their treatment [7-11]. Moreover, pediatric patients undergoing genomic sequencing and their parents have expressed the desire to learn about actionable genomic research results [12-14]. As such, the increasing number of clinical genetic tests, research endeavors that use exome and genome sequencing, and increasing professional opportunities in genomics (eg, bioinformatics and genetic counseling) for adolescents entering the workforce point to a need to develop educational material on genomics for young people [15]. A systematic review by McGill et al [7] found that although children and adolescents in the general community may have a basic understanding of genetic concepts such as inheritance, they generally lack a deeper knowledge of concepts related to genetics and genetic testing. Although a high level of genomic health literacy is unlikely in children and adolescents, it may be valuable for young people who are affected or at risk of genetic conditions to have a general understanding of genomic concepts [7].

Navigating through the transitional stages of childhood and adolescence with a genetic condition could lead to difficulties with autonomy, identity development, and self-esteem [16]. Moreover, results from genetic testing of a child may have implications for parents and other family members [17]. The American College of Medical Genetics and Genomics guidelines recommend that children as young as 8 years should be actively involved in the decision and interpretation of the clinical exome or genome sequencing process to the extent that they are considered cognitively capable, which includes the assent of the child whenever reasonable and respecting their preferences [18].

Research has highlighted both positive and negative implications for the psychological outcomes for those who undergo genetic testing [19], and the ethical implications for returning genetic information to children have been widely debated, especially in the context of informed consent for genetic and genomic testing [20]. This attention resonates with the presumptions that parents know what is in their children's best interest and that minors are unable to provide informed consent [20,21]. As children age, they gain decision-making capacity and an understanding of health conditions [20]. Therefore, including children and adolescents to various degrees as they age in health decisions related to genomic information is important yet challenging.

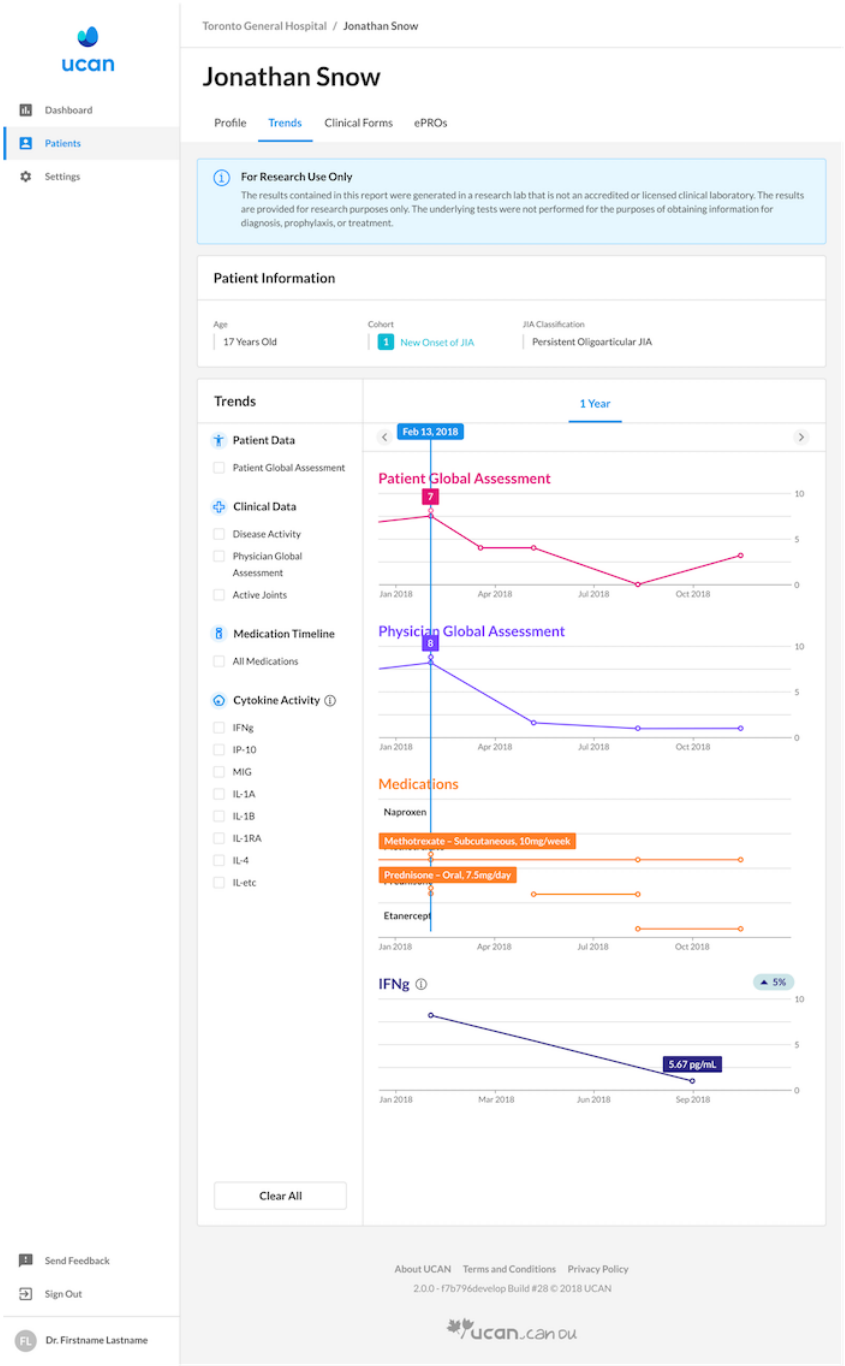
Goal of the Study

This review was conducted as formative research for the Understanding Childhood Arthritis Network (UCAN) team to inform the design of a digital health intervention: a genomics patient education feature for patients living with juvenile idiopathic arthritis (JIA). JIA is the most common childhood

chronic rheumatic disease and has a prevalence of 16-150 cases per 100,000 population [22] and can have a negative impact on the health-related aspects of quality of life [23]. Children and adolescents with JIA experience physical symptoms such as stiffness, fatigue, and sleep impairments; emotional symptoms such as stress, anxiety, and depression; and reduced social interactions [23]. As the etiology of JIA is unknown and is currently attributed to different genetic and environmental factors, a variety of pharmacological therapies are used to manage symptoms [24]. Biological disease-modifying antirheumatic therapies that target specific cytokines involved in the inflammatory cascade, such as tumor necrosis factor-α inhibitors, interleukin-1 inhibitors, and interleukin-6 inhibitors, have greatly changed the outcomes and morbidity associated with JIA but are associated with high costs [25,26] and safety concerns such as the risk of infection [25,26].

The ongoing UCAN study combines genomic discovery with patient-reported outcomes and health economic analyses to identify children at high risk of poor disease outcomes, define optimal ways to manage affected children, and develop a sustainable transdisciplinary network to improve the quality of life for all children with arthritis. One of the key features of the innovative UCAN platform is a novel genomics dashboard, which displays genomic information and trends in cytokine activity for patients. This tool acts as a visual aid for providers to discuss the severity of childhood arthritis with the patients with JIA and their parents and to identify the potential treatment targets based on the patient's genomic profile (Figure 1).

Figure 1. Understanding Childhood Arthritis Network platform genomics dashboard.



In studies such as UCAN, where genomic information is shared with patients, there is a need to educate patients and their parents by improving the levels of genomic health literacy; to foster a better understanding of the disease; for meaningful conversation; for decision-making for disease management; and to foster a better understanding of implications on treatment, outcomes, quality of life, and long-term consequences. Although numerous studies have explored genomic health literacy among adult populations [27-29] and interventions to improve patient genetic education [30], there is a general lack of research regarding how children and adolescents understand genetic illnesses [7] and genetic and genomic testing, how such information should be conveyed to them, and what factors may affect communication efficacy [8]. In addition, no studies have investigated genomic health literacy or tools to educate the patients with JIA and their parents about genomic concepts.

Objectives

We aim to perform a scoping review to identify and synthesize existing literature regarding the genomics health literacy levels and attitudes relative to receiving genomic information among pediatric patients and their parents to identify current practices and existing interventions that aim to improve genomic health literacy among pediatric patients and their parents. The term *genomics* is used as an umbrella term throughout the review as it encompasses the fields of genetic and genomic information; genomics describes the study of genes in their entirety, including their function, interaction, and environment and application of genome-based strategies [31]. Our research questions were intentionally broad to capture all the relevant literature relating to genomic health literacy and informational needs within pediatric patients:

- What are the genomic health literacy levels and attitudes toward receiving genomic information among pediatric patients and their parents?
- What interventions are known to educate pediatric patients and their parents about genomics to improve genomic health literacy levels and to facilitate a better understanding of their treatments?

Methods

Protocol and Registration

The protocol was not registered as scoping review protocols do not require registration. The scoping review methodology used was modeled based on the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) protocol [32]. This approach was used to study all the aspects of the topic, allow for a comprehensive exploration of patient knowledge and experiences, identify the existing literature relevant to the topics of interest, and identify gaps in the evidence.

Eligibility Criteria

Studies were included if they met all of the following eligibility criteria: the study included genetic, genomic, or a combination of genetic and genomic information; the study population was pediatric (children and adolescents <18 years) and parents of pediatric patients or only parents of pediatric patients; the study included an assessment of the knowledge, attitudes, and understanding of genomic information; the study was conducted in the last 12 years between January 2008 and September 2020; the study only included human participants; and the study was in the English language. The time frame of the past 12 years was selected to capture the most recent and emerging practices in the genomics field.

Information Sources

A formal electronic search and extraction was conducted between June 2020 and September 2020 on 4 electronic databases: MEDLINE, Embase, CINAHL, and Scopus. A gray literature search was also conducted on the following databases: Open Gray, CenterWatch, Cochrane Library, University of Toronto Libraries, TRIP database, ISRCTN registry, and advanced Google search.

Guidance and support from a faculty-affiliated librarian at the University of Toronto was received to formulate keywords and subject headings for the search strategy.

Search Strategy

The search strategy included 3 main concepts: pediatrics, patient education, and genomics. Textbox 1 displays the full electronic search strategy used for MEDLINE. Multimedia Appendix 1 outlines corresponding searches for all the databases used during the search process for this scoping review.

Selection of Sources of Evidence

Duplicates were removed electronically, and the titles and abstracts were screened by 2 reviewers (AG and MT). Related articles that were removed during the screening process were stored in a reference list for relevant studies. The full-text screening was conducted (by AG and MT), and any discrepancies and disagreements were resolved by discussion and consensus. The most common reasons for exclusion of articles were that they involved a nonpediatric population (eg, health practitioners and adult patients), did not convey any genetic or genomic information to patients, did not have human participants, were not in the English language, were conference abstracts, were not published between 2008 and 2020, and were focused on disease etiology rather than genetic or genomic information.

Data Items and Data Charting Process

To chart and extract data from the articles selected for the scoping review, an extraction criterion was developed by 2 reviewers (AG and MT) to extract information from each publication about the study country, city, urban or not urban geography, population, sample size, age of participants, pediatric disease types, duration, demographic information, design, methodology, journal of publication, and results of the study (Multimedia Appendix 2 [3,12,16,33-43]).

Synthesis of Results

A thematic analysis of the nature and content of the articles was conducted to identify the common and recurring themes, topics, ideas, and patterns and to categorize the articles [44]. Both reviewers examined the data produced from charting and data extraction and identified the key codes relating to the research questions. The codes were used to summarize and report studies according to their main findings. A total of 6 major themes were identified during the thematic analysis: *knowledge of genomic concepts*, *use of the internet and social media for genomic information*, *use of genomic information for decision-making*, *hopes and attitudes toward receiving genomic information and support*, *experiences with genetic counseling*, *and interventions to improve knowledge of genomics.*

Screening Process

A total of 4583 articles were identified from 4 electronic databases listed, and 35 articles were identified from a gray literature search. After the removal of 540 sets of duplicates, the remaining 3349 articles were screened according to the

eligibility criteria. After the title and abstract screening stages, 41 articles were included in the full-text review and 27 articles were excluded owing to the reasons outlined in Multimedia Appendix 3. In total, 14 studies were included in the scoping review.

Overview of the Included Studies

Of the 14 studies, 5 (36%) studies included populations where children were clinically diagnosed with various genetic conditions [16,33-36]; 4 (29%) studies had populations that were not diagnosed with an illness [12,37-39]; 1 (7%) study included children who were suspected to have a genetic condition but not diagnosed [40]; 1 (7%) study included children who were hospitalized for various reasons [3]; and the remaining 3 (21%) studies reported pediatric populations with illnesses such as cancer [41], congenital heart defects [42], and congenital lower limb deficiencies [43]. Most (11/14, 79%) of the studies selected for the review were from the United States [3,12,33-36,38-42], 14% (2/14) from Canada [16,43] and 7% (1/14) from the United Kingdom [37]. Table 1 presents the overview of the included studies.

Table 1. Overview of the studies included in the scoping review (N=14).

Theme and study	Population	Samples, n	Study design	Aims of the research
Knowledge of genomic concepts				
Fitzgerald-Butt et al [42]	Parents of children with LVOT[a]	287	Quantitative	To examine the genetic knowledge and attitudes toward genetic testing of parents of children with heart defects affecting the LVOT
Gallo et al [34]	Parents in families in which the child has a single gene condition	142	Mixed methods	To identify unique patterns of information management and to explore the relationship between these patterns and individual and family characteristics and functioning
Lewis et al [37]	Children	539	Quantitative	To develop and validate a robust kids-KOGS[b] suitable for use in the pediatric setting and for general public education
Rew et al [39]	Parents and adolescents	33 (22 adolescents and 11 parents)	Qualitative	To determine the levels of knowledge about genetics and approaches to decision-making related to genetic testing among adolescents and parents
Use of the internet and social media for genomic information				
Barton et al [33]	Parents of children (<18 years) who underwent genetic testing	20	Qualitative	To analyze parent views about the use of the internet and social media for informational and emotional support needs at different stages of their child's genetic testing process
Roche et al [35]	Parents of children referred for genetic services	100	Qualitative	To investigate how parents of a child referred for genetic services search the internet for information before and after referral to a university pediatric genetics clinic, interpret and evaluate the information they obtained, and identify barriers that they encountered
Schaffer et al [36]	Mothers of children with genetic disorders	100	Qualitative	To investigate how mothers of children with genetic disorders use the internet to interpret, produce, and circulate genetic knowledge pertaining to their child's condition; come to value their own experiential knowledge; and help shift the boundaries of what is considered as authoritative knowledge
Use of genomics information for decision-making				
McGowan et al [12]	Parents and adolescents (aged 13-18 years)	33 (15 adolescents and 18 parents)	Qualitative	To investigate decision preferences about values and involvement in choices of genomic sequencing results and to inform and guide practices of genomic researchers working with adolescents
Myers et al [38]	Parents and adolescents (aged 13-17 years)	326 (163 dyads)	Mixed methods	To examine decisions about learning genomic research results for the adolescents and whether choices were associated with demographic factors
Hopes and attitudes toward receiving information and support				
Campbell et al [43]	Parents of children with CLD[c]	25	Mixed methods	To collect data on Canadian pediatric patients affected by CLD followed to determine emotional supports, communication information, and implementation of genetics referrals

Theme and study	Population	Samples, n	Study design	Aims of the research
Khan et al [40]	Adults and parents of children with a suspected genetic condition	270, (191 adults and 79 parents)	Mixed methods	To investigate motivation and perceived resources to predict the amount and kinds of information that adult patients and parents of pediatric patients hoped to receive from diagnostic sequencing results
Experiences with genetic counseling				
Pichini et al [16]	Adolescents	11	Qualitative	To investigate the experiences and perspectives with respect to genetic counseling interactions and to understand adolescent-specific issues to better educate and support this population of patients
Interventions to improve knowledge of genomics				
Johnson et al [41]	Parents of children enrolled in the Genomes for Kids program; patients with cancer	121	Mixed methods	To determine whether a 2-step consent using a structured communication model would improve knowledge and understanding of key genetic concepts
Newcomb et al [3]	Children (aged 5-10 years) and parents	52 (26 children and 26 parents)	Mixed methods	To determine whether an original children's book contributes to learning about the meaning of the terms *DNA* and *gene* in a sample of school-age children and whether experiencing the book with a pediatric nurse results in a better understanding of basic concepts than experiencing the book with a parent

[a]LVOT: left ventricular outflow tract.

[b]A 10-item knowledge of genome sequencing measure for young people.

[c]CLD: congenital limb deficiency.

Results of the Review

Knowledge of Genomic Concepts

Of the 14 studies, 4 (29%) studies investigated the knowledge and understanding of genetic concepts among pediatric patients or parents of pediatric patients [34,37,39,42]. These studies found varying results among participants of different age groups regarding the knowledge and understanding of genetic concepts including DNA, genome, genetic and environmental factors, the human genome project, and the sharing of genetic information.

Lewis et al [37] found that among school children between the ages of 11 and 15 years completing a 10-item kids-knowledge of genome sequencing measure for young people, the mean score was 4.24 (SD 2.49), on a scale where 0=low knowledge and 10=high knowledge. Age was also positively associated with the score in multivariate linear regression and the mean kids-knowledge of genome sequencing score was higher among girls than boys (4.44 vs 4.09, respectively; t_{535}=1.61; P<.001). The most frequent correctly answered questions by children were related to DNA, such as *Our DNA is inside our cells* and *Our DNA doesn't have an effect on how our body works* and the most frequent incorrectly answered questions were related to the genome, such as *Around 1% of our genome is the same as other people's* and *Our complete set of DNA is called our genome*.

Fitzgerald-Butt et al [42] tested genetic knowledge using a modified 18-item true or false instrument among parents of children with congenital heart defects and found that the mean genetic knowledge summary score was 73.8% correct. The most frequent correctly answered items were related to the interaction of genetic and environmental factors, such as *some diseases are caused by genes, environment, and lifestyle* (true; 97.2% correct) and *genes determine traits such as height, eye color and facial appearance* (true; 97.8% correct). The questions that the participants had the most difficulty with were related to basic genetic knowledge, such as identifying that *humans have 20 pairs of chromosomes* (false; 28% correct) and *parents pass both copies of each chromosome to their child* (false; 36.5% correct) are both false statements. Furthermore, educational attainment and household income were directly and significantly associated with genetic knowledge (P<.001).

Among parents and adolescents, Rew et al [39] found that although most participants had heard of genetic testing, the knowledge about the human genome project was generally lacking and inaccurate among younger adolescents (14-17 years), whereas older adolescents (18-21 years) demonstrated a better knowledge and accurate understanding of the human genome project. Most participants listed the internet and physicians as the sources of additional genetic information, and few participants listed books, articles, testing sites, teachers, and professional organizations as their sources.

Gallo et al [34] identified 4 unique information management patterns among parents of children (3-15 years) who have a single gene condition: *accurate understanding–open pattern* (30/86, 35%), *accurate understanding–selective pattern* (21/86, 24%), *discrepant understanding pattern* (13/86, 15%), and *confused understanding pattern* (22/86, 26%). In the accurate understanding–open and accurate understanding–selective (51/86, 59%) patterns, the parents had an accurate understanding of genetic concepts and were differentiated from one another based on their views about sharing information. The participants in the accurate understanding–open group actively sought information about conditions in addition to the information received from the health care providers (HCPs) and were open to sharing information about the child's condition. On the other hand, participants in the accurate understanding–selective group struggled with sharing information about the child's condition. In the discrepant understanding group, the parents within a family differed in the accuracy of their understanding of the genetic aspects of the condition and varied in their beliefs about seeking and sharing information. In the confused understanding group, the parents generally had an inaccurate understanding of one or more of the genetic aspects of the condition and some felt that they were unable to share information with others owing to a lack of understanding.

Use of Internet and Social Media for Genomic Information

Of the 14 studies, 3 (21%) studies investigated how parents of children with genetic disorders or children referred for genomic services searched the internet for information and emotional support about their child's condition [33,35,36]. Barton et al [33] interviewed the parents of children who underwent genetic testing for clinical care, Roche et al [35] interviewed parents of children referred for genetic services, and Schaffer et al [36] interviewed mothers of children with genetic disorders.

Barton et al [33] reported that at each stage of the genetic testing process (ie, before testing, pending results, and after results), informational and support needs of the parents were different. Before testing, many parents had little knowledge of genetic testing or conditions; some parents said that knowledge of genetic conditions and testing was restricted to Down syndrome. The internet was used to explore the possible diagnoses or explanations for their child's symptoms or challenges before testing, information about the genetic process during testing, and information about their child's new diagnosis and possible treatments after testing [33].

All 3 studies found that parents search the internet to learn about the child's condition, locate services for treatment, and find emotional support [33,35,36]. For example, Facebook groups [33], personal web pages, listservs, and chat rooms hosted by parent support groups [36] were mentioned as important resources to find support networks of families with similar experiences. Parents also found that searching using symptoms or diagnostic terms on widely available search engines such as Google or Yahoo or other websites sponsored by large health or advocacy groups (American Medical Association, Web MD, National Organization for Rare Disorders) played a key role in web-based searches [35]. Other targets for parents' searches included preparing for the visit, learning about genetic testing options, diagnostic and prognostic information, management and treatment, finding clinical trials, and reading about research advances [33,35,36].

Roche et al [35] reported that the advantages of using the internet for information included convenience, feeling that clinicians were taking the parents more seriously, privacy, and the ability to find previously unobtainable information. In addition, Schaffer et al [36] reported that internet-searching allowed parents to gain traditional forms of scientific literacy, confidence in communicating with clinicians, and a sense of authority over genetic knowledge. Barriers to using the internet for information included emotional distress, unavailability of valid diagnosis to search for, discouragement from providers, misinformation, false hope, anxiety, concerns about the child's privacy [33], keywords for searches, relevancy, and difficulty in remembering or spelling the diagnosis [35].

Use of Genomics Information for Decision-making

Of the 14 studies, 3 (21%) studies explored parents' and adolescents' preferences in decision-making in relation to genomic sequencing results [12,38,39]. These studies reported mixed feelings about receiving genomic results; some participants felt that it may be burdensome or raise privacy concerns [12], whereas others felt that it would help with future planning [12,38]. Myers et al [38] found that adolescents, in particular, expressed a desire to receive genomic information. However, adolescents were significantly less likely than parents to learn all results and that carrier status was the most frequent category that adolescents chose to learn about followed by adult-onset conditions, preventable conditions, and treatable conditions.

McGowan et al [12] found mixed perceptions among the participants regarding the adolescents' capacity to participate in decision-making regarding genetic results [12]. In general, the participants agreed that participation in decision-making about the return of genomic research results should depend on age, maturity, and personality of the adolescent [12]. Regarding collaborative decision-making, parents felt that they should have the final say in decision-making about the return of genomic results. However, many adolescents felt that their decisional preferences would differ from their parents and that a collaborative decision-making model involving a health care representative could serve as an advocate for adolescents' preferences.

Rew et al [39] found that when asked to make decisions about genetic testing, the mean age that young adolescents (aged 14-17 years) suggested was 16.6 years, whereas older adolescents (aged 18-21 years) suggested a higher mean age of 18.25 years. Almost half (45.5%) of the young adolescents also said that their parents would be their main source of information and advice related to decision-making regarding genetic testing.

Hopes and Attitudes Toward Receiving Genomic Information and Support

Of the 14 studies, 2 (14%) studies explored the hopes and attitudes toward receiving genomic information and support among parents of pediatric patients [40,43]. Khan et al [40]

investigated the types of information used by adult patients and parents of pediatric patients who have a suspected genetic condition that has not been definitively explained or diagnosed. Campbell et al [43] explored the emotional supports, communication information, and implementation of genetic referrals among parents of children with congenital heart defects. Khan et al [40] found that the most common kinds of information that parents hoped to learn from diagnostic sequencing were the cause of illness (119/269, 44.2%), directions for illness management (98/269, 36.4%), diagnosis (72/269, 26.8%), disease risk for family members (62/269, 23%), helping others (31/269, 11.5%), advancing science (16/269, 5.9%), miscellaneous knowledge (14/269, 5.2%), prevention (8/269, 3%), and family planning (5/269, 1.9%).

Campbell et al [43] found that 16.7% of parents reported they were very satisfied, 33.3% were satisfied, 25% felt neutral, and 25% felt dissatisfied with the emotional support they received from their HCPs. Moreover, 80% of parents did not recall being referred to a support group by their HCP. When asked whether their child had been given a specific diagnosis, 48% of parents could not correctly recall their child's specific diagnosis and 72% of parental classifications did not correspond to specific clinical classifications. In total, 56% of parents also reported that they sought additional information resources after talking to their HCP.

Experiences With Genetic Counseling

Of the 14 studies, 1 (7%) study investigated the experiences of genetic counseling for adolescents with a genetic condition [16]. The 3 main themes that emerged during interviews were understanding the genetic counselor's role, increasing perceived personal control, and adolescent-specific factors influencing adaptation to one's condition. The participants generally felt that they had a better understanding of what genetic counseling entailed and the distinct differences of a genetic counselor's role from other HCPs after the session. This was owing to the discussion of biological pathways, inheritance and recurrence risk for future children, and preparation for the future during the session. In addition, all the participants felt that learning about genetics, inheritance, and origins of the condition was an important outcome of the genetic counseling session. In addition, genetic counseling helped the participants to contextualize the condition as part of their identity, receive anticipatory guidance about the future, and feel a higher sense of ownership and control over their health.

The main adolescent-specific factors that were reported to influence adaptation to one's genetic condition were isolation, social connectedness, independence and privacy, and the timing of genetic counseling [16]. Adolescents noted feeling isolated as a result of their condition and being treated differently to others. In addition, the adolescents' perspectives about their condition were influenced by social connectedness with family, peer groups, and the larger community of other individuals with the same condition. As such, the participants expressed a desire to fit in and be perceived as *normal* by their friends. Although adolescents sought social connectedness, they expressed a need for independence and privacy, particularly within the family construct. Finally, the participants stated that they felt a greater sense of stability during the middle school to high school period than during the elementary school period and felt that it was a more appropriate timing for genetic counseling.

When asked about the tools and strategies for genetic counseling practice, the participants suggested using video clips and animations on a computer or tablet to describe the inheritance or biological processes, the normalization of their condition, and the ability to choose whether parents are present for all or a part of the session. In addition, the adolescents suggested that the genetic counselor could assist them with identifying reliable resources to gather information about their condition, support groups, and a postsession letter highlighting the key points relevant to them.

Interventions to Improve the Knowledge of Genomics

Of the 14 studies, 2 (14%) studies investigated the impact of interventions in improving the knowledge and understanding of genetic concepts [3,41]. The results of these 2 studies are presented in Table 2. Both studies used the Genetic Knowledge Index (GKI) developed to assess lay knowledge of genetic concepts among a general population not known to be at risk for genetic disease and not exposed to genetic counseling or research involving genomics, to test the understanding of genetic concepts among participants [45].

Table 2. Overview of studies that investigated the impact of interventions on improving the knowledge and understanding of genetic concepts.

Study	Aims of the research	Pretest results	Posttest results
Newcomb et al [3]	Whether an original children's book called "What DNA Does," designed as a visual aid to assist in the assent process for children enrolling in genetic testing research, could increase the child's and parent's understanding about "DNA" and "genes" and whether children reading the book with a pediatric nurse would result in a better understanding of genetic concepts than reading the book with a parent.	• Median GKI[a] score was 4 (0=all incorrect and 5=all correct), with 54% of respondents making only 1 incorrect response; most difficult item: "Racial differences in academic ability are caused by genetics." • Both parents' and child's understanding of the terms was minimal before reading the book; no participants mentioned learning about genetics or DNA in school. • A total of 65% (17/26) of parent respondents said they did not know what DNA was or stated vague or inaccurate definitions. • None of the child respondents was able to explain DNA in simple terms, although some were able to repeat phrases they had heard. • The primary recurring theme in the conversations about DNA before reading the book was "blood"; both children and parents expressed the idea that DNA is somehow closely related to or is a part of blood and that blood has something to do with human identity.	• GKI was not completed after the test. • After reading the book, most children had more articulate and accurate understandings of "DNA," but no better understanding of its function; 2 children were more confused after reading than before. • Children who read the book with a nurse had a better understanding of DNA's function than those who read it with a parent. • Increased accuracy of describing the meanings of DNA and gene was demonstrated by all the participants in the nurse–child–parent reading group and in two-third of the children in the parent–child reading group.
Johnson et al [41]	Whether a 2-step consent using a structured communication model would improve the knowledge and understanding of key genetic concepts among parents of children with cancer. The model involved a single study nurse who approached and obtained consents from the families with a standardized script, an informational cover sheet, and baseline pretest responses to educate parents on genetic concepts during the study introductory visit. At the subsequent informed consent visit, the nurse used a checklist and an informed consent document to review and reinforce concepts.	• More than 85% of the parents identified correct answers to 4 of 11 genetic concepts; most knew that "genes are made of DNA," "genetic risk is the chance of having an inherited (passed down) disease or disorder," "healthy parents can have a child with an inherited disease," and "genomic testing of your child's tumor and healthy tissue may teach you things about (multiple choice responses).". • Baseline understanding of differences between somatic and germline mutations was poor; 31% of parents answered correctly, "nontumor (germline) mutations are in every cell of your body," and 18% answered correctly, "tumor (somatic) mutations are only found in cancer cells."	• After completion of the 2-visit intervention, correct responses increased significantly for 9 of 11 genetic concepts and overall genetic knowledge; the median percentage of total correct answers improved from 77.8% to 88.9%. • The rate of understanding that somatic mutations are only found in cancer cells increased from 18% to 59% and understanding that germline mutations are found in every cell of the body went from 31% to 64%. • No association was detected between the change in the overall percentage of correct answers and parental numeracy, literacy, or sociodemographic factors.

[a]GKI: Genetic Knowledge Index.

Discussion

Principal Findings

This review reveals important information regarding the current genomic health literacy levels among pediatric populations and the attitudes they hold toward receiving genomic information and decision-making. The findings from this review are valuable in informing the design of digital health platforms, such as the UCAN genomics education platform, that aims to educate young patients with JIA about genomic concepts. We found that age is associated with increased genomic health literacy levels and increased perceived capacity to participate in decision-making regarding genomic information. It was also found that internet-searching is valued by young people and parents for information on diagnoses and symptom management and to fill critical gaps in communication with their HCPs. In addition, we found that adolescents found key differences in receiving genomic information from genetic counselors, compared with HCPs, which helped them contextualize their condition as a part of their identity.

Patient education regarding genomics is an emerging area of research and nearly half of the selected studies describe the goal of assessing genetic or genomic knowledge among the participants. The studies in this review found that genomic

health literacy is generally low among patients with genetic conditions and their parents. Several studies in our review found that age plays a significant role in young people's understanding of genetics [16,37,39] and their decision-making capabilities [12,38]. These findings might reflect the general teaching practices in the United States, Canada, and the United Kingdom, where genetic concepts, such as genetics, inheritance, and DNA, are formally introduced to students during the high school period (15-16 years) [46-48]. A study by Dougherty et al [46] assessing grade 12 students' understanding of essential genetic concepts across the United States, using core concepts developed by the American Society of Human Genetics as normative benchmarks, found that the states' understanding of genetic concepts was generally poor, with more than 85% of the states receiving overall scores of *inadequate*. A total of 14% (2/14) of studies in our review evaluated the change in understanding and knowledge of genetic concepts using the GKI among the participants [3,41]. These studies found that the oral presentation of information combined with a visual aid such as a brochure [41] or a children's book [3] improved understanding among participants. Both studies also indicated that the presence of a nurse to explain genetic information was beneficial in guiding knowledge acquisition among both children and parents. Although both interventions reported an improvement in genetic literacy after the intervention compared with before the intervention, the understanding of some genetic concepts such as the difference between somatic and germline mutations [41] and DNA functionality [3] remained suboptimal after the intervention. Owing to the complex nature of genetic concepts and the general difficulty that children face in understanding the functionality of genes, genetics [3,37], and whole-genome sequencing [39], it may be valuable to limit patient education to high-level information about genomics, genetics, and how they relate to the patient's disease.

Numerous studies highlighted the importance of internet-searching and seeking emotional support on the web among parents of children with genetic illnesses [33,35,36,39,45]. In general, searching the internet was reported as a key step in knowledge acquisition, improving understanding, and finding treatment options and to fill the gap of social support by finding networks of families with similar experiences. These findings are consistent with research on patients with JIA, who have listed the internet as a source for general information on JIA and emotional support [49,50]. Studies also reported that having a diagnosis played a key role in internet-searching; other research in children undergoing exome sequencing has found that families place significant value on receiving a timely diagnosis, information, and knowledge for rare illnesses [14,51]. The internet has drastically increased parents' access to the previously privileged health information, potentially changing their expectations and affecting their relationships with HCPs [36,52-54].

eHealth users list the internet as a source of health information but may not always feel comfortable sharing this information with their child's physician; a study by Tuffrey and Finlay [55] found that 84% of parents who used the internet before a pediatric visit evaluated the information they obtained as useful but only a small proportion of these parents discuss what they found on the internet with their child's physician. Similarly, several studies in this review reported that parents generally felt dissatisfied with the information they received from their health care practitioners [43], received discouragement from providers to search the internet for information, [33] or felt uncomfortable sharing the information they found on the internet with their physicians [35]. In addition, parents expressed the need for receiving more information from their HCPs and sought additional resources after talking to their HCPs. These findings are similar to the research with patients with JIA; a study by van Dijkhuizen et al [56] found that patients with JIA were most dissatisfied with the low rates of referrals and the information about immunizations, research, and existence of transition of care clinics. It is evident that eHealth resources play a large role in knowledge acquisition for parents of pediatric patients. Future research should aim to find strategies to improve knowledge-sharing among HCPs, patients, and parents; decrease the discouragement of internet-searching from providers; and guide parents toward reliable and credible internet resources for information and emotional support.

Similar to the studies that highlighted the differences in the knowledge of genomic concepts among young children, adolescents, and parents, several studies highlighted the importance of age in decision-making and the preferences related to genetic information [12,38,39]. Although most adolescents wished to be involved in the decision-making process, parents expressed concerns regarding their child's privacy and capacity to understand genetic information. In general, most participants preferred a shared decision-making model involving the child, parents, and health care practitioners. Several studies exploring decision-making views among patients with chronic illnesses have also reported that a shared decision-making model is preferred by adolescents and their parents [46-48]. In particular, research in the population with JIA has shown that adolescents wish to be a part of the decision-making process and that the parents and providers play a key role in involving children in decision-making and educating them about their disease [57,58].

Research regarding the psychological impact of returning genetic information to children has shown mixed results. A review by Wakefield et al [59] found that serious adverse psychological outcomes such as anxiety, depression, and distress from receiving genetic information were uncommon among children; however, some children experienced interfamilial distress, discrimination, and regret. Research has also shown that receiving genetic information during childhood may allow for early psychological adjustment and the ability to share information with other family members [60]. More research is required to assess the psychological impact and ethical implications of returning genetic information to children, especially for conditions that may not be treatable or modifiable [59]. Therefore, although adolescents prefer to be involved in the decision-making process, a shared decision-making model involving the adolescent, parents, and HCPs may be best suited for decision-making involving the return of genetic information for adolescents with genetic illnesses.

Although only 7% (1/14) of studies explored adolescents' experiences with genetic counseling [16], it presents important

implications for sharing genomic information with young adolescents. Adolescents reported key differences in their experiences talking to a genetic counselor compared with an HCP and felt that learning about genetics, inheritance, and origins of the condition helped them contextualize their condition as a part of their identity and helped them understand their disease. Interestingly, the participants also suggested using videos to describe genomic concepts; a study by Sabatello et al [15] also found that a video format was more effective in increasing self-reported genomic knowledge compared with a pamphlet format. Similar to our findings in the knowledge and decision-making categories, the participants reiterated that age was an important factor in their understanding of genetic information and that high school was a more appropriate period to receive genetic counseling compared with elementary school. However, it is important to consider that 1 study is not representative of the general attitudes that adolescents have toward genetic counseling and more research must be done in the field of genetic counseling and patient education among children and adolescents.

Although the primary purpose of our research was to investigate the knowledge of genomic concepts, in particular, most results from our search returned studies focused on genetic testing, perhaps owing to the novelty of the field of genomic education among pediatric populations. We leveraged a broad search strategy to encompass findings from various fields of genomics health literacy and patient education, which can be leveraged to inform the design of digital health interventions for genomics education. In addition to conducting formative research for the UCAN study, The Centre for Global eHealth Innovation at the University Health Network has developed and conducted usability studies for multiple patient-centric digital applications that aid in the self-management of chronic diseases such as diabetes [61], asthma [62], arthritis [63], prostate cancer [64], and heart failure [65]. The overarching theme among these studies has been to find strategies to engage and educate patients about their chronic illness to facilitate informed decision-making and disease self-management. Thus, the following findings (in no particular order) presented in Textbox 2 could be considered for developing design principles for digital health interventions.

Textbox 2. Key findings for informing the design of patient education digital health interventions.

Key findings

- Providing the patients and parents a high-level overview of genomic concepts relevant to their condition, supplemented by an overview of genetics if applicable to the patient.
- Curating and separating educational content for different age groups (young children, adolescents, and parents) based on their differing capacity to understand genomic information.
- Using visual aids such as illustrations and videos to facilitate engagement.
- Testing the understanding of genomic and genetic concepts without creating the pressure of a test environment, for example, by leveraging quizzes such as the Genetic Knowledge Index before and after providing the patient and parents with educational materials or through a deeper discussion among patients, parents, health care providers or nurses to evaluate the understanding of genomic and genetic concepts.
- Providing a repository of credible and reliable web resources for patients and their parents to seek information relevant to their condition and to seek emotional support in the community.

Most studies in this review were qualitative or mixed methods studies and used methods such as interviews or surveys to gather data from patients, which likely reflects the state of science in pediatric populations and, for most genetic illnesses, remains at the purely exploratory or descriptive level at this time. A limitation of our study is that our understanding of patient education interventions is still limited as only 14% (2/14) of studies leveraged an intervention design to evaluate the change in genetic knowledge of the participants [3,41]. A key limitation of the intervention by Newcomb et al [3] was that the participants were not asked to complete the GKI questionnaire after the test and the understanding of concepts such as *DNA* and *genes* was assessed qualitatively among the participants, which may have led to subjectivity and bias in reporting of posttest results. Another limitation was that the study by Johnson et al [41] investigated learning in parents with a mean age of 37.5 years. Thus, the findings from the study by Johnson et al [41] may not be applicable to inform the design of patient education interventions for children. More research that incorporates intervention methodology to evaluate participants' genomic health literacy levels and attitudes is required to evaluate the best tools for improving genomic literacy in children.

Another limitation of our review is that 29% (4/14) of the included studies investigated the understanding of genetic concepts among populations that do not have any specified disease [12,37-39]. Although it is valuable to gauge the level of genetic knowledge and understanding in the general public, the knowledge and attitudes toward receiving and seeking genomic information may be very different for families in which a family member has a medical condition compared with populations that are not diagnosed with a genetic condition. Moreover, of the 14 studies, 8 (57%) included parent study populations and only 6 (43%) included child and adolescent populations, which may be because of the ethical barriers that currently exist in returning genetic information to children or evaluating their role in genetic decision-making [20,21].

In addition, a key consideration is that we used a broad definition for the terms *genetic* and *genomic* information for the inclusion criteria, which align with the definition of genomic health literacy: "basic knowledge of genetic and genomic concepts and the capacity to obtain, process, understand, and use genomic information for health-related decision-making" [6]. The rationale behind using a broad definition and including study populations with a broad range of genetic and genomic

illnesses was to capture a diverse range of ongoing initiatives that aim to improve genomic health literacy. However, the key findings to curate design principles for digital health interventions are considerations to create digital health interventions for all pediatric populations with genetic conditions and not specific to a singular genetic illness.

Furthermore, the inclusion criteria were limited to studies from the past 12 years to capture lead practices and emerging trends in digital health interventions and genomics. However, a larger sample of relevant studies on patient education and genomic health literacy may have been captured if studies older than 12 years were also included.

Moreover, the ability to cross-culturally compare the knowledge and understanding of genetic concepts was limited because most of the studies were conducted in the United States and only studies published in English were included in this review. This may have also led to bias when reporting results of genomic knowledge among children and their parents as educational systems vary across different countries.

Conclusions

Our review indicates that although pediatric patients and their parents have a positive attitude toward learning genomic information, we still have little knowledge about the genomic health literacy levels among children and adolescents, their capacity to understand genomic concepts, how this information can be presented, and what best practices can be leveraged to design digital health patient education interventions for genomic education. The rise of the personalized and precision medicine approach demands more patient and parent engagement, and it is the medical world's mandate to develop tools that improve patient education on disease knowledge and genomic factors involved. Thus, there is a need for studies that examine the genomic health literacy and modalities to inform the design of digital interventions that aim to educate adolescents and children with pediatric illnesses about genomics.

Abstract

Background: The importance of effective communication during public health emergencies has been highlighted by the World Health Organization, and it has published guidelines for effective communication in such situations. With video being a popular medium, video communication has been a growing area of study over the past decades and is increasingly used across different sectors and disciplines, including health. Health-related video communication gained momentum during the SARS-CoV-2 pandemic, and video was among the most frequently used modes of communication worldwide. However, although much research has been done regarding different characteristics of video content (the message) and its delivery (the messenger), there is a lack of knowledge about the role played by the characteristics of the recipients for the creation of effective communication.

Objective: The aim of this review is to identify how health video communication outcomes are shaped by recipient characteristics, as such characteristics might affect the effectiveness of communication. The main research question of the study is as follows: do the characteristics of the recipients of health videos affect the outcomes of the communication?

Methods: A scoping review describing the existing knowledge within the field was conducted. We searched for literature in 3 databases (PubMed, Scopus, and Embase) and defined eligibility criteria based on the relevance to the research question. Recipient characteristics and health video communication outcomes were identified and classified.

Results: Of the 1040 documents initially identified, 128 (12.31%) met the criteria for full-text assessment, and 39 (3.75%) met the inclusion criteria. The included studies reported 56 recipient characteristics and 42 communication outcomes. The reported associations between characteristics and outcomes were identified, and the potential research opportunities were discussed. Contributions were made to theory development by amending the existing framework of the Integrated-Change model, which is an integrated model of motivational and behavioral change.

Conclusions: Although several recipient characteristics and health video communication outcomes were identified, there is a lack of robust empirical evidence on the association between them. Further research is needed to understand how the preceding characteristics of the recipients might affect the various outcomes of health video communication.

Introduction

Communication in Public Health Emergencies

Effective communication in public health emergencies is crucial, as people need to not only know but hopefully also understand the health risks they face and what actions they can take to protect themselves, their close ones, and the society from health hazards. The importance of communication in public health emergencies has been highlighted by the World Health Organization in the guidelines for risk communication in public health emergencies policy and practice [1]. The guidelines reflect the complexity of the topic, as several dimensions prove to determine the effectiveness of communication and must therefore be taken into consideration. Dimensions include information accuracy, timeliness and frequency of communication, clarity of language, use of appropriate media channels, building trust with local communities, the use of visuals in combination with—or instead of—text, and the use of new communication channels such as social media. Adding to the complexity, multimedia approaches have been found to be more effective than single media approaches [2].

In recent years, video communication has received increased attention across multiple fields, from education to science, risk, and health communication. Video allows rapid communication, is flexible and able to incorporate empathy, and has good outreach potential. Video communication gained further momentum during the COVID-19 pandemic, and most of the communication aimed at the population was through video. The effectiveness of delivering education through video has been widely investigated even before 2019 [3-7]; however, the COVID-19 pandemic has magnified and speeded up its adoption, and consequently, we can see increased research efforts in the area of effective communication using video [8-14].

Health Communication

Health communication, which is defined as the dissemination and interpretation of health-related messages [15], is a well-established research area, with >300,000 search results in Google Scholar. A total of 4 elements have emerged from this extensive body of literature. The first element is the pervasive effort of theorizing health communication and putting it into practice [16-21]. The second element is the importance of cultural context for the planning and effectiveness of health communication interventions. On the one hand, different cultures require different health communication strategies [22,23]; however, within the same cultural context, different population groups need diversified communications to ensure effectiveness [24-26]. Thus, international literature often mentions the terms *tailored* and *targeted* health communication strategies designed to enhance the relevance of health information to a given audience [27,28]. The third element is empirical evidence concerning the effectiveness of health communication in achieving behavioral change or other public health goals (eg, the eradication of polio and other immunization coverage interventions) [29-32]. The fourth element is the challenge of reshaping and adapting health communication to reflect technological developments and societal changes. Indeed, the web-based environment, social media, advancements in artificial intelligence, and developments of health care (eg, eHealth and telemedicine) pose a challenge to health communication in the information age [33-37]. Furthermore, societies—especially those with universal health care systems—are called to tackle the health inequalities arising from technological advancements. Health communication must consider the digital divide and the different digital health literacies of the population to be effective [38]. This can be extremely relevant during pandemics, as, in the case of the COVID-19 pandemic, the groups affected by the digital divide and generally having less digital health literacy were the most affected [39-41].

Although much research has been conducted on video communication itself, there is less evidence regarding whether the outcomes (eg, knowledge, attitudes, compliance, and behavior) of health video communication are affected by the various characteristics (eg, sociodemographic, personality and values, and environmental factors) of the *recipients* of this communication. Health video communication refers to communicating health information through video format regardless of style (eg, animation, text over image, interviews, and voice over image). Health communication is multifaceted and variably affected by the messenger, message attributes, and recipient characteristics (eg, sociodemographic, personality and values, and environmental factors). This study aims to address this gap by identifying the relevant recipient characteristics and health video communication outcomes reported in the literature and the relationship between them. In this review, the concept of health video communication does not refer solely to public health communication videos but rather to health videos in general, including instructional videos for patient training and education, videos from public health prevention campaigns, and in-hospital informational videos.

A Health Communication Framework

For this study, we chose the Integrated-Change (I-Change) model (Figure 1) developed by Hein de Vries [42] as the study's theoretical framework. As the driving research question is to identify recipient characteristics, outcomes of health video communication, and any relationship between them, the I-Change model fits the research question and the methodological approach of this study. Moreover, the categorization presented in the model is useful for discussing results and understanding the current state of knowledge and research practice. The I-Change model is an integrated model of motivational and behavioral change that combines elements from the theory of planned behavior [43], the social cognitive theory [44], the Transtheoretical Model of Health Behavior Change [45], the Health Belief Model [46,47], and the goal-setting theory [48,49]. The integration of these elements into a single health communication framework has made the adoption of the I-Change model appropriate as a basis for this study. The model states that both covert (hidden and not observable) and overt (visible and observable) behavior is determined by a person's motivation or intention. In turn, motivation depends on attitudes, social influences, and self-efficacy. Attitudes are defined as the perceived cognitive and emotional advantages and disadvantages of a person's behavior. A person's social influences comprise social modeling (the perception of others having this behavior), social norms

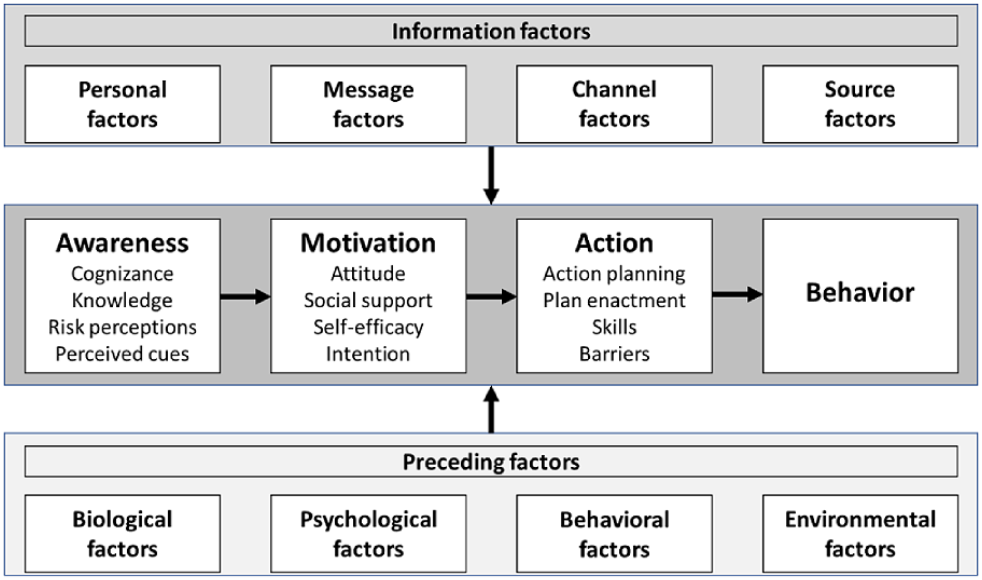
(the norms that people have regarding this behavior), and social support received from others when performing the behavior. Self-efficacy refers to the personal judgment of how well one can execute the courses of action to deal with prospective situations [44].

The model assumes that the communication outcomes (awareness, motivation, action, and behavior) depend on 2 determinants: information factors and preceding factors.

The information factors (Figure 1) have long been debated in international literature, and the importance of the source, channel, message, and messenger's personal factors in influencing the outcomes of communication has been demonstrated in a wide range of disciplines, including, but not limited to, health, education, marketing, and risk communication [23,50-54].

The preceding factors (Figure 1) are predisposing factors of the recipients of the communication and comprise four categories: biological factors (eg, gender or sex and ethnicity), psychological factors (eg, personality, depression, and anxiety), behavioral factors (eg, lifestyle and adherence to recommendations), and environmental factors (eg, public health policies and availability or lack of resources at the community level). We are aware that gender is not a biological factor and is distinct from sex, but for the purpose of this study, we chose not to further elaborate on the difference between the 2 concepts. The terminology introduced by the I-Change model was adopted, and throughout the article, the terms *preceding factors* and *characteristics* of recipients are used interchangeably. This study focuses on the influence of preceding factors on health video communication outcomes.

Figure 1. The Integrated-Change model.



Methods

Overview

The literature on recipient characteristics is heterogenous with regard to subject groups, methods, research questions, and disciplines. Thus, a scoping review approach was chosen to identify the nature and degree of evidence available in the international literature. Our review followed the five stages according to the methodological framework developed by Arksey and O'Malley [55], which we chose for its completeness: (1) identification of the research questions, (2) identification of relevant studies, (3) selection of studies, (4) data extraction and management, and (5) summary and analysis of results.

Research Questions

This scoping review aimed to explore the role that recipient characteristics (biological, psychological, behavioral, and environmental factors) play in the outcomes of health video communication by (1) identifying which recipient characteristics and outcomes of health video communication were reported in peer-reviewed literature, (2) adapting the I-Change model to health video communication [42], (3) providing a categorization of both recipient characteristics and outcomes into the adapted model, and (4) investigating the relationships between recipient characteristics and health video communication outcomes reported in the international literature. This process will contribute to the existing knowledge on health communication by providing a comprehensive framework for health video communication effectiveness studies. The research questions driving this study were as follows:

1. What are the characteristics of recipients that might influence the outcomes of health video communication?
2. What are the outcomes of health video communication?
3. What relationships exist between the recipient characteristics and the outcomes of health video communication?

Literature Identification

We searched three main databases for public health, social sciences, and biomedical studies on health video communication: PubMed, Scopus, and Embase. Additional

literature was identified using the snowball method [56,57]. The relatively large number of papers identified in the initial search led us to limit the search to peer-reviewed literature. The search string was designed by relying on the population-concept-context framework, as suggested by the scoping reviews chapter of the Joanna Briggs Institute Manual for Evidence Synthesis [58]. The framework comprises defining a string for each component and subsequently combining them into the final search string. The string for the population component was (*people OR patient* OR recipient* OR receiver* OR viewer* OR person*).

The string referring to the concept was (*[past OR previous OR prior] AND [knowledge OR experience]) OR ([person* OR individual*] AND [characteristic* OR propert* OR value*]) AND (outcome* OR attitude* OR behavi* OR accept* OR learn* OR react* OR respon**).

The string for the context component was (*communic* AND video AND health*).

Data from the 3 databases were extracted on December 12, 2020. The search was limited to results published in English only, whereas no restriction was applied to the publication year. The complete search strategy was validated by 2 of the coauthors and is available in Multimedia Appendix 1.

Selection of Studies

The first step of the selection process comprised removing duplicates (approximately one-third) to confirm the completeness of the search string and strategy. In addition to incomplete or unavailable studies, studies were excluded based on title and abstract assessment if (1) they did not focus on recipient characteristics or on specific populations (eg, people who are visually impaired or deaf), (2) they did not focus specifically on health video communication (video used for other purposes, eg, video as a recording tool, referred to video games, video teleconference, video for the education of medical students, video calls, video physician–patient communication, or video simulation), or (3) they did not use video as the main communication method. Studies were included if they met both of the following criteria: (1) they focused on health video communication, and (2) they took into account at least one recipient characteristic. No inclusion or exclusion criteria were set for the design of the identified studies. Studies included in this phase went through full-text assessment, and the final inclusion depended on their coherence with respect to the 2 inclusion criteria mentioned above. The criteria and the results of each stage were made available to all the coauthors, and their feedback was used to solve potential inconsistencies among the scope of the study, the inclusion and exclusion criteria, and the selected articles.

Data Extraction

Microsoft Excel was used to create data extraction forms. For title and abstract assessment, the information stored were the digital object identifier, inclusion or exclusion status, and reason for exclusion. In the second stage of full-text assessment, the information about the publication year, journal, authors, title, document type, country, research domain, recipient characteristics, and reported outcomes were added. All the selected papers were saved using Mendeley, and the library was shared among all the coauthors.

Data Analysis

The extracted data were imported into the NVivo (version 12 Pro; QSR International). The relevant topics, both regarding the recipient characteristics and communication outcomes, were coded. A nested coding methodology [59] was used to organize the information in layers. The relationships between nodes were also coded to keep track of the associations between recipient characteristics and communication outcomes reported in the literature. The found relationships are reported in the description of outcomes in the *Results* section.

After the completion of the coding process, we moved on to define a conceptual framework, starting with the I-Change model and the way it highlights how the 4 dimensions of health communication outcome (awareness, motivation, action, and behavior) are influenced by information factors (eg, message, channel, and source) and preceding factors (biological, psychological, behavioral, and environmental factors). The existence of prior research allowed us to conduct a directed content analysis aimed at validating or conceptually extending the existing theoretical framework, as suggested by Hsieh and Shannon [60]. The content analysis, and especially the identification of key concepts or variables as initial coding categories, was guided by a structured and deductive approach according to the I-Change model [60-62].

The need to adapt the original model emerged at the first attempt to allocate the coded nodes to model categories, as some nodes lacked a fitting category in the original I-Change model. A similar approach of using content analysis to conduct knowledge building and theory development was described by Finfgeld-Connett [63]. The model was refined by an initial discussion between 2 coauthors (DAL and KKB) and then validated by the whole research group.

The final stage of data analysis was to assign nodes to the categories of the refined model. This process was conducted independently by 2 of the coauthors (KKB and DAL), and the divergencies were solved through discussion. In case the discussion did not lead to consensus, a third coauthor (SHB) was involved to have a majority. Finally, the relationships between the nodes reported in the literature were charted.

Results

Search Findings

The database search strategy yielded 1040 records (331/1030, 32.13% from Scopus; 392/1030, 38.05% from PubMed; and 307/1030, 29.81% from the Embase). Approximately 34.66% (357/1030) were duplicates and thus removed, and the title and abstract assessment was performed for the remaining 65.34% (673/1030) of articles. Of the 673 articles, 555 (82.5%) were removed according to the eligibility criteria. A total of 10 additional documents were identified through cross-checking the references. In total, 128 documents were assessed for full-text. Of the 128 papers, 39 (30.5%) met the inclusion criteria and were included in the content analysis. The PRISMA (Preferred Reporting Items for Systematic Reviews and

Meta-Analyses) chart of the selection process is presented in Figure 2. The characteristics of the selected studies are available in Multimedia Appendix 2 [64-100].

All the included studies were published between 2000 and 2020. There is an increasing worldwide publication trend over the past years. As highlighted in Figure 3, the publication trend for the articles included in this study is in line with the international trend, which displays the novelty and growing interest in this research topic.

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) chart of the selection process.

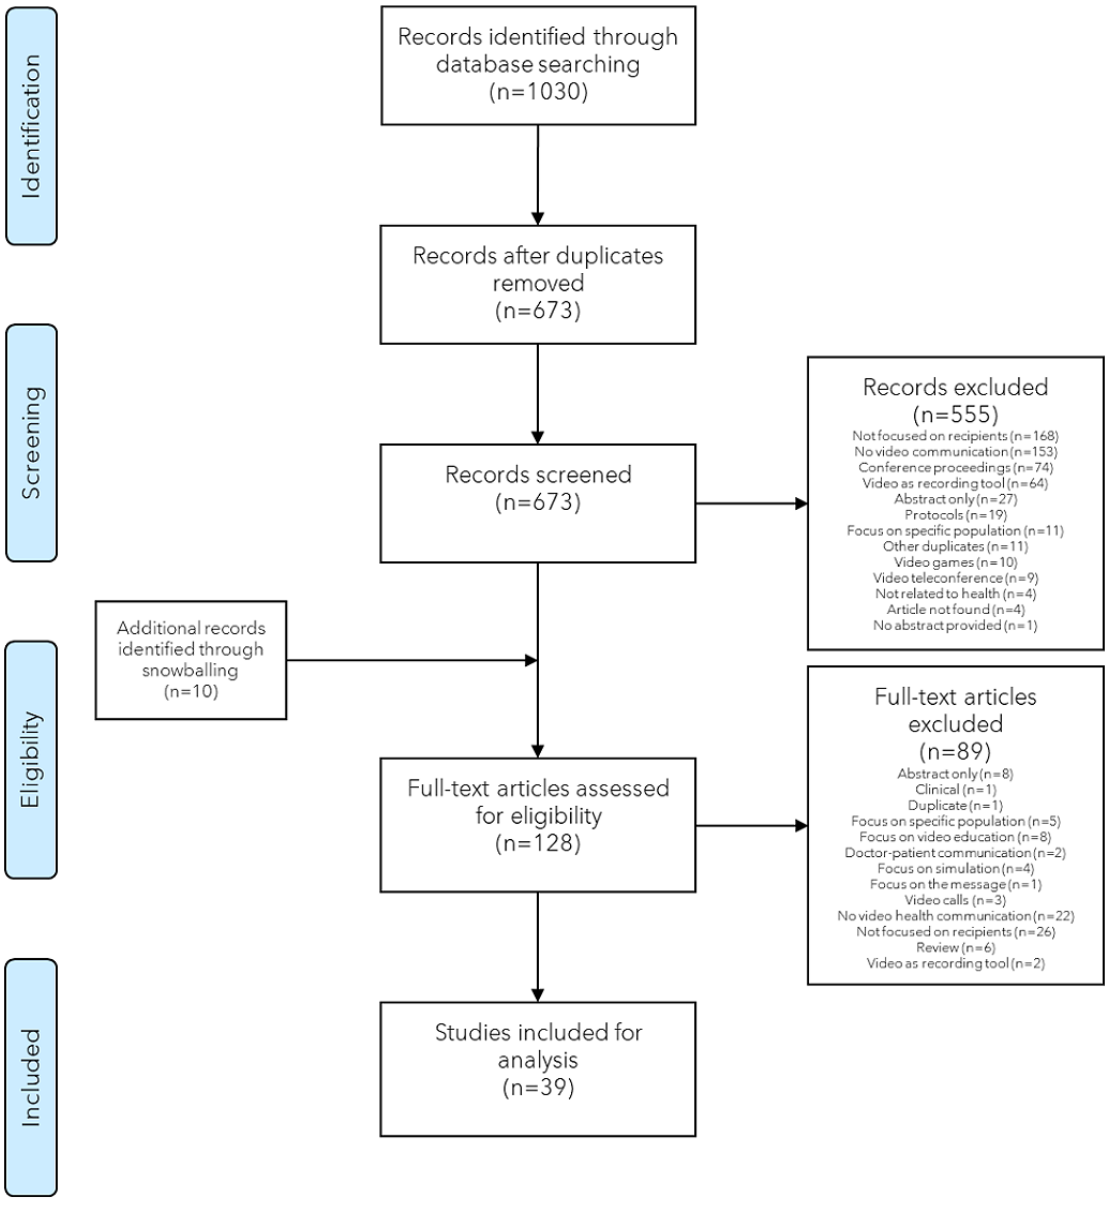


Figure 3. Cumulative number of papers published (worldwide and included in this study). Note that the x- and y-axes have different scales.

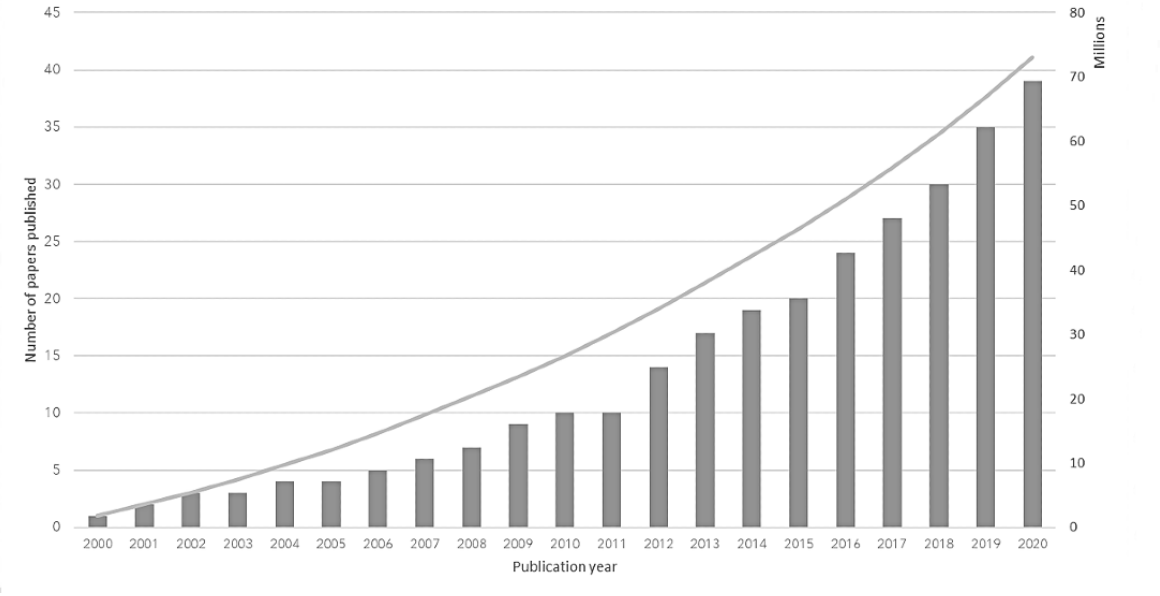


Recipient Characteristics

The included studies reported 56 different recipient characteristics. Some characteristics were frequently reported, with age (reported in 33/39, 85% of analyzed articles), ethnicity or race (26/39, 67%), gender or sex (25/39, 64%), and education (24/39, 62%) being the most investigated, whereas others such as sexual orientation, social network, emotional factors, or decisional control preferences being reported only by 3% (1/39) of studies each. Some characteristics were reported by a fair number of studies, such as income or socioeconomic status (SES; 13/39, 33%), beliefs and attitudes (12/39, 31%), level of knowledge (11/39, 28%), disease severity (10/39, 26%), previous experience (10/39, 26%), and health literacy (7/39, 18%). A complete overview of all the characteristics and the number of reporting documents is available in Multimedia Appendix 3, Table S1.

Preceding Factors

Overview

The analysis identified 56 different recipient characteristics. Of the 56 characteristics, 48 (86%) could be assigned to a corresponding category in the I-Change model. However, some factors could not be naturally fitted in the I-Change model and were assigned to a new category termed *Knowledge factors*. Refer the *Additional Category of Knowledge Factors* section for further discussion into this.

Biological Factors

The category of biological factors encompassed 14% (8/56) of the recipient characteristics, namely age, comorbidities, ethnicity or race, gender or sex, self-reported health status, disease severity, current symptoms, and clinical factors. Most of these characteristics were frequently reported by the analyzed studies, with age, ethnicity or race, and gender or sex being the most investigated by international literature. Clinical factors, current symptoms, and comorbidities were rarely investigated as preceding factors that influence health video communication outcomes.

Psychological Factors

Almost half of the identified factors (27/56, 48%) were attributed to the category of psychological factors such as anxiety, depression, decisional control preferences, influential personal factors, information priorities, preferences, values, expectations, psychological distress, beliefs, attitudes, emotional factors, ability to process information, motivation, perception of treatment efficacy, treatment concerns, self-efficacy, trust in information sources, confidence, empathy, trust in health care, health locus of control, regulatory focus, confidence, hesitancy, sexual orientation, hope, and personal relevance. Furthermore, 13% (7/56) factors that were attributed to other categories could also have been included in this category, as they also have psychological implications but were a better fit into other categories. For example, comorbidities, self-reported health, disease severity, current symptoms, and clinical factors were assigned to the biological factors category; risk estimation was attributed to the knowledge factors category; and social norms were assigned to the environmental factors category.

Behavioral Factors

Only 4% (2/56) of the recipient characteristics were ascribed to the category of behavioral factors: involvement and self-reported adherence.

Environmental Factors

The environmental factors category encompassed 20% (11/56) of the identified characteristics. The most recurrent ones were income and SES (reported by 13/39, 33% of the studies), marital status (7/39, 18%), and type of health insurance (6/39, 15%). The remaining factors, generally seldom reported, were the level of information and support that people can rely on, employment, financial comfort, living with someone, social network, social norms, culture, and geographical location.

Additional Category of Knowledge Factors

The added category of knowledge factors contained 14% (8/56) of the factors. Similar to the biological factors, a significant degree of within-group variation was observed for these factors.

Of the 39 included studies, the education level, knowledge, and previous experience were reported by 24 (62%), 11 (28%), and 10 (26%) studies, respectively. On the other hand, information, perceived knowledge, and health history were reported only by 3% (1/39) of the studies analyzed. The category also included 2 relevant factors that received an average amount of coverage in the international literature: health literacy and risk estimation and perception.

Health Video Communication Outcomes

Overview

The included studies reported 42 different health video communication outcomes that covered a wide range of topics. The most frequently reported outcomes were knowledge, including an increase in knowledge and knowledge transfer (15/39, 38%), attitudes (9/39, 23%), behavior (9/39, 23%), and intentions (8/39, 21%). The least frequently included outcomes were awareness, compliance, activation, and attention, reported by only 3% (1/39) of studies each. Some of the outcomes that were reported by a fair number of studies included acceptance (7/39, 18%), beliefs (5/39, 13%), usefulness of the communication (4/39, 10%), and choice of treatment (4/39, 10%). A complete overview of all the health video communication outcomes is available in Multimedia Appendix 3, Table S2.

The 42 health video communication outcomes reported by the included studies were attributed to the categories of the I-Change model as follows: 28 (66%) outcomes were attributed to awareness and motivation (14/42, 33% of outcomes to each), 5 (12%) outcomes were attributed to a new category termed emotions, and the remaining 9 (21%) outcomes were attributed to the category of action that encompassed the original categories of action and behavior. These decisions will be further discussed in *The Revised I-Change Model* section.

Awareness

The most frequently reported outcomes belonged to the awareness category, which encompassed 33% (14/42) of the identified outcomes. Most of the included studies focused on elements of the awareness category as the main outcome of health video communication. The most frequently reported outcome was knowledge, which was explored in 38% (15/39) of the studies. The other included outcomes were expectations, usefulness, recall of information, uncertainty, comprehension, beliefs, perceived benefit, information, information processing, information seeking, perceived risk, perceived prevalence, and awareness.

Most of the reported evidence on awareness was focused on beliefs, knowledge gain, risk and prevalence perception, recall of information, and usefulness of communication. Syrjala et al [64] studied patient training in cancer pain management using integrated print and video materials and found that participants of color were much more likely to report the perception of severe pain than White participants (odds ratio [OR] 18.4, 95% CI 2.1-56.3; *P*=.01). In a study that assessed the effectiveness of smoking cessation communication on YouTube, Romer et al [65] found that ethnicity and current behavior affect beliefs: Hispanic participants were found to have stronger beliefs regarding the mortality effects of smoking, whereas current tobacco use was negatively related to these beliefs. Pretest beliefs, in turn, affected information processing, which is a relevant outcome in health communication [101]. In clinical trials video communication, Curbow et al [66] have found that higher levels of information processing were associated with more negative pretest beliefs about clinical trials. Recall of information was found to be correlated with knowledge factors, namely health literacy and level of education. In an oncology communication setting, Visser et al [67] showed that poor functional health literacy was a predictor for poor information recall when using a standard communication condition without emotional involvement. When the standard was replaced with emotion-oriented communication, health literacy did not have any statistically significant effect. In the context of maternal and neonatal health clips, results showed that the higher the level of education, the greater the information recall [68].

The generation and transfer of knowledge is one of the main health video communication outcomes investigated in international literature and reported by the studies included in this review [69-73]. Evidence regarding the impact of preceding factors on knowledge is mixed. McKenzie et al [74] reported no significant effect of health literacy and education on prepost maternal safety knowledge after exposure to injury prevention video recommendations. Similarly, Bekalu et al [75] investigated the effect of age, gender, education, race or ethnicity, and income on increase in the knowledge of pandemic influenza after video exposure and found no significant effect [75]. A similar result was obtained by Curbow et al [66] in the context of oncology clinical trial communication and by Phelan et al [76] in the context of back surgery, where a randomized trial showed no significant effect of preceding factors on knowledge increase [76]. Grindel et al [77] reported both a nonsignificant impact of preceding factors on breast cancer knowledge after video exposure and a significant drop in knowledge scores after 1 year, meaning that 1-time communication generally leads to increased knowledge in the short run; however, it may not be enough to sustain the knowledge gain in the long term. An opposite finding was reported by Hickey et al [78], who claimed to have achieved long-term (2-month follow-up) knowledge gain after a single viewing of a breast cancer video.

When analyzing the perceived smoking prevalence as an outcome of peer smoking cessation communication, Romer et al [65] found that Hispanic ethnicity (b=10.07; *P*=.02), female gender (b=2.67; *P*=.01), increasing age (b=1.55; *P*=.01), and current tobacco use (b=3.16; *P*<.001) were positively related to perceived smoking prevalence.

The final communication outcome belonging to the awareness category is perceived usefulness, and some studies have reported it to be relevant in the context of educational videos for patients with advanced gastrointestinal cancers [70] and in the context of urologic oncology of patients with localized prostate cancer [79]. However, the article by Albert et al [80] is the only study that investigated the relationship between preceding factors and perceived usefulness. Patients with higher self-confidence in using health devices and less severe conditions (*P*=.02) and patients of color (*P*=.03) perceived higher usefulness of telemonitoring devices. Higher perception of ease of use was

affected by higher health literacy (*P*=.01), previous and current use history (*P*=.01), higher education level (*P*=.03), and married or cohabitating status (*P*=.02).

Motivation

The motivation category encompassed 33% (14/42) of the identified outcomes. Attitudes and intentions were the most investigated outcomes, being explored by 9 (23%) and 8 (21%) of the 39 analyzed studies, respectively. Acceptance, perceived self-confidence, perceived response efficacy, treatment preference, satisfaction, compliance, engagement, confidence, self-efficacy, and relevance are the remaining outcomes, and all of them were reported by less than 10% (4/42) of the selected studies.

More positive attitudes after exposure to video communication have been reported by the included studies in the context of outpatient surgical care and breast, prostate, and colorectal cancer [77,81,82]. Only Engler et al [81] reported that, in the German context, there were differences in the percentage of patients with positive attitudes toward health information on the web, with 92% of patients with colorectal cancer compared with 79% of patients with breast cancer and 53% of patients with prostate cancer.

The topic of confidence after exposure to health videos has been investigated in the United States regarding vaccinations, which is a topic that has been increasingly debated in the context of the COVID-19 pandemic. Nowak et al [83] found overall moderate confidence in the influenza vaccine (mean 2.78 on a scale of 1-5 scale, with *1* corresponding to *not at all confident*), with no differences between communication modalities (video, virtual reality, and electronic pamphlet story), although the influence of preceding factors was not investigated. When analyzing childhood vaccine-related confidence, Mendel-Van Alstyne et al [84] found that familiarity with the vaccine and high SES are associated with high confidence, whereas lacking information about issues that people were concerned about (eg, vaccine ingredients), uncertainty of the interaction of vaccines with children's immune systems, and negative beliefs (eg, that vaccines can cause illnesses) led to low confidence.

Literature from health communication has investigated the effect of individual characteristics on intentions, focusing mainly on biological factors [102]. Results showed that high intentions toward activities that improve health are associated with being a woman [103-105], increasing age [106,107], and being White [108,109]. In the context of health video communication, all the included studies that focused on intentions either did not investigate the effect of preceding factors on them or reported a nonsignificant relationship [72,74,83,85,86].

Emotions

The added category of emotions received fair attention in previous studies, with 12% (5/42) of the identified outcomes belonging to the emotions category. The identified outcomes were emotional response, decisional conflict, decision quality, decision satisfaction, and reactions. Moreover, each emotional outcome was reported by a very limited number of studies, which highlighted the limited amount of focus these factors have attracted and a potential gap in the literature.

There is a general lack of evidence about how emotional factors affect communication outcomes. Although there is some evidence regarding emotional reactions and trust, nothing was reported regarding the acceptance of health messages or the effects on the decision-making process (eg, decision satisfaction and decisional conflict) of recipients in the studies that were eligible for inclusion in this review.

The emotional response to health video communication has been reported to be significantly influenced by the age and gender of the recipients. A study by Prieto-Pinto et al [68] found, by using pupillary dilatation measures, which correlates with autonomous nervous system arousal, that men tend to have a greater emotional reaction after being exposed to maternal and neonatal health video clips. In a study conducted in China that aimed to test video versus virtual reality health communications, Liu et al [87] found that the young and older population differ in positive emotions after being exposed to communication: the young individuals show a greater emotional response to virtual reality, whereas the older individuals show a greater emotional response to health video communication. Of the 39 included studies, trust, which is a key outcome of health communication, was rarely investigated, with only 3 (8%) of the papers included in this review reporting on trust and only 2 (5%) providing empirical evidence regarding the impact of prior mistrust, age, and education on trust. By using a multilevel analysis model in the context of oncology communication, Hillen et al [88] reported a positive effect of age (*P*<.001) and a negative effect of education (*P*=.04) on trust. By applying structural equation modeling to investigate the reactions to survivor of breast cancer stories, McQueen and Kreuter [89] found that the level of medical mistrust at baseline affects the evaluation of the communication video (β=−.29; *P*<.001). The lack of further empirical evidence on trust highlights a potential gap in the literature that future research should address.

Action

The action category, which was obtained by merging the categories of action and behavior of the original I-Change model, encompassed 21% (9/42) of the identified health video communication outcomes. Outcomes belonging to this category received little attention in the literature, with all of them reported by less than 10% (4/42) of the included studies. Capabilities, time to treatment, quality of communication, participation, activation, spreading the message, and behavior complete the list of outcomes included in the action category.

Adherence to treatment is one of the main action outcomes of health video communication. Although adherence was often reported by the studies included in this review, there is little evidence of how the preceding factors affect it. In a study that investigated the risk of nonadherence to antiplatelet medication at the time of coronary stent placement, Palacio et al [90] reported no significant effects of gender, race or ethnicity, health literacy, income, education, and access to care on adherence. Instead, adherence was statistically higher for patients with a spouse or a domestic partner (*P*=.05), with a low Charlson comorbidity score (*P*=.03) and high English proficiency (*P*=.05). Low adherence was observed among those with a positive

screening for depression and among patients with moderate to severe depressive symptoms (*P*=.01).

In the context of maternal vaccine information communication in the United States, Dudley et al [86] investigated the factors associated with referring close contacts after exposure. The likelihood of referring contacts increased for women who intended to receive a maternal influenza vaccine (OR 1.37, 95% CI 1.04-1.81), whereas it decreased for those who were unsure about their infant vaccine intentions (OR 0.47, 95% CI 0.27-0.83). Participants were more likely to refer contacts if they were confident in the safety (OR 1.64, 95% CI 1.13-2.38) and efficacy of the maternal vaccine (OR 1.9, 95% CI 1.21-2.98), had higher perceived susceptibility to (OR 1.62, 95% CI 1.1-2.4) and severity of (OR 2.19, 95% CI 1.28-3.73) influenza during pregnancy, and had trust in the maternal vaccine information from academic institutions (OR 1.56, 95% CI 1.09-2.25) and the infant vaccine information from the Center for Disease Control (OR 1.44, 95% CI 1.02-2.05) and academic institutions (OR 1.85, 95% CI 1.27-2.71). The associations between the likelihood of referring contacts and ethnicity, education, state, or having prior children were not statistically significant.

None of the included studies reported any associations between the preceding factors and the other action outcomes such as activation, behavior, participation, time to treatment, or treatment choice.

Almost one-third (12/39, 31%) of the papers included in this analysis focused on both preceding factors and health video communication outcomes but did not investigate the relationship between them. Information about the preceding factors was collected and used mainly for descriptive purposes rather than explanatory variables [74,91-100,110].

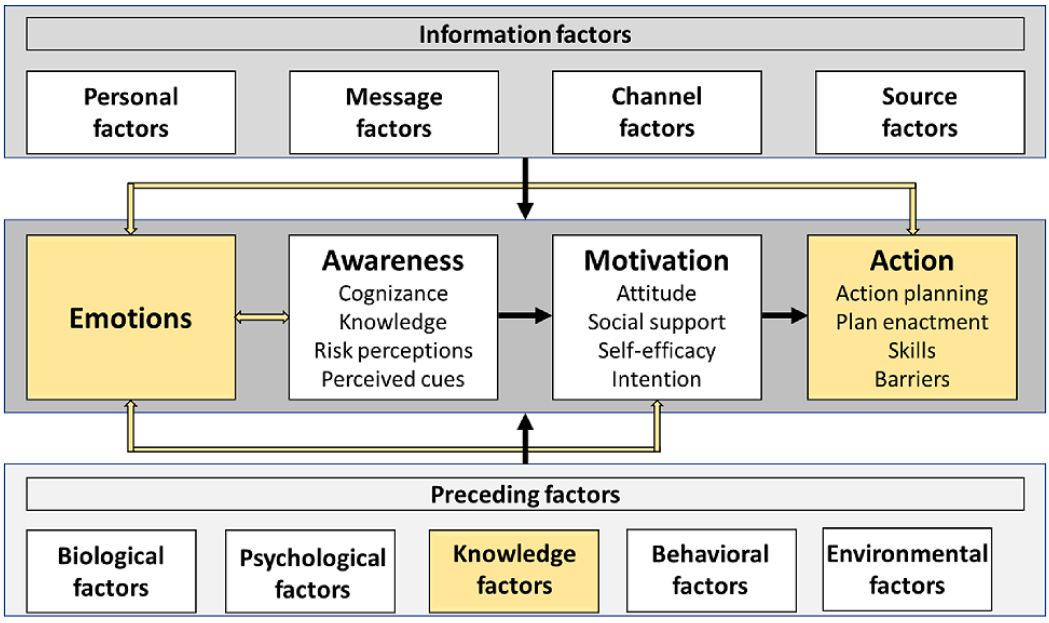
It is noteworthy to observe how the action category received relatively low attention from the included studies, as health videos are often designed and used to drive behavior and behavioral change (eg, smoking cessation, vaccination decisions, and weight loss). Indeed, a tendency to focus on awareness and motivation rather than on the actual behavioral outcome of the recipients emerged from the included studies.

The Revised I-Change Model

When analyzing the included studies—coding the content and identifying relevant nodes regarding both recipient characteristics and communication outcomes—some gaps emerged in the I-Change model when applied to health video communication. Thus, we revised the I-Change model to adapt it to health video communication and obtained an adapted version (Figure 4) that fits the purpose and comprises three main novelties with respect to the original version:

- The inclusion of a fifth category termed knowledge factors within the preceding factors
- The merging of the action and behavior outcome categories into a single category termed action
- The inclusion of an emotions category among the outcomes

Figure 4. The revised Integrated-Change model.



The category of knowledge factors was included as 1 of the preceding factors categories as many included studies reported multiple characteristics associated with knowledge that did not meaningfully belong to biological, psychological, behavioral, or environmental factors. Examples of such characteristics include the recipients' level of knowledge, health literacy, level of information, ability to process information, and information priorities.

The original model foresees action and behavior as distinct communication outcomes, whereas our analysis demonstrated an overlap between the 2 categories using the data from the 39 studies included in this review. Thus, we decided to merge them into a single category termed as action.

The emotional dimension has been shown to play an important role in multiple outcomes of communication: risk perception, judgment, and decision-making [111]. Emotions can both provide significant inputs to judgments and decision-making and can fundamentally change the process of judging and deciding, especially when knowledge about the events is not easily remembered or expressed [112]. Moreover, not only are emotions influenced by preceding and information factors but are also in a mutual relationship with the other outcome categories, as highlighted by the 2-way arrows in Figure 4. This represents an important amendment to the original model, as it considers the feedback effect that awareness, motivation, and action have on emotions.

Discussion

Principal Findings

The included studies provide an extensive overview of the recipients' preceding characteristics that might affect a wide range of health video communication outcomes and present evidence on the relationship between them. The trend observed in Figure 3 displays the novelty and growing interest in this research topic.

Although subsequent analysis revealed that many of the preceding factors belong to the psychological category, only a limited number of papers reported evidence of their impact on outcomes, inviting further research in the area. Biological factors were often reported by the analyzed studies.

Although knowledge and environmental factors received fair attention in international literature, systematic and robust evidence of their effect on communication outcomes is scarce. Moreover, the recipients' first language and their ability to speak and understand the content of videos were surprisingly not identified as relevant factors. This is because the selected studies included only people who were able to speak the language presented in the communication. Further research investigating the magnitude of the impact of linguistic skills on outcomes would positively contribute to the effectiveness of health communication.

The category of behavioral factors appears to be underinvestigated, with only 2 factors identified in all 39 studies and no evidence available on the relationship with outcomes. Although the awareness and motivation categories included the most communication outcomes, those belonging to the action and emotions categories were less reported by the included studies, and there is very little evidence of how they are affected by the preceding factors. Communication and health research would benefit from further efforts focusing on the action category, as it currently represents less than 10% (4/42) of the outcomes identified in our study, with most studies preferring to focus on awareness and motivation outcomes. This number appears low with respect to the general aim of most health communication interventions aimed at changing behavior.

The scarcity of evidence regarding emotions is particularly relevant for effective health communication. Feelings and moods motivate people to reproduce those feelings and moods, whereas, in risk communication, the topic communicated (eg, earthquakes and other natural disasters) usually evokes negative feelings and moods, motivating people to act to avoid them. Emotions are states that are not under voluntary control but are shaped and learned associatively through experiences while being partly innate at birth. Emotions affect attention, memory, motivation, and action [113]; therefore, we included them as a category of preceding factors in the adapted version of the I-Change model.

Our contribution to theory development followed the research approach, in which the theory is understood as emerging from data [114,115]. Indeed, the empirical approach comprises the development of a new theory by relying on empirical observations followed by careful analysis and verification of hypotheses. We started with an existing theoretical framework; however, the empirical data highlighted the misfit of the I-Change model to the topic of health video communication. Therefore, through data analysis, we revised the original model and adapted it to the specific characteristics and needs of health video communication.

As we decided to conduct a scoping review, we are aware of the common limitations of this approach [116]. Information was gathered from a wide range of study designs and methodologies, and the quality of evidence was not formally evaluated. As for the results, it does not provide a synthesized answer to a specific question but rather an overview of the available evidence in the literature.

Further understanding of the gaps presented in this review could have a great impact on the effectiveness of public health emergency communication strategies, as in these contexts, the psychological and behavioral factors of people are key, and emotions are able to significantly affect their decisions and behavior.

Conclusions

Although some evidence of associations between recipients' preceding factors and health video communication has been reported in the literature, our analysis revealed a significant gap in the literature, with many health video communication outcomes and factors not yet explored. This scoping review of the available evidence demonstrated a potential research gap, especially concerning the emotional outcomes of communication and the behavioral and psychological preceding factors of recipients. The review showed that, currently, only a partial picture of the role of recipient characteristics on the outcomes of health video communication is available. Moreover, this study also contributed to the theoretical development of the I-Change model to adapt it to the needs of health video communication.

Acknowledgments

The COVID Communication: Fighting a Pandemic through Translating Science project has received funding from the Trond Mohn Foundation, under grant agreement number TMS2020TMT10 and the University of Stavanger.

Authors' Contributions

This study was conducted by an interdisciplinary team of researchers. DAL and KKB conceived the study, discussed the methodological approach, and analyzed the data. DAL drafted the initial manuscript. All the authors (JR, FF, HT, SW, SHB, and MTS) provided critical feedback on the manuscript and approved the final version.

Abstract

Background: Loneliness and social isolation can have severe effects on human health and well-being. Partial solutions to combat these circumstances in demographically aging societies have been sought from the field of information and communication technology (ICT).

Objective: This systematic literature review investigates the research conducted on older adults' loneliness and social isolation, and physical ICTs, namely robots, wearables, and smart homes, in the era of ambient assisted living (AAL). The aim is to gain insight into how technology can help overcome loneliness and social isolation other than by fostering social communication with people and what the main open-ended challenges according to the reviewed studies are.

Methods: The data were collected from 7 bibliographic databases. A preliminary search resulted in 1271 entries that were screened based on predefined inclusion criteria. The characteristics of the selected studies were coded, and the results were summarized to answer our research questions.

Results: The final data set consisted of 23 empirical studies. We found out that ICT solutions such as smart homes can help detect and predict loneliness and social isolation, and technologies such as robotic pets and some other social robots can help alleviate loneliness to some extent. The main open-ended challenges across studies relate to the need for more robust study samples and study designs. Further, the reviewed studies report technology- and topic-specific open-ended challenges.

Conclusions: Technology can help assess older adults' loneliness and social isolation, and alleviate loneliness without direct interaction with other people. The results are highly relevant in the COVID-19 era, where various social restrictions have been introduced all over the world, and the amount of research literature in this regard has increased recently.

KEYWORDS

loneliness; social isolation; older adults; physical information and communication technology; systematic literature review

Introduction

Loneliness and social isolation can occur at any stage of human life. Particular attention has been paid to these circumstances among older adults, an increasing demographic in many societies. In 2050, over 20% of the population of most countries will be over 60 years old [1], and there is a strengthening global trend of those living alone later in their life [2]. During old age, the size of one's social network and the extent of social activities are likely to reduce [3-5]. This topic has also become timely

due to the COVID-19 crisis where various country-level restrictions and governmental recommendations on social distancing have been introduced [6,7]. These factors together bring forth the importance of addressing loneliness and social isolation among older adults.

Loneliness refers to perceived social isolation or a subjective unpleasant and distressing feeling that results from a significant discrepancy or mismatch between one's actual and desired social relationships [8-10]. In the typology of social and emotional loneliness, social loneliness is characterized by the lack of engaging social networks, and emotional loneliness refers to the lack of close emotional attachment [11,12]. Social isolation typically concerns an objectively limited or a lack of social contact with others [8], and some of its common quantifiable markers are a shortage in one's social contacts and network size [13]. Despite their similarities, loneliness and social isolation are not the same [12,14]. Loneliness is a subjective emotional feeling, whereas social isolation describes an objective and a quantifiable aspect of social relationships [13]. For instance, the quality of social relationships is more closely related to loneliness compared to the quantity of social relationships [12,15,16].

Recent prevalence estimates from the United States show that more than 40% of older adults are lonely (29% occasionally and 19% frequently) [8,17]. In Europe, prevalence estimates range from Central and Eastern Europe's 30%-55% to Northwestern Europe's 10%-20% [18,19]. As for social isolation, a recent estimate considers 24% of older adults aged 65 and above as socially isolated [20]. Various demographics can also be used for prevalence estimation purposes [21]. Prevalence estimates fluctuate across research studies due to differences in the considered populations, measures, age groups, sample sizes [22], definitions, intensity and duration of the experience [23], and cultural differences [24]. The extent to which people are willing to self-report their loneliness experiences needs to be critically considered. For example, research indicates that men are more reluctant to admit their loneliness than women, likely due to a stigma associated with it [25]. However, instead of asking about loneliness directly, indirect validated measures can also be applied [17].

Loneliness and social isolation are significant predictors of mortality [13,14,26,27], and they are associated with poorer physical and mental health [8]. For instance, loneliness is associated with poorer cardiovascular health [28], lower cognitive function [29,30], depression [31,32], anxiety, suicide ideation [33], higher psychological distress [34,35], lower self-esteem [36], sleep and stress problems [37,38], and health behaviors such as lower physical activity [39]. In turn, social isolation is associated with lower self-rated physical health [40], lower health-related quality of life and health status [41], worse cardiovascular and mental health [42], and increased vulnerability to dementia [43]. Therefore, it is evident that solutions to combat both circumstances are needed.

Partial solutions to assess loneliness and social isolation among older adults have been sought from the field of information and communication technology (ICT). Previous literature reviews have examined empirical studies on various types of technologies and their effectiveness in alleviating social isolation [44]. Other reviews address interventions targeting loneliness and social isolation among older people, which include technological and nontechnological approaches [45,46]. There are also reviews on diverse technologies and caregiving that have identified their impact on loneliness and social isolation alleviation, among other effects [47,48]. These studies address loneliness and social isolation from the perspective of fostering social networking and support, together with community interaction and engagement.

However, we assume that there are habits other than communication with other humans that can also be related to loneliness and social isolation, and these habits can be assessed and tracked using novel intelligent technologies. In particular, robots, wearables, and smart homes hold potential value in this area. In this review, these technologies are grouped under the term "physical ICT," broadly referring to physical technologies able to collect and communicate information. Robots are viewed as embedded agents that can interact with humans or with other robots in a socially acceptable manner, also known as social robots [49,50]. Wearables refer to technologies that can be worn on the human body, such as virtual reality (VR) headsets, fitness trackers, smart watches, or smart jewelry. The term "smart home" (or "smart house") refers to a residence equipped with "smart technology," namely a variety of internet-connected sensors and systems enabling monitoring and management to automate and optimize control of the home environment, home appliances, and the inhabitant's quality of life [51].

