Methods: We included patients with multiple myeloma and chronic lymphocytic leukemia who were already participating in routine monitoring at the hospital for use of the patient portal. Patients were introduced to the portal and asked to complete questionnaires prior to their next hospital visits. We used system access logs and 3 consecutive semistructured interviews to analyze patient use and evaluation of the portal.

Results: Between July 2017 and August 2020, we approached 122 patients for participation in the study, of whom 83.6% (102/122) consented to use the patient portal. Patients were on average 60 (SD 10.4) years old. Of patients providing data at all study time points, 37% (26/71) consistently used the portal prior to their hospital visits. The main reason for not completing PROMs was forgetting to do so in between visits (25/84, 29%). During an average session, patients viewed 5.3 different pages and spent 9.4 minutes logged on to the portal. Feedback from interviews was largely positive with no patients reporting difficulties navigating the survey and 50% of patients valuing the self-management tools provided in the portal. Regarding the portal content, patients were interested in reviewing their own results and reported high satisfaction with the dynamic self-management advice, also reflected in the high number of clicks on those pages.

Conclusions: Patient portals can contribute to patient empowerment by offering sought-after information and self-management advice. In our study, the majority of our patients were open to using the portal. The low number of technical complaints and average time spent in the portal demonstrate the feasibility of our patient portal. While initial interest was high, long-term use was considerably lower and identified as the main area for improvement. In a next step, we will improve several aspects of the patient portal (eg, including a reminder to visit the portal before the next appointment and closer PROM symptom monitoring via an onconurse).

quality of life; monitoring; patient portals; multiple myeloma; chronic lymphocytic leukemia; patient-reported outcome measures; eHealth; mHealth

Introduction

Patient-reported outcomes (PRO) are defined as all reports about the health status given directly by the patient without interpretation of the patient's response by a clinician or anyone else [1]. While they have long been used in clinical trials, they have, in recent decades, also progressed to enriching routine clinical care [2,3]. Driven by technological progress and an increased availability and use of the internet in the population [4], it has become easier to incorporate the patient's perspective into clinical care using electronic patient-reported outcome measures (ePROMs).

In oncological care, PROs can support patient-clinician communication [5,6] and aid early detection of symptoms [7,8] and have been linked to a decrease in hospitalization and emergency department visits [9]. Building on the evidence base showing the benefits of PRO use at the hospital, the use of web-based solutions to assess ePROMs outside the hospital has gained traction. In the last decade, the number of web-based patient portals that enable the completion of ePROMs has risen and recent research has demonstrated the potential benefits of patient portals in large-scale clinical trials [10-13]. For example, in a randomized controlled trial by Denis et al [10], web-based symptom monitoring was associated with increased survival compared to standard imaging surveillance following treatment for lung cancer. The authors argue that web-based symptom monitoring may allow for earlier symptom detection and appropriate reaction by health care professionals (HCPs). Moreover, PRO web monitoring can be highly cost-effective [11] and reduce the administrative burden of assessments inside the hospital, as patients can complete ePROMs from home. Finally, remote assessments are especially helpful in an outpatient setting, as assessments conducted on the day of chemotherapy administration at the hospital have shown to systematically underestimate patients' symptom burden associated with treatment [14].

Despite the benefits shown in study settings, and even though detailed guidance on how to implement PROs into clinical practice exists [15,16], electronic PRO monitoring and especially patient portals are still only occasionally adopted in routine clinical practice. This can be attributed to the limited integration into electronic health records, a lack of financial reimbursement for ePROM assessments, and a lack of standardized assessment methods, which hinder implementation in routine care [2]. Patient portals also vary considerably regarding the focus of the implementation and their goals and use of PROs [17]. More research is needed that evaluates the usability and acceptability of different applications in routine practice to extend and strengthen the evidence base in this heterogeneous and evolving field of research.

At the Department of Internal Medicine V in Innsbruck, a patient portal for outpatients with multiple myeloma (MM) and chronic lymphocytic leukemia (CLL) was developed to conduct remote PRO assessments. The primary aims for development of the portal were to enhance patient empowerment, encourage patient engagement with PROs, and reduce the administrative burden of PRO assessments inside the hospital.

In this study, we evaluated patient use of the various components of the portal and aimed to identify patient lack of motivation for not using the patient portal and potential barriers to accessibility.

Methods

Study Design

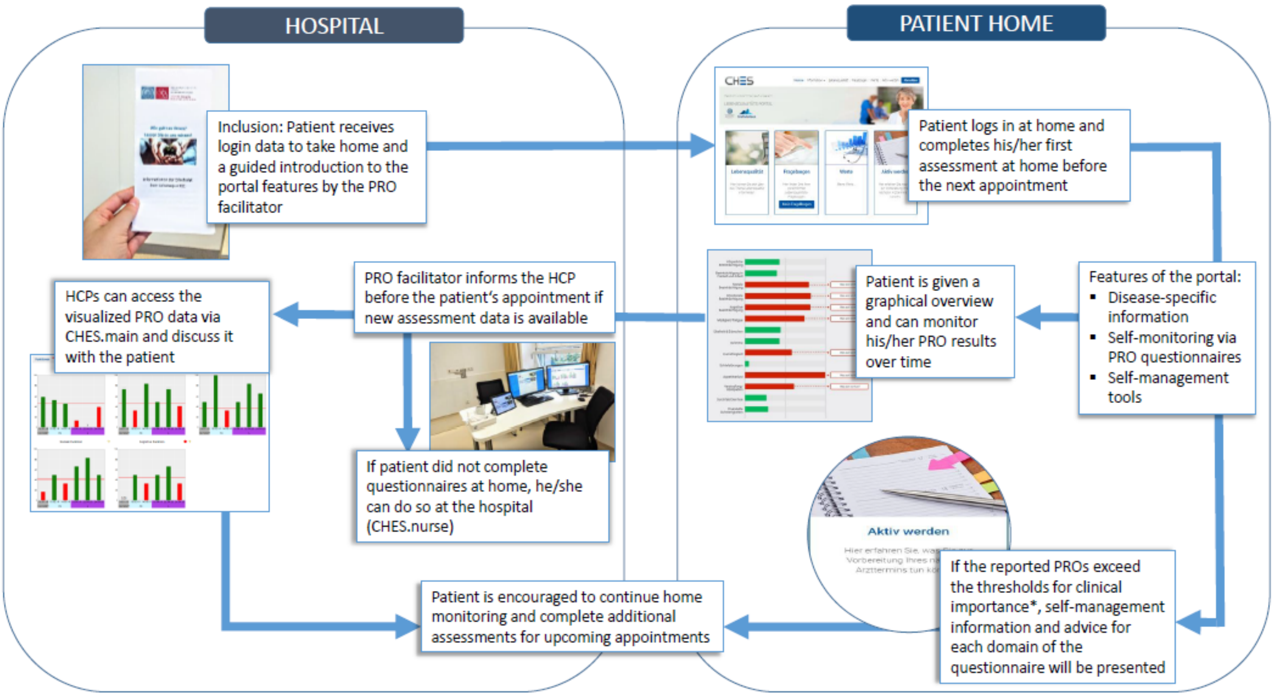
In our observational, longitudinal study, we evaluated patient use of the portal based on two data sources: semistructured interviews conducted during 3 consecutive visits to our unit after introducing eligible patients to the patient portal and system access logs recording the duration of user sessions and how often each page of the web portal was accessed.

Description of the PRO Monitoring and the Patient Portal

In June 2016, we implemented routine ePROM assessments to supplement care of outpatients with MM at the Department of Internal Medicine V in Innsbruck. The two primary aims of the implementation of ePROM assessments were to supplement the Austrian Myeloma Registry (AMR) with PRO data and enrich clinical care with the data [18]. In July 2017, patients with CLL were added as a second patient group. The use of the Computer-based Health Evaluation System (CHES) [19] enables immediate processing and graphical representation of the results. For monitoring at the hospital, patients complete PRO measures before their medical appointment, and the results are presented to the HCP prior to the consultation. The implementation and feasibility of the assessments at the hospital and use of data from patients have been evaluated in the past for the AMR [18], and more details on HCP use of the system are presented elsewhere [20]. This study builds upon our previous implementation strategy and is focused on process evaluation, refinement, and extension (as described in phase IV of the implementation process described by Sztankay et al [18]).

There are 3 main components of CHES: (1) the HCP interface (CHES.main), which presents PRO and patient data to HCPs; (2) the survey interface (CHES.nurse), where the patients complete questionnaires at the hospital; and (3) the patient portal (CHES.portal), which allows remote questionnaire completion and access to supplemental information and self-management advice. See Figure 1 for a visualization of the patient portal and its functionality. See Multimedia Appendix 1 for screenshots of the software and portal.

Figure 1. Computer-Based Health Evaluation System patient portal functions when patients are at home and in the hospital. *Thresholds for clinical importance [21] are used to highlight domains that require discussion with the health care provider. PRO: patient-reported outcome; HCP: healthcare professional.



Inclusion: Patient receives login data to take home and a guided introduction to the portal features by the PRO facilitator

Patient logs in at home and completes his/her first assessment at home before the next appointment

HCPs can access the visualized PRO data via CHES.main and discuss it with the patient

PRO facilitator informs the HCP before the patient's appointment if new assessment data is available

Patient is given a graphical overview and can monitor his/her PRO results over time

Features of the portal:
- Disease-specific information
- Self-monitoring via PRO questionnaires
- Self-management tools

If patient did not complete questionnaires at home, he/she can do so at the hospital (CHES.nurse)

If the reported PROs exceed the thresholds for clinical importance*, self-management information and advice for each domain of the questionnaire will be presented

Patient is encouraged to continue home monitoring and complete additional assessments for upcoming appointments

In this paper, we assess patient use of the patient portal, which features the following functionalities:

- Disease-specific information on CLL and MM: diagnosis, possible symptoms, possible treatments, and links to further information and self-help groups
- PRO assessments with the cancer-specific European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30) in combination with the disease-specific modules EORTC QLQ-MY20 for patients with MM and EORTC QLQ-CLL17 for patients with CLL. The EORTC QLQ-C30 is the most frequently used cancer-specific questionnaire [22] and can be used to measure patient symptoms, functional health, and global quality of life. The modules QLQ-MY20 and QLQ-CLL17 supplement the QLQ-C30 and cover disease-specific issues of quality of life for MM (eg, future perspective, treatment side effects) and CLL patients (eg, symptom burden due to disease and/or treatment, worries/fears regarding health and functioning).
- PRO score review by patient: results are displayed as colored bar charts (longitudinal and cross-sectional). Results that exceed the thresholds for clinical importance [21] are colored red, and results that do not exceed these threshold are colored green (see Lehmann et al [20] for more information).
- Self-management tools and tailored information: based on EORTC QLQ-C30 data, patients are presented with self-management tools for the symptoms and functional health domains. If a patient reports a potentially clinically important result [21], they are directed to the self-management tools (see Lehmann et al [20] for more information). Patients are reminded that in case of severe impairments, they should contact the clinical team directly.

At the outpatient clinic, patients are introduced to the portal by a PRO facilitator (ie, person responsible for the assessments at the hospital). The role of the PRO facilitator is that of a study assistant with a background in psychology or nursing who is trained in the use of PRO data and motivates both patients and HCPs to use the PRO data. Patients are given instructions for use and their personal log-in data for accessing the portal at home by the PRO facilitator.

Typically, patients are advised to complete ePROM assessments in the week before their hospital visits. Visits are scheduled at regular intervals that range between 1 week and 12 months, depending on the disease stage and treatment plan. Patients are encouraged to complete questionnaires as often as they like, even on a daily basis. Questionnaires completed within 7 days of a hospital visit are used to inform the HCP of the patients' health status and linked to the clinical data in the AMR. Data from assessments in between hospital visits are used for research purposes and enable more continuous tracking of patients' health status in the AMR.

Although patients participating in the routine monitoring are encouraged to use the patient portal to report PROs, they can still complete assessments at the hospital (eg, if they forgot to use the portal before their hospital visit).

Study Sample

We defined the following inclusion criteria for participation in monitoring via the patient portal: fluency in German, age 18 years or older, diagnosis of MM or CLL, current treatment at the outpatient clinic of the Department of Internal Medicine V or the Comprehensive Cancer Center Innsbruck of the Medical University of Innsbruck, consent given to routine PRO monitoring at the hospital, and completion of at least one ePROM during a prior visit to the hospital.

Patients were deemed ineligible if they had no access to a computer or the internet or lacked sufficient knowledge to log into a website using a username and password. All patients provided informed consent to use the patient portal. Patients who declined to use the portal were asked for the reason for their refusal. The study and use of patient data are covered by the ethics approval for the AMR issued by the ethics committee of the Medical University of Innsbruck (study number AN3252 266/4.2 386/5.14).

At baseline, demographics (sex, age, marital status, education level, and employment status) and experience with the internet and computer technology (frequency, duration) were collected via a questionnaire. Diagnosis and cancer stage were obtained from the hospital's medical records.

Selection of Outcome Measures

We used different sources to evaluate patient use and perception of the patient portal. Table 1 displays the selection of outcome measures.

Table 1. Selection of outcome measures.

Questions addressed	Outcome measure	Assessment method	Data type
How often do patients use the portal? Is the portal feasible for use during routine clinical care?	ePROM[a] completion rate (number of completed ePROMs before study time points)	Assessed via CHES[b]	Quantitative data
Why do patients use (or not use) the portal? What is their feedback on portal components?	Patient perspectives on portal components and motivation to use (or not use) the portal; accessibility barriers identified	Semistructured interviews	Qualitative and quantitative data/questions
How often do patients log into the portal? How long do patients log into the portal in a single session? Which pages are viewed and how often?	Patient user patterns in the portal: number and duration of log-ins per patient; portal page views	Assessed via CHES portal log data	Quantitative data

[a] ePROM: electronic patient-reported outcome measure.

[b] CHES: Computer-based Health Evaluation System.

Patient Interviews

Each patient participated in 3 semistructured face-to-face interviews conducted by authors LN, PB, and JL following a fixed schedule during 3 consecutive visits to the outpatient unit. See Figure 2 for a flowchart of the interview process. The topics covered in the interviews were as follows:

T1: Guided introduction to the portal and user log-in

- Possible difficulties logging in
- Navigating the portal
- Reviewing PRO results
- Other suggestions/remarks by patients

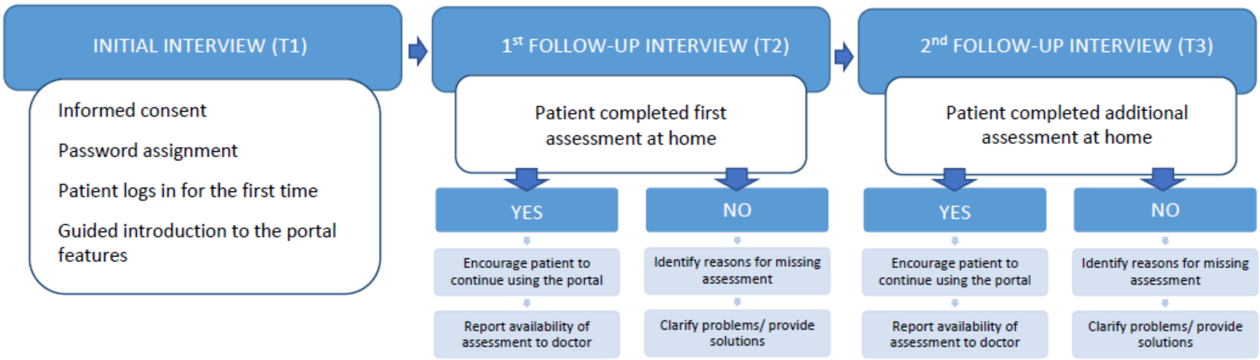
T2: Evaluation of use: acceptability and usability

- Satisfaction with instructions for completion of questionnaire
- Navigating the portal
- Technical difficulties
- Reviewing PRO results and accessing self-help tools
- Relevance and usefulness of provided content

T3: Evaluation of use: acceptability and usability

- Technical difficulties
- Interest in content not explored during previous log-ins
- Satisfaction with design
- Other suggestions/remarks by patients

Figure 2. Patient interview procedure and topics.



ePROM Completion Rate

To evaluate initial interest in the portal, we assessed the proportion of patients in routine monitoring at the hospital consenting to use the patient portal at T1. To evaluate continued use, we assessed the proportion of patients who completed ePROMs prior to hospital visits at T2 and T3; ePROMs were considered to be linked to a hospital visit if they were completed in the 7 days before the visit.

CHES Log Data

The frequency (absolute number) and duration (in minutes) of the use of the website were determined by the CHES system log. These data were gathered irrespective of the interview time points each time the patient logged into the system. Log data were collected per session but were not linked to individual patients. Therefore, patients with more sessions have a greater weight in this analysis. Log-ins that occurred on the same day were considered a single session, and durations of these sessions were summed.

Data Analysis

Sociodemographic and clinical data were analyzed at time point T1. Comparison of patients completing ePROMs via the patient portal and of those who declined to use the portal were made with *t* tests (for parametric variables) and chi-square tests (for nonparametric variables).

The interviewer took field notes during the interviews and for each open question. Responses from the interviews were either analyzed descriptively (for yes/no questions) or paraphrased and category-coded (for open answers) independently by two researchers (JL and PB) and harmonized by discussion in case of different coding. We translated selected quotes into English for the results section of this paper.

We also analyzed the frequency (number) of views for each portal page, excluding views on the start page, where patients are directed automatically after logging in. Further, we calculated the time patients needed to complete the questionnaires online (mean completion time per patient averaged across all patients).

Results

Participant Enrollment and Baseline Characteristics

Recruitment began in July 2017 and was open until August 2020. During the study period, we identified 142 eligible patients already participating in the electronic PRO monitoring in the hospital, of whom 85.9% (122/142) were approached for study participation and use of the patient portal. Of those, 83.6% (102/122) consented to be included in the patient portal. Of 20 patients not willing to use the patient portal, 18 patients stated a preference of questionnaire completion only at the hospital as the reason. The complete enrollment process is shown in Figure 3.

The full sociodemographic information and clinical data are given in Table 2. There were no statistically significant differences regarding age, sex, education, time since the initial diagnosis, and type of internet use between those who agreed and those who refused to participate (all $P>.09$). The age range of patients included in the portal was 39 to 83 years, and the age range of patients not included in the portal was 39 to 77 years. A statistically significant difference was found for general internet use (see Table 2), with participants who consented to use the portal reporting higher internet use than those who did not consent to use the portal: of patients who used the portal, 94% (94/100) reported using the internet at least multiple times per week compared to 76% (17/22) for patients who did not use the portal.

Figure 3. Recruitment flowchart (study patient denotes patients who were also participating in other clinical studies and were not included in our study so as not to overburden the patient with clinical questionnaires).

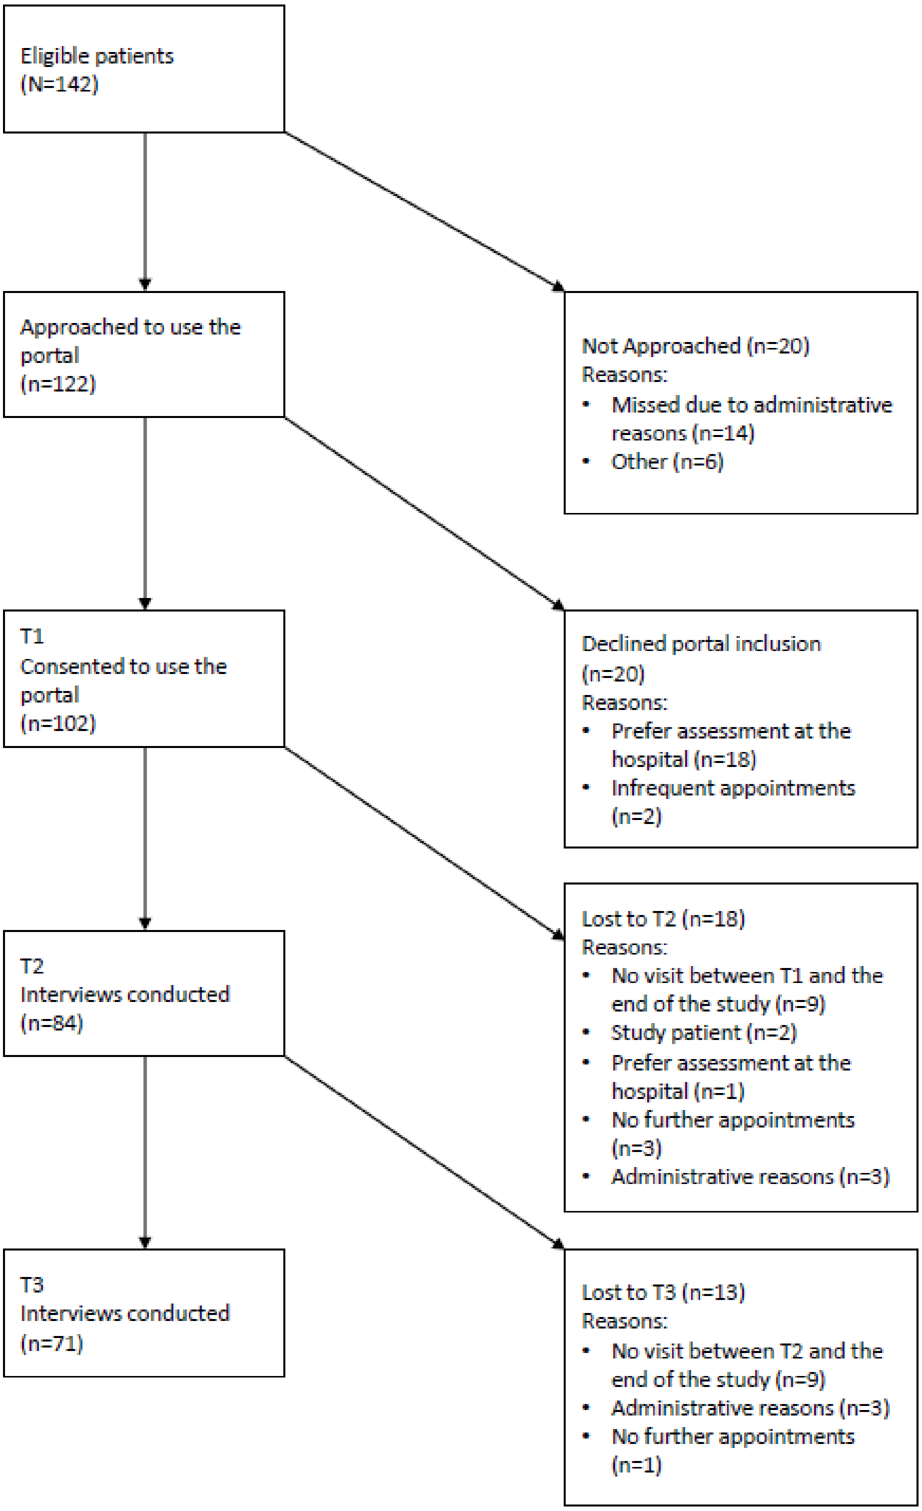


Table 2. Sociodemographic information.

[a] Not applicable.

[b] Missing values were not included in the calculation of percentages.

Interviews

Interviews lasted between 10 and 30 minutes. Only 5% (5/102) patients required help from the PRO facilitator because they were not able to read their username and password (small font size). After the log-in and during the first interview, no patients reported technical difficulties or had difficulties navigating the portal or the questionnaire. Table 3 shows the number of completed questionnaires before the interviews and the reasons for noncompletion. Of the patients who participated in all 3 interviews, 37% (26/71) completed the questionnaires prior to the T2 and T3 interview, while the others completed the questionnaires only at the hospital visit.

Table 4 shows the use and evaluation of the portal as reported by patients who completed questionnaires prior to the interviews. Patients who completed questionnaires prior to their follow-up appointments reported using the portal in different ways: the percentage of patients reading additional portal content (eg, disease-specific information) declined over time from 71% (27/38) at T2 to 41% (13/32) at T3. The self-management tools were used and deemed useful by 50% (17/34) of patients at the second and 42% (13/31) at the third interview.

Table 3. Questionnaire completion rate and reasons for not completing questionnaires in the patient portal before hospital visits.

Completion rate or reason for noncompletion	Interview 1 (n=102), n (%)	Interview 2 (n=84), n (%)	Interview 3 (n=71), n (%)
Questionnaire completed before appointment			
Yes	102 (100)	38 (45)	32 (45)
No	—[a]	46 (55)	39 (55)
Reasons not completed			
Forgot	—	25 (29)	18 (25)

[a] Not applicable.

[b] Missing values were not included in the calculation of percentages.

[c] If a patient did not report impairments above the thresholds for clinical importance, the software did not suggest viewing self-management tools when looking at their own results.

Patient Comments

Patients were encouraged to provide additional comments following their answers to the interview questions. In the first interview, patients reported high satisfaction with the presentation of the results as bar charts.

> *...bar charts are a good way of presenting the results. I like that I can compare my results to those of other patients with cancer.*
>
> *I like that I can see my results after having completed the questionnaire.*

Patients who did not inspect their own results expressed that they were feeling fine and therefore had no interest in viewing their results.

Similarly, patients who were feeling fine or reported no impairments did not inspect the self-management tools, while others provided positive feedback on the self-management tools or the color-coding of questionnaire results.

> *I did not check the self-management advice because I am not feeling ill. Why would I check it?*
>
> *I like the design. The arrow in the results [direct link from the results to the self-management information] was very helpful.*
>
> *...liked the color coding [red/green] as it was simple and easy to understand.*

Four patients expressed the wish for a reminder (email or text message) before the next appointment to complete the questionnaires online. Two patients mentioned that they would like to be able to choose their password or username themselves (which the software currently does not allow). Three patients also explicitly reported a decline in motivation toward the end of the study, caused by a lack of sufficient feedback from physicians who did not discuss their PRO results during the consultations.

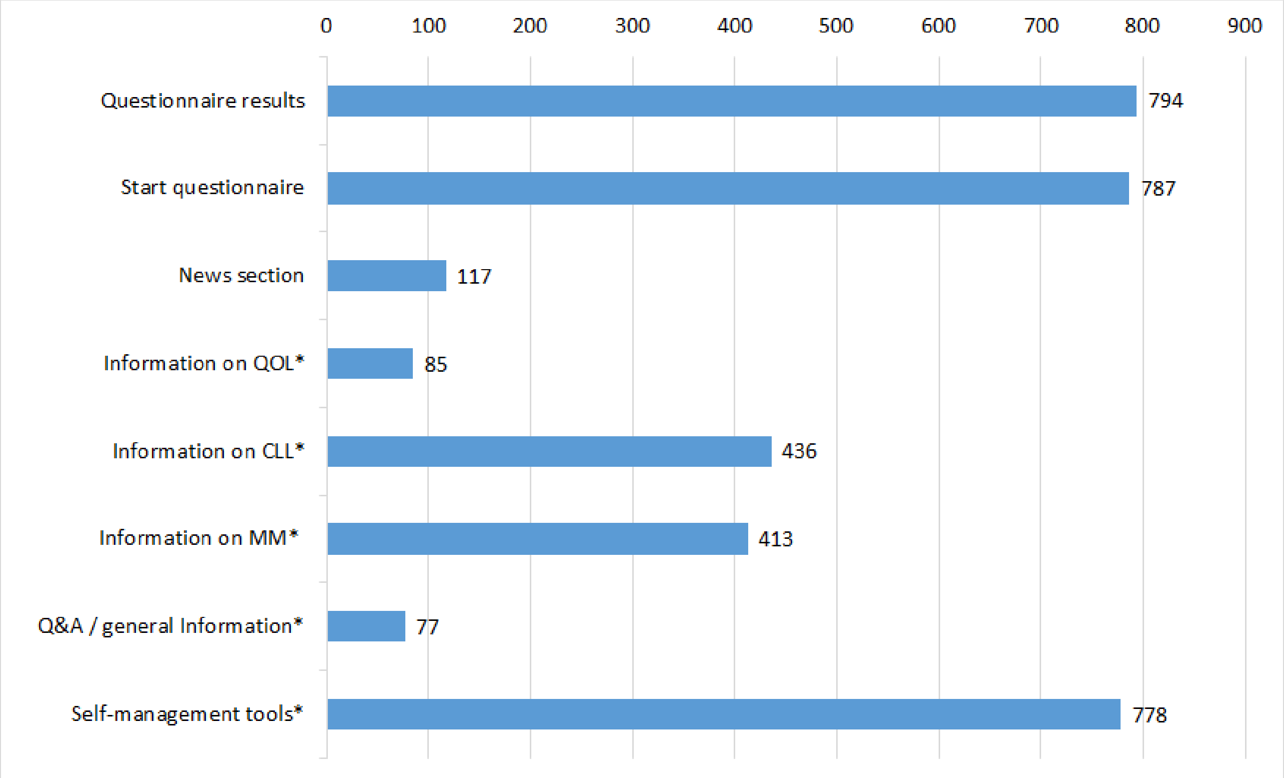
CHES Log Data

Over the study period, we registered a total of 796 sessions (ie, log-ins by patients). Of the patients who logged into the patient portal, 27% (28/102) logged in once, 18% (18/102) logged in twice, 9% (9/102) logged in 3 times, 15% (16/102) logged in 4 to 6 times, 14% (14/102) logged in 7 to 10 times, and 17% (17/102) logged in more than 10 times (total range of 1-57).

The mean duration of a session was 9.4 (median 6, range 1-90) minutes. It took patients on average 2.9 minutes to complete the EORTC QLQ-C30, 1.8 minutes to complete the EORTC QLQ-MY20, and 1.5 minutes to complete the EORTC QLQ-CLL17. This adds up to an average questionnaire completion time of 4.7 minutes for patients with MM and 4.4 minutes for patients with CLL.

During an average session, patients viewed 5.3 (median 4, range 1-28) different pages. Figure 4 shows how often specific components of the patient portal were viewed. A total of 3487 views were registered. The most frequently viewed self-management pages were those providing information on dyspnea (89 views), diarrhea (80 views), cognitive functioning (64 views), and emotional functioning (49 views). The least frequently viewed self-management pages were those providing information on obstipation (11 views), role functioning (12 views), social functioning (21 views), and pain (18 views). Multimedia Appendix 2 shows the view count on all self-management pages.

Figure 4. Page views in the patient portal by category (excluding home page). Categories marked with an asterisk combine multiple pages and subpages. QOL: quality of life; MM: multiple myeloma; CLL: chronic lymphocytic leukemia; Q&A: questions and answers.



Discussion

Principal Findings

In our study, we evaluated the use of the patient portal in patients with MM and CLL participating in routine electronic PRO monitoring. We found that in those patients who were eligible to use the patient portal, the majority (84%) were willing to use the portal. Only a few users reported difficulties logging in, but no users reported problems navigating the survey. However, we found that considerably fewer patients (37%) than initially included adopted a continued use of the portal across all 3 study time points. On average, patients spent 9.4 minutes in the portal per session.

Uptake of Home Monitoring

Our recruitment rate (ie, patients consenting to try the patient portal) is high compared to rates found in other studies. For example, other feasibility or usability studies report that between 21% and 64% [23-25] of patients were willing to use patient portals. Our high recruitment rate is most likely a consequence of the fact that patients were already participating in electronic PRO monitoring and so had already approved some form of monitoring. We would like to note the high inclusion rate for PRO monitoring at the hospital, which was, as reported previously, 94% of all MM patients treated in the department [18]. Our study emphasizes the possible synergy between assessments inside the hospital and home monitoring; patients who had already participated in electronic PRO monitoring inside the hospital were open to also using a patient portal. Moreover, the high acceptance of the patient portal might have been induced by the opportunity to get accustomed to ePROMs at the hospital with the help of a PRO facilitator before being introduced to the patient portal. We hypothesize that such a stepwise approach can reduce potential reservations about using electronic measures and contribute to user empowerment.

The adoption of home monitoring by a considerable proportion of patients also meant that those patients did not need to be assessed at the hospital. In this way, the patient portal reduced the administrative burden of assessing those patients' PROs at the hospital and allowed us to allocate those resources elsewhere.

Long-Term Use of the Portal

Over the course of the study, slightly less than half of the participants used the portal prior to their follow-up appointments. The main reason reported by patients was that they had forgotten to report their PRO data using the patient portal. Especially for patients with an infrequent appointment schedule (intervals between hospital visits of up to 12 months), forgetting to use the portal is, in fact, not surprising. This issue might be addressed by implementing an automated reminder (email or text message) as has been done with similar home monitoring systems [24,26]. For example, the AmbuFlex system in Denmark has, in the past, used different forms of reminders, including letters, emails, and text messages. They ultimately implemented communication via a national secure email program, which accounts for 93.2% of communication to patients and secures high completion rates [27].

Additionally, it is important to note that due to our routine monitoring approach, ePRO data from patients who did not use the portal prior to the follow-up appointments were not lost. Instead, those patients were invited to complete the ePROMs at the hospital as was done with other patients who did not use the portal.

While only a few of our patients directly mentioned a decline in motivation to complete ePROMs due to HCPs not picking up on the results during the consultations, this is in fact a frequent problem of PRO implementations in clinical settings [3,26,28,29]. For patients, there is little perceived benefit of completing the questionnaires if the results are not reviewed and discussed by HCPs. Instead, sharing their health status via questionnaires might even become burdensome. Therefore, it is important to engage HCPs with the concept of PROs and train them in the use of PRO results to prevent PRO data from becoming meaningless busywork that hinders clinical practice instead of enhancing it [28]. This requires the education and training of HCPs, which can be achieved by conducting specialized training programs [30]. A buy-in strategy may be used to increase HCP engagement with PROs, for example, via the adoption of the user interface to HCP needs and preferences, regular meetings, or analyses of PRO data in the registry upon request of HCPs. Another important approach is to make PRO data comprehensible and actionable for HCPs (eg, by providing advice on how to react to results) [26,31,32]. In our system, this is done, for example, by using thresholds for clinical importance for the EORTC QLQ-C30 [21] that facilitate the interpretation of patient PRO data.

Finally, the literature shows that in order to provide a sound theoretical basis for sustainable PRO solutions in routine care settings, an implementation science approach can be followed [33]. Implementation science can help identify barriers (which are often similar across contexts) and enablers (which often depend on the given hospitals' context) of patient-reported outcome measure (PROM) implementations.

User Patterns in the Portal

As has been found in other studies [13,17,25], the majority of our patients found the display of self-management advice linked with their results to be valuable. A recent review of electronic systems to measure PROs found that less than one-third (29%) of published electronic systems include features that provide tailored automated advice to patients, and less than half (41%) provide general educational information [17]. In a qualitative study evaluating another eHealth application, tailored feedback and advice was rated as appealing by most participants [34]. Participants valued the option of accessing information remotely between appointments and having a low threshold to receiving such information (compared to having to consult their treating physician or having to search for information) [34]. These are notions that echo the high number of views of pages with self-management advice we found in our study.

Nevertheless, despite the approval for self-management advice we found in our study, a recent clinical trial showed that, while patient portals can contribute to improved health-related quality of life [13], their measurable benefits on patient activation (knowledge, skills, and confidence for self-management) could not be shown in a diverse sample of cancer survivors [13]. However, previous evidence suggested that such effects may be more pronounced in newly diagnosed patients [25,35]. Another randomized controlled trial showed that weekly PRO monitoring along with the provision of tailored self-management advice, compared to usual care, significantly enhanced self-efficacy in patients with cancer [36].

Limitations

Our study was designed to be carried out during routine care with minimal interruption of the clinical workflow. Therefore, interview time points were integrated into the patients' hospital visits. This resulted in varying intervals between interviews (between 1 week and 1 year in a few cases), which may have influenced the results. However, we point out that these are real-world visitation schedules, and any application designed for routine care should be evaluated accordingly. Similarly, we included more males than females in our study. This reflects the epidemiology of MM and CLL, and the male/female ratio was comparable to data from the AMR.

Second, the CHES log data did not allow for detailed analysis of individual user page-view patterns but only for analysis of overall page views and duration and frequency of sessions. This means that patients logging on to the portal more frequently have a greater weight in the analysis of page views. Moreover, page view numbers have to be interpreted with care as they provide no information on whether the pages were actually read.

Another limitation is that the interviews were conducted by the authors (LN, PB, and JL), who introduced patients to the portal. Therefore, some patients might have been reluctant to voice criticism in the interviews, even though we actively encouraged patients to also report negative feedback.

Finally, we consider some sample-related limitations: We included only German-speaking patients in the patient portal. While the EORTC questionnaires are available in a large number of languages (and can be completed at the hospital [20]), translating and updating the content of the portal would require considerable resources. This results in a potential bias, and our findings may not be generalizable to patients with other first languages and limited German language proficiency. We are aware that this can create an imbalance in the provision of care, as this systematically excludes certain patient groups. In fact, patients not speaking the primary language of the country might profit most from receiving disease-specific information and from being able to report symptoms online in their native language. Moreover, we observed a selection bias due to patients' age (patients with MM were on average 11 years younger than the mean age of patients in the AMR), as older patients might be less proficient using the internet and were consequently not included in our study. While this is an important limitation to consider, its impact should decrease over time, as the population's internet capabilities have been steadily increasing [37] and should further increase in the years to come.

Future Steps

Following the insights gained in this study, we are currently in the process of updating our monitoring procedure and software. One important step is to more closely monitor patients' PROMs to swiftly identify deteriorations and act accordingly; we aim to have a trained onconurse monitor patient results and check on patients in case of deteriorations. If necessary, the nurse can schedule an earlier appointment or alert the treating HCP. Another planned improvement is to implement an email or text message reminder to improve PROM completion rates.

Conclusion

Our study shows that a patient portal enabling remote PRO data assessment can complement routine electronic PRO implementation at the hospital by reducing the burden of administration for the clinical team and offering an additional way for patients to engage with PROs. We found that the majority of patients were open to using the patient portal and interested in assessments from home. The low number of technical problems and absence of complaints demonstrate the general user-friendliness of our portal. While initial uptake was high, fewer patients adopted regular use of the portal prior to their appointments. To increase long-term participation rates, further motivational (eg, increasing HCP engagement with the PRO data) and technical (eg, email reminder) measures are needed.

Acknowledgments

We thank the patients who participated in this study for their valuable time and input, without which the study would not have been possible. We thank the Department of Internal Medicine V in Innsbruck and the Comprehensive Cancer Center Innsbruck for their support with the project. We thank Janny Sauter for her help in the collection of data.

Authors' Contributions

JL and PB wrote and edited the manuscript and collected and analyzed the data. BH, GR, JMG, LW, MS, RW, WWeyrer, and WWillenbacher conceptualized the study, supported the implementation of the patient portal, and edited the manuscript. LN conceptualized the study, supported the implementation of the patient portal, assisted in data collection, and edited the manuscript. All authors read and approved the final version of the manuscript.

Conflicts of Interest

BH and GR have intellectual property rights to the software tool CHES. All remaining authors declare that they have no conflict of interest.

Abstract

Background: The use of artificial intelligence has revolutionized every area of life such as business and trade, social and electronic media, education and learning, manufacturing industries, medicine and sciences, and every other sector. The new reforms and advanced technologies of artificial intelligence have enabled data analysts to transmute raw data generated by these sectors into meaningful insights for an effective decision-making process. Health care is one of the integral sectors where a large amount of data is generated daily, and making effective decisions based on these data is therefore a challenge. In this study, cases related to childbirth either by the traditional method of vaginal delivery or cesarean delivery were investigated. Cesarean delivery is performed to save both the mother and the fetus when complications related to vaginal birth arise.

Objective: The aim of this study was to develop reliable prediction models for a maternity care decision support system to predict the mode of delivery before childbirth.

Methods: This study was conducted in 2 parts for identifying the mode of childbirth: first, the existing data set was enriched and second, previous medical records about the mode of delivery were investigated using machine learning algorithms and by extracting meaningful insights from unseen cases. Several prediction models were trained to achieve this objective, such as decision tree, random forest, AdaBoostM1, bagging, and k-nearest neighbor, based on original and enriched data sets.

Results: The prediction models based on enriched data performed well in terms of accuracy, sensitivity, specificity, F-measure, and receiver operating characteristic curves in the outcomes. Specifically, the accuracy of k-nearest neighbor was 84.38%, that of bagging was 83.75%, that of random forest was 83.13%, that of decision tree was 81.25%, and that of AdaBoostM1 was 80.63%. Enrichment of the data set had a good impact on improving the accuracy of the prediction process, which supports maternity care practitioners in making decisions in critical cases.

Conclusions: Our study shows that enriching the data set improves the accuracy of the prediction process, thereby supporting maternity care practitioners in making informed decisions in critical cases. The enriched data set used in this study yields good results, but this data set can become even better if the records are increased with real clinical data.

machine learning; prediction model; health care; cesarean; delivery; decision making

Introduction

Background

Machine learning is increasingly prevalent in and vital to health care industries in terms of predicting and identifying quality treatments for patients and enhancing other health care services. Therefore, machine learning techniques are used for extracting knowledge from huge and complex data sets in an organized form so that it can be used for making effective decisions. According to Sana et al [1], machine learning techniques provide diagnosis and analytical amenities in several medical fields and their applications in clinical factors and analytics such as disease prediction, decision making based on extracted medical knowledge, and serving in patient management. Moreover, with the increasing amount of available data, machine learning techniques have significant benefits as prediction tools in health care [2] that sometimes provide surprising prediction models that help in clinical counseling [3]. These tools are fundamental to biomedical research and are utilized as an integral part of the clinical decision-making process [4].

Child delivery can be performed through several methods in hospitals, but the most common methods are either traditional vaginal birth or cesarean (c-section), while vacuum extractions and obstetric pincers can be used during complications in vaginal deliveries [5]. There are several assumptions pertaining to the mode of delivery, but it is still challenging to predict the type of childbirth accurately [6,7]. C-section is a technique used in maternity care for delivering children by performing a surgical incision to the woman’s abdomen and uterus [8], which normally takes place when complications arise related to the mother or a child in a normal delivery [9]. The possible complications of c-section for mothers are infections, excessive bleeding that could cause anemia, and reaction to anesthesia; therefore, maternal death rates with c-sections are higher than that for vaginal deliveries [8]. However, a c-section could be necessary to save the lives of both the mother and the child if the baby is located in a wrong position in the womb, the head of the baby is larger than the birth canal, the direction of the baby is reversed, or the mother has a c-section history or even heart-related diseases [10]. Molina et al [11] further explained that c-sections are lifesaving for obstructed labor and any other obstruction in the delivery process for decreasing baby and mother mortality, but the risk of complications and overuse can harm both mothers and babies. Every mode of delivery has its pros and cons, but selecting the wrong type may lead to a variety of risks such as baby cessation, excessive bleeding, baby breathing problems, and other similar issues [7].

The rate of c-sections is higher than the rate of normal deliveries, especially in high-income countries, where in 2012, around 23 million deliveries were conducted by c-section worldwide [11]. Prema and Pushpalatha [8] indicated that the highest rate of c-section was 29.1% in November 2005, while nearly one-third of the deliveries were conducted using c-section in 2015 [12] as reported by the Centers for Disease Control and Prevention [13]. In the United States, the c-section rate significantly increased to 60% from 1996 to 2009, and the c-section rate was 32% of all deliveries in 2007 [12]. Li et al [14] reported that in China, 46.2% of the 14,541 deliveries across 3 provinces in different hospitals were conducted by c-section in the years 2007 and 2008. Similarly, in Pakistan, around half of the total deliveries are conducted at home, but a high number of c-sections are conducted at hospitals [9]. Fergus et al [4] argued that overinterpretations increase the numbers of c-section, even if there are no specific risks involved in the normal deliveries. It is difficult to know the optimal level of the c-section rate because although the World Health Organization advocates that national rates do not exceed by 10 to 15 c-sections per 100 births, the rates of c-sections are noticeably higher [11].

Related Work

Studies related to identifying the mode of childbirth were found in different databases such as Google Scholar, Science Direct, IEEE explorer, Wiley, ResearchGate, and other data sources. The major keywords used in the browsers were phrases such as cesarean sections using machine learning, c-sections using machine learning, machine learning in maternity care, AI in maternity care, etc. C-section is the most commonly increasing mode of delivery worldwide, and areas of concerns such as ideal c-section rate, safety, and cost are still under debate [15]. Moreover, many researchers have investigated different features to determine the main causes for cesarean delivery and have built a prediction model based on these features. Some main causes are related to the medical and obstetric history of the mother [5,6,8,15-17]. The study of Lee and Gay [18] found that sleep disturbance and fatigue in late pregnancy lead to greater chances of delivery by c-section. Others analyzed the socioeconomic or sociodemographic features [1,19] and some have determined the main causes to be the region and level of medical services afforded [9].

Wollmann et al [3] attempted to predict the chances of normal births after a c-section. In this regard, they collected data of women with one previous birth in Sweden during 2008-2014 and built 3 machine learning models and 1 regression model. They concluded that the majority of the women with a history of c-sections could still successfully deliver a baby in the normal way. Similarly, Prema and Pushpalatha [8] investigated the main causes of cesarean delivery based on the extracted features. Several machine learning models were trained on a data set collected from a pregnancy risk assessment survey. Their models have predicted c-sections with 96% accuracy for women who had a history of c-sections compared to 89% accuracy for women who had no previous c-section. Khan et al [10] presented a study to predict whether c-section is compulsory along with increased safety for both mother and child during and after delivery. They trained 3 ensemble models and found the highest accuracy model of 87.66%. They also found that for predicting the target mode of delivery, several features such as previous c-sections, amniotic fluid, fetal intrapartum pH, and preinduction should be considered. Sana et al [1] figured out the socioeconomic features that cause cesarean delivery. They trained decision tree (DT) and artificial neural network models to predict the mode of delivery in which artificial neural networks showed a high accuracy of 82%. Abbas et al [9] believed that c-section causes can be influenced by regions and therefore, they selected a region with a limited health care infrastructure. They trained several models based on 23 features in order to predict the mode of delivery, and the highest accuracy model was 91.8%. They also concluded that the maternal age and the previous mode of delivery considerably influenced the mode of the next delivery.

Ricciardi et al [20] adopted classification methods DT, random forest (RF), AdaBoostM1, gradient boosting, and DECORATE (Diverse Ensemble Creation by Oppositional Relabeling of Artificial Training Examples) for predicting patients' mode of delivery. They applied these methods to a data set of 370 records collected from public and private hospitals from the years 2000 to 2009. RF outperformed with 91.1% accuracy, 90% sensitivity, and >96% ROC. In the study of Improta et al [2], the 4 classification methods, namely, DT, RF, AdaBoost, and gradient boosting were trained on a cardiotocographic data set for identifying the mode of delivery, in which RF showed the highest performance with 87.6% accuracy, 87.9% precision, and 93% ROC. In a study conducted by Saleem et al [21] for classifying the mode of delivery using 4 machine learning methods, the AdaBoost model showed the highest accuracy of 91.8%, sensitivity of 95.5%, and specificity of 98%. Of the 4 classification algorithms used by Pereira et al [5] to predict the mode of delivery, DT outperformed with accuracy of 84%, sensitivity of 88%, and specificity of 80%. A DT method was adopted by Soleimanian et al [15] to investigate the mode of delivery in a data set of 80 patients and they found an accuracy of 86.25%. In the study of Fergus et al [4], ensemble methods were used for classifying the mode of delivery by using a cardiotocographic tracer in which all 3 methods showed promising results of 87%, 90%, and 96% for sensitivity, specificity, and ROC, respectively. Moreover, Fergus et al [22] established that machine learning with fetal heart rate signals significantly improved the efficacy of detecting the mode of delivery compared to obstetrician and midwife predictions and other systems. Their results showed 94%, 91%, and 99% sensitivity, specificity, and ROC, respectively.

Objective of This Study

This study aims to provide prediction models for identifying the mode of childbirth based on antenatal signs and symptoms by using machine learning techniques. To achieve the objectives of this study, the data set was first enriched with additional cases using the Synthetic Minority Oversampling Technique (SMOTE) [23]. Second, several prediction models were trained and tested on original and enriched data sets. A cross-validation of 10 folds was used for evaluating the performance of the models. In the outcomes, the enriched data set showed better performance in terms of accuracy, sensitivity, specificity, F-measure, and receiver operating characteristic (ROC) compared to the original data set. These findings encourage the applications of these models for maternity care decision support systems to predict the mode of delivery before birth.

Methods

Software Used

The data synthesis and analysis in terms of classifications and predicting the mode of delivery were performed using Weka software (University of Waikato, New Zealand) [24]. Weka has many machine learning algorithms that are useful for training data sets and then testing them on unseen cases to predict target values [25,26].

Data Collection

The data set used in this study was harvested from the study of Soleimanian et al [15] and is publicly available in the University of California, Irvine machine learning repository [12,27]. The data set contains 5 features, namely, age, delivery_number, delivery_time, blood_of_pressure, and heart_problem, while cesarean is a class attribute to label whether the delivery was performed by c-section. In the data set, each attribute shows different values, such as age ranges from 22 years to 38 years, delivery_number shows the number of births from 1 to 4, delivery_time shows 3 different statuses that are premature, timely, or latecomer, blood_of_pressure also shows 3 different statuses that are low, normal, and high, the heart_problem is categorized as either yes or no, and the last attribute (cesarean) is categorized as to whether the birth was by c-section or not. This data set contains 80 records of pregnant women and information about whether delivery was conducted by c-section or normal birth.

Data Enrichment

The data set used in this study originally contained 80 records, of which 46 records were normal vaginal deliveries while the remaining 34 were c-sections. According to the criteria of Vapnik [28], the total number of records was insufficient for predictive purposes [25]. Therefore, the data set needed more records to ensure that the prediction models are reliable and trustworthy. For this reason, the existing data set was enriched with more records using the standard method of SMOTE [23]. SMOTE is a popular method of machine learning used for oversampling [29] in which the minority class in a data set is generated by a synthetic example in the feature area based on the selected k-nearest neighbor (k-NN) from the minority class [21]. This practice has been adopted in several biomedical studies [4,30-36]. Mohammed et al [34] used the SMOTE method for enriching the minority class and concluded that oversampling has a positive impact on the prediction models. Similarly, Ramezankhani et al [32] adopted the SMOTE method for increasing the samples in the minority class in the original data set with various percentages (ie, 100%, 200%....,700%), which resulted in increased sensitivity of the different classifiers used. Another study of Hussain et al [37] used the SMOTE method and compared the results with the original data, concluding that the prediction models' performance after oversampling was enhanced compared to the original data. According to Ebenuwa [38] and Frank [39], SMOTE can be used for increasing the size of a data set. This study used the SMOTE method for enriching the samples in both classes with 100%; therefore, the total number of records after oversampling increased to 160 while the ratio between the 2 classes remained the same as in the original data set. At the current stage, the enriched data set was sufficient for reliable prediction.

Prediction Models

The ability to gain meaningful insight from the available unstructured and unorganized data and to utilize it as an integral part of a business decision support system is an art. There are several technologies available that work in this domain for structuring and organizing the historical data for predicting new patterns for the unseen scenarios, including machine learning. Similarly, these techniques are widely used in the health care industry, where prediction models have evolved with clinical practice in every medical field. In the literature, several studies have attempted to classify the types of childbirth from different perspectives by using machine learning models. The most widely used classifiers for predictions are DT, RF, AdaBoost, support vector machine, k-NN, Naïve Bayes, and several other techniques. This study has utilized 5 machine learning classifiers for developing prediction models that can help health care practitioners in deciding the favorable mode of delivery, primarily based on the mother's history and condition. A brief discussion of these classifiers is presented below.

DT

DT is a nonparametric supervised learning technique used for both classification and regression and it uses large and complicated data sets to explore features and mined patterns that are vital to discrimination and predictive modeling. In this technique, the large data sample is divided into training and testing data sets, and based on the training data set, building a DT model and a testing data set in order to decide on the suitable tree size required to attain an optimal final model is performed [40].

RF

RF is an ensemble technique used for classification or regression that utilizes the input data and constructs multitude of DTs at the training time and outputs the class (classification) or the prediction mean (regression) of an individual tree [41]. In this technique, each DT is randomized using a bootstrap resampling method with random feature selection, and the classification is performed based on the voting of various randomized DTs on the final outcome [4]. Furthermore, the optimum split is computed using various feature sets and lingers until the tree is completely grown without pruning. This process is iterated for all trees in the forest by using different bootstraps of data, and the classifications of new samples are therefore based on the majority of votes cast [4].

AdaBoost

AdaBoost is an ensemble technique of linear member classifiers that is constructed to enhance the efficiency of the binary classifiers. In this technique, the weak learning models with better accuracy can be boosted to develop a strong prediction model. AdaBoost is an iterative-based technique where each iteration detects the misclassified data points and increases the weights of the correct points to increase the chance of the next classifiers getting them right. Moreover, in this method, the instances are moved from the iterative samples of the training data to the subsequent data set, and the classifiers are combined based on the weighted majority of votes [10,42].

Bagging

Bootstrap aggregation (or bagging) is an ensemble technique used for classification or regression. In bagging, a repeated sample is made from a training set by using simple random sampling with replacement, and for each bootstrap sample, a weak classifier is trained. These classifiers are then utilized for predicting class labels on testing data, and the class that obtains the majority of the votes wins [43].

k-NN

k-NN is a supervised learning technique that takes a data set in which the data points are labeled with different classes and uses them for learning to label the new points. The labeling of new points is based on the closest of its neighbors' labels and the majority of votes cast; therefore, the labels of the nearest neighbors are the labels of the new points. In k-NN, k is the criteria number of checking the nearest neighbors [12,44].

Performance Evaluation Method

There are several methods for evaluating the performance of prediction models such as using the whole data set as a training set, providing a separate test set, cross-validation, and percentage split, of which cross-validation is regarded as the most reliable method [45]. In this study, each prediction model built was evaluated using cross-validations of 10 folds [46]. In 10-fold cross-validation, the training set is divided into 10 subsets, and each subset is used once in the testing phase [47]. Amin and Ali [12] and Soleimanian et al [15] trained their models by using the whole data set as training data, but this method was not recommended in several other studies such as those of Mitchell [48], Smith and Frank [45], and Brownlee [49] because machine learning methods learn the training data and can predict them easily. As explained by Mitchell [48], utilizing the entire data set for training and testing purposes at the same time may produce unrealistic outcomes that are extremely positive and prone to overfitting. As further explained by Smith and Frank [45], the results achieved using training data as test data give rise to resubstituting errors, which are typically unjustifiably optimistic for predicting the performance of a model with future unseen data. Moreover, a training set for a model evaluation can be useful if one is more interested in a descriptive rather than a predictive model [49]. This is usually the challenge of machine learning: to predict unseen cases that have not been trained. To the contrary, cross-validation is regarded as the most profound and reliable method for model evaluation in machine learning when all data exist in 1 set [45]. Furthermore, in cross-validation, the test set contains unseen cases that are unknown to the model during the training phase, which can help reliable assessment of a classifier's performance [50] because cross-validation helps render generalization errors and variance [51]. As further explained by Schaffer [52] cross-validation can be used to choose a classifier in case of lack of pertinent domain-specific knowledge. In short, cross-validation provides practical estimation because a model is predicting actual results that may have been unknown to the model in the training process.

Results

This study has applied the selected prediction models to both the original data set (80 cases) and the enriched data set (160 cases). The performance of each model was evaluated using cross-validations of 10 folds [46]. In 10-fold cross-validation, the training set is divided into 10 subsets, and each subset is used once in the training phase [47]. In the implementation phase, when the required parameters are set for testing the model, a confusion matrix is calculated for each classifier run. Specifically, the confusion matrix provides 4 important values that are computed based on the correctly and incorrectly classified instances of a data set. These values are commonly known as true positive, true negative, false positive, and false negative. This matrix is the basis for calculating important measures such as model performance, model accuracy, sensitivity, specificity, and F-measure. All these measures are calculated using different equations. For example, the accuracy of a model is calculated using the following equation:

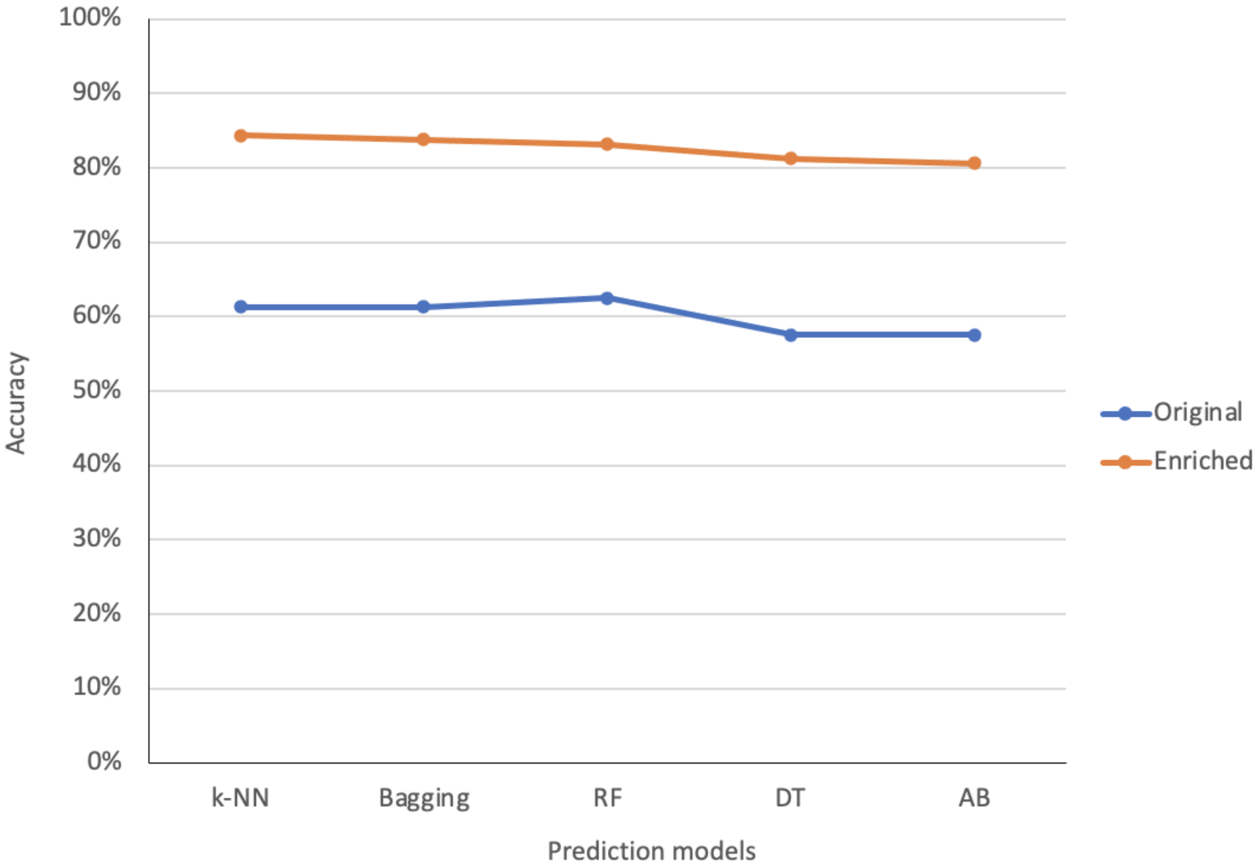
where FP=false positive, FN=false negative, TP=true positive, and TN=true negative.

The accuracies of the different models before and after enriching the data set for identifying the mode of delivery were evaluated using equation 1, and the outcomes are depicted in Table 1 and Figure 1.

Table 1. Accuracies and kappa values of models before and after data enrichment.

Method	Original data set		Enriched data set	
	Accuracy (%)	Kappa value	Accuracy (%)	Kappa value
k-Nearest neighbor	61.25	0.228	84.38	0.685
Bagging	61.25	0.192	83.75	0.664
Random forest	62.50	0.215	83.13	0.654
Decision tree	57.50	0.181	81.25	0.612
AdaBoost	57.50	0.124	80.63	0.603

Figure 1. Comparison of the accuracy between models before and after data enrichment. AB: AdaBoost; DT: decision tree; k-NN: k-nearest neighbor; RF: random forest.



According to Table 1 and Figure 1, the performances of all the models in terms of accuracy were very low when they were trained with the original data set; however, accuracy was tremendously improved when the models were trained with the updated enriched data set, whose improvement reached approximately 20%-23%. In the original data set, RF showed the highest accuracy of 62.50%, which was far lower in performance than the lower model trained with the enriched data. Moreover, for the models trained with the enriched data set, k-NN showed the highest accuracy of 84.38%, while bagging, RF, DT, and AdaBoost showed accuracies of 83.75%, 83.13%, 81.25%, and 80.63%, respectively.

Kappa values or kappa statistics [53] is a measure that compares the observed accuracy with the expected accuracy (random chance) and is the appropriate method when 2 or more independent classifiers are analyzing the same case [9]. There are different thresholds ranges for the kappa values [54]; however, in machine learning, when investigating an unseen scenario, a kappa value higher than 0.40 might be considered exceptional [55]. According to Table 1, the kappa values of k-NN, bagging, RF, DT, and AdaBoost in the original data set are lower than the threshold, but in the enriched data set are 0.685, 0.664, 0.654, 0.612, and 0.603, respectively, surpassing the threshold value. Moreover, Figure 2 shows the confusion matrix of the models used in this study, where “a” represents 0 class while “b” represents 1 class in the data set. Furthermore, the accuracies of the models for identifying the mode of delivery were also measured using recall, precision, and F-measure. These are the important measures computed based on the values of the confusion matrix. Recall, which is also referred to as sensitivity, is the proportion of the real positive values that are correctly classified as positive, while precision, which is referred to as predictive positive value or confidence [56] or specificity [57], is the proportion of the predicted positive values that are correctly real positives [56]. Similarly, F-measure [58] is the hormonic mean of precision and recall [59]. Table 2 and Table 3 exhibit the values of recall, precision, and F-measures for all models trained before and after data enrichment, respectively.

Figure 2. Confusion matrix of applied models before and after data enrichment. AB: AdaBoost; DT: decision tree; FN: false negative; FP: false positive; k-NN: k-nearest neighbor; RF: random forest; TN: true negative; TP: true positive.

AdaBoost	0.625	0.652	0.638	0.500	0.471	0.485

Table 3. Precision, recall, and F-measure of the models trained with enriched data.

Method	Cesarean section			Normal delivery		
	Precision	Recall	F-measure	Precision	Recall	F-measure
k-Nearest neighbor	0.894	0.826	0.859	0.787	0.868	0.825
Bagging	0.837	0.891	0.863	0.839	0.765	0.800
Random forest	0.849	0.859	0.854	0.806	0.794	0.800
Decision tree	0.816	0.870	0.842	0.806	0.735	0.769
AdaBoost	0.828	0.837	0.832	0.776	0.765	0.770

There is a clear difference between the values of all measures in Table 2 and Table 3 due to the feeding of additional records into the data set for data enrichment. The models' performance based on the enriched data set has shown the values of precision, recall, and F-measure above 80% accuracy, except for a few values in Table 3. This is empirical evidence that populating the data set with additional records can increase the performance of the prediction models. Hence, Table 3 supports that these models can be used for maternity care decision making in identifying the mode of delivery before birth. Similarly, the models were analyzed using ROC curve evaluation [60]. ROC curves are highly useful for establishing the classifiers and envisioning their performance and are commonly used in health care decision making [61] because it visualizes the entire scenario of trade-off between recall and (1-specificity) across a set of cutoff points and is considered an effectual measure of inherent validity of a diagnostic test [62]. Moreover, as discussed in a previous study [9], ROC curves provide the percentage between precision and recall in which higher values of precision represent a low false-positive rate, which means that the classifier returns an accurate outcome, and the high values of recall showing a low false-negative rate, which means that the classifier returns positive outcomes. Figure 3 and Figure 4 show the ROC curves of all classifiers used for predicting the mode of delivery based on before and after data enrichment, respectively. The ROC curve has several advantages over single values of precision and recall in which one of its important benefits is that 2 or more diagnostic tests can be graphically compared at the same time in 1 graph [62]. Moreover, a curve that is nearer to the left upper corner shows the best accuracy of a classifier, while a curve closer to the lower right corner shows the worst [63]. In Figure 4, the curves closer to the left upper corner provide solid evidence, indicating that the accuracies of the classifiers used in the models based on enriched data are high. Therefore, these models are reliable and can be used for predicting the mode of delivery in the antenatal stage and can also be a part of the maternity care decision support system. Figure 3 shows ROC curves as middle lines, which are far away from the left upper corner compared to Figure 4; thus, Figure 4 is significantly more reliable.

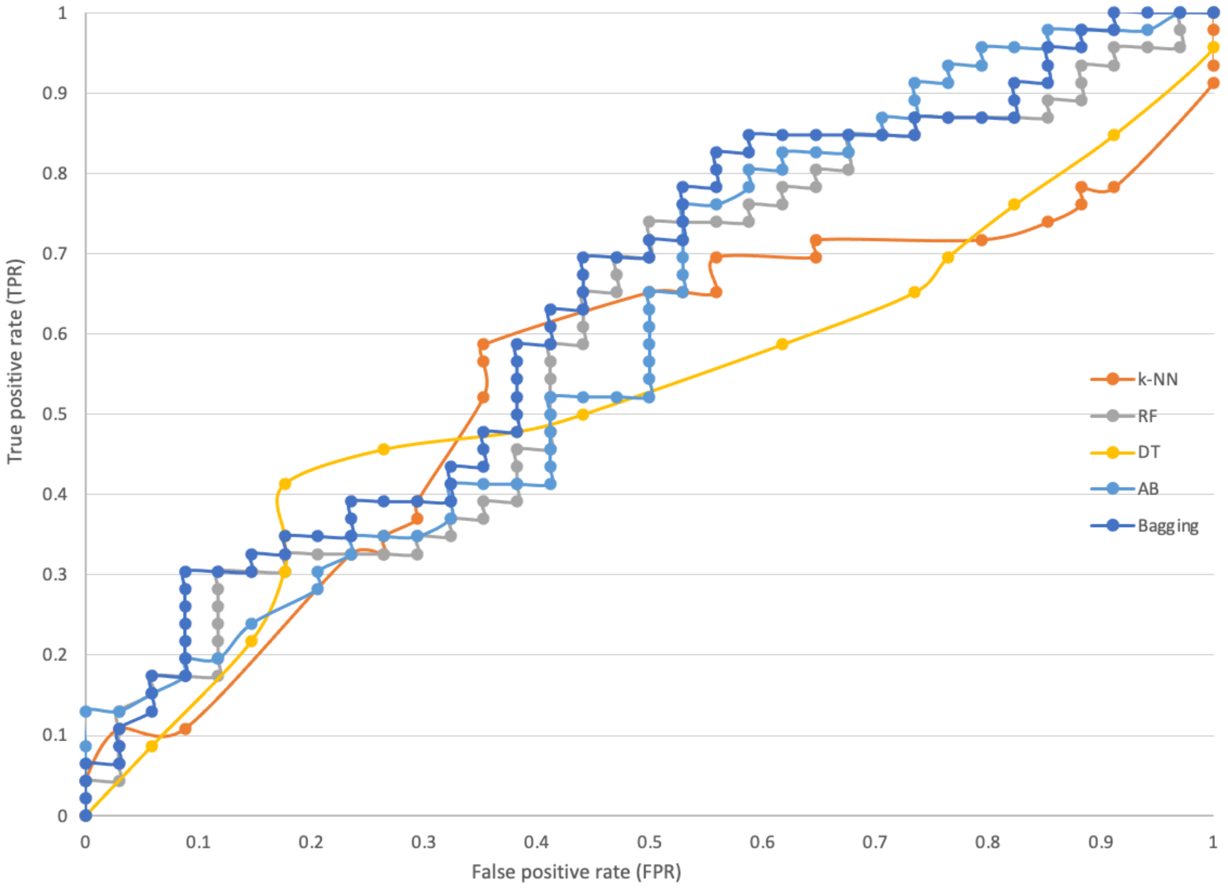

Figure 4. Receiver operating characteristic curves of all classifiers based on enriched data. AB: AdaBoost; DT: decision tree; k-NN: k-nearest neighbor; RF: random forest.

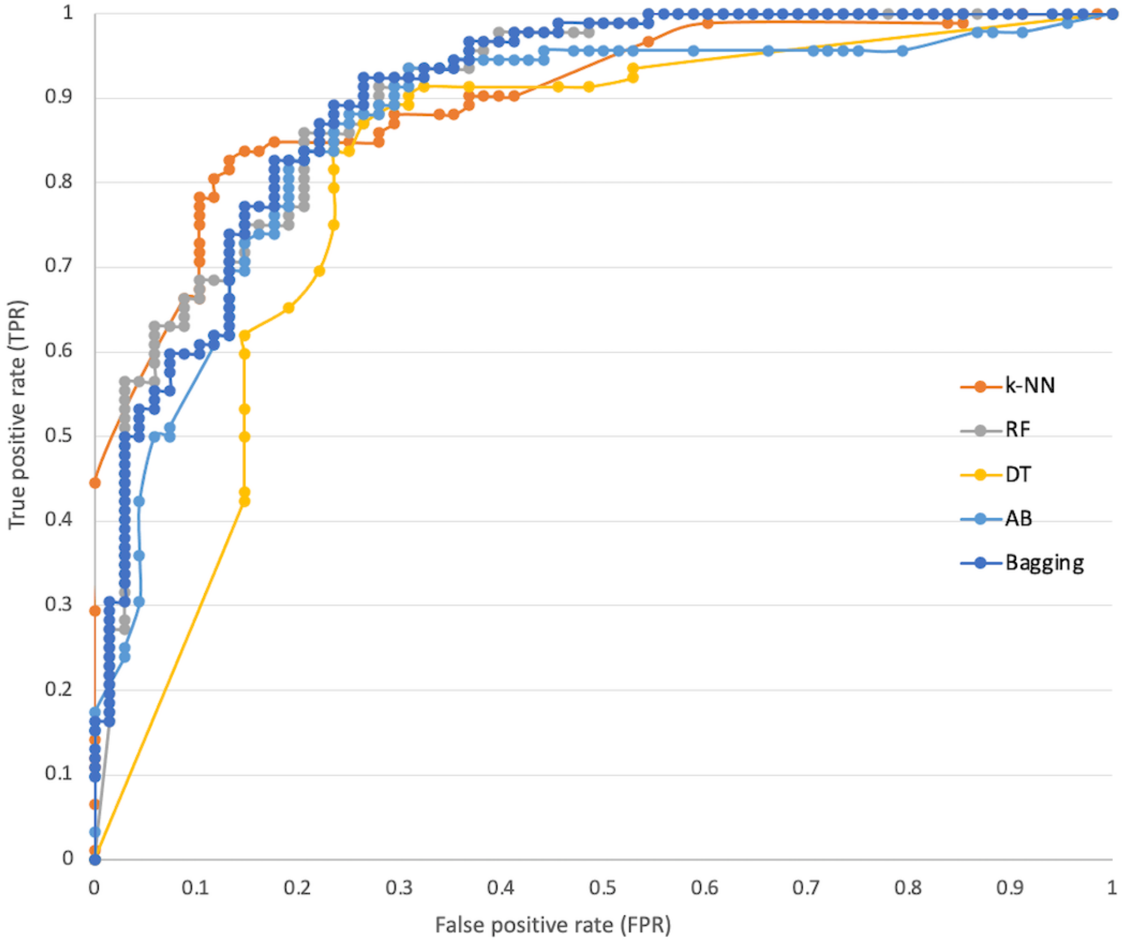
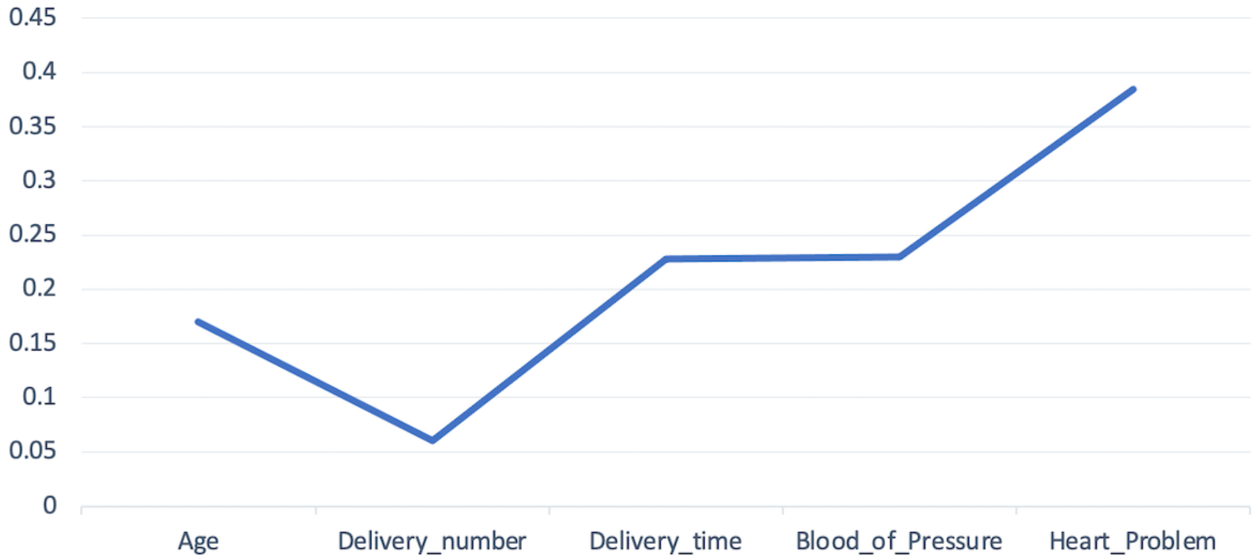


Discussion

Principal Findings

The outcomes in the above tables and figures show that the models' performance in terms of accuracy, sensitivity, specificity, F-measure, and ROC curve is high when trained using the enriched data set compared to the measures achieved using the original data set. In particular, the outcomes shown in Table 1 and Table 3 and Figure 4 represent high model accuracies based on the enriched data set computed using various evaluation methods. All these models were evaluated using cross-validation, which is a commonly adopted method that is considered reliable for models' evaluation in machine learning. In comparison, Amin and Ali [12] and Soleimanian et al [15] trained their models using the same data set (original) and achieved higher accuracy results than those in this study. The reason for achieving higher accuracy results was due to the optimistic method adopted for evaluation using the whole data set as a training set, which was not encouraged in several other studies such as that of Mitchell [48], Smith and Frank [45], and Brownlee [49]. Moreover, this study investigated the relationship of each attribute to its class. A correlation test was performed to identify factors influencing the mode of delivery. In this regard, the relationship of each attribute to its class was estimated. Figure 5 shows the correlation of each attribute to its class. The correlation of each attribute to its class is not high, but on closer investigation, this study concluded that the attribute "heart problem" is strongly correlated with class compared to other attributes, and this factor positively influences the mode of delivery. Thus, a patient with chronic heart-related issues may lead the obstetrician to a decision that is more favorable to c-section than normal delivery.

Figure 5. Correlation between attributes and class.



Conclusion and Future Directions

This study investigated the mode of childbirth by pregnant women by using a machine learning approach. To this end, 5 classification models were trained in order to identify the optimal prediction model to assist obstetricians in decision making for the mode of delivery before birth. In the first part, the original data set was synthesized by populating its records based on the existing ones by using a standard machine learning approach referred to as SMOTE. In the second part, 5 machine learning models were trained based on the original and modified enriched data sets. The models that were trained using the enriched data set performed far better than those trained using the original data set in terms of accuracy, sensitivity, specificity, F-measure, and ROC. This clear difference in the results between the 2 sets of models was due to the increase of records in the original data set. In particular, for the model set trained with the enriched data set, k-NN outperformed the rest of the models with accuracy of 84.38%, while bagging, RF, DT, and AdaBoost showed accuracies of 83.75%, 83.13%, 81.25%, and 80.63%, respectively. Overall, the prediction models developed based on the enriched data set showed similar performances, and therefore the accuracy, sensitivity, specificity, F-measure, and ROC all indicate that these models should be used in the maternity care decision-making process as well as in assisting the obstetrician and midwife in making decisions about the mode of delivery before birth. The data set was artificially populated using a machine learning method. However, in future, if the same data set with the same features enriched with real clinical data will help identify more accurate results, the accuracy may be even more enhanced. The enriched data set in its current stage used in this study yields better results than the original data set, but this data set can become the best if the records are increased with real clinical data.

Acknowledgments

This research work was funded by Institutional Fund Projects under grant no. (IFPHI-272-611-2020). Therefore, the authors gratefully acknowledge technical and financial support from the Ministry of Education and King Abdulaziz University, DSR, Jeddah, Saudi Arabia.

Abstract

Background: Lying on the floor for a long period of time has been described as a critical determinant of prognosis following a fall. In addition to fall-related injuries due to the trauma itself, prolonged immobilization on the floor results in a wide range of comorbidities and may double the risk of death in elderly. Thus, reducing the length of Time On the Ground (TOG) in fallers seems crucial in vulnerable individuals with cognitive disorders who cannot get up independently.

Objective: This study aimed to examine the effect of a new technology called SafelyYou Guardian (SYG) on early post-fall care including reduction of Time Until staff Assistance (TUA) and TOG.