Previous reviews have also generally reflected the effectiveness of social robots in elderly care, including studies that address loneliness or social isolation [52,53], and the influence of smart houses on older adults' quality of life, including their effect on social isolation [54]. Recently, in the face of the COVID-19 pandemic, there has also been a stream of studies from different fields reviewing and considering the importance and possibilities of robots and computer agents in alleviating loneliness [55-58]. To the best of our knowledge, no prior studies have focused on role of physical ICT solutions in assessing and combating loneliness and social isolation among older adults.

When the solutions relate to health and care, the concept of ambient assisted living (AAL) comes into play. AAL is a subarea of ambient intelligence and can be defined as "an emerging multidisciplinary field aimed at providing an ecosystem of different types of sensors, computers, mobile devices, wireless networks, and software applications for personal health care monitoring and telehealth systems" [59]. AAL was first coined in 2006 by the International Medical Informatics Association in recognition of this emerging technology with the creation of a working group on smart homes and AAL [60].

The aim of this study is to gain insight into how physical ICTs can help overcome loneliness and social isolation among older adults other than by fostering social communication with people and what the main open-ended challenges according to the reviewed studies are. Our focus is on empirical research conducted from January 2006 to late May 2021, starting from

the year in which the concept of AAL was introduced. In line with these aims, we established the following research questions:

> *(RQ1) What has been studied so far, from a sociotechnological perspective, in the field of loneliness and social isolation in older adults using physical ICT solutions?*
>
> *(RQ2) How can physical ICT solutions help overcome the issues of loneliness and social isolation among older adults other than by fostering social communication with people?*
>
> *(RQ3) What are the main open-ended challenges according to existing studies?*

Methods

Data Collection

A systematic literature review was conducted to answer our research questions. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) procedure [61] was followed, when applicable, for the study objectives. The data were collected in 2 phases. The first phase took place in April 2020, covering the period from January 2006 to late March 2020. The second phase was conducted in June 2021, covering the time frame from April 2020 to the end of May 2021, which allowed us to keep the data up to date.

In both phases, the procedure was the same. We used 7 bibliographic databases: Scopus (Elsevier), Web of Science (Clarivate), EBSCOhost (EBSCO), Social Science Premium Collection (ProQuest), PsycINFO (Ovid), PubMed (National Library of Medicine), and IEEE Xplore Digital Library (IEEE), with all databases selected. The following search phrases were used in the databases: (“ambient assisted living” OR “ambient intelligence” OR “smart house” OR “smart home” OR “smart environment” OR “smart assistant*” OR “intelligent assistant*” OR sensor* OR “internet of things” OR wearable* OR robot* OR “artificial intelligence”) AND (eld* OR age* OR old* OR geriatr* OR senior*) AND (lone* OR “social* isolat*”).

The search was targeted toward the “title,” “abstract,” and “keywords.” In PsychINFO, “key concepts” were selected as corresponding to keywords. In Social Science Premium Collection, “all subjects and indexing” including keywords and index terms was the term used in addition to abstracts and document titles. EBSCOhost and Social Science Premium Collection searches were filtered to include only peer-reviewed entries, and IEEE Xplore Digital Library was filtered for conference and journal publications to manage the number of irrelevant entries. All searches were limited to English language publications.

In the first phase, the search from the 7 different databases first produced 1830 results in total. After removing duplicate results, the data consisted of 1001 entries. In the second phase, the search resulted in 559 entries. After removing the duplicates and overlaps with data from the first phase, the additional data consisted of 270 entries. In both phases, all papers were screened according to the predefined inclusion criteria. The studies were included based on the following criteria:

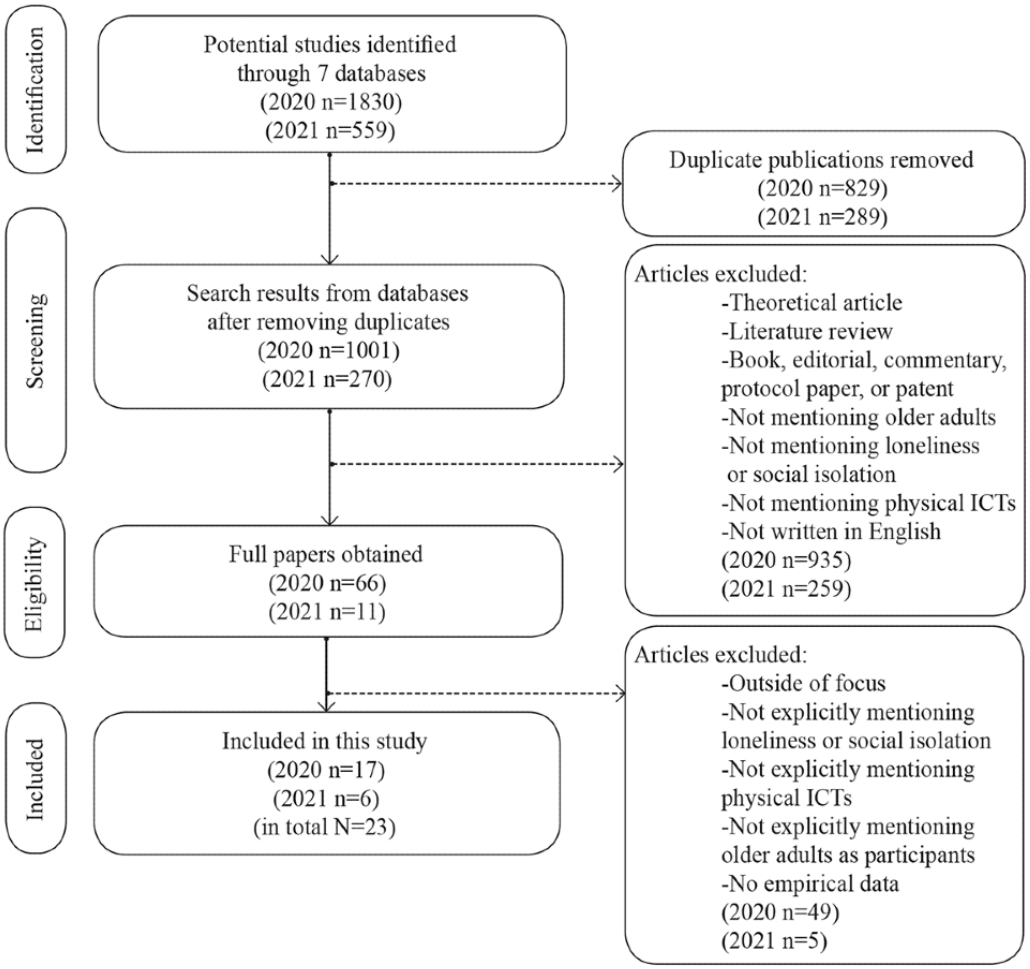
> *(C1) It is a peer-reviewed article or a conference publication.*
>
> *(C2) It is a fully empirical study, using quantitative, qualitative, or mixed methods.*
>
> *(C3) The study does fully or partially research older adults.*
>
> *(C4) The study does fully or partially research human loneliness or social isolation.*
>
> *(C5) The study does fully or partially research physical ICTs (robots, wearables, or smart homes and houses).*

Consequently, we focused on empirical studies in which physical ICT solutions are researched with older adults and loneliness or social isolation is explicitly examined. To be included, ICT solutions had to be physically exploited and studied in relation to older adults’ loneliness and social isolation, and not solely aimed at mediating or fostering communication between people. All study participants referred to as older adults in the selected studies were considered eligible for our study purposes (starting from people over 50 years old). Due to a technology-focused research topic, all relevant studies were searched, including peer-reviewed journal and book articles, as well as conference publications. Studies were excluded if they were theoretical articles or literature reviews; if they were whole books, editorials, commentaries, study protocols, or patents; if they did not explicitly mention older adults, loneliness, social isolation, or any physical ICT solution; or if the full text was not written in English.

In the first search phase, 2 coders first independently reviewed the papers’ titles, abstracts, and keywords, after which selections based on the predefined inclusion criteria were made. An interrater reliability test was conducted and resulted in an interrater agreement of 94.57% on average (mean Cohen κ=0.83, range 0.74-0.88), indicating a successful set of criteria. Borderline cases and disagreements were discussed with the members of the research team. Then, 66 full papers were screened by 2 coders against the predefined inclusion criteria, of which 17 papers were included in the data set.

In the second search phase, we extended data collection until the end of May 2021, and the same procedure was followed. An interrater reliability test resulted in an interrater agreement of 94.67% on average (mean Cohen κ=0.79, range 0.48-1.00), replicating the success of the set criteria. Further, 11 full papers were independently screened by 2 coders, of which 6 papers were included in the data set. Hence, the final data set consisted of 23 empirical studies. The diagram depicting the entire data collection and data selection process is presented in Figure 1.

Figure 1. Diagram of the entire data collection and data selection process including both search phases. ICTs: information and communication technologies.



Method of Analysis

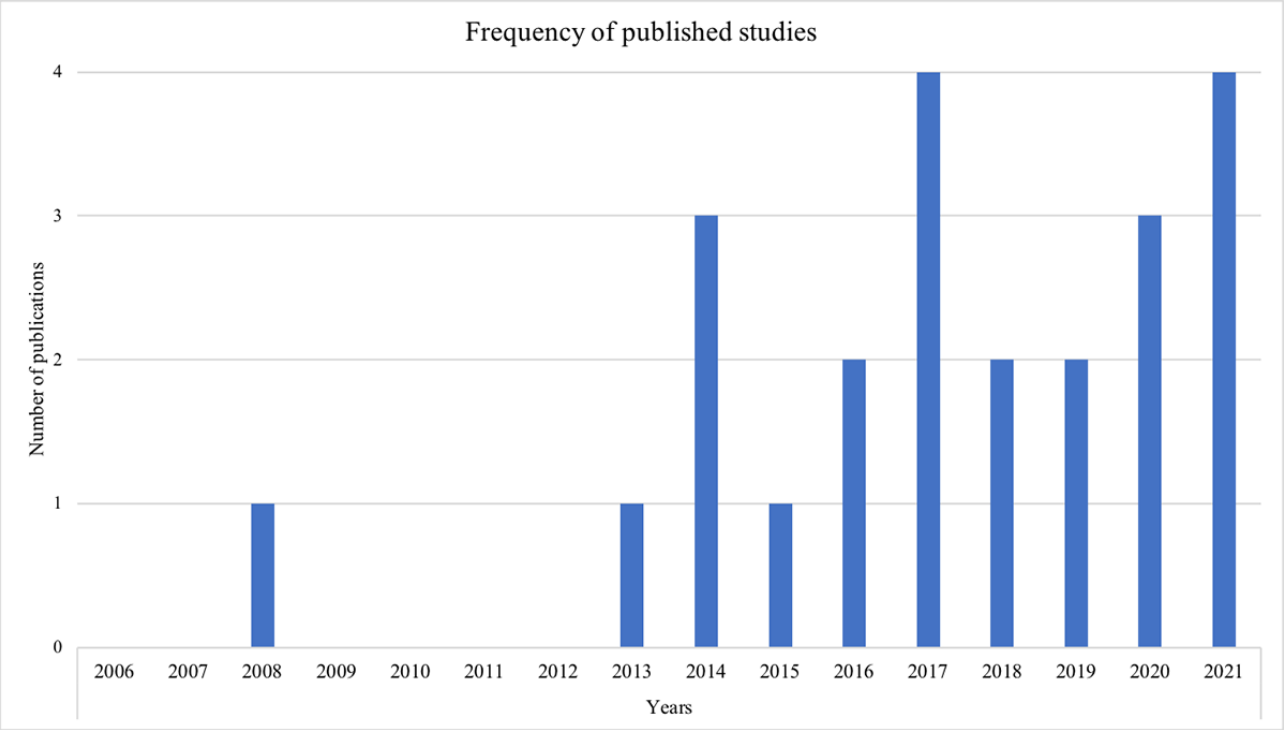
We began the analysis by examining what has been studied from a sociotechnological perspective in the field of loneliness and social isolation in older adults using physical ICT solutions. A descriptive overview of the studies was obtained to include the following basic characteristics of the studies coded into an Excel sheet (Microsoft Corporation): research method (quantitative, qualitative, or mixed), type of study, time frame, study setting, older adults' sample size, age, and gender information, research instrument for measuring loneliness or social isolation, type of physical ICT addressed, and focus of the paper (detection or prediction, alleviation, or other). Then, content analysis was performed to summarize the ways in which new technologies can help overcome issues of loneliness and social isolation among older adults and the main open-ended challenges according to the included studies. Meta-analysis was not conducted due to the heterogeneity of the reviewed technologies and methods used in these studies. Furthermore, our methodological choices were limited by the small number of existing studies on the topic.

Results

Descriptive Details of the Reviewed Studies

The final data set consisted of 23 studies conducted from 2006 to the end of May 2021. Except for 1 study, all the others were published after 2012. This suggests that the amount of research has increased over the past decade, as depicted in Figure 2. Studies have mostly been conducted in the United States (n=10), Germany (n=2), and Singapore (n=2). Other countries include Australia, Canada, Ireland, Mexico, the Netherlands, New Zealand, and Taiwan. Among these, 2 studies included cross-national data, 1 with participants from the United Kingdom, Italy, and Ireland, and another with participants from England and Japan. Most of the studies have applied quantitative (n=13) or mixed methods (n=7), whereas very few studies have applied qualitative methods (n=3). Most of the included studies contributed to the field of older adults' loneliness (n=17), whereas the rest examined social isolation or both phenomena (n=6).

Figure 2. Frequency of publications per year from 2006 to the end of May 2021.



Main Areas of Research

The 2 main areas of the reviewed research comprised "detection and prediction" and "alleviation" of older adults' loneliness and social isolation using physical ICT. Here, the category of detection and prediction refers to studies that hypothesize the potential of certain activities or daily habits (attributes), including time spent in certain rooms of the house and outdoors, to infer the levels of loneliness or social isolation in older adults. In the reviewed studies, certain daily activities are tracked in real time through physical ICTs, namely smart home solutions, or a combination of smart homes and smartphones. Then, algorithms derive behavioral patterns from the gathered data. Afterward, these factual scores are correlated with subjective standard measurements to identify the attributes that meaningfully relate to loneliness or social isolation. In addition, studies validate their predictive models using different evaluation methods and indexes.

Alleviation studies include examining whether the use of technology would result in reducing perceived loneliness or social isolation in older adults, or the possible roles physical ICT could play in combating older adults' loneliness and social isolation, if not serving as an actual intervention. Further, 1 paper was categorized as "other," referring to a study examining the association between perceived loneliness and acceptance of robots. It was also included in the final data set, as it has implications in terms of overcoming loneliness from an opposite perspective; without acceptance of the intervention for reducing perceived loneliness, there is no possible cure.

The focus was on detection and prediction in less than half of the studies (n=7), whereas the alleviation of loneliness or social isolation was the focus in most of the considered studies (n=15). None of the studies directly examined both aspects. The basic information of the included studies is presented in Table 1.

Table 1. Basic information of the selected studies (N=23).

Types of Technologies Assessed

Within the reviewed studies on the detection and prediction of loneliness and social isolation, platforms with several types of sensor-based technologies were commonly used, namely, smart home solutions. Austin et al [62], Goonawardene et al [63], Petersen et al [64,65], and Walsh et al [66] assessed smart home solutions explicitly, whereas Huynh et al [67] analyzed sensor-enabled homes. Martinez et al [68] combined smart homes and smartphones in their study. In the reviewed studies focusing on loneliness and social isolation alleviation, older adults have been introduced most often to social robots [69-79]. Studies have also examined the use of a smart home solution [80], VR systems [81,82], and an ambient activity system that includes an activity sensor (AAL-VU system) [83]. Furthermore, 1 study focusing on how loneliness associates with physical ICT acceptance exploited social robots Paro and Giraff [84].

Study Designs and Settings

The reviewed studies applied various study designs ranging from explorative pilot studies to randomized controlled experiments. Longitudinal design was applied in some studies [62,65], and 3 studies followed the randomized controlled trial protocol [69,76,77]. A majority of the 23 studies applying quantitative measurements used validated scales for subjectively measuring loneliness and social isolation: the original, revised, or short version of the University of California Los Angeles (UCLA) Loneliness Scale (n=12), Dong Jong Gierveld Loneliness Scale (n=4), or Lubben Social Network Scale (n=2). However, most studies were conducted with relatively small sample sizes, which is also understandable due to the use of new technologies and the experimental nature of the studies. Many studies targeted healthy older adults with no cognitive impairment with the exceptions of Appel et al [81], focusing on older adults with cognitive and physical impairments; Robinson et al [77], in which 19 out of the 40 participants had cognitive impairment; Fields et al [72], where roughly half of the participants had dementia; and Casey et al [70] focusing on people with dementia. Further, Chen et al [71] focused on older adults with depression, and Hudson et al [74] and Tkatch et al [79] noted that their participants had higher levels of depression compared to the ones who declined from participating in the study. Studies were conducted in the older adults' own homes, different forms of care facilities, sensor-enabled houses and apartments, and hospitals. Table 2 gives a descriptive overview of the considered studies.

Table 2. Descriptive overview of the selected studies (N=23).

Detecting and Predicting Older Adults' Loneliness and Social Isolation via Behavioral Attributes

The studies aiming to overcome loneliness and social isolation through detection and prediction are framed within the assumption that an early diagnosis of loneliness and social isolation in older adults can prevent their physical and psychosociological decline. All 7 papers report relevant results and provide a meaningful quantitative or qualitative evaluation of their experiments. All the solutions are shown, at least to some extent, to be capable of detecting and predicting older adults' loneliness or social isolation; thus, they help in the process of overcoming such circumstances by recognizing the existence of these phenomena. Overall, researchers refer to these detection systems as promising research paths toward overcoming loneliness and social isolation.

In practice, studies assess various older adults' behavioral attributes and compare them with subjective measures. Older adults' out-of-home habits measured in 5 of the studies [63-65,67,68] are reported as relevant attributes in inferring loneliness and social isolation. Thus, tracking attributes related to outings (time spent outside the house, number of outings, and number of places visited) seems consistently relevant in unobtrusive models to detect loneliness or social isolation. Nevertheless, other attributes analyzed in these studies are not as consistent across the studies in terms of their relevance to detection. Different studies report that diverse variables should be considered in prediction models with this type of technology. Time spent in the house is generally relevant in 1 study [68], whereas it is not in another [62]. Other reported significant variables include time spent in the living room [63,66], time spent across various locations [66], walking speed [62], nocturnal movements [66], and daytime napping [63].

Studies vary in terms of the development phase of the system. Martinez et al [68] propose a smartphone app that enables the users and caregivers to interact and receive feedback from the

system, whereas Huynh et al [67] and Walsh et al [66] elaborate on potential interfaces. Some studies expand on the core issue of loneliness and social isolation inference. Huynh et al [67] also assess depression among independently living seniors in their study. Petersen et al [65] focused on monitoring the broad cognitive, physical, and emotional states of older persons, and Walsh et al [66] also explored anxiety, cognition, depression, independent living skills, sleep quality, and quality of life.

Papers also report some study-related issues, such as small sample sizes [62,66,68], study durations [65,67], and nonoptimal study designs [62,65]. Likewise, some studies report technical problems, such as ensuring that sensor configurations work continuously [66], assessing situations with more than one person living in a house [66,67], and the intrusiveness of smartphone models [68]. Moreover, 2 studies note general ethical challenges regarding issues such as privacy, respect, or consent [62,66].

Alleviating Older Adults' Loneliness and Social Isolation Through Physical ICT

Studies on alleviation indicate that some physical ICT solutions can help overcome loneliness among older adults by decreasing it based on self-reported measures. None of the studies report complete elimination of older adults' loneliness experiences with the help of physical ICT, but they report success in alleviating them. Studies that report statistically significant results for a decrease in perceived loneliness of older adults include interventions using social robots [69,71-73,77,79] and an ambient activity system including an activity sensor [83]. Moreover, 2 studies report qualitative evidence of using social robots in alleviating loneliness [70,74]; in addition, 1 study reports unexpected qualitative evidence regarding the unexpected positive impacts of an intervention using a smart home solution on loneliness [80]. No statistically significant results were demonstrated for a decrease in social isolation, but 2 studies suggest that social robots could help combat social isolation by providing social contact with the robots and through video calls with people [70,73].

Due to the variety of physical ICTs employed in the studies on loneliness alleviation, common characteristics regarding intervention designs or technological features are limited. However, a common feature of the successful solutions is that they can interact with the user in one way or another. The successfully employed social robots (Paro, AIBO, NAO, MARIO, temi, and animatronic or robotic pets) are all designed to engage with the user, thus providing means for interaction with the device itself. MARIO and temi robots also provide means for video communication with other people as a central feature besides speech, activity, and entertainment capabilities. In an ambient activity stimulating system [83], a virtual coach gives recommendations to the user based on the planned activities for the day and the data from an activity sensor. The smart home solution [80] also interacts with the user via messages.

Banks et al [69] assessed the mechanism leading to changes in loneliness and report that the intervention did not succeed in alleviating loneliness through attachment to the robotic dog (AIBO) or a living dog. Hudson et al [74] report that many of their participants stated that the presence of the robotic pet positively influenced their feelings of loneliness. Curumsing et al [80] also report that older adults missed the voice of that "somebody" in their home when they uninstalled the smart house system. Casey et al [70] describe that their participants thought that MARIO reduced their feelings of loneliness because the robot provided distractions, allowed them to engage in various activities and interact with family members.

However, the evidence found by these studies must be interpreted cautiously. Studies acknowledge that more valid results would have been obtained with larger sample sizes [70,72,73,76,77], and the lack of control or comparison groups limits the interpretations of the effectiveness of the intervention [71,72,77,79]. Scholars also recognize the possible influence of the presence of a researcher on their results [70,72,76,77] and raise concerns on study dropouts due to older adults' health issues [77]. Robinson et al [77] performed the only study conducting a group session, and they reflect on the possible effects of that group setting on the intervention in a subsequent study [85]. Banks et al [69] noticed that the robotic dog AIBO was not used at full capacity in the study, which may have influenced the results. Further, 6 studies using social robots included participants with cognitive impairment [77], dementia [70,72], and depression [71,74,79], which must also be acknowledged when interpreting the results. Curumsing et al [80] did not focus on alleviating loneliness in their initial study plan, but the topic emerged during the investigation, leading to unexpected results.

Perceived Loneliness in Technology Acceptance

One study shed light on the link between perceived loneliness and acceptance of robots. Baisch et al [84] investigated emotional loneliness as a component of psychosocial functioning and its link with the intention to use social robots Paro and Giraff in 2 different user-technology fit scenarios. According to the results, participants with lower psychological resources, including perceived emotional loneliness, accepted the Giraff robot less when the user-technology fit was poor. The same results were not obtained for a companion robot. However, researchers warn against generalizing the results due to a small and nonrepresentative sample.

Main Open-Ended Challenges According to the Reviewed Studies

The main common open-ended challenges according to the reviewed studies relate to the need for more robust study samples and study designs. Across studies, researchers suggest future studies using larger study samples that could also be more diverse [62,65] and more geographically widespread [77,82], include more people with different conditions [77], and vary more in terms of the living environments [77,82] to add statistical power for generalization, to validate the interpretation of results, and to understand for whom the technologies are best suited. However, researchers admit that realistically obtaining larger samples includes challenges such as the health problems of the seniors [77] and finding isolated adults for recruitment in general [66,78]. Further, it is critical for future studies to incorporate control and comparison groups and confounding factors to the study designs to aid the interpretation of the

effectiveness of the interventions [71,72,76,77,79]. Finally, scholars note that research would benefit from longer study periods [63,65,67,70,73,74,76,84].

Among the detection and prediction studies, Goonawardene et al [63] and Petersen et al [64] propose introducing potentially confounding variables (eg, depression or mobility) and establishing causal relationships between them, applying multivariate estimation models to improve accuracy. For accuracy purposes, Walsh et al [66] recommend tracking the exact day when data are gathered instead of relying on average measurements, and Petersen et al [65] encourage implementing detailed environmental variables (eg, weather conditions, seasonal changes, proximity of resources, ease of transportation, living alone or within a community, or neighborhood demographics).

Regarding the alleviation interventions, more knowledge is needed regarding the effect of group sessions on the intervention results [77,85] to ascertain whether to conduct studies individually or in group settings [72]. The need for advanced and low-cost robotic devices to be used for research purposes [72,75] sets an open challenge for the growing robot market. The study by Lazar et al [75] challenges the perception of seeing pet robots as "technological fixes" for loneliness or social isolation alleviation; instead, it suggests reimagining their potential to suit specific needs and existing social lives. Brandenburgh et al [83] state that future developments may focus on how to change human behavior in addition to which behavior should be changed.

Regarding technological features, Appel et al [81] mention open challenges for future VR studies to succeed better in alleviating feelings of being lonely by applying joint or multiuser experiences with multidisplay setups. Lin et al [82] state that other VR-related systems and technologies could also be examined, but they do not specify the types of systems. Casey et al [70] suggest that robots used in dementia care could have more human-like features and better capabilities for communication and understanding speech in future. Chen et al [71] advocate a reliable method for measuring interaction time, such as an in-built function in Paro. Tkatch et al [79] propose effect comparisons between having a real pet or a robotic pet, and between a robotic cat and a robotic dog. Hudson et al [74] suggest implementing robotic pets with increased interactivity in future interventions; however, they also raise a potential ethical issue where older adults become dependent on their pet. Sidner et al [78] add that instead of using predetermined methods for introducing activities in the system, more flexible and teachable methods could be sought to prevent failures during activity usage in future.

Baisch et al [84] recommend more comprehensive research on the psychological mechanisms and human characteristics with respect to the acceptance of robots, as well as the diversity of older adults' life circumstances. The stage is also open for new ideas to enhance the perceptions of user-technology fit among older adults.

Discussion

Principal Results

This systematic literature review examined the research conducted on older adults' loneliness and social isolation and physical ICT solutions in the era of AAL. The aim was to gain insight into how technologies can help overcome such circumstances without fostering social communication with people and what the main open-ended challenges according to the included studies are. The results demonstrate that issues of loneliness and social isolation among older adults cannot be eliminated using physical ICTs, but that physical ICTs are used to help detect and predict, or alleviate such circumstances. ICT solutions such as smart homes can help predict and detect loneliness and social isolation, and technologies such as robotic pets and some other social robots can help alleviate loneliness to some extent. The main common open-ended challenges according to the reviewed studies are related to the need for more robust study samples and study designs. In addition, studies reported some technology- and topic-specific open-ended challenges.

Based on our findings, all the reviewed smart home and house solutions in the area of detection and prediction were considered capable of detecting and predicting older adults' loneliness or social isolation to some extent. Tracking the outings, including the time spent outside the house, number of outings, and number of places visited, stood out as a relevant activity to be examined in the unobtrusive models. Overall, these methods show a promising research path for overcoming loneliness and social isolation.

Open-ended challenges in the area of detection and prediction included a more flexible adaptation of predictive models to contingencies and contextual situations and the development of learning algorithms that allow the systems to accurately respond to the evolving circumstances of older adults. In addition, ethical issues posed by the intrusiveness of monitoring systems in older adults' lives, as well as economic concerns, remain to be assessed. Further, as pointed out in one of the studies [65], it is relevant that researchers continue to find a way to implement the complexity and variety of living spaces in their experiments if they seek accuracy in their results and solutions to overcome loneliness and social isolation. It is clear that the environment shapes individuals, and thus, these technologies could be exploited further to "attune" [86] the built environment with "typical human situations" [87] to contribute toward increasing the social inclusion of older adults and alleviate feelings of loneliness.

According to the results, some forms of physical ICT hold promising value in alleviating older adults' loneliness. Significant positive results were obtained in interventions using social robots, an ambient activity system that includes an activity sensor, and a smart home solution. A common feature of these solutions is that they are able to interact with the user in one way or another, which may have served as the key to their success by fostering reciprocity between the device and the user, thus providing increased social contact opportunities for older adults. Some studies suggest that social robots could also

help reduce social isolation by providing social contact and activities for older adults, but more robust evidence is still needed to prove that social contact is being increased and not being replaced by technology. One reviewed study demonstrated that the experience of loneliness itself as part of psychological functioning was associated with lower acceptance of a telepresence robot in a poor user-technology fit scenario. Future studies should continue investigating the role of subjective feelings of loneliness in technology acceptance and adoption longitudinally to draw comprehensive conclusions.

Open-ended challenges related to alleviation included uncertainty about whether the interventions should be conducted individually or in group settings and the high cost of technologies. Regarding technological features, such as VR, joint or multiuser experiences with multidisplay setups could be explored in future. For social robots, scholars seek enhanced interaction and speech recognition capabilities, possibly in-built means for measuring interaction time, and further comparisons on the effectiveness of different robotic pets. There is also a need for more flexible and teachable methods for systems aiming to alleviate loneliness and developing knowledge on how technologies can be used for changing human behavior.

Furthermore, we found that none of the solutions in the reviewed studies aimed to alleviate and detect as well as predict older adults' social isolation or loneliness explicitly. Some of the solutions are perhaps able to do so, but none of the studies have examined both aspects by empirical methods. Solutions to assess and combat social isolation have so far been less researched compared to loneliness and are particularly needed. The need is evident in the COVID-19 era with on-going lockdowns and social restrictions all over the world, and where fast digitalization and ICT adoption on large scales have also happened at an unprecedented pace [88]. As discussed by Christina R Victor [89], scholars may also shift from a problem-based focus to preventive aspects, namely toward enhancing healthy social habits. Along these lines, the theoretical framework of the studies might be enriched, going beyond this consideration of loneliness as a contingent and transient or chronic experience by embracing other philosophical perspectives that consider it to be the existential condition of each of us; thus, loneliness is a permanent and unavoidable condition generated by the activity of consciousness [90].

Limitations

This study explicitly concentrated on loneliness and social isolation among older adults. Thus, it contributes most in situations where loneliness and social isolation can be suspected or are already present among older adults, which may be seen as a limitation of this study. In addition, the existing setup could be broadened to include other dimensions related to loneliness and social isolation, and other technologies to yield larger data sets for future reviews. For instance, there are studies using smartphones for detecting and predicting older adults' loneliness and social isolation [91,92]; studies also consider numerous forms of technical systems different from the ones we considered, aiming to reduce older adults' loneliness [93,94]. There are also other studies conducted regarding the effects of loneliness on technology adoption [95], and those neither exploiting physical ICTs [96,97] nor assessing the technology directly in relation to loneliness or social isolation but in terms of related factors [98,99]; these are beyond the scope of this review but closely related to it. However, we did not include all possible technologies and approaches in our study to keep it focused.

Comparison With Prior Work

This review differs from other reviews addressing ICT technologies to assess older adults' loneliness and social isolation focusing on mediating human-human interactions. It addresses ICTs that perform by themselves and do not aim to foster human relationships as the main objective of their interventions. This study also complements some other systematic literature reviews by addressing partially overlapping technologies, namely robots and smart houses; thus, it provides a more comprehensive view of the research in this regard. Further, to our knowledge, this review is the first one compiling the studies on detection and prediction of older adults' loneliness and social isolation, which is an emerging field that has received only little attention thus far [100].

Conclusions

This paper provides a comprehensive overview of the existing attempts aiming to combat older adults' loneliness and social isolation using physical ICTs, namely robots, wearables, and smart homes. Our findings demonstrate that physical ICTs such as smart home solutions can help detect and predict loneliness and social isolation, and technologies such as robotic pets and some other social robots can help alleviate loneliness to some extent. Technologies such as social robots and some of the smart home solutions that can react to human behavior or interact with people are promising, and the literature on these topics has increased recently. These findings have relevant implications to the discussion on combating loneliness and social isolation among older adults that challenge the prejudices about the use of technology in this sensitive area. The results benefit the academic community by accumulating research evidence and finding future research targets, as well as informing other professionals and practitioners of the current state of research, developed solutions, and interventions conducted. The results are also useful in the COVID-19 era, where it is extremely important to find solutions to cope with social isolation and loneliness.

Abstract

Background: The National Cancer Institute Informatics Technology for Cancer Research (ITCR) program provides a series of funding mechanisms to create an ecosystem of open-source software (OSS) that serves the needs of cancer research. As the ITCR ecosystem substantially grows, it faces the challenge of the long-term sustainability of the software being developed by ITCR grantees. To address this challenge, the ITCR sustainability and industry partnership working group (SIP-WG) was convened in 2019.

Objective: The charter of the SIP-WG is to investigate options to enhance the long-term sustainability of the OSS being developed by ITCR, in part by developing a collection of business model archetypes that can serve as sustainability plans for ITCR OSS development initiatives. The working group assembled models from the ITCR program, from other studies, and from the engagement

of its extensive network of relationships with other organizations (eg, Chan Zuckerberg Initiative, Open Source Initiative, and Software Sustainability Institute) in support of this objective.

Methods: This paper reviews the existing sustainability models and describes 10 OSS use cases disseminated by the SIP-WG and others, including 3D Slicer, Bioconductor, Cytoscape, Globus, i2b2 (Informatics for Integrating Biology and the Bedside) and tranSMART, Insight Toolkit, Linux, Observational Health Data Sciences and Informatics tools, R, and REDCap (Research Electronic Data Capture), in 10 sustainability aspects: governance, documentation, code quality, support, ecosystem collaboration, security, legal, finance, marketing, and dependency hygiene.

Results: Information available to the public reveals that all 10 OSS have effective governance, comprehensive documentation, high code quality, reliable dependency hygiene, strong user and developer support, and active marketing. These OSS include a variety of licensing models (eg, general public license version 2, general public license version 3, Berkeley Software Distribution, and Apache 3) and financial models (eg, federal research funding, industry and membership support, and commercial support). However, detailed information on ecosystem collaboration and security is not publicly provided by most OSS.

Conclusions: We recommend 6 essential attributes for research software: alignment with unmet scientific needs, a dedicated development team, a vibrant user community, a feasible licensing model, a sustainable financial model, and effective product management. We also stress important actions to be considered in future ITCR activities that involve the discussion of the sustainability and licensing models for ITCR OSS, the establishment of a central library, the allocation of consulting resources to code quality control, ecosystem collaboration, security, and dependency hygiene.

Introduction

Background

The Informatics Technology for Cancer Research (ITCR) program [1] was established by the National Cancer Institute (NCI) in 2012 to create an ecosystem of open-source software (OSS) that serves the needs of cancer research. ITCR supports informatics technology development initiated by cancer research investigators and includes 4 extramural divisions: cancer biology, cancer control and population science, cancer prevention, and cancer treatment and diagnosis. The coordinating body for ITCR is the NCI Center for Biomedical Informatics and Informatics Technology.

The specific goals of ITCR include (1) promoting the integration of informatics technology development with hypothesis-driven cancer research and translational or clinical investigations; (2) providing flexible, scalable, and sustainable support using multiple mechanisms matched to the various needs and different stages of informatics technology development throughout the development life cycle; (3) promoting interdisciplinary collaboration and public–private partnerships in technology development and distribution; (4) promoting data sharing and development of informatics tools to enable data sharing; (5) promoting technology dissemination and software reuse; (6) promoting communication and interaction among development teams; and (7) leveraging the NCI program expertise and resources across the institute and bridging gaps in the existing NCI grant portfolios for informatics.

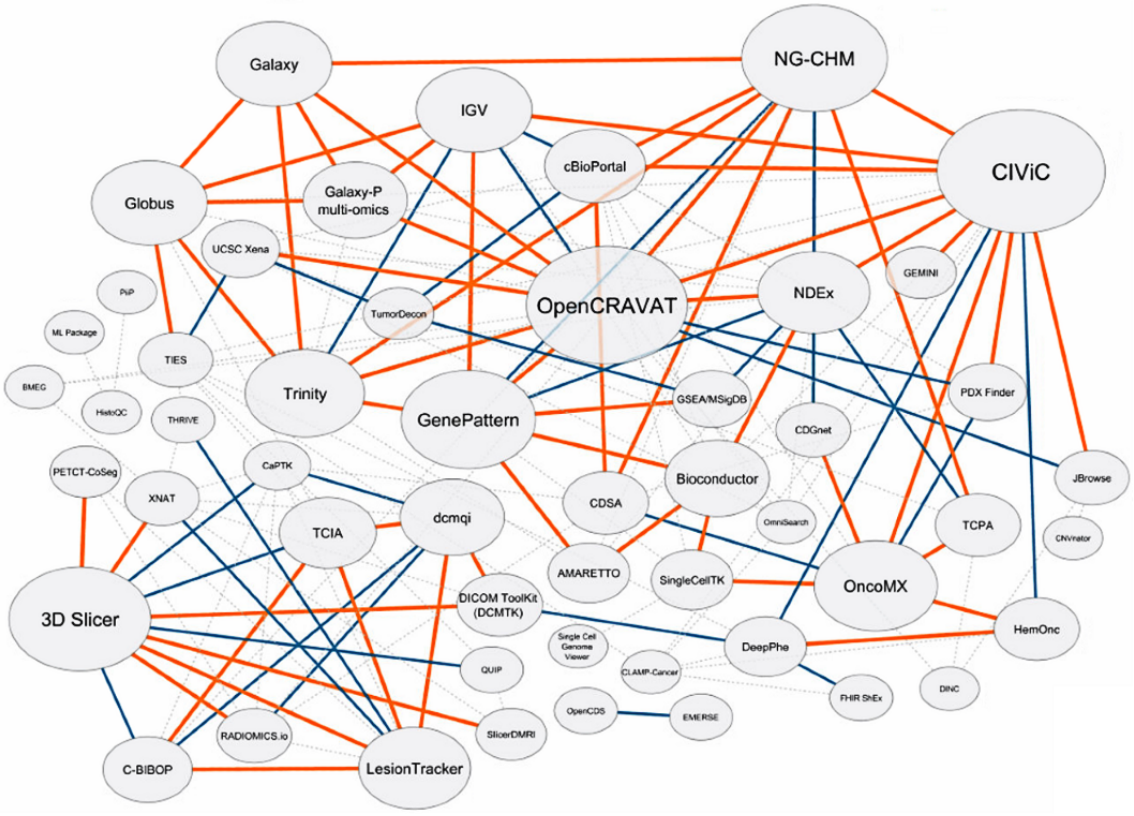
The scope of the ITCR program is to serve informatics needs that span the cancer research continuum. The ITCR program provides a series of funding mechanisms that support informatics resources across the development life cycle, including the creation of innovative methods and algorithms (R21), early-stage software development (R21), advanced stage software development (U24), and the sustainment of high-value resources (U24) on which the cancer research and translational informatics community has come to depend (Table 1). The program also offers supplements (*competitive revisions*) to currently funded NCI grantees to incorporate ITCR technologies into their ongoing research. Current funding opportunities are available on the ITCR website [2].

Table 1. Informatics Technology for Cancer Research (ITCR) funding mechanisms.

Mechanism	Purpose	Awards before September 9, 2020	Direct cost cap
R21	Innovative informatics methods and algorithms	25	US $275,000 over 2 years
U01	Early-stage software development	34	US $300,000 per year for up to 3 years
U24	Advanced stage software development	40	US $600,000 per year for up to 5 years
U24	Sustainment of high-value resources	6	No budget cap and up to 5 years of support
Competitive revisions (new)	Adoption, adaptation, and integration of ITCR tools and resources	1	US $100,000 per year for up to 2 years

This series of funding mechanisms is innovative and unique across all National Institutes of Health (NIH) institutes and centers. These mechanisms address a fundamental need to create a computational infrastructure that is interoperable and collaborative, linking many informatics and computational biology teams performing translational informatics. The ITCR ecosystem has grown substantially and now includes 55 funded efforts that are highly collaborative, as evidenced by its *connectivity map* (Figure 1). This map is copied from the Network Data Exchange website [3,4]. In this map, each node represents a project funded under ITCR. Links among these nodes represent connections among projects. Existing connections are represented by orange solid lines, ongoing connections by blue solid lines, and proposed connections by gray dashed lines. The node size is determined by the connectivity score, which is calculated by assigning 0 points for each proposed connection, 1 point for each ongoing connection, and 3 points for each existing connection. A large node usually indicates that the project has many existing connections with other projects. The connectivity scores are available on the Network Data Exchange website.

Figure 1. The map of Informatics Technology for Cancer Research projects.



As the ITCR program moves into its second phase, it faces the challenge of long-term sustainability for the software being developed by its grantees. Whether viewed from the angle of a single funded project or all ITCR-funded projects, some of the software will naturally *graduate* upon reaching maturity to leave room for continuing innovation through the program. As mature projects often lead to complex and successful products based on years of investment in human effort, funding, and cumulative expertise, these projects need to move into the next phase of support rather than risk being abandoned.

Addressing the challenge of the projects' long-term sustainability was the primary task of the ITCR sustainability and industry partnership working group (SIP-WG) [5], which was convened in 2019. The working group initially set the goals of addressing 4 topics of interest to the translational cancer informatics community: (1) to publish a collection of case studies of successfully disseminated software products supported by open-source licenses and to provide practical examples of approaches that have proven viable for licensing and sustainability, (2) to develop a workflow or decision tree to support informed decision-making consistent with ITCR expectations and the future licensing needs of open-source tools, (3) to provide a licensing consultancy service in collaboration with the ITCR program, and (4) to develop a collection of business model archetypes that can serve as starting templates and to formally document the dissemination and sustainability plans for new software development initiatives. The ITCR licensing resources will represent *best practice* approaches and leverage our extensive network of relationships with organizations such as the Open Source Initiative, the Software Sustainability Institute, and the Chan Zuckerberg Initiative to maintain relevant knowledge in this field. As described above, the first major topic—publication of case studies—is the subject of this paper. The remaining 3 topics will be the focus of future white papers and manuscripts by the ITCR SIP-WG.

Literature Review

We briefly introduce several software sustainability models that are present in the literature [6-8]. First, Aartsen et al [8] described 2 models for sustaining digital assets from

public–private partnerships in medical research: the not-for-profit organization model and the distributed network model. The *not-for-profit organization model* uses, for example, a foundation (also discussed by Kuchinke et al [6]) as the backbone organization to assure the maximum value of the assets. The Apache Software Foundation is one such example. An advantage of nonprofits is that they can take a long-term view. The sustainability of nonprofits can be mitigated through memberships. The concept of a foundation has the advantage that the development of an artifact is strongly influenced by academic users, so its design can be focused on scientific goals instead of commercial ones. The disadvantage of the not-for-profit organization model is its dependency on one organization for all digital assets. The *distributed network model* is built on the premise that individual partners who contribute to the development of digital assets have a stake in seeing these assets sustained and gaining future value through further development. The disadvantage of the distributed network model lies in the conflicting missions of research and industry; organizations with a research mission do not focus on producing digital assets that are ready to be commercialized by industry.

Gabella et al [9] provided a comprehensive review that adds 10 models for the sustainability of assets, including 4 noncommercial and 6 commercial models. As a noncommercial model, the *national funding model* supports infrastructure directly through noncyclical funding programs. On the other hand, in the *infrastructure model*, funding agencies set aside a fixed percentage of their research grant volumes to be redistributed among core data resources according to well-defined selection criteria. In the *institutional support model*, funds are provided internally from the institution, whereas the *donation model* depends on external philanthropic funding. In terms of the 6 commercial models, the *content licensing or industrial support model* requires commercial users to pay a fee for access and for-profit use, with the assets being free for noncommercial users (also discussed by Kuchinke et al [6]). The *user subscription model* (also discussed by Chang et al [7]) relies on a subscription for a set period. The *freemium model* (also discussed in Chang et al [7]) provides a core that is free, with add-ons requiring a fee. The *razor and blades model* (also discussed in a Wikipedia introduction for business models of OSS [10] as a commercial model) offers a free initial trial (*razor*) that encourages the continuing future purchases of follow-up services (*blades*). The *mixed model* relies on multiple diversified funding streams. For instance, a common mixed model practice is the combination of OSS with services (provided by companies) on installation, configuration, and troubleshooting. Linux is a familiar example of this. However, the Linux model relies on a large user base, which may not necessarily be the case with biomedical research tools.

In addition to the models discussed in last paragraph, the *macro research and development infrastructure* is based on funding that comes from governmental research grants or from research grants from local or international partner institutes [7]. The *split licensing model* offers a free version under a general public license (GPL) and a commercial version with its own license that does not allow software redistribution (eg, MySQL [Sun Microsystems, Inc] and openClinica [OpenClinica, LLC]) [10].

The current literature has also discussed the importance of the strength and health of the community behind a software product [11-13]. Iaffaldano et al [11] used the sleep stage metaphor to describe developer cycles: the awake stage is when developers are active in the project, the sleep stage is when developers pause their package commit activity, and the dead stage is when developers abandon the project. They further explored the reasons for the stage transitions, listing both personal factors (eg, life event, financial, and change of interest) and project factors (eg, social, changes in the project, and role change) as playing a role. Atiq et al [12] suggested sponsoring of open-source projects in various ways as an increasing number of proprietary firms participate in, sponsor, and offer their developers for open-source projects. Jiménez et al [13] provided 4 recommendations for a sustainable open-source project: (1) making the source code publicly accessible from day 1, (2) making the software easy to discover by providing software metadata via a popular community registry, (3) adopting a licensing system that complies with the licenses of third-party dependencies, and (4) defining clear and transparent contributions, governance, and communication processes. Nyman et al [14,15] discussed code forking (implementing an existing code base found in a separate project) within the context of OSS. The right to fork code is built into the very definition of open source. Code forking can revive community interest in a project or provide an alternative to acquisitions, which was the case with MySQL after Oracle's acquisition of Sun Microsystems. The MySQL code was forked under a different name, MariaDB, because of concerns regarding the governance and future openness of the MySQL code. Nyman and Lindman [14] state, "Given that forking ensures that any project can continue as long as there is sufficient community interest, we have previously described forking as the 'invisible hand of sustainability' in open source." For specifically big biology, Prins et al [16] described the challenges of creating sustainable software solutions: most OSS are developed as prototype software, many OSS are not scaled to terabytes of data, and there is a lack of scientific attribution for software development.

Methods

We conducted a survey among the members of the working group to select a collection of case examples of successfully disseminated software products. We asked each member to provide the *best 3* examples of sustainable OSS to serve as models for ITCR open-source projects. The survey was completed by 13 participants, most of whom were authors of this white paper and had years of experience developing OSS for cancer research. To profile the models of success in sustainability, 22 OSS use cases were provided by this survey, and the top 10 tools were then assigned to authors who were then asked to profile the following models: 3D Slicer [17], Bioconductor [18], Cytoscape [19], Globus [20], i2b2 (Informatics for Integrating Biology and the Bedside) [21] and tranSMART [22], Insight Toolkit (ITK) [23], Linux [24], Observational Health Data Sciences and Informatics (OHDSI) [25], R [26], and REDCap (Research Electronic Data Capture; provides a nonprofit end user license agreement but its code base is not open to individual developers) [27].

After reviewing the literature and discussing it in the ITCR working group, we determined that each OSS use case should be profiled according to recommendations by Nesbitt [28] in his paper: "What does a sustainable open source project look like?" Accordingly, each of the top 10 OSS use cases was profiled in the following aspects of sustainability: governance, documentation, code quality, support, ecosystem collaboration, security, legal issues, financing, marketing, and dependency hygiene. Profiling mainly relies on information that is publicly available. As some of the coauthors are key developers of 3D Slicer (AF, SP, JCFR, JVM, and AL) and Globus (IF and BER), we were able to provide more firsthand information on these 2 cases.

Results

In this section, we examine each OSS use case in terms of these 10 sustainability aspects. Full descriptions of the OSS use cases are available in Multimedia Appendix 1.

Governance

All 10 OSS use cases have a management committee and a technology development team. ITK and REDCap have established consortiums. The 3 models (i2b2 tranSMART, R, and Linux) have established foundations. Stakeholders usually choose a consortium management model during the early stages of software development. In a consortium model, members have stronger control over the direction of development. A consortium management model may later migrate into a foundation model. In a foundation model, the organization considers the interests of all stakeholders, encouraging more new contributors and users to participate in the software development testing process. As a result, foundations usually require serious community efforts and diverse skills (eg, fundraising) [29].

The 6 OSS tools have provided their roadmaps publicly. The i2b2 tranSMART Foundation [30] defines a road map guiding the integration of tranSMART with i2b2 [31]. The 3D Slicer's road map [32] lists community suggestions related to a transition plan for Slicer 4.10 and the proposed changes for Slicer 5.x. Cytoscape's road map [33] shows that it is going down a number of roads simultaneously, including Cytoscape Desktop, Cytoscape Expansion to the Cloud, and Cytoscape Community Outreach. Globus's product road map [34] has plans to provide *research information technology as a service*. ITK's team has been continuously updating its road map [35-37] based on feedback from its community of users and developers as well as from the medical research community. OHDSI has several roadmaps, including an architecture road map [38], a road map for CDM v6.0 [39], and a road map for webAPI [40]. On the other hand, LWN.net, a computing webzine on software for Linux and other Unix-like operating systems, points out that the free software development model is resistant to central planning in general [41]. Although not always reliable, Linux's future can be reasonably predicted by looking at its current projects.

Regular meetings allow stakeholders to make operational decisions and set development priorities. The 3D Slicer's core developers and users meet in person twice a year, and Globus has an annual conference for its users and subscribers. The subgroups usually have more frequent regular meetings. On the other hand, the technical advisory board of Bioconductor meets monthly to develop strategies that ensure the long-term technical suitability of the core infrastructure. To reach a broader group of potential developers and users, some models (3D Slicer and i2b2 tranSMART) provide completely open communication channels, such as web-based forums and recorded webinars.

Owing to the limited amount of public information on these 10 OSS use cases, we do not know the exact size of each core development team or the individual assignments on core infrastructure. If there is a single person handling the complicated details of a critical component, an OSS project will go adrift quickly after losing that key person.

Documentation

All 10 OSS use cases provide documentation to users in various formats, such as user guidebooks (ITK [42], Linux [43], R [44], and 3D Slicer [45]), Wiki pages (3D Slicer [46] and i2b2 [47]), tutorials (Bioconductor [48], Globus [49], Cytoscape [50], tranSMART [51], 3D Slicer [52], and OHDSI [53]), and YouTube (Google, Inc) videos (REDCap [54], 3D Slicer [55], and Cytoscape [56]).

Further documentation is provided to new developers to encourage new contributions to OSS extensions. Bioconductor offers 3 levels of documentation—workflows, package vignettes, and function manual pages [57]—to encourage users to become developers who can make their own algorithms and approaches available to others. Similarly, the Cytoscape *App Ladder* teaches essential skills in app development [58]. R provides a variety of fully developed documentation, adequately covering 2 types of development: writing R extensions and developing R itself (by providing internal structure and coding standards) [59].

Code Quality

Releasing software without testing could be very dangerous to its reliability and reproducibility, so rigorous tests are critical for OSS. Before propagating the latest packages to user-facing repositories, Bioconductor developers conduct tests to ensure overall package integrity and integration with current versions of package dependencies. The 3D Slicer has established infrastructure to continuously run approximately 700 tests for its core application, with the test results being publicly available [60]. However, the quality control of some of the extensions of the 3D Slicer is slightly weaker than that of the core application. The extension contributors themselves manage the code quality and tests, and the 3D Slicer's core developer team does not enforce or verify these extensions. Cytoscape developers use Jenkins to build software projects continuously and test packages thoroughly before releasing them. Globus uses a continuous integration environment, automated tests, multiple prerelease environments, and documented, standardized, human quality assurance testing to ensure code quality, with at least one engineer other than the code author reviewing the code before releasing it to production. Both i2b2 and tranSMART have extensive automated and manual testing as part of their well-defined release processes. ITK had automated nightly builds and tests as far back as 1999, being an early adopter of

this software engineering best practice before the widespread adoption of continuous integration and GitHub (GitHub, Inc). R provides extensive support to facilitate external developers' package testing and release, which includes release guidelines, software packages, and servers for testing [61]. A few models (3D Slicer [62], ITK, and R [63]) enforce a consistent coding style.

Support

All OSS use cases provide support to users and new developers. For example, the OHDSI community provides 2 support channels: the community-based discourse forum provides support for implementing OHDSI tools, proposing or participating in network research studies, and requesting information on OHDSI-related topics [64]; and the GitHub project sites of OHDSI manage specific technical questions through tickets that anyone can issue [65]. Globus has several support options: web-based self-help tools, listserv groups, and a ticketing submission system with a responsive support team. R mainly relies on web-based self-help tools, frequently asked question listings, and subscription-based email lists, including a general R help email list, an R developer list, and an R package developer list. Although these models provide various support channels, Linux and Cytoscape mainly rely on dedicated channels (Linux: LF JIRA [66]; Cytoscape: a specific help desk [67]).

Not all support models for OSS are free. For example, ITK has a 3-way support: (1) ITK's discourse forum enables discussion and mutual help among users, and dedicated volunteers usually provide detailed example codes [68]; (2) the NIH has continued to provide maintenance contracts for bug fixes, incremental improvements, and a moderate level of user support (maintenance has typically been performed by Kitware (Kitware, Inc), providing continuity and expertise); and (3) Kitware also offers commercial ITK support for a fee. Another example is that of Globus, which provides free support lists, operates a ticketing system [69], and guarantees subscribers a 1-business day response time on support tickets.

Surprisingly, free support is often available in a timely manner. One good example is the 3D Slicer, which had >13,000 forum posts in 2018, with an average response time of <2 days (or <8 hours during weekdays). For 3D Slicer, support may be provided either by the core developers or by experienced members of the user community. Public forums can be extremely active; for example, Bioconductor has >100 visitors per hour.

Ecosystem Collaboration

Ecosystem collaborations are usually organized by working groups, conferences, networks, and community forums. Limited public information is available on how well OSS projects collaborate with other projects.

Security

Security is important for biomedical software tools, as they are often used to manage and process patient data. To protect patient privacy, i2b2 provides secure remote access to patients in institutions through web services that anonymously list the number of patients in each institution [21]. Globus has maintained a strong security model for many years, using standards-based components and protocols that address message protection, authentication, delegation, and authorization for distributed infrastructures. Globus's authorization is based on well-established standards, such as OAuth 2 and OpenID Connect, and leverages a federated log-in system to allow user authentication using one of the many supported identity providers (eg, institutional identities, eRA Commons, ORCID, and Google [Google, Inc]). The Globus high assurance tier provides additional security controls to meet the higher authentication and authorization standards required for access to restricted data, such as protected health information. Data transfers can be encrypted using OpenSSL libraries, and communication channels with the Globus service are Transport Layer Security 1.2 encrypted.

Linux has strong security features and is widely used outside biomedical domains. The Linux kernel allows administrators to improve security at the lowest level by modifying the attributes of the kernel's operation, building additional security measures into the kernel to avoid common buffer overflow attacks, and setting different access restrictions for different kinds of users [70]. In addition, there are many Linux security extension enhancements, such as ExecShield and Position Independent Executable [71]. The other examined OSS use cases did not provide detailed information publicly about security. However, security enhancement should become the focus of future releases of research software.

Legal Concerns

Among the 10 OSS use cases, a popular licensing model is the GPL, which allows the distribution and sale of modified and unmodified versions but requires that all the copies be released under the same license and be accompanied by the complete corresponding source code. For example, Linux was released under GPL version 2, whereas R and tranSMART used GPL version 3.

It is also feasible to use different licensing models for different components of an OSS. For example, Bioconductor packages belong to multiple license groups: artistic license version 2, GPL, Massachusetts Institute of Technology (MIT), Berkeley Software Distribution (BSD), and creative commons licenses that have minimal requirements regarding how the software can be redistributed [72]. Globus also uses mixed licensing models. The client-side software is licensed under the Globus community license, which allows subscribers to access the source code for the purposes of code review and contribution, whereas the software operated by Globus as a service is not licensed.

Open-source licensing models used by the other OSS use cases include Apache 2 (OHDSI and ITK), Mozilla Public License version 2.0, with the Health care Disclaimer addendum (i2b2) [73], and GPL version 3 (tranSMART). REDCap requires a nonprofit end user license agreement between an institution and the Vanderbilt University, and its code base is not open to an individual developer. Finally, the 3D Slicer license, although generally highly permissive, is not a standard Open Source Initiative certified license. Instead, it is a custom license that was defined via coordination with the legal department of Brigham and Women's Hospital, which primarily aims to

mitigate liability risks because of the nature of the application (visualization and analysis in support of research applications on clinical images).

Financing

Of the 10 OSS use cases, 8 (80%) started with federal research funding. For example, Bioconductor began receiving the NIH National Human Genome Research Institute's support in 2003 and NCI/ITCR funding in 2014. The 3D Slicer has received direct or indirect support from many research grants (primarily NIH) over the course of several decades [74] but no sustained funding from any single source or program. Cytoscape received support from the National Institute of General Medical Sciences and the National Resource for Network Biology. REDCap received early support from the National Center for Research Resources. The early development of Globus was supported by the National Science Foundation and the Department of Energy, whereas more recent work on high assurance mechanisms has been supported by the NIH. Federal research funding is vital, as it encourages research on OSS to focus on scientific explorations and research ecosystem development. At the same time, although grants guarantee the researchers money to experiment, researchers still have to look for sustainable solutions beyond the grant cycle [29].

Industry and membership support are common in mature OSS cases. For example, premium Globus features (eg, data sharing, use reporting, and guaranteed support levels) are offered to institutions under an annual subscription, which is a flat annual fee based on the institutions' level of research activity. Linux continues to be supported by individual memberships (thousands of members) and annual corporate memberships (>1000 corporate members) [75]. The R Foundation is largely supported by members (membership fees from supporting persons, institutions, and benefactors) and *one-off donations*.

Multiple sponsor programs involving both academic and industry sponsors are also feasible. For example, ITK has continual funding from the NIH for maintenance to enable its free use and, at the same time, has commercial-grade support. OHDSI also has both private and public funding support. The i2b2 tranSMART Foundation has 4 sponsorship programs: contributing sponsors, corporate sponsors, sustaining sponsors, and event sponsors [76]. Through the tranSMART and the successor i2b2 tranSMART Foundation efforts, Keith Elliston and colleagues started Axiomedix (Axiomedix, Inc) in 2018 specifically to provide a commercial (for-profit) support mechanism for government-funded OSS. Axiomedix offers a 4-part business model that helps to support and sustain the open-source platforms: first, a commercial-grade software publishing and support model; second, a full-service solution offering for these supported platforms that includes installation, configuration, data loading, curation, and more; third, a software development and customization model (the Axiomedix Expert Network) that enables core open-source developers to take up contracts and consulting for customers; and finally, a model for developing new products and platforms that leverages open-source tools, a network of experienced open-source developers, and the knowledge of subject-matter experts to develop new open-source or commercial tools.

Marketing

The 10 OSS use cases have a variety of marketing channels, including the use of logos (3D Slicer, Globus, and i2b2 tranSMART), websites (3D Slicer, Bioconductor, Globus, and i2b2 tranSMART), mailing lists (Cytoscape, Globus, and i2b2 tranSMART), forums (3D Slicer, Cytoscape, and i2b2 tranSMART), Twitter (Twitter, Inc; 3D Slicer, Bioconductor, Cytoscape, Globus, and i2b2 tranSMART), LinkedIn (LinkedIn, Inc; Globus and i2b2 tranSMART), Facebook (Meta Platforms, Inc; i2b2 tranSMART), YouTube (Google, Inc; 3D Slicer, Bioconductor, and i2b2 tranSMART), Tumblr (Tumblr, Inc; Cytoscape), Vimeo (Vimeo, Inc; Cytoscape), and Pinterest accounts (Pinterest, Inc; Cytoscape).

Additional channels include conferences, workshops, and publications. For example, the ITK is introduced at medical imaging conferences. R gains market share through an *evangelist* approach among statisticians, data analysts, and others from the biomedical community. Moreover, surveys administered to collect user feedback also act as a form of marketing. For example, the 3D Slicer team conducts small-scale surveys on forums and collects feedback forms during training courses. Similarly, the Globus team conducts surveys during workshops and tutorials.

Dependency Hygiene

Of the 10 OSS (all except R), 9 (90%) have many dependencies on other packages. Bioconductor and OHDSI depend on many R packages, and REDCap depends on MySQL, whereas Cytoscape relies on external services, including cxMate. As dependencies may complicate installation and use, i2b2 provides Docker containers for easy installation [77]. Software models mainly provide dependency information through documentation, for example, installation guides; however, few models describe the license and security status of each dependency. Crichton [78] points out the potential danger of complicated dependencies, warning that "Blackbox can make it difficult to see that there are far fewer maintainers working behind the scenes at each of these open-source projects than what one might expect." Thus, it is critical to provide transparent information about the dependency tree of the code libraries. The 3D Slicer is a good example, as it provides an extensive list of dependencies that is publicly available.

Discussion

We discussed 10 representative OSS use cases that have demonstrated sustainable practices, particularly in the biomedical domain. Although not a comprehensive list, these examples highlight the following as essential attributes of successful OSS development: alignment with unmet scientific needs, a dedicated development team, a vibrant user community, a feasible licensing model, a sustainable financial model, and effective product management.

Alignment With Unmet Scientific Needs

At the inception of an OSS project, it must identify and meet important scientific needs instead of complying with mandatory rules or obtaining external financial rewards [79]. Meeting these needs gives the software its *soul*, that is, its unique identity. For

example, Cytoscape fulfills the need for a visualization tool to represent complex interactions among molecules, Bioconductor reduces the barrier to entry involved in the effective use and sharing of computational biology and bioinformatics tools [57], and Globus addresses the need for frictionless data transfer and sharing. As the scientific community's needs are diverse and dynamic, developers should consider the potential expansions beyond the first application and adopt a highly reusable infrastructure even at the initiation stage.

Dedicated Development Team

An OSS project should have a core development team, which has not only developed an initial version of the software but will also continue to be committed to future versions. The team is the *brain* of the software and its intellectual center. For example, Globus includes services for identity management, data transfer, data sharing, and group management; interfaces such as application programming interfaces, web apps, and a command-line client; and software to manage data access on >10 distinct storage platforms and file systems. Only a dedicated and highly experienced development team can put all these components together in a concerted fashion.

However, maintaining such teams can be difficult. According to Atiq et al [12], the motivations of developers usually include both intrinsic (eg, creativity and fun) and extrinsic aspects (eg, financial rewards, development of job-related skills, and peer recognition). Atiq et al [12] further pointed out that transparent and fair extrinsic rewards and effective and open communications among developers are key characteristics for ensuring the long-term sustainability of OSS projects.

More importantly, the whole research community needs to realize that the creation of a dedicated development team is incredibly difficult if that team cannot gain recognition for their contribution. Unfortunately, it is still true that, in academia, the effort invested in the development of software is often not recognized as important and is certainly viewed less favorably than traditional research activities.

Vibrant User Community

To be successful, an OSS project should also have a vibrant user community whose organizational structure and ongoing activities can facilitate communication both among and across the developer and user groups. This community would foster the *materialization* of the value of the software while specifying the functionality requirements for future versions. A vibrant user community represents the *heart* of the software, which drives the development cycle. For example, 3D Slicer and ITK have large and stable user bases, mainly in the radiology and biomedical imaging communities. OHDSI tools have large user bases in the clinical informatics and population health informatics communities. Moreover, we highly recommend engaging scientists outside the original team and involving a broad array of stakeholders. In addition, we support encouraging the *diaspora effect*, where postdoctorates and students who move on to other institutions continue using the software used or created by their original group.

It is also important to realize that the *users* of enterprise-level OSS are institutions, not individual researchers. In fact, Masys et al [79] defined successful adoption as at least 50% of the intended institutions adopting and implementing a tool. They suggested that, instead of a one-size-fits-all technical approach, developers should provide flexible local implementations and customizations, such as the optional use of terminology standards. This flexibility is essential for building a vibrant user community and facilitating successful adoption.

Feasible Licensing Model

A sustainable OSS project also needs a licensing model that fits the nature of the software, its distribution channel, and stakeholder interests. A licensing model resembles a *skeletal system*, providing a framework for the software to function legally.

OSS licensing generally falls into 4 categories: nonpermissive, weakly permissive, fully permissive, and noncompliant. Open-source licenses are evaluated as to whether they conform to the Open-Source Definition by the Open Source Initiative, a 501c3 nonprofit established to be a steward of open-source licenses.

Nonpermissive licenses, such as the GPL and the Affero GPL, not only allow commercial and noncommercial reuse but also require the release of all modified code and any external code linked to this code. The most well-known example is Linux, which is now under GPL version 2. Without the use of lawyers, its founder, Linus Torvalds, wrote a brief license stating that no fee may be charged for its distribution. As internet-based delivery systems were in an early stage of development, this move eliminated the *floppy drive mills* whereby individuals or companies could send copies of Linux to consumers for a fee. As the goal was not to allow others to make money on *free software distribution* at the time of writing, the model fit. When OSS code was to be modified or added on to, several open-source licenses were created and evolved. GPL version 3 (used by R and tranSMART) is the most restrictive open-source license, which requires that any enhancements (such as new features) incorporated into the software must be released along with the source code. Commercial software companies refer to the GPL version 3 as a *toxic license*. Once the software contains any GPL version 3 codes, its future licensing and that of all other software that carries it would be forever under the GPL version 3 license. The *infectiousness* keeps commercial companies away from using GPL code in their products; however, it could be one of the most important reasons why R is widely used and is successfully evolving. From our point of view, nonpermissive licenses may fit best for software that is fundamental to essential scientific discovery and highly used by researchers from very broad domains and where funding support may mostly come from noncommercial sources.

Weakly permissive licenses (eg, Mozilla Public License 2) allow commercial and noncommercial use and require release on a file-by-file basis for any modified code. Fully permissive licenses provide unrestricted reuse of code for commercial and noncommercial purposes. Fully permissive licenses include the Apache 2, MIT, and BSD licenses, among others. One of the main motivations of the popular Apache 2 license was to enable the ability to integrate open-source code into a project without having to release any enhancements to the code, that is, the

ability to *build on the shoulders of giants*. Finally, many projects that are considered open-source release codes under custom licenses are non–Open Source Initiative compliant. Thus, although these projects may make the code available, they cannot be considered open-source compliant.

There is a slow migration in the research software field toward fully permissive licenses because of limited commercial support. Elster [80] discusses how the license of research software may have an impact on obtaining industrial funding support. Many informatics technology companies choose research software with full permissive licenses over nonpermissive licenses, as nonpermissive licenses add restrictions to code reuse in commercial software, raising concerns about future commercialization. BSD license, as an example of a fully permissive license, allows the inclusion of open-source code in commercial code. On the other hand, some companies prefer nonpermissive licenses to fully permissive licenses, as they do not want their competitors to build commercial code on top of the OSS that those companies previously funded. Although this type of self-interested licensing prevailed in the early days of the software industry, the industry soon realized that having tens or hundreds of groups reinventing the same code was limiting the progress of the industry. As a result, there has been a wide and growing adoption of fully permissive licenses such as MIT and Apache [81].

Software licensing creates a binding agreement on the way a licensee may use or distribute the programs or codes. Just as a software-wrapped or click-through user licensing agreement is binding, so too is the use of OSS and code. When a research software is commercialized, a *free version* for academic use may be kept; however, if it is used outside the terms of that license, a *commercial license* must be purchased. Thus, the environment of the use of the software can play an important role in whether a user is in violation of the applicable license. A violation may result in harsh additional fees or even legal actions.

Sustainable Financial Model

An OSS project requires a sustainable financial model (formal or informal) that can keep the software and its user community moving forward. A sustainable financial model is a part of the *circulatory system*, supplying *blood* to sustain the software ecosystem. The i2b2 tranSMART, Globus, and Linux are excellent examples that leverage multiple types of sources to sustain software development.

The public–private partnership is becoming a feasible way to support an OSS project in the long term; however, the establishment of these partnerships may not be easy. Industry partners usually have concerns regarding profitable commercialization time. The public release of an OSS project, including its knowledge and source code, may allow the market competitors to catch up quickly, as opposed to traditional commercialized software business practices, where intellectual property is commonly concealed as long as possible. However, at the same time, an OSS project may quickly attract a large number of outside users and new developers whose contributions can improve the robustness of a product, enabling platform-based customizations across multiple institutions. Robust implementations and large user bases increase the commercial potential of OSS projects.

Along with the development of OSS, its financial model can change over time. Globus has tried a mix of several financial sustainability strategies: relying on grant-based federal funding, offering free OSS, forming an international research consortium, launching a commercial company, and forming an industry organization [82]. Globus found that many activities critical to sustaining software are outside the mission of federal funding agencies. Few developers have the freedom to contribute to a software project that addresses the research community's needs at large and does not directly advance the contributor's own mission. Contributors are not always able to provide ongoing maintenance or user support for the code they contributed, much less for the rest of the code base. As copies (*forks*) are maintained by separate teams, new features may no longer be shared with the entire community, and user requirements between the nonprofit research community and the industry do not always align. After 15 years, Globus pivoted to a sustainable model of providing free, cloud-based software-as-a-service to researchers and premium subscriptions for institutions. Focusing the primary software product on the needs of researchers and the revenue mechanism of creating value for resource providers is proving to be a viable financial model for sustaining Globus.

In the literature review section, we summarized a gamut of financial models for long-term software sustainability. Each approach has its own strengths and weaknesses. For example, community-based sustainability (eg, the not-for-profit organization model mentioned in the literature review), including appropriate forking of branch-development efforts, is in many ways ideal as it leverages the collective and continuous efforts of entire communities. However, it might not be appropriate for important niche areas of development; it might overemphasize broad adoption rather than quality, novelty, or significance, and it might not be able to leverage efforts that do not follow the same open-source licensing structure. Commercialization (eg, content licensing model, user subscription model, freemium model, razor and blades model), such as the adoption of software modules in clinical workstations, leverages a large pool of resources and software libraries in addition to creating a direct path to a broad user base willing to pay for it. However, commercialization is limited by proprietary restrictions and by its dependency on profit-making motives, which might not align well with biomedical significance or with *investment for the future* policies. Various infrastructure-based models (eg, macro research and development infrastructure model) can be effective ways to pool resources and avoid replication; however, they depend on a decision mechanism for the selection of the small percentage of software products that would be supported. Moreover, infrastructure-based models might be less prone to supporting innovation because of their not-so-dynamic nature. Various funding-based mechanisms (eg, national funding model and institutional support model) combine the advantages of dynamic selection and evolution of software products through the process of merit-based reviews. Unfortunately, they are limited by the harsh reality that existing funding is far less than the cost of

long-term maintenance of meritorious software, a situation that is unlikely to change in the foreseeable future.

Effective Product Management

Finally, an OSS project requires effective product management, which is a part of the *neural system*, enabling fast communications between the *brain* and other systems.

Roadmaps outline the development status of projects, including both the dates of past events and future events, so individuals can understand the speed, goals, and activities of specific projects, thereby improving sustainability through well-conceived deadlines and structures [83]. We found that 6 of the OSS cases on our list had well-designed roadmaps. The design of a road map is usually an evolving process that requires multiple rounds of internal discussions as well as extensive communication with the community of users and external developers. R and Linux offer a road map publicly. It is possible that these 2 OSS tools rely highly on the developer community's contributions, whereas the community makes its own decision about what it thinks is important, showing its partial resistance to central planning.

Although a road map designates the plans, it is the software release that shows the actual achievement. As OSS often involve the participation of a large number of external developers, the coordination of software releases can be more complicated. R provides a very good example by providing extensive support to facilitate external developers' package testing and release. Regarding the release strategy, OSS communities adopt either feature-based or time-based releases [84]. A feature-based release strategy is more often adopted by early-stage OSS projects. As an OSS project grows in size and complexity, it may move to time-based release, which helps prioritize development activities.

With regard to OSS quality assurance, a large user community may provide the project with good coverage in terms of bug hunting, performance, and scalability testing; however, most users do not consciously explore uncharted edge functionalities and thus leave certain bugs unfound [84]. Therefore, it is recommended to have professional testing and share a core bug report with the public through a public ticket tracker [85]. Moreover, an OSS project needs a version control system to coordinate release management, bug management, code stability and experimental development efforts, interdeveloper communication, and the authorization of changes by particular developers [86]. Public information shows that most of the 10 OSS use cases discussed go through rigorous testing.

As the *instruction manual for software* [87], documentation is essential in creating a sustainable community, as it allows users and external developers to rapidly become familiar with the software and use it for their own projects. Therefore, documentation is a key way of creating smoother internal transitions among generations of core developers. When familiarizing themselves with the OSS through the documentation is not enough for new users and external developers, specific support is essential to engage them, such as answering questions in a public forum. As mentioned in the *Results* section, all 10 OSS use cases provide comprehensive documentation and various types of support to users and new developers.

Strengths and Limitations

The selection of the examined software products was completed by 13 participants, comprising a group of people with rich knowledge of the sustainability of OSS tools and the promotion of industry partnerships. Although we conducted a comprehensive analysis of 10 aspects of the selected OSS use cases, there appears to be a risk of biasing the paper's findings toward the interests of the ITCR working group and overlooking potentially important sustainability models. Limited to publicly available information, we were not able to discuss failed OSS examples and important checkpoints. Our future goal is to conduct a survey of a much broader research community to continue these discussions.

In addition to the information discussed about general OSS aspects using the Nesbitt list [28], we would like to briefly discuss other important aspects of research software, such as scientific accuracy and reproducibility, compliance, and ethics and integrity. Rougier et al [88] defined reproducible software as the publishing of software and data as a product of the used software, its related data, and the articles involved. For software to be reproducible, its source code must be investigated, and its models must be documented thoroughly and precisely. Buck [89] explains that to improve reproducibility, transparency must be a top priority, despite the interference of high cost. To increase transparency, free OSS provides other scientists (besides software developers) with cheap options to validate their reported results and further apply this open science framework to other scientific research activities. Another aspect, compliance, is also critical for OSS, as the software may be incorporated into commercial uses, used to raise awareness about compliance, or used to display specific cases of noncompliance [90]. When distributed to external sources, the OSS licenses must be reviewed before compliance can be achieved (eg, for sharing, license fees, and compatibility purposes). Finally, ethics and integrity are essential for software in biomedical research. The use of OSS should allow researchers to meet the professional standards of practice, and the use of OSS must align with the 4 basic principles in the field: nonmaleficence, beneficence, autonomy, and justice.

Other Initiatives and Future Perspectives

In addition to the NCI ITCR, several informatics efforts across the NIH have also emphasized creating an approach to OSS sustainability. The National Center for Advancing Translational Sciences, Clinical and Translational Science Awards links with programs from the NIH Office of the Director, including the Big Data to Knowledge (BD2K) [91,92] and the Data Science program [93], and most recently, the All of US Precision Medicine Initiative [94]. BD2K is a trans-NIH initiative launched in 2013 to support the research and development of innovative and transformative approaches and tools that maximize and accelerate the integration of big data and data science into biomedical research. BD2K recognizes that software is a necessary part of any modern solution to biological problems. Representing the shared interest of the national Clinical and Translational Science Awards consortium, the

National Center for Data to Health is particularly interested in sustainability strategies for data management infrastructure, which again inevitably involves the sustainability of software tools revolving around clinical data.

Other countries, such as the United Kingdom and Germany, are also making national policies to improve software sustainability. Currently, the United Kingdom has developed a research and innovation road map and is using the *research and development system* as a connection to sources of funding that can flow to universities, research institutes, government laboratories, charities, and businesses [95]. The United Kingdom is moving toward minimizing bureaucracy in the public funding system to keep checks and approvals that will effectively manage public money and make informed decisions for the system. Moreover, the United Kingdom is increasing clarity and coherence in research and development funding to allow researchers to have confidence in long-term investments and enable agile funding to allow the system to tackle issues of national priority and urgency. For biomedicine, scholars in the United Kingdom recommend OSS in health care information systems to improve safety and effectiveness [96]. Similarly, Germany has created a more unified software policy [97] and has outlined the following recommendations: (1) in its foundation, research software must have an open-source code, as well as trustworthy, supportive, and appropriate infrastructure and infrastructure facilities; (2) senior researchers and research managers must develop good scientific practices, and there must be a general shift toward the acquisition of central licenses rather than commercial software and services; and (3) in the provision of research software, there must be a shift from the role of developer to the role of provider. There are still many challenges at the organizational and technical levels related to the development, use, and provision of research.

Looking forward, it will be important to learn from international governance examples and engage with other groups interested in sustainable software models. One notable community is the Workshop on Sustainable Software for Science: Practice and Experiences (WSSSPE) [98], a workshop series aimed at promoting sustainable research software by focusing on principles and best practices, careers, learning, and accreditation. The fourth WSSSPE created a group interested in writing white papers that focus on scientific environments and their implications, targeting developers and project managers of research software. Another notable community is the Science Gateways Community Institute, which provides consulting services for sustainability and business planning [99].

Conclusions

Overview

Our review of the existing sustainability models and 10 OSS use cases strongly confirms the importance of the 3 proposed future focus areas of the SIP-WG: (1) to develop a workflow or decision tree to support informed decision-making that is consistent with ITCR expectations and the future licensing needs of open-source tools; (2) to provide a consultancy service for the 10 sustainability aspects, especially governance, licensing, code quality, and community building, in collaboration with the ITCR program; and (3) to develop a collection of business model archetypes that can be used as starting templates to formally document the dissemination and sustainability plans for new software development initiatives. In addition, we stress on 5 important actions that should be considered in future ITCR activities, as described in the following sections.

Discussion of the Feasibility of Sustainability Models for ITCR Projects

An important agenda item of the SIP-WG's future work should be a discussion of the feasibility of various sustainability models for the many ITCR support projects, including nonprofit models (eg, the not-for-profit organization model, the national funding model, the infrastructure model, the institutional support model, and the donation model), and commercial models (eg, the distributed network model, the content licensing or industrial support model, the user subscription model, the freemium model, the split licensing model, the razor and blades model, the macro research and development infrastructure model, and the mixed model).

Exploration of the Potential Licensing Models

The licensing of research software will have a direct impact on public–private partnerships. A mixed licensing model may be the best way to strike a balance between free use (for broad use) and paid use (for funding support). Given the potential complexities of different OSS approaches, key stakeholders should consider the licensing structure of their software models as early as possible. Important decisions and changes must align well with the road map of software development and maintenance, as changing the licensing of existing projects can be very challenging. Once an open-source project integrates code from external contributors, it becomes logistically difficult to legally change the licensing on the code.

Provision of Reward Mechanisms to Enhance Stakeholders' Motivation to Focus on Sustainability

The WSSSPE community has pointed out the importance of enhancing stakeholders' motivation through credits and rewards [98]. Currently, the main credit given for developing a research OSS is through publications. Key contributors should be encouraged to list the creation of software resources on their resumes and further value the OSS in the grant funding review process. We should also provide reward mechanisms to fairly allocate credit to external developers who have contributed to successful expansions and adoptions. Finally, universities and research institutions should create viable career paths for researchers developing software in academia to encourage them to continuously work on research OSS development.

Establishment of a Central Library to Make OSS Visible and Reusable

In addition, we should consider establishing a central library to make ITCR-funded OSS more visible and reusable for a large number of biomedical researchers. The open-access library should index the OSS tools with brief descriptions of their functions and simple examples. This library should point to the latest version of each OSS tool. It would especially serve as a repository for retired OSS tools, which may have short-term difficulties in obtaining funding support. Ideally, this library

should be searchable, enabling something like a Google search for research OSS. When researchers have certain needs, they can first search within this library to find out if there is an existing tool available to meet their needs or if there is an existing tool they may expand upon to meet their needs.

Before establishing such a software library, we need to fully understand who the expected users of the library would be, what their incentive to use it would be, how often entries would be added and updated, whose responsibility would be to update the records, and what funding sources would support the future releases of a piece of software. Without continuous curation, there is an eventual risk that software libraries may become software graveyards.

Provision of Industry Standard Support

Finally, we should allocate consulting resources to research OSS projects (especially at the early stage of development), which can guide these projects to follow state-of-the-art industry standards on code quality control, ecosystem collaboration, security, and dependency hygiene.

Acknowledgments

The authors thank the ITCR program for supporting the SIP-WG authors who contributed to this manuscript. The authors especially want to thank Mervi Heiskanen for her support in the many meetings and the strategic coordination required to publish this manuscript. Finally, special thanks go to Juli Klemm, Program Director of the Center for Strategic Scientific Initiatives and Director of ITCR, for her strategic advice, inputs into the ITCR SIP-WG, and this important OSS sustainability model effort. The authors thank Dr Richard Boyce from the University of Pittsburgh for contributions to the OHDSI case study, Lee Liming and Vas Vasiliadis from the University of Chicago for contributions to the manuscript revisions, and Dr Rudi Pillich from the University of San Diego for providing guidance on the ITCR connectivity map. The authors thank the 2 reviewers for their insightful comments. The authors received the following funding support: MJB and YY, Centers for Disease Control and Prevention, National Institute for Occupational Safety & Health U24 OH009077; YY, National Library of Medicine K99LM013383; AF, NIH NCI U24 CA180918; MM, NIH U24CA180996; BDS, NCI-ITCR U01CA204826; GS, U24CA248010; SP, NIH-NIBIB grant P41 EB015902; and GQZ, ITCR R21 CA231904.

Authors' Contributions

MJB, YY, JRG, GS, GQZ, CD, and KOE defined the scope of the manuscript and drafted the initial sections. AF, IF, BER, and JCS provided critical reviews and contributed to the editing of the manuscript. AF, SP, JCFR, AL, GS, MM, JCS, MKD, IF, JRG, BER, DPT, JBZ, MJB, KOE YY, BDS, JVM, and GQZ reviewed OSS use cases and drafted Multimedia Appendix 1. SB contributed to the additional discussions about product management and the United Kingdom’s and Germany’s national policies of OSS. JC contributed to the additional discussions on licensing models.

Conflicts of Interest

KOE is a shareholder or investor in Ingentium, Inc; Axiomedix, Inc; Seneca Creek Research LLC; and Trazend, Inc; KOE holds advisory roles with Open-Source Pharma Foundation nongovernmental organization and i2b2 tranSMART Foundation and currently serves as the chief executive officer of PHEMI Systems Corp. MJB is a founder and has equity (stock) in SpIntellx, Inc.

Multimedia Appendix 1
Full descriptions of open-source software use cases.

Abstract

In digital medicine, patient data typically record health events over time (eg, through electronic health records, wearables, or other sensing technologies) and thus form unique patient trajectories. Patient trajectories are highly predictive of the future course of diseases and therefore facilitate effective care. However, digital medicine often uses only limited patient data, consisting of health events from only a single or small number of time points while ignoring additional information encoded in patient trajectories. To analyze such rich longitudinal data, new artificial intelligence (AI) solutions are needed. In this paper, we provide an overview of the recent efforts to develop trajectory-aware AI solutions and provide suggestions for future directions. Specifically, we examine the implications for developing disease models from patient trajectories along the typical workflow in AI: problem definition, data processing, modeling, evaluation, and interpretation. We conclude with a discussion of how such AI solutions will allow the field to build robust models for personalized risk scoring, subtyping, and disease pathway discovery.

KEYWORDS

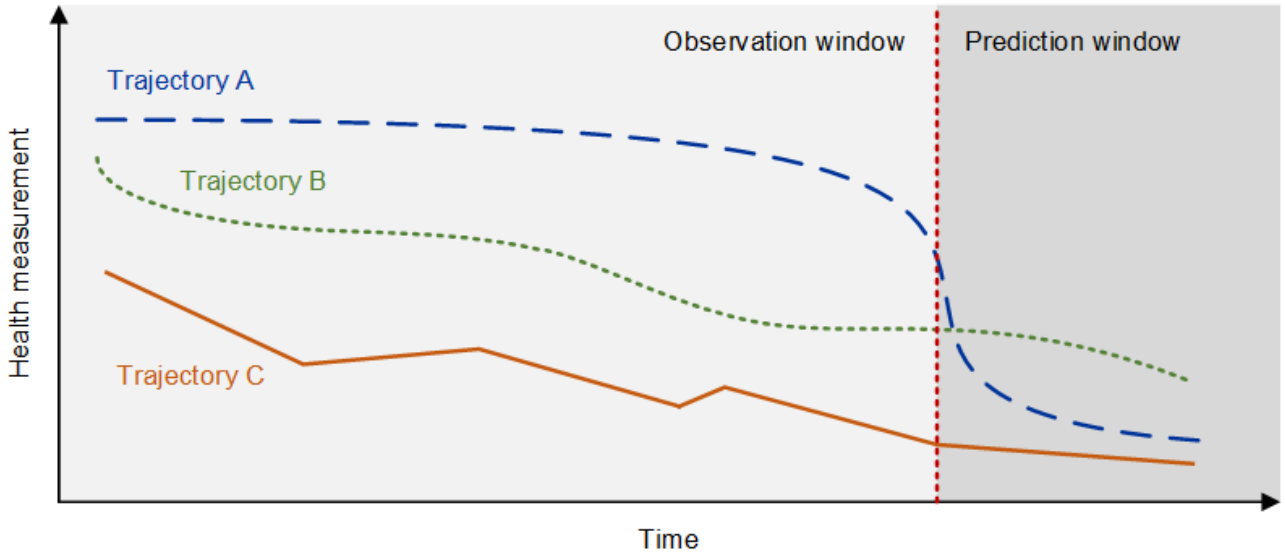
patient trajectories; longitudinal data; digital medicine; artificial intelligence; machine learning

Introduction

Digital medicine facilitates broad access to large volumes of patient data, typically through recordings of health events over time. For example, electronic health records store the history of a patient's diagnoses, medications, laboratory values, and treatment plans [1-3]. Wearables collect granular sensor measurements of various neurophysiological body functions over time [4-6]. Intensive care units (ICUs) monitor disease progression via continuous physiological measurements (eg, electrocardiograms) [7-10]. As a result, patient data in digital medicine are regularly of longitudinal form (ie, consisting of health events from multiple time points) and thus form *patient trajectories*.

Analyzing patient trajectories provides opportunities for more effective care in digital medicine [2,7,11]. Patient trajectories encode rich information on the history of health states that are also predictive of the future course of a disease (eg, individualized differences in disease progression or responsiveness to medications) [9,10,12]. As such, it is possible to construct patient trajectories that capture the entire disease course and characterize the many possible disease progression patterns, such as recurrent, stable, or rapidly deteriorating disease states (Figure 1). Hence, modeling the patient trajectories allows one to build robust models of diseases that capture disease dynamics seen in patient trajectories. Here, we replace disease models with data from only a single or a small number of time points by disease models that account for the longitudinal nature of patient trajectories, thus offering vast potential for digital medicine.

Figure 1. Analyzing patient trajectories with artificial intelligence in digital medicine.



Several studies have previously introduced artificial intelligence (AI) in medicine for practitioners [13,14]. Some studies review potential medical applications that could benefit from AI [15,16], whereas others review specific methods (eg, deep learning [17,18]) or specific data types (eg, electronic health records [18] and medical images [19]). Some studies suggest reporting guidelines [20,21] or discuss the integration of AI into medical practice [22]. Our research contributes to the literature by discussing AI-powered digital medicine based on patient trajectories.

Patient trajectories refer to time-resolved representations of patient health events across multiple time points (eg, hospitalization or treatment events, sensor measurements from wearables, and physiological measurements from ICUs). AI-powered analysis of patient trajectories allows for an assessment of the heterogeneity of patient disease courses. In Figure 1, trajectory A predicts a sudden but sharp decline in a health state, whereas trajectories B and C depict 2 types of progressively declining disease states. Analyzing trajectory-like representations of patient data can generate new insights for better care in digital medicine.

To unlock the value of patient trajectories for digital medicine, there is a need for new AI solutions that can deal with time-resolved sequential data consisting of multiple health events. Although many models from the area of AI have become standard in digital medicine (eg, deep learning [18]), a naïve application of such models might not be effective when modeling the longitudinal nature of patient trajectories. Instead, this requires customized approaches. For example, in a study by Alaa et al [23], a direct application of deep learning has been found to be outperformed in terms of both predictive accuracy and interpretability when one instead uses a carefully engineered sequential model (ie, referred to as Hawkes process) that treats the time between medical events as informative for the course of the disease. On the basis of this background, we discuss challenges and solutions for AI that are unique to analyzing patient trajectories. Specifically, we examine the implications for developing disease models from the patient trajectories along the typical workflow in AI: (1) problem definition, (2) data processing, (3) modeling, (4) evaluation, and (5) interpretation, as detailed in the following section.

Applying AI to Patient Trajectories

Problem Definition

Applying AI to patient trajectories is relevant for different objectives in digital medicine (Table 1). One objective is *risk scoring* [3,23,24], where patient trajectories are leveraged to predict patient outcomes. Here, the rationale is that the predictions based on health measurements from patient trajectories with multiple time points have greater predictive power than the predictions from those with a single or a few time points. For instance, risk scoring in ICUs becomes more accurate when traditional scores (eg, Acute Physiology and Chronic Health Evaluation II and Simplified Acute Physiology Score) are replaced with AI-based predictions incorporating data from patient trajectories [9,10,25]. Similarly, for cardiovascular diseases, existing risk scores (eg, the Framingham risk score that predicts the 10-year risk of developing coronary heart disease) become more accurate when replaced by AI solutions that work with longitudinal patient data [12]. These examples show that the underlying patient trajectory provides rich, granular insights into the disease dynamics that can then be captured by AI solutions for trajectory analysis. Therefore, additional patient information, such as past medications, comorbidities, or other risk factors, can be considered. For instance, in the context of cardiovascular diseases, it might be informative for risk scoring to analyze the patient's past journey, which comprises whether the patients have been prescribed nicotine replacements and *when* (eg, only recently or several years ago). Different patient outcomes including mortality, hospital readmission, hospital length of stay, disease onset, disease severity, or adverse drug reactions can be of interest in risk scoring. The risk score can then inform treatment planning (or in general, assess the patients' needs). In addition, AI solutions can further generate insights for defining (early) disease states.

Table 1. Overview of different objectives in artificial intelligence–based trajectory analysis.

Objective	Description	Examples	Selected references
Risk scoring	The objective is to estimate the likelihood of future health outcomes (eg, mortality, readmission, and adverse drug reactions)	• Predict the 10-year risk of developing coronary heart disease for patients as in the Framingham risk score • Predict the need for an intensive care unit in an emergency ward through measurements from wearables	[3,17,23,26-32]
Subtyping	The objective is to cluster the patient cohort into different disease dynamics (ie, subtyping) while accounting for the longitudinal form of patient trajectories	• Cluster disease progressions into "recurrent course" and "progressive decline"	[26]
Pathway discovery	The objective is to detect clinically meaningful subpatterns in patient trajectories	• Identify frequent patterns in patient trajectories that are indicative of disease onset	[1,33,34]

Here, we see several paths for risk scoring based on patient trajectories. First, to ensure high accuracy, AI-based risk scores must be tailored to each patient outcome while considering the desired forecast horizon and the patient cohort. So far, there are several studies that showcase the successful use of AI-based risk scores [35,36]; however, there is a need to develop other risk scores, especially for the settings in which AI-based risk scores are scarce or not yet available (eg, predicting the transition from prediabetes to diabetes or predicting specific adverse reactions to medication). Second, the AI-based risk scores will need to be integrated more extensively in clinical practice. Third, the risk scores should be extensively combined with approaches for explainability or interpretability, which allow the derivation of clinically relevant insights from patient trajectory data (eg, which information in a patient trajectory is a risk factor). Finally, if one includes data on treatments in the risk scoring model, one may infer the expected individualized treatment effect and eventually guide the treatment selection [37-42]. Here, we see further potential to transition from a purely predictive approach (ie, what is the expected risk level) to a prescriptive approach (ie, what treatment do we expect to reach a desired patient outcome). However, many AI solutions for estimating individualized treatment effects from patient trajectories have recently emerged [37-42] without being tailored to specific disease settings and patient cohorts. Therefore, further research at the interface to digital medicine should be a priority that will eventually yield effective and robust implementations for clinical practice.

Another objective of AI in digital medicine is *subtyping*, where AI can understand the heterogeneity observed in patient trajectories and identify the corresponding digital markers. A simple approach is to cluster the different patient trajectories (ie, subtyping) to match patients with similar disease dynamics, clinical pathways, or care patterns [26]. As a practical benefit, subtyping can support clinical tasks related to cohort building and, for instance, can provide patient stratification (eg, to define a cluster of patient trajectories that serves as an inclusion criterion for a clinical trial). However, subtyping requires a suitable notion of patient similarity, which can be challenging to define mathematically because of the longitudinal form of patient trajectories. Thus, it is crucial not only to cluster risk factors at baseline but also to find mathematical approaches that account for the temporal nature of the trajectories (ie, time-series clustering). This allows clinical practice to identify subgroups or subtypes based on the underlying disease dynamics (eg, to distinguish subgroups with a recurrent course vs a progressive decline). We expect an added value from comparing different subtyping approaches in terms of their relative strengths (eg, generated insights) for future research. On this basis, digital medicine could develop a principled procedure for defining *patient trajectory similarity* in the context of subtyping.

A related objective is *pathway discovery***,** where patterns in patient trajectories should be detected [1,33]. For instance, 1 application analyzes time series with laboratory measurements from patients with hepatitis B and C to discover frequent patterns indicative of liver damage [34]. This application can help to understand the underlying course of diseases and identify short- and long-term patterns (ie, motifs) in patient trajectories.

Depending on the objective and explicit assumptions, implications arise regarding the AI workflow and thus highlight the importance of selecting an appropriate modeling strategy. Additional details are provided in the following sections.

Data Processing

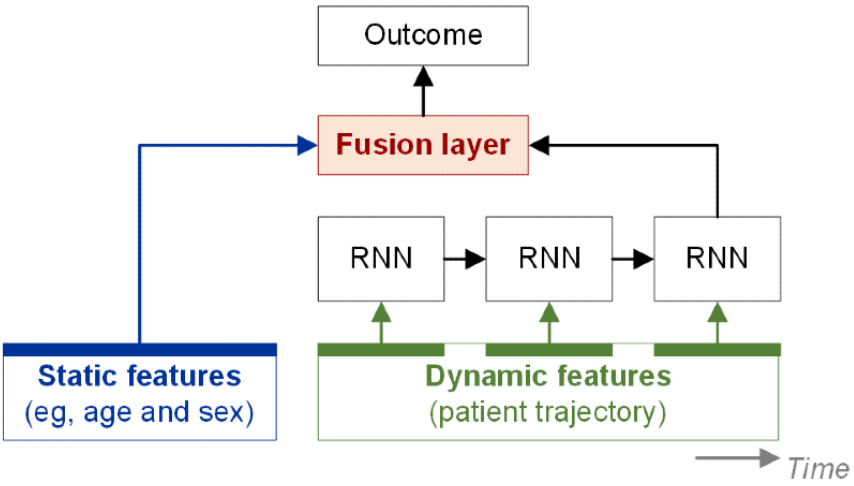
A fundamental question is concerned with data collection as this defines how time is encoded in the data. The example of nicotine replacement suggests that we should know whether such a medical event was recent or several years ago. This illustrates where we are now: when we have longitudinal data, it is often a matter of whether a medical event happened *recently* or *a while back*. Thus, the underlying time (or the underlying time lag) must be carefully considered to capture the longitudinal dimension of patient trajectories correctly. This is currently a challenge when considering the survey designs (eg, for risk scores). For example, one survey may ask a patient whether an event occurred last month or earlier, whereas another survey may ask to consider events that occurred within the last 12 months or earlier. As such, the meaning of *recent* may be inconsistent across survey designs. As a way forward, it will be necessary to develop a more consistent understanding, ideally involving data collection that considers precise time stamps (eg, by leveraging electronic health records).

The AI-based trajectory analysis often combines data from patient trajectories and baseline variables that describe risk

factors at the patient level (eg, sociodemographic, genomic data, or multimodal data). To combine sequential and static baseline data, tailored AI solutions will need to be developed [27]. Figure 2 shows an example of this approach. The literature shows larger variability regarding the modeling approaches; hence, further evaluations are needed to inform an effective approach.

Figure 2 shows an AI-based trajectory analysis in which a fusion layer combines the static (eg, age or sex) and dynamic features (eg, health measurements over time). The dynamic features have a longitudinal form and are processed by a sequential model (here, a recurrent neural network [RNN]).

Figure 2. Example of artificial intelligence–based trajectory analysis. RNN: recurrent neural network.



Data from patient trajectories are often complex and high-dimensional, which presents difficulties to humans and AI solutions for making accurate inferences. As a remedy, one can apply approaches that map patient trajectories onto a lower-dimensional representation that is eventually more meaningful. A simple analogy from medical practice is when one simplifies the age in years of a patient into a binary yes or no flag indicating whether a patient is above a critical age threshold. Here, we see a particular value for representation learning (eg, embeddings [31]) tailored to the unique characteristics of longitudinal health time series from clinical practice. Such AI solutions must be effective in dealing with the high-dimensional nature of medical data (clinical, genetic, social data, etc), avoid overfitting, and overcome the *curse of dimensionality* in the analysis. Mathematically, the idea of learning lower-dimensional representations is linked to manifold learning, for which embeddings are a special case [43].

Another challenge that further limits the use of AI-based trajectory analysis in medicine is data access and sharing. The current system is characterized by having data locked in *silos* where each hospital or health care institution limits access to their data and requires *lots of bureaucratic* work from researchers before allowing them to study and analyze the data. However, many initiatives are circumventing this status quo, such as the Observational Health Data Sciences and Informatics program, an international network of researchers aiming to provide reusable, collaborative, and reliable open-source solutions for large-scale health analytics [44]. Notably, there is interest in compiling extensive observational studies combining the electronic health record data from diverse health care organizations using standards to (1) design meaningful randomized controlled trials, (2) test clinical hypotheses on observational data, and (3) gain a better understanding of population characteristics, facilitated through framework efforts such as the Observational Health Data Sciences and Informatics program [44].

Furthermore, in the last couple of years, there has been an increasing number of studies focused on federated learning [45-47] that allows for AI algorithms to operate on decentralized data sets/systems in a privacy-preserving manner. In federated learning, the underlying algorithms (eg, FedAvg [48] and FedProx [49]) use the data stored in silos at different local sites for iteratively training a *global/central* model from a set of *local* models trained separately at each local site to perform prediction and classification tasks [48,50]. At the interface to health care, more research is being conducted that uses federated learning [45,51] for tasks such as clinical note phenotyping (ie, clinical natural language processing [52]) or predicting patient mortality in ICUs [53,54]. Here, we particularly point to the recent attempts to develop such approaches for patient trajectories. Examples include clustering patients through community-based federated machine learning for in-hospital mortality and length of stay prediction [55] or privacy-preserving patient similarity learning [56]. Federated learning may be further supported by secure hardware implementations, often with little computational overhead (eg, referred to as trusted execution environments [47]).

Moreover, there is more research on the privacy-preserving aspect of the technology, such as the differential privacy framework [57] (ie, applied to the model parameters), homomorphic encryption [58], and data anonymization techniques offering a *defensive level of privacy* as required by the General Data Protection Regulation and the Health Insurance Portability and Accountability Act [59]. Although these provide valuable tools for developers, we foresee more research that tailors them to the context of patient trajectories (eg, by offering sequential models for longitudinal data). More importantly, the availability of software packages [60,61] that allow both simulation of federated learning scenarios and their deployment

in real clinical settings will accelerate the adoption of federated or distributed learning approaches and open a wide array of research exploration and experimentation possibilities. This will eventually yield longitudinal trajectory analyses that span patient journeys across multiple hospitals or health care institutions.

Modeling

Fundamentally, analyzing patient trajectories requires AI solutions that can effectively handle sequential data structures that can vary in length (ie, from a few time points to multiple seconds, minutes, days, months, and year time windows). Hence, AI-based trajectory analysis must carefully adapt to the sequential structures by choosing appropriate modeling approaches.

In *risk scoring*, predictions from patient trajectories are often based on neural networks that are tailored to sequential data structures. These include tailored RNNs [3,17,27-29] owing to their strength in modeling long-term dependencies. One example of RNNs is the long short-term memory networks that iteratively process a time series with physiological measurements and aim to learn a lower-dimensional representation of the complete time series, regardless of its length, in their internal code layer. We can then use this lower-dimensional representation to predict patient outcomes from the patient's trajectory. Gated recurrent units proceed analogously but have a more parsimonious structure that, in medical applications, may help in obtaining robust predictions (eg, with a lower risk of overfitting for small-sized data sets) [8,27,62]. Recently, digital medicine has also processed the patient trajectories through transformer networks [30]. Transformer networks involve attention layers that learn to weigh different parts in a patient trajectory differently while optimizing for the outcome prediction and may therefore outperform other RNNs. In our view, a particular benefit of transformer networks is that the developers from digital medicine can train them in using semisupervised learning. One can use a set of patient trajectories *without* observing the patient outcomes to learn an abstract representation (ie, via unsupervised pretraining). Subsequently, one can customize the transformer network to predict a specific patient outcome (ie, via supervised fine-tuning). Semisupervised learning often facilitates more efficient learning when the number of available observations with patient outcomes is comparatively low.

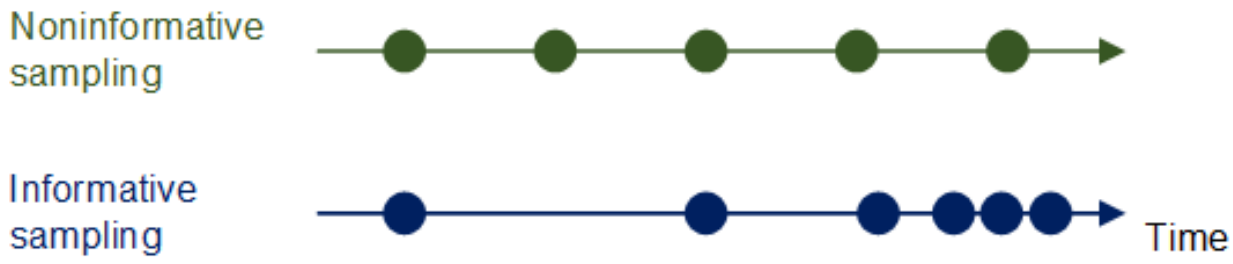
In risk scoring, other common prediction approaches are probabilistic models (eg, Markov models, point processes, and Gaussian processes) [23,32]. Here, we see several benefits for patient trajectory analyses in clinical settings. Probabilistic models often have a more parsimonious structure than the out-of-the-box neural networks, which facilitates efficient learning and reduces the risk of overfitting in data-scarce settings. In addition, such a parsimonious structure can facilitate interpretation by clinical practitioners. Probabilistic models can be naturally extended by latent structures (eg, hidden Markov models [63-67]), where latent states capture different trajectory phases and further improve interpretability. For instance, in the context of alcoholism treatment, patient trajectories have been modeled to undergo phases of *abstinence*, *moderate drinking*, and *heavy drinking*, each of which is captured by a separate latent state. In our view, such a latent structure represents a natural way to describe the different patterns in patient trajectories (eg, acute vs stable phases) and, more importantly, relates model characteristics to established clinical terminology. In the future, we expect hybrid models that combine the benefits of probabilistic modeling and neural learning (eg, deep Markov models [25]). The former benefits from theory-informed, interpretable structures that account for different disease states, whereas the latter are particularly effective for long-term dependencies.

Across these risk models, it is further essential to consider the timing of the health measurement. Trajectories may consist of health recordings in equally spaced time intervals (eg, uniformly sampled every minute in ICUs or yearly intervals in patient registries). Often, they contain irregular time intervals, reflecting nonuniform and patient-specific interactions with the health care system. As a result, the sampling might be informative of the disease state (Figure 3). For instance, health professionals record more health measurements during deterioration in the patient's health state. Therefore, AI solutions can use shorter time intervals to predict future decline in the trajectory. If the sampling is informative, we encourage researchers to develop models that consider the time intervals between the health measurements. For instance, 1 class of such models is point processes (eg, Hawkes processes). Here, a shorter time interval between health measurements makes further health measurements more likely and influences the expected risk score [23].

Figure 3 shows individual health recordings (eg, medical events, hospital visits, and laboratory data) in the form of dots. *Top:* an example patient trajectory where all medical events are equally spaced and thus there is a uniform time interval between the events. Here, the timing of the events is not informative of the current disease state. *Bottom:* an example patient trajectory that indicates a gradual decline in the disease state. Owing to this, additional health recordings are collected with higher frequency, which are thus informative about the disease state.

For objectives beyond risk scoring, we need other modeling approaches. When using risk scoring for *prescriptive purposes* (eg, treatment planning or dose finding), we encourage broader adoption of modeling strategies designed for decision making (eg, causal machine learning [37,68,69], Markov decision processes [70,71], dynamic treatment regimens [72,73], and policy learning [74]). There is a growing traction to extend many of these modeling strategies to handle longitudinal data, where health practitioners make treatment decisions over time.

Figure 3. Difference between noninformative and informative sampling.



For *subtyping*, one typically draws upon time-series clustering [26]. For this objective, the definition of a similarity metric is key [75,76]. One option is to set explicit rules for establishing patient trajectory similarities, for example, according to a specific condition such as heart disease [77] or a combination of clinical or phenotypic features [78]. Domain experts may be familiar with such approaches, but their definition may not perfectly integrate with AI algorithms and may thus require customization. Hence, an alternative is to view patient trajectory analysis from a methodological, *data-driven* angle. For example, when modeling the underlying temporal dynamics for performing data-driven clustering of longitudinal data, we can loosely group the approaches into (1) model-free approaches and (2) model-based approaches. In the model-free approaches, a similarity metric on sequential data is defined and then serves as input to conventional clustering algorithms. On the other hand, in the model-based approaches [79], a representation of the patient trajectory is learned, and the model parameters are then used for clustering (eg, mixture hidden Markov models). For future research, we find model-based approaches intriguing, as they no longer focus on raw observations but cluster the underlying disease dynamics (and, as such, can account for different latent disease states).

For *pathway discovery*, several descriptive approaches have emerged that allow for the discovery of subpatterns (ie, motifs) and common patient trajectories [76]. For example, Beck et al [33] analyzed disease pathways leading to septicemia in 110,000 patients. The study revealed prototypical pathways starting from 3 initial states (alcohol abuse, diabetes, and anemia) and established the trajectory-specific probability of sepsis mortality. This and similar studies reveal great potential to further our understanding of disease etiology and the possible means of changing disease trajectories [80,81]. Similarly, Oh et al [82] constructed patient trajectories consisting of specific health events (hyperlipidemia, hypertension, and impaired fasting glucose) and evaluated the probabilities of such trajectories (and their permutation) in increasing or decreasing the log odds of developing type 2 diabetes mellitus. Zhang and Padman [83] identified the most probable clinical trajectories from patients with chronic kidney disease by first grouping the patients and then fitting a first-order hidden Markov model to infer the most probable clinical pathways given sequences of multiple laboratory test observations and other patient characteristics. Huang et al [84] proposed a probabilistic model (based on latent Dirichlet allocation) to identify clinical pathway patterns from the event logs for patients with unstable angina and cancer. Dabek and Caban [85] offered another perspective by analyzing trajectories using automata (ie, deterministic and nondeterministic finite state automata) and using a grammar induction algorithm to identify common trajectories in neurology. Further approaches for pathway discovery are based on association rule mining [86] and functional dependencies mining [87].

Related to these objectives are models that adopt a structural lens to examine the causal mechanisms [88]. This would allow not only to understand *how* health measurements change over time but also *why*. The underlying AI algorithms are still under active research (eg, causal structure learning and neural causal discovery [89]). Here, it will be a rewarding direction for the future to develop more approaches that are tailored to longitudinal data.

Evaluation

Evaluations through randomized controlled trials are needed to confirm the effectiveness of AI-based analysis of patient trajectories in clinical practice. Recently, there have been such trials for traditional AI solutions that rely on snapshot data from a single or few time points [90]. However, similar trials for patient trajectory analysis are rare [90]. We expect significant value in conducting such trials and foresee challenges owing to the unique characteristics of patient trajectories. Foremost, evaluations through rigorous randomized controlled trials are a prerequisite to building trust in clinical practice, thereby expediting further AI-based trajectory analysis. However, evaluating such an AI solution might be a multiyear undertaking depending on the time window of the patient's trajectory. Thus, it is also essential to recognize that the evaluations are likely to involve a 2-step procedure. In the first step, trajectory data are collected to train the AI solution. In the second step, the previously trained AI solution is then deployed to analyze how the AI solution generalizes to new patient trajectories. When conducting such trials, it is crucial to acknowledge that the patient trajectories capture data from multiple time points and might thus be subject to an inherent domain shift (ie, where data distributions change over time, that is, over the patient journey) [91]. Such domain shifts might affect the performance of AI solutions [92], especially when the patient trajectories span a long time horizon. For example, AI-based predictions have been recently applied to patients with COVID-19 to compare the predicted health trajectory with the observed trajectory in a prospective study, finding that the performance of some risk scores decreased over time [93]. One reason was because of temporal domain shifts over time [94] as medical professionals learned about the emerging infectious disease and adapted their clinical routines over time, thus yielding different and, in particular, better outcomes than in the data used for training.

Furthermore, there is a need to ensure reproducibility of the AI-based analyses. Here, we consider 3 priorities. First, there is a need to develop a framework. For instance, the existing AI frameworks (such as scikit learn in Python) are designed for modeling static data. Conversely, more effort is necessary to define standardized building blocks for longitudinal data to effectively model the patient trajectories. Moreover, such frameworks should also involve tools for automation so that the disease models can be trained in a semiautomated manner (subsumed under the term *automated machine learning* [*AutoML*]). Although AutoML has become widespread for static data sets, only a few libraries are designed for time-series AutoML [95]. Here, we see enormous potential for future research at the interface to digital medicine. On the basis of our own experience, we expect such frameworks to play a critical role in achieving scalable and increased adoption of AI-based patient trajectory analysis in clinical settings. Second, future research should carefully assess and, if needed, revise the best practice guidelines for AI in medicine [96], so that they consider the longitudinal form of patient trajectories. For example, the reporting guidelines should involve information on whether the period between health measurements is informative (however, such information is not part of existing reporting guidelines for static patient data). Other examples could be the choice of the model (eg, whether latent dynamics were considered and why or which alternative architectures of recurrent neural networks were tested and eventually discarded), how the timing of the health care event was collected (eg, whether a time stamp was retrieved from a medical health record or whether this was a survey question referring to the *last 12 months* and the resulting uncertainty about the correct time), or the rationale behind how patient similarity was measured in subtyping. Finally, more data sets with patient trajectories should be made publicly available for benchmarking. Although data access is a common issue for AI research in medicine in general, the challenges are exacerbated in the context of patient journeys, where it is common to merge the health measurements from different sources (eg, from other health registries). So far, only a few longitudinal data sets are public (as compared with static data sets with patient data) [76]. Notable exceptions are large initiatives, such as the Healthcare Cost and Utilization Project, that offer longitudinal data sets for evaluating trajectory-based AI approaches [97].

Interpretations

To generate insights for clinical practice, it is often necessary that AI solutions overcome their black-box nature [98]. Here, we see enormous potential for new AI solutions that adhere to the needs of clinical practice with the objective of knowledge discovery.

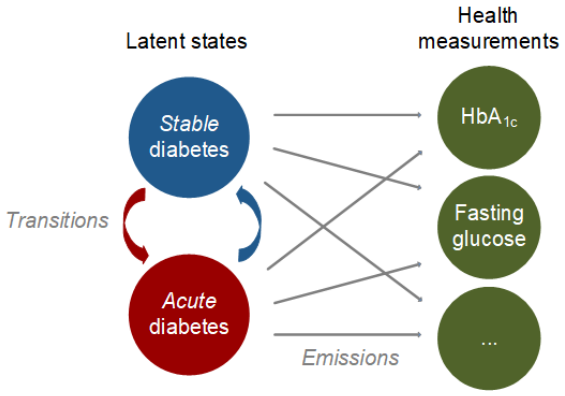
One approach is explainability, which aims to understand how a model arrives at a particular outcome [10,99]. However, AI explainability is typically developed in the context of static data and therefore, meaningful time-varying patterns from the course of a disease might not be revealed. For instance, SHAP values [99] inform which health measurements are used by the AI model and what values indicate risk. However, SHAP values cannot directly interpret the *dynamics* in health measurements (eg, whether there is an increase or decrease or large variability in health measurements, which would be needed to characterize changes in disease states over time). As a road map for research in digital medicine, we require techniques that interpret the temporal dynamics of disease progression, thereby being closely aligned with the demands of clinical practice. Here, digital medicine might find inspiration in other disciplines, for instance, financial technical analysis [100], where a systematic set of short-term movements of stock prices is used for interpretation. Similar patterns in patient trajectories could be inferred by researchers via short-term patterns (ie, trajectory markers) that characterize a disease course or a combination of short- and long-term motifs that help identify distinct disease states.

Another approach to generating insights is via interpretability, which builds upon inferences where the underlying logic is transparent. Interpretability often requires tailored modeling approaches. For static data, this is usually achieved through (penalized) linear regression or decision trees, whereas interpretability for longitudinal data is typically achieved through parsimonious models. Different strategies exist to obtain parsimonious models. For neural networks, there are techniques that tweak a neural network to provide a sparse one with similar performance (eg, enforcing feature sparsity through architecture design, modifying the objective function and the weight updating scheme [101], post hoc via reservoir computing or pruning, or a priori via cognitive networks [102]). Alternatively, one can draw upon structural formalizations (eg, dynamic fuzzy cognitive maps [78] to simulate patient trajectories) and probabilistic models (eg, Markov models, hidden Markov models, and Hawkes processes [23,25,63-67]).

Out of these modeling approaches, we expect hidden Markov models to be beneficial for interpretability, especially for risk scoring. The reason being hidden Markov models use latent variables to capture different disease phases in patient trajectories. These latent variables often have clinically relevant meanings and can thus be mapped onto existing clinical terminology (Figure 4). For instance, in diabetes mellitus, the latent states are characterized as *acute* and *stable* disease states [64] and thus are of clinical meaning. In addition, recent evidence suggests that interpretable models might also improve prediction performance [23]; however, more effort is needed to explore this further. In the future, we expect to see other modeling approaches that combine the strengths of hidden Markov models (for interpretability) with neural learning (for representation learning and capturing long-term dependencies in patient trajectories).

The health measurements are observable and thus obtained via standard data collection practices. In contrast, the latent states cannot be observed directly and, instead, are recovered from the health measurements. The latent states then describe different disease states in a patient trajectory (eg, *acute* vs *stable* disease states). During estimation, the latent states and health measurements are mathematically linked via components for both transition and emission probabilities.

Figure 4. Example of a hidden Markov model. HbA1c: hemoglobin A1c.



Implications for Digital Medicine

Analyzing patient trajectories using AI has multiple benefits. Dissecting the variability of disease pathways allows research to better understand both the disease etiology and disease course, facilitating a more extensive personalization of care. For instance, it enables the identification of short-term patterns predictive of future health states, which are then used during risk scoring. Similarly, patient trajectories capture the responsiveness of patients to treatments, and by leveraging this information in patient trajectories, AI solutions can guide treatment planning. In summary, AI-based trajectory analysis promises to strengthen the existing computational approaches to prevent, detect, diagnose, and treat diseases.

To address these challenges, we see particular importance in community building and in the development of computational patient trajectory tools that lower the barrier of entry. Community building will help to set a clear agenda and define an established terminology, bridging both practice and research in digital medicine. Here, we point to several valuable directions: (1) further effort will be needed to extend traditional clinical terminology (eg, cohort building and patient similarity) to AI-based trajectory analysis, thereby facilitating communication between the experts in AI and medicine; (2) it is essential to build communities by connecting different actors from regulation, law, data science, and medicine, as this will eventually be a prerequisite for deploying AI solutions in medical practice; and (3) such communities may promote data exchange, thus allowing for more extensive benchmarking of AI solutions. Similarly, we also suggest hosting leaderboard competitions as conducted in other fields (eg, the SemEval benchmark competitions in natural language processing). Leaderboard competitions will eventually help to identify robust AI solutions and thus to condense best practices during modeling.

Abstract

Social media is increasingly being leveraged by researchers to engage in public debates and rapidly disseminate research results to health care providers, health care users, policy makers, educators, and the general public. This paper contributes to the growing literature on the use of social media for digital knowledge mobilization, drawing particular attention to TikTok and its unique potential for collaborative knowledge mobilization with underserved communities who experience barriers to health care and health inequities (eg, equity-seeking groups). Setting the TikTok platform apart from other social media are the unique audiovisual video editing tools, together with an impactful algorithm, that make knowledge dissemination and exchange with large global audiences possible. As an example, we will discuss digital knowledge mobilization with trans and nonbinary (trans) communities, a population that experiences barriers to health care and is engaged in significant peer-to-peer health information sharing on the web. To demonstrate, analytics data from 13 selected TikTok videos on the topic of research on gender-affirming medicine (eg, hormonal therapy and surgeries) are presented to illustrate how knowledge is disseminated within the trans community via TikTok. Considerations for researchers planning to use TikTok for digital knowledge mobilization and other related community engagement with equity-seeking groups are also discussed. These include the limitations of TikTok analytics data for measuring knowledge mobilization, population-specific concerns related to community safety on social media, the spread of disinformation, barriers to internet access, and commercialization and intellectual property issues. This paper concludes that TikTok is an innovative social media platform that presents possibilities for achieving transformative, community-engaged knowledge mobilization among researchers, underserved health care users, and their health care providers, all of whom are necessary to achieve better health care and population health outcomes.

trans; nonbinary; marginalized communities; gender-affirming care; digital health; community-engaged research; knowledge mobilization; mobile phone

Introduction

Background

Social media is increasingly being leveraged by researchers to engage in scholarly debates and rapidly disseminate research results. Rapid dissemination strategies can facilitate the uptake of life-saving information, fill gaps in critical information, and correct misinformation, as has been documented throughout the COVID-19 pandemic [1]. However, social media also provides a platform for challenging disseminated knowledge that is produced about communities without appropriate community engagement and critical attention to ethical considerations. As an example, significant controversy erupted in 2019 when a researcher published a controversial study that presented a medically unsubstantiated term, *rapid-onset gender dysphoria*,

arguing that trans and nonbinary (trans) identity is a *social and peer contagion* [2]. In response, several trans-identified community-engaged researchers challenged these findings on Twitter to draw attention to the study's methodological flaws and its potential harm to trans-people [3-5]. Scientific critiques of this study were later published by researchers in peer-reviewed journals and again shared through social media and web-based news media channels, leading to corrections made to the original article [6,7]. This is only one striking example demonstrating the transformative potential of community-engaged digital advocacy.

This paper extends the existing research on the use of social media for knowledge mobilization and collaborative knowledge exchange, focusing explicitly on TikTok. It is among the first academic papers to draw attention to this fast-growing social media platform and its potential use as a digital knowledge mobilization tool. In so doing, the article highlights (1) how TikTok functions, including its unique algorithm, which creates the opportunity to reach larger international audiences in comparison with other social media platforms and relatedly, (2) TikTok's potential for audiovisual knowledge exchange with communities who are active TikTok users—also referred to as *creators* on the platform. As an example, we specifically highlight the possibilities for knowledge mobilization with trans communities, drawing from the first author's (KRM) TikTok analytics data. Some of TikTok's anticipated pitfalls and limitations have also been discussed to inform researchers. This viewpoint study is also of practical use to researchers engaging with an expansive number of web-based communities on TikTok, such as youth, and more [8]. Although important, in-depth considerations of the intersections among social media technologies, ethics, and society are out of scope. For interested readers, these discussions may be sought out within science and technology studies and other interdisciplinary literature [9-11].

Knowledge Mobilization and Health Equity

Knowledge mobilization is of primary concern to researchers whose study findings have tremendous consequences on the health equity of underserved, minoritized populations, who are also termed *equity-seeking groups*. For example, trans individuals constitute a growing population whose shared experiences and health care needs have garnered significant attention in recent years. Trans persons identify with a different gender than was assigned at birth, with many undergoing a gender transition to align their physical characteristics with their internally felt gender identity [12]. Gender transitions may include the use of a new name and gender pronoun and/or changes to one's physical appearance (eg, clothing and hairstyle); updating some or all of one's legal identity documentation (eg, passport and driver's license); or accessing gender-affirming hormonal therapy or surgical procedures, among other social, legal, and medical processes [12]. Although not all trans people seek gender-affirming medicine (eg, hormones and surgeries) to transition, improving access to these medical treatments is of great concern to trans communities and their health care providers. Gender-affirming medicine is associated with improvements in trans people's mental health outcomes [13,14], and in some jurisdictions, these treatments are a prerequisite for changing legal sex designations [15]. Recently, in the United States and in Britain, there have been numerous legislative attempts to limit young trans people's access to gender-affirming medicine [16,17], despite evidence that such a law could increase mental health concerns such as suicide risk [13,17]. Compounding these health inequities, health care providers rarely receive sufficient education or training to provide care that is sensitive to, or tailored to the needs of, trans health care users [18,19]. The fear of nonaffirming or discriminatory and/or incompetent health care can contribute to delayed health care among trans persons and teaching their own health care providers, which has been shown to increase the odds of delaying needed medical care [20,21]. At the same time, this may explain much of the intracommunity, peer-to-peer sharing of health-related content via web-based platforms [22]. In this paper, we discuss why and how trans people's health care inequities can be addressed by bolstering digital knowledge mobilization and community-engaged knowledge exchange.

Community-engaged research broadly refers to various processes and practices involving collaborative partnerships with communities and/or people who have been historically underrepresented within, and poorly served by, the academic knowledge production process (eg, trans communities). An aspiration of community-engaged research is to form a symbiotic relationship whereby communities, for instance, health care users and researchers, work together with a common goal such as improving access to care [23]. Knowledge mobilization and collaborative knowledge exchange are integral components of community-engaged research. Knowledge mobilization is an umbrella term referring to the collaborative flow of research knowledge including "knowledge synthesis, dissemination, transfer, exchange, and cocreation or coproduction by researchers and knowledge users" [24]. Knowledge mobilization activities are associated with a faster translation of research findings to achieve transformation of publicly held beliefs, changing provider practices, inciting policy change, and exchanging or coconstructing knowledge together with key stakeholders or knowledge users.

Social Media, Knowledge Mobilization, and Exchange

The use of social media as a strategy for disseminating research findings beyond academic contexts has been previously established. Social media provides opportunities for knowledge to be publicly discussed and debated almost instantaneously by researchers, together with knowledge users such as educators, health care providers, health care users, and the general population. Croatian medical researchers have used Facebook to translate evidence-based medicine and high-quality health information to laypeople, health professionals, and journalists alike [25]. A 2019 scoping review identified a sharp rise in the use of Facebook, Twitter, and podcasts to translate knowledge between physicians and their trainees since 1996 [26]. In total, this scoping review revealed 12 different social media platforms used for knowledge mobilization. TikTok was not included in this list (likely because of the literature search parameters including studies published between 1990 and 2018). In another recent example, web-based discussions of hydroxychloroquine and remdesivir enabled public interdisciplinary medical discussions and the discrediting of false claims [27]. These constitute communicative spaces where diverging "viewpoints

have the potential to circulate and be negotiated" [28]. TikTok has also been noted as a platform through which credible COVID-19 public health messaging circulates [29], for instance, the collective responsibility to keep communities healthy by practicing social distancing [30]. A literature review of young people's use of digital technology highlighted that lesbian, gay, bisexual, trans, and intersex youth value storytelling about identity and concluded that there is a need to further establish how social media platforms influence young people's peer-to-peer sharing of health information [31]. Trans people, in particular, use social media as a *vehicle of transformation* to artistically document their gender transitions through a process of coproduction and storytelling with other trans people [32], with trans women engaging in extensive community-based digital advocacy on the web through the hashtag *#GirlsLikeUs* [33].

Increasingly, knowledge exchange and coconstruction of knowledge occur on social media platforms. Before the COVID-19 pandemic, much of researchers' community engagement work and knowledge mobilization occurred in person. However, due in part to widespread social distancing and lockdown policies intended to mitigate COVID-19 transmission, social media use has accelerated over the past year, as these technologies enable people to stay connected with family, friends, and community [34]. For instance, TikTok use exploded in 2020, with it being one of the most frequently downloaded smartphone apps [35]. Social media platforms now serve as replacement access points for communities and other social connections. For this reason, community-engaged researchers must continue to develop digital knowledge mobilization strategies to join communities in which they are organizing. At the present moment, trans communities are primarily connected on the web.

TikTok: A Social Media Platform for Short, Creative Knowledge Mobilization Videos

A subsidiary of the Beijing technology company ByteDance, TikTok currently sits among the world's most popular smartphone apps [35]. According to TikTok's *Our Mission* section, "TikTok is the leading destination for short-form mobile video. Our mission is to inspire creativity and bring joy" [35]. The TikTok platform enables users to create, share, and otherwise digitally engage with short videos (<3 minutes), which are simply referred to by users as *tiktoks*. Approximately 800 million people are registered as TikTok account holders worldwide [36]. In 2020, the proportion of global internet users aged 16 to 68 years engaging with TikTok was estimated to be approximately 18% [37]. Although userbase demographics include significant diversity in terms of gender, ethno-racial, cultural, and other characteristics, approximately 42% of TikTok users are aged 18 to 24 years [29]. Importantly, people >30 years are increasingly joining TikTok, including health care providers, researchers, and educators [38].

Integrating music, text, and video together, tiktoks aim to be audiovisually entertaining, and the platform itself provides creators with several built-in tools useful for engaging in digital knowledge mobilization and the collaborative exchange of ideas. Not unlike other social media platforms, such as Twitter, the TikTok video comment section enables text-based responses. However, TikTok users are also provided with the option of creating a video response to text comments, which makes more nuanced and in-depth audio-video discussions possible. Using the video-response-to-comment option, a creator can produce an entirely new tiktok, which features the original comment in a speech balloon. The 2 additional popular TikTok video editing options are the *stitch* and the *duet*. Creating a stitch video involves responding to another user's video by inserting—quite literally stitching—a segment of the original video to trigger the start of a new tiktok, establishing a public knowledge exchange between 2 users within the same short video. A duet serves a similar purpose; however, a duet typically amplifies and preserves the original video's content while at the same time offering notes of endorsement or critiques toward the original information shared. In many cases with duets or stitches, the original tiktok creator explicitly requested other users to stitch or duet the video to answer a question or otherwise engage in a larger public discussion. Taken together, these video creation options bolster a creative, audio-video digital knowledge exchange environment through which TikTok users engage with one another's videos. These in-house features of the TikTok app are especially conducive to community-engaged knowledge exchange, as they involve direct, audiovisual communication with other TikTok users.

Those who have experience with opening social media accounts on other platforms may appreciate that one of the first hurdles is gaining an audience (eg, subscribers or *followers*) with whom to exchange information surrounding particular topics. Contrasting with other social media apps built around individual subscribers, TikTok connects an international user base through a unique algorithm. Each TikTok user has a personalized *For You* page, which is fine-tuned by the TikTok algorithm, reflecting each user's individual interests and engagement on the platform. The algorithm is sensitive to the user's TikTok activity, including past videos commented on, liked, or shared, as well as the hashtags these videos apply. Not unlike other social media, it is primarily through all of these platform-based activities that a user's *For You* page is curated by the algorithm [39]. The TikTok platform may ameliorate this barrier of finding an audience to engage with, given that when a video's content resonates with other platform users, it may gain the attention of a large global audience in relatively little time as it is shown to other users [38]. TikTok videos shared, stitched, and duetted extensively by other users also tend to attract larger audiences, and the algorithm mirrors this activity by sending popular videos to be viewed by an increasing number of users, thereby compounding a trending video's attention.

To demonstrate, Basch et al [40] sampled 100 popular, trending English-language tiktoks that applied the hashtag *#WearAMask* and compared these with 32 videos posted by the World Health Organization (WHO), which were also related to mask wearing. The metadata of each of the 132 sampled videos were collected and analyzed. Although the ratio of trending tiktoks to WHO videos was approximately 3:1, TikTok videos were viewed 500 million times versus the WHO's 57 million views. The *#WearAMask* TikTok campaign received approximately 10 times the views, indicating *widespread reach* and TikTok's

transformative, community-engaged potential for communicating health information. Eghtesadi and Florea [41] also observed that TikTok is an important social media platform that could be used to share medical research with physicians and the general public. Useful for public knowledge exchange on topics of community concern, TikTok could help to achieve a wider discussion inclusive of individuals who may be otherwise inaccessible to academic researchers who use more traditional or in-person community engagement strategies.

The hashtags *#AcademicTikTok*, *#LearnOnTikTok*, and *#ProfessorsofTikTok* are just a few of the many examples demonstrating knowledge dissemination and educational content creation already occurring on the platform. These hashtags link researchers, educators, health care providers, and health care users together with diverse audiences around the world, creating innovative digital knowledge exchange. Some of the content uses humor to critically reflect on academia—for example, poking fun at the peer-review publication process—whereas other videos serve to share the results of a research paper and educate or even recruit study participants. For example, the popular science communicator Hank Green (@hankgreen1) boasts approximately 4.5 million followers. In the context of the digital trans TikTok community, the gender-affirming surgeon Dr Sidhbah Gallagher (@gendersurgeon), who shares information about gender-affirming surgeries, has approximately 165,000 followers. Peer-to-peer knowledge sharing is another form of digital knowledge exchange that often occurs on TikTok (and on other social media). Examples of peer-to-peer knowledge sharing happening on TikTok include instances of trans people sharing with other trans peers Dr Gallagher's educational videos about gender-affirming surgery or tagging their peers in the comment section to notify them about the video. In another example of peer-to-peer sharing, the trans-identified physician Dr AJ Eckert (@drajeckert) creates tiktoks containing medical information about gender-affirming hormonal therapy intended for audiences of trans health care users and other health care providers.

Over time, knowledge mobilization has shifted from a positivist, linear, top-down translation of research findings to increasingly complex, iterative approaches that include knowledge coproduction in the context of its use [42]. Said differently, the former model is being replaced by knowledge activities that endorse research as a creative enterprise defined by human relationships, the salience of quality partnerships with health care users, and power-sharing techniques [43]. In fact, knowledge mobilization strategies have more reach and better engagement when involving collaboration or co-design with stakeholders, such as patients, thereby capitalizing on already established web-based community networks [44]. Accordingly, boundaries are increasingly porous between researchers and communities under study, as evidenced by the knowledge exchange happening on TikTok. The platform engenders not only the sharing of research findings by researchers but also collaborative knowledge exchange between all TikTok users through features such as the stitch and the duet. Such collaborative approaches harness co-design between researchers and knowledge users, in turn, minimizing power differentials while engaging underrepresented voices and valuing the legitimacy of lay, or community-level, knowledge [42]. In the following section, we further discuss why trans communities specifically present unique opportunities for collaborative and community-engaged knowledge mobilization via TikTok.

Community-Engaged Knowledge Mobilization and Trans Peer-to-Peer Information Sharing

Trans people comprise approximately 0.5% to 1.3% of the general population [45]. Trans populations also confront significant barriers to health care, such as gender-affirming medicine, and experience discrimination within these settings [46]. Despite more public visibility of trans populations, trans-related stigma compounds social and health injustices [45]. Trans-related stigma occurs when ideologies, policies, and structural systems enforce a male/female binary that disadvantages trans people [47]. Trans-related stigma can occur at the systemic level through discriminatory policies and can be enacted at the interpersonal level through discrimination within individual interactions [48]. To demonstrate, the US Trans Survey found that 25% of trans-identified respondents encountered a problem with their health insurance provider denying claims related to gender-affirming medicine, with 33% experiencing at least one negative interaction with a health care provider such as verbal harassment or having to teach their own provider about appropriate care for trans people [20].

Disrupting trans-related stigma as well as sharing up-to-date empirical trans health knowledge about topics such as gender-affirming medicine are fundamental to improving health care access, health outcomes, and social conditions for this population. At the same time, social media platforms such as TikTok enable trans people to create alternative and trans-affirming knowledge that can counter stigmatizing beliefs. TikTok also provides a platform for health care providers and researchers who specialize in gender-affirming medicine to educate other clinicians and policy makers. Reflecting contemporary collaborative knowledge coproduction [42], trans communities are digitally well-connected and are active in peer-to-peer information sharing, support, and intracommunity education on the web [22,49,50]. This creates optimal conditions for community-engaged research and digital knowledge exchange between researchers, health care providers, and trans health care users. TikTok is especially popular with trans people, and *#TransTikTok #TransTok #NonbinaryTikTok and #GirlsLikeUs* are just a selection of hashtags that collate content and make peer-to-peer knowledge exchange possible. Then, through the power of the TikTok algorithm and individually curated *For You* pages, information relevant to this population is widely digitally disseminated via hashtags, duets, stitches, and the sharing and tagging of these videos between users.

However, it is important to stress the reality that trans people may seek out social media as a means of escaping a discriminatory world to connect with, and provide mutual support to, others who share a similar understanding of gender identity and expression. A 2021 scoping review found that social media and web-based communities were sources of both

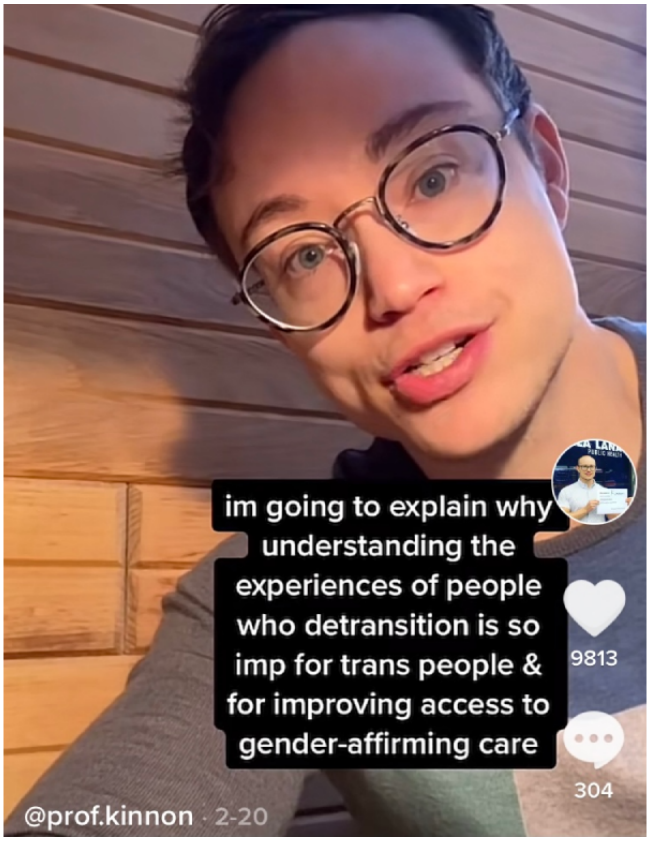
peer-based support and resilience for trans people, which in turn could buffer poor mental health outcomes experienced by this population [49]. Another 2021 scoping review identified *advocacy and education* as prominent themes of trans peer-to-peer information sharing and support [22]. Lupton [31] specifically recommends examining how TikTok and other social media platforms are used for health-related content creation and peer-to-peer sharing among young people. It is important to point out that peer-to-peer information sharing on trans health–related topics may also emerge in response to gaps in health professionals' education and competency in this domain; thus, tiktoks could be shown to clinician learners in health professions education and training. This may explain, in part, why videos concerning gender-affirming medicine generate significant attention and knowledge exchange on TikTok. In the following section, the tiktoks created by KRM (@prof.kinnon; ~13,800 followers) are shared, and analytics data are presented.

TikToking About Gender-Affirming Medicine: Digitally Mobilizing Knowledge

We sampled 13 different tiktoks created by KRM and posted them between February 19, 2021, and March 4, 2021 (Multimedia Appendix 1). These tiktoks focus on gender-affirming medicine and primarily feature his own research and related studies by other trans health researchers. Each of these videos is <52 seconds in duration and covers academic research on topics of interest to health care providers and trans people seeking and receiving hormones and surgeries. Figure 1 shows one of these tiktoks about gender-affirming medicine eligibility assessments [51] that, to date, has received >70,000 views and 8746 positive endorsements (eg, likes or hearts). For our purposes, we simply present the number of views and shares for this compiled group of 13 tiktoks. At the time of writing (May 7, 2021), these videos were cumulatively viewed >378,301 times and shared >1313 times. Taken together, the creation of these short videos alongside much engagement from web-based trans communities via *#transtiktok* demonstrates the potential for innovative, digital knowledge mobilization and exchange on TikTok.

TikTok analytics data are included within each video, updated daily, and provided to every TikTok user with >1000 followers, enabling opportunities for researchers to monitor and measure the impact of their videos. These data provide researchers with important analytics metrics to track the impact and reach of their videos, such as the average view time, the total number of likes or hearts, and very basic viewer demographics (gender and country). Although counterintuitive, it is not uncommon for videos posted at an earlier date to gain traction with the algorithm at a later date, be pushed to users' *For You* page, and subsequently go *viral*—a term used to denote a trending video. In such cases, a video has been liked, commented on, and/or shared by thousands of TikTok users, and the algorithm is sensitive to this activity, thus prompting the algorithm to showcase it on other users' *For You* page [38]. The more that users watch and engage with individual tiktoks, the more the algorithm shows the video to other users with a history of engaging with videos of similar content. Thus, videos can gain TikTok users' attention at discrete periods unrelated to the original time and date posted.

Figure 1. "Regret" and gender-affirming care.



Considerations for Researchers Planning to Use TikTok for Digital Knowledge Mobilization and Exchange

Overview

Although researchers in past years primarily used mass media, including newspapers or radio, to communicate the latest scientific research study findings, the public's newfound reliance on social media to access information about current events has increased. A survey commissioned by the Canadian Journalism Foundation found that 52% of Canadians and 48% of Americans aged ≥18 years use social media for news-related information [52]. In another example, survey data collected by Pew Research suggest that approximately 1 in 5 American adults access political news from social media, with 48% of those aged 18 to 29 years reporting social media as their main news source [53]. The demographics of these individuals who use social media as the main news source also tend to be "younger, are less likely to be white and have lower levels of education" [53]. Within the new digital age of disinformation and *fake news*, social media engagement is a contentious subject, particularly for academic researchers [54]. Social media platforms have clearly become indispensable tools for disseminating empirical knowledge widely and equitably.

TikTok is an innovative digital platform embedded with possibilities for transformative, collaborative knowledge mobilization and community-engaged knowledge exchange between researchers, underserved health care users, and their health care providers. As we have shown in discussing trans populations as an exemplar, TikTok presents unique opportunities for collaborative and community-engaged knowledge mobilization, and it may effectively promote critical dialog and information sharing to advance health care access for populations who experience poor health outcomes and barriers to care. However, there are several issues that researchers need to consider before launching their first tiktoks into the digital world. These can be summarized as follows: (1) TikTok analytic tools to measure knowledge mobilization and exchange, (2) population-specific safety concerns on social media, (3) the spread of disinformation and the need for legislation and regulation, (4) reaching those who have barriers to internet access, and (5) commercialization and intellectual property concerns.

Of relevance to those interested in using TikTok analytics to measure and evaluate the reach and impact of their videos, Basch et al [40] pointed out the challenge in distinguishing between the number of video views from viewers. Although TikTok provides users with viewer analytics data, it is not possible to identify when individual viewers watch a video multiple times or whether the videos are watched to completion. TikTok analytics do track the overall average watch time of each video; however, disaggregating these analytics data is not currently possible. These are platform-specific confounding factors that researchers must be aware of when seeking to measure and evaluate their digital knowledge mobilization activities on TikTok.

When leveraging TikTok for knowledge mobilization and exchange, there may be population-specific psychosocial developmental or safety considerations depending on the target stakeholder or equity-seeking group. For instance, youth aged <25 years comprise most of the TikTok users; however, social media use is positively correlated with depression, anxiety, and sleep disturbances in young people [55]. Some research cautions that youth engaging with health-related content on social media tend to compare their bodies with popular social media influencers [31] and that there are psychosocial risks, given the publicized evaluation metrics of likes, shares, and comment sections that allow users to openly criticize the video creator [34]. Similarly, young trans people use TikTok, and trans people of all ages regularly experience trans-related stigma on the web and in person. Trans people further report high rates of body image concerns and eating disorders, and a literature review published in 2016 concluded that body dissatisfaction is central to trans people's psychosocial distress [56]. Moreover, Maly [39] noted that it is through the algorithm that these metrics contribute to the creation of a populist voice whereby followers, likes or hearts, and shares become *political facts*. However, a study of a Facebook group suicide prevention program with youth concluded that young people could be safely and effectively engaged on social media, even on psychologically sensitive topics such as suicide [57].

A possible solution to account for these population-specific safety risks is through the piloting of digital knowledge mobilization products, or knowledge exchanges, on other social media that offer private and anonymous engagement options. These alternative options may include private Facebook groups, Twitter, or Discord. Given TikTok's powerful international algorithm and its stitch and duet video editing features, this platform may not always be the most accessible option for marginalized communities who are not public about their identities or who confront harassment on the web, such as trans people.

Although TikTok presents opportunities for collaborative knowledge exchange in the spirit of health equity and social justice, the app itself is not impervious to wider social discrimination. TikTok has admitted to *shadow-banning* or otherwise suppressing content created by people from minoritized groups, such as lesbian, gay, bisexual, trans, intersex, fat, disabled, and racialized people [58,59]. According to TikTok, creators from these groups may be more vulnerable to cyberbullying; therefore, the hashtags often used within these communities are rendered less discoverable by the algorithm [59]. In the wrong hands, TikTok's stitch and duet film editing features could be used maliciously to misappropriate the original video's message. Furthermore, the possibility of facing swapping or creating *deep-fake* videos has been noted [38]. Despite TikTok's description of the functions of shadow-banning content, this measure may result in restrictions on the reach and impact of knowledge mobilization and exchange. Furthermore, there also exists disinformation and hateful content on the app, including expressions of transphobia [60]. Further analyses on the use of TikTok to share hate and right-wing propaganda has been demonstrated in the study by Weimann and Masri [60]. Minoritized populations have been misrepresented, and their

experiences misinterpreted in knowledge creation and dissemination long before TikTok and other social media. This is a harsh reality that all researchers working with marginalized communities must be accustomed to thinking about and developing plans to account for these risks.

An obvious approach to disrupt antiscience, disinformation, or other related ideologies harmful to trans and equity-seeking populations is for academic researchers, health care providers, and educators to debunk these beliefs with research [54]. This could be done using TikTok's stitch or duet video editing options to directly respond to disinformation with a new TikTok video or by downloading the original video and engaging critically with its content in the context of teaching and learning. Health professions educators should note that tiktoks can be shown to learners by linking the TikTok's URL address or by downloading the video to a device such as a smartphone. Once stored on a smartphone, a TikTok video can be uploaded and shared on other social media platforms. Of note, each of these options risks amplifying harmful disinformation as the algorithm is sensitive to such activities; in response, the original TikTok video could be pushed to be viewed by more users of the TikTok app itself. Better legislation and regulation of TikTok are clearly required to prevent the spread of disinformation. In cases where researchers are aware that the content of their video may ignite significant controversy, it is possible to disable the duet and stitch options, the option for others to download the video, and turn off the comment section, thereby foreclosing the potential for tampering with the original, intended messages. Cautious researchers may consider disabling these features permanently, although in doing so, some of the collaborative knowledge co-design opportunities with others via stitch and duet would be limited.

Like other economically marginalized populations, trans people have varying access to smartphones and reliable internet connections because of individual socioeconomic and regional factors. Given the existing literature on the digital divide [61], it is plausible that trans adults living in rural regions with sparse access to the internet, those with limited resources to purchase a smartphone, and those who are older may face barriers to participating in these forms of digital knowledge exchange occurring on TikTok. The US Trans Survey of 27,715 respondents indicated that 15% of the sample were aged 45 to 65 years, with 3% aged >65 years [20]. Moreover, 30% of the participants who responded to an income question reported an annual household income <US $20,000 per year, with half of those reporting an annual household income < US $10,000 per year. Furthermore, 3% of the sample who responded to a technology question reported not having a cell phone, which accounted for 882 people [20]. Given that the US Trans Survey was administered in a fully web-based format, this prevalence may be even higher.

Some researchers may be hesitant to share study results using a commercial, for-profit app or may hold reservations because of intellectual property concerns. To this, we note that the TikTok platform includes an intellectual property and copyright policy which "protects original works of authorship (eg, music, videos, etc.)" and it pertains broadly to the expression of users' ideas and the ways that videos or music are created rather than the ideas or facts contained within the videos or music. According to the TikTok policy, using copyrighted content may violate TikTok's policies and can be removed [62]. Diligent researchers may consider consulting in-depth, professional intellectual property legal advice, as well as their own institutional affiliations and funding bodies, before communicating their study findings on TikTok. At the same time, community-engaged researchers who are planning to share study results on TikTok may want to proactively discuss with and elicit feedback from community members and/or health care providers at the early stages of their projects (before dissemination phases). In fact, TikTok could be used as a digital community engagement tool to solicit research topic ideas from health care users, and other stakeholders, before commencing a community-engaged research study.

Despite this myriad of considerations, TikTok may still be a potential digital mechanism for researchers to share knowledge with international audiences or to target specific knowledge user groups, such as health care providers or underserved health care users. We stress that, given the shifting landscape of social media as a primary information source, TikTok is a novel technology for collaborative digital knowledge mobilization and exchange with communities that are organized on the web and who engage in extensive peer-to-peer knowledge sharing, such as trans communities. Leveraging TikTok for community-engaged, digital knowledge mobilization and transformation is, therefore, an important strategy to achieve health equity for populations in need of better health care and social justice overall.

Acknowledgments

This was an unfunded project.

Authors' Contributions

KRM wrote and created each of the tiktoks described in this manuscript, collected analytics data, and drafted the original manuscript. Coauthors (HK and ALD) contributed equally to the manuscript's conception and contributed to cowriting and editing the final version submitted.

Conflicts of Interest

None declared.

Abstract

Research using artificial intelligence (AI) in medicine is expected to significantly influence the practice of medicine and the delivery of health care in the near future. However, for successful deployment, the results must be transported across health care facilities. We present a cross-facilities application of an AI model that predicts the need for an emergency caesarean during birth. The transported model showed benefit; however, there can be challenges associated with interfacility variation in reporting practices.

(J Med Internet Res 2021;23(12):e28120) doi:10.2196/28120

KEYWORDS

Introduction

The integration of artificial intelligence (AI) into health care is expected to significantly influence the practice of medicine [1-4]. Machine learning (ML) as a modeling strategy is an attractive option for characterizing and predicting complex biological phenomena [5].

Critics of AI applications note that the applications are primarily based on retrospective research, with insufficient focus devoted to "real-life" implementation and verification of reproducibility in clinical practice [5,6]. For example, an ML prediction algorithm developed in an urban tertiary care center with a diverse patient population may be unsuitable for a community hospital treating a homogenous population according to local protocols.

Therefore, transporting AI models across health care facilities is critical to effectively translating AI research into medical practice [7]. In this study, we aimed to investigate the validation of a model to predict the need for an emergency caesarean during birth, the critical challenge stemming from interfacility variation in subjective measurements, and to devise a method to address this challenge.

Methods

In brief, we developed 2 ML models to predict the risk for emergency caesarean delivery (for a detailed description of the methods and model features, see Multimedia Appendix 1 and [8]). The first model was designed to be used at admission to the labor and delivery unit (admission model); the second model was designed for use during labor, integrating additional data that accumulate as labor progresses (labor progression model). These additional data supplementing the model allow for more accurate prediction. Both models will alert the staff of the likelihood that a parturient might require an emergency caesarean delivery, allowing for the preparation of staff and patient.

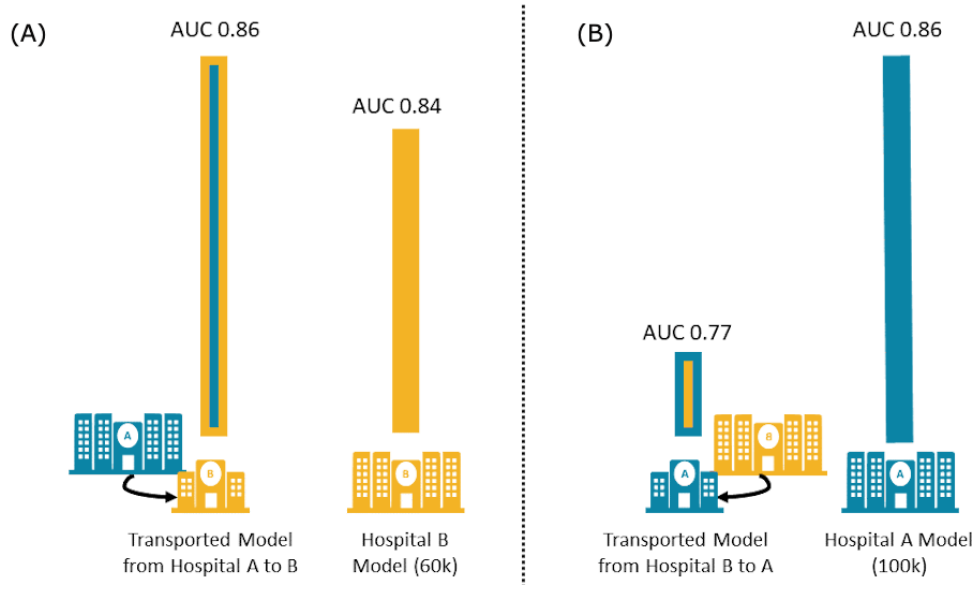
The models were trained using data from approximately 100,000 births at Hospital A. We extracted multiple data features from individual parturient electronic medical records (EMRs), totaling approximately 11 million data points. The institutional review boards at Hadassah Hebrew University Medical Center and Soroka Medical Center approved the study.

Both models were able to predict the need for emergency caesarean delivery, with the admission model achieving an area under the curve (AUC) of 0.82 and the labor progression model showing an increased performance, with an AUC of 0.86.

Having created and trained an ML-based model at a given health care facility, model transport can provide a smaller facility its benefits, without the large stored medical records or the expense and expertise required for development. However, care must be taken to monitor how the transport may affect the performance of the models, given differences in populations or settings.

We compared the prediction performance of the models trained and tested at Hospital A when transported to a second facility, Hospital B, where they were tested on data from approximately 60,000 births. Both the admission and labor progression models transported from Hospital A showed comparable prediction performance at Hospital B. Figure 1A illustrates the transport and performance of the labor progression model (see Multimedia Appendix 2 for the hospital characteristics and Multimedia Appendix 3 for the AUCs and 95% CIs of all models).

Figure 1. (A) Comparing the performance of Hospital A labor progression model (in blue) transported to Hospital B (yellow/blue bar) versus Hospital B local model (in yellow) and (B) Comparing the performance of Hospital B labor progression model (in yellow) transported to Hospital A (blue/yellow bar) versus Hospital A local model (in blue). AUC: area under the curve.



We then reversed the process and retested the success of transporting the models, by training the models at Hospital B and testing the prediction accuracy at Hospital A. Although the admission model trained at Hospital B provided similar levels of prediction at Hospital A, the labor progression model showed a reduced level of prediction (AUC 0.77 vs AUC 0.84; Figure 1B). We examined the model features to determine the cause of this decreased performance (see Multimedia Appendix 1).

Two important measurements of labor progression are fetal head station and cervical dilation. Fetal head station denotes the fetal descent within the maternal pelvis based on the position of the fetal head in centimeters above (–) or below (+) the maternal ischial spines [9]. Cervical dilation refers to the opening of the maternal uterine cervix, in centimeters, from closed cervix (0 cm) to full cervical dilation (10 cm). These 2 measurements represent the primary features of the progress of the birth; how rapidly descent and dilation progress depends on several factors, including parturient parity, medical history, pelvic anatomy, the size of the fetus, and the position of the fetus at the time of labor [10]. Results are operator-dependent, and measurements can vary between facilities based on local protocols and practice habits [11].

We identified a difference between the 2 facilities in fetal head station measurements used by the labor progression model. Specifically, we found that the dispersion and central tendency of this variable, as stratified to cervical dilation, differed between the 2 hospitals: Data from Hospital A were widely distributed across the full –3 to +3 scale, while those from Hospital B were more concentrated around –2 to +2. This difference may explain the reduced performance when transporting from Hospital B,

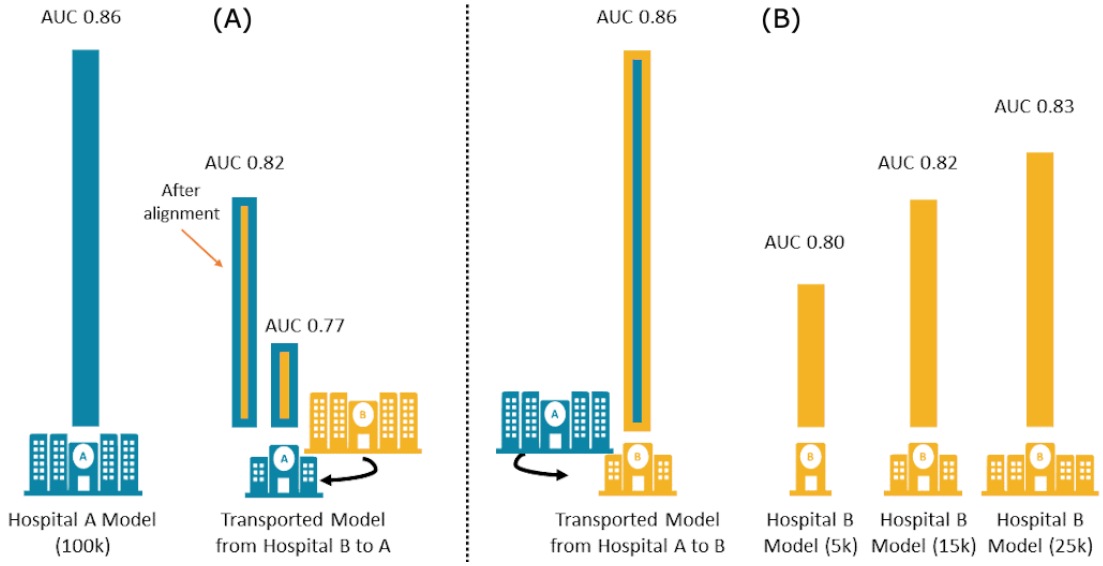
while no reduction in performance was observed when transporting from Hospital A.

In order to overcome this disparity, we evaluated the patterns of distribution of fetal head station as distributed across the dilation. We aligned the station within the distribution of the cervical dilation in order to encompass both approaches. This partly adjusted for the variation and improved the cross-facility prediction (AUC 0.82; Figure 2A; see Multimedia Appendix 1 and Multimedia Appendix 3 for the AUCs and 95% CIs of all models).

This difference highlights the difficulties introduced by discrepancies in reporting practices between facilities. Alignment can resolve some disparities, but here, it only partly recouped model performance.

To further evaluate whether our labor progression model could potentially benefit an even smaller facility, we simulated a hospital with a smaller EMR. The 100,000-case Hospital A model transported to Hospital B showed better performance (AUC 0.86) than a Hospital B model based on small samples of 5000 (AUC 0.80), 15,000 (AUC 0.82), and 25,000 (AUC 0.83) cases, emphasizing the benefit that can accrue to a smaller facility from a model trained at a larger facility and that the additional benefit decreases as the size of the available local EMR grows (Figure 2B).

Figure 2. (A) Comparing the performance of Hospital B labor progression model (in yellow) transported to Hospital A versus Hospital B model after alignment adjustments transported to Hospital A (blue/yellow bars) versus Hospital A local model (in blue) and (B) Comparing the performance of Hospital A labor progression model transported to Hospital B (yellow/blue bar) versus Hospital B local models trained on progressively larger local electronic medical record (EMR) data sets of 5000, 15,000, and 25,000 (in yellow). AUC: area under the curve.



Conclusions

In conclusion, integrating ML applications into clinical medicine will require validation and transportation between medical facilities [7,12-14]. We demonstrated that ML may be applied to clinical practice and to obstetrics in particular. A big data–driven ML algorithm can be successfully transported, and a data-poor center can benefit from work performed in a larger facility.

However, transportation requires careful investigation of specific features and consideration of variations in local populations, protocols, and reporting to calibrate the system fit [7,12]. Nevertheless, model predictions are heavily dependent on the data used in training and by the variations in recording practices and protocols operative in a given health care facility. We observed that the more detailed labor progression model, when trained without accounting for reporting differences, provided a lower AUC than the admission model. Although the progression model contained more detailed information on the progression of the labor and intrahospital showed benefit over the admission model, the benefit provided was lost when transporting the model to a different hospital: The transported model performance was inferior to that of the simpler model. Interfacility variation between health care centers may introduce unexpected effects into a prediction model. Generalizability and transportability among medical facilities necessitate overcoming biases via external validation and adapting the model to local protocols [15].

Successful translation of AI research into practice depends on transport across health care facilities. This can individualize health care, improve outcomes, and reduce complications across broader populations.

Abstract

Safety issues for researchers conducting and disseminating research on social media have been inadequately addressed in institutional policies and practice globally, despite posing significant challenges to research staff and student well-being. In the context of the COVID-19 pandemic and given the myriad of advantages that web-based platforms offer researchers over traditional recruitment, data collection, and research dissemination methods, developing a comprehensive understanding of and guidance on the safe and effective conduct of research in web-based spaces has never been more pertinent. In this paper, we share our experience of using social media to recruit participants for a study on abortion stigma in Australia, which brought into focus the personal, professional, and institutional risks associated with conducting web-based research that goes viral. The lead researcher (KV), a postgraduate student, experienced a barrage of harassment on and beyond social media. The supportive yet uncoordinated institutional response highlighted gaps in practice, guidance, and policy relating to social media research ethics, researcher safety and well-being, planning for and managing web-based and offline risk, and coordinated organizational responses to adverse events. We call for and provide suggestions to inform the development of training, guidelines, and policies that address practical and ethical aspects of using social media for research, mental and physical health and safety risks and management, and the development of coordinated and evidence-based institutional- and individual-level responses to cyberbullying and harassment. Furthermore, we argue the case for the urgent development of this comprehensive guidance around researcher safety on the web, which would help to ensure that universities have the capacity to maximize the potential of social media for research while better supporting the well-being of their staff and students.

KEYWORDS

cyber bullying; online bullying; research activities; occupational safety; research ethics; students; bullying; social media

Introduction

Social media is rapidly becoming a mainstream tool for the conduct and dissemination of research, health interventions, and evaluations [1]. Researchers and research students are increasingly expected to conduct and communicate their research on the web [2], including using a range of social media platforms to conduct and promote their work. Such spaces present new opportunities and risks for research. Rapid and potentially targeted recruitment and (perceived) anonymity provide access to historically hard-to-reach populations. At the same time, the boundaries between researchers' professional and personal identities have become increasingly blurred as images, information, and work are shared and searchable across platforms. As such, communication with and harassment of researchers on the web can move rapidly from public to private spaces, with a suite of personal and professional consequences that are in line with those of web-based bullying and trolling more broadly.

In this context of new risks and opportunities, research ethics processes, the literature, and guidelines are beginning to address the specific concerns associated with research participant safety and well-being in web-based and social media research. However, robust and constructive cross-institutional and interdisciplinary conversations and guidance addressing the management of and support for researcher safety and well-being

continue to be largely missing. In this paper, we argue that there is an urgent need for robust guidance on the use of social media for research, paying particular attention to the need for institutional and ethical frameworks and researcher training that address web-based safety and mental well-being. By outlining our extraordinary and challenging experience of *going viral*, along with the limited published experiences of other researchers, this paper calls for institutional and industry-wide practices that aim to keep researchers and their work safe in increasingly unavoidable web-based workspaces.

New Norms, New Risks

Under consistent pressure to meet research performance expectations in the context of time constraints, in the COVID-19 pandemic environment of limited travel and face-to-face engagement opportunities, and given the benefits of engaging with technological innovations to improve research processes, researchers increasingly occupy web-based networks and social media platforms for the communication and conduct of research. In this context, social media–enabled recruitment has never been more relevant. The reach, speed, affordability, flexibility, and potential for multidirectional communication and *sharing features* afforded by social media make it a favorable alternative to traditional research processes and their limitations [3-6]. In particular, social media has been found to be an effective tool in health research and promotion. Social media has been used to successfully recruit hard-to-reach populations and may be particularly "well-suited to research and practice on 'taboo' public health topics" [4], such as sexual health. This is partly because of the potential for anonymity on social media, along with the high number of young people present on these platforms [4,6-10]. Engaging research participants via social media can help to minimize research fatigue, facilitate engagement and retention of research participants, and contribute a richer data set than traditional methods can achieve on their own [5].

Along with these benefits, the limited (albeit growing) body of literature on using social media for research also describes challenges, including self-selection bias, engagement, and underrecruitment, along with a lack of control over the framing and sharing of content shared on the web [8,11,12]. Social media platforms have been described as *echo chambers*; users are constantly and progressively exposed to content aligned to their pre-existing belief systems, confirmation bias thus being a feature of social media use [13]. This allows for the specific targeting of messaging and advertisements beneficial to the conduct of science and health promotion; it also means politically charged or emotionally arousing content is most likely to spur engagement and *go viral* [13,14].

There are additional potential challenges associated with the use of social media in research. The absence of facial and social cues and gestures on the web that would otherwise be present in face-to-face interactions and the real or perceived anonymity that web-based interactions can afford increase the potential for interpersonal conflicts and escalation of arguments [15-17]. "Language truncation, the use of images and hashtags, results in inappropriate, inaccurate or mis-judged commentary in 140 characters" [18], which can affect the narrative that surrounds research shared on the web and limit the ability of researchers to control it [8]. Misinformation, misinterpretation, and misappropriation of research or research activities on the web could be described as somewhat of an inevitability, as is highlighted in the discussion of our own experience. Users' perceived anonymity and strength in numbers also means that communication and harassment among users can escalate rapidly, shifting from public to private and professional to personal web-based spaces [17,19,20]. Harassment on the web is not new; however, cultural and technological changes are likely to increase the risks of experiencing harassment and the speed at which *cyber mobs* rally, posing evolving challenges to researcher privacy, safety, and well-being.

Despite the myriad of challenges it poses, social media will be increasingly used by researchers who will become fluent in navigating and imagining its potential. Concurrently, these researchers will inevitably face evolving and fluent forms of harassment. As such, there is an onus on higher education and research industries and institutions to assume greater responsibility for the well-being of staff and students on the web, supporting and equipping them with the tools needed to safely navigate and effectively use these platforms and appropriately responding when harassment occurs.

Going Viral: Triumphs and Troubles

As part of the primary author's (KV) PhD research on abortion stigma in Australia, Facebook was used to recruit members of the Australian public to a web-based survey.

A number of professional, academic, and ethical challenges were faced by our research team during this process, which we share here in the hope that they will inform conversation and debate around the role of universities in better understanding, mitigating, and addressing researcher and student safety on the web.

Over 2 years, the authors developed a quantitative survey measuring abortion attitudes, knowledge, and perceived abortion stigma, which is the first of its kind to be developed and implemented in Australia. The survey tool was informed by extensive literature searching and qualitative and quantitative testing. It included, among others, a combination of items that endorsed and rejected stigmatizing abortion-related statements. The study received approval from the Flinders University ethics committee, including approval to omit all researcher names from the study documents.

Participants were recruited to the study using Facebook advertisements, which were targeted broadly at anyone living in Australia aged ≥16 years. Our ability to alter and retarget advertisements over time to ensure that the self-selected sample was as representative of the population as possible, the team's familiarity with using paid Facebook advertising and the relative speed at which recruitment could occur made recruitment via Facebook an appealing and logical choice. It may be relevant to consider that the survey was released during the height of the first round of the COVID-19 pandemic restrictions in Australia in April 2020 when other methods of recruitment were likely to be more challenging than usual.

In just 2 weeks of Facebook advertising, 3500 participants completed the survey. At this time, the advertisements were

retargeted to facilitate the recruitment of participants aged >40 years and male participants, underrepresented among the respondents. During the process of releasing these more targeted advertisements, the survey attracted the attention of a prominent antiabortion (prolife) lobby group who shared it with their membership via email and on their Facebook page. Within 48 hours, >5000 survey responses and close to 100 emails were received by the lead researcher (KV). At this time, the paid Facebook advertisements were halted, although the survey link remained live.

Comments undermining and debating the survey method and style, along with common antichoice sentiments around the "irresponsibility of women seeking abortion" and "abortion as murder" were noted as relevant social media posts. Emails to the research team and the university ethics committee contained *concerned queries* and *recommendations* for improvements, along with explicit hostility and requests to have the study ceased. McPherson et al [21] found that users who are the first to share a study (on social media) are likely to affect the composition of the resulting sample, reflecting the power and influence of individuals to amplify and influence messaging and information accuracy on the web. Our experience supports their finding, as the vast majority of the 5000 responses received in the days following the lobby group's sharing of the study reflected their otherwise minority (in Australia) strong antiabortion views.

Coordinated attempts by this lobby group to undermine rights or evidence-based laws, policies, or programs, such as those pertaining to abortion, contraception, and lesbian, gay, bisexual, transgender, queer, intersex, and asexual (LGBTQIA+) rights, including marriage equality, are common in Australia [22,23]. Along with the use of more formal lobbying channels, direct communication (often abusive) with staff involved in projects or organizations that the group does not agree with have been reported [24,25]. The potential for such a response to our research was likely amplified by the growing (at least in prominence) public mistrust in science more broadly. This was facilitated by social media and exemplified by apparent global shifts towards conservatism over recent years [18], along with the abortion decriminalization process that fueled antiabortion activism in South Australia at the time our research was taking place.

Although it has been difficult to formally track *shares* and *reposts* of the study, 3 days after the survey was shared by the antiabortion group, a prominent feminist politician, feminist author and public figure, and a number of women's health and women's rights organizations became aware of the study. To counter the perceived attempts by antiabortionists to sway the findings, these individuals and groups began sharing the survey in their networks. The survey was subsequently shared at least several thousand times across Twitter and Facebook and emailed to multiple women's health, women's rights (feminist), health provider, and lobby group mailing lists across a 4-day period. Much of the narrative around these *shares* sought to encourage people to complete the survey to balance the nature of responses received. However, in a number of social media posts, the survey purpose was misconstrued as being a tool for promoting an antichoice agenda, causing anger from proponents of abortion rights. Items asking participants to select their level of agreement or disagreement with statements reflecting common abortion-related stereotypes and antiabortion sentiments were construed as evidence that the survey was inherently antichoice, which further fueled this narrative. As such, hostility from both proponents and opponents of abortion rights was directed at the research team and the university.

Going viral resulted in 67,000 responses in 6 days, with a total of 70,051 responses received over the 3-week recruitment period. Ultimately, the final sample broadly represented the Australian public regarding support for or opposition to abortion accessibility and legality, with approximately 89% (9/10) supporting legal abortion always or mostly [26,27]. The survey link was made inactive after a week of *going viral*, 3 weeks after it was first published, as the responses received represented a mix of views and were deemed more than sufficient to facilitate a detailed and meaningful analysis. Within days of ending the recruitment, the antichoice lobby group *claimed victory* in their email newsletter, suggesting it was their campaign against the study that resulted in it being closed.

A month later, a freedom of information request was submitted to the university to seek documents related to the study, including documents that indicated the reasons for the survey being closed and the survey responses themselves. As the lead researcher (KV) was a student, their name and most of the information requested were redacted. Details regarding other members of the research team and the content of several personal emails between the lead researcher and her supervisors were provided; some of them were later published on the web by the antiabortion lobby group.

Despite such a successful recruitment process, our unpreparedness for the speed with which the survey would be shared on the web led to a number of challenges for the research team. For example, we were initially unprepared to manage (practically and emotionally) the hundreds of hostile emails, which appeared to be a coordinated attempt to shut down the project and were received in a span of a few days. Although the researchers' names were not in the public sphere, staying anonymous was a short-term solution, with the need to publish the work and findings, along with the freedom of information request, making disclosure inevitable.

A number of safety concerns arose, including concerns and uncertainty around the following: best practices for keeping safe on the web and preventing disclosure of personal details and location (of residence, in particular), the safety precautions that ought to be considered or implemented offline, and a lack of institutional capacity to provide such knowledge and support, the research team awareness of other strategies (with associated risks) that lobby or activist groups were likely to engage in, ways to balance the potential professional benefits of media interest with researcher and student well-being, and an understanding of risks and managing them to protect the university and individual reputations.

Phone and web-based meetings with the research team (because of the COVID-19 pandemic restrictions), on-campus phone-based mental health support, and the university media team and ethics committee were all available to support and

respond to the lead researcher's (KV) questions throughout the process of *going viral*. Although the responses received from individuals within the university were unanimously supportive, they were also ad hoc and sometimes conflicting. A coordinated response across departments, from media to ethics and student support, would have been beneficial in bolstering a sense of safety and clarity around how to respond and manage risks in relation to social media commentary, media requests and email communications, and threats.

Although it was deemed unlikely that web-based harassment would translate into offline risks of violence, a history of hostile activism and violence against abortion providers and supporters by antiabortion individuals and groups, both locally and abroad [28-30], contributed to heightened anxiety and fear throughout the experience. Recently, Glenza [31] described the antiabortion movement in the United States as *radicalized* and posing an *increased threat* [31]. Similarly, the decriminalization process and surrounding antiabortion campaign that occurred in South Australia, where the research team was located during the time of the research, heightened perceived risks. Overexposure to unpleasant social media commentaries and emails and comments on social media calling on people to *inundate* the research team with *concerned emails* resulted in the lead researcher (KV) experiencing both short- and long-term mental health consequences.

Researcher Harassment on the Web: An Anomaly?

There is a dearth of literature documenting research *going viral* and its impact on research outcomes and researcher well-being. Kosinski et al [6] described a project that, owing to web-based snowball sampling, successfully recruited 6 million participants over 4 years, with safety concerns not reported. Cuevas [19], a social scientist in the United States, described his experience of a large-scale, coordinated harassment campaign. It began in response to a comment Cuevas [19] had made on a social media post regarding the 2016 US presidential campaign, which rapidly moved into private and personal messages, threats, racist slurs, and false reviews, resulting in coordinated attempts to undermine his employment and family well-being. Cuevas [19] filed police charges, and the harassment was treated as a hate crime; however, he continued to experience harassment and threats to his job security. Cuevas [19] published about his experiences in the hope of giving a "voice to others who have been similarly harassed," stating in a media interview that he later received "emails from more than 60 professors from all over the world telling stories of their own" [32]. An Australian academic and antiracism activist, Dr Stephen Hagan, has also reported receiving hate mail and death threats in response to fake news reports about his work in advocating for the renaming of consumable products with racist connotations. Similar to that experienced by Cuevas [19], this hate campaign was fueled by right-wing political campaigns with racist dynamics [33]. Although neither of these harassment campaigns was initially in direct response to research activities, they were in response to web-based communication regarding their areas of expertise; in the Cuevas [19] case, the harassment rapidly became about his role as an academic and threatened it. As Viney [34] described, "academics have privileged knowledge that should be put to use in the community in a form of 'ethical academia'."

As such, activism and academia are often fundamentally intertwined. As social media becomes a vital stage for the performance and communication of science and research, the relevant social media posts made by academics may be necessarily considered to be part of their work.

Other researchers have reported harassing experiences in response to Facebook advertising, including in response to advertisements for LGBTQIA+ research participants [20,35]. Mitchell and Jones [20] reported cyberbullying in the form of Facebook comments, private messages, and voicemails to their research team, demonstrating the way harassment moves effortlessly from public to private spaces. Researchers working with marginalized communities or on marginalized social issues are most likely to face web-based harassment (usually not originating from the marginalized communities in which they are working). Research has also found that "harassment often arises in spaces known for their freedom, lack of censure, and experimental nature" [36]. This suggests that there is a particular risk for academics who are inherently working in *experimental* spaces (ie, conducting research) and who may be conducting research with or are members of marginalized communities themselves.

Trolling, defined as web-based behavior deliberately intended to antagonize or offend someone [37,38], is often intended as a silencing strategy, as was much of the response to our abortion stigma work. However, trolling is not the only method used to silence victims of web-based harassment and abuse. The advice offered to victims to help them cope with trolling is often to *not engage* with or *further provoke* abusers. However, such advice further silences the voices of victims and their stories and is situated within a victim-blaming narrative, whereby conducting work on the web is in itself deemed a *provocation* and harassment a normal response [36].

Among the Australian public, negative web-based experiences are common. In 2019, 14% of adults in Australia were estimated to have been the target of hate speech [39], and 67% had negative experiences on the web [40]. Studies with university students internationally report varied rates of cyberbullying, in part likely because of definitional and measurement variations; however, it is common for such studies in the United States, Canada, and Australia to find that between 20% and 40% of participants have experienced cyberbullying [41].

Cyberbullying and harassment result in social, mental, physical, financial, and academic consequences for victims, and these impacts are more commonly experienced by minority or marginalized individuals and communities [16,17,39,42]. *Secondary traumatic stress* may be of particular concern for researchers witnessing harassment of their target populations or for those who have experienced personal trauma themselves [35]. Studies that have addressed cyberbullying in universities (investigating contexts of web-based learning and web-based bullying of staff by students or colleagues) have found that it can lead to significant psychological harm (in terms of mental health, productivity, and engagement), occupational impacts (including risks to job security, satisfaction, and employment opportunities), and physical consequences (including the risk of violence) [17,19,41].

Ethical Considerations: Something Is Missing

The literature describing the ethical challenges associated with social media use in research are rooted in traditional ethical frameworks, with a focus on participant safety and protection. Ethical dilemmas regarding the appropriateness of the use of social media users' web-based data as *research data* and the automatic sharing of social media users' web-based behavior (including engagement with research-related content) with data companies are being increasingly addressed as they pertain to issues of consent, anonymity, and privacy [8,12]. Privacy and confidentiality risks to consenting research *participants* and nonparticipatory bystanders and the implications for participant *aftercare* (ie, the need for researchers to remain available to participants post data collection) have also been described [8,12,43]. Issues of inclusion and accessibility have also been raised, with the *digital divide* continuing to signal and exclude already-disadvantaged communities [5].

Ethics committees routinely request, as they must, detailed information about potential risks to participant safety and strategies to manage these risks. However, what is often neglected in ethics processes, the published literature on social media–based research, and institutional policies is researcher safety and well-being on the web. We acknowledge that this gap exists within a broader gap regarding researcher safety issues, described most frequently as relating to fieldwork and sensitive research, which are not new but remain inadequately addressed [5,44].

A Call for Guidance and Integrated Management of Researcher Safety on the Web

Health and social scientists and research students can face considerable risks and consequences associated with conducting research on politically contested or otherwise sensitive topics, which are characteristic of many areas of health research [45,46]. However, such risks, particularly their relevance in web-based settings, have been insufficiently acknowledged in the literature, policy, or practice. Researcher safety and work health and safety in research are most often defined in terms of risks of physical violence in field and laboratory work [47-49]. Cyberbullying policies and the literature focus largely on peer-to-peer or peer-to-staff (or vice versa) interactions.

There appears to be a dearth of comprehensive and integrated frameworks, training, and guidance for preparing research staff and students to implement and manage their work and safety on the web, both at the institutional and research levels [50]. There is limited evidence-based or regulatory guidance on the use of social media for research broadly [3,6,8,12]. This contributes to ambiguity around relevant ethical considerations and best practices, including how to interpret and apply existing ethics principles [51]. Guidelines published by The British Psychological Society note that exposure to distressing content, unsolicited attention or messages, or *derogatory attacks* may cause emotional distress and threaten researcher and institutional reputations as a result of web-based research [20]. However, descriptions of risks and implications of ethical considerations regarding public–private distinctions, confidentiality, and anonymity (among others) for researchers are not provided, nor is guidance on mitigating or managing risk and adverse events. The under- or overestimation of risks resulting from a lack of ethical and practical guidance for web-based research and inconsistent approval outcomes from ethics boards affects researchers' ability to conduct ethical web-based research and may discourage social media use in research, resulting in lost opportunities [5,6].

Research from North American universities has found that over half of their faculty members are unsure whether there are resources available to support them if they experience web-based bullying; however, they believe universities should be responsible for preventing and stopping web-based bullying [17]. Although Cuevas [19] reported a *uniformly supportive* response from the faculty to the harassment campaign against him, he also noted that he would have preferred a more assertive organizational response that would call out his attackers and deter future harassment campaigns rooted in the use of *collective power* against a public minority figure. Our own experience mirrors that of Cuevas [19] as responses to our experience were *uniformly* and personally supportive; however, there was no sense that a broader institutional response or positioning against the harassment was considered. This leads us to consider whether a desire to appear *objective* (and, likely, to appease diverse funders) mutes what should be confident, evidence-based, inclusive responses by academic and scientific institutions toward homophobic, antichoice, or other hate-fueled harassment of their staff and students.

Research institutions have a duty of care toward staff and students and, as such, an obligation to develop and implement strategies to protect researchers in the diversity of their modern workspaces. Although universities in Australia are legally mandated to hold policies addressing cyberbullying of staff, similar policies are not legally required for students [41]. A study found that although approximately 70% of Australian universities have policies relating to *bullying via computers*, less than half indicate *support for victims of bullying*, and only 20% provide *advice for students about bullying* [41]. An analysis of 465 policies at Canadian universities conducted in 2015 found that only one-third referenced cyber behaviors, and few addressed the prevention of web-based harassment [52]. Furthermore, such policies tend to focus on cyberbullying among peers or colleagues and often fail to address web-based safety management more broadly.

Failing to remain current with and address web-based safety concerns is not unique to universities. The *Guide for Preventing and Responding to Workplace Bullying* by Safework Australia [53] acknowledges the health and safety risks of bullying but fails to mention web-based harassment or bullying at all. However, as thought leaders and public institutions, it is questionable whether these gaps in universities—organizations that are designed to lead in knowledge generation and translation—are acceptable any longer.

Recommendations

In 2019, Russomanno et al [35] published what they described as "the first formal, safety and monitoring guidelines for researchers using social media" for recruitment, particularly of marginalized population group members. These guidelines recommend protection for both participants and researchers,

with a focus on minimizing, managing, and addressing negative comments and cyberbullying. Recommendations include assigning research team members to regularly administrate and monitor recruitment posts; posting advertisements for at most a 1-week period (at a time) to minimize researcher burnout; using inclusion *and* exclusion terms to minimize negative responses; restricting who can respond to or comment on public pages; frequent reviewing of Facebook policies around privacy, profanity, and reporting before recruitment to reduce the burden on research staff and decrease users' experiences of negative comments and bullying; screenshotting and reporting all negative interactions to internal review boards; organizing regular staff debriefs and team meetings to minimize compassion fatigue (secondary traumatic stress); and making a relevant referral to mental health services or resources for staff as needed [35]. Evidence also suggests that the use of both inclusion and exclusion terms when targeting Facebook advertisements could help to minimize the likelihood of cyberbullying toward both the study population and, presumably, web-based researchers [20,35]. It is the specifics of managing safety, such as those that we believe should be shared and understood widely across research institutions and ethics boards.

On the basis of our experiences, relevant guidance addressing researcher safety on the web could also speak to the following:

1. The need for the routine provision of evidence-based training in ethical issues in web-based research for both researchers and ethics committees; this could support increased confidence of institutional review boards and individual researchers in using social media research strategies effectively, along with encouraging the teaching of techniques to minimize the risk of exposure to potentially harmful content and responses
2. Information on and strategies addressing the blurring of private and professional boundaries on the web and changing notions of privacy, including the implications for researcher safety and security, and guidance on the responsibilities of institutions in cases where harassment occurs and may move through public and private spaces
3. Emphasis on the legal, practical, and ethical implications of working across various social media platforms
4. The need to understand, support, and strengthen the digital fluency and mental health risks and capacity of researchers to prevent, manage, and respond to potential harassment and bullying, including clear protocols for individual and institutional support and response when harassment does occur
5. Strategies for engaging with media, both in the more traditional sense of media training and in regard to responding and communicating on the web, ensuring such strategies are not centered around avoidance of social media or on a victim-blaming mentality
6. Understanding language use, inclusion and exclusion terms, and other platform-specific features that can help researchers to minimize risks associated with social media–based recruitment

Universities may also benefit from institution-wide efforts toward understanding and planning for the ways in which various departments and roles across the organization need to contribute to and work together toward coordinated and effective responses to adverse events.

There appears to be a consensus in the literature that guidance pertaining to web-based research ethics should be based on traditional ethical and well-being frameworks, partially to aid ethics bodies in their transition to assessing risks in these *new* web-based workspaces, particularly as overarching ethical concerns remain the same across the various locations of research [5,8,50,54]. However, the evolving risks, expectations around privacy, personal and professional boundaries, and ethical norms will necessarily generate new understandings and definitions of safety and require new applications and imaginations of existing ethical frameworks [50].