Methods: SYG uses continuous video monitoring, artificial intelligence, secure networks, and customized computer applications to detect and notify caregivers about falls in real time while providing immediate access to video footage of falls. The present observational study was conducted in 6 California memory care facilities where SYG was installed in bedrooms of consenting residents and families. Fall events were video recorded over 10 months. During the baseline installation period (November 2017 to December 2017), SYG video captures of falls were not provided on a regular basis to facility staff review. During a second period (January 2018 to April 2018), video captures were delivered to facility staff on a regular weekly basis. During the third period (May 2018 to August 2018), real-time notification (RTN) of any fall was provided to facility staff. Two digital markers (TUA, TOG) were automatically measured and compared between the baseline period (first 2 months) and the RTN period (last 4 months). The total number of falls including those happening outside of the bedroom (such as common areas and bathrooms) was separately reported by facility staff.

Results: A total of 436 falls were recorded in 66 participants suffering from Alzheimer disease or related dementias (mean age 87 years; minimum 65, maximum 104 years). Over 80% of the falls happened in bedrooms, with two-thirds occurring overnight (8 PM to 8 AM). While only 8.1% (22/272) of falls were scored as moderate or severe, fallers were not able to stand up alone in 97.6% (247/253) of the cases. Reductions of 28.3 (CI 19.6-37.1) minutes in TUA and 29.6 (CI 20.3-38.9) minutes in TOG were observed between the baseline and RTN periods. The proportion of fallers with TOG >1 hour fell from 31% (8/26; baseline) to zero events (RTN period). During the RTN period, 76.6% (108/141) of fallers received human staff assistance in less than 10 minutes, and 55.3% (78/141) of them spent less than 10 minutes on the ground.

Conclusions: SYG technology is capable of reducing TOG and TUA while efficiently covering the area (bedroom) and time zone (nighttime) that are at highest risk. After 6 months of SYG monitoring, TOG was reduced by a factor of 3. The drastic reduction of TOG is likely to decrease secondary comorbid complications, improve post-fall prognosis, and reduce health care costs.

KEYWORDS

artificial intelligence; video monitoring; real-time video detection; fall; time on the ground; Alzheimer disease; dementia; memory care facilities

Introduction

Falls are the leading cause of injuries among people aged 65 and older, with estimated yearly direct medical costs of US $637.2 million for fatal falls and US $31.3 billion for nonfatal falls in the United States [1]. Older adults with cognitive impairment have an increased risk of falling [2], and those with dementia living in nursing care facilities fall 4.1 times per year on average versus 2.3 times for other residents [3]. Additionally, individuals with dementia are the least likely to call for assistance when they cannot rise alone from the ground, and cognitive impairment is found to be the most significant factor that predicts lying on the floor for a long time after a fall [4].

Reducing the length of time on the floor after a fall is crucial because fall-related injuries include not only traumatic injuries associated with the acute fall but also comorbid complications related to prolonged post-fall immobilization. Artificial intelligence (AI) in the field of computer vision; innovative health technology using secure, network-attached storage; and a customized computer application together offer the potential to detect falls rapidly without the need for wearable devices and to support care in dementia care facilities [5]. In previous work using SafelyYou Guardian (SYG) technology [5], we showed that video monitoring of falls along with regular fall review by facility staff resulted in more accurate identification of falls, fall mechanisms, and the injuries related to the trauma itself (such as traumatic brain injury, for instance) [6]. More recently, we compared nonbeneficiaries to beneficiaries of SYG and found that review of fall footage enabled a significant reduction of visits to the emergency department, by 72% on average, due to better triaging of fall-related injuries [7]. In this article, we focus on subsequent length of time spent on the floor after falling as automatically measured by SYG technology in beneficiaries of SYG.

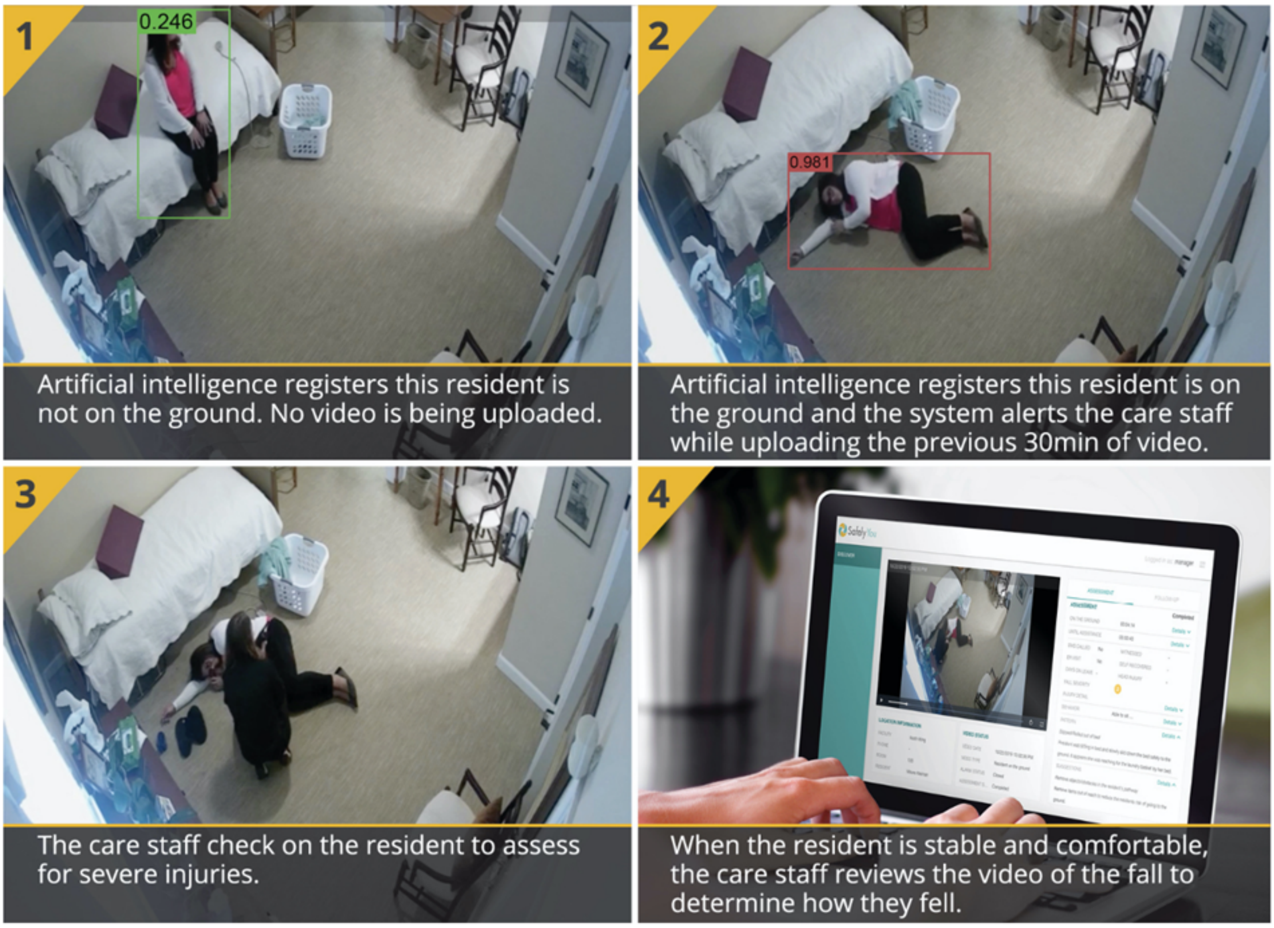
The objective here was to investigate the effect of the SYG real-time notification (RTN) system on early provision of post-fall care. We analyzed 2 lengths of time associated with a fall event: (1) The length of Time Until staff Assistance arrives (TUA) reflects the first support provided by professional caregivers, and (2) the length of Time On the Ground (TOG) in fallers is a prognostic marker reflecting risks for secondary post-fall complications in residents. Discrepancies between TUA and TOG are common. For example, a professional caregiver who arrives in a resident's room shortly after a fall may wait for a second caregiver to come and assist the resident to his or her bed. These 2 digital care markers were measured over 10 months for consenting residents living in 6 memory care facilities. We hypothesized that introducing SYG would reduce TUA and TOG. Comparison of TUA and TOG markers between the baseline period and RTN period were computed to assess the effect of SYG technology on early post-fall care.

Methods

Design of the Study and Technology Equipment

This study is part of a larger project involving multilevel collaborations between engineers, researchers, clinicians, and care providers. SafelyYou develops computer vision algorithms (a subfield of AI focused on visual understanding) for automated, real-life, real-time detection and notification of falls in memory care facilities [5]. This observational study was carried out during 10 months in 6 memory care facilities in California, and a progressive introduction of SYG technology was carried out so that facility staff could get familiar with the technology. In each of the 6 facilities, wall-mounted cameras were installed in residents' bedrooms of consenting elderly and families (at the exclusion of residents' personal bathrooms, where no camera was placed) and in accordance with the privacy and ethical guidelines discussed below. There was no requirement about where the camera was placed, but cameras were generally placed in order to capture as much of the room as possible since the camera would not detect a fall that it could not see. The field of view of the camera was greater than 90 degrees such that an entire room could be captured if the camera was placed in an upper corner of the room. A fall was defined as an "unexpected event in which the participant comes to rest on the ground, floor, or lower level" [8]. A fall incident was detected by the AI-enabled camera system when a resident was identified on the floor, whatever his or her position (sitting or lying). This detection is independent of camera position, the number of individuals in the room, and which individual is on the floor. "On the floor" was defined to be when one body part other than the feet touched the floor, such as a knee, forearm, or the posterior. Falls were video captured 24 hours a day, 7 days a week, and video data were securely transmitted using a local network storage device. A secure, customized computer application gave facility staff access to the video footage and fall information of fall incidents (Figure 1).

Figure 1. SafelyYou Guardian (SYG) technology provides automated notification of the fall, video footage (to assess fall severity), and care recommendations to facility staff.



Artificial intelligence registers this resident is not on the ground. No video is being uploaded.

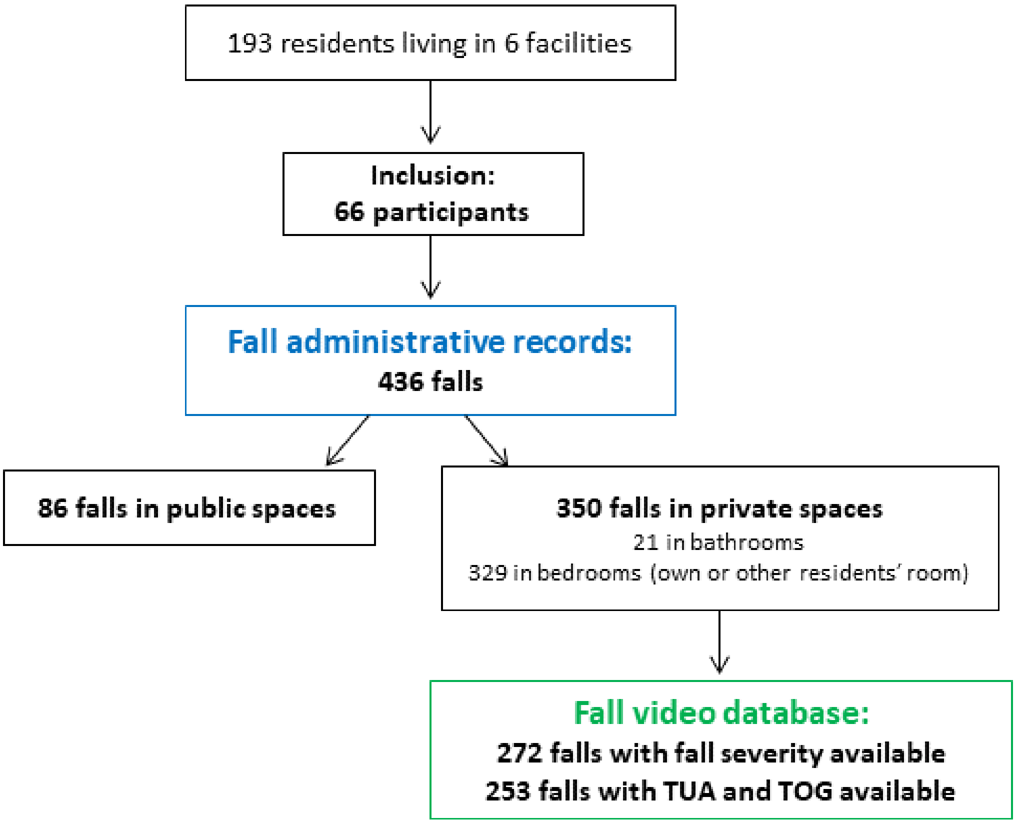
Artificial intelligence registers this resident is on the ground and the system alerts the care staff while uploading the previous 30min of video.

The care staff check on the resident to assess for severe injuries.

When the resident is stable and comfortable, the care staff reviews the video of the fall to determine how they fell.

Between November 1, 2017 and August 31, 2018, falls were prospectively recorded in administrative reports and were video captured for consenting participants (Figure 2). The study entailed 3 successive periods over 10 months. During the 2-month baseline installation period (November 2017 and December 2017), a set of control measures was performed following setup of the cameras and SYG video captured falls, but video footage was not provided on a regular basis to facility staff review. During a second 4-month period (January 2018 through April 2018), video captures of falls were delivered to facility staff on a weekly basis so that they could get familiar with the technology and footage review; however, RTN directly occurring after a fall was not activated. Finally, during the third 4-month period (from May 2018 through August 2018), RTN of any fall was provided to facility staff via a phone call so that the faller could receive immediate assistance after the alarm onset.

Figure 2. Flow chart showing inclusions and fall databases. TOG: Time On the Ground; TUA: Time Until staff Assistance arrives.



Outcome Measures

For each participant, the number of falls occurring in private and public spaces of the memory care facility was recorded by facility staff over the 10-month period: Private spaces refer to resident's personal areas (ie, individual's bedroom and bathroom), while public spaces refer to common areas shared by residents (eg, dining rooms, hallways, lounges). Falls happening in bathrooms, in nonparticipants' bedrooms, and in common spaces of the memory care facilities were not video recorded but were reported through existing incident reporting processes.

For participants only, a video review allowed the classification of falls according to their severity. A fall was classified as a "behavioral fall" when the resident showed an intentional slow descent with safe landing but no recovery to prior position. Other falls were granted a severity score using the 4-point Hopkins Falls Grading Scale [9]. This scale stratifies fall severity in near fall (Grade 1), minor fall with no need for medical attention (Grade 2), moderate fall requiring medical attention (Grade 3), and severe fall requiring hospital admission (Grade 4).

Two care markers were automatically generated by the SYG technology in order to assess early provision of post-fall care. TUA timed the delay between the detection of the fall and the detection of staff arrival in the resident's bedroom. TOG timed the delay between the detection of the fall and the resident's return to a comfortable position with assistance from facility staff. Measurement of these 2 digital markers allowed classification of falls according to their duration [4] (less than 10 minutes, 10 to 30 minutes, 30 to 60 minutes, and more than 60 minutes).

Ethical Procedures and Privacy

Privacy and consent procedures were developed with support from the Institutional Review Board of the University of California, Berkeley [10] and in collaboration with the California Department of Social Services Community Care Licensing Division. The Committee for Protection of Human Subjects of the University of California, Berkeley approved the study protocol. Procedures have been published in detail [6].

Residents living within the care facilities showed severe cognitive impairment related to Alzheimer disease and related dementias. As a consequence, surrogate consent by a legally authorized representative (usually next of kin) was required for the present study. The legally authorized representatives of the residents were given oral and written detailed information about the study and were provided the informed consent document. The study was explained to the affected individuals living in the facility, and if they provided any verbal or nonverbal indication that they did not wish to have the cameras in their bedroom, they were not included. The legally authorized representative was the person who could say yes to the study, thus providing informed consent, but the resident retained the right to decline the study at any time, thus providing assent. Cameras were located high in a corner in the bedroom, but not in the bathroom, and remained visible to the participants. Camera audio recording was disabled. Signs were posted visibly on the door of each bedroom in which video recording occurred as a reminder to residents, families, and facility staff that participants were being video monitored in the bedrooms.

Statistical Analyses

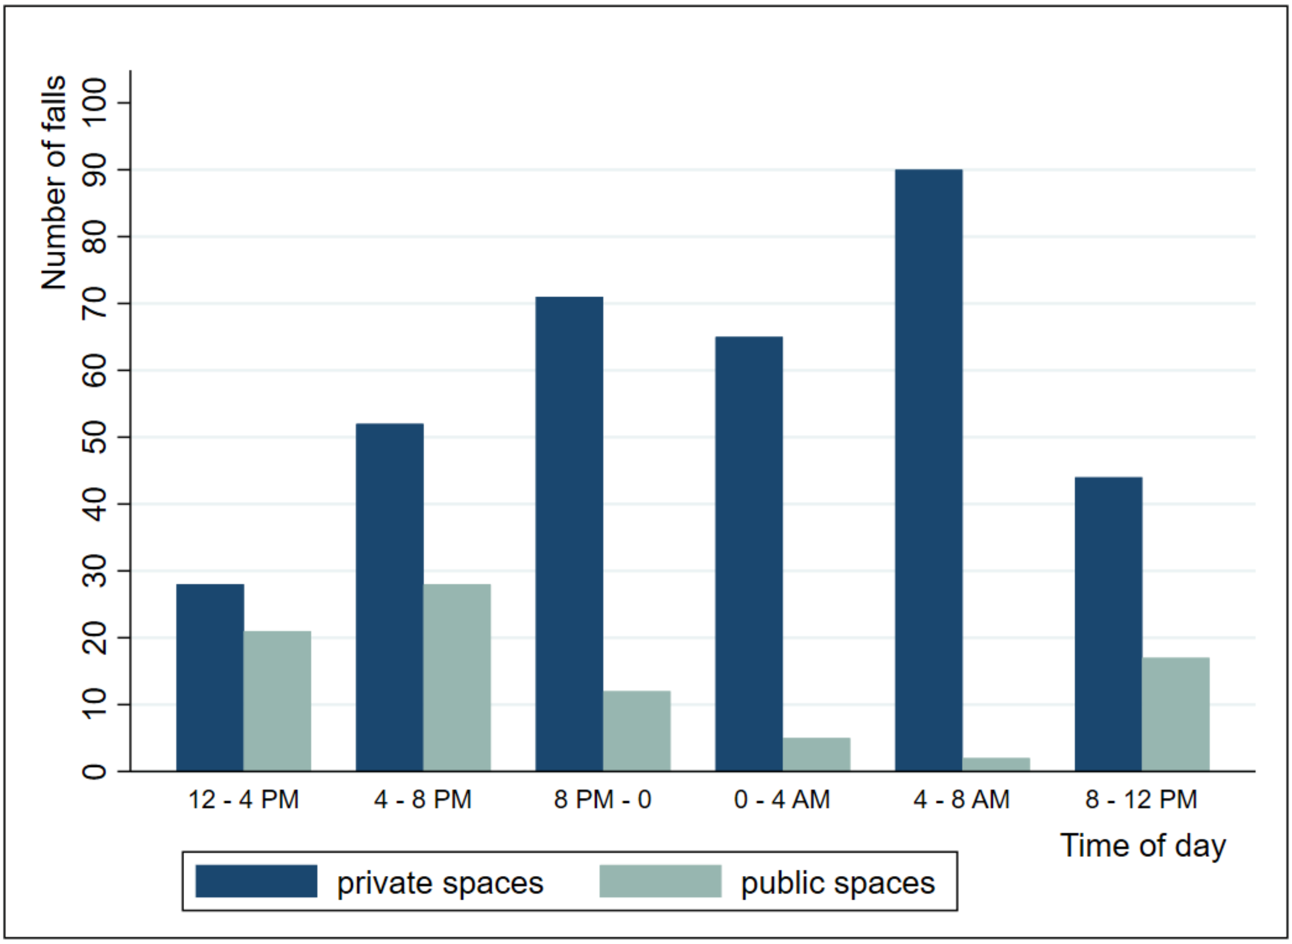
TUA and TOG variables were quantified in minutes and are described with means, median, standard deviation, minimum, and maximum. Comparison of means of TUA and of TOG between the baseline period and the RTN period was performed with nonparametric Wilcoxon rank-sum tests because of nonnormality of the data. A one-way analysis of variance (ANOVA) was conducted to determine if TUA differed between facilities. The TUA amounted to 0 minutes when a facility staff was already in the bedroom witnessing the live fall. Falls with a TUA equal to 0 were counted over the 3 periods, and Wilcoxon rank-sum comparison tests were performed with and without falls with TUA equal to 0. Statistical analyses were performed using Stata version 15 (Stata Corp; College Station, Texas) and R (R Programming).

Results

A total of 66 individuals out of 193 residents (34.2%) living in the 6 facilities at the time of inclusion participated in the study. These 66 participants suffered from Alzheimer disease and related dementias. They had a mean age of 87 (SD 6.9; minimum 65, maximum 104) years and were nearly two-thirds women (42/66, 64%). The majority of the participants (54/66, 82%) were determined to be recurrent fallers with an average of 6.6 (SD 8.6; minimum 1, maximum 49) falls per individual over the 10-month period. No difference in the number of falls per faller was found according to gender.

A total of 436 falls were reported in administrative records of those 66 study participants over 10 months. Among these falls, 86 (86/436, 19.7%) occurred in common areas, and 350 (350/436, 80.3%) occurred in private spaces (including falls in participants' personal bedrooms, in participants' personal bathrooms, and in bedrooms of other nonparticipant residents). As displayed in Figure 3, 64.6% (226/350) of falls that happened in private spaces occurred during nighttime (8 pm to 8 am), with a maximal spike of incidents between 4 am and 8 am. Video data about fall severity were fully available for 272 events, including a total of 93 falls (93/272, 34.2%) classified as "behavioral falls with safe landing." Grading of the severity of the remaining falls showed 18 (18/272, 6.6%) near falls with independent recovery, 139 (139/272, 51.1%) minor falls, and 22 (22/272, 8.1%) moderate and severe falls (18 and 4, respectively).

Figure 3. Display of falls according to location and day schedule. Private spaces refer to residents' personal areas (ie, individual's bedroom and bathroom); public spaces refer to common areas shared by residents (eg, dining rooms, hallways, lounges).

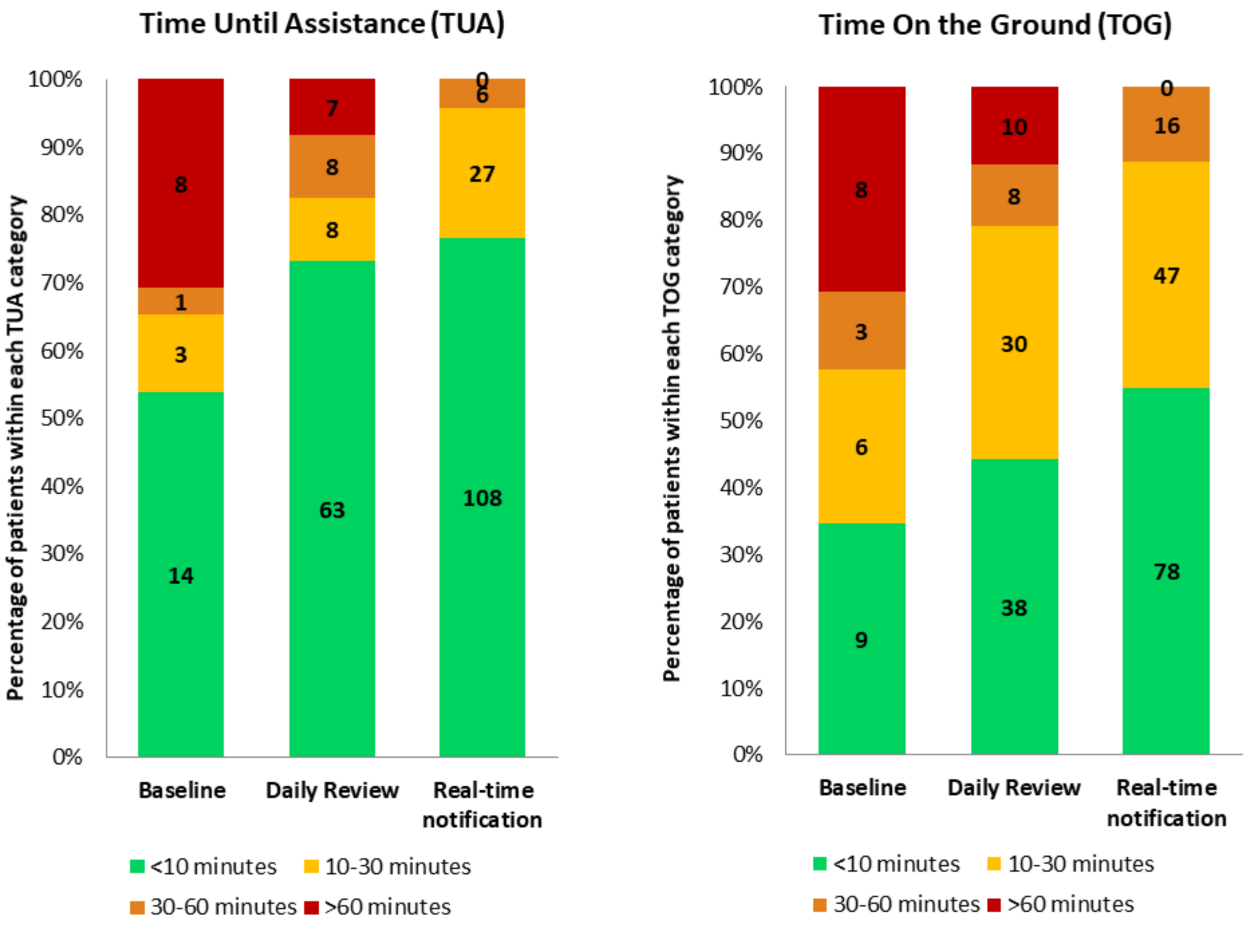


Video data about TUA and TOG markers were fully available in 253 falls (missing videos and gaps in video are attributed to technical issues such as gaps in WiFi connectivity). Both TUA and TOG showed a wide variation ranging from zero (or a few seconds) to more than 3.5 hours (maximum TUA: 214.2 minutes; maximum TOG: 215 minutes; both during the 2 first periods before RTN). The one-way ANOVA showed that there was a statistically significant difference in TUA between facilities (F_5=3.79, *P*=.003). We found that TUA was higher in the standalone memory care facilities (2 of the 6 facilities) than in the other 4 facilities (ie, memory care units within larger assisted-living facilities; Wilcoxon rank-sum test *P*=.002). The difference between TOG and TUA over 10 months was similar over the 3 time periods (7.8 minutes at baseline, 6.6 minutes during weekly review, and 6.9 minutes during the RTN period) and often related to the need for more than one health care professional to help lift fallers. In 2.4% (6/253) of falls, residents got up independently before staff arrival, resulting in a larger TUA than TOG. A facility staff member was already in the bedroom during the fall event for 17.4% (44/253) of cases, resulting in a TUA of 0 minutes.

The TUA amounted to an average 35.3 (SD 48.3, median 7.6) minutes, 15.9 (SD 32.1, median 2.4) minutes, and 7.0 (SD 9.5, median 2.8) minutes during the baseline, weekly review, and RTN periods, respectively. TUA differed significantly between the baseline period (November 2017 and December 2017) and the RTN period (May 2018 to August 2018; *P*=.004), with a mean reduction in TUA of 28.3 (CI 19.6-37.1) minutes. The TOG amounted to an average 43.2 (SD 48.8, median 23.3) minutes, 22.9 (SD 32.9, median 11.5) minutes, and 13.6 (SD 12.1, median 9.3) minutes during the baseline, weekly review, and RTN periods, respectively. TOG differed significantly between the baseline period and RTN period (*P*=.043), with a mean reduction in TOG of 29.6 (CI 20.3-38.9) minutes. We found similar results after removing those falls with a TUA equal to 0 minutes (ie, a significant difference in TUA between the baseline period and RTN period [*P*=.004], with a mean reduction in TUA of 37.7 [CI 27.8-47.7] minutes).

As shown in Figure 4, there was an increase in the proportion of individuals lying on the floor for less than 10 minutes and a related decrease in the proportion of individuals experiencing a TOG of over 60 minutes, with no such case during the RTN period. During the RTN period, 76.6% (108/141) of fallers received human assistance in less than 10 minutes and 55.3% (78/141) of them spent less than 10 minutes on the ground. In parallel, there was a drastic drop from 31% (8/26) to zero cases of those individuals who experienced a TOG of more than 1 hour (Figure 4).

Figure 4. Proportion of falls with short, medium, and long (A) Time Until staff Assistance arrives (TUA) and (B) Time On the Ground (TOG) measures during the 3 time periods.



Discussion

The present observational study provides novel insight about real-life falls and early post-fall care as captured through continuous video monitoring, AI detection, and notification of falls in bedrooms in memory care facility settings. We found that a significant reduction (0.5 hour) in TUA and TOG was associated with video monitoring and RTN of falls. During RTN, three-quarters of fallers received staff assistance in less than 10 minutes, and half of them recovered to a comfortable position in less than 10 minutes, while the proportion of very long TOG (ie, more than 60 minutes) was reduced. These results suggest that SYG technology was able to reduce a crucial severity marker of falls (ie, prolonged immobilization on the ground) that is usually associated with medical complications and poor post-fall prognosis.

The study provides ecological data of falls happening in memory care facilities using both administrative records and video monitoring reports. Regarding locations of falls, over 80% of the fall incidents happened in private spaces (mostly residents' bedrooms) confirming a similar finding that 75% of falls happen in bedrooms, as estimated from 70,000 fall incidents recorded administratively in 528 long-term care facilities [11]. Since residents are usually alone when they are in their bedrooms (as opposed to common areas where more facility staff can assist them), it appears necessary to place fall detector systems like SYG primarily in these high-risk areas to ensure continuous fall monitoring [4]. Regarding time of the day when residents fall, we found a high occurrence during nighttime (when there are fewer facility staff and residents spend more time on their own in their rooms), suggesting potential for adapting schedules and safety rounds in order to minimize risk of falls. Indeed, sleep disturbances (such as reduced sleep time, sleep fragmentation, and nocturnal wandering [12]), impaired circadian rhythmicity with sundowning [13], nocturnal effects of drugs [14], and urination disorders [15] are common in dementia and yield an augmented risk of night falls. Regarding the severity of falls, our results parallel previous research reporting that the vast majority of falls are classified as minor falls and do not include traumatic injuries [16,17]. In turn, this result points out the benefit of reviewing video footage in order to better screen injuries and avoid unnecessary referral to the emergency department and unnecessary health care costs [7]. The review also allows identification of the mechanisms of falls [18]. In long-term care facilities, most falls were related to self-induced weight shifting (with an equal frequency during walking, transferring, and standing) that can further lead to more balance assessment and fall prevention [18].

The study provides quantitative post-fall measures (TUA, TOG) that were automatically measured with an AI-driven technology. To our knowledge, our group is one of the first to report these automatically derived time measures. By contrast, research in the field relies primarily on surveys and retrospective interviews of patients and proxies, leading to recall bias [19] and estimation errors [4,13,16,20]. Our baseline result of 30.8% of residents lying on the floor for more than 1 hour (TOG) replicates a similar proportion of 30% stemming from a large survey of 265 falls from a mixed population of home-dwelling and institutionalized elderly people over 90 years old [4]. For the first time, we were able to show that this major and frequent risk of long TOG events could be successfully modified in just a few months and was reduced down to zero events. We found a TUA logically lower than TOG in more than 93% of the cases; as previously reported, 80% of vulnerable individuals are unable to get up without help, and getting up from the floor often requires more than one health professional [4]. The same study also showed that 94% of institutionalized elderly who could not get up alone and who had access to a call alarm did not activate the alarm system to summon help [4]. In geriatric patients visiting the emergency department after a fall, only 16% of fallers used their personal emergency response system to call for assistance [20]. Our results highlight how AI fall detector systems like SYG do not require a faller's direct action to activate staff assistance [20], which is necessary to deliver a critical care need and enhance safety for vulnerable individuals. Variations in TUA might be related to different facility protocols and staff availability, and caregivers also show diverse experience and training. In turn, facility staff began to incorporate the video review in their care practice after an adoption period (accounting for a reduction of TUA during the second period), and policy changes might also be observed (such as additional safety rounds for residents at high risk and environmental changes as previously documented [6]).

TUA and TOG care markers showed an average 29-minute decrease, indicating that much faster assistance to help fallers recover to a comfortable position could be provided, instead of relying on regular care rounds only. There is extensive literature about the additional critical comorbidities that are related to the long lie [21] and inability to get up [22], including metabolic and physical consequences (dehydration, hypothermia, rhabdomyolysis, renal failure, pressure ulcers [23]), psychological complications (post-fall syndrome with fear of falling again [24] and activity limitation [16]), higher risk for recurrent falls [4], and loss of autonomy [16]. Lying on the floor after a fall for a long period of time was also found to nearly double the risk of death in elderly adults [23]. On average, the RTN resulted here in assigning a "fall incident" to staff as a red flag priority among their other ongoing care tasks, accounting for the substantial reduction in TUA and in TOG.

TOG has been long considered a core severity factor of falls as well as a predictor of post-fall prognosis [22], while it has suffered from quantification weaknesses at the same time [4]. We demonstrate here that AI technology can overcome this issue and can now generate a robust and reliable care marker. In turn, shorter TUA could be considered a quality-of-care criterion for patients, families, and care providers, while TOG could be integrated more systematically in falls reporting. Taking into account that fall guidelines and management entail standardization needs [8,25-27], our contribution to the field is to provide evidence for the feasibility and usefulness to integrate these digital care markers into dementia care practice. Other strategies in the field of fall detection use different technology including wearable alert systems [28] (which require residents and staff to remember to wear and reload the device regularly), accelerometer-based fall detection [29], and nonwearable fall detection systems [30] (either based on radar and optical sensors or that use fall mats and bed alarms). As SYG, these emerging technologies warrant further controlled trials in order to assess and compare industrial responses to fall detection needs and their associated costs.

This study has some limitations. All residents were not included: Residents or their legally authorized representatives who did not opt in cited privacy concerns of video recording or that their relative was not yet at fall risk in need of the technology. Regarding variations in TUA, we were able to observe that standalone facilities had higher TUA than memory care units based within larger assisted living facilities, but other unreported factors might account for slower assistance received by fallers. We did not evaluate the cognitive-behavioral disorders in fallers with a formal cognitive assessment, and rates and types of comorbidities related to the long TOG were not measured. In the near future, implementation of randomized trials is needed to compare SYG use versus no use on the potential differences associated with diverse levels of cognitive-behavioral impairment and secondary comorbid outcomes related to falls in parallel to TUA or TOG outcomes. Cost-effectiveness analyses of interventions involving new fall detectors are needed in the field: an economic evaluation would compare costs, including those associated with the new technology and those reduced because unnecessary referrals to the emergency department were avoided.

To conclude, SYG focuses on unmet care needs and efficient new strategies in memory care facilities while enhancing safety in the bedroom and during time zones that represent the highest risk of falls. Unlike other nonmodifiable risk factors in falls [31], TOG can be significantly reduced to improve post-fall prognosis. Automated quantification of TUA and TOG can complement current care practice and support better quality of care for vulnerable individuals. In turn, reducing TOG has the potential to decrease future morbidity, unnecessary referral to the emergency department, and related costs [4,7].

Acknowledgments

The authors wish to thank the care facilities for their support. It was truly inspirational to work with care teams so dedicated to improving the quality of care and who take such pride in the quality of care provided. This research has been supported by the National Institutes of Health (#1R43AG058354) and the National Science Foundation (#1648753).

Abstract

Background: Considerable effort has been devoted to the development of artificial intelligence, including machine learning–based predictive analytics (MLPA) for use in health care settings. The growth of MLPA could be fueled by payment reforms that hold health care organizations responsible for providing high-quality, cost-effective care. Policy analysts, ethicists, and computer scientists have identified unique ethical and regulatory challenges from the use of MLPA in health care. However, little is known about the types of MLPA health care products available on the market today or their stated goals.

Objective: This study aims to better characterize available MLPA health care products, identifying and characterizing claims about products recently or currently in use in US health care settings that are marketed as tools to improve health care efficiency by improving quality of care while reducing costs.

Methods: We conducted systematic database searches of relevant business news and academic research to identify MLPA products for health care efficiency meeting our inclusion and exclusion criteria. We used content analysis to generate MLPA product categories and characterize the organizations marketing the products.

Results: We identified 106 products and characterized them based on publicly available information in terms of the types of predictions made and the size, type, and clinical training of the leadership of the companies marketing them. We identified 5 categories of predictions made by MLPA products based on publicly available product marketing materials: disease onset and progression, treatment, cost and utilization, admissions and readmissions, and decompensation and adverse events.

Conclusions: Our findings provide a foundational reference to inform the analysis of specific ethical and regulatory challenges arising from the use of MLPA to improve health care efficiency.

Introduction

Background

Machine learning–based predictive analytics (MLPA) products are emerging as a strategy for controlling rising health care costs [1]. Advanced statistical analyses have long been used to estimate the likelihood of future health outcomes based on previous events and inform clinical and administrative decisions. MLPA offers a benefit over current approaches because of its ability to draw from larger and more diverse electronic health record (EHR) data sets and potentially draw inferences without human involvement in defining input variables to predict outcomes, with the goal of improving speed and accuracy [2,3]. A particular aspect of health care seen as especially ripe for MLPA application is health care efficiency, which improves patient outcomes while reducing health care costs [4]. By gaining insights from large amounts of clinical information stored in EHR systems, MLPA is being used to identify and direct resources toward patients at higher risk of poor outcomes.

Incentives for health systems to adopt products focused on health care efficiency stem—at least in part—from federal policies and payment structures that encourage value-based care under the Affordable Care Act and value-based purchasing and bundling programs instituted by the Centers for Medicare & Medicaid Services (CMS). For example, the CMS Hospital Readmissions Reduction Program reduces reimbursements to hospitals with excess unplanned 30-day hospital readmissions for certain health conditions [5]. Linking CMS payments to the quality of care creates a financial incentive for health systems to adopt MLPA products that aim to improve health care efficiency.

However, experts recognize that although MLPA could improve the efficiency of delivered care, its use in the health care domain poses distinct ethical challenges because of its lack of transparency, continuous adaptation without human intervention, and its potential for systematic error leading to unfair decisions or actions [6-8]. These challenges have been demonstrated by high-profile cases, such as the predictive risk-stratification algorithm developed by Optum, which resulted in significant racial bias against Black patients when health costs were used as a proxy measure of health needs [9]. Obtaining, sharing, and handling the sensitive data necessary for MLPA in health care also raises privacy concerns. In another high-profile case, technology giant Google was sued for alleged violation of the Health Insurance Portability and Accountability Act in its handling of patient records from the University of Chicago Medical Center for the development of predictive artificial intelligence tools [10]. More recently, Google's partnership with Ascension, one of the largest private, faith-based health care systems in the United States, came under investigation after revealing that the tech company had obtained protected health information without patient consent [11,12]. Many of the ethical challenges mentioned, such as privacy concerns, are not unique to the utilization of MLPA and are relevant to other uses of advanced statistical analyses implemented in health care. However, continuous self-learning and the lack of transparency in MLPA algorithms are two unique aspects of the techniques that make it difficult to evaluate the models and understand how decisions are made.

These cases also highlight the importance and challenges of oversight of these complex software products. Unlike drugs and medical devices that the Food and Drug Administration (FDA) typically regulates, MLPA-based products are constantly and inherently mutable, complicating the definition of the final product. The US FDA is actively testing a regulatory framework for software as a medical device through a precertification pilot program. The framework shifts the emphasis away from the evaluation of completed products to the evaluation of processes that demonstrate a "culture of quality and organizational excellence" [13,14]. It is unclear whether or how such a framework applies to MLPA products to improve health care efficiency or what features constitute a *culture of quality and organizational excellence* capable of facilitating the development of safe and effective products. This ambiguity is because of, at least in part, a lack of systematic information on the characteristics of organizations that develop such MLPA, which is essential to understanding their potential ability to self-regulate. The diversity of expertise required to develop MLPA for health care, including computer science, software engineering, and medicine, suggests that teams brought together to develop and implement particular products will include members who are unfamiliar with the norms and culture of biomedical research and development and clinical practice [15,16]. The types of organizations developing MLPA products and the types of expertise at the organizations are largely unknown, precluding analysis of the alignment of interests and expertise with the needs of patients and health care providers [17].

Objective

The main objective of this study is to map the landscape of currently available MLPA products marketed with the aim of improving health care efficiency. The study also seeks to characterize organizations developing these MLPA products, with the subsequent goal of identifying relevant ethical, regulatory, and policy implications.

Methods

Search Strategy

We sought to identify MLPA products based on publicly available marketing information. To identify these products, we assessed 4 databases: LexisNexis, PubMed, Web of Knowledge, and Indeed.com. PubMed references frequently omitted necessary details to judge a product's current use, and many of the results were duplicative with Web of Knowledge results. On this basis, we eliminated PubMed and conducted our research using the other 3 databases. LexisNexis searches returned the highest number of nonduplicative results. Indeed.com (the world's largest job listing website) and Web of Knowledge were used because they returned additional nonduplicative results. Search terms such as "hospitals," "health care organizations," "machine learning," and "predictive analytics" were used (see Multimedia Appendix 1 for further details). Search terms were tested, reviewed, and refined to maximize the number of returned MLPA products that met our inclusion criteria. LexisNexis search parameters included the United States and English language, and a date range from April 1, 2015, to February 1, 2019, selected to capture efforts launched likely in response to April 2015 American Recovery and Reinvestment Act-mandated changes to CMS reimbursement policies.

Eligibility Criteria and Screening Process

We first removed all duplicates and any results that did not mention specific products (ie, congressional transcripts). For the identified products, we conducted additional targeted searches as needed to elucidate whether specific products met the eligibility criteria. The final list of eligible products for which the marketing materials were identified made the following claims: (1) the MLPA product made health care–related predictions, (2) the product primarily aimed to improve health care quality and reduce costs (ie, improve health care efficiency), (3) the product used EHR-sourced data, and (4) the product had been implemented by an identifiable US health system or provider, and possibly, though not necessarily, utilized on a routine basis. In addition, we excluded products if, based on marketing language, they (1) lacked a predictive element, (2) were not directly related to improving the quality of delivered care (eg, managing appointment schedules), or (3) solely used patient data that were not EHR-sourced (eg, data from a wearable device).

Data Extraction

For all remaining products, we used the product website to collect additional information about the product characteristics and the organization that developed it. Characteristics included health care partners using the product, sources of data used to create and train the MLPA algorithms, and the type and size of the organization marketing the product. We also characterized the companies by the number of employees, the type of business, and whether the chief executives or board members had a clinical degree, including doctor of medicine, registered nurse, or other.

Data Analysis

We used content analysis to generate MLPA product categories based on the type of prediction made [18]. To do this, we first generated initial codes from the verbatim marketing language available on the organization websites. If a single product made multiple predictions, we applied multiple codes to capture all the product predictions, and 2 researchers independently coded 50% of the products. All discrepancies were resolved through discussion with the full research team. A single researcher coded the remaining products. After all MLPA products received initial codes, we grouped the initial codes into overarching categories based on the prediction type. We counted the total number of products in each category as well as membership in multiple categories.

Results

Search Results and Characterization of Companies

From 1288 articles and other sources, we found 106 MLPA products developed by 96 companies that met our inclusion and exclusion criteria (Figure 1). The products and characteristics of the companies are listed in Table 1.

Figure 1. Identification of machine learning–based predictive analytics products.

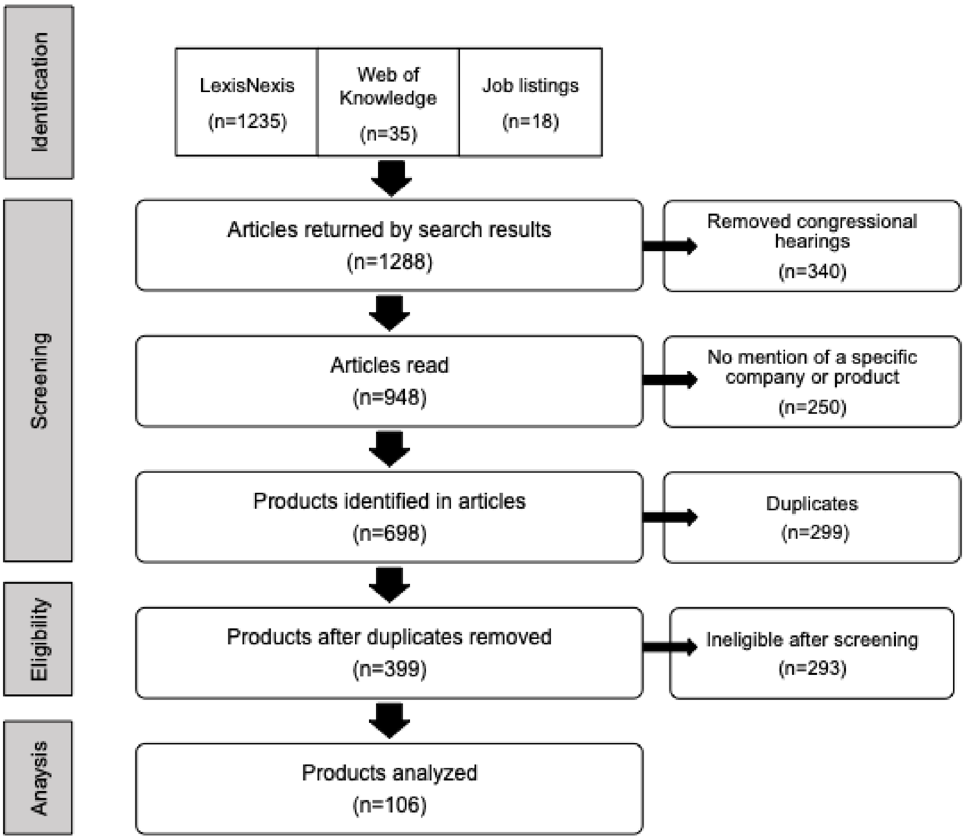

Table 1. Characteristics of companies developing machine learning–based predictive analytics products (N=96).

Characteristics and categories	Values, n (%)
Organization size	
Small (1-50 employees)	34 (35)
Medium (51-1000 employees)	25 (26)
Large (more than 1000 employees)	37 (39)
Organization type	
Computer software company—health care	68 (71)
Computer software company—general	14 (15)
Health insurer	6 (6)
Provider (hospital or health system)	8 (8)
CEO[a] with a clinical degree	
Yes	15 (16)
No	81 (84)
C-suite or board member with a clinical degree	
Yes	62 (65)
No	34 (35)

[a] CEO: chief executive officer.

Many organizations did not meet the inclusion criteria because their products were not yet implemented by an identifiable health system or provider. Other organizations were similarly ineligible because the marketing language did not claim that their product used MLPA for predicting how to reduce cost and improve quality of care. Of the organizations, 92% (88/96) developed 1 product that met the inclusion criteria, whereas 8% (8/96) had more than one product. Companies were broadly distributed in terms of size. The vast majority 85% (82/96) were computer software companies, of which 83% (68/82) specialized in health care–related products. Of the MLPA developers, 15% (14/96) were health insurers, hospitals, or health systems.

Although chief executive officers (CEOs) of 84% (81/96) of companies did not have a clinical degree, 65% (62/96) listed a C-suite or board member who did. Of the software companies specializing in health care, 16% (11/68) had a clinician CEO, and 72% (49/68) had a clinician C-suite or board member. Computer software companies specializing in health care made up 94% (32/34) of small organizations with 50 employees or less. None of the large general computer software companies had a clinician as CEO, 75% (9/12) had a chief medical officer, and 8% (1/12) had a clinician C-suite or board member. All providers (hospitals or health systems) were large organizations with more than 1000 employees. Of the providers, 50% (4/8) had a clinician as CEO, and all providers had a clinician C-suite or board member.

Classification of MLPA Products

Overview

We identified 5 categories of predictions made by MLPA products based on the publicly available product marketing materials: disease onset and progression, treatment, cost and utilization, admissions and readmissions, and decompensation and adverse events (Table 2).

Of the products, 67% (71/106) were assigned to more than one category. A full list of products and their assigned categories can be found in Multimedia Appendix 2. Here, we describe the categories qualitatively and describe a typical product from each category.

Table 2. Categories of predictions made by MLPA products.

MLPA[a] prediction category[b]	Examples of specific predictions	Example quotes from product descriptions provided by developers
Disease onset and progression predictions (n=62)	Patient outcome; unspecified diseases; chronic illnesses; specified diseases; mortality; comorbidities	• "Enables early prediction of disease onset." • "Clinicians can now see red flags for admitted patients at elevated risk of mortality three to five days in advance."
Treatment predictions (n=48)	Best course of treatment; candidates for palliative care or hospice; untreated or undertreated individuals (often referred to as *gaps in care*); expected recovery trajectory; type of care required; best medication or drug efficacy; patients at risk of receiving unnecessary clinical care (visits, tests, procedures, or antibiotics); next steps of medical care that a physician would order	• "Identify members earlier in their disease progression who are likely going to be overmedicalized during the last 6-12 months of life." • "Helps clinicians make data-driven decisions about a patient's care plan."
Cost and utilization predictions (n=38)	High-cost members of a population; high utilizers in a population; risk stratification; cost of caring for a specific patient; Medicare's predicted risk	• "Predict health care cost for individuals for customer specified time periods."
Decompensation and adverse events predictions (n=34)	Hypotensive event; sepsis; hemodynamic instability; inpatient or outpatient decompensation; postoperative complications or surgical site infections; risk of adverse event; adverse medication reactions; hospital-acquired infection; hospital-acquired pressure injury	• "Identify patients at risk of surgical site infection." • "A respiratory failure detection algorithm...can highlight patients at a higher risk of prolonged ventilation up to 48 hours before onset."
Admissions and readmissions predictions (n=33)	Readmission risk; avoidable hospital admission or readmission or ED[c] use; unplanned ICU[d] admission or readmission; ED presentation volume; hospitalization; patient flow; length of stay or risk of an extended length of stay; discharge date; disposition at the end of hospitalization	• "Predicted output is the % chance that the patient will not return/be readmitted." • "Using only six vital signs and patient age, our machine learning tool more accurately predicted down-transfer success."

[a] MLPA: machine learning–based predictive analytics.

[b] Totals do not add up to 106 because categories are not mutually exclusive.

[c] ED: emergency department.

[d] ICU: intensive care unit.

Disease Onset and Progression

A total of 62 products were used to predict the disease onset and progression (see Textbox 1 for an example product). The marketing language for some of these products did not specify particular conditions or diseases. For products that did specify diseases or health states, 22 products were identified as predicting the onset and development of diabetes, cancer, or cardiovascular conditions. In addition, 5 of those 22 products predicted more than one of the 3 listed conditions. Nearly half of these products also explicitly performed cost and utilization prediction instead of simply providing data that could be used to reduce cost.

Textbox 1. Example of a disease onset and progression product.

Medictiv by CitiusTech

- CitiusTech is a large private health care information technology company. Medictiv is a statistical analysis tool advertised as having machine learning capabilities to analyze longitudinal electronic health record–sourced data to predict the onset and progression of various unspecified diseases. Medictiv also advertises specific use cases for chronic kidney disease (CKD) and diabetes. For CKD, Medictiv uses longitudinal patient and laboratory data to predict disease progression risk for CKD stage 3 patients. For diabetes, Medictiv uses data available within 72 hours of admission, including laboratory results, demographic data, comorbidities, and health insurance claims to predict patients' length of stay, risk of readmission, and risk stratification [19].

Treatment

A total of 48 products made predictions related to patient treatment (see Textbox 2 for an example product). The most common type of prediction was identifying patients with *care gaps* or who were *untreated* or *undertreated*. The available marketing language does not specify the meaning of these terms. Nearly all products identifying care gaps explicitly mentioned performing a cost and utilization prediction. In the treatment category, other products made predictions meant to aid clinicians in therapeutic decision making (eg, identifying the best medication to use, predicting adverse reactions, predicting drug interactions, and predicting unnecessary antibiotic use). A large proportion (29/48, 60%) of the products in the treatment category were also categorized as predicting disease onset and progression.

Textbox 2. Example of a treatment product.

Identifi by Evolent Health

- Identifi is Evolent Health's value-based care product, which aims to reduce costs and improve the quality of delivered care. Identifi's machine learning–based predictive analytics algorithms use clinical, social, and administrative data to predict the best course of treatment for a patient and identify gaps in a patient's care. They also make predictions about patient outcomes, risk of readmission, and risk stratification. Evolent Health is a public health care company with between 1000 and 5000 employees. It advertises Identifi to providers and health plans [20].

Cost and Utilization

This category comprises products whose MLPA algorithms predict the cost or utilization of health care (n=38; see Textbox 3 for an example product). As one of our inclusion criteria was a focus on improving health care efficiency, all products in our sample had the goal of reducing costs. However, only products that aimed to reduce costs by making explicit predictions about costs and utilization were included in this category. As there were numerous products that used MLPA primarily to predict admissions or readmissions (n=33), they were assigned their own category (described below and not included in the n=38 of the cost and utilization category). In the cost and utilization category, financial risk stratification of patient populations was the most common MLPA use, with a wide margin. Other common use cases were predicting which patients would be high cost or become high utilizers and predicting Medicare's predicted risk. Half of the products in this category also fell into the categories of disease onset, progression predictions, and treatment predictions.

Textbox 3. Example of a cost and utilization product.

Waystar Platform by Waystar

- Waystar uses social determinants of health, along with hospital and consumer data, to stratify the patient population according to risk and cost [21]. The company also helps with revenue integrity by identifying incorrectly coded and undercoded claims to help providers maximize revenue. Waystar is a medium-sized private information technology company with 500-1000 employees.

Decompensation and Adverse Events

The products in this category (n=34) were designed to act as early warning systems for the occurrence of adverse events or decompensations (see Textbox 4 for an example product). We grouped decompensation and adverse event predictions together when we defined our prediction categories because of the frequent overlap in the clinical application of the products. Algorithms typically use vital signs combined with EHR data to closely monitor in-patient populations and alert care teams for decompensation. Products alerting for general inpatient decompensation were the most common in this category (n=18), followed by early warning systems for sepsis (n=14). Monitoring for an outpatient decline, hospital-acquired infections, and postoperative complications were also quite common. The decompensation and adverse events category had the least overlap with other categories.

Textbox 4. Example of a decompensation and adverse events product.

InSight by Dascena

- Dascena's InSight is a paradigmatic application of machine learning–based predictive analytics used to provide an early warning of an adverse event. Dascena is a small, private company with less than 50 employees. The InSight algorithm warns of sepsis onset using vital sign data located in patients' electronic health records, which is typical of products in this category. InSight provides physicians with real-time alerts and boasts its ability to forecast a patient's condition 4 hours in the future [22].

Admissions and Readmissions

In this category (n=33), predicting the risk of readmission was the most common application (n=21), where the marketing language had to explicitly state *predicting risk of readmission* as a use case of the product (see Textbox 5 for an example product). Other admissions predicted length of stay and intensive care unit occupancy. More than half of the products predicting admissions and readmissions fell into the disease onset and progression category; overlap with the treatment category was also fairly high (8/33, 24%).

Textbox 5. Example of an admissions and readmissions product.

Conduent's Midas Readmission Penalty Forecaster

- Midas Readmission Penalty Forecaster is a common product developed in response to Centers for Medicare & Medicaid Services Hospital Readmissions Reduction Program [23]. Conduent's white pages market the product as a web-based tool to forecast 30-day unplanned readmissions to help health care organizations predict penalties and adjust their care delivery. Midas Readmission Penalty Forecaster estimates total readmissions, excess readmissions, and financial penalties for 6 Centers for Medicare & Medicaid Services cohorts: patients diagnosed with acute myocardial infarction, heart failure, pneumonia, or chronic obstructive pulmonary disease or patients receiving a coronary artery bypass graft, total hip arthroplasty, or total knee arthroplasty. This product was developed by Conduent, an information technology company with more than 10,000 employees working in health care and 20 other industries, ranging from insurance and government to casinos, oil, and gas.

Discussion

Principal Findings

Our results provide an overview of the emerging MLPA applied to improve health care efficiency and provide a systematic categorization of actual applications of this technology in patient care. The products identified as being currently in use are predominantly marketed by computer software companies. Our results also provide a systematic framework for mapping the characteristics of organizations operating in the field of MLPA in health care and the products they produce, based on the specific predictions that these products are intended to provide in a health care setting.

The potential for MLPA to transform health care has generated much anticipation to the possibilities for this technology to improve health care quality and reduce costs. Bates et al [2] previously forecasted 6 likely targets of predictive analytics in health care: high-cost patients, readmissions, decompensation, adverse events, triage, and diseases affecting multiple organ systems. Our results suggest that many of these uses materialized in the markets. For example, our results confirmed a large market presence of MLPA products that aim to predict hospital readmission within 30 days of initial discharge as well as decompensation and adverse events. In addition, among the MLPA products categorized as predicting disease onset and progression within our framework, diabetes, cancer, or cardiovascular conditions were the most common—conditions all affecting multiple organ systems. Furthermore, our categories focused on prediction of cost and utilization as well as on prediction of treatment; both have close ties to the previously forecasted focus of predictive analytics on high-cost patients and triage in health care. However, our framework also goes beyond these original predictions by providing a systematic, evidence-based approach to mapping the field of MLPA products in health care organized around the specific predictions provided by these products instead of the intended use or target population.

Our results also suggest that MLPA products are increasingly being used in response to CMS reimbursement policies. The readmissions predictions may reflect a response to the recent CMS Hospital Readmissions Reduction Program, which reduces payments to hospitals with excessive numbers of readmissions [5]. The focus on diabetes, cancer, or cardiovascular conditions in MLPA products identified in our analysis maps directly to conditions subjected to bundled payments under the CMS's Bundled Payments for Care Improvement initiative [24]. In addition, products marketed as predicting high-cost patients (while also identifying some additional applications, such as predicting Medicare's predicted risk score) likely emerged, at least in part, in response to Medicare's reimbursement policies transitioning from fee-for-service to risk-adjusted fixed payments per episode of care [25]. Although the use of MLPA to respond to shifting reimbursement policies is perhaps unsurprising, it also raises questions about the alignment of these financial incentives with the goal of improving patient care. These goals address critically important needs of the health care system in the United States, but trying to meet them can raise ethical issues. Improving care quality and outcomes without increasing costs poses a myriad of challenges. Thus, when efficiency is improved by reducing costs, there are concerns that quality of care has been negatively affected. Although the aims of improving quality and cost are ideally aligned with the stated goals of these MLPA products, it is difficult to know whether this is indeed the case when employing MLPA products without further information on how the underlying models are developed and implemented in the clinical setting. Moreover, many MLPA algorithms have not been rigorously tested, and little is known about their comparison with other predictive analytics or clinical judgment. Evaluation of MLPA algorithms is particularly difficult given the opacity of the models and their *black box* nature.

Our results also provide an essential framework for considering various approaches to regulation in this diverse and rapidly changing marketplace. The FDA is currently developing a framework that incorporates the level of risk to the patient in its review process. Having a systematic framework of categories that may reflect varying degrees or types of risk to patients (eg, treatment recommendations vs prediction of health care costs) may therefore be important. Traditionally, software products have not been subjected to the level of regulatory scrutiny applied to drugs or medical devices, nor has the technology sector established processes for identifying or evaluating ethical issues that may arise from their products. Developing an effective regulatory framework requires an understanding of various stakeholders and organizations involved in this marketplace, potential sources of conflict, and the resources necessary for success. In examining MLPA products, which inherently change and adapt as they incorporate new data, regulators may need to consider the extent to which business requirements—including production schedules, fundraising, and profit goals—are aligned with the design process.

In addition, further examination is needed regarding the role of clinical expertise within these companies in light of the FDA's self-regulation approach in evaluating companies based on *a culture of quality and organizational excellence*. There is a relative dearth of clinical training among CEOs and others in company leadership. Of the organizations we identified, only 1 in 6 was led by a clinical degree-holding CEO, and more than a third did not have a clinician in the C-suite or on their board of trustees. Although clinicians may be involved in different roles, they are underrepresented in the highest leadership positions, which may have implications for the level of awareness that a company has of the norms and culture of biomedical research and clinical practice. The influence of business requirements and expertise may also vary depending on the size of the company: although small health care technology startups might be under more significant financial and time pressures with the need to raise venture capital, larger companies likely have more resources to draw from. However, our analysis suggests that large companies are also less likely to specialize in health care software or technology and less likely to have a clinician in a leadership position than small health care technology startups. More research is needed to determine the extent to which factors such as company size, business requirements, and clinical expertise influence the design and implementation of MLPA in health care and their potential importance in designing regulatory frameworks.

Our study has several limitations. Our results are limited by our reliance on publicly available web-based information, such as product websites, press releases, and health system websites. Products developed by nonprofit health systems, academic institutions, or large insurers may not have been readily identifiable, as their products are often not marketed externally. Therefore, we are less likely to have identified products developed by a health system or health insurer that are not sold for use in other systems. Another limitation is that the predictions were categorized based on the marketing language used by the companies to describe their own products, so the actual extent to which these products do what they are marketed to do remains unclear. In addition, we do not know how often the tools are used by the health care system where they are implemented. Some may be used frequently and others rarely.

Conclusions

There is a rapidly emerging set of products that utilize MLPA with the dual goals of improving health care and addressing cost containment. These goals address critically important needs of the health care system in the United States. Improving care quality and outcomes is not necessarily at odds with lowering costs. There is an underlying ethical tension, however, when health care efficiency is improved by reducing cost with possible negative effects on quality. How MLPA developers perceive these trade-offs and whether reliance on such tools may exacerbate discrimination based on underlying biases is difficult to assess using currently available data. The significant role of the software and technology companies, which might have little experience in understanding clinical care, using health data, or applying medical ethics or law, suggests that regulatory approaches that rely on self-regulation and organizational culture may be challenging for the evaluation of MLPA products. More research on the process of developing these novel tools is needed to further assess the implications for policy and regulation.

Abstract

Background: In epidemiological studies, finding the best subset of factors is challenging when the number of explanatory variables is large.

Objective: Our study had two aims. First, we aimed to identify essential depression-associated factors using the extreme gradient boosting (XGBoost) machine learning algorithm from big survey data (the Korea National Health and Nutrition Examination Survey, 2012-2016). Second, we aimed to achieve a comprehensive understanding of multifactorial features in depression using network analysis.

Methods: An XGBoost model was trained and tested to classify “current depression” and “no lifetime depression” for a data set of 120 variables for 12,596 cases. The optimal XGBoost hyperparameters were set by an automated machine learning tool (TPOT), and a high-performance sparse model was obtained by feature selection using the feature importance value of XGBoost. We performed statistical tests on the model and nonmodel factors using survey-weighted multiple logistic regression and drew a correlation network among factors. We also adopted statistical tests for the confounder or interaction effect of selected risk factors when it was suspected on the network.

Results: The XGBoost-derived depression model consisted of 18 factors with an area under the weighted receiver operating characteristic curve of 0.86. Two nonmodel factors could be found using the model factors, and the factors were classified into direct ($P<.05$) and indirect ($P\geq.05$), according to the statistical significance of the association with depression. Perceived stress and asthma were the most remarkable risk factors, and urine specific gravity was a novel protective factor. The depression-factor network showed clusters of socioeconomic status and quality of life factors and suggested that educational level and sex might be predisposing factors. Indirect factors (eg, diabetes, hypercholesterolemia, and smoking) were involved in confounding or interaction effects of direct factors. Triglyceride level was a confounder of hypercholesterolemia and diabetes, smoking had a significant risk in females, and weight gain was associated with depression involving diabetes.

Conclusions: XGBoost and network analysis were useful to discover depression-related factors and their relationships and can be applied to epidemiological studies using big survey data.

Introduction

Importance of Depression

Depression is a common debilitating psychiatric condition characterized by a low-spirited mood, loss of interest, and a range of emotional, cognitive, physical, and behavioral symptoms. It has a high global disease burden and had been projected to become the second most common cause of disability-adjusted life years worldwide by 2020 [1]. Thus, the determination of risk factors causing depression could have important implications in its prevention and intervention efforts by reducing modifiable risk factors. However, proper prevention and treatment of depression have been difficult owing to heterogeneity in the etiology and pathophysiology of depression [2].

Conventional Modeling for Depression

Given the complex biological, psychological, and sociocultural factors underlying the pathogenesis of depression, an integrated model with confounder adjustment may provide a better understanding and multifaceted individualized approach for depression. In a typical study, survey-weighted logistic regression is used to identify depression-associated factors. A simple regression model for each candidate factor is built to adjust for age and sex. Then, a complex model is presented by adding more covariates to control potential confounders [3].

Principal Factor Identification Problem in Conventional Modeling

A confounder has associations with both exposure and disease but is not in the causal pathway between exposure and outcome [4]. Confounding is a mixing of effects that obscures the real effect of exposure [4]. We might fit a regression model on all the measured potential confounders and minimize the confounding risk [5]. However, too many variables can cause multicollinearity or redundancy and make a regression model unstable with a high coefficient variance [5,6]. In contrast, variable selection may cause the exclusion of essential confounders [5]. Identification of the best subset of variables is challenging when the number of explanatory variables is large or when multicollinearity is present within the data [7].

Benefits of Machine Learning–Based Modeling for Big Survey Data

For big survey data with numerous variables, the machine learning model can detect principle factors for a condition by attempting to maximize its predicting performance. During the training, dimensionality reduction (which reduces the number of features) is essential because many features may cause overfitting, and the generated model may not be generalized appropriately [8]. Moreover, feature selection can resolve multicollinearity by removing redundant features from a group of highly correlated features [8]. Regularization is a more advanced machine learning algorithm that reduces model complexity and improves generalizability [8]. A popular regularization method is LASSO (L1 regularization; least absolute shrinkage and selection operator) [8], also called a shrinkage method, which can be applied to collinear confounders and has shown advantages over conventional methods [5].

Advantages of the Extreme Gradient Boosting Algorithm and Strategies of This Study

We speculate that extreme gradient boosting (XGBoost) can help select an optimal subset of essential variables from a large volume of survey data. XGBoost is an advanced implementation of a gradient-boosting decision-tree algorithm. XGBoost has been used in a few studies to predict or screen depression [9-11]. XGBoost is advantageous because of its high speed and performance, making it dominant in applied machine learning for structured data. XGBoost also offers regularized gradient boosting and feature importance scores using a trained predictive model, which can be used for feature selection [12].

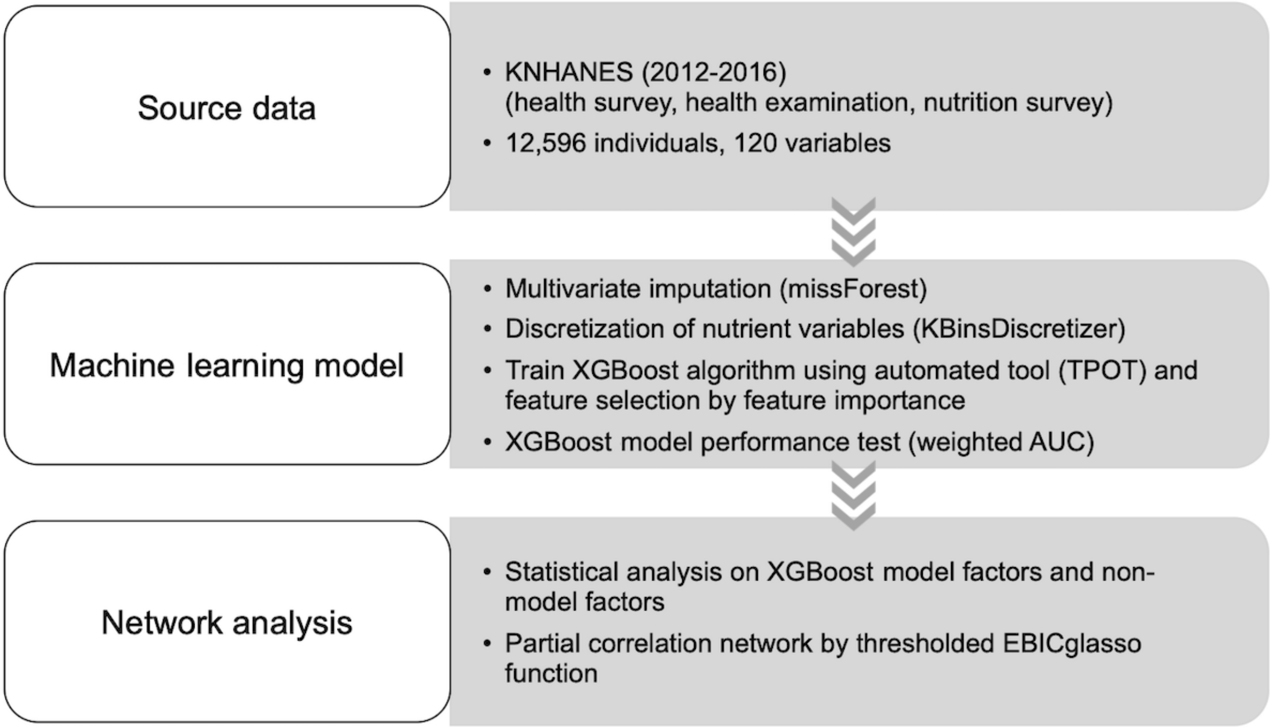
However, XGBoost has many hyperparameters that should be manually specified, and optimal parameter tuning can be challenging. To solve this problem, we have chosen an automated machine learning tool, the tree-based pipeline optimization tool (TPOT), along with genetic programming [13]. To the best of our knowledge, this study is the first attempt at an XGBoost-supported epidemiologic investigation regarding depression in the general population using national survey data.

Methods

Overview of Survey Data

The overall study flowchart is provided in Figure 1. We used survey data obtained from 12,596 Koreans (aged 19-64 years) who participated in the Korea National Health and Nutrition Examination Survey (KNHANES, 2012-2016), which is an annual survey conducted by the Korea Centers for Disease Control and Prevention (KCDC) in the Republic of Korea, wherein population-wide health and nutritional statuses are assessed [14]. The maximum age was set to 64 years because the food frequency survey was conducted for those aged 19 to 64 years. The design and methods of the KNHANES and the data resource profile are available in previous reports [14-16]. KNHANES V-3 (2012), KNHANES VI (2013-2015), and KNHANES VII-1 (2016) were approved by the KCDC research ethics committee (2012-01EXP-01-2C, 2013-07CON-03-4C, 2013-12EXP-03-5C, and 2015-01-02-6C), and written informed consent was obtained from all the subjects.

Figure 1. Flow diagram of the study. AUC: area under the curve; EBICglasso: extended Bayesian information criterium graphical lasso; KNHANES: Korea National Health and Nutrition Examination Survey.



In the annual KNHANES (2012-2016) following a multistage clustered probability design, 192 primary sampling units (PSUs) were generated from approximately 200,000 geographically defined PSUs for the entire country; subsequently, 20 final target households were sampled for each PSU as secondary sampling units (ID_fam) [16]. The sample weights were calculated using the inverse of selection probabilities and the inverse of response rates that were adjusted to gender- and age-specific Korean populations (poststratification). Therefore, the sampled individuals accurately represented the Korean population.

Depression Case Definition

Positive depression diagnosed by a physician (DF2_dg) and positive present depression (DF2_pr) represented the positive case “current depression,” and these indicated that the individual had a diagnosis of depression and was currently experiencing depression, respectively. In terms of the negative case, both DF2_dg and DF2_pr were negative and represented “no lifetime depression,” which indicated that the individual had never experienced depression. DF2_dg and DF2_pr were reported by the participants in this survey.

XGBoost-Derived Model for Depression

We included as many variables as possible (Textbox 1) and imputed missing values using univariate imputation (filling with the last valid value for categorical or discrete variables) or multivariate imputation for missing continuous variables. The nutrient variables were discretized into three bins as follows: low, medium, and high. We converted categorical variables to numerical variables using one-hot encoding and dropped reference categories. We standardized variables, except for a binary dummy variable, by removing the mean and scaling them to unit variance before machine learning.

Textbox 1. Study variables of the Korea National Health and Nutrition Examination Survey data.

Health Examination Data

Physical examination

- Waist circumference, BMI, regularity of pulse, and periodontal disease

Blood tests

- Anemia (hemoglobin <13.0 g/dL for men; hemoglobin <12.0 g/dL for nonpregnant women; hemoglobin <11.0 g/dL for pregnant women), white blood cell count, platelet count, red blood cell count, aspartate aminotransferase, alanine aminotransferase, creatinine, urea nitrogen, hepatitis B surface antigen, and hepatitis C antibody

Fasting (≥8 hours) blood tests

- Sugar level, high-density lipoprotein cholesterol (HDL), and triglyceride (TG)

Urine strip test

- pH, nitrite, specific gravity, protein, glucose, ketones, bilirubin, blood, urobilinogen

Pulmonary function test

Hypercholesterolemia: total cholesterol (TC) ≥240 mg/dL or lipid-lowering medication

Hypertension: systolic pressure ≥140 mmHg or diastolic pressure ≥90 mmHg or medication

Diabetes mellitus: fasting blood sugar level ≥126 mg/dL, diagnosis, medications, or insulin injections

Prediabetes: fasting blood sugar level ≥100 and <126 mg/dL

Low-density lipoprotein cholesterol (LDL) = TC – (HDL + TG/5), where TG ≤400 mg/dL

Health Survey Data

- Age, marital status, educational level, occupational class, household income, weight changes in the past year, alcohol consumption frequency, sleep hours per day, perceived stress, current smoking status, walking for more than 10 minutes (days/week), muscle-strengthening activities (days/week), childbirth experience, and EuroQol five-dimension three-level (EQ-5D-3L) questionnaire (mobility, usual activities, self-care, and pain/discomfort; three levels for each) [17]

Morbidity

- Chronic obstructive pulmonary disease, stroke, ischemic heart disease, osteoarthritis, rheumatoid arthritis, pulmonary tuberculosis, asthma, thyroid disease, gastric cancer, hepatoma, colon cancer, breast cancer, cervix cancer, lung cancer, thyroid cancer, atopic dermatitis, renal failure, hepatitis B, hepatitis C, and liver cirrhosis

Oral health

- Difficulty chewing, caries treatment within the last 1 year, root canal treatment within the last 1 year, and prosthetic treatment within the recent 1 year

Food Frequency Survey Data (daily intake)

- Carbohydrates, proteins, saturated fatty acids, monounsaturated fatty acids, polyunsaturated fatty acids, n3 fatty acids, n6 fatty acids, n6:n3 fatty acid ratio, cholesterol, fiber, vitamin A, vitamin B1, vitamin B2, vitamin C, niacin, iron, calcium, potassium, phosphorus, and sodium

The training set included 80% “current depression” and 80% “no lifetime depression” (10,076 cases). The remaining cases were assigned to the test set (2520 cases). We used TPOT to choose the best XGBoost hyperparameters from the training set to predict “current depression” from “no lifetime depression.” Then, the model features were selected further using the feature importance of XGBoost. The XGBoost model was explained using shapley additive explanation (SHAP) values that showed each feature’s impact on the model prediction [18].

The weighted area under the receiver operating characteristic curve (AUC) of the final model was calculated using the sample weight [19]. The optimal threshold was computed as the prediction probability at which Youden’s index (sensitivity + specificity – 1) was the maximum on the test set. We also estimated the weighted AUC of the model for the Patient Health Questionnaire-9 (PHQ-9) score (depression when score ≥10) instead of the reported depression.

Statistical Test for Model Factors and Exploring Nonmodel Factors

Survey-weighted multiple logistic regression was performed using the model features from all samples (training and test sets). We defined the “direct” factor of depression as the model feature whose multiple logistic regression coefficient significantly differs from zero ($P<.05$); the other model features were designated as “indirect” factors. Subsequently, we performed a statistical test on factors excluded by the model to identify significant “nonmodel” factors that were not chosen by XGBoost as optimal for predicting depression. Nonmodel factors whose coefficients of multiple logistic regression with the model features were significantly different from zero (P<.05 with Bonferroni correction) were chosen.

Network Analysis for Depression-Related Factors

A correlation matrix of model features and nonmodel factors was generated using all samples. Based on the correlation matrix, a thresholded EBICglasso (extended Bayesian information criterium graphical lasso) network was plotted, in which the network model was estimated using graphical LASSO regularization with EBIC model selection. Each edge weight was the correlation coefficient between two nodes after controlling all other network correlations [20,21].

Three centrality indices (strength, closeness, and betweenness) were computed. Strength centrality is the absolute sum of the edge weights connected to the node. Closeness centrality is the sum of the shortest distances from the node to all other network nodes. Betweenness centrality is the number of times when the node lies on the shortest path between two other nodes [21,22].

Confounding or Interaction Effects on Indirect Risk Factors

If an indirect risk factor was positively connected to direct risk factors, the direct factor confounding effects were tested. If the indirect factor's coefficient on survey-weighted multiple logistic regression became significant without the direct factors, we assumed they were the indirect factor's confounders.

If an indirect risk factor was positively connected to a direct preventive factor or negatively related to a direct risk factor, the interaction effect was tested using the interaction term on survey-weighted multiple logistic regression.

Statistics and Software

We used the following two programming languages: Python (version 3.8.5, Python Software Foundation) and R (version 3.6.3, R Foundation for Statistical Computing).

Scikit-Learn Tools

The following scikit-learn tools [23] were applied: for imputing missing continuous values, *IterativeImputer* class with the ExtraTreesRegressor estimator; for discretization, *KBinsDiscretizer* with a k-means strategy based on a k-means clustering procedure; for standardization, *StandardScaler*; and for weighted AUC, sensitivity, specificity, and threshold, *roc_auc_score* and *roc_curve*.

TPOT

TPOT starts from a collection of random models (first generation). Subsequently, those with higher performance are chosen and copied into the next generation's population. The offspring crossover with other offspring or are randomly changed by mutation. The algorithm repeats this evaluate-select-crossover-mutate process for multiple generations. Finally, the best model is selected from the run [13].

We used TPOT to tune the hyperparameters of the XGBClassifier, such as the number of boosting rounds ("n_estimators"), boosting learning rate ("learning_rate"), maximum tree depth for base learners ("max_depth"), minimum sum of instance weight needed in a child ("min_child_weight"), minimum loss reduction required to make a further partition on a leaf node of the tree ("gamma"), subsample ratio of the training instance ("subsample"), subsample ratio of columns when constructing each tree ("colsample_bytree"), L1 regularization term on weights ("reg_alpha"), and L2 regularization term on weights ("reg_lambda"). To control the balance of positive and negative weights, we set "scale_pos_weight" as the number of negative cases/the number of positive cases. The "objective" option was set to a default value, "binary:logistic" (ie, logistic regression for binary classification).

Two parameters of TPOTClassifier, namely, number of iterations to run the XGBoost optimization process ("generation") and number of individuals to retain in the genetic programming population every generation ("puplation_size"), were set to 100 (default) each. Finally, TPOT evaluated models using AUC ("roc_auc").

Extreme Gradient Boosting (XGBoost) and Feature Selection

XGBoost incorporates an ensemble technique (boosting) of adding new models to correct errors made by previous models. When adding new models, gradient boosting uses a gradient descent algorithm to minimize the loss. More details on XGBoost's working principles can be found in published articles [24]. For feature selection, we sorted the model features according to their importance (importance_type = "gain," the average gain of splits that use the feature) and selected a subset of features by omitting the least important feature. If the AUC of the model with the subset of features was not compromised or became higher, we omitted the next least important feature. Subsequently, we retested it until the model performance reached the best AUC.

R Packages

The *Survey* package allows to specify a multistage sampling survey design and provides functions to estimate total population counts, means, and variances for a survey sample [25]. In this study, the survey design of the KNHANES was applied using the variables *psu* for PSU, *ID_fam* (family ID) for the secondary sampling unit, *kstrata* for strata, and sample weight (*wt_tot*/5) for weight. Additionally, we used the "svyglm" function from the *survey* package for survey-weighted multiple logistic regression. The odds ratio was calculated by exponentiating the coefficient of multiple logistic regression.

Receiver operating characteristic (ROC) curves were generated using the *ggplot2* package [26], and the weighted AUC was calculated by using the "WeightedAUC" function with the sample weight (*WeightedROC* package) [19].

Network Graph

For a correlation matrix in network analysis, a correlation between two variables was calculated using the wtd.cor function with the sample weight for "weight" in R's weights package, which produced weighted Pearson correlation coefficients for survey data [27]. The network graph was generated using the qgraph function in the *qgraph* package of R by setting the graph argument to “glasso” and layout to “spring” with threshold [20]. For node sizes in the network, the effective size of the variable’s odds ratio was calculated by exponentiating the absolute coefficient of multiple logistic regression. For the calculation of centrality indices, the qgraph object and the centralityTable function in the *qgraph* package of R were used [20].

Results

XGBoost-Derived Model and the Performance

The population was estimated to be 22,262,880 (SE 355,977) (97.3%) for no depression reported during lifetime and 616,082 (SE 40,273) (2.7%) for current depression (complex-survey-design-based estimation). After TPOT training, the number of XGBoost model features was reduced from 120 to 81 (33% reduction) by the L1 regularization term of XGBoost. Furthermore, we decreased the feature number to 18 (78% reduction) by applying feature selection without performance loss.

The final model features included mental health, quality of life (QoL), socioeconomic factors, morbidity, sex, marital status, urinalysis, and health behavior (Figure 2). Nutrition factors failed to be included in the model. For the test set, the weighted AUC of the model was 0.86 for reported depression and 0.82 for PHQ-9 score depression (Figure 2). The model’s accuracy was 0.82 at the best threshold of the test data (Table 1).

Figure 2. XGBoost model for the depression and performance test. Red dots represent positive for a binary factor or high feature values for a continuous factor on the beeswarm plot of shapley additive explanation (SHAP) values (log odds of the current depression) for the training data (A). On the weighted receiver operating characteristic curve (ROC) (B), sensitivity is 0.78 and specificity is 0.82 at the best threshold of probability of 0.461 for test samples. The model is also tested using the Patient Health Questionnaire-9 (depression when score ≥10) for 6098 samples (C). AUC: area under the curve.

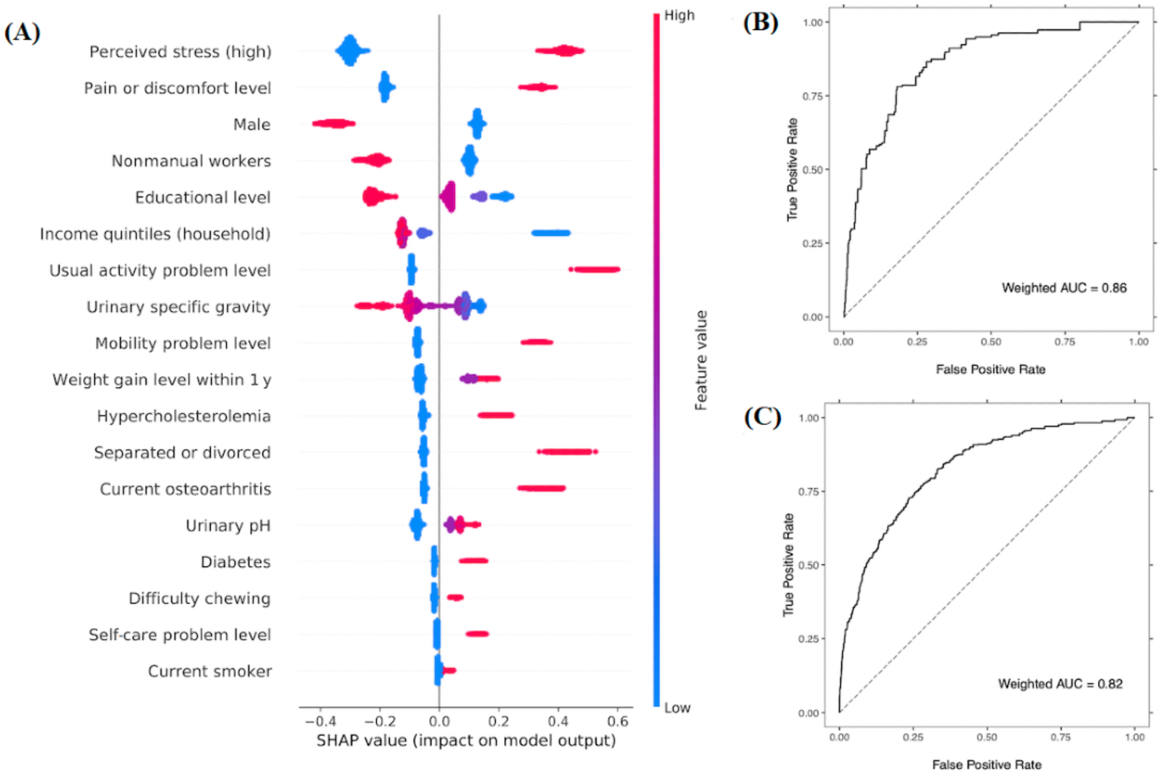


Table 1. Confusion matrix for the test data set.

Actual depression	Predicted depression[a]	
	Current	No lifetime
Current	103,182	28,933
No lifetime	804,195	3,657,604

[a] Case numbers are estimated using complex-survey-design weights at the best threshold.

Statistical Significance of Depression-Associated Factors

Perceived stress and current asthma were top-ranked statistically significant risk factors (Table 2). Triglycerides, current asthma, and farm workers were nonmodel factors having a significant association with depression and added on the network with model factors. Eight features out of 18 model factors were not statistically significant and classified as indirect (Table 2).

Table 2. Survey-weighted multiple logistic regression analysis of depression-related factors.

Variable	No lifetime depression[a] (N=22,262,880)	Current depression[a] (N=616,082)	Odds ratio (95% CI)[b]	*P* value

Pain or discomfort level (1 to 3 points), mean (SE)	1.2 (0.004)	1.6 (0.034)	1.3 (1.1-1.5)	<.001
Fasting serum triglyceride (mg/dL)[d], mean (SE)	134.8 (1.3)	161.8 (12.0)	1.2 (1.1-1.3)	.002
Weight gain level within 1 year (0 to 3 points), mean (SE)	0.4 (0.009)	0.6 (0.047)	1.2 (1.1-1.3)	.003

Variable	No lifetime depression[a] (N=22,262,880)	Current depression[a] (N=616,082)	Odds ratio (95% CI)[b]	*P* value
Urine specific gravity, mean (SE)	1.020 (0.00007)	1.018 (0.0004)	0.8 (0.7-0.9)	.003
Usual activity problem level (1 to 3 points), mean (SE)	1.0 (0.002)	1.3 (0.029)	1.1 (1.0-1.3)	.006
Income quintiles (household) (1 to 5 points), mean (SE)	3.4 (0.02)	2.6 (0.09)	0.8 (0.7-0.9)	.007
Educational level (1 to 4 points), mean (SE)	3.2 (0.01)	2.6 (0.06)	0.8 (0.7-1.0)	.01
Urine pH, mean (SE)	5.7 (0.009)	5.8 (0.050)	1.1(1.0-1.3)	.07
Mobility problem level (1 to 3 points), mean (SE)	1.1 (0.002)	1.3 (0.032)	1.1 (1.0-1.2)	.22
Self-care problem level (1 to 3 points), mean (SE)	1.0 (0.001)	1.1 (0.017)	1.0 (0.9-1.1)	.98
Age (years)[e], mean (SE)	40.7 (0.2)	45.1 (0.8)	1.1 (0.8-1.3)	.61

[a] Population counts (n), means, and standard errors are estimated using complex-survey-design weights.

[b] For continuous factors, the value was standardized by removing the mean and scaling to unit variance.

[c] N/A: not applicable.

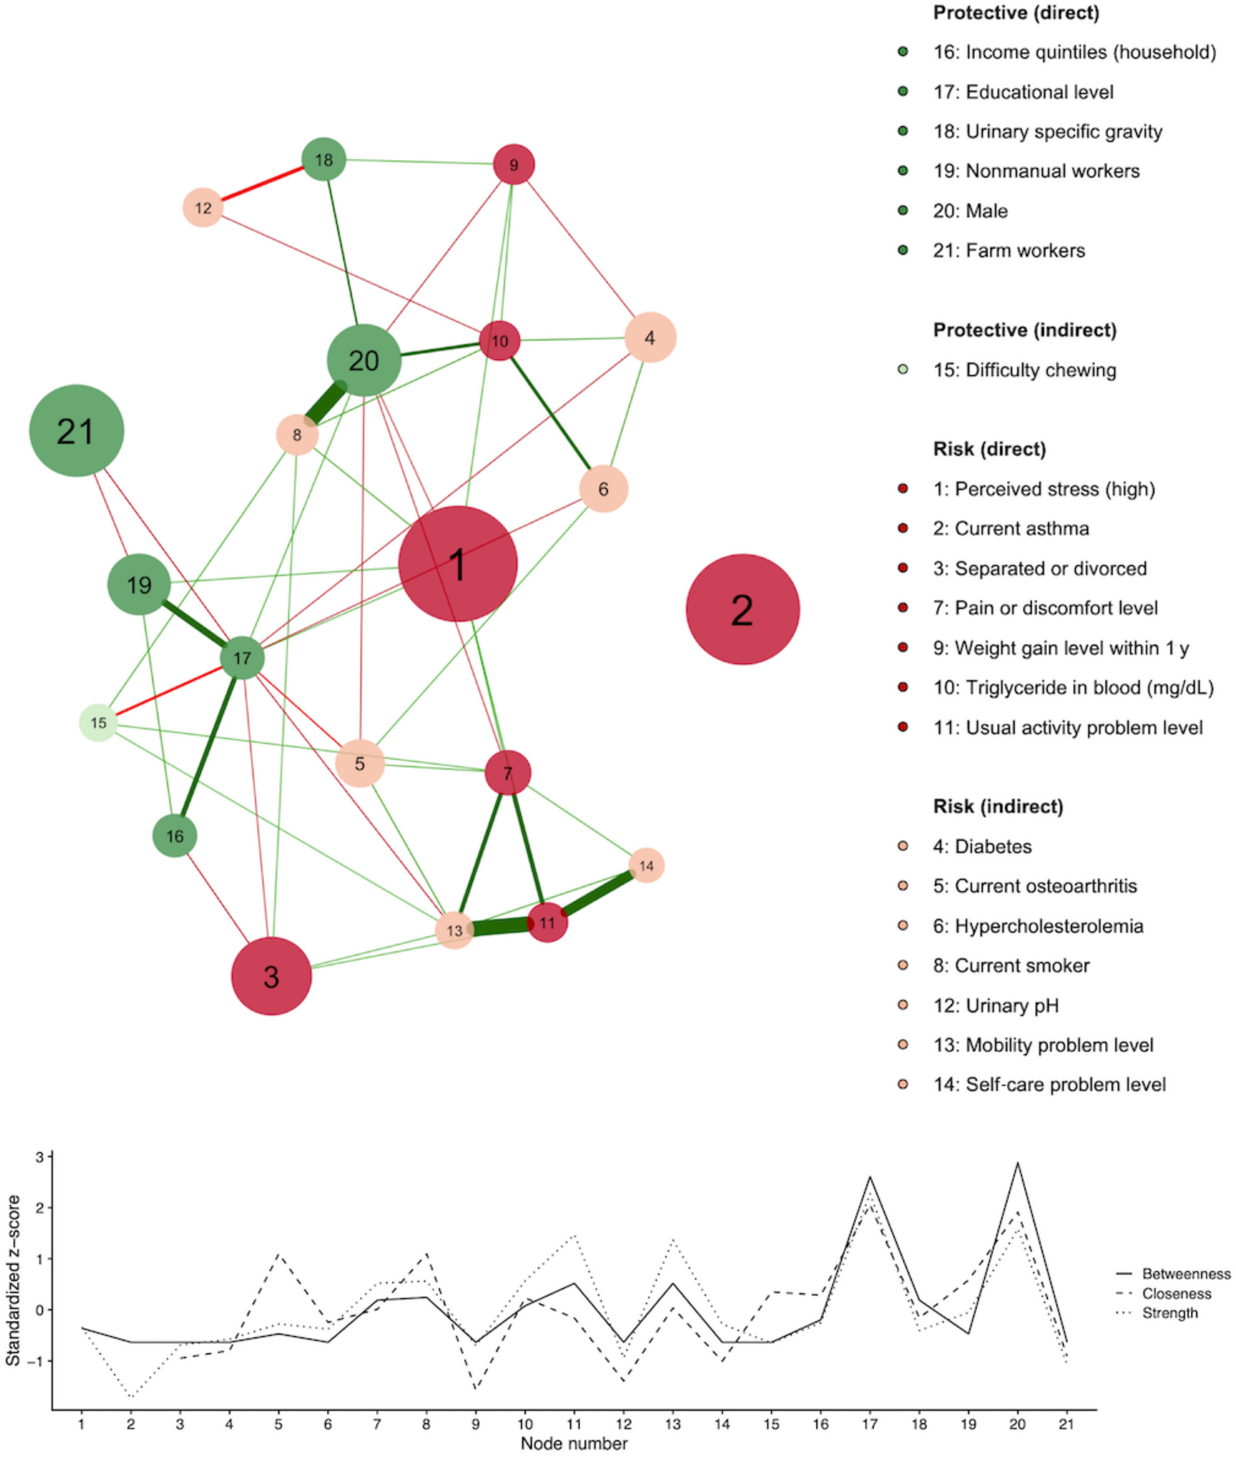
[d] Nonmodel factors were found by controlling for model features and age.

[e] Not a depression-related factor, but included to control confounding effects of age.

High-Centrality Nodes and Clusters in the Depression Network

Based on the centrality indexes, the network had two high-centrality nodes, namely, “educational level” and “male,” which meant both nodes were highly connected with various factors (Figure 3). Some factors were strongly connected to form a cluster (eg, the socioeconomic status [SES] cluster consisted of nonmanual workers, farm workers, educational level, and household income) (Figure 3). The QoL cluster comprised four EuroQol five-dimension three-level (EQ-5D-3L) domains (“pain or discomfort level,” “usual activity problem level,” “mobility problem level,” and “self-care problem level”) (Figure 3).

Figure 3. Partial correlation network graph and centrality indices for depression-associated factors. The factors can be positively (risk) or negatively (protective) related to current depression. Node size is proportional to the effective size of the odds ratio. Green and red edges represent positive and negative correlations, respectively. The edge with the highest absolute weight has full-color saturation and the widest width.



Confounders and Interaction Effects of Indirect Factors

Two indirect factors, namely, hypercholesterolemia and diabetes, were positively connected with triglyceride on the network, and triglyceride was a confounder of hypercholesterolemia and diabetes (Table 3). Another indirect factor, current osteoarthritis, became statistically significant after excluding its positive associates, namely, “pain or discomfort level” and “mobility problem level” (Table 3).

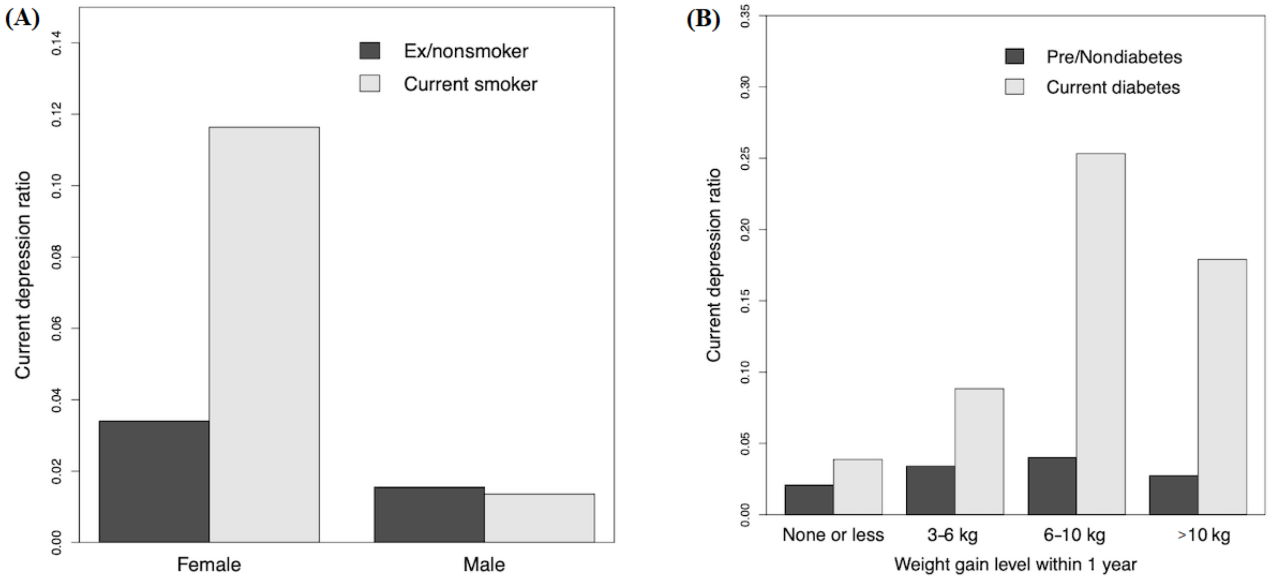
Table 3. Possible confounders on indirect factors in depression.

Indirect factors	Confounders[a]	Odds ratio (95% CI)	
		With confounders	Without confounders
Current osteoarthritis	Pain or discomfort level and mobility problem level	1.4 (0.9-2.1)	1.6 (1.1-2.5)
Hypercholesterolemia	Triglyceride	1.4 (1.0-1.9)	1.5 (1.0-2.1)
Diabetes	Triglyceride and hypercholesterolemia	1.4 (0.9-2.2)	1.7 (1.1-2.6)

[a] A group of confounders to make a coefficient of the indirect factor statistically insignificant.

Another indirect factor, “current smoker,” interacted with sex and was statistically significant in females (odds ratio 2.2, 95% CI 1.3-3.7; *P*=.003) (Figure 4). Current diabetes interacted with the weight gain level that was not statistically significant for prediabetes or nondiabetes (*P*=.05) (Figure 4).

Figure 4. The proportion of current depression according to sex and smoking (A) and according to weight gain and diabetes (B). The interaction effects between them are significant (*P*=.001 and .01, respectively; survey-weighted logistic regression).



Urine Specific Gravity and Depression

We found an interesting relationship between urine specific gravity (USG) and depression. Because USG was associated with the “male” node on the network (Figure 3), we stratified it into males and females and plotted it according to age. USG was lower in “current depression” than in “no lifetime depression,” especially in females who were in their early 50s or younger (Figure 5). However, the daily water intake was not higher in “current depression” than in “no lifetime depression” (Figure 6).

Figure 5. Linear regression plots between age and urine specific gravity in females and males. In the images, 95% confidence intervals for the regression estimate are drawn using translucent bands around the regression line.

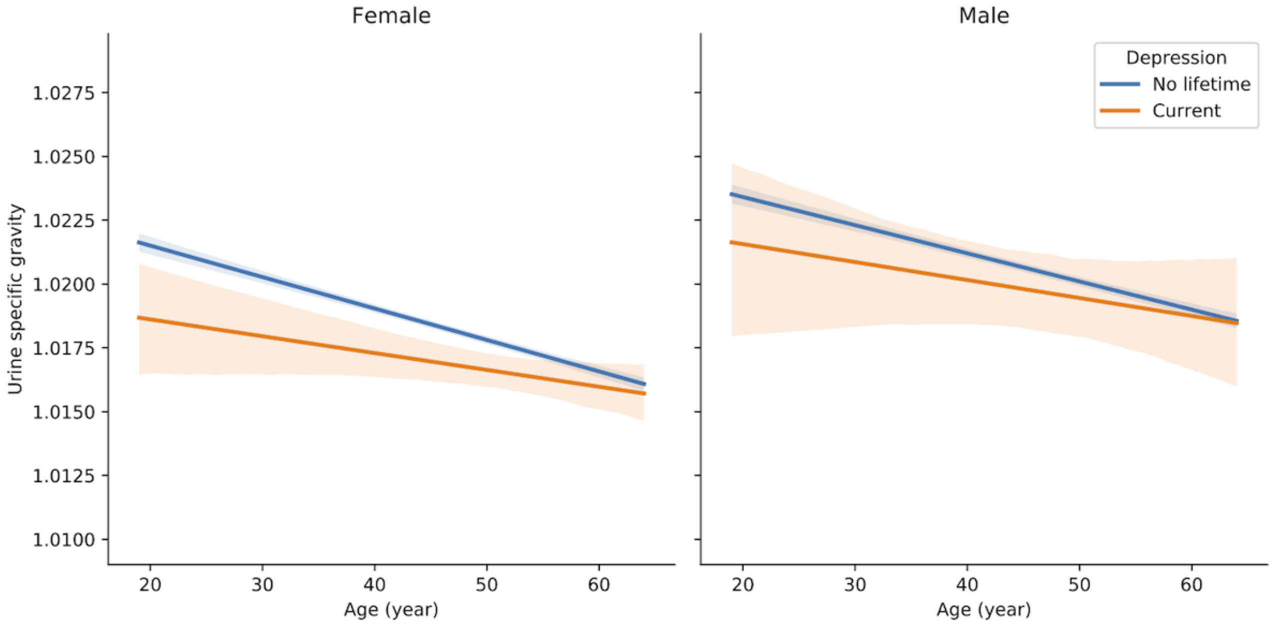


Figure 6. Linear regression plots between age and daily water intake in females and males. In the images, 95% confidence intervals for the regression estimate are drawn using translucent bands around the regression line.

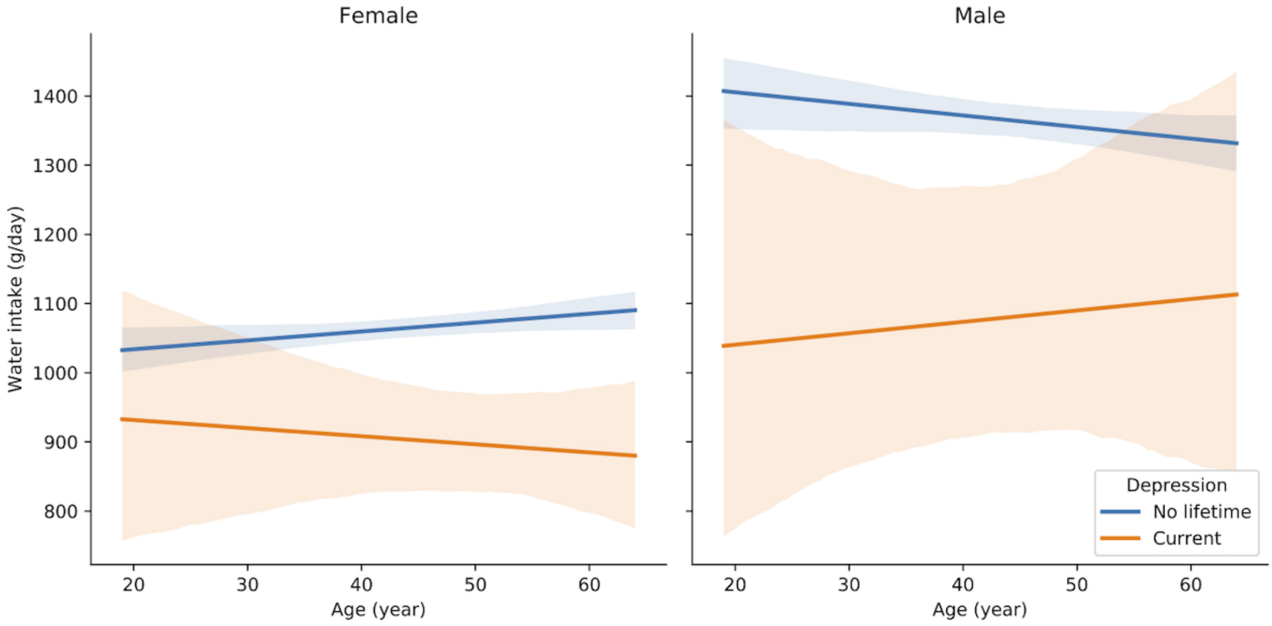

Discussion

Addressing Class Imbalance and Generalization Problems

Our data set was highly imbalanced, with a 2.7% prevalence of depression. Therefore, it may be difficult for a machine learning algorithm to predict depression because this diagnosis is not sufficiently represented [28]. We used the “scale_pos_weight” parameter of XGBoost that enables class-weighted or cost-sensitive learning to make the model more sensitive to misclassification in the minority class [12]. The performance of our XGBoost model showed that the TPOT-trained class-weighted XGBoost model was working well for our imbalanced classification.

There would have been a generalization problem with this survey data because we did not train the model using the sample weight. However, the weighted AUC for the test set (0.86) was not lower than the mean unweighted AUC for the training set (0.84, SD 0.02; seven repeats of five-fold cross-validation). Therefore, our model was not overfitted, and we expect that our model can be applied to the general population.

Reliability of Self-Reported Depression

A model may be less reliable when it is based on self-reported depression than on clinically diagnosed depression. However, for PHQ-9 scores, a clinical module, the model performance was still satisfactory when the model was retested with available cases (Figure 2). PHQ-9 is a validated screening tool for depression and is known to exhibit an acceptable diagnostic accuracy for cutoff scores between 8 and 11 [29,30]. It might be possible because we strictly defined depression by requiring both conditions (ie, current symptoms and a physician's diagnosis). In addition, we restricted "negative depression" only to the cases when depression was never diagnosed, and respondents with a past diagnosis of depression were excluded.

Combination of the XGBoost Model and Statistical Analysis: Feature Reduction, Indirect Factors, and Nonmodel Factors

XGBoost L1 regularization did not ultimately reduce the feature number; however, feature selection using XGBoost feature importance could decrease the feature number more at a higher reduction rate. Therefore, we suggest feature reduction using XGBoost feature importance to obtain a sparser model that contains the most principle factors of the disease.

Because of the relatively small number of predictors, a sparse model is interpretable without irrelevant features, which could be shown by the impact on the depression of each feature (Figure 2). Furthermore, we performed statistical tests on the sparse model features using multiple logistic regression at a lower risk of multicollinearity or redundancy problems. Overall, 44% of the model features were not statistically significant, and we classified them as indirect factors because they affected depression without a direct statistical association with depression.

Additionally, nonmodel factors (triglyceride, current asthma, and farm worker) exhibited statistical significance by multiple regression with depression model factors. By controlling principle depression factor effects (eg, confounding effects), nonmodel factors' significance was reliable. Therefore, we might use a sparse disease model as a testing tool for candidate factors.

Elements of the Depression Network: Node Size and Edge

Our network was composed of differently sized nodes (statistical strength of the association) and edges (net correlation between two factors). "Perceived stress" and "current asthma" were prioritized in depression risk factor control because of their large nodes (Figure 3). In addition to genetic factors, stressful events affect the onset of depression and cause depression through psychological stress responses, such as activating the hypothalamic-pituitary-adrenal axis [31]. Additionally, the network indicated that "perceived stress" could accompany other risk factors, such as "pain and discomfort" and "weight gain," and we might consider them together for risk factor control (Figure 3). In contrast, current asthma was an independent node, which suggests asthma may directly link with depression (eg, asthma medications or dysregulation of specific stress-sensitive biological processes) and be an individual control target [32].

Depression Network Centrality and Clusters: Indication of Predisposing Factors and Factor Groups

In terms of the network's centrality indexes, "male" and "educational level" showed the highest values. Scale-free networks are characterized by growth and preferential attachment in which earlier nodes in the network increase their connectivity at a higher rate [33]. Therefore, high-centrality nodes might be preceding factors. For example, the high centrality of "educational level" might explain that a higher educational level has accumulated protective effect throughout life [34]. Therefore, the network centrality suggested that gender and the education level would be predisposed to biological and socioeconomic depression factors. Statistically, gender and the education level might be must-have covariates because of their multiple relations to other factors.

Clusters in the disease network can be potent risk intervention targets because factors in a cluster are connected and controlled together [35]. The SES cluster on our depression network is reported as the most prominent risk among psychosocial risks [35], and low SES is common in depression because of poor care, low treatment compliance, and job strain [36]. For the QoL cluster, a study reported that the usual activity problem and the pain level of EQ-5D are mainly affected by depression, and the treatment of depression improves the EQ-5D index score [37]. Depression symptoms were negatively connected to health-related QoL in the network in a previous study [38].

Confounding and Interaction Effects of Indirect Risk Factors

If an indirect risk factor is connected to a direct risk factor, the direct factor could be the confounder. Furthermore, if the direct factor is on the causal pathway, it can be a mediator of the indirect factor action. We found potential confounders of current osteoarthritis, hypercholesterolemia, and diabetes using the network (Table 3). Osteoarthritis causes pain and physical disability, which can reduce QoL and lead to the development of depression [39]. This can be seen in our network based on the relationships among current osteoarthritis, pain, and mobility problems in the QoL cluster (Figure 3).

Obesity and metabolic syndrome may mediate the relationship between diabetes and depression [40]. This fact could be captured in our network because diabetes was associated with weight gain, higher triglycerides, and hypercholesterolemia (Figure 3). Additionally, the elevated triglyceride level was a confounder of hypercholesterolemia (Table 3), which may explain a recent meta-analysis reporting that the first episode of major depressive disorder is associated with elevated triglyceride levels, not low-density lipoprotein cholesterol or total cholesterol levels [41]. Previous studies reported that an elevated triglyceride level is associated with depression and suicidality in men [3] or women [42]. However, there was no interaction effect between "male" and triglyceride level in our study (*P*=.82).

If an indirect risk factor is connected to a direct protective factor or negatively associated with a direct risk factor, its role could be revealed by the interaction effect. "Current smoker," which is an indirect factor strongly connected to "male," was a significant risk factor in females, but not in males (Figures 3 and 4). Smoking cessation might be considered, especially for female depression patients [43]. Weight gain occurred in depression in current diabetes, but not clearly in prediabetes or nondiabetes (Figure 4).

USG as a Novel Depression-Related Factor

To the best of our knowledge, USG was a novel factor of depression, and the level was low in female depressive subjects (Figure 5). USG correlates with urine osmolality and reflects the subject's hydration status or the kidney's concentrating ability [44]. However, our study showed that low USG in depression might not be caused by hydration because daily water intake was not low in depression (Figure 6). One study suggested that patients with depression concentrate the urine less well and excrete less solute in the urine [45].

Limitations

This cross-sectional study involved people aged 19 to 64 years and could analyze only associations, not causalities. Therefore, the associations established in this study, such as weight gain in diabetes, elevated triglyceride, low USG, and smoking in females, require future clinical research to prove their efficacy in depression control. We used Bonferroni correction for nonmodel factors, and this conservative method might miss other possibly significant factors. Several cancers (hepatoma, gastric cancer, colon cancer, breast cancer, and lung cancer), renal failure, pulmonary tuberculosis, liver cirrhosis, and hepatitis C might not have enough positive cases to be tested. Finally, psychiatrists' structured interviews to diagnose depression would be more valid than the self-reported approach to identify depression used in this study.

Conclusions

We successfully created a sparse model for depression using TPOT-assisted XGBoost training and feature selection based on the feature importance of XGBoost from a large number of variables in KNHANES data. Because of the data-driven approach, we could discover a novel factor. We constructed a network of the depression-associated factors using association strength and interfactor correlations. The model factors were classified into direct and indirect according to their statistical significance, and the role of indirect factors was explained by confounding or interaction effects. The network also indicated predisposing factors by high centrality and cluster factors by a closely connected edge. Therefore, XGBoost and network analysis can be useful for discovering and understanding disease-associated factors in epidemiological studies.

Abstract

Background: Over the past decade, there has been an increase in the use of information technologies to educate and support people with dementia and their family caregivers. At the same time, chatbot technologies have become increasingly popular for use by the public and have been identified as having benefits for health care delivery. However, little is known about how chatbot technologies may benefit people with dementia and their caregivers.

Objective: This study aims to identify the types of current commercially available chatbots that are designed for use by people with dementia and their caregivers and to assess their quality in terms of features and content.

Methods: Chatbots were identified through a systematic search on Google Play Store, Apple App Store, Alexa Skills, and the internet. An evidence-based assessment tool was used to evaluate the features and content of the identified apps. The assessment was conducted through interrater agreement among 4 separate reviewers.

Results: Of the 505 initial chatbots identified, 6 were included in the review. The chatbots assessed varied significantly in terms of content and scope. Although the chatbots were generally found to be easy to use, some limitations were noted regarding their performance and programmed content for dialog.

Conclusions: Although chatbot technologies are well established and commonly used by the public, their development for people with dementia and their caregivers is in its infancy. Given the successful use of chatbots in other health care settings and for other applications, there are opportunities to integrate this technology into dementia care. However, more evidence-based chatbots that have undergone end user evaluation are needed to evaluate their potential to adequately educate and support these populations.

Introduction

Background

Over the past decade, chatbot technologies have increasingly been used by people to meet a variety of daily needs, including social and emotional support and information seeking [1]. The term *chatbot* refers to technologies that facilitate human-computer interaction by mimicking natural language conversations with users, either through text or spoken words [2]. Chatbots are also referred to as *conversation agents*, *dialog assistants*, *or intelligent virtual assistants*, the latter often referring to Google Assistant, iPhone *Siri*, and Amazon *Alexa*. Although interest in chatbots has increased among researchers, software developers, and end users alike, little is known about the efficacy of using chatbots to support people with dementia (which includes Alzheimer disease and related dementias) and or their caregivers. To address this gap in scholarship, the aim of this paper is to systematically review and evaluate the characteristics of chatbots that are currently available on the market and focus on dementia. The findings have implications for advancing technologies that support dementia care and caregiving, which has been identified as a top research priority [3].

Technologies for People With Dementia and Dementia Caregivers

There has been a growing interest in developing and testing technologies that can improve the quality of life and care for people with dementia and their family caregivers. Indeed, in 2018, the Family Caregiving Institute held a Research Priorities in Caregiving Summit: Advancing Family-Centered Care Across the Trajectory of Serious Illness. Among the 10 research priorities identified, the first 2 are “evaluate technologies that facilitate choice and shared decision making” and “determine where technology is best integrated across the trajectory of caregiving” [3].

Previous research has found that people with dementia have the ability to use a number of technologies designed to fit their needs, including computers [4] and touchscreen technologies [5,6]. Similarly, over the last decade, there has been increasing effort to develop technology-based interventions for dementia caregivers [7]. There is also a growing number of smartphone apps that target the needs of people with dementia and/or dementia caregivers [8,9]. In their systematic review of computer-based cognitive interventions for people with dementia, García-Casal et al [4] concluded that computer-based interventions demonstrated greater efficacy in improving cognition than noncomputer-based interventions. In a systematic review of technology-based interventions for dementia caregivers, it was reported that technology-based interventions often demonstrated efficacy in improving psychosocial outcomes but did not demonstrate efficacy in improving caregiving skills or care self-efficacy. Little is known about the use of chatbots among people with dementia and their caregivers [7].

Chatbot Technology and Health

Chatbots may use a variety of platforms, including websites, smartphones (eg, Siri), mobile apps (specialized in a domain such as depression or for general purpose, such as WhatsApp and Messenger), SMS text messaging, and in-home smart technologies (eg, Alexa) chatbots. Loranjo et al [10] identified 3 approaches for chatbots to manage dialog: (1) finite state, where there is a predetermined sequence of dialog steps that the user is led through; (2) frame based, where the chatbot asks the user questions and the user responses guide the chatbot through a flow of communication that is not predetermined; and (3) agent based, where artificial intelligence allows the chatbot and user to engage in complex communication. The same review reported that chatbot programs may allow dialog to be led by the chatbot system or the human user; dialog may either be in text or verbal formats.

One of the first established chatbots was programmed in the 1960s, called ELIZA, which was used for text-based psychiatric interviews [11]. This sparked the development of several early chatbots, such as GURU [12], CONVERSE [13], ALICE, and Elizabeth [14]. The renewed interest in chatbots in recent years is largely because of the advancements in deep learning technology [15], which enables agent-based chatbots, and the advancements in voice recognition technology, which have facilitated voice assistants such as Apple’s Siri, Microsoft’s Cortana, Amazon’s Alexa, and Google’s new Assistant [16].

Having been used for customer service, education, website user support, and entertainment, chatbots were found to have promising use in health care [10,17], especially for symptom self-assessment (eg, Babylon Health [18], Sensely, Ada Health, and your.md), and telemedicine [19,20]. Over time, chatbots have been developed and tested to address a number of health conditions and topics, including HIV and sexual health [21], substance abuse, assessment, mental health assessment [22], and weight management [23]. Overall, research on health-related chatbots has demonstrated promising results. In a review of chatbots for psychiatric care, it was reported that chatbots demonstrate efficacy in facilitating psychoeducation and self-adherence to treatment [24].

The benefits of using chatbots for health care have been identified for patients and health care systems alike. For example, chatbots may support patients in treatment management and moral support [25]. For health care systems using telehealth, well-designed chatbots can be a cost-effective way to collect patient data, facilitate patient education, improve engagement with patients, and allocate resources more efficiently [19]. A recent systematic review by Laranjo et al [10] concluded that despite the potential benefits of conversational agents in the health care field, limited research has evaluated the efficacy and safety of this technology.

Chatbots for Aging and Health

As the state-of-the-art advances, more older adults are using information technologies to meet a number of chronic health needs, such as increasing health self-efficacy, supporting self-care management, engaging in health promotion, and interacting with health care providers [26]. Previous studies have highlighted that auditory chatbots may be especially useful for older adults for health-related communication and information seeking because they operate through voice-driven conversation, which may be helpful for those with low computer literacy [27,28]. Chatbots, such as virtual assistants, have been used by older adults for many purposes. A previous study showed that voice-activated personal assistants were used as medication reminders for older adults [28]. Another study also indicated the application of chatbots to follow up older patients with cancer receiving chemotherapy at home [25].

In the case of dementia care and caregiving, information technologies have specifically been identified as a potential way to overcome the existing challenges of accessing education and emotional support [29,30]. Caregivers of people with dementia often experience depression, burden, and poor health outcomes because of lack of emotional and caregiving support, knowledge, and coping strategies for the complexity of dementia care [31]. This can have a negative impact on the quality of care and outcomes for people with dementia [31]. Information technology can overcome existing barriers to education and support for caregivers who are unable to attend in-person services or need flexible scheduling of services [8]. Preliminary studies on information and other mobile technologies have also demonstrated positive benefits for caregivers [8,32]. Mobile information technologies targeting people with dementia have mostly focused on improving memory and engagement [5]. Given the previous evidence presented on the benefits of using chatbots among older adults and in health care in general, they may pose unique benefits in providing education and support to people with dementia and their caregivers. They may especially be beneficial for those living in rural communities, who may face the challenge of distance and limited resources for interacting with providers and services [33]. It should be noted that there are commercially available apps that use chatbots for making clinical assessments of people with dementia [34]. However, many of these are designed to be used with the assistance of a professional and are not focused on education and support for care at home.

Need for Critical Review

Many of the identified uses for chatbots, such as self-assessments and health education, are potentially helpful in educating and supporting people with dementia and their caregivers. Advancing such technologies for the purpose of dementia care is critical, given that states are projected to increase the incidence of neurodegenerative diseases by up to 33% between 2019 and 2025 [31]. However, little is known about how chatbots may be useful for dementia care and caregiving. To address this gap, this study systematically identified and evaluated existing chatbot apps that are available on the market to educate and support people with dementia and their caregivers.

Methods

Overview

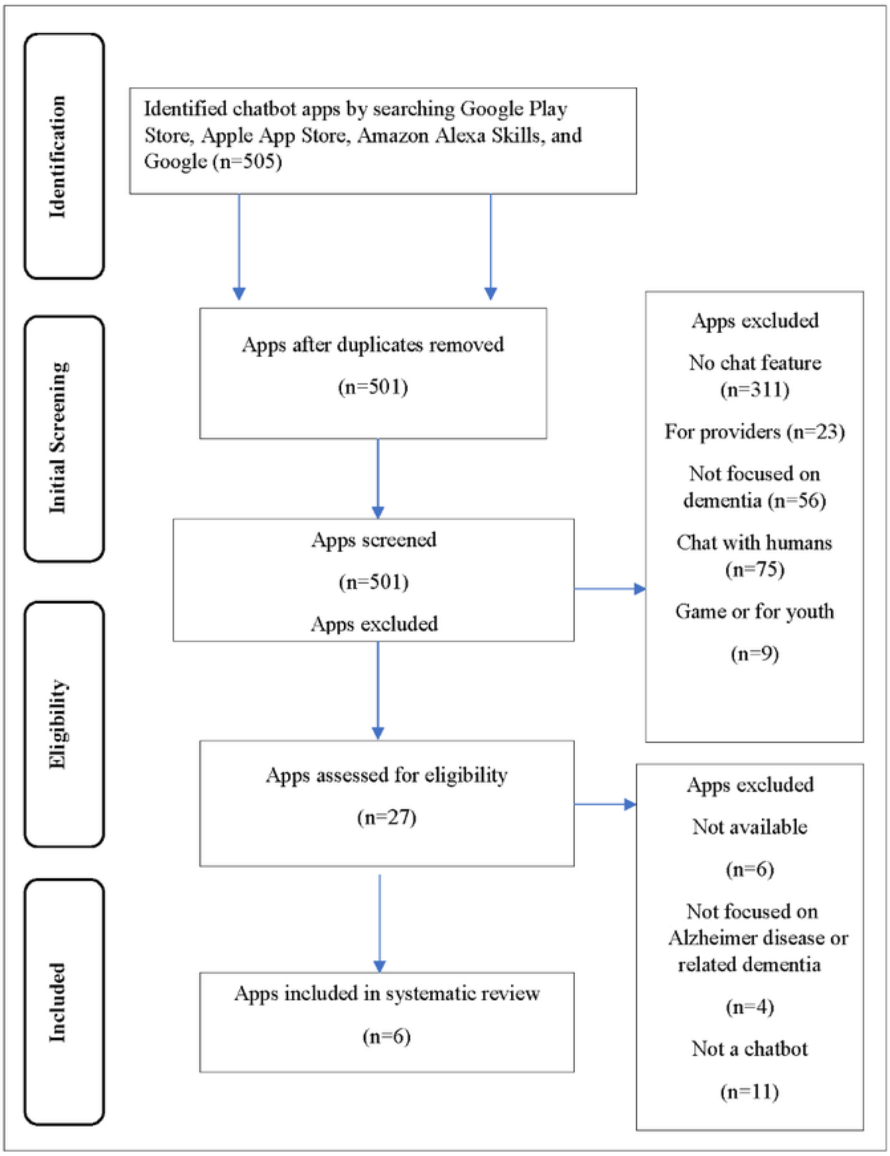
Previous studies on smartphone apps informed the methodology for evaluating existing chatbots [35]. A review of chatbot apps that focus on dementia was conducted between December 2019 and April 2020. Given the lack of chatbot app research in the academic literature, 3 investigators (NR, YL, and ZH) independently conducted searches on Google Play Store, Apple App Store, Amazon's Alexa Skills, and the internet. Key search terms used alone or in combination included "Chatbot," "Virtual Assistant," "Alzheimer's,"" dementia," "health," and "caregiver."

Chatbot apps were included for evaluation if they were programmed to engage in interactive dialog with the technology, verbally or through text; were focused on the topic of dementia; were designed for use by dementia caregivers and/or people with dementia; were available for download and use; were available in English; and were not games. Chatbots were excluded if they were programmed so that users chat with a live person, did not have content related to dementia, were designed to be used by providers, were not currently available for use, were not available in English, or were games. A total of 6 investigators were involved in evaluating apps for inclusion or exclusion criteria, and at least two investigators reviewed each app independently.

Critical Review

The evaluation tool of identified chatbots was developed using the framework developed by Radziwill and Benton [36] for evaluating chatbots, which is grounded in the computer science literature. The characteristics assessed are shown in Figure 1 and include *efficiency*, which included the category of *productivity*; *effectiveness*, which included the categories of *functionality* and *humanity*; and *satisfaction*, which included the categories of *affect* and *ethics and behavior.* A total of 3 authors (ELB, LR, and CVFS) evaluated each item of the assessment and graded the item using the following scale: ✓ (check), indicating that the evaluators could observe the attribute and/or the app-performed attribute function; — (em dash), indicating that the attribute or function was nonfunctional or inconsistent in functionality when accessed, and N/A (not applicable), indicating that the attribute did not apply to the stated functions of the app. The authors then compared their grades for each item and discussed discrepancies until an agreement was reached. A thematic analysis then was conducted based on the trend in scoring on the assessment across chatbots. All observations made by the team about the chatbot were based on their performance when evaluated in April 2020.

Figure 1. Flowchart of the chatbot apps searched and the screening procedures conducted using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines.



Results

Overview

The results of the search strategy are shown in Figure 1. Overall, 6 chatbot apps targeted the topic of dementia: 1 text-based mobile app and 5 Alexa Skills voice apps. It should be noted that the text-based mobile app (CogniCare, CogniHealth Ltd) was associated with one of the Alexa Skills apps, and these apps were the only ones identified to have an associated website. Half of the apps focused on education about dementia, whereas the other half focused on memory and reminiscence. The educational content provided through the apps was generally about the epidemiology and symptoms of dementia and less focused on caregiving skills and activities. None of the apps made claims about the expected outcomes of using the app, and no peer-reviewed research was identified for any of the apps. General information about the apps reviewed can be found in Table 1, and the assessment of the apps can be found in Table 2. The assessment of the apps took place in May 2020; therefore, the characteristics of the app presented here may have changed since then.

Table 1. General information about the chatbot apps.

App name	App ID	Developer name	Operating system	Downloads (N)	Price	Privacy statement
CogniCare mobile app	1	CogniHealth Ltd (in partnership with Alzheimer Scotland)	Android and iOS	≥1000	Free	Yes
CogniCare (Alexa Skills version)	2	CogniHealth Ltd (in partnership with Alzheimer Scotland)	Alexa Skills	Not reported	Free	Yes
My Life Story	3	Z55-Studios	Alexa Skills	Not reported	Free	Yes
Dementia Types	4	T Tillman	Alexa Skills	Not reported	Free	Yes
Build Your Brain Power	5	Fire Up Your Goals LLC	Alexa Skills	Not reported	Free	Yes
Everything Memory	6	jaimiles23	Alexa Skills	Not reported	Free	Yes

Table 2. Assessment tool informed by the framework developed by Radziwill and Benton and evaluation of apps by the research team.

[a] Apps were evaluated in May 2020.

[b] Evaluators could observe the attribute and/or the app-performed attribute function, as described earlier.

[c] The attribute or function was nonfunctional or inconsistent in functionality when accessed.

[d] N/A: not applicable.

Efficiency in Performance

For all apps, their functions and features were described in detail on Google Play Store or Alexa Skills pages. A total of 2 apps (app number 4 and 6) had more detailed instructions for getting started with using the apps than the others. One app (app number 2) offered an extensive guide to using the app with Alexa, although this guide was found on the developer's website and was not linked or listed on Amazon.com, where the app could be found and accessed. On Amazon.com, there was only a list of voice commands in speech bubbles that suggested questions to ask the chatbot. This posed challenges for the evaluators who initially accessed the apps for evaluation. The mobile text–based chatbot (app number 1) was the easiest to get started.

The evaluators also faced linguistic challenges when initially accessing the functions of the voice chatbot apps. For instance, some instances of Alexa's voice recognition were not flexible with the user's pronunciation of commands or required a specific command to get started in the chatbots, which was not immediately understood by the researchers. This may also be the reason that for voice chatbots, the evaluators noted that they would perform some of their described features, but not others. Only 1 chatbot (number 3) performed well on all 3 performance attributes. This was an audio chatbot that went through a series of questions about the user's life history, where the information was programmed into the app and the chatbot would tell the user their life story on command. For 3 of the chatbots, not all performance attributes were applicable.

Effectiveness

Functionality

In general, the chatbots were evaluated more favorably for their functionality, compared with the other categories assessed. In total, 5 of the 6 chatbots were found to be easy to use once the researchers were able to get the programs started. Of the 5 chatbots designed to educate about dementia, 3 were found to have a breadth of knowledge and flexibility in interpreting information.

Humanity

All apps demonstrated the ability to interact with users through voice or text responses to users' input. Although users found the apps' responses to their input to be understandable and logical, their responses were perceived to be more automated than natural conversation. Only 1 app (app number 3) passed the Turing test, which is the extent to which one can tell the difference between conversing with a human and the chatbot. The researchers also found that the programmed dialog in all the chatbots was limited in scope, which made extended language exchange between the user and chatbot to also be constrained. For example, 1 chatbot (app number 4) provided a definition for each type of dementia, but there was no additional content for a true back-and-forth exchange.

Satisfaction

Affect

In general, the evaluators assessed the chatbots as having features aimed at increasing the user's enjoyment while using them. For instance, 1 app (number 3) played calm music in the background while the users accessed its other features. All audio chatbots provided greetings and/or conveyed personality. Only 3 chatbots appeared to provide conversational cues to facilitate the user's ongoing engagement. For example, 1 chatbot would instruct the user to "Say, 'tell me more'" after it completed its dialog (app number 4). A total of 3 apps were evaluated as having the potential to make caregiving tasks more enjoyable or interesting.

Ethics and Behavior

Safety and privacy protection were evaluated for chatbot apps. In total, 5 apps had privacy statements describing the terms of use and security of users' input. In all the privacy statements, the developer confirmed that none of the users' information would be shared with third parties, unless the user gave permission to do so. In total, 2 apps (app number 2 and 6) included statements in their app descriptions that the chatbot was not a substitute for medical care or advice. In terms of trustworthiness of information, 4 apps were created by private developers. Two of the chatbot apps (app number 1 and 2) were developed by the same entity, which partnered with the nongovernmental organization Alzheimer Scotland to develop both the apps. It should be noted that since the time of review of the chatbots, the organization has also partnered with the University of Edinburgh for development. Hence, these apps were viewed as having the highest perception of trustworthiness.

Although the apps had content and functions that were deemed interesting and useful, some of the limitations in programmed content (as described earlier) presented challenges in this category as well. For instance, none of the apps were available in languages other than English, although 1 app (number 2) listed that their app was available in English from 5 different countries. The evaluators were not able to assess whether this resulted in language differences (eg, idioms and pronunciations) that were country specific. None of the apps were programmed to respond to patterns or the social context of user input.

Discussion

Principal Findings

At the time of this review, it was found that commercially available chatbot apps for people with dementia and their caregivers appeared to be in an early stage, with only 6 identified apps that met the search criteria across Google Play Store, the Apple Store, Amazon Alexa Skills, and the internet. All but one of these chatbot apps was the Alexa Skills app. Although chatbots, and specifically intelligent voice assistants, have been suggested as a potential source of assistance for older adults in general [37], their assessment indicates that people with dementia and their caregivers may experience challenges in using them. For instance, most apps had limitations in their programmed content, which created challenges when evaluators did not use specific commands. This may create barriers for populations with cognitive impairment or populations that use English as a second language. It may also create challenges for those who are not already familiar with chatbot technologies. Hence, people with dementia and caregivers could become frustrated when chatbots do not function as expected.

Limited program content also created challenges in having extended and/or varied conversations between users and chatbots. Owing to the complexity of dementia and variations in symptoms, this could limit the amount of education and support provided to a diverse population of people with dementia and their caregivers. This could impede the use of chatbots for information seeking and support. However, the hardware required for intelligent voice assistant platforms, such as Alexa, is recognized as having potential benefits for people with dementia and their caregivers. For instance, Alexa Skills relies on voice for navigation, which may be easier for older adults than typing, and does not require technical accessories, such as a mouse or keyboard. Hence, it may be worthwhile to further investigate how chatbots can be designed with user-friendly features for older adults, especially those who may have cognitive or memory impairments.

Several of the chatbots reviewed included educational information, although references were not provided for the informational sources; therefore, it was unclear whether health-related information provided by the chatbots is evidence based or whether information has been updated as needed. Designers should consider providing and using peer-reviewed references used in programming chatbots. In addition, although chatbot apps appeared to focus on education about dementia and engagement, the apps did not offer much information on caregiving skills and activities. However, the guidebook found for the CogniCare Alexa Skills chatbot reported that such content was being planned for the future. Such content would increase the usefulness of the chatbots for caregivers, who often feel isolated and have low caregiving self-efficacy.

Humanity Versus Usefulness

We found that most chatbots did not pass the Turing test, which mainly means that they were unable to keep the conversation going while pretending to be human. We note that acting human may not be enough if the chatbot does not achieve its goals of educating or helping caregivers or patients. Most early research on chatbots has focused on the humanity aspect [11], whereas more recent research has focused on how to create goal-oriented chatbots, which understand the user and complete a transaction, such as making an appointment or answering a question. Much of this recent work assumes that there is a data set of conversation on the domain to train, which is not the case for dementia care, where there are no available conversations between patients and providers. Nevertheless, as more artificial intelligence tools are created, we expect that the responsiveness of dementia chatbots will improve as well.

Need for Evidence-Based Chatbots for Dementia Care and Caregiving

It is important to explore how chatbots may be used to educate and support people with dementia and their families. There are many potential chatbot functions that those affected by dementia may value depending on their preferences and needs. For instance, given the previous applications of chatbots to adult learning, chatbots could be used to educate and train caregivers on a variety of topics, especially those who feel isolated [38]. Chatbots can also be programmed so that caregivers can take self-assessments and receive evidence-based feedback or be linked with resources. For people with dementia, designers may consider how evidence-based cognitive training and other evidence-based programs can be administered via a chatbot [39].

When considering people with dementia as targeted end users, designers should also consider that there is a continuum of severity in dementia symptomology and assess how content and functions may be appropriate for different stages of disease progression or adaptable to be used as symptoms progress. For example, people with mild dementia may look for and benefit from features that support independence or memory-building activities. However, people in later stages of dementia and their caregivers may prefer features that promote engagement and reminiscence, such as a recorded message from a loved one or a favorite song. Listening to music can be a shared enjoyable activity by the care recipient and caregiver, and music therapy has been found to be therapeutic in managing behavioral disturbance in people with dementia [40].

Although there are opportunities to advance the state of the science on dementia-focused chatbots in general, it is important that such chatbots should be evidence based. It is unclear whether the chatbots included in this review underwent empirical user testing. It should be noted that since conducting the chatbot review, the developers of CogniCare have published a peer-reviewed article on the development of their apps [41], although this article did not report outcome findings for users. Overall, this underscores the importance of developing chatbot technologies that undergo extensive user testing, given that the technical literacy required to use chatbots can pose a barrier to older adults' use and acceptability [25]. This is very important for chatbots designed to be used within the context of health care, given the previously stated concerns that input inflexibility of a particular chatbot could pose risks to patients [10]. This point also relates to the quality of the content programmed in a chatbot. For instance, it is unclear the extent to which educational material provided through the chatbots assessed for this study were based on evidence from the literature on dementia.

Opportunities for Integrating Chatbots Into Dementia Care Delivery

There are particular potential benefits of integrating chatbot technology into dementia care settings. People with dementia and their caregivers are at an increased risk of social isolation, especially for people with dementia who are in long-term care settings. The potential for chatbots for socially isolated populations has been particularly evident during the COVID-19 pandemic, where the Center for Disease Control and Prevention launched its Clara Bot app as an interactive way to educate the public and provide emotional support [42]. Integrating chatbots into dementia clinical settings could also potentially reduce the burden on staff by offering vetted information to patient and caregiver populations, which could reduce calls and questions for clinical staff. It should be noted that the quality of the information provided by chatbots in this review was not fully evaluated, and it is unclear if they provided vetted information. In addition, the limitations of the chatbots critically reviewed in this study, such as the need for specific phrases and pronunciations, highlight the need for developing health care chatbots that support diverse patient populations. For instance, dementia chatbots that are flexible in their understanding of varying accents and dialects will increase their acceptability and ease of use.

A key obstacle in integrating chatbots into care delivery is the Health Insurance Portability and Accountability Act (HIPAA) compliance needed for the chatbot to be able to exchange information with a health care entity (covered entity). Fortunately, Amazon Alexa has recently begun offering HIPAA-compliant skills [43]. Mobile apps can also be HIPAA compliant, but this is not the case for chatbots deployed on existing platforms, such as Messenger, SMS text messaging, or WhatsApp [44].

Limitations and Future Needs

There are limitations to this critical review that should be considered when interpreting the results. Despite the extensive search and review process used to identify chatbots, it is possible that there may be additional chatbots that address dementia but were not identified. In addition, there are no standardized measurement tools for chatbot technology. The authors initially attempted to conduct this review using the widely used mobile app rating scale [45]. However, too many items did not apply to chatbots. It should be noted that the evaluation tool used for the review developed by Radziwill and Benton [36] is heavily grounded in evidence on chatbots.

Conclusions

Although chatbots offer the potential for an engaging technology that can benefit people with dementia and their caregivers, more work is needed to develop evidence-based chatbots that are easy to use for these populations. Future research in this area should involve interdisciplinary scientific teams that have the expertise to develop a high-performing chatbot technology as well as expertise in dementia or health education.

Conflicts of Interest

VH is the founder of SmartBot360, which is a health care chatbot company. SmartBot360 was not included in this survey, as it does not focus on dementia caregivers.

Abstract

Background: Body image and eating disorders represent a significant public health concern; however, many affected individuals never access appropriate treatment. Conversational agents or chatbots reflect a unique opportunity to target those affected online by providing psychoeducation and coping skills, thus filling the gap in service provision.

Objective: A world-first body image chatbot called "KIT" was designed. The aim of this study was to assess preliminary acceptability and feasibility via the collection of qualitative feedback from young people and parents/carers regarding the content, structure, and design of the chatbot, in accordance with an agile methodology strategy. The chatbot was developed in collaboration with Australia's national eating disorder support organization, the Butterfly Foundation.

Methods: A conversation decision tree was designed that offered psychoeducational information on body image and eating disorders, as well as evidence-based coping strategies. A version of KIT was built as a research prototype to deliver these conversations. Six focus groups were conducted using online semistructured interviews to seek feedback on the KIT prototype. This included four groups of people seeking help for themselves (n=17; age 13-18 years) and two groups of parents/carers (n=8; age 46-57 years). Participants provided feedback on the cartoon chatbot character design, as well as the content, structure, and design of the chatbot webchat.

Results: Thematic analyses identified the following three main themes from the six focus groups: (1) chatbot character and design, (2) content presentation, and (3) flow. Overall, the participants provided positive feedback regarding KIT, with both young people and parents/carers generally providing similar reflections. The participants approved of KIT's character and engagement. Specific suggestions were made regarding the brevity and tone to increase KIT's interactivity.

Conclusions: Focus groups provided overall positive qualitative feedback regarding the content, structure, and design of the body image chatbot. Incorporating the feedback of lived experience from both individuals and parents/carers allowed the refinement of KIT in the development phase as per an iterative agile methodology. Further research is required to evaluate KIT's efficacy.

Introduction

Background

Mental disorders are a major public health concern, with a 29% lifetime prevalence rate across the general population [1]. In addition to reduced quality of life and individual impact, mental disorders have a significant global economic cost, which has been predicted at US $16.3 trillion worldwide from 2011 to 2030 [2]. Eating disorders have the highest mortality rate of any mental health diagnosis [3,4], and global prevalence rates have doubled from 3.4% to 7.8% of the population from 2000 to 2018 [5]. Despite the significant physical, mental, and social consequences associated with eating disorders, more than 75% of these individuals do not access appropriate treatment [6].

A major risk factor for developing eating disorders or other serious mental health conditions is body image dissatisfaction or concern [7]. This risk is increased by using social media, particularly image-based platforms such as Facebook, Instagram, and TikTok [8]. For example, using social media for 30 minutes a day, particularly looking at photos of peers and celebrities, has been shown to negatively impact women's body image and mood [9]. Over 3.6 billion people worldwide used social media in 2020, with many young people spending a significantly increasing amount of time on these platforms [10]. Consequently, social media, where young people are spending their time, presents a unique pathway to prevent and intervene with body image and eating concerns.

Guidelines for the evidence-based treatment of eating disorders recommend prevention and early intervention strategies for the best prognosis, with most individuals developing these concerns as young people [7,11]. Therefore, there is a need for early intervention and support delivery that is accessible and available to young people. The therapeutic approach with the strongest evidence base across the full spectrum of eating disorder presentations is enhanced cognitive behavioral therapy (CBT-E) where the core psychopathology addressed in treatment is the overevaluation of weight and shape (broadly, negative body image) [12]. Psychoeducation, or communicating relevant information about mental health conditions and treatments, is deemed an essential part of all psychological treatments, including CBT-E [12,13], especially given the wealth of misinformation in the general community about "healthy" eating and weight [11]. Psychoeducation is associated with small yet significant improvements in body image, which is further enhanced when combined with additional interventions [14,15].

The development of alternative coping skills is another requirement of evidence-based treatments [16], such as mindfulness practice, which involves the nonjudgemental awareness and acceptance of the present moment. Mindfulness training has been shown to significantly improve body image dissatisfaction and can effectively be delivered online as brief microinterventions [17-19]. When combined with psychoeducation, these brief evidence-based interventions (microinterventions) are likely to be beneficial in reducing body image concerns. Therefore, providing an accessible platform where individuals and support people can access evidence-based psychoeducation and coping skills may assist in addressing negative body image, and, in turn, potentially intervene in the development of eating disorders.

Prior Work

Digital mental health interventions have been increasing in popularity and efficacy, with chatbots being one such format. A chatbot allows the provision of information and services through a message-based interface, which is available on messaging platforms, websites, and apps. The conversational language and format of chatbots are relevant in connecting with youth, and are a promising avenue to supplement traditional support services [20]. Chatbots in the mental health sphere offer several benefits, including wider accessibility, instantaneous responses, and low or no cost to users, and can act as a stepping stone to link with more individualized or alternative services [21]. An additional barrier to accessing traditional services can be mental health stigma or lack of available services, where individuals may feel uncomfortable or unable to reach out for help. Digital mental health services can help bridge this gap, as anonymously conversing with artificial intelligence can feel less intimidating, particularly for young people who have grown up in the digital age [21].

The evidence for chatbots as supplements to mental health support is growing, with generally positive outcomes [20,22]. A recent systematic review and meta-analysis of 12 studies suggested that while heterogeneity among chatbot studies limits the interpretations of pooled efficacy, individual studies have evidenced improvements in symptoms of depression, anxiety, and general coping skills [23]. Owing to the limited conclusions that can be made, the authors recommend that chatbots be used to supplement treatment from mental health professionals rather than as a replacement. A scoping review of 41 chatbots reported that the most common uses of chatbots are therapy provision, information delivery, and screening, with the majority focused on mood and anxiety disorders [24]. However, to the authors' knowledge, there are no chatbots currently available that specifically target the increasingly common issue of negative body image. Given the rise of social media leading to increased appearance comparisons, "proeating disorder" content online, and "health" misinformation, there is a need for a reliable, evidence-based, and supportive digital mental health service within the field so users can receive more timely support for body image concerns.

Our Study

Based on this gap in service provision, we initiated the development of a novel body image chatbot. The chatbot provides psychoeducation and coping skills targeting body image concerns, for the purposes of prevention and supplementing traditional forms of treatment. This study aimed to assess the preliminary acceptability and feasibility of such a chatbot by collecting qualitative data from focus groups. This was an early stage evaluation, predominantly focused on the content, structure, and design of the chatbot in order to refine the design prior to launch, and the assessment of efficacy.

Methods

KIT Intervention

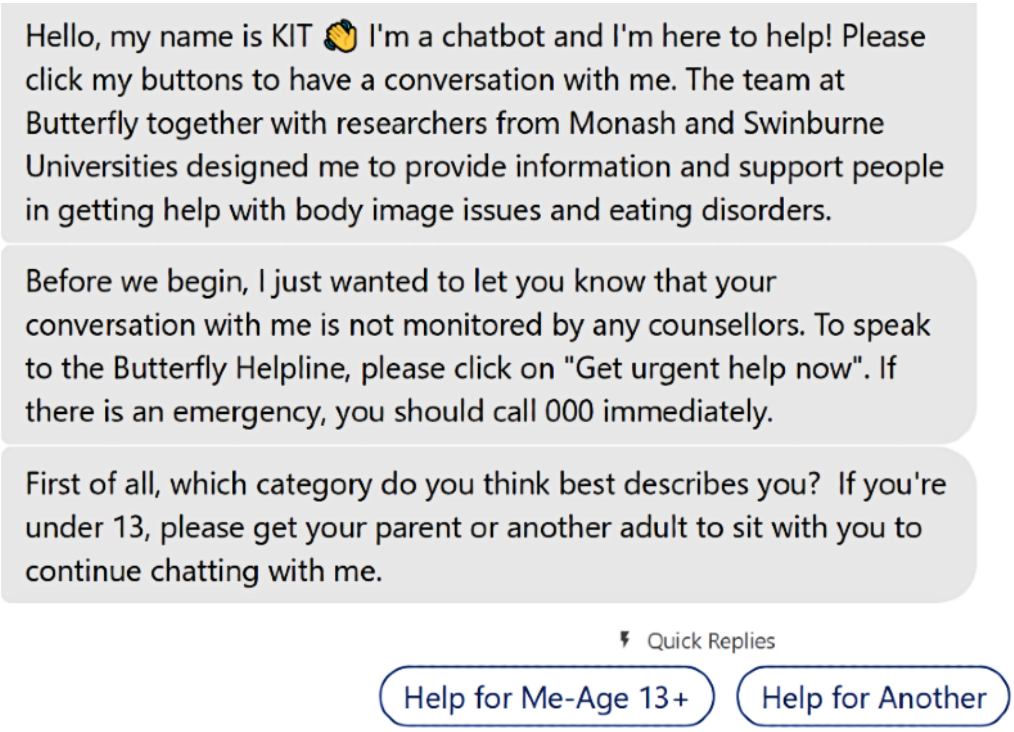
The chatbot, called “KIT,” is a conversational agent designed to support people with concerns surrounding body image and eating issues, as well as their loved ones (eg, parents, partners, and friends). The preliminary conversational content and decision tree for KIT was developed by the authors, in collaboration with the helpline and communications teams at the Butterfly Foundation (a national charity based in Australia, which provides support for body image and eating disorders). The conversation content was based on evidence-based information/interventions for eating disorders, specifically, psychoeducation, cognitive behavioral therapy (CBT), acceptance commitment therapy (ACT), and mindfulness [25,26], and adapted for delivery by a chatbot. Owing to the short and simple style of conversations KIT was designed to deliver, we were highly selective in the therapeutic elements we chose from CBT (eg, education on cognitive distortions or unhelpful thinking styles), ACT (eg, practicing detaching from unhelpful thoughts via cognitive defusion exercises), and mindfulness (eg, mindful breathing) [17,25,26].

In an effort to enhance the co-design of KIT, preliminary online forums were held with young people aged 13 to 18 years who self-identified as having lived experience with body image concerns and/or eating disorders. Please note that the reason this age range was chosen was to ensure that KIT’s dialog was understandable to the youngest users possible, not that KIT’s usage is limited to people aged 13 to 18 years. We also ran preliminary online forums with parents/carers of people with lived experience of body image concerns and/or eating disorders. The preliminary forums were crucial to assist with the refinement of the dialog, particularly devising shorter and more conversational ways of delivering educational information, as well as the design of the decision tree. The importance of involving end users in a software project has garnered strong support over recent years.

A professional chatbot production company, Proxima, using Iris Conversational Intelligence software [27], built the prototype chatbot based on the co-designed decision tree and conversation content. The prototype chatbot took the form of a webchat and was accessible on both mobile and desktop devices.

In terms of the specific chatbot content, each interaction with KIT began with a welcome message explaining the purpose and capabilities of the chatbot (Figure 1). This included directions to proceed through KIT by selecting buttons and information that the service was not monitored by any counsellors. Users were directed to speak to the Butterfly helpline or call emergency services if they required a higher level of assistance. KIT then asked the primary reason the user was there (“help for me [aged 13+]” or “help for another”). Once users were directed down one of these two pathways, they could self-direct to various psychoeducation or microintervention contents. The minimum age to use KIT was determined to be 13 years, as this is generally the age at which young people are permitted to sign up for a social media account [28].

Figure 1. KIT’s welcome message for users explaining capabilities and prompts for users to choose the “help for me” or “help for another” pathway.



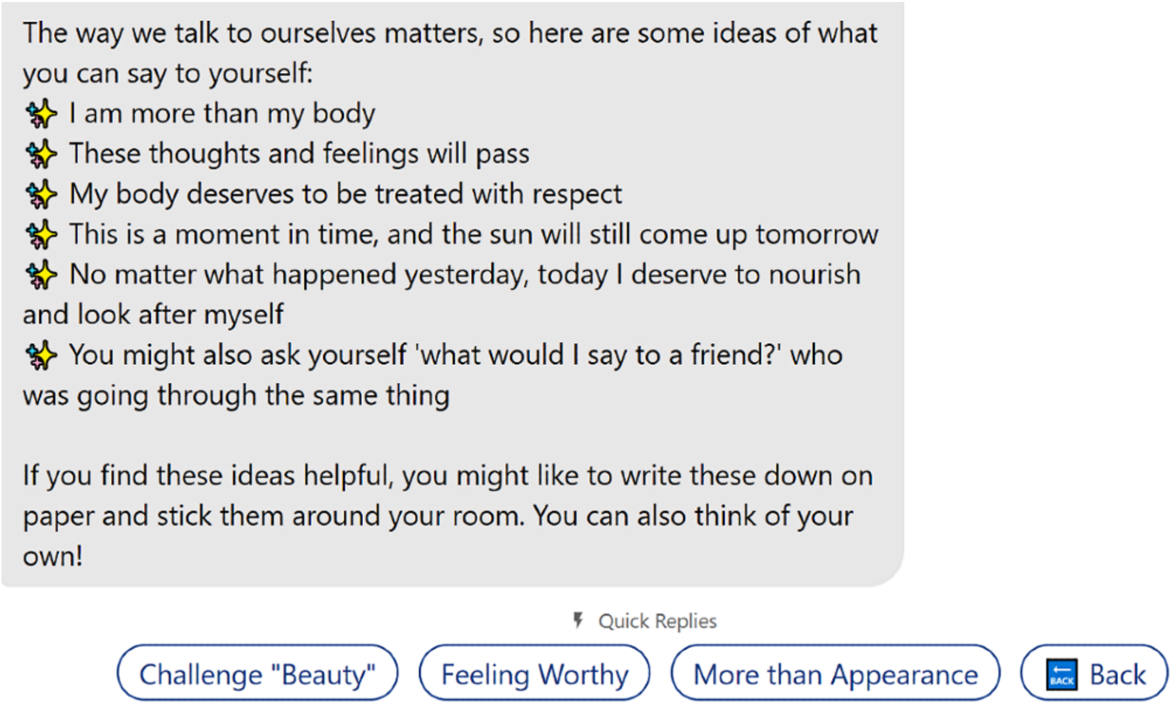
Hello, my name is KIT 👋 I'm a chatbot and I'm here to help! Please click my buttons to have a conversation with me. The team at Butterfly together with researchers from Monash and Swinburne Universities designed me to provide information and support people in getting help with body image issues and eating disorders.

Before we begin, I just wanted to let you know that your conversation with me is not monitored by any counsellors. To speak to the Butterfly Helpline, please click on "Get urgent help now". If there is an emergency, you should call 000 immediately.

First of all, which category do you think best describes you? If you're under 13, please get your parent or another adult to sit with you to continue chatting with me.

For people aged 13 years or above, KIT included psychoeducation conversations regarding body image, eating disorders and body dysmorphic disorders, health impacts, risk and protective factors, how to seek help, and support during the COVID-19 pandemic. The coping skills section covered strategies for managing social media, “busting myths” about food, comparisons and self-perception, challenging beauty ideals, mindfulness, managing difficult thoughts and emotions, body positive self-talk, enjoyable movement, and improving self-worth (Figure 2).

Figure 2. An example of one of KIT's coping skills conversations, "Positive Self-Talk," with prompts to continue the conversation with other skills that also aim to promote positive body image.

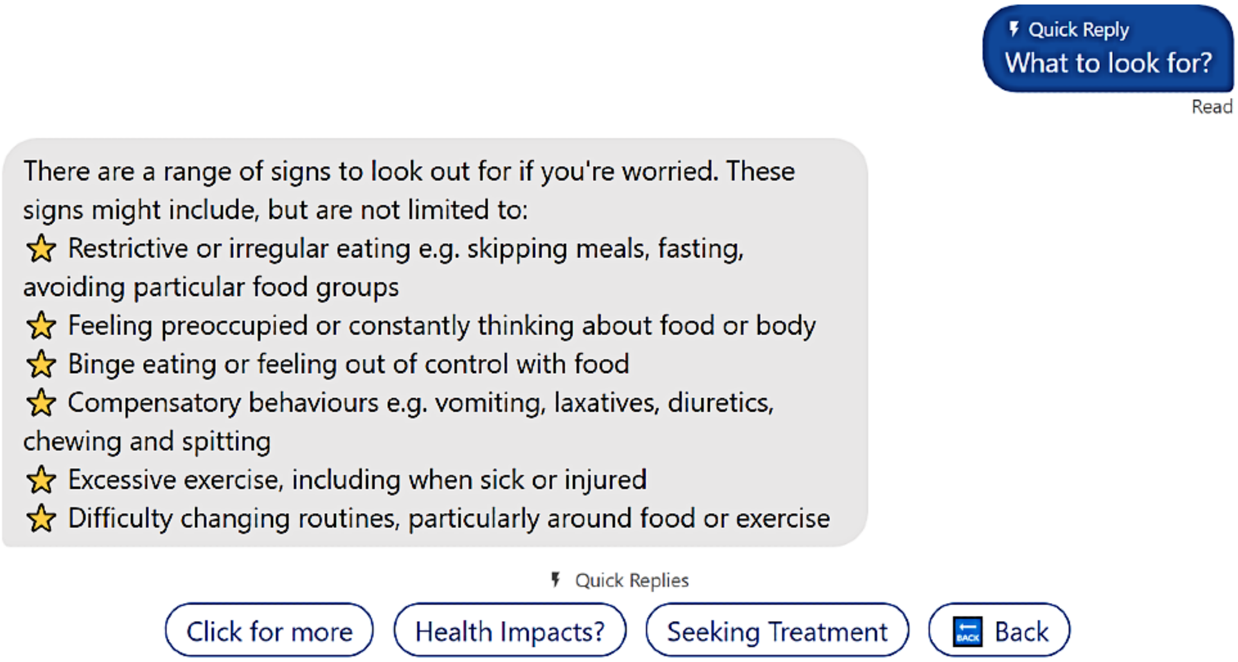


The way we talk to ourselves matters, so here are some ideas of what you can say to yourself:
✨ I am more than my body
✨ These thoughts and feelings will pass
✨ My body deserves to be treated with respect
✨ This is a moment in time, and the sun will still come up tomorrow
✨ No matter what happened yesterday, today I deserve to nourish and look after myself
✨ You might also ask yourself 'what would I say to a friend?' who was going through the same thing

If you find these ideas helpful, you might like to write these down on paper and stick them around your room. You can also think of your own!