Instead of fearing the unknowns and risks of web-based research, the development of comprehensive guidance around web-based safety will help to ensure that universities and research groups have the capacity to maximize the potential of social media for research while better supporting the well-being of research staff and students. As such, we propose that the higher education sector, research institutions, and ethics bodies need to engage more fully with the emerging risks social media presents. When the potential benefits for the quality of research outcomes and for staff and student well-being are weighed against the risks of not better engaging with these issues, the urgency and importance of this work become clear.

Abstract

Digital technologies offer unique opportunities for health research. For example, Twitter posts can support public health surveillance to identify outbreaks (eg, influenza and COVID-19), and a wearable fitness tracker can provide real-time data collection to assess the effectiveness of a behavior change intervention. With these opportunities, it is necessary to consider the potential risks and benefits to research participants when using digital tools or strategies. Researchers need to be involved in the risk assessment process, as many tools in the marketplace (eg, wellness apps, fitness sensors) are underregulated. However, there is little guidance to assist researchers and institutional review boards in their evaluation of digital tools for research purposes. To address this gap, the Digital Health Checklist for Researchers (DHC-R) was developed as a decision support tool. A participatory research approach involving a group of behavioral scientists was used to inform DHC-R development. Scientists beta-tested the checklist by retrospectively evaluating the technologies they had chosen for use in their research. This paper describes the lessons learned because of their involvement in the beta-testing process and concludes with recommendations for how the DHC-R could be useful for a variety of digital health stakeholders. Recommendations focus on future research and policy development to support research ethics, including the development of best practices to advance safe and responsible digital health research.

Introduction

Background

The increasingly familiar term *digital health* was defined by a United States National Institute of Mental Health working group in 2017, as the "blending of mobile health (mHealth) and health information technology (smartphones, wearable sensors, web-based resources, and electronic health records) with genetic, biological, social, and behavioral science to help consumers, clinicians, and researchers measure, manage, and improve health and productivity" [1]. For this commentary, we focus on

commercially available and research-grade digital health strategies used in behavioral health research and reflect on the ethical, regulatory, and social behavioral issues inherent in this work.

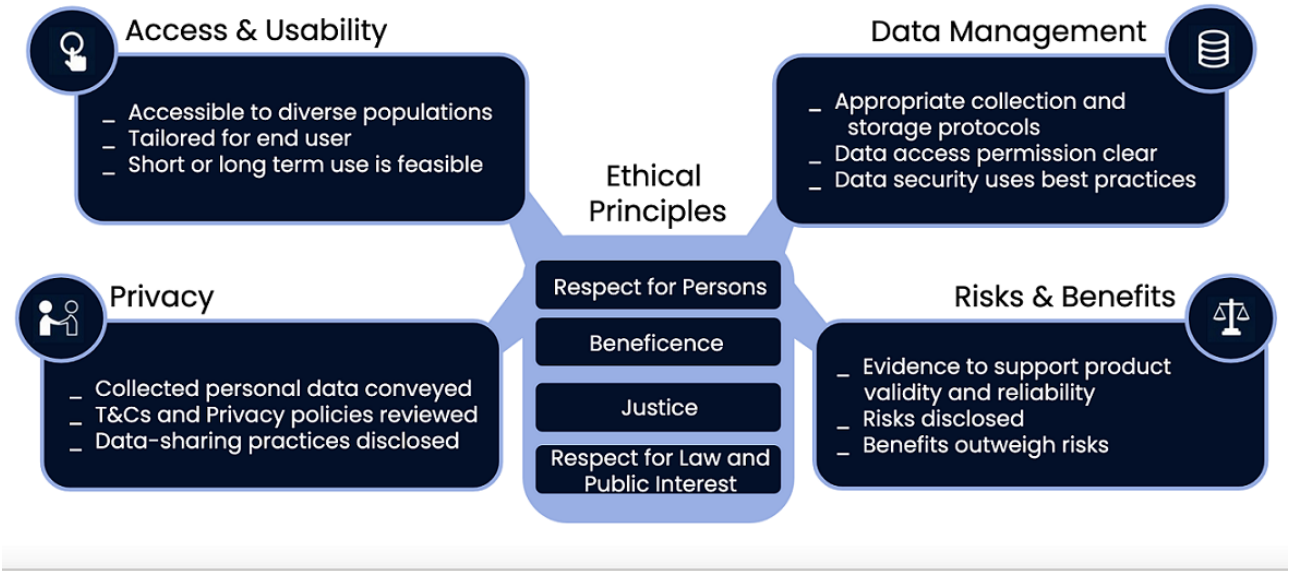
The ability to leverage digital health strategies and tools (eg, wearable and remote sensors, social media platforms, and mobile apps) to support health research holds enormous potential for behavioral and social scientists by offering accessible, scalable, and cost-effective approaches to delivering interventions to promote health behavior change, prevent disease, identify illness, and facilitate diagnosis [2]. The US National Institutes of Health began funding digital health research over a decade ago and, although the use of digital tools and strategies in research remains somewhat novel, it is escalating rapidly [3,4]. A study of United States National Institutes of Health funding of digital health research documented a 386% increase in funding of digital research between 2005 and 2015 [4]. Digital tools and strategies are increasingly used to reach populations previously understudied in biomedical research [3,5,6], including vulnerable populations with stigmatizing illnesses [7]. In the United States, the rapid onset of the pervasive technology era has preceded the development of ethical guidelines and regulatory infrastructure, which leaves researchers and potentially patients or participants vulnerable in making decisions about the selection of digital technologies and decisions about whether to participate in research. Although efforts are moving forward, these regulatory and governance gaps challenge our scientific community to inform responsible practices in digital health research, particularly new challenges and *unknown unknowns* with regards to risk assessment and data management [8,9].

Harnessing these technologies for use in health research comes with new social and ethical responsibilities to ensure that the products are effective, accessible, usable, sustainable, considerate of privacy expectations, and with good faith efforts to secure volumes of personal and sensitive health information—all of which influence the potential risks of harm and potential benefits of using such technologies [10]. The ethical responsibility to evaluate digital products for use in health research lies not only with those developing the technologies for research-grade use but also with companies that sell these products. Moreover, other key stakeholders, including researchers using digital tools and strategies to study health promotion and ethics review boards (eg, institutional review board [IRB] in the United States, research ethics board in Canada and research ethics committee [REC] in the European Union) that are charged with protecting research participants, have an important role in shaping ethical digital health research [9,11]. However, for researchers, digital health guidance for selecting tools and strategies is lacking. To promote informed decision-making in keeping with social and ethical responsibilities of those who conduct research, the Digital Health Checklist for Researchers (DHC-R) was developed [10]. This paper describes researchers' perspectives when beta-testing the first iteration of a digital health framework and checklist. Although the perspectives voiced in this paper are those of US-based researchers, we anticipate that our lessons learned, recommendations, and call to action will be relevant globally where regulations and standards to guide ethical digital health research are either limited or nonexistent.

DHC-R Background

The DHC-R is grounded in well-established ethical principles of biomedical and behavioral research and supports the following 4 domains: (1) access and usability, (2) privacy, (3) data management, and (4) risks and benefits (Figure 1) [12]. The ethical principles of respect for persons, beneficence, justice [12], and respect for law and public interest form the core of the DHC-R framework (Figure 1). The DHC-R is licensed under a Creative Commons Attribution-Non-Commercial 4.0 International License (2018-2020) and available through the Research Center for Optimal Digital Ethics (ReCODE) Health research tools webpage [13].

Figure 1. Digital health framework with examples of checklist prompts embedded within each domain (used with permission of C. Nebeker, ReCODE Health).



These 4 domains intersect with foundational ethical principles that undergird responsible practices in health research. However, researchers face a lack of consistent governance in digital health spaces. Regulations such as the US Health Information Portability and Accountability Act (HIPAA) do not always protect the granularity and volume of data and the safe storage of data derived from digital tools and strategies [14]. Moreover, not all entities conducting digital health research are governed by federal regulations created to protect research participants. This inconsistent governance creates confusion about how to assess risks of harm, manage data, and convey information to potential participants [15]. Awareness of these inconsistencies is useful when making choices about which digital solutions may work best to support the research aims and be safe for use with research participants.

Beta-Testing Approach

The DHC-R checklist was developed in 2 phases and has been reported elsewhere [10]. The DHC-R was developed in the United States and anchored to ethical principles that guide biomedical and behavioral research in the United States. Briefly, during phase 1, an expert panel was convened to review a decision-making framework published by the American Psychiatric Association, which was designed for clinicians who might prescribe or recommend a mobile app to their patients [16]. Phase 2 involved beta-testing a modified version of the American Psychiatric Association checklist for use by digital health researchers. Beta-testing involved a group of behavioral scientists who agreed to serve as the second expert panel. Expert panel members were asked to identify a recent digital health research study that they had designed and obtained IRB approval to conduct. Each panel member then applied the modified checklist, administered via the SurveyMonkey (Momentive Inc) platform, to their specific use-case study. Following completion of each domain area within the checklist (eg, privacy and data management), each panelist was asked to comment on the clarity of the prompts and whether additional criteria or content should be included (eg, *is anything missing* or *anything else to add*).

When beta-testing was completed, the lead authors (RBE and CN) reviewed all qualitative and quantitative responses and subsequently revised and published the DHC-R development process. Qualitative comments also revealed personal reflections by the panelists and a few concerns; specifically, that their prospective risk assessment may have been incomplete. With the goal of exploring their experiences during the beta-testing process, the lead authors scheduled 2 meetings with the panelists. After the first meeting, the lead authors reviewed open-ended comments and meeting notes and identified emerging themes using a thematic analysis approach [17]. During a second meeting to confirm and refine the themes, the lead authors discussed how best to share these valuable and personal insights leading to this paper's *lessons learned* summary. For context, the lessons learned presented in this paper arise from the authors' experiences working with technologies and research participants in the United States. Collectively, we conducted behavioral change intervention research that is both preventive (ie, physical activity and healthy eating) and aimed at treating chronic conditions, such as kidney disease, diabetes, and cardiovascular disease. We leverage technologies, such as wearable sensors, mobile apps, web-based social networks, and other connected technologies (ie, smart pillboxes and weight scales) in our research. Therefore, the lessons learned presented in this paper are shaped based on the United States context, including relevant United States legal protections of human subjects in research, and other relevant legislations such as US privacy laws. The goal of sharing our collective experience as panel members and behavioral scientists is to support the broader digital health research community and encourage other stakeholders to share responsibility for individually and collectively shaping ethical and responsible practices.

Results and Lessons Learned

The following 3 key themes were labeled: (1) researcher vulnerability, (2) lack of control, and (3) researchers' responsibility for human research protection. For each theme, we address what actions can be taken and future directions to consider.

Researcher Vulnerability

Overview

Reflecting on the design and implementation of their study use case left many panelists feeling vulnerable. This vulnerability stemmed from recognizing, in our role as behavioral scientists and researchers, we lacked a framework to guide the selection of the digital health tools and strategies used in our research studies. Without guidance, we needed to rely on our personal experience, technical savviness, and best judgment. Before beta-testing the DHC-R, there were no evidence-based tools or resources available to inform the selection of a digital health tools or strategy that would be appropriate for our studies and safe for participants. As researchers, we have used important and practical considerations for selecting a digital health product, such as whether the technology could be adapted to meet the needs of the research study across research sites and whether it had reasonable technical specifications. However, too often, we were not aware of important ethical aspects, and although our studies had received IRB approval, there were aspects of the digital tools and strategies we were not familiar with or knew how to consider prospectively when planning our research. Often, these issues are not known until a problem arises, which is what the DHC-R is working to preempt by helping researchers develop awareness as well as decision-making skills needed to be purposeful in advancing responsible and safe digital health research. The following response to the DHC-R beta-testing survey conveys this vulnerability:

> *Yes [I would do things differently]...That said, I also feel powerless as there is so little, I feel I understand in making decisions on use.*

Reducing Vulnerability

As researchers, we are trained to ask scientific questions and design studies to answer these questions. We have become experts in our respective disciplines; however, when we have the opportunity to use new tools or methods, we must recognize that we are novices and seek guidance from those with greater

expertise, as well as diverse experiences. We may find that working with a technologist, privacy expert, or participants can help to shed light on the *known unknowns* and potential *unknown unknowns* that are inherent when learning how to use a new research tool. Recognizing our vulnerability is necessary and humbling and will certainly lead us to become better scientists. Nevertheless, it is important to balance the fear of making the wrong decision with that of moving fast and potentially causing damage and harm. The slogan "Move purposefully and fix things" aligns with our intention of embracing vulnerability [18].

Future Directions

Our developmental research revealed that using the initial checklist can facilitate reflection on factors that influence responsible digital health research [10]. Whether this reflection process prevents one from blindly moving into work that could be risky is unknown. We also do not know if reflecting on potential risk may discourage one from pursuing important health research. Although additional research on the DHC-R is required, the checklist was useful in prompting our awareness of important considerations when selecting digital tools and strategies for health research.

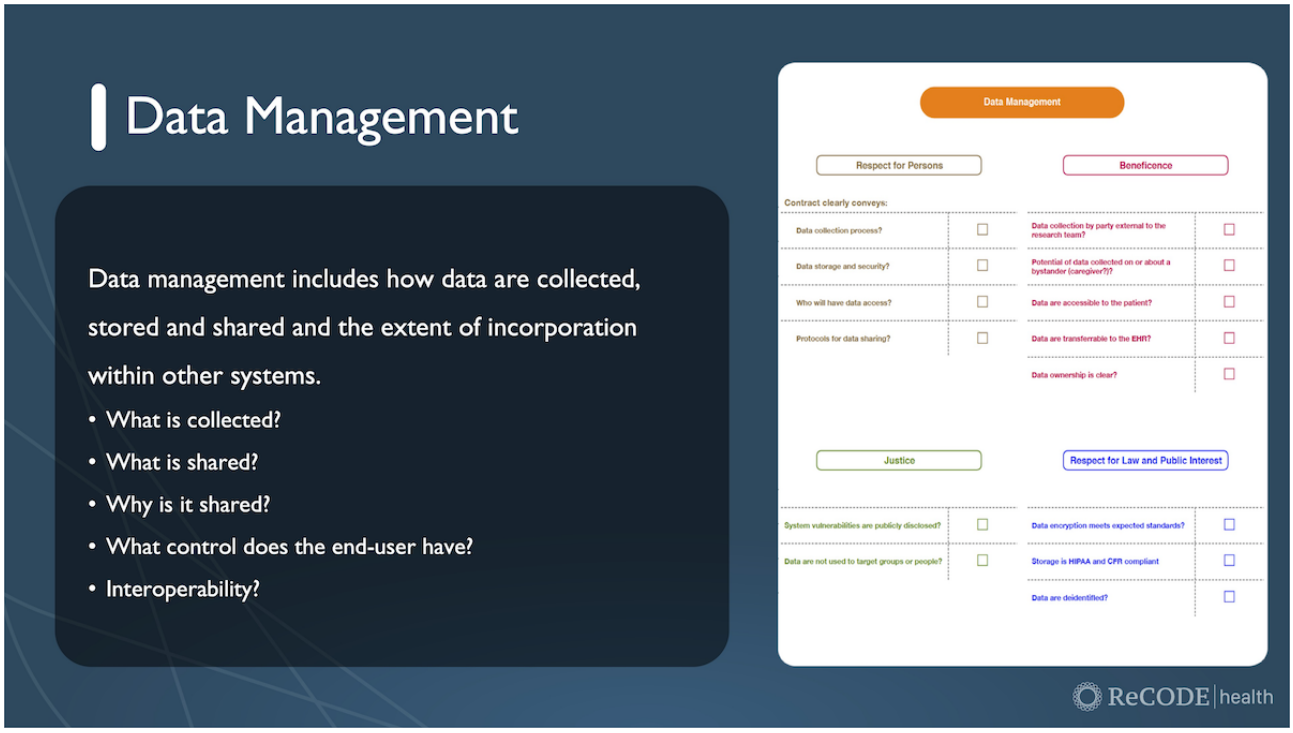
The framework (Figure 1) may reduce the vulnerability. Researchers are encouraged to consider digital tools and strategies from both the researcher and participant perspectives during the study design phase. The domain of *access and usability* prompts the consideration of the extent to which training may be required. For example, although commercial health wearables (eg, Fitbit) are designed for ease of use, participants may not intuitively know how to use real time data to make decisions about their future health behaviors. Assessing the need for and potential methods to train participants could prevent technology naivete from limiting intervention effects and influencing outcomes.

The *privacy* domain prompts researchers to take a deep dive into the vendor's terms and conditions of service to understand what data are collected, where data are stored, and how data might be shared. For example, researchers should be able to select specific variables of interest from a health technology platform (eg, location and time of day) without burdening participants to provide these data. Moreover, requiring participants to download the data file and transfer it to researchers could compromise the data quality and security. Assessing the need for a third-party data management system is also an important consideration.

Finally, items in the *risks and benefits* domain of the checklist cue researchers to think about what evidence exists to support using the technology (reliability) and the validity of the device for the particular study in question. Checklist prompts (Figure 2) guide the researcher to consider potential risks and weigh them against the potential benefits of the technology.

During beta-testing, one comment describes how future thinking may be demonstrated: "I plan to more fully consider what details to include in the informed consent, particularly about data sharing." Applying the checklist used during beta-testing was beneficial in that it prompted reflection. Moving forward, we anticipate that other researchers will find it useful to prospectively consider how a particular digital health tool or strategy aligns with their goals of doing good science and protecting research participants. For example, a researcher evaluates an app that also happens to collect GPS data, but GPS data are not needed for the research study. In this case, the DHC-R would prompt the researcher to think about either using another app, if the GPS feature cannot be *turned off*, or explaining to participants during informed consent that these data are being collected so that they can make an informed decision about whether to volunteer. Technologies on the horizon, such as the *smart toilet*, will likely continue to challenge our ability to evaluate situations in which researchers collect data that extend beyond their original research questions. The DHC-R may prove useful for decision support today, and in the future, provided it is a dynamic tool that changes with time. These choice points become particularly important if the researcher uses a third-party app that provides little or no control over the use of data outside the research study.

Figure 2. Example of data management domain from the digital health checklist (used with permission of C. Nebeker, ReCODE Health).



Lack of Control

Overview

Experiencing vulnerability stems from the awareness that researchers sometimes lack control when selecting digital technologies. For instance, researchers often sacrifice control for the benefits of using commercial products. Many commercial products make the application programming interface available to all or select approved researchers. This allows researchers to access data and deploy interventions using commercial products. For example, in a statewide dissemination of a web-based behavioral weight loss program offered through primary care clinics, participants have the option of linking a commercially available calorie counter smartphone app to their patient portal, where they are responsible for uploading weekly data on calories consumed per day, daily exercise minutes, and daily body weight [19]. Calorie counter apps are widely available, but the majority of the most popular ones do not have a researcher-accessible application programming interface. Consequently, researchers are limited in which apps they can use if they wish to access these data. At the same time, smartphone apps regularly add new (or discontinue) features, which may impact researcher access to data or make a training guide for participants obsolete when features change. In the traditional research timeline, commercial digital health products will update repeatedly during the course of a single trial, and these updates are out of the researcher's control. These updates can wreak havoc with regards to measurement and implementation and undermine the entire study design. Finally, researchers often lack control when they choose to use a commercially available digital tool or strategy because they cannot control modifications made to the data structure, algorithms, or equations, nor control whether the company stays in business, which is crucial to maintain consistent technology support and potentially data management.

Although digital tools and strategies create opportunities for researchers, the field is dynamic, making it difficult to foresee all potential risks. However, we learned that the decision-making domains of the DHC-R helped to focus panelist attention on key areas, including privacy, data management, risks and benefits, access, and usability. In this sense, the DHC-R builds awareness around important decision-making domains. The following comment made during beta-testing reflects this increased awareness:

> *There were various factors around interoperability and privacy that I did not previously consider, especially with the use of commercial apps within my study. Data from these apps weren't collected for my study, but I did request that participants try a variety of apps, which could have put them at risk for loss of confidentiality that wasn't as clear at the time of the study. Will consider this more in the future and also include transparent language in the consent forms.*

Future Directions

To move the field and researchers toward building awareness of the controllability of the digital tools and strategies, the DHC-R is best used during the planning phase of research. Not only can it be useful in prompting researchers to consider what they can and cannot control and guide development of contingency plans, the DHC-R can be used throughout the project for ongoing assessment of factors that influence responsible and ethical practices. By conducting an ongoing assessment of the products selected for a particular study, we anticipate an increased sense of control that comes with being informed. In addition to being informed, we as individuals and members of the digital health research community need to be honorable stewards of funding received to conduct behavioral health research with integrity. The responsibility to take action

resides with all in the digital health research ecosystem; however, it is not presently a norm. As such, we collectively need to commit to affecting changes in standards such that poor practices do not become the default standards. For example, if a product is not *research* friendly (eg, terms of use conflict with federal regulations for human subject protections and platform changes without notification), then those vendors become less desirable than vendors that are supportive to the research enterprise. Moreover, there is a need to prioritize the training of researchers in the pipeline such that they recognize their role in shaping policy and the dynamic development of best practices. With these added responsibilities, we recognize that research funders need to step up to support research on research ethics in the digital health sector, ideally as part of strategic planning. These collective efforts will serve to advance the development of future digital health research and raise awareness of what is acceptable verses a deal breaker.

Researcher Responsibility in Protecting Participants

Overview

Two important lessons emerged about the researcher's responsibility. The first lesson is recognizing our responsibility for due diligence in the protection of human subjects when selecting technologies and embedding them in our study design. This includes how researchers communicate and plan studies that are submitted to the IRB/REC. The second lesson is on how we take our DHC-R assessment outcome and communicate it in a way that potential participants can understand and make an informed decision about whether to participate. These 2 lessons highlight researcher responsibilities and suggest actions needed when planning future studies and how the DHC-R can assist with research design and implementation.

Due Diligence

Using the DHC-R places a shared responsibility of due diligence on both the researcher and IRB/REC—rather than relying solely on the IRB/REC or other body to determine participant safety. For example, if researchers use the DHC-R during the protocol development phase and then share that evaluation process with IRB/REC members, researchers demonstrate that they are thinking critically about designing research with prioritized participant safety. However, there were concerns that an IRB/REC may use additional knowledge about digital health tools and strategies to act more conservatively and overprotect participants, thus slowing the approval process and, possibly, stopping important health research from occurring. Moving forward, it is critical that both researchers and review boards play an equally active role in developing awareness of factors that influence study risks and benefits and learn how to use decision support tools such as the DHC-R.

We collectively agreed that researchers should not exclusively outsource the responsibility of risk assessment to the IRB/REC. Specifically, researchers should not rely on the review board as an *ethics* expert, especially in the area of rapidly changing tools and strategies used in digital health research [8]. For example, digital technology companies can be acquired by other companies, which is not often discussed in typical research consent forms. In such cases, researchers must consider how the acquisition affects research data collection, storage, and sharing while considering the long-term availability of the product for continued use. Researchers should plan to communicate this information to prospective participants during the consent process and provide updates to the currently enrolled research participants. In effect, the DHC-R helps to shape the research protocol with respect to complex aspects of data management, privacy, access, and usability, and also how to convey these concepts when crafting the information conveyed during the informed consent process.

Moving From Responsibility to Accountability

The DHC-R can help researchers identify ethical and regulatory issues that have typically been left to the review board members to identify and resolve. Moving forward, researchers as well as others who make up the digital health research sector must design an ecosystem where we collectively use checks and balances. The organization of this ecosystem is beyond the scope of this paper; however, we highlight the following steps. First, to improve informed consent, we need to make information accessible and meaningful and to present it in a way that facilitates sound decision-making. At present, researchers tend to use words to convey complex concepts that may not be useful to people with low technology and data literacy. Designing a consent process that actually informs decision-making may require that researchers partner with prospective participants and communication and design experts to learn how best to convey information. This goal is not trivial and will require dedicated funding to overhaul how we approach informed consent. For now, the DHC-R provides a framework for deep consideration of what information participants may need to make informed decisions. In addition, the DHC-R facilitates an opportunity to consider how researchers can best assist individuals in becoming better informed with respect to information contained in a terms of service agreement. Although many agree that service terms and privacy agreements are not meant to be read or understood, as researchers, we have an obligation to educate prospective participants and help them to understand what permissions are given when accepting terms to use a commercial product (eg, Fitbit and Facebook) [20]. This education can include information on privacy limitations and data management, along with the potential unknowns inherent in digital health research participation.

Future Directions

When technology is used in health research, data security and privacy responsibilities should be shared to an extent by all stakeholders, including technology developers, researchers, hosts, and participants. It is also the researcher's responsibility to inform participants when product functionality that may alter privacy and data management risks changes. Presently, institutions focus on research risk assessments to reduce legal culpability. That may be important; however, the need for institutions to help researchers to develop sound data management protocols that protect research data is critical, particularly when potentially granular personal health data collected using digital tools and strategies are not covered by United States HIPAA regulations. One beta-tester indicated the following:

> *I think it was critical that when using a commercial device, we included the creator [tech developer] as a co-investigator. This helped us think through generalizability and future applicability issues once the software and hardware are updated. I have done other studies in the past where we did *not* do this, and it was a mess. I highly recommend doing this whenever possible.*

Moving forward, we envision the DHC-R inspiring awareness of our collective responsibility in framing the ethical, legal, and policy-related decisions that support a robust digital health research culture. Ideally, researchers will be better able to identify problems and craft risk management solutions that align with developing best practices—this includes elevating awareness of products that are neither *research friendly* nor in the best interest participants who engage in our research studies.

Discussion

As researchers, we have a responsibility to (1) lead the narrative for accountable, fair, and transparent practices; (2) inform best practices by sharing experiences and conducting empirical research; and (3) help our colleagues avoid pitfalls. Following our experiences of beta-testing the checklist, which led to the DHC-R, we realized that by openly sharing our experiences, both failures and successes, we could advance the development of best practices. The DHC-R is a new decision support tool that uses a framework consisting of the following 4 domains: (1) access and usability, (2) privacy, (3) data management, and (4) risks and benefits anchored to the ethical principles of biomedical and behavioral research used in the United States [12]. Our lessons learned serve as the starting point for openly sharing successes and failures in selecting and using technologies in health research. However, with the rapidly changing digital landscape, there is an urgent need to engage researchers and the extended digital health research community in the open sharing of experiences to expand the body of lessons learned. The DHC-R provides a structure that could be useful for other responsible parties, including technology developers and IRB/REC members. Scientific and clinical progress is most likely to be achieved if the digital health research community collaborates with global stakeholders and regulatory bodies to ensure safe and innovative science.

To inform best practices, a global and multi-stakeholder perspective is needed, including traditional researchers at academic institutions, health technology companies, and citizen science initiatives. With this diverse research ecosystem comes variation in formal research training, ethics acculturation, and regulations, all of which call for elevating opportunities for engagement and dialogue [15]. Furthermore, the DHC-R was developed and beta-tested with US-based researchers; thus, the perspectives described herein may only be applicable to the United States. Engaging international stakeholders is needed to understand the extent to which the findings are applicable outside the United States.

In considering the *lessons learned*, a cluster of issues emerged surrounding the importance of, and the need for, educating stakeholders, particularly IRB/REC members and participants (who may also be patients). With that in mind, we propose *a call to action* inviting key digital health stakeholders, including review boards, participants, professional societies, and funders, to consider their respective roles in designing a responsible and ethical digital health research ecosystem.

Ethical and Regulatory Review

The IRB/RECs perform an important function in the review and approval of regulated research with human subjects. However, as technology changes and digital health studies increase, we see gaps in the ability of review boards to be well informed and make appropriate decisions [8]. The digital health community needs to collaboratively develop processes to advance ethical digital health research. Organizations that support IRB/REC professionals (eg, Public Responsibility in Medicine and Research) and recognize the unique challenges introduced by technologies in health research (eg, Society of Behavioral Medicine, American Psychological Association, American Medical Association, and Computer and Human Interaction) are well-positioned to increase educational opportunities specific to the ethical, legal, and social implications of digital health. Over the past decade, we have seen an increase in meetings that bring together experts from across sectors and disciplines, and given the increase in internet-based meetings owing to the COVID-19 pandemic, convening across professions and sectors is easier than ever. However, more work is needed to advance safe, responsible, and ethical digital health research. Researchers also have a responsibility to suggest innovative strategies for protecting patient privacy and safety to their colleagues, review boards, and professional societies. Ethical practices must be shaped as a system rather than being siloed within research areas and organizations.

Educating Participants or Patients

Educating participants about digital health research has ethical, legal, and practical considerations. From an ethical perspective, it is important to anticipate or consider how to make the informed consent process accessible, especially in studies that are completely remote. There has been some research on the process and use of e-consent [21] and efforts to improve how complex concepts are conveyed through a smartphone or tablet. We encourage efforts to involve participants (and their caregivers where appropriate) as partners and working with prospective participants to complete the DHC-R can be an approach to engage them in study planning, informing study feasibility, and assisting with risk assessment and mitigation planning.

Professional Societies

We encourage professional societies to foster a culture among members that put the ethical, legal, and social implication responsibilities of researchers at the forefront. To do so, we recommend that professional societies use the DHC-R framework and companion checklist as a decision support tool for member education efforts that encourage the conduct of socially and ethically responsible research. Furthermore, the intersection between academic researchers and industry calls for scientists to become collaborators with technologists, rather

than only being seen as end users. To accomplish this, professional societies can encourage industry partners to attend scientific meetings, not solely as vendors or industry sponsors, but as attendees. The DHC-R could be a useful framework for developing targeted education and introducing concepts of ethical decision-making in the digital health sector.

Funding and Policy

The current funding paradigm, both within the United States and abroad, typically requires compliance with regulatory mandates for human subject protection, including guidance for obtaining and documenting informed consent. However, our existing methods for obtaining informed consent do not require the assessment of the extent to which an approved consent process results in an informed participant; hence, further research is needed here. Funders can also support researchers interested in shaping digital health research policies and norms by creating a mechanism to support the empirical research that will advance evidence-based policy development. Moreover, similar to the importance of having a biostatistician on the research team, researchers should consider engaging a health technology ethicist as a coinvestigator and include aims that advance knowledge of risk assessment and meaningful consent.

Learning Communities

Learning communities that support safe and open sharing are recommended. As digital health and related new technologies continue to emerge, unknowns are expected and will continue to surface. These unknowns, when they do occur, create learning opportunities from which researchers and other stakeholders could benefit—particularly if we embrace a learning community approach. To accomplish this type of open sharing culture, a platform is required. One such platform that could serve as a model (or be the *go to* resource) is the Connected and Open Research Ethics (CORE) platform hosted by ReCODE Health [22]. To succeed, open sharing would be rewarded. For example, a novice digital health researcher who plans to use wearable sensor technologies to observe free-living daily behavior with the goal of documenting physical activity and then deploying a behavioral intervention may benefit by accessing IRB/REC-approved protocols that have been shared by a more experienced researcher. This can occur at the CORE Resource Library, where IRB/REC-approved protocols and consent documents are tagged and freely shared by and with members of the global CORE network [23,24]. Experienced researchers who share their digital health protocol to help others may be motivated through altruism or with service credits that contribute to productivity metrics for promotion. The motivation to participate as a member of the CORE should be driven by a commitment to advocate and a desire to contribute to the shaping of best practices. How that is realized will be up to our collective community efforts. Alternative metrics or rewards for researcher transparency, whereby researchers get credit for open sharing, will be how researchers are able to lead within the academic community.

Limitations

The lessons learned and call to action recommendations described in this paper are based on experiences in the United States and framed on current relevant and applicable laws, or lack thereof. Although the United States lacks a regulatory framework to guide researchers in using digital technologies in research, there are emerging state efforts that show promise. For example, in California, the recent privacy regulation will protect resident personal information collected by unregulated, for-profit businesses in cases where the United States HIPAA does not apply [25]. Internationally, there have been advances in privacy and data management. The World Health Organization has published a resolution on health technology assessments to improve decision-making and policy development [26]. In Europe, policy-driven [27,28] impact assessments have advanced from privacy impact assessments [29,30] to mandated data protection impact assessments, which are required when processing data “is likely to result in result in a high risk to the rights and freedoms of natural persons” (General Data Protection Regulation) [28,31]. The United States could learn from these efforts occurring in other countries and align with these best practices, as applicable to the United States. There is much we can learn from other countries that have been successful or are leading successful efforts in these areas.

Conclusions

Digital technologies offer potential benefits for advancing health research, yet introduce unique ethical, legal, and social implications. For researchers, due diligence in selecting technologies for research purposes requires awareness of known risks and anticipation of unknown risks to both individuals and society. Decision support tools can help researchers systematically consider the selection and use of technologies for use in health research. The DHC-R described in this commentary is one decision support tool that prompts researchers to anticipate participant privacy, consider risk of possible harms against benefits, evaluate access and usability, and review data management protocols. For researchers, the DHC-R can be used to facilitate informed research planning and preempt downstream problems associated with digital health research. Researchers who tested the DHC-R learned valuable lessons, which were synthesized to inform recommendations and a call to action directed at key stakeholders. Encouraging strategies that promote open and transparent discussions about the promise and pitfalls of digital health are required to ensure ethical and trustworthy research. Through collective action to identify issues and unmet needs within the global digital health ecosystem, an ethical and responsible digital health architecture can be realized, but only if stakeholders act now to do their part.

Abstract

As many as 80% of internet users seek health information online. The social determinants of health (SDoH) are intimately related to who has access to the internet and health care as a whole. Those who face more barriers to care are more likely to benefit from accessing health information online, assuming the information they are retrieving is accurate. Virtual communities on social media platforms are beginning to serve as venues for seeking health information online because peers have been shown to influence health behavior more than almost anything else. As a positive mediator of health, social media can be used as a direct or indirect mode of communication between physicians and patients, a venue for health promotion and health information, and a community support network. However, false or misleading content, social contagion, confirmation bias, and security and privacy concerns must be mitigated to realize the full potential of social media as a positive mediator of health. This paper presents the shifting dynamics of how such communities are affecting physician-patient relationships. With the intersections between the SDoH, social media, and health evolving, physicians must take into consideration these factors when establishing their relationships with patients. We argue a paradigm shift in the physician-patient relationship is warranted, one where physicians acknowledge the impacts of the SDoH on information-seeking behavior, recognize the positive and negative roles of social media as a mediator of health through the lens of the SDoH, and use social media to catalyze positive changes in the physician-patient relationship. We discuss how the physician-patient relationship must evolve to accommodate for the ever-increasing role of social media in health and to best use social media as a tool to improve health outcomes. Finally, we present a fluid and multicomponent diagram that we believe will assist in framing future research in this area. We conclude that it is ineffective and even counterproductive for physicians to ignore the relationship between social media, the SDoH and health, their impact on one another, and the effect it has on designing the medical encounter and the delivery of care under the definition of precision medicine.

social media; social determinants of health; precision medicine; patient care

Introduction

Precision medicine, a comprehensive approach to patient care that takes into consideration genetics and the social determinants of health (SDoH) when diagnosing and treating disease [1,2], is prevailing among the priority areas for research in Canada and should be considered the standard for patient care worldwide [3]. The SDoH include socioeconomic factors that affect health

and well-being, such as income, education, and employment [4]. Such factors are affected by societal systems of oppression and are intimately linked to an individual's position in society relative to the societal status quo. As neither genetics nor the SDoH alone can indicate health status, the two must be viewed as intrinsically and inextricably linked to one another and thus to an individual's overall health and well-being [5]. By definition, a precision health care approach should be both personalized to the patient and humanistic. With a multitude of health factors that can influence and are influenced by the SDoH, they should be considered by physicians when managing their patients' health concerns. However, many SDoH and barriers to care issues continue to be overlooked by physicians [6-8].

Research has shown that as many as 80% of internet users seek health information online [9,10]. Social media platforms, internet-based user-driven community platforms for communication and sharing user-created content [11], have flourished as virtual communities where people exchange information and opinions, and seek support and advice from peers [12-14]. Such platforms include blogs (eg, WordPress), wikis (eg, Wikipedia), social bookmarking (eg, Reddit), social network sites (eg, Facebook), status update services (eg, Twitter), virtual world content (eg, Minecraft), and media-sharing sites (eg, YouTube) [11]. Specifically, health information seeking is among the most popular online activities with diet/nutrition, physical activity, signs and symptoms, treatment, and public health interventions as some common examples [8-10,12,13,15]. Social media has been studied in attempts to improve health outcomes with mixed results, but it is not yet clear what aspects of successful interventions precipitated their success [16]. Likewise, the reasons for failure of unsuccessful interventions, which led to worsened health outcomes or increased health inequity, are not clear. Thus, social media has the potential to positively moderate patient health, but how it can be used correctly to maximize benefit and minimize repercussions for patients remains to be seen.

In part related to the accepted importance of understanding patients' voices and perspectives, it has been implied that social media use should also be taken into consideration by physicians as a determinant of health [6]. Although health care practitioners remain the principal trusted authority for health information, the SDoH of the patient—including accessibility barriers such as geography, cost, and time—result in patient preference for online searching over in-person consultations [12]. Due to its social connectedness, social media is one of the preferred venues for obtaining health information and community support, and peers have been shown to influence health behaviors more than almost anything else [14]. There are questions as to the accuracy and unbiased nature of online health information, especially that which is disseminated on user-created content platforms such as social media [8,17,18]. Further, an individual's internet competency does not necessarily equate to their medical literacy. However, whether or not social media is a net positive or negative mediator of health, as we will argue, it undoubtedly affects individual health status in unique and substantial ways and thus cannot be ignored by physicians.

In this paper, we examine the complex relationship between social media and the SDoH. We propose that social media's effects on health should be considered as part of the standard of care. Moreover, we argue that a paradigm shift in the physician-patient relationship is warranted, one where physicians acknowledge the impacts of the SDoH on information-seeking behavior, recognize the positive and negative roles of social media as a mediator of health through the lens of the SDoH, and use social media to catalyze positive changes in the standard of care. We suggest that only by broadening our understanding of the intimate linkages between social media and the SDoH, and incorporating it as part of patient care, can the gap be bridged effectively to deliver a vision of precision medicine that is inherently and sufficiently personalized.

The Impacts of the Social Determinants of Health on Information-Seeking Behavior

The Government of Canada recognizes 12 determinants of health, including but not limited to biology and genetic endowment, childhood experiences, physical environment, and access to health services [4]. Not all determinants of health are SDoH. Rather, the SDoH are those that focus on social and economic factors such as race, income and social status, education and literacy, and employment and working conditions. The World Health Organization's Commission on the Social Determinants of Health has defined SDoH as "the conditions in which people are born, grow, live, work and age" [19].

It is imperative to consider who has access to the internet when discussing the demographics of social media users, as social media users are by definition a subset of internet users. Access to the internet in general, a requisite for accessing social media, is related to factors underlying the SDoH. This relationship between internet access and the SDoH influences what information individuals are accessing and how they are accessing it [20,21]. This, in turn, affects their use of digital tools such as social media, which encompasses a wide array of websites and applications. Nearly 60% of the global population have access to the internet [22]. Nevertheless, a digital divide exists, and although internet use increases every year, this digital divide highlights disparities in access for underserved populations, especially those in low- and middle-income countries (LMIC) [14,22,23].

Age, an SDoH, is also a factor contributing to the differentiated use of social media; older adults tend to search for health information online significantly less than younger age cohorts such as Generation Y (1977-1990) because they lack prior internet experience and thus possess lower internet competency [8,14,24,25]. In addition, evidence indicates that education, another recognized SDoH, and specifically higher education correlates with an increased likelihood of searching for health information online as does identifying as female [20,26].

Overall, people of low socioeconomic status or from LMIC, older adults, and less educated individuals face the most substantial barriers to accessing the internet in general and social media in particular. Unfortunately, this is the same population who stand to benefit the most, healthwise, from having access to health information online [14]. The apparent need for internet

access in specific SDoH segments reinforces clearly the statement delivered by the United Nations Human Rights Council that access to the internet is a basic human right [27].

Social Media's Potential as a Positive Mediator of Health

Accessibility barriers to in-person care are currently unacceptably high [14,22,23], and methods of communication between physicians and patients remain strictly in traditional formats [7]. Despite enormous advancements in internet technology and virtual communication, patients are still required to appear in-person at a physician's office to communicate with a physician and receive care. To do so requires substantial privilege on the part of the patient, such as having the time and resources to attend an appointment. Recently, due to the COVID-19 pandemic, there has been an acute increase in emphasis on providing more virtual care. However, this is still quite limited and "temporary" as "there isn't a lot of readiness" for using virtual health care [28]. Although methods of communication between physicians and patients are "at the heart of healthcare" [7], they are traditionally designed using practices that appear to lag substantially behind modern methods, in part due to regulatory bodies' regulations and practice guidelines [28]. Although patients tend to seek health information online for a number of reasons, the majority state that they would prefer to obtain this information from health care practitioners, but it is simply not within their means to do so due to an inability to access care as a result of economic, social, cultural, or physical barriers [23,29].

Social media is largely free, easy to access from multiple geographical locations, and considered by patients to be "more convenient, timely, cost-effective" [8]. In some cases, receiving care in person may be impeded by stigma (eg, for treatment of mental health or sexually transmitted infections). In that regard, social media is reported by users as "privacy protective, and [less embarrassing]" [8] as a venue for seeking health information. Such perceptions are not always accurate, as will be discussed in the following section, and they by no means represent all social media users [30]. Further, social media is inclusive; provides a sense of solidarity, hence enhancing the attribute of community support; and grants a greater perceived sense of control to patients over their own health [29].

Patients have reported that information received from physicians during in-person consultations was "not clear, satisfactory, or conductive for asking additional questions" [31]. This may be one of the reasons that patients turn to social media for health information. When this occurs, they report feeling more knowledgeable, confident, and empowered in their abilities to communicate with health care practitioners [6]. Patient satisfaction (the perceived standard of care) is thus improved when social media is used as a tool for obtaining health information.

Perhaps equally important to decreasing accessibility barriers and increasing patient access to health information, social media also acts as a support network [12,13]. One study found that support networks are a preferred venue for obtaining health information, second only to physicians [12]. Support networks, including those facilitated by social media, are linked to the SDoH [32-34] and substantially affect health behaviors [35]. This is useful for health promotion and health outcomes, as people may be persuaded to partake in positive health activities such as healthy diet, exercising [36-38], and receiving their annual flu shot if their peers have posted publicly about participating in these activities [39]. In sum, social media has the ability to mitigate the SDoH that result in limited physical accessibility, enhance personal confidence, and empower patients' communication with their physicians.

Social Media's Potential as a Negative Mediator of Health

For all the aforementioned benefits, social media is not exclusively a positive mediator of health [29,40]. There are notable problems with obtaining health information on social media; direct implications of social media use on health; and a problematic, homogeneous, "single story" narrative that is presented. It is important to acknowledge the negative and potentially dangerous effects of social media on health to reconcile them.

Social media tends to present information of questionable credibility, and it is oftentimes sponsored by a potentially biased entity [8]. Occasionally, online health information is entirely false [17]. In addition, although it may provide patients with a sense of privacy in comparison to discussing stigmatized topics in person with physicians, there are notable concerns about anonymity and privacy when obtaining health information online [29]. Confirmation bias (ie, the tendency to seek and trust information that is belief consistent and to discredit information that is belief inconsistent) is another well-documented danger associated with seeking health information online [18]. Personalization algorithms on social media platforms can further polarize the information available to patients though "recommended" or "suggested" content [13,41]. This content is automatically sourced based on previous social media activity, and it is presented to the user whether they are seeking it or not. Antivaccination content is a particularly good example, as parents who search for vaccine information online are more likely to hold antivaccination beliefs and possibly be active on similar communities of interest [10,18].

Emerging literature is increasingly documenting the direct impacts of social media on health [13,35]. Social media has been found to promote a sedentary lifestyle, increase self-isolation, decrease quantity and quality of sleep, and negatively impact mental health [13]. Social contagion, a recently documented phenomenon, depicts the contagious nature of certain noncommunicable health conditions over social media, including obesity and emotions such as happiness, anxiety, and depression [35]. Social influence and peer recommendations may substantially alter a person's health behaviors as well, likely due to susceptibility to peer pressure, desire to belong to a group or feel supported, and perception of credibility of the recommendations [14,35,42]. A vicious cycle between anxiety and online health information seeking is another documented phenomenon, where high levels of anxiety are associated with

online health information seeking, the findings of which further increases anxiety [43].

In 2009, Chimamanda Ngozi Adichie delivered a now renowned TEDtalk about the dangers of a "single story" narrative. Single stories emerge when only one narrative about a group of people is widely shared and accepted. It then becomes assumed that all members of said group shared the same experience, one that aligns with the single story. Recently, this concept was extended to stories of health experiences shared on social media [40]. An anthropological study found that single stories of health experiences (surrogacy, in this particular example) are disseminated widely across social media platforms. Not only do these single stories ignore variation in individual experiences and personal SDoH, but they also tend to hold little truth at all. Any deviation from the single story on social media, including any disclosure of personal experiences, is discredited and rejected, dehumanizing those who do so. Physicians must be made aware of the homogeneity of information on social media and how this may affect their patients' perceptions of health and health experiences. Further, patients using social media as an online community wherein they may communicate with others with similar health conditions must be empowered to tell their own story while acknowledging that it may not align with the stories of others. Subjective recounts of disease are not necessarily misinforming so long as patients understand the difference between individual perception and experience of disease versus etiology and treatment of disease, the latter of which necessitates a degree of prerequisite medical knowledge that goes above and beyond digital literacy [44,45].

Using Social Media to Catalyze Positive Changes in the Physician-Patient Relationship

Although the positive role of social media as a mediator of health is ample (ability to improve methods of direct and indirect communication between physicians and patients, increase access to health information, and foster a community support network), it is also imperative to address and mitigate the negative aspects of social media, such as security and privacy concerns. Work must be done on the part of the physician and the patient to shift the physician-patient relationship toward one that is inclusive of the role that social media plays in health and that uses social media as a tool to promote health and well-being.

During in-person consultations, physicians must be open to discussing the roles of social media as a mediator of health. In a recent interview, patients perceived health care workers to be in "overt or tacit opposition" [6] to any mention by patients of health information retrieved online. Such mentality reflects the traditional physician-patient relationship where patients hold little autonomy over their own medical journey [23]. Take, for example, a scenario wherein a patient, Cindy, a 24-year-old veterinary technician, discloses to her physician concerns around the COVID-19 vaccines. Cindy is a first-generation immigrant living in a multigenerational home and is worried that she may become contagious with the virus immediately after immunization, posing a health risk to her older adult immunocompromised grandmother. If her grandmother were to fall ill, Cindy fears that her family would not be able to afford the necessary care. Therefore, Cindy feels it is best for her family not to get the vaccine. For the physician to mitigate these concerns, it is imperative that they attempt to discern from where these anxieties originate. To write off Cindy's beliefs simply because they are biomedically unfounded and derived from information sought on social media could be counterproductive in protecting or improving her health.

Further, social media may be used as an indirect line of communication between physicians and patients, if used as a venue for health knowledge dissemination and translation for the purpose of health promotion [46,47]. To elaborate, physicians or health care experts may communicate with their patients on social media via public posts about health-promoting behaviors they recommend and providing them with trusted links for further information. In addition, physicians may refer their patients to patient-driven online advocacy groups such as the Light Collective, a nonprofit organization that, among other objectives, works to shine a light on privacy breaches and so-called "bad data-sharing" [30]. This would aid in decreasing misinformation and diversifying the pervasive single-story narratives that encapsulate many health conditions. We recognize that it is not only up to the physician to identify and quell misinformation on social media; it is largely up to the platform itself to create regulatory policies and practices—or better yet, algorithms to identify problematic posts [48]—to minimize false or misleading content and to ensure that it is not being amplified in "recommended" or "suggested" content. In the previously discussed scenario, it is possible that Cindy would not have developed such concerns over the COVID-19 vaccines had she viewed credible biomedical data, or conversely, had she not viewed biomedically unfounded data, on social media. This is especially likely if Cindy is passively consuming data (ie, not actively seeking data).

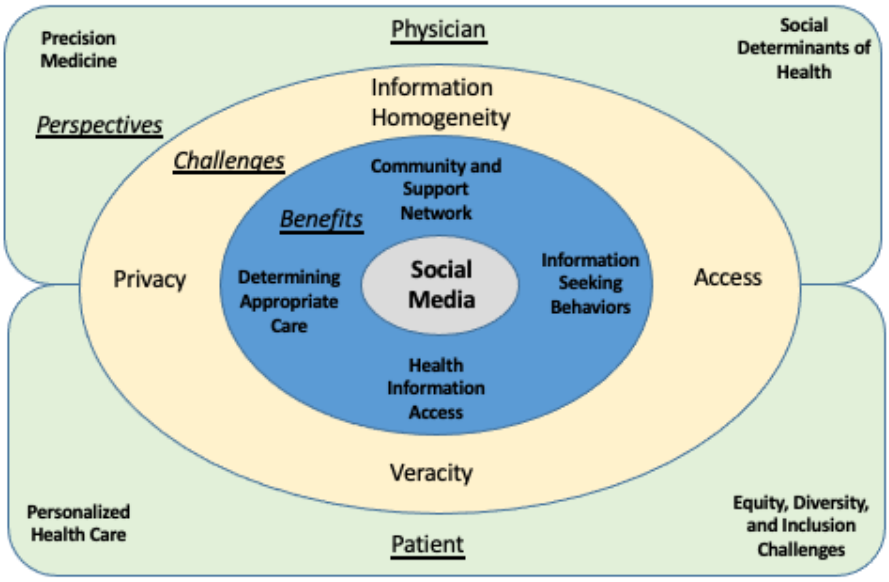
A patient's level of education and literacy as an SDoH impacts their level of medical literacy [49], which is only as good as the information they have acquired; it may be rendered obsolete if the knowledge they have gained is inaccurate. Therefore, patients should feel empowered to ask questions during their in-person consult or through anonymous or confidential online forums wherein knowledgeable health care practitioners provide answers. Although it is important for physicians to provide health care information to patients in terms that they are able to understand, we posit that it may also be beneficial to provide patients with a list of the formal medical terms associated with their condition. This may improve the caliber of search results they find online and reduce the likelihood of conflating different conditions or symptoms based on the colloquial descriptions given to them by their health care provider. Finally, patients should be encouraged to approach social media platforms in the context of health with curiosity and skepticism, embracing the community and solidarity aspects they may provide to those facing similar health problems while ensuring that objective medical data are not trusted until substantiated by scholarly sources or health care practitioners. For Cindy, a list of search terms will allow her to return home and actively seek reputable information on the COVID-19 vaccines. On the contrary, a lack

of take-home information may result in Cindy searching what she knows—"contagious after COVID-19 vaccine"—which may elicit misguiding results that confirm her bias. A brief but thorough discussion with her physician about the dangers of passively consuming bad data on social media may also prevent such encounters in the future.

Summary

In this paper, we reviewed the complex, multifaceted, and dynamic intersections of social media and SDoH in the era of precision medicine. We argued for its inclusion as part of routine patient care and demonstrated the potential of social media to be used as a positive mediator of health so long as its negative mediation effects are minimized. Further, we discussed how the physician-patient relationship must shift to accommodate for the ever-increasing role of social media in health and best use social media as a tool to improve health outcomes. These intricacies warrant further research. However, to conceptualize our study into a framework of understanding and development in this area, we present Figure 1 that we believe captures the potential challenges and areas of contention in bringing social media into precision medicine.

Figure 1. A fluid and multicomponent diagram to assist in framing future research around social media and the transformation of the physician-patient relationship.



1. The benefits of social media use in health care are listed in the first ring surrounding social media. Social media can act as a support network, promoting information-seeking behaviors, allowing patients to determine their own appropriate care, and enabling health information access, all affected by and affecting the SDoH.
2. However, social media also brings challenges to promoting health, as is illustrated in the second ring. Although privacy and access to social media are common issues, the public also faces the issue of veracity of information. Further, patients face an information homogeneity problem in the form of social media's single story, which does not account for diversity of experiences embodied by the SDoH.
3. Physicians and patients have different perceptions of how social media may be used in relation to health care, largely due to miscommunication. Although the public expects to receive personalized health care, physicians deliver their version of this as precision medicine. In addition, although the public perceives societal issues as equity, diversity, and inclusion challenges, physicians understand these issues as they relate to health and categorize them as the SDoH. This is not an issue of incongruity but one of language. Communication barriers must be acknowledged to be overcome.
4. Future research in this domain needs to recognize the complex dynamics of how social media interacts with the SDoH to develop solutions that can comprehensively improve the delivery of health care in the future.

Conclusion

As the role of social media in health evolves, new directions of research are needed to better understand the impacts of social media on health and inform physicians on how it can be integrated as part of patient care. Our discussion posits that health and social media are intimately linked through the prism of the SDoH and that this linkage is only amplifying over time. We argue that it is thus ineffective and even counterproductive for physicians to ignore this relationship and the impact it has on designing the medical encounter and the delivery of care. For physicians to deliver the highest standard of care under the definition of precision medicine, the complex interaction between social media and the SDoH and their impact on one another must be taken into consideration.

Abstract

Background: Current treatments for generalized anxiety disorder (GAD) often yield suboptimal outcomes, partly because of insufficient targeting of underlying psychological mechanisms (eg, avoidance reinforcement learning). Mindfulness training (MT) has shown efficacy for anxiety; yet, widespread adoption has been limited, partly because of the difficulty in scaling in-person–based delivery. Digital therapeutics are emerging as potentially viable treatments; however, very few have been empirically validated.

Objective: The aim of this study is to test the efficacy and mechanism of an app-delivered MT that was designed to target a potential mechanism of anxiety (reinforcement learning), based on which previous studies have shown concern regarding feedback and the perpetuation of anxiety through negative reinforcement.

Methods: Individuals with GAD were recruited using social media advertisements and randomized during an in-person visit to receive treatment as usual (n=33) or treatment as usual+app−delivered MT (Unwinding Anxiety; n=32). The latter was composed of 30 modules to be completed over a 2-month period. Associated changes in outcomes were assessed using self-report questionnaires 1 and 2 months after treatment initiation.

Results: We randomized 65 participants in this study, and a modified intent-to-treat approach was used for analysis. The median number of modules completed by the MT group was 25.5 (IQR 17) out of 30; 46% (13/28) of the participants completed the program. In addition, the MT group demonstrated a significant reduction in anxiety (GAD-7) compared with the control group at 2 months (67% vs 14%; median change in GAD-7: –8.5 [IQR 6.5] vs –1.0 [IQR 5.0]; P<.001; 95% CI 6-10). Increases in mindfulness at 1 month (nonreactivity subscale) mediated decreases in worry at 2 months (Penn State Worry Questionnaire; P=.02) and decreases in worry at 1 month mediated reductions in anxiety at 2 months (P=.03).

Conclusions: To our knowledge, this is the first report on the efficacy and mechanism of an app-delivered MT for GAD. These findings demonstrate the clinical efficacy of MT as a digital therapeutic for individuals with anxiety (number needed to treat=1.6). These results also link recent advances in our mechanistic understanding of anxiety with treatment development, showing that app-delivered MT targets key reinforcement learning pathways, resulting in tangible, clinically meaningful reductions in worry and anxiety. Evidence-based, mechanistically targeted digital therapeutics have the potential to improve health at a population level at a low cost.

anxiety; generalized anxiety disorder; worry; mindfulness; mHealth; digital therapeutics; mobile phone

Introduction

Background

Anxiety disorders are the most common class of mental illnesses, with a 31% lifetime prevalence [1]. This has already increased during the COVID-19 pandemic [2-4]. For example, in the United States, the Census Bureau reported that adults were more than 3 times more likely to screen positive for an anxiety disorder in 2020 than they were in 2019 (31% vs 8%), and a cross-sectional survey of people in China in 2020 reported the prevalence of generalized anxiety disorder (GAD) to be 35.1% [2]. A recent meta-analysis of 17 studies (N=62,000) found an average prevalence of anxiety of 32% during COVID-19 [5].

Treatment for Anxiety

However, anxiety, particularly GAD, is difficult to treat. Current practice guidelines recommend pharmacological and psychological interventions [6], but most patients favor psychotherapy over medications [7]. Benzodiazepines have the risk of tolerance and addiction; the United Kingdom National Institute for Health and Care Excellence guidelines state that benzodiazepines "should not be used routinely to treat anxiety disorders" [6]. First-line treatment for anxiety, such as selective serotonin reuptake inhibitors, can have limitations, including delayed patient responses and adverse effects (eg, gastrointestinal and sexual) [8,9]. The number needed to treat (NNT) for selective serotonin reuptake inhibitors is 5.2; one needs to treat >5 individuals to see a significant response in 1 individual [10].

Cognitive behavioral therapy (CBT), the most commonly used and researched psychological intervention for anxiety, has been associated with reduction in symptoms using measures such as the Beck Anxiety Inventory (small to medium effect sizes), and yet is typically delivered in-person [11]. Given the growing need and shortage of trained therapists [12,13], new mechanistically based treatments that can be delivered at scale and a distance are needed for those unable to attend in person because of barriers such as living in a resource-limited area or unwillingness to go to a mental health clinic because of stigma. In addition, treatments that target more recent mechanistic underpinnings of anxiety are needed.

Psychological Mechanisms of Anxiety

From a theoretical standpoint, reinforcement learning mechanisms have been suggested to drive anxiety disorders [14,15]. Worry is widely regarded as the central defining feature of GAD and has been shown to be triggered as an avoidance reaction to emotional experiences [16], thus learned as "a negatively reinforced avoidant behavior" [17]. Recent research has linked reinforcement learning with biological mechanisms and clinical symptoms [18]. Worry represents an attempt to engage in mental problem solving on an issue with an uncertain outcome [19]. Although worry is unpleasant, the immediate emotions that are avoided by focusing on worry, such as fear, are often perceived as *more* unpleasant [20,21]. Therefore, aversive stimuli can trigger worry as an avoidant behavior, which then becomes habitual [22]. Theoretically and mechanistically, worry is learned and reinforced in a manner similar to other types of operantly conditioned behaviors [14]. With cycles of reinforcement learning, when triggered by feelings of anxiety, individuals with GAD learn a maladaptive thinking style that uses worry as a focus on the future rather than the present. As described by Borkovec et al [14,15], when worry becomes habitual, its negative reinforcement pathway can spiral out of control; when the negative emotional experience of worry rises to the same level as unpleasant emotional states that trigger it, it may become its own trigger for more anxiety, which leads to more worry directly driving anxiety *habit loops* (Gao et al, unpublished data, 2021).

In conventional frameworks, anxiety is conceptualized as an overestimation of danger and an underestimation of one's ability to cope with it [23]. Cognitive therapies aim to interrupt the cycle of worry by replacing maladaptive cognitions with more constructive ones. For individuals who cycle into anxious worry to a degree that impairs prefrontal cortical function and the ability to use cognitive therapies [24], other strategies are needed. New treatments such as mindfulness training (MT) have shown promise in efficacy and cost, with effect sizes rivaling current treatments [25]. Furthermore, cross-sectional studies of nonclinical populations have suggested a mediating role of worry in the effects of MT on anxiety [26].

Mindfulness

Mindfulness can be defined as the awareness that arises when paying attention to the present moment on purpose and nonjudgmentally [27]. The attitudinal quality of not judging and allowing experience to unfold with curiosity targets maladaptive reinforcement learning by helping individuals to simply observe repetitive cycles of perseverative worry rather than to habitually react and reinforce them [28]. MT has been found to mechanistically break key links in the reinforcement pathway for other habitual behaviors such as smoking and emotional eating [29,30], with concomitant changes in related brain regions predicting clinical outcomes [31]. Worry has been shown to activate brain networks associated with self-referential processing, such as the default-mode network, suggesting that the more one is *caught up* in perseveration about uncertain events, the more this network is activated [32,33]; meditation has been shown to directly deactivate these brain regions [34], and neurophenomenological studies suggest that this may be because of the ability to observe thoughts and emotions rather than being caught up in them [35-37]. Specific to GAD, MT has been associated with changes in the fronto-limbic brain regions involved in emotion regulation with simultaneous improvements in reported symptoms [38].

App-Delivered MT

Regarding treatment delivery, mindfulness-based interventions, such as mindfulness-based stress reduction, are generally delivered in a group format. However, concerns remain

regarding the scalability of in-person–delivered treatment [39]. Digital therapeutics (ie, app-delivered interventions) have garnered much attention as a new modality that can deliver high-fidelity treatment at scale and low cost. However, empirically tested apps are not widely used, and widely used apps do not have an evidence base (<0.05%)—a clear "digital research practice gap" [40]. To date, only 1 study has reported the clinical efficacy of a digital therapeutic specifically for people diagnosed with GAD (showing that CBT may be effective when delivered in this format) [41].

To address the digital research practice gap, we designed an app-delivered digital therapeutic program for anxiety that mechanistically targets reinforcement learning using MT to help individuals identify habitual worry thinking patterns and learn not to habitually react to unpleasant emotions (ie, break the worry cycle). In a single-arm study of anxious physicians, we found preliminary evidence for its utility in reducing anxiety (57% reduction in GAD-7 scores after 3 months) [42]. However, randomized controlled studies are required to determine the efficacy and mechanisms of action. We tested the following hypotheses in a randomized controlled trial of individuals with GAD: (1) app-delivered MT would show superior efficacy in reducing anxiety and worry than standard treatment; (2) increases in nonreactivity would mediate reductions in worry; and (3) reductions in worry would mediate reductions in anxiety.

Methods

Study Overview and Participants

We used a parallel-group randomized controlled trial design with analyses and outcome measures preregistered at ClinicalTrials.gov. Individuals were recruited using Facebook advertisements and screened for eligibility via a phone call by the project director (AR). Textbox 1 details the inclusion and exclusion criteria. These criteria were chosen to mimic, as closely as possible, real-world clinical situations while minimizing potential confounders (eg, a recent change in medication dose may mask treatment effects). Eligible participants attended an in-person research visit at Brown University, where they underwent informed consent procedures with the project director before enrolling in the study. Participants were provided Amazon gift cards worth up to US $80 to complete the questionnaires. This study was approved by the Institutional Review Board of Brown University.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Score ≥10 on the Generalized Anxiety Disorder (GAD) 7-item scale, which is suggestive of a diagnosis of GAD (sensitivity and specificity of 89% and 82%, respectively) [43]
- Owns a smartphone
- Willingness to receive check-in calls
- 18 years or older

Exclusion criteria

- Dose changes for any psychoactive medication in the last 2 months
- As-needed use of benzodiazepines or hypnotic sleep aids
- History of bipolar, schizophrenia, schizoaffective, or another psychotic disorder
- Significant medical condition that would impact the ability to complete study tasks
- Cohabitation with someone already enrolled in the study
- Previous use of other related apps

After enrolling participants in the study, the project director, who had previously undergone training and was supervised by a psychiatrist, conducted an in-person, abbreviated version of the Mini-International Neuropsychiatric Interview to confirm a diagnosis of GAD, along with the assessment of other potential comorbid disorders, such as major depressive episode, panic disorder, agoraphobia, social anxiety disorder, obsessive compulsive disorder, and posttraumatic stress disorder [44]. Participants were then asked to complete a web-based questionnaire via Qualtrics [45], which included demographic and self-report items. Participants in both groups received questionnaires via email 1 and 2 months after treatment initiation. Upon completion of the final questionnaire, the treatment as usual (TAU) group received instructions on how to download and install the app.

Randomization and Blinding

After completing the baseline questionnaire, participants were given a sealed, opaque envelope (prepared, reviewed, and sealed by individuals independent of the study team) by the project director that contained their group assignment: TAU+app-delivered MT or TAU. The 1:1 randomization scheme was generated by an independent statistician with variable block sizes of 4 and 6. Team members who randomized the participants and carried out the study procedures did not perform the study analyses. The principal investigator and the statistician who conducted the statistical analysis were blinded to the group allocation until all analyses were complete.

Intervention

The app-delivered MT program, Unwinding Anxiety (version 2), is a Health Insurance Portability and Accountability Act

compliant digital therapeutic that teaches individuals to understand how anxious worry develops and perpetuates through reinforcement learning and how to bring mindful awareness to moments of stress and worry so that they can observe feelings of anxiety rather than perpetuate reactive worry thinking. This process helps individuals *unlearn* or extinguish worry at the core mechanistic level. This experiential education is delivered via a smartphone-based platform, which includes a progression through >30 daily modules of brief didactic and experience-based MT (videos and animations approximately 10 minutes per day; Multimedia Appendix 1), app-triggered check-ins, user-initiated guided meditations (5-15 minutes), and brief (30 seconds) on-demand mindfulness exercises to help disrupt anxiety cycles in vivo (Textbox 2; Multimedia Appendix 2). The content for this intervention was developed based on a combination of clinical experiences and previously developed, in-person and app-delivered MT protocols for habit change that have yielded clinically meaningful outcomes (eg, smoking and overeating) [28-30,46-49]; an open-label pilot study of the app demonstrated a 57% reduction in GAD-7 scores in anxious physicians [42].

Textbox 2. Overview of Unwinding Anxiety themes and content.

Modules 1-7 (goals, curiosity, reinforcement learning, body scan, and self-monitoring)

- Set goals and introduce how habits are formed around worry (eg, reinforcement learning and distraction); introduce curiosity to foster the nonjudgmental aspects of mindfulness and basic mindfulness practices, including the body scan; and unpack worry and fear both from a brain and behavior perspective.

Modules 8-14 (noting practice; RAIN [recognize, accept, investigate, and note]; barriers to change; and reinforcement of concepts)

- Introduce how to mindfully work with worry cues and affective states using RAIN (recognize, accept, investigate, and note what emotions feel like as they arise and pass away); build on basic mindfulness using noting practice (the N of RAIN) during everyday life; and introduce additional animations to reinforce mindfulness concepts that show how we feed our anxiety by worry thinking and distraction.

Modules 15-21 (noting practice [continued from previous modules]; RAIN [continued from previous modules]; thinking versus knowing; and *un*resistance)

- Reinforce noting practice and continue to train and support self-kindness; specifically address the difference between trying to think our way out of uncertainty (or anxiety) and resting in a kind, curious awareness of it; and focus on not resisting experience and not getting tripped up by worry thinking.

Modules 22-30 (noting practice [continued from previous modules]; RAIN [continued from previous modules]; and working with uncertainty and change)

- Help individuals reflect on their own evidence base for working with worry to solidify their shift from reactivity to mindfully being with emotions as a new habit.

Modules 30 and onward (reinforcing concepts via *theme weeks* and individual customization via *personal week*)

- >8 themed weeks and unlimited personalization of content by picking modules to develop a custom week for review.

Intervention Orientation and Engagement

Individuals randomized to TAU+app-delivered MT were assisted with the installation of the app on their smartphone and the reviewing of the features. They were instructed to complete 1 module per day over the subsequent 30 days at a time of their choice. In addition, the intervention would check in with them 3 times throughout the day (this could be modified by the user) and offer brief mindfulness exercises. Participants were encouraged to use other app features but were informed that this was not a requirement for the study. The project director sent check-in messages on days 3, 7, 14, and 21 from treatment initiation to help mitigate technical difficulties and encourage engagement. Specifically, participants were asked "how things were going with the app since the last time they received a check-in." If the participant expressed difficulties, efforts were made to resolve the problem.

TAU Condition

As part of TAU, participants were asked to continue the standard care set forward by their clinician or clinicians. This could include pharmacological treatment or psychotherapy. Participants were also provided with a list of local resources.

Outcome Measures

The primary outcomes were changes in anxiety, as measured by the GAD-7, and emotional reactivity at 2 months after treatment initiation. Secondary outcomes included changes in worry, as measured by the Penn State Worry Questionnaire (PSWQ) and interoceptive awareness.

GAD 7-Item

GAD-7 is a validated 7-item questionnaire used clinically to screen for probable diagnosis of GAD (sensitivity of 89% and specificity of 82%; high internal consistency, with Cronbach α=.92) and track symptom severity [43]. Individuals are asked, "in the last week, how often have you been bothered by the following problems" with prompts such as *feeling nervous, anxious, or on edge* and *trouble relaxing* [50]. The scale ranges from 0 (*not at all sure*) to 3 (*nearly every day*), with scores ranging from 0 to 21 [50]. Total scores of 5, 10, and 15 serve as cut-off points for mild, moderate, and severe anxiety, respectively; therefore, remission is a score of ≤4 [50]. The

minimal clinically important difference for GAD-7 was 3.8; the clinically relevant change was ≥4 points [51]. GAD-7, which is highly correlated with the Hamilton Anxiety Scale (r=0.852), was used based on its *real-world* utility, as it is the most commonly employed tool in primary care and other outpatient settings and has been incorporated into most large-scale electronic medical record systems [52].

Five Facet Mindfulness Questionnaire Nonreactivity Subscale

The nonreactivity subscale is composed of 7 questions from the 39-item Five Facet Mindfulness Questionnaire (FFMQ) with acceptable internal consistency (Cronbach α=.75) [53]. It is validated for use independently and assesses nonreactivity to inner experience [54]. Individuals are asked questions about what is generally true for them on a scale from 1 (*never or very rarely true*) to 5 (*very often or always true*) [53]. Examples include "I perceive my feelings and emotions without having to react to them" and "When I have distressing thoughts, I feel calm soon after" [53]. Scores range from 7 to 35, with higher scores indicating an increase in nonreactivity.

Penn State Worry Questionnaire

The PSWQ is a validated 16-item questionnaire with high internal consistency (Cronbach α=.93) used to assess worry [55]. Individuals are asked to rate statements on a scale ranging from 1 (*not at all typical of me*) to 5 (*very typical of me*) [55]. Example items include "My worries overwhelm me" and "When I am under pressure I worry a lot" [55]. Scores range from 16 to 80, with higher scores indicating a higher degree of worry.

Multidimensional Assessment of Interoceptive Awareness

The Multidimensional Assessment of Interoceptive Awareness (MAIA) is a 32-item questionnaire that assesses 8 domains of interoceptive awareness: noticing, not distracting, not worrying, attention regulation, emotional awareness, self-regulation, body listening, and trusting (Cronbach α=.66-.87) [56]. On a scale of 0 (*never*) to 5 (*always*), individuals are asked how often each statement applies to them generally in daily life [56]. Statements include "I distract myself from sensations of discomfort" and "I trust my body sensations" [56]. Scores range from 0 to 160, with higher scores indicating greater interoceptive awareness.

Safety and Adverse Events

Monitoring of safety occurred continuously during the study, and if an adverse event was reported, follow-up was conducted via phone by the project director using National Institute of Mental Health reportable events templates [57]. A final check was conducted by the project director at the conclusion of the study to assess adverse events potentially related to the intervention. If an event was reported, the same process was followed.

Sample Size

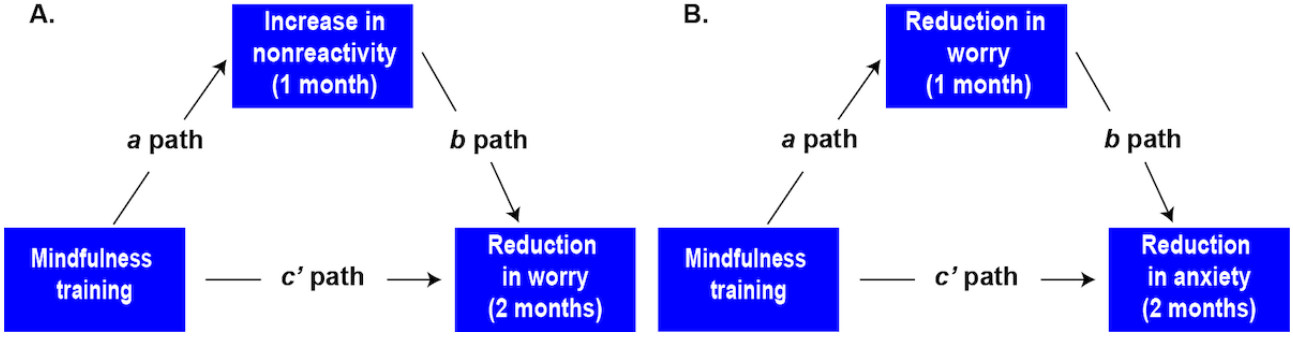
As there are no prior studies using the intervention, the target sample size of 65 was determined using pilot data. A pilot study of individuals with GAD-7 scores >9 (n=17) demonstrated a 39% reduction in the scores after completing 21 modules. Assuming a 10% reduction in the TAU group, a 1-tailed t test determined that a sample size of 52 would have 80% power with 1-sided 5% type I error to detect a statistically significant between-group difference in GAD-7 scores (Cohen d=0.7). We recruited 65 individuals to account for 25% attrition.

Statistical Analysis

Analyses were conducted using R (version 3.4.1), and a modified intent-to-treat approach was employed. This was defined as all participants who downloaded the app and completed all study assessments, regardless of treatment completion. A robust, mixed analysis of variance (ANOVA) was used to evaluate the primary outcomes, changes in anxiety, and emotional reactivity 2 months after treatment initiation in the TAU+app-delivered MT group relative to those in the TAU group. This and other robust statistical tests were chosen to avoid violating underlying model assumptions, such as normality. Because of the use of these nonparametric tests, the median and IQR were calculated. Post hoc comparisons of single effects were performed using the WRS2 package in R. In addition, Mann-Whitney U tests were performed, and the Hodges-Lehmann estimate of location shift was used to calculate the difference between groups at each time point [58]. Bonferroni correction was used to adjust for multiple comparisons. Effect sizes (r) were calculated by dividing the z score by the square root of the sample size using the Cohen criteria for r, where 0.1 is small, 0.3 is medium, and 0.5 is large [59].

We then conducted exploratory mediation analyses to evaluate (1) model A, whether increased nonreactivity mediated the relationship between MT and reduced worry, and (2) model B, whether reduced worry mediated the relationship between MT and reduced anxiety. To reduce the impact of the unit on the comparison of direct and indirect effects, the variables were standardized to have 0 means and unit SD. To have causal interpretations, the mediation models were built on the longitudinal [60]: In model A, MT was the independent variable, worry was the dependent variable, and nonreactivity was the mediating variable (Figure 1); in model B, MT was the independent variable, anxiety was dependent variable, and worry was the mediating variable (Figure 1). We calculated the direct and indirect effects, for which the SEs and 95% CI were computed using the bootstrap method with 1000 bootstrapped resamples [61].

Figure 1. (A) Path model for longitudinal causal mediation evaluating if increases in nonreactivity mediate the relationship between MT and reduction in worry. (B) Path model for longitudinal causal mediation evaluating if reduction in worry mediates the relationship between MT and reduction in anxiety. MT: mindfulness training.



The median and IQR were calculated to evaluate the engagement or the total number of modules completed. To explore the impact of anxiety on engagement at 2 months after treatment initiation, a robust regression model based on an M-estimator, which uses iteratively reweighted least squares estimation, was fitted, with the anxiety score as the independent variable and the total number of modules completed as the dependent variable.

Number Needed to Treat

The NNT, defined as the total number of individuals who need to receive treatment to prevent 1 adverse event, is a standard epidemiological measure used to communicate the effectiveness of a health care intervention [62]. The inverse of the absolute risk reduction was calculated by subtracting the total percentage of individuals who achieved remission (GAD-7 score ≤5, minimal anxiety) in the TAU group from the total percentage of those in the TAU+app-delivered MT group.

Reliable Change Index

Unlike statistical significance, clinical significance has traditionally lacked a consistent definition [63]. To address this need, a reliable change index (RCI) was created to evaluate the reliability of clinically significant changes [63]. We used the method developed by Jacobson and Truax to calculate the RCI for changes in anxiety scores [64]. If the RCI exceeded the *z*-scored level of significance from –1.96 to +1.96 ($P<.05$), we evaluated the percentage of participants with clinically significant change who met or exceeded it at 1 and 2 months after treatment initiation [63].

Risk of Bias

Six areas of potential bias across 7 domains were assessed using the Cochrane Collaboration tool for evaluating the risk of bias [65].

Results

Participants

We recruited 65 participants, obtained their consent to participate, and randomized them between May 2019 and October 2019. Baseline demographic characteristics are reported in Table 1. Of the 65 participants, 61 completed the study and were included in the modified intent-to-treat analysis (Figure 2). Before treatment initiation, 30% (19/63), 25% (16/63), and 32% (20/63) of participants reported comorbid anxiety, depression, and anxiety and depressive disorders, respectively (Table 1).

Safety

There were no adverse events in the TAU group and 11% (3/28) of adverse events in the TAU+app-delivered MT group (2/3, 66% *anxiety* and 1/3, 33% *back pain*).

Changes in Outcome Measures

Effects of Intervention on Anxiety (GAD-7)

Baseline GAD-7 scores indicated moderate (36/63, 57%) to severe (24/63, 38%) anxiety in individuals with GAD (TAU+app-delivered MT: median 12, IQR 8; TAU: median 13, IQR 7). To examine the effect of MT on reduction in anxiety, we fitted a robust mixed ANOVA with group as the between-subjects factor, time as the within-subjects factor, and GAD-7 score as the dependent variable. We found a main effect of group ($F_{1,39.99}$=22.54; P<.001) and time ($F_{2,33.49}$=29.98; P<.001), with a significant group×time interaction ($F_{2,33.49}$=11.19; P<.001). At 1 month after treatment initiation, there was a significant difference between groups (P<.001; r=0.59) and the Hodges-Lehmann estimate, the nonparametric estimate of population change, was 5 (95% CI 4-7). The TAU+app-delivered MT group reported a median reduction in

anxiety scores of 5 (IQR 7.3; *P*<.001; *r*=0.89) compared with no change in the TAU group. At 1 month, the calculated RCI for the TAU+app-delivered MT group was –4.6 and a reliable change was seen in 64% (18/28) of the participants, while the calculated RCI for TAU was 0. A significant between-group difference (*P*<.001; *r*=0.68) was maintained at 2 months, and the Hodges-Lehmann estimate was 6 (95% CI 5-8; Figure 3); the TAU+app-delivered MT group reported a median reduction in anxiety scores of 8.5 (IQR 6.5; *P*<.001; *r*=0.96), while the TAU group reported a median reduction of 1 (IQR 5; *P*=.01; *r*=0.37), representing a 67% versus a 14% reduction. The RCI was –7.9 for the TAU+app-delivered MT group and reliable change was seen in 54% (15/28) of the participants. The RCI was –0.9 for the TAU group. See Table 2 for medians and IQRs, in addition to the means and SDs.

Effects of Intervention on Nonreactivity (FFMQ Subscale)

To examine changes in nonreactivity, we performed a robust mixed ANOVA with group as the between-subjects factor, time as the within-subjects factor, and nonreactivity score as the dependent variable. This demonstrated a main effect of group ($F_{1,39.38}$=34.06; *P*<.001) and time ($F_{2,28.75}$=24.77; *P*<.001), with a significant group×time interaction ($F_{2,28.75}$=23.23; *P*<.001). At 1 month after treatment initiation, there was a significant difference between the groups (*P*<.001; *r*=0.53) and the Hodges-Lehmann estimate was –5 (95% CI –7 to –3). The TAU+app-delivered MT group reported a median increase of 5 (IQR 6.3) in nonreactivity scores (*P*<.001; *r*=0.95), whereas participants in the TAU group reported no change (Figure 3). A significant between-group difference (*P*<.001; *r*=0.67) was maintained at 2 months, and the Hodges-Lehmann estimate was –7 (95% CI –9 to –5); the TAU+app-delivered MT group reported a median increase of 7.5 (IQR 6) in nonreactivity scores (*P*<.001; *r*=0.95), while a median increase of 1 (IQR 6; *P*=.43, *r*=0.14) was seen in the TAU group.

Effects of Intervention on Worry (PSWQ)

To examine the effects of MT on worry, we ran a robust mixed ANOVA with group as the between-subjects factor, time as the within-subjects factor, and PSWQ score as the dependent variable. This revealed a main effect of group ($F_{1,37.85}$=19.66; *P*<.001) and time ($F_{2,27.12}$=34.78; *P*<.001), with a significant group×time interaction ($F_{2,27.12}$=10.30; *P*<.001). Participants in the TAU+app-delivered MT group reported a median

reduction in worry scores of 7.5 (IQR 8.5) at 1 month (P<.001; r=0.67; Figure 3), whereas the TAU group reported a median reduction of 3 (IQR 4; P=.01; r=0.44). There was a significant between-group difference (P<.001; r=0.55) at 2 months after treatment initiation, and the Hodges-Lehmann estimate was 14 (95% CI 9 to 19); the TAU+app-delivered MT group reported a median reduction in worry scores of 15 (IQR 14.3; P<.001; r=0.88) compared with a median reduction of 3 (IQR 6) reported by the TAU group (P<.001; r=0.61).

Effects of Intervention on Interoceptive Awareness (MAIA)

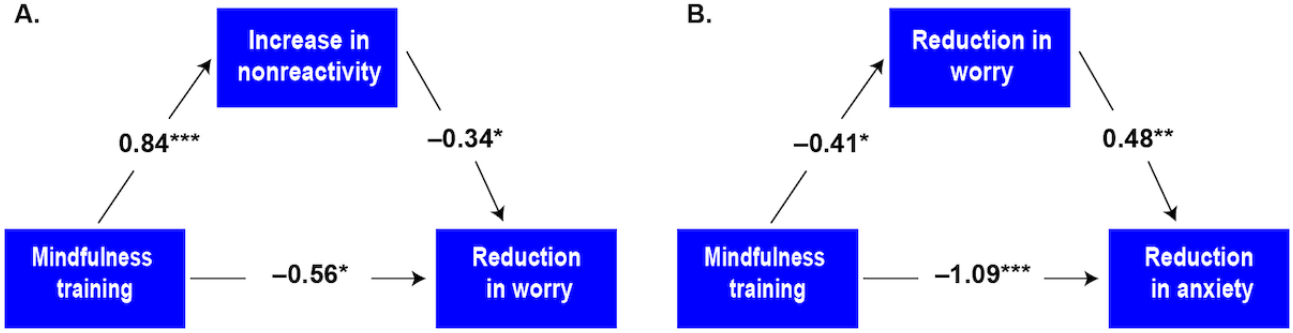
To examine changes in interoceptive awareness, we fitted a robust mixed ANOVA with group as the between-subjects factor, time as the within-subjects factor, and MAIA score as the dependent variable. We found a main effect of group ($F_{1,39.19}$=22.53; P<.001) and time ($F_{2,29.93}$=10.79; P<.001), with a significant group×time interaction ($F_{2,29.93}$=12.45; P<.001). At 1 month after treatment initiation, participants in the TAU+app-delivered MT group reported a median increase of 22 (IQR 30) in interoceptive awareness scores (P<.001; r=0.72), whereas the TAU group reported no change (median 0, IQR 18) in interoceptive awareness scores (P=.71; r=0.07; Figure 3). At 2 months, there was a significant between-group difference (P<.001; r=0.87), and the Hodges-Lehmann estimate was –13 (95% CI –15 to –10); the TAU+app-delivered MT group reported a median increase of 26 (IQR 28.5) in interoceptive awareness scores (P<.001; r=0.85), whereas the TAU group reported a median reduction of 2 (IQR 12; P>.99; r=0).

Mediation Analysis

Model A (Figure 4) shows the direct effect of MT on the reduction in worry and its indirect effect through nonreactivity. Reduction in worry and an increase in nonreactivity were defined as change in the PSWQ at 1 month and change in the nonreactivity scale from the FFMQ at 2 months after treatment initiation. Mediation analysis indicated that MT was related to a significant reduction in worry at 2 months with a direct effect of β=–.56 (SE=0.25; P=.03). MT also significantly increased nonreactivity (β=.84; SE=0.21; P<.001), which was significantly related to reduction in worry at 2 months (β=–.34; SE=0.14; P=.01). This implies that the relationship between MT and reduction in worry was partially mediated by an increase in nonreactivity ($\beta_{\text{indirect effect}}$=.84×–.34=–.29; 95% CI –0.68 to –0.04; P=.02). The total effect of MT on reduction in worry at 2 months was estimated to be β=–.85 (SE=0.23; P<.001). No effects were observed in the control group.

Model B (Figure 4) shows the relationship between MT and reduction in anxiety with a direct effect and an indirect effect mediated by a reduction in worry. These indicate that MT also had a significant impact on reduction in anxiety at 2 months, with a total effect of β=–1.28 (SE=0.26; P<.001). The direct effect of MT was estimated to be β=–1.09 (SE=0.25; P<.001). MT was related to significant reductions in worry at 1 month (β=–.41; SE=0.20; P=.04), whereas the latter was significantly related to reductions in anxiety at 2 months (β=.48; SE=0.16; P=.004). Thus, reductions in worry partially mediated the relationship between MT and reduction in anxiety ($\beta_{\text{indirect effect}}$=–.41×.48=–.19; 95% CI –0.40 to –0.02; P=.03). No effect was observed in the control group.

Figure 4. (A) Longitudinal causal mediation model with standardized regression coefficients illustrates how an increase in nonreactivity mediates the effects of mindfulness training on reduction in worry. (B) Longitudinal causal mediation model with standardized regression coefficients illustrates how a reduction in worry mediates the effects of mindfulness training on reduction in anxiety. *P<.05; **P<.01; ***P<.001.



Engagement

To evaluate program engagement, we calculated the median and IQR. At 1 month, the median number of modules completed was 18 (IQR 16.3). At 2 months, it was 25.5 (IQR 17), and 46% (13/28) participants completed the program. To explore the association between anxiety and module completion, we fitted a robust regression model and found that for each additional completed module demonstrating further progression through intervention, anxiety scores decreased by 1.37 (β=–1.37; SE=0.23; P<.001). The adjusted R^2 value for this model was 0.25.

Number Needed to Treat

At 2 months after treatment initiation, we found an NNT of 1.6: 64% (18/28) of the participants achieved remission in the TAU+app-delivered MT group compared with 3% (1/33) in the TAU group.

Risk of Bias

Using the Cochrane Collaboration criteria for evaluating bias [65], we found a low risk of bias in 6 of 7 categories, including random sequence generation, allocation concealment, blinding of outcome assessment, incomplete outcome data, selective reporting, and other bias. Blinding of participants and personnel

was deemed to have a medium risk of bias because the project director and participants were unblinded to group allocation.

Discussion

Principal Findings

Anxiety is a debilitating and difficult-to-treat condition that affects hundreds of millions of people worldwide. Using a theory-based approach (targeting reinforcement learning), we developed a digital therapeutic that demonstrated a significant and clinically meaningful reduction in anxiety in individuals with GAD (NNT=1.6) [66]. This was confirmed by our finding that anxiety decreased with further progression through the program through the completion of more modules. Furthermore, we determined a potential mechanism underlying its effect: increases in mindfulness mediated decreases in worry and decreases in worry mediated reductions in anxiety. These effects were specific to the MT intervention. The mediation effect was significantly higher at 2 months (45%) than at 1 month (15%), which is consistent with participants having more exposure to the treatment (ie, a dose effect), a sleeper effect [67-69], or a combination of the two. These results are in direct alignment with the theoretical underpinnings that anxiety can be perpetuated through negative reinforcement—worry can feed back and perpetuate anxiety by introducing the *reward* of feeling more in control or temporarily distracting an individual from the aversive feelings of anxiety [14,15,21,42,70].

Treatment for Anxiety

Anxiety treatment has largely relied on antidepressant medications and psychotherapy (eg, CBT). These have yielded medium effect sizes for anxiety [9]. RCI is increasingly being used in treatment studies to assess whether changes are clinically significant [63]. A longitudinal study of low-intensity CBT using an RCI of ≤5 demonstrated a reliable change in 43.8% (181/439) of the participants [71]; our study found that 64% (18/28) and 54% (15/28) of the participants demonstrated reliable change at 1- and 2-months posttreatment using RCIs of 4.6% and 7.9%, respectively. For GAD, the NNT with antidepressants was 5.15. In this study, we found that specifically targeting a mechanistic pathway yielded large effect sizes with an NNT of 1.6. A previous single-arm pilot study in physicians with comparable levels of anxiety (median baseline GAD-7 score of 11.5) showed a similar magnitude of reduction in anxiety (57% reduction at 3 months) using the same app-delivered MT program [42]. This randomized controlled trial extends previous results and broadens these findings beyond anxious physicians to individuals with moderate to severe anxiety.

The Psychological Mechanisms of Anxiety

Potential mechanisms underlying anxiety have been hypothesized for over a century; yet, refinement in recent decades has opened the door for specific hypothesis testing [14,15]. For example, Mkrtchian et al [18] recently demonstrated avoidance as a part of reinforcement learning pathways in individuals with anxiety disorders. Our findings provide an important extension of these results by showing that targeting worry and avoidance yields clinically meaningful reductions in anxiety. These results and the finding that individuals reported increases in interoceptive awareness (measured by the MAIA) are in line with broader theoretical mindfulness frameworks that suggest that MT helps individuals learn to become more aware of and observe unpleasant emotions with awareness imbued with curiosity [72].

App-Delivered MT Targets Worry

MT may promote decentering, defined as a "metacognitive capacity to observe items that arise in the mind as mere psychological events" [73]. Decentering may help individuals disengage from perseverative worry habit loops that are perpetuated through reinforcement learning [46-48,74]. Our findings show that increases in mindfulness directly mediate the effects of app-delivered MT on reductions in worry. This may be the case possibly because of helping individuals step out of perseverative worry habit loops that are at the core of GAD and, in doing so, reduce their reinforcement. Furthermore, our results show that reductions in worry mediate the effects of MT on reductions in anxiety.