The pathway for people seeking to help someone else explored similar psychoeducation conversations, with the addition of further information regarding warning signs and treatment pathways (Figure 3). An additional section was included where users could seek support for themselves, including individual support and information about support groups. For all users, KIT included a "get urgent help now" section that was linked to the Butterfly helpline and other crisis support services.

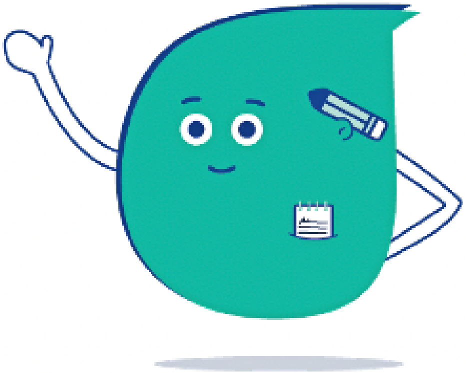
Figure 3. An example of one of KIT's psychoeducation conversations in the "help for another" pathway where the user has asked "What to look out for?" as in eating disorder warning signs. The "Click for more" option provides further warning signs.



There are a range of signs to look out for if you're worried. These signs might include, but are not limited to:
⭐ Restrictive or irregular eating e.g. skipping meals, fasting, avoiding particular food groups
⭐ Feeling preoccupied or constantly thinking about food or body
⭐ Binge eating or feeling out of control with food
⭐ Compensatory behaviours e.g. vomiting, laxatives, diuretics, chewing and spitting
⭐ Excessive exercise, including when sick or injured
⭐ Difficulty changing routines, particularly around food or exercise

To increase the appeal of the chatbot KIT service, a chatbot "character" (Figure 4) was designed by a professional graphic design company, Yoke, in collaboration with the authors and the helpline and communications teams at the Butterfly Foundation. Preliminary online forums were held with young people and parents/carers to inform the feature development of the character prior to the design by the graphic design company.

Figure 4. The main pose for the chatbot character of KIT.



Participants

Online advertisements were placed on Butterfly Foundation social media pages for people living in Australia (aged 13 to 18 years) with lived experience of body image concerns and/or eating disorders, and parents/carers of people with these lived experiences. Potential participants completed an online expression of interest form linked to the advertisement and were then invited (by the author GS or FB) to participate in the online focus group based on availability.

There were two focus groups for parents/carers, which included participants aged 46 to 57 years, with two males and six females, evenly split into groups of four. There were four focus groups for participants with lived experience (aged 13-18 years) seeking help for themselves. In each of these groups, there were four to five participants, with a total of 17 participants. Among these participants, there were five males, 10 females, one gender diverse individual, and one transgender individual. All participants were reimbursed with an Aus $30 (approximately US $23) online gift voucher for their focus group participation.

Data Collection

Semistructured interview questions were used to guide the focus group discussion based on the capacity to gather in-depth descriptive data. The interview guide was developed by the research team. Example questions included “How likely would you be to recommend KIT to someone else?” and “How easily were you able to find the information you were looking for?”. The questions focused on the content, structure, and design of the chatbot, as well as the design of the chatbot character. The use of a semistructured interview allowed the researchers to explore the research questions, while permitting for flexible responses and any follow-up questions.

The focus groups were conducted by the authors GS and FB, who both have doctoral-level training in psychology and practice as clinical psychologists. All focus groups were conducted online via Zoom, over a period of 2 weeks in October 2020. Focus groups lasted from 61 to 86 minutes, with an average of 75 minutes.

Data Analysis

Qualitative data analysis was conducted using thematic analysis, following the guidelines of Braun and Clarke [29]. The audio recordings for all focus groups were transcribed by a professional transcription service, which were read thoroughly multiple times. The data were coded by the author FB based on basic-level content and then grouped into appropriate categories. The themes were developed to capture the key aspects of participants’ responses, which were regularly reviewed by GS.

Ethics

This project was approved by the Monash University Human Research Ethics Committee (MUHREC ID: 22527). All participants provided either written or audio-recorded verbal consent to participate in the focus group and the audio recording of the focus group, with parental/guardian consent recorded for all participants under the age of 18 years.

Results

The results of the qualitative analysis are presented together for both types of focus groups as the overarching themes were identical (chatbot character and design, content presentation, and flow). Quotes for each of the subthemes are presented in Table 1.

Table 1. Themes, subthemes, and quotes from the focus groups.

Themes and subthemes	Quote number	Data extraction
Key theme 1: Chatbot character and design		
Diverse appeal	1	*To me, KIT felt like non-binary, and I know it's like a ridiculous thing, but I felt seen by this little character drawing, and I think that that never happens, so I really appreciate that, especially because gender diverse folks and eating disorders, there's a really high correlation of the two.* [age 17 years, gender diverse, "help for me" group]
Diverse appeal	2	*I like how it's very gender non-specific. It doesn't scream like either male or female or anything like that, it's just very basic, very good, so that appeals to everyone.* [age 17 years, transgender male, "help for me" group]
Diverse appeal	3	*I also like how KIT doesn't have like really a body as much? I think that's a good thing to avoid, triggers and getting to that minefield.* [age 18 years, male, "help for me" group]
Diverse appeal	4	*I love the fact that KIT is essentially just a head with arms coming out so we've taken away any sense that it could be a body and I think that's really important.* [age 51 years, male, "parent/carer" group]
Diverse appeal	5	*I like its expressions and I love that you've incorporated all those in non-gender way, it's fantastic.* [age 53 years, female, "parent/carer" group]
Visual appeal	6	*I think like helpful, problem-solving, like that second expression with the light-bulb, it's like "let's figure something out here." I was going to say helpful, curious, that kind of thing.* [age 18 years, male, "help for me" group]
Visual appeal	7	*I think he looks really kind of positive and cheerful. I think automatically, all of his expressions look really happy would come across to me.* [age 15 years, female, "help for me" group]
Visual appeal	8	*Ten out of ten! Wholesome, very good looking bot. I love it!* [age 17 years, female, "help for me" group]
Visual appeal	9	*I think it's like kind and simple? Like it's uncomplicated and I think that's a really positive thing because often when you're looking for information, it's really full-on and whereas this just looks like "oh this is going to be simple."* [age 53 years, female, "parent/carer" group]
Visual appeal	10	*It's got a cheery disposition so you know, it probably encourages you to at least investigate what's on offer and if you're feeling down or lost, hopefully you can get something positive out of.* [age 54 years, female, "parent/carer" group]
Key theme 2: Content presentation		
Brevity	11	*I feel like there's a lot of information in there and it's all really good information, but it's all kind of piled onto you, and that can be quite overwhelming for some people.* [age 15 years, female, "help for me" group]
Brevity	12	*I definitely think for a chatbot, you want it to be little text things, not full chunks so I think all the information and the content was really good but if you did split it up into smaller bits, that you could click "more" if you wanted to see more. It would make it seem more like an interactive chat.* [age 15 years, female, "help for me" group]
Brevity	13	*Because it's in big chunks of text, it sometimes gets a bit hard to read and I liked the ones where it had emoji dot points.* [age 17 years, transgender male, "help for me" group]
Brevity	14	*I love the way that the information is simplified and then there's the link that goes to the detailed pages, because I remember when you're in that initial teary "mum phase," when you were going straight to those pages, it was just "Whoa!" whereas this is "oh, go here for the more information" and that gives your brain the time to adjust and be ready so I loved that about it.* [age 53 years, female, "parent/carer" group]
Brevity	15	*I think it's important to have the links to allow people to go and look for more information for when you're at that point and ready to seek more, but I think what everyone's saying about the need for it to be more punchy in the speech bubble is probably the key thing. You must want the facts I guess, but you also need to be able to look further if you want additional information.* [age 46 years, female, "parent/carer" group]

Themes and subthemes	Quote number	Data extraction
Tone	16	*It was worded very factually and formally which is good when you're looking at facts, but I think to make it more approachable for people if you used more informal language but obviously still making it accurate information, I think that would make it seem easier to process for people.* [age 15 years, female, "help for me" group]
Tone	17	*If somebody clicks something like you know the bit where it's like, "seeking help for myself," you're like, "I'm really glad that you've reached out to us." Or if somebody clicks a particular button, that's so valid. Here's some resources.* [age 17 years, gender diverse, "help for me" group]
Tone	18	*Even if you had a line that said at the start, "it is not uncommon to feel alone in this." Because that's probably how support people are feeling, however help is available to reduce your isolation and your fears or whatever like that.* [age 54 years, female, "parent/carer" group]
Key theme 3: Flow		
Navigation	19	*I like the idea of just buttons. I think it's just easier to use. Especially because I feel like it's hard to describe it sometimes – what you're feeling and what you want to know about, so having the buttons just makes it easier because you can just look at what you want.* [age 17 years, male, "help for me" group]
Navigation	20	*I do like the idea of having obviously more things come up as you're reading one because then it feels a lot more flowy, as opposed to seeing something going back. It feels like you're having more of a conversation.* [age 17 years, transgender male, "help for me" group]
Navigation	21	*I think a lot of people going on it might not know specifically what they're looking for, so having to type it all out, you might not even know what you want. So I think the buttons are good because it's all laid out there in front of you instead of looking for anything.* [age 15 years, female, "help for me" group]
Navigation	22	*I think the buttons are okay, but I wonder if they can be ordered differently. I guess if you're going into something like this, you're probably looking for more immediate kind of answers and help so as a carer, you're probably looking at the "what should I look out for?"* [age 46 years, female, "parent/carer" group]
Navigation	23	*I found the navigating really easy and the way that it told you what buttons you'd pushed in the history. That's really good.* [age 53 years, female, "parent/carer" group]
Purpose	24	*I think we're just in such a hurry for information so I was looking for a survey that would tell whether my kid is okay or not. I just want to know if he's okay.* [age 55 years, female, "parent/carer" group]
Purpose	25	*I would be giving them step-by-step instructions. This will empower you when you go to the doctor [with your child].* [age 54 years, female, "parent/carer" group]
Purpose	26	*To have something that people can use 24/7 is really important when they can't access any other help or just to get ideas of where to go.* [age 54 years, female, "parent/carer" group]

Key Theme 1: Chatbot Character and Design

Diverse Appeal

Overall, both groups of participants were satisfied with the appearance of KIT, the character, and reported that it would appeal to a wide audience of users. Favorable comments were made regarding the nongender specific design of KIT (quotes 1, 2, and 5) as participants reported this would appeal to users across the gender spectrum. This was noted to be important given the high correlation of eating disorders and body image concerns among gender diverse people [30].

Both groups of participants found the nonhuman design of KIT to be important as it felt safe and unlikely to trigger body image concerns (quotes 3 and 4). The participants in the parent/carer role provided particularly favorable comments regarding the nonhuman design due to multiple concerns raised that young people would compare their appearance to the character. It was expressed that "the less body parts the better" for the chatbot character. There was some discussion regarding the age appropriateness of KIT's character, as both groups reported that it was slightly more targeted toward youth, but overall did not appear too "childish." However, the parents/carers reported that it was more important for the character to appeal to young people and users rather than solely appealing to older users.

The young people in the "help for me" focus groups commented on the importance of including the pictorial character of KIT within the conversation text so it still seemed like they were conversing with "someone," even though they knew this was a nonhuman chatbot. Interspersing images of KIT, the character, within the lengthy written information increased engagement and useability.

Visual Appeal

Both groups were positive regarding the design and style of KIT's character and described KIT as "wholesome," "engaging," "resourceful," and "nonjudgemental" (quotes 6-10). KIT's expressions were reported by both groups to appeal to young people in particular and were perceived as engaging and approachable. Overall, the two groups of participants approved of the color scheme, with the majority of young people perceiving blues and greens as calming colors. When asked to describe their first impressions of KIT, the opinions of both groups were overwhelmingly positive, including "knowledgeable," "inviting," "approachable," "kind," "fun," "professional," and "cheerful." These impressions centered around the idea of KIT as a character who could provide resources and high-quality information, while also appearing friendly and engaging (quote 6).

In addition to the visual design of the character, parent/carer and young participants commented upon the design of the webchat. Of importance to the parents/carers was the design, which was perceived as simple and thus promoting useability, as compared to other mental health resources that can appear "complicated" and "overwhelming." The design of the webchat page was described as "clean and modern," which was reported to be appealing and accessible for both groups of participants.

Key Theme 2: Content Presentation

Brevity

The majority of participants in the two groups regarded the content of the webchat as positive and reported that this would be best presented in smaller sections (than was included in the prototype) to avoid overwhelming the user (quote 11). The preference for brevity was noted by both groups. It was expressed that individuals seeking this information may be feeling stressed and scared, and experiencing a sense of urgency; therefore, "short and sharp" content was reported to be more supportive.

Both groups of participants liked the use of emojis as dot points to enhance readability of the text (quote 13). In addition, the ideas of staggered messages, a "click for more" button and putting the content into multiple message bubbles (quote 12) were also raised to optimize the presentation of the written information within the chatbot. Some participants related this to receiving a long message from a friend and preferring multiple shorter messages instead. The young people and parents/carers reported that breaking up the content into "chunks" would feel more "conversational and interactive." Participants from both groups appreciated the strategy of providing some information with additional resources available via external weblinks (quotes 14 and 15). This format was reported to be more inviting and accessible so users could explore the content at their own pace.

Tone

The interactivity of KIT was discussed in relation to the tone. Most participants from both groups reported that in addition to the factual information KIT presented, KIT could include supportive statements (eg, "I'm really glad that you've reached out to us" [quote 17]), which would provide a more conversational tone as well as normalize any concerns of the user (quote 17). Amongst the younger people in the "seeking help for myself" group, these participants preferred a more casual tone of conversation, while acknowledging it was necessary to present the information accurately (quote 16).

The parent/carer participants reported comments regarding the guided nature of the content, so they could feel reassured by the information, given their own experiences of feeling isolated, scared, and lost, as carers of young people with eating disorders (quote 18). Parents/carers reported that it was important not to "soften" the information, and alternatively present factual and realistic guidance, given the severity and risk of death associated with eating disorders [4]. All participants from both groups agreed that it was important for the content to be presented as factual and accessible, while balancing the supportive tone required.

Key Theme 3: Flow

Navigation

The majority of participants in both groups reported that the button-based navigation was sufficient in navigating the chatbot rather than free text. The younger participants reported this was useful for people who might not know specifically what information or support they require (quotes 19 and 21). The buttons appealed to broader accessibility, with parent/carer and younger participants citing that the buttons would be beneficial for those with language difficulties. The buttons were reported to cover the relevant information, and the navigation was described as simple and straightforward to use (quote 23).

Some participants in both groups expressed that a free text option would be beneficial for more specific questions, but also described frustration at the current level of artificial intelligence technology available in other chatbots whose natural language processing was not sufficiently capable of understanding their typed queries. Generally, the parents/carers expressed a preference for having both button-directed navigation as well as the option to type in specific questions. These participants expressed that individuals using the "help for another" pathway would likely already be concerned about their loved one and would by this point have specific questions to which they would be seeking answers.

Regarding the flow of the chatbot conversation, some parents/carers and younger people suggested having "categories" where a user could flow through these suggested themes or having "next" buttons for relevant sections. Improving the flow of the conversation was considered important to enhance the interactivity of the experience. Some young people reported getting "decision fatigue" when "overwhelmed" with multiple buttons, and reported that merging the sections into categories would be helpful. The main feedback from parents/carers was to change the order of how information was presented in the buttons, as they reported that the immediate questions of "what do I look out for?" and "how can I help my child?" were the most important (quote 22). Both groups of participants appreciated seeing the history of the chat and the ability to scroll back and reread the conversation.

Purpose

One point of difference between the two groups of focus group participants was that the parent/carer group discussed the purpose and capabilities of the chatbot. This included queries around the proposed audience of the chatbot and how it might differ from other available resources. Some participants reported conversing with the chatbot with a specific question in mind, such as “Should I be worried about my child?” or “Where can I find a psychologist?” (quote 24). The researchers provided feedback regarding the ethical and practical limitations of the chatbot, with the purpose focused on providing psychoeducation and “in the moment” coping skills. It was apparent that the younger users were more familiar with the purpose and limitations of such technology, whereas the parents/carers presented different expectations regarding the specificity of their requests (quote 25). Both groups of participants praised the 24/7 availability of the chatbot as a major strength, particularly when other body image and eating disorder–focused supports are not available 24/7 (quote 26). In summary, the parents/carers reported that the chatbot would likely be a useful resource, and acknowledging the capabilities and limitations of the technology from the start of the conversation with KIT would be helpful to manage user expectations.

Discussion

Principal Findings

The aim of this study was to explore the preliminary acceptability and feasibility of a world-first chatbot designed to support people experiencing body image and eating concerns, and parents/carers. The qualitative results from the focus groups illustrated three main themes as follows: chatbot character and design, content presentation, and flow. Across these themes, both people seeking help for themselves and parents/carers generally provided positive feedback. The chatbot was praised for its clean design, ease of navigation, and engaging character. Both the groups approved of the gender nonconforming and nonhuman design of KIT, which was believed to improve the accessibility of the chatbot and help diverse users feel safe. Most participants approved of KIT’s facial expressions and found the character approachable, resourceful, and calming.

Most participants reported the content was appropriate, accessible, and helpful. To improve the chatbot, both audiences recommended presenting the amount of information differently, with a preference for “short and sharp” content. This preference for brevity was balanced by implementing a supportive tone and using opportunities to normalize concerns as well as provide information.

The participants seeking help for themselves preferred the navigational style using buttons, whereas the parents/carers requested the option to type specific queries as well as be guided through the content via buttons. This difference in preferences likely reflected the different mindsets these two audiences expressed. The young people preferred to be guided with the options laid out, whereas parents/carers often had specific queries and concerns. Overall, the participants expressed positive feedback regarding the body image chatbot, and specific recommendations were implemented in the development of KIT as per iterative agile methodology [31].

Comparison With Prior Work

To our knowledge, this is the first chatbot designed to specifically target body image and eating concerns, with the majority of other digital mental health interventions focused on mood and anxiety disorders [24]. In addition, reports specifically addressing the development and design of chatbots in the field of mental health are rare [21,32]. However, our study found that users valued the chatbot’s useability, quality of content, and engagement, which was similar to previous research [33].

One area of divergence from the existing literature was related to the subtheme of brevity. A systematic review of mental health chatbots illustrated that most participants perceived conversations as too short or shallow [33]. However, in this study, participants reported a preference for shorter information. It is possible this difference reflects KIT’s strong focus on psychoeducational information, but nevertheless highlights the necessity of providing users with appropriate length responses for their needs.

Within the literature, the empathy of nonhuman agents has received much research attention, with evidence indicating the importance of the development of therapeutic bonds [20,34,35]. While there were recommendations to increase the interactivity of KIT within conversations, the use of a pictorial character within conversation text appeared to be a useful “shortcut” for building rapport with users.

Future research with larger sample sizes is required regarding the use and efficacy of KIT, which will provide user feedback and allow for further refinements of KIT’s content. After such evaluations, KIT can be more easily compared with other pre-existing and well-established mental health chatbots such as Woebot and Wysa [13,34,36]. With KIT’s focus on delivery of coping skills, particularly based on CBT, KIT is in line with chatbots like Woebot and Wysa, but has the unique focus of body image and eating issues compared to anxiety and depression [24].

Strengths and Limitations

The main strength of this study was the diverse recruitment of participants for the focus groups, which strongly benefitted the co-design process of KIT. Both the parent/carer and young people groups included individuals from all regions of Australia owing to the online format. In the young people group, care was taken to include participants across the gender spectrum, including transgender and gender diverse individuals. This process included ensuring there was a mix of genders in each focus group. The majority of participants were female, which is reflective of the higher prevalence of eating disorders among women and girls. The study was limited by a smaller sample size. Furthermore, the sample was diverse in all but one demographic feature, which was ethnicity, with most participants identifying as Caucasian.

Given that participants were recruited through online advertising, bias is inherent in those who can access and respond to research advertisements. In addition, a small percentage of participants had previously been involved in preliminary online co-design forums for KIT, which may have influenced their opinions and feedback in the subsequent focus groups. Social desirability may have also influenced the feedback provided by participants, as the authors were conducting the focus groups. However, the authors strongly encouraged honest responses, and a range of positive, negative, and neutral comments were made by participants.

Conclusions

Our study findings provide preliminary support for the acceptability and feasibility of KIT, the body image chatbot. The results showed overall positive feedback regarding the content, structure, and design of the body image chatbot, from both groups of participants in the "seeking help for myself" and "seeking help for another" pathways. The participants' recommendations and feedback were used to refine KIT prior to public launch in order to improve the layout, content, and navigation of the chatbot. If proven effective, KIT would likely provide a valuable resource of psychoeducation and coping skills by meeting young people where they spend their time (online) and those who might not feel ready to follow traditional formats of seeking help. KIT may assist in filling the gaps in service delivery in terms of both prevention and intervention by supporting people and those concerned about them, with appealing and accessible evidence-based psychoeducation and skills.

Acknowledgments

The authors would like to thank the focus group participants for their valuable participation and for sharing their lived experience, and Dr Sally Bradford for her invaluable support in the earliest stages of this project. The authors would also like to thank Dr Sarah Rotstein and Marcia Scott for their creative support. The development of KIT was a collaboration with the Butterfly Foundation (Melissa Wilton, Belinda Kerslake, Juliette Thomson, Alex Cowen, and Michaela Del Casale), chatbot production company Proxima (Sebastian Pedavoli, Dan Nolan, and Roshni Roy), and graphic design team Yoke (Sarah Lawrey, Ryan Nadzielski, and Krysa Allison). GS was the recipient of an AMP Tomorrow Maker Grant to fund this project and holds a National Health and Medical Research Council (NHMRC) Early Career Fellowship (GNT1146033). SLR holds a Senior NHMRC Fellowship (GNT1154651).

Abstract

Background: Obesity is a global public health challenge, and there is a need for more evidence-based self-management programs that support longer-term, sustained weight loss.

Objective: This study used data from the Commonwealth Scientific and Industrial Research Organisation (CSIRO) Total Wellbeing Diet Online program to determine the reach and weight loss results over its first 5 years.

Methods: Participants were adults who joined the commercial weight loss program of their own volition between October 2014 and September 2019 (N=61,164). Information collected included year of birth, sex, height, weight, and usage data (eg, entries into the food diary, views of the menu, and program content). Weight loss and percentage of starting body weight lost were calculated. Members were divided into 2 groups for analysis: “stayers” were members who signed up for at least 12 weeks of the program and recorded a weight entry at baseline and at the end of the program, while “starters” began the program but did not record a weight after 12 weeks. Descriptive statistics and multiple linear regression were used to describe weight loss and determine the member and program characteristics associated with weight loss.

Results: Data were available from 59,686 members for analysis. Members were predominately female (48,979/59,686, 82.06%) with an average age of 50 years (SD 12.6). The average starting weight was 90.2 kg (SD 19.7), and over half of all members (34,195/59,688, 57.29%) were classified as obese. At week 12, 94.56% (56,438/59,686) of the members had a paid program membership, which decreased to 41.48% (24,756/59,686) at 24 weeks. At week 12, 52.03% (29,115/55,958) of the remaining members were actively using the platform, and by week 24, 26.59% (14,880/55,958) were using the platform. The average weight loss for all members was 2.8 kg or 3.1% of their starting body weight. Stayers lost 4.9 kg (5.3% of starting body weight) compared to starters, who lost 1.6 kg (1.7% of starting body weight). Almost half (11,082/22,658, 48.91%) the members who stayed on the program lost 5% or more of their starting body weight, and 15.48% (3507/22,658) achieved a weight loss of 10% or more. Of the members who were classified as class 1 obese when they joined the program, 41.39% (3065/7405) who stayed on the program were no longer classified as obese at the end, and across all categories of obesity, 24% (3180/13,319) were no longer classified as obese at the end of the program. Based on multiple linear regression, platform usage was the strongest predictor of weight loss (β=.263; P<.001), with higher usage associated with greater weight loss.

Conclusions: This comprehensive evaluation of a commercial, online weight loss program showed that it was effective for weight loss, particularly for members who finished the program and were active in using the platform and tools provided. If the results demonstrated here can be achieved at an even greater scale, the potential social and economic benefits will be extremely significant.

Introduction

Background

Obesity is a global public health challenge, with significant social and economic impacts. In Australia, two-thirds of adults are classified as overweight or obese [1], and this is expected to increase to more than three-quarters of the adult population by 2030 [2]. The costs to the Australian economy attributable to overweight status and obesity were estimated to be A $8.6 billion between 2011 and 2012 [1]. There is growing recognition that nutrition plays a crucial role in the etiology of chronic diseases and that chronic diseases such as type 2 diabetes can also be reversed by diet and lifestyle interventions [3]. With most adults struggling to control their weight, there is a need for more evidence-based self-management programs that support healthy diet and lifestyle patterns to promote longer-term, sustained weight loss [4].

In 2020, commercial weight loss services in Australia were estimated to be worth A $452 million [5]. Although there are several programs with a variety of dietary patterns, multiple literature reviews have concluded that weight loss results across programs are similar and that the vast majority produce only small to moderate effects which are not maintained in the longer term [6-8]. Reviews of branded and commercial programs have been primarily based on randomized controlled trials (RCTs) and suggest individuals who complete these programs can achieve significant weight loss [8]. However, in evaluations undertaken through longitudinal follow-up of participants, only a small proportion of the original number of individuals are included [9,10]; therefore, the findings are unlikely to be representative of the full participant population.

Web-Based Delivery of Weight Loss Programs

In an attempt to increase the accessibility and success of commercial weight loss programs, a number of web-based programs have been developed. One early meta-analysis suggested that web-based interventions achieved similar weight loss to controls but that those with enhanced features could achieve greater weight loss than those providing education alone [11]. Some but not all more recent reviews suggest that web-based programs can be more successful than alternate delivery approaches, but the effect sizes are small, and the heterogeneity in study designs makes it difficult to determine the key elements driving weight loss [12-15].

Programs delivered online are growing in popularity and account for 17% of the market share for the diet industry [5]. Commercial programs that have traditionally relied on face-to-face group sessions have now shifted their focus to primarily digital delivery. An early review suggested that self-directed, online commercial programs were suboptimal [16], but since then, more advanced features have improved the offerings in the market, with associated RCTs suggesting moderate effects for weight loss. For example, one RCT that included 309 people on the 12-week Biggest Loser Club program reported weight losses of 2.0-3.2 kg compared to 0.5 kg in a wait-listed control group [17]. More recently, an evaluation of participants receiving the Weight Watchers Online program reported a 2.7 kg weight loss relative to a 1.3 kg loss in a control group receiving only a newsletter [18]. However, in a US study, participants on an eDiets program lost less weight over a 1-year period than did those receiving a comprehensive information manual (1.1% vs 4.0% of starting body weight, respectively). It should be noted that this evaluation was small and included only 47 participants in total [19]. Thus, based on the data from existing RCTs, it appears that online commercial weight loss programs can be successful. However, less has been published about how these programs may work in everyday contexts [16] where attrition is likely to be significant, especially when users are self-directed and incurring possible program costs.

In late 2014, the Commonwealth Scientific and Industrial Research Organisation (CSIRO) and Digital Wellness launched a commercial, online version of the CSIRO Total Wellbeing Diet. The dietary components were developed through clinical trials [20-23] and were initially translated into a series of popular books [24], estimated to have delivered weight loss benefits to 290,700 Australians, with an average weight loss of 5.7 kg [25]. The online format delivered the same program as the books did but through a digital platform, allowing for several enhancements, including personalized eating plans, customized weekly meal plans, food and exercise diaries, the ability to record and see progress of weight loss, a member forum, and supportive correspondence via email. Our study analyzed the data from the CSIRO Total Wellbeing Diet Online program in the first 5 years after it launched to determine the program’s reach and weight loss results over this period and to investigate the key determinants of weight loss success. Specifically, we aimed to determine average weight loss and its relationship to the duration of membership, features of the platform that members used most, and the member and usage characteristics that were associated with greater weight loss.

Methods

Study Design and Participants

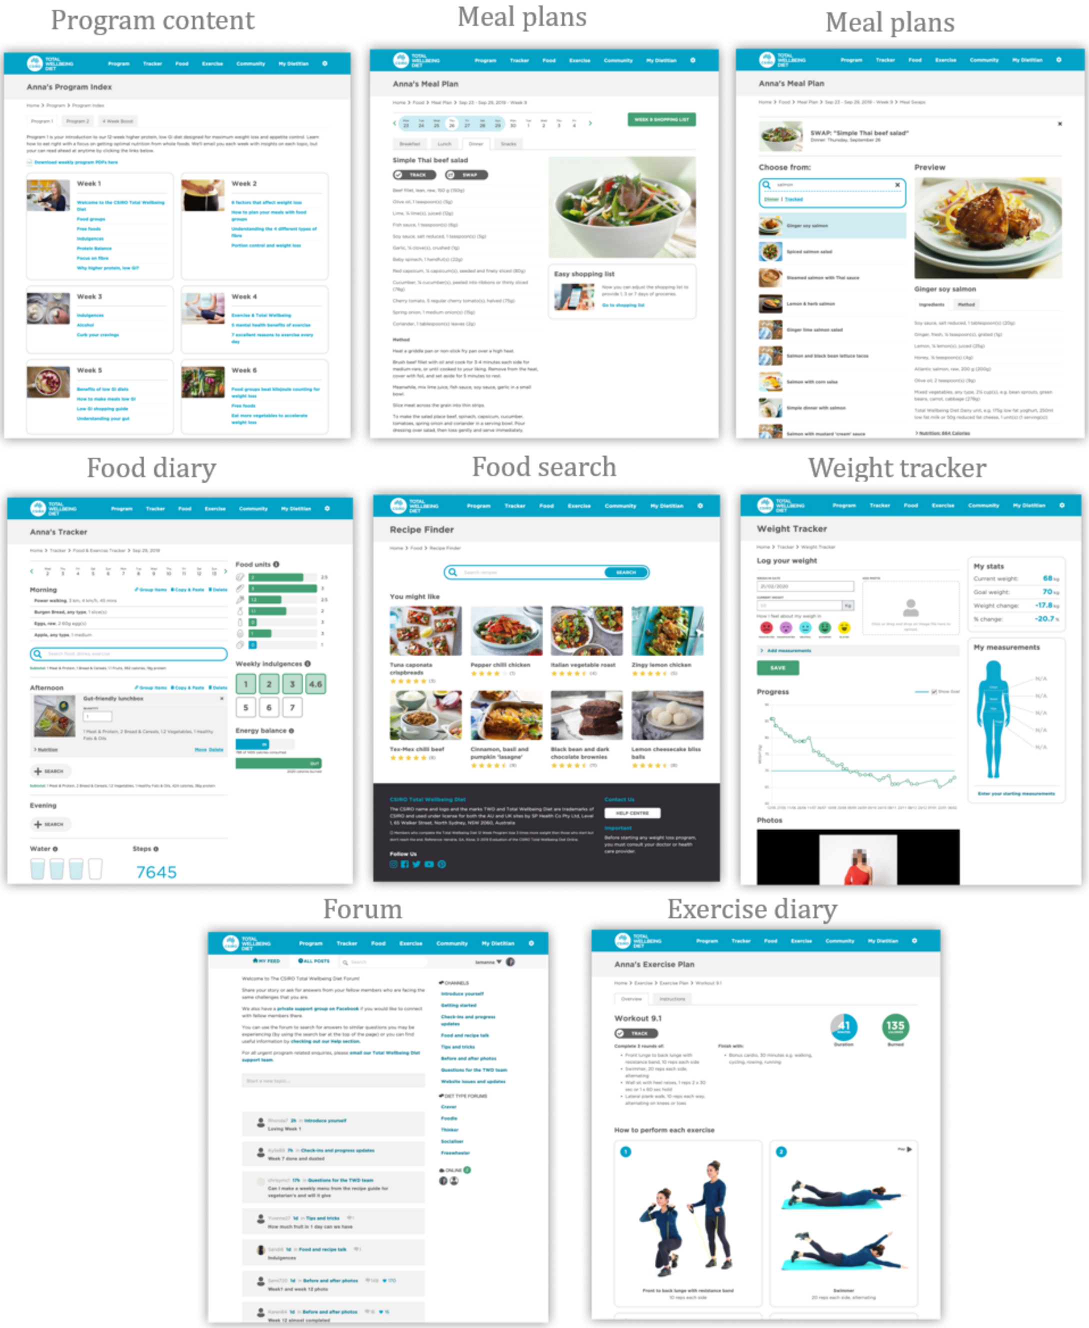
Participants were individuals aged ≥18 years who joined the CSIRO Total Wellbeing Diet Online of their own volition between October 2014 and September 2019 (N=61,164; referred to as “members”). In the registration and setup processes, individuals younger than 18 years or who had a BMI that placed them in the underweight category (BMI <18.5 kg/m^2) were automatically excluded. The participants who were removed from this analysis were as follows: pseudomembers (ie, platform testers or affiliated staff), those whose membership was paid for by their employer because their motivations might have been different to those who signed up and paid for their membership voluntarily, members living outside of Australia because the context in which they were following the program was different and the menu plans were not optimized for seasonal or local produce, and members without a paid subscription. These combined exclusions resulted in 1478 records being removed (1478/61,164; 2.4% of the available data).

Intervention

The CSIRO Total Wellbeing Diet Online [26] is a 12-week higher-protein, lower–glycemic index, commercial weight loss program managed by Digital Wellness and available to individuals at a cost of A $199 for the first 12 weeks. The user registration process collects information on year of birth, sex, physical activity levels, and weight loss goals to tailor eating and exercise plans. Individuals are assigned to 1 of 3 kilojoule bands depending on their starting weight (6000, 7000, or 8000 kJ/day). The diet is structured around 3 meals (breakfast, lunch, and dinner) and 2 snacks each day through use of a food group system where portions of food are presented as standard units for each food group. There are 7 food groups: fruit, vegetables, meat and alternatives, breads and cereals, dairy, healthy fats and oils, and indulgences. Meals are designed around a template of standard units, which ensures daily allowances of food groups are met and provides optimal nutrition and energy to promote weight loss. Daily and weekly meal plans can be customized by swapping meals using the recipe database.

The online platform is a fully responsive web app with an interface that is optimized for viewing on a desktop and on mobile devices. The platform features are designed to support individuals throughout the program (Figure 1). Program content provides general information, nutrition advice, weekly tutorials available for viewing at any time, and some content sent out to members in a weekly email. The meal plans provide individuals with meals and snacks planned for the day or week ahead. The food diary can be used to log meals and snacks consumed, either by entering prepopulated recipes from the meal plan or recipe database, or by entering individual foods from a comprehensive food database. The food search function allows members to search through the food database for individual foods or recipes and view information about their composition and food units. The food tracker tallies the food units and total energy consumed over the day. The exercise diary is where completed exercises can be logged or where activities chosen from a database of different exercise types and intensities can be recorded. Members receive weekly emails on their nominated weigh-in day to remind them to weigh themselves and record their weight into the weight tracker. Progress data are presented in a graph and table form. The platform also has a forum for members to share their stories or discuss relevant issues with other members.

Figure 1. Screenshots of the features of the CSIRO Total Wellbeing Diet Online platform.



Data Collection and Study Outcomes

Digital Wellness manages the collection and storage of data, including registration details and all user activity and interactions with the platform. In addition to information collected at registration, individuals' body measurements, such as height, weight, and waist circumference, are also collected. Other data collected included program details (eg, paid membership duration) and platform usage data, including entries into the food diary, views of the menu plans, views of exercise plans, views of program content information, forum visits, searches of the food database, and weight entries. These data were provided to the research team in a deidentified format with each individual member assigned a unique identifier. As part of registration, participants agreed to their data being used for research purposes; therefore, no direct participant consent was sought. Ethics approval to conduct this research was received from the CSIRO Health and Medical Human Research Ethics Committee (approval #2019_090_LR).

Weight loss was calculated as the difference in kilograms between the last and first weight entered into the platform, with a larger number representing greater weight loss. Weight loss was also calculated as a percentage of starting body weight and was categorized into 4 groups: weight gain (greater than 0% difference), a weight loss of over 0% and less than 5% of starting body weight, 5% to less than 10% of starting body weight, and greater than or equal to 10% of starting body weight lost.

The date of program setup and total duration of paid membership were used to calculate the number of participants remaining in the program within the first 24 weeks from registration. Once paid membership duration lapsed, a member was considered to have left the program (dropped out of the program). Platform usage attrition within the first 24 weeks from registration was also determined by calculating the difference in days between the date of last user activity and the date of the program setup.

Platform usage was considered to be any logged activity and was assessed as usage of each of the 7 features and as overall usage (all features combined). Platform usage was described in 3 ways: “total days active” referred to the number of unique days a member used the platform irrespective of whether usage occurred multiple times per day, “percent active days” was calculated as total days active divided by the number of days of membership expressed as a percentage, and “activity per day” was calculated as the total user activity divided by the number of days of membership. Levels of platform usage were then calculated by creating quintiles (5 groups) based on activity per day, where quintile 1 represented the lowest platform activity and quintile 5 the highest platform activity. There was a small group of participants with very high use, and thus the creation of quintiles helped to manage this skewness.

Statistical Analysis

All data were inspected for invalid records through a systematic and previously used data cleaning process based on erroneous height (less than 1 m or greater than 3 m) or weight values (less than 13 kg or greater than 250 kg), and extreme BMI values (less than 13 kg/m^2 or greater than 97 kg/m^2). Members were removed from analysis if a total weight loss could not be calculated (n=1451) due to no starting weight reported or only a single weight entry being made. Members were also removed from analysis if their weight value was the contributing factor to an invalid BMI (n=14) or if age at registration was calculated from entered data as less than 18 years or above 100 years of age (n=7). In addition, there were 6 pseudomembers removed from analysis. After these exclusions, 59,686 members were included in this analysis (59,686/61,164, 97.58% of all members).

Members were divided into 2 groups for analysis: “stayers” were defined as members who signed up to at least 12 weeks of the program and entered their weight into the platform at baseline and at the end of the program. This was calculated as members with a paid membership equal to or greater than 84 days (12-week program duration) and for whom days between their first and last entered weight were equal to or greater than 77 days (plus or minus 1 week for first or last weigh-in). There were 22,658 members who were categorized as stayers, and the average time between first and last weigh-in was 268 days. Starters were defined as members who started the program and had some level of engagement with the platform but did not enter a weight at the end of the 12-week program. By definition, starters had a shorter duration of paid membership or a last-entered weight that was before 77 days after baseline. There were 37,028 members who were categorized as starters with an average of 23 days between the first and last weigh-in.

The average (and SD) weight loss and percentage weight loss were calculated at a group level for all members and by subgroups of interest. These subgroups included those of sex, age (19-30 years, 31-50 years, 51-70 years, and 70 years and over), starting BMI category (normal weight, overweight, obese class 1, obese class 2, and obese class 3), and socioeconomic status according to quintiles of Socio-Economic Indexes for Areas (SEIFA), where a lower quintile represents a greater disadvantage [27]. Differences in weight loss, percentage weight loss, and platform usage were examined between subgroups of members, with significance being tested by 1-way analysis of variance (ANOVA).

Multiple linear regression was used to assess which member characteristics (sex, age, SEIFA quintile, starting BMI) or program characteristics (membership length, activity per day) were the strongest predictors of weight loss. The primary analysis used the last weight entered into the platform (ie, the last observation carried forward). The models were run to predict total weight loss on the program (using total weight loss in kilograms and as a percentage of starting body weight). Member and program characteristics (predictors) were added to the model simultaneously. A secondary sensitivity analysis was conducted to determine the robustness of the primary results with baseline weight carried forward being used when participants did not have a weight value available in the platform at 12 weeks or beyond. The regression models were run for all members and by subgroup for starters and stayers separately. The significant predictors of weight loss were similar to those used for total weight loss and percentage of body weight lost; therefore, only the regression results for all members predicting percentage of body weight lost are presented. Statistical analyses were performed using SPSS Statistics 25 (IBM Corp).

Results

Characteristics of Members

Members who signed up to the program were predominately female (48,979/59,686; 82.06%) with an average age of 50 years (SD 12.6). Overall, 40.16% (23,969/59,686) of members were aged between 31-50 years, and 48.70% (29,068/59,686) were between 51-70 years (Table 1). The average starting weight of members when they joined the program was 90.2 kg (SD 19.7), the average BMI was 32.2 (SD 6.3; Table S1, Multimedia Appendix 1), and over half of all members were classified as obese (34,195/59,686, 57.29%). More specifically, 30.75% (18,353/59,686) of members were classified as class 1 obese, 16.11% (9613/59,686) as class 2, and 10.44% (6229/59,686) as class 3, the highest risk group (Table 1). Men were heavier than women (104.9 kg vs 87.0 kg, respectively), but the starting BMI of men and women was similar (32.8 vs 32.0, respectively; Table S1, Multimedia Appendix 1).

Members resided in all states of Australia (data not shown). One-quarter (15,005/59,686, 25.14%) of members lived in areas classified in the lowest 2 quintiles of disadvantage (most disadvantaged), and 32.84% (19,598/59,686) lived in areas classified as the least disadvantaged (Table 1). Members living in the most disadvantaged areas were heavier (94.1 kg vs 87.7 kg) and had a higher BMI (33.9 vs 31.1) compared to those in the least disadvantaged areas (Table S1, Multimedia Appendix 1).

Table 1. Demographic characteristics of starters (n=37,028), stayers (n=22,658), and all members (N=59,686) at the time of joining the CSIRO Total Wellbeing Diet Online.

Member characteristics	Starters, n (%)	Stayers, n (%)	All members, n (%)
Sex			
Male	6204 (16.75)	4503 (19.87)	10,707 (17.94)

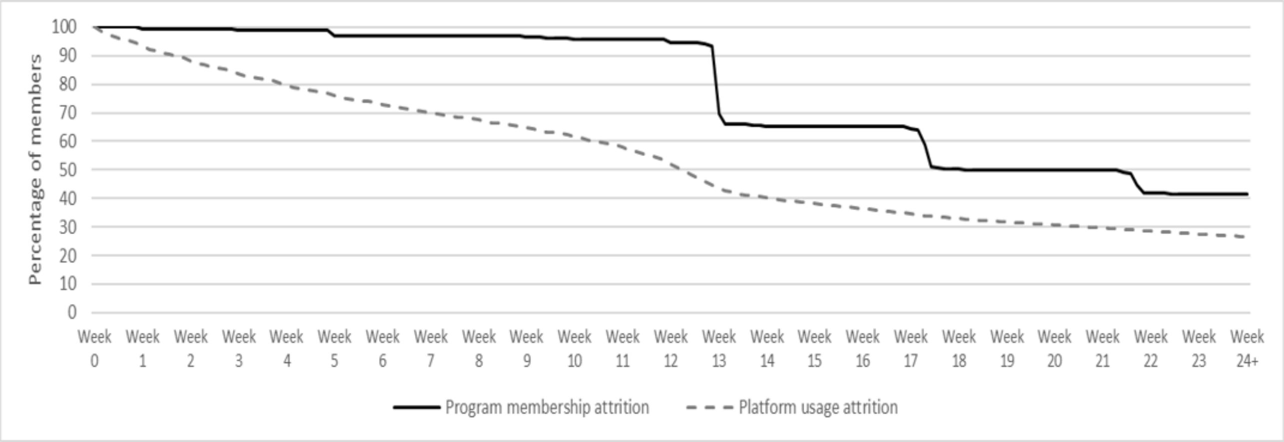
Unknown	530 (1.43)	210 (0.93)	740 (1.24)

Membership and Platform Attrition

The percentage of members with paid membership and active platform usage declined gradually over the first 24 weeks (Figure 2). At week 12, 94.56% (56,438/59,686) of members had a paid membership, and at week 13, this decreased to 69.65% (41,573/59,686) of members. By week 14, 65.34% (39,000/59,686) of the original membership base had a paid membership, which continued to decrease to 41.48% (24,756/59,686) of members at 24 weeks. In terms of platform usage, 83.80% (46,893/55,958) of members were using the platform (that is any logged data recorded) after 3 weeks, 52.03% (29,115/55,958) of remaining members were using the platform at week 12, and 26.59% (14,880/55,958) of those remaining were still using the platform by week 24 (Figure 2).

Figure 2. Program membership and platform usage attrition over 24 weeks for members of the CSIRO Total Wellbeing Diet Online (n=59,686).



Weight Loss

The primary analysis using last observation carried forward indicated an average weight loss for all members of 2.8 kg or 3.1% of starting body weight. Stayers lost an average of 4.9 kg (5.3% of starting body weight) compared to starters, who lost an average of 1.6 kg (1.7% of starting body weight). The starting BMI of members classified as starters and stayers was similar to that at the start of the program. Stayers who were classified as overweight when they joined the program lost 4.9% of their starting body weight, compared to 5.5% for those classified as class 1 obese, 5.6% as class 2, and 5.9% as class 3. Stayers living in the most disadvantaged areas lost 5.8% of their starting body weight compared to 4.9% for those in areas of least disadvantage (Table 2).

Overall, 24.37% (14,546/59,686) of all members achieved a weight loss of 5% or more of their starting body weight. Almost half (11,082/22,658, 48.91%) of the stayers lost 5% or more of their starting body weight compared to 9.36% (3464/37,028) of starters (Table 3). Among stayers, 33.43% (7575/22,658) achieved a weight loss of 5% to <10%, and 15.48% (3507/22,658) achieved a weight loss of 10% or more of their starting body weight. The proportion of members losing >10% of their starting weight was highest for males (lost 10% or more of their starting body weight: 1012/4503, 22.47%), members classified as class 3 obese at baseline (445/2263, 19.66%), and those living in the most disadvantaged areas (409/2322, 17.61%; Table 3).

Table 4 shows the weight status of members at the time they joined and at the end of the program. Overall, 14.27% (2701/18,930) of all members who were classified as overweight when they joined the program had achieved normal weight by the end. Among stayers, this proportion was 24.59% (1911/7770). Across all levels of obesity, 24% (3180/13,319) of stayers who were classified as obese when they joined the program were no longer classified as obese at the end. More specifically, among stayers who were classified as class 1 obese at baseline, 41.39% (3065/7405) had shifted to a lower weight status category at the end of the program (ie, overweight or normal weight). In addition, 47.86% (1748/3652) and 36.78% (832/2262) of stayers who were classified as class 2 and 3, respectively, achieved a lower weight status at the end of the program.

Table 2. Weight loss in kilograms and percentage of body weighta in starters (n=37,028), stayers (n=22,658), and all members (n=59,686) on the CSIRO Total Wellbeing Diet Online.

Member characteristics	Starters, mean (SD)		Stayers, mean (SD)		All members, mean (SD)	
	Weight loss (kg)	% body weight	Weight loss (kg)	% body weight	Weight loss (kg)	% body weight
Total	1.60 (3.51)	1.73 (3.36)	4.87 (5.60)	5.25 (5.56)	2.84 (4.69)	3.07 (4.65)

Platform Usage

Overall members used the platform on 29.8% of their membership days, and this was higher in stayers than starters (46.5% vs 19.6%, respectively). The most commonly used platform features were the weigh-in (used by all members), food diary (52,828/59,686, 88.51% of members), and menu plans (51,718/59,686, 86.65% of members). The total number of days (irrespective of membership length) members were active on the features was highest for the food diary (15.10 days), menu plans (13.17 days), and weigh-in feature (12.27 days), but activity per day of membership was highest for the food diary and menu plan (used approximately 2 out of every 3 days; Table 5).

The usage per day of membership was higher in stayers for all features. On average, stayers used the menu plans and food diary once per day, while starters used these less than once every 2 days. Stayers used the weigh-in once per week, while starters used this feature less than once every fortnight (Table 5).

Table 5. Platform feature usage for starters (n=37,028), stayers (n=22,658) and all members (n=59,686) of the CSIRO Total Wellbeing Diet Online.

Food search	20,914 (35.04)	1.50 (5.99)	0.89 (3.12)	0.05 (0.40)

[a] Percentage of the sample who used the platform or feature at any time during their membership.

[b] Total days active refers to the number of unique days a member used the platform irrespective of whether usage occurred multiple times per day.

[c] Percent active days was calculated as total days active divided by number of days of membership expressed as a percentage.

[d] Activity per day was calculated as the total user activity divided by the number of days of membership.

Weight Loss Across Levels of Platform Usage

Table 6 shows the average weight loss by levels of platform usage. High usage was characterized as viewing the menu plans 2-3 times per day, making 2 food diary entries per day, searching for foods once per week, recording a weight about once per week, and viewing the exercise plans and the forum a little less than once per week. Weight loss in kilograms and percentage body weight increased with increasing levels of platform usage. Overall, members with the highest usage lost 5.3% of their starting body weight compared to 0.9% for those with the lowest usage. Stayers who used the platform most lost 6.6% of their starting body weight compared to 3.0% for those with the lowest usage. Among stayers, 1 in 5 in the highest category of usage lost 10% or more of their starting body weight and 2 in 5 lost 5%-<10% of their starting body weight.

Table 6. Weight loss by level of platform usage for starters (n=37,028), stayers (n=22,658), and all members (N=59,686) in the CSIRO Total Wellbeing Diet Online.

[a] Average weight loss in kilograms and percentage of starting body weight were calculated using last observation carried forward.

[b] Proportion of the sample within each category of weight loss: weight gain, 0 to less than 5% of starting body weight lost, 5% to less than 10% of starting body weight lost, and greater than or equal to 10% of starting body weight lost.

Predictors of Weight Loss

On the basis of multiple linear regression, member characteristics (sex, age, socioeconomic status, starting BMI) and program characteristics (duration of membership and usage of the platform per day) accounted for 29.4% of the variance associated with the percentage total weight loss ($F_{6,58434}$=920.01; *P*<.001). All predictors were significant, with platform usage being the strongest predictor of weight loss (β=.263; *P*<.001) and higher usage per day being associated with greater weight loss. Sex (β=–.086; *P*<.001) and starting BMI (β=.062; *P*<.001) were the next 2 strongest predictors of percentage body weight lost, with men and those with a higher starting BMI losing more weight.

Sensitivity Analysis

Starters, by definition, did not have a weight entered into the platform at 12 weeks or more; therefore, we used baseline observation to carry forward their assumed weight loss to zero. The average weight loss for stayers was 4.9 kg. Using the baseline-observation-carried-forward approach, we assumed the average weight loss for all members was 1.8 kg. Multiple linear regression showed similar results to those of the primary analysis. The model accounted for 31.5% of the variance associated with percentage total weight loss, and platform usage was the strongest predictor of weight loss (β=.272; *P*<.001).

Discussion

Principal Results

This study examined the data generated through the CSIRO Total Wellbeing Diet Online, a commercial weight loss program, to determine its reach and effectiveness over its first 5 years of use. This analysis included usage data from almost all (59,686/61,164, 97.58%) of the individuals who had signed up between October 2014 to September 2019. The results indicated that the average weight loss across all members was 3.1% of their starting body weight but was considerably higher (5.3% of starting body weight) in the 22,658 members who completed the full 12-week program or more (37.96% of all members analyzed). This magnitude of weight loss was consistent with similar programs [17,19] and greater than that reported for some other web-based commercial programs [10]. However, it was less than that of commercial programs that use a more intensive, one-to-one consultation model [28].

Our finding that almost 1 in 2 members who completed the CSIRO Total Wellbeing Diet Online program lost 5% or more of their starting body weight has considerable public health relevance, as a loss of 5% of body weight is considered clinically significant in relation to reductions in risk of comorbidities [29]. This result is also similar to the findings of a 6-month German-based commercial weight loss program, although the evaluation of this program used a much smaller sample (N=479) [30]. Furthermore, overweight and obese status are related to the development of several chronic conditions, which place a huge burden on the health care system [1]. This study was also able to demonstrate that about 40% of members with obesity who stayed on the program were able to shift down a weight status category, with about 24% no longer classified as obese when they finished the program. Moreover, approximately 25% who were classified as overweight at the start of the program achieved a normal weight at the completion of the program. The increased risk of morbidity and mortality from many chronic conditions means programs that can shift people out of the higher-risk, obese weight status category can confer significant potential gains in health and quality of life for these individuals [31]. If the results demonstrated here can be achieved at an even greater scale, the potential social and economic benefits will be extremely significant.

One of the most important findings from this study was that members who were living in the most disadvantaged areas were one of the most successful groups on the program based on percentage of total weight loss. About 10% of members were living in areas considered to be among the most disadvantaged in Australia, and their average weight loss was 5.8% of starting body weight, and about 53% lost 5% percent or more of their starting body weight. Although this may be partly attributable to the higher starting BMI in this group, it is nevertheless an encouraging finding given that individuals of lower socioeconomic status are at increased risk of weight gain and obesity [32,33] but tend to have lower rates of uptake and completion of weight loss programs [34]. There are many unique challenges that have been cited for disadvantaged groups, including literacy, insufficient time, and lack of motivation [32]. It has also been suggested that individuals with lower income are less likely to recognize their unhealthy weight and therefore less likely to attempt weight loss than are higher income individuals [35]. It is likely that motivations for joining a weight loss program may vary across groups of differing socioeconomic status [32]. Overall, the CSIRO Total Wellbeing Diet Online program appears to be an effective weight loss program for individuals in lower socioeconomic groups, representing a simple, evidence-based, and effective intervention to address the public health challenge of being overweight or obese.

Platform Usage and Weight Loss

Participant adherence is known to be a primary determinant of program success [36], and this study, like others [11,37], showed that higher engagement with an online platform and more frequent usage of program features was associated with greater early weight loss and greater total weight loss. Members with the highest platform usage lost twice as much weight than did those with the lowest levels of usage. A review of technology-driven weight loss interventions suggests that self-monitoring, feedback and communication, social support, use of a structured program, and use of an individually tailored program are factors that could facilitate weight loss [38]. Opportunity for self-monitoring through entries in a diary [30,37,39,40] and engagement with social forums have been shown to be associated with greater weight loss and weight loss maintenance in web-based interventions [11,37,41]. On this program, members with the highest platform usage were using the food diary to record dietary intake about twice per day. They were also monitoring their body weight more closely by entering a weight value into the platform once per week. Consistent self-monitoring of weight is crucial to successful weight loss and weight loss maintenance [42] and is central to behavioral weight loss programs [43].

The specific features of a program are important and can influence engagement and weight loss. Different technologies may lend themselves to different features. The focus of this study was on a web-based program, but commercial weight loss programs delivered through mobile phone apps are also common. One of the most popular publicly available apps for weight loss is Noom Coach, with tens of millions of installs worldwide. An evaluation of Noom Coach used data from a very select group who had recorded their data at least twice per month for 6 consecutive months (n=36,000). In this highly motivated subsample, who were engaged and used the app in this way, 23% of users achieved a weight loss of 10% or more over the 6-month period examined [44]. For the CSIRO Total Wellbeing Diet Online, 20% (4532/22,658) of an engaged subsample (that is the highest platform usage users who stayed on the program for at least 3 months) achieved a weight loss of 10% or more. However, it would be interesting to see a larger-scale study with a greater proportion of total Noom users to better understand the weight loss a typical user can expect when embarking on the program. Mobile phone apps can offer different features, such as push notifications and real time information, which may provide additional support that is not available in a web-based program. An increasing number of technologies are being used in parallel, and programs are available across multiple platforms to offer users greater flexibility and choice. As the complexity of program delivery increases, it is vital that robust evaluations are conducted to determine the elements of programs, the components of their delivery, and the combinations of these that are associated with successful weight loss.

Achieving sufficient engagement and user retention is a challenge. For commercial weight loss programs, high attrition rates of up to 70% are common [28,45], and nonusage attrition is also high on web-based weight loss programs [46]. It is important to look at both program attrition and attrition in terms of technology usage because it is possible that people stop using the platform features before they formally drop out [46]. Platform usage could be thought of as the equivalent of treatment dose in medical studies, and so, while the optimal dose for web-based interventions is unclear, strategies to improve engagement need to be determined. Engagement and retention on a program might be related to user characteristics such as starting weight, as people who are heavier have more weight to lose to reach their weight loss goal and therefore are willing to stay on a program for longer [28]. In this study, starters and stayers had a similar starting BMI, but stayers might have been more intrinsically motivated to adhere to the program and achieve weight loss. A greater understanding of user behaviors that predict engagement and whether this varies for different user groups is needed to develop strategies to increase engagement and drive more successful weight loss outcomes. For example, posting a profile picture has been shown to predict higher engagement with an online weight loss program [47], and more frequent input of evening meal information is the most important behavior for weight loss in a commercial weight loss app [48]. If more specific behaviors like these were recognized, then they could be incorporated and specifically promoted to help achieve higher levels of engagement and weight loss.

Rapid initial weight loss has been shown to predict greater longer-term weight loss [30,49], and while this study showed higher usage of the platform was associated with greater early weight loss, further exploration could determine specific behavioral patterns that support early success. Data were not available for members once they had dropped out (and thus our results represent the best-case scenario), and the reasons for drop-out and nonplatform usage are also worthy of further investigation. It is unknown how weight loss is maintained once membership has ceased, but the achievement of long-term weight loss or weight loss maintenance following completion of the program is the true goal.

Strengths and Limitations

A key strength of the current study is that a broad set of inclusion criteria was applied for analysis, and data from all members were used in reporting the weight loss results, which is not always the case for commercial programs [9,10,44]. Weight loss was conducted using self-reported values with the last weight entered into the platform being carried forward. As we split the sample into starters and stayers and presented the data separately, the weight losses reported for stayers are likely to be reflective of an “average” member that joins and finishes the program and not a selected subsample. Although this is a retrospective analysis, it represents a very large cohort of people who had chosen to join a commercial weight loss program and followed the program in their own everyday context. However, a limitation associated with this design is that the study included only the member characteristics that were collected as part of the registration process. Although a range of personal demographic data was included, other factors, such as past dieting history or motivation, were not available. Platform usage provided an indication of engagement, while viewing the menu plans and use of the food diary may relate to compliance with the eating plan. However, more objective and validated measures of dietary intake would better represent dietary program compliance.

Conclusions

To our knowledge, this 5-year evaluation of the CSIRO Total Wellbeing Diet Online represents one of the most comprehensive evaluations of a commercially available, online weight loss program and has provided insights into predictors of weight loss success among members. Health care practitioners and individuals require evidenced-based weight management programs that have been shown to achieve meaningful weight loss. The findings suggest that this program is effective for weight loss, particularly for members who finish the program and are active in using the online platform and tools provided. Importantly, members with a higher starting BMI and those from more disadvantaged socioeconomic areas were among those who lost the most weight.

Acknowledgments

We acknowledge the team at Digital Wellness for their support in maintaining the CSIRO Total Wellbeing Diet Online platform, retrieving the data, and assisting in the data management prior to analysis.

Conflicts of Interest

This study was cofunded by CSIRO and Digital Wellness. Digital Wellness manages the CSIRO Total Wellbeing Diet Online under a commercial agreement. Authors from CSIRO conducted the analysis and were responsible for the interpretation of results and preparation of the manuscript. Digital Wellness was not involved in the analysis or preparation of results. Digital Wellness has approved the manuscript for publication.

Multimedia Appendix 1

Mean (SD) starting body weight and body mass index of starters (n=37,028), stayers (n=22,658) and all members (n=59,686) at the time of joining the CSIRO Total Wellbeing Diet Online.

Abstract

Background: Frequent self-weighing is associated with successful weight loss and weight maintenance during and after weight loss interventions. Less is known about self-weighing behaviors and associated weight change in free-living settings.

Objective: This study aimed to investigate the association between the frequency of self-weighing and changes in body weight in a large international cohort of smart scale users.

Methods: This was an observational cohort study with 10,000 randomly selected smart scale users who had used the scale for at least 1 year. Longitudinal weight measurement data were analyzed. The association between the frequency of self-weighing and weight change over the follow-up was investigated among normal weight, overweight, and obese users using Pearson's correlation coefficient and linear models. The association between the frequency of self-weighing and temporal weight change was analyzed using linear mixed effects models.

Results: The eligible sample consisted of 9768 participants (6515/9768, 66.7% men; mean age 41.5 years; mean BMI 26.8 kg/m2). Of the participants, 4003 (4003/9768, 41.0%), 3748 (3748/9768, 38.4%), and 2017 (2017/9768, 20.6%) were normal weight, overweight, and obese, respectively. During the mean follow-up time of 1085 days, the mean weight change was –0.59 kg, and the mean percentage of days with a self-weigh was 39.98%, which equals 2.8 self-weighs per week. The percentage of self-weighing days correlated inversely with weight change, r=–0.111 (P<.001). Among normal weight, overweight, and obese individuals, the correlations were r=–0.100 (P<.001), r=–0.125 (P<.001), and r=–0.148 (P<.001), respectively. Of all participants, 72.5% (7085/9768) had at least one period of ≥30 days without weight measurements. During the break, weight increased, and weight gains were more pronounced among overweight and obese individuals: 0.58 kg in the normal weight group, 0.93 kg in the overweight group, and 1.37 kg in the obese group (P<.001).

Conclusions: Frequent self-weighing was associated with favorable weight loss outcomes also in an uncontrolled, free-living setting, regardless of specific weight loss interventions. The beneficial associations of regular self-weighing were more pronounced for overweight or obese individuals.

KEYWORDS

self-monitoring; self-weighing; weight change, weight loss, normal weight, overweight, obese, temporal weight change

Introduction

Self-monitoring of body weight is the cornerstone of behavioral weight loss interventions [1]. Increased awareness gained through self-weighing is expected to trigger a self-evaluation process that involves interpretation of weight data against one's goal and subsequently results in weight loss–promoting actions [2,3]. Regular self-weighing is consistently associated with weight loss and weight loss maintenance as well as weight gain prevention [2-7]. There is also evidence of a dose-response relationship with more frequent self-weighing and greater weight loss [8-11]. Currently, less is known about self-weighing practices and their effectiveness independent of the context of weight loss interventions.

To date, most studies have investigated self-weighing behaviors through self-reported methods. Self-weighing frequency is often retrospectively reported and evaluated in predefined categories (eg, “daily weighing,” “weekly weighing,” or “monthly weighing”) [9,12,13]. Some studies have determined self-weighing frequency from actual self-weighing data, but further reduced it to a single aggregated frequency value [10,14,15]. Although valuable in research, self-reported data collection methods have their limitations, including selective reporting and susceptibility to recall bias [16,17]. Moreover, single aggregated categories may not reflect long-term weighing practices, as self-weighing frequency tends to change or decline over time [18-20].

Self-monitoring of body weight has become easier and increasingly popular with modern smart scales that automatically transmit weight data to network servers that users can access online or through smart phone applications. As a result, date-stamped and time-stamped weight record data accumulate from a large number of users, providing unique insights into behavioral patterns of weight-tracking individuals. Advantages of using these data in health research include objectivity and accuracy of the information they provide [16,21]. In addition, they provide longitudinal weight measurement data, which are rarely, although increasingly, obtained or used in research. However, while being a strength, self-weighing with smart scales is done by individuals in their daily lives (ie, in uncontrolled, free-living settings), which introduces challenges for the analytics and interpretation of the data. These include the possibility of weight measurement outliers, daily variation, and inadequate background information, among others [21-25].

In our previous work, we demonstrated a dose-response relationship between self-weighing frequency and weight change and an increased risk for weight gain when weight monitoring was stopped [8]. However, the generalization of the findings was limited due to the small sample size (n=40) and the sample consisting of overweight individuals engaged in a workplace health promotion program. The objective of this study was to investigate self-weighing patterns and their association with weight change in a large international sample of smart scale users in their free-living settings. We divided the sample into 3 groups to further study the differences among normal weight, overweight, and obese individuals.

Methods

Design and Data Source

The data used in the current study were collected from 10,000 anonymous Withings (Withings Ltd, Paris, France) smart scale users randomly retrieved from the company’s smart scale user database between May 2009 and June 2015. A user was defined as a person who had access to a smart scale and had a user account in which his or her measurements were linked. In the connection of setting up the user account, the user consented to his or her data being used for research purposes by accepting the Terms and Conditions of Withings [26]. For each measurement, the scale automatically saved the weight record and the date stamp and time stamp of the measurement, and the information was further sent to the network servers. Multiple users could share the same scale; however, they were advised to create an individual user account. The scale automatically detected to which user the weight measurement belonged. Users were able to remove weight observations or attach unknown observations to their account manually through a web-based application interface. The data used in the study were pseudonymized before data retrieval and contained all weight measurements attached to a single user account.

In order to study both long-term and short-term weight changes, the smart scale users who fulfilled the following inclusion criteria by June 2015 were eligible for random sampling: engaged with self-weighing for at least 1 year (based on a time difference between the first and the last weight measurements) and had ≥30 weight measurements linked to a user account.

Background information of smart scale users included the following self-reported measures: age in years, height, gender, and location information (ie, country and time zone) that were automatically recorded.

Study Subjects

In addition to the inclusion criteria used for data extraction, smart scale users who fulfilled the following criteria were included in the current study: age between 18 and 100 years at the time of the first weight measurement, height between 1.40 m and 2.10 m (defined to exclude possible errors in height records that would lead to erroneous BMI values), BMI ≥18.5 kg/m^2 based on the weight measurements made during the first follow-up week.

Data Processing

As the weight measurement data were not collected through a structured protocol, but instead accumulated in a free-living setting, the data required preprocessing to exclude possible outlying measurements and multiple intraday measurements from the current analyses. Outliers may arise from situations such as different users using the same devices or due to external, uncontrolled influences such as exceptionally heavy clothing or carrying an object during self-weighing. We identified and removed the outliers using the following steps. First, all measurements below 30 kg were removed. Second, the outlying measurements were identified with the median absolute deviation method (window=30 samples, threshold=4) and subsequently removed. Third, weight measurements resulting in an unrealistic weight change from the preceding measurement were identified and excluded using a specific algorithm: A weight change was considered unrealistic if it was voted 3 times as an outlier by the 2 preceding and 2 successive measurements, with each measurement encompassing 1 vote. A vote was defined as a difference between the 2 consecutive weight measurements that exceeded the threshold of 3% daily plus 0.1% times day difference between the measurements. The measurements were removed iteratively by removing 1 observation at a time, starting from the outlier that had the highest number of votes and then the highest total sum of absolute weight difference. The process was repeated until no outliers were detected. After removing the outliers, the minimum weight values for each day were identified, and other day duplicates were excluded from the analyses to reduce diurnal variation of weight. Finally, if more than 10 original daily minimum weight values were removed as a result of the outlier detection algorithm (compared to before any processing) or if less than 30 observations were left after preprocessing, the user was excluded from the final analyses.

Variables

Follow-Up Time

The individual follow-up time for each user was defined as the time difference between the first and the last weight measurements.

Weight Change

Weight change during the follow-up period was defined as a difference between the mean weight of the last 7 days and the mean weight of the first 7 days (*initial weight*), divided by the initial weight. A similar approach was used by Zheng et al [19]. Negative and positive weight differences indicate weight loss and weight gain, respectively.

Temporal Weight Change

Temporal weight change per day was calculated by dividing weight change between 2 consecutive measurements by the corresponding day difference between the measurements.

BMI

Height was retrieved from the Withings research database. The baseline BMI was calculated from the self-reported height and the initial weight. Individuals were categorized into 3 categories based on BMI thresholds: normal weight (18.5 kg/m^2 to <25.0 kg/m^2), overweight (25.0 kg/m^2 to <30.0 kg/m^2), and obese (≥30.0 kg/m^2).

Frequency of Self-Weighing

The self-weighing frequency was defined as a percentage of follow-up days with a weight measurement recorded. We also calculated the number of weight measurements per week defined by dividing the number of all weight measurements with the number of follow-up weeks to be used as a proxy for weekly self-weighing intensity.

For the analysis of temporal weight changes, we used a categorical self-weighing frequency that was defined based on the number of days between the 2 consecutive measurements. The categories were based on commonly used self-weighing categories. The categorization was also motivated by the fact that the majority of measurements were done on a weekly basis or more frequently, and thus, the distribution was strongly skewed. The self-weighing categories were as follows: daily — 0 days between 2 consecutive weight measurements; every other day — 1 day between 2 consecutive weight measurements; 2-4 times per week — 2 days between 2 consecutive weight measurements; 1-2 times per week — 3-7 days between 2 consecutive weight measurements; every other week — 8-14 days between 2 consecutive weight measurements; monthly — 14-29 days between 2 consecutive weight measurements; less than monthly — ≥30 days between consecutive measurements.

Break in Self-Weighing

A break in self-weighing was defined as ≥30 days between 2 consecutive weight measurements. The weight change during the break was calculated as a difference between the last preceding weight measurement and the first weight measurement after the break. If the user had multiple breaks, the mean weight change and the mean duration of all breaks were calculated.

Time of the Day and the Weekday

To control time effect, weight measurements were each categorized based on their time stamp to either a morning (measurement made between 5 am and 1 pm) or an evening (measurement made between 1 pm and the 5 am the next day) measurement. We further defined a combination variable accounting for time stamps of the present and the previous weight measurement with 4 possible categories: morning-morning, morning-evening, evening-evening, evening-morning. This variable was used in the analyses of temporal weight changes. Similarly, as weekday is shown to affect weight variation [24,27], we defined the weekday of the weight measurement and used the variable in the analyses of temporal weight change.

Statistical Analyses

Participant characteristics are presented using means (SDs) or frequencies and percentages. Characteristics were compared across the 3 BMI groups using a Chi-square test or analysis of variance or Kruskall Wallis test if the distributions were strongly skewed. Similar comparisons across the BMI groups were made among participants who had a break in self-weighing.

The Pearson correlation coefficient (r) between weight change (kg) and the frequency of self-weighing, measured as a percentage of follow-up days with a weight measurement, was calculated for the whole study population and separately for each BMI group. We then built linear models with an interaction term between the BMI group and the frequency of self-weighing to investigate whether the association was different across the BMI groups. The adjusted models were further performed including the following covariates: sex, age, initial BMI, and the duration of the follow-up.

In the secondary analyses, we focused on temporal weight changes and analyzed the association between temporal weight change and the corresponding day difference by using linear mixed effect (LME) models. Day difference between 2 consecutive weight measurements was added in the model as a fixed effect and participants as a random effect. Each participant was allowed to have a subject-specific intercept and a slope. The adjusted analyses included the following covariates: sex, age, initial BMI, weekday, and time of the day combination. Temporal weight change was also modeled using the categorized self-weighing frequency variable as a dependent variable and further adding the interaction between the self-weighing category and BMI group in the model as a fixed effect.

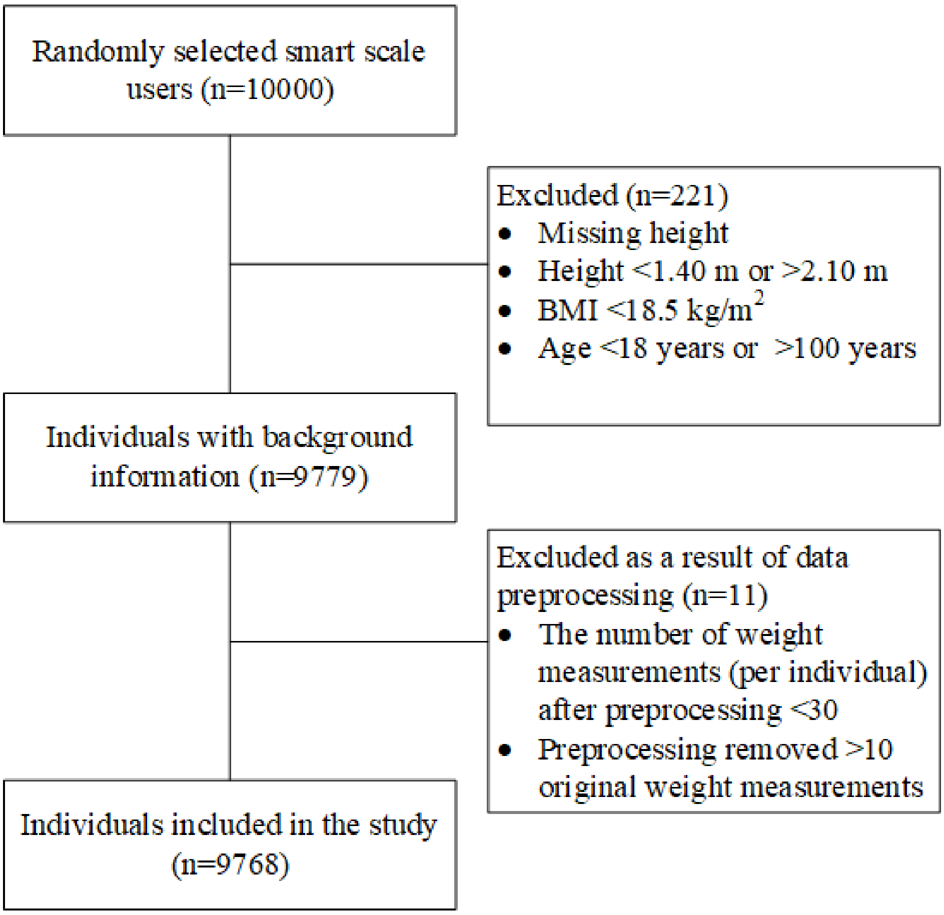
Statistical analyses were carried out with R version 3.6.2 [28] using dplyr [29] and nlme [30] packages. An alpha level of 0.05 was used in all statistical analyses, and all statistical tests were two-sided.

Results

Participant Inclusion and Background Characteristics

The participant inclusion and data preprocessing flow is depicted in Figure 1. Of the 10,000 smart scale users, 9768 (97.7%) were included in the study. In total, participants recorded 4,230,928 weight measurements.

Figure 1. Participant inclusion and data prepreprocessing.



Participants' background characteristics and self-weighing–related information are summarized in Table 1. The majority (6515/9768, 66.7%) were male. The mean age was 41.52 years, and the mean BMI was 26.78 kg/m^2. Of all participants, 4003 (4003/9768, 42.0%) were of normal weight, 3748 (3748/9768, 38.4%) were overweight, and 2017 (2017/9768, 20.7%) were obese at the beginning of the follow-up. The proportion of male participants was higher in the overweight and obese groups than among the normal weight group (2969/3748, 79.2%; 1551/2017, 76.9%; 1995/4003, 49.8%, respectively; *P*<.001). Of the included participants, 4837 (4837/9768, 49.5%) were from Europe, 3744 (3744/9768, 38.3%) from the Americas, 887 (887/9758, 9.1%) from Asia, and the rest (300/9768, 3.0%) from other continents. The most represented countries were the United States (3332/9768, 34.1%), Germany (1230/9768, 12.6%), France (811/9768, 8.3%), Japan (600/9768, 6.1%), and the United Kingdom (585/9768, 6.0%).

The mean duration of the follow-up was 1085 days, which did not differ across the 3 BMI groups (*P*=.35). The median number of self-weighs was 352, which equals 2.80 weight measurements per week. The highest self-weighing intensity was seen among overweight individuals; however, the differences between the groups were small, although statistically significant, varying from 38.99% among obese individuals to 40.86% among overweight individuals (*P*=.006). The mean percentage days with a weight measurement was 39.98%.

[a] N/A: not available because no statistical test was performed to test differences between the groups.

[b] KW: Kruskal-Wallis.

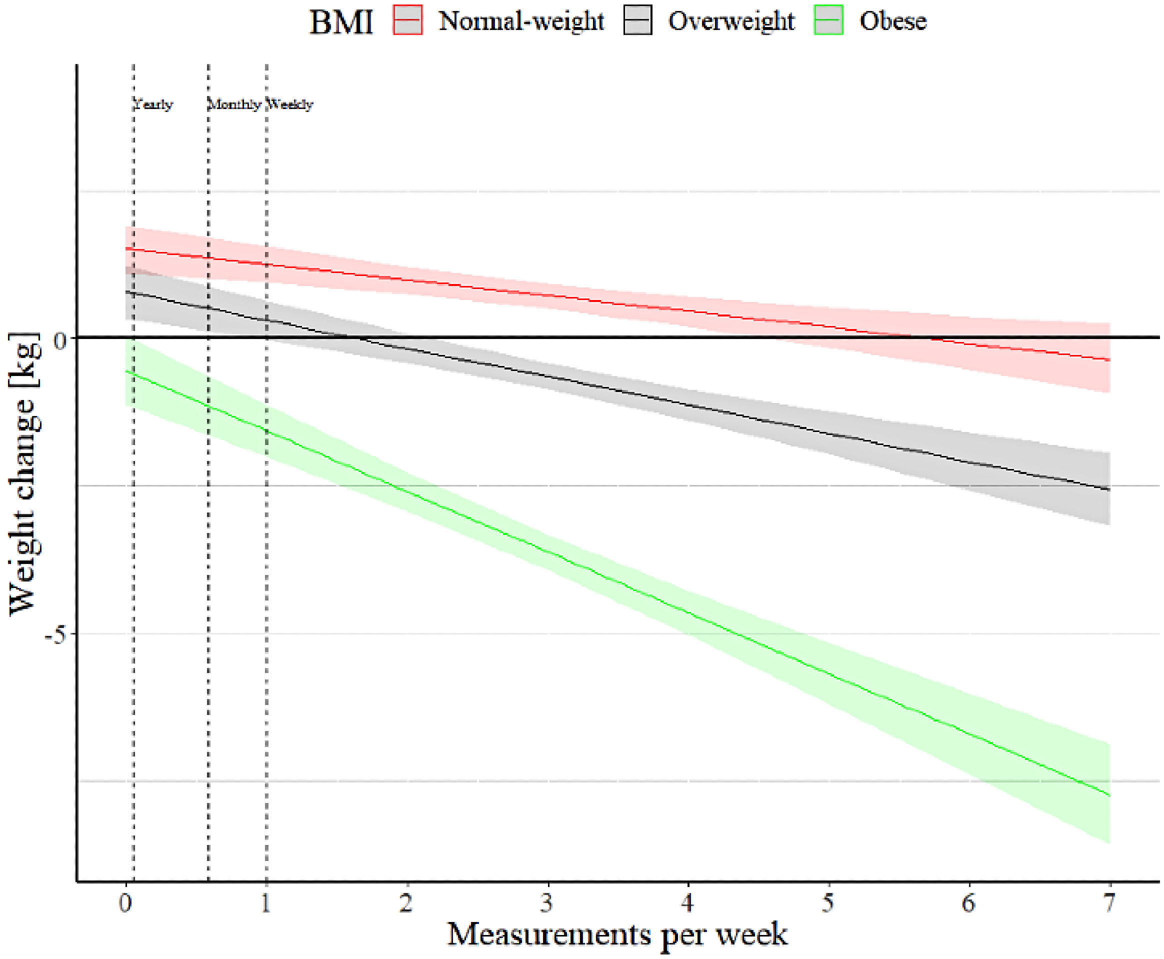
Frequency of Self-Weighing and Weight Change

During the mean follow-up of 1085 days, the participants lost 0.59 kg of their initial weight (Table 1). The mean percentage weight change was –0.37%. Weight changes varied between the BMI groups, with an increase of 0.78 kg in the normal weight group and decreases of –0.58 kg and –3.35 kg in the overweight and obese groups, respectively.