Practical Implications

The high prevalence of anxiety "vastly exceeds the capacities of mental health services," and this gap has only increased over the past several years [75]. App-based digital therapeutics offer a viable and practical route toward augmenting traditional mental health care and, in some cases, serve as a first-line treatment [76]. For example, if a patient in a primary care clinic screens positive for anxiety, an evidence-based digital therapeutic such as the one described in this study can be offered as an augmentation to standard medication treatment, or in some cases, it can be offered if a trial of medications has yielded suboptimal results or if a patient is not interested or willing to try a medication as an alternative. In addition, for individuals who are concerned about the confidentiality of mental health care (eg, feeling the need to ask a boss for regular time off for therapy visits), Health Insurance Portability and Accountability Act compliant digital therapeutics can offer discretion, privacy, and convenience. As integrative care models (eg, embedding psychiatric or psychological services within primary care clinics) gain momentum, one of the primary limitations is the cost and availability of trained therapists. However, because 85% of the US population has a smartphone, digital therapeutics may be able to serve as the *mobile* component of an integrative care clinic at a low cost, filling in for the lack of physical space and trained mental health clinicians [76]. In addition, in corporate settings where employers are increasingly aiming to meet the mental health needs of employees, it may be possible to quickly and confidentially deploy evidence-based digital therapeutics to help employees with mild or moderate anxiety. For employees with severe anxiety, who may have to wait several months to see their doctor or to obtain a mental health referral, a digital therapeutic may serve as a bridge to therapy or even a first-line treatment.

TAU Condition

We chose the GAD-7 as an outcome measure because it is widely used in clinical practice, yielding results that are interpretable in nonresearch settings. We chose TAU because

clinicians deliver standard treatment, such as prescribing a medication, and bolster these with an additional medication or recommendation for psychotherapy if a patient does not achieve a reduction in symptoms (ie, the TAU+X *add on* model). Although far from perfect as a control condition, TAU is standardly used in pragmatic clinical trials for these and other reasons [77,78].

Although the TAU group showed a significant decrease in anxiety symptoms (14%), there may be several reasons why TAU failed to show a greater reduction in symptomatology or achieve remission (3% vs 64%). These include a higher NNT for current medications and current models in which medical practices are designed more as a *sick care* model, in which acute, physically based issues are prioritized over mental health despite clear advantages of integrating mental health care into primary care settings [79,80]. This study demonstrated a clear proof-of-concept trial of a mindfulness-based digital therapeutic to deliver specific theory-driven and mechanistically based treatment in a clinically relevant setting. Furthermore, we aimed to recruit a real-world population by minimizing the exclusion criteria, such as comorbid disorders. In this study, most of the individuals (84%) presented with comorbid disorders, such as depression, which is consistent with how individuals present in primary care settings and to treatment specialists.

Limitations

This study has several strengths and notable findings, including designing for real-world applicability (eg, including individuals with comorbid disorders and concomitant medication treatment), accounting for engagement, assuring adequate sample sizes, registering outcomes, and minimizing the risk of bias. However, this study has some limitations. The TAU+ model was chosen to closely match the treatment a patient would encounter in a clinical setting. Whereas standard clinical care is highly variable, the study was designed such that randomization would ensure that this variability was equally distributed between the groups. Future studies using an active comparator (eg, CBT-based app) to control for attentional effects, longer follow-up periods, and incorporating multiple sites are needed to confirm the efficacy of this program. Second, this study sample comprised 90% (57/63) women. Although future sex-balanced studies are needed to determine the generalizability of these findings, women are twice as likely to develop an anxiety disorder and have a higher lifetime prevalence of GAD (7.1% vs 4.2%) than men [81,82]. Third, this study was designed to evaluate anxiety symptoms at 2 months after treatment initiation. Long-term follow-up studies are necessary to establish the long-term effects. Furthermore, although this study identifies potential psychological mechanisms of app-delivered MT, such as increased mindfulness mediating decreases in worry and anxiety, future studies are needed to explore its neurobiological mechanisms. In addition, studies performed in research laboratory settings (eg, National Institutes of Health stages I and II) may select more motivated individuals in general. Although randomization controls for between-group differences, real-world efficacy (National Institutes of Health stage III) is needed as the next step to determine efficacy in clinical settings.

Conclusions

In summary, for a large portion of the world's population that is affected by moderate to severe anxiety, targeted and mechanistically based treatments are needed. By combining theory and a new field of treatment delivery (digital therapeutics), we found that app-delivered MT significantly reduced anxiety, and its effects were mediated by increases in psychological nonreactivity and reductions in worry, suggesting a specific targeting of reinforcement learning.

Abstract

Background: Many weight loss programs show short-term effectiveness, but subsequent weight loss maintenance is difficult to achieve. Digital technologies offer a promising means of delivering behavior change approaches at low costs and on a wide scale. The Navigating to a Healthy Weight (NoHoW) project, which was funded by the European Union's Horizon 2020 research and innovation program, aimed to develop, test, and evaluate a digital toolkit designed to promote successful long-term weight management. The toolkit was tested in an 18-month, large-scale, international, 2×2 factorial (motivation and self-regulation vs emotion regulation) randomized controlled trial that was conducted on adults with overweight or obesity who lost ≥5% of their body weight in the preceding 12 months before enrollment into the intervention.

Objective: This paper aims to describe the development of the NoHoW Toolkit, focusing on the logic models, content, and specifications, as well as the results from user testing.

Methods: The toolkit was developed by using a systematic approach, which included the development of the theory-based logic models, the selection of behavior change techniques, the translation of these techniques into a web-based app (NoHoW Toolkit components), technical development, and the user evaluation and refinement of the toolkit.

Results: The toolkit included a set of web-based tools and inputs from digital tracking devices (smart scales and activity trackers) and modules that targeted weight, physical activity, and dietary behaviors. The final toolkit comprised 34 sessions that were distributed through 15 modules and provided active content over a 4-month period. The motivation and self-regulation arm consisted of 8 modules (17 sessions), the emotion regulation arm was presented with 7 modules (17 sessions), and the combined arm received the full toolkit (15 modules; 34 sessions). The sessions included a range of implementations, such as videos, testimonies, and questionnaires. Furthermore, the toolkit contained 5 specific data tiles for monitoring weight, steps, healthy eating, mood, and sleep.

Conclusions: A systematic approach to the development of digital solutions based on theory, evidence, and user testing may significantly contribute to the advancement of the science of behavior change and improve current solutions for sustained weight management. Testing the toolkit by using a 2×2 design provided a unique opportunity to examine the effect of motivation and self-regulation and emotion regulation separately, as well as the effect of their interaction in weight loss maintenance.

Introduction

Background

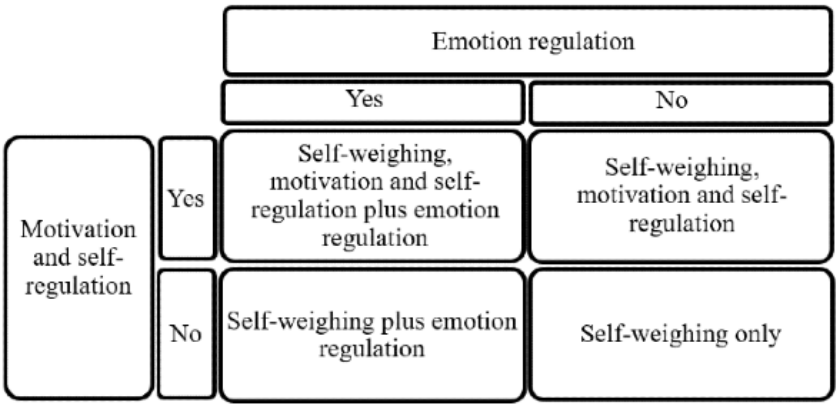
Behavior change interventions for overweight and obesity that target dietary behaviors, physical activity, and other weight management components show beneficial effects in reducing weight and improving health, at least in the short term [1,2], but most individuals experience weight regain over subsequent months and years [3,4]. Thus, a key challenge for such interventions is to find sustainable and scalable methods for long-term weight loss maintenance (WLM) [5,6]. The emergence and rapid growth of digital behavior change interventions (ie, sets of activities or products designed to change specified behavior patterns through digital technology) are a response to the urgent need for scalability and sustainability and can help to better understand the complexity behind individuals' decisions and engagement in behaviors that affect their health and well-being, including sustained weight management [1,7].

Although research on the effectiveness of digital behavior change interventions is at an early stage, existing reviews have found small effects and between-study variability on outcomes and behaviors [8,9]. These interventions can be optimized by identifying the features that contributed to their effectiveness through systematic theory- and evidence-based processes of intervention development, implementation, testing, and reporting (eg, Medical Research Council [10] and Template for Intervention Description and Replication guidance [11]).

In the context of weight management, the core features of effective interventions include techniques in line with self-regulation theories, such as goal-setting, self-monitoring of weight and behavior, feedback on behavior and weight, and plans to cope with risk factors for weight regain and relapse prevention (eg, problem-solving) [12-15]. Autonomous motivation has also been associated with change in energy balance behaviors for obesity management [16]. As the number of digital interventions based on motivation and self-regulation approaches to sustained weight management is limited [17], it is important to test if these theoretical approaches produce sustained behavior changes in the context of WLM. In addition, contextual-based emotion regulation strategies that promote compassion, acceptance, and mindfulness [18-20] may also have an impact on behavior changes that promote WLM [21]. With these considerations in mind, we developed a theory-based toolkit, delivered as a portfolio of embedded digital tracking technologies (smart scale and activity trackers), mini apps, and web resources accessible through a computer, tablet, and mobile phone, as part of the European Union's Horizon 2020 project *NoHoW: Evidence-Based Tools for Weight Loss Maintenance*.

The toolkit was used in the international Navigating to a Healthy Weight (NoHoW) innovative, 2×2 factorial, single-blind randomized controlled trial (RCT) for WLM. All 4 arms of the intervention included self-weighing and self-monitoring of activity using commercial Wi-Fi scales and activity trackers. The active control arm included access to generic weight management content, and the 3 intervention arms consisted of *motivation and self-regulation* content, *emotion regulation* content, and *combined motivation and self-regulation+emotion regulation* content (Figure 1; detailed information about the NoHoW project and trial can be found elsewhere [22]).

Figure 1. The Navigating to a Healthy Weight trial design.



Aim

This paper aims to describe the processes involved in the development of the NoHoW Toolkit to a stage appropriate for an RCT evaluation (trial registration number: ISRCTN88405328) and provide a detailed overview of the NoHoW Toolkit.

Methods

Systematic and Iterative Process

The development of the NoHoW Toolkit involved a multidisciplinary team of researchers in behavioral science, obesity and weight management, exercise and nutrition, software development, data analytics, biomathematics, and user experience (UX). It followed a systematic and iterative process incorporating both theory- and evidence-based approaches, as well as user testing to refine usability, and it also followed best practices by conducting the steps that are commonly recommended by the Behaviour Change Wheel [23], the intervention mapping approach [24], and the Medical Research Council [25] guidance for intervention development. It consisted of the following five steps: (1) development of theory-based logic models; (2) selection of the content, that is, behavior change techniques; (3) translation of these techniques into a coherent web-based app (NoHoW Toolkit components); (4) technical development; and (5) user evaluation and refinement of the toolkit for subsequent evaluation in the context of an RCT.

Step 1: Development of Theory-Based Logic Models

The selection of the psychological and behavioral factors to be targeted by the toolkit was based on existing studies on the most relevant theoretical frameworks in the context of physical activity, healthy eating, and weight management [2]. These studies were reviewed by the core research team and informed the NoHoW theoretical logic models that were developed. These logic models schematically represent the relationships among (1) the primary and secondary outcomes, including behavioral outcomes; (2) the theoretical mediators that were hypothesized to explain the effect of the toolkit content on the primary and secondary outcomes; (3) the content of the toolkit; and (4) the hypothesized moderators of the intervention effects. This task was executed by the behavioral science team with feedback from the members of the larger project consortium and the external advisory board.

Step 2: Selection of Behavior Change Techniques

The next developmental task was the identification and selection of the specific techniques that would form the content of the NoHoW Toolkit. This selection was derived from the studies reviewed (step 1) describing the behavior, motivation, and emotion regulation techniques hypothesized to have an impact on the theory-based mediators of WLM as represented in the logic models. For example, providing choice is a core technique to foster autonomy. We conducted an additional scoping review to identify the frequently used and effective intervention techniques and modes of delivery used in digital behavior change interventions for changing health behaviors in the context of long-term weight management (Multimedia Appendix 1). The selection of the final set of techniques was carried out through discussions among the team members. To ensure standardization in the description of the NoHoW Toolkit, the selected techniques were reported using the identifiers and labels from reliable taxonomies (when available) such as the Behavior Change Techniques Taxonomy (BCTT) version 1 (eg, BCTT 1.2 Problem Solving) [26] or the classification of Motivation and Behavior Change Techniques (MBCTs; eg, MBCT 6: Providing Choice) [27]. No taxonomy is yet available for the emotion regulation techniques.

Step 3: Translation of the Techniques Into the NoHoW Toolkit Components

Table 1 presents an overview of the development tasks (steps 3 to 5). Initially, the research team created user cases involving personas based on recent research identifying individuals involved in WLM [28] (who varied in age, gender, weight history, digital literacy, and reasons for participating in a WLM intervention) and scenarios (eg, first visit, throughout the intervention, and during a relapse) to describe the target users and their potential experiences when using the toolkit. This exercise provided the starting point for specifying the functional requirements of the toolkit and identifying how the techniques selected in step 3 would be implemented and also facilitated the development of a common language between the content development and technology development partners. A guidance manual was created to aid the teams involved in the development of the modular content of the toolkit. The manual stipulated that the content of each module should identify (1) specific behavior

goals; (2) theoretical constructs targeted; (3) techniques targeted; (4) rationale: how the goal, theoretical construct, and techniques are linked; and (5) the mode of delivery of each technique (eg, video or text) described in a way that would inform their implementation by the software developers and designers. Scripts were developed for each implementation.

Table 1. NoHoW Toolkit[a] development process.

Tasks	Team responsible
Task 1: persona and scenario development	Behavior change team and UX[b] team
Task 2: development of the overall content of the toolkit (eg, sessions) based on the motivation, self-regulation, and emotion regulation theories of behavior change	Behavior change team
Task 3: system architecture design	Software development team
Task 4: full description of each implementation (technique or clusters of techniques) for each content feature (eg, session)	Behavior change team
Task 5: development of a list of possible modalities in which the techniques would be implemented (eg, quiz, animation video, audio, text, and testimonial)	Behavior change team
Task 6: feedback about feasibility of implementation, engagement, and other options and details of the technical implementation	Software development team
Task 7: adjustments in accordance	Behavior change team
Task 8: UI[c] design	UX team and software development team
Task 9: functional description	Software development team
Task 10: programming	Software development team
Task 11: feasibility study plan	UX team
Task 12: toolkit sessions upload using a content management system	Behavior change team
Task 13: the implementation is user tested	Behavior change team and software development team
Task 14: final adjustments	Behavior change team and software development team

[a]NoHoW: Navigating to a Healthy Weight.

[b]UX: user experience.

[c]UI: user interface.

Step 4: Toolkit Technical Development

We identified that the 2 most important functionalities of the toolkit were (1) providing the WLM intervention in 3 theoretically informed, evidence-based versions and a control version and (2) supporting the digital tracking of weight, physical activity, and sleep. Given that the toolkit was intended to be used for several months, a positive user interaction and an attractive user interface (UI) were considered necessary. A UX designer was involved in the iterative development of the most crucial UI elements. The design process started with scenario development and identification of the user requirements for the toolkit based on the scenarios, informing the development of the initial UI concepts. The concepts were visualized by the UX designer and tested in small-scale interviews with participants who were similar to the target users. The UI for the intervention sessions was designed through collaboration between the behavior change team and the intervention designers. An admin UI was developed to serve the needs of the intervention designers and trial managers. The intervention designers needed to be able to add, refine, and update content continuously during the toolkit development as well as to define the content, rules, and schedules for different email prompts and reminders to be sent to the toolkit users. The trial managers needed to create new users of the toolkit, assign them to different intervention arms, and manage their status depending on whether they were still involved in the study.

Step 5: User Evaluation and Toolkit Refinement

We conducted 2 user evaluation studies. The first, which sought to identify key technical and UX-related issues and results from this study, informed the refinements to the NoHoW Toolkit version 1.0. This study was conducted in the United Kingdom with English-speaking adults, recruited primarily by advertisement or invitation from the University of Derby. The inclusion criteria were as follows: aged ≥18 years, able to travel to the University of Derby, able to follow written and verbal information in English, ability to access the internet, and currently overweight or have been overweight in the past, with at least one weight loss attempt. Approval was obtained from the research ethics committee of the University of Derby. A mixed methods approach was used for the analysis of the data through questionnaires, interviews, toolkit use log data, and data from wireless scales and activity trackers (Fitbit [Fitbit LLC]; see Multimedia Appendix 2 for the study description).

After refinement of the toolkit version 1.0 into version 2.0 and translation from English into Portuguese and Danish (languages of the 3 countries where the NoHoW trial was conducted), we conducted a second usability testing study with the Portuguese sample. This was a qualitative study consisting of in-depth

interviews, with the aim of understanding users' motivation to engage with the toolkit and determining which functionalities of the toolkit could promote user engagement (see Multimedia Appendix 3 for the full description). In these interviews, conducted after changes were implemented on top of toolkit version 1.0, the participants were shown a beta version of the toolkit, which included a demonstration of the navigation procedures, and 1 session of the toolkit. The interviews, which lasted approximately 1 hour, were audio-recorded and transcribed verbatim. Thematic analysis was conducted using MAXQDA version 12 (VERBI GmbH). Approval was obtained from the research ethics committee of the University of Lisbon.

Results

Step 1: Development of Theory-Based Logic Models

Available evidence from behavioral weight management interventions [17] showed some support for the effectiveness of interventions based on self-regulation theories [13,14,29] and self-determination theory [16]. There is also increasing evidence showing the impact of emotions in weight management [30-34] and indicating that contextual behavioral approaches can contribute to psychological well-being and weight management through the development of skills aimed at reducing the automaticity of maladaptive patterns of behavior (eg, mindfulness, acceptance, and compassion toward internal negative states) [34-38].

The available evidence formed the basis for the NoHoW research hypotheses that WLM could be supported by strategies that promote (1) self-regulation (setting optimal goals and reviewing them, action and coping planning, and action control) and motivation factors (promotion of autonomous motivation vs controlled motivation, intrinsic goals, and flexible regulation to change behaviors and maintain weight loss), (2) emotion regulation factors that may undermine self-management of energy balance–related behaviors (reduce weight-related shame and self-criticism, reduce difficulties in emotion regulation, and increase psychological flexibility, mindfulness, and compassion) and (3) interactions between (1) and (2).

The NoHoW logic models, presented in Figures 2-4, schematically represent the relationships derived from these theoretical approaches. We developed 3 logic models, one for each of the intervention arms: *motivation and self-regulation* arm, *emotion regulation* arm, and the *combined* arm.

Figure 2. Logic model: motivation and self-regulation arm.

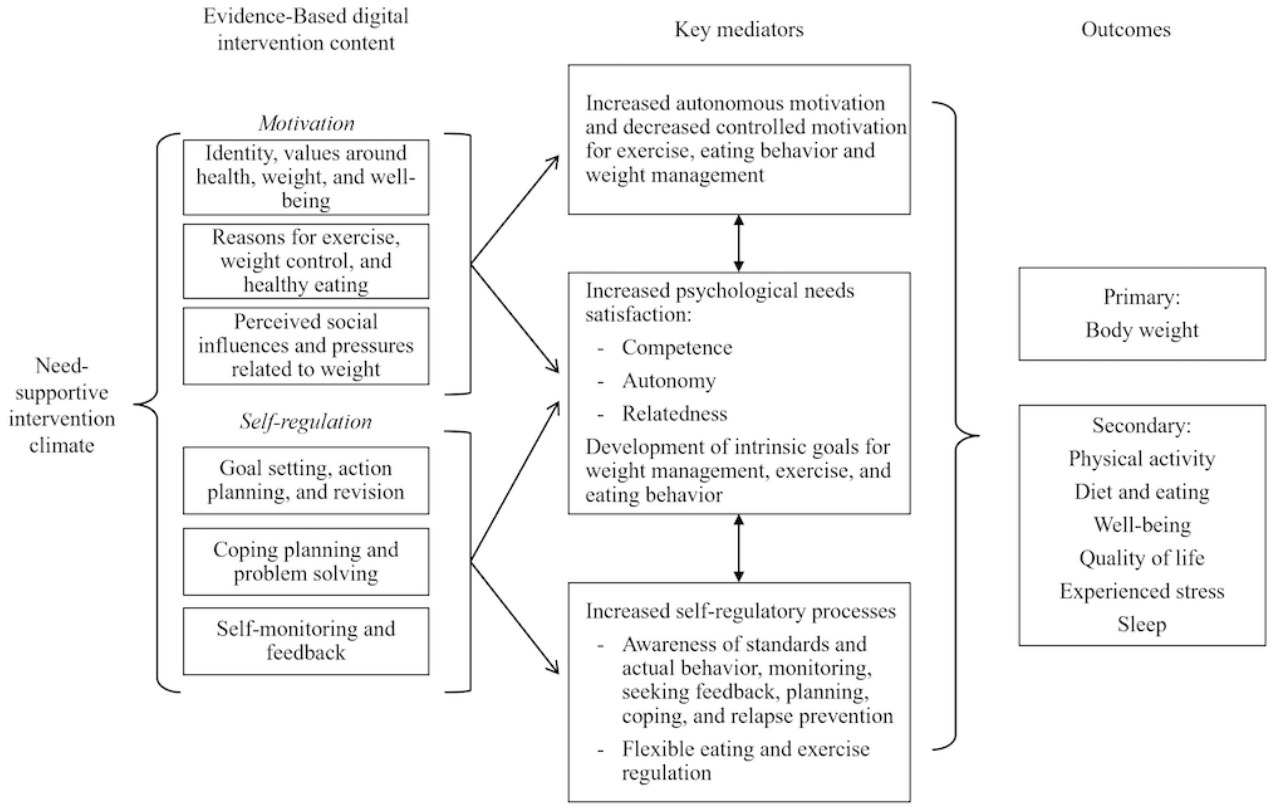


Figure 3. Logic model: emotion regulation arm.

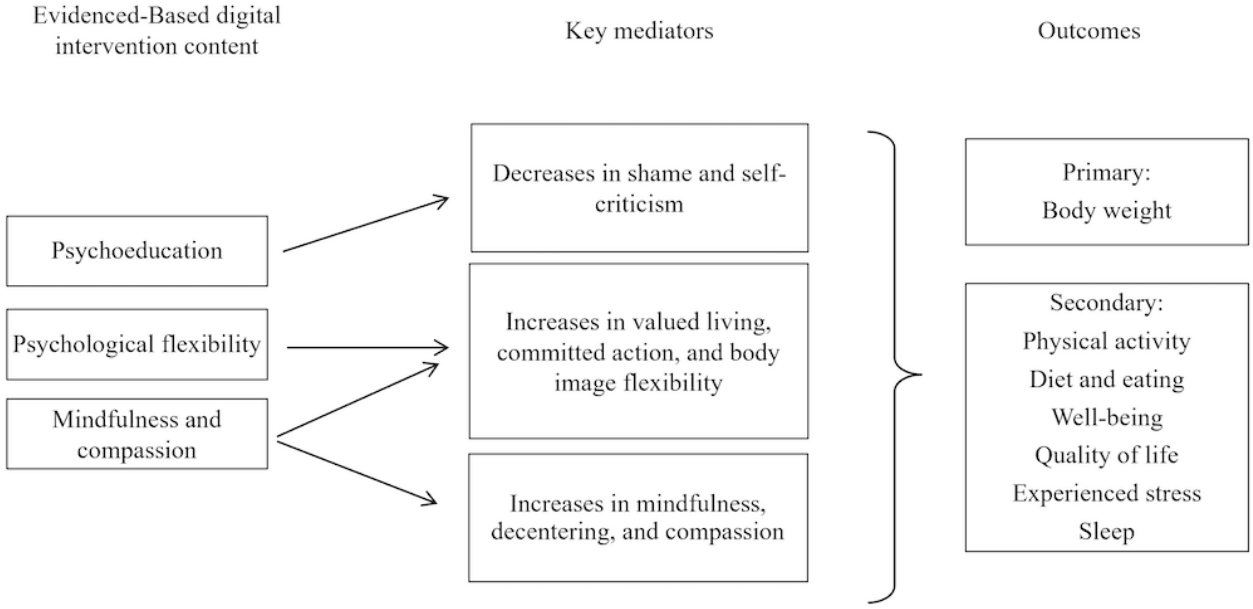

Figure 4. Logic model: combined arm.

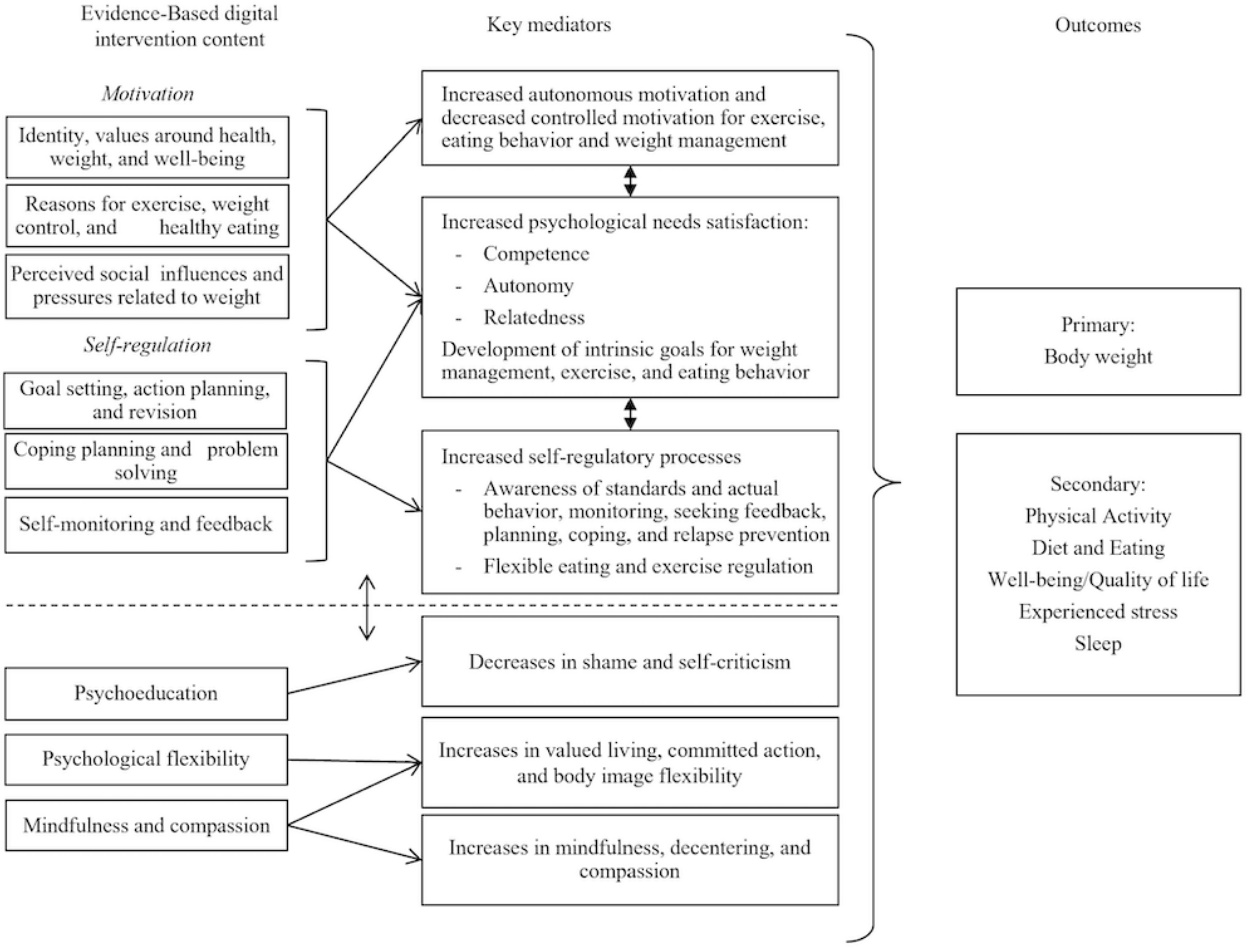


Step 2: Selection of Behavior Change Techniques

For the *motivation and self-regulation* version of the toolkit, 29 intervention techniques were selected: 11 from the BCTT version 1, mainly focusing on goals, planning, and self-monitoring, and 18 from the classification of MBCTs, targeting autonomy, relatedness, and competence (see Multimedia Appendix 4 [26,27] for the full list of techniques). For the *emotion regulation* arm, 25 techniques were defined based on contextual behavioral science approaches, specifically,

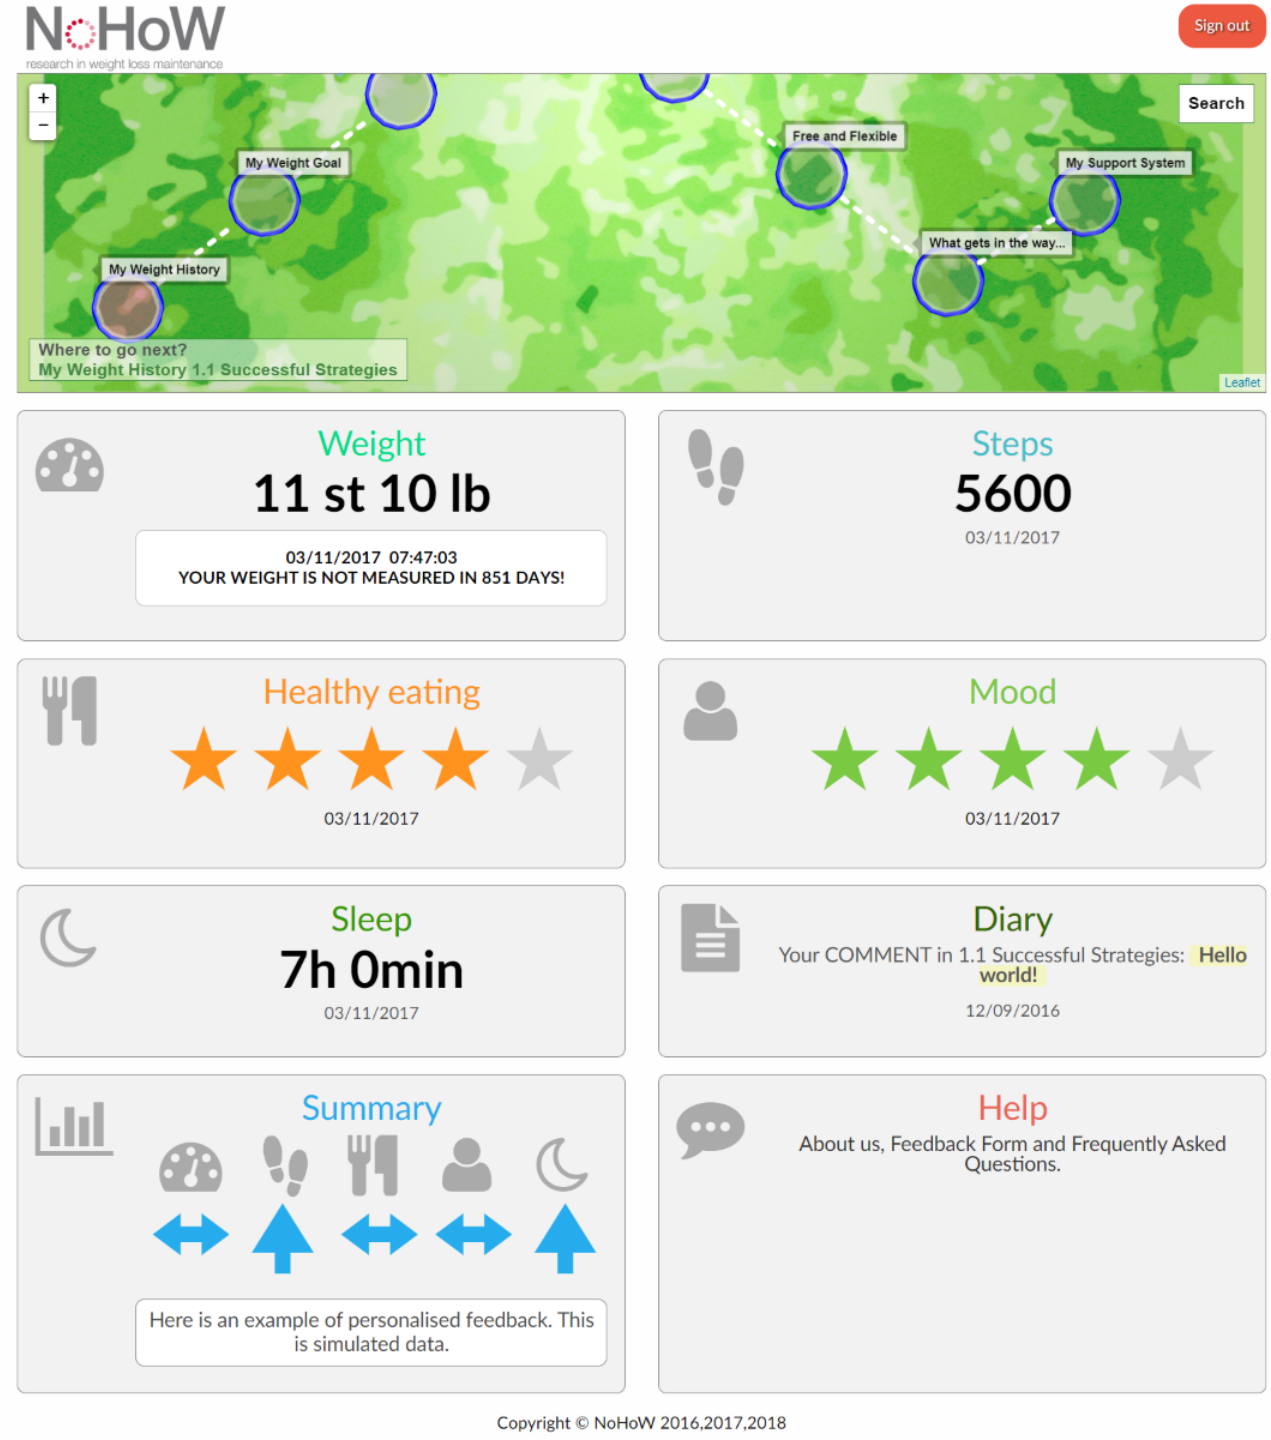
compassion-focused therapy, mindfulness-based interventions, and acceptance and commitment therapy (see Multimedia Appendix 5 for the full list of techniques).

Step 3: Translation of the Techniques Into the NoHoW Toolkit Components

Overview

The implementations of the techniques in the toolkit components are described below. When a user logged in to the toolkit, the main view (Figure 5) consisted of a tile-based dashboard, which was available for all toolkit users; a personal route map, which was only available for intervention users; weekly emails; a diary section (list of comments or reflections that a user could add at the end of each session); and a help section (information about the study, frequently asked questions, and instructions for navigating in the toolkit). The first 3 are described in detail next.

Figure 5. Navigating to a Healthy Weight Toolkit dashboard. st: stone; lb: pounds; h: hours; min: minutes



Tile-Based Dashboard

The dashboard tiles provided an at-a-glance view of the user's most recent data. The toolkit presented separate tiles on physical activity, sleep, and weight data retrieved from the Fitbit activity tracker (Charge 2) and the Fitbit smart Wi-Fi scale (Aria). All users could visualize their data for 1 week and for 1 month, 3 months, and 6 months. For the *motivation andself-regulation* arm and for the *combined* arm, the tiles also presented the user's goals and action plans as well as coping plans related to physical activity and diet. These plans could be reviewed at any time in the tiles. In addition, there were 2 tiles for mood and diet, each based, respectively, on the response to a single question, "How do you rate your mood, at the moment?" and "How satisfied are you with your diet, at the moment?" (5-star response scales). The tiles highlighted if no recent data existed, thus prompting continuation of monitoring. By clicking on a tile, the user could view long-term graphical feedback in different time scales and make self-assessments with a star rating feature (Multimedia Appendix 6).

Personal Map

The personal map (not available to the control arm) contained the modules of the toolkit, expressed in sessions (Multimedia Appendix 7). The sessions available depended on the arm to which the user was randomized. As the full content for each arm of the toolkit was available from the first day of use, it was considered useful to have a map to guide the user through the optimal theory-informed order of the content. When a user clicked on a module, the sessions of a module were displayed (Multimedia Appendix 7). There were regular sessions (lasting approximately 5 minutes) and short sessions (lasting 1 minute each), and the user was prompted to access a specific activity during the week. The *motivation and self-regulation* arm presented 17 regular sessions, organized in 8 modules. The estimated duration of these sessions ranged from 3 to 19 minutes. There were also 4 short sessions. The *emotion regulation* arm presented 17 regular sessions as well as 2 short ones distributed through 7 modules. The estimated duration ranged from 2 to 27 minutes. The *combined* arm presented all sessions from both arms distributed in 17 weekly modules.

Tables 2 and 3 describe the modules' sessions for all trial arms. The techniques selected were implemented in the sessions using various types of activities, or implementations, which are described in brief here (Multimedia Appendix 8):

1. Whiteboard animations: 1-minute videos that use animation to provide educational content. The toolkit presented videos about self-monitoring, self-confidence, myths and facts, flexibility and body image, autonomous motivation, evolutionary perspective of eating, conflicting messages, food functions, shame and self-criticism, obstacles to a healthier life, compassion, and mindfulness (Multimedia Appendix 9).
2. Questionnaires: interactive exercises to collect data from the user and provide immediate feedback (eg, a brief questionnaire concerning the reasons for personal ideal weight [motivation and self-regulation arm] or concerning compassionate attitudes [emotion regulation arm]; (Multimedia Appendix 10).
3. Testimonials: short personal stories describing, for example, the difficulties, challenges, and successes in a weight management process (Multimedia Appendix 11). Users could choose between a story of a male or female character.
4. Downloadable audios: audios containing mindfulness exercises, lasting approximately 5 minutes. They were only available in the emotion regulation and combined arms.

Table 2. Theme and goals of each module of the motivation and self-regulation arm.

Module (theme)	Core goals	Mechanisms of action
Module 1: My weight history	• Review weight change history: weight trajectory and characteristics of previous weight changes (strategies and feelings associated) • Identify weight loss strategies or approaches used in the last weight loss attempt and assess their sustainability in time	Self-awareness and competence
Module 2: My weight goal	• Learn about self-monitoring and self-referenced feedback and its role in goal-setting and revision, and reflect on individual options and preferences • Reflect on ideal and acceptable weights (and where these terms originated and what they mean to the person) • Understand the importance of setting self-relevant and optimal goals: set weight-related goal	Self-regulation capacity, competence, autonomy (ownership), and intrinsic (vs extrinsic) goals
Module 3: Myths and facts	• Promote factual knowledge about energy balance–related behaviors (exercise and diet) and WLM[a]	Competence and autonomous motivation
Module 4: My healthy goals	• Promote awareness of multiple choices around behavior changes and WLM in the long term (there is no “right” way) • Find individual interests and seek enjoyment and personal meaning around health behaviors • Explore personal resources for engaging in health behaviors (eg, skills)	Autonomy (perceived choice), autonomous motivation, competence, and self-regulation capacity
Module 5: My goals and values	• Prompt reflection on personal reasons for WLM (weight goals) and related behaviors by differentiating internal (autonomous) and external (controlled) motives and their relationship to sustained behavior change (sense of ownership) • Explore sources of body image or ideal (eg, societal norms, media, and significant others) and its consequences (motivation and well-being)	Intrinsic (vs extrinsic) goals (ie, life aspirations), autonomous versus controlled motivation, autonomy (ownership), and perceived social influences and pressures related to weight
Module 6: Free and flexible	• Identify functional and dysfunctional investment in body appearance (by exploring sources of body image or ideal (eg, societal norms, media, and significant others) and its consequences (motivation and well-being) and promote satisfaction with one’s body, at any size • Explore links between internal (feels free and choiceful) and external (feels pressured) motives and eating and exercise regulation (eg, rigid vs flexible approach)	Intrinsic (vs extrinsic) goals, autonomous versus controlled motivation, autonomy (ownership), and rigid versus flexible behavior regulation
Module 7: What gets in the way	• Identify challenges and barriers to current behavioral patterns and identify resources to increase capability to deal with them • Identify strategies to deal with these barriers (coping plans) and to focus attention on how behavior changes serve other important life goals	Competence, autonomous motivation, and self-regulation capacity
Module 8: My support system	• Identify sources of social support and reflect on what they mean (eg, pressured and conditional support vs unconditional support) • Increase skills in seeking social support and dealing with social and peer pressures (eg, assertiveness) • Explore reaching out to others as a role model or source of support and expertise in WLM	Relatedness, autonomous motivation, perceived social influences and pressures related to weight, and self-regulation processes

[a]WLM: weight loss maintenance.

Table 3. Theme and goals of each module of the emotion regulation arm.

Module (theme)	Core goals	Mechanisms of action
Module 1: Why do we eat?	• Promote the understanding of the difficulties in regulating eating behavior because our systems are not yet evolved to restrict eating behavior (it is not our fault) • Promote the knowledge about how our body works to stop people fighting against their bodies and begin working with them instead • Promote the understanding that food has multiple functions (it is not our fault) • Promote the reflection about the conflicting messages in our modern society about eating and physical activity and using food as a way of comfort and achieving a thin and fit body image • Clarify how these conflicting messages create additional stress and how eating may emerge as a way to soothe the self and manage stress	Evolutionary approaches to eating behavior and physical activity, deshaming, and emotion regulation
Module 2: Eating awareness	• Unveiling emotional and stress eating • Identify the traps in using food to regulate emotions and cope with stress • Learn how to eat mindfully • Promote awareness of satiety and hunger cues	Emotional eating, emotion regulation, and mindfulness
Module 3: Roadblocks to change	• Do we need shame and self-criticism to manage our weight? Understand the evolved functions of shame and self-criticism • Clarify the negative effects of self-criticism and shame on weight management, body image, and physical activity • Consolidate the inefficacy of shame and self-criticism to cope with stress and maintain changes • Promote creative hopelessness	Shame, self-criticism, creative hopelessness, and stress management
Module 4: Living a healthy life	• Foster creative hopelessness • Promote the clarification of values • Identify how life can be so disconnected from values • Identify the obstacles to a valued life • Discuss the role of avoidance and the control agenda as obstacles to a valued life • Create value-related goals and step-by-step actions • Encourage committed actions to values in daily life (ie, the importance of healthy eating patterns and physical activity)	Creative hopelessness, values, avoidance, control agenda, and committed action
Module 5: Learning to just be	• Introduce and reduce automatic pilot • Reflect on the needed shift from the doing mode to the being mode • Clarify what mindfulness is and evidence of its benefits • Increase awareness and acceptance of the present moment • Use the breath as an anchor for the present moment • Introduce the 3-minute breathing space as a way of being fully present with a different frame of mind • Learn how to use the 3-minute breathing space to deal with difficult emotions, sensations, thoughts, or the stress of daily life • Learn how to use the body as an anchor to the present moment experience • Increase awareness and acceptance of unwanted internal experiences (emotions and physical sensations) • Increase awareness of the body and the body in movement • Use mindfulness to take better care of your body • Increase awareness and acceptance of thoughts • Promote a defused perspective on thoughts: Thoughts are not facts • Promote an observer perspective of internal experiences • Promote the identification and awareness of stress responses in the body • Foster a more adaptive and healthy way to cope with stress and negative emotions	Mindfulness, automatic pilot, being mode, acceptance, awareness, coping, bodily awareness, mindful movement, decentering, and emotion regulation

Module (theme)	Core goals	Mechanisms of action
Module 6: Cultivating compassion	• Introduce loving-kindness • Understand how the need for compassion emerges from our evolved brain and emotional systems • Understand what compassion is • Clarify that compassion takes courage • Learn the basic skills of cultivating compassion • Learn how to prepare the body for the compassion practices • Develop and cultivate the qualities of the compassionate self • Understanding the role of interpersonal difficulties and how stigma generates stress • Cultivate compassion in my relationship with others • Identify the main reasons people report fearing compassion • Clarify what compassion is and what it is not • Discuss the paradoxical effects of fears of compassion • Help people to overcome their fears of compassion • Cultivate self-compassion (of one's body image, thoughts, and emotions) • Build the capacity for acting compassionately toward one's body • Take the courage to engage in hard but necessary actions: The importance of physical activity	Compassion, loving-kindness, postures, facial expressions and voice tones, soothing rhythm breathing, compassionate imagery, compassion for others, fears of compassion, and self-compassion
Module 7: Final destination: A new start	• Promote the early identification of relapse signals • Distinguish lapse from relapse • Draw an action plan to deal with the relapse • Prevent new relapses	Relapse prevention, mindfulness, and committed action

In addition, the toolkit presented 2 other features, as follows:

1. Extra support, which was triggered when individuals reached a threshold of weight regain >3% above their target weight. This extra module stayed available until users returned to a weight interval of ±3% (ie, the interval defined as weight maintenance). For users in the *motivation and self-regulation* arm and the *emotion regulation* arm, this support further directed the user to content useful for coping with relapses (Multimedia Appendix 12).

2. Individualized feedback, which was included as a feature in the *motivation and self-regulation* arm and in which time series data retrieved over 1-2 months for each participant (activity and sleep patterns from Fitbit devices, daily and weekly body weight measures taken by the Fitbit Aria Wi-Fi scales, and use of the toolkit) were analyzed to examine weight change patterns. There were also indicators of weekly versus weekend and earlier versus later in the week used as possible predictors to alert participants to weekly cycles in weight change. Feedback could only be provided if sufficient data were collected (at least 30 days and variation in weight) and consisted of short messages such as "For you, being active or exercising seems linked to better weight management" or "Your weight management seems better on weekdays" that were displayed on the homepage.

Weekly Emails

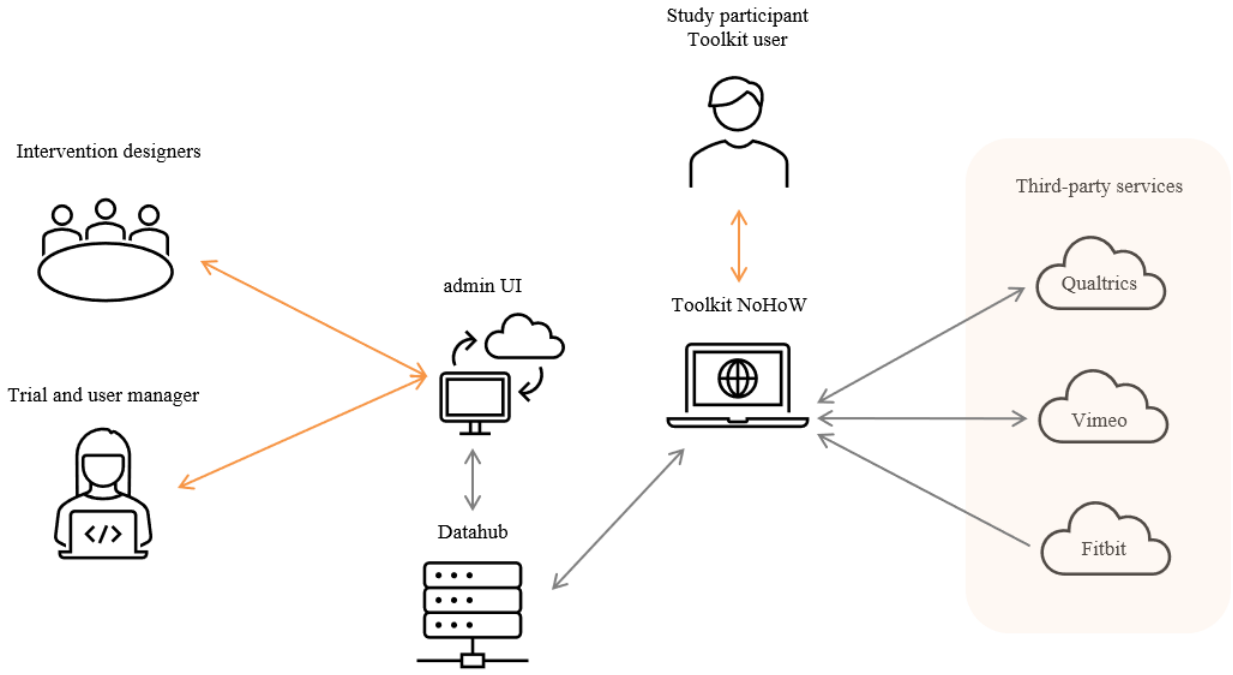
During the intervention period, weekly emails were sent to the control arm, prompting the users to access the dashboard. These emails also included links to general information about weight management (eg, guidelines for healthy lifestyles from government or scientific association websites).

The other arms also received weekly emails prompting the users to access a specific session in the toolkit suggested for that week, that is, the participants from the *motivation and self-regulation* arm received the link for a session developed with that rationale, whereas the participants from the *emotion regulation* arm received the link to an emotion regulation–specific session.

Step 4: Toolkit Technical Development

Figure 6 depicts the final overall architecture of the NoHoW Toolkit and its connections to other systems required to deliver the intervention. The toolkit consisted of 2 layers. The front end consisted of an HTML skeleton with JavaScript modules. A responsive web design approach and mobile-first concept was used in the development. The back end responds to front end requests, communicates with the MySQL database on the datahub server, and accesses Fitbit data on Fitbit's server. The datahub stores and analyzes data, providing personalized feedback to users by relaying information back to users through the personalized feedback panels on the dashboard of the toolkit. The intervention content was delivered through text, images, videos, questionnaires, and interactive exercises. The text and images were implemented as HTML. The videos were hosted on Vimeo (Vimeo, Inc) and embedded in the intervention sessions. The embedded questionnaires were implemented with Qualtrics (Qualtrics XM), which was also used for managing the study questionnaires in the RCT. New interfaces were built to retrieve questionnaire answers from Qualtrics and visualize them in the toolkit front end to enable exercises where instant feedback was needed. Interactive exercises were tailor made as mini apps. One example of a mini app was an exercise enabling the users to visualize key moments in their personal weight management history as a graph.

Figure 6. The overall architecture of the Navigating to a Healthy Weight Toolkit and its connections to third-party systems. NoHoW: Navigating to a Healthy Weight; UI: user interface.



Each user was provided with a user account for the toolkit website as well as a Fitbit account to gather activity, sleep, and weight data. The personal map was designed iteratively with the help of a UX designer. First, 3 different concepts for visualizing the personal map were designed, and paper prototypes illustrating the concepts in different stages of use were created. The prototypes were evaluated with 6 participants in 2 evaluation rounds, first with 3 participants, after which major usability issues were fixed. Next, the updated prototypes were evaluated with another 3 participants. The evaluation consisted of 45-minute face-to-face sessions with each of the participants, who were asked to complete different tasks with the prototypes and provide feedback on the usability and visual appearance of the concepts. Finally, the participants were asked to rate the concepts as the best, second best, and worst. A concept illustrating a path on a map received the highest ratings and was selected. The final design was created by incorporating user feedback and some highly rated features from the other 2 concepts. All intervention modules were displayed on the main level of the map, and completed modules were highlighted in pink; modules that had not been completed were highlighted in a lighter shade of pink. When a user clicked on a module, the sessions of that module were displayed. This level of the map also indicated which of the sessions had been completed. By clicking on a session, the user gained access to the intervention content. On both levels of the map, there was also a box at the bottom left of the screen, indicating the next recommended session and providing a shortcut to the session.

The admin UI served intervention developers and trial managers. The most important component in terms of the intervention was the content management system (CMS) because of the large volume of intervention content and the need to constantly refine and update it during the iterative development of the toolkit. Thus, enabling the intervention designers to manage the content facilitated the collaboration between the software developers and the intervention designers. The CMS enabled the intervention designers to describe the intervention structure, content items, and their relationships to each other with a web-based UI without programming expertise. The CMS is based on the Django CMS (Django CMS Association), but its functionality has been tailored to meet the needs of the intervention design.

Step 5: User Evaluation and Toolkit Refinement

A total of 37 eligible participants expressed interest in participating in the first study. Of the 37 participants, 20 (54%) started using the toolkit, 14 (38%) completed the 5-day questionnaire, and 9 (24%) completed the 30-day questionnaire. The average age of the participants was 41.4 (SD 11.7; range 23-63) years, and of the 37 participants, 22 (59%) were women. Although retention was low, the collected data were sufficient to allow for the analysis of the feasibility study. The results from the study were used to revise the toolkit specifications. The main threats to engagement and acceptance of the toolkit were identified, and several improvements were made regarding UX design, content development, technical performance, and usability (Multimedia Appendix 2). For example, to facilitate navigation in the toolkit, the personal map component was included, videos were refilmed to make them more energetic and less clinical, and technical performance and usability were improved by ensuring scaling of the toolkit to different screen sizes and ensuring compatibility with different browsers and mobile platforms. Ethical approval was obtained from the Psychology Research Ethics Committee of the University of Derby.

The qualitative study assessing users' needs support when engaging with toolkit version 2.0 had a sample size of 12 adults aged 23-57 years (women: 9/12, 75%) who lost between 10% and 43% of their weight before taking part in the qualitative study. Most of the participants had experience in using digital tools, mainly to monitor their diet and physical activity. When testing the toolkit, the participants did not report difficulties, and the fact that the toolkit could be used on both a computer and mobile phone was considered an advantage. The participants considered that the self-monitoring tools were positive elements and considered that engaging in the toolkit sessions for 5-10 minutes per week was a reasonable time commitment. From the interviews, it was concluded that all participants felt that the toolkit content was acceptable; in particular, the whiteboard videos were considered to be very appealing and engaging in terms of both the design and content, with a participant stating, "I think I prefer the drawing hand, in my opinion the hand is more engaging, it has a lot of movement." There were no major issues or suggestions for changes from the interviews (Multimedia Appendix 3). Approval from the research ethics committees at the University of Lisbon was obtained before recruitment and data collection.

The final version of the NoHoW Toolkit was presented in 4 versions available for each of the trial arms as well as in 3 languages for each of the trial centers. All versions included a tile-based dashboard displaying data from digital tracking devices (Fitbit Charge 2 wrist device and Aria smart scale) for weight, steps, and sleep, as well as manually entered data for eating and mood. It also included a diary section and a help section. In addition, the 3 versions available to each of the intervention arms—*motivation and self-regulation*, *emotion regulation*, and *combined*—displayed a personal map containing the modules of the toolkit. The final toolkit comprised 34 sessions, distributed through 15 modules, with active content being presented for 4 months. The *motivation and self-regulation* arm consisted of 17 sessions, distributed through 8 modules; the *emotion regulation* arm was presented with 17 sessions distributed through 7 modules; and the *combined* arm received the full toolkit. A detailed logging of user interactions with the toolkit was implemented to enable determining how often the users visited the toolkit and how much time they spent in the toolkit and in the intervention sessions.

Discussion

Principal Findings

The NoHoW Toolkit was one of the first theory and evidence-based digital approaches for WLM that was systematically developed using standardized guidance, an interdisciplinary approach, design principles, and user testing. In all, 4 toolkit versions were designed and formally evaluated through a 2×2 factorial RCT. In the RCT, the control version of the toolkit only presented self-monitoring information on weight and physical activities, whereas the 3 intervention arms of the toolkit presented additional modular content targeting (1) motivational factors of behavior change, including the promotion of autonomous motivation (vs controlled motivation), intrinsic goals, and flexible regulation to change behaviors and maintain weight loss and self-regulation skills; the setting and review of optimal goals; action and coping planning; and action control; (2) emotion regulation and stress management to reduce weight-related shame and self-criticism, reduce difficulties in emotion regulation, and increase psychological flexibility, mindfulness, and compassion; or (3) both 1 and 2. These are factors that have been shown to have an impact on energy balance–related behaviors (physical activity and healthy diet), weight changes, and well-being [12-15,35-38].

The systematic approach used in the development of the NoHoW Toolkit—making use of guidance for complex behavior change interventions and taxonomies—was a core contributor to the best reporting, replication, and accumulation of evidence on effective behavioral approaches to WLM. The logic models created for the NoHoW Toolkit allow for statistical modeling of the components of the intervention, contributing to understanding what works in the context of long-term weight management. Furthermore, using explicit theory when developing interventions allows for the identification of the factors that influence the target behavior, the mechanisms of actions that operate along the pathway to change, and the best techniques to influence these factors, as well as an understanding of how these can affect engagement. In addition, the use of digital tools and engagement metrics (eg, real-time data on weight or activity changes and use patterns of the intervention content) can contribute to improving our understanding of the behavioral dynamic patterns as well as theory testing and refinement. Users were engaged in the design and iteration of the toolkit at several stages, and the findings from these studies informed several improvements in the design of the toolkit and its content.

Challenges and Lessons Learned

A challenge we faced in the development of the NoHoW Toolkit concerned the integration of the motivation and self-regulation theoretical approaches with emotion regulation to be tested in the 2×2 factorial trial. As there was no theory regarding, or empirical support for, the interactions between these approaches, the *combined* arm provided access to all the toolkit content available, and the users were prompted each week to access the emotion regulation content and the motivation and self-regulation content. In addition, there was some overlap among the sessions from the different approaches, for example, the sessions on values and on flexible eating. Furthermore, the content of the activities provided in the toolkit mainly focused on maintenance of weight loss by, for example, addressing the myths and facts of WLM, asking users to indicate the strategies they used to lose weight and how these strategies could fit with a long-term approach, and offering activities that addressed autonomous motivation as well as content that focused on mindfulness and compassion as ways to prevent relapses.

Although we used up-to-date frameworks to guide our choices for the content, structure, and flow of the toolkit, the final decisions on which components and features were to be included and how these would be implemented drew on the research team's judgment through iterative discussions that were informed by user testing and feedback. It should be noted that the decisions made in the development process were not

systemically justified and documented. Current frameworks and guidance provide little information on how to translate behavior change techniques into digital content (features). For example, what is the best way to implement a modeling technique in a digital intervention for it to be most effective? Should video or text or audio be used? Or should a combination of these be used? Behavior change techniques do not influence only the intervention content, but also the functionality of that content: how users interact with, and use, the app. This in turn affects how behavior change techniques can be translated into individual functionalities and how these functionalities form an overall concept that creates value for the user. Efforts are currently ongoing to develop tools to support researchers and interventionists in standardizing reporting to inform intervention design, content, and delivery [39,40].

The development of the NoHoW Toolkit involved close collaboration between behavioral scientists and web developers. The toolkit (and hence intervention) design was developed at the beginning of the project and limited by time and resource constraints. Where possible, development was accelerated by using existing commercial solutions, such as implementing intervention exercises using Qualtrics questionnaires and using commercially available tracking devices and their data aggregation capabilities. The resource constraints meant negotiating acceptable compromises between the teams in the implementation of some toolkit components. It was difficult to evaluate beforehand how much work each functionality required and how essential it actually was, considering the evidence base.

It can be challenging to develop a totally new digital behavior change intervention in a time-constrained project that includes a large-scale effectiveness evaluation. Although users were involved in the iterative development of the toolkit, it was not possible to simulate long-term, real-life experiences of users of such a large entity in qualitative interviews or even in a 1-month feasibility study. This compromise is also relevant when judging if the toolkit was suitable for participants from different socioeconomic status and literacy levels. Future studies should consider adopting methodologies such as coparticipatory design or formative research to improve the suitability of the app content for diverse populations. Another limitation related to this was that user testing was not conducted with Danish users.

The UX data collected during the NoHoW RCT will be valuable in understanding how users' experiences change during the use of a long-term digital intervention. In future studies, when a complex long-term intervention is involved, it might be worthwhile to conduct a longer feasibility study to enable observation of the changes in user engagement and experience and use qualitative methods to investigate the reasons. Furthermore, an adaptive trial design might be a good alternative for testing and comparing different designs.

The schedule for the development was tight, which led to pressure to use existing commercial platforms in the development. Although including commercial options such as Fitbit can be an advantage because we can test real-world solutions, it also means less control over the features that are regularly added to the Fitbit app and trackers, which can contradict, or be in conflict or overlap with, the content provided in the NoHoW Toolkit, for example, the built-in *breathe* exercise in the Fitbit tracker was not aligned with the relaxation techniques recommended in the toolkit. Future interventions may favorably control these features by using devices used for research or codeveloping these with commercial partners, for example, by integrating new features on the Fitbit native app that would be released to the NoHoW participants only. Furthermore, developing a web app instead of a native mobile app limited the functionality and interaction mechanisms from the intervention design point of view. Focusing on the web-based app saved the trouble of developing separate apps for multiple platforms (Android and iOS), and the related CMS enabled updating of the intervention content in real time.

Although a factorial RCT allows a rigorous testing and comparison of different theory-based components, it also presents constraints regarding the continuous optimization of content to the individual that may arise during the trial (ie, the content could not be updated during the full length of the NoHoW trial). The use of optimization designs for digital interventions (eg, sequential multiple assignment randomized trial [41] or microrandomized trial [42] approaches) can support the identification and delivery of the content of interventions through the modeling of causal and time-varying effects, providing a more personalized and dynamic approach to complex behavior change in the context of long-term weight management.

Considering these challenges, it is likely that the interaction between academia and industry will be crucial to the development of digital behavior change solutions in the years to come. The industry has technical capabilities and capacity that could potentially synergize with academic efforts in developing rigorous, systematic, and dynamic behavior change interventions grounded in sound theoretical principles.

Conclusions

The NoHoW Toolkit is a theory-based web app aimed at supporting individuals who have already lost weight and are trying to manage their weight in the long term. It was systematically developed using standardized guidance, an interdisciplinary approach, design principles, and user testing, and it was formally evaluated through a 2×2 factorial RCT. It presents modular content on motivational factors of behavior change as well as behavior regulation and emotion regulation skills, and it integrates data from activity trackers and weight scales. The development of the toolkit involved a multidisciplinary and international team of experts who used a systematic and rigorous approach to derive its technical specifications and content limitations. The toolkit has been tested in the context of a multicountry randomized trial; in addition to the main trial results, the results from the mediation-moderation analysis, guided by the logic models, will provide further information about the most effective and engaging components for WLM, thereby contributing to the optimization of the NoHoW Toolkit in future deployments.

Acknowledgments

The authors thank Heather Patrick, Kirby Sainsbury, Paul Sacher, and Sarah Scott for their valuable inputs to the toolkit development and evaluation.

This project has received funding from the European Union's Horizon 2020 research and innovation program under grant agreement number 643309. The materials presented and views expressed here are the responsibility of the authors only. The European Commission takes no responsibility for any use made of the information in this study.

Authors' Contributions

RJS, BLH, PJT, FFS, ME, and GH conceived the NoHoW project. MMM, ALP, PJT, EM, PV, MM, CD, GH, ME, and JL designed the toolkit. All authors contributed to the development of the content and functionalities of the toolkit. MH, EM, and RJS designed the user evaluation in the United Kingdom. MMM, ALP, and JE conducted the Portuguese usability study. MMM, ALP, JE, EM, MH, CD, and MM drafted the manuscript. MMM and EM contributed equally to this work. All authors reviewed and approved the manuscript.

Conflicts of Interest

RJS consults for Slimming World through Consulting Leeds, which is a wholly owned subsidiary of the University of Leeds. MMM and GH have previously consulted for Slimming World. Slimming World is a former partner in the Navigating to a Healthy Weight project. All other authors declare that they have no conflicts of interest.

Abstract

Background: Elective colorectal cancer (CRC) surgeries offer enhanced surgical outcomes but demand high self-efficacy in prehabilitation and competency in self-care and disease management postsurgery. Conventional strategies to meet perioperative needs have not been pragmatic, and there remains a pressing need for novel technologies that could improve health outcomes.

Objective: The aim of this paper was to describe the development of a smartphone-based interactive CRC self-management enhancement psychosocial program (iCanManage) in order to improve health outcomes among patients who undergo elective CRC surgeries and their family caregivers.

Methods: A multidisciplinary international team comprising physicians, specialist nurses, a psychologist, software engineers, academic researchers, cancer survivors, patient ambassadors, and ostomy care medical equipment suppliers was formed to facilitate the development of this patient-centric digital solution. The process occurred in several stages: (1) review of current practice

through clinic visits and on-site observations; (2) review of literature and findings from preliminary studies; (3) content development grounded in an underpinning theory; (4) integration of support services; and (5) optimizing user experience through improving interface aesthetics and customization. In our study, 5 participants with CRC performed preliminary assessments on the quality of the developed solution using the 20-item user version of the Mobile App Rating Scale (uMARS), which had good psychometric properties.

Results: Based on the collected uMARS data, the smartphone app was rated highly for functionality, aesthetics, information quality, and perceived impact, and moderately for engagement and subjective quality. Several limiting factors such as poor agility in the adoption of digital technology and low eHealth literacy were identified despite efforts to promote engagement and ensure ease of use of the mobile app. To overcome such barriers, additional app-training sessions, an instruction manual, and regular telephone calls will be incorporated into the iCanManage program during the trial period.

Conclusions: This form of multidisciplinary collaboration is advantageous as it can potentially streamline existing care paths and allow the delivery of more holistic care to the CRC population during the perioperative period. Should the program be found to be effective and sustainable, hospitals adopting this digital solution may achieve better resource allocation and reduce overall health care costs in the long run.

Introduction

Colorectal cancer (CRC) is known to be one of the leading causes of cancer-related morbidity and mortality among both men and women worldwide [1]. It will continue to be a global threat because of its profound impact on societies and public health [2]. Surgical tumor resection is the primary treatment for colorectal cancer, and as worldwide incidences continue to surge, the corresponding demand for elective surgeries is expected to rise as well [3]. The period leading up to and following an operation can be exceptionally sensitive and challenging for some patients, given the state of psychological vulnerability they are in, the debilitating symptoms, and the lifestyle changes they concurrently contend with [4]. Under the current enhanced recovery program or "fast-track surgery," much of the preoperative physiologic optimization occurs outside of hospital [5,6], and shortened hospitalization stays further mandate or pressurize CRC survivors to be independent and competent in self-care and disease management postdischarge [7,8]. Despite the introduction of various interventions in recent years, frequent, unwarranted hospital readmissions resulting from postoperative complications (eg, surgical site infections, intestinal obstruction, bleeding, and ostomy malfunction) imply that moderate self-efficacy levels reported among CRC survivors are suboptimal [9-12]. Furthermore, informal caregivers have been reported to lack confidence and have inadequate training in managing their care recipients' bowel problems, pain, fatigue, medications, and other symptoms [13]. These combined findings justify the need for more comprehensive and targeted measures. Therefore, this paper aimed to describe the development of a smartphone-based interactive CRC self-management psychosocial program (iCanManage) in order to improve perioperative health outcomes among patients with CRC undergoing elective CRC surgeries and their family caregivers.

Methods

Overview

The initial stage involved the establishment of a multidisciplinary international team by the study's principal investigator. Following the recruitment of a few academics, clinicians from the 2 largest acute hospitals in Singapore, ostomy care appliance specialists, as well as software engineers from a renowned Finnish company were approached. Meetings were organized to assemble all parties to brainstorm for ideas and kick-start the construction and mapping of timelines delineating critical milestones to be reached. The roles and the respective responsibilities were delegated (Table 1), and a reporting cascade was put in place to facilitate consistency and consensus throughout the development of the patient-centric digital solution. The appointed project manager assisted with the arrangement of all team-based activities and timely documentation of the project's progress.

Table 1. Multidisciplinary team members and roles.

Key personnel	Partner country	Role in the development process
Principal investigator	Singapore	• Conceptualize and supervise the iCanManage development and trial process
Project manager	Singapore	• Coordinate communication among collaboration partners and key stakeholders
Medical doctors	Singapore	• Provide content expertise for the creation of surgery care paths
Specialist nurses	Singapore	• Provide content expertise on perioperative assessments and counseling, symptom management, and self-care
Psychologist	Singapore	• Provide content expertise to develop, structure, and arrange mindfulness-based practices and activities • Provide formal psychological support
Software engineers	Finland and Singapore	• Design digital solution, input content within care path, and maximize functionality and customization of the software interface
Academic researchers	Singapore and Finland	• Collect field data, expert opinion, and public feedback before trial testing
Cancer survivors and patient ambassadors	Singapore	• Provide informal peer support through sharing of personal experiences, identification of common challenges, and coping strategies. • Provide information on external support services
Cancer institute and society	Singapore	• Provision of patient education pamphlets, brochures, and booklets
Ostomy care medical equipment suppliers	Denmark (Coloplast) and United States (ConvaTec)	• Provide multimedia on ostomy care, instructional guidelines, and practical tips on lifestyle adjustment after stoma creation

Review of Current Clinical Practice

To grasp a better understanding and to identify gaps in the current perioperative workflow of local hospital outpatient settings, the academic study team members conducted multiple clinic visits and on-site observations. Physical examinations, clinical procedures, care plan discussions, as well as types of queries and concerns raised by the patients and their accompanied caregivers during medical consultation sessions, were manually recorded. Preoperative assessments and instructions, educational reference materials, and relevant counseling advice provided by specialist nurses based on the patients' physiological status were also collected and documented. Besides the aforementioned, some study team members attended in-house peer support sessions, organized by patient ambassadors, and talks involving ostomy awareness to get a sense of the topics shared and activities availed for participation. These public events enabled conversations exploring patients with CRC and their caregivers' struggles, needs, satisfaction with care, and support preferences. Information about the referral process for formal psychosocial support was sought for knowledge about equity of access to such resources.

Through these reviewed processes, a few critical issues were identified. Apart from the occasional linguistic mismatch, a handful of patients, in particular those who attended the preoperative counseling alone, expressed confusion at the information provided by the specialist nurses. Caregivers who were unavailable for the face-to-face teaching were often left at a loss, resulting in multiple calls to the hospital for clarifications. Moreover, nurses themselves opined that the session was too overwhelming for those still fragile from receiving their diagnosis. They noticed that many of the seniors with CRC had difficulty retaining the given instructions and misplaced the reference materials provided. It was a constant challenge for 1 of the hospitals to ensure that the patients and their caregivers were competent with stoma care within the short hospitalization stay before discharge. Furthermore, peer-sharing sessions came to a halt as soon as COVID-19 emerged, further depriving the patients of the already minimal psychosocial support. These gaps highlighted major deficiencies in current practice and triggered this initiative to involve novel technologies to address the complex needs of this population.

Review of Literature and Findings From Preliminary Studies

The existing empirical evidence postulates that individuals with higher self-efficacy are more likely to be able to overcome illness-related challenges. Within the CRC population, substantial literature has reported positive associations between self-efficacy, adjustment to colostomy, lifestyle adaptation, symptom coping, social support, physical health, psychological well-being, and quality of life [8,14-19]. One study found presurgery self-efficacy, anxiety, and depression to be important predictors of one's recovery [12], and this is a significant finding because of the interdependent relationships between patients and their caregivers' self-efficacy as well as physical and mental health [20,21].

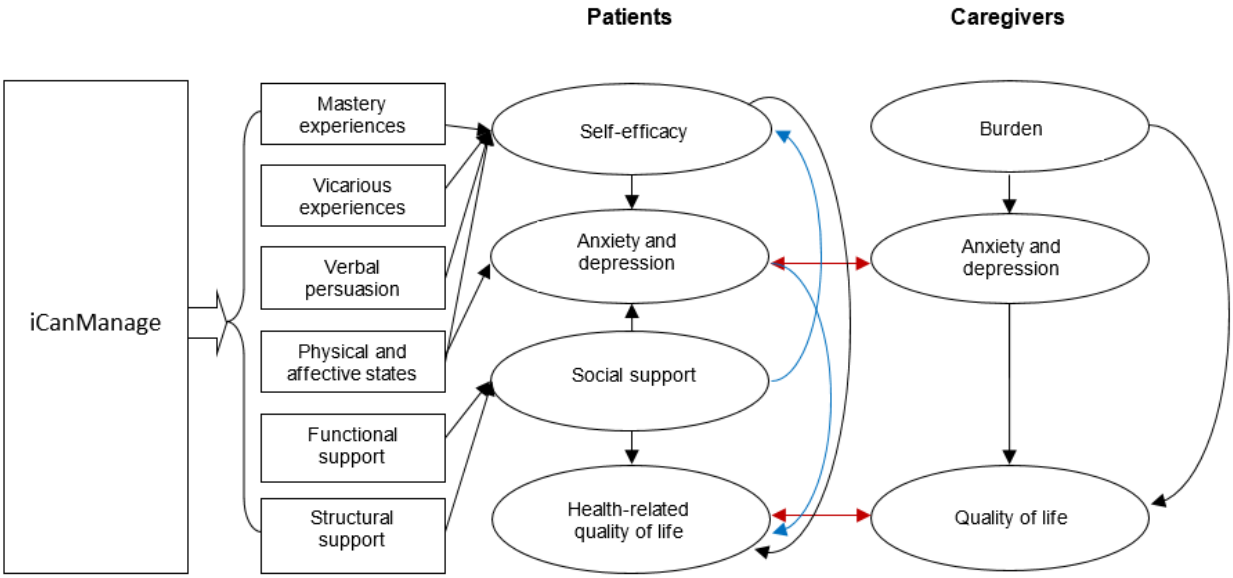
For CRC patients in particular, psychosocial care plays a subsidiary role in biomedical treatment where its positive effects on multiple mental health outcomes and quality of life have been verified in several reviews [22-24]. However, as

COVID-19 continues to persist, conventional face-to-face perioperative counseling by health care professionals has become increasingly challenging. Access to psychosocial support is limited and confined to those deemed to be at risk of significant psychological morbidity. This affects up to approximately 160 patients, who undergo elective colorectal resections annually in 1 local health care institution alone [25], and aggravates the mental distress already prevalent within this population [26]. Moreover, a preliminary study found great appetite for easily retrievable, in-depth, credible information about treatment and interest in the use of health technologies with embedded multimedia [27]. Such indications call for the need to review existing care delivery models and consider possible shifts toward the adoption of telemedicine.

Content Development Based on Self-efficacy Theory and Literature

Having put together all the gathered information, we developed the iCanManage program based on the self-efficacy theory by Bandura [28] and the interrelationships between self-efficacy, anxiety, depression, social support, burden, and quality of life, as previously described (Figure 1). This theory rides on the core assumption that the likelihood of a person engaging in a behavior depends on their conviction that they are able to successfully execute the course of action required to produce the intended outcome. Once the behavior has been adopted, the individual estimates and evaluates whether the given behavior leads to certain outcomes. In this theory, it is postulated that self-efficacy stems from four sources, namely mastery experiences, vicarious experiences, verbal persuasion, and emotional and physiological states, which we will describe in the following section.

Figure 1. Conceptual framework for the iCanManage program.



Mastery Experiences

Mastery experiences are especially influential, and they accumulate from persistent and sustained efforts in achieving performance success and overcoming failures, obstacles, and adversity. The self-efficacy developed through mastery experiences refers to resilience and the ability to quickly rebound when faced with setbacks.

Vicarious Experiences

Vicarious experiences are gained from assimilation to the successes and failures of social models. Through the observation of similar individuals who succeed, people come to believe that they too are capable of succeeding. Conversely, observing similar individuals who fail despite their high effort will lower one's expectations and prevent self-criticism.

Verbal Persuasion

Verbal persuasion from social interactions can also enhance one's perceived self-efficacy. Through the use of positive words, people's belief that they have the capacity to succeed is strengthened, and they are motivated to mobilize greater effort to sustain or confront the challenges that come their way.

Physical and Affective States

Self-efficacy is also influenced by how an individual views and understands emotional and physical reactions, including stress, tension, fatigue, and mood states, to be a reflection of their performance abilities. By learning how to regulate their responses when encountering difficult and challenging situations, one can cultivate a greater locus of control and develop self-efficacy.

CRC surgeries, unlike those for other cancer types, bring about many physical and lifestyle changes that require the acquisition of new behavior patterns [29]. Yet, successful adaptation and adjustment usually follow a feedback loop involving response consequences and predictive cues, which are largely influenced by the individual's cognitive processes and perceived locus of control [28]. Bandura's self-efficacy theory has been widely used within the cancer population to guide intervention

development, where significant positive effects on numerous health outcomes were reported [19,30]. Knowing how demanding and unpredictable the course of this illness is, it became imperative to design the iCanManage program to empower our trial participants by enabling access to the four sources of self-efficacy. By doing so, the participants will have greater preparedness for surgery, which may benefit recovery after surgery [31]. At the same time, they will also be better positioned to respond and withstand the ordeal in the long run [14]. A description of how the contents were designed based on this theory is presented in Multimedia Appendix 1.

Integration of Support Services

Apart from formal professional support, tangible and practical help are also essential for sustained adaptive coping, especially after an individual is discharged from the health care institution and reintegrates back into the community [4,32]. Hence, cancer survivors and patient ambassadors of external support groups (eg, Ostomy Association of Singapore, Singapore Cancer Society, and Patient Advocacy Network) were invited to share their personal experiences in the form of videos to relay useful messages on resuming activities of daily living while at the same time providing companionship throughout the receiving patient's cancer journey. These videos were later embedded within the digital solution.

In Singapore, a majority of patients with CRC fitted with a stoma (ie, ileostomy or colostomy) obtain their ostomy care appliances from Coloplast (Coloplast A/S) and ConvaTec (ConvaTec Group plc). For many years, these 2 companies from Denmark and the United States, respectively, have been committed to providing advanced therapies for wound, ostomy, and continence care [33,34]. To ensure our trial participants are able to manage their stoma and quickly familiarize themselves with the use of different ostomy products, partnerships with these companies were built to borrow educational multimedia for dissemination through the digital solution. This collaboration also opened a platform for the trial participants to connect with the product suppliers and ostomy care specialists directly.

Optimizing User Experience

Once the final version of the proposed contents was ready, software engineers from Buddy Healthcare were engaged to input all materials into the created digital solution known as BuddyCare. Buddy Healthcare is known for its pioneering efforts in designing award-winning automated care pathways for improved care coordination and patient engagement [35]. To date, they have over 200 care pathway templates for elective surgeries in use by hospitals across various continents (Europe, United States, and Asia Pacific), where positive results have been attained, including significant reductions in preoperative phone calls and the time spent on counseling, as well as high recommendation ratings from health care professionals who have subscribed to the platform.

To ensure seamless navigation and optimal user experience, iterative processes of trial and error took place to format and arrange the content layout to be displayed. During these evaluation sessions, some notable points were raised: (1) ensuring a sizeable but digestible amount of information load; (2) modulating the appropriate time spent and the daily app usage; (3) using elderly friendly fonts, text size, and colors; (4) using icons to increase the visibility of new instructions; and (5) controlling the frequency of reminders, alerts, and notifications.

After the smartphone-based digital solution was fine-tuned, it was formally implemented as part of the intervention component of a multicenter randomized controlled trial (NCT04159363) conducted at 2 large-scale acute tertiary hospitals. At present, the full-scale randomized controlled trial is ongoing, and the data are insufficient for analysis. However, apart from our main study outcomes, preliminary assessments and feedback on BuddyCare were solicited using the Mobile App Rating Scale: User Version (uMARS). This 20-item instrument was developed by Stoyanov and colleagues to measure the quality of mHealth apps across the 5 subscales of engagement (5 items), functionality (4 items), aesthetics (3 items), information quality (4 items), and the mHealth app's subjective quality (4 items) [36]. Each question is rated against 5 different response options, which are later summed and averaged to generate a mean score for the individual subscales. Mean scores range from 1 to 5, with higher scores denoting better quality in the particular domain represented by the subscale. This tool has been used to evaluate mHealth apps on well-being [37] and mindfulness [38], and it has been found to possess high internal consistency (Cronbach α=.90) and test-retest reliability (intraclass correlation coefficient range 0.66-0.70). Additionally, it is pitched at a readability level of those aged 12 to 13 years, which also renders it suitable for use among elderly participants who are less educated.

Prior to study initiation, the team sought and received approval from the local ethics board (National Healthcare Group Domain-Specific Review Board [2019/01002]). Written informed consent was obtained from all enrolled participants, and the respective institutions' personal data protection act will be strictly adhered to during the trial period.

Results

The iCanManage Mobile App

Our eventual product was the iCanManage mobile app on the platform of BuddyCare, which has three special features: a surgical timeline, search functionality, and a menu tab. The timeline stretches over a 29-day perioperative phase (14 days before surgery, the day of surgery, and 14 days after surgery) where users will receive information packages listing important tasks about how to prepare for surgery, postsurgery monitoring, and discharge care on a daily basis. In addition, users will also be introduced to mindfulness-based practices, which are purposed to facilitate emotional coping and regulation. Examples of such include mindful breathing, body scan, loving-kindness meditation, and mindful coping. Daily tasks are color coded based on the urgency for review and completion, and reminders are sent at scheduled timings to ensure tasks are acknowledged before they become overdue. Positive slogans are also refreshed periodically to motivate users to maintain a positive outlook or comfort them in their setbacks.

The search functionality enables participants to locate and retrieve information within the timeline easily by entering keywords. This is necessary given the vast amount of text, files, and multimedia materials embedded in the app, which may only become relevant for the user at specific time points of the treatment continuum. Users may also revisit information retrospectively or prospectively as they wish.

Under the menu tab, users will find peer support videos, ostomy care videos, and help hotlines. Through the messaging feature, users may also communicate their concerns to the attending care team and seek tailored advice. Pictures of wound and stoma conditions can be sent anonymously, and remote surveillance and consultation can be conducted. Through this digital solution, we hope users will be more equipped, confident, and independent when undergoing elective CRC surgery. During the trial period, the participants randomized to the intervention arm will be given an activation code that permits personalized access to the digital care path within the mobile app installed on their handheld devices. By doing so, individuals may feel more invested in their own treatment progress and work toward their set goals. An overview of the components and content is outlined in Multimedia Appendices 2 and 3, while screenshots of the developed solution are shown in Multimedia Appendix 4 (image A: English version; image B: Chinese version).

Preliminary Findings on the Quality of BuddyCare

The uMARS survey data from 5 patients with CRC were analyzed descriptively. Among these participants, 4 were females and 1 was male. The mean age of these participants was 57.8 years old (SD 3.77) (range: 54 to 64 years old). The mean subscale scores were 2.8/5 (SD 0.40) for engagement, 3.9/5 (SD 0.34) for functionality, 3.5/5 (SD 0.38) for aesthetics, 3.4/5 (SD 0.34) for information quality, and 2.4/5 (SD 0.42) for app subjective quality. Besides these 5 subscales, an additional component of the uMARS known as perceived impact (consisting of 6 items) rated from “1=strongly disagree” to “5=strongly agree” was measured. The mean score for perceived impact was 4 out of 5, and the overall app quality mean score was tabulated to be 3.4 out of 5. Moreover, 2 participants provided additional comments in the empty field of the questionnaire; 1 of them stated that some of the contents within the app were repetitive, while the other said it was good to try out a new program, and that it was a well-done initiative with room for improvement.

Strategies to Overcome Potential Limitations

Although much has been done to increase the usability and acceptability of the digital solution, there remain several potential limitations. For instance, elderly users who are not technology savvy may encounter difficulties when navigating the mobile app and, as a result, become more confused and distressed. Once a scenario as such occurs, users tend to become hesitant or resistant to subsequent health technologies. Moreover, poor eHealth literacy may further hinder their understanding of the presented information. Given the high incidence rates proportionate to the age of individuals diagnosed with CRC in the local context [39], we propose the inclusion of family caregivers during the trial to avoid underutilization of the app and its benefits being diminished. Study team members will provide face-to-face training on the day of recruitment to introduce all features, functions, and materials within the app. An instruction manual will be provided at the end of the training session for reference should any technical issues render the user unable to return to the app’s main page. Moreover, telephone calls will be made by academic researchers weekly to ensure the app is operating properly. Lastly, all contents were translated and will be made available in simplified Chinese language to suit the linguistic demographics of the local population. That being said, our multicenter trial will recruit both English- and Chinese-speaking patients scheduled to undergo elective CRC surgeries.

Discussion

Principal Findings

Telemedicine has been around for some time, but it was not until lately that a growing interest in interactive health communication technologies has been observed among users of health care and their providers [40]. As the world continues to battle COVID-19 and countries strive to embrace smart technologies, there is a compelling need for more initiatives to consistently lead seniors toward the adoption of digitalization, and our trial paved the way for such opportunities. In this regard, our multidisciplinary international collaboration also unveiled the following valuable insights.

Firstly, as with most studies, researchers are inclined to focus only on raising the technical skill level of the users, often forgetting that health care providers themselves ought to be knowledgeable and proficient in the said technology [41]. Cancer care is complex and requires multimodal treatment over prolonged periods of time. As mentioned earlier, disease management and self-care for patients with CRC can be exceptionally trying due to altered bowel patterns, dietary intolerance, and stoma-related concerns [42]. Multiple points of contact with various allied health care professionals are common and necessary, yet this would mean frequent hospital visits. Our collaboration is hopeful that health technologies will strengthen the delivery of holistic care through better integration of medical data, standardization of educational counseling, and increased patient autonomy. To achieve this, barriers prohibiting health care professionals from actual utilization, such as shortage of easily accessible and high connectivity computers, security issues, and the lack of staff training, should be eliminated [43].

Secondly, much controversy has been associated with web-based or online psychotherapies. The use of technology is generally perceived to impede the interpersonal therapeutic relationship between the psychologist and the patient, thereby reducing treatment effectiveness [44]. However, input from our multidisciplinary teammates ushered possibilities of transforming traditional, formal psychotherapy into informal practices that can be applied or exercised in the individual’s daily life. While such options offer greater flexibility [45], careful attention should be paid to maintain open channels for communication and assessment of patients’ responses, as well as to safeguard the confidentiality of information shared over the internet platform being used, which will be further explored in our trial.

Lastly, preliminary uMARS data from the actualization of our digital solution raised several points for reflection and future consideration. Although these findings cannot be generalized to the entire CRC population, scores of each subscale provided a glimpse of the participants' preferences and helped gauge how well the digital solution addressed their needs. According to the results, high levels of functionality, aesthetics, information quality, and perceived impact indicated that the BuddyCare mobile app is generally usable, pleasant to look at, credible, and relevant for our participants' medical condition. Conversely, moderate levels of engagement revealed that our digital solution was still lacking in interactivity and customization. This could mean that participants desire an exchange of information between themselves and the software, researchers, or clinicians, even though the enablement of such feature may increase the technical complexity of the app. In terms of subjective quality, lower-than-midpoint values suggest that the app was likely not convincing enough to warrant a recommendation to others or payment for its usage in the long run. This is reasonable given the relatively young age of these 5 participants who reported the data. The young, being more exposed to digital technologies, may have higher expectations when evaluating new mobile apps. Moreover, our findings agree with some of the consolidated themes derived from stakeholder perceptions delineated in a study by Mercer and colleagues [46]. These include the need to explore flexibility in design to achieve sustained usage, as well as to leverage the knowledge of behavioral psychology to improve user engagement. Considering these pertinent issues, more data from the full-scale randomized controlled trial will be necessary to verify and support these findings before any change is to be made to the digital solution.

Conclusion

This paper detailed the sequential development of the iCanManage smartphone-based psychosocial program to be used in a multicenter randomized controlled trial. This patient-centric digital solution will be the first to deliver a combination of surgery and psychosocial care to patients scheduled to undergo elective CRC surgeries and their family caregivers. If found to be effective, the iCanManage will see increased adherence to prescribed treatments, increased patient satisfaction through better health outcomes, and smoother transitions from hospital to home following surgery. In the long run, better allocation of personnel, time, and costs can be attained, and the economic burden can be significantly reduced when extended to elective surgeries for other disease types.

Acknowledgments

The authors wish to thank the clinicians, administrators, and those who have directly and indirectly contributed their expert or public opinion to the development of this program. This study would not have been possible without the support of the National University of Singapore, Singapore General Hospital, National University Hospital in Singapore, University of Oulu, and Buddy Healthcare Ltd Oy in Finland. The team deeply appreciates the funding provided by the Singapore Cancer Society and Business Finland. This research work is funded by the Singapore Cancer Society Cancer Research Grant 2018 and the Business Finland Grant 203/31/2018.

Abstract

Background: Previous research has confirmed that symptoms of postnatal depression (PND) can be ameliorated through internet-delivered psychological interventions. Advantages of internet-delivered treatment include anonymity, convenience, and catering to women who are unable to access face-to-face (FTF) treatments. To date, no research has examined the efficacy of such interventions compared directly with FTF treatments in women clinically diagnosed with PND.

Objective: This study aims to compare the efficacy of one of the first web-based cognitive behavioral therapy (CBT) interventions (internet CBT+coach calls) for PND (*MumMoodBooster* [MMB]) with FTF-CBT in a randomized controlled trial (RCT).

Methods: In this study, 116 postnatal women with a *Diagnostic and Statistical Manual for Mental Disorders, Fourth Edition* (*DSM-IV*) diagnosis of major or minor depression were randomized to MMB (39/116, 33.6%), FTF-CBT (39/116, 33.6%), or a treatment-as-usual (TAU) control condition (38/116, 32.8%). Diagnostic status was determined at baseline and at 21-week follow-up using the Structured Clinical Interview for the DSM-IV. Severity of anxiety and depressive symptoms was evaluated using the Depression Anxiety Stress Scales and the revised Beck Depression Inventory at baseline, 12-week follow-up (after treatment), and 21-week follow-up.

Results: Of the 116 participants, 107 (92.2%) had a diagnosis of major depression at baseline. Rates of remission from a major or minor depressive episode at 21 weeks in both the FTF-CBT and MMB groups were superior to that of the TAU group (56.6% and 47.7% less likely to be depressed, respectively) and they were not significantly different from each other. Although remission rates differed between TAU and FTF-CBT, growth models showed that, in terms of symptom reduction across time, the FTF-CBT treatment was not significantly better than TAU. By comparison, MMB was statistically superior to both TAU and FTF-CBT in reducing symptoms of depression, anxiety, and stress from baseline to the 21-week follow-up (large and moderate effect sizes). Thus, after 21 weeks, the average symptom scores for depression and anxiety of women receiving MMB were approximately half those of women in both the TAU and FTF-CBT groups.

Conclusions: In this RCT, MMB was at least as effective as FTF-CBT in achieving remission from a diagnosed PND episode. MMB was superior to TAU and FTF-CBT in encouraging and maintaining reduction of symptom severity over the 21-week follow-up for depressed postnatal women. These findings replicate results of prior studies on MMB that showed clinically significant improvements in depressive symptoms, and they provide direct empirical support that internet-delivered treatment for depressed postnatal women is a viable alternative to FTF treatment. The generalizability of the results needs to be examined

in future research, as RCTs of internet-based versus FTF treatments necessarily involve a subset of people who are willing to undertake either modality of treatment.