There was a low, statistically significant, correlation between the frequency of self-weighing, measured as the percentage of self-weighing days, and weight change (r=–0.111, P<.001). The correlation was stronger in the highest BMI groups: r=–0.100 (P<.001) for normal weight, r=–0.125 (P<.001) for overweight, and r=–0.148 (P<.001) for obese. The linear model, including the interaction term between the BMI group and the frequency of self-weighing, showed a statistically significant interaction for the overweight and obese groups and the frequency of self-weighing (β=–0.015, P=.03 and β=–0.053, P<.001, respectively); see Table S1 in Multimedia Appendix 1 for all model coefficients. The result indicates that, when compared to the normal weight group, the association between the frequency of self-weighing and weight change was different among obese and overweight individuals. Similar parameter estimates were obtained from the adjusted models (β=–0.017, P=.01 for the overweight group and β=–0.057, P<.001 for the obese group).

Figure 2 shows the weight change (kg) in the 3 BMI groups predicted by the weekly weighing frequency. A slightly steeper slope was seen in the obese group as compared to the normal weight group illustrating the interaction. A higher frequency of self-weighing was associated with bigger weight loss in the obese group. The magnitude of the interaction was smaller in the overweight group. The figure shows that weighing oneself at least once a week was associated with negative weight change in the obese group, whereas in the overweight and normal weight groups, the confidence intervals overlap the 0 line or remain above it. It seems that a self-weighing frequency of 2-3 times per week, or more frequently, was associated with negative weight change in the overweight group. However, in the normal weight group, the upper limit of the 95% confidence interval was not below 0 at all.

Figure 2. Weight change during the study follow-up predicted by the number of weight measurements per week.

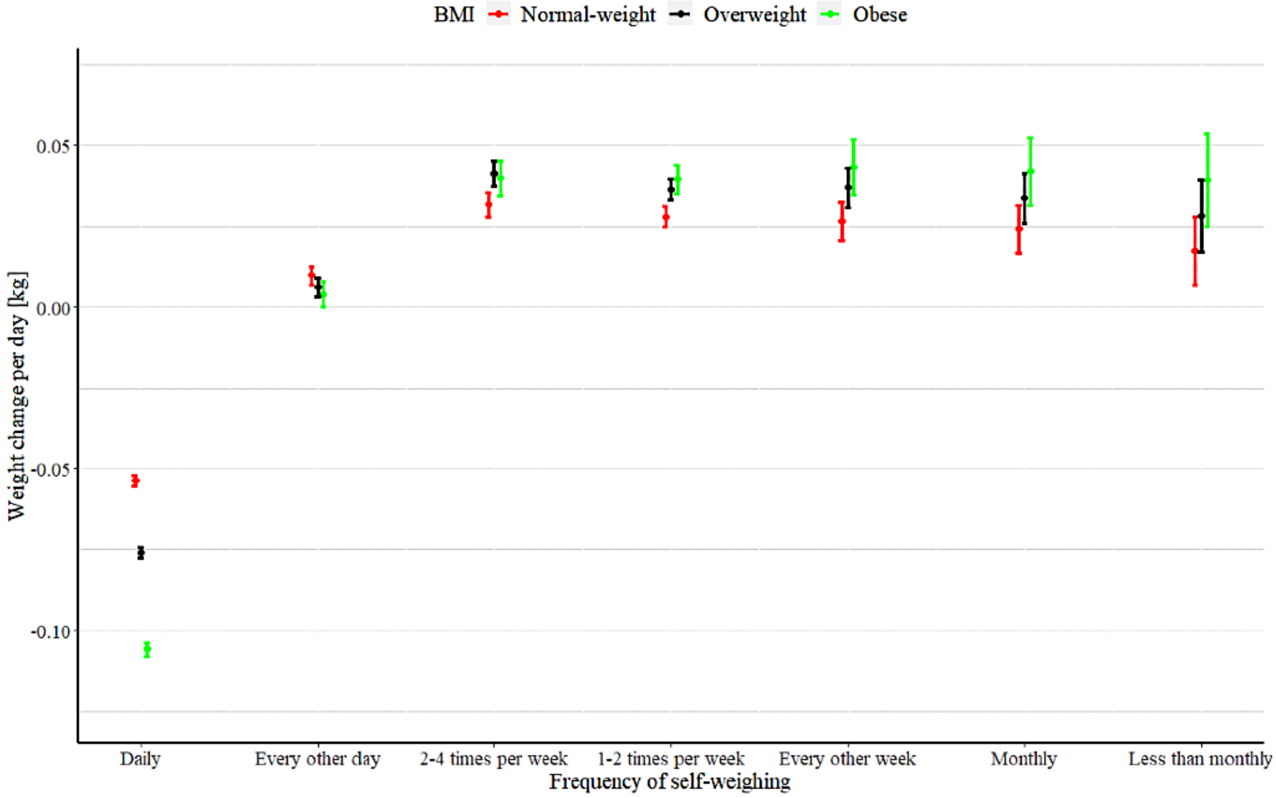


Temporal Weight Change and Self-Weighing Frequency

After calculating the temporal weight change variable, we excluded measurements that exceeded the threshold of 20% weight change per day (n=35). The number of individuals in the analyses remained at 9768. The LME model showed that the number of days between 2 consecutive weight measurements was a significant predictor of temporal weight change (β=0.001, *P*<.001); weight increased by the number of days between the weight measurements. The adjusted model did not alter the parameter estimate (β=0.001, *P*<.001).

The mean weight changes per day in the self-weighing frequency categories were as follows: daily, –0.058 kg; every other day, 0.012 kg; 2-4 times per week, 0.036 kg; 1-2 times per week, 0.028 kg; every other week, 0.026 kg; monthly, 0.022 kg; less than monthly, 0.016 kg. Temporal weight changes in each category were significantly different from the "daily" value, which was used as a reference category (Multimedia Appendix 1, Table S2). Figure 3 shows the interactions between self-weighing categories and the BMI groups. The parameter estimates of the model are shown in Multimedia Appendix 1 Table S3. Only daily self-weighing was associated with a negative temporal weight change per day in all BMI groups.

Figure 3. Weight change per day predicted by the interaction between the frequency of self-weighing and BMI group.



Breaks in Self-Weighing

A majority of the participants (7085/9768, 72.5%) had at least one break in self-weighing of ≥30 days during the follow-up (Table 2). In the normal weight, overweight, and obese groups, 73.5% (2941/4003), 70.7% (2648/3748), and 74.2% (1496/2017), respectively, had at least one break. The median number of breaks was 3 with an average duration of 58.83 days.

During the break, the participants gained 0.85 kg on average. The median increase was bigger in the obese group (1.37 kg) than in the overweight (0.93 kg) and normal weight (0.58 kg) groups (*P*<.001). The Spearman correlation coefficients between the duration of the break and weight change (kg) were ρ=0.153 (*P*<.001) among all participants and ρ=0.090 (*P*<.001), ρ=0.161 (*P*<.001), and ρ=0.245 (*P*<.001) in the normal weight, overweight, and obese groups, respectively.

Table 2. The numbers of breaks in self-weighing, their durations, and the subsequent weight change among all study participants who had a break from self-weighing and in the 3 BMI groups.

Characteristic	All who had a break from self-weighing (n=7085)	Normal weight (n=2941)	Overweight (n=2648)	Obese (n=1496)	Kruskal Wallis statistic for the difference between the BMI groups	*P* value
Number of breaks, median (IQR)	3 (2 to 5)	3 (2 to 5)	3 (1 to 5)	3 (2 to 6)	8.48 (df=2)	.01
Duration of the break (days), median (IQR)	58.83 (44.00 to 86.30)	58.33 (44.00 to 85.00)	57.75 (43.62 to 85.55)	61.20 (45.36 to 90.00)	11.44 (df=2)	.003
Weight change (kg), median (IQR)	0.85 (0.03 to 1.92)	0.58 (–0.13 to 1.46)	0.93 (0.06 to 1.99)	1.37 (0.38 to 2.61)	247.32 (df=2)	<.001
Weight change (%), median (IQR)	1.05 (0.04 to 2.30)	0.87 (–0.18 to 2.20)	1.10 (0.08 to 2.32)	1.30 (0.36 to 2.46)	58.54 (df=2)	<.001

Discussion

Principal Findings

This study extends the well-established relationship between frequent self-weighing and favorable weight loss outcomes beyond specific weight loss interventions by using a large international sample of 9768 long-term smart scale users, tracking their weight in uncontrolled, free-living settings. We found that the intensity of self-weighing was inversely associated with weight change, and the beneficial associations of frequent self-weighing were more pronounced in obese and overweight individuals as compared to normal weight individuals. Daily self-weighing in particular was associated with weight loss.

During the mean follow-up time of 1085 days, the participants measured their weight 2.8 times per week, which is notably higher than what is reported in the general population of the United States [15]. However, a comparable self-weighing intensity was reported in the Heart eHealth (HeH) study [19], a prospective observational cohort study on health behaviors and cardiovascular risk. Similarly, the HeH study reflects free-living behaviors, as study participants did not receive any recommendations for self-weighing practices, but those who owned smart scales connected them to the HeH study account.

While the self-weighing frequency was rather high, more than two-thirds of the study participants also had at least one longer break in self-weighing (≥30 days) during the follow-up. The break in self-weighing was associated with increased weight, with a dose-response relationship with the length of the break: The longer the break, the more weight tended to increase. Moreover, weight gain following the break in self-weighing was largest among obese individuals (+1.37 kg) and overweight individuals (+0.93 kg) when compared to normal weight individuals (+0.58 kg), while the average length of the break was rather similar between all 3 BMI groups (varying between 58 days and 61 days). Similar findings were also reported by VanWormer et al [12], who found that monthly self-weighers actually gained weight during the 24-month follow-up. These results suggest that regular self-weighing might be of particular importance in terms of promoting weight loss for individuals with excess weight, possibly by helping them attain weight management–promoting behaviors.

The correlation between frequent self-weighing and weight loss supports the beneficial effect of weight monitoring and, as such, is in line with other studies [3,8,9,11,13]. The association seemed to be stronger in individuals who needed it most, namely obese and overweight individuals, as seen earlier [12]. The motivation for weight tracking in individuals who do not have excess weight is likely different, as they may not pursue weight loss, which might at least partly explain the lower correlation in the normal weight group. It should be noted that the correlation coefficients were generally very low, which indicates that self-weighing explains relatively little of the weight change variation. Other factors, such as long-term goals, motivation for self-weighing, and behavioral factors as well as diet and physical activity, may have stronger effects on weight loss efforts, although weight-loss–promoting practices are important. It has also been suggested that the consistency of self-weighing is more important than the frequency of self-weighing [31].

As self-weighing practices tend to vary and decline over time [13,20,32], we analyzed temporal weight changes using consecutive weight measurements and the corresponding day differences to investigate the short-term associations. These results were consistent with aggregated data showing a significant relationship between weight change and the corresponding day difference. The higher the number of days between self-weighs, the more weight increased. In these analyses, we used weight change per day as an independent variable, which adjusted the weight change by the number of days between the measurements to control for the possibility of bigger weight changes during longer breaks. When using the self-weighing categories, we found that only daily self-weighing was associated with weight loss in all BMI groups, whereas weighing oneself every other day or less frequently was associated with unchanged or increased weight. Interestingly, weighing every other day was associated with increased weight in normal weight and overweight groups, whereas in obese individuals, it was associated with unchanged weight. Consistent with our findings, it has been shown that daily weighing is associated with greater weight loss [33], even when compared to weighing oneself 5 days of the week [11]. However, not all studies have reported the superiority of daily self-weighing over weekly monitoring [5]. The positive impact of daily weighing vs weighing oneself every other day or on a weekly basis in our observational study should be interpreted with caution. It is possible that the differences between daily and every-other-day categories reflect an ongoing weight loss process rather than daily self-weighing being remarkably more effective than weighing oneself every other day.

Limitations

The findings of this study should be interpreted in the light of the following limitations. First, as an observational study, a causal relationship between self-weighing and weight change cannot be established. Efforts at self-weighing could promote weight loss or be a consequence of favorable weight change. In fact, a recent study by Frie et al [25] found that declining motivation for weight control and possible difficulties with making use of negative weight feedback, the Ostrich effect, precede a break in self-weighing. Thus, it might not be the break in self-weighing that increases the risk of weight gain, but that the decline in self-weighing behavior is a result of weight gain. In line with this, Tanenbaum et al [34] showed that calorie intake on a given day increased the risk of not self-weighing the following day; in another study, a reduction in BMI was independently associated with greater engagement with self-weighing [21]. In light of those studies, the findings of the current study may also indicate that the relationship describes the process of weight loss rather than promotes it.

Second, participants' background information was limited to demographic variables, preventing us from controlling for important variables, such as goals for weight management or the underlying motivation for using the smart scale. For example, among normal weight individuals, it might be that they did not pursue weight loss but rather weight (loss) maintenance, which might explain a weaker correlation seen in this subgroup. On the other hand, obese individuals might be more likely to use the scale for weight loss purposes.

The third limitation is the selection bias. Our sample consisted of individuals who were predominantly men (66.7%), had excess weight (BMI of 26.8 kg/m^2), and, importantly, were engaged with regular self-monitoring of weight for a longer time period. The sample is not representative of the general population; Sperrin et al [21], who used comparable data from the same company, showed that the traits of those self-weighing individuals differed from the general British population. Participants' characteristics in our study were quite similar to the study by Sperring et al [21], although they required only one weight measurement per subject and used data from a single country. Another study found that individuals using smart scales in wireless settings were mostly well educated, white, and male [19]. Moreover, due to the inclusion criteria we applied for sampling, our cohort may not be representative of smart scale users, as those who used the scale for a shorter period (less than a year) and made fewer than 30 measurements were excluded. Nevertheless, this was a large international cohort including almost 10,000 individuals from 109 different countries who provided self-weighed measurements for approximately 3 years. These individuals were not participating in a specific weight loss program, but the data reflect self-weighing behaviors in real-world settings. We consider the overrepresentation of men as a strength of this study. Typically, participants in weight management interventions are women. Thus, the findings of this study shed light on self-weighing patterns and weight loss attempts by men, who are less investigated. Moreover, together with other smart scale–based studies, the findings indicate that including technology to support weight loss may have the potential to appeal to men to participate in weight control trials.

Fourth, measuring longitudinal changes in self-weighing behaviors remain a challenge. Aggregating data over multiple days and weeks, as we did in the first analysis, does not account for changing behavioral patterns. In an attempt to tackle the challenge, we investigated short-term weight changes by analyzing consecutive weight measurements. However, these results may have been affected by the underlying trend of the weight loss process; individuals who lose weight may be more likely to weigh themselves daily, and thus, even 1-day breaks from the daily self-weighing may appear as short-term weight gains. As there were some differences in results obtained with these 2 analysis approaches, future studies should note that the length of the follow-up might affect the results when investigating how the frequency of self-weighing affects weight loss. Another alternative for the analysis of similar data to ours would be to identify slots with unchanged self-weighing pattern as was done by Frie et al [25] and to analyze associated weight changes.

Conclusions

This study showed that frequent self-weighing is associated with favorable weight loss outcomes also in an uncontrolled, free-living setting, regardless of specific weight loss interventions. The positive association of regular self-weighing was more pronounced for individuals who needed it most, namely overweight and obese individuals. We found that daily self-weighing in particular was associated with weight loss, whereas breaks of 30 days or longer were associated with increased weight. However, although, there was a dose-response relationship between self-weighing intensity and weight change, the correlation remained low, indicating that self-weighing explains only a small fraction of the variations in weight. Yet, our results underscore the evidence that missing self-weighing data do not occur randomly and might be a sign of risk for weight gain.

Acknowledgments

We would like to thank Angela Chieh from Withings for her contribution to the study design and data collection. We are also grateful to Withings for the collaboration and kindly providing data for this research. The work was funded by VTT Technical Research Centre of Finland.

Authors' Contributions

All authors contributed to the conception and design of the study. EH and IK were responsible for data collection. EH, JP, and AV contributed to data processing. EH and AV performed data analyses. AV wrote the first draft of the article. All authors revised the draft and approved the final version of the manuscript to be submitted.

Conflicts of Interest

None declared.

Abstract

Background: In recent years, robots have been considered a new tech industry that can be used to solve the shortage in human resources in the field of health care. Also, animal-assisted therapy has been used to provide assistance, companionship, and interaction among the elderly and has been shown to have a positive impact on their emotional and psychological well-being. Both pets and robots can provide dynamic communication and positive interaction patterns. However, preferences for middle-aged and older adults in this regard are not clear.

Objective: This study explored the degree of acceptance of robots and pets as partners in later life and to determine the needs and preferences of elderly individuals related to companion robots.

Methods: A total of 273 middle-aged and older adults aged ≥45 years and living in the community were invited to answer a structured questionnaire after watching a companion robot video. Sociodemographic data, physical health status and activities, experience with technology, eHealth literacy, and acceptance and attitude toward robots and pets were recorded and analyzed using multinomial logistic regression analysis.

Results: Age, level of education, type of dwelling, occupation, retirement status, number of comorbidities, experience with pets, experience using apps, and eHealth literacy were significantly associated with acceptance of robots and pets. Middle-aged and older women preferred robots with an animal-like appearance, while men preferred robots that resembled a human adult. In terms of robot functions, participants preferred a companion robot with dancing, singing, storytelling, or news-reporting functions. Participants' marital status and whether or not they lived alone affected their preference of functions in the companion robot.

Conclusions: Findings from this study inform the development of social robots with regard to their appearance and functions to address loneliness in later life in fast-aging societies.

middle-aged adults; older adults; companionship demand; robot; pet; acceptance

Introduction

Along with increases in the size of the aging population, the demands for care and medical and health care manpower for the elderly population are also increasing. Determining how to adapt to these changes, using limited resources to meet the needs of care recipients, and reducing the burden on caregivers so that middle-aged and older adults have a high quality of life in their old age is an important issue that cannot be ignored.

Cowan [1] divided the issues to be faced by an aging society into 8 categories: dependent living, fall risk, chronic disease, dementia, social isolation, depression, poor well-being, and poor medication management. However, an existing literature review pointed out that in order to establish relevant advanced-age health technologies designed to solve the issues mentioned above, the issues could be divided into 6 groups: general information and communications technology (ICT), robotics, telemedicine, sensor technology, medication management applications, and video games [1].

Over the past decade, the elderly population has been the demographic with the fastest growing use of technological products such as the internet and computers [2,3], and a growing number of studies have shown that health-related ICTs can effectively reduce medical expenditures and care costs and enhance the quality of life of middle-aged and older adults [4,5]. In addition, technological products can help middle-aged and older adults live independently at home and provide health care and medical services in remote areas through mobile health (mHealth) strategies [6]; among these technological products are robots that can assist humans in performing repetitive and dangerous work and become the additional manpower needed for health care [7].

A health care robot is a robot that monitors or promotes physical and mental health and mitigates social psychological problems in the elderly. According to their functions, these robots can be divided into 2 types: rehabilitation robots and social robots [8]. Rehabilitation robots are auxiliary devices that provide physical assistance and make it easier for users to perform physical tasks. They include such things as smart wheelchairs, artificial limbs, and exoskeletons. Social robots interact with the elderly, providing companionship or improving daily life. These robots can be further divided into service-type robots and companionship robots. The function of the service-type robot is mainly related to supporting the independent life of the elderly individual, such as assisting with eating, bathing, toileting, or dressing, as well as performing housework and providing health and safety monitoring. A companionship robot promotes the physical and mental health of elderly persons and enhances their quality of life through companionship, such as the robotic seal PARO that accompanies elderly individuals with dementia; the robot Huggable, which was specially developed for elderly care experimental research; and the robotic dog Aibo, which was intended to improve the quality of life of older individuals and disabled patients [9,10]. Studies have shown that older people prefer less human-looking robots [11,12] and especially enjoy pet-like robots, which are widely used in the care of elderly persons with intellectual disabilities and provide pet-like companionship in lieu of real animals [13,14]. For example, the therapeutic robotic seal pet PARO, which was developed in Japan in 2004, has a body covered with more than 100 sensors and can interact with people. Survey results show that because PARO's appearance is unfamiliar to people, it is less likely that people will feel a sense of artificial interaction with an animal, and it is more likely to be accepted by the elderly [15]. Many studies have also shown that PARO can improve depression, increase social interaction, and positively stimulate cognitive functions in elderly persons with dementia [16,17], which suggests that robot-assisted therapy is a new therapeutic tool for use among the elderly [18-20]. According to the literature review [21], robot-assisted therapy is beneficial to the moods and behavior of elderly persons. A pet-like social robot can stimulate elderly persons to interact and talk with others and remind older adults of their past experiences with companion pets, while posing fewer concerns about safety (such as attacks or bites) and hygiene (allergies, infections, or dirt) that are associated with real pets. Older adults with dementia can also get the same emotional comfort from robot-assisted therapy as they would from their interaction with real pets. As a result, a pet-like robot provides not only simple entertainment but also assistance, companionship, therapy, interaction, and stimulation, as well as other functions and services [21].

However, technology may not be a substitute for human assistance, companionship, and interaction. A study was conducted to enable "robotic dog doctors" to accompany the elderly through animal-assisted therapy, and the results of the study showed that it had a positive effect on the mental and social health of the elderly participants. The study indicated that animal-assisted therapy can improve emotional and behavioral problems, as well as problems with aggression, in elderly individuals with dementia and can have a positive effect on the mental and social health of all elderly persons. Animal-assisted therapy is often recommended as a goal-oriented nonpharmaceutical therapy for mental problems [22]. For example, a study by Garrity et al [23] on widowed and socially isolated elderly persons over the past year found that those who had no experience with keeping pets were more depressed than those who had such experience. There are also studies showing that keeping pets is related to the survival rate of cardiovascular disease in the elderly [24], suggesting that pet companionship has a curative effect that cannot be ignored in clinical care and treatment. Some scholars have suggested that patients with dementia can experience a reduction in their degree of loneliness and engage in social interaction by interacting with robot pets and get pleasure and attention from it as well as spiritual comfort [25,26]. Thus, robot pets provide a new therapeutic option for the elderly with dementia. Furthermore, animal protection regulations in countries in addition to a lack of adequate animal training makes robot pets more attractive than animal pets. For example, people generally have doubts about the safety and health of animals in Taiwan, which leads to a lot of restrictions on their implementation in therapy [27]. Therefore, robots or robot pets provide the elderly with dynamic, 2-way communication and a positive interaction mode, which can be regarded as another option for them in later life. Robots can do more dangerous and tiring work in the home care of elderly persons, but they may undergo failure and present financial and ethical issues. Although pets have more spontaneous reactions and richer emotional responses and can provide more tactile stimulation, they present safety and health issues that must be taken into consideration, as well as extra time-consuming care requirements. The aforementioned factors affect the user's choice. According to the theory of planned behavior proposed by Ajzen [28], the occurrence of a behavior depends on the intensity of people's intentions, and the intensity of intentions is determined by 3 factors: attitude, subjective norms, and perceived behavioral control. Therefore, it is important to explore what factors affect the acceptance of robots and pets among middle-aged and older adults in Taiwan and to understand whether these factors correspond to the theory of planned behavior.

Thodberg et al [29] performed a study that compared pets with robotic dogs. At the beginning of the study, the robotic pet PARO and real pets (dogs) had the same impact on residents. However, with increases in interaction time, residents decreased their conversation and eye contact with PARO, but their focus on and interaction with the dogs remained stable [29]. The study also found that the real animals had more spontaneous and richer emotional responses than the robotic pets and that subjects could get more active tactile stimulation. Compared with toy animals, both robotic pets and real animals can provide 2-way dynamic communication, so it is feasible to use a robot/robot pet as a companion object and an auxiliary technological device for stimulating the sensory and cognitive functions of elderly individuals. However, most of the existing studies exploring the effectiveness of robot pet interventions in the elderly population (eg, psychological and behavioral effects and impact on quality of life) have been conducted on institutionalized elderly individuals with dementia for which long-term care was provided [30-33]; few of the studies have included elderly persons in the community as the study population. In particular, there has been a lack of study on the attitudes, degree of acceptance, and needs of middle-aged and older adults as they relate to robots. In the past, there have also been no studies comparing pets with robots in terms of their use as companion objects. This study is aimed toward closing these gaps in the existing literature to discuss the companion needs of middle-aged and older adults in Taiwan in order to understand their choices of robots or live pets as companion objects in later life and to further discuss the preferences of middle-aged and older adults for companionship robots, as well as other related factors.

Methods

Participants

Adults over age 45 years in Taiwan were invited to participate in this study using a convenience sampling method based on the sample selection standard. The number of participants needed for the study was determined as the number of variables (n=26) multiplied by 10. Thus, a total of 273 older adults living in the community comprised the sample. The questionnaire was distributed in gathering places for the elderly in Taiwan such as community universities, senior citizen learning centers, community care strongholds, day-care strongholds, and hospital clinics all over Taiwan. The inclusion criteria for participants were as follows: (1) able to communicate in Mandarin and Taiwanese; (2) willing to be interviewed by researchers, to fill out the questionnaire on their own, or to fill out an electronic questionnaire with a tablet computer; and (3) agreed to participate in the study and to sign a consent form. The exclusion conditions were as follows: (1) resided somewhere other than Taiwan, and (2) were suffering from moderate to severe cognitive impairment or unable to answer questions without coercion.

Measures

A structural questionnaire was used as the research tool. The content of the questionnaire included 4 parts: sociodemographic data, physical and mental health status and activities, technology use and eHealth literacy, and robot and pet experience.

The sociodemographic data included age, gender, education level, marital status, number of children, place of residence, whether living alone or not, working status, economic status, self-rated health status, and number of chronic diseases.

The physical and mental health status and activities included social participation, leisure activities, social support, depression status, and personality traits. Among them, social participation and leisure activities were measured using the Ministry of Health and Welfare Taiwan Longitudinal Study on Aging questionnaire [34]. Social support was measured using the Inventory of Socially Supportive Behavior (ISSB [35,36]). This inventory consists of 10 questions relating to 4 types of social support: emotional support (3 questions), information support (2 questions), substantive support (2 questions), and social integration (3 questions). In the scoring system for the ISSB, a score of 1 represents unsatisfied, 2 represents neutral, and 3 represents satisfied; the higher the score, the higher the perceived social support. An overall internal consistency coefficient of .91 represents emotional support for each support type α reliability coefficient; a coefficient of .81 represents information support; a coefficient of .73 represents substantive support; and a coefficient of .81 represents social integration [37]. The depression status was measured using the simplified, 10-item version of the Center for Epidemiologic Studies Depression Scale (CES-D [38]), which was translated into Chinese. The CES-D comprises 10 positive and 10 negative questions that are scored on Likert scales ranging from 0 to 3, with the total score ranging from 0 to 30 and a total score of greater than 10 representing depression. The overall internal consistency Cronbach α value ranges from .78 to .87 [39]. The personality assessment was carried out using the International Personality Item Pool (IPIP) big 5 personality scale developed by Goldberg in 1992 [40], which was first translated into a simplified Chinese version [41] and then changed to a traditional Chinese version with customary modifiers used by the Taiwanese population [42]. A single factor was screened out from the original 50 questions, and the questions with higher factor loadings in each domain were developed into a new, 15-item version of the IPIP (IPIP-15). This simplified version of the IPIP big 5 personality scale is divided into 5 dimensions—extroversion, friendliness, rigorousness, emotional stability, and intelligence/imagination—that are scored from 0 to 5, where 1=imprecise, 2=slightly imprecise, 3=ordinary, 4=slightly precise, and 5=very precise. The Cronbach α reliability coefficient judging the internal consistency of each scale ranged between .67 and .83, and the factor loading ranged between .61 and .83, indicating convergent validity. The correlation between the IPIP-15 and the personality scales corresponding to the original IPIP-50 ranged between .81 and .88, which indicated that the convergent validity was acceptable [42].

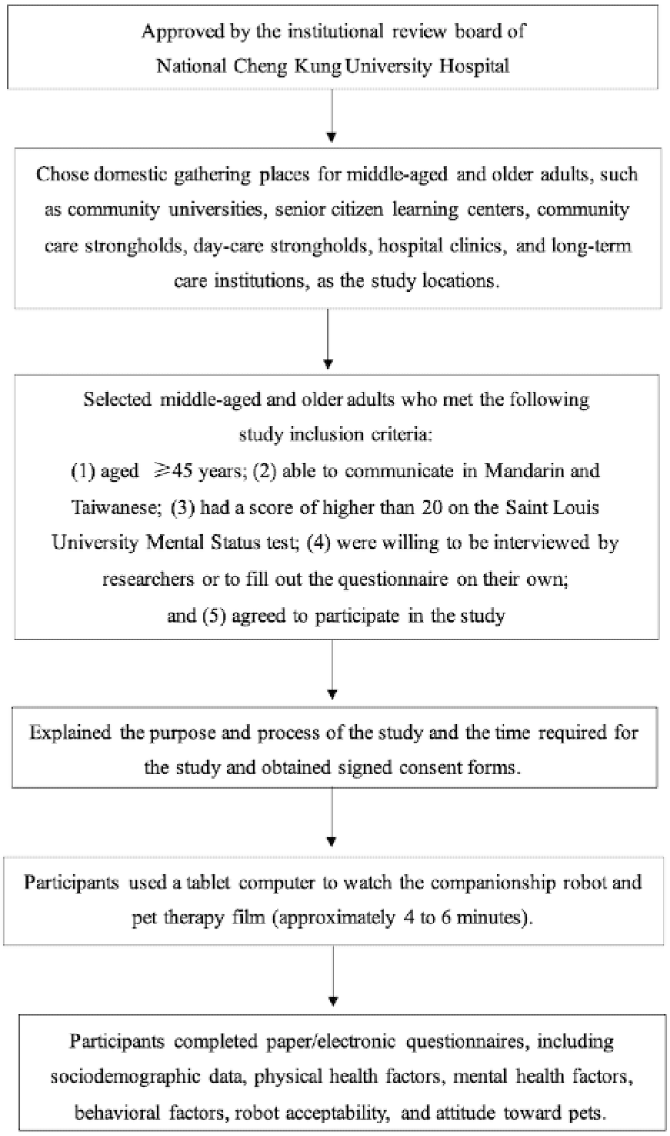
Participants' experience in the use of technology, networking, and eHealth literacy were also assessed. The question about experience with the use of technology and networking was answered by subjects based on their past experience (ie, whether they had experience using the internet and downloading and using mobile apps). The question about eHealth literacy was assessed using the eHealth Literacy Scale (eHEALS), which is an 8-item measure that assesses the participant's internet use and search skills, ability to evaluate online content, and confidence in their internet-searching abilities. This scale is scored with 4 points, with the options being entirely disagree, disagree, agree, and strongly agree, which are scored 1, 2, 3, and 4, respectively. The internal consistency Cronbach α reliability coefficient for each item is .88, and the factor load ranges between .60 and .84 [43,44].

Experience with and acceptance of robots and pets included the acceptability of choosing a robot or pet as a companion object in later life, the type of companionship robot desired/favored, and past experience with keeping pets. Among these indices, the question about the acceptability of robots/pets was answered based on the response, "Acceptability of choosing a robot or pet as a companion object in later life." It was scored from 0 to 10, with 0 representing completely unacceptable and 10 representing quite acceptable, and the higher the score, the higher the degree of acceptability. In addition, when the type of companion robots desired/favored was also evaluated, subjects were requested to choose the types and functions of the robots according to their preferences or needs. The choices included the companionship robot's services (eg, assisting with family tasks, health monitoring, safety monitoring), skills (eg, juggling, dancing, singing), interaction (eg, chatting, storytelling, news reporting, joke telling, providing child-like dialogue), expression, and appearance (eg, resembling an animal, human infant or adult, or nonbiological form), as well as other functions.

Procedure

The study was conducted between May and June 2018. A cross-sectional survey research method was used to survey the degree of acceptance and factors related to the choices made by middle-aged and older adults in Taiwan of a robot or pet as their companion object in later life. This study was approved by the institutional review board (IRB) of National Cheng Kung University Hospital in Taiwan (No. A-ER-105-509). The study collection methods and procedures are shown in Figure 1.

Figure 1. Research and data collection flowchart.



Approved by the institutional review board of National Cheng Kung University Hospital

Chose domestic gathering places for middle-aged and older adults, such as community universities, senior citizen learning centers, community care strongholds, day-care strongholds, hospital clinics, and long-term care institutions, as the study locations.

Selected middle-aged and older adults who met the following study inclusion criteria:
(1) aged ≥45 years; (2) able to communicate in Mandarin and Taiwanese; (3) had a score of higher than 20 on the Saint Louis University Mental Status test; (4) were willing to be interviewed by researchers or to fill out the questionnaire on their own; and (5) agreed to participate in the study

Explained the purpose and process of the study and the time required for the study and obtained signed consent forms.

Participants used a tablet computer to watch the companionship robot and pet therapy film (approximately 4 to 6 minutes).

Participants completed paper/electronic questionnaires, including sociodemographic data, physical health factors, mental health factors, behavioral factors, robot acceptability, and attitude toward pets.

With the consent of the IRB of National Cheng Kung University Hospital in Taiwan, middle-aged and older adults in Taiwan were invited to participate in the study, and gathering places for the middle-aged and older adults, such as community universities, senior citizen learning centers, community care strongholds, and day-care strongholds, were chosen as places to distribute questionnaires. Middle-aged and older adults who met the following inclusion criteria were selected: (1) aged ≥45 years, (2) able to communicate in Mandarin and Taiwanese, (3) had a Saint Louis University Mental Status test score higher than 20, (4) willing to be interviewed by the researchers or to fill out the questionnaire on their own, and (5) agreed to participate in the study and sign a consent form. The researchers explained to the subjects the study's purpose, process, and duration. After signing the consent form, the subjects used a tablet computer to watch a companionship robot film, after which they completed a questionnaire.

A companionship robot film was used in the study to provide a brief introduction to each type of companionship robot and was explained by the researchers at the time it was played. The film included robots with various physical characteristics (Multimedia Appendix 1), such as resembling an adult, an infant, an animal, or a nonbiological object, and presented the different functions of each robot, such as assisting with family tasks, health monitoring, safety monitoring, and other services, and the content of the robots' interactions with users, such as chatting, reporting news, reporting weather, singing, dancing, and making various expressions, among other functions.

Statistics

The descriptive statistics included an analysis of the sociodemographic variables, physical health factors, past experience with keeping pets, and experience in the use of technology as they related to variables such as the acceptability of choosing a robot or pet as a companion object in later life using a *t* test and a 1-way analysis of variance. Differences among the sociodemographic variables, physical health factors, past experience with keeping pets, and experience with the use of technology, as well as other variables related to the elderly, were verified using the chi-square test among 4 groups of robot/pet preferences. The analysis of the correlation between the continuous variables was related to the Pearson correlation and included age, number of years living alone, IPIP-15 score, CES-D score, ISSB score, eHEALS score, and the level of acceptance of a robot or pet as a companion object in later life. A multiple regression analysis was used to analyze the between-variable correlations, such as gender, age, education level, living alone or not, retirement status, number of comorbidities, ISSB score, eHEALS score, IPIP-15 score, and acceptance of either robots or pets. Finally, a multinomial logistic regression analysis was used to analyze the predictive power of different groups of robot or pet acceptability in the middle-aged and older adults based on the following variables: (1) both robots and pets were highly acceptable (HH), (2) preferred choice was a robot (HL), (3) preferred choice was a pet (LH), and (4) neither robots nor pets were acceptable (LL).

Results

Descriptive Analysis of the Subjects' Basic Data

For the purpose of discussing the degree to which the middle-aged and older adults preferred a robot or pet as their companion object in later life in Taiwan, the questionnaires were distributed at 6 community care strongholds, 5 community centers, and 3 large-scale activities related to respecting the elderly and Mother's Day events in the north, middle, and southern parts of Taiwan. A total of 273 subjects who met the inclusion criteria were selected out of 300 middle-aged and older adults living in the community who were aged ≥45 years, and a total of 240 valid questionnaires were obtained after those with missing data or incorrect answers (n=33) were removed. The minimum and maximum ages of the participants were 45 years and 94 years, respectively. The average age was 60.68 years, and there were 172 (71.7%) female participants and 68 (28.3%) male participants. The majority of participants were highly educated (183/240, 76.2%), had a partner (170/240, 70.8%), lived in the city (214/240, 89.2%), did not live alone (215/240, 89.6%), lived with children (221/240, 92.1%), had no experience with using robots (197/240, 82.1%), had experience using the internet (196/240, 81.7%), could download and use an app (184/240, 76.7%), had experience with keeping pets (152/240, 63.6%), and had no experience with animal-assisted therapy (226/240, 94.2%). The subjects reported an average of 0.65 chronic conditions and an average self-reported health score of 3.53 (out of 5). On average, subjects' level of acceptance of robots and pets was 5.69 points and 4.72 points, respectively. A detailed chart of the data distribution is shown in Table 1.

Table 1. Basic sociodemographic data of participants.

Characteristic		Preference of robot or pet as a companion				
	Full sample (N=240)	Both are highly acceptable[a] (n=81, 33.8%)	Prefer robot (n=42, 17.5%)	Prefer pet (n=56, 23.3%)	Neither is acceptable (n=61, 25.4%)	Verification value (F/χ^2)

eHealth Literacy Scale score, mean (SD)	21.65 (7.773)	22.04 (7.825)	21.36 (8.316)	23.43 (6.494)	19.69 (8.123)	2.400
Acceptability[a] (0 to 10 points), mean (SD)						
Robot	5.69 (3.142)					
Pet	4.72 (3.564)					

[a] Acceptability was deemed to be high or low if it was higher or lower, respectively, than the average points of acceptability.

[b] Because the number of people who had few expectations was less than 5, the test was conducted using Fisher exact test, and the results showed no significant differences.

[c] IPIP-15: 15-item International Personality Item Pool big 5 personality scale.

[d] CES-D: Center for Epidemiologic Studies Depression Scale.

**P*<.05; ***P*<.01; and ****P*<.001.

Factors Associated With Intention to Use a Robot or Pet as Their Companion Object in Later Life

The variables related to acceptance of robots and pets were divided into 4 groups: both robots and pets were highly acceptable (HH), preferred a robot (HL), preferred a pet (LH), and neither robots nor pets were acceptable (LL). The level of acceptability was deemed to be high if it was higher than average and was deemed to be low if it was lower than the average. As Table 1 shows, 33.8% (81/240) of the subjects reported both robots and pets to be acceptable (HH), 17.5% (42/240) preferred a robot (HL), 23.3% (56/240) preferred a pet (LH), and 25.4% (61/240) reported neither robots nor pets to be acceptable (LL). The results of the study showed that retirement status (χ^2_3=9.40, *P*=.024), experience with keeping pets (χ^2_3=20.55, *P*=.000), and the number of comorbidities ($F_{3,236}$=4.43, *P*=.005) were all significantly associated with the 4 acceptance groups. However, none of the psychological measures, including personality traits, CES-D score, and social participation, were associated with the preference for robots or pets as their companion.

Results of the multinomial logistic regression analysis used to analyze the variables in terms of their predictive power on the 4 groups of robot/pet acceptability among the middle-aged and older adults is presented in Table 2. The results showed that those with more comorbidities were 1.688 times more likely to fall into the HL group than into the LL group (*P*=.048); those who could download and use an app were 0.170 times more likely to fall into the HL group than the LL group as compared with those who had not used or downloaded apps (*P*=.022). Those who could download and use apps were 0.159 times more likely to fall into the HL group than into the LL group as compared with those who had not used or downloaded apps (*P*=.012). Those with experience with keeping pets were 3.527 times more likely to fall into the HH group than into the LL group as compared with those who had no experience with keeping pets (*P*=.002). Those who had experience with keeping pets were 2.498 times more likely to fall into the LH group than into the LL group as compared with those with no experience in keeping pets (*P*=.034). Those with a higher score on eHEALS were 1.084 times more likely to fall into the HH group than into the LL group (*P*=.039). Those with higher scores on eHEALS were 1.139 times more likely to fall into the HL group than into the LL group (*P*=.005). Finally, those with higher scores on eHEALS were 1.100 times more likely to fall into the LH group than into the LL group (*P*=.020).

Subjects' Preferences for Companionship Robot Functions

This section discusses the participants' preferences for the functions of the companionship robot as their companion object in later life. The subjects filled out questionnaires regarding their preferences or needs for functions of the companionship robot. The functions of the companionship robot included (1) family services, (2) health status monitoring, (3) safety monitoring, (4) skill and recreation-type functions (eg, juggling, dancing, singing, storytelling, news reporting, joke telling, the ability to make various expressions), and (5) interactive functions (eg, chatting, providing child-like dialogue).

The results of the study showed that the functions of the companionship robot that the subjects most desired were the skill and recreation-type functions (211/240, 87.9%), followed by family services (185/240, 77.1%), interactive functions (160/240, 66.7%), health status monitoring (147/240, 61.3%), and safety monitoring (144/240, 60.0%), as shown in Table 3. By analyzing the correlation between the sociodemographic characteristics and the function selection for the companionship robot, it was found that in addition to skill and recreation-type functions (60/68, 88.2%) and family services (50/68, 73.5%), male subjects desired health status monitoring functions (46/68, 67.6%) of the companionship robot more than its interactive functions (44/68, 64.7%). Female subjects desired the safety monitoring functions (103/172, 59.9%) of the companionship robot more than its health status monitoring functions (101/172, 58.7%). Among these, although the differences were not statistically significant, the middle-aged and older female subjects still preferred family service–type robots and interactive function–type robots more than the male subjects.

Table 3. Analysis of the preference of middle-aged and older adults for the companionship robot functions (N=240).

*P<.05; **P<.01; and ***P<.001.

According to the results of the analysis on residential status and preferences for functions of the companionship robot, 64% (16/25) of the people living alone had a greater preference and demand for interactive functions, which took second place among those living alone in terms of the desired functions of the companionship robot. Among these subjects, whether or not they lived alone was significantly related to the preference for family service (ie, housework) functions (P=.032). The results for choosing skill and recreation-type functions for the companionship robot by those living alone were not statistically significant, but there was still a tendency toward choosing this type of robot.

The results of the analysis on the marital status and the preference for the companionship robot functions showed that for subjects who had no partner, the level of preference and demand for safety monitoring functions was higher than for health status monitoring functions, and having a partner was significantly related to the choice of health status monitoring functions (P=.045).

The subjects were divided into 3 age groups: 45 to 54 years, 55 to 64 years, and ≥65 years. By analyzing the choices made by the elderly in each age group for the functions of the companionship robot, it was found that the subjects ranging in age from 45 to 54 years mainly preferred the family service–type robot followed by the skill and recreation-type robot. However, subjects who were aged 55 to 64 years and over 65 years all chose the skill and recreation-type robot, including the functions of juggling, dancing, singing, storytelling, news reporting, joke telling, and the ability to make various expressions, followed by the family service–type robot. The different ages were significantly related to the choice of family service (*P*<.001), health status monitoring (*P*=.009), and safety monitoring (*P*=.026) functions of the companionship robot.

Subjects' Preferences for the Appearance of the Companionship Robot

This section discusses the preferences of the middle-aged and older adults for the appearance of the companionship robot as their companion object in later life. The subjects filled out a questionnaire according to their preferences or requirements for the appearance of the companionship robot, which included animal, infant, adult, and nonbiological or other form.

It was found that the appearance of the companionship robot that the subjects most desired/preferred was one resembling an animal (94/240, 39.2%), followed by one resembling an adult (72/240, 30.0%), an infant (43/240, 17.9%), and a nonbiological or other form (21/240, 8.9%). The results are shown in Table 4. The analysis of the correlation between the sociodemographic characteristics and the choice of the appearance of the companionship robot showed that male subjects preferred a companionship robot that resembled an adult (29/68, 42.6%), followed by an animal-like appearance (23/68, 33.8%), where gender was found to be significantly related to the preference for the companionship robot to look like a human adult (*P*=.007). The correlations between residential status and marital status with choice of robot appearance did not reach statistical significance, but living alone and with a partner had the same ranking as the full sample in terms of this preference. Regardless of age, the appearance of animals was the most popular choice of robot appearance. The second most preferred robot appearance was that of a human adult among subjects who were aged 45 to 54 years old and those aged 55 to 64 years; subjects who were ≥65 years preferred the infant- and adult-like appearances equally.

Table 4. Analysis of the preference of the middle-aged and older adults for the appearance of the companionship robot (N=240).

Characteristic	Preferred appearance of companionship robot

Discussion

Principal Findings

The main purpose of this study was to discuss the level of acceptance of middle-aged and older adults toward a robot or pet as their companion object in later life; to understand the correlation between sociodemographic variables, physical health, mental health, behavioral factors, and preferences for either a robot or pet as a companion object in later life; and to further analyze the needs and preferences of the subjects for the functions and appearance of a companionship robot. The results of the community survey showed that the level of acceptance of subjects in the community toward a pet as their companion object in later life was significantly correlated with their age, with a higher age being associated with a lower average score for acceptance of a pet. Acceptance of pets was significantly correlated with education level, type of occupation, retirement status, number of comorbidities, past experience with keeping pets, an extroverted personality, an intellectual/imaginary personality, and eHealth literacy. In terms of the acceptance toward robots, there were no significant differences in the level of acceptance based on age group. The level of acceptance toward robots was only significantly related to the type of dwelling the subject lived in. No correlation between the acceptance toward robots and other sociodemographic variables, or physical health, mental health, or behavioral factors was observed in this study.

According to the acceptability score, the level of acceptance of the middle-aged and older adults for choosing between a robot or pet as their companion object in later life was divided into 4 groups: both are highly accepted (HH), preferred a robot (HL), preferred a pet (LH), and neither was acceptable (LL). When the average acceptability score was used as the grouping standard, there were significant differences in terms of retirement status, number of comorbidities, and past experience with keeping pets among each group of subjects. The results of the multinomial logistic regression analysis on the key variables showed that the number of comorbidities, experience with keeping pets, experience with using apps, and eHealth literacy had significant predictive power for the level of acceptability among all of the groups; however, gender, intergenerational differences, education level, whether or not subjects lived alone, social support, and past experience with keeping pets had no significant impact on the level of acceptability among the various groups.

According to the theory of planned behavior, attitude, subjective norms, and perceived behavioral control are the 3 factors that determine behavior [28]. In the research, although the reasons for the significant variables were not further explored, we can infer that personality, education level, type of occupation, and past experience with keeping pets, which can affect the experience of life, might be related to personal attitude. The type of dwelling in which a person resides may affect their preference for robots or pets. It may be related to subjective norms; after all, sometimes living conditions such as neighbors or house size might restrict one from keeping pets. On the other hand, age (related to one's functional ability to keep pets), retirement status (ie, how much leisure time someone has), number of comorbidities, experience with using apps, and eHealth literacy might be related to perceived behavioral control. Overall, the results showed that preferences for robots and pets among middle-aged and older adults conformed to the theory of planned behavior.

By analyzing the needs and preferences of middle-aged and older adults for the companionship robot, it was found that these individuals desired/favored robot skills such as juggling, dancing, singing, storytelling, news reporting, joke telling, or the ability to make various expressions, followed by family service, interactive, health status monitoring, and safety monitoring functions. In terms of the appearance of the companionship robot, the middle-aged and older adults preferred the robot to look like an animal, followed by it having an adult-like appearance, infant-like appearance, and nonbiological or other appearance, in that order. By further analyzing the impact of sociodemographic characteristics on the preferences for the companionship robot, it was found that whether the subjects lived alone or not significantly affected the choice of the family service function of the robot, and whether there was a partner or not also significantly affected whether the subjects chose the health status monitoring function of the robot. Male subjects showed a greater preference for an adult-like appearance in the robot than did female subjects, and the difference was statistically significant. Female subjects preferred an animal-like appearance to the robot over an adult-like appearance.

Comparison With Prior Work

Most studies on the appearance of robots have pointed out that elderly individuals prefer less human-looking robots such as pet-like robots, which have been widely used in the past to care for the elderly and are highly accepted by them [12,13,45]. Studies in Japan showed that the robotic seal pet PARO, because its seal-like appearance was unfamiliar to people, did not lead to an unreal sense of interaction with a fake animal and was easily accepted by the elderly [46]. A study discussing robots in the daily lives of the elderly in Taiwan pointed out that older adults were more likely to accept robot pets of traditional pet animals, such as cats or dogs, because the elderly associated the robots with animals they were familiar with, and those who had no experience with keeping pets wanted pet-like robots as pets [47]. A study discussing the needs of the elderly for the companionship robot when they entered the "empty-nest" period indicated that the appearance of a future companionship robot needed to be based on human life experiences. For example, the Hug is a robot that allows the elderly to maintain social and affective interactions by communicating closely with their families. It was designed to look like a human offering a hug and has specific types of communication functions [48]. The SenseChair is a robot that was designed to look like a "chair" that the elderly are familiar with in their daily life [49]. In terms of the robot's functions, the main purpose of using a home-based robot was to obtain the "home service" function, following by providing assistance to people with mobility disabilities, home security management, remote monitoring, emotional pacification, and so on. The study also pointed out that companionship robots with more social functions are more likely to elicit expressions and responses from the elderly and to promote the participation of the elderly in social interactions and enhance the quality of their interactions [19,50].

Limitations and Future Work

There were some limitations to this study. First, the research tool was self-reported, and the subjects' understanding of the questions in the questionnaire and their personal perception of their own situation all affected their answers. The subjects' answers might have been affected by extrinsic factors beyond their control such as mood and social expectations, so the results of the inventory might have been different from their actual situation, resulting in measurement errors in the results of the study. Second, the sampling sites for the study were gathering places for the elderly, such as community care strongholds and community centers, and at activities intended to respect the elderly and as part of Mother's Day events. The subjects were middle-aged and older adults who were more active and had the intention and ability to go out, so the results of the study are limited in terms of extrapolation. Third, the sample size and representativeness of the subjects were not as good as probability sampling, which affected any inferences that could be made based on the results, although the study areas covered the northern, central, and southern parts of Taiwan to increase the robustness of the results of the study. Fourth, this research is the first attempt at understanding companionship preferences toward pets and robots among the elderly in the community in Taiwan. Therefore, cultural factors were not considered. Similarly, because there have been few studies of this topic abroad [29], it is difficult to know whether there are similarities or differences between cultures, which is an expectant direction for future work.

In spite of these limitations, this study is a rare survey of the perceptions of elderly individuals living in the community toward companionship robots. The subjects in this study were aged 45 to 94 years and included active middle-aged and older adults living in the community in the northern, central, and southern parts of Taiwan. It is the only study in Taiwan to compare pets and robots from the point of view of choosing them as a companion object. From the results of the study, we can preliminarily understand the current situation and preferences of the needs for companionship in middle-aged and older adults living in the community. In addition to contributing to the literature, middle-aged and older adults at home can find a suitable companion object in later life based on their sociodemographic characteristics. First-line community practitioners can also design care projects for middle-aged and older adults living with different needs and backgrounds and provide a future implementation plan for the welfare system, as well as provide empirical evidence for policy promotion and the development of science- and technology-related industrial products.

Conclusion

The key findings of this study are as follows. First, variables such as age, education level, type of dwelling, occupation, retirement status, number of comorbidities, experience with keeping pets, experience with using apps, and eHealth literacy significantly affected the degree of acceptance of a robot or pet as a companion object in later life. Community practitioners working with middle-aged and older adults could plan curricula according to the different backgrounds and characteristics of the population of interest to develop care projects for middle-aged and older adults based on their different needs and backgrounds and help them to select appropriate companion objects in later life. Second, the study found that eHealth literacy significantly affected the degree of acceptance of robots and pets in the middle-aged and older adults as well as the type of functions desired in a companion robot. Those with higher eHealth literacy scores were more likely to respond that both robots and pets were acceptable as companion objects. This indicates that those with better eHealth literacy are more likely to choose a robot or pet as their companion object in later life and that eHealth literacy is significantly associated with age. First-line staff or policy makers in relevant fields can conduct eHealth literacy promotion courses for middle-aged and older adults in order to facilitate the implementation of relevant plans. Third, in terms of the development of companionship robot products, middle-aged and older women generally preferred animal-like robots as companion objects in later life, while men preferred an adult human-like robot. In terms of functions, middle-aged and older adults in the community are more likely to need a companionship robot that has functions including dancing, singing, storytelling, or news reporting. Whether or not they live alone or with a partner also affects their preferred robot functions, so technology-related industries should consider designing products to suit the needs of different target groups. It would be useful to increase the number of study samples or select specific groups to carry out intensive studies. Heterogeneous populations in residential institutions or extension of the sampling sites could make the results more generalizable. In addition, qualitative study methods such as in-depth interviews would help lead to an understanding of the needs of middle-aged and older adults in terms of a companion in later life. Study methods attaching equal importance to quality and quantity in the future could potentially better reflect the current needs of middle-aged and older adults.

Abstract

Background: Over the recent decades, Vietnam has attained remarkable achievements in all areas of health care. However, shortcomings including health disparities persist particularly with a rapidly aging population. This has resulted in a shift in the disease burden from communicable to noncommunicable diseases such as dementia, cancer, and diabetes. These medical conditions require long-term care, which causes an accelerating crisis for the health sector and society. The current health care system in Vietnam is unlikely to cope with these challenges.

Objective: The aim of this paper was to explore the opportunities, challenges, and necessary conditions for Vietnam in transforming toward a patient-centered care model to produce better health for people and reduce health care costs.

Methods: We examine the applicability of a personalized and integrated Bespoke Health Care System (BHS) for Vietnam using a strength, weakness, opportunity, and threat analysis and examining the successes or failures of digital health care innovations in Vietnam. We then make suggestions for successful adoption of the BHS model in Vietnam.

Results: The BHS model of patient-centered care empowers patients to become active participants in their own health care. Vietnam's current policy, social, technological, and economic environment favors the transition of its health care system toward the BHS model. Nevertheless, the country is in an early stage of health care digitalization. The legal and regulatory system to protect patient privacy and information security is still lacking. The readiness to implement electronic medical records, a core element of the BHS, varies across health providers and clinical practices. The scarcity of empirical evidence and evaluation regarding the effectiveness and sustainability of digital health initiatives is an obstacle to the Vietnamese government in policymaking, development, and implementation of health care digitalization.

Conclusions: Implementing a personalized and integrated health care system may help Vietnam to address health care needs, reduce pressure on the health care system and society, improve health care delivery, and promote health equity. However, in order to adopt the patient-centered care system and digitalized health care, a whole-system approach in transformation and operation with a co-design in the whole span of a digital health initiative developing process are necessary.

Introduction

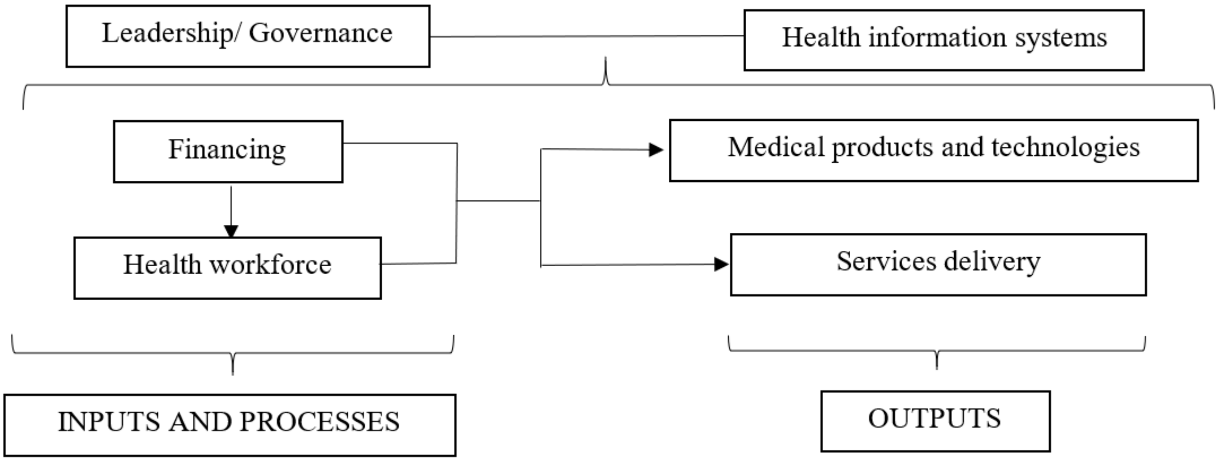
Overview

Following broad economic reforms known as Doi Moi in 1986, Vietnam has attained remarkable health care improvement, reflected in core health indicators [1]. From 1988 to 2018, life expectancy at birth increased from 69.9 years to 75.3 years, under-5 mortality rate decreased from 56‰ to 20.7‰, and infant mortality reduced from 39.6‰ to 16.5‰ [2]. Health care expenditure gradually increased and was forecasted to triple from US $15.6 billion in 2018 to US $42.9 billion in 2028 [3]. Despite these improvements, the health care system still faces significant challenges including wide disparities in health and growing health care costs. The disparities in core health indicators are particularly observed between urban and rural residents, across different regions, and among population groups [4]. For example, the maternal mortality ratio and infant mortality rate in some mountainous areas are 3 to 4 times higher than those in lowland and urban areas and almost double the national average rates [4].

Vietnam is undergoing a dramatic demographic transition resulting in an aging population. The number of people aged 65 years and over is estimated to increase from 10% of the population in 2015 to 28% in 2050 [5]. The combination of an aging population, increased industrialization, and changes in population lifestyle have created a double disease burden, with a shift from communicable to noncommunicable diseases (NCDs). Specifically, the mortality rate caused by NCDs rose from 45.5% in 2010 to 77% in 2016 and is projected to climb [3,4,6]. The double disease burden means that Vietnam is facing more costly health conditions such as dementia, cancer, and multimorbidity. In addition to this, the country still faces significant burden of infectious conditions and a number of new epidemics such as COVID-19. These health challenges must be addressed using a systemic approach by the whole government of Vietnam to improve health for its population.

To improve health care problems and the health status of the population, there is a critical need for a well-functioning health care system that can deliver services equitably and efficiently [7]. The World Health Organization (WHO) developed an evidence-based building blocks framework as a tool to help its member states analyze their health care systems. This framework allows nations to consider the multifaceted nature of their health systems and interdisciplinary and multilevel responsibility in health care [7]. The WHO framework assesses health systems using 6 core components or building blocks. Each building block and its indicators were initiated by a group of agency representatives and technical experts, shared broadly with country experts, and followed by evaluations through a series of case studies and reviews of country experiences [7]. These components focus on the key chains of the monitoring and evaluation framework developed by the International Health Partnership, namely inputs, processes, and outputs [8]. The relation between the 6 building blocks and this monitoring and evaluation framework is summarized in Figure 1. In the following section, the 6 building blocks and corresponding indicators are used to describe Vietnam's health care system, comprising financing and health workforce components (inputs and processes), medical products, technologies, and service delivery components (immediate outputs), and cross-cutting components: leadership/governance and health information systems [7].

Figure 1. Health system strengthening: relationship between the World Health Organization building blocks (6 core components, top) and International Health Partnership monitoring and evaluation framework (inputs, processes and outputs, bottom).



Health Care System in Vietnam

Health Financing

Health financing is a key building block in a national health system, largely influencing the inputs, thus affecting the availability, affordability, and accessibility of health services. A good health financing system should move toward universal health coverage, where all people have access to needed health services without financial hardship. This could be achieved through increasing total health expenditure (THE) and decreasing the proportion of households facing financial catastrophe as a result of out-of-pocket payments (OPP) [7].

With multiple health financing reforms, Vietnam's THE per capita increased from US $14 in 1995 to US $113 in 2014 [9,10], thus within the internationally defined range and enough for universal coverage of key health interventions [7]. The increase in public health expenditure (mainly comprising state budget [11] and social health insurance [12]) has increased health care coverage for some groups including the poor, ethnic minorities, under–6-year-old children, over–80-year-old people, and socially vulnerable groups through the government's subsidized schemes [13]. However, patient OPP remained high, accounting for 40.8% of THE in 2015, which was higher than that of other countries in the Asia Pacific region and the WHO recommended level [10,11]. The high OPP led to catastrophic expenditure and pushed many Vietnamese families into poverty, resulting in health care inequity [14,15]. The current model of the health care system and financing needs further reforms to address a surge in health care expenditure caused by the aging population and shifting disease pattern in Vietnam.

Health Workforce

The health workforce is another key building block to provide inputs and processes to the monitoring and evaluation chain of health systems. The ability of a country to meet its health goals largely depends on people in charge of organizing and delivering health services. Evidence of the direct and positive link between numbers of health workers and population health outcomes has been demonstrated in several studies [16,17].

The health workforce in Vietnam has gradually improved in both quantity and quality. The number of doctors and pharmacists increased from 7.2 and 1.76 per 10,000 people in 2010 to 8.0 and 2.2 per 10,000 people in 2015, respectively [4]. In 2015, 65% to 95% of the health facilities and about 90% of the health workers in hospitals at central and provincial levels were licensed [4]. Despite this significant improvement, Vietnam's health workforce was still insufficient to meet staffing norms and clinical needs [4] and inappropriately distributed across regions and levels/areas of care. The aging population and shifting disease burden to those requiring long-term care for chronic NCDs are likely to lead to severe shortages in health resources, which occur in highly specialized fields such as cancer, palliative care, and mental health and in hard-to-reach areas such as North West, Central highlands, and Mekong Delta regions [4,18-20]. The mountainous and remote areas lack not only specialists trained in advanced diagnostic and treatment approaches but also standard medical and diagnostic equipment, which diminishes the quality of health care services in these areas compared to urban regions [4]. This wide disparity in health care between the rich and the poor, urban and rural, is demonstrated in the disparity of core health indicators such as life expectancy at birth and infant and under-5 mortality rates [4].

Overcrowding in health facilities, especially in urban and specialized hospitals, is a main cause of health worker exhaustion. Nearly one-fifth of Vietnamese clinical nurses experienced burnout and occupational stress [21]. Clinician burnout directly reduces the quality of life of clinicians and adversely affects the quality of care to patients. It also indirectly contributes to the reduction of health staffing [22]. Hence, a vicious negative cycle for Vietnam's health sector is created.

Health Service Delivery

Health service delivery is reflected in the availability and readiness of services across the health care continuum. Vietnam has achieved significant service improvement in health care: for example, the ratio of hospital beds per 10,000 people increased from 21.5 in 2011 to 24.0 in 2015 [4]. The hospital quality management system was established in 2013 and available in 55.4% of hospitals throughout the country in 2015 [23].

Service provision is immediate outputs of the inputs into the health system such as financing, workforce, procurement, and supplies [7]. It will be difficult to achieve the outputs if the inputs are insufficient. Even if the inputs are adequate, whether the outputs are obtained depends very much on the efficiency of the health system's functioning. According to Bentley et al [24], there are 4 key inefficiencies: duplication of services, inefficient processes, overly expensive inputs, and medical errors. All of these forms of inefficiency occur in Vietnam's health sector.

Vietnamese patients' laboratory tests and results are not usually archived at medical facilities or shared between different health care providers. This poses a challenge as patients experience multiple visits to doctors and specialists for the same health conditions thus leading to duplication of services [3]. Public hospitals, especially in large cities, are usually overcrowded with 2 to 3 patients sharing a bed. Limited quality of health care services at the commune level leads to reduced patient trust in primary care. Also, if patients use OPP, the health care system allows them to easily bypass lower level facilities (eg, commune health stations) and seek health care services in leading tertiary hospitals in big cities without referrals (ie, inefficient processes), even just to treat common diseases that primary care is well equipped to manage (ie, overly expensive inputs) [4,25]. Consequently, higher level hospitals are drained of resources, while there is waste at lower levels due to underuse [26]. Overcrowding in high-level health facilities is associated with medication errors. A large prospective study in two urban hospitals in Vietnam revealed that medication errors occurred in more than one-third of all medication doses [27].

There are also discrepancies in health service readiness and quality across areas of health care. Vietnam has an extensive primary health care system that reaches almost every administrative jurisdiction and acts as the main entry point to public health care. However, grassroots level facilities have inadequate infrastructure required for basic health care delivery. For example, only 76% of commune health stations in Dien Bien province (a Northern mountainous province) have a source of clean water, and a significant number of district hospitals lack essential equipment such as child ventilators and electrocardiograms [28]. Also, there have been increasing concerns about the equity and quality of basic health service provisions in primary health care. These limitations were reflected in key health indicators, with the infant mortality rate among the ethnic minority population being over 4 times higher than that of Kinh and Hoa ethnic groups, who mostly live in urban areas [28].

Access to Essential Medicines

According to WHO, a well-functioning health system should be able to provide the population it serves with equitable and affordable access to essential medicines, medical products, and technologies and use this resource efficiently [7]. However, published literature consistently reported that medicine prices in Vietnam were high and unaffordable for many Vietnamese people [29-31]. A fragmented medical information system within and between health care and other sectors such as General Department of Vietnam Customs and Ministry of Finance, as well as a shortage of personnel and resources for enforcing medicine pricing policies was one of the reasons for their high price in Vietnam [32]. Because of high medicine prices, irrational selection and use of medicines, unsustainable pharmaceutical production and distribution systems, and a lack of financial support systems for medicine procurement, access to the right medicines at the times people need them remains a major challenge for the majority of the Vietnamese people [33-37].

Health Information

The health information system (HIS) is a crosscutting building block because it creates a foundation for all decision-making processes in a health system. Vietnam has achieved significant progress in this area. A number of health statistics are generated annually: for example, the Annual Health Statistic Yearbook, Joint Annual Health Review, and Statistical Yearbook. Information technology is applied widely in the health administration and management of all 63 provinces and cities across the country. Vietnam is also strongly promoting the development of a health management database for its over 90 million citizens [4].

Vietnam's HIS, however, still faces a number of issues and challenges, including data generation, validation, and uses. For example, data from health care facilities, especially from private and industrial sectors, are neither timely nor complete. Information from local death registration is incompatible with WHO recommendations. There are discrepancies in the quality of medical records across regions and levels of care, which creates challenges for continuing health monitoring, disease prevention and treatment, and management of medical errors and adverse drug reactions. Even after the data are collected, the unclear data dissemination mechanism in Vietnam will likely restrict data use [4]. Given the importance of this crosscutting building block of the health system, reform is needed to operate HIS more effectively, especially in the new era of information technology.

Leadership and Governance

Health leadership and governance is another crosscutting building block in a health care system. It mediates other building blocks by connecting all issues surrounding the accountability of various stakeholders in the system to ensure adequate resources (finance, workforce, medical supplies, and information) are available to deliver essential health services. In terms of health care governance, Vietnam has attained remarkable progress, demonstrated in the development of a strong policy framework in health care. The enactment of important laws and policies, such as health insurance and pharmacy laws [38,39], and the Health Sector Strategy for 2011-2020 with a Vision to 2030 [40] provided a solid foundation and led to the formation of regulations, guidelines, initiatives, and plans in these areas. The organizational structure of Vietnam's health system has been adjusting to meet health care needs at various levels, such as establishing information technology administration at central levels and formally affirming the function and tasks of community health services at local levels [4]. Nevertheless, health policies in Vietnam are sometimes overlap, inconsistent and lack evidence. Lack of detailed plans and information cause difficulty for the effective implementation of policies. Additionally, insufficient sanctions and a weak inspection network for policy enforcement are also shortcomings of Vietnam's health care governance [4].

In summary, Vietnam has attained significant achievement and improvement in all 6 areas of the health system framework. However, shortcomings persist. To address all these systemic challenges and achieve optimal and equitable health outcomes for the population, the Vietnamese government must consider adapting the current model of health care operation to meet rapidly changing population trends, patterns of disease, and health care needs and use existing resources more efficiently while improving health infrastructure. The application of digital health technologies to underpin the health care system transformation is critical to success [41]. "The use and scale-up of digital health solutions can revolutionize how people worldwide achieve higher standards of health and access services to promote and protect their health and well-being" [42]. As in many other countries, Vietnam's health care system will need to be migrated to the patient-centered care model, which focuses on patients and their particular health care needs, and patients will need to be empowered to become active participants in their care to optimize health and economic outcomes [43]. This study was conducted to explore the opportunities, challenges, and necessary conditions for Vietnam in transforming toward a patient-centered care model to produce better health for people and reduce health care costs.

Methods

Approach

In this paper, we explored a Bespoke Health Care System (BHS) developed by Schofield et al [44] as an ideal example of a comprehensive patient-centric care model. The current Vietnamese digital health and health care landscape was examined using a strength, weakness, opportunity, and threat (SWOT) analysis to argue for the potential of developing a BHS in Vietnam. We then discuss necessary and sufficient conditions and challenges for Vietnam in transforming toward this patient-centered care model to produce better health for people and reduce health care costs.

Bespoke Health Care System

In 2019, Schofield et al [44] first introduced the concept of the BHS in the context of Australian health care, which has been adapted to other contexts [45,46]. The development of the BHS was based on the pedagogical model of flipping the classroom in modern education [47] and its application in health care [48]. In Australia, this approach has been applied by many health professionals [47]. Patients were equipped with necessary knowledge before consultations. Therefore, the consultation time was effectively used to solve health problems and make joint decisions [47]. The core component of the BHS is "increasing patient involvement in health care decisions and self-management assisted by the use of technology" [49]. In this model, patients will be educated about their illness and management options, flipping their role from passengers to drivers to manage their own health care, with clinicians playing more of a support role being the "guide by the side." Although the BHS was proposed as an ideal comprehensive patient-centric care system with several advantages and benefits, there is no one-size-fits-all approach. Novel health care solutions will work best when they are adapted to suit a country's specific conditions and have broad-based acceptance among the community, health care providers, and government agencies.

SWOT Analysis

The SWOT analysis has been used widely in policy research to provide policy makers with a sound basis for strategy development and formulation and identify new avenues for national health care reform [50]. The technique examines 4 parameters: strengths, weaknesses, opportunities, and threats. In this paper, strengths and weaknesses refer to internal factors of the proposed BHS that place it at an advantage or disadvantage over the current Vietnamese health care system, respectively. Opportunities and threats refer to external factors to the BHS that support or prevent it from being adopted in Vietnam.

Results

Strengths

The BHS brings a number of potential benefits to a health care system. First, the BHS proposes integrating electronic medical records (EMRs) into a patient-centered management platform. Currently, EMRs act as passive information depositories mainly for the purposes of health data storage or analysis. In the proposed BHS, every person would have their EMR containing all relevant personal and medical information that is shared across health care providers. As such, relevant health workers and agencies would have access to patients' real-time health information, saving time in managing people's health, saving costs of unnecessary or duplicated examinations and laboratory tests, and reducing medication errors. Studies have revealed that one-fifth of medical errors were due to insufficient patient medication information [48,51]. Clinical access to patients' real-time health information would enable tailored precision and holistic health solutions for individuals.

Second, the BHS proposes that the EMR is an active tool in promoting optimal health management. The proposed platform would remotely track symptoms, prompt patients to perform routine screening tests, allow patients to book medical appointments and remind them to attend, and provide scheduled reminders for adherence to medical recommendations. Electronic prompts and reminder alerts have been shown to assist individuals in adhering to clinical intervention effectively, particularly in managing long-term chronic conditions [49].

Third, the BHS serves as an education platform, upskilling patients and health workers. In the BHS, patients would optimally be equipped with a comprehensive understanding of their conditions, treatment options, and self-management strategies. This is an effective way to empower people to have greater ownership in managing their health. Additionally, clinicians would be provided with up-to-date, evidence-based optimal health care pathways suitable for their specific patients' conditions. This offers an ongoing mechanism to support clinicians' continuing professional development using their own case studies. Moreover, the platform might be used to upskill patient families and carers, which would strengthen community care and lessen the health care burden due to staff shortages [51]. Potentially, the BHS would facilitate reducing the health inequities in terms of accessing optimal health care, particularly for the economically disadvantaged or those living in remote areas.

In summary, adopting the BHS model may assist Vietnam in addressing the health crisis and achieving the country's health care goals in the new decade. This model can increase patient accessibility to health care facilities and state-of-the-art health management, including the most vulnerable and hard-to-reach people, thus enhancing health equity across the country. It can also increase operational efficiencies for both health care providers and users, resulting in lessening overcrowded hospitals and enabling coordinated health care, which is currently missing [3,52]. Moreover, digital solutions can assist teaching, tertiary, or specialized hospitals to deliver training or conduct eHealth consultations with satellite, primary, or secondary hospitals. Therefore, the quality of health care would be strengthened across the country.

Weaknesses

Although the BHS model has many strengths, we need to articulate inherent weaknesses in the model. First, the high cost and complexity of implementing digital health information systems, such as EMRs, may be a barrier to broad dissemination. Second, the digitalization of data and services represents a potential cybersecurity threat to privacy and trust of people in a new health care system [3]. Finally, the establishment of nationwide unique health IDs (unique codes used to identify individuals within the health care system) often takes time, especially for socially disadvantaged members of the community.

Opportunities

Vietnam has a high-level policy framework (ie, political and legal environment) supporting the transition toward the BHS. The 2017 Resolution 20-NQ/TW of the Communist Party of Vietnam has provided a strategic orientation for reforming the health care system. This includes systemic implementation of information technology in management of primary health care, prevention, disease management, and the establishment of electronic health records (EHRs) for all citizens that link to their health insurance card.

Based on this strategic orientation, the Vietnamese Ministry of Health (MOH) in 2017 set out national goals for the protection, care, and improvement of people's health in the period to 2030. One of the 5 key priorities for action to achieve the national health care goals was developing human resources, medical sciences, and technology [4,53]. Since then, a national agenda for digitalization of the health care system has been driven by MOH with a number of initiatives that aim to adopt digital solutions in health care network across the country. Vietnam is rapidly embracing digital health. Digitalized health care is perceived as a useful solution that could help to address the rapidly growing gap between service demand and capacity [44].

To implement health care digitalization, MOH issued Circular 54/2017/TT-BYT regarding assessment criteria for information technology applications in health care facilities [50] and a plan to develop smart health care during the period 2018-2025, with a vision toward 2030 [54]. In this plan, targeted smart health outcomes were specified, such as development of a national health care data center, electronic health and medical records, and electronic government and smart medicine management systems. Particularly in the field of examination and treatment, telemedicine is regulated by Circular 49/2017/TT-BYT, which provides guidelines for a range of telemedicine consultations in Vietnam (eg, allowing doctors to provide telemedicine services to patients under certain infrastructure requirements [55]).

To accelerate the application of information technology in the health sector, in 2018, MOH issued Circular 46/2018/TT-BYT regulating EMRs. According to Häyrinen et al [56], EMR was defined as "a repository of patient data in digital form, stored and exchanged securely, and accessible by multiple authorized users. It contains retrospective, concurrent, and prospective information, and its primary purpose is to support continuing, efficient, and quality integrated health care." In the circular, EMRs include inpatient records, outpatient records, and other medical records prescribed by MOH, such as traditional medicine medical records and medical records of abortion. This is the first time Vietnam has specific guidance for EMR establishment, use, and management at health care facilities [57]. As the health care system in Vietnam is centralized under MOH and provincial health authorities, the integration of EMRs within the existing system, at least in the 47 central-level hospitals and possibly also at 419 provincial-level hospitals [58], will be easier than in countries with a more fragmented health care system.

The plan for implementing EHRs was approved by MOH in 2019 in Decision 5349/QĐ-BYT [59]. According to this decision, EHRs are medical documents that record the health care process of a person from birth to death in the form prescribed by MOH. This plan guides and directs all 61 cities and provinces of Vietnam to simultaneously deploy and make EHRs available for use by 80% and 95% of population in 2020 and 2025, respectively. If this aim is achieved, Vietnam will be perfectly positioned to adapt and adopt the BHS model. EHRs may be able to assist every citizen to understand and manage their health information continuously for life, enabling them to prevent disease proactively, and actively manage their health conditions if used as the basis for a BHS. EHRs will also support physicians in providing health care for people in real time and according to best practice health care recommendations. Importantly, EHRs will provide complete, accurate, and timely data on population health, enabling policy makers to advance evidence-based health policy and health authorities to examine the relative efficacy of treatments to manage health care expenditure more efficiently.

Supportive social and technological environments also place Vietnam in a good position to adopt advanced digital health solutions of the BHS. Today, Vietnam is benefiting from a golden population proportion with 70% of the population being of working age (aged 18 to 65 years) [6]. This generation is rapidly embracing new communication technologies. In 2020, Vietnam was the seventh highest number of Facebook users in the world [60]. On average, Vietnamese people spend about 7 hours per day on the internet [61]. The high uptake is associated with a high acceptability of digital technologies by Vietnamese people. Studies have shown that people's attitudes toward mobile health solutions is highly positive. Two-thirds of Vietnamese youth and adolescents found mobile health apps useful [62,63].

Online communication is backed by a rapid and strong development of the country's information and communication technology infrastructure: penetration rate of internet access is 67%, which is among the highest in the Asia Pacific region [64], and 95% of households are now able to use 4G network [3]. Vietnam's technology infrastructure is also embracing cloud-based services, which will facilitate innovative and cost-effective health care delivery solutions. In recent years, a number of projects have initiated and implemented digital health services in large urban hospitals, including teleradiology, teleconsultation, telediagnosis, and videoconferencing. Examples of these initiatives include raising disease awareness and encouraging people to adopt heathier behaviors [65-69], improving accessibility to health care services among disadvantaged and vulnerable target groups [70-72], and upskilling health care workers [73-80].

A supportive economic environment has resulted in an increased need for high-quality health care services and precision medicine. Strong economic growth with an average annual gross domestic product growth rate of 6.4% [81] is creating a booming middle class in the society. It is estimated that this population will increase sharply from 10% in 2015 to more than 50% in 2035 [82]. The growth in disposable income among digitally literate, educated, and wealthy individuals creates economic conditions for higher personal expenditure on easily accessible, high-quality health care. Public health facilities often do not meet their needs due to long waiting times, inadequate consultation time, overcrowding, and high-occupancy bed rates [3]. This has resulted in the rapid expansion of a private health system, which was projected to grow from US $6.6 billion in 2016 to US $8.7 billion in 2020 [83]. Smart solutions that use big data, cloud computing, and mobile technology are strongly encouraged to alleviate overcrowded public hospitals and increase quality health care overall [4].

Together, all these supportive policy, social, technological, and economic environments provide a good foundation for the health care system in Vietnam to shift toward innovative models of care that are being proposed in developed countries, such as the BHS, which focus on patient-centered care.

Threats

In Vietnam, patient medical records remain paper-based at all levels of the health care system and currently are required for legal purposes [84]. Moreover, although electronic administration management has been adopted in some large hospitals, the quality of medical records and databases varies across hospitals and clinics. In most health care facilities, the medical record system is not centralized [52]. As such, one patient can have multiple medical records. This is a barrier for timely medical information exchange and sharing between hospitals [69]. In addition, the development of EMRs and EHRs, a precondition for BHS adoption, is still in the early stages [4,44]. Although MOH has taken initial steps toward the development of EMR and EHR systems, the readiness to implement the EMR nationally in real clinical practice still requires considerable preparatory effort.

First, Vietnam needs to assign a unique patient identifier to every citizen, which is a core requirement for successfully introducing EHRs [52]. In 2019, MOH issued Decision 4376/QĐ-BYT, regulating the establishment, use, and management of IDs [85]. According to the decision, an ID will be created, comprising two series of numbers separated by a dot. The first series is the social insurance code of the individual while the second series is a product of an algorithm of administrative information including the social insurance code, full name, date of birth, gender, and place of birth. The social insurance, however, is a compulsory income protection insurance for employed people only to fully or partially offset their income that is reduced or lost due to sickness, maternity, labor accident, occupational disease, retirement, or death [86]. Although Vietnam has made significant progress in expanding social insurance coverage in recent years, enrollment rates are still low, especially in small- and medium-size enterprises due to multiple barriers such as cost of contribution, lack of trust in the government system, and administrative factors [87]. Despite large increases in government subsidies, low enrollment rates in compulsory social and health insurance still persist [88]. In May 2020, only 27% of Vietnam's workforce had social insurance [89,90], which is far short of the government's target of 50% social insurance coverage [87] and 80% health insurance coverage by 2020 [91,92]. The IDs, when established, therefore, will only cover a small proportion of the population.

Second, although many health workers and patients are aware of the advantages of using EMRs and EHRs, there are concerns about the risks of privacy violation. The Law on Network Information Security No. 86/2015/QH13, enacted in 2015, includes a requirement of "providing an adequate level of protection for personal data, following the technical standards for protection of personal data." However, there are no clear definitions of "an adequate level of protection" and "technical standards" [93]. As such, there is a lack of regulatory rigor and sanctions in managing data processors. Strengthening the legal and regulatory system to protect patient privacy and information security is fundamental for the success of EMR development and application.

Finally, since Vietnam is still in the very early stage of health care digitalization, there is no empirical evidence about the effectiveness and sustainability of digital health initiatives. Over the past few years, there have been a growing number of organizations and health startups delivering digital health solutions to improve the quality of medical services. For example, eHospital software, developed by the Corporation for Financing and Promoting Technology, was first launched in 2000 [94]. This is a comprehensive hospital management system providing supports to manage all activities relating to patients in health care facilities. In 2018, eHospital with the application of the latest 4.0 technologies such as artificial intelligence and big data was introduced. Until now, this system has been used in more than 400 hospitals and clinics in Vietnam. [95].

Another example is the Hospital Information System of the Vietnam Posts and Telecommunications Group, which was introduced in 2015. This solution with its three levels of management—state, hospital and patient—aims at supporting provincial health authorities and hospital managers to make well-informed decisions for health care improvement and assisting patients to facilitate and adhere to their health care appointments online. This allegedly leads to increasing transparency and reducing overcrowding in health care facilities [96]. Nevertheless, these initiatives have not been rigorously evaluated. Lack of evaluation results will prevent the government from evidence-based policymaking and hinder the broader implementation of existing projects or development of new initiatives.

Discussion

Necessary Conditions for Successful Adoption of the BHS Model in Vietnam

Vietnam has identifiable opportunities to adopt the BHS model and implement digitalization in health care. To grasp these opportunities, the following strategies are recommended.

First, establishing a national ID for each individual based on their social insurance code is one core requirement for successfully introducing EHRs. In a recent Organisation for Economic Co-operation and Development policy report, recommendations have been proposed for the Vietnamese government to increase the enrollment rates of social insurance. They include reducing obstacles to participation (eg, simplifying administration processes for paying insurance), introducing incentive scheme for employees to participate (eg, providing government subsidies for participation of low-income people in the voluntary system), and adopting a systematic approach to social protection (eg, considering the interaction between various social protection mechanisms) [87].

Second, successful adoption of the BHS requires a whole-system approach involving the support of different sectors in the society. Obviously, MOH would have to play a key role in this adoption process but would need to collaborate with related ministries—in particular, the Ministry of Science and Technology and the Ministry of Information and Communications—in developing and implementing a digital health strategy. The resources needed to improve the health care system are sizeable. MOH would need to garner funding from different sources, both domestic and foreign agencies: government, social entrepreneurs, or private businesses [69,70].

Third, integrating personal data in EHR and EMR systems will increase the risk of privacy violation and cybersecurity breaches. The Vietnamese government needs to improve the security of information technology platforms in general and health care in particular to protect patient privacy and information security [70].

Fourth, to improve the adoption of evidence-based practices, it will be necessary to provide resources to demonstrate the effectiveness and impact of digital health initiatives and establish a network of collaborators including health care administrators, clinicians, community representatives, digital health researchers, information technology developers, and public health education experts [69]. This will be a great opportunity for further enhancing strong collaborations between multisectors and multistakeholders at various levels, which are essential for successfully reforming the health care system in Vietnam. BHS implementation would require the involvement of local educators to provide education for communities, raising awareness of the benefits the system could bring to individuals and society, coaching to enhance self-management behaviors, and increasing engagement with the system [97]. Strong evidence about the effectiveness of digital health initiatives in Vietnam will encourage the government to develop appropriate health policies and increase opportunities for ongoing projects to scale-up by attracting funding and support [70]. Thus, there is a substantial need for further research in this area in the future.

Finally, to increase the acceptability and feasibility of digital health initiatives, a co-design approach is crucial. Co-design is defined as the “collective creativity as it is applied across the whole span of a design process” [98]. In the design process, diverse experts such as researchers, designers or developers and potential customers and users work closely together to understand the needs and preferences of end users [99,100]. A co-design approach is likely to increase scalability and dissemination of the initiative [99].

Conclusions

The overarching goal of the BHS is, with the support of digital technologies, to deliver best practice health care and reduce pressure on the current health care system by empowering people to direct their own health care, regardless of their geographical location and economic status [44]. The BHS offers a promising and intelligent health care that which may be efficient and suitable for Vietnam in the new era of the Fourth Industrial Revolution [101]. Vietnam has tremendous opportunities and a favorable policy, social, technological, and economic environment to adopt this model of comprehensive patient-centric health care. In order to uptake, adapt, and implement the BHS successfully, Vietnam needs to apply a whole-system approach in transformation and operation processes.

Abstract

By applying advanced health information technology to the health care field, health informatization helps optimize health resource allocation, improve health care services, and realize universal health coverage. COVID-19 has tested the status quo of China’s health informatization, revealing challenges to the health care system. This viewpoint evaluates the development, status quo, and practice of China’s health informatization, especially during COVID-19, and makes recommendations to address the health informatization challenges. We collected, assessed, and evaluated data on the development of China’s health informatization from five perspectives—health information infrastructure, information technology (IT) applications, financial and intellectual investment, health resource allocation, and standard system—and discussed the status quo of the internet plus health care service pattern during COVID-19. The main data sources included China’s policy documents and national plans on health informatization, commercial and public welfare sources and websites, public reports, institutional reports, and academic papers. In particular, we extracted data from the 2019 National Health Informatization Survey released by the National Health Commission in China. We found that China developed its health information infrastructure and IT applications, made significant financial and intellectual informatization investments, and improved health resource allocations. Tested during COVID-19, China’s current health informatization system, especially the internet plus health care system, has played a crucial role in monitoring and controlling the pandemic and allocating medical resources. However, an uneven distribution of health resources and insufficient financial and intellectual investment continue to challenge China’s health informatization. China’s rapid development of health informatization played a crucial role during COVID-19, providing a reference point for global pandemic prevention and control. To further promote health informatization, China’s health informatization needs to strengthen top-level design, increase investment and training, upgrade the health infrastructure and IT applications, and improve internet plus health care services.

KEYWORDS

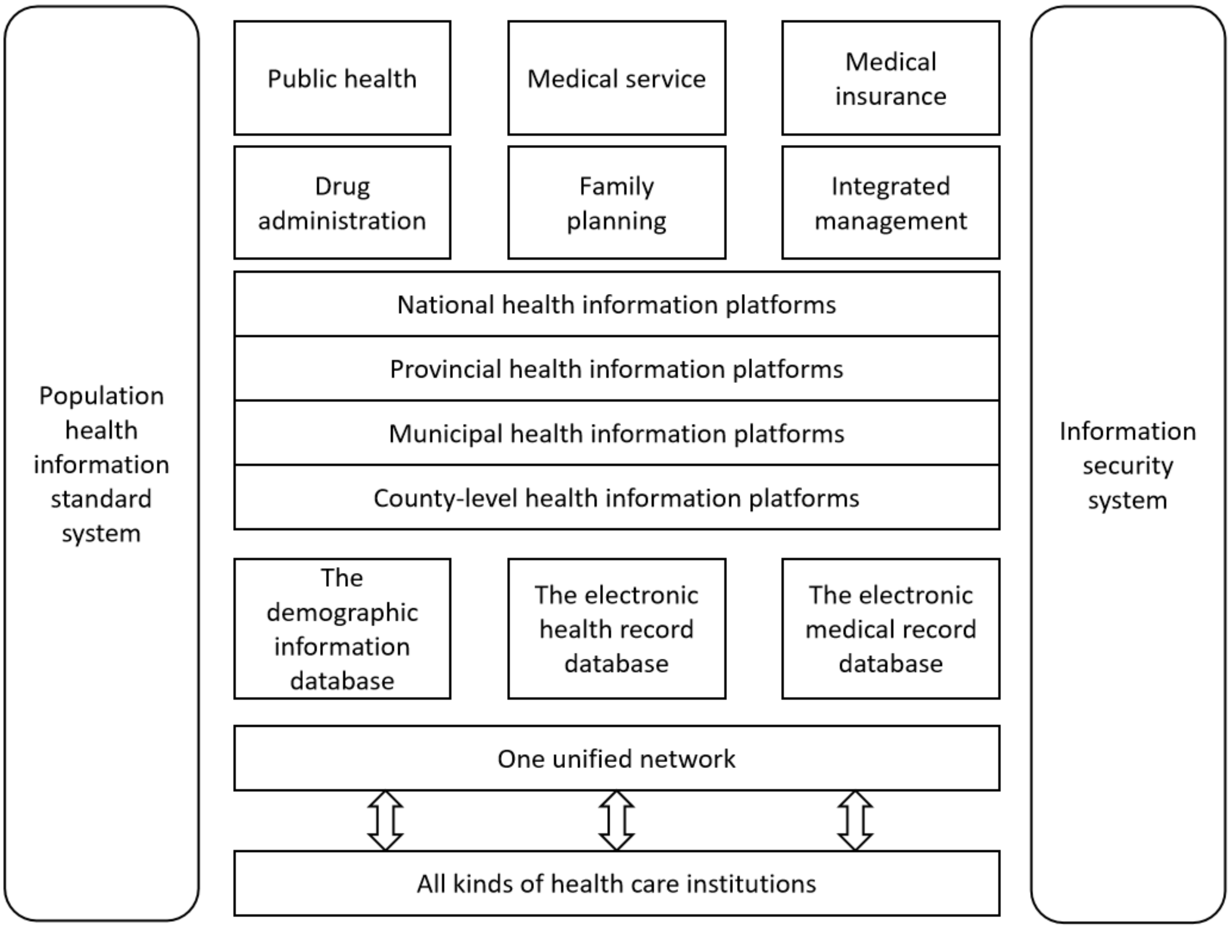
health informatization; COVID-19; health policy; digital health; health information technology; China

Introduction

Background

Building on China’s highly developed information-based society, including big data, cloud computing, mobile internet, and artificial intelligence, health information technology (HIT) provides a key impetus for the Chinese government to maximize health resource allocation, address the uneven geographical distribution of medical resources, ensure China’s universal health coverage, and enable health care providers to optimize health care services with lower medical costs and better quality [1-6]. China’s health informatization has developed through several stages, and the policy system at every stage has sought consistency and coordination. In 2010, the National Health and Family Planning Commission (NHFPC) issued the “3521 framework” for health informatization, which was then upgraded to the “4631-2 framework” in 2013 [7-10]. Figure 1 presents a structural figure of the “4631-2 framework” based on NHFPC policy documents. As shown in Figure 1, the “4631-2 framework” referred to 4 levels of national health information platforms (national, provincial, municipal, and county level), 6 primary applications (public health, medical service, medical insurance, drug administration, family planning, and integrated management), 3 major health information databases (the demographic information database [DID], the electronic health record database [EHRD], and the electronic medical record database [EMRD]), 1 unified network covering all kinds of health care institutions (including traditional Chinese medical institutions), and 2 systems (population health information standard system and information security system) [8,11].

Figure 1. The “4631-2 framework” of health informatization.



Building on the “4631-2 framework” of health informatization, the 2016 Plan of Healthy China 2030 committed to expanding the health information service system. The NHFPC released the National Population Health Informatization Development Plan in 2017, emphasizing the essential role of health informatization in national IT (information technology) construction, health reform and the Healthy China initiative [12]. In 2018, the National Health Commission (NHC) was established, further emphasizing the role of health informatization by targeting comprehensive and lifelong intelligent health services by utilizing advanced technologies.

Objective

Surprisingly, the development of China’s health informatization system has not been detailed nor its status quo effectiveness assessed. The early COVID-19 period, where, for example, the extensive use of internet plus health care, including internet hospitals and telemedicine, helped to ensure the normal operation of the medical system, provides a unique opportunity to evaluate China’s health informatization [13-15]. Our study aimed to map the development of China’s health informatization; evaluate China’s status quo health informatization experiences and lessons learned during

COVID-19; identify the challenges to health informatization; and provide recommendations for the improvement of health informatization.

Data Sources and Approach

The NHC conducted a 2018 survey on national health informatization, which was published in the 2019 National Health Informatization Survey Report [16]. The NHC also held several expert meetings to assess the survey data, which was also published in the survey report [16]. The data in the NHC Survey Report can be divided into two parts: regional health informatization and hospital informatization. The Regional Health Informatization Survey covered 1650 health commissions (HCs), including all 32 provincial HCs, 69.6% (296/425) of municipal HCs, and 47.1% (1322/2803) of county-level HCs. The Hospital Informatization Survey covered 5470 hospitals, including 70.1% (1480/2112) of tertiary hospitals, 62.1% (3730/6004) of tertiary hospitals, and 6.2% (260/4180) of other hospitals (at lower levels). As shown in Multimedia Appendix 1, the survey identified key aspects of health informatization, including infrastructure, IT application, capital investment, and human resources, providing data for evaluating the status quo of China’s health informatization. Multimedia Appendix 1 also displays other information we collected, interpreted, and evaluated from primary sources, academic papers, government reports, and institutional reports regarding the current status and challenges of health informatization.

Figure 1 sets out a diagrammatic representation of the conceptual basis of China’s health informatization, while Multimedia Appendix 1 summarizes the main primary and secondary sources used to outline the development, evaluate the status quo, and identify the challenges to China’s health informatization.

Development and Status Quo of China’s Health Informatization

Health Information Infrastructure

China’s health information platforms form the basis of the country’s regional health informatization. In 2012, the Ministry of Health in China proposed a 3-level (national, provincial, and regional) health information platform [9]. As displayed in Figure 1, the health information platform was extended in 2013 to consist of 4 administrative level platforms: the national, provincial, municipal, and county-level information platforms [10]. On each platform, the medical data from different regions were integrated and shared [7]. The platforms were designed to be unified, authoritative, and interconnected so as to exploit and statistically analyze health information of the whole population, thus providing support for management and decision making on a national health level [12,17,18]. The platforms also provided the basis for an information business system covering the whole industry chain of health and medical big data, linking medical care, medical insurance, and medicine. By 2018, 93.8% (30/32) of provincial health information platforms, 66.2% (196/296) of municipal health information platforms, and 48.2% (637/1322) of county-level health information platforms had been established [16]. During COVID-19, by sharing data with internet hospitals and health care institutions at all levels, regional health information platforms connected online and offline services to provide patients with full process services before, during, and after diagnosis [19,20]. During the COVID-19 period, the NHC promoted new infrastructure construction in health informatization, emphasizing the need to improve health information platforms and health information databases [19].

National health information databases include three major databases: the DID, the EHRD, and the EMRD. The DID contains fundamental population information, family planning service management information, and the nonresident population management information. The EMRD stores all information from electronic medical records while the EHRD holds residents’ personal health information from the electronic health record (EHR), which is defined as “digitally stored health care information about an individual’s lifetime with the purpose of supporting continuity of care, education, and research and ensuring confidentiality at all times” [7,21]. In recent years, the NHC has promoted the EHR to be opened to individuals. In pilots undertaken in selected areas, residents are able to enter the EHR system with a password and access their own EHRs [22,23]. The 2010 “3521 framework” contained only two databases—the EHRD and the EMRD [24]—with DID added under the 2013 “4631-2 framework” [25].

The three major databases are relatively independent but interrelated. Supported by the national health information platform, information in the three databases is shared and dynamically updated to ensure consistency, accuracy, and integrity of the information [12,26]. According to the 2019 National Health Informatization Survey, the average construction rate of EHRDs was 79.5% (1312 out of 1650 HCs had built EHRDs), the highest among the three databases, with 93.8% (30/32) of provincial, 84.8% (251/296) of municipal, and 78.0% (1031/1322) of county-level EHRDs. The average construction rate of the DIDs was 77.5% (1278 out of 1650 HCs), with 100% (32/32) of provincial, 80.4% (238/296) of municipal, and 76.2% (1008/1322) of county-level DIDs. Lowest among these three databases, the average construction rate of EMRD was 49.5% (816 out of 1650 HCs), which was 93.8% (30/32) of provincial, 59.5% (176/296) of municipal, and 46.1% (610/1322) of county-level EMRDs [16].

IT Applications

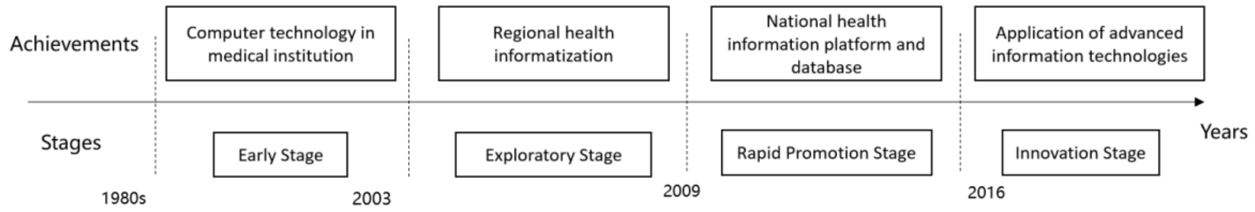
To illustrate the historical development of technology applications, we constructed Figure 2, which sets out the four development stages in China’s health informatization: the early stage from the 1980s to 2003, the exploratory stage from 2003 to 2009, the rapid development stage from 2009 to 2016, and the innovation stage since 2016 [27,28]. In the early stage (1980s-2003), the emphasis was placed on the application of computer technology in information systems, such as the financial management system and charging system, in large medical institutions. Manual operations were replaced by computer functions in the management of traditional businesses, including financial management, fee management, and drug management. At the exploratory stage (2003-2009), drawing on the experience of SARS (severe acute respiratory syndrome) in 2003, China strengthened its informatization in health emergency command, disease prevention and control, and public health resources and health information management [29]. Importantly, a direct internet reporting system for infectious diseases and public health emergencies was established, and regional health informatization emerged. In the context of health care reform, the rapid development stage (2009-2016) completed the construction of the national health information platform and database, dealing with the information islands in health services as well as realizing the platform connectivity and information sharing of the medical and health systems. Since 2016, more advanced information technologies, such as internet plus, big data, cloud computing and artificial intelligence have been widely applied to health industries. In the innovation stage, a people-centered medical service principle was adopted [30], with advanced IT applications improving the health information system and providing more diverse health information services [12].

Currently, advanced technologies commonly used in China's health informatization include cloud computing, big data, Internet of Things, mobile internet, and artificial intelligence. The 2019 National Health Informatization Survey showed that advanced technologies, especially mobile internet and big data, were more commonly applied on provincial than municipal and county platforms. In 2018, on provincial health information platforms, the application rate of cloud computing was 68.8% (22 out of 32 provinces), big data was 53.1% (17 out of 32 provinces), Internet of Things was 21.9% (7 out of 32 provinces), mobile internet was 71.9% (23 out of 32 provinces), and artificial intelligence was 12.5% (4 out of 32 provinces). On municipal and county-level platforms, advanced technologies were less utilized, where 40.2% (119/296) of municipal and 46.1% (609/1322) of county-level platforms had not utilized any advanced technologies [16]. Higher-level hospitals had higher IT application rates, with mobile internet being the most commonly used technology (tertiary hospitals: 747/1480, 50.5%; secondary hospitals: 767/3730, 20.6%; and other hospitals: 63/260, 24.2%) and artificial intelligence being the least used technology (tertiary hospitals: 137/1480, 9.3%; secondary hospitals: 62/3730, 1.7%; and other hospitals: 3/260, 1.2%).

COVID-19 tested the informatization of China's health system. In COVID-19 prevention and control, advanced information technologies were effectively utilized in monitoring and forecasting the pandemic's trends as well as constraining the spread of the virus. Based on big data, the intelligent risk assessment system and automatic early warning system were utilized to fight the virus. Big data was used to track the mobility of the population and locate crowds after the outbreak. With the help of artificial intelligence, the number of infections was estimated, and high-risk areas identified, which helped the government to implement timely control methods and determine the allocation of resources [31]. Using a series of data statistics and model analysis, big data population movement information on Baidu Maps was one of the most popular technologies to estimate the number and locations of patients with COVID-19 and carriers. The big data methods also predicted disease trends based on real-time reporting of new cases.

In order to improve data utilization, some hospitals promoted the connection between hospital information systems and regional health information platforms. Hospital information departments extracted data from major information systems such as Hospital Information System, Laboratory Information System, Picture Archiving and Communication Systems, and EMRs to build a clinical data center [32,33]. An induction model based on artificial intelligence was constructed to help predict the risk and trend of infectious diseases and enhance prevention efforts [1].

Figure 2. The development history of health informatization in China.



Financial and Intellectual Investment

As seen in Multimedia Appendix 1, the importance of health informatization can be assessed by China's increased levels of investment. During the 2011-2015 12th Five-Year Plan, the central government invested more than ¥10 billion (US $1.5 billion) into health informatization [7]. In 2017, the first phase of the National Health Security Informatization Project was approved by the National Development and Reform Commission, with ¥340 million (US $52.5 million) invested in national platform construction and 32 national hospital informatization projects approved by the NHFPC, and ¥310 million (US $47.9 million) invested by the NHFPC in the construction of information platforms and clinical data centers [34]. In 2018, the Ministry of Finance invested ¥670 million (US $103.5 million) to equip 832 poor county hospitals and 1664 primary-level medical institutions with telemedicine equipment. In 2019, the central government allocated ¥180 million (US $27.8 million) to increase technology applications, including the internet, big data, and artificial intelligence in 9 provinces, with the aim of improving the diagnosis and treatment capacity of family doctors [35].

Although governmental investment in health informatization expanded rapidly, it failed to cover China's current financial informatization needs, reflecting a lack of stable and sustainable capital input. For example, China's health expenditure accounted for 7.56% of the financial expenditure, while health informatization expenditures accounted for only 0.7% of the total health expenditure [36]. Second, there were obvious regional differences in governmental investment, with Beijing, Guangzhou, Shanghai, and the eastern coastal provinces achieving rapid development of health informatization versus the less developed provinces [37]. The capital input in informatization was positively associated with the local economic development level, where informatization tended to increase regional health inequality [16]. The 2019 National Health Informatization Survey showed that hospital informatization investment was limited. The proportion of informatization investment in a hospital's annual revenue was between 0.1% and 1% in 67.3% (3681/5470) of hospitals and 1% to 5% in 23.7% (1296/5470) of hospitals, with only 3.7% (202/5470) of hospitals investing over 5% of their annual revenue in informatization. With the construction of health informatization requiring multisectoral collaboration, the lack of social supervision led to a lack of initiative and a waste of resources. In 2017, according to the China Hospital Information Management Association survey, hospital self-raised funds accounted for 68.8% of the total investment in hospital informatization, with government financial funds accounting for 28.4% and other funds accounting for 2.8% of the total investment [38,39]. Although the Chinese government has implemented policies to encourage enterprise initiative, an incentive mechanism to encourage social capital to participate in health informatization construction has not been set up in China. Measures to promote government-enterprise cooperation in health informatization are still being explored [12,40].

Both the quantity and quality of technical informatization personnel failed to meet demand [12]. The number of health informatization personnel was small. In 2019, the average staff number in provincial information departments was only 20, while 91.6% (271/296) of municipal information departments and 93.6% (1238/1322) of county-level information departments had less than 9 informatization staff. In hospitals, the information department of tertiary hospitals had on average 10 staff, while 74.1% (2764/3730) of secondary hospitals and 89.5% (233/260) of other hospitals had less than 4 informatization staff. In particular, there was a lack of highly educated and specialized informatization personnel and an uneven distribution of high-quality personnel in administration and hospitals at different levels [41]. High-level administrations and hospitals tended to have staff with higher education [16], with the proportion of staff with a bachelor's degree or above in provincial information departments (88.9%) and in municipal information departments (83.8%) significantly higher than that in county-level information departments (51.6%). In tertiary hospitals, 67.5% of information department staff had bachelor's degrees, while in secondary and other hospitals, most staff had degrees below the junior college level. The proportion of staff with a master's degree or above in tertiary hospitals (14.3%) was significantly higher than that in secondary hospitals (2.3%) and in other hospitals (0.7%). Staff specialized in computer science accounted for 85.1% of informatization staff in tertiary hospitals compared to 49.1% in secondary and 26.5% in other hospitals. In addition, IT staff with senior professional titles were scarce in all types of hospitals, with only 2.0% in tertiary, 1.9% in secondary, and 0.6% in other hospitals [16].

Health Resource Allocation

Medical resources distribution and health service capacity were unevenly distributed regionally and by type of medical institution [3,4]. The data from Multimedia Appendix 1 reveals that the construction strategies of health informatization varied according to the health care resource allocation status in different regions [1].

For developed regions (mainly the eastern coast) with abundant medical resources, the local health administration undertook the major responsibilities for integrating high-quality medical resources and promoting health informatization. These regions had stronger abilities to independently develop informatization and provide stable and sufficient funds for informatization. Bottom-up building of health information platforms and data centers were established by the local health administration to connect the information system of health institutions at all levels in the administrative region, achieving the sharing and exchange of medical information. For example, municipal and county-level health commissions in each province independently carried out informatization construction, driving the development of provincial health informatization and promoting the development of regional health information infrastructures, information technologies, and professionals. Municipal and county-level health resource information was integrated, and the connectivity of health information within the province was realized [24].

In developing regions, mainly in western and central China, where medical resources were scarce, large hospitals generally connected with several local primary health care institutions to realize medical information exchange and sharing [24]. For instance, the West China Hospital of Sichuan University cooperated with surrounding secondary hospitals and community health service centers to achieve regional medical collaboration. Shengjing Hospital of China Medical University, in cooperation with public hospitals at all levels in Liaoning and Shenyang, constructed the Shengjing Medical Alliance, a nonprofit medical cooperative alliance. In these less developed and health resource scarce regions, unified management was implemented within the medical alliances to integrate medical resources at different levels. To optimize medical resources, resource-poor regions utilized telemedicine, or the use of telecommunications technologies to provide medical information and services, [1,4,42] for remote consultation and two-way referral, where primary medical units can get support from large hospitals and gain access to high-quality medical resources and services.

The COVID-19 pandemic typically led to a surge in demand for medical care, which overwhelmed local capabilities [43,44]. During the pandemic, telemedicine played an increasingly important role in medical resource allocation [1,4,42]. As the worst-hit area of COVID-19 in China, Hubei Province's medical institutions were overloaded with a severe shortage of medical resources and services [43]. Due to the implementation of control measures such as lockdowns, traffic control, and community closure management, residents' access to health care resources was severely restricted. Telemedicine was widely used to overcome geographical barriers and expand the supply of medical resources [45-47]. With the aid of informatization technologies, many doctors from other parts of China provided remote diagnosis and treatment services. For instance, the medical team from Guangdong Province built an internet hospital to provide online clinical support for patients in Jingzhou, Hubei Province. More than 1300 doctors from 15 medical institutions in Guangdong participated, with the total number of online visitors exceeding 100,000 within 18 days of its launch, making up for local medical service deficits in Hubei Province [48].

The Standard System

As seen in Figure 1 and Multimedia Appendix 1, emphasis has been placed on the standardization of health information, or the standard system [12]. In 2006, the Special Committee on Health Information Standards was approved by the Ministry of Health, where work on health information norms were standardized. Started in 2012, the National Medical Health Information System's Interconnection and Interoperability Standardization Certification [16] aimed to strengthen the management and promote the implementation of health information standards, so as to achieve health information interoperability [11]. The Regional Health Informatization Survey and Hospital Informatization Survey found that by 2017, 54 regional platforms (1 provincial platform, 45 municipal platforms, and 8 county-level platforms), and 90 hospitals (84 tertiary hospitals and 6 secondary hospitals) had been certified. Between 2018 and 2019, the number certified significantly increased with an additional 48 regional platforms and 101 hospitals certified [49].

The security system of regional health information platforms contained 4 levels: physical security, network security, system security, and application security. Physical security required hardware security and the geographical location security of the computer room and key infrastructure. Network security included link redundancy, firewall setup, and intrusion detection. System security included data backup, virus prevention, operating system security, and vulnerability checks. Application security included identity authentication and authority management [8,50]. By 2018, all provincial platforms, 90.9% (269/296) of municipal platforms, and 78.9% (1043/1322) of county-level platforms had formulated an information security system. Meanwhile, 99.2% (1468/1480) of tertiary hospitals, 95.9% (3577/3730) of secondary hospitals, and 81.5% (212/260) of other hospitals had formulated an information security system. By August 2020, with 227 effective information standards approved, the standard system for regional health informatization and hospital informatization had been basically established throughout the health system [26].

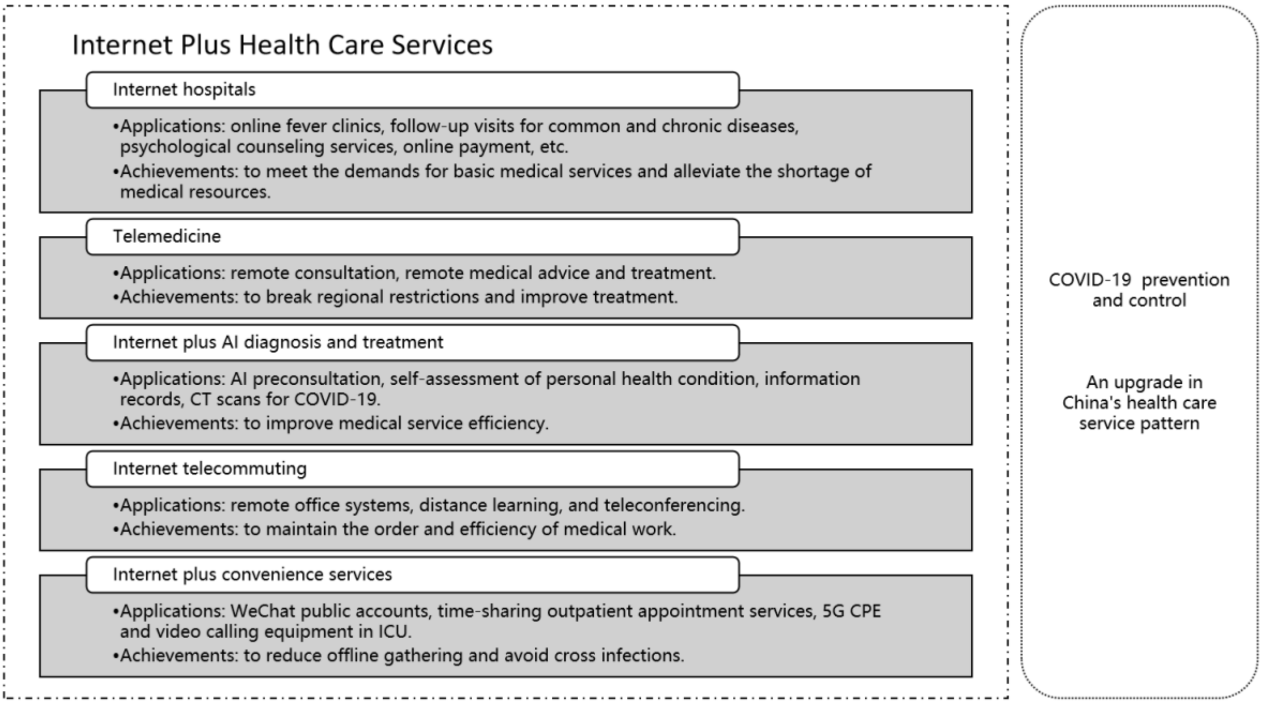
During COVID-19, continuing shortcomings in the standard system were addressed by the 2020 Notice on Strengthening the National Health Information Standardization System, which defined four key tasks for the construction of the national health information standardization system: (1) to promote the standardization of the national health information infrastructure, including the national health information platform, national hospital information platform, government services integration platform, and to standardize the information from grassroots health institutions, public health systems, and traditional Chinese medicine hospitals; (2) to strengthen the standardization of the DID, the EHRD, the EMRD, and the health care resource database; (3) to promote the standardization of advanced IT applications, comprising five technologies: internet plus health care, health and medical big data, health care artificial intelligence, health care 5G technology, and blockchain technology for health care; and (4) to improve the standardization of network security, namely industry network security standard system, data security standard, and industry application security standard. In order to improve the disease prevention and control system and enhance the ability to respond to public health emergencies, the NHC formulated the National Public Health Informatization Construction Standard and Specification on December 11, 2020, to further regulate national public health informatization, specifying 21 first-level indicators, 125 second-level indicators, and 421 third-level indicators of health service management and IT application content in all types of health institutions [26].

Even with these reforms, shortcomings in China's health information standard system remain. There was a lack of standard evaluation, and the consistency and interoperability of the standard system needed strengthening [1]. The formulation of China's standard system lagged behind the development of new technologies. The safety standards, data standards, functional standards, quality assessment standards for information technology products, and management standards for data quality were incomplete. In terms of information security standards, the ownership and usage rights of patients' health information, as well as the division of rights and responsibilities among all parties, needed further clarification in laws and regulations. There was a lack of security standard evaluation. The Regional Health Informatization Survey reported that in 2018, 75.0% (24/32) of provincial platforms, 30.4% (90/296) of municipal platforms, and 17.7% (234/1322) of county-level platforms had implemented the evaluation of classified information security protection. Only 46.4% (687/1480) of tertiary hospitals, 18.6% (694/3730) of secondary hospitals, and 10% (26/260) of other hospitals had participated in the evaluation. Although China continues to develop health information standards, due to the large number of departments involved, many standards and norms were not unified. There were also problems related to unclear management responsibility for the standards and ineffective supervision mechanism [11].

Status Quo of the Internet Plus Health Care Service Pattern During COVID-19

As shown in Figure 3, the new service pattern of internet plus health care sought to meet increasing medical demands and virus prevention and control needs during the COVID-19 pandemic.

Figure 3. The applications and achievements of internet plus health care in COVID-19. AI: artificial intelligence, CT: computed tomography, CPE: customer premise equipment, ICU: intensive care unit.



Internet plus health care has the characteristics of remoteness, efficiency, intelligence, and convenience, providing online consultation, remote diagnosis, psychological counseling, chronic disease follow-up, and drug distribution to meet people's medical demands [40,48]. During COVID-19, internet plus health care aimed to break through time and space constraints to both identify and service infected people, block transmission routes, and reduce the risk of population infection. The popularization of internet plus health care has not only improved the efficiency of health care institutions at all levels [51] but also stimulated innovation and accelerated the upgrading of China's health care service pattern. We set out below the contours of internet plus health care during the COVID-19 pandemic.

Internet Hospitals: To Meet the Demands for Basic Medical Services and Alleviate the Shortage of Medical Resources During COVID-19

Figure 3 identifies the role of internet hospitals and online fever clinics after the COVID-19 outbreak, which were widely established to provide follow-up visits for common and chronic diseases, as well as for psychological counseling services. In an internet hospital, a full set of medical services such as registration, consultation, diagnosis, and prescription were completed by means of video, voice, and graphic communication [52]. Hospitals arranged the delivery of drugs while patients made online payments [53]. By effectively serving a large number of patients with COVID-19, internet hospitals reduced diagnosis and treatment pressure in brick-and-mortar hospitals, greatly alleviating the shortage of medical resources in severely affected COVID-19 areas.

Telemedicine: To Break Regional Restrictions and Improve Treatment During COVID-19

As specified in Figure 3, remote consultation through the telemedicine platform integrated high-quality medical resources and provided support from large institutions and well-known experts to improve treatment. Due to the uneven distribution of medical resources in different regions, China attached great importance to constructing a telemedicine system, which played a particularly significant role during the pandemic. As discussed above, a typical case was the establishment of 9 telemedicine centers in Guangdong Province to support the hard-hit COVID-19 city of Jingzhou. While on-site diagnosis was carried out, remote medical advice and treatment were provided via the telemedicine platform at the same time.

Internet Plus Artificial Intelligence Diagnosis and Treatment: To Improve Medical Service Efficiency During COVID-19

As shown in Figure 3, online artificial intelligence preconsultation functions were widely used to assess COVID-19 risks and provide emotional care. People made a self-assessment of their personal health condition with the help of technologies powered by artificial intelligence, where patients provided their personal information, past medical history, and current medical conditions through dialogue before seeing a doctor. This information was recorded by artificial intelligence and integrated into the health information system, then directly added into the patient's medical record to facilitate subsequent diagnosis. Artificial intelligence was also applied to CT (computed tomography) scans for COVID-19, improving the accuracy and efficiency of front-line medical work [31].

Internet Telecommuting: To Maintain the Order and Efficiency of Medical Work During COVID-19

As noted in Figure 3, distance learning and teleconferencing had become mainstream working modes during the pandemic. Many hospitals used virtual private network (VPN) technology to establish secure data links, and combined with virtual desktop infrastructure technology, a remote office environment was built. By opening the VPN account and private cloud desktop, the remote office system enabled medical staff to log into intranet workstations to work remotely [54].

To enhance the service ability of medical staff, distance education was also used widely during the pandemic. Learning content was issued on online learning platforms. To check the effectiveness of these learning platforms, medical staff were required to take regular online tests, and test results were recorded in real time. Moreover, IT companies such as Tencent and Alibaba launched free online meeting systems to support antipandemic work, enabling the pandemic prevention working groups to arrange work, and discuss diagnosis methods and pandemic prevention countermeasures, through video conferencing. It not only reduced crowd gathering but also improved hospital management efficiency.

Internet Plus Convenience Services: To Reduce Offline Gathering and Avoid Cross Infections During COVID-19

During the pandemic, many hospitals provided internet plus convenience services for the public, as specified in Figure 3. Through the publication function of WeChat public accounts, hospitals launched real-time news and science articles about COVID-19 as part of information campaigns, which prevented rumors and helped the public acquire accurate pandemic knowledge [14,43]. In addition, many hospital information departments opened time-sharing outpatient appointment services, where the hospital's WeChat public account allowed patients to enter the appointment and registration system according to patients' personal needs. The appointment service helped separate patients' arrival time and reduced the number of people in the doctor's waiting room at one time, containing the spread of the virus [53]. To facilitate communication between intensive care unit (ICU) patients and their families, while avoiding staff gathering, some hospitals installed 5G customer premise equipment and video calling equipment in ICUs, substituting 5G mobile video for physical visits during COVID-19.

China's internet plus service pattern also played an important role for overseas Chinese people, providing authoritative and scientific knowledge of COVID-19 prevention. The platform was launched on April 7, 2020, bringing together 26 well-known Chinese medical institutions and third-party service institutions to provide free internet consulting services for overseas Chinese individuals. On April 30, a special column aimed at overseas students was launched to provide free health consultation and psychological counseling services. By September 2020, the platform had been visited more than 150 million times, with more than 6 million people providing direct consulting services [48].

Challenges and Recommendations

Challenges Ahead

According to the findings presented above, significant challenges to China's health informatization remain. Table 1 classifies and summarizes the challenges to health informatization. First, the number of informatization professionals is small, and the distribution of human resources is unbalanced. Second, the investment from government and medical institutions is insufficient to support the development of health informatization. An incentive mechanism to encourage social capital to participate in health informatization construction has not been set up in China [3,28]. Third, the IT application on health information platforms and in hospitals at all levels remains low. Fourth, the information standards and security systems are incomplete.

Table 1. Challenges to national health informatization.

Factors	Descriptions
Personnel	
Quantity	The number of senior technical personnel and grassroots practical personnel is insufficient
Structure	Human resource allocation as measured by quality, educational background, professional title, and age is unbalanced
Funds	
Financial	Financial support is generally insufficient and shows regional differences
Institutional	Low proportion of hospitals' annual revenue allotted to informatization investment
Social	A lack of social capital's participation and government-enterprise cooperation
IT[a] applications	
Regional health information platform	Low application rate on municipal and county-level information platforms
Hospital information system	Low application rate in secondary hospitals and primary hospitals
Systems	
Information standard system	A lack of system interoperability and interconnection, standard management, and supervision
Information security system	A lack of complete and specific systems for standard evaluation and health information security protection

[a] IT: information technology.

Recommendations

Below we present recommendations to further promote health informatization in China.

Strengthen Top-Level Design

As identified in Table 1, there is a need to strengthen top-level design. Legal restrictions on some key aspects of national health informatization, such as health care big data management, internet medical information services, privacy protection, information facilities security, and network security, need to be enhanced. The information standard and security systems should be designed in more unified and specific ways, and information security supervision needs to be strengthened [55]. An incentive mechanism should be set up to encourage a diverse range of organizations and institutions, including health care institutions, research institutes, universities, associations, and enterprises, to participate in the construction of health informatization.

Increase Financial Investment

As specified in Table 1, finance, taxation, and investment arrangements need to be increased to support health informatization, especially from the central government and especially in regions with limited financial resources for health informatization. To address informatization financial constraints, public-private partnerships should be expanded to strengthen the cooperation between the government, business enterprises, and various social institutions [28].

Increase Qualified Personnel

As shown in Table 1, there is an urgent need to increase qualified personnel specializing in HIT. An integrated and comprehensive training system should be built to cover junior college, undergraduate, graduate, and continuing education students to enlarge the scale of skilled workers. An incentive mechanism should be established to attract experienced professionals and maintain existing personnel in health information departments. To improve the professional level and comprehensive quality of health information personnel, measures should include establishing a national health big data research institute jointly with universities and research institutes, setting up health information majors in colleges and universities and carrying out continuing education to combine teaching content with practical work.

Promote IT Applications

Addressing the deficits in information platforms and systems identified in Table 1 requires the reallocation of health resources and promotion of advanced technologies to support the new service pattern of internet plus health care. Advanced IT applications, such as cloud computing, big data, mobile internet, and artificial intelligence, need to be popularized in grassroots health units. It is necessary to construct more internet hospitals, building an integrated online and offline medical service model covering prediagnosis, in-treatment, and postdiagnosis to improve health care service efficiency.

Conclusions

As shown by its crucial role in COVID-19 prevention and control, health informatization was "fit for purpose" in China. Developed over the past decade, health information platforms and health information databases facilitated data sharing between health care institutions at all levels, connecting online and offline services. Advanced information technologies, including cloud computing, big data, and artificial intelligence, effectively monitored and forecasted the pandemic's trend that facilitated health authorities' COVID-19 control and prevention ability. The new service pattern of internet plus health care broke through time and space constraints, reduced cross infections, improved medical service quality and efficiency [51], alleviated the shortage of medical resources, and met the increasing medical demands during COVID-19. However, China’s health informatization is a work in progress; informatization is incomplete and the uneven regional distribution of health resources continues to persist. To address the challenges to health informatization, we recommend the strengthening of top-level design, increasing investment and training, upgrading the health infrastructure and IT applications, and improving internet plus health care services.

Acknowledgments

The authors appreciate the support from the National Health Commission of the People’s Republic of China. The authors also thank the anonymous reviewers and the editor for their constructive comments.

Abstract

Background: The implementation of eHealth in low-resource countries (LRCs) is challenged by limited resources and infrastructure, lack of focus on eHealth agendas, ethical and legal considerations, lack of common system interoperability standards, unreliable power, and shortage of trained workers.

Objective: The aim of this study is to describe and study the current situation of eHealth implementation in a small number of LRCs from the perspectives of their professional eHealth users.

Methods: We developed a structural equation model that reflects the opinions of professional eHealth users who work on LRC health care front lines. We recruited country coordinators from 4 LRCs to help recruit survey participants: India, Egypt, Nigeria, and Kenya. Through a web-based survey that focused on barriers to eHealth implementation, we surveyed 114 participants. We analyzed the information using a structural equation model to determine the relationships among the constructs in the model, including the dependent variable, eHealth utilization.

Results: Although all the model constructs were important to participants, some constructs, such as user characteristics, perceived privacy, and perceived security, did not play a significant role in eHealth utilization. However, the constructs related to technology infrastructure tended to reduce the impact of concerns and uncertainties (path coefficient=−0.32; *P*=.001), which had a negative impact on eHealth utilization (path coefficient=−0.24; *P*=.01). Constructs that were positively related to eHealth utilization were implementation effectiveness (path coefficient=0.45; *P*<.001), the countries where participants worked (path coefficient=0.29; *P*=.004), and whether they worked for privately or publicly funded institutions (path coefficient=0.18; *P*<.001). As exploratory research, the model had a moderately good fit for eHealth utilization (adjusted R^2=0.42).

Conclusions: eHealth success factors can be categorized into 5 groups; our study focused on frontline eHealth workers' opinions concerning 2 of these groups: technology and its support infrastructure and user acceptance. We found significant disparities among the responses from different participant groups. Privately funded organizations tended to be further ahead with eHealth utilization than those that were publicly funded. Moreover, participant comments identified the need for more use of telemedicine in remote and rural regions in these countries. An understanding of these differences can help regions or countries that are lagging in the implementation and use of eHealth technologies. Our approach could also be applied to detailed studies of the other 3 categories of success factors: short- and long-term funding, organizational factors, and political or legislative aspects.

KEYWORDS

eHealth; low-resource countries; eHealth implementation effectiveness; end user survey; eHealth utilization

Introduction

Background

> *eHealth is the cost-effective and secure use of information communication technology in support of health and health-related fields, including health-care services, health surveillance, health literature, and health education, knowledge and research [1].*

Properly implemented eHealth has the potential to scale up the delivery of health care to people in low-resource countries (LRCs) [2]. Quality of health care has been found to contribute the most to the success of these eHealth interventions, whereas cost contributes the most to intervention failures [3]. The challenges faced when implementing eHealth vary among countries. For eHealth solutions to succeed in LRCs, an organized approach must be used to address these challenges.

A 2016 World Health Organization report [1] indicates significant progress in eHealth planning:

> *More than half of WHO Member States now have an eHealth strategy, and 90% of eHealth strategies reference the objectives of UHC [Universal Health Coverage] or its key elements. It is becoming mainstream for countries to have policies for managing information. When well-articulated, eHealth strategies should enable the interoperability needed to support people-centred health services for everyone, and the move from disease silos to resilient health systems which can deliver UHC.*

Although the World Health Organization claims that more than half of their member states have an eHealth strategy, actual implementation of their strategies is not always followed. This is clear from published studies and concerns expressed by many researchers [3-7]. For example, Kiberu et al [4] suggest that although many sub-Saharan African countries are evaluating eHealth as a means of improving health care accessibility, several are engaged in the proof-of-concept stage of unsustainable pilot projects. There are no national guidelines in many LRCs for the secure management of individual digital health information and services, placing personal data at risk. Implementation issues with standards and interoperability can create barriers to the use of eHealth and its spread across regions or nations to support the full realization of potential health system benefits. The potential for eHealth to reduce health care costs and enable access to better quality health care is limited, often due to inadequate funding, inadequate infrastructure causing power blackouts, poor internet connectivity, and an unskilled eHealth workforce. However, regardless of having to work in such difficult circumstances, progress is being made in implementing eHealth in many LRCs. For example, a few of the many research papers that have been published by LRC researchers include critical issues such as eHealth being used to combat infant mortality in rural and remote regions of India [8] and Nigeria [9], open-source electronic health record systems that support interoperable links among them have been installed in Kenya [10], and telecom policies developed to encourage optimal digital network implementation to support eHealth in Egypt [11].

Objective

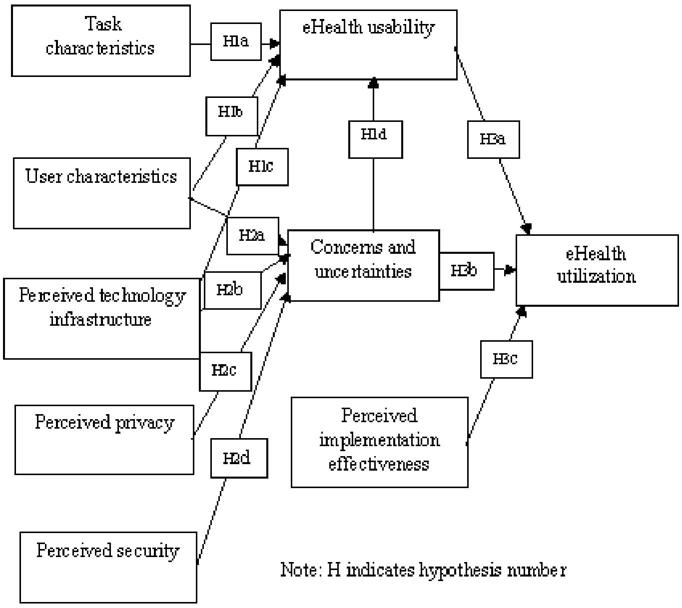
The objective of this study is to create and validate a model of the factors that influence the successful implementation of eHealth in LRCs, based on eHealth challenges identified in a survey of LRC eHealth end users. A recent categorization [12], modified by Ahmed et al [13], has synthesized eHealth success factors into 5 categories: (1) technology and its support infrastructure, (2) user acceptance, (3) short- and long-term funding, (4) organizational factors, and (5) political or legislative aspects. Our study focuses on factors 1 and 2, which are likely to be of interest and intimately familiar to the end user participants we surveyed.

Methods

Construct Development for the eHealth Implementation Issues Model

Figure 1 shows the model used in this study. The following discussion describes the details of the model's development and related hypotheses (shown in small rectangles in the diagram), including the background of the model constructs. The study based on this model was implemented through a web-based questionnaire detailed in Multimedia Appendix 1.

Figure 1. Structural equation model of eHealth implementation issues in low-resource countries.



Note: H indicates hypothesis number

Task Characteristics

Tasks are the activities that support the organization. Information systems facilitate completion of the organization’s tasks. Compatibility with work processes or work styles and task difficulty are often used to characterize tasks [14]. Research has shown [15] that if a system is more aligned with the needs of the users, there is a greater chance of system success. A fit-variability model [16] (related to the task-technology fit model by Goodhue [15]) showed that different stakeholders may perceive eHealth viability and fit of the same eHealth services very differently and that there can be discrepancies between organizational viability and individual fit of specific eHealth services. Relevant information from the study by Goodhue and Thompson [15] was used to derive the task characteristics construct for the questionnaire (Multimedia Appendix 1). This leads to:

- Hypothesis 1a: Task characteristics will positively affect eHealth usability.

User Characteristics

“User characteristics are attitudes, perceptions, and demographics that are specific to the individual users of the information system” [14]. A survey of 465 medical professionals in northwest Nigerian hospitals [7] showed that the majority of the participants had a good level of literacy for implementing and working with new eHealth systems. They found statistically significant positive correlations between intention to use eHealth and attitude toward eHealth, perceived usefulness toward eHealth, information technology experience and eHealth, and technical infrastructure for eHealth. The user characteristics construct for the questionnaire (Multimedia Appendix 1) was adapted from the study by Zayyad and Toycan [7]. This leads to:

- Hypothesis 1b: User characteristics will positively affect eHealth usability.
- Hypothesis 2a: User characteristics will negatively affect concerns and uncertainties.

Perceived Technology Infrastructure

Information communications and technology is a key component of any eHealth program. For an eHealth program to succeed, technology must be available to support a database that is always directly and easily accessible to practitioners for health record input, retrieval, analysis, and sharing within the patient’s circle of care. The infrastructure must include stable and reliable digital communications network hardware and software to support health record access and sharing through point-of-care devices used by health care providers. Highly reliable electrical power must also be available at all times to drive the components of the infrastructure [4,6,7,17]. The relevant perceived technology infrastructure construct for the questionnaire (Multimedia Appendix 1) was adapted from the study by Zayyad and Toycan [7] as follows:

- Hypothesis 1c: Perceived technology infrastructure will positively affect eHealth usability.
- Hypothesis 2b: Perceived technology infrastructure will negatively affect concerns and uncertainties.

Perceived Privacy

A study of eHealth in Bangladesh found that privacy concerns by patients [18] did not have a significant impact on provider concerns about eHealth use. An explanation is that poor eHealth privacy and security considerations resulted in eHealth systems being judged by patients as failures [19]. This is the opposite of the findings from users of eHealth (clinicians) who may tend to believe that privacy and security are less important when an eHealth system provides superior health care. The perceived privacy construct for the questionnaire (Multimedia Appendix 1) was derived from the study by Wilkowska and Ziefle [20], as follows:

- Hypothesis 2c: Perceived privacy will positively affect concerns and uncertainties.

Perceived Security

Security and privacy issues are related in eHealth systems; it is not possible to manage privacy without a secure system. A survey of professionals working in Nigerian hospitals addressed the professionals' intentions to use eHealth [7]. A question related to security concerns showed a nonsignificant correlation of this issue with the intention to use eHealth. The perceived security construct of the questionnaire (Multimedia Appendix 1) was derived from the study by Wilkowska and Ziefle [20] as follows:

- Hypothesis 2d: Perceived security will positively affect concerns and uncertainties.

eHealth Usability

Usability represents an important yet often overlooked factor impacting the implementation and meaningful use of eHealth systems. Without usable systems, doctors, medical technicians, nurses, administrative staff, and other users would have great difficulty in realizing the potential benefits of eHealth systems. The usability of technical systems has been studied in the information systems field, beginning with the landmark work by Davis [21]. This is a key measure of an eHealth system and directly reflects how users may react positively to its use. In general, if the system is built to perform specific user tasks, its usability will be greater. The eHealth usability construct for the questionnaire (Multimedia Appendix 1) was adapted from the study by Davis [21]. The foregoing leads to the following:

- Hypothesis 3a: eHealth usability will positively affect eHealth utilization.

Concerns and Uncertainties About eHealth

A review of empirical research classifying eHealth implementations as successes or failures [3] found that quality of health care was most often mentioned as contributing to the success of eHealth interventions. This review found that costs were most frequently mentioned as contributing to failure, although workflow issues were also mentioned in most of the articles reviewed. Workflow issues could lead to disagreement among the affected clinicians, increasing uncertainties, and the potential for failure of the eHealth system. The concerns and uncertainties about eHealth construct of the questionnaire (Multimedia Appendix 1) adapted ideas expressed by Aranda-Jan et al [22] in a systematic review of what does not work in African eHealth projects, leading to the following hypotheses:

- Hypothesis 1d: Concerns and uncertainties about eHealth systems will negatively affect eHealth usability.
- Hypothesis 3b: Concerns and uncertainties about eHealth systems will negatively affect eHealth utilization.

Perceived Implementation Effectiveness

Underlying factors affect health care professionals' decisions to implement eHealth technology applications in LRCs [7]. These include the perceived usefulness, belief, willingness, and attitude of health care professionals. Our study implicitly reflects these factors in terms of survey feedback from users who have chosen to implement eHealth in their workplaces. The technological capability of eHealth systems is one of the key factors that influence the successful implementation of a technology [17]. Technological success factors include functional and nonfunctional requirements, interoperability, and user interface design. The long-term sustainability of a system depends on the economic, social, and organizational sustainability in which the technology is embedded. The perceived eHealth implementation effectiveness construct of the questionnaire (Multimedia Appendix 1) was developed from ideas expressed by Rezai-Rad et al [23] and is stated as:

- Hypothesis 3c: Perceived implementation effectiveness will positively affect eHealth utilization.

eHealth System Utilization

Utilization of an eHealth system is a measure of how popular the system is with the users and if it will be sustainable and worth the operating cost in the long run. This was measured in our study by eHealth system utilization, a one-indicator formative construct Q10 (Multimedia Appendix 1) that lists possible eHealth utilization levels by the participant's organization.

Table 1 summarizes the reference sources mentioned above that were used to create the eHealth implementation model.

Table 1. Summary of sources for eHealth implementation model constructs.

Title	Construct	Type	Study
Perceived task characteristics	Validated	Reflective	Goodhue and Thompson [15]
Individual characteristics	New	Reflective	Zayyad and Toycan [7]
Perceived technology infrastructure	New	Reflective	Zayyad and Toycan [7]
Perceived eHealth privacy	Validated	Reflective	Wilkowska and Ziefle [20]
Perceived eHealth security	Validated	Reflective	Wilkowska and Ziefle [20]
eHealth usability	Validated	Reflective	Davis [21]
Concerns and uncertainties about eHealth	New	Reflective	Aranda-Jan et al [22]
eHealth implementation effectiveness	New	Reflective	Rezai-Rad et al [23]
eHealth utilization	New	Formative (1-indicator variable)	N/A[a]

[a] N/A: not applicable (as this construct is developed in this study).

Implementation

Overview

This study was approved by the McMaster University Research Ethics Board. In addition to its own approval process, the board contacted eHealth authorities in each of the 4 LRCs to ensure that the research proposal was acceptable. The study proceeded in 2 phases: I and II. An individual country coordinator with experience in eHealth implementations was recruited for each of the 4 countries involved in the study. They received nominal reimbursement for managing the recruitment of eHealth expert consultants for phase I and survey participants for phase II in their respective countries. eHealth consultants in the phase 1 study also received a nominal sum. Participants were not paid for completing the survey (phase II). In the 2 countries where 35 or more participants were recruited, a random draw prize was awarded to 1 participant in each country.

Phase I

On the basis of a detailed review of the relevant eHealth literature, we developed a draft questionnaire. Our study focused on eHealth users and support staff in the 4 representative LRCs: Kenya (East Africa), Nigeria (West Africa), India (South Asia), and Egypt (North Africa). Consultations with the experts on the phase I questionnaire informed the design of the final questionnaire and highlighted the importance of the factors identified from the literature. A key finding was that the model was too broad, including a number of strategic concerns that individual participants, as clinicians or other end users, were less likely to be directly concerned with. These strategic concerns (3 of the 5 categories [12] referenced earlier in this paper: short- and long-term funding, organizational factors, and political or legislative aspects) made the questionnaire too long for busy eHealth users to be willing to complete. Therefore, we reduced the scope of the issues covered to the first 2 categories (technology and its support infrastructure and user acceptance). The final questionnaire was based on the more limited model shown in Figure 1. Each reflective construct in the model included at least three indicator variables, which were presented on a 7-point Likert scale. The resulting questionnaire is provided in Multimedia Appendix 1, and the information, consent, and invitation to participate messages to the survey participants are provided in Multimedia Appendix 2. The web-based version, developed using *Qualtrics* software[24], took about 15 minutes for the participants to complete.

Phase II

A convenience sampling survey of eHealth users in the 4 LRCs was arranged by the relevant country coordinators, who recruited suitable participants. Participants were from public and private institutions in rural and urban areas and had varying levels of eHealth experience. Details of the survey process are provided in Multimedia Appendix 3. From 177 invitations to participate, 114 (64.4% overall response rate) valid responses were completed from India (39/114, 34.2%), Egypt (52/114, 45.6%), Kenya (11/114, 9.6%), and Nigeria (12/114, 10.5%). Statistical data were analyzed using partial least squares with *Smart PLS3* software [25].

Results

Participant Demographics

Participant demographics are detailed in Table 2, including country comparisons. In the table, the *Total* column represents the number of participants from each country who completed the survey successfully. All data are presented as absolute values and percentages. Percentages in the total column on the righthand side sum to 100% for the categories presented in each of the 5 table divisions that were also used, along with country, as control variables (occupation, employer, eHealth experience, urban or rural experience, and employment experience).

Table 2. Participant demographics.

Characteristics	Country, n (%)				Total (N=114), n (%)
	India (n=39)	Egypt (n=52)	Kenya (n=11)	Nigeria (n=12)	
Occupation					
Physicians	8 (20.5)	20 (38.4)	1 (9.1)	1 (8.3)	81 (71.1)
Nurses	1 (2.5)	1 (1.9)	1 (9.1)	0 (0)	8 (7)
Allied health personnel	4 (10.2)	3 (5.8)	1 (9.1)	1 (8.3)	25 (21.9)
Employer					
Work in privately funded health care	10 (25.4)	10 (19.2)	1 (9.1)	1 (8.3)	61 (53.5)
Work in publicly funded health care	3 (7.7)	14 (26.9)	1 (9.1)	1 (8.3)	53 (46.5)
eHealth experience					
No previous experience with eHealth	4 (10.2)	7 (13.4)	0 (0)	0 (0)	26 (22.8)

eHealth Implementation Model Results

Figure 2 shows the results calculated from the structural equation model, which was run with bootstrapping using 1000 subsamples. The calculated path coefficients for the proposed hypotheses, shown in Figure 2, are listed in Table 3. Hypotheses H1a, H2b, H3b, and H3c were supported, whereas the remaining hypotheses (H1b, H1c, H1d, H2a, H2c, H2d, and H3a) were not supported (all with *P*>.05).

Control variables (for the demographic categories in Table 2) were also run against the model, and those with significant results are included in Figure 2. These are (1) participant's country and (2) employer private or public funded. The results for these control variables are shown in the lower part of Table 3.

The composite reliabilities and average variance extracted (AVE) for the reflective constructs are shown in Table 4. The composite reliability of a construct measures the reliability of the indicator variables included in the construct. All the composite reliabilities were above the accepted lower limit of 0.70 [26]. The AVE results measure the fit of the internal structure of the model. AVE is slightly below the accepted lower limit of 0.50 for *concerns and uncertainties*, but all the other values meet the lower limit within the rounding error; therefore, with this exception, the model has convergent validity. The heterotrait ratio of correlations [27], shown in Table 5, assesses the discriminant validity in the model. The resulting maximum value of 0.79 is below the 0.85 threshold, so discriminant validity is established. The adjusted R^2 values for usability, concerns and uncertainties, and eHealth utilization are listed in Table 6.

Participants' responses to the *eHealth utilization* construct were analyzed according to the extent to which the participants indicated that eHealth was used in their organization. The results, stratified by country, are shown as absolute values and percentages in Table 7.

To a very great extent	7 (6.1)	0 (0)	3 (7.7)	1 (8.3)	3 (27.3)

Discussion

Principal Findings

The focus of our study was on providers and support staff with applied experience in eHealth and the extent of use they perceived of eHealth in their organizations. The structural equation model we developed resulted in an estimate of the extent of eHealth utilization in their organizations (adjusted R^2=0.42). This result is in the range of a moderately good result [28] for an exploratory study.

In the model, only task characteristics contributed significantly to usability (Figure 2). When the model was run without control variables in place, it gave an adjusted R^2 of 0.310 for eHealth utilization, with the path coefficient usability→eHealth utilization significant at 0.18 (*P*=.01). Other path coefficients changed very little, but this one became nonsignificant at a value of 0.015 (*P*=.88) when the 2 significant control variables (country and public or private employment) were included in the final model. This result tells us that there was variability among the opinions of the participants about eHealth utilization that depended upon their home country and their employer (private or public).

eHealth Utilization

eHealth utilization in participant organizations was dealt with in question 10 of Multimedia Appendix 1. Its raw data results were analyzed and are presented in Table 7. These results show a similar distribution of engagement level of eHealth in health care organizations in each of the 4 countries. The median use of eHealth by the LRC participant organizations was *to a moderate extent*, as indicated by calculations from the raw data in response to the question in Multimedia Appendix 1*the extent of eHealth use in your organization*. This suggests a generally favorable reaction to the applicability of eHealth to health care organization work. Although the sample sizes of the Nigerian and Kenyan responses were too small for statistical comparisons, there was little difference in their average results from the Egyptian and Indian responses.

Privacy and Security

Privacy and its related supporting functionality, that is, security, were not found to be significant to the model construct eHealth concerns and uncertainties and, thus, to eHealth utilization, which is in agreement with similar studies [7,18]. Although this may be the case for eHealth users such as our participants, patients themselves in other LRC studies were found to be concerned about privacy violations through secondary or unauthorized access [19,29]. However, the lack of significance in our model did not mean that privacy and security were unimportant to the participants. From the raw data for question 4 in Multimedia Appendix 1, the overall result was a median value of 7 (you strongly agree) and a mean value of 6.3 (you agree) for the 3 positive statements in the questionnaire about the relevance of privacy, and similar results for the 3 positive statements in the questionnaire about the relevance of security (Multimedia Appendix 1). These are favorable results that did not have a significant impact on the model results because they did not seem to be of concern to most participants in relation to eHealth utilization.

Relevance to Previous Literature

The recent history of eHealth implementation and experimentation in many LRCs has resulted in research and publication of many relevant results, including those that touched on sustainable implementation of eHealth in these countries [3,7,17,18,30,31]. In addition, Mauco et al [32] developed and validated an eHealth readiness assessment framework for developing countries. It includes a comprehensive set of readiness factors, including organizational, technological or infrastructural, government, societal, health care provider, engagement, core, and public- or patient-related. Another study by Ahmed et al [13], adapted from the study by Broens et al [12], synthesized 5 mobile health and telehealth (generalizable to eHealth) success factors, which we referenced in the introduction to this paper. Our research focused on 2 of these success factors (technology and its support infrastructure and user acceptance) to portray their effects on user perceptions.

The implementation of eHealth systems in LRCs differs from past activities with the more mature systems in developed nations. For example, many LRCs have been implementing pilot eHealth systems, some of which have been successful whereas others have not. Some of these implementations have ignored long-term effects, such as nonstandard systems that do not interoperate with other existing or planned systems [4]. Mistakes of this nature were also made when eHealth systems were initially being used in developed nations, and it is important to avoid making the same expensive mistakes in LRCs.

Other eHealth Implementation Measures

Whether hospitals implement experimental or full eHealth applications, their operations are a source of data and user opinions that could be harvested to deduce predictions and possible causes of success or failure in future installations. The problem is that almost all related research on LRCs has been based on single installations or systematic reviews [3,7,22,23,32], and it is difficult to generalize from these to validate a theoretical framework. We note that there are organizations that publish hospital rankings in different regions and countries, including most, if not all, LRCs (eg, *Ranking Web of Hospitals* [33]). These rankings do not specifically include eHealth considerations. More specific to hospital implementations of eHealth is the Electronic Medical Record Adoption Model (EMRAM; HIMSS Analytics) [34]. EMRAM is an 8-level maturity model, beginning at level 0 (no eHealth facilities) and improving to level 7 (virtually complete implementation of eHealth, including electronic medical records, external digital links, privacy, security, disaster recovery, data analytics, and data governance). Forward-looking hospital managers aspire to move upward on this scale. Although few hospitals outside the United States have reached levels 6 or 7, many hospitals in the United States have reached levels 6 or 7. Although the EMRAM approach has been used primarily in developed nations, its advantage is that it encourages hospitals to modernize their facilities through eHealth implementation in a carefully managed manner. It also helps the hospital management to look for advice from other hospitals to help them move more effectively to a higher level of eHealth implementation. The need for this more organized approach is similar in LRCs, except that LRC hospitals are often starting at an introductory, low level of eHealth use, where initial eHealth system adoption requires extensive changes in hospital operations and employee training.

Implications for Future Design

Our research takes the first step in the use of local eHealth experience by combining the opinions of actual eHealth end users from several LRCs. Regardless of the digital design of eHealth systems with which participants worked, the results of this study can be generalized to other proposed installations. Our findings could ultimately influence the design of eHealth systems, apps, and interfaces.

We also believe that we have demonstrated in a small way how to improve the general theory of eHealth implementations in LRCs by assessing a simultaneous combination of opinions of end users about 2 of the main eHealth success factors [13]. By redesigning the model; extending the survey scope; and expanding the participant audience to users, planners, developers, decision makers, and politicians, an evaluation of all 5 success factors [13] in multiple eHealth installations could be undertaken. This would help LRC planners, aided by a modified maturity model approach, to develop an appreciation of the impact of the various factors [35] that may differ among LRCs or among different installations in the same LRC, through the expressed opinions of participants. This would also help to direct strategic investments in eHealth more effectively.

Strengths and Limitations

Our eHealth research in LRCs was the first time this approach was used to gather users' perceptions of how eHealth utilization differed among the countries involved in the study. Acknowledging some limitations in our survey design, it is clear that studies of this nature with revised survey formats could be undertaken on an expanded scale, involving participants with a wider range of eHealth backgrounds. The ultimate gain would be a wider development and understanding of an approach similar to maturity modeling to help the hospital management move ahead with eHealth implementation in an organized and optimal manner.

We received many interesting and useful comments from participants that we were unable to analyze and include here because of space limitations.

Limitations included our use of convenience sampling to identify participants, which was not fully representative of each country's health care workforce. The participant response rate was also considerably less than statistically desirable, and we could have achieved a higher response rate if we had been able to pay participants a nominal fee.

Acknowledgments

This research was supported by a joint grant from the McMaster University Faculty of Health Sciences, the DeGroote School of Business, and the McMaster University Research Excellence Fund. The authors wish to thank them for their generous support. We also relied on our support network members to oversee the gathering of data from eHealth users in the four countries in our study. The support network included Adekunle Ajiboye, MEEI, MSc, CEO AAJIMATICS, Hamilton, Canada; Victor Gbenro, BMBCh, PgD, MSc, Dep. Registrar, Medical & Dental Council Nigeria, Abuja, Nigeria; and the four country research coordinators Chythra Rao, MD, Kasturba Medical College, Manipal, India; Ahmed Shaarawy, MD, MSc, MBBcH, Clinical Informatics Director, Welcare Hospital, Giza, Egypt; Wycliffe Ayieko, PgD, University of Nairobi, Kenya; and Nkem Momah, MBBS, MPH, Deputy Director, eGovernment Development & Regulatory Dept, National Information & Technology Development Agency, Abuja, Nigeria. Finally, we want to thank the participants in the 4 countries who completed the questionnaires for this research.

Abstract

Background: Prior to the COVID-19 pandemic, major shortcomings in the way mental health care systems were organized were impairing the delivery of effective care. The mental health impacts of the pandemic, the recession, and the resulting social dislocation will depend on the extent to which care systems will become overwhelmed and on the strategic investments made across the system to effectively respond.

Objective: This study aimed to explore the impact of strengthening the mental health system through technology-enabled care coordination on mental health and suicide outcomes.

Methods: A system dynamics model for the regional population catchment of North Coast New South Wales, Australia, was developed that incorporated defined pathways from social determinants of mental health to psychological distress, mental health care, and suicidal behavior. The model reproduced historic time series data across a range of outcomes and was used to evaluate the relative impact of a set of scenarios on attempted suicide (ie, self-harm hospitalizations), suicide deaths, mental health–related emergency department (ED) presentations, and psychological distress over the period from 2021 to 2030. These scenarios include (1) business as usual, (2) increase in service capacity growth rate by 20%, (3) standard telehealth, and (4) technology-enabled care coordination. Each scenario was tested using both pre– and post–COVID-19 social and economic conditions.

Results: Technology-enabled care coordination was forecast to deliver a reduction in self-harm hospitalizations and suicide deaths by 6.71% (95% interval 5.63%-7.87%), mental health–related ED presentations by 10.33% (95% interval 8.58%-12.19%), and the prevalence of high psychological distress by 1.76 percentage points (95% interval 1.35-2.32 percentage points). Scenario testing demonstrated that increasing service capacity growth rate by 20% or standard telehealth had substantially lower impacts. This pattern of results was replicated under post–COVID-19 conditions with technology-enabled care coordination being the only tested scenario, which was forecast to reduce the negative impact of the pandemic on mental health and suicide.

Conclusions: The use of technology-enabled care coordination is likely to improve mental health and suicide outcomes. The substantially lower effectiveness of targeting individual components of the mental health system (ie, increasing service capacity growth rate by 20% or standard telehealth) reiterates that strengthening the whole system has the greatest impact on patient outcomes. Investments into more of the same types of programs and services alone will not be enough to improve outcomes; instead, new models of care and the digital infrastructure to support them and their integration are needed.

Introduction

Mental illness is a major cause of disability and early mortality globally [1-3]. The early onset, chronicity, and complexity of mental illness means that the human, social, and economic costs are enormous [4]. Yet, mental health systems often struggle to provide adequate care that effectively intervenes to mitigate the short- and long-term negative outcomes [5].

For some, access to mental health care has improved [6-9]; however, most health systems lack effective coordination between service silos, which impacts on the delivery of holistic, timely, and quality mental health care [10,11]. Service fragmentation, delayed care, mental health treatment isolated from other physical and social needs, complicated service pathways, and inefficient resource allocation are persistent features of an underperforming service system [5,12]. This is particularly problematic for people with more complex needs who tend to report higher rates of disengagement from education or employment [7-9], suicidality [13,14], and comorbidity [15]. These cases are the norm among those who frequently engage with health systems and typically require multidisciplinary team-based care approaches [16]. These approaches embrace collaborative care models, which recognize that effective care coordination between service providers, including intensive assessment, personalized treatment plans, targeted referrals, clinical information systems use, and outcome monitoring can improve treatment engagement, satisfaction with care, and mental health outcomes [17-19].

The integrated use of digital technologies offers significant potential to enable effective coordination of mental health care [20-23]. The accessibility, scalability, and standardization mean that technology is well-placed to play a major role in the digitization of health care and can be leveraged to deliver quality mental health care across settings, especially those that are remote or rural and may be underresourced when compared to urban centers [24]. Their use in mental health systems has already demonstrated utility to improve access to care and communication between service providers and consumers [25]. This may be particularly important for people with more complex needs, such as housing and employment support, whereby mental health treatment may be an additional burden in terms of time, effort, and finance. Technology offers an opportunity to alleviate some of this burden through greater flexibility in terms of access to effective care, greater efficiencies through the sharing of information between providers, and improving engagement with care [26].