Introduction

Background

A substantial proportion of new mothers suffer from postnatal depression (PND). A meta-analysis by Gavin et al [1] estimated a point prevalence of 12.9% at 3 months postpartum. Left untreated, PND has significant deleterious effects on the mother (eg, absence of well-being, feelings of lack of competence in the mothering role, and interactional difficulties with her infant), her partner (eg, partner's mental health and marital functioning or couple relationship problems), and her child (eg, diminished cognitive and psychosocial development) [2-5]. Children of mothers with PND are at an elevated risk of mental health difficulties during adolescence [6].

A considerable body of research supports the effectiveness of cognitive behavioral therapy (CBT) interventions for depression in clinical settings [7,8]. Approximately two-thirds of individuals in CBT trials are no longer diagnosed with depressive disorders at follow-up [8], and CBT also reduces the risk of relapse [9], particularly in cases of mild-to-moderate depression [10]. A range of treatment approaches is effective specifically for PND, and these have been systematically reviewed by Dennis and Hodnet [11] and Cuijpers et al [12]. Treatment approaches supported by positive research findings include CBT [13], counseling [14], pharmacotherapy [15], and interpersonal psychotherapy [16]. Milgrom et al [13] successfully adapted CBT treatments to the needs of new mothers with PND. These treatments were developed to be sensitive to specific needs during the perinatal period, for example, less time commitment to homework, techniques of relaxation on the run, and inclusion of women's partners where appropriate [13].

Reviews of the available evidence [17-19] have concluded that self-guided internet interventions are beneficial to depressed individuals but that the largest effect sizes are achieved when these are combined with guided human support, typically delivered via telephone or email contact. Such support can increase adherence to internet-delivered mental health treatments [20,21] and may also provide a *safety net* for individuals who may need additional help should their situation worsen. Alliance with a *trustworthy* coach is central to this model, and a number of studies have shown that a strong web-based working alliance can be achieved in guided internet-delivered treatments for posttraumatic stress disorder and depression [22,23]. The emerging picture is that very encouraging therapeutic effects can be achieved through structured internet programs, supported by low-intensity human guidance (typically <3 contact hours in a 6-week program) [17-19].

Effectiveness of Internet Psychological Interventions

The balance of existing evidence [18,24-26] suggests that psychological treatments delivered via the internet can be as effective as traditional face-to-face (FTF) approaches [27,28]. Moderate-to-large effects are generally reported [27], although it should be noted that, in many studies, the typical counterfactuals are waitlist controls and treatment as usual (TAU). For depression and anxiety in particular, the efficacy of internet-based treatment has been demonstrated relative to control conditions in populations with elevated symptoms and increasingly in clinically diagnosed groups [25,29-34]. Multiple meta-analyses and systematic reviews of internet interventions have confirmed clinically and statistically significant improvements in symptoms compared with TAU [25,27,34-36].

The Need for Internet Interventions Specific to PND

PND is undertreated: fewer than half of perinatal women seek help even when identified as depressed [37]. Barriers to clinic-based treatment uptake include fear of stigma, being perceived as a *bad* mother, feelings of failure, poor understanding of depression or the available help, concern about medication being passed through breastmilk [38], and difficulty attending because of the demands of the new baby [39]. Internet psychological interventions may offer advantages in this population. The perception that the internet is somewhat anonymous may assist in circumventing stigma [40]. Similarly, better accessibility may be achieved with a treatment program available from home. The flexibility of being able to review program content at any time on any day in a convenient location may help in minimizing childcare logistics and fitting in with changing and sleep-disrupted family schedules. Such interventions could then potentially provide psychological treatment to many women with PND who otherwise would not access support.

Spurred by these possibilities, a number of such internet interventions have been developed to address maternal perinatal depression. Beginning with our own work [41], the delivery of cognitive and behavioral internet interventions for perinatal symptoms of depression has emerged as a major focus. Several feasibility studies and randomized trials using CBT and behavioral activation have shown significant effects on postnatal depressive and anxiety symptoms, including those in the clinically severe range [42-46]. Compared with a TAU comparison group, Milgrom et al [43] reported a 4-fold increase in remission from a diagnosed depressive disorder using the

Structured Clinical Interview for the DSM-IV (SCID-IV) at 3 months after enrollment in the 6-session internet CBT intervention named MumMoodBooster (MMB; the US program version is named MomMoodBooster). O'Mahen et al [44,45,47] reported similar reductions in depressive symptoms with a 12-session intensive coaching behavioral activation therapy (the Net Mums program). Laughnan et al [48,49] have shown encouraging short-term effects for their brief, transdiagnostic internet intervention (MUMentum postnatal) that targets symptoms of both depression and anxiety. These internet interventions vary considerably in length and in the amount and nature of guidance or support offered (ranging from extended contacts with professional therapists to brief, low-intensity *technician* or coach support). The emerging picture suggests that internet interventions may help overcome several important barriers to seeking treatment in perinatal populations, and they have the potential to offer a scalable alternative for the delivery of psychological treatments.

Meta-analyses suggest that internet interventions have achieved medium-sized effects in reducing perinatal depressive symptoms, usually in comparison with TAU or waitlist control conditions [50-52]. To date, no published study has examined the efficacy of an internet intervention versus FTF psychological treatment designed specifically for postnatal women with diagnosed depressive disorders.

Aims of This Research

This study aims to evaluate remission from clinical depression and reduction of depressive and anxiety symptom severity among a sample of postnatal women with diagnosed depression. We aim to evaluate the relative efficacy for women randomly assigned to (1) MMB, a guided version of an internet intervention for PND; (2) a validated FTF-CBT program for PND; and (3) TAU. The secondary aim of this randomized controlled trial (RCT) is to compare the 2 active conditions with respect to symptom trajectory, stress, and process measures of treatment engagement, competence in the mothering role, marital functioning, acceptability, and satisfaction.

Our a priori hypothesis was that women allocated to either of the 2 active conditions (MMB and FTF-CBT) would have significantly higher remission rates, greater reductions in depression and anxiety symptoms, and greater improvement in secondary outcomes compared with the TAU condition but that MMB and FTF-CBT would not differ significantly from each other.

Methods

Experimental Design

This study was a parallel 3-group RCT involving 116 participants and consistent with the CONSORT standards [53,54]. The trial was prospectively registered in the Australia and New Zealand Clinical Trials Registry (trial registration number ACTRN12613000881730) and was approved by the human research ethics committee of Austin Health, Melbourne (approval number H2013/04972).

Procedure

Screening and recruitment were conducted via maternal and child health centers in rural and metropolitan Victoria, Australia, and by localized advertising on the internet, in newspapers, and on the radio. The project was conducted between August 2014 and November 2017.

Inclusion criteria were determined in 2 phases. Phase 1 criteria included the following: Edinburgh Postnatal Depression Scale [55] scores of 11-25, aged ≥18 years, 6 weeks to 1 year postpartum; home internet access, familiarity with internet and email, and able and willing to give informed consent that included agreeing to be assigned to any of the 3 experimental conditions. Women who scored >0 on item number 10 of the Edinburgh Postnatal Depression Scale (thoughts of self-harm) were asked follow-up questions to ascertain intentionality, plan, lethality, access to means, and history of suicide attempts. Women deemed to be at risk of suicide were excluded and referred to receive immediate crisis attention.

Women found eligible in the screening phase 1 were subsequently assessed in phase 2 by a clinical psychologist or a provisional psychologist in a phone-administered SCID-IV [56]. Prospective study participants were excluded if they met any of the following exclusion criteria in screening phase 2: current substance abuse, manic or hypomanic symptoms or depression with psychotic features meeting the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* (*DSM-IV*) criteria, posttraumatic stress disorder, risk of suicide, and under current treatment for depression (medication or psychotherapy). Women who received a diagnosis of major or minor depressive episodes and who met all other eligibility criteria were invited to participate. Women who gave written consent and completed the baseline assessment were then randomized to a study condition.

Randomization

Women were randomized in a 1:1:1 ratio to 1 of the 3 conditions: internet-based CBT with telephone support (MMB; 39/116, 33.6%), individual FTF-CBT (39/116, 33.6%), or TAU (38/116, 32.8%). An automated permuted block (block sizes of 3, 6, and 9) allocation schedule was pregenerated by a computer by an independent technician. Allocation concealment was ensured by a central, computer-automated administration. Upon completion of baseline questionnaires, the system assigned the participants to 1 of the 3 conditions. Their allocation was subsequently revealed to them in a phone call. Given the nature of the treatment conditions, allocation could not be concealed from participants beyond the point of allocation.

Experimental Conditions

MumMoodBooster

MMB is designed to deliver content that is similar to FTF depression treatment, with tailored, interactive activities used to address individual issues and engage women. Support from a telephone coach is intended to encourage women to use and complete the program. The initial steps of the program provide explicit direction, whereas the latter steps encourage participants

to assume increasingly greater responsibility for managing their own plan for change.

MMB uses tunnel information architecture [41,57] with step-by-step guidance through 6 sessions, with a new session becoming available for use every week. Session content is similar to that found in traditional FTF-CBT treatment using a scaffold approach that builds upon concepts presented in the previous sessions. MMB's charting function was designed to help participants see the functional relationship between mood and activity levels—a key therapeutic concept in CBT that can be maximized in an internet program and, therefore, an important functionality in this program. Information from past sessions is used to reinforce gains made, and program content is tailored to individual issues with the provision of ipsative feedback [58]. A printable summary describes the key content covered in each session and a tailored list of recommended home practice activities. MMB includes content designed to enhance participant self-efficacy to accomplish recommended strategies as well as text, audios, and videos to engage participants in a program with some personalized elements. In recognition of the important role of partners and paternal depression in the treatment process of PND [59], an article in the MMB library entitled *You and Your Partner* provides content relevant to partners of women with PND. In addition, MMB enables participants to choose whether to invite their partner to use a free-standing partner support website with a separate user log-in. The MMB library also includes articles on relaxation, problem solving, and getting support for parenting (for further details on the development of the program, see the study by Danaher et al [41]). As described in earlier publications [42,43,60,61], to encourage optimal engagement and resulting behavior change [57], although the intervention can be accessed and used on smartphones, MMB was designed and optimized for use on desktop computers, laptops, and tablets and designed to function on popular browsers for both Windows PCs and Mac computers.

Weekly low-intensity telephone coaching support (30 minutes maximum per week) was provided. Rather than providing therapy per se, coaches were instructed to reinforce participant progress, encourage program use (practice of strategies and completion of tasks), and introduce the themes of upcoming sessions. In an initial welcome call, the assigned MMB coach explained the MMB core structure, additional library articles, and partner website. Coaches were able to access a secure administrative website to review each participant's program use to help tailor their support. Coaching call fidelity was facilitated by the use of a manualized script and a session-by-session checklist. Coaching calls were provided over a period of 9 weeks, which enabled participants to work through the 6 sessions at <1 session per week and allowed for the rescheduling of up to 3 missed coach calls.

The FTF-CBT Condition

Women in the FTF-CBT condition were scheduled to receive weekly individualized CBT therapy from an experienced psychologist who followed a detailed, scripted manual for delivery of the *Getting Ahead of Postnatal Depression* program [13,62]. This is a manualized 9-session CBT-based program whose core content has been shown to be effective in several RCTs [13,63,64], and this was drawn upon in the original design of MMB. The program addressed maternal mood (depression and anxiety), behavioral activation, cognitive strategies, self-esteem, relaxation (*relax on the run*), getting support, and dealing with partner issues. The program included 1 additional session that involved both participants and their partners [62].

After screening was completed on the web, the research protocol was explained to potential recruits and following a SCID-IV interview, if randomized to FTF-CBT, participants visited their general practitioner (GP) with a referral letter from the study to arrange treatment with a suitable local psychology provider located by the research team. Psychologists kept session-by-session checklists of items covered in the FTF-CBT program. A report was also sent to the GPs of participants in the other 2 conditions; however, their GPs were not actively encouraged to connect their patients with a local psychology provider.

The TAU Condition

Women in the TAU condition were referred back to their GP supplemented with a written summary of their diagnostic assessment. Support and referral to other services could then occur as necessary as typically occurs in Australia when specialized programs are not available.

Measures

Measures were collected primarily using web-based questionnaires, although phone calls were also used, as described in the following section (Table 1). All participants received automated email prompts reminding them to complete the web-based assessments. Participants were given a modest reimbursement in consideration of their time spent in completing questionnaires and assessments at the 12-week posttest and 21-week follow-up: Aus $20 (US $14.90) and Aus $35 (US $26), respectively.

[b]Measurement collected.

[c]CBT: cognitive behavioral therapy.

Primary Outcome Measures

Trained diagnostic interviewers blinded to treatment allocation conducted the SCID-IV [56] by phone to determine a *DSM-IV* diagnosis of major depression or minor depression [65]. To measure the severity of depression, we used a web-based version of the revised Beck Depression Inventory (BDI-II) [66,67], a well-validated, 21-item clinical instrument that measures cognitive, affective, and physiological factors. The BDI-II has been used in numerous studies involving perinatal women [68-70] and has been validated against diagnostic criteria in perinatal populations [69]. The 9-item Patient Health Questionnaire (PHQ-9) [71] was used as a serial measure of depression for trajectory analysis. The PHQ-9 measures depressive symptoms in the past 2 weeks; it (1) is well-validated [71,72] (including with perinatal women [73]), (2) has high test–retest reliability [74], (3) has high internal consistency (α=.86) [75], and (4) is shown to be sensitive to changes in response to treatment [76]. Participants' anxiety symptom severity was measured using the 7-item Anxiety Scale of the Depression Anxiety Stress Scale, 21-item (DASS-21) [77,78]. The DASS-21 uses a 4-point scale to describe agreement with statements over the past week and is rated as 0=did not apply to me at all, never; 1=applied to me to some degree or some of the time, sometimes; 2=applied to me to a considerable degree or a good part of the time, often; and 3=applied to me very much or most of the time, almost always. The sum of responses to the Anxiety Scale is scored as normal (0-7), mild (8-9), moderate (10-14), severe (15-19), and extremely severe (>20). The DASS-21 has good concurrent validity with other established anxiety scales [77].

Secondary Outcome Measures

CBT Skills: Negative Thinking

Participants completed the 30-item Automatic Thoughts Questionnaire (ATQ) [79]. The ATQ asks respondents to rate their agreement with a series of statements (eg, "My life is a mess") using a 5-point scale (1=not at all to 5=all of the time). The maximum ATQ score is 150.

CBT Skills: Behavioral Activation

Participants completed the 25-item Behavioral Activation for Depression Scale [80], which measures changes in activation, avoidance or rumination, work or school impairment, and social impairment. Respondents rated their agreement with a series of statements (eg, "I stayed in bed for too long even though I had things to do") on a scale of 0-6. The maximum Behavioral Activation for Depression Scale score is 150.

Maternal Self-efficacy

Drawing upon Bandura's theoretical work, Wittkowski et al [81] described parenting self-efficacy as a parent's belief in their ability to perform the parenting role successfully. To measure this, we used the Maternal Self-efficacy subscale of the Parenting Sense of Competence Scale [82], which asks respondents to rate the extent of their agreement with 7 items relating to self-perception of knowledge and competence in the mothering role. Each statement (eg, "I honestly believe I have all the skills necessary to be a good mother to my baby") is rated from 1 (strongly disagree) to 6 (strongly agree). The maximum score is 42.

Marital Functioning

Women's relationships with their partners were assessed using the 7-item Dyadic Adjustment Scale [83]. The general satisfaction score was calculated as the sum of all items. The maximum score is 36.

Treatment Satisfaction and Helpfulness

Participants in the MMB and FTF-CBT conditions were asked to rate their satisfaction with their assigned treatment as well as a set of select treatment components using a 4-point scale (0=not at all satisfied, 1=somewhat satisfied, 2=moderately satisfied, and 3=very satisfied). MMB participants were also asked to rate the helpfulness of phone coach calls using a 4-point scale (0=not at all helpful, 1=somewhat helpful, 2=moderately helpful, and 3=very helpful).

Use of Other Supports or Treatments

Participants were asked to complete a checklist of other support services and treatments they used during the study interval.

Participant Engagement

MMB use (overall number and duration of discrete visits from enrollment to the end of the follow-up assessment) was tracked continuously and unobtrusively via database flags and analysis of server activity logs (see our earlier MMB trial publications for more details [41-43]).

Coaches in the MMB condition and psychologists in the FTF-CBT condition recorded data on participant session completion on session-by-session compliance checklists itemizing the elements of each session plan covered. A subset of coaching calls and FTF-CBT therapy sessions were audio recorded (with permission) to facilitate fidelity checks.

All measures were collected at baseline, 12-week posttest, and 21-week follow-up, except for the SCID-IV diagnostic assessment, which was not conducted at 12 weeks. In addition, the PHQ-9 was also monitored during safety calls at weeks 3, 5, 9, and 16 after enrollment. The follow-up time point of 21 weeks was selected to reflect 3 months of posttreatment completion (with MMB and FTF-CBT treatment taking 9 weeks to complete).

Safety Monitoring

Symptom severity and safety of participants in each of the RCT conditions were monitored in calls for all conditions using the PHQ-9. A written risk management protocol, based on the successful approach of Simon et al [84], was initiated if any risk of harm to self or infant or marked deterioration of depressive symptoms was indicated. These assessments of symptom severity and safety were scripted and accomplished on the phone by trained research staff who were blind to the respondents' treatment allocation. In the 2 intervention conditions, weekly contact with therapists and coaches enabled additional monitoring of depression severity and safety.

Data Analysis

Depression remission was assessed using the evidence-based definition of Frank et al [85], which requires a person to be asymptomatic (defined as no longer meeting the criteria for the disorder and having ≤2 symptoms for ≥2 weeks).

Categorical outcomes (eg, diagnostic status based on the SCID-IV) were analyzed using contingency tables and logistic regression; survival analysis (Cox regression and Kaplan–Meier product limit) was used to predict time-to-remission of the index depressive episode using the results from follow-up interviews. Continuous outcomes (eg, symptom severity) were analyzed using random-effects regression models, accommodating time-independent and time-dependent covariates, fixed and random factors, and incomplete data.

Random-effects growth models were estimated from baseline (the intercept) to the 21-week follow-up using the PROC MIXED procedure in SAS 9.2 (SAS Institute). The growth models were estimated with full information maximum likelihood and an unstructured variance/covariance matrix, and the intercepts and slopes were allowed to vary. First, unconditional means models were run for each outcome and the estimated and observed data plotted. Next, linear conditional growth models were run with time coded in weeks since the pretest assessment. All primary analyses to address major hypotheses adhered to intention-to-treat principles, and 3 a priori comparisons were examined: MMB versus TAU, FTF-CBT versus TAU, and MMB versus FTF-CBT (for each comparison, the first group was the reference group). The condition×time interaction is a test of the efficacy of the program for each a priori comparison. The effect size for the condition×time interaction was computed as a d-statistic equivalent [86].

Descriptive statistics and plots were used to screen all outcomes for normality and outliers. No serious violation of normality was found, with the exception of anxiety at 12 and 21 weeks, which showed a preponderance of zeros. During modeling, anxiety scores were examined in their normal metric and also log transformed to better approximate normality. A participant was flagged as an outlier on anxiety and stress at the 12-week assessment. During modeling, the outlier was evaluated for its impact on change over time.

Clinical Significance, Power, and Sample Size

An a priori consideration of power suggested that for the survival analysis predicting time-to-remission from the index episode, with a 2-tailed α of .05, n=70 per condition would yield 80% power to detect a small effect size (hazard ratio 2.0). For the measure of depressive symptoms (BDI-II), data from previous work by Milgrom et al [13] provided a baseline value=23, σ=8.09. A difference of 6.5 takes scores below the threshold of *clinical* depression (ie, a score <17 points). With 80% power at α=.05, the required $n=15.7\times(8.09/6.5)^2=24.3$, which rounds up to 25. Taking into account a prudent noncompliance rate of 30%, the adjusted sample size, $n^* = 25 / (1 - 0.3)^2 = 51$, which rounds up to 55. Thus, an estimated n=70 per condition yielded sufficient power to detect a small between-group effect size and a minimum clinically important difference in the primary measure of symptom severity. This sample size was not achieved within the funding period; however, post hoc analysis of power with the sample size achieved confirmed sufficient power to address the minimum clinically important difference for the primary outcomes. We had sufficient power (>80%) to detect significant group differences ($P<.05$) in our primary outcomes. We used a simulation approach with 1000 replications using the likelihood ratio test [87] and implemented it in SAS. We estimated the power to detect condition effects for changes in the primary outcomes. Unlike the a priori power estimates, this post hoc power estimation included observed parameter estimates (eg, sample size, effect size, and correlations between intercept and slope). Thus, this study was sufficiently powered to detect group differences between MMB and TAU for medium to large effects.

Depressive Symptom Trajectory

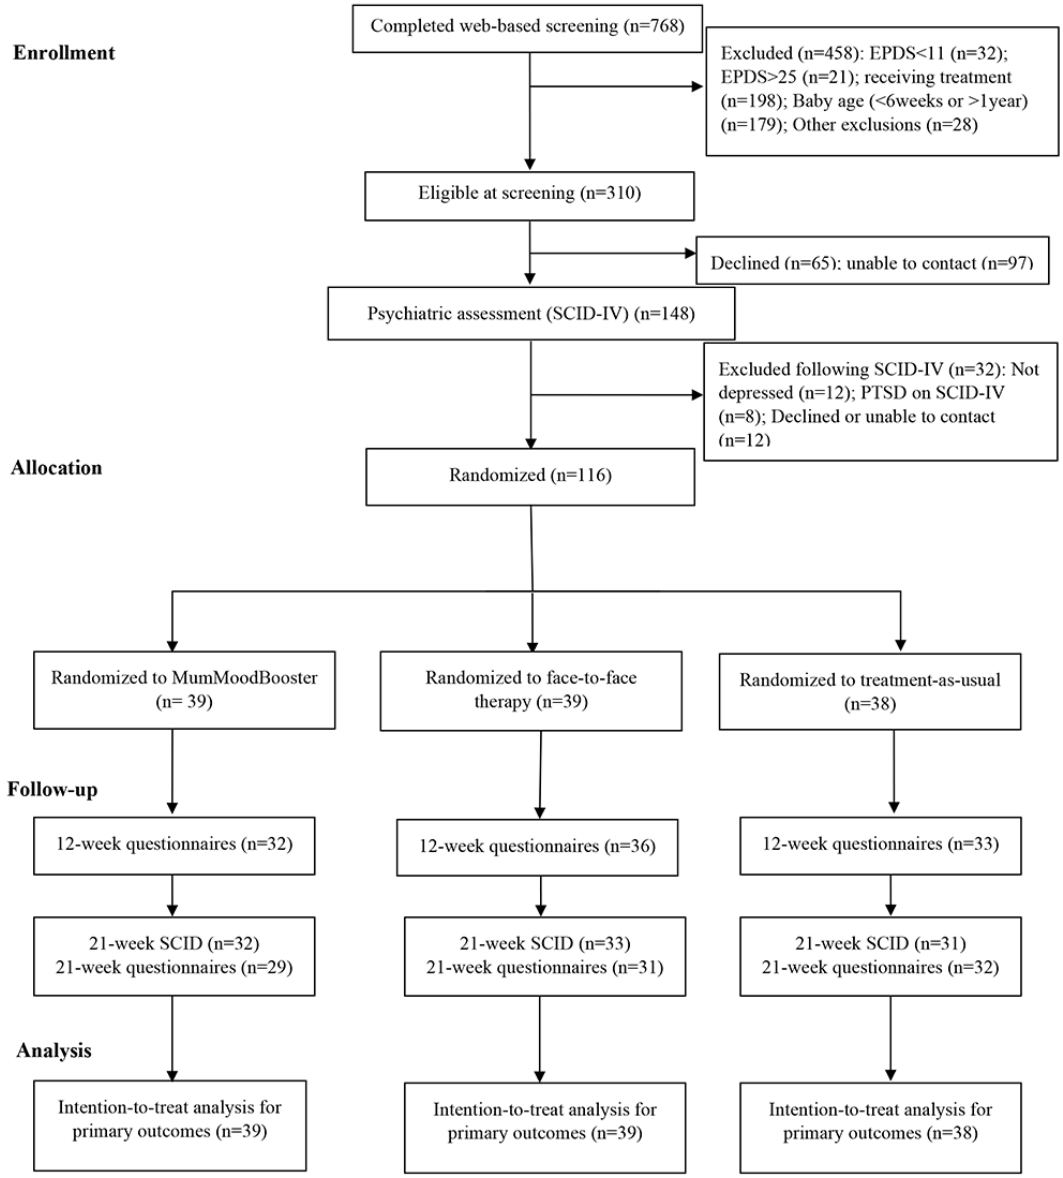
At baseline and during the routinely scheduled safety monitoring calls (at weeks 3, 5, 9, 12, and 21), all participants completed the 9-item PHQ-9 over the telephone. These data were used to calculate the trajectory of depressive symptom changes over time.

Results

Sample

A total of 116 participants were randomized during the study period. Figure 1 presents a CONSORT chart of participant flow through the trial.

Figure 1. Participant flow through the study. EPDS: Edinburgh Postnatal Depression Scale; PTSD: posttraumatic stress disorder; SCID-IV: Structured Clinical Interview for the DSM-IV.



Participant Characteristics

A range of primiparous and multiparous, high-income and low-income women were included (see participant baseline characteristics in Table 2). On average, participants were aged 32.1 years (SD 4.7); 66.4% (77/116) of participants were married, and regarding the highest level of education, 12.2% (14/115) completed high school, 26.1% (30/115) had completed a bachelor's degree, and 34.8% (40/115) had completed graduate or postgraduate programs. The average infant age was 26.1 (SD 14.5) weeks. Chi-square tests and one-way analysis of variance were used to examine baseline demographic characteristics by condition. No group differences were found, confirming that randomization produced initially equivalent groups.

[a]Column totals in percentages may not sum to 100; values in percentages are rounded upwards to the nearest full integer.

[b]MMB: MumMoodBooster.

[c]FTF-CBT: face-to-face cognitive behavioral therapy.

[d]TAU: treatment as usual.

Missing Data and Attrition

Failure to complete scheduled assessments (attrition from the study) was 12.9% (15/116) at the 12-week assessment and 20.7% (24/116) at the 21-week assessment (Figure 1). Analysis indicated that attrition at these times was not related to study condition (P=.57), any of the demographic characteristics in Table 1 (all P>.22), or baseline measures of the primary or secondary outcomes (all P>.07).

Engagement in MMB Program

Of the women allocated to the MMB intervention, 85% (33/39) completed ≥3 MMB sessions, and 72% (28/39) viewed all 6 MMB sessions. The MMB program was not visited by 3% (1/39) of participants. Of the women who visited MMB at least

once, the mean number of sessions viewed was 5.6 (SD 1.7), and the mean number of visits was 15.6 (SD 8.7). The mean total time spent using MMB averaged 230 (range 2-440) minutes. The mean number of library articles accessed was 3.5 out of a possible 8, and the mean number of activities accessed was 15 out of 63. Approximately 39% (15/39) of participant partners accessed the partner support website.

Engagement in FTF-CBT

Of the women offered FTF-CBT, 62% (24/39) completed ≥3 sessions, 51% (20/39) finished ≥6 sessions, and 46% (18/39) completed all 10 sessions. Approximately 31% (12/39) of women did not attend any FTF sessions. The mean number of FTF-CBT sessions attended for all 39 women was 5.5 (SD 4.5).

Primary Outcomes

At baseline, all women in all 3 groups had a *DSM-IV* diagnosis of either major or minor depression; 92.2% (107/116) of the sample had a major depression diagnosis. Table 3 shows the change in the profile of depressive diagnostic status from baseline to the 21-week follow-up. On the basis of the observed data available at the 21-week follow-up assessment, the FTF-CBT group was 56.6% less likely to have a diagnosis of major or minor depression relative to the TAU group. The MMB group was 47.7% less likely to have a diagnosis of major or minor depression relative to the TAU group. Remission rates in the FTF-CBT and MMB conditions were not significantly different from each other (χ^2_1=0.1, *P*=.81). Table 4 provides descriptive statistics for the primary continuous outcome measures for each of the 3 conditions at baseline, 12 weeks, and 21 weeks, and Table 5 provides descriptive statistics for the secondary outcome measures.

Table 3. Diagnostic status of participants from baseline to the 21-week follow-up (N=116).

Conditions	Baseline, n (%)		21-week follow-up, n (%)			
	Major	Minor	Major	Minor	Lost to follow-up	Remission[a]
MMB[b] (n=39)	36 (92)	3 (8)	4 (10)	3 (8)	7 (18)	25 (78)
FTF-CBT[c] (n=39)	35 (90)	4 (10)	5 (13)	1 (3)	6 (15)	27 (82)
TAU[d] (n=38)	36 (95)	2 (5)	12 (32)	1 (3)	7 (18)	18 (58)

[a]Remission was defined as the absence of a Structured Clinical Interview for the DSM-IV diagnosis for major or minor depression at the follow-up interview and excludes cases lost to follow-up.

[b]MMB: MumMoodBooster.

[c]FTF-CBT: face-to-face cognitive behavioral therapy.

[d]TAU: treatment as usual.

Table 4. Descriptive statistics for continuous primary outcomes.

Primary outcome	Baseline, mean (SD)	12-week, mean (SD)	21-week, mean (SD)
Depressive symptoms (BDI-II)[a,b]			
MMB[c]	28.10 (7.91)	11.63 (8.96)	8.70 (6.92)
FTF-CBT[d]	27.18 (9.95)	21.36 (12.15)	15.00 (10.71)
TAU[e]	29.97 (8.76)	18.85 (10.16)	17.41 ()11.51
Anxiety symptoms (DASS-21)[f,g]			
MMB	8.87 (7.02)	1.81 (2.61)	2.69 (4.29)
FTF-CBT	9.23 (7.31)	8.11 (8.01)	4.45 (5.45)
TAU	8.58 (7.85)	4.73 (5.22)	5.19 (5.52)

[a]BDI-II: Beck Depression Inventory, revised.

[g]CBT: cognitive behavioral therapy.

[h]BADS: Behavioral Activation for Depression Scale.

[i]ATQ: Automatic Thoughts Questionnaire.

[j]PSOC: Parenting Sense of Competence Scale.

Growth Models

Parameter estimates from the growth models for each a priori comparison are provided in Tables 6-8. These include parameter estimates for intercept, condition, time, and condition×time interaction.

In Table 6, the intercept reflects the model-implied estimated baseline depressive score (PHQ-9) for the TAU group (29.02). The *t* value and *P* value indicate that the intercept is significantly different from 0 (*P*<.001). The condition parameter (−2.154) indicates that the MMB condition had an estimated baseline score that was 2.15 points lower than the TAU group. The *t* value and *P* value indicate that the lower baseline depressive score for the MMB condition was not statistically significant (*P*=.24). The time parameter (−0.614) indicates that the TAU group had an estimated linear decrease in depressive symptom score of 0.61 points for each week through the 21-week follow-up assessment. The *t* value and *P* value indicate that the weekly linear decrease for the TAU group is significantly different from 0 (*P*<.001). The condition×time interaction term (−0.3029) indicates that the MMB group decreased an additional 0.30 points each week through the 21-week follow-up. The *t* value and *P* value indicate that the greater decrease over time for the MMB group relative to the TAU group was statistically significant (*P*=.01). Figure 2 shows the trajectory of the PHQ-9 scores for each condition over the course of the study. Significant condition×time effects were also found for anxiety and perceived stress (Table 6), indicating that MMB was statistically superior to TAU in reducing symptoms of depression, anxiety, and stress from baseline to the 21-week follow-up.

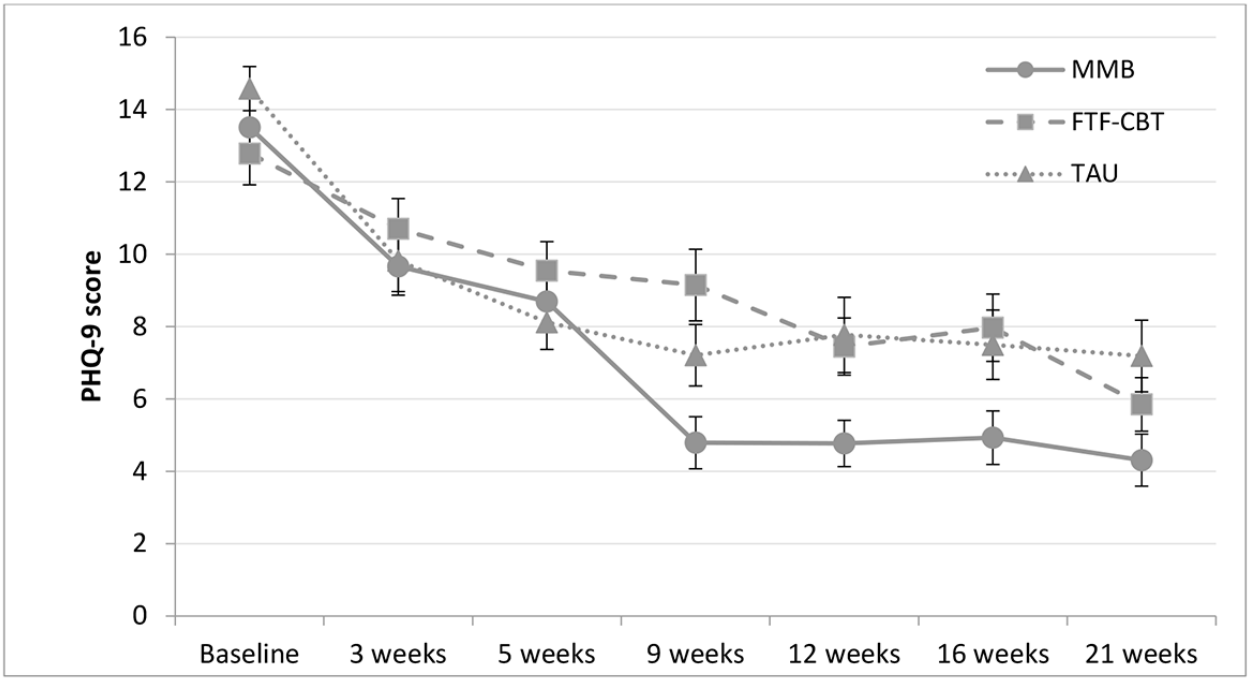
[c]PSOC: Parenting Sense of Competence Scale.

Figure 2. Change from baseline to 21-week follow-up for the MMB, FTF-CBT and TAU groups on the PHQ-9. Mean values are observed values plotted ±1 SE. PHQ-9 score ranges: minimal or none=0-4, mild=5-9, moderate=10-14, moderately severe=15-19, and severe ≥20. FTF-CBT: face-to-face cognitive behavioral therapy; MMB: MumMoodBooster; PHQ-9: Patient Health Questionnaire–9; TAU: treatment as usual.



Tables 7 and 8 show the results for the other a priori comparisons: FTF-CBT versus TAU and MMB versus FTF-CBT. Although none of the condition×time effects were significant for the FTF-CBT versus TAU comparison (Table 7), the MMB versus FTF-CBT comparison revealed that MMB performed significantly better than FTF-CBT in reducing depressive symptoms and perceived stress (Table 8).

The effect size (*d*) for all the condition×time interaction terms is presented in Table 9. Compared with TAU, the MMB group reported a large reduction in depressive symptoms (*d*=−0.83) and medium-sized reductions in anxiety (*d*=−0.42) and perceived stress (*d*=−0.73). Compared with the FTF-CBT condition, MMB participants reported large reductions in both depressive symptoms (*d*=−0.98) and perceived stress (*d*=−0.89). The TAU and FTF-CBT conditions did not differ significantly in any of the outcome measures.

Use of Other Treatments

Of the 79.3% (92/116) of participants who responded to this questionnaire, approximately 19% (6/32) of participants in the TAU group and 6% (2/31) of participants in the FTF-CBT group reported using depression medication. None of the MMB participants reported using medication. Approximately 3% (1/31) of women in the FTF-CBT group, 7% (2/29) of women in the MMB group, and 6% (2/32) of women in the TAU group reported having taken part in group therapy. Approximately 23% (7/31), 21% (6/29), and 13% (4/32) of women in the FTF-CBT, MMB, and TAU conditions, respectively, reported using self-help books, and 2 women each in the MMB and TAU groups reported having used acupuncture or hypnotherapy.

Helpfulness and Satisfaction

Participants in the 2 active conditions (FTF-CBT and MMB) rated the helpfulness of their treatment on a rating scale of 0 to 3. Compared with those in the MMB group (mean 2.31, SD 0.89), participant ratings in the FTF-CBT group (mean 2.84, SD 0.38) were significantly higher ($P=.02$).

MMB participants rated the helpfulness of the coach calls an average of 2.56 (SD 0.67) out of a possible 3 points. MMB participants further rated their satisfaction (from 0 to 3) with the following features of the internet program: mood tracking (mean 2.06, SD 0.91), pleasant activities (mean 2.28, SD 0.85), strategies to reduce negative thinking (mean 2.26, SD 1.03), strategies to increase positive thinking (mean 2.19, SD 0.91), partner support program (mean 1.19, SD 1.02), library articles (mean 1.96, SD 1.04), and videos (mean 1.87, SD 1.07).

Discussion

Existing research confirms that PND can be successfully treated by internet-delivered psychological interventions [51]. However, no previously published study has made a direct comparison of the efficacy of such interventions with traditional FTF treatment in a clinically diagnosed population.

Principal Findings

In a sample of postpartum women, 92.2% (107/116) of whom had a major depression diagnosis and were in the moderate-to-severe range for depression symptoms on the BDI-II, we found that the MMB internet-delivered treatment program performed at least as well as FTF-CBT on remission from a diagnosed depressive episode at 21 weeks. Moreover, MMB was also significantly more effective than FTF-CBT in reducing depression symptom severity and perceived stress over time. Compared with TAU, MMB was significantly more effective in reducing depression, anxiety, and perceived stress. At follow-up, depression and anxiety symptom scores for MMB participants were approximately 50% lower than those observed in the FTF-CBT and TAU conditions.

These results are broadly consistent with the literature that delivery of psychological treatments via the internet can be as effective as traditional FTF approaches for treating depression and anxiety [26-28,88,89]. Moderate-to-large effects are generally reported [90], although it should be noted that in many studies, waitlist controls and TAU are the typical comparators. The findings also parallel the results from our previous RCT [43], which showed a significantly larger reduction in depression symptoms in the MMB condition compared with TAU.

The use of coaches as an adjunct to the MMB program may have contributed to the relatively low attrition in this condition and enhanced the effectiveness of the MMB program. This is consistent with our previous trials of MMB [43,91] and with current evidence suggesting that fully automated treatments can be enhanced through support, whether guided by a technician or therapist via phone, email, or SMS text messages [19,29,31]. For example, Karyotaki et al [92] conducted a meta-analysis of a range of guided internet interventions for depression and found

significantly better efficacy for guided interventions compared with fully automated interventions. The current evidence base confirms that self-guided interventions do produce benefits; however, guided support seems to enhance the efficacy of many internet interventions [25,27,93].

Strengths

This study has a number of strengths. First, this RCT produced very similar effect sizes for reductions in depression and anxiety symptoms and the rate of session attendance and program adherence compared with those we observed in our 2 previous trials of MMB [42,43]. In our earlier RCT [43], MMB produced a 4-fold difference in remission compared with TAU as measured at the 12-week follow-up. In this study, follow-up occurred considerably later (at 21 weeks). Remission rates in the MMB condition were still found to be similar to those in our previous RCT [43] and superior to TAU, albeit with a smaller between-group difference in depression remission rate than at 12 weeks in the previous trial. This may indicate that the gains made during the program were maintained over this longer follow-up period. This difference between our previous RCT (measured at 12 weeks) and in our current RCT (measured at 21 weeks) is perhaps not unexpected, given that meta-analyses suggest considerable spontaneous remission rates even in untreated individuals over longer time frames [7].

Importantly, this research provides the first direct comparison of internet-delivered psychological treatment for perinatal depression with evidence-based FTF treatment. This was achieved in a sample of women clinically diagnosed with depressive disorders rather than in a sample of women with a mix of subclinical symptoms assessed using screening tools as in many existing studies.

Furthermore, the rate at which participants accessed other treatments outside of those provided in the trial was low and appeared similar in the 2 active treatment groups. However, despite the higher use of *other supports* found in the TAU group, the participants assigned to the MMB condition reported greater reductions in depression and anxiety symptom scores.

Our use of a 3-arm RCT that included TAU and intention-to-treat analyses gives us further confidence in interpreting these results. As such, this study extends the literature showing promising results from trials of internet-based treatments for PND [50,51].

The FTF-CBT intervention was primarily provided by practicing psychologists in the community, making the comparison as close an approximation as possible to a real-world treatment option. In Australia, FTF-CBT is 1 of the 2 main treatments that postnatal women with depression are likely to be offered (the other being antidepressant medication).

As our results showed that MMB was at least comparable with traditional FTF-CBT in efficacy, its more widespread implementation could potentially increase the reach of treatment to benefit women with PND not currently accessing traditional services because of geographic or social isolation or through a preference for anonymous, nonclinical settings.

Limitations

The study has a number of limitations that should be noted, some of which are common to most RCTs. Our observed 21-week outcomes may have reflected some cases in which relapse occurred after treatment completion, perhaps in both of the active treatments as well as some spontaneous recovery over time in the TAU group. Participants in this study agreed to be assigned to any of the 3 possible experimental conditions; therefore, they may be a particular subset of the population and not representative of postnatal women with depression as a whole. It is possible that our study results may not generalize to women who would have preferred to use only the internet intervention (MMB) or alternatively only attend the clinic-based FTF-CBT treatment. Furthermore, given the nature of the intervention, the participants could not be blinded beyond the point of treatment allocation. Finally, the limited sample size was not sufficiently powered to examine subgroup differences or the moderating effects of baseline participant characteristics.

Future Directions

Emerging evidence suggests that the COVID-19 pandemic is seeing substantial increases in perinatal mental health difficulties [94,95] concurrent with mandatory restrictions on population movement. Therefore, access to FTF psychological services may be problematic in many locations, and effective, accessible internet interventions for perinatal depression are likely to be highly relevant. There is increasing recognition that the impact of real-world implementation of internet mental health interventions and their cost-effectiveness [96] depends upon how treatments are configured and integrated into the mental health treatment landscape as a whole [97,98].

Various options for deploying digital delivery as part of a *blended* or guided approach that combines clinical therapy or counseling with internet program content show promise [99-101], with relevance across a range of diagnoses [102]. Systematic reviews suggest that programs that combine traditional and digital approaches can achieve clinically meaningful effects on depression and anxiety outcomes [103], and based on current evidence [96,104,105], it seems reasonable to infer that internet CBT could also be a cost-effective complement to the support provided to women with PND in primary care. An important potential advantage is that internet CBT can be commenced more or less immediately, with reduced or no waiting time. This could facilitate very early intervention if, for example, the intervention program were linked to routine depression screening in the very early postpartum period.

Evaluation is also warranted for the stepped-care model or adaptive treatment strategies for moderate depression and anxiety symptoms that offer a standalone internet intervention as an initial treatment option [106,107]. Future research is needed to examine program effectiveness and implementation scenarios associated with offering standalone internet PND interventions that do not include human guidance. For example, the scalability and sustainability of supported internet CBT depend at least in part on the resources available to such programs, so that unguided programs of comparable efficacy may be a useful alternative in many service delivery contexts [34]. Important questions also remain around issues such as

patient adherence and the specific health care population from which users of internet psychological interventions are drawn, both in the real-world setting [108,109] and in efficacy RCTs [110]. We found some evidence that session attendance in the MMB condition may have been somewhat higher than in FTF-CBT. Finally, variations of (or complements to) MMB deserve additional research attention, including internet depression treatment programs for pregnant women as well as for new fathers who have so far been largely neglected.

Conclusions

The current trial replicated key findings of prior MMB studies, providing further evidence that internet-delivered treatment for postnatal women with depression is a viable treatment option. These findings are broadly consistent with the notion that speed of access, anonymity, and convenience may be specific advantages of internet-delivered treatment for women who prefer not to engage in traditional treatment modalities. Notably, this study also provides empirical evidence that participants assigned to the MMB condition report greater treatment gains compared with those assigned to the TAU and FTF-CBT conditions.

Acknowledgments

The authors thank all the women who took part in the study. Sarah Maher at the Parent-Infant Research Institute kindly assisted with data retrieval, management, screening, and cleaning. This work was supported by a grant from the National Health and Medical Research Council, Australia (project grant 1046875).

Authors' Contributions

JM, BGD, JRS, MST, JE, and CH conceived the MumMoodBooster intervention. JM, AWG, BGD, JRS, CH, and CJH contributed to the study design and funding applications. JM, CJH, CH, JE, and AWG implemented the trial procedures and collected the data. CH, JM, and JE trained the phone coaches. CJH project managed this trial. JRS (50%), JM (30%), BGD (10%), and AWG (10%) designed and executed the statistical analysis. AWG and JRS wrote the bulk of the first draft of the manuscript. All authors contributed to subsequent drafts, interpretation of results, and approval of the final manuscript for submission.

Conflicts of Interest

None declared.

Abstract

Background: The long-term management of irritable bowel syndrome (IBS) poses many challenges. In short-term studies, eHealth interventions have been demonstrated to be safe and practical for at-home monitoring of the effects of probiotic treatments and a diet low in fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs). IBS has been linked to alterations in the microbiota.

Objective: The aim of this study was to determine whether a web-based low-FODMAP diet (LFD) intervention and probiotic treatment were equally good at reducing IBS symptoms, and whether the response to treatments could be explained by patients' microbiota.

Methods: Adult IBS patients were enrolled in an open-label, randomized crossover trial (for nonresponders) with 1 year of follow-up using the web application IBS Constant Care (IBS CC). Patients were recruited from the outpatient clinic at the Department of Gastroenterology, North Zealand University Hospital, Denmark. Patients received either VSL#3 for 4 weeks (2 × 450 billion colony-forming units per day) or were placed on an LFD for 4 weeks. Patients responding to the LFD were reintroduced to foods high in FODMAPs, and probiotic responders received treatments whenever they experienced a flare-up of symptoms. Treatment response and symptom flare-ups were defined as a reduction or increase, respectively, of at least 50 points on the IBS Severity Scoring System (IBS-SSS). Web-based ward rounds were performed daily by the study investigator. Fecal microbiota were analyzed by shotgun metagenomic sequencing (at least 10 million 2 × 100 bp paired-end sequencing reads per sample).

Results: A total of 34 IBS patients without comorbidities and 6 healthy controls were enrolled in the study. Taken from participating subjects, 180 fecal samples were analyzed for their microbiota composition. Out of 21 IBS patients, 12 (57%) responded to the LFD and 8 (38%) completed the reintroduction of FODMAPs. Out of 21 patients, 13 (62%) responded to their first treatment of VSL#3 and 7 (33%) responded to multiple VSL#3 treatments. A median of 3 (IQR 2.25-3.75) probiotic treatments were needed for sustained symptom control. LFD responders were reintroduced to a median of 14.50 (IQR 7.25-21.75)

high-FODMAP items. No significant difference in the median reduction of IBS-SSS for LFD versus probiotic responders was observed, where for LFD it was –126.50 (IQR –196.75 to –76.75) and for VSL#3 it was –130.00 (IQR –211.00 to –70.50; *P*>.99). Responses to either of the two treatments were not able to be predicted using patients' microbiota.

Conclusions: The web-based LFD intervention and probiotic treatment were equally efficacious in managing IBS symptoms. The response to treatments could not be explained by the composition of the microbiota. The IBS CC web application was shown to be practical, safe, and useful for clinical decision making in the long-term management of IBS. Although this study was underpowered, findings from this study warrant further research in a larger sample of patients with IBS to confirm these long-term outcomes.

Introduction

Irritable bowel syndrome (IBS) is a functional gastrointestinal disorder that affects 10% to 20% of the population in westernized countries [1]. The main gastrointestinal symptoms include bloating, pain, diarrhea, constipation, and altered bowel habits; psychological comorbidity is common with IBS, thereby symptoms are often accompanied by coexisting conditions like stress, anxiety, and depression that, together, greatly impact patients' quality of life (QoL) [1-3]. Studies have shown that approximately 60% [4] of IBS onset is associated with psychosocial stressors, and up to 32% [5] is associated with prior acute gastroenteritis. The pathophysiology of IBS is not fully understood, but some of the underlying mechanisms include altered gastrointestinal motility, visceral hypersensitivity, psychosocial disturbance, low-grade inflammation, altered gut-brain function, and microbial ecosystem dysbiosis [3,6].

Managing IBS continues to be challenging because of the complexity of its chronicity, heterogeneous patient groups with and without comorbidities, and a lack of both diagnostic tools and well-documented treatment strategies for long-term purposes. Treatment strategies for IBS range from lifestyle and dietary advice to pharmacological solutions that generally target only the primary symptom. Recently, holistic eHealth solutions that monitor symptoms and support patients with digestive diseases have proven valuable in involving and empowering patients, and are used as an adjuvant to current treatment regimens [7,8]. Ideally, an app for IBS would include dietary education supported by clinical dieticians, since dietary triggers are reported to be central to symptom generation in 50% to 84% of patients with IBS [7,9].

An exclusionary diet low in fermentable oligosaccharides, disaccharides, monosaccharides, and polyols (FODMAPs) has proven effective in reducing gastrointestinal symptoms, in particular abdominal pain, bloating, and diarrhea [10], with a response rate between 50% and 80% among patients with IBS [9]. In addition, a low-FODMAP diet (LFD) has been shown by some studies to improve the disease course of IBS [11,12] and inflammatory bowel disease (IBD) with IBS-like symptoms [11]. A previous study has shown that short-term, web-based management of IBS patients, while treating their symptoms with LFD and probiotics, is practical and effective [13]. Yet, the LFD has also been linked to a reduction in beneficial gastrointestinal bacteria [14] and to compromise nutritional intake, especially calcium [15]. Therefore, eventual reintroduction of foods high in FODMAPs is essential in long-term management [9].

The composition of gut microbiota differs between subgroups of IBS patients and healthy individuals [16]. This fact, together with an increasing awareness of the importance of a "healthy gut" and the gastrointestinal microbiome, has led to growing research, financial investment, and consumer interest in probiotic treatments that may provide benefits to patients with IBS [17,18]. Probiotic treatments are not currently included in recommended treatment strategies for IBS, but in some countries, national guidelines, such as those issued by NICE (the National Institute for Health and Care Excellence) in the United Kingdom [19], suggest that IBS patients could benefit from probiotic treatments for alleviating symptoms. However, the results for various probiotic solutions, as well as their dosing, duration, and efficacy as a treatment for IBS, are inconclusive [18,20,21]. Moreover, probiotic treatments do not seem to sustain any of the microbial changes they induce after cessation of treatment [22].

So far, no one has been able to fingerprint patients based on their fecal microbial composition and tailor a particular intervention for them individually [4].

The primary aim of this 1-year, web-based study was to determine whether a 4-week probiotic treatment, VSL#3 (Actial Farmaceutica Srl), and the LFD were equally as effective at reducing IBS symptoms, and whether the response to either of the two treatments could be explained by fecal microbiota. The study's secondary aims were to evaluate patients' QoL, the effect of multiple VSL#3 treatments in sustaining symptom control across 1 year, and reintroduction of FODMAPs among LFD responders, as well as to evaluate the web application IBS Constant Care (IBS CC) [23] for its efficacy in long-term clinical use.

Methods

Participants

Adult IBS patients, 18 years or older, fulfilling the Rome III criteria and subdiagnosed with either IBS-diarrhea (IBS-D) or IBS–mixed type (IBS-M) by a gastroenterologist were consecutively included in the study at North Zealand University Hospital (August 23, 2018, to October 18, 2019). Patients were excluded if they did not have a smartphone, had previously undergone gastrointestinal surgery, had been diagnosed with celiac disease or lactose intolerance, had been subdiagnosed with constipation or unspecified IBS, were pregnant, followed alternative diets, had a history of alcohol or drug abuse, had a BMI below 18.5 or above 35 (calculated as weight in kg divided by height in m^2), had been diagnosed with any comorbidities (eg, diabetes), had previously been on an LFD guided by a dietician, had been on any probiotic or antibiotic treatment within the 3 months prior to inclusion, or had an IBS severity score lower than 175 at inclusion.

Healthy controls (HCs) older than 18 years, with a normal BMI (18.5-25), fecal calprotectin (FC) less than 70 mg/kg, and not taking daily medication or food supplements were recruited internally from our institution.

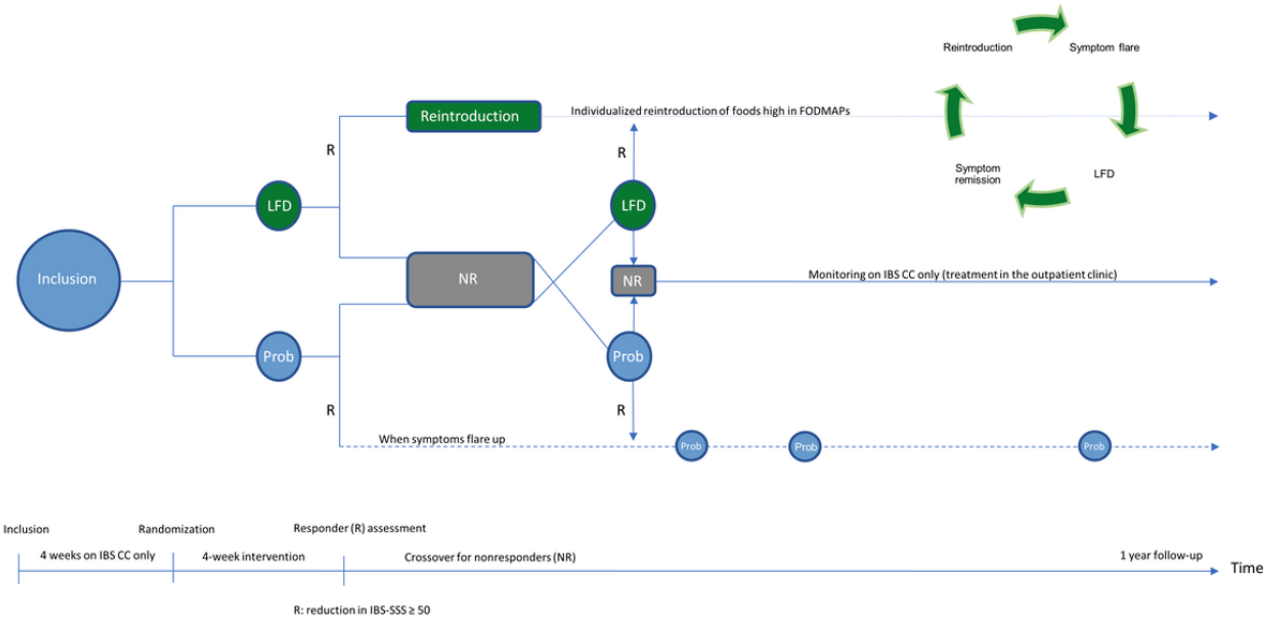
The Ethical Committee of Denmark (H-16023499) and the Danish Data Protection Agency (I-Suite No. 6262, NOH-2018-002) approved this study. The study was registered at ClinicalTrials.gov (NCT03586622; see Multimedia Appendix 1 for the CONSORT-EHEALTH checklist). All patients in the study gave written informed consent prior to their inclusion.

Study Design and Protocol

Overview

This eHealth study was an open-label, randomized, crossover trial (for nonresponders), with 1 year of follow-up (Figure 1). HCs home-monitored their weight, QoL, and symptoms at four points during the year using the IBS CC web application. These measurements were then represented in a traffic light format to the participants (see the Applications Used in the Study section for a description). At inclusion, patients were trained, for approximately 1 hour, in home monitoring of symptoms using IBS CC, including inflammation measured via FC. FC was measured using the CalproSmart app (Calpro AS). Patients were instructed to home-monitor every week for at least 4 weeks before randomization to either the LFD or probiotic treatment group.

Figure 1. The 1-year design of this study. The IBS Constant Care (IBS CC) web application was used for home monitoring of symptoms and clinical decision making. Treatments included 4 weeks of monitoring on IBS CC, followed by randomization to either a 4-week low-FODMAP diet (LFD) or probiotic treatment (Prob; VSL#3, Actial Farmaceutica Srl). Responders (R) to the LFD would subsequently be reintroduced to foods higher in FODMAPs. Responders to probiotic treatment would receive multiple treatments upon symptom flare-ups (ie, an increase in the IBS Severity Scoring System [IBS-SSS] of more than 50 points). Response was defined as a decrease in IBS-SSS of at least 50 points. Nonresponders (NR) waited for a minimum of 2 weeks wash-out before being crossed over (this is not shown in the figure). FODMAPs: fermentable oligosaccharides, disaccharides, monosaccharides, and polyols; IBS: irritable bowel syndrome.



Patients randomized to the LFD group had a consultation at the hospital with a nutritionist, who guided the patients individually through the diet's principles and how to monitor their symptoms (see Multimedia Appendix 2 for home monitoring and screening intervals). Patients randomized to the probiotic treatment group were instructed on how to consume the sachets and home-monitor using IBS CC during treatment (Multimedia Appendix 2). After 4 weeks of either the LFD or probiotic treatment, patients' response to treatment was evaluated. Response to treatment was defined as a reduction of at least 50 points in the IBS Severity Scoring System (IBS-SSS) [24]. If patients responded to the LFD, they were scheduled for a consultation on how to reintroduce high-FODMAP foods using IBS CC (described in Multimedia Appendix 2). Patients were instructed to resume a strict LFD for a few days when they encountered any symptom flare-ups (ie, an increase of at least

50 points in their IBS-SSS) during this reintroduction period (Figure 1). If patients responded to probiotic treatment, they were instructed to home-monitor their symptoms every week; if or when they relapsed (ie, saw an increase of at least 50 points in their IBS-SSS), they would receive another 4-week probiotic treatment, and so on, until 1 year of follow-up had elapsed (Figure 1). If patients did not respond to the initial treatment, they were instructed to take a wash-out period of at least 2 weeks, all the while continuing to home-monitor on IBS CC, and were subsequently crossed over. If patients did not respond to either of the two treatments, they could still home-monitor using IBS CC, following treatment advice from the outpatient clinic at the Department of Gastroenterology, North Zealand University Hospital. Web-based ward rounds were performed daily by the study investigator, based on an electronic patient list (green: inactive symptoms; yellow: mild to moderate symptoms; or red: severe symptoms, according to the IBS-SSS). Instructions to patients regarding how often they should monitor themselves at home using the IBS CC web application are listed in Multimedia Appendix 2, and email reminders (ie, "time to home-monitor") were sent to participants that accepted these.

Fecal Sampling

Participants (IBS and HCs) were trained at inclusion in downloading the CalproSmart app and performing the FC home test. Participants received FC kits, including pads, frame, and tubes with buffer fluid, and were instructed to perform an FC home test within the first 4 weeks of home monitoring and again after 1 year of follow-up.

Participants were provided with easy sampler kits and were instructed to either send fecal samples for microbiota analysis via their general practitioner, or to store fecal samples in their domestic freezer (–20 ◦C). Participants (IBS and HCs) delivered their frozen fecal samples to the study investigator whenever they had an on-site consultation at the hospital. All samples were immediately frozen (–80 ◦C) upon receipt at the hospital. Patients were instructed to store or send fecal samples at study inclusion, at randomization, after 4 weeks of follow-up, and after 1 year of follow-up. Patients responding to probiotic treatment were further instructed to store samples every time they received a new 4-week probiotic treatment, sampled before and just after the treatment (Figure 1). HCs were instructed to collect a fecal sample four times during the course of 1 year and to store these samples in their domestic freezer. All fecal samples were shipped on dry ice to the microbiome laboratory in Germany.

Interventions

Low-FODMAP Diet and Reintroduction of High-FODMAP Foods

One hour of dietary advice was provided on an individual basis by an experienced dietician or nutritionist that took into account the dietary history of each patient. Participants received guidance for the LFD using the Danish Low FODMAP Diet app (Muusmann Publisher), and were further instructed to measure their QoL, weight, adherence to the diet, and any symptoms on the IBS CC web application. In addition, participants also received supplementary materials (prepared by the study authors) on the LFD, with suggestions for LFD-friendly meals and recipes (eg, bread and ice cream); these documents were uploaded to each individual patient's folder on IBS CC. Patients were advised to significantly reduce their intake of foods high in FODMAPs. Patients were advised only to consume foods low in FODMAPs, which were labeled green in the Low FODMAP Diet app; only two yellow-labeled foods, in small quantities, were allowed per day for reluctant participants.

Responders in the LFD group were taught to reintroduce foods high in FODMAPs using the food preference approach, all while taking into account their usual, preferred diet (described in Multimedia Appendix 2).

Probiotic Treatment

VSL#3, distributed by Ferring Inc in Europe, is a high-concentration multi-strain probiotic mix containing one strain of *Streptococcus thermophilus* BT01, three strains of Bifidobacteria (*B breve* BB02; *B animalis* subspecies [subsp] *lactis* BL03, previously identified as *B longum* BL03; and *Banimalis* subsp *lactis* BI04, previously identified as *B infantis* BI04), and four strains of Lactobacilli (*L acidophilus* BA05, *L plantarum* BP06, *L paracasei* BP07, and *L helveticus* BD08, previously identified as *L delbrueckii* subsp *bulgaricus* BD08). VSL#3 contains no less than 450 billion colony-forming units (CFU) per sachet. This formulation is sold as an over-the-counter food supplement at pharmacies in Denmark and by a variety of commercial websites.

VSL#3 sachets used in this study were provided by Actial Farmaceutica Srl, Italy, with the following batch numbers: 804033 and 908081. VSL#3 was administered for 26 days (approximately 4 weeks) for subjects allocated to the treatment group. Patients were instructed to take one sachet twice daily and store the sachets in the refrigerator. Patients were advised not to consume VSL#3 together with any hot or carbonated drinks. Side effects, if any, were registered throughout the study period.

Measures

Applications Used in the Study

IBS CC has previously been used in other web-based studies [13,25]. The updated and expanded version of IBS CC [23] used in this study includes various patient-reported outcome measures (PROMs), listed in Multimedia Appendix 2 and described in detail below. Patient-reported satisfaction with the current version of IBS CC was evaluated before randomization and at 1-year follow-up. Participants gained access to IBS CC via a log-in procedure that includes two-factor authentication. IBS CC meets the requirements of the European Union's General Data Protection Regulation.

Participants made their FC measurements at home using the CE (Conformité Européenne)–marked CalproSmart app. This home test can be performed in 18 minutes and is integrated into the IBS CC application, providing patients with an opportunity to see FC and other measures, such as the IBS-SSS, the Bristol Stool Chart (BSC), bowel movement frequency, weight and BMI, and QoL, all longitudinally and in a traffic light form. Two examples of a 1-year disease course, from a responder in

the probiotic group and another in the LFD group, in IBS CC are shown in Multimedia Appendix 2.

The Low FODMAP Diet app is available from the App Store or Google Play and was provided free of charge to the patients in this study. The app includes sections about IBS, the LFD, recipes, grocery lists, a diary, and a module illustrating foods in green, yellow, and red. This mobile app is not integrated with IBS CC.

IBS Severity and Responder Definition

IBS severity was measured using the IBS-SSS [24]. This questionnaire consists of five items (ie, distention, bowel habits, interference with QoL, and two questions about abdominal pain) that are to be rated from 0 to 100 on a visual analog scale (VAS), with a total score ranging from 0 to 500. The IBS-SSS was made available on IBS CC with permission from Mapi Research Trust, Lyon, France. For ease of interpretation and patient involvement with IBS CC, a score of 0 to 175 was classified as "symptom remission and mild activity" (green), 175 to 300 as "moderate activity" (yellow), and 300 or more as "severe activity" (red). These cutoffs have been used in previous IBS web intervention trials [13,25]. Responses to an intervention or a symptom flare-up were defined as a change in IBS-SSS of at least 50 points [24].

Bristol Stool Chart and Bowel Movement Frequency

The BSC illustrates seven different stool types that represent constipation (types 1 and 2), "normal" stools (types 3-5), and diarrhea (types 6 and 7) [9]. Patients were instructed to assess their stool type either daily or weekly, together with bowel movement frequency, using the IBS CC web application. Results were illustrated via IBS CC to the patients longitudinally, with types 1 and 2 and types 6 and 7 in red, and "normal" stool types in green.

Adherence to Treatments

The FODMAP Adherence Report Scale (FARS) and the Medical Adherence Report Scale (MARS) measured adherence to the diet and probiotic treatment, respectively. The FARS and the MARS are self-assessment questionnaires consisting of five questions that have been used previously in IBD web intervention trials [26,27], one IBS study [11], and one IBD-IBS retrospective study [11]. The total scores range from 0 to 25, where 25 indicates maximum adherence. A score of 22 or higher was considered as adherent and was indicated as green to the patients in IBS CC.

Quality of Life

QoL was measured using the IBS-QoL questionnaire [28] (courtesy of Mapi Research Trust, Lyon, France) via IBS CC. The IBS-QoL questionnaire consists of 34 items, each with a 5-point response scale, resulting in a maximum score of 170. Scores were transformed to a scale of 0 to 100, where scores of 0 to 49 were indicated with a red color and a score of 50 or above was indicated in green, meaning a better QoL.

Disease Course Types

The Copenhagen disease course types describe four different IBS disease courses:

- A: Mild IBS with indolent course
- B: Mild IBS with aggressive course
- C: Chronic IBS with continuous course
- D: Chronic IBS with intermittent course.

These IBS types have previously been used in IBS studies by Maagaard et al [11] and Weynants et al [12]. Our patients were instructed to choose the disease course type that best described their course at inclusion and at 1-year follow-up. These measures were accessible to the participants on IBS CC.

Other Measures Included in IBS CC

Patients also registered their weight in kilograms on a weekly basis at home, and this measure was presented to patients longitudinally, together with their BMI, in IBS CC. Patients were instructed to use their bathroom scale, either in the morning or evening, with or without clothes, as long as they did so consistently throughout the study. The number of probiotic treatments needed for sustaining symptom control and the time between probiotic treatments (in days) were evaluated during the course of 1 year for multiple responders. Participants evaluated their satisfaction with IBS CC, including FC home testing, before their randomization on a VAS from 1 to 10, where 10 was the greatest possible satisfaction. Patient satisfaction with the study and IBS CC at 1 year, including FC home testing, was assessed using an e-questionnaire in IBS CC that was prepared by the authors, consisting of nine "yes or no" questions and two other questions: one regarding the time used for home monitoring and the other asking for suggestions on improving IBS CC for future clinical use. Clinical metadata were exported from the IBS CC database for statistical analyses.

Microbiome Analysis

Fecal samples were analyzed by CeGaT GmbH in Tübingen, Germany. The method used by CeGaT GmbH is based on culture-independent, whole-genome, shotgun metagenomic, next-generation sequencing. Genomic DNA was extracted from the participants' fecal samples using CeGaT GmbH's proprietary protocol, including enzymatic cleavage of genomic DNA. Approximately 100 ng of DNA was used per sample for library preparation, which was performed with the Nextera DNA Flex Library Prep Kit (Illumina). Sequencing was performed on the NovaSeq 6000 Sequencing System (Illumina), which resulted in at least 10 million 2 × 100 bp paired-end sequencing reads (2 Gb) per sample. Demultiplexing of the sequencing reads was performed with bcl2fastq Conversion Software (version 2.20; Illumina) [29]. Adapters were trimmed with Skewer [30]. Taxonomic classification and sequence abundance were estimated by Unseen Bio anpartsselskab, Greater Copenhagen, using an in-house bioinformatics pipeline [31] consisting of quality control with FastQC [32] and fastp [33], removal of human DNA by mapping reads with Kraken 2 [34] to its human library, and a summary using MultiQC [35]. The remaining sequencing reads were then mapped to a human gut microbiome-specific reference database, MGnify [36], with Kraken 2 in order to estimate bacterial and archaeal sequence abundance. Sequence abundance counts were then re-estimated to the species level using Bracken [37].

Statistical Analyses

Counts, means, medians, and IQRs were computed from the PROMs. Wilcoxon rank-sum tests, Wilcoxon signed-rank tests with continuity correction, or Dunn all-pair tests were performed to compare medians. Analysis of sequence counts or reads and visualization of results were performed in R (version 4.0.4; The R Foundation). A list of R packages used in this study can be found in Multimedia Appendix 2. Sequence counts were rarefied to the smallest common value of 15 M using uniform sampling without replacement from the phyloseq package [38]. Sequence abundance was used as a proxy for taxonomic abundance. The α and β diversity were assessed using the inverse Simpson index [39] and Bray-Curtis dissimilarity [40], respectively. A *P* value lower than .05 was considered significant. We used a uniform manifold approximation and projection (UMAP) [41] technique in order to visually inspect potential clustering of the Bray-Curtis dissimilarity reduced to two dimensions. We estimated differential sequence abundance using a β-binomial model provided by the R package, corncob [42], with false discovery rate (<0.1)–adjusted *P* values. Clinical outcomes were assessed in a post hoc analysis by linear mixed-effect models [43]. Patients diagnosed with other diseases during the course of the study were excluded from the analyses if the disease affected their results; otherwise, they were included.

Results

Participants and Study Course

In total, 34 IBS patients were included in the study (Figure 2). A total of 3 (9%) patients dropped out before randomization, and an additional 9 (26%) IBS patients discontinued participation during the course of the year. Reasons for discontinuation were divorce or other stress-related events. In total, 5 (15%) IBS patients were diagnosed with other diseases during the study: 1 with microscopic colitis, 1 with neuroendocrine tumor, 2 with bile acid malabsorption, and 1 with breast cancer; 4 of these completed the study. A total of 6 HCs were included, all of whom completed the 1-year study. Baseline data of participants are shown in Table 1. The number of IBS patients enrolled, randomizations to interventions, and responders and nonresponders to interventions can be found in Figure 2. Out of 21 patients, 12 responded to LFD (57%) and 8 (38%) completed the reintroduction to high-FODMAP foods. Out of 21 patients, 13 (62%) responded to their first VSL#3 treatment and 7 (33%) responded to multiple VSL#3 treatments. A total of 180 fecal samples (156 from IBS patients and 24 from HCs) were analyzed. Out of 180 fecal samples, 7 (3.9%) were removed from the metagenomic data set due to medical treatments undergone by the participants (ie, antibiotics or cholestyramine treatment). An additional 22 samples (12.2%) were removed from the data set for analyses that excluded patients diagnosed with other diseases during the study.

Figure 2. Flowchart of inclusion, individualized treatment response, and 1-year follow-up. Response to a 4-week probiotic treatment or LFD was defined as a decrease in the IBS Severity Scoring System (IBS-SSS) of at least 50 points. *One patient did not manage to cross over to probiotic treatment; however, this patient completed 1 year on the web application. This participant is labelled as "discontinued" in the figure. **Diagnosed with another disease and treated medically in the outpatient clinic. FODMAPs: fermentable oligosaccharides, disaccharides, monosaccharides, and polyols; IBS CC: IBS Constant Care.

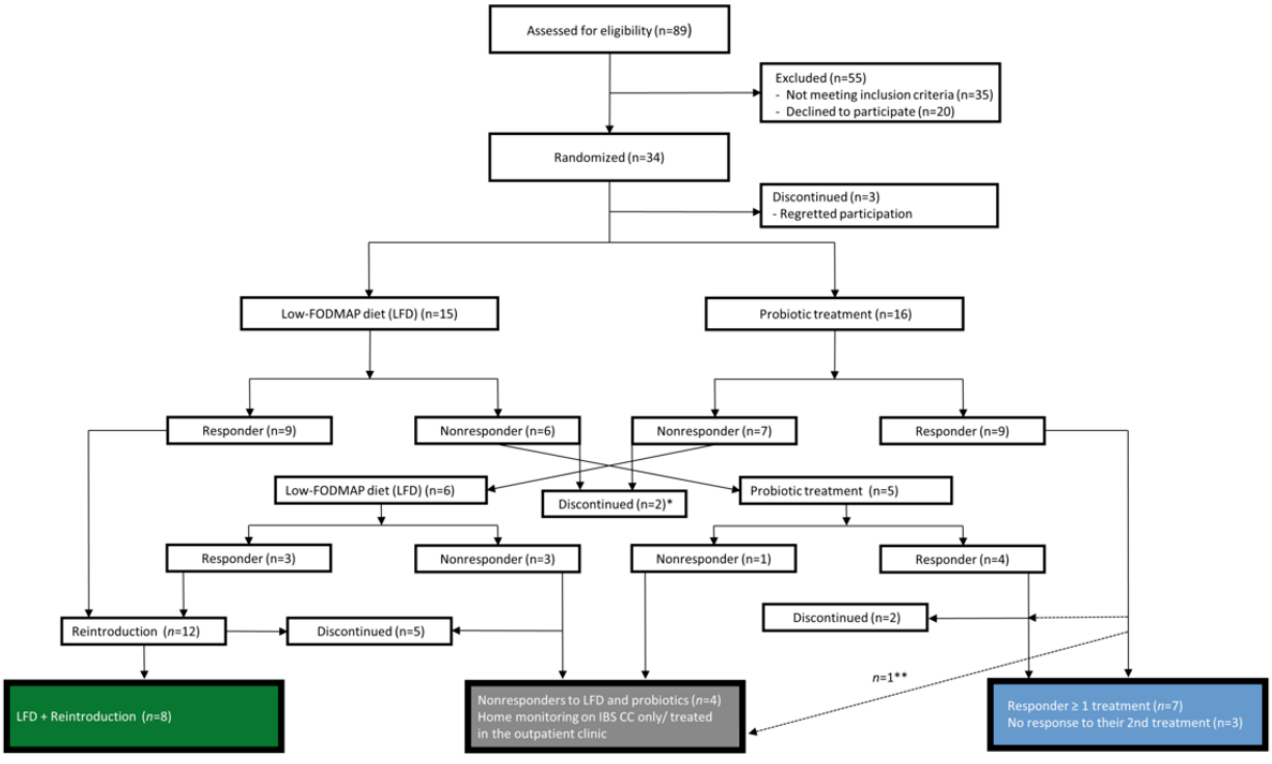


Table 1. Characteristics of participants at inclusion and upon randomization.

Characteristic	Inclusion (day 0; N=34 patients)	At randomization (week 4; n=31 patients)
Irritable bowel syndrome (IBS) patients		
IBS subtype, n (%)		
Mixed	15 (44)	15 (48)
Diarrhea	19 (56)	16 (52)
Gender, n (%)		
Female	23 (68)	22 (71)
Male	11 (32)	9 (29)
Smoking status, n (%)		
Never	18 (52)	18 (58)
Current	4 (12)	4 (13)
Previous	9 (26)	9 (29)
Missing	3 (9)	0 (0)
Disease course type, n (%)		
A (mild IBS with indolent course)	0 (0)	0 (0)
B (mild IBS with aggressive course)	11 (32)	11 (36)
C (chronic IBS with continuous course)	16 (47)	16 (52)
D (chronic IBS with intermittent course)	4 (12)	4 (13)
Missing	3 (9)	0 (0)
Age (years), median (IQR)	44.5 (27.5-51.5)	44 (26-50)
Patient-reported years with IBS, median (IQR)	5 (2.9-15.0)	5 (2.5-15.0)
BMI[a], median (IQR)	23.9 (21.9-26.4)	23.6 (21.2-26.1)
Fecal calprotectin (FC; mg/kg), median (IQR)	N/A[b]	53 (0-69)
IBS-SSS[c] score (0-500), median (IQR)	312 (243-370)	292 (225-356)
Bristol Stool Chart score (1-7), median (IQR)	5 (3-6)	5 (3-6)
Bowel movement frequency per day, median (IQR)	2 (1-5)	2 (2-4)
IBS-QoL[d] questionnaire score (0-100) , median (IQR)	54 (38-77)	53 (38-80)
Evaluation of IBS CC[e], including FC home test (1-10)[f], median (IQR)	N/A	8 (7-9)
Healthy controls (n=6)[g]		
Gender, n (%)		
Female	5 (83)	N/A
Male	1 (17)	N/A
Age (years), median (IQR)	46 (30.8-58.5)	N/A

IBS-SSS score (0-500), median (IQR)	13.5 (0.75-22.25)	N/A
Bristol Stool Chart score (1-7), median (IQR)	4 (3.75-4.5)	N/A
Bowel movement frequency per day, median (IQR)	1.5 (1-2.25)	N/A
FC (mg/kg), median (IQR)	0 (0-72.75)	N/A
IBS-QoL questionnaire score (0-100), median (IQR)	100 (98.25-100)	N/A

[a]BMI is calculated as weight in kg divided by height in m^2.

[b]N/A: not applicable; data were not collected for this characteristic at this time point.

[c]IBS-SSS: IBS Severity Scoring System.

[d]IBS-QoL: IBS quality of life.

[e]IBS CC: IBS Constant Care.

[f]Satisfaction with the expanded IBS CC web application, including the FC home test, was evaluated by patients on a visual analog scale from 1 to 10, where 10 indicates the greatest possible satisfaction.

[g]Data for healthy controls were collected only at inclusion.

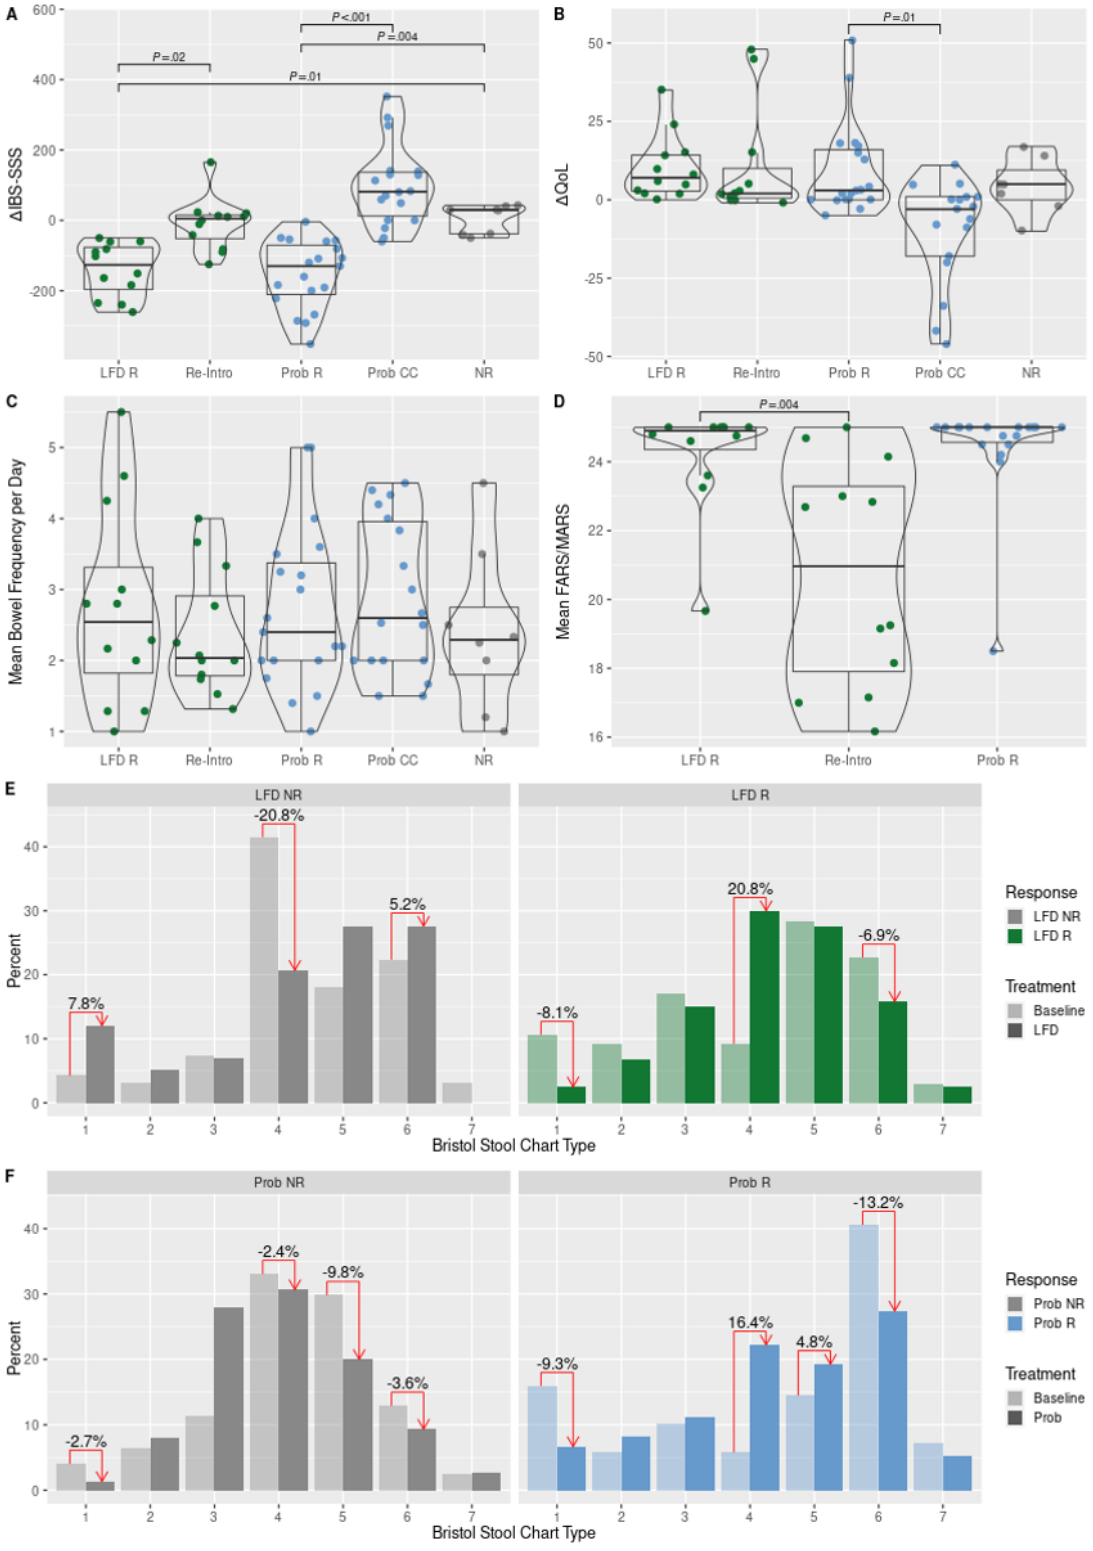
Treatment Duration and Effect Sizes of the LFD and Probiotic Treatments Based on Response Types

The median time spent dieting by LFD responders (12/21, 57%) was 36 days (IQR 28.00-41.25), and the median time spent for reintroduction of high-FODMAP foods (8/21, 38%) was 296 days (IQR 227.00-305.75). For "true" responders (ie, participants who responded to multiple probiotic treatments [7/21, 33%]; see Figure 2), the median number of probiotic treatments needed for maintaining symptom control during the course of 1 year was 3 (IQR 2.25-3.75), and the median number of days between probiotic treatments was 46.5 (IQR 26.25-65.75). Symptom remission (ie, an IBS-SSS lower than 175) was achieved by 8 out of 12 (67%) LFD responders and 5 out of 7 (71%) multiple probiotic responders, the latter corresponding to 12 out of 19 (63%) VSL#3 treatments bringing about symptom remission in probiotic responders.

As shown in Figure 3, A, significant decreases in IBS-SSS were observed for LFD and probiotic responders relative to nonresponders; both responder types were adherent to treatments (Figure 3, D). However, no significant difference in effect size between the two treatments was found; the median IBS-SSS effect sizes were –126.50 (IQR –196.75 to –76.75) for LFD responders and –130.00 (IQR –211.00 to –70.50) for probiotic responders (P>.99). The corresponding changes in QoL among LFD and probiotic responders was not significant compared to nonresponders, nor were the median increases in QoL significant between the two responder groups, which were 7 (IQR 2.75-14.20) for LFD responders and 3 (IQR 0-16.00) for probiotic responders (P>.99). During reintroduction to high-FODMAP foods, patients deviated significantly from the principles of the LFD (Figure 3, D; P=.004), resulting in a small but significant median increase in symptom severity relative to the time period where they were on the LFD (Figure 3, A). In median terms, probiotic responders experienced a significant increase in symptom severity between active probiotic treatments, which also resulted in a significant median decrease in QoL (Figure 3, A and B). No significant changes in bowel movements per day based on responder type were observed (Figure 3, C). LFD and probiotic responders showed a tendency of normalizing stool appearance to type 4 (Figure 3, E and F). These results are generally substantiated by fitting linear mixed-effect models of clinical metadata from the IBS CC database (ie, not considering delta values alone) to estimate effect sizes (eg, for responder groups). These post hoc models of QoL showed that LFD responders saw significant increases in their QoL while on the LFD (by an estimated 9.08), and even more during reintroduction (13.48) relative to their baseline QoL (an estimated 60.20). The model estimating the effect on severity scoring showed significant decreases for all responder types, including probiotic responders between active treatments. Outputs from the linear mixed-effect models are shown in Multimedia Appendix 2.

No significant changes in FC based on responder type were registered between baseline and 1-year follow-up (Multimedia Appendix 2). At baseline, none of the IBS patients reported an indolent disease course type (ie, type A). At 1-year follow-up, 42% (5/12) and 43% (3/7) of the LFD and probiotic responders, respectively, reported an indolent disease course type (ie, type A). None of the nonresponders reported an indolent course at 1-year follow-up.

Figure 3. Effect sizes for select patient-reported outcome measures based on responder types. LFD responders (LFD R, n=12); reintroduction (Re-Intro, n=12); probiotic responders (Prob R, n=7; "true" responders; 19 treatments); in between active probiotic treatments (Prob CC, n=7; 18 between periods); nonresponders (NR, n=4). A. Change in IBS-SSS. B. Change in IBS-QoL. C. Mean bowel movement frequency per day. D. Mean adherence for LFD responders (FARS) and during reintroduction (FARS) and for probiotic responders (MARS). E and F. Change in Bristol Stool Chart scores, expressed as percentages. FARS: FODMAP Adherence Report Scale; FODMAPs: fermentable oligosaccharides, disaccharides, monosaccharides, and polyols; IBS: irritable bowel syndrome; IBS-SSS: IBS Severity Scoring System; LFD: low-FODMAP diet; MARS: Medical Adherence Report Scale; Prob: probiotic treatment; Prob CC: in between probiotic treatments, where patients are only measuring on IBS Constant Care (IBS CC; ie, not receiving any active treatments); QoL: quality of life; Re-Intro: resuming consumption of foods high in FODMAPs.



Reintroduction of High-FODMAP Foods

A total of 8 out of 12 (67%) participants completed the process of reintroducing high-FODMAP foods (Figure 2) and succeeded in developing an individualized diet at 1-year follow-up. They reintroduced a median of 14.50 (IQR 7.25-21.75) high-FODMAP foods, of which they categorized a median of 7 (IQR 3-13) foods as green (ie, not symptom-triggering foods), while they categorized 5 (IQR 4-8) foods as yellow and 2 (IQR 1-4) foods as red (ie, symptom-triggering foods). Common among symptom-triggering foods were wheat and rye bread, pasta, pointed cabbage, onion, garlic, leek, broccoli, green peas, cauliflower, kidney beans, chickpeas, sweet potatoes, avocado, mushrooms, apples, and apple juice.

Safety and Patient Satisfaction With IBS CC

No adverse events were registered for either intervention. The evaluation at 1-year follow-up showed overall satisfaction with the study, the support received during the study, and with IBS CC itself (further details can be found in Multimedia Appendix 2). During the 1-year study period, originating from both the personnel doing the daily web-based ward rounds and participants (n=33, including HCs), 887 web consultations and 781 text messages were registered.

Healthy Controls

HCs did not receive any intervention during the study period and were in IBS-SSS remission at inclusion and at 1-year follow-up. No significant change was detected (median 13.5 [IQR 19.25] vs 15.5 [IQR 14.75], *P*=.79). They had high IBS-QoL scores at inclusion and 1-year follow-up (median 100 [0.75] vs 100 [0.75], *P*>.99). The primary purpose for the inclusion of HCs was to generate microbiome profiles that could serve as a reference.

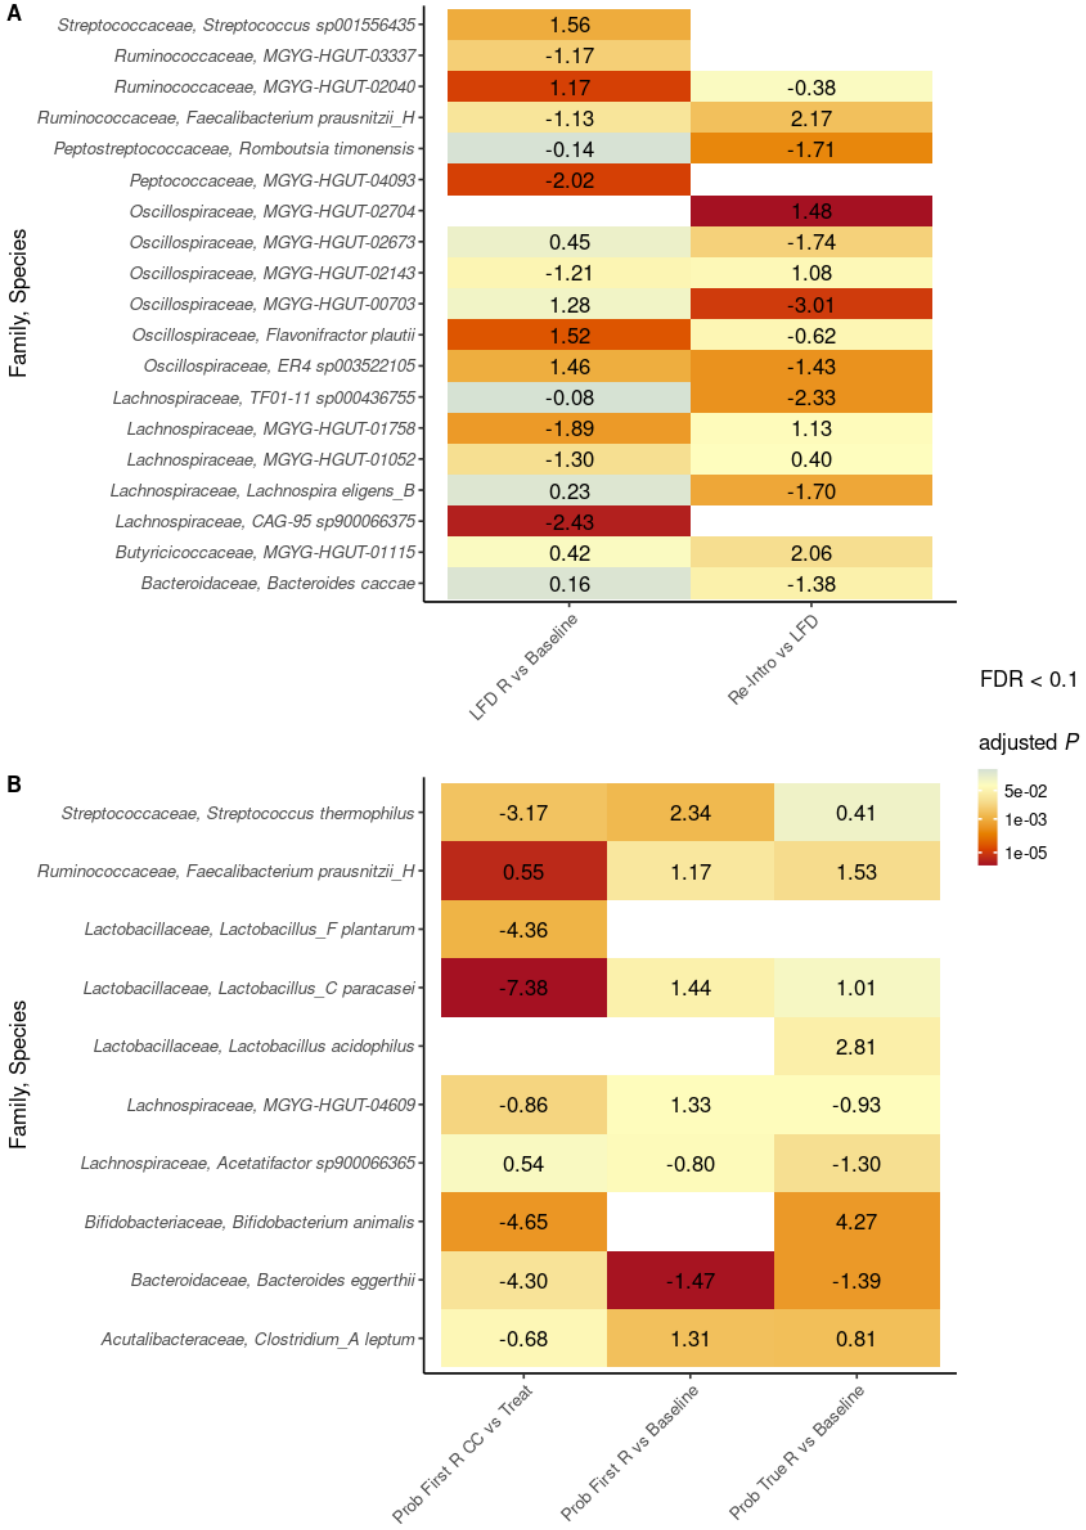
Basic Microbiota Descriptions in Relation to Diagnoses and Responder Types

A total of 10 million reads per sample were matched with high confidence to a median of 940 (IQR 18, range 821-1007) microbial species per sample. Median α diversity (measured by inverse Simpson index) was significantly greater for HCs (n=6) than for IBS patients (n=31), with median values of 51.60 (IQR 23.5) and 42.10 (IQR 16.1), respectively (*P*=.03; Multimedia Appendix 2). Across the entire study population, the Bray-Curtis dissimilarity within individuals was a median of 0.42 (IQR 0.14), and between individuals it was 0.72 (IQR 0.12; *P*<.001). There was also a significantly higher median of intraindividual Bray-Curtis dissimilarity in IBS-D compared to IBS-M patients (*P*=.03). UMAP plots based on IBS subtypes and responder types are shown in Multimedia Appendix 2. Those plots do not suggest any clusters, except for those given by the individuals themselves. The importance of individuals is also substantiated in the linear mixed-effect models estimating the change in α diversity for responder types (Multimedia Appendix 2). This model showed that approximately 24% of the variance was explained by the random effect of the individual and only 4% was explained by the fixed effect of responder type. In the model, nonresponders to the LFD had a lower inverse Simpson index that was close to significance (*P*=.07). No significant changes in α diversity for probiotic responders and nonresponders were found. Nonresponders to both probiotics and LFD showed a significantly higher median of intraindividual Bray-Curtis dissimilarity relative to probiotic responders (*P*=.01; Multimedia Appendix 2).

Differential Analyses of Species Abundances Based on Responder Types

No significant differential species abundances were found when comparing nonresponders to LFD and probiotic responders. Significant changes in relative species abundances induced by interventions (ie, LFD, reintroduction, and probiotic treatment) relative to baseline are shown in Figure 4 and further elaborated on in Multimedia Appendix 3. The corresponding Kyoto Encyclopedia of Genes and Genomes modules can be found in Multimedia Appendix 4.

Figure 4. Heat maps showing the 10 most differentially abundant species for low-FODMAP diet (LFD) comparisons (A) and the top five species for the probiotic (Prob) comparisons (B). A. LFD responders (LFD R, n=12) and reintroduction (Re-Intro, n=8). B. Probiotic responders. First-time responders (Prob First R) to treatment (Treat) and the time between active treatments (the period in between active probiotic treatment is abbreviated as CC; n=13). Second-time treatment responders ("true" responders, Prob True R; n=7; 19 treatments). The values shown in the heat maps denote the expected difference in the logit-transformed relative abundances between two samples from the groups being compared, controlling for the effect of individuals. The color scale represents the false discovery rate (FDR) (<0.1)–adjusted *P* values. The scale ranges from red to yellow to blue. Yellow marks the *P* value .05. All *P* values smaller than .05 tend toward red, and those larger than .05 tend toward blue. FODMAPs: fermentable oligosaccharides, disaccharides, monosaccharides, and polyols.



Discussion

Principal Findings

In this study, we have shown that the new and expanded IBS CC web application for long-term management of IBS is practical, safe, and useful in clinical decision making. This was demonstrated by two year-long treatment interventions: the LFD (with subsequent reintroduction of high-FODMAP foods for LFD responders) and a probiotic treatment (repeated for 4 weeks every time a symptom flare-up occurred in probiotic responders). These therapeutics were found to be equally good at managing IBS symptoms in the short term and the long term. We also investigated participants' fecal microbiota, in order to try to predict response to the interventions, in the hope of being able to individualize future treatments for IBS; however, we were unable to make these predictions. Due to the small sample size of the study, larger ones are needed to confirm our results and would, ideally, include other medical options for managing IBS, especially for nonresponders to the LFD and probiotic treatments.

Sample Size and the Effect of the Individuals

Although the prevalence of IBS is high in westernized countries [1] such as Denmark, we were only able to include 34 out of an estimated target of 104 patients. This was mainly due to a high prevalence of comorbidities among eligible subjects that resulted in our excluding 64% of them. The high prevalence of comorbidities among eligible subjects is the topic of a newly published Danish nationwide study reporting that two-thirds of the Danish population, aged 16 years or older, suffer from one or more chronic conditions [44]. Our aim in excluding participants with multiple conditions, including other medical treatments, was to collect untarnished data for microbial analyses. The 5 patients with comorbidities or other diagnoses did not appear to affect the clinical data from IBS CC, nor did they affect the UMAP, inverse Simpson, or Bray-Curtis measures. However, these 5 patients did affect the results for the differential species abundance analyses based on responder types, possibly due to (1) the comorbidities themselves or (2) the fact that the individuals accounted for approximately 24% of the variance in the metagenomic data set. We aimed for including 104 IBS patients and 20 HCs. However, we did not manage to include our target population due to a high rate of co-morbidities among eligible subjects and implementation of new regulation (GDPR) in Denmark (data approval of the study took longer than expected).

Probiotic Treatment

The response rates, adherence, effect sizes of median reductions in symptoms, and increases in QoL for probiotic and LFD responders were similar (ie, not significantly different); however, probiotic responders experienced a significant increase in median symptom severity and a decrease in QoL in the times between the 4-week probiotic treatments, as compared to the effect obtained during active probiotic treatment. However, the linear mixed-effect model estimated that probiotic "true" responders sustained significant symptom control in between their 4-week treatments relative to their first measure (ie, the intercept). This is also partly explained by the study design, which instructed probiotic responders to contact the study investigator for a new 4-week probiotic treatment upon experiencing a symptom flare-up (ie, an increase in their IBS-SSS of at least 50 points). Sustaining IBS symptom control in between active probiotic treatments has, to our knowledge, not been investigated before among "true" responders. The concept of sustaining symptom control among "true" responders—with a median of three 4-week treatments across the year-long study—and the timing of new probiotic treatments using eHealth, require further investigation in larger, clinical web-based trials. The high dose (2 × 450 billion CFU per day) and short duration combination used in this study seems reasonable, based on a meta-analysis that concluded that (1) probiotics are effective and safe for IBS patients (moderate evidence) and (2) single probiotics at a higher daily dose and for a shorter duration (less than 8 weeks) seem to be more efficacious (needs further evidence) [45]. Although the higher dose and shorter duration were related to single-strain probiotics, we have also documented the effect of multi-strain VSL#3. Among the top five most differentially abundant bacterial species found when comparing samples from probiotic responders to their baseline samples, we identified four species (ie, *S thermophilus*, *L paracasei*, *L acidophilus*, and *B animalis*) that are representative of strains contained in the VSL#3 mixture. Furthermore, all four species were completely absent from baseline samples, which means that the consumption of VSL#3 is the most plausible explanation for their presence. Future long-term studies need to investigate whether it is safe for patients to stop probiotic treatment after 4 weeks and to only resume when symptom flare-ups occur. Abrupt suspension of probiotics have been hypothesized to increase host pathogen susceptibility by inducing gut dysbiosis [46].

LFD and Reintroduction of High-FODMAP Foods

Several key studies, meta-analyses, and reviews [10,47-50] have investigated the effects of an LFD on symptom reduction and changes in microbiota during an LFD [14,51-53]. Similar effect sizes and response rates to those we found have also been reported before [13,25,52]; however, the changes observed in the microbiota profile induced by the LFD in this study are not the same as reported in previous studies [14,51-53]. In one of these studies, easing of FODMAP restrictions (ie, reintroduction of foods high in FODMAPs) was recommended based on microbiota results indicating a significant decrease in total bacteria abundances, including significant changes in relative abundances of *Clostridium* cluster XIVa (reduced), *A muciniphila* (reduced), and *R torques* (increased) relative to a normal Australian diet [14]. Others have shown that the LFD, relative to sham diet advice, induces significant changes in the relative abundances of *Bifidobacterium* (reduced), an unclassified genus in the Ruminococcaceae family (reduced), and *Bacteroides* (increased) [53]. The same authors, in other papers, suggest that coadministration of probiotics with an LFD can restore *Bifidobacterium* [52], or that a β-Galactooligosaccharide supplement taken alongside the LFD can improve IBS symptoms [54]. Our results suggest that the LFD nonresponders tended to have reduced α diversity, as measured by the inverse Simpson index, whereas responders did not. *Faecalibacterium prausnitzii*, a commensal bacterium

of the Ruminococcaceae family that produces short-chain fatty acids (SCFAs) from dietary fiber [55], was significantly reduced by the LFD and restored by the reintroduction of foods high in FODMAPs. It should be noted in this context that it was *Faecalibacterium prausnitzii* H that was significantly increased; G, E, J, K, and I were decreased, while C and F were increased, but none significantly so (Multimedia Appendix 3). The main explanations for the discrepancies between studies investigating the effects of an LFD on microbiota include, but are not limited to, different DNA extraction protocols [56,57]; different storage conditions [58]; different parameters and bioinformatic analyses, including different comparisons "between groups" rather than changes "within groups"; and use of different sequencing methods [59].

Although significant median increases in symptoms were observed during reintroduction of high-FODMAP foods, in this study, and relative to the changes caused by the LFD, a post hoc analysis (ie, a linear mixed-effect model based on clinical metadata) suggests that sustained long-term symptom control and improvement of QoL could be obtained relative to patients' baseline. Sustained symptom control during reintroduction has recently been documented by other researchers in Italy, who concluded that the benefit of an LFD persisted during reintroduction (after 3 months) and at 6 months follow-up [60]. Based on this study's results, the combination of using a food preference approach for reintroduction and eHealth seems fit for long-term disease management. However, further eHealth studies with larger cohorts are needed to confirm these results.

IBS and Web-Based Management

Other researchers have suggested that web-based and app-based LFD and probiotic treatments may provide therapeutic benefits [61] and should be more widely implemented for IBS management [13]. This study supports these existing results and recommendations and adds further evidence of using eHealth for clinical decision making and long-term management.

However, it is our recommendation that future electronic-based IBS management include valid and quick point-of-care measures that can (1) predict response to treatments and (2) be correlated to symptom severity scores, both of which can support the patients and the personnel doing the daily web-based ward rounds in tailoring treatments and guiding their supervision. We were unable to predict response to treatments (ie, probiotic treatment and LFD) based on the microbiota alone. Others have also failed in this attempt in IBS using a different method (ie, 16S ribosomal RNA [rRNA] next-generation sequencing) than the one we used [53]. It could be that predicting a response to treatment and symptom activity would gain from larger cohorts and more detailed analyses of the gut ecosystem (eg, including other microbes, such as parasites [62]) and metabolites. A promising, low-cost, and noninvasive measure for predicting response to LFD and probiotic treatments in IBS patients is currently under development by researchers at King's College London that examines volatile organic compounds (VOCs) in feces (ie, VOC profiling) [63]; future evaluation of this method will hopefully determine whether it has clinical utility. A final, important aspect of research into long-term IBS management is the exclusion of other gastrointestinal diseases and comorbidities, as these frequently occur together [44]. A review by Kim et al [64] reported that FC had the highest sensitivity and specificity relative to IBD, whereas fecal SCFAs were most accurate relative to HCs. In the present study, neuroendocrine tumor showed itself with repeatedly elevated FC measures, but this measure did not indicate bile acid malabsorption or microscopic colitis. Future research might reveal new and valid point-of-care markers for detection of other diseases, for surveillance of IBS activity (ie, predictors for symptom relapse), and for predicting responses to therapeutics, thereby helping us tailor treatments and their timing, via improved surveillance, for patients.

Strengths and Limitations

The strength of this study is its use of an updated and expanded eHealth web application to monitor and treat IBS patients according to their treatment response across 1 year of follow-up. To our knowledge, this is the first eHealth trial to monitor the effect, prospectively and longitudinally, of multiple probiotic treatments and the LFD with subsequent reintroduction of foods high in FODMAPs, and to compare responses to patients' microbiota.

The main limitations of the study are its sample size and that it is based on a single study center. Another limitation is the use of the Rome III criteria rather than the Rome IV criteria for IBS [65]. Furthermore, gut microbiota were analyzed using fecal samples and metagenomic shotgun sequencing as a proxy. While metagenomic, whole-genome shotgun sequencing allows for a better genome resolution compared to 16S rRNA amplicon sequencing, organisms that are extremely GC-rich or -poor will be underrepresented [66]. Due to costs, samples were also sequenced at a lower depth (an average of 20 M reads), which limits the possibility of detecting microbes in very low abundances. In order to analyze the microbiota, we used a read-based mapping approach that is faster than metagenomic genome assembly, avoids the many problems that can occur during assembly, and provides full-genome information for low-abundance microbes that cannot be assembled otherwise [67]. However, this also meant that we could not capture the specific capabilities of each microbe in a patient, encoded by their particular genome. The *in situ* genome sequences likely differ compared to our reference due to, for example, horizontal gene transfer.

Conclusions

In conclusion, we have shown the IBS CC web application to be practical, safe, and useful for clinical decision making in the long-term management of IBS. A probiotic treatment, VSL#3, and the LFD were equally efficacious in short- and long-term treatment strategies for managing IBS. We failed to predict response to treatments based on patients' fecal microbiota, which might someday help individualize treatments. To confirm our results, larger studies are needed and would ideally combine LFD and probiotic treatments or other medical options for managing IBS, especially for nonresponders to the LFD and probiotic treatments.

Acknowledgments

We wish to thank Thomas Janum (J-Consult) for support in developing the IBS CC application, integration of CalproSmart, and the export function from the IBC CC database. Grants supporting this study were provided by North Zealand University Hospital, Ferring Pharmaceuticals, the Handelsgartner Ove William Buhl Olesen and ægtefælle fru Edith Buhl Olesen memorial fund, the Dagmar and Ivar Enevoldsen memorial fund, and the Crohn's & Colitis Patient Society, Denmark. This study was also supported, in part, by Unseen Bio ApS and Calpro AS.

Authors' Contributions

DVA prepared the manuscript, which was critically reviewed by all coauthors. DVA, JB, and PM designed the study. DVA, PM, MB, AH, EF, SS, NDV, TR, and SF conducted the study. DVA, MEB, and PM had full access to the data in the study and take full responsibility for their integrity. DVA prepared the data tables and MEB performed the statistical analyses. All authors approved the final version of the manuscript.

Conflicts of Interest

MEB and CL are cofounders of Unseen Bio ApS, a company that offers microbiome profiling to consumers. The remaining authors have no conflicts of interest to declare.

Abstract

Background: There has been a cultural shift toward patient engagement in health, with a growing demand from patients to access their results.

Objective: The Lymphoma Intervention (LIVE) trial is conducted to examine the impact of return of individual patient-reported outcome (PRO) results and a web-based self-management intervention on psychological distress, self-management, satisfaction with information, and health care use in a population-based setting.

Methods: Return of PRO results included comparison with age- and sex-matched peers and was built into the Patient-Reported Outcomes Following Initial Treatment and Long-Term Evaluation of Survivorship registry. The self-management intervention is an adaptation of a fully automated evidence-based intervention for breast cancer survivors. Patients with lymphoma who

completed the web-based questionnaire were equally randomized to care as usual, return of PRO results, and return of PRO results plus self-management intervention. Patients completed questionnaires 9 to 18 months after diagnosis (T0; n=227), 4 months (T1; n=190), 12 months (T2; n=170), and 24 months (T3; n=98).

Results: Of all invited patients, 51.1% (456/892) responded and web-based participants (n=227) were randomly assigned to care as usual (n=76), return of PRO results (n=74), or return of PRO results and access to Living with lymphoma (n=77). Return of PRO results was viewed by 76.7% (115/150) of those with access. No statistically significant differences were observed for psychological distress, self-management, satisfaction with information provision, and health care use between patients who received PRO results and those who did not (*P*>.05). Use of the self-management intervention was low (2/76, 3%), and an effect could therefore not be determined.

Conclusions: Return of individual PRO results seems to meet patients' wishes but had no beneficial effects on patient outcome. No negative effects were found when individual PRO results were disclosed, and the return of individual PRO results can therefore be safely implemented in daily clinical practice.

KEYWORDS

lymphoma; patient-reported outcomes; return of individual results; randomized controlled trial; self-management

Introduction

Background

Patients with lymphoma are at risk of experiencing adverse effects of cancer and its treatment, such as fatigue, cognitive problems, and neuropathy [1-4]. In addition, up to a quarter experience persistent levels of anxiety, depressive symptoms, and fear [5], also known as psychological distress. Both symptoms and psychological distress may be exacerbated when information and supportive care are unavailable [6,7]. This may, in turn, lead to increased health care use [8]. Regular screening of physical and psychosocial symptoms using patient-reported outcomes (PROs) could increase awareness and recognition of symptoms and can contribute to their management [9-13].

Since the past decade, there has been a cultural shift toward patient engagement in health, with a growing demand from patients to access their individual results [14-17]. Returning individual PRO results enables patients to monitor their functioning and create awareness of symptoms. Furthermore, it offers patients the opportunity to compare their scores with peers [15] to evaluate if their scores are *normal* and to incorporate this information into personal decision-making [16]. However, some clinicians have expressed reservations about disclosing PRO research results to patients, as it may cause patients to become more concerned and lead to increased health care use by patients and higher workload for clinicians. Therefore, it is important to investigate whether patients will be in a better or worse condition with their PRO results being disclosed and which patients wish to receive their PRO results.

To improve health outcomes, subsequent steps such as self-management interventions are expected to be necessary in addition to monitoring and returning PRO results [18]. Self-management interventions intend to enhance patients' knowledge and skills and empower them to play an active role in the management of their disease and its consequences [19,20]. Studies on the outcomes of self-management are mainly based on patients with solid cancers and are not consistent, with some randomized controlled trials (RCTs) showing no effects [21-23]. In addition, most self-management interventions are not specifically aimed at patients with lymphoma and are found to be effective among selected groups of patients. Little is known about the effects of such interventions in a population-based setting within an unselected group of patients.

Objectives

To investigate the effect of (1) return of individual PRO research results, including comparison with peers [24], and (2) a web-based self-management intervention Living with lymphoma, the Lymphoma Intervention (LIVE) trial was performed. The primary objective of the LIVE RCT was to examine the effects of return of PRO results to patients with or without access to Living with lymphoma on self-management, satisfaction with information, and psychological distress in a population-based setting of patients with lymphoma [24]. We hypothesized that those with access to the return of PRO results or access to LIVE would have higher levels of self-management and satisfaction with information and lower levels of psychological distress. On the basis of new insights that psychologically distressed patients reported increased health care use [8], we also investigated the effects of return of PRO results to patients with or without access to Living with lymphoma on health care use (secondary objective). Furthermore, we explored sociodemographic, clinical, and psychological differences between patients who viewed their individual PRO results and those who did not.

Methods

Design and Participants

This RCT was embedded in the population-based Patient-Reported Outcomes Following Initial Treatment and Long-Term Evaluation of Survivorship (PROFILES) registry [25]. PROFILES enables PRO data collection management and links PRO data to clinical data from the Netherlands Cancer Registry (NCR).

Between October 2015 and February 2019, patients diagnosed with lymphoma (Hodgkin lymphoma, non-Hodgkin lymphoma, or chronic lymphocytic leukemia), as defined by the International Classification of Diseases for Oncology-3 codes [26], from 13 hospitals in the Netherlands were selected for participation 9 to 18 months after diagnosis. The NCR registers all newly diagnosed patients with cancer in the Netherlands within the first year after diagnosis and routinely collects detailed data on sociodemographic and clinical characteristics (eg, age and sex, date of diagnosis, cancer type, and primary treatment). Treating hemato-oncologists were asked to verify the eligibility of the patients. As we aimed to keep a population-based approach, we only defined a few exclusion criteria, such as presence of severe psychopathology or dementia, being in transition to terminal care, and not being able to complete a Dutch questionnaire. Patients were informed that completion of the web-based questionnaire resulted in RCT enrollment with automatic randomization to 1 of the 3 study arms. Paper respondents were not eligible for the RCT (as the return of PRO results and *Living with lymphoma* were web-based) and were observationally followed within the PROFILES lymphoma registry. A reminder mail was sent after 3 weeks. Respondents received follow-up questionnaires at 4 months (T1), 12 months (T2), and 24 months (T3) after the baseline questionnaire. More details about the study design, enrollment, and sample size calculation have previously been published in the research protocol [24]. The RCT was centrally and locally approved by a medical research ethics committee [24].

Randomization

Randomization was performed using block randomization to ensure a balance in sample size across arms over time [27]. Participants were equally randomized to (1) care as usual (CAU), (2) CAU plus return of PRO results, or (3) CAU plus return of PRO results and Living with lymphoma.

Interventions Versus CAU

Arm 1: CAU

In arm 1, patients received CAU from their hemato-oncologists and oncology nurses. In general, they provided verbal information to their patients and provided leaflets regarding the diagnosis and treatment they received.

Arm 2: Return of PRO Results

In arms 2 and 3, in addition to CAU, individual PRO research results were disclosed to patients. This feedback was automatically generated after the completion of the questionnaire. On the basis of respect for autonomy, patients had the choice as to whether they wanted to receive the results [14] and could click on the *feedback* button for return of results.

Detailed information about the return of PRO results (also known as PRO feedback) has been described elsewhere [15,24]. In short, individual research results on general health-related quality of life (HRQoL), physical, emotional, cognitive, and social functioning, fatigue, neuropathy, anxiety, and depressive symptoms were returned to patients [24]. Individual scores were integrated into graphical displays with colored bar charts [28,29]. Patients had the opportunity to compare their scores to mean scores of other patients with lymphoma and an age- and sex-matched normative population without cancer [30] to determine whether their scores were average or not. The colors of the bar charts were related to clinically relevantly mean differences of the evidence-based guidelines of the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Organization [31] and considered *average* (amber); *above average* (green); or *below average* (red). Patients with above-average symptom scores were advised to contact their general practitioner.

Arm 3: Return of PRO Results + Living With Lymphoma

In addition to the return of PRO results, patients in arm 3 had access to a web-based self-management intervention—Living with lymphoma. A detailed description of Living with lymphoma has been described elsewhere [24]. Living with lymphoma, an adaptation of the evidence-based BREATH (Breast Cancer eHealth) intervention for breast cancer [32,33], was based on psychoeducation and cognitive behavioral therapy techniques to enhance patients' knowledge and skills. The intervention also included a library with background and additional information on various subjects (eg, work, sexuality, lifestyle) and reference to additional health care services (eg, psychologists, physiotherapists). It was left to the discretion of the patients how and to what extent they used the intervention. The intervention was fully automated, nonguided, and delivered without professional therapist support.

Measures

Sociodemographic and Clinical Measures

Sociodemographic characteristics (age and sex) and detailed clinical information (date of diagnosis, cancer type, and primary treatment) were obtained from the NCR. NCR data were available for both RCT participants and nonparticipants. Information on educational level and marital status was assessed in the questionnaire (data only available for RCT participants).

Comorbidities at the time of questionnaire completion were assessed using an adapted version of the Self-Administered Comorbidity Questionnaire [34]. Patients were asked to identify comorbidities present within the past 12 months—heart disease, hypertension, arthritis, stroke, lung disease, diabetes, stomach disease, kidney disease, liver disease, anemia, thyroid disease, and rheumatoid arthritis. Positive responses were summed to a total score ranging from 0 to 12 (data only available for RCT participants).

Psychological Measures

Personality traits were assessed using the Big Five Inventory [35], a 44-item inventory for measuring the Big Five personality traits—neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness. Items are scored on a 5-point scale. Scale scores were obtained by averaging all items for each trait and range from 0 to 5 [36].

The 40-item Mental Adjustment to Cancer scale was used to assess adjustment to cancer in terms of coping strategies [37,38]. Items were grouped on five categories: *Helplessness/Hopelessness*, *Anxious Preoccupation*, *Fighting*

Spirit, *Fatalism*, and *Avoidance*. Each item is rated on a 4-point scale. Scale scores were obtained by averaging all items of each strategy and range from 1 to 4. Higher scores represent higher endorsement of the coping strategy.

Health-related quality of life was assessed using the 30-item Quality of Life Questionnaire from the European Organisation for Research and Treatment of Cancer [39]. This questionnaire includes five functional scales, three symptom scales, a global health and quality of life scale, and several single-item symptom measures. Items are scored on a 4-point Likert scale, except for the global health and quality of life scale that is scored on a 7-point linear analog scale. After linear transformation, all scales and single item measures range in score from 0 to 100. Higher scores on functional and health and quality of life scales indicate better functioning or HRQoL, whereas higher scores on symptom scales indicate more complaints.

Self-management Skills

Self-management skills were assessed using the Health Education Impact Questionnaire, which contains 40 items across 8 scales—positive and active engagement in life, health-directed activities, skill and technique acquisition, constructive attitudes and approaches, self-monitoring and insight, health service navigation, social integration and support, and emotional distress [40]. Each item was scored on a 4-point scale. Scale scores were obtained by averaging all items of each domain and ranged from 1 to 4. Higher scores indicate better status or self-management, except for emotional distress, in which higher scores indicate higher distress [40].

Satisfaction With Information Provision

Satisfaction with overall information provision was assessed using an adapted version of the 9-item Information Satisfaction Questionnaire [41]. Patients were also asked to rate their level of satisfaction with overall information on a scale that ranged from 1 (“very unsatisfied”) to 5 (“very satisfied”). In addition, information on patient information preferences was available. Patients were asked to categorize themselves into those who would like (1) all available information, (2) only positive information, and (3) only limited information about their disease. Finally, patients had to categorize themselves into those who would like (1) to be involved in the decision-making process about their disease, or (2) the physician to make the decisions.

Psychological Distress

Psychological distress was assessed using the 14-item Hospital Anxiety and Depression Scale [42]. Each item was rated on a 4-point scale ranging from 0 to 3. The sum score was obtained by adding all item scores and ranged from 0 to 42. Higher scores indicated higher levels of psychological distress [43]. Patients with a Hospital Anxiety and Depression Scale sum score ≥13 were categorized as *psychologically distressed* [44].

Health Care Use

Two open questions were asked to assess health care use: (1) “How often did you contact a general practitioner in the past 12 months?” and (2) “How often did you visit a medical specialist in the past 12 months?”

Statistical Analyses

Overview

Sociodemographic and clinical characteristics between the three arms were compared using univariable analyses of variance and chi-square tests. If at least half of the items from a subscale were completed, the missing items were replaced by the average of those that were present for the participant.

To model between-group differences in change from baseline (T0) to follow-up (T1-T3), mixed-effects models were used with an unstructured covariance structure and a restricted maximum likelihood solution [45]. A random intercept at the patient level was included to adjust for interdependency between repeated measures. The CAU-arm (arm 1) was assigned as the reference group. The *P* value for overall model effects was set at .05, and for specific contrasts at .01, lowering the risk of type I errors as a result of multiple testing. In the iterative process of variable selection, a priori selected covariates (age, sex, cancer type, and treatment) were removed from the model as they were nonsignificant and had no confounders. However, as those in the CAU arm seemed to be somewhat more often psychologically distressed (17/77, 22%) than patients in the return of results arm (9/74, 12%) and the arm with return of results and access to Living with lymphoma (8/76, 11%; *P*=.10; Table 1), we considered psychological distress as a confounding factor and adjusted for baseline psychological distress in analyses (when psychological distress was not the outcome variable). Group differences in mean change scores from baseline to follow-up were accompanied by Cohen effect size (ES). Cohen ES was calculated by dividing the difference in mean change scores between the control and intervention groups by the pooled baseline SD. An ES of 0.20 was considered small, 0.50 moderate, and 0.80 large [44,46]. All analyses were conducted on an intention-to-treat basis. All statistical analyses were performed using SAS version 9.4.

[b]PRO: patient-reported outcome.

[c]Reports comparisons between the intervention arms and the care as usual arm.

[d]Reports comparisons between randomized controlled trial participants and nonparticipants.

[e]Education levels were low=none or primary school; medium=lower general secondary education or vocational training; or high=preuniversity education

or high-level vocational training or university.

[f]N/A: not applicable.

[g]Not available.

[h]NHL-HG: high-grade non-Hodgkin lymphoma.

[i]NHL-LG: low-grade non-Hodgkin lymphoma.

[j]CLL: chronic lymphocytic leukemia.

Power Calculation

With more than 74 participants per study arm, the study had 90% power to detect an ES of 0.50 with a two-tailed *P* value set at .05 [47].

Results

Baseline Characteristics of RCT Participants

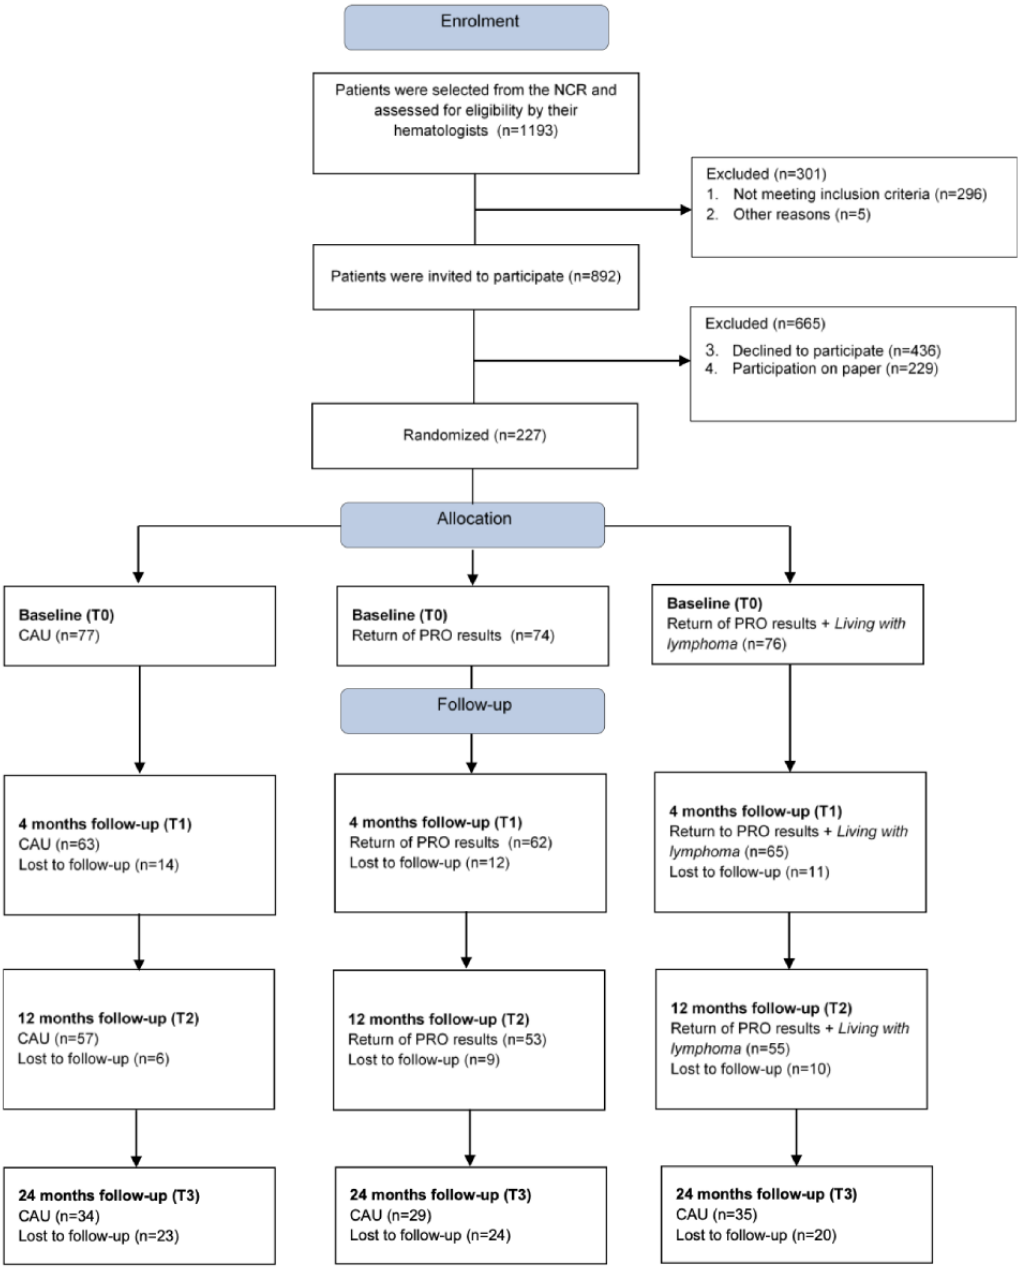
In total, 1193 patients were selected from the NCR and 892 patients were invited to participate. Of these, 51.1% (456/892) participated, of which 25.7% (229/892) were excluded for the RCT as they completed the questionnaire on paper (CONSORT [Consolidated Standards of Reporting Trials] diagram; Figure 1).

Overall, 25.4% (227/892) completed the web-based questionnaire and were included in the RCT. They were randomly assigned to CAU (control group; n=76), return of PRO results (n=74), or return of PRO results and access to Living with lymphoma (n=77). Completion rates of follow-up questionnaires were 84.1% (191/227) on T1, 74.9% (143/191) on T2, and 68.5% (98/143) on T3, and did not differ significantly among groups.

Those who declined participation or completed the questionnaire on paper were analyzed as nonparticipants in this study. All participants provided written informed consent.

RCT participants were younger than nonparticipants (60.7 vs 65.3 years; *P*<.001), and more often men (161/227, 70.9% vs 377/666, 56.6%; *P*<.001). RCT participants were on average 14.0 months after diagnosis (SD 3.2 months). The majority of RCT participants had a partner (190/227, 83.7%). Of the RCT participants, 75.8% (172/227) received active treatment, mostly chemotherapy (137/227, 60.4%), whereas 23.3% (53/227) were on active surveillance. The majority of patients had Ann Arbor stage IV disease at the time of diagnosis. Other baseline sociodemographic and clinical characteristics did not differ across groups (Table 1).

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) flow diagram of the progress of the patients with lymphoma through the phases of the Lymphoma Intervention (LIVE) trial. CAU: care as usual (control group); NCR: Netherlands Cancer Registry; PRO: patient-reported outcome.



The Living With Lymphoma Self-management Intervention

The use of self-management intervention was very low (3/76, 4%). Therefore, the effects of *Living with lymphoma* could not be determined within this RCT and were not included in the results. The analyses were performed with the three original RCT arms to maintain a power of 90%.

As we observed that adherence to Living with lymphoma intervention was very low one year after starting patient inclusion, research assistants sent an email for inquiry. A random sample of 5 patients who had access to the intervention and signed up were asked to respond without any obligation and were asked for their reasons for nonadherence. Two patients responded that they felt well and still had regular appointments with their hematologist, and therefore were not in need of an intervention:

> *In the first place, I feel very well, both physically and mentally. Secondly, I have regular appointments with my treating haematologist. Furthermore, I do not always want to be confronted with my disease.* [Male, 79 years]

> *I am not really concerned about the fact that I have had cancer. I am in remission for one year now, and that is how I feel. Every three months, I still have checkup appointments, but other than that I live my life the way I did before I had cancer. I feel fine, I have no limitations, and therefore I do not need information about a disease from the past.* [Male, 54 years]

Return of Individual PRO Results

No statistically significant differences were observed for psychological distress, self-management subscales, and satisfaction with information provision between patients who received their individual PRO results and those who did not (Table 2). In addition, the return of PRO results did not have a significant effect on health care use. As no significant overall group-by-time interaction was found for the outcome variables, we were not allowed to explore specific contrasts.

Table 2. Between-group differences in mean change from baseline to follow-up.

[a]HADS: Hospital Anxiety and Depression Scale (psychological distress subscale range, 0-42, with higher scores indicating more psychological distress).

[b]*P* value of the overall time-by-group interaction.

[c]CAU: care as usual (control group; reference category).

[d]N/A: not applicable.

[e]PRO: patient-reported outcome (T0, baseline assessment; T1, short-term follow-up assessment at 4 months postrandomization; T2, follow-up assessment at 12 months postrandomization; T3, follow-up assessment at 24 months postrandomization).

[f]HeiQ: Health Education Impact Questionnaire (self-management ability subscales range, 0-4, with higher scores indicating higher levels of self-management ability).

[g]ISF: Information Satisfaction Questionnaire (information satisfaction subscale range, 0-5, with higher scores indicating more satisfaction with perceived information).

Of the 150 patients who were randomized to arm 2 or 3 and had access to individual PRO results, 115 (76.7%) patients viewed their PRO results. The majority (79/115, 68.7%) viewed their PRO results more than once, and 16% (13/79) viewed it more than 5 times.

Patients with lymphoma who viewed their PRO results were more recently diagnosed (13.6 vs 15.0 months; *P*=.03), had a more conscientious personality (3.8 vs 3.6; *P*=.01), and had a less fatalistic coping style than those who did not (2.1 vs 2.2; *P*=.02; Table 3). In addition, patients who did view their PRO results more often wished to receive all available information about the disease compared with those who did not (68/115, 59.1% vs 10/35, 29%; *P*=.004).

Of those who viewed the PRO results, 91.3% (105/115) wished to compare their individual results to other patients with lymphoma and 80.8% (93/115) to a normative population without cancer. Only 7.8% (9/115) solely wanted to view their individual results.

Table 3. Baseline characteristics of patients who viewed their individual patient-reported outcome (PRO) results and those who did not.

[a]*P* reports comparisons according to analysis of variance and chi-square tests.

[b]Educational levels were defined as follows: low=none or primary school; medium=lower general secondary education or vocational training; or high=preuniversity education or high-level vocational training or university.

[c]NHL-HG: high-grade non-Hodgkin lymphoma.

[d]NHL-LG: low-grade non-Hodgkin lymphoma.

[e]CLL: chronic lymphocytic leukemia.

Discussion

Principal Findings

The results of this RCT demonstrated that patients were neither in a better nor in a worse situation when their individual PRO results were disclosed, as no effects of return of PRO results were found on psychological distress, self-management skills, and satisfaction with information provision. In addition, patients who received their PRO results did not report more contact with their general practitioner or medical specialist compared with those receiving CAU.

Return of individual PRO research results seems to meet patients' wishes, as the majority of those with access viewed their individual results, of whom two-thirds viewed it more than once. The possibility of comparing their scores with peers was most often chosen, indicating the importance of including normative data to place outcomes in perspective. Almost a quarter chose not to receive their results. Therefore, patients should have the choice as to whether they would like to receive their outcomes [14].

We observed little statistical differences in characteristics of patients who did view their PRO results and those who did not. Patients who viewed their PRO results more frequently wanted to receive all available information about the disease compared with those who did not view their results. This is in line with the literature that patients with a monitoring (information seeking) coping style tend to benefit from more provided information, whereas patients with a blunting (information avoiding) coping style benefit from less information [48,49].

There is increasing interest in integrating the collection of PROs in routine practice to enhance clinical care [50]. Weekly measurement of symptoms by patients during active treatment has proven to be effective, as 2 landmark studies on advanced solid tumors showed improvement in HRQoL and survival [51-53]. In our RCT, return of PRO results took place after treatment completion, including patients without advanced cancer stage, not specifically focusing on symptoms and was returned to patients only and not to their treating physician, which all may have contributed to differences in effects. With the continuing development of new and often expensive therapies for patients with cancer (eg, immunotherapy), further research and monitoring of the early onset and course of symptoms remains highly needed [54].

We could not compare our results to the evidence-based BREATH intervention for breast cancer [32,33], the original web-based self-management intervention from which Living with lymphoma intervention was derived, as uptake in our RCT was too low to study the effect. With respect to the design of the study, it was our explicit intention to examine the uptake and effects of a self-management intervention (without personal contact with a therapist) in a population-based setting (where all patients were asked, and no screening took place) to evaluate if this would be a possibility to provide low-intensity care to the continuously growing group of cancer survivors. This may have contributed to the much lower uptake compared with that of BREATH. Therapist guidance may improve patient engagement with a self-management intervention [55]. An important aspect of engagement is self-efficacy, which is a central element of several therapies, such as behavior change theory and planned behavior as a health access approach.

With respect to the *Living with lymphoma* intervention, we were not able to determine an effect as uptake was too low (3/76, 4%). Only 2 patients opened several components of the cognitive behavioral therapy parts, and various items from the library were viewed: *Reliable information*, *Fatigue*, *Emotional counselling*, and *Nutrition and cancer*, *Exercise*, *Physical counselling*, *Sexuality*, and *Reintegration*. As we observed that adherence was very low, we asked patients about reasons for nonadherence, and they indicated they felt well and still had regular appointments with their hematologist and therefore were not in need of an intervention. Furthermore, the majority of participants were men, and poor engagement in self-management was more common for men, as men may be more reluctant to seek help [56]. In addition, the timing of the intervention may not have been optimal, as participants were on average 14 months after diagnosis and patients appeared more receptive to interventions offered near diagnosis [57]. There is evidence that unguided self-management interventions could be more effective when targeted to those in the greatest need of an intervention, such as patients with low distress [32,58]. This might suggest that the need for intervention in our sample may be low and we may have not reached the right group, despite the invitation of a population-based sample and limited exclusion criteria.

This is the first RCT to study the effect of the return of individual PRO results to patients with lymphoma or to patients with cancer in general. The strengths of this study include the design and linkage of PROs with clinical data from the NCR. Owing to the design of our RCT, within a population-based observational cohort, we had access to sociodemographic information about nonparticipants. This provides a unique opportunity to make clear statements about the representativeness of the sample. Participants of the RCT were younger, more often male, and more often highly educated [59]. Ideally, the RCT sample will be representative of the entire target population so that generalizations about the population can be made. More research is needed to understand why underrepresented patients were not reached and how they could be reached in the future.

Conclusions

In conclusion, the return of individual PRO results seems to meet patients' wishes, even though it had no beneficial effects on patient outcomes; it did not have negative effects either. Therefore, we decided to include and implement the return of individual PRO results in the PROFILES registry. In addition, at this moment, the return of individual PRO results is extended to other cancer types, such as colorectal cancer, and is used in daily clinical practice. No conclusions could be drawn about the effectiveness of the self-management intervention because the uptake was too limited.

Acknowledgments

This randomized controlled trial was financially supported by the Jonker-Driessen Foundation. The Patient-Reported Outcomes Following Initial Treatment and Long-Term Evaluation of Survivorship registry was funded by an investment grant (480-08-009) of the Netherlands Organization for Scientific Research (The Hague, The Netherlands). Both funding agencies had no further role in study design; in the collection, analysis, and interpretation of data; in the writing of this paper; and in the decision to submit the paper for publication.

Authors' Contributions

SO was responsible for data collection, data analysis, and drafting of the manuscript. LPJA was responsible for patient recruitment, data collection, data analysis, and drafting of the manuscript. JMK was responsible for data analysis and contributed to the writing of this manuscript. JP designed the intervention that was originally developed for breast cancer patients and wrote the intervention content. MH, MVDP, AK, CL, WS, DI, JP, MO, RVDG, MN, LT, and EP were responsible for data collection and contributed to writing this manuscript. LVDPF was the project leader and was a major contributor in drafting this manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Internationally, the implementation of evidence-based healthy eating policies and practices within early childhood education and care (ECEC) settings that encourage children's healthy diet is recommended. Despite the existence of evidence-based healthy eating practices, research indicates that current implementation rates are inadequate. Web-based approaches provide a potentially effective and less costly approach to support ECEC staff with implementing nutrition policies and practices.

Objective: The broad aim of this pilot randomized controlled trial is to assess the feasibility of assessing the impact of a web-based program together with health promotion officer (HPO) support on ECEC center implementation of healthy eating policies and practices. Specifically, we seek to describe the completion rate of study evaluation processes (participant consent and data collection rates); examine ECEC center uptake, acceptability, and appropriateness of the intervention and implementation strategies; understand the potential cost of delivering and receiving implementation support strategies; and describe the potential impact of the web-based intervention on the implementation of targeted healthy eating practices among centers in the intervention group.

Methods: A 6-month pilot implementation trial using a cluster-randomized controlled trial design was conducted in 22 ECEC centers within the Hunter New England region of New South Wales, Australia. Potentially eligible centers were distributed a recruitment package and telephoned by the research team to assess eligibility and obtain consent. Centers randomly allocated to the intervention group received access to a web-based program, together with HPO support (eg, educational outreach visit and local technical assistance) to implement 5 healthy eating practices. The web-based program incorporated audit with feedback, development of formal implementation blueprints, and educational materials to facilitate improvement in implementation. The centers allocated to the control group received the usual care.

Results: Of the 57 centers approached for the study, 22 (47%) provided consent to participate. Data collection components were completed by 100% (22/22) of the centers. High uptake for implementation strategies provided by HPOs (10/11, 91% to 11/11, 100%) and the web-based program (11/11, 100%) was observed. At follow-up, intervention centers had logged on to the program at an average of 5.18 (SD 2.52) times. The web-based program and implementation support strategies were highly acceptable (10/11, 91% to 11/11, 100%). Implementation of 4 healthy eating practices improved in the intervention group, ranging from 19% (2/11) to 64% (7/11).

Conclusions: This study provides promising pilot data to warrant the conduct of a fully powered implementation trial to assess the impact of the program on ECEC healthy eating practice implementation.

Introduction

Background

Poor dietary intake in early childhood, including inadequate intake of fruit and vegetables and excessive intake of discretionary foods (high in added sugar, sodium, and saturated fat), is a leading contributor to the development of childhood overweight, obesity, cardiovascular disease, and specific types of cancers [1,2]. Globally, preschool aged children do not meet national dietary recommendations for intake of fruit and vegetable servings, while overconsuming discretionary food items [2-5]. As dietary behaviors developed during childhood are known to track into adulthood [6], population-level interventions (ie, interventions targeting a large proportion of the population) to improve child nutrition are recommended [7,8]. Early childhood education and care (ECEC) is a promising setting for interventions aimed at improving children's nutrition behaviors, as they provide access to a large proportion of children [3,9] for prolonged periods [10] during a crucial period of development [11].

Systematic review evidence has identified numerous ECEC-based interventions effective in improving child nutrition behaviors [12] and center nutrition environments [13], including the implementation of evidence-based ECEC practices associated with improved child dietary intake in care [13,14]. The implementation of such evidence-based practices is recommended within national and international ECEC guidelines and includes the provision of healthy foods, positive educator feeding practices (eg, role modeling healthy food choices), and developing center nutrition policies, which detail center strategies and guidelines to enforce the implementation of healthy eating practices [15-17]. However, despite the existence of such guidelines, numerous studies have indicated that the current implementation of evidence-based healthy eating practices is inadequate [18-21].

A recent Cochrane systematic review identified that multicomponent implementation strategies, including researcher delivered face-to-face nutrition education sessions and ongoing support, can produce small but significant improvements in the implementation of healthy eating practices in ECEC centers [13]. Although potentially effective, there are significant challenges in delivering such interventions at scale (ie, to a large number of ECEC centers), including financial and resource burden on centers and the lack of alignment with center capabilities and infrastructure [13]. Web-based modalities provide a potentially effective and less costly approach to implementing nutrition interventions at scale in this setting. Previous research suggests that the use of such modalities to deliver support to center staff is highly acceptable and fits within the existing center infrastructure (eg, access to computers and internet) [12,22,23]. In addition, these modalities can reach a large proportion of the population [24] and have been associated with improvement in a range of provider behaviors and implementation outcomes in previous research delivered outside the ECEC setting [25,26].

Recent trials examining the impact of web-based interventions on ECEC healthy eating practices have been conducted within menu-based centers (ie, centers that provide food to children). A randomized controlled trial (RCT) conducted in 54 Australian childcare centers evaluated the impact of a web-based menu planning program on center compliance with sector dietary guidelines [27]. Results of the RCT found statistically significant improvements in the servings of core food groups and child diet intake; however, the intervention had nonsignificant improvements in the primary outcome of menu compliance with all food groups. The study reported variable levels of engagement with the web-based program, despite the high uptake of implementation support strategies and high acceptability of the intervention and implementation support provided [27]. In addition, the web-based intervention was deemed a cost-effective alternative to traditional menu planning approaches [23]. Within the United States, a pilot RCT conducted in 31 centers evaluated the impact of the web-based Nutrition and Physical Activity Self-Assessment for Child Care (Go-Nutrition and Physical Activity Self-Assessment for Child Care [Go-NAPSACC]) program on center nutrition environments [28]. Despite improvements in food and beverages provided within intervention centers, no statistically significant differences in center nutrition environments were reported at follow-up [28]. Center engagement with the web-based program was not reported; however, the uptake of the implementation support strategies was high among intervention centers. Findings from the process evaluation indicated that a lack of computer literacy among center staff and the need for additional technical support were barriers to program use [28]. Despite these studies showing promise, no RCTs examining the impact of web-based interventions on ECEC healthy eating practices within lunchbox centers (ie, where parents pack foods for children to consume in care) have been conducted.

Objectives

Given the differences between menu-based and lunchbox centers, there is a need to understand whether such interventions

are feasible in the ECEC setting. Feasibility studies are recommended as they allow researchers to collect data to determine whether an intervention is appropriate for more robust testing and to pilot-test recruitment and data collection methods and tools to inform a larger trial [29]. Thus, the aim of this pilot RCT is to determine the feasibility of conducting a fully powered implementation trial assessing the impact of a web-based program together with health promotion officer (HPO) support, on childcare center implementation of healthy eating policies and practices. Specifically, we seek to (1) describe the completion of study evaluation processes (participant consent and data collection rates); (2) examine ECEC center uptake, acceptability, and appropriateness of the intervention and implementation strategies; (3) understand the potential cost of delivering and receiving the implementation strategies; and (4) describe the potential impact of the web-based intervention on the implementation of healthy eating practices among centers in the intervention group.

Methods

Registration and Ethics Approval

This trial was prospectively registered with the Australian New Zealand Clinical Trials Registry (ACTRN12619001158156) and followed the CONSORT reporting guidelines for pilot and feasibility studies [30]. Ethical approval for the trial was obtained from Hunter New England (HNE; HNE approval 06/07/26/4.04) and the University of Newcastle (approval H-2008-0343) Human Research Ethics Committees.

This trial was originally designed as a cluster RCT using an effectiveness-implementation hybrid type-II design. A hybrid effectiveness-implementation design was used to pilot the potential impact and assess the feasibility of an implementation intervention, while assessing the effectiveness of the intervention in improving child dietary intake in care as described by Curran et al [31]. Owing to COVID-19 precluding center site visits to conduct follow-up data collection, we were unable to undertake child lunchbox and dietary assessments and, as such, have not been reported. Therefore, this paper reports on the pilot implementation outcomes that could still be evaluated at follow-up and were specified in the trial registration and protocol.

Study Design and Setting

A protocol detailing the study design and methodology has been published elsewhere [32]. In brief, a pilot implementation trial using a cluster RCT design was conducted in center-based childcare centers within the HNE region of New South Wales, Australia. The HNE region is socioeconomically and geographically diverse, encompassing metropolitan, regional, and remote communities, with a population of over 920,000 residents [33]. Approximately 422 center-based childcare centers, including preschools and long day care, are located within the HNE region, which typically enroll children aged 0-6 years for an average of 21 hours per week [10,34].

Participant Eligibility and Recruitment

Centers

Centers were eligible to participate in the trial if (1) they enrolled >20 children per day, (2) had internet access, (3) parents provided food for children to consume while attending care (ie, centers did not provide food), (4) they did not participate in any other healthy eating or physical activity intervention, and (5) they were not fully compliant with healthy eating practices (ie, not implementing all 5 practices) specified in the NSW state obesity-prevention program (ie, *Munch & Move*) targeted by the intervention, according to the NSW Ministry of Health data monitoring [35]. Centers were ineligible if they were a mobile preschool or family day care center, did not cater to children aged 2-5 years, catered exclusively for children requiring specialist care, or were classified as an NSW Department of Education center owing to differing operational characteristics.

A list of potentially eligible centers located within the HNE region was obtained from the NSW Ministry of Health [35]. One member of the research team with experience recruiting centers to health promotion trials led the recruitment process and monitored consent rates. First, centers were progressively distributed a recruitment package consisting of a study information statement and consent form in random order. Second, the research team member leading recruitment telephoned centers to discuss study details, assess eligibility, and request consent for study participation [19,36]. The centers continued to be contacted until the required number (n=22) consented. During the telephone call, the research team member also scheduled a 2-day baseline data collection site visit for consenting centers. Recruitment for the study was conducted between August 2019 and October 2019.

Children

For children to be eligible to participate, they were required to (1) have written consent from a parent or guardian, (2) be between the ages of 2 and 5 years, (3) be enrolled to attend the center on at least one of the scheduled days of data collection, and (4) not have a dietary restriction requiring specialized tailoring of their diet (eg, allergies or intellectual or physical disability).

Approximately 2 weeks before the baseline data collection site visit, centers were asked to distribute consent forms and information statements to parents via usual communication methods, including email, communication apps, and child pigeonholes. Trained research assistants with experience in recruitment and data collection attended the childcare centers approximately one week before the site visit and on the days of the site visits to request written consent from parents for their children to participate in the study.

Randomization and Blinding

Following baseline data collection, centers were randomly allocated to the intervention or control group, stratified by center socioeconomic status (SES). On the basis of center postcodes, the 2016 Socio-Economic Indexes for Areas was used to classify centers as being located in the least disadvantaged (high SES) or most disadvantaged (low SES) areas [37]. Center postcodes

ranked in the top 50% of NSW were classified as least disadvantaged and the lower 50% of postcodes as the most disadvantaged. The centers were also stratified by those with a high number of Aboriginal child enrollments (defined as those with >10% Aboriginal child enrollments), in a 1:1 ratio through a block randomization procedure (block sizes 2 or 4) conducted by an independent blinded statistician. Given the nature of the intervention (ie, intervention centers were provided access to a web-based program), the centers were not blinded to group allocation. Data collectors were not blinded to group allocation at follow-up.

Intervention

The intervention aimed to improve the implementation of childcare center–level healthy eating practices. The practices targeted within the intervention are recommended by the NSW state obesity-prevention program (ie, *Munch & Move*) [17] as well as national and international guidelines, acknowledging the association between such practices and improved child dietary intake in care [15,16]. Specifically, the practices included the following:

1. Supporting families to provide healthier foods consistent with dietary guidelines: center staff within the intervention group were provided with healthy eating information and resources via the web-based program and were asked to disseminate these to families via usual center communication methods, such as mobile apps, email, and written information, twice during the intervention period. Center staff were also asked to monitor children's lunchboxes daily for consistency with sector-specific dietary guidelines and provide feedback to parents.
2. Provision of intentional healthy eating learning experiences (eg, gardening and cooking lessons): center staff were asked to provide children with intentional healthy eating learning experiences at least twice per week.
3. Using feeding practices that support children's healthy eating (eg, educator role modeling healthy food choices): center staff were asked to provide encouragement to children to promote healthy eating and trying new foods at every meal and snack occasion. Center staff were also asked to role model consuming healthy food choices and avoid the use of foods to encourage desired behavior.
4. Staff participating in professional development targeting healthy eating: center staff were asked to have at least 50% of the staff to participate in web-based training opportunities specific to staff healthy eating behaviors and center practices.
5. Having a comprehensive written nutrition policy that outlines key healthy eating practices: centers were asked to develop or modify existing nutrition policies to document procedures and strategies to facilitate the implementation of healthy eating practices to improve child diet.

A detailed description of these practices is provided in the study protocol [32].

A web-based program, known as Childcare Electronic Assessment Tool and Support (EATS), was developed by the research team to support center implementation of the 5 targeted healthy eating practices. The centers allocated to the intervention group were provided with free access to the web-based program. The intervention was developed by behavioral science researchers, HPOs, state government representatives, and end users from the ECEC setting, including nominated supervisors and educators.

The Behavior Change Wheel (BCW) [38] was used to guide the development and selection of implementation strategies to support center staff in achieving behavior change. During this process, barriers and enablers to center behavior change identified through a literature review and engagement with ECEC staff and stakeholders were mapped to specific behavior change techniques (BCTs) within the BCW [38]. A suite of implementation strategies, defined according to the expert recommendations for implementing change taxonomy, were then selected to action the BCTs within the intervention [39]. The content and implementation strategies within Childcare EATS were selected to ensure user (ie, center staff) engagement, including self-assessment and action planning components to allow center nominated supervisors to reflect on current practice and housed educational resources to facilitate improvements in staff behavior and center processes. The features of the program were developed to integrate within existing center procedures, (eg, the ability to download feedback from the self-assessment quiz) and national assessment and rating standards (eg, the development of action plans as evidence within quality improvement plans). Extensive pilot testing was undertaken with ECEC staff through face-to-face meetings with HPOs to ensure that the functionality and content of Childcare EATS was appropriate and that any potential barriers to program use were addressed. Limitations from previous web-based interventions conducted within the ECEC setting, including low staff computer literacy, need for ongoing technical support, and competing priorities of ECEC staff were also considered during the development of the program [28,40].

Implementation strategies additional to those embedded within the web-based program identified via the BCW process above were used by HPOs who work within the state local health districts to deliver health promotion initiatives within community-based settings such as childcare centers. The HPOs received a training session and implementation manual before delivering the intervention. In addition, HPOs conducted 2 pilot training sessions, with both internal (health service staff with extensive experience supporting ECEC centers to implement obesity prevention initiatives) and external (ECEC center staff) stakeholders. The application of these implementation strategies within the intervention is summarized in Table 1 using the Proctor framework [41] to enable replication.

Table 1. Implementation strategies and behavior change techniques used within the web-based intervention.

Mode of delivery and implementation strategy according to ERIC[a] [39]	Application of the implementation strategy according to Proctor [41]	Behavior change technique actioned via the implementation strategy
Web-based program		
Audit with feedback	• Actor: web-based program • Action: the Childcare EATS[b] program contained a self-assessment feature for centers to assess implementation of targeted healthy eating practices. Centers were automatically provided with tailored feedback on practice performance. • Target: nominated supervisors and center champion knowledge, behavior and abilities, perceived capabilities, and confidence to implement change • Temporality: commencement of the intervention. Centers were encouraged to complete the self-assessment at least twice during the intervention period to monitor change in practice, following the educational outreach visit. • Dose: twice during the intervention period • Implementation outcome: implementation of healthy eating practices • Justification: provision of feedback on center behavior has been used within previous interventions to facilitate improvement in practice within ECEC[c] centers [28,42]	• Feedback on behavior • Feedback on outcome of behavior • Self-monitoring of behavior
Develop a formal implementation blueprint	• Actor: web-based program • Action: following the completion of self-assessment, centers were encouraged to select goals and develop an action plan within the Childcare EATS program. • Target: nominated supervisors and center champion prioritization and investment and perceived capabilities to implement change; formalized guidance and demonstrated support to implement change • Temporality: commencement of the intervention. Centers were encouraged to develop an action plan at least twice within the intervention period, immediately following the self-assessment (audit with feedback). • Dose: twice during the intervention period • Implementation outcome: implementation of healthy eating practices • Justification: developing a formal implementation blueprint has been used within previous interventions to facilitate improvement in practice within ECEC centers [28].	• Goal-setting (outcome and behavior) • Action planning • Problem solving • Review goals (outcome and behavior)
Distribute educational materials	• Actor: web-based program • Action: the Childcare EATS program housed a suite of materials to assist center implementation of the targeted practices, including fact-sheets and resources to facilitate communication with parents; educational materials to improve staff knowledge; example healthy eating learning experiences; professional development and policy templates. • Target: nominated supervisors and center champions to increase staff member knowledge and abilities to implement practices • Temporality: commencement of the intervention. Centers were encouraged to access resources immediately following action planning (development of a formal implementation blueprint). • Dose: accessed at any time during the intervention period • Implementation outcome: implementation of healthy eating practices • Justification: the provision of support and resources via web-based programs is highly acceptable among ECEC staff and has been used within previous interventions within the ECEC setting [22,27,28].	• Demonstration of behavior • Restructuring the physical environment • Adding objects to the environment • Prompts or cues • Credible source
Health promotion officer		

Mode of delivery and implementation strategy according to ERIC[a] [39]	Application of the implementation strategy according to Proctor [41]	Behavior change technique actioned via the implementation strategy
Educational outreach visit	• Actor: HPO[d] • Action: 1.5-2–hour practical face-to-face training session with an HPO was provided to nominated supervisors and center champions to introduce the web-based program and support implementation of the healthy eating practices. • Target: nominated supervisors and center champion knowledge and ability to implement change • Temporality: one-off face-to-face training session (1.5-2 hours) at the start of the intervention (2-8 weeks after baseline) • Dose: one-off training session • Implementation outcome: adoption of the intervention • Justification: face-to-face training within previous ECEC-based interventions has been highly acceptable and used within previous interventions conducted by the research team [27,42]	• Instruction on how to perform behavior • Demonstration on how to perform behavior
Identify and prepare a center champion	• Actor: center champion • Action: center nominated supervisors were asked to identify and prepare a staff member who could dedicate themselves to endorsing and driving implementation of the intervention within their center and asked to attend the educational outreach visit. • Target: center champions; staff investment and motivation to change, formalized guidance and demonstrated support for staff • Temporality: commencement of the intervention period • Dose: ongoing endorsement and support for use of the web-based program throughout the intervention period • Implementation outcome: adoption of the intervention and implementation of healthy eating practices • Justification: preparing a champion has been identified as an effective strategy to drive implementation and has been used in previous trials by the research team [39,43,44].	• Identification of self as role model • Social support (unspecified)
Mandate change	• Actor: HPO, nominated supervisor, and center champion • Action: an MoU[e] was developed to outline the responsibilities and level of commitment expected from both the center and the HPO in working to implement the targeted healthy eating practices. Center nominated supervisors and champions discussed the MoU with the HPO and tailored the content of the MoU to suit the needs of the center. • Target: nominated supervisors and center champion investment and motivation to change, formalized guidance and demonstrated support for staff • Temporality: MoU drafted during the face-to-face educational outreach visit and finalized and signed by the nominated supervisor, center champion, and HPO 2 weeks following the training • Dose: one-off MoU during the face-to-face educational outreach visit, followed by ongoing advocating and support for use of the web-based program by the nominated supervisor and center champion to center staff during the intervention period • Implementation outcome: adoption of the intervention • Justification: securing executive support from nominated supervisors has been effective in improving implementation of healthy eating practices in previous ECEC-based interventions [19]	• Commitment • Social support (unspecified)
Ongoing consultation and local technical assistance		• Social support (unspecified) • Verbal persuasion about capability

Mode of delivery and implementation strategy according to ERIC[a] [39]	Application of the implementation strategy according to Proctor [41]	Behavior change technique actioned via the implementation strategy
	• Actor: HPO • Action: a telephone call was provided to nominated supervisors and center champions to discuss barriers to center implementation of healthy eating practices and the use of the Childcare EATS program, and to develop strategies to address such barriers. Email and telephone support was provided by HPOs upon center request. • Target: nominated supervisors and center champion prioritization and confidence to implement change, formalized guidance, and support • Temporality: 1 telephone call made to centers approximately 2 months following the face-to-face training session • Dose: once during the intervention period • Implementation outcome: adoption of the intervention and implementation of healthy eating practices • Justification: ongoing consultation has been shown to be effective in improving implementation, staff motivation and problem solving within ECEC-based interventions [45,46].	

[a]ERIC: expert recommendations for implementing change.

[b]EATS: Electronic Assessment Tool and Support.

[c]ECEC: early childhood education and care.

[d]HPO: health promotional officers.

[e]MoU: memorandum of understanding.

Control

Centers allocated to the control group received usual care during the intervention period, including general support from HPOs external to the research team upon request to implement the NSW state obesity-prevention program (ie, *Munch & Move*). The provision of such support was centrally monitored by the research team, with 1 center receiving educational materials to support the implementation of healthy eating and physical activity practices before baseline data collection.

Data Collection and Measures

Baseline data were collected between September 2019 and December 2019, and follow-up data were collected between September 2020 and October 2020. A summary of the study outcomes and time points of measurement is provided in Table 2.

Table 2. Study outcomes and time points of measurement.

Study outcome	Time points of measurement
Center and child demographics	Baseline
Feasibility of the evaluation procedures	
Childcare center and child consent rates	Baseline
Completion of data collection components	Baseline
Uptake, acceptability, and appropriateness of the intervention and implementation strategies	
Delivery of the implementation strategies	6 months
Engagement with the Childcare EATS[a] web-based program	6 months
Acceptability of the implementation strategies	12-month follow-up
Appropriateness of the intervention	12-month follow-up
Cost of implementation strategy delivery	Continuously across study period
Implementation of targeted healthy eating practices within the intervention group	Baseline and 6 months

[a]EATS: Electronic Assessment Tool and Support.

Outcomes: Center and Child Demographics

At baseline, a web-based or telephone interview (depending on center preference) with center nominated supervisors was conducted to collect center demographic information, including the type of center (ie, preschool or long day care), center operating hours, number of Aboriginal or Torres Strait Islander enrollments, and number of children enrolled aged between 2 and 5 years. Center area SES and geographic location were determined using the center postcodes. Nominated supervisor demographic information, including age, was also collected during the baseline interviews. A web-based or telephone

interview (depending on center preference) was conducted with center champions at follow-up to collect demographic information, including age.

Information recorded on parent consent forms was used to examine the child demographics. Parents reported the child's age, sex (as recorded on the child's birth certificate), Aboriginal or Torres Strait Islander background, and usual number of days attending care.

Feasibility of the Evaluation Procedures

The feasibility of the evaluation procedures, defined as the extent to which the research can be effectively carried out within the ECEC setting [47], was assessed via parent and center consent rates and completion of data collection components.

Childcare center and child consent rates were assessed using internal records kept by the research team, center, and child consent forms. Center consent rates were calculated as the number of consenting centers divided by the number of eligible centers that were approached to participate in the study. Reasons for centers declining to participate and ineligibility were recorded by the staff member conducting the recruitment telephone calls. Research assistants present on the days of data collection collated all returned child consent forms, including those from parents who did not provide consent for their child to participate in the study. Class lists specific to the days of data collection were obtained from each participating center to determine the total number of eligible children, with consent rates calculated as the number of consenting children divided by the total number of eligible children.

Completion of data collection components including lunchbox observations and measurements, web-based or telephone interviews with nominated supervisors, and observations of the center nutrition environments, was monitored via internal records kept by the research team. These data collection components were used to evaluate the originally planned trial outcomes related to the center nutrition environment and child dietary intake. Center completion of each individual component of data collection (web-based or telephone interview and assessment of center nutrition environments) was collated and entered into a tracking spreadsheet by a member of the research team. The number of complete child dietary intake data collection forms completed during center site visits was counted and included in the tracking spreadsheet.

Uptake, Acceptability, and Appropriateness of the Intervention and Implementation Strategies

The delivery of the implementation strategies was monitored using internal records maintained by the research team. For each center, the following information was recorded: center receipt of each implementation strategy (ie, number of centers that were offered and accepted or declined each strategy), date, duration, and type (ie, email, telephone, or face-to-face) of each implementation strategy delivered, the role of center staff receiving the implementation strategy (ie, nominated supervisor or center champion), and the delivery of BCTs within each implementation strategy (Table 1).

Engagement with the Childcare EATS web-based program was assessed via Google Analytics [48] embedded within the program. Information collected via the analytics included center completion of self-assessments (ie, audit with feedback), development of action plans (ie, developing a formal implementation blueprint), frequency of centers accessing educational materials, total log-ins to Childcare EATS, and average duration of the log-ins. Such measures have been reported in previous ECEC web-based interventions [27,49].

The acceptability of the implementation strategies, defined as the perception among center staff that the implementation strategies are satisfactory, palatable, or agreeable [47], was assessed through web-based and telephone interviews with nominated supervisors and center champions at follow-up. Interview items were modified from those developed by Weiner et al [50] and those used by the research team in previous ECEC-based studies [27,51]. In total, 10 items captured information on the perceived effectiveness (eg, ease of use and helpful in assessing and improving implementation of practices) of the Childcare EATS web-based program and usefulness of the implementation support strategies [27,47,51]. Nominated supervisors responded to each item on a 5-point Likert scale (1=strongly agree to 5=strongly disagree), with the proportion reporting 2 or lower (agree and strongly agree) for each item calculated.

The appropriateness of the intervention, defined as the perceived fit, relevance, or compatibility of the intervention and for the childcare setting [50], was assessed during the web-based or telephone interview with nominated supervisors at follow-up. In total, 4 items captured information on the perceived fit and suitability of healthy eating practices, using modified items by Weiner et al [50]. Nominated supervisors responded to each item on a 5-point Likert scale (1=strongly agree to 5=strongly disagree), with the proportion reporting 2 or lower (agree and strongly agree) for each item calculated.

Cost to Deliver and Receive Implementation Strategies

The direct cost of each implementation strategy delivered by HPOs, including labor (ie, HPO preparation, administration, and delivery of the strategy) and travel, was calculated. Service delivery costs were recorded by the HPOs delivering the intervention. Costs (in Aus $ and US $, 2019/2020) were calculated by multiplying the time spent (in hours) on each implementation strategy by the hourly wage rate of HPOs delivering the intervention. The cost for nominated supervisors and center champions to receive the implementation strategies delivered by HPOs and embedded within the web-based program was also calculated. Data to calculate center costs were recorded by the HPOs delivering the intervention in addition to the time spent in the web-based program captured by the analytics data. Similar to previous studies examining the cost of receiving interventions within the childcare setting [23], costs were calculated by multiplying the time spent (in hours) receiving each implementation strategy by the estimated hourly wage rate of nominated supervisors and educators [52].

Implementation of Targeted Healthy Eating Practices Within the Intervention Group

Self-reported implementation of the 5 targeted healthy eating practices within the intervention group was assessed via baseline nominated supervisor interview data and self-assessments completed by centers via the web-based program at any time point throughout the intervention. In total, 26 items were based on the validated Environment and Policy Assessment and Observation Self-Report [53] and the tool developed by Dodds et al [54] were used to measure the implementation of the 5 healthy eating practices.

In addition, we also assessed contextual factors influencing the center implementation of healthy eating practices, assessed through web-based and telephone interviews with nominated supervisors at follow-up. A total of 5 interview items were based on constructs within 3 of the 5 domains of the Consolidated Framework for Implementation Research (inner setting: compatibility with center values and direction), innovation characteristics (perceived complexity and cost), and outer setting (external influences such as policies and regulations) to identify factors associated with implementation [55]. Nominated supervisors responded to each item on a 5-point Likert scale (1=strongly agree to 5=strongly disagree), with the proportion reporting 2 or lower (agree and strongly agree) for each item calculated.

Statistical Analysis

All statistical analyses were performed using STATA v14 (StataCorp LLC) [56]. All data were analyzed using descriptive statistics. Chi-square analyses were used to compare characteristics of consenting and nonconsenting centers as well as center and child characteristics between the intervention and control groups at baseline. Center locality was classified as either urban (ie, major cities) or rural (ie, inner regional, outer regional, and remote) according to the Australian Statistical Geography Standard [57]. The 2016 Socio-Economic Indexes for Areas was used to classify centers as being located in the least disadvantaged (high SES) or most disadvantaged (low SES) areas [37]. Center postcodes ranked in the top 50% of NSW were classified as least disadvantaged and the lower 50% of postcodes as the most disadvantaged.

Results

Overview

A total of 22 centers and 448 children participated in the study, with 11 (50%) centers randomized to the intervention group and 11 (50%) to the control group (see Figure 1 for the CONSORT diagram). The demographic characteristics of consenting centers and children are summarized in Table 3. There were no significant differences in center SES or center geographic location between the consenting and nonconsenting centers. In addition, there were no significant differences in the center or child characteristics between the intervention and control groups at baseline.

Figure 1. Study flow diagram.

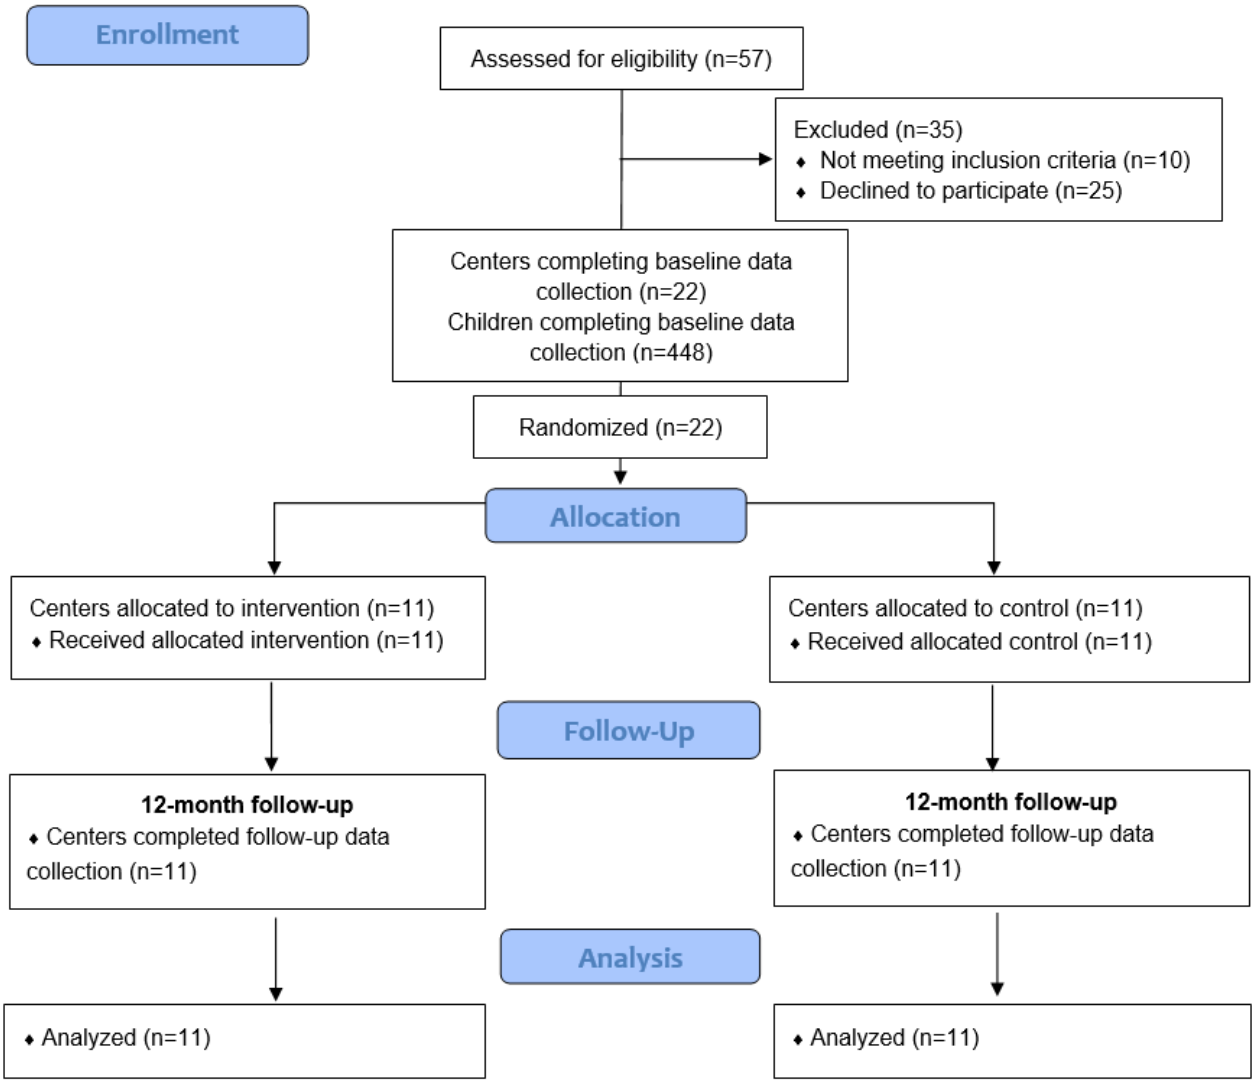

Table 3. Demographic characteristics of participating centers and children (N=11).

Center characteristics	Intervention	Control
Type of center		
Preschool, n (%)	10 (90)	10 (90)
Long day care, n (%)	1 (10)	1 (10)
Child enrollments aged 2-5 years, mean (SD)	30.73 (11.24)	29.0 (8.63)
Aboriginal child enrollments, mean (SD)	5.0 (4.58)	4.64 (3.32)

[a]SEIFA: Socio-Economic Indexes for Areas.

[b]The 2016 Socio-Economic Indexes for Areas was used to classify centers as being located in the least disadvantaged (high socioeconomic status) or most disadvantaged (low socioeconomic status) areas. Center postcodes ranked in the top 50% of New South Wales were classified as least disadvantaged and the lower 50% of postcodes as the most disadvantaged.

[c]SES: socioeconomic status.

[d]Data not available (this item was only applied to nominated supervisors).

Feasibility of the Evaluation Procedures

Childcare Center and Child Consent Rates

Of the 85 potentially eligible centers within the sampling frame, 57 (67%) centers were approached in random order to participate in the study. Of the 57 centers, 10 (18%) centers were ineligible (NSW Department of Education center: 6/10, 60%; involved in another healthy eating or physical activity research trial: 1/10, 10%; and provided food to children: 3/10, 30%) and 25 (44%) centers declined to participate (lack of time: 21/25, 84%; study of lessor importance: 2/25, 8%; and lack of staff capacity: 2/25, 8%). This resulted in an overall study consent rate of 47% (22/57). No centers withdrew from the trial following randomization.

A potential 670 children were eligible to participate in the lunchbox measurements, of whom, 502 (74.9%) provided consent to participate. The consent rate ranged from 53% (16/30) to 96% (24/25) within the participating centers (285/374, 76.2% children within intervention centers and 217/296, 73.3% children within control centers).

Completion of Data Collection Components

Baseline lunchbox observations and measurements conducted to assess the impact of the intervention on child dietary intake were completed for 100% (448/448) of consenting children who were in attendance on data collection days at baseline. The remaining 10.8% (54/502) of the children were absent on the data collection days. Baseline observations of the nutrition environment and web-based or telephone interviews with center nominated supervisors were completed for 100% (22/22) of participating centers.

Uptake, Acceptability, and Appropriateness of the Intervention and Implementation Strategies

Delivery of Implementation Strategies

For implementation strategies delivered by the HPO, 100% of center nominated supervisors or directors were offered and

received the educational outreach visit (ie, face-to-face training session) with the HPO at the commencement of the intervention. The mean duration of the educational outreach visit was 92.73 (SD 21.83) minutes. All centers (n=11) were invited to nominate and prepare a staff member as center champion, with 55% (6/11) of centers nominating a staff member, and 83% (5/6) of these also attending the educational outreach visit. The memorandum of understanding (MoU; ie, mandate change) was drafted with all intervention centers (n=11), with a signed MoU returned by 55% (6/11) of the centers. Ongoing consultation and local technical assistance (ie, follow-up support call provided by the HPO) were offered to 100% (11/11) of the intervention centers, with 91% (10/11) of the centers accepting the call. The mean duration of the follow-up support call was 11.9 (SD 4.70) minutes.

For implementation strategies within the web-based program, overall, 100% (11/11) of centers were provided access to and undertook audit with feedback (ie, self-assessment), developed a formal implementation blueprint (ie, action plan), and accessed the educational materials via the Childcare EATS web-based program.

All intervention centers (n=11) received BCTs as intended in 57% (4/7) of the implementation strategies (Table 4). Additional BCTs (instruction on how to perform the behavior, problem solving, social support [practical], and action planning) were used within the ongoing consultation and local technical assistance strategy in 37% (4/11) of the centers owing to the HPO responding to the needs of the center and tailoring the advice accordingly. Low uptake of the mandate change and identification and preparation of center champion implementation strategies resulted in only 55% (6/11) of the centers receiving the BCTs within these strategies.

Table 4. Behavior change techniques delivered within implementation strategies (N=11).

Mode of delivery, implementation strategy, and behavior change technique	Number of centers
Web-based program	
Audit with feedback	
Feedback on behavior	11 (100)

[a]Additional behavior change techniques used within the ongoing consultation and local technical assistance implementation strategy beyond that specified in the intervention protocol.

Engagement With the Web-Based Program

The intervention center's engagement with the Childcare EATS web-based program is detailed in Table 5. At the 6-month follow-up, intervention centers had logged in to the program on an average of 5.18 (SD 2.52) times, spending an average of 19.90 (SD 11.21) minutes in the program per log-in. Centers completed an average of 2.90 (SD 2.02) self-assessments and developed an average of 2.09 (SD 1.30) action plans. A total of 6 staff members from 4 intervention centers completed web-based professional development accessible via the web-based program or the NSW state obesity-prevention program website (ie, *Munch & Move*) during the intervention period compared with no staff members from control centers.

Table 5. Center engagement with Childcare Electronic Assessment Tool and Support web-based program across 6 months.

Engagement	Value, mean (SD)	Value, median (IQR)
Total log-ins	5.18 (2.52)	4.00 (4.00-5.00)
Average log-in duration (minutes)	19.90 (11.21)	17.44 (10.24-30.03)
Self-assessments completed	2.90 (2.02)	2.00 (1.00-4.00)
Action plans developed	2.09 (1.30)	2.00 (1.00-3.00)
Number of times educational materials were accessed	12.36 (6.71)	10.00 (6.00-18.00)

Acceptability of the Intervention and Implementation Strategies

The web-based program was reported to be an acceptable method for assessing healthy eating practices by most nominated supervisors (10/11, 91%) and center champions (5/6, 83%; Table 6). The implementation strategies provided by HPOs, including the educational outreach visit (ie, face-to-face training) and ongoing support (ie, support call), were considered to be acceptable by nominated supervisors (10/11, 91% to 11/11, 100%). Acceptability of the implementation strategies was lower among center champions (2/6, 33% to 5/6, 83%).

Table 6. Acceptability and appropriateness of the web-based intervention and implementation strategies.

Characteristics	Nominated supervisors (n=11), n (%)	Center champions (n=6), n (%)
Measure (agree or strongly agree)		
Using the web-based program is an acceptable method for assessing if our service is meeting the healthy eating policies and practices.	10 (91)	5 (83)
The web-based program was useful in my service to help meet the healthy eating policies and practices.	11 (100)	5 (83)
Using the web-based program improved my service's performance in meeting the healthy eating policies and practices.	10 (91)	5 (83)
I would recommend the web-based program to other childcare services.	10 (91)	5 (83)
I intend to continue to use the web-based program to help our service meet the healthy eating policies and practices.	10 (91)	5 (83)
I thought the web-based program was easy to use.	10 (91)	—[a]
Measure (useful or very useful)		
I found the face-to-face training session (ie, educational outreach visit) useful.	10 (91)	5 (83)
I found the garnering of managerial support (ie, mandate change) useful.	11 (100)	2 (33)
I found the ongoing telephone support (ie, ongoing consultation and local technical assistance) provided by the health promotion officers useful.	10 (91)	2 (33)
I found nominating a center champion (ie, identify and prepare a center champion) useful.[b]	5 (83)	—
Appropriateness (agree or strongly agree)	11 (100)	—
The healthy eating policies and practices seem fitting.		
The healthy eating policies and practices seems suitable.		
The healthy eating policies and practices seem applicable.		
The healthy eating policies and practices seem like a good match.		
Contextual factors influencing implementation of healthy eating practices (agree or strongly agree)		—
The healthy eating policies and practices are consistent with our center philosophy.	10 (91)	
The healthy eating policies and practices are consistent with the National Quality Framework.	10 (91)	
The healthy eating policies and practices are costly to implement.	0 (0)	
The healthy eating policies and practices are difficult to implement.	4 (36)	
Centers within our region would be supportive of the healthy eating policies and practices.	10 (91)	

[a]Data not available (this item was only applied to nominated supervisors).

[b]This item was only applied to centers that nominated a center champion (n=6).

Appropriateness of the Intervention

In total, 100% (11/11) of nominated supervisors within the intervention group agreed or strongly agreed that healthy eating policies and practices seem fitting, suitable, applicable, and a good match (Table 6).

Cost to Deliver and Receive Implementation Strategies

The total cost to the health service for the HPO to deliver the implementation strategies (ie, educational outreach visit, mandate change, and ongoing consultation) was Aus $ 1351.25 (US $972.64), average per center: Aus $ 122.84 (US $88.42). Overall, the educational outreach visits cost a total of Aus $ 1143.08 (US $822.79), average per center: Aus $ 103.92 (US $74.80), including travel to the center and follow-up correspondence with center staff; mandate change cost a total of Aus $ 43.44 (US $31.27), average per center: Aus $ 3.95 (US $2.84); and ongoing consultation cost a total of Aus $164.73 (US $118.57), average per center: Aus $ 14.98 (US $10.78). The total cost to centers for nominated supervisors and center champions to receive all implementation strategies (ie, those delivered by the HPO and embedded within the web-based program) was Aus $ 1516.40 (US $1091.51), average per center: Aus $ 137.85 (US $99.23). The cost to receive the implementation strategies delivered by the HPO was Aus $ 1052.29 (US $757.44), average per center: Aus $ 95.66 (US $68.86), whereas the cost to receive the implementation strategies embedded within the web-based program was Aus $ 464.11 (US $334.07), average per center: Aus $ 42.19 (US $30.37).

Implementation of Targeted Healthy Eating Practices Within the Intervention Group

The proportion of centers implementing targeted healthy eating practices improved in 4 of the 5 practices from baseline to follow-up (Table 7). The greatest improvement was reported in center educator use of feeding practices that support children's healthy eating, increasing from 18% (2/11) to 82% (9/11). The proportion of centers supporting families to provide healthier foods consistent with dietary guidelines decreased from 82% (9/11) to 55% (6/11). At follow-up, 18% (2/11) of centers were implementing all 5 healthy eating practices, whereas none were at baseline. The mean number of practices implemented per center increased from 3.36 (SD 1.21) at baseline to 4.36 (SD 1.21) at follow-up. When examining the change in practice implementation between the most (low SES) and least (high SES) disadvantaged centers, the number of most disadvantaged centers supporting families to provide healthier foods consistent with dietary guidelines reduced from 100% (4/4) at baseline to 25% (1/4) at follow-up compared with no change in least disadvantaged centers (Table 8).

In total, 91% (10/11) of nominated supervisors reported that healthy eating practices were consistent with the philosophy of their service and consistent with the ECEC settings regulatory standards (ie, the National Quality Framework; Table 6).

Table 7. Intervention group implementation of healthy eating practices (N=11).

Healthy eating practice	Centers implementing at baseline, n (%)	Centers implementing at follow-up, n (%)	Change, n (%)
Provision of intentional healthy eating learning experiences	4 (36)	6 (55)	2 (18)
Comprehensive written nutrition policy that outlines key healthy eating practices	8 (73)	10 (91)	2 (18)
Staff participating in professional development targeting healthy eating	3 (27)	6 (55)	3 (27)
Educator use of feeding practices that support children's healthy eating	2 (18)	9 (82)	7 (64)
Supporting families to provide healthier foods consistent with dietary guidelines	9 (82)	6 (55)	−3 (27)

Table 8. Intervention group implementation of healthy eating practices by Socio-Economic Indexes for Areas classification (N=1)[a].