Never has this capability been more vital than amid a pandemic and recession whose effects are disrupting nearly every aspect of life: familial, educational, vocational, health, and social structures. This disruption is threatening population mental health and well-being and is likely to generate service demand of unprecedented magnitude for many years [27,28]. Some governments are responding by instituting measures to reduce economic and social hardship, investing in mental health programs and services, and improving access via virtual mental health services (ie, basic telehealth). These investments represent a move in the right direction; however, without addressing the fundamental models of care, the rapid adoption of telehealth poses the risk that it may digitize the problems that already exist in existing models of care across the mental health system [29,30].

Systems modeling and simulation is a low-risk method of exploring likely impacts of counterfactual scenarios. This study uses an existing local system dynamics model developed for regional mental health services planning to identify the impact of using digital technologies to facilitate care coordination on mental health outcomes and health system burden (ie, technology-enabled care coordination). Here, we aimed to compare technology-enabled care coordination to three other likely intervention scenarios: (1) business as usual, (2) an increase in the growth rate of existing service capacity (ie, increasing throughput of people into existing systems), and (3) digital technologies used to extend existing services online (eg, via videoconferencing) without changing the underlying model of care (ie, standard telehealth). We aimed to model the impacts of each scenario within both a *typical* context and a public mental health crisis resulting from the pandemic and economic recession.

Methods

Context

The North Coast NSW (New South Wales) Primary Health Network supports a population of 502,524, as of 2016 [31], distributed over a geographic area of approximately 35,570 square kilometers and takes in both coastal and inland rural communities. The region is more socioeconomically disadvantaged compared to the state and national averages, with higher rates of unemployment, domestic and family violence, and homelessness [32,33].

Model Overview

The system dynamics model was developed using a participatory modeling approach that involved over 50 local stakeholders, including representatives from health and social policy agencies, local government, nongovernmental organizations, primary care providers, emergency services, research institutions, community groups, and, importantly, people with lived experience. The process employed a broad systems perspective drawing on the deep tacit knowledge of the diverse perspectives of these system actors. Input from stakeholders was provided through a series of workshops, meetings, surveys, and local system mapping activities between July and December 2019. This process involved iteratively working on the model structure and assumptions; regular face validity checks by a diverse group of academic, clinical, policy, program planning, emergency services, and lived-experience stakeholders were undertaken to ensure accurate model representation, conceptualization, and outputs. A more detailed description of the model development process, structure, outputs, and calibration can be found in the primary paper [34].

In summary, the core model structure included the following dynamically interacting components:

1. A population component, capturing changes over time in the size and structure of the population resulting from births,

net migration, and mortality across the following age groups: 0-14 years, 15-24 years, 25-64 years, and 65+ years old.

2. A psychological distress component that captures changes in the rates and severity of psychological distress in the population (ie, states of low psychological distress, with a Kessler 10 [K10] score of 10-15; moderate psychological distress, with a K10 score of 16-21; and high to very high psychological distress, with a K10 score of 22-50).
3. A series of components capturing pathways within and between key social determinants of mental health and suicidal behavior, namely, early life exposures, substance abuse, domestic violence, homelessness, and unemployment.
4. A mental health service system component that models the movement of psychologically distressed people through one of several possible service pathways, potentially involving general practitioners; psychiatrists; allied mental health professionals, including psychologists and mental health nurses; emergency department (ED) and psychiatric inpatient care; community- and hospital-based outpatient care; and online services, and one that captures changes over time in service demand and capacity.
5. A suicidal behavior component that captures self-harm hospitalizations and suicide deaths. Figure S1 in Multimedia Appendix 1 details the key social determinants identified by the participatory process and their hypothesized impact on mental health and the other model outcomes.

Model construction and analysis were performed using Stella Architect, version 1.9.4 (isee systems inc). The model was validated by (1) testing whether the model could replicate historic data across a range of key indicators, namely, time series of psychological distress, psychiatric hospitalizations, mental health–related ED presentations, self-harm hospitalizations, and suicide deaths, and (2) ensuring face validity among diverse system actors in the model structure and performance. The AdViSHE (Assessment of the Validation Status of Health-Economic decision models) checklist was also used to assess the validation status of this model and its outputs [35].

Model Outputs

For this study, model outputs included both mental health outcomes and service usage for the total population. Mental health outcomes and health system burden include total cumulative numbers of self-harm hospitalizations, which are a proxy for suicide attempts; suicide deaths; prevalence of high to very high psychological distress; and mental health–related ED hospitalizations. All outputs were calculated every 0.4375 days (ie, one-sixteenth of a week) starting from January 1, 2011; these permitted comparisons of model outputs with historic data from 2011 to 2017 for validation. Forecasts of the impacts of intervention scenarios described below are simulated from the time of implementation in 2021 to the end of 2029 [34].

Intervention Scenarios

Four distinct intervention scenarios were tested. The first scenario is *business as usual*, whereby there is no change to the existing services system and the rate of growth in existing services is maintained. The second scenario is *an increase in service capacity growth by 20%*, whereby the yearly growth of existing service capacity is increased. These services include those provided by general practitioners; psychiatrists; allied mental health professionals, including psychologists and mental health nurses; and community-based mental health services. The third scenario is *standard telehealth*, whereby digital technologies are used to extend existing services online (eg, via videoconferencing) without changing the underlying model of care. The fundamental assumption here is that technologies are being used to remotely provide existing models of care delivered by individual providers rather than being used to improve the coordination of care between service providers: a coordinated, multidisciplinary, team-based approach to care. This means that there is no change to referrals between services nor to the per-service recovery rate, since the only element that has changed is the mode of delivery. The fourth scenario is *technology-enabled care coordination*, which involves the use of online technology to facilitate delivery of multidisciplinary team-based care, in which medical and allied health professionals consider all relevant treatment options and collaboratively develop an individual treatment and care plan for each patient. Online technology enables enhanced coordination of care and facilitates communication between medical and allied health professionals, since each health professional involved in the care of a patient has access to the same information about that patient's treatment history (see parameter details in Textbox 1 [17,25,34,36,37]).

Each scenario was operationalized by varying key parameter estimates in the model, as outlined in Table 1. Each of these intervention scenarios was tested under *pre–COVID-19 conditions*, which are based on original trends in socioeconomic circumstances (ie, all policies and programs currently in place remain unchanged and service capacity continues to increase at current rates). Each intervention scenario was also tested under *post–COVID-19 conditions*, which reflect a new baseline for socioeconomic circumstances to compare and contrast the qualitative and quantitative performance of this intervention when faced with new realities (eg, socioeconomic shocks). The interventions considered here are not intended to be a complete evaluation of strategies to mitigate the effects of the COVID-19 pandemic, but rather we aimed to determine the robustness of each scenario under these changed conditions. Table 2 details how the pre– and post–COVID-19 initial conditions were implemented in the model.

Textbox 1. Parameters determining the direct effects of technology-enabled care coordination [34].

Maximum rate per service:

This refers to the maximum proportion of mental health services provided that involve technology-enabled care coordination. This proportion will depend on the number of medical and allied mental health professionals adopting technology-enabled care coordination, as well as the number of patients consenting to the use of these technologies in the management of their care (ie, uptake among service providers and patients). The default value (0.7) assumes that when fully implemented, technology-enabled care coordination will be provided in 70% of mental health services completed.

Effect on recovery rate:

This refers to the multiplicative effect of technology-enabled care coordination on the per-service recovery rate (ie, the probability that a patient's level of psychological distress will decrease after receiving treatment). The default estimate (1.177) implies that technology-enabled care coordination increases the per-service probability of a reduction in psychological distress by 17.7% [17,25].

Effect on referrals to specialized care:

This refers to the multiplicative effect of technology-enabled care coordination on general practitioners' rates of referral to specialized psychiatric care (ie, psychiatrists and allied mental health services). The default value (1.266) implies that technology-enabled care coordination increases the per-consultation probability that a general practitioner will refer a patient with high or very high psychological distress to specialized psychiatric care by 26.6% [36]. Note that technology-enabled care coordination is assumed to have no effect on the referral rate for patients with moderate psychological distress.

Effect on disengagement:

This refers to the multiplicative effect of technology-enabled care coordination on rates of disengagement from mental health services, including waiting for services and dissatisfaction with services received. The default estimate (0.520) implies that technology-enabled care coordination reduces rates of disengagement by 48.0% [25,36].

Effect on referrals to alcohol and other drugs services:

This refers to the multiplicative effect of technology-enabled care coordination on the rate of referral of patients with a substance abuse disorder to alcohol and drug treatment services. The default value (1.1) assumes an increase in the rate of referral of 10% (ie, patients with a substance abuse disorder receiving technology-enabled care coordination are 10% more likely to be referred to alcohol and drug treatment services than patients with a substance abuse disorder receiving usual care).

Effect on substance use relapse rate:

This refers to the multiplicative effect of coordinated treatment of co-occurring substance abuse and mental disorders on the substance use relapse rate (ie, the probability that a patient treated for a substance use disorder will relapse when treatment is completed). The default value (0.869) implies that coordinated substance abuse and psychiatric treatment reduces the rate of substance use relapse by 13.1% (ie, compared to substance abuse treatment alone) [37].

Effect on employment initiation:

This refers to the multiplicative effect of technology-enabled care coordination on the rate at which unemployed patients gain employment, through referral to employment services. The default value (1.1) assumes an increase in the employment initiation rate of 10% (ie, unemployed patients receiving technology-enabled care coordination are 10% more likely to gain employment than unemployed patients receiving usual care).

Effect on exiting homelessness rate:

This refers to the multiplicative effect of technology-enabled care coordination on the rate at which homeless patients secure housing, through referral to homelessness services. The default value (1.1) assumes a 10% increase in the rate that patients exit homelessness, equal to the inverse of the duration of homelessness (ie, homeless patients receiving technology-enabled care coordination are 10% more likely to secure housing than homeless patients receiving usual care).

Effect on psychiatric service capacity:

This refers to the multiplicative effect of technology-enabled care coordination on the total capacity of specialized psychiatric services (ie, the maximum number of services that can be provided by psychiatrists and allied mental health providers per year). The default value (1.1) assumes an increase in service capacity of 10%.

Effect on referrals to online services:

This refers to the multiplicative effect of technology-enabled care coordination on the rate of referral of patients with moderate psychological distress to online services. The default value (1.1) assumes an increase in the rate of referral of 10% (ie, patients with moderate psychological distress receiving technology-enabled care coordination are 10% more likely to be referred to online services than patients with moderate psychological distress receiving usual care).

Table 1. Parameter values for each intervention scenario.

Parameter[a]	Parameter values for each scenario			
	Scenario 1[b]	Scenario 2[c]	Scenario 3[d]	Scenario 4[e]
Direct effects on technology interventions				
Maximum rate per service	0	0	0.70	0.70
Effect on recovery rate	1.00	1.00	1.09	1.18
Effect on referrals to specialized care	1.00	1.00	10.00	1.27
Effect on disengagement	1.00	1.00	0.76	0.52
Effect on alcohol and other drugs services referral rate	1.00	1.00	1.00	1.10
Effect on substance abuse relapse	1.00	1.00	0.93	0.87
Effect on employment	1.00	1.00	1.00	1.10
Effect on exiting homelessness rate	1.00	1.00	1.00	1.10
Effect on service capacity	1.00	1.00	1.10	1.10
Effect on referrals to online services	1.00	1.00	1.00	1.10
Direct effects on service capacity				
General practice service capacity increase per year	125.85	151.02	125.85	125.85
Psychiatrist and allied service capacity increase per year	216.31	259.57	216.31	216.31
CMHC[f] service capacity increase per year	0	75.14	0	0

[a] See Textbox 1 for more details about each parameter.

[b] Scenario 1: business as usual.

[c] Scenario 2: increase in service capacity growth rate by 20%.

[d] Scenario 3: standard telehealth.

[e] Scenario 4: technology-enabled care coordination.

[f] CMHC: community mental health capacity.

Table 2. Comparison of parameters used to model pre– and post–COVID-19 initial conditions.

Parameter	Parameter values for each condition	
	Pre–COVID-19	Post–COVID-19
Youth job loss rate ratio	1.00	5.00
Unemployment total	1.00	15.00
Unemployment effect decay rate	0	0.05
Sense of community index (ie, social connectedness)	9.61	8.24
Years to reach sense of community index	0	1.00
Duration (years) of social disconnection	0	2.00

Statistical Analysis

Sensitivity analyses were performed to assess the impact of uncertainty in parameter estimates of the direct effects of each intervention scenario on the simulation results. Latin hypercube sampling was used to draw 100 sets of values for selected model parameters determining the direct effects of the interventions on suicidal behavior in young people, from a uniform joint distribution spanning ±20% of the default values. Differences in each of the model outputs (eg, cumulative numbers of self-harm hospitalizations, suicide deaths, and mental health–related ED presentations) between the baseline and intervention scenarios were calculated for each set of parameter values and were summarized using simple descriptive statistics. All intervals reported in this paper are derived from the distributions of model outputs calculated in the sensitivity analyses; they provide a measure of the impact of uncertainty in the intervention effect estimates but should not be interpreted as confidence intervals.

Results

Overview

Under the baseline scenario (ie, business as usual pre–COVID-19), approximately 12,274 self-harm hospitalizations, 953 suicide deaths, and 81,263 mental health–related ED presentations were forecast for the period from 2021 to 2030. By 2030, the prevalence of high psychological distress was expected to be on a trajectory of decline and was set to reduce by 2 percentage points (ie, from 17.60% in 2021 to 15.60% in 2030). Figure 1 shows the relative impact of each scenario on mental health and suicide outcomes. The implementation of technology-enabled care coordination (scenario 4) had the largest impact on outcomes for the total population. For the total population, self-harm hospitalizations and suicide deaths were reduced by 6.71% (95% interval 5.63%-7.87%), mental health–related ED presentations were reduced by 10.33% (95% interval 8.58%-12.19%), and the prevalence of high psychological distress in 2030 was reduced by 1.76 percentage points (95% interval 1.35-2.32 percentage points). This would result in the prevention of 844 self-harm hospitalizations, 66 suicides, and 8448 mental health–related hospitalizations over the forecast period and a decline in the prevalence of high psychological distress to 14% in 2030. The rate of uptake of technology-enabled care coordination has a major impact on the effects of this intervention (Figure 2). The impact on all outcomes is greater as the rate of uptake across the mental health system increases from 20% to 50% and then to 80%.

Figure 1. Mental health outcomes for each intervention scenario. ED: emergency department.

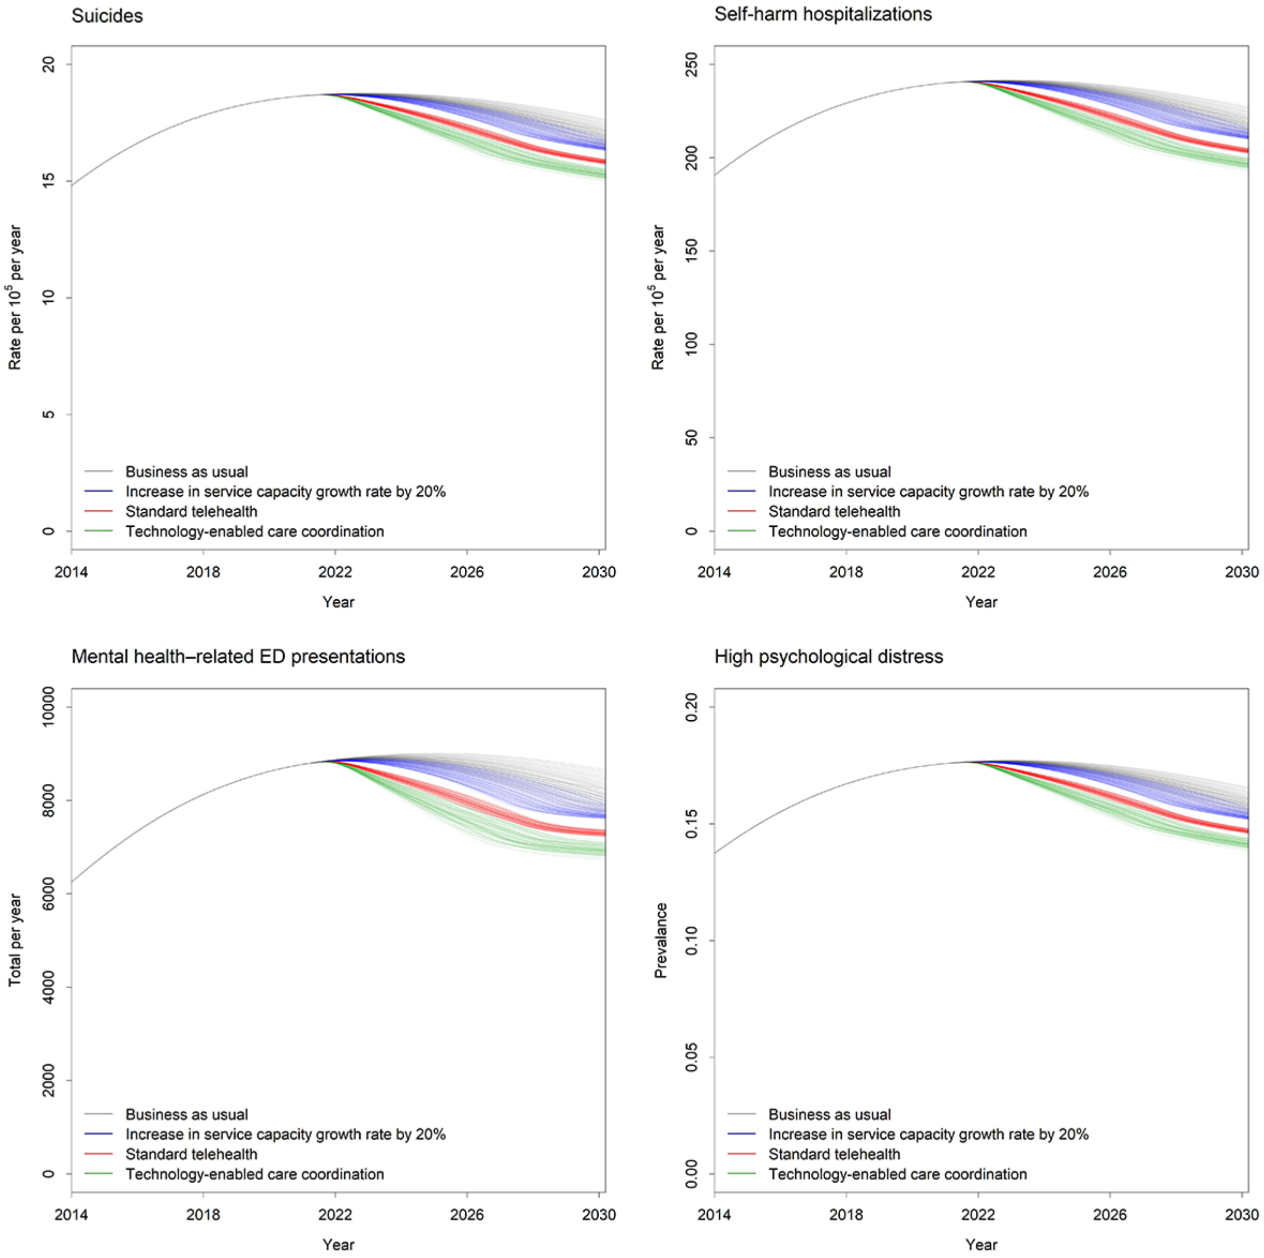

Figure 2. The impact of the rate of uptake on mental health outcomes. ED: emergency department.

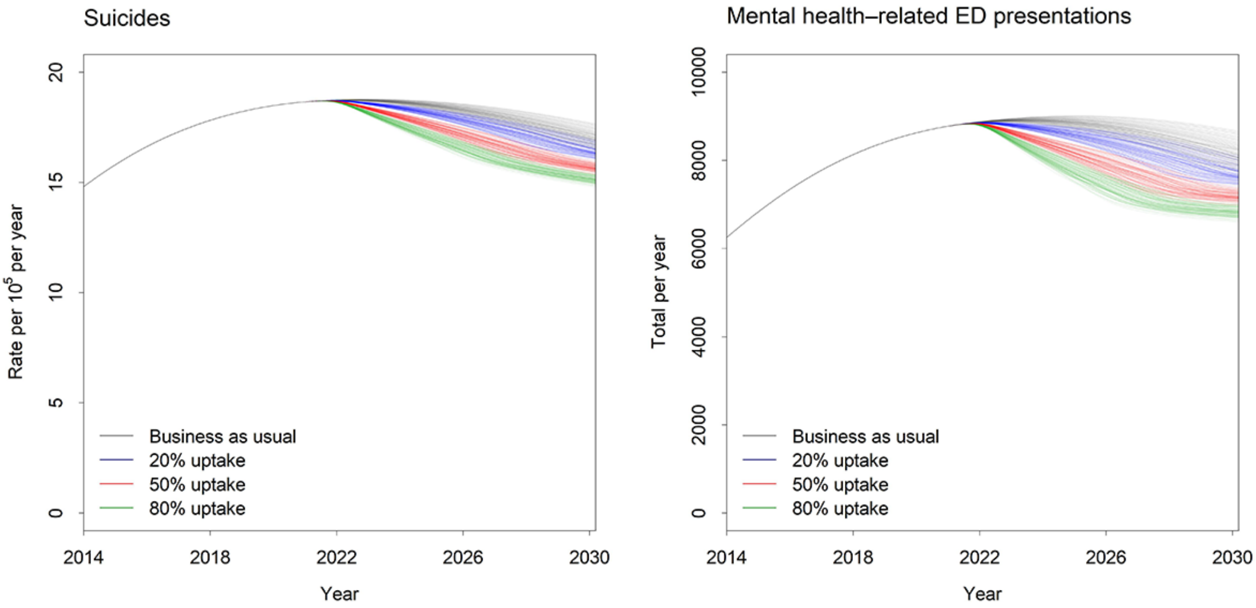

Increasing the service capacity growth rate by 20% (scenario 2) only had a minor impact on both populations; for the total population, it was forecast to reduce self-harm hospitalizations and suicide deaths by 1.64% (95% interval –0.20% to 3.51%), mental health–related ED presentations by 2.76% (95% interval –0.41% to 5.95%), and the prevalence of high psychological distress in 2030 by 0.57 percentage points (95% interval –0.08 to 1.29 percentage points). This would result in the prevention of 274 self-harm hospitalizations, 21 suicides, and 3023 mental health–related hospitalizations. The prevalence of high psychological distress was projected to decline to 15% in 2030.

When digital technologies were used for standard telehealth (scenario 3), the impact on outcomes was better than scenario 2 but lower than scenario 4, reducing self-harm hospitalizations and suicide deaths by 3.50% (95% interval 1.58%-5.03%), mental health–related ED presentations by 5.48% (95% interval 2.24%-5.43%), and the prevalence of high psychological distress in 2030 by 0.99 percentage points (95% interval 0.42-1.67 percentage points). Over the forecast period, this would result in the prevention of 418 self-harm hospitalizations, 32 suicides, 4244 mental health–related hospitalizations, and a decline in the prevalence of high psychological distress to 14.8% in 2030.

Post–COVID-19 Scenario Modeling

The impact of the public mental health crisis was estimated to have detrimental effects on all outcomes, with 14,973 self-harm hospitalizations (22% increase from baseline figures), 1176 suicide deaths (23% increase), and 98,591 mental health–related ED presentations (21% increase). By 2030, the prevalence of high psychological distress was forecast to be 18.3%, a 2.7–percentage point increase from the baseline figures forecast for 2030. During this public mental health crisis, technology-enabled care coordination (scenario 4) was forecast to have a similar impact on outcomes, with a 6.43% (95% interval 5.29%-7.46%) reduction in self-harm hospitalizations, a 6.40% (95% interval 5.26%-7.42%) reduction in suicide deaths, a 10.01% (95% interval 8.06%-11.71%) reduction in mental health–related ED presentations, and a reduction of 2.52 percentage points (95% interval 1.82-3.08 percentage points) in high psychological distress in 2030. The pattern of results for each scenario was consistent under these changed conditions; technology-enabled care coordination represents an important and effective part of the strategy to mitigate the social and economic impacts of the COVID-19 pandemic, with outcomes reduced back down to the initial *business as usual* estimates from pre–COVID-19.

Discussion

Principal Findings

These findings suggest that the use of technology-enabled care coordination is likely to result in better mental health outcomes and reduce health system burden at a population level. When compared to increasing the service capacity growth rate across a variety of settings by 20% and standard telehealth, technology-enabled care coordination led to greater reductions in suicide deaths, the total number of self-harm hospitalizations or mental health–related ED hospitalizations, and the prevalence of high psychological distress in the population. This emphasizes that strengthening how the whole mental health system functions together will have a greater impact on outcomes than simply improving the capacity across individual components of the mental health system. Investments into more of the same types of programs and services alone will not be enough to improve the outcomes for the whole system; instead, new models of care and the infrastructure to support them and their integration need to accompany these investments.

Increasing the service capacity growth rate does have a minor impact; however, since it primarily acts to increase throughput into the current mental health system, it does not address existing challenges of service fragmentation. Many structural barriers and misaligned incentives remain across the system, which contribute to the health system burden and inefficient allocation of resources that often result in poor outcomes for individuals

[38-40]. Addressing these systemic issues will most likely involve ensuring that the mental health system has the appropriate infrastructure in place to not only meet the demand for services, but provide timely care that appropriately targets the diverse needs of people presenting for care.

This work supports calls for increased use of digital technologies in mental health care [41]; however, it also suggests the importance of the way these technologies are employed. The modeling shows that when digital technologies are used for standard telehealth practices by extending existing services online (eg, via videoconferencing), without changing the underlying model of care, then the impact is lower. This type of scenario reflects what we might expect to see when telehealth is more widely implemented to deliver existing services, yet little effort is made to utilize these technologies in ways that promote multidimensional team-based care and maximize the benefits that technologies provide. As such, while telehealth stands to improve access, reach, and throughput to the mental health system and is a critical improvement in health service delivery, it does not necessarily ensure that people receive the appropriate type of mental health and social care that improves their chances of recovery. For this, a transformation in the models of care provided by services within the mental health system are required to achieve the full potential benefits of digital technologies.

Research regarding the effectiveness of digital technologies for mental health is growing, yet many of these innovations focus on the use of technologies within closed systems of care, often in isolation from other parts of the mental health system [30,42]. This neglects the way people typically need to access multiple parts of the system to receive effective care. This study illustrates that the benefits of technology-enabled care coordination for the whole system continues to increase as the proportion of services using this intervention increases. Unfortunately, realizing this type of widespread usage will require overcoming specific implementation barriers that have plagued most attempts to implement new technologies into existing health systems [22,43]. Common barriers include technology design, variation in the level of integration into existing service pathways and clinical protocols, process dynamics, contextual factors (eg, local leadership and organizational support), and other factors (eg, resourcing and training) [44-46]. Addressing these barriers requires a whole system approach that challenges the traditional and often rigid health systems to ensure that these tools are developed and integrated with services in a way that truly transforms clinical practice for the whole system.

This work should be considered in light of some limitations. The use of multiple secondary data sets introduces potential measurement bias for the estimates used to parameterize the model. Strategies were used to reduce the impact of such biases, including the triangulation of multiple data sources, parameter estimation via constrained optimization, and local verification to identify plausible estimates. The impacts of simulated scenarios are not necessarily generalizable to other regions, due to the specificity of the population, demographic, behavioral, social, economic, and mental health service dynamics that drive outcomes in a particular modeled region. Yet, for regions contextually similar to the modeled region, many of the model insights are likely to be relevant and provide a compelling case for exploring the likely impacts of similar technologies elsewhere. Further, the distinctions between the assumptions of scenarios 3 and 4 are likely to provide more generalizable insights about what components of digital transformation are projected to have large impacts in health systems. Future work should also focus on validating these model outputs over time by embedding them in local monitoring and evaluation of the implemented technology. In addition, comparisons of the modeled impacts of the technology applied to regions with similar or different social, economic, and mental health system contexts will provide additional broader insights. Finally, this study focuses on population effects of scenarios whereby the effects of interventions are generalized at the population level and cannot account for individual differences in the way that digital technologies may be rolled out or implemented at a local level. To address these specific issues, individual-level approaches, such as agent-based modeling, may be more appropriate to determine the effect of digital technologies on different agents within a mental health system (eg, people, clinicians, and services) and the impact this has on mental health and suicide outcomes.

Conclusions

Systems modeling and simulation of the likely impact of technology-enabled care coordination in ordinary and extraordinary times has highlighted its significant potential in improving population mental health and suicide outcomes. This work also provides important evidence to support a push for major investment to scale up the implementation of digital technologies that support new models of care facilitating care coordination.

Acknowledgments

The model was developed in partnership with the North Coast Primary Health Network and was intended as a contribution to the North Coast Collective, which is a regional collaboration initially between three organizations—North Coast Primary Health Network, Northern NSW Local Health District, and Mid-North Coast Local Health District—and is growing to include partners and a range of community stakeholders, including those outside of the health sector and people with lived experience of mental ill-health and suicidal behavior. Critically, this regional focus seeks to deliver on regionally agreed outcomes, optimizing the intervention and investment portfolio to achieve the greatest gain—value is defined by the quadruple aim of health care—in the most efficient way. This work was made possible by generous contributions of time, local knowledge, data, and content area expertise by the North Coast Collective modeling group, which includes the following members: Fay Adamson, Dr Graeme Browne, Dr Ashlea Broomfield, Luke Buckley, Warren Burgess, Dale Cara, Vigeeta Chauban, Christopher Clark, Dr Trish Collie, Janet Cormick, Katrina Dart, Swati Devmurari, Samara Finlayson, Guy Flaherty, Robyn George, Dr Adrian Gilliland, Dr Nicola Holmes, Rebecca Hope, David Horseman, Danica Hudson, Glen James, Darren Kershaw, Nicholas Kosseris, Deborah Kuhn, Dr Toney Lower, Dr Corrine Maynard, Tracey Mills, Lyn Moran, Niall Mulligan, David Noble, Stanley Nebo, Stuart Nunan, Judy O'Mara, Margarete Anna Ogonowski, Anne-Maree Parry, Alan Pretty, Leavina Reid, Rachel Richardson, Deidre Robinson, Vicki Rose, Shelly Rowe, Sara Shaughnessy, Dr Peter Silberberg, Janny Sinclair, Liz Stirling, Julie Sturgess, Trent Taylor, Claudine Tule, Dr Richard Tranter, Darryl Walker, Tracey Wild, Leigh Williamson, Diana Wilson, and Jami-Lee Winnacott.

Conflicts of Interest

IBH was an inaugural commissioner on Australia's National Mental Health Commission (2012-2018). He is the Co-Director, Health and Policy at the Brain and Mind Centre (BMC), University of Sydney. The BMC operates an early-intervention youth services program at Camperdown under contract to Headspace. He is the Chief Scientific Advisor to, and a 5% equity shareholder in, InnoWell Pty Ltd. InnoWell was formed by the University of Sydney (45% equity) and PwC (Australia; 45% equity) to deliver the Aus $30 million (~US $23,212,500) Australian Government–funded Project Synergy (2017-2020; a 3-year program for the transformation of mental health services) and to lead the transformation of mental health services internationally through the use of innovative technologies. JAO is Head of Systems Modelling, Simulation & Data Science and Co-Director of the Mental Wealth Initiative at the University of Sydney's BMC, and is Managing Director of Computer Simulation & Advanced Research Technologies (CSART). TD is the Director of Research & Insights at the Australian Digital Health Agency.

Abstract

Background: Caregivers of people with dementia find it extremely difficult to choose the best care method because of complex environments and the variable symptoms of dementia. To alleviate this care burden, interventions have been proposed that use computer- or web-based applications. For example, an automatic diagnosis of the condition can improve the well-being of both the person with dementia and the caregiver. Other interventions support the individual with dementia in living independently.

Objective: The aim of this study was to develop an ontology-based care knowledge management system for people with dementia that will provide caregivers with a care guide suited to the environment and to the individual patient’s symptoms. This should also enable knowledge sharing among caregivers.

Methods: To build the care knowledge model, we reviewed existing ontologies that contain concepts and knowledge descriptions relating to the care of those with dementia, and we considered dementia care manuals. The basic concepts of the care ontology were confirmed by experts in Korea. To infer the different care methods required for the individual dementia patient, the reasoning rules as defined in Semantic Web Rule Languages and Prolog were utilized. The accuracy of the care knowledge in the ontological model and the usability of the proposed system were evaluated by using the Pellet reasoner and OntOlogy Pitfall Scanner!, and a survey and interviews were conducted with caregivers working in care centers in Korea.

Results: The care knowledge model contains six top-level concepts: care knowledge, task, assessment, person, environment, and medical knowledge. Based on this ontological model of dementia care, caregivers at a dementia care facility in Korea were able to access the care knowledge easily through a graphical user interface. The evaluation by the care experts showed that the system contained accurate care knowledge and a level of assessment comparable to normal assessment tools.

Conclusions: In this study, we developed a care knowledge system that can provide caregivers with care guides suited to individuals with dementia. We anticipate that the system could reduce the workload of caregivers.

KEYWORDS

caregiver; caregiver for person with dementia; knowledge model; ontology; knowledge management; semantic reasoning

Introduction

People with dementia exhibit memory loss, personality changes, depression, and instability in daily life, and they become highly dependent on family members and caregivers [1]. If a person has severe memory loss, family members must regularly check whether they are taking their medication, and they need to remind them of the detailed procedures of daily activities such as using the toilet or taking a shower. This high level of dependency demands constant attention and frequently requires additional support from care professionals. For this reason, most of the care costs relate to the need for family and social support rather than to the medical diagnosis [1]. Furthermore, the symptoms of dementia will differ depending on factors such as the living environment and personality [2]. The complexities of the care require a careful assessment of the physical and psychological abilities of the person with dementia and an assessment of the competence of those providing the care. One of the most difficult tasks for dementia caregivers is to choose the most effective approach for meeting the care needs and matching the behavioral characteristics of the individual [1,3-5].

To alleviate the care burden on caregivers, several studies have developed computer-based support systems that improve the well-being of the person with dementia [6-13]. These studies propose systems that support the caregivers by monitoring the health and daily activities of the person with dementia. The ambient-assisted intervention system (AAIS) offers ambient intelligence to improve quality of life by identifying the presence of behavioral and psychological symptoms of dementia (BPSDs) and by suggesting an appropriate intervention for the various symptoms [8]. For example, the AAIS will give repeated reminders to a person who frequently forgets to take their medicine. The K4Care project offers a computer-supported structure that represents the health care procedures needed to assist a person suffering from a particular disease, syndrome, or social issue [10]. In order to improve the quality of treatment that a person with dementia receives, decision support tools that help physicians detect wrong diagnoses, unobserved comorbidities, incomplete descriptions of the patient's condition, and appropriate prevention measures have been proposed [12,13]. For example, the Dementia Management and Support System (DMSS-R) supports the clinical routines and decision processes implemented by health professionals in their daily practice [12]. However, existing studies mainly focus on the clinical and statistical significance of the psychosocial and environmental interventions used to improve the welfare of persons with dementia [8-13].

Other studies have proposed interventions that can improve the independence of the person with dementia and so provide relief to caregivers [14-16]. A tablet-based app called MapHabit provides a customizable visual map that helps those with various Alzheimer-related disorders. For example, persons with memory loss can obtain step-by-step support in completing their daily activities by themselves while keeping connected with family members [14]. Another study introduced a digital memory notebook (DMN) application that is designed to help individuals with mild cognitive impairment to improve their everyday functioning [15]. The DMN is equipped with daily notes, schedule management, and to-do lists, and it helps patients to plan longer-term goals and to complete their everyday activities. Another study reviews the mobile apps that are designed to support the caregivers of older adults and that can be found on Google Play and iTunes [16]. These mobile apps generally address specific aspects such as information and resources, family communication, memory aids, care for the caregiver, behavioral solutions, medication management safety, or personal health record tracking [16].

On the whole, previous studies have attempted to enhance the physical and mental ability of the individual with dementia by proposing an intelligent system that either diagnoses their medical condition or increases their level of independence in daily activities. It is hoped that as the person with dementia becomes increasingly independent, less attention will be required from caregivers, and that this will eventually result in a reduced care burden for both family members and caregivers. However, since the BPSDs are highly complex and fluctuate sporadically, caregivers will still need to constantly monitor the health condition of the person with dementia and detect any changes in their behavioral symptoms [2,3]. This means that caregivers may have difficulty in choosing an appropriate care method regardless of the symptoms diagnosed previously. It has been suggested that to lessen the care burden on family members and caregivers, new approaches that are tailored to the patients, to the contexts where the symptoms occur, and to the caregivers are required [2,3,7].

In this study, we propose a care knowledge management system that can provide a care guide that is suited to the variable behavioral and psychological symptoms of the person with dementia by using an ontological knowledge model of dementia. The ontology-based model is a computer-interpretable knowledge model for formalizing and representing shared concepts in a specific domain of interest. This is expressed in a language that enables knowledge sharing among different applications and for various reasons [17-19]. The model can help improve data-driven decisions by explicitly defining and providing semantic concepts in a specific domain. Because of these advantages, the knowledge model for the proposed system could represent various care situations, which would include the symptoms of dementia. The Pellet and Prolog reasoner that will be built into the system can infer the proper care approach required for different individuals with dementia [20]. The graphical user interface (GUI) of the system will provide an easy way for family members or caregivers in care centers to share and update care data so that each caregiver can receive appropriate care guidelines simply by sending queries to the system without needing to ask the other caregivers or family members. To evaluate the accuracy of the care knowledge in the ontological model and the usability of the proposed system, we conducted a brief survey and interviews with caregivers working in care centers in Korea.

Methods

Determining the Domain and Scope of the Ontological Model of Dementia Care

To determine the domain and scope for the ontological knowledge model of dementia care, we tried to answer the following questions: (1) What is the target and scope to be covered by the ontology? (2) What will the ontology be used for? (3) How should the data be classified within the whole area of data available to users of the knowledge model? (4) How can the model represent knowledge to the target? (5) Who will be the users of the ontology? Based on the responses to these questions, we set the target for our knowledge model as a caregiver who actively cares for a person with mild dementia, who may be a family member, and we set the scope of the knowledge to include environmental information, schedule information, daily activity information, and disease information such as would be necessary to determine a care method for the individual with dementia.

Consideration of the Reuse of Existing Ontologies

We reviewed existing ontologies that contain various concepts and knowledge descriptions relevant to the care of persons with dementia. From the relevant ontologies, disease information relating to dementia was based on the AAIS [8] and K4Care approaches [10], and concepts involving environmental information were drawn from the KnowRob ontology [11].

Collecting Terms and Developing the Ontological Model of Dementia Care

We used two different methods to collect the terms and to define the classes for the ontological model: (1) a text-based document about caring for those with dementia and (2) interviews with care experts in the field of dementia. First, we collected the handbooks on dementia care that are already used in dementia care facilities in Korea [21-23]. From these care handbooks, we retrieved several sentences that describe the daily activities of people with dementia and related care methods. These care manuals also contain questions devised to evaluate the physical and psychological condition of the person with dementia and to assess their daily activities. From the sentences and questions collected, we extracted concepts relating to dementia care and then defined a top-level class with a hierarchy of concepts following a top-down approach [18]. A top-down development process starts with a definition of the most general concepts in the domain and is followed by subsequent specializations of the concepts. For example, we started with creating classes for the general concepts of “person,” “assessment,” “task,” “medical knowledge,” “environment,” and “care knowledge.” Then we specialized those classes further by creating their subclasses. The subclasses extracted were then arranged by mapping or by adding them to the class hierarchy. Overall, it took 3 months to build our initial version of the ontological model.

We then updated the terms and classes of the ontological model by interviewing 2 experts at a dementia center in Korea. Both experts had more than 10 years of experience in the dementia center, one as a director and the other as a manager. It took a total of 6 months to update the initial model, including 3 interviews with these experts. For example, we added relationships between the causes of the BPSDs in the “Medical Knowledge” class and the care methods in the “Care Knowledge” class and updated the decision rules based on the information provided during the interviews.

The Web Ontology Language (OWL) 2 language proposed by the World Wide Web Consortium was chosen to describe the ontology model [24]. The naming convention for class labels uses nouns and verbs with the first letter of a word being capitalized and multi-word labels (eg, Take_Meals and Take_Drug) having an underscore inserted between the words. Likewise, multi-word instance labels have an underscore inserted between the words and the instance (eg, Take_Meals_01 and Hypertension_Drug_01). The property names are set in the same way. The ontology was developed using the Protégé-OWL ontology editor [25]. Its consistency was checked using the Pellet reasoner [20] and the OntOlogy Pitfall Scanner (OOPS!) [26].

The two co-first authors were actively engaged in the entire process of building the ontological model. Both of them had previous experience in building an ontological model, and one of them has a PhD degree in ontology.

Decision Rules

We constructed reasoning rules using the OWL following Protégé, and the semantic rules were created using Semantic Web Rule Language (SWRL) and Prolog [24]. Reasoning rules in SWRL are easily defined within the Protégé-OWL ontology editor, but negative rules cannot be defined. We therefore decided to use SWRL for inferring the general care methods and Prolog for inferring individual care methods that reflect the behavior or psychological condition of a person with dementia. We followed actual care guidelines that we obtained either from interviews with care experts or from care manuals used in the dementia care center in Korea. Based on the information acquired, we designed the decision rules for caring for a person with dementia in different situations and when exhibiting different symptoms of dementia. For example, when retrieving the location of an object, the system utilizes reasoning rules that are defined in SWRL. However, for individual care methods, the system first infers general care methods using SWRL, and then the appropriate care methods for the individual are determined based on the reasoning rules in Prolog. Examples of SWRL rules are presented in Figures 1 and 2. The rules in Figure 1 are used to deduce the location of the hypertension drug for the patient. Person(?x) indicates that the variable x is a person. The binary relation hasDrug (?x, ?a) indicates that person x takes the drug a. If the person takes drug a and the location of the drug is known, the SWRL rule will provide the location of the drug for the person.

The rules in Figure 2 illustrate the process by which care guides direct the toilet use methods and procedures of the person with dementia. By following the rules, the system provides the inference result and informs the individual about the use of tissue, water, toilet rails, and schedule confirmation. The reasoning results from SWRL are refined by the Prolog reasoner, which utilizes the assessment information of the individual. For example, if the person with memory impairment frequently forgets to flush the toilet bowl, the Prolog reasoner will generate an additional care method that reminds the person with dementia to flush the water at the end of using the toilet.

Evaluation of the Knowledge Management System

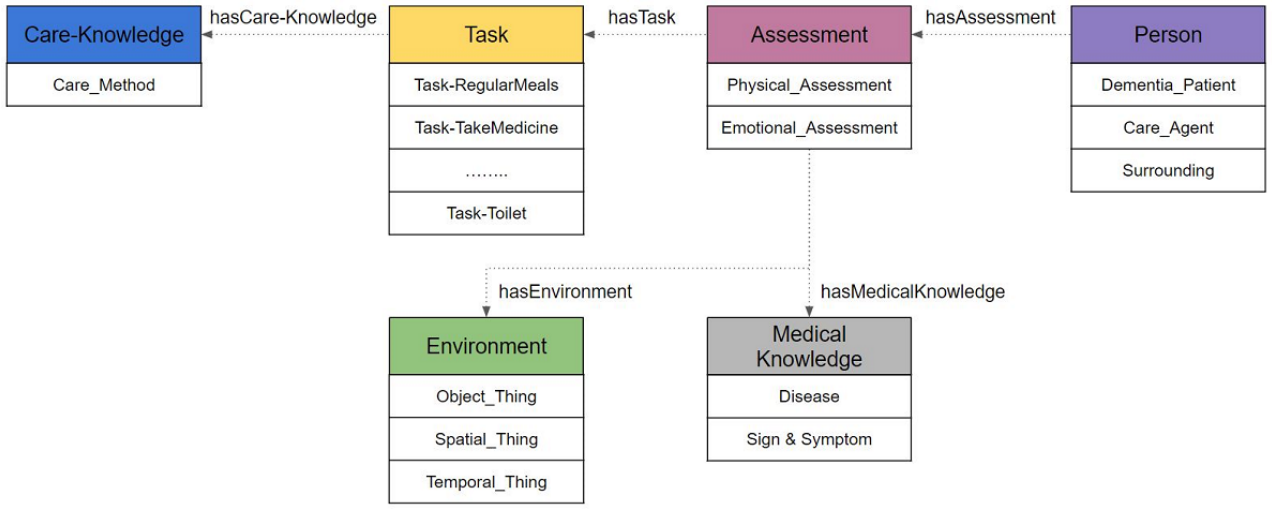
We first checked the care ontology with the OOPS! tool [26] to check its compliance with ontology authoring principles in addition to its structural quality. The knowledge model was also evaluated by care experts. Initially, we recruited 30 participants who each had more than a year of experience in caring for a person with dementia. However, only 4 of these participants had professional knowledge of dementia patient care, and we excluded the other 26 participants who had not been trained with professional nursing skills. The 4 participants selected had worked in the same dementia welfare center in Korea for an average of 10 years each, which included periods spent with other organizations. The average age of the participants was 60 years, with a range of 57 to 63 years. The respondents were all female (4/4, 100%). For evaluation, we provided the experts with a video introducing the knowledge management system we had built, followed by an opportunity to use the actual system. After watching the video, the experts were instructed to input patient information, and they then had an opportunity to check or to update the instances generated, such as the location of objects and the assessment data for the patient. A survey and an interview were conducted for 20 minutes after the actual experience with the knowledge management system. The whole evaluation took 30 minutes to an hour. Prior to the test, all participants gave their consent for the use of the experimental results, and the experiment was conducted with privacy protection (IRB number: K-2019-033). During the survey and interview, we asked the experts the following questions: (1) Is the ontology for the care of people with dementia consistent with the knowledge that the care expert holds? (2) Is the ontology for the care of people with dementia sufficient to determine their care guidelines? (3) Are the terms expressed in the ontology the same as the terms as used in actual care knowledge? (4) Is the knowledge management application convenient to use? (5) Does it seem useful for use in a real environment? The responses covered the accuracy, completeness, consistency, and usability of care knowledge on a 5-point scale (1=very invalid, 2=invalid, 3=moderate, 4=valid, and 5=very valid) [27-30]. The content validity index of the answers was calculated by taking the average.

Results

Care Ontology for People With Dementia

The ontological model for caring for people with dementia was based on six different top-level concepts achieved by classifying and defining information that is important in determining the care method needed for a person with dementia: person, task, environment, assessment, medical knowledge, and care knowledge. Figure 3 shows the overall structure of the top-level concepts and the relationships between them. The domain and range of each concept was defined, and the concepts were given properties. The proposed knowledge model has 502 classes and 230 properties.

Figure 3. Upper classes of the proposed care ontology for persons with dementia.



Person Class

The Person class represents the basic profile information on the person with dementia and their caregivers and family members. The basic profile information includes age, address, gender, and social relationship. The Person class was based on a previously developed ontology for supporting chronically ill patients and on the care handbook used in domestic dementia facilities in Korea [10].

Task Class

In order to provide a care method for the person with dementia, the activities of their daily life are defined as a Task class, and the Task class has a total of 20 different subtasks. These subtasks cover activities such as eating meals, sleeping, using the toilet, washing, taking medicine, and exercising. To describe the temporal and statistical aspects of each task, the Task class has the properties of task frequency, task execution cycle, task preference, task result, and task step.

Environment Class

The Environment class contains three different subclasses: Object_Thing, Spatial_Thing, and Temporal_Thing. Subclass Object_Thing consists of various objects in the living environment of the person with dementia. Subclass Spatial_Thing describes the location of an object, while temporal concepts such as time, birthday, and age are represented in the subclass Temporal_Thing. The structure of this class is based on the existing knowledge model KnowRob, which contains knowledge of various objects in the human environment [11].

Assessment Class

The Assessment class covers the behavioral competence of the person with dementia, including their physical ability to perform daily activities at home or in the care facilities and the psychological symptoms of their dementia. Most of the concepts in this class were adopted from the care manual used in welfare centers in Korea and from similar care handbooks [21-23]. The class is organized into the physical and psychological knowledge of the individual, and each instance of the class is associated with a care method described in the Care Knowledge class.

Medical Knowledge Class

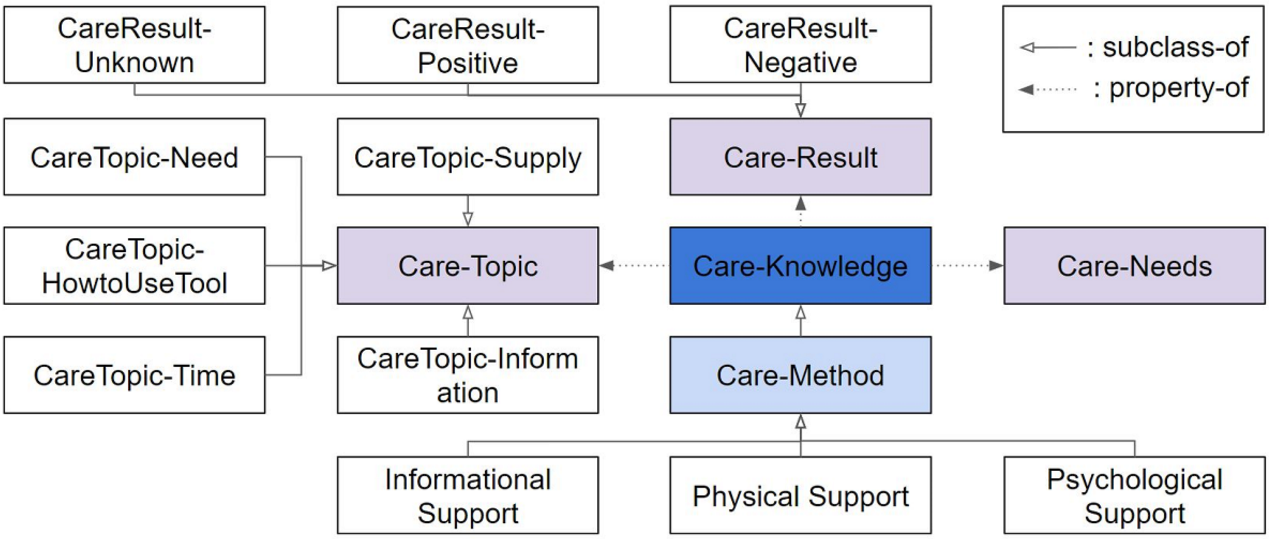
The Medical Knowledge class is a class that expresses the diseases and symptoms of dementia patients. The basic concepts and structure of this class were adopted from the K4Care ontology and the AAIS ontology [8,10].

Care Knowledge Class

The Care Knowledge class describes the various circumstances involved when helping the person with dementia, and most of the concepts defined in this class are linked with the Assessment, Environment, and Medical Knowledge classes.

The detailed structure of the Care Knowledge class is shown in Figure 4. The Care Knowledge class has three different subclasses: Informational Support, Physical Support, and Psychological Support. The Care Knowledge class has the properties of Care-Topic, Care-Needs, and Care-Result, which are used to describe the details of the care method and the history of the care results provided by the caregivers.

Figure 4. The structure of the “Care Knowledge” class in care ontology.



Care Knowledge Management System

We developed a care knowledge management system based on the knowledge model of caring for persons with dementia so that caregivers can access appropriate care guides and manage the care information through a GUI on personal computers. The overall architecture of the proposed system is shown in Figure 5. The knowledge management system can utilize cloud-based data such as weather and calendar information from Google. The context data manager handles the incoming queries from the user application and passes on the care knowledge inferred by the reasoner module. The reasoner is equipped with two different reasoning rules as described in the Methods section. The SWRL is defined for care ontology and is used for inferring general care methods. The Prolog reasoner infers individualized care methods for a particular patient based on the knowledge described in the assessment class that contains the physical and psychological conditions of the individual with dementia.

The care knowledge management system can be accessed via a GUI where the caregivers can manage or review instances of the ontology (Figure 6). For example, instances of Person class and Environment class can be accessed through the Profile and Location sections, respectively. To add new instances or to update the existing instances of assessment, the user needs to answer the list of questions corresponding to the selected topic (Care Method, Task, Body State, Psychological State, and Sociality). All the questions were created based on the actual assessment document used at the care center in Korea. Figures 6B and 6C show an example of questions on Care Method and instances of objects contained in the ontology.

Case Study: Instances of Persons With Dementia

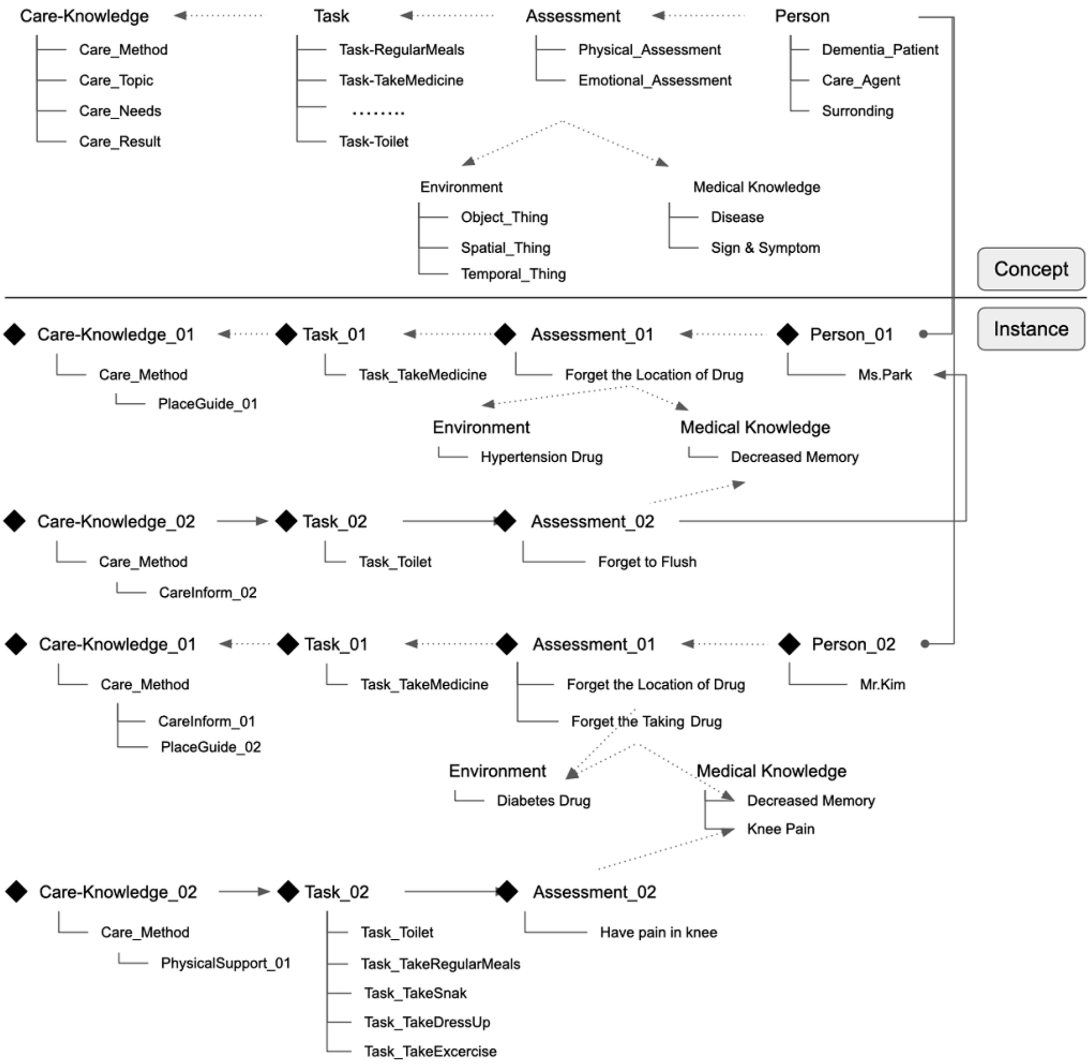
Table 1 presents a summary of the actual information for people with dementia written in a care manual obtained from a care center in Korea (we modified personal information such as name, address, and phone number). Ms Park has been diagnosed with mild dementia and is currently taking medication for chronic high blood pressure. She shows memory impairment symptoms such as not remembering the location of her drugs and the sequence of daily activities (eg, using the toilet). She can eat meals by herself but cannot control her appetite. The care manual also contains care guidelines for dealing with the individual's symptoms, such as helping her to remember an object's location and to flush the toilet bowl. Mr Kim has been diagnosed with mild dementia and is currently taking medication for diabetes. He has particular problems with memory impairment and regulation of his emotions.

Table 1. Assessment information on people with dementia obtained from the care center in Korea. Personal information such as name, gender, and address are modified.

Item	Example 1	Example 2
Name	Sooji Park	Inja Kim
Gender	Female	Male
Age (years)	70	80
Address	Jongno-gu, Seoul	Sungin-dong, Seoul
Contact	010-1234-0000	010-9876-0000
Dementia condition	Mild dementia	Mild dementia
Areas that need care	When she takes her high blood pressure medication, caregiver must remind her of the location of the medication. She eats well but cannot control her appetite. Caregiver should remind her to flush the toilet.	When he takes medicine, caregiver must remind him where the drug is and whether or not he has taken the medicine. He takes his diabetes drug three times a day after meals. When he moves to the bedroom, bathroom, or kitchen, he needs the caregiver's physical support. He cannot remember the number of meals taken.
Mental illness and symptoms	She has emotional anxiety. She has hallucinations and delusions.	He is emotionally unstable. He can suddenly become angry and sometimes throws objects violently.
Physical illness	She has high blood pressure.	He has diabetes and knee pain.
Activity	She goes to church every Sunday. She likes to clean her room.	He goes to church every weekend.
Others	She uses diapers at night. She uses dentures.	He uses dentures. A picture of his family helps to cheer him up.

We used the knowledge management system to add the information for Ms Park, and Figure 7 illustrates the instances of her data together with the structure of the upper concepts in the ontology. The individual's name, gender, age, address, and contact information are represented as instances of the Person class. Her mild dementia information, mental illness, and physical illness are represented in the Medical Knowledge class. Her task-related abilities, activities, and other precautions are expressed in the Assessment class. The care knowledge for informing on the location of the patient's hypertension drug is expressed as an instance, Assessment_01 with Care-Knowledge_01. The care knowledge of the patient's defecation activity is represented in Assessment_02 with Care-Knowledge_02. Care-Knowledge_02 thus expresses notification about using an object as a care method related to the defecation activity of the person with dementia.

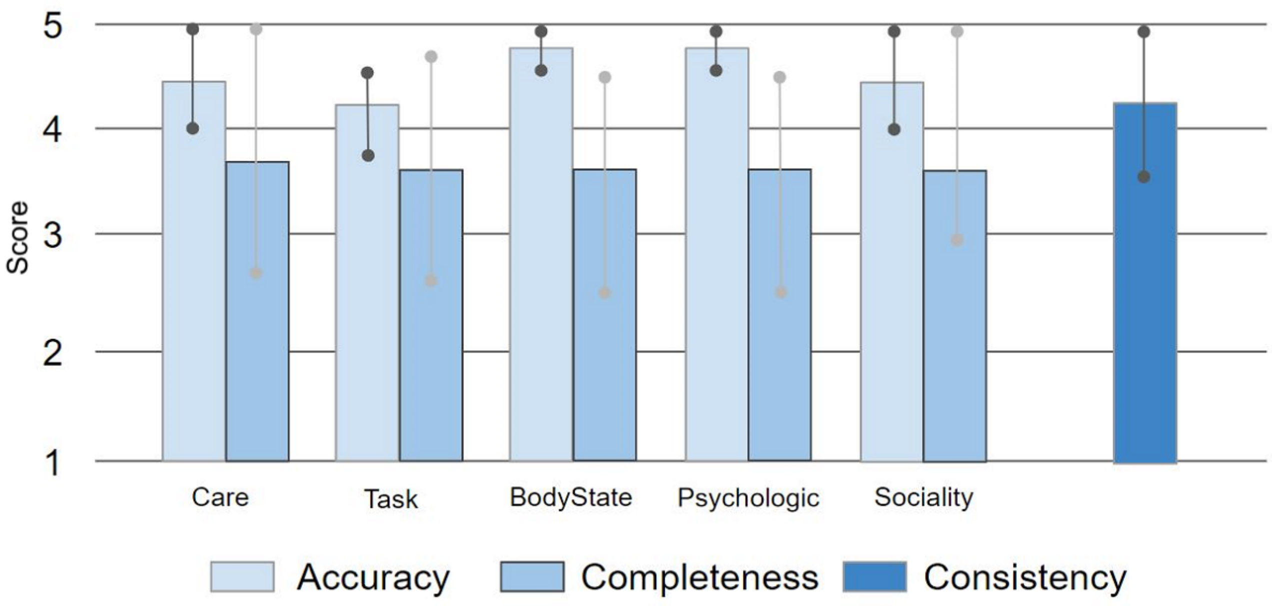
Figure 7. The structure of instances of a person with dementia together with upper-level concepts of care knowledge.



Evaluation of Care Knowledge Management System

We evaluated the care ontology with the OOPS! tool. We scored well on consistency, completeness, and conciseness, except for several minor issues such as a problem in determining the domain range and the property range for subclasses. In addition, we had our proposed system evaluated by 4 experts who had all been working in dementia care facilities for more than 10 years (the detailed procedure is described in the Methods section). The results of the evaluations received from experts are shown in Figure 8. To assess the accuracy of the ontology knowledge, we asked experts how accurately the proposed knowledge model described the actual knowledge used in a real care situation. In addition, in order to assess the completeness of the knowledge, we asked the experts whether the proposed system contained enough knowledge on caring for persons with dementia. In other words, the completeness score represents whether or not the knowledge model covers the necessary knowledge for caring for persons with dementia. Finally, regarding the consistency of the knowledge, the experts were asked whether or not the terms in the system developed were consistent with the terms used in the actual welfare centers. As a result, the caregivers evaluated that the current system contains accurate care knowledge (accuracy score: mean 4.55, SD 0.46) and covers most of the required care knowledge (completeness score: mean 3.80, SD 1.12). Regarding the consistency of the assessment information, the results show that the current ontology contains a comparable level of assessment information to the assessment tools (consistency score: mean 4.25, SD 0.83).

Figure 8. Evaluation of the care knowledge assessed by care experts in Korea.



Discussion

Principal Findings

In this study, we built an ontological knowledge model for dementia care and developed a care knowledge management system that can provide care guidelines tailored to various behavioral and psychological symptoms of dementia. The care knowledge management system includes specific activity types of the people with dementia with different dementia symptoms and care methods that are based on their dementia assessment. With the system, caregivers can easily get basic information on the different dementia patients that they care for and can be assisted with a care guide for the different tasks of the individuals.

It is well known that the symptoms of dementia are an important source of the burden and stress carried by caregivers. There is also evidence that exposure to chronic stress in the caregivers of those with dementia is associated with decreased physical health, mental illness, and poor quality of life in the caregiver [31-33]. Due to the high stresses of the care, caregivers often neglect or even abuse the person with dementia [4]. Numerous interventions have been proposed to change caregivers' behavior by increasing their social support and thereby improving their psychological state. There are home-based interventions, technology-driven interventions (ie, interventions that use computers or web-based applications), and interventions that are delivered via telephone. In a study by Godwin et al, 271 articles were reviewed for the efficacy of technology-driven interventions for the caregivers of persons with dementia [13]. They found that some of the studies showed reduced depression and anxiety among caregivers in the intervention group. However, the authors cautioned that no intervention method could completely reduce the burden on the caregiver because of the lack of technologies that monitored the patient's condition while supporting the caregiver.

Recent studies have attempted to provide better care service to persons with dementia by diagnosing their medical condition or by increasing their independence in daily activities. The DMSS-R supports the interventions performed by individual health professionals in daily practice with dementia patients [12]. DMSS-R is based on the Clinical Practice Guidelines for dementia diagnosis and provides diagnostic results, focusing on the physician's perspective on the patient. However, in addition to a clinical diagnosis of the dementia, caregivers need more information regarding the tasks of persons with dementia and their ability to perform these tasks. Other technologies, including a visual map and a memory notebook, help persons with dementia by presenting images relevant to their daily lives and schedules in context [14]. The visual map is a system that informs the individual of action guidelines through images and sound. It shows the necessary actions step by step through images that can help the person with memory impairment. However, there is a limit to the ability of persons with memory and behavioral impairments to live by themselves using only these systems without a caregiver's help. For example, an individual with dementia and physical disability could not be completely independent without the physical support of a caregiver, and this may inevitably require a care guide when making decisions.

We therefore focused on a situation where the caregivers could be relieved of remembering all the symptoms of the dementia patients they care for and of deciding on appropriate care methods for each one. To build a care knowledge system, we used the AAIS ontology and the K4Care ontology to obtain information on the disease types for dementia [8,10]. The AAIS ontology contains concepts of BPSDs that deal with the symptoms of impairment in perceptions, emotions, and behavior, while the K4Care ontology deals with the disease and the symptoms observed in the health care records of mild dementia patients. We included information about patients' physical diseases and social situations in addition to knowledge from the AAIS and K4Care ontologies, which included intervention information. We acquired object and spatiotemporal information from the KnowRob ontology to express knowledge regarding objects, times, and places relating to the person with dementia [11]. Additionally, the care ontology included individual care methods obtained from care-related books and the actual care guidelines used in dementia care facilities. Therefore, the proposed care ontology could represent not only the patient's disease symptoms, individual condition, and environmental information but also care methods suited to the different care situations.

To give caregivers easy access to the care knowledge and allow them to update information on the person with dementia, we developed a GUI for the knowledge management system (Figure 6). The GUI was designed for communication not only of personal information but also of symptoms, diseases, and social relationships that need to be considered when determining a care method. The system is able to manage and provide care-related knowledge for an unlimited number of persons with dementia and a large volume of additional care information. Although the main users of the proposed system would be professional caregivers in dementia care facilities, we believe that such a system could be easily extended so that nonprofessionals, such as family members, could access care information without special knowledge and that this would be beneficial by reducing both the burden and cost of caring for persons with dementia.

Limitations

Based on our interviews with professional caregivers, we realized that caregivers also pay considerable attention to emotional factors when deciding how to care for a person with dementia, and this explained the relatively low scores achieved by the current ontology for completeness (Figure 8). The proposed care ontology only considers the environmental factors, task performance, physical illness, mental illness, and social activities of the dementia patient. Due to the highly complex situations that can affect a person's emotional state, it is not easy to provide suitable care guidelines for the different emotional states of individuals with dementia. Future studies should investigate the range of psychological symptoms exhibited by persons with dementia with the relevant care that should be performed in care facilities so as to include the emotional dimension in future care knowledge. Various ontological models of human emotions could also be examined [34,35]. In addition, the developed care knowledge model targeted patients with mild dementia, and the experts who evaluated it cared for patients with mild dementia. Since the knowledge model deals only with knowledge related to mild dementia patients, it would be less helpful for the caregivers of patients with severe dementia.

The decision rules defined in the proposed knowledge management system are based on care methods described in interviews with care experts and in care manuals used in a care facility in Korea. The "Care Knowledge" and "Assessment" classes include terms and concepts that are described in these care manuals. For this reason, the care guidelines outlined in the proposed system would only be applicable to caregivers working in care facilities in Korea. Further studies are needed to extend the ontological model and the decision rules so that the proposed system would apply in places outside of Korea.

Finally, in this study, the accuracy and consistency of the care knowledge and the usability of the proposed knowledge system were evaluated by only 4 different care experts, although these experts each had an average of 10 years of dementia care experience. In addition, it remains to be tested whether the current system could reduce the care burden and help with care decision making in real care conditions. Currently, we are preparing a web-based application that can be accessed through mobile systems such as a tablet PC or smartphone for more convenient access to the care knowledge management system, and we plan to apply this updated system in real care situations.

Conclusions

In this study, we proposed a care knowledge management system that can provide the caregiver with detailed care information for the person with dementia. The system includes an ontological model of dementia care, a context data manager, and a rule-based reasoner in SWRL and Prolog. In addition, the system is equipped with a GUI, and it can be used anywhere in the home or welfare center regardless of the number or location of the dementia patients. Since the proposed system can provide care guidelines suitable for dementia patients, it is anticipated that the proposed system could reduce the workload of caregivers, but it remains to be tested in a future study.

Acknowledgments

We thank the caregivers working at the Seongbuk Welfare Center and the Gwangju Hanul Nursing Home for providing valuable feedback on the proposed system and helping us to improve it. This work was supported by the Technology Innovation Program (10077553, Development of Social Robot Intelligence for Social Human-Robot Interaction of Service Robots) and funded by the Ministry of Trade, Industry and Energy (Korea) and by a National Research Council of Science and Technology grant from the Korean government (Ministry of Science, ICT and Future Planning; grant CRC-15-04-KIST).

Abstract

Background: Canada has been slow to implement virtual care relative to other countries. However, in recent years, the availability of on-demand, "walk-in" virtual clinics has increased, with the COVID-19 pandemic contributing to the increased demand and provision of virtual care nationwide. Although virtual care facilitates access to physicians while maintaining physical distancing, there are concerns regarding the continuity and quality of care as well as equitable access. There is a paucity of research documenting the availability of virtual care in Canada, thus hampering the efforts to evaluate the impacts of its relatively rapid emergence on the broader health care system and on individual health.

Objective: We conducted a national environmental scan to determine the availability and scope of virtual walk-in clinics, cataloging the services they offer and whether they are operating through public or private payment.

Methods: We developed a power term and implemented a structured Google search to identify relevant clinics. From each clinic meeting our inclusion criteria, we abstracted data on the payment model, region of operation, services offered, and continuity of care. We compared clinics operating under different payment models using Fisher exact tests.

Results: We identified 18 virtual walk-in clinics. Of the 18 clinics, 10 (56%) provided some services under provincial public insurance, although 44% (8/18) operated on a fully private payment model while an additional 39% (7/18) charged patients out of pocket for some services. The most common supplemental services offered included dermatology (15/18, 83%), mental health services (14/18, 78%), and sexual health (11/18, 61%). Continuity, information sharing, or communication with the consumers' existing primary care providers were mentioned by 22% (4/18) of the clinics.

Conclusions: Virtual walk-in clinics have proliferated; however, concerns about equitable access, continuity of care, and diversion of physician workforce within these models highlight the importance of supporting virtual care options within the context of longitudinal primary care. More research is needed to support quality virtual care and understand its effects on patient and provider experiences and the overall health system utilization and costs.

KEYWORDS

virtual care; primary care; Canada; virtual health; patients; physicians

Introduction

Canada has lagged behind other countries in its uptake of virtual care as an integrated component of the health care system [1-3]. In 2018, less than 5% of physicians offered virtual services [2] despite most Canadians expressing their desire for video and phone visits as care options with the required technology being available.

The slow uptake prior to 2020 may be explained by multiple regulatory and physician compensation barriers, with few provinces providing a billing mechanism to physicians for virtual consultations [4]. The onset of the COVID-19 pandemic in Canada dramatically increased virtual care owing to the need for physical distancing to prevent disease transmission. This shift was supported by new or temporary billing codes and updated provincial mandates for providing virtual care where possible; in areas where provincial insurance plans, physician funding models, and limits on billable virtual visits had previously hindered physician uptake of virtual care, telephone or video consultations have now been adopted [5].

In addition to community-based physicians adapting their brick-and-mortar practices to include virtual care provision, the new fee codes for virtual visits provide an opportunity for the development of on-demand, “walk-in” virtual clinics that provide low-acuity, low-complexity care disconnected from existing physician-patient relationships. Some of these services are funded through provincial health insurance plans while others charge patients or are funded by supplemental private insurance plans directly.

Concerns have been raised that these services encourage episodic care, potentially contributing to fragmentation and poor continuity [1], and that they operate in a way that is not consistent with care that produces the best outcomes [6-10]. Additional research suggests that virtual walk-in services may have a detrimental effect on the quality of care [11,12], health care costs [13-15], and data privacy [11,12,15]. Furthermore, compared with virtual walk-in models, virtual care provided in the context of existing physician-patient relationships has proved more effective [7-9].

Despite these concerns, there is no existing research that catalogs the availability of these clinics or the services they offer. We conducted a national environmental scan to determine the availability and scope of virtual walk-in clinics offering synchronous appointments and prescriptions without the requirement or expectation of a longitudinal physician-patient relationship. We cataloged the services advertised by these clinics and determined whether they operated through public or private payment.

Methods

Approach

We used a structured Google search to identify virtual walk-in clinics across Canada, as we assumed this as one of the primary means that prospective patients would use to identify, locate, research, or connect with these services. We conducted a preliminary search on March 15, 2020, and a secondary search on June 2, 2020, to update and verify our initial results.

Keyword Search and Power Term

We compiled a list of words related to virtual health care and general medical care, from which we developed groups of search terms. Each term consisted of 3 words, with the first being Canada, the second relating to virtual care, and the final relating to the physician or clinic.

We analyzed 18 search terms for their strength in identifying virtual clinics. This process involved entering each term into Google, tallying the number of relevant sites listed, and analyzing 10 result pages per search term. Following this, we organized terms based on their strength; of the 18 search terms analyzed, the 6 strongest terms were selected. These were then combined using Boolean operators to form the following final search term: *Canada AND (virtual healthcare OR virtual health) AND (family medicine OR clinic OR general practitioner OR personalized care)*. We developed an initial list of clinics while developing our search strategy and then compared our final results with this initial list to ensure that the selected power term was displaying all the relevant sites.

Inclusion/Exclusion Criteria

To be included, the identified clinics had to meet the following criteria: (1) be based in Canada; (2) have a practicing medical doctor capable of remotely prescribing medication (ensuring all the services included for data extraction functioned as complete alternatives to traditional walk-in clinics and family physician appointments); (3) provide virtual visits through synchronous communication of some form (ie, phone, video, SMS text messaging); and (4) have English language websites. We excluded clinics that provided virtual services only to patients already enrolled with an associated brick-and-mortar clinic and those not providing primary care (eg, cancer clinics). Although such clinics provide care through virtual media, we felt their dependence on a preexisting physician-patient relationship and focus on specialist care largely differentiated them from their virtual walk-in counterparts.

Data Extraction

From each identified virtual walk-in clinic that met our inclusion criteria, we abstracted the following details from each site’s main pages and frequently asked questions sections and recorded them in a spreadsheet:

- virtual clinic name
- internet address
- geographic region(s) where services are available (select province[s] or all over Canada)
- enrollment type (membership, single visit, or both)
- source of payment (public provincial health insurance, private payment, or mixed)
- forms of synchronous communication offered (telephone, video, or SMS text messaging)
- use of artificial intelligence software to check symptoms and recommend treatments
- cost of membership and single visit

- examples of services offered (categorizing them iteratively, adding new categories when they were discovered, and then retroactively coding previous websites)

Additionally, we extracted free text that described data sharing or relationships with the patients' existing primary care physicians to investigate the extent to which these clinics are prioritizing continuity of care within the broader system and reflecting a prominent concern among health professionals regarding virtual walk-in clinics disrupting continuity [16]. Although we captured this information wherever available, we recognized that not all virtual clinics explicitly advertised their engagement with patients' existing physicians, and that in some cases, clinics may be limited in their ability to share patient information. Similarly, service listings are not expected to comprehensively represent everything offered; rather, they are a high-level indication of the type and scope of services available.

Analysis

We grouped similar services into service categories to streamline the data analysis. These categories included the following:

- specialist services (eg, oncology, endocrinology, pediatrics, obstetrics and gynecology, and sports medicine)
- individual behavior changes (eg, diet, weight loss, sleep therapy, smoking cessation, and problem gambling support)
- chronic disease management (eg, chronic obstetric pulmonary disease, diabetes, and heart failure)
- others (eg, hemorrhoid consultation, veterinarian consultation, emergency services, lactation consultation, and disability insurance claims/workers' compensation requests)

We grouped virtual clinics according to the mechanism of compensation for primary care services (publicly funded, privately funded, or mixed funding) as of June 2, 2020. Virtual clinics that bill the public health insurance plan in some provinces and patients directly in others were classified in the "mixed funding" category. We compared the availability, enrollment, communication type, and services offered across funding categories using Fisher exact tests (rather than chi-square tests owing to small cell counts). We have reported statistical significance using *P* values; however, as this analysis was descriptive, no decision rule with respect to statistical significance was applied. Analyses were conducted using Stata (StataCorp LLC) and Excel (Microsoft Corporation).

Ethics Statement

As all material gathered for data analysis was publicly available on the internet, no ethics approval was required.

Results

Search Results

We identified 19 virtual walk-in clinics during our initial March 15 search, 3 of which (Ontario Telemedicine Network [17], Novari Health [18], and Copeman Health [19]) were subsequently excluded owing to their requirement that clients already be associated with, or initiate care at, their brick-and-mortar clinics. We identified 2 additional services during our second search conducted on June 2, bringing the total to 18 walk-in clinic services that met our inclusion criteria.

Between the first and second searches, 2 virtual walk-in clinics added public reimbursement options. One of the services, Lumeca [20], switched from a national pay-for-use service to a completely publicly funded service available only to Saskatchewan residents. Similarly, Tia Health [21] added a public funding option for Alberta residents with a valid care card.

Source of Payment

More than half of the services we identified offered some form of public payment, with 5 being fully publicly funded and 5 operating on a public model in some provinces and a private one in others (Table 1). The other 8 clinics required patients to pay out of pocket for accessing services. Among pay-for-use services, the median cost per appointment was $41 ($32-$82). The median costs of memberships for individuals and families were $25 ($8-$29) and $41 ($12-$54) per month, respectively. The membership rates of 4 out of the 8 services were not made public on their websites.

Table 1. Services and fee structures categorized by compensation mechanisms.