Healthy eating practice	Low SES[b] (n=4), n (%)			High SES (n=7), n (%)		
	Most disadvantaged centers implementing at baseline	Most disadvantaged centers implementing at follow-up	Change	Least disadvantaged centers implementing at baseline	Least disadvantaged centers implementing at follow-up	Change
Provision of intentional healthy eating learning experiences	2 (50)	2 (50)	0 (0)	2 (29)	4 (57)	2 (29)
Comprehensive written nutrition policy that outlines key healthy eating practices	3 (75)	3 (75)	0 (0)	5 (71)	7 (100)	2 (29)
Staff participating in professional development targeting healthy eating	1 (25)	1 (25)	0 (0)	1 (14)	5 (71)	4 (57)
Educator use of feeding practices that support children's healthy eating	1 (25)	4 (100)	3 (75)	1 (14)	5 (71)	4 (57)
Supporting families to provide healthier foods consistent with dietary guidelines	4 (100)	1 (25)	−3 (75)	5 (71)	5 (71)	0 (0)

[a]The 2016 Socio-Economic Indexes for Areas was used to classify centers as being located in the least disadvantaged (high socioeconomic status) or most disadvantaged (low socioeconomic status) areas. Center postcodes ranked in the top 50% of New South Wales were classified as least disadvantaged and the lower 50% of postcodes as the most disadvantaged.

[b]SES: socioeconomic status.

Discussion

Principal Findings

This study aimed to assess the potential feasibility of a pilot cluster RCT of a web-based healthy eating implementation intervention in ECEC centers to undertake a fully powered implementation trial. The study also examined the uptake, acceptability, appropriateness, and actual cost of delivering the intervention and implementation strategies. Overall, the study findings indicate that the web-based intervention and most implementation strategies are highly feasible, low-cost, and acceptable to childcare center staff and can improve the implementation of healthy eating practices in ECEC centers.

The study obtained a high overall parental consent rate of 74.9% (502/670) for children to participate in lunchbox measurements. However, the variability in parental consent across centers (ranging from 16/30, 53% to 24/25, 96%) is worth noting. This variation may be owing to the differing relationships within centers between staff and parents regarding the contents of children's lunchboxes with previous studies reporting a reluctance from staff to communicate with parents in fear of having difficult conversations [58,59]. As such, some parents may have been reluctant to consent to lunchbox measurements owing to perceived judgment [58,59]. Although not dissimilar to previous web-based studies conducted within the ECEC setting, the overall study consent rate among centers was moderate at 47% [27,60,61]. Similar to previous studies, barriers to center participation reported by staff included a lack of time and competing priorities [62]. As this study attempted to address such barriers by embedding the intervention within usual center processes (ie, aligning with ECEC accreditation standards), further consideration needs to be taken to better promote the intervention by aligning with current center priorities during study recruitment. However, once consented to the trial, the study data collection components were highly feasible, with 100% of participating centers completing child lunchbox measurements, center nutrition environment observations, and interviews with nominated supervisors. This indicates that such methods should be retained for a fully powered implementation trial.

Promising levels of uptake and acceptability of the implementation strategies used in this study were observed. The level of engagement with the web-based program was consistent with recommendations for centers to complete the self-assessment (audit with feedback) and develop action plans (formal implementation blueprint) twice during the intervention period. Such findings suggest that centers are likely to receive the intended dose of the intervention with the current implementation strategies. The promising levels of engagement may be attributed to the web-based program being easy to use as reported by nominated supervisors and aligned with usual center processes [63]. However, large SDs and wide IQRs for the number of log-ins and log-in duration indicate high variability in engagement with the web-based program across centers. Despite such variability being consistent with previous studies within the ECEC setting that used web-based modalities [27], exploration is needed to better understand the reasons behind the relatively lower levels of engagement for some centers.

As the intervention was largely delivered remotely, the overall cost to deliver the implementation strategies was minimal (total of Aus $ 1351.25 [US $ 931.88]; average per center: Aus $ 122.84 [US $ 86]). Therefore, the web-based intervention may be considered a low-cost alternative to support center implementation compared with traditional, highly intensive modalities. However, the study was unable to capture the costs associated with center staff implementing healthy eating practices, including the time spent disseminating information to parents. As such, future studies should consider conducting a cost-effective analysis, while capturing costs associated with center implementation of practices, to enable researchers, practitioners, funding bodies, and centers to determine whether investment in the web-based intervention produced an acceptable return and is a cost-effective approach to support the implementation of healthy eating practices at scale. Consistent with previous studies conducted within the ECEC setting [51,64], high levels of uptake and acceptability were found for most implementation strategies provided by HPOs, particularly the educational outreach visit (11/11, 100%) and local technical assistance (10/11, 91%). Despite previous literature suggesting that implementation strategies such as the MoU and center champions are useful for facilitating the uptake of interventions [19,39,44], the relatively low uptake of these strategies is worth exploring. Although there was high acceptability of the center champion strategy in centers that nominated a champion (9/10, 83%), a potential explanation for the lower uptake of the strategy may be the differing organizational structures within centers. Anecdotally, the uptake of center champions was higher in larger centers with greater staffing numbers and child enrollments, where the nominated supervisor often engages educational leads. The educational lead takes on additional advocacy roles among staff, lending them to the role of the center champion. In smaller centers however, the nominated supervisors often work as the educational lead themselves, acting as the main advocate among center staff. Therefore, the research team should consider alternative strategies, such as a local consensus approach [51] (ie, the entire center), to ensure that the uptake of the intervention remains high in centers where a sole champion is not a feasible strategy.

The improvement in implementation of 4 of the 5 targeted healthy eating practices within the intervention group is promising, with effect sizes ranging from 19% (2/11) to 64% (7/11). Such effect sizes are encouraging when compared with previous studies aimed at improving the implementation of practices within the ECEC setting [13]. A recent Cochrane systematic review, which examined the effectiveness of strategies aimed at improving the implementation of healthy eating and physical activity policies and practices, reported effect sizes as low as 2.5% [13]. Therefore, our findings show great promise for testing in a fully powered implementation trial. However, a decrease in centers supporting families to provide healthier foods consistent with dietary guidelines, particularly in those centers classified as most disadvantaged, is worth noting given this practice had the highest rates of implementation at baseline. A potential explanation for this

reduction may be the competing information relating to COVID-19 distributed to parents during the intervention period (eg, communication regarding center safety protocols and changes to child attendance fees), resulting in support for parents to provide foods consistent with sector dietary guidelines being of lesser priority at this time. Research suggests a lack of skills, knowledge, and confidence in communicating with parents regarding healthy eating [58,59,65] may also negatively impact the implementation of this practice. Using strategies, such as ongoing professional development, coaching, and training, have been suggested in recent studies to address such barriers and support ECEC staff to engage in positive and effective communication with parents [65]. As centers were encouraged to distribute the healthy eating resources to parents via usual communication methods (eg, parent communication apps, email, and written information), further consideration of the most effective method to facilitate staff communication with parents regarding healthy eating and nutrition may be required. Although the Childcare EATS engagement data provided important insights into the center use of the web-based program, the methods used and the reach of the center distribution of healthy eating information and resources (eg, number of parents who received the resources) could not be measured. In addition, we were unable to assess whether parents within the intervention group communicated healthy eating information provided by the center staff to other parents. There was a notable contrast in the implementation of this practice between centers classified as most and least disadvantaged. This contrast may potentially be explained by COVID-19 related impacts on resourcing (eg, staffing, budget, and time) within disadvantaged centers, who may have already been experiencing limited resources before the pandemic. A better understanding of the barriers faced by centers classified as most disadvantaged in communicating with parents should be sought to enable the development of appropriate strategies to support implementation of this practice. However, given the small sample size in this study, this finding is highly exploratory and should be interpreted with caution. In addition, collecting contextual data from parents regarding their preferred method of receiving healthy eating information from centers may also provide guidance on the most effective way to support parents in packing healthy lunchboxes for children to consume in care.

The findings from this study provide compelling data to support the conduct of a fully powered implementation trial. Importantly, despite the relatively low level of support provided to childcare centers to use the program, the level of engagement with the web-based program was relatively high, and large changes in practice implementation were observed. Findings from this study suggest that several improvements could be made to the intervention, including considering the appropriateness of the MoU and center champion and using strategies to support ECEC center staff engagement with parents regarding healthy eating. Finally, the inclusion of a nested evaluation within a future trial to assess the impact of the web-based intervention on individual-level outcomes, including child dietary intake and parent lunchbox packing practices, should be considered to gain greater insight into the effectiveness of the intervention beyond center-level outcomes.

Limitations

Although unavoidable because of restrictions relating to the COVID-19 pandemic, the inability to assess center nutrition environments and conduct child lunchbox assessments via direct observation to assess child-level outcomes as originally intended is a limitation of the study. In addition, although the data regarding the impact of the intervention on center implementation are promising, these data were only able to be collected within intervention centers with no comparison to the control group, and as such, should be interpreted with caution. Finally, as the study was conducted within 1 region of NSW, the generalizability of the findings beyond the region may be limited.

Conclusions

This pilot study provides compelling data to support the conduct of a larger trial assessing the impact of the web-based intervention on ECEC center implementation of healthy eating practices. The findings of this pilot study indicate that the web-based intervention is highly feasible, acceptable, appropriate, and low-cost. As this study is one of few examining the potential impact of a web-based intervention within the ECEC setting, a fully powered implementation trial is warranted to establish the true effects and examine the impact of the intervention at scale.

Acknowledgments

The authors wish to thank the staff at Hunter New England (HNE) Population Health, Population Health Aboriginal Advisory Network Group, and Christophe Lecathelinais for their statistical support. The authors would also like to thank the participating center staff, parents, and children. Finally, the authors would like to thank Kasia Bolsewicz, Melody Ng and Hannah Lamont for their contribution to the planning, implementation, and evaluation of the study. This project was partly funded by the Hunter Children's Research Foundation, Priority Research Center for Health Behavior University of Newcastle, Hunter Cancer Research Alliance, HNE Local Health District Grant, and Hunter Medical Research Institute. The funders played no role in conducting the trial. HNE Population Health and the University of Newcastle provided infrastructure and in-kind funding. CB receives salary support from a cofunded industry scholarship between HNE Population Health and the University of Newcastle. SLY receives salary support from the Australia Research Council Discovery Early Career Research Awards (DE170100382). LW receives salary support from the National Health Medical Research Council Career Development Fellowship (grant APP1128348), Heart Foundation Future Leader Fellowship (grant 101175), and a HNE Clinical Research Fellowship. The contents of this manuscript are the responsibility of the authors and do not reflect the views of Hunter Children's Research Foundation, Hunter Cancer

Research Alliance, Priority Research Center for Health Behavior, Hunter Medical Research Institute Australian Research Council Heart Foundation, HNE Local Health District, or National Health Medical Research Council.

Authors' Contributions

CB drafted the manuscript. SLY, AG, CB, NN, and LW conceived and designed the research and interventions. CB, AG, and JK delivered the intervention. CB, AG, TW, and JK developed the evaluation protocols and led to the acquisition of data. CB conducted the data analyses. All authors contributed to drafting and final approval of the manuscript.

Conflicts of Interest

Authors CB, LW, AG, TW, and JK received salary support from Hunter New England Local Health District, which provided infrastructure and funding for the study.

Abstract

Background: Populations globally are ageing, resulting in higher incidence rates of chronic diseases. Digital health platforms, designed to support those with chronic conditions to self-manage at home, offer a promising solution to help people monitor their conditions and lifestyle, maintain good health, and reduce unscheduled clinical visits. However, despite high prevalence rates of multimorbidity or multiple chronic conditions, most platforms tend to focus on a single disease. A further challenge is that despite the importance of users actively engaging with such systems, little research has explored engagement.

Objective: The objectives of this study are to design and develop a digital health platform, ProACT, for facilitating older adults self-managing multimorbidity, with support from their care network, and evaluate end user engagement and experiences with this platform through a 12-month trial.

Methods: The ProACT digital health platform is presented in this paper. The platform was evaluated in a year-long proof-of-concept action research trial with 120 older persons with multimorbidity in Ireland and Belgium. Alongside the technology, participants had access to a clinical triage service responding to symptom alerts and a technical helpdesk. Interactions with the platform during the trial were logged to determine engagement. Semistructured interviews were conducted with participants and analyzed using inductive thematic analysis, whereas usability and user burden were examined using validated questionnaires.

Results: This paper presents the ProACT platform and its components, along with findings on engagement with the platform and its usability. Of the 120 participants who participated, 24 (20%) withdrew before the end of the study, whereas 3 (2.5%) died. The remaining 93 participants actively used the platform until the end of the trial, on average, taking 2 or 3 health readings daily over the course of the trial in Ireland and Belgium, respectively. The participants reported ProACT to be usable and of low burden.

Findings from interviews revealed that participants experienced multiple benefits as a result of using ProACT, including improved self-management, health, and well-being and support from the triage service. For those who withdrew, barriers to engagement were poor health and frustration when technology, in particular sensing devices, did not work as expected.

Conclusions: This is the first study to present findings from a longitudinal study of older adults using digital health technology to self-manage multimorbidity. Our findings show that older adults sustained engagement with the technology and found it usable. Potential reasons for these results include a strong focus on user-centered design and engagement throughout the project lifecycle, resulting in a platform that meets user needs, as well as the integration of behavior change techniques and personal analytics into the platform. The provision of triage and technical support services alongside the platform during the trial were also important facilitators of engagement.

Introduction

Background

Multimorbidity, the presence of 2 or more chronic conditions in an individual [1], is a major global health concern [2], and in many high-income countries, it is now considered the norm rather than the exception [3]. Some evidence suggests that it is more common in older adults, likely because of the aging population, whereas other research states that it is more prevalent in disadvantaged groups, such as those with lower socioeconomic status [3,4]. Prevalence rates suggest that, globally, 1 in 3 people live with multimorbidity, with rates of 65% in people aged >65 years and 85% in people aged >85 years and rising [5]. However, multimorbidity is also known to affect younger adults, with social deprivation being a key determinant in younger and middle-aged adults [3,6]. Multimorbidity reduces life expectancy, decreases quality of life and physical functioning, and negatively affects mental health [7]. It also results in health inequalities [4]. Some evidence suggests that reported outcomes, such as lower self-reported health, increased medication issues, and higher health care utilization, are poorer for older populations [8].

Self-management is recognized as an important component of care for those with multimorbidity to maintain good health [9,10]. Self-management can be defined as the actions taken by an individual to manage symptoms, treatment, emotions, and lifestyle changes as part of living with a chronic condition [11]. Compared with those with one chronic condition, people with multimorbidity experience more challenges with self-management, associated with numerous self-care tasks such as symptom monitoring, management of multiple medications, and liaising with multiple health care professionals [10,12-14]. For people with multimorbidity, self-management is an iterative process requiring constant readjusting and reframing to understand their conditions and the associated changeable symptoms to inform personalized self-management responses [15,16].

Numerous digital health technologies have been developed to support the self-management of single chronic diseases, primarily diabetes [17]. However, given the rise in the number of people managing multiple chronic conditions, it is imperative to consider how such technologies can be designed and implemented to deal with the additional complexities of multimorbidity, such as the management of multiple symptoms and self-care tasks. Prior work has noted that technologies that help those with multimorbidity manage their health will only be successful if they do not exert further burden or inconvenience on the user [18]. Furthermore, little attention has been directed toward the importance of understanding how to support people with multimorbidity through the use of digital interventions [19]. Integrating the management of multiple conditions onto a single platform, where users can monitor their symptoms and relevant lifestyle parameters (such as activity), interact with all their data, share their data, and receive educational support, could help to minimize the known burden of multimorbidity self-management. In recent years, a small number of researchers have begun to examine how to design digital health apps for multimorbidity self-management [20-27], including medication management [20,28], how to manage health care conflicts [21,24], and how those with multimorbidity collaborate and communicate with informal caregivers and health care professionals [25,27]. However, we are unaware of platforms that have been implemented to tackle multimorbidity or evaluated over longitudinal periods. Indeed, a recent systematic review has highlighted the lack of digital health platforms, that include architectures and analytics capable of fully supporting chronic disease self-management [29], beyond what is possible through simple *apps*. The review identified 7 papers, all of which support single disease management, and not multiple diseases.

The research on longitudinal engagement with digital health and wellness technologies, particularly for older adults, is lacking. Engagement is necessary to achieve intended and effective outcomes [30]. However, it is understood that the adoption of digital health technologies is low [18]. It has also been argued that older adults are not seen as the primary users of such technology [31] and are not ready to adopt it [32]. However, recent research goes some way to resolve this issue. A study examining the use patterns of 9051 users (mean age 50.4 years) with a diabetes management app over a period of 180 days found that older adults were more actively engaged

with the app than younger users [33]. Wei et al [34] studied habit formation using wearable activity trackers with 20 older adults who had been tracking activity for 6 months. They found a range of factors contributing to sustained use, such as contextual factors such as the placement of the tracker, how often it needs to be charged, and the presence of features such as goal setting and reminders. It is generally accepted that the successful design of a health and well-being intervention to motivate engagement requires a user-centered design process and an iterative approach to development [29,30]. This is particularly important for older adults, who may be unfamiliar with such technology and who may have additional interaction requirements because of the physical and cognitive effects of aging [31]. It is therefore crucial that designers of health technologies for older adults involve them closely in the design of technologies to ensure that they can benefit from them.

Our main objectives were as follows:

1. Design and develop a digital health platform (ProACT) to support people with multimorbidity to self-manage multiple conditions on a single platform, including monitoring a collection of symptoms and well-being parameters, helping users to understand relationships between their symptoms and conditions, providing education personalized to the person's condition profile, and supporting the sharing of data with a care network.
2. Evaluate ProACT in a year-long proof-of-concept (PoC) trial with people with multimorbidity supported by people in their care network to determine engagement, usability, and experiences with the digital self-management of a set of multiple symptoms and well-being parameters.

In this study, we present the ProACT platform that is designed to support people with multimorbidity to self-manage multiple conditions and results from a 12-month PoC trial of the platform with respect to engagement and usability. Our findings indicate that the vast majority of people with multimorbidity stayed engaged with the platform over the 12-month period, a novel finding with respect to this cohort. The participants found the platform to be usable and of low burden. Qualitative data from participant interviews indicated that participants experienced a number of benefits as a result of using ProACT, such as improved self-management, health, and well-being. For those who withdrew, barriers to engagement were poor health and frustration with the elements of the technology, particularly the sensing devices to monitor health parameters.

The ProACT Platform

The aim of the ProACT project was to design a single platform for supporting people with multiple conditions, specifically 2 or more of the following: chronic obstructive pulmonary disease (COPD), congestive heart failure (CHF), chronic heart disease (CHD), and diabetes, to self-manage. These conditions were chosen, as the World Health Organization identified the 4 key types of chronic diseases as cardiovascular, chronic respiratory diseases, diabetes, and cancer [35]. In addition, outcomes from a multimorbidity study by Barnett et al [6], with data collected from 1,751,841 people in 314 medical practices in Scotland, showed CHF, COPD, and diabetes as significantly linked disease conditions with related comorbidities (eg, hypertension). Although the platform was initially developed to support people self-managing combinations of these conditions, it is sufficiently flexible to allow new conditions to be added to the platform over time.

The ProACT platform was designed and developed using an extensive user-centered design process. This process involved interviews, focus groups, co-design sessions (hands-on design activities with participants; Figure 1), and usability testing before the platform's deployment in the trial. A total of 58 people with multimorbidity and 106 care network participants, including informal carers, formal carers, and health care professionals, across Ireland and Belgium participated in this process. The findings from the user-centered design process have been published elsewhere [21,28,36,37].

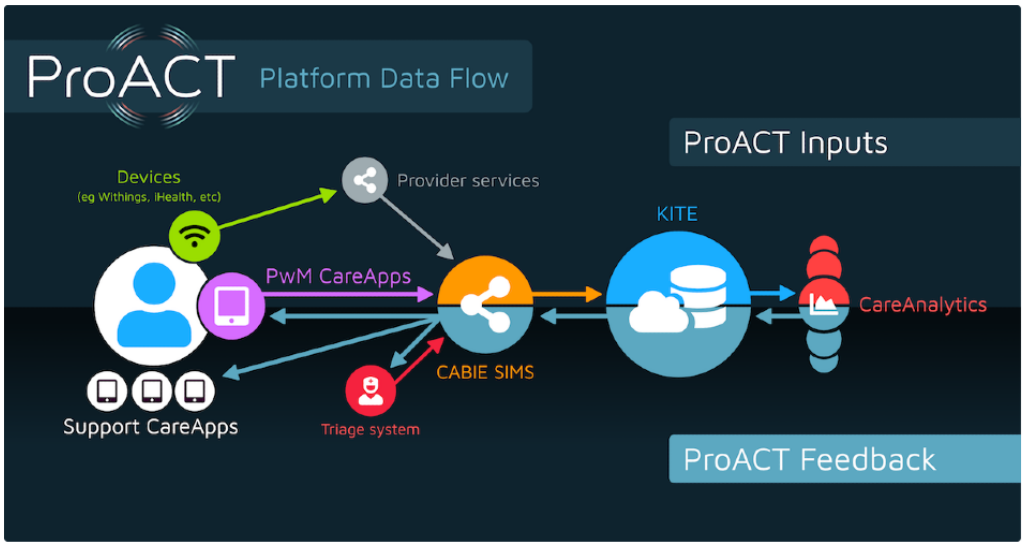
Figure 1. Participants in co-design workshops (A) choosing color schemes; (B) matching icons to labels.

The ProACT platform, designed and developed based on the findings from the above phases, has the following components:

- Measurement and sensing devices: off-the-shelf devices were used to collect health (blood pressure, heart rate, blood glucose, and pulse oximetry) and well-being (weight, activity, and sleep) readings from people with multimorbidity in their homes.
- ProACT person with multimorbidity CareApp: a web-based app delivered on an interactive device such as a tablet or smartphone that supports the monitoring of person with multimorbidity status and provides feedback and education to support health and wellness self-management. The CareApp has been designed to minimize the burden of self-management, for example, by helping people with multimorbidity prioritize condition management.
- ProACT care network CareApps: customized CareApp interfaces, developed for people in the person with multimorbidity's care network (informal carers, formal carers, and health care professionals), enables the viewing of the person with multimorbidity's health and well-being data, once the person with multimorbidity has agreed to share it.
- Context-aware brokering and inference engine (CABIE+): a source-agnostic data collection system to collect and organize sensor and self-reported data collected through the CareApp.
- Subject information management system (SIMS): a user management system allowed researchers or service organizations to personalize CareApps to individuals and manage, inspect, and analyze data.
- SIMS Triage: a version of the SIMS user management system was developed specifically for the clinical triage staff to view and respond to risk-stratified alerts from data collected by people with multimorbidity. This system provides clinical triage staff with a holistic view of the person with multimorbidity, displaying data relevant to their various conditions.
- KITE (Knowledge InTEgration) platform: a cloud-based infrastructure that allows the aggregation and processing of health data using a dynamic set of analytical components.
- CareAnalytics: innovative analytics to detect and react to data collected using ProACT. CareAnalytics support multimorbidity self-management, for example, by ensuring that any recommended content considers the person's overall condition profile, and behavior change, for example, by recommending educational content or highlighting a condition that needs attention, based on a person with multimorbidity's current health and well-being status.

The platform focused primarily on supporting the management of a collection of health symptoms and well-being parameters (relevant to the conditions of interest outlined above), helping users to understand the relationships between their symptoms and conditions, providing education relevant to individual conditions while also ensuring that this education considers multiple conditions, and provides a single app where people with multimorbidity or care network users could view all data and relevant content. The platform was developed to be compliant with the European Union's (EU's) General Data Protection Regulation (Regulation [EU] 2016/679) and underwent a data protection impact assessment before its deployment in the trial. Figure 2 illustrates the data flow between the different ProACT components. The following section provides a more in-depth overview of the components, primarily focusing on the person with multimorbidity CareApp.

Figure 2. Data flow within the ProACT platform. CABIE: context-aware brokering and inference engine; KITE: Knowledge InTEgration; PwM: person with multimorbidity; SIMS: subject information management system.



ProACT Person With Multimorbidity CareApp

Overview

In this section, we describe the CareApp used by the person with multimorbidity participants during the PoC trial. Further details on how we mapped specific user requirements to ProACT design features have been published elsewhere [37]. The following subsections outline the various features within the CareApp. The content of the CareApp is personalized at both *condition* and individual levels. For example, participants with diabetes and COPD will not see any features or content with respect to CHF management. Individuals with diabetes may

decide that they do not want to collect blood glucose data. This personalization is achieved within the SIMS system and is described below. The CareApp was developed as a responsive web app and is therefore accessible across a wide range of devices and platforms.

Symptom Monitoring and Reflection

Findings from our requirements gathering study highlighted that those managing multimorbidity need to monitor several health and well-being parameters on a regular basis; therefore, digital health apps to support multimorbidity need to consolidate multiple health and well-being parameters into a single app [21]. Access to data has also been shown to support behavioral change and the self-management of chronic conditions [16]. Where available, off-the-shelf sensors and devices were sourced to monitor these parameters, whereas questions delivered through CareApp's *Add Info* section supported the monitoring of additional parameters not measured through a device (eg, foot care for diabetes, fatigue, and breathlessness). Figures 3-5 show the person with multimorbidity CareApp. The flower of the dashboard (Figure 3) provides a quick overview of the person with multimorbidity's current status (eg, their current step count and their last blood pressure reading). Petals can be blue, orange, or pink. An orange petal highlights to the user that they have not taken a reading for a particular parameter in the past 5 days. Pink represents a *nudge* to the user to further explore the petal, for example if a reading is outside the person's defined *normal* threshold. A symptom reflection feature was designed as an extension of the flower dashboard design. Figure 4 shows what happens when a user clicks on the pink petal containing COPD symptoms in Figure 3. In addition to measuring and viewing their symptoms, this feature encourages users to *reflect* on their recent symptom readings with respect to their normal readings by asking them whether their reading is within a normal range for them. This feature was designed to support people in understanding their symptom readings rather than passively recording them. This may be particularly important when a person first starts self-managing with the platform, whereas later reflection may become more intrinsic.

Findings from our requirements study revealed that, sometimes, the management of one chronic condition can be forgotten, particularly if another is currently more acute [21]. The flower design, and the logic behind it, ensures that if a condition is not being monitored, it is brought to the attention of the person with multimorbidity. This could be a prompt or alert to monitor symptoms relating to that condition or educational content being pushed to them. The flower acts as a subtle, unobtrusive prompt—it is up to the person with multimorbidity to act on it. Our requirements study [21] and research by others [12,38] have identified that with multiple self-management tasks across different conditions, there is an increased need to support people with multimorbidity in prioritizing their activities, to reduce complexity and time burden. Therefore, within the CareApp, only the areas that require attention are highlighted. In addition to the flower petals, people with multimorbidity can view any of their historical readings through the *View Readings* section of the CareApp (Figure 5).

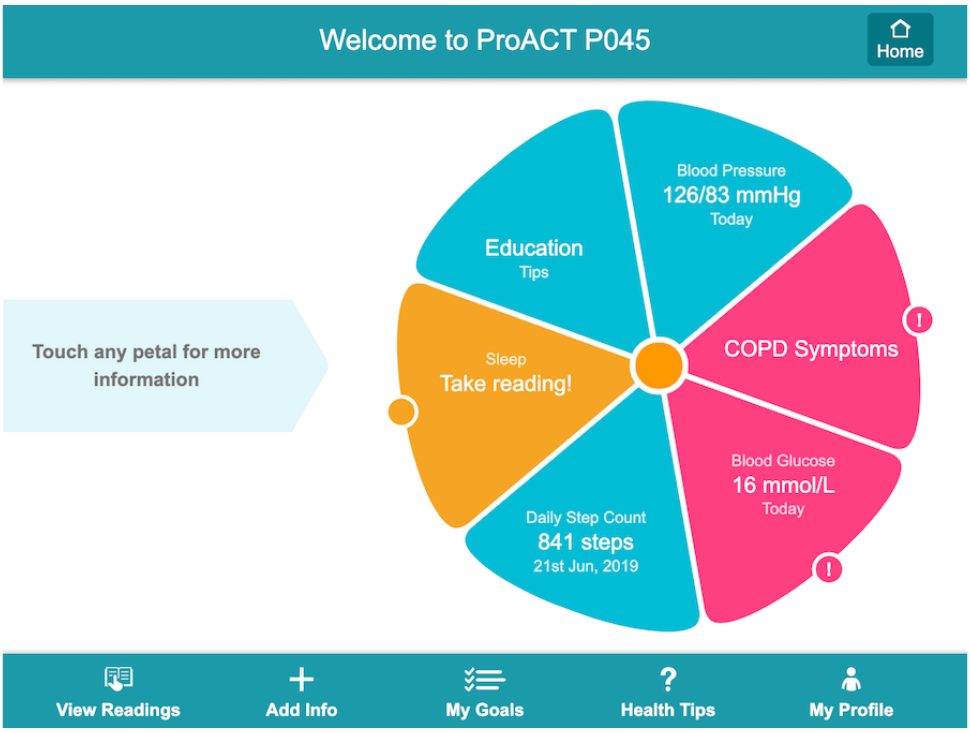

Figure 4. Reflection screen for abnormal chronic obstructive pulmonary disease symptoms.

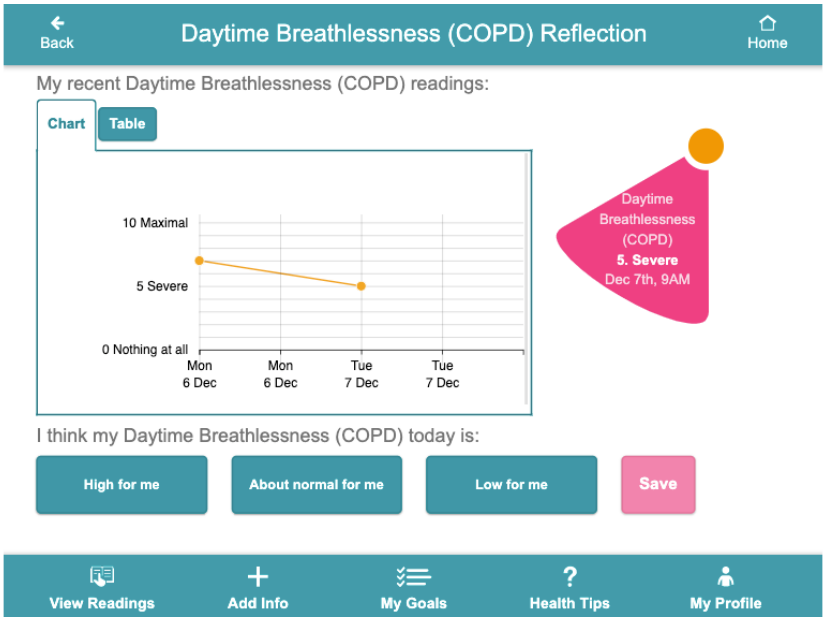

Figure 5. Data trends over time.

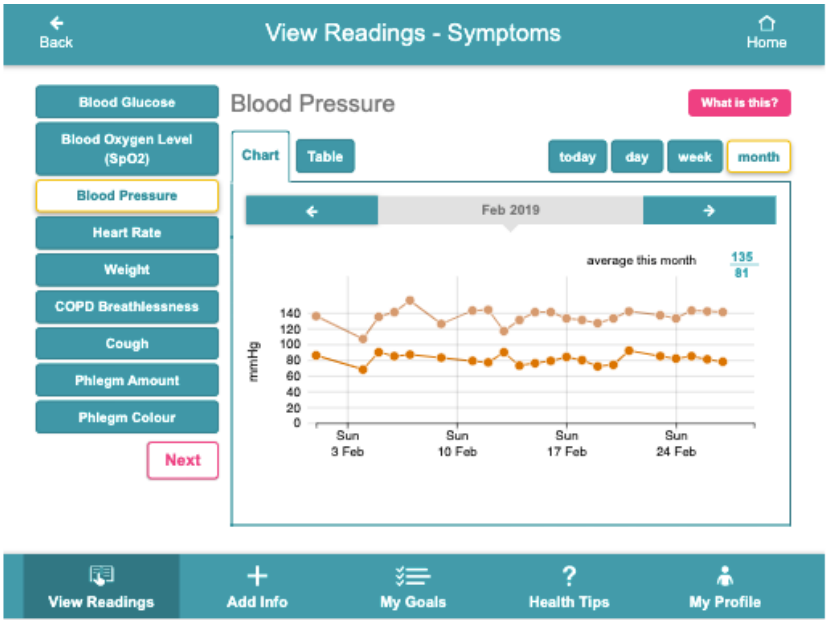
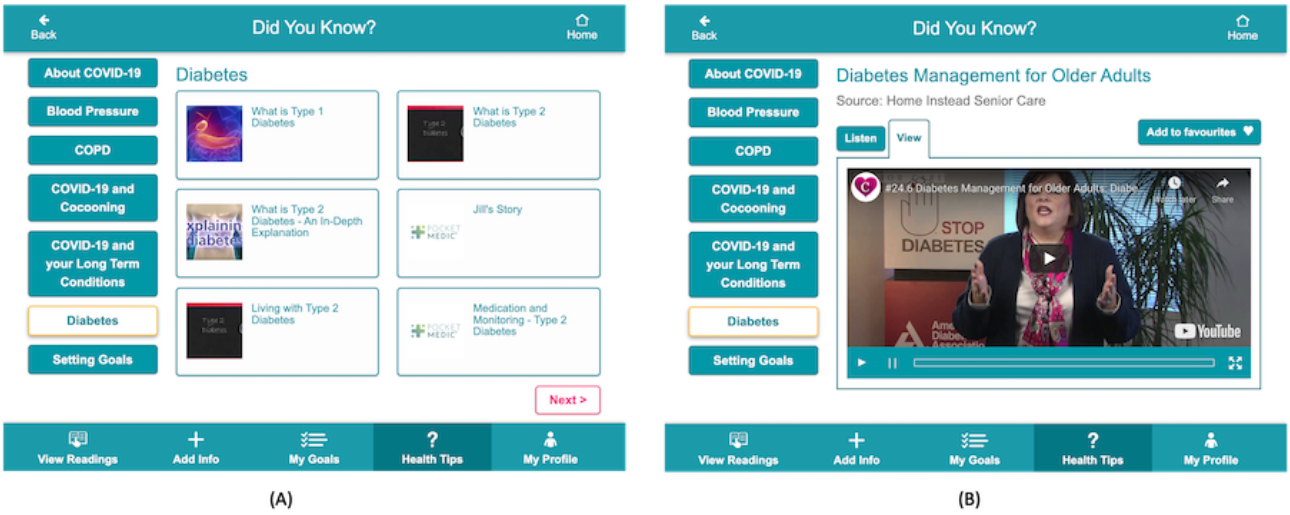


Education and Training

Findings from the requirements study, and those of others, highlighted that a lack of information is a significant barrier to both effective self-management and motivation to engage in self-management actions [21,39,40]. The selection of content for the education section of the CareApp and its planned delivery were therefore important tasks, and it was important to ensure the provision of trusted, reliable information tailored to a person with multimorbidity's specific conditions and management needs (including device and CareApp training). Within the *Health Tips* section of the CareApp, there are two categories of content: *Did you know?* contains educational content relevant to self-management of the person's conditions and well-being (Figure 6), and *How do I?* contains custom-made video training content on how to use the devices and CareApp. Educational information for each disease was sourced from reputable sources known to people with multimorbidity (eg, from national health services in each country). Where possible, content was delivered in three modalities (video, audio, and text) to cater to differences in learning styles and accessibility. An important consideration for the management of multiple conditions is that any education provided to the person with multimorbidity considers their current health status and their complete condition profile. This is achieved through ProACT CareAnalytics, as discussed in the section *CareAnalytics*.

Figure 6. Educational content in ProACT (A)The library of educational content; (B) A tip in video format.



Personal Goals

Setting goals and progressing toward goal achievement are key features for supporting the self-management of multimorbidity. People with multimorbidity can set physical activity goals in the ProACT CareApp. An overview of their weekly progress, measured through their activity watch, and an intuitive interface to help them set different goal modalities (eg, steps, distance, and time spent walking), are accessible through the *My Goals* section of the CareApp. Through messages and prompts, ProACT users are supported in setting achievable and incremental goals. The goal recommender described in the *CareAnalytics* section below suggests realistic activity goals based on the user's most recent activity data. As the user progresses and surpasses their targets, prompts suggest more challenging goals. Similarly, if the person with multimorbidity has difficulty reaching their target, they can say why this is by choosing a reason from a predefined list (eg, they were unwell this week), providing some context for why a particular goal was not achieved. Our requirements gathering identified additional features with respect to goal setting, such as collaborative goal setting with the person with multimorbidity's care network and feedback on goal progress [36], which will be integrated into future versions of the CareApp.

The Care Network

People with multimorbidity should be empowered to be contributors in the selection of their care network. Research has shown that the effective self-management of chronic disease does not occur in isolation but often involves, and is directly influenced by, support from informal carers and formal carers, as well as health care professionals during clinical visits [41,42]. Our findings from the requirements gathering also highlight, however, that the person with multimorbidity is often the coordinator of their own care, given the lack of integration among health care providers. Therefore, it is important that the person with multimorbidity can choose whom, within their care network, can support and contribute to their digital self-management. A feature within the *My Profile* section of the person with multimorbidity CareApp supports this, whereby the person with multimorbidity can add someone to their network and choose what data to share with them. CareApps for informal carers, formal carers, and health care professionals are accessible on their own devices (all CareApps are web based and responsive), allowing these care network stakeholders to see person with multimorbidity data that have been shared with them.

Usability and Accessibility

The usability and accessibility of the technology are crucial to ensure that users can easily interact with it. The CareApp was designed and developed to comply with relevant accessibility guidelines from tools, which are as follows:

- The Web Content Accessibility Guidelines 2.0 [43]: these guidelines state that (1) content must be perceivable; (2) interface components in the content must be operable; (3) content and controls must be understandable; and (4) content should be robust enough to work with current and future user agents (including assistive technologies).
- British Broadcasting Corporation mobile accessibility guidelines [44]: the British Broadcasting Corporation standards and guidelines for mobile accessibility are a set of technology-agnostic best practices for mobile web content and hybrid and native apps.
- Automated accessibility checkers and tools: although not as accurate as manual audits, automated accessibility checking tools such as the Web Content Accessibility Guidelines 2.0 offer better accuracy. A checker compliance tool (website shutting down in April 2021 [45]) was used. In addition, as color and contrast are important accessibility features for older users, tools were sourced that automatically check that colors have sufficient contrast within the interface (such as the web aim color contrast checker; [46]).

An accessibility and traceability spreadsheet was maintained detailing each guideline and was used to record accessibility issues and outline how they were resolved during the design of the CareApps. Accessibility guidelines should only form a part of an inclusive user-centered design process, as the most definitive test of accessibility can only be evaluated with end users [47]. End users, including people with multimorbidity and

care network stakeholders, were involved as co-designers throughout the entire iterative design and development process. Usability sessions were conducted with person with multimorbidity users from the early design phases, and throughout the various time points of the trial, allowing us to observe and gather feedback on usability and accessibility. The results of these evaluations informed interface updates, further enhancing the usability and accessibility of the app iteratively across the project.

Context-Aware Brokering and Inference Engine

CABIE+ is a source-agnostic cloud-based data aggregation platform. CABIE+ was the primary exchange mechanism used to connect the distinct technology components in ProACT. This component was used to centrally collect data from all connected devices used by people with multimorbidity, to normalize these data for storage, to make these data available to additional CABIE+ and ProACT components (SIMS and KITE), and to provide a configurable processing pipeline allowing incoming data to be inspected and reacted to in real time.

Subject Information Management System

SIMS is an administrative tool that facilitates the management of trial technologies, provides an abstraction layer for managing multiple CABIE+ instances and provides researchers or service organizations with a user-friendly, centralized service for monitoring and inspecting the various elements of the ProACT platform. SIMS also provides a user-facing application programming interface, which was used in the creation of the ProACT CareApps.

SIMS provides a number of features to facilitate the setup and management of trials and data. End users can be added to the system and their personalized profiles can be configured; for example, entering demographic information, configuring conditions being monitored within ProACT, and linking sensors and devices to their profile (Figure 7). Adding and scheduling educational content and self-report questions for delivery through the CareApp was also done via SIMS (Figure 8). For example, various categories of education and self-report questions can be created and delivered to all participants or to those with specific conditions. Furthermore, only participants configured in the system as having heart failure will see educational content and symptom questions related to that condition. Participant data can be queried via the *Inspect* feature (Figure 9), which shows the most recent inputs for each participant, including how long ago they logged in to the system (green indicates within the past day, red over a week ago). Each parameter measured by the participant can also be queried and viewed as a chart or table or exported for further analysis. SIMS also allows for personalized symptom thresholds to be set and generates alerts when symptom readings fall outside these thresholds (eg, alerting a triage nurse when a person's blood glucose level is outside their normal parameters).

The SIMS triage interface (Figure 10) presents clinical triage nurses with a list of alerts for individuals. Alerts are generated when thresholds for different parameters, defined within the system, are breached. For example, an alert for high blood glucose is a reading over 14 mmol/L (configurable per participant). Participants' placement on the list is prioritized by their alert status, that is, those with a *red alert* status appear first. A tag also appears alongside the alert, indicating whether it is new or under review. Within the dashboard, the nurse can also view recently resolved alerts. Nurses can query the person with multimorbidity's health and well-being data (as shown in Figure 9) to give them a holistic picture of the person with multimorbidity's status before calling them to discuss their alerts. Nurses can also create notes with respect to alerts, thereby allowing for a rich description of the context linked to alert readings.

Knowledge InTEgration

KITE is a cloud-based platform providing a reliable storage system for large volumes of data. In addition to being highly scalable, it eases data maintenance and access through an easily configurable data access configuration and transparently kept traceability metadata. KITE is exposed as a set of authenticated services for managing deidentified health data and coordinating collaboration among data providers, system data analytics, and data consumers. Figure 11 shows the actors of a typical workflow within KITE: providers push new deidentified data (eg, sensor data, self-reports, questionnaire results), which read the already deidentified data and create new results, whereas consumers read analytics' output and show it to the final users (people with multimorbidity and care network members). In a real-world scenario, analytics can selectively share output among themselves, allowing a complex CareAnalytic to be decomposed into a set of simpler and smaller analytics before reaching a data consumer.

From a logical point of view, KITE acts as a gate for all communications, modeled in an asynchronous fashion to ease maintenance and monitoring. Figure 12 shows the data flow diagram within ProACT (for simplification, CareAnalytics are represented with one box only; however, they might be implemented as a set of simpler subcomponents). The diagram is divided into three main areas: (1) data fetching, (2) personal information, and (3) deidentified information. The left section

lists all the data collected and pushed into the monitoring system managed by CABIE+. The data are deidentified and sent to the analytics that deal with deidentified information (right section). Although personal information data are stored on CABIE+, the deidentified information data (used by analytics) are stored in KITE.

Within KITE, CareAnalytics have two main purposes: making recommendations to people with multimorbidity (eg, by suggesting a goal or picking the most appropriate training material) and augmenting data (eg, creating aggregation or person-centered results).

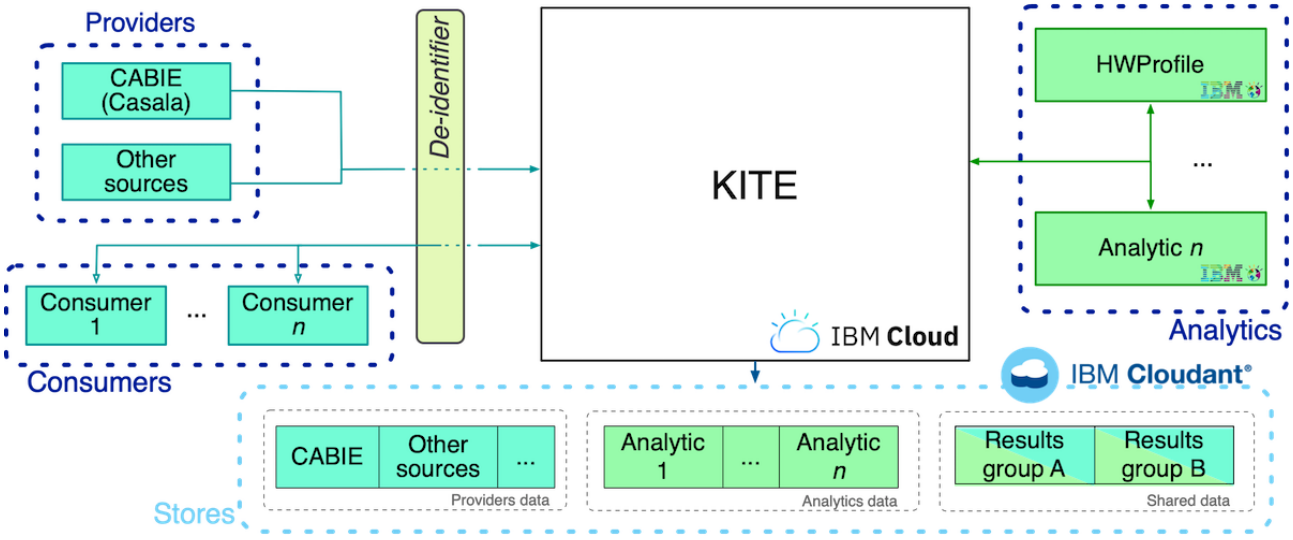

Figure 12. Data flow diagram implemented in ProACT. Blue arrows: data exchanges that occur with any new data input; red arrows: data exchanges happening at regular intervals, depending on the analytic. PwM: person with multimorbidity.

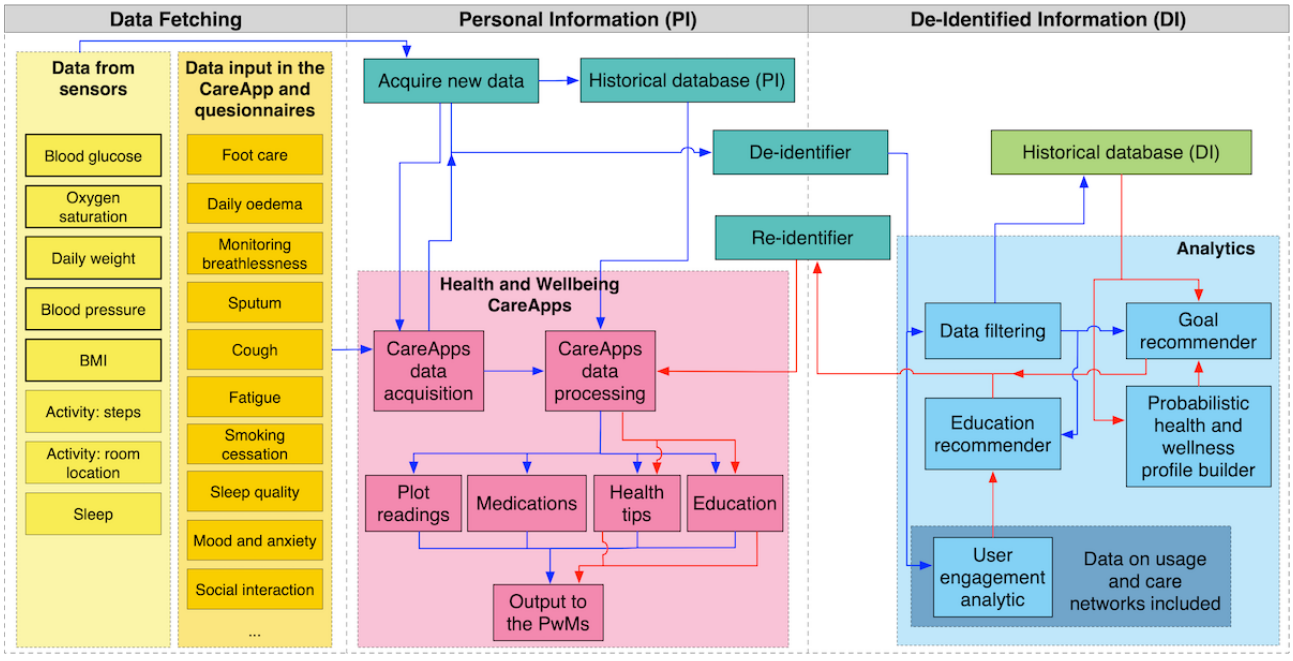


CareAnalytics

A *CareAnalytic* in ProACT is defined as a contextually aware procedure or algorithm that can detect and react to patterns in current or historic data available to ProACT systems. The current catalog of CareAnalytics in ProACT is as follows:

- *Data Cleaner*: this analytic classifies the different types of data in terms of quality (or reliability). In particular, the analytics that require vitals as input work on the results of the data cleaner instead of working on raw data. In addition, it calculates thresholds (ranges considered as normal) for the vitals that serve as an input for the *Education Recommender* (described below).
- *Goal Recommender*: this analytic supports people with multimorbidity in setting the weekly activity goals. The user can choose to set a goal in terms of distance, steps, or minutes spent walking. To suggest a goal value, the recommender considers the person with multimorbidity's physical activity over the previous week and whether they have met their previous goals. It also considers physical activity guidelines for older adults and adults with chronic conditions [48] to avoid giving major leaps in

recommendations. Finally, a maximum threshold (18,000 steps per week) was set as the total recommendation to ensure that the levels of activity were not too high for patients with chronic conditions and older adults [48].

- *Education Recommender*: this analytic facilitates the presentation of personalized educational and training materials within the CareApp. It uses thresholds on vitals; therefore, if any parameter has reached a value outside the normal range, then the person with multimorbidity will be presented with relevant educational material.
- *User Engagement Analyser*: this analytic tracks the person with multimorbidity's use of sensing devices and the ProACT CareApp.
- *Probabilistic Health and Wellness Profiler*: this is a probabilistic model of the person with multimorbidity describing them through several dimensions. Specifically, a categorical Bayesian network was learned using the open The Irish Longitudinal Study on Ageing (TILDA) data set. The TILDA data set holds data on 8504 individuals aged 50 years and above [49]. Variables were selected to cover several dimensions relevant to the conditions being monitored by ProACT and other relevant parameters such as vitals (eg, symptoms such as blood pressure), assessments (eg, nonsensor data such as fear of falling), self-reported wellness (eg, sleep quality), behaviors (eg, steps or physical activity), demographics and conditions (including the ProACT conditions COPD, CHF, CHD, and diabetes), and relevant comorbidities, such as additional chronic conditions, depression, and anxiety. The main goal of the model is to provide a comprehensive overview for a specific person with multimorbidity and their health and well-being states across different dimensions. Furthermore, the Bayesian network model could be used to infer the level of a missing variable based on the available measurements. For instance, a possible output would be the probability of a low physical activity score for a male aged 70-75 years with high blood pressure and diabetes. Some or all of these outputs can be used by other analytics. Further information can be found in Deparis et al [50].

During the ProACT PoC trial, detailed below, the *Data Cleaner*, *Goal Recommender*, and *User Engagement Analyser CareAnalytics* were implemented and used within the ProACT platform. The development of the *Health and Wellness Profiler* and the *Education Recommender* only occurred as data became available during the trial to help build and validate these analytics, and as such these were not present within the ProACT platform during the trial. However, the goal is to integrate these into future versions of the platform to further enhance personalization and multimorbidity management.

Methods

Inclusion Criteria and Recruitment

Trials occurred in Ireland and Belgium. The inclusion criteria for people with multimorbidity were that they were aged >65 years and had a diagnosis of two or more of the following diseases: diabetes, COPD, CHD, and CHF. It should be noted that 1 participant in Belgium was aged 60 years. This participant had initially recorded an incorrect date of birth on the screening documentation, and this was not discovered until after the participant had already begun the trial. This person was excluded from the core analysis presented in this paper. However, a separate analysis of their data was conducted, and the outcomes reflected those participants aged 65 years and above. Participants were recruited from a number of sources, including social groups for older adults, condition support groups, social media, radio and local newspaper advertising, formal care organizations, health care professionals, pharmacists, and living lab agencies. People with multimorbidity could also nominate up to 5 people to be part of their care network (including informal and formal carers and health care professionals). A total of 73 care network participants consented to participate. However, this paper focuses solely on the person with multimorbidity participants.

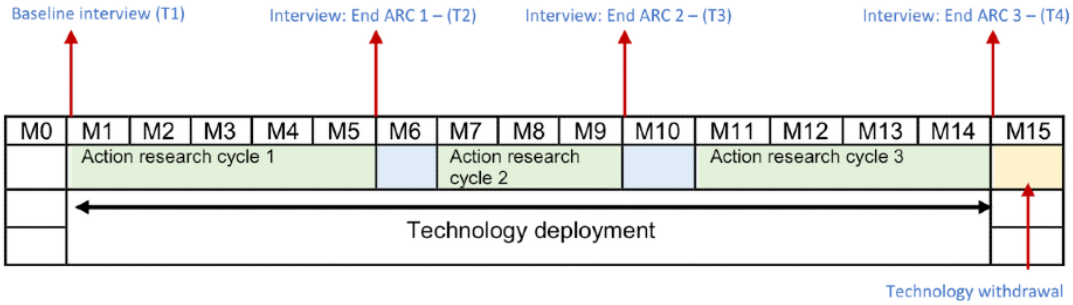
Study Design

The study was a PoC trial, which used an action research design, to allow for continuous feedback from participants and refinement of the ProACT platform throughout the trial. There were 3 action research cycles (ARCs) and 4 time points (T1-T4) of data collection, involving collection of questionnaire data, semistructured interviews, and usability testing (Figure 13). Refinements were made to the ProACT platform based on the feedback from participants at the end of each ARC. The same study design and methodologies were used across Ireland and Belgium to ensure consistency and comparability. The specific objectives were as follows:

- Evaluate the *usability and acceptability* of the ProACT CareApp and devices
- Evaluate *user adoption and satisfaction* with the technology and services
- Evaluate *experiences of using* ProACT

In this paper, we focus on the findings from studies that relate to engagement with the platform and usability.

Figure 13. Study timeline across action research cycles. ARC: action research cycle.



Procedures

Each participant was provided with an iPad, a smart watch to monitor sleep and activity, a digital weight scale, and a digital blood pressure cuff. Those with diabetes were provided with a blood glucose monitor (glucometer), whereas those with COPD were provided with a pulse oximeter to measure oxygen saturation levels. During the initial visit to the participant's home, the devices were set up by the researcher, and training was provided on using the devices. A second visit, approximately 1 week later, introduced the ProACT CareApp to the participants, and further training was provided. Each of the participants received a detailed paper-based training manual, while training videos on how to use the devices and CareApp were also available in the *Tips* section of the CareApp. The participants were asked to use the ProACT platform as they wished to evaluate how ProACT would fit into their lives naturally. During the trial, data from the participants were monitored by a clinical triage service in each country, appointed through a tendering process. The triage staff determined a protocol for alerts and escalation procedures in the case of an alert. The alerts were set within the SIMS triage platform described above. These were initially set at a global level (eg, the same blood glucose thresholds were set for all diabetic participants) and as the trial progressed, these could be individualized based on a person's normal range or input from their health care professional. The triage staff responded to alerts between 9 AM and 5 PM, Monday-Friday (hours were limited because of project budget) and made monthly check-in phone calls. Participants were made aware of the hours of triage, both through their project information sheet and a weekly pop-up message in the CareApp. Participants also had a helpdesk number they could call if they experienced any technical issues or wanted to request further training. A researcher was available to answer calls between 9 AM and 5 PM, Monday-Friday. Outside these hours, the participants could leave a message.

Data Collection and Analysis

The full study protocol, including details on all data collected during the trial and full analysis procedures, can be found in Dinsmore et al [51]. For the purposes of this study, data collection comprised interview data and questionnaire data on usability and user burden at each time point, which coincided with the end of each ARC. These data were collected at the participants' homes. Interview protocols at time point T1 covered motivations and expectations, whereas interviews at later time points covered a range of topics with respect to participants' experiences in terms of using the technology, benefits and challenges, their self-management practices, and care network support. Interviews were audio recorded and transcribed verbatim. A semantic thematic analysis [52] of these transcripts was then conducted using NVivo for Mac (version 11) in Ireland and MAXQDA in Belgium. A selection of transcripts was coded by 2 researchers to ensure a thorough iterative identification of a wide range of semantic themes. Initial broad coding was performed to identify the themes of interest, as covered within the interview protocols. Within these broader themes, an iterative thematic analysis was conducted to uncover the subthemes. Themes with respect to engagement are presented in this paper, whereas other themes (such as those relating to the self-management journey, experiences with the technology, behavioral change, and collaboration with the care network) are being submitted for publication elsewhere. Data on engagement with the system were logged through the ProACT platform, and metrics analyzed included the number of symptom readings per day and engagement with different sections of the CareApp.

Although additional data were collected during the trial, such as interview data with care network participants and triage staff, as well as the symptom and well-being data collected through the ProACT platform, the analysis of such data is outside the scope of this paper and will be published elsewhere.

Ethical Considerations

Ethical approval was received from 3 ethical committees in Ireland and 4 in Belgium. All procedures were in line with the General Data Protection Regulation for research projects, with the platform and trial methods and procedures undergoing data protection impact assessments in both countries. Written informed consent was obtained on an individual basis from participants in accordance with legal and ethical guidelines in each trial region, following a careful explanation of the study and provision of patient information and informed consent forms in plain language. All participants were informed of their right to withdraw from the study at any point without having to provide a reason for this.

Results

Overview

In total, 120 people with multimorbidity consented to participate, 60 in Ireland and 60 in Belgium. In Ireland, the average age of the participants was 74.23 (SD 6.4) years, and 60% (36/60) were male. In Belgium, the average age of the participants was 73.61 (SD 6.49) years, and the participants were predominantly male (43/60, 72%). Additional demographic data are presented in Table S1 of Multimedia Appendix 1. In this section, we present findings with respect to engagement with the ProACT platform, usability, and user burden and outline findings from the interviews with person with multimorbidity participants across the different time points that relate to engagement with ProACT. In particular, we focus on motivations to engage along with facilitators and barriers to engagement. At the end of the participant quotes, we identified the participant with the legend (ID, gender, age, inclusion conditions, time point, and country).

Engagement With ProACT

Over the course of the 12-month trial, the majority of participants remained engaged with ProACT. By the end of the trial, 3 participants had died in Ireland and 8 had withdrawn, resulting in 49 participants in Ireland completing the trial. In Belgium, 16 people withdrew, resulting in 44 participants completing the trial. Exit interviews were conducted with a subset of those who withdrew early and who consented to this. The reasons for withdrawal are discussed below in the *Barriers to Engagement* section.

Engagement with the sensor devices (used to record key symptom data) and ProACT CareApp were measured through

the platform. The heat maps in Figures 14 and 15 illustrate high levels of engagement with the ProACT devices for measuring key symptoms and well-being parameters, by the majority of participants in Belgium and Ireland, respectively. The horizontal bars of each graph depict one participant, with the start of the bar indicating their recruitment to the trial and the end of the bar indicating their exit from the trial. White bars indicate dropouts or those who died. During the trial, there was an average of 40 (SD 7.6) users in Ireland and 43 (SD 16.6) users in Belgium, taking measurements on a daily basis. The maximum number of participants recorded taking measurements on any day during the trial was 48 in Ireland and 60 in Belgium. Participants had an average of 2 daily readings in Ireland and three daily readings in Belgium.

Figure 16 shows how the ProACT CareApp was used across all trial participants: each row is a session and each cell is colored depending on the time spent on each section of the CareApp (the sections can be seen in the bottom menu in Figures 3-5). White cells are sessions with no visits to the correspondent section. With this in mind, *My Profile* and *Tips* were less visited sections. The rest of the sections are quite dense in the graph, which means that they have been frequently visited. More green cells are visible in *View Readings*, which means that participants spent more time checking their vitals than entering data or looking at their *Dashboard* (Figure 3). Furthermore, *Tips*, despite being a less visited section, has a significant number of green cells, which is expected as participants would likely spend more time here, viewing relevant educational videos or reading health tips.

Figure 14. User engagement in Belgium—daily symptom readings.

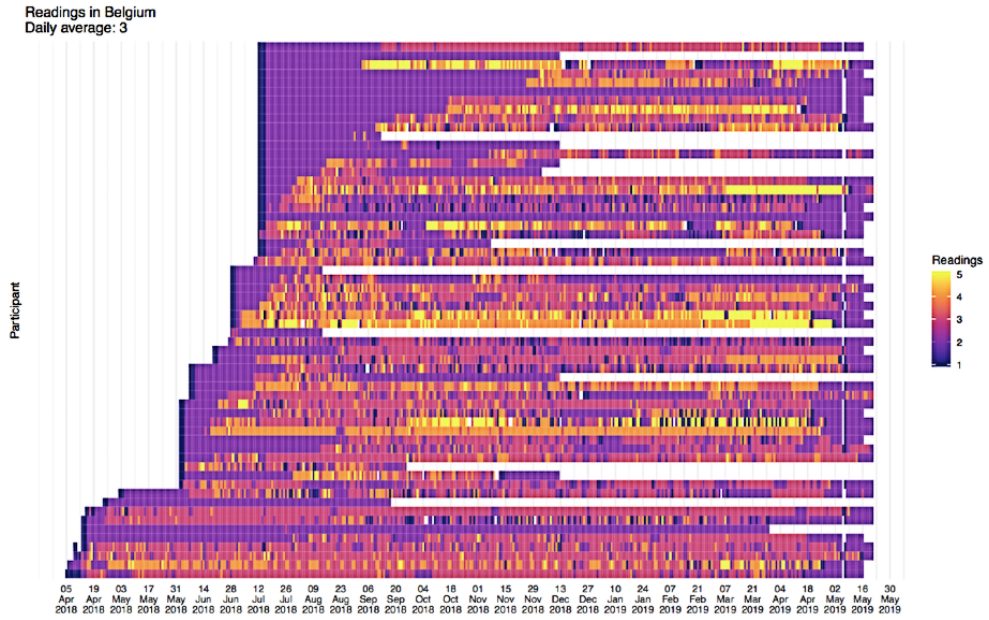


Figure 15. User engagement in Ireland—daily symptom readings.

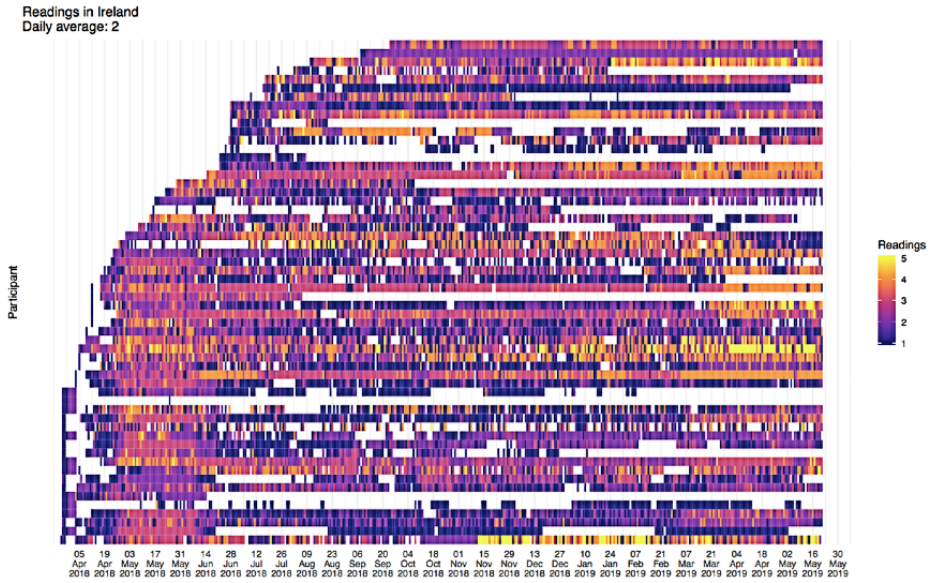

Figure 16. Heatmap of CareApp section visits across the trial period.

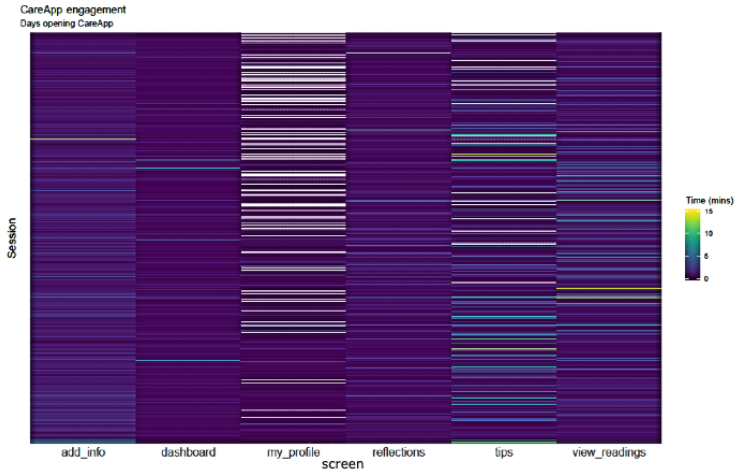

Figure 17 shows the percentage of time, on average, that trial participants spent in different sections of the CareApp. No significant difference was recorded for those aged less than 74 years compared with those aged over 74 years across the different sections of the CareApp. When a user opens the CareApp, they land on the *Dashboard*, which accounts for the highest percentage of section visits. The *View Readings* (where participants could see an overview of all their health and well-being data) and *Add Info* sections (where participants could answer the daily questions or add a manual symptom reading) were the most frequently visited sections by both age groups. Participants navigated to the *Tips* section less often. This may be because the *Tips* were used mostly at the beginning of the trial, as participants were learning about their conditions and self-management. Future work will examine this issue further. Similarly, the reflection feature (Figure 4), which asks participants if a particular daily reading is high or low for them, was not used as much as other sections of the CareApp, and our data show that its use declined over time.

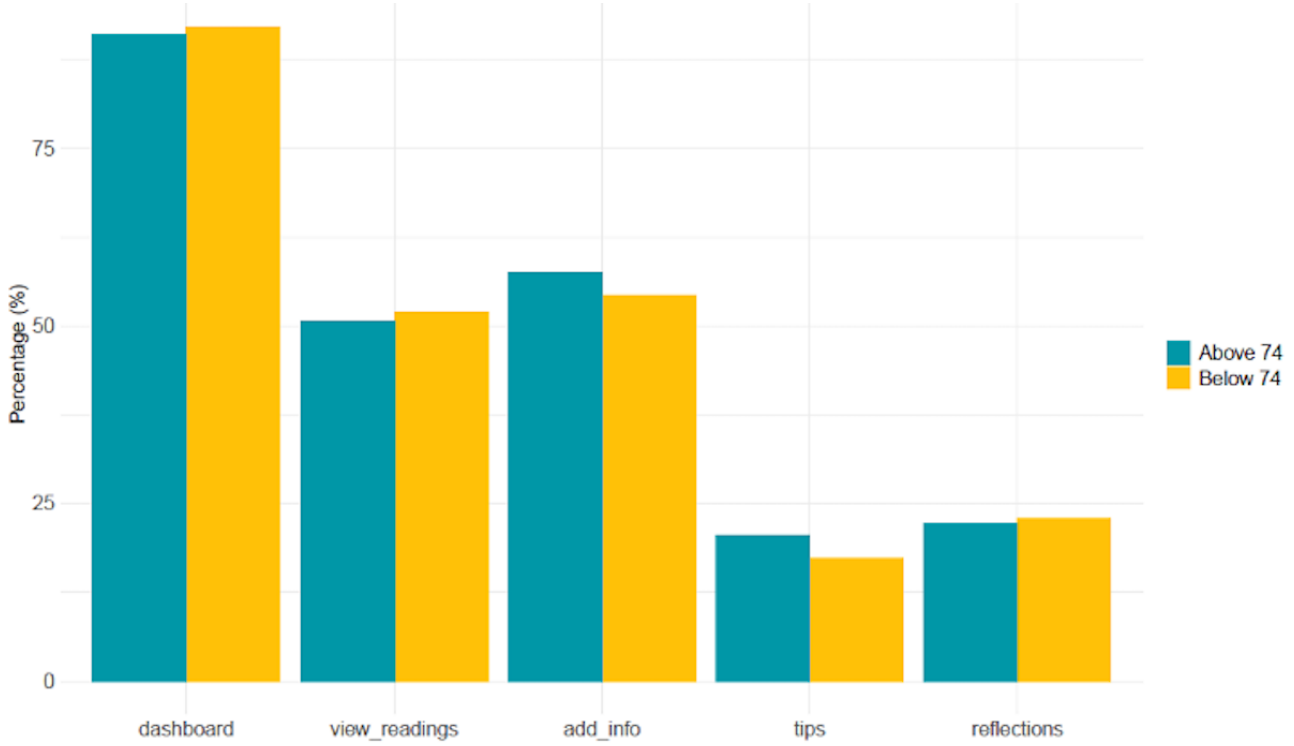
Finally, the *Goal Recommender* was implemented within the platform for the final 8 weeks of the trial, primarily to test whether it worked as expected. Approximately half of the participants (53/96, 55%) set at least 1 activity goal during this period. Almost 75% (39/53) of participants set their goals in steps rather than meters or minutes. Furthermore, participants felt comfortable with the metric chosen—just 3 changed it over the course of the 8 weeks (from distance to steps).

Figure 17. Percentage of time participants engaged with different sections of the CareApp across the trial period, categorized by age group.



Usability and User Burden of ProACT

The participants completed the system usability scale (SUS) at T2, T3, and T4. The SUS is a 10-item questionnaire and is a quick and reliable tool for measuring the usability of both hardware and software products [53]. SUS scores range from 0 to 100. A value above 68 indicates that the system is usable. Table 1 indicates that SUS scores during the trial over time points T2, T3, and T4 remained relatively the same in Ireland and Belgium and above the threshold of 68, which indicates that participants considered ProACT to be usable. User burden was also measured at T2, T3, and T4 using the user burden questionnaire that measures the burden across six constructs, including difficulty of use, physical, time and social, mental and emotional, privacy, and financial [54]. No significant increases in burden were experienced over time.

Table 1. Usability and user burden scores across time points in Ireland and Belgium.

	Time points, mean (SD)		
	T2	T3	T4
Usability			
Ireland	74.6 (14.6)	72.4 (14.5)	75.6 (14.7)
Belgium	78.1 (17.0)	74.9 (16.8)	75.5 (20.8)
User burden			
Ireland	4.7 (4.0)	5.0 (4.4)	5.5 (4.6)
Belgium	3.2 (3.1)	5.2 (5.1)	5.8 (6.6)

Participant interviews provided insights into possible usability and burden issues associated with using the platform. The SUS did not distinguish between the ProACT CareApp and symptom-monitoring devices. However, participant feedback suggests that the majority of usability issues lay with using the devices, in particular the blood pressure monitor and the glucometer, which was a source of frustration for some participants:

> *I just stopped taking the blood pressure measurements. Because all the equipment wasn't working properly. In that it wasn't connecting to the iPad. There was one morning I timed it and it was only after spending half an hour connecting the thing on the screen.* [P009, male, 71 years, COPD+CHD+Diabetes, T3, Ireland]

Questions about accuracy were also noted: "Look last Friday it did not register sleep, why not?" [P106, male, 70 years, diabetes+CHD+CHF, T2, Belgium]. P103 (female, 79 years, diabetes+CHD+CHF, T2, Belgium) who had mobility issues stated that her limited steps do not always register.

Despite several reported device issues, participants felt that the platform was usable:

> *The app itself I think is very good. And I think it's helpful to get people to focus on a small number of things. That are key to their, you know their health. To also have a system that was easy to use, it is easy to use.* [P015, male, 82 years, diabetes+CHD, T3, Ireland]

> *Everything links in quickly enough...And I don't have a problem, there's no delay or whatever in it. It's straightforward. I think the equipment is excellent.* [P012, male, 67 years, diabetes+CHD, T3, Ireland]

Motivations to Engage

Overview

Two primary subthemes emerged with respect to motivation to engage at T1, which remained present at T2, T3, and T4 as reasons for continued engagement with ProACT:

- Improving self-management
- Improvement of health and well-being

Improving Self-management

At the start of the trial, improving self-management was noted by the majority of participants as the reason they wanted to engage with ProACT:

> *I haven't focused sharply enough [on health] and this is where I think this programme maybe will give me a bit of a kick in the backside, where it's very in your face and very visual and you know, just to see like say the blood pressure or the blood sugar readings.* [P033, male, 65 years, diabetes+CHD, T1, Ireland]

The participants felt that improved self-management would be achieved by gaining insights into their health from actively self-managing and seeing results, learning about conditions, learning what to avoid, and learning what to do if symptoms are changing.

At the start of the trial, a number of participants discussed how they hoped using ProACT would lead to increased confidence both in terms of managing their health and engaging with activity:

> *You know, seeing the results, it might give more confidence...I'd like to be able to have a round of golf and also I'd love to get back and play an odd set of tennis.* [P052, 78 years, male, diabetes+CHD, T1, Ireland]

P052, like many participants before beginning the trial, was fearful of undertaking physical activity in case it exacerbated

their conditions. Interview data from later time points in the trial show the participants became more empowered and confident in their self-management, as they used the ProACT CareApp to reflect on and compare data from a range of devices, in 1 place, across multiple symptom and well-being readings:

> *[The technology] gives you confidence, to be honest with you. And I quite like being able to take my own blood pressure and stats, so as I'm still in control.* [P031, male, 70 years, CHF+CHD, T2, Ireland]

P115 spoke of her fear before the trial, as an exacerbation could happen at any time:

> *I was living on a timebomb. Now, I do not live on any different timebomb than anyone else.* [P115, female, 73 years, CHF+CHD, T3, Belgium]

> *You are not as frightened because you know your readings and everything like that.* [P036, male, 72 years, COPD+CHD, T4, Ireland]

This was partly linked to higher levels of awareness:

> *Well, I suppose by being a bit more aware and a bit more in control, it's a positive thing and I suppose you have a bit more confidence as a consequence.* [P033, male, 65 years, diabetes+CHD, T2, Ireland]

Participants also reported making sense of how their actions affected their health, giving insight into what behaviors they could moderate or change to improve their various health readings:

> *Well it's telling me what's going on I suppose, I've a better idea myself and can relate the two together. If I haven't had activity, I can see how that is affecting blood sugars. I can see the relationship between the two, it's becoming clearer.* [P012, male, 67 years, diabetes+CHD, T3, Ireland]

Related to this, participants reported taking action based on their insights across their conditions and well-being, including changing their behaviors to improve their health readings. Participants also reported taking action with respect to their use of health care and interactions with health care professionals:

> *It is one of the reasons, through the use, that I went to my GP. That I said look, I am a bit worried. And then we looked for a solution and different medication and such. And that has changed due to [ProACT].* [P71, male, 69 years, COPD+CHD, T2, Belgium]

Notably, some participants reported going to the doctor less as they had more confidence from knowing their readings:

> *When I get an attack, the COPD or whatever flares, I can recognise [now] whether I need an antibiotic or not...Whereas before [using the technology], as soon as my breathing sort of laboured I'd be at the doctor.* [P045, 74 years, female, diabetes+COPD, T4, Ireland]

Many participants experienced benefits from such actions, which motivated engagement with the ProACT platform:

> *It's a whole health awareness...That's what [the technology] has created. Before this, I knew I needed to look after my health, but nobody does, and I got this system, now it's become a matter of routine.* [P053, male, 71 years, diabetes+CHD, T3, Ireland]

For P034, who reported struggling with mental health challenges, it was especially reassuring to see mood changes including periods of positive mood:

> *Oh, that was the highlight of my week, looking back on how I was doing...If I saw my graph was going up, and I wasn't as anxious yesterday as I was before, that would give me a bit of a boost.* [P034, 67 years, male, COPD+CHF, T4, Ireland]

Improving Health and Well-being

At T1, many participants expressed hope that engaging with ProACT and improving their self-management skills would in turn lead to improved health and a better quality of life, and this was the case for a number of participants:

> *My health has improved immensely...I've probably got the AFib [atrial fibrillation] under control...But, as I say, I've lost weight and I feel much better in myself. Mentally, physically, every way.* [P031, male, 70 years, CHF+CHD, T3, Ireland]

Indeed, throughout the trial, there were a number of critical clinical outcomes reported by participants in both Ireland and Belgium, where engagement with ProACT exerted a clear impact on a health outcome or directly influenced a change in treatment or care for the participant:

> *I've been in with my GP, he's increasing the medication. And we're still not there with it, so it may need to be tweaked further. So, without this system I might've been, you know, pretty oblivious to the fact that there is an issue there you know.* [P033, male, 65 years, diabetes+CHD, T3, Ireland]

Participants reported *symptoms stabilizing* as a result of implementing self-management practices:

> *I mean on average they [blood glucose readings] were 14 or 15 [14 mmol is threshold for a high alert], before this research started. And that was continuous. Now it's halved. Because I'm focused on improving it.* [P014, male, 70 years, diabetes+CHD, T3, Ireland]

Changes in food and diet were also widely reported, as well as increased activity levels, particularly as participants began to see the links between their activity and symptoms:

> *Well, the whole thing for me really is trying to get my weight down and keep my blood sugars down. And it's more stable...It's [ProACT] done everything really, it's gotten my exercise levels up because it focused me on it. It's got my blood sugars back in order.* [P048, male, 67 years, diabetes+CHD, T2, Ireland]

> *When I started [ProACT] up to now, I feel fitter...It is only 4000 steps, but I used to do maybe like 300 steps a day.* [P111, male, 76 years, diabetes+CHD+COPD, T3, Belgium]

Although participants in Belgium reported experiencing stabilization of symptoms and improvements in terms of activity and weight, few participants explicitly stated that they thought their health had improved. Most of the perceived health situations remained stable, except for those who endured health setbacks because of their illnesses or unfortunate incidents (eg, P117 had a fall and P81 had a car accident). However, 1 participant linked his engagement with the technology and the triage service with his continued ability to live alone:

> *They [family] were planning on doing that last year [sending him to a nursing home], now I do not have to, because I can make my own plan, because I can control myself.* [P74, male, 72 years, diabetes+CHD+CHF, T3, Belgium]

When participants attributed potential changes in health to using the platform, they were related to changes in attitude or behavior.

Potential Facilitators of Engagement

An important element of the ProACT platform, which was implemented during the trial, was the service provided alongside platform usage. A large theme that emerged across T2, T3, and T4 was *Service and Support*, which had 2 elements, namely, the triage service and the technical helpdesk. The triage service was one of the most commonly discussed topics by ProACT users in Ireland and Belgium**.** The majority of participants commented on the *reassurance* of having their readings monitored by the triage service. Most found it beneficial to know someone was looking out for them behind the scenes and making sure their readings were within a normal range:

> *The fact that...I knew someone was keeping an eye on it. And if that something was going out of kilter [range] that I'd get a nudge. And that's all I'd need...I know there's a nurse there who's looking at these figures.* [P015, male, 82 years, Diabetes+CHD, T3, Ireland]

Participants also noted how the triage nurses acted as a *backup* if they were to miss something, which gave further peace of mind:

> *It has given my wife a feeling of reassurance. People are keeping an eye on me. For me...it is also a reassurance.* [P81, male, 68 years, CHD+CHF, T4, Belgium]

As noted above, a number of participants reported clinical outcomes during the trial, and many of these were a result of triage intervention:

> *They [triage] had suggested maybe to go and get my cholesterol checked and my cholesterol was a bit high. It had been going a bit high and then my medication was changed, and it was as a result of ProACT.* [P039, female, 66 years, COPD+CHD, T4, Ireland]

> *[Triage nurse] told me get her into a hospital straight away otherwise you're going to have a body on your hands. Bring her out to the hospital and tell them the way she is. And I did that, and they kept her in...Yeah she [nurse] wanted to send an ambulance.* [Husband speaking during T3 interview for P018, female, 73 years, diabetes+CHD, T3, Ireland]

Social connection and personalized care were also identified as a subtheme within the triage service theme, whereby users felt that the triage nurses truly cared about their well-being. The majority of participants commented on how the nurses took the time to chat to them, enquire about their health, and found the phone calls to be a very pleasant experience: "What I think is so good about it, is that you have the feeling that someone thinks it is important what I do." [P101, male, 72 years, CHF+CHD, T3, Belgium]. Participants also appreciated the continuity of care and that the nurses always followed up on any issues, something many participants felt was lacking with their usual health care providers.

The research teams also operated a technical helpdesk that participants could call (Monday-Friday, 9 AM-5 PM) if they were experiencing any difficulties using the technology. When a participant called the helpdesk, the researcher attempted to troubleshoot with the participant over the phone. If this was not possible, then a researcher visited the participant to ensure that the issue was resolved. The responsiveness of this service was an important element in ensuring that participants could remain technically engaged with the ProACT platform and provide a fast and meaningful response to technical barriers encountered by participants, which might otherwise have resulted in disengagement:

> *I was helped along every time...[researchers] arrived straight away or as soon as possible to sort it out for me.* [P043, female, 77 years, COPD+CHF, T4, Ireland]

To offer context to the necessity of the helpdesk, there were a total of 355 calls to the helpdesk in Ireland over the course of the trial (helpdesk calls were not tracked in Belgium). Of these, 22% (78/355) were administrative calls, such as participants informing the team of an upcoming holiday or requesting clarification on interview dates. The remaining 78% (277/355) were related to tech support. Of these, 76 calls were requests for peripherals (eg, batteries for the blood pressure cuff and additional testing strips for the blood glucose monitor), 121 were for devices not working (eg, a blood pressure cuff that would not turn on), 50 related to data syncing issues (eg, if participants did not see their readings appear in the ProACT CareApp), 31 related to data accuracy concerns (eg, if a participant's own blood glucose monitor had a different reading to the digital one provided with ProACT), and 29 involved pairing or connection problems (eg, accidentally turning off Bluetooth).

Barriers to Engagement

Although the majority of participants learned to master the ProACT technology over time, technical issues were a barrier that ultimately led to some participants withdrawing from the trial. For P007 and P037 in Ireland, the reasons for withdrawal were *frustration with the devices*. Both found the devices and apps complicated to use: "It was just too hard to do because you couldn't in the first place take the blood pressure anyway because it wasn't working." [P037, female, 82 years, COPD+CHD, Ireland]. Although care was taken to address

these issues, for example, by replacing devices and providing further training, the initial experience for these participants resulted in a negative perception of the technology, which led to their disengagement. Related to this was a lack of trust in the readings. Some participants, including P93 and P105 in Belgium, found that the digital glucometer provided for the trial gave higher readings than their own personal glucometer, which caused them to distrust data from the trial device.

The second most common reason for withdrawing from the trial involved the complexity of the participants' conditions. For some, monitoring with ProACT felt like an added burden. Three participants in Ireland who withdrew did so as they felt they had enough to deal with in managing their conditions or with health complications which had arisen since the start of the trial. This was expressed by an informal carer for P007: "I think P007 has enough to contend with at the moment" [IC for P007, female, 78 years, diabetes+CHD, Ireland] and by P037 who felt under pressure to generate readings:

> *Well I was conscious of how much I was walking, you know and I'd walk up and down to the shed a whole lot of times if I wasn't out. So that was it, but I couldn't stick that for a year.* [P037, female, 82 years, COPD+CHD, IE]

P007's informal carer noted that readings generated concern: "Sometimes it was a little bit scary when you were getting those readings." P105 (76 years, female, diabetes+COPD+CHD, Belgium) stated that she experienced an extra burden by being confronted by some of the information provided by ProACT. She said that as a patient with diabetes, she already needed to be aware of a lot and that the pressure she felt from seeing the additional readings, such as activity, was experienced as too much of an extra burden.

Discussion

Principal Findings

This paper has presented the ProACT platform alongside findings with respect to engagement and usability from a 1-year PoC trial of the platform with 120 older people with multimorbidity across 2 EU countries. The findings demonstrate that the majority of participants actively engaged with the platform over the full duration of the trial, taking on average between 2 and 3 readings every day and engaging with self-reporting and their data in the CareApp. The qualitative data indicate that participants were motivated to engage as they found value and benefit in using the platform, including improving their self-management, gaining confidence, and experiencing health and well-being benefits. The results also indicate that participants found the platform usable and of low burden. Our study makes two primary contributions to the literature. First, we describe a novel, comprehensive digital platform, including CareApps, participant management, clinical triage, and analytics, and outline how it has been designed to support the self-management of multimorbidity. A recent systematic review highlighted that such platforms are lacking, and those that exist only target single disease management [29]. Second, we demonstrated that older adults were actively engaged with the platform over a 1-year period and we presented qualitative data to understand the possible reasons for this result. Textbox 1 summarizes the potential factors that may have enhanced engagement, which are elaborated upon in the remainder of this section.

Textbox 1. Likely impact of ProACT components on engagement.

Outcomes

- Engaging with symptom and well-being monitoring
- Engaging with reviewing data and acting on it

Potential Factors That Enhanced Engagement

- User-centered design (understanding needs and requirements)
- Usability of app
- All data on 1 platform
- Benefits experienced because of monitoring
- Technical support when needed, including face-to-face training during deployment and technical training via the application supplemented by paper-based materials
- Clinical oversight and support provided by triage nurses

Recently, researchers of human-computer interaction have begun to explore how technology can support the self-management of multimorbidity [18,21,22,24,55]. The majority of this research has focused on suggesting design requirements for technology, including understanding the requirements of people with multimorbidity and those who care for them [21-23,55], supporting communication about values with people with multimorbidity and health care professionals [27], managing health care conflicts [24], and medication management [20,28]. Research has also suggested potential reasons for those with multimorbidity not engaging with technology-supported self-management (including self-tracking being experienced as *work* and perceptions that health care professionals are not interested in self-tracked data) [18]. Our work in designing and developing the ProACT platform occurred before much of this recent research was published, with the trial beginning in April 2018. However, there are parallels in terms of design suggestions for multimorbidity management. Ancker et al [18] stated that

technologies for multimorbidity self-management will only be successful if they do not place further inconvenience or burden on the person. Indeed, earlier phases of our work, to understand user needs, highlighted how consuming it is living with and managing multimorbidity [21]. This was one of the primary drivers for designing a single platform for multiple self-management tasks, which includes features and analytics to help people with multimorbidity prioritize their conditions (eg, by highlighting on the dashboard *flower* those currently needing attention; Figure 3).

Caldeira et al [24] suggested three design guidelines for technology to support multimorbidity management: promoting conflict awareness (between disease and self-management approaches), supporting conflict resolution (to the most relevant approaches depending on symptom changes), and promoting patient expertise (to enact the approaches needed), which were considered while designing the ProACT platform. Considering patient expertise, the authors suggest that providing detailed health information and education can facilitate learning and contribute to expertise [24]. Our earlier findings also highlighted the lack of support people with multimorbidity receive in self-management [21], which identified the need for educational material, appropriate training on using self-management technology, and a triage service that would not only respond to symptom alerts but also motivate, support, and reinforce education presented through CareApp. People with multimorbidity in our study reported more awareness and increased confidence with respect to self-management, demonstrated the knowledge of their conditions, and what can impact them. With respect to designing for conflicts, CareAnalytics within ProACT have been designed to support the recognition and resolution of conflicts. For example, the Health and Wellness Profiler computes a probabilistic description of the person with multimorbidity, which is particularly important for multimorbidity, and all conditions can be considered while assessing the risk associated with the other variables in the model. For instance, the estimated probability of a given physical activity level is not the same if the person with multimorbidity has a fear of falling in addition to COPD. Using an automated goal recommender that considered individual patterns related to the performance of a given behavior (eg, goal achievement, optimal levels of activity), disease, symptoms, and usage of the recommendation feature, contribute to more personalized and adaptive digital health interventions. The goal recommender was only implemented for 8 weeks during the trial and was focused solely on physical activity goals. Future work with respect to this feature and analytic will focus on a more holistic approach to goal setting to better support the self-management of multimorbidity, in line with findings identified in our previous research [36]. Similarly, the education recommender will ensure that any recommended content considers the person with multimorbidity's condition and comorbidity profile as well as their current status to help them better understand potential conflicts and how to deal with them. With time, the artificial intelligence systems within ProACT are expected to learn from the data to provide more accurate recommendations and include additional parameters of personalization (eg, progress in other health behaviors, personalized education).

Despite this promising recent interest in understanding how to design technologies for the self-management of multimorbidity, there is little research on platforms that have actually been designed and implemented or evaluated for longitudinal periods. However, there is an abundance of research exploring how technology can support the management of single chronic diseases, including diabetes [56-58], COPD and related respiratory diseases [59], chronic kidney disease [60], and hypertension [61]. Our findings have many parallels with these studies. For example, Visser et al [58] explored the experiences of older adults using blood glucometers to monitor type 1 diabetes. The majority of participants reported that they sustained use of the device over time to know how much insulin was required before meals and because using the device gave a sense of safety and confidence. A greater confidence in practicing self-management was observed in our qualitative findings. The ability of the technology to provide novel insights into one's conditions and support the prevention of exacerbations (keeping symptoms under control) was also identified in our study, with similar benefits reported by Tenendez et al [59] in their study of older people self-managing chronic respiratory disease. There are also some differences between our findings and those of others. Tenendez et al found that participants took a reactive approach to self-managing, including the monitoring of symptoms, only doing so when they felt unwell [59]. The authors suggested that the potential reasons for this are that monitoring chronic respiratory conditions can be overwhelming and make people more conscious of their disease. They also suggest that long-term daily self-monitoring can lack value for those with chronic respiratory conditions, something that has also been highlighted by others [62,63]. Our findings contradict this result, thus indicating that people did find value and benefit in engaging in monitoring and seeing their data, with additional perceived value because of the triage service providing backup and peace of mind.

Our findings with respect to engagement with the sensor devices and CareApp indicate a high level of engagement with symptom and well-being monitoring and review. However, research has noted the importance of *effective* engagement rather than simply sustained or *more* engagement, with effective engagement being defined as *sufficient engagement with the digital intervention to achieve intended outcomes* [30]. Intended outcomes, from the perspective of digital health interventions, often relate to changes in behavior and improved health and well-being. For the ProACT trial, the key behavior under examination was engagement with the platform for self-management. Given that the ProACT platform represents a novel technology, the objectives of the trial were to evaluate usage, usability, and experiences to allow for the refinement of the technology before a trial to determine its effectiveness. This has been deemed a necessary approach to digital health intervention development and evaluation [64,65]. For example, Klasnja et al [64] suggest that evaluations of novel technologies should focus on human-computer interaction outcomes, including efficacy evaluations of specific intervention strategies such as self-monitoring and gaining a deep understanding of user experiences. Engagement with interventions has also been described as a precondition for effectiveness [30]. Although effectiveness was not specifically measured in our study, the