Characteristic	Compensation mechanism, n (%)				*P* value
	Private (n=8, 44%)	Public (n=5, 28%)	Mix (n=5, 28%)	Total (N=18, 100%)	
Service availability					.002
National	7 (88)	0 (0)	5 (100)	12 (67)	
Provincial	1 (13)	3 (60)	0 (0)	4 (22)	
Multiprovincial	0 (0)	2 (40)	0 (0)	2 (11)	
Enrollment type					.21
Membership	5 (63)	4 (80)	1 (20)	10 (56)	
Single use	0 (0)	0 (0)	2 (40)	2 (11)	
Both	3 (38)	1 (20)	2 (40)	6 (33)	
Communication form					
Video call	7 (88)	5 (100)	5 (100)	17 (94)	.99
Telephone	4 (50)	3 (60)	3 (60)	10 (56)	.99
SMS text messaging	5 (63)	2 (40)	2 (40)	9 (50)	.71
Continuity with community general practitioners	2 (25)	2 (40)	0 (0)	4 (22)	.51

Virtual Walk-in Clinic Availability

Of the 18 walk-in clinics, 12 (67%) operated nationally, 4 (22%) within a single province, and 2 (11%) in multiple provinces. Privately funded services were more likely to be offered at the national level (7/8, 88%) than at the provincial (1/8, 13%) and multiprovincial (0/8, 0%) levels (*P*=.002). Of the 5 publicly funded services available, 3 were limited to single provinces, Saskatchewan and British Columbia, and 2 were offered to residents of multiple provinces. Although 5 nationally offered services had private and public payment options, they limited the public payment option to residents of British Columbia, Alberta, and Ontario having a valid health care card. Canadians using these services outside of these selected provinces would need to pay out of pocket.

Enrollment Type

Of the 18 services identified, 10 (56%) required membership, 2 (11%) were single-use services, and the remaining 6 (33%) offered both options. We observed that 63% (5/8) of the private payment clinics required membership, compared to 80% (4/5) of the public and 20% (1/5) of the mixed payment clinics (*P*=.21).

Communication Form

Possible communication forms consisted of video calls, telephone calls, and SMS text messaging. Video calls were the most common options across all clinics, offered by 88% (7/8) of the private payment clinics and 100% (5/5) of the mixed and publicly funded clinics. Among the 18 clinics, only 1 offered medical services and prescriptions without using video calls. This service, GOeVisit [18], instead relied on a medical form filled out by the patient and subsequently reviewed by a practitioner. Telephone and SMS text messaging options were still offered by most services but were less common than video calls.

Continuity of Care

Only 4 of the 18 services (22%) mentioned any form of continuity, information sharing, or communication with the consumers' existing primary care providers. Wello [22] and Akira [23], 2 privately funded services, mention an ability to work in tandem with their consumers' current practitioners and seeking access to the patients' current medical records; however, neither service explained how this was accomplished. Vivacare [24], a British Columbia–based clinic, offered continuity with physicians via their available in-person clinics (but not with physicians operating outside of their affiliated clinics). Lumeca [20], a publicly funded service for Saskatchewan residents, indicated that it would work with the family practitioners after obtaining written consent from the patients.

Telus' Babylon [25] and Tia Health [21] mentioned their ability to assign the same physician for each virtual appointment to help develop a patient-practitioner relationship; however, neither indicated the ability to support the existing relationships between patients and community-based primary care physicians, either by accessing the patients' existing records or by sharing the records of a virtual visit with the patients' regular primary care physicians. Of the 18 services, 3 explicitly stated that their services were not intended to replace a family doctor. Although other services may offer a form of information sharing without explicitly mentioning this on their websites, the results do suggest that continuity of care is not a primary concern for most virtual clinics.

Examples of Services Offered

Of the 18 virtual walk-in clinics included for data extraction, all except one—Outpost Health [26]—provided a list of their services (Table 2). The 3 most commonly mentioned services included skin care/dermatology, mental health services, and sexual health, mentioned by 83% (15/18), 78% (14/18), and 61% (11/18) of the clinics, respectively. Clinics using private payment were less likely to explicitly mention mental health services when compared with publicly funded and mixed payment clinics (*P*=.06).

Allergy treatment, support for individual behavior change, and specialist physician services were listed on the websites of more than half of the virtual care clinics. The remaining services offered were listed on the websites of one-third or fewer clinics. Clinics operating on a mixed funding model (private in some provinces and public in others) advertised the greatest breadth of health care services. It is also notable that none of the private payment clinics formally listed chronic disease management in their list of services, while 20% (1/5) of the public clinics and 60% of the mixed clinics (3/5) offered this service. One walk-in clinic—Teladoc [27]—listed emergency medical care among the services offered; this is in contrast with all other clinics, which explicitly stated that clients should visit a doctor or hospital immediately in the case of an emergency.

Table 2. Examples of offered services categorized by compensation mechanisms.

Services	Compensation mechanism, n (%)				*P* value
	Private (n=8, 44%)	Public (n=5, 28%)	Mix (n=5, 28%)	Total (N=18, 100%)	
Skin care/dermatology	5 (63)	5 (100)	5 (100)	15 (83)	.22
Mental health services	4 (50)	5 (100)	5 (100)	14 (78)	.06
Sexual and reproductive health	4 (50)	4 (80)	3 (60)	11 (61)	.82
Allergies	4 (50)	3 (60)	3 (60)	10 (56)	.99
Individual behavior change	3 (38)	2 (40)	5 (100)	10 (56)	.09
Specialist services	3 (38)	2 (40)	5 (100)	10 (56)	.09
Erectile dysfunction	1 (13)	1 (20)	4 (80)	6 (33)	.05
Chronic disease management	0 (0)	1 (20)	3 (60)	4 (22)	.04
Travel vaccinations	3 (38)	0 (0)	1 (20)	4 (22)	.51
Medical cannabis	1 (13)	1 (20)	1 (20)	3 (17)	.99
Naturopathy	1 (13)	0 (0)	2 (20)	3 (17)	.41
Other[a]	2 (25)	0 (0)	4 (80)	6 (33)	.03

[a] "Other" includes all services offered by <3 clinics, including the following: hemorrhoid consultation (2), veterinarian (2), emergency services (1), lactation consultation (1), and disability insurance claims/workers' compensation requests (1).

Discussion

Principal Results

Through a structured Google search, we identified 18 virtual walk-in clinics currently operating within Canada. This represents a 6-fold increase since 2015, when only 3 were available [28]. The rapid increase in the availability of these services coincides with the interest levels reported in existing consumer surveys [29] and the dramatic move toward virtual care delivery to facilitate physical distancing during the COVID-19 pandemic [5].

Virtual walk-in clinics provide a broad array of services, including primary care and other specialties, regardless of their payment models. Most clinics specifically advertised skin care, mental health, and sexual health services, supplementing basic primary care consultations, although less focus on mental health services was notable in privately funded clinics. Most relied on video calls as their primary means of communication; however, phone calls and SMS text messaging were also provided as communication options by most clinics.

Of the 18 virtual walk-in clinics that we identified, 15 charge patients out of pocket for core primary care services depending on the provinces where the patients resided. For example, 5 clinics were available nationally but limited public payment to patients with a valid health care card in British Columbia, Alberta, and Ontario. Conversely, 8 clinics operated on an entirely private payment model. Beyond the payment for primary care services, we noted that some clinics, namely Babylon [25] and Maple [30], also bundled supplemental services for which patients would pay out of pocket. Charging membership fees or out-of-pocket payments for physician consultations or services that are covered by provincial health insurance systems may contravene the *Canada Health Act* and provincial health insurance legislation [31], thus raising equity concerns. Additionally, although virtual walk-in clinics can offer an attractive work model for physicians—with predictable salaries and benefits, less overhead costs, and fewer administrative responsibilities [32,33]—this care model may attract physicians away from longitudinal community-based primary care services either partially or fully.

Few clinics reported that they facilitated communication or data sharing with patients' regular primary care providers (in either direction), suggesting that poor continuity of care may be a salient concern, thus reinforcing their suitability only for minor, less complicated conditions. The extensive use of virtual visits can potentially enhance access for patients who would normally face barriers when receiving primary care, such as people living in rural or remote areas, and those with compromised mobility and immune system challenges [34]; however, virtual walk-in clinics should not be used as substitutes for longitudinal relationships with primary care providers, particularly for patients with complex health and mobility issues.

Early evidence indicates that although the proportion of virtual visits has decreased since the lifting of pandemic restrictions, it has not returned to prepandemic levels. It remains to be seen where the balance between virtual care and in-person visits will settle following the pandemic; however, it is unlikely to return to prepandemic levels given the substantial federal investments and level of public demand [35]. Significant research is needed to address gaps in the knowledge on the quality of virtual episodic care and its effects on patient and provider experiences and overall health system utilization and costs.

Limitations

Our clinic searches were conducted in English only. This may have particularly resulted in the undercounting of the virtual walk-in clinics in Quebec. Second, our data extraction relied on the source material taken directly from clinic websites. Consequently, services not directly listed were not included. We may have underestimated the scope of services offered by some virtual walk-in services, as well as their potential information sharing with the patients' existing care providers. In future, clinics should be contacted directly to determine their service scope accurately and explore whether and how they receive information from or share information with community-based physicians. Third, our reliance on Google for executing the search strategy could have potentially underrepresented or missed clinics. Future research should involve multiple individuals and use additional search engines and virtual primary care service advertisements to strengthen the results. Lastly, given that only 18 nationwide virtual walk-in clinics were identified through our Google searches, our statistical analyses were hampered by the lack of statistical power.

Conclusions

This environmental scan sought to characterize the availability and scope of virtual walk-in clinics across Canada. We found a rapid increase in this care model, with 18 distinct services operating across the country, 15 of which required patients to pay out of pocket for some or all services offered. The implications of the rise in episodic virtual care could have negative effects on health care equity, quality, and costs; moreover, the growth of this model should be closely monitored and regulated by policy makers.

Availability of Data and Materials

The data that support the findings of this study are based on publicly available sources. The data set is available from the authors upon reasonable request.

In their recent paper, Acquaviva et al [1] developed a set of guidelines to standardize curriculum vitae (CV) documentation of scholarly contributions made via social media platforms. Appropriately, the authors crowd-sourced contributions for the guidelines from the popular social media platform Twitter. Their work underscores the value of social media in idea sharing, highlights the growing role of online platforms in medical education, and signifies an important step in modernizing academic recognition to match the modernization of current medical learners.

Social media offers numerous scholarly and professional benefits [2,3]. These platforms have grown popular among the academic and medical communities as they are a means of networking with colleagues around the globe, discussing hot topics in various fields, engaging in medical education, sharing experiences through narrative medicine, and disseminating information to the lay-public [4]. More recently, social media has also taken on a vital role in residency recruitment. Without in-person interviews, programs have had to adopt new methods of sharing program strengths, highlighting unique program qualities, and appealing to applicants at an individual level [5].

We are avid proponents of academic social media. We can anecdotally attest to the educational value that arises from academic posts and discourse on social media platforms. Twitter, for example, offers a highly diverse pool of opinions covering all niches of medicine. It allows communication between individuals who might otherwise never interact. Sharing articles of interest via “tweeting” brings primary literature to your network’s fingertips. Twitter brings full professors and first-year medical students into the same arena of idea sharing. In a world that has increasingly recognized the shortcomings of traditional didactic lectures, social media offers modern educational methods better suited for today’s learners. Examples of this include “Tweetorials” (educational threads exploring a particular topic or phenomenon), podcasts, infographics, blogs, and virtual journal clubs among others [4].

These innovative methods of education through social media are intriguing to passionate educators. Those who seek to share knowledge and contribute to the advancement of scholarship will teach in whatever methods are most effective and will reach the most pupils. Importantly, social media is free, offering accessible medical education in a climate rife with expensive online materials and rising tuition. The value of these academic contributions must not go unrecognized. The time and dedication that goes into the development of educational posts through innovative methods should not be left out of an individuals' portfolio simply because the medium is not classic. If anything, the ingenuity and adaptability of the medium creates added value to the material. As the face of education evolves with our digital world, propelled forward by the COVID-19 pandemic, academia must evolve in unison to recognize these contributions.

We are thankful to Acquaviva and associates [1] for providing us with much-needed guidelines that allow for the documentation of education portfolios representative of today's evolving medical education environment.

artificial intelligence; machine learning; mobile apps; medical diagnosis; mHealth; symptom assessment

We have several comments on the recent publication of Ćirković [1], in which repeated testing of four symptom assessment applications with clinical vignettes was carried out to look for "hints of 'non-locked learning algorithms'." As the developer of one of the symptom assessment applications studied by Ćirković [1], we are supportive of studies evaluating app performance; however, there are important limitations in the methodology of this study.

Most importantly, the methodology used in this study is not capable of addressing its main objective. The approach used to look for evidence of nonlocked algorithms was the quantification of differences in performance using 3 ophthalmology vignettes, first in 2018, then in 2020. This methodology, although highly limited due to the use of only 3 vignettes in one medical specialism, could be used to detect changes in app performance over time. It, however, cannot be used to distinguish between nonlocked algorithms and the manual updating of apps' medical intelligence, through the normal process of the manual release of updated app versions. Medical device regulations and quality system requirements provide standard mechanisms through which apps can be further developed, validated, and released as updated versions. The manual of medical knowledge in this manner has been acknowledged by the manufacturers of all the apps studied by Ćirković [1]. In response to previous independent vignettes studies [2,3], spokespeople for Your.MD and Babylon stated that they update their medical knowledge periodically, and this is also clear on Buoy's website. In Gilbert et al [4], the Ada app is described as having a knowledge base "built and reviewed by medical doctors in a curated process of knowledge integration from medical literature. It is being expanded continuously following this standardized process."

As is acknowledged in the limitations listed in Ćirković's work [1], the study used vignettes designed, entered, and with results adjudicated by a single clinician. This could result in bias and a narrow type of case. It is also acknowledged that 3 vignettes represent a small sample size for a vignettes study and that "standardized and transparent procedures" are needed for symptom assessment app–vignettes studies. We recently published a 200-vignette assessment of symptom assessment applications [4], including those studied by Ćirković [1], which used standardized and transparent procedures, including the separation of vignette design, entered and with results adjudication. It is our view that the effect of the limitations described by Ćirković [1], together with only including ophthalmological cases, is that the accuracy results reported have limited generalizability or repeatability. Our own internal validation testing shows an improvement in Ada's medical intelligence in all-condition top-3 suggestion accuracy (also known as M3, as defined by Miller et al [5]) of 4.8% between 2018 and 2020. We take account of all performance feedback we receive, and incorporate this, when judged appropriate by our medical knowledge experts, into updates of our app, through periodic releases of locked versions of our app.

I would like to thank Gilbert et al [1] for their useful contributions and tips to help improve our work [2].

Regarding their first point of critique, it is true that the evaluation lacked the technique to determine with certainty whether the algorithms used were or were not “locked” according to the terminology used by the Food and Drug Administration. For that reason, I stated in the *Discussion* section that some details of the study results only *suggest* a nonlocked direction [2]. Unfortunately, the abstract lacks this softening term. It remains true, however, that for regulators and physicians to correctly assess the functions of such software, either the algorithms would have to be disclosed—which might not be in the interest of the competing companies—or advanced testing models would have to be developed, possibly leading to a “cat-and-mouse” game similar to other regulatory fields. In developed countries where legal liabilities have to be clearly distributed and delimited, neither responsible physicians nor authorities will want to rely on mere published statements of company spokespeople alone—hard data from unbiased sources will be needed in the future.

The subsequent publication of the Ada study of a 200-vignette assessment is highly appreciated, as herein the authors were able to evaluate a considerably larger amount of data [3]. As I had stated, with a small sample size as a limitation, it does remain a possibility that the apps’ poor results as demonstrated in our study are within data variance norms or due to our own bias. However, the results did capture an experience that any potential user or patient with eye problems could have possibly encountered in the same way. Regulations will hopefully minimize risks for all users. Only thorough investigations, including but not limited to manufacturers’ evaluations, will help us better understand the effects the apps will have on public health. Until then, our knowledge base will consist of various analyses with possibly conflicting results that we will have to make sense of.

KEYWORDS

bibliometric analysis; machine learning; mental health; social media; bibliometrics

Bibliometric studies like the recent article by Kim et al [1] in the *Journal of Medical Internet Research* play an essential part in understanding the evolution of emerging, fast-moving research on machine learning for mental health in social media. However, the intended value of this paper’s contribution is tempered by some important lessons it teaches us about the current state of research on this topic.

The first key lesson is that computationally oriented research on mental health remains highly fragmented. Notably, variants on the cover term “mental health” are included in the illustrative search query but, crucially, “clinical psychology” and “psychiatry” are not. The terminological difference here reflects a prevailing technological focus often separated from clinical research and even more distant from clinical practice. Kim et al [1] do discuss a trend toward clinically validated self-report questionnaires to gather clinically relevant information. However, the review’s overall approach, from the search terms to the keyword analysis, simultaneously reflects and reinforces a widespread technological disregard for basic considerations in clinical psychology and psychiatry, such as the distinction between the symptoms of the disorders versus the disorders themselves. As technologists, we are often happy just to get our hands on enough data to work with. However, real progress toward solving these important problems demands a more careful definition of the actual mental health constructs under investigation and greater attention to the question of validity [2,3], with research questions and experimental choices guided by knowledge of the subject domain.

Second, the inclusion terms reflect a widespread narrow focus on methods, such as “neural network” and “hybrid intelligent system,” rather than the problems for which those methods are contributing solutions, such as “screening,” “risk assessment,” or “monitoring.” Even the cover term “natural language processing” focuses narrowly on engineering versus “computational linguistics” as a parent scientific discipline. Further lacking in the methodology-centric perspective are searches based on theoretical frameworks (which guide research, treatment, and intervention) or DSM-5 (Diagnostic and Statistical Manual of Mental Disorders, 5th Edition) diagnoses (eg, major depressive disorder or persistent depressive disorder versus “depression,” which is not a diagnosis). The review reflects and reinforces a general tendency to frame machine learning research in terms of technical “tasks” rather than connecting them more directly with real-world problems, a necessary step toward translating technological progress into the broader mental health ecosystem within which the technology will ultimately need to be situated [4,5].

Third, the bibliometric approach taken here reflects a traditional top-down view that fails to break down information silos in a rapidly evolving field. It is now standard to cast the net more broadly by searching for citations in resources like Google Scholar and/or looking at papers’ references (cf Franklin et al [6]), and then narrow using exclusion criteria. Such practices can illuminate the wider space of relevant search terms and sources—for example, the notable absence of suicidality here among mental conditions, at least in the illustrative search—and uncover unexpected connections. Even within the most rigorous meta-analysis frameworks (Moher et al [7]), studies can miss “gray literature” (eg, conference proceedings, preprints, collected data that have never been analyzed, presented on, or published). For example, the substantially similar prior study by Chancellor and De Choudhury [3] needed to adjust for the limitations of indexing services, which had large gaps for conferences known to be important in this research area (eg, Association for the Advancement of Artificial Intelligence [AAAI], Association for Computational Linguistics [ACL], Association for Computing Machinery [ACM], Neural Information Processing Systems [NIPS/NeurIPS], American Medical Informatics Association [AMIA])—they were careful in particular to include the Workshop on Computational Linguistics and Clinical Psychology (CLPsych), a key interdisciplinary publication venue for natural language processing, machine learning, and mental health since 2014.

Kim et al [1] are to be commended for undertaking a bibliometric study with the goal of advancing our understanding of machine learning for mental health in social media. However, we would encourage thinking about their article as a different kind of contribution, even if not the intended one: it is an opportunity to draw attention to an increasing need, as the field grows, to approach this research space not only as technologists, but also as partners with clinical researchers and clinicians.

KEYWORDS

bibliometric analysis; machine learning; mental health; social media; bibliometrics

We thank all comments and critical insights on our study, "Machine Learning for Mental Health in Social Media: Bibliometric Study" [1]. In this letter, we responded to the discussion points raised by Resnik and colleagues [2].

First, Resnik et al [2] pointed out the limited scope of the search query selected in our bibliometric study, which concealed the approaches taken in the clinical research field. We agree that the search query may seem to be lacking in covering clinical research; however, we did not intend to distort the recent trends in machine learning for mental health in social media. Moreover, considering that publication venues including the *Journal of Medical Internet Research, BMJ Open, International Journal of Environmental Research and Public Health, Frontiers in Psychiatry*, and *Frontiers in Psychology* were listed as productive publication sources in the analysis results, we believe that the publications employed in our analysis cover the invaluable research methodologies in the medical research area. The completed list of retrieved publications can be found in the appendix [1].

Moreover, Resnik et al [2] also stated that the machine learning–related terms in the search query lean toward specific technological methodologies, which may not include solutions including screening, risk assessment, and monitoring. We could not agree more with their point of view on the importance of practical works applied to "real" clinical settings. However, since such approaches directly related to diagnosis or treatment required careful consideration, we had difficulties fully diving into it. Thus, we want to stress that the main focus of our research was to help clinical researchers and field affiliates understand the technical needs of machine learning, which we believe is necessary for the initiation phase of this research field. Besides, we conducted a thorough trend review analysis of highly cited papers to provide a more in-depth understanding of related research fields [3].

We appreciate the suggestions on keywords for the search query to include "clinical psychology," "psychiatry," and "computational linguistics." This led us to consider interviewing domain experts to set more domain-specific keywords in future research, following the procedure of the previous bibliometric study [4].

Third, Resnik and colleagues [2] raised concerns about only using indexing services and excluding search engines such as Google Scholar. Considering the rapidly changing trends in this research area, we employed both Web of Science and Scopus for the analysis to cover not only journal publications but conference proceedings. Nevertheless, we acknowledge Resnik and colleagues' concern and also mentioned the need to employ other medical-oriented databases, which may provide more significant academic and practical information in the *Discussion* section. We would also like to take this opportunity to recap the importance of nonpublished work by sharing a preprint paper in this research field [5], which helped us to take a step toward future research on applying machine learning and social media in mental health counseling.

We hope our analysis may trigger all stakeholders to further consider how to employ machine learning approaches toward mental health in social media and be a support to bridge the gap between technologists and clinicians.

Acknowledgments

This research was supported by the MSIT (Ministry of Science and ICT), Korea, under the ICAN (ICT Challenge and Advanced Network of HRD) program (IITP-2020-0-01816) supervised by the IITP (Institute of Information & Communications Technology Planning & Evaluation). This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (NRF-2020R1C1C1004324).

Related Article:

Correction of: https://www.jmir.org/2020/9/e19716/

(J Med Internet Res 2021;23(6):e29776) doi:10.2196/29776

In “Mobile Insight in Risk, Resilience, and Online Referral (MIRROR): Psychometric Evaluation of an Online Self-Help Test” (J Med Internet Res 2020;22(9):e19716) one correction was made. This does not affect the analysis nor does it affect the interpretation or presentation of the results in the study.

In the “Methods” section, under “Measures” and “Depression, Anxiety and Stress”, the following phrase appears:

> *A 5-point response scale measures the extent to which each state has been experienced over the past week ranging from 0 (not at all) to 4 (most certainly).*

This has been replaced by the following:

> *A 4-point response scale measures the extent to which each state has been experienced over the past week ranging from 0 (did not apply to me at all) to 3 (applied to me very much, or most of the time).*

The correction will appear in the online version of the paper on the JMIR Publications website on June 4, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 20.04.21; this is a non–peer-reviewed article;accepted 22.04.21; published 04.06.21.

Related Article:

Correction of: https://www.jmir.org/2020/11/e20050/

(J Med Internet Res 2021;23(6):e30764) doi:10.2196/30764

In “An Environmental Scan of Sex and Gender in Electronic Health Records: Analysis of Public Information Sources” (J Med Internet Res 2020;22(11):e20050) the authors noted three errors.

1. Under the “Results” section, second paragraph of “Types of Information Sources” subsection, the statement “*(3) OpenEHR and BioPortal as 2 international collaborations that have developed the Gender Archetype and Gender, Sex, and Sexual Orientation (GSSO) ontology, respectively;*” was published incorrectly. This has now been corrected as follows:

> *(3) OpenEHR as an international collaboration that has developed the Gender Archetype, and the BioPortal where the Gender, Sex, and Sexual Orientation (GSSO) ontology developed by Kronk [111] is hosted;*

2. Reference 111 was originally published as follows:

Gender, Sex and Sexual Orientation Ontology – Gender and Sex. BioPortal. URL: https://bioportal.bioontology.org/ontologies/GSSO/?p=classes&conceptid=root [accessed 2020-10-27]

This has been corrected to:

Kronk CA, Dexheimer JW. Development of the Gender, Sex, and Sexual Orientation ontology: Evaluation and workflow. J Am Med Inform Assoc 2020 Jul 01;27(7):1110-1115. [doi: 10.1093/jamia/ocaa061] [Medline: 32548638]

3. In the original article, the phone number of the corresponding author was published with a duplicate country code as *'1 12504725131'*.

This has been corrected to *'1 2504725131'*.

The correction will appear in the online version of the paper on the JMIR Publications website on June 4, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 27.05.21; this is a non–peer-reviewed article;accepted 31.05.21; published 04.06.21.

In “Patient Empowerment During the COVID-19 Pandemic by Ensuring Safe and Fast Communication of Test Results: Implementation and Performance of a Tracking System” (J Med Internet Res 2021;23(6):e27348) the authors noted one error.

In the originally published manuscript, the author Nensi Ikonomi was not credited as an equal contributor. This has been corrected to show that Gunnar Völkel, Axel Fürstberger, Julian D Schwab, Silke D Werle, Nensi Ikonomi, Thomas Seufferlein, and Hans A Kestler all contributed equally to the manuscript.

The correction will appear in the online version of the paper on the JMIR Publications website on June 21, 2021, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 15.06.21; this is a non–peer-reviewed article;accepted 16.06.21; published 21.06.21.

Abstract

Background: Since the declaration of COVID-19 as a global pandemic by the World Health Organization, the disease has gained momentum with every passing day. Various private and government sectors of different countries allocated funding for research in multiple capacities. A significant portion of efforts has been devoted to information technology and service infrastructure development, including research on developing intelligent models and techniques for alerts, monitoring, early diagnosis, prevention, and other relevant services. As a result, many information resources have been created globally and are available for use. However, a defined structure to organize these resources into categories based on the nature and origin of the data is lacking.

Objective: This study aims to organize COVID-19 information resources into a well-defined structure to facilitate the easy identification of a resource, tracking information workflows, and to provide a guide for a contextual dashboard design and development.

Methods: A sequence of action research was performed that involved a review of COVID-19 efforts and initiatives on a global scale during the year 2020. Data were collected according to the defined structure of primary, secondary, and tertiary categories. Various techniques for descriptive statistical analysis were employed to gain insights into the data to help develop a conceptual framework to organize resources and track interactions between different resources.

Results: Investigating diverse information at the primary, secondary, and tertiary levels enabled us to develop a conceptual framework for COVID-19–related efforts and initiatives. The framework of resource categorization provides a gateway to access global initiatives with enriched metadata, and assists users in tracking the workflow of tertiary, secondary, and primary resources with relationships between various fragments of information. The results demonstrated mapping initiatives at the tertiary level to secondary level and then to the primary level to reach firsthand data, research, and trials.

Conclusions: Adopting the proposed three-level structure allows for a consistent organization and management of existing COVID-19 knowledge resources and provides a roadmap for classifying future resources. This study is one of the earliest studies to introduce an infrastructure for locating and placing the right information at the right place. By implementing the proposed framework according to the stated guidelines, this study allows for the development of applications such as interactive dashboards to facilitate the contextual identification and tracking of interdependent COVID-19 knowledge resources.

KEYWORDS

information organization; resource management; knowledge graphs; interactive dashboard; dependency tracking; COVID-19; pandemic; information technology; tracing information; dashboards; digital health

Introduction

The novel coronavirus—SARS-CoV-2—first appeared in December 2019 and has quickly spread over other regions of the world. The World Health Organization (WHO) declared COVID-19, the disease caused by SARS-CoV-2, a global pandemic [1,2]. It gained momentum as every day passed, and private and government sectors of different countries pushed funding toward research on COVID-19 in various capacities. A portion was dedicated to investing in vaccine discovery and personal protective equipment manufacturing. The other portion was devoted to information technology and service infrastructure development, including research to develop intelligent models and techniques for alerts, diagnosis, treatment, prognosis, prevention, and other relevant services [3]. Our study focused on the second part of the research initiatives related to COVID-19 and provides a comprehensive review of such initiatives.

A rapid and timely response was required from the world to circumvent the challenge of COVID-19. Various organizations from different countries concentrated on investigations and discoveries in data, information, and knowledge to support population health [4]. We designed a structure for categorizing efforts and initiatives related to COVID-19 into three levels or categories: primary, secondary, and tertiary. The primary level represents resources and initiatives that accrue raw data or research about patients with COVID-19 and bring it into the global space. The secondary level encompasses resources and initiatives that analyze primary-level resources, making it more meaningful by adding metadata and filtering out unnecessary items in the data. The tertiary level includes resources and initiatives that consolidate the first- and second-level efforts by creating guidelines, code systems, standard resources, and vocabularies. This study provides a review of initiatives globally at these three levels and proposes a novel research dashboard for tracking COVID-19 resources with dependency workflows. The proposed dashboard will provide a gateway to global initiatives with enriched contextual metadata to help users track the information flow at different levels for validation and verification.

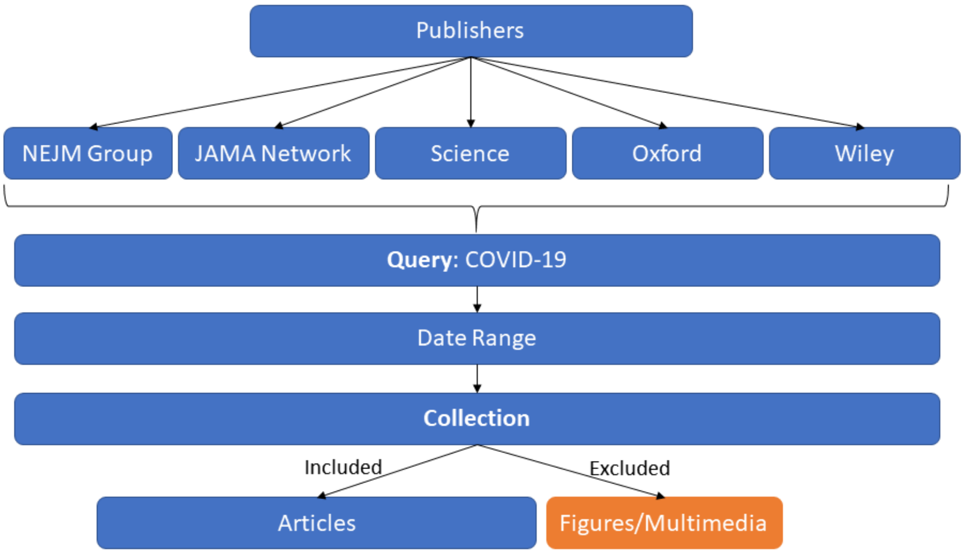
This study is the first of its kind to categorize efforts and initiatives in the form of resources related to COVID-19. It was inspired from the research sources outlined in commentaries and library handouts we consulted [5,6]. This study improvises the three types of information sources to map COVID-19–related initiatives to each kind and devises a method of finding their interdependence for easy tracking of information in contextual trails and metadata. In the context of COVID-19, we can find studies that discuss data sets and techniques, but no such research has been found to categorize initiatives and their dependencies.

Methods

Review of COVID-19 Efforts and Initiatives

This study explored initiatives through an informal search strategy to identify key initiatives at each level; however, the authors do not claim the list to be exhaustive. The authors' experience in evidence-based medicine and translational research made it easy to reach out to well-known data resources and look for COVID-19–related efforts. The study did not distinguish the type of data and information pertinent to a specific initiative; instead, it focused on resources. For different resources, different search strategies were employed. For example, primary-level studies were searched in top publisher networks by using the procedure described in Figure 1. For secondary- and tertiary-level resources, a mixed method of free searching, word of mouth, and expert recommendations were used.

Figure 1. Publisher-wise searching for published research articles on COVID-19. NEJM: New England Journal of Medicine, JAMA: Journal of the American Medical Association.



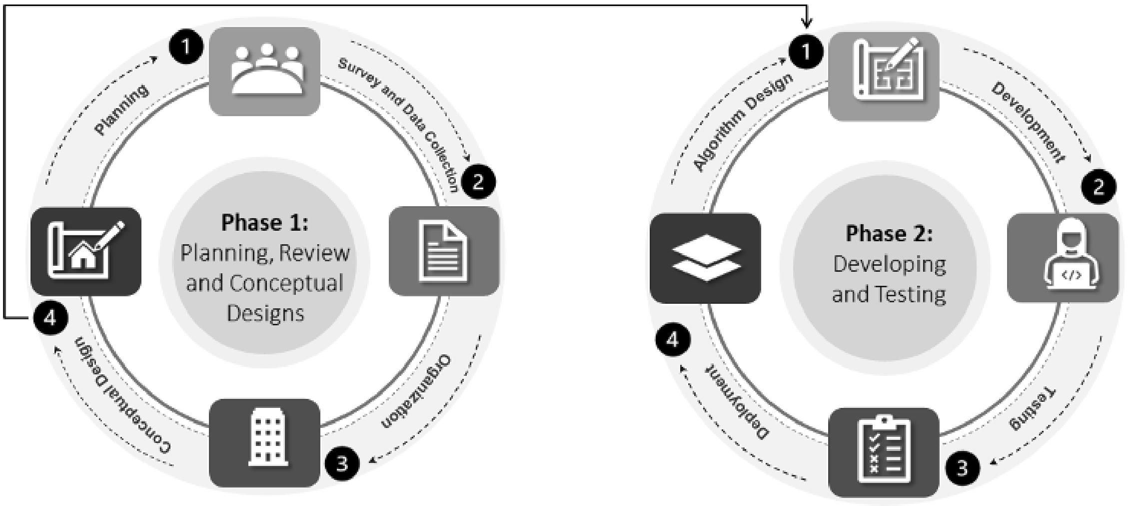
Research Design

This research reports on phase 1 of an action research project. We designed a conceptual framework for categorizing COVID-19 resources and surveyed the efforts and initiatives that contributed to creating these resources. This first phase establishes the infrastructure for locating and placing the right information at the right place. It provides a schema guideline for developing implementation models and systems.

Phase 2 involves the development of a software system and testing the viability of the proposed approach by undertaking the software development process model for each component and deploying on to an open repository for global access.

Figure 2 provides an overview of the two phases of the action research design. Planning includes brainstorming sessions, informal and formal meetings, and surveying COVID-19 efforts and initiatives to collect data. The initial data were organized to get a sense of the data elements through visuals that included bar graphs, pie charts, and histograms. Conceptual design is the design of an architecture framework for the categorization of resources. Algorithm design involves knowledge graphs, data management and querying, data-driven approaches, and user interface and user experience. Development is the actual implementation of the designed methods in the chosen programming languages. Deployment is the reflection and availability of developed methods and models to the community via open-access platforms like GitHub. As described, at any stage of phase 2, the process of phase 1 can be accessed and replicated.

Figure 2. Action research phases.



Results

COVID-19 Efforts and Initiatives

Primary Resources

The primary level includes resources that accumulate raw data or research about patients with COVID-19 and bring it into the global space. Primary-level resources were categorized into three groups: research literature, data, and clinical trials. Research literature includes published information like journal publications, raw data includes firsthand patient information like demographic and clinical information, and clinical trials includes registered trials with the objective to prove the effectiveness of a treatment like a drug or surgery. We provided a statistical overview of different resources in each group.

Research Literature

The research literature group was divided into two categories: preprint and postprint. Preprint articles are “work in progress” research that are yet to be published in a peer-reviewed journal. Postprint articles are “submitted to journal” research that are considered published after going through copyediting and typeset formatting.

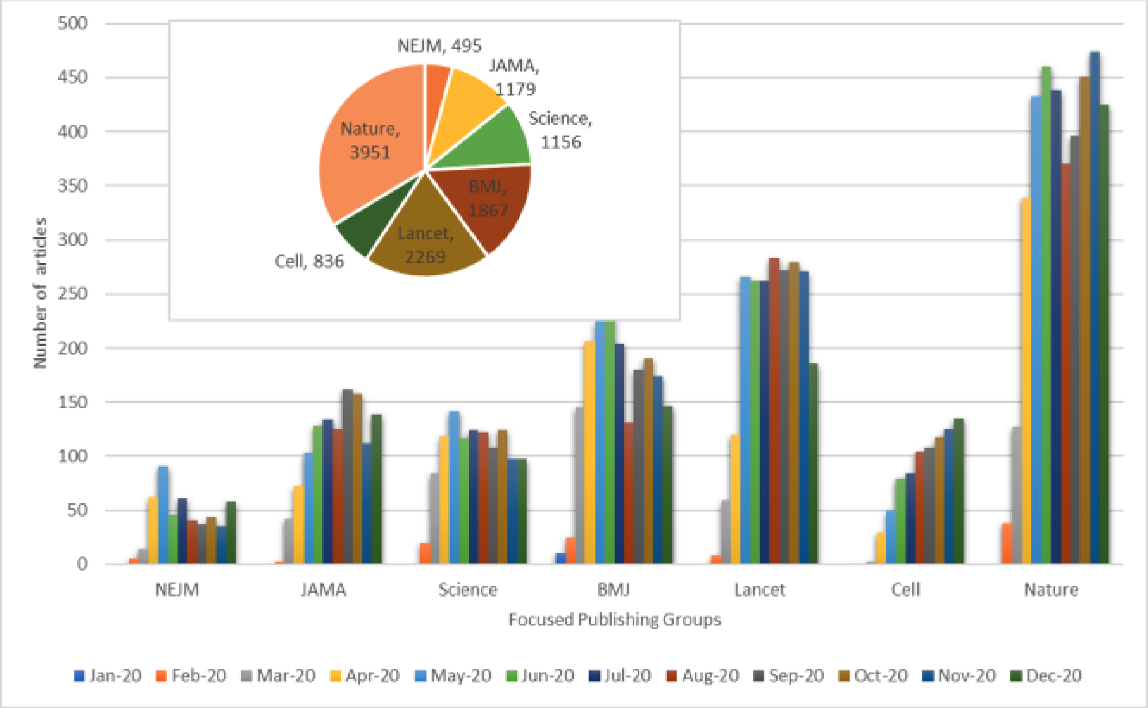
Preprint Literature

Alongside published research literature, many research articles were submitted to preprint repositories, which are unreviewed. They may eventually be published in a peer-reviewed journal. Due to unpredictable review durations, most researchers first submit an earlier version of their paper to a preprint database to disseminate their work quickly. Among popular preprints, arXiv [7] is an extensive multidisciplinary archive with 1.7 million scholarly articles in physics, mathematics, computer science, quantitative biology, quantitative finance, statistics, electrical engineering and systems science, and economics. It published 2842 articles on COVID-19 in 2020. Related to the medical and biology domains, two archives—medRxiv and bioRxiv [8]—are at the forefront in the collection unreviewed literature. As of 2020, medRxiv and bioRxiv published 9487 and 3058 articles, respectively. Other archives like ChemRxiv, a preprints server for chemistry and related areas, has also published a considerable number of prereviewed articles on COVID-19 (n=364).

Postprint (Published) Literature

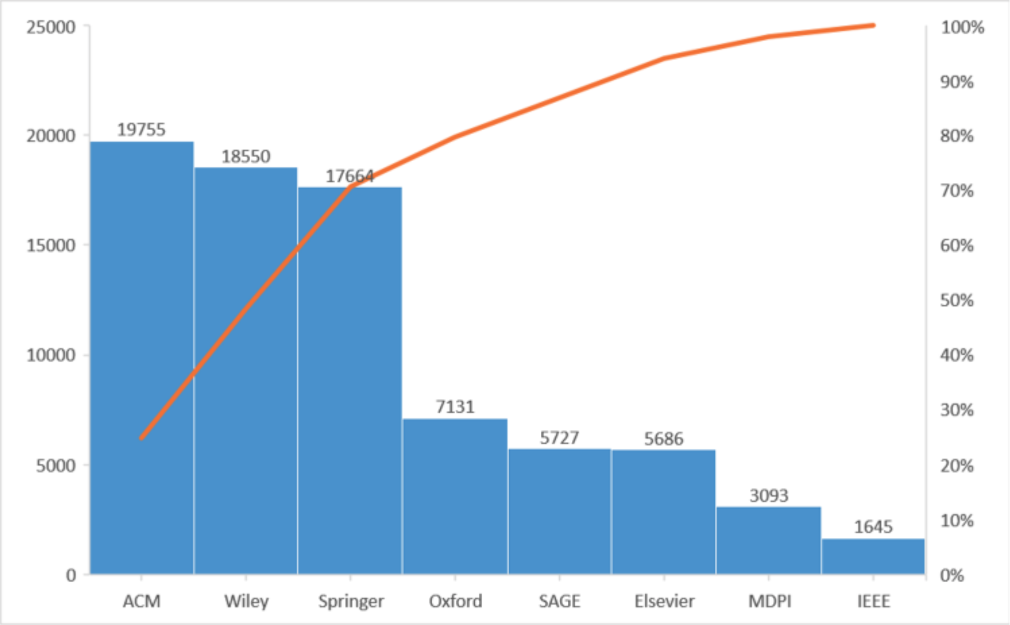
At present, a vast number of publications in the biomedical literature mention “COVID-19” in the title, the body of text, the keywords, or metadata. From January 1 to December 31, 2020, about 12,000 articles were published by prominent publishers that include Nature, Science, Cell, the New England Journal of Medicine (NEJM), the Journal of the American Medical Association (JAMA), Lancet, and BMJ. As shown in Figure 3, Nature published a total of 3951 articles, contributing about 34%, followed by Lancet (19%), in the given group of 7 publishers. It should be noted that this quantitative representation does not discuss the quality of articles. Later in this study, we will discuss COVID-19–relevant and COVID-19–specific articles. Article count increased every month initially, with the maximum number of articles appearing between May and October 2020. Starting in January 2020, there were hardly any substantive articles specific to COVID-19, although the count increased to a two-digit number in February. A maximum number was observed in October with 1364 articles. Articles continue to be published at a steady rate.

Figure 3. Monthly progression of publications on COVID-19 according to publisher. NEJM: New England Journal of Medicine, JAMA: Journal of the American Medical Association.



Many articles are being added to major libraries daily. We surveyed 8 major scientific libraries: Association for Computing Machinery (ACM), Wiley, Springer, Oxford, SAGE, Elsevier, MDPI, and IEEE. All these databases are accessible to researchers; therefore, we opted to present their statistics. We used the term "COVID-19" to keep the search simple, with increased coverage and reduced chances of missing COVID-19–related publications. As shown in Figure 4, ACM alone identified about 20,000 entries on COVID-19–related articles. Figure 4 indicates that COVID-19–related articles are published everywhere, including in IEEE Explore even though its focus is more on engineering.

Figure 4. Number of articles that appeared in major scientific libraries accessible to a researcher, presented in decreasing order from January to December 2020. The orange line displays the cumulative %, demonstrating that only three major scientific libraries (ACM, Wiley, and Springer) contributed about 70% of the articles. ACM: Association for Computing Machinery.



Patient Data Sets

Data play a crucial role in the ability to research, study, and explore population health and safety, and this is truer than ever in the context of a global pandemic. Access to data sets and associated tools that can examine that data are increasingly crucial to the research process and are particularly necessary for the worldwide response to the novel coronavirus.

To aid researchers, developers, and analysts in the struggle to fight COVID-19, different platforms offer data sets about patients with COVID-19 like the Johns Hopkins Center for Systems Science and Engineering (CSSE) [9], the Google COVID-19 Public Dataset Program [10], Kaggle [11], and GitHub [12]. Only on Kaggle are there 972 data sets of small (n=773), medium (n=168), and large (n=24) sizes. Most of these data sets are available in CSV (comma-separated value) or MS Excel (Microsoft Corp) formats. On GitHub, which is primarily a repository for hosting project code files developed in different languages, such as Python, data are also stored for the code reproducibility alongside the code files. As of June 10, 2020, 4073 public repositories have been added to GitHub matching the topic of COVID-19. Several other resources, including data.world [13], AMiner [14], and IEEEDataPort [15], provide free data sets related to COVID-19. Hundreds of regional and country-specific data sets are available through different channels; however, it is not within the scope of this study to describe them here. Rather, this study aims to present platforms that host data sets across regions and countries.

For public health safety and security, a few global-level information resources such as the WHO [16] and Centers for Disease Control and Prevention (CDC) [17] are worthy of mention as they provide important information for public awareness. The WHO is a global entity that accumulates information from its member organizations and disseminates it on its website and through other public interest channels. The WHO developed a specialized tool called the Coronavirus Disease (COVID-19) Dashboard [9], which provides a rich spectrum of metadata and analytics about COVID-19.

Whether in the United States or abroad, the CDC fights diseases that are chronic or acute, curable or preventable, and caused by human error or deliberate attack. It is a rich source of information on COVID-19 in terms of symptoms, risk factors, and guidelines on social distancing, and provides important information to different stakeholders like policymakers, travelers, businesspeople, schools, health professionals, the general public, and high-risk populations. To facilitate users' understanding of the nature of data, we describe popular data set platforms in Table 1, reporting characteristics helpful for developing statistical and machine learning models for further analysis and research. In addition to defining the platform's aim and scope, we also provide a brief explanation of the nature of the data sets hosted on that platform to help users spend their time appropriately. Some platforms offer data that can be used solely for statistical analysis and reporting purposes. In contrast, others could be used for assistance in clinical decision making related to patient diagnosis, treatment, and prognosis. In Table 2, we provide summarized information about data resources on COVID-19.

Table 1. A brief description of COVID-19 platforms that offer an open repository of data sets and their scope and usefulness.

Data set platform	Description	COVID-19 data sets/repositories, n
Kaggle [11]	Kaggle is the world's largest data science community with powerful tools and resources to achieve data science goals.	972 data sets
GitHub [12]	GitHub is primarily a host for software development and version control; however, alongside the code files, the associated data are also available for code reproducibility.	4073 repositories
data.world [13]	data.world is an open data resource hub on COVID-19 with contributions from thousands of users and organizations worldwide.	40 data sets
AMiner [14]	AMiner collects all kinds of data sets about COVID-19 with daily updates. The data are open and available for download.	438 data sets
IEEEDataPort [15]	IEEEDataPort provides free data set storage and hosts different types of data sets. It provides space to host data sets related to COVID-19. It hosts a large set of tweets data (n=174,573,543) in the English language from around the globe.	15 data sets
Google COVID-19 Public Dataset Program [10]	To make data more accessible to researchers, data scientists, and analysts, Google created a COVID-19 Public Datasets Program that hosts a repository of public data sets and is free to access and analyze.	3 data sets (JHU CSSE[a] data set, global health data from the World Bank, and OpenStreetMap data)

[a] JHU CSSE: Johns Hopkins University Center for Systems Science and Engineering.

Table 2. A brief description of COVID-19–related information resources.

Organization	Description	Key information services
World Health Organization (WHO) [18]	The WHO works with 194 member states across 6 regions and from more than 150 offices, striving to combat diseases—communicable diseases like influenza and HIV, and noncommunicable diseases like cancer and heart disease.	• A COVID-19 dashboard that provides up-to-date case information, including the number of deaths and recovery • Generates advice for public awareness to reduce the chances of being infected or spreading COVID-19 • Situation reports, released daily, provide the current COVID-19 epidemiological situation and present official case and death counts and transmission classifications. As of June 16, 2020, 148 situation reports have been released • Other services include travel advice, training and exercise, technical guidance, response funds, etc
Centers for Disease Control and Prevention (CDC) [17]	The CDC is a US-based organization that aims to provide information on health safety and security threats, both foreign and domestic.	• Information on symptoms, risk factors, and social distancing • A bank of answers to important questions and many guidance materials for various stakeholders including travelers, health care professionals, etc
EU[a] Open Data Portal [19]	The European CDC publishes a data set that contains the latest available public data on COVID-19 worldwide by screening up to 500 relevant sources every day between 6:00 and 10:00 CET.	• COVID-19 cases worldwide for download • Visualizations of cases geographically, situation dashboard, and other graphical representations • Documentation as to how the data are collected, a script of R software, and webinars
Johns Hopkins University (JHU) COVID-19 Dashboard [9]	JHU experts designed a rich and interactive COVID-19 dashboard to inform the public, help policymakers create awareness, and save lives.	• An interactive dashboard for tracking global COVID-19 cases • Animated maps that show total cases, deaths, and new cases • Critical trends on how the novel coronavirus is spreading around the globe • Worldwide mortality analysis
The World Bank COVID-19 case data [20]	The World Bank provides an array of real-time data, statistical indicators, and other types of data relevant to COVID-19, particularly on the economic and social impacts of the pandemic and the World Bank's efforts to address them.	• Global poverty estimates of the impact of COVID-19 • Health nutrition and population statistics • Understanding the COVID-19 pandemic through data on indicators and worldwide cases • Map of the World Bank's operational response to the coronavirus and relevant services
DXY [21]	DXY provides timely, accurate, and authoritative real-time reports on the COVID-19 pandemic through global mapping and knowledge.	• Global mapping of coronavirus cases • COVID-19 knowledge for the public, doctors, etc
National Institutes of Health (NIH) COVID-19 Research [22]	The NIH offers a specialized service that provides the latest research information on COVID-19.	• ACTIV (Accelerating COVID-19 Therapeutic Interventions and Vaccines) • Treatment guidelines • Grants and funding information • COVID-19 testing information

[a] EU: European Union.

Clinical Trials

Clinical trials are conducted to evaluate the effectiveness and safety of medications or medical devices by monitoring their effects on a select population. Clinical trials pass through two stages: registration and publishing. Preferably, every trial should have at least one results article, even if the results are not significant or produce negative findings; however, sometimes it may be harder to publish due to publication bias [23]. A trial can be linked to a journal article through an unstructured trial-article link (may not involve unique identifiers) or a structured trial-article link (a computable link assigned with unique identifiers such as the ClinicalTrials.gov ID or the PubMed ID) [24].

Several platforms are functional such as those that register primary clinical trials related to COVID-19 and are freely accessible and searchable. The WHO International Clinical Trials Registry Platform (ICTRP) [25] was established to facilitate a network of international clinical trial registers to ensure a single point of access, the unambiguous identification of trials, and public accessibility. From January 2020 to June 2020, a total of 3163 clinical trials have been registered in the WHO ICTRP database from 18 different sources that include ClinicalTrials.gov; Chinese Clinical Trials Registry (chiCTR); Australia New Zealand Clinical Trial Registry; Clinical Research Information Service, Republic of Korea; Clinical Trial Registry–India; EU Clinical Trials Register; German Clinical Trials Register; Iranian Registry of Clinical Trials; International Standard Randomised Controlled Trial Number Registry (ISRCTN); Japan Primary Registries Network; Lebanese

Clinical Trial Registry; Netherlands Trial Register; Pan African Clinical Trials Registry; Brazilian Clinical Trials Registry; Peruvian Clinical Trial Registry; Cuban Public Registry of Clinical Trials; Sri Lanka Clinical Trials Registry; and Thai Clinical Trials Registry.

The US-based ClinicalTrials.gov [26] is perhaps the largest database of privately and publicly funded clinical studies conducted worldwide. In this database, we found a total of 2172 studies related to COVID-19 as of June 18, 2020. The second largest clinical trials database is the chiCTR [27], a nonprofit Chinese platform that has registered 721 clinical trials. All the registries are region or country specific except the ISRCTN Registry, which initially focused on randomized controlled trials; however, but has now widened its scope to include other study types to evaluate the efficacy of human-related health interventions [28]. As of June 18, 2020, the ISRCTN database registered 70 clinical trials, out of which only 6 have been completed, 4 have been suspended, and 60 are in progress.

Figure 5 shows a progress bar of trials registered in the first 6 months of 2020. The highest number of trials (n=967) had been registered in April. The number started declining after April, which was generally seen across all databases except the chiCTR, where the decline began after February. This may be because, in China, the peak number of COVID-19 cases was observed in February. The number of trials in May and June should be higher than in April as the number of positive cases continues to rise globally.

Figure 5. Progression of the number of trials registered in major databases between January and June 2020. chiCTR: Chinese Clinical Trials Registry, WHO ICTRP: World Health Organization International Clinical Trials Registry Platform.

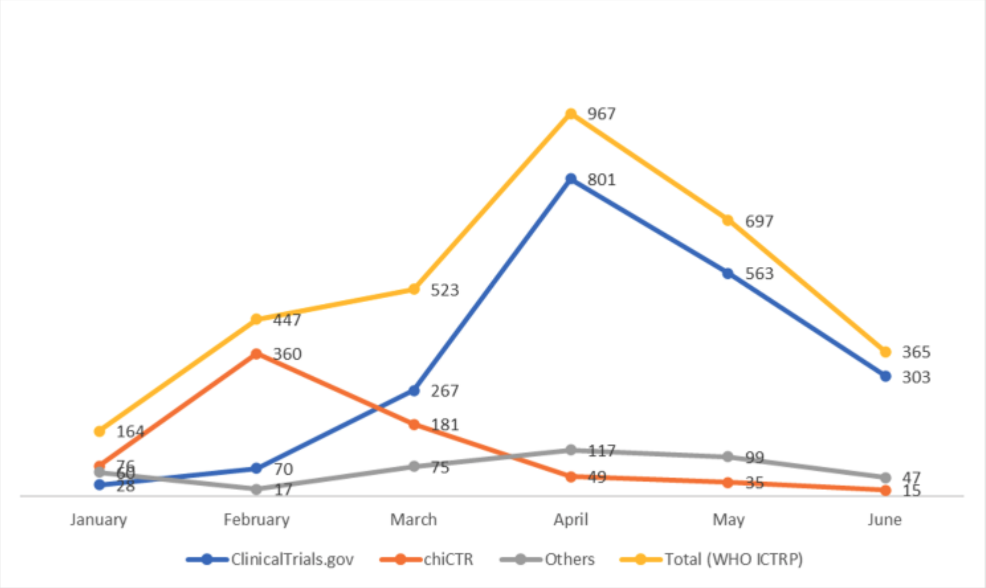


Figure 6 provides a statistical summary of ClinicalTrials.gov that includes the number of trials in 2020. The data show that only 572 trials have been completed, out of which only 19 have been reported with results. Phase IV, also called a postmarketing surveillance trial, occurs after the Food and Drug Administration has approved a drug for marketing and is the only trial that is eligible for observing drug use in public. At present, the number of phase IV trials (n=98) is far less than the phase III trials (n=432) and other trials in other phases. However, it is a reasonable number to raise the hope of obtaining significant results from watching the effects of drug on a large number of patients with COVID-19 around the world.

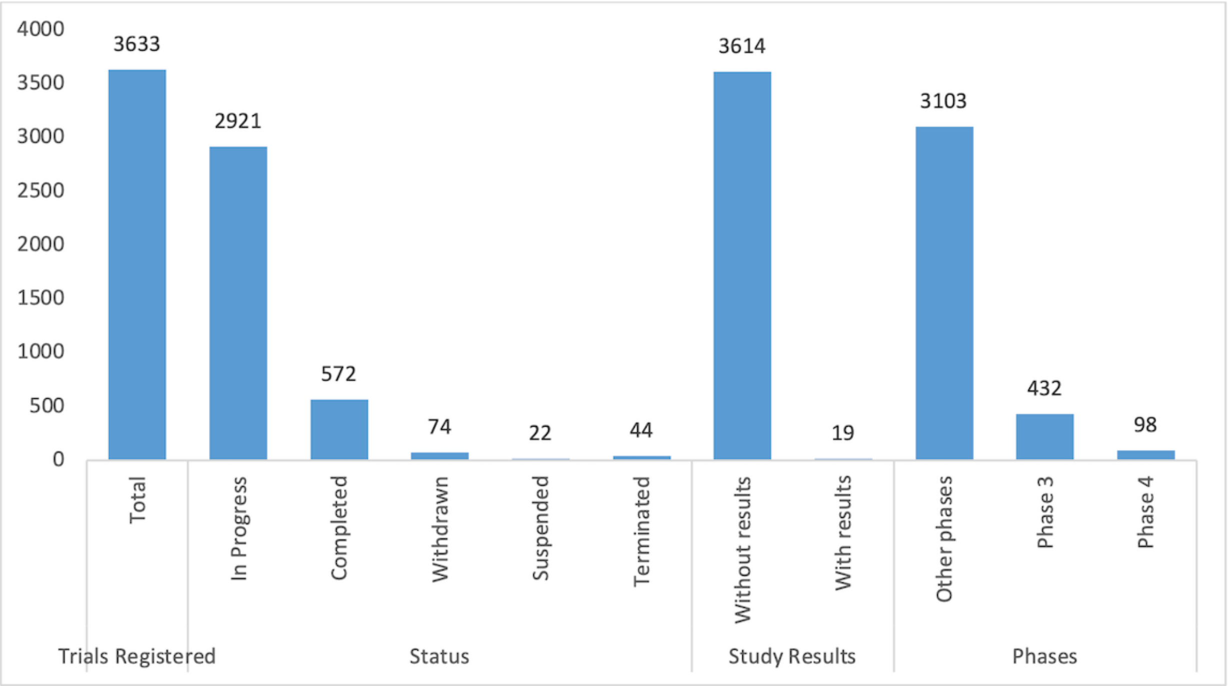
Figure 6. Statistical summary of clinical trials registered in the ClinicalTrials.gov database according to the trial status (eg, completed, withdrawn, suspended, terminated, or in progress), trials with results, and trials registered in different phases.



Secondary Resources

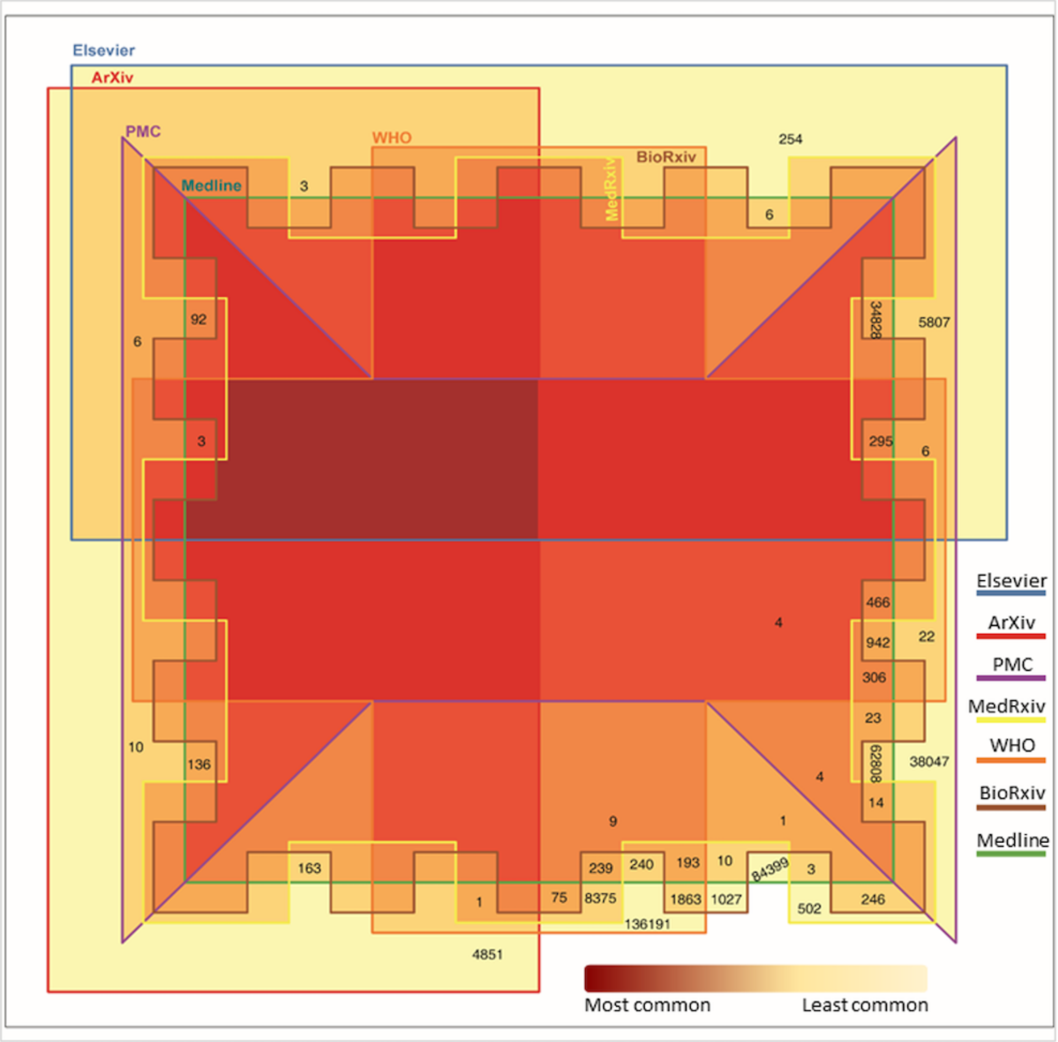
In this section, we present global-scale initiatives founded on the data acquired from primary-level sources at the secondary level. These initiatives are not discussed in any specific order. Most of these initiatives were pertinent to creating metadata on research literature articles for subsequent analysis and research.

CORD-19

CORD-19 (COVID-19 Open Research Dataset) is a free, open research data resource consisting of 130,000 scholarly articles about the novel coronavirus available for the global research community [29]. CORD-19 is updated every week with newly published research to facilitate the development of text mining and information retrieval systems, and it has been downloaded over 75,000 times in the first month of its release [29]. The articles in CORD-19 are derived from four primary-level repositories that include PubMed Central (PMC) [30], the bioRxiv and medRxiv preprint servers, and the WHO COVID-19 Database. The significant accomplishment of CORD-19 is the cleaning of metadata and machine readability of the full text. A simple deduplication logic of creating clusters for retaining similar articles, unless there is a conflict, is applied after metadata from each source is cleaned and formatted into CORD-19. After cleaning, the content is parsed from PDF-formatted papers into a JSON (JavaScript Object Notation) schema, which is simple to utilize for different text-mining tasks.

One of the CORD-19 data set features is the article's source, which represents the name of the publisher. Overall, 7 unique sources are enlisted; however, multiple sources are mentioned for articles published in more than one source. The 7 individual sources comprise articles that are either unique to them or are shared with other sources. In Figure 7, the articles shared among different resources are visualized using a Battle Venn diagram where the common area represents the number of shared articles. The intensity of color shows the high number of sources that share those articles. For instance, Medline has 84,399 articles that are not published anywhere else. However, it shares several articles with other sources; for example, with PMC, it shares 62,808 articles. No article is common in all the sources; however, 4 articles were shared among all the sources except Elsevier and arXiv. The R programming code and data files are available from the "COVID-19-Resource-Categorization" GitHub repository [31].

Figure 7. Number of articles published unique to each resource with no intersection (ie, these articles were not published in more than one resource). PMC: PubMed Central, WHO: World Health Organization.

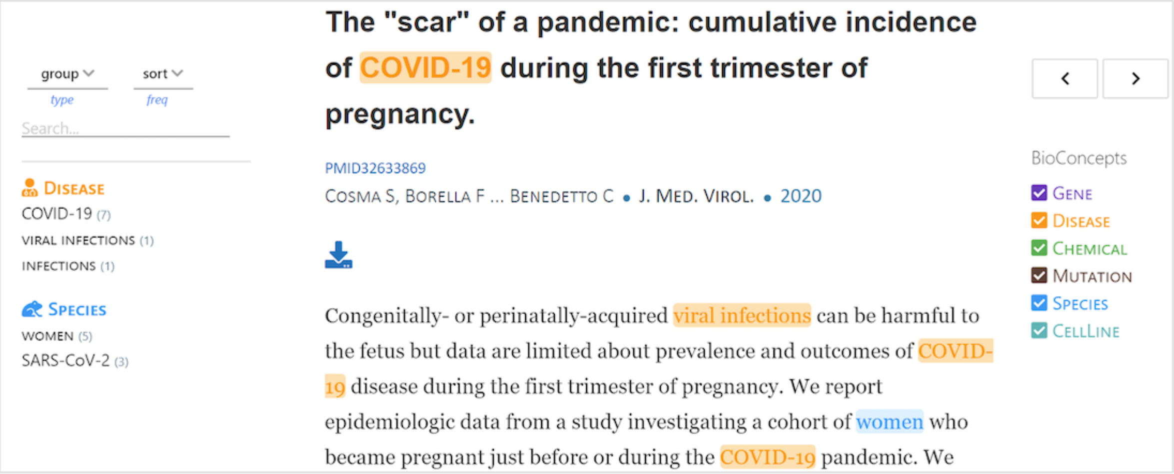


LitCovid

LitCovid is a hub of curated literature of scientific articles about COVID-19 [32-34]. The source is updated daily and has access to about 29,000 (and still growing) articles in PubMed. One unique feature of this effort is that identification of relevant articles is 35% better than the conventional keyword-based searches [34]. For improved accessibility, additional information has been added. The articles are categorized by research topics that include general information, mechanism, treatment, case report, transmission, disease diagnosis, prevention and epidemic forecasting, and geographical locations [34]. Under each topic, three additional important pieces of information are indexed—chemicals (the name of chemical products, like Remdesivir, used in different trials), journals, and countries (the host country of the research).

An associated effort extended by PubTator Central [35] derives articles from LitCovid and annotates them with 6 entity types, also called bio concepts—gene, disease, chemical, mutation, species, and cellline. The annotations of these entity types are made in different colors (Figure 8). For example, if a disease concept appears in the title or abstract, it is highlighted in yellow. Similarly, chemical names appear in green and a gene in purple. These annotations support text- and data-mining activities and are available for download in XML (Extensible Markup Language) format.

Figure 8. Annotated entity types highlighted in different colors in the title and abstract.



The "scar" of a pandemic: cumulative incidence of COVID-19 during the first trimester of pregnancy.

PMID32633869

COSMA S, BORELLA F ... BENEDETTO C • J. MED. VIROL. • 2020

Congenitally- or perinatally-acquired viral infections can be harmful to the fetus but data are limited about prevalence and outcomes of COVID-19 disease during the first trimester of pregnancy. We report epidemiologic data from a study investigating a cohort of women who became pregnant just before or during the COVID-19 pandemic. We

COVID-19 Evidence Alerts

COVID-19 Evidence Alerts is a McMaster University service that alerts users to current best evidence about COVID-19 [36]. It notifies users about the reports published in MEDLINE-based journals, which are critically appraised for scientific merit. Each appraised report is assigned a study category: diagnosis, etiology, treatment, prognosis, guideline, and clinical prediction. Reports with sufficient scientific merit are appraised as "higher-quality studies for clinical attention." Studies that provide lower-quality scientific evidence are posted as well with at least one reason for their lower-quality designation (eg, not a randomized controlled trial). There are also reports that are relevant but may not be assigned to a specific study category.

This service is beneficial for applications that involve clinical decisions. As of June 30, 2020, about 2700 reports had been posted accumulatively in all three categories; this list is growing and updated every weekday. Out of all the appraised reports, about 70 belong to the higher-quality category; this demonstrates that less than 3% of reports meet the criteria for clinical relevance and scientific merit; 34% did not meet the criteria for scientific merit, and 63% did not belong to a study category. There were two times more studies that did not belong to a study category than those that belonged to at least one study category.

CALC-19

The COVID-19 Advanced Literature Classifier (CALC-19) is a classifier of medical literature about COVID-19. The data are updated every week; as of July, the data set included more than 150,000 scholarly articles where each article is tagged by country, year, source, topic, and keywords [37]. CALC-19 extracts all of its articles from the CORD-19 data set and adds metadata like MeSH (Medical Subject Headings) keywords, authors, date of publication, and journal of publication in addition to the title and abstract. Users can search for articles of interest using different filters and tags provided by the service. The searched articles can be downloaded in Excel, CSV, Endnote, RIS, BibTex, and a new Health Level Seven (HL7) Fast Healthcare Interoperability Resources (FHIR) JSON format. The CALC-19 service is powered by the PICO Portal, which provides a platform to accelerate research and innovation by leveraging artificial intelligence and creating efficient systematic reviews of studies.

Evidence Aid COVID-19

Evidence Aid [38] is a collection of summaries of high-quality research studies. The collection is available in English with translations in 5 languages: French, Spanish, Portuguese, Arabic, and Chinese. This collection comprises summaries of systematic reviews to provide a quick overview of relevant and impactful information about COVID-19 concerning health conditions, outcomes, and other aspects necessary for the recovery period.

Each summary of a systematic review consists of subsections such as "Citation," "What is this?" and "What was found." The citation section includes information on the title of the systematic review, authors, publishing venue, date, and page information. The "What is this?" section summarizes information about population, experimental setup, environment, location, etc. The "What was found" section describes the findings and outcomes of the trials included in the systematic review (eg, the impact of a drug on patients with COVID-19 as positive, negative, or no effect).

Comparative Summary of Initiatives

The initiatives discussed as a part of the secondary-level resources are summarized in Table 3 to provide a comparative analysis of different aspects, such as dependent resource information, applications, language support, human validations, and download formats.

Table 3. Comparative summary of secondary-level resources based on different features that are important for researchers to expand their work on COVID-19.

Initiative or feature	Baseline resource	Direct applications	Update frequency	Multilingual support	Human expert verified	Export format
CORD-19[a]	Original research	IR and TM[b]	Weekly	N/A[c]	N/A	CSV[d]
LitCovid	PubMed	IR and TM	Daily	N/A	Yes	RIS[e], TSV[f]
COVID-19 Evidence Alerts	CORD-19	Systematic review	Every weekday	N/A	Yes	N/A
CALC-19[g]	CORD-19	IR and TM	Weekly	N/A	Users can filter records and tags to find records relevant to their work	Excel, CSV, Endnote, RIS, BibTex, HL7 FHIR[h] JSON[i]
Evidence Aid COVID-19	Systematic review	Evidence-based medicine, clinical decision support, guidelines	N/A	Yes	Yes	N/A

[a] CORD-19: COVID-19 Open Research Dataset.

[b] IR and TM: information retrieval and text mining.

[c] N/A: not applicable.

[d] CSV: comma-separated value.

[e] RIS: Research Information Systems.

[f] TSV: tab-separated value.

[g] CALC-19: COVID-19 Advanced Literature Classifier.

[h] HL7 FHIR: Health Level Seven Fast Healthcare Interoperability Resources

[i] JSON: JavaScript Object Notation.

Tertiary Resources

The tertiary-level initiatives use the outcomes of secondary resources for creating clinical guidelines, standards, and vocabularies to provide direct assistance to medical professionals and implementers of clinical decision support systems. The WHO and the CDC are the two comprehensive resources that provide general and all technical guidelines to the public and health professionals. On top of this, other resources add, refine, and customize their findings. The WHO publishes technical guidelines in 14 different categories (eg, clinical care, infection prevention and control, laboratory and diagnosis, etc) [39]. The CDC offers guidelines for various stakeholders; for health workers alone, it provides guidance in terms of 12 categories (eg, testing, clinical care, infection control, etc) [40]. Numerous initiatives derive guidance from the WHO and CDC guidelines, such as Duodecim: EBM Guidelines Coronavirus Infections [41] and COVID-19 guidelines listed in DynaMed [42].

COVID-19 Knowledge Accelerator

COVID-19 Knowledge Accelerator (COKA) [43] was first initiated in late March 2020. Led by Brian Alper, COKA is an add-on effort to an ongoing project, Evidence-Based Medicine on FHIR [44], to accelerate the processing of massive research data on COVID-19 in order to summarize and synthesize the evidence in a standard format for computable expression. It aims at resolving inefficiencies in current scientific dissemination systems in which research data are transformed into various noncomputable forms for human displays [45]. This initiative rightly identified the problem area of noncomputable communication and channelized its efforts to construct computable (structured) results directly from research publications, thus accelerating evidence synthesis.

The initiative gained momentum over a short period of time, and as of July 2020, COKA had more than 150 working meetings with more than 40 active participants from more than 25 organizations from academia, industry, government, and nonprofit organizations in 7 countries. Activities under this initiative are divided into 3-team setups: project, process, and system. Under each setup, four workgroup meetings are held every week (for a total of 12 meetings/week). Participants actively contribute to different meetings of their choice every week, and a report of the discussion is shared at the end of each day.

One of the key achievements of this initiative is the development of citation resource schemas and instances. As of July, COKA has created more than 36,000 citation resources for biomedical publications in the CORD-19 data set. Moreover, a profile resource, *EvidenceReport*, is another important outcome of this initiative, an extension of the *Composition* resource. The EvidenceReport resource provides a comprehensive report referring to one or more than one resource(s). As of July, more than 30 example reports related to COVID-10 have been generated. In addition to resource schemas, COKA made tremendous efforts in vocabulary mappings for evidence-related resources. In a short time, COKA developed a 13-step Code System Development Protocol in September 2020. HL7 FHIR is used as the underlying standard to meet interoperability needs and support the global development of terminologies for the exchange of scientific evidence [46].

ACTS COVID-19 Guidance-to-Action Collaborative

The AHRQ (Agency for Healthcare Research and Quality) Evidence-Based Care Transformation Support (ACTS) initiative of the COVID-19 Guidance-to-Action Collaborative aims to improve the development, dissemination, and use of “living” COVID-19 guidance [47]. The collaborative supports the COVID-19 “knowledge supply chain,” that is, the data-to-evidence-to-knowledge-to-guidance-to-action sequence to make the processes of guidance development, workflow integration, and knowledge supply chain more efficient and effective. Among its primary functions, the collaborative provides current solutions to urgent clinical challenges faced by health professionals, helps guidance developers in tracking COVID-19–related recommendations, fosters collaboration among implementers of COVID-19 guidance summaries, and facilitates coordination to optimize the flow of COVID-19 “evidence to action.”

The collaborative produces rapid guidance summaries that provide a comprehensive description of existing evidence and guidance from various sources such as the CDC, the WHO, and the European CDC. The guidance summaries are not clinical practice guidelines; therefore, they should not be used or interpreted as such. Instead, they can help develop local recommendations and policies. As of July, 20 guidance summaries have been produced under two categories (ie, patient care and operations). The guidance summary is structured with a question form at the top addressing major recommendations, followed by a list of evidence collected from various sources.

National Institutes of Health COVID-19 Treatment Guidelines

In collaboration with other organizations, the National Institutes of Health has developed treatment guidelines to support 297 clinicians in caring for patients with COVID-19 [48]. These guidelines are updated frequently due to the quickly evolving nature of clinical information on the new coronavirus. The guidelines’ recommendations, which are based on scientific evidence and expert opinion, possess two ratings: the strength of the recommendations indicated as a letter (A, B, or C), and the quality of the evidence indicated using a Roman numeral (I, II, or III). A panel composed of experienced representatives from 14 different organizations and societies, such as the American College of Chest and Emergency Physicians, the Food and Drug Administration, and the Society of Critical Care Medicine, has been established to develop these guidelines. The panel utilizes data from the published scientific literature on COVID-19 and the experience of its members to develop the recommendations in these guidelines.

The panel develops recommendations in clinical care areas, that is, care of critically ill patients with COVID-19, including antiviral therapy, immune-based therapy, and adjuvant therapy guidelines for special populations such as pregnant women and children. The panel’s approach to publishing the recommendation in these guidelines can be learned from the example recommendation provided about chloroquine or hydroxychloroquine in the category of antiviral therapy: “The Panel recommends against the use of high-dose chloroquine (600 mg twice daily for ten days) for the treatment of COVID-19 (AI).” This example tells us that the strength of the recommendation is “A,” which means that the statement is a strong recommendation, and the quality of evidence is “I,” which means it is supported with data from one or more randomized trials with clinical outcomes and validated laboratory endpoints.

American College of Surgeons Elective Case Triage Guidelines for Surgical Care

The American College of Surgeons (ACS) has developed recommendations for surgeons to identify which procedure should be curtailed [49]. The ACS releases newsletters to update recommendations on curtailing the performance of surgical procedures continuously 2 times a week. As of July, the ACS has published guidelines in 14 categories (eg, cancer surgery, gynecology, neurosurgery, urology, vascular surgery, etc). Most of the guidelines are provided in a descriptive form, but a few include vascular surgery and orthopedic procedures. An example of COVID-19 guidelines for the triage of vascular surgery patients is provided in Table 4, describing the meaning of each tier class (1, 2a, 2b, and 3) concerning surgery postponement.

Table 4. Examples of COVID-19 guidelines for the triage of vascular surgery patients.

Category	Condition	Tier class
AAA[a]	Ruptured or symptomatic TAAA[b] or AAA	3: Do not postpone
Peripheral aneurysm	Asymptomatic peripheral aneurysm	2a: Consider postponing
Bypass graft complications	Revascularization for high-grade restenosis of previous intervention	2b: Postpone if possible
Carotid	Asymptomatic carotid artery stenosis	1: Postpone

[a] AAA: abdominal aortic aneurysm.

[b] TAAA: thoracoabdominal aortic aneurysm.

COVID-19–SNOMED Clinical Terms

SNOMED International, a leading health care terminology organization, took steps to identify codes for different terms related to COVID-19 [50]. In the March 2020 interim release, 24 records had been added, which increased to 49 records as of August 11, 2020. A complete list of these concepts with Uniform Resource Identifiers, fully specified name, and preferred term is now available on Confluence [51]. The two most important terms, “SARS-CoV-2” (organism) and “COVID-19” (disorder) have been given the identifiers 840533007 and 840539006, respectively. A map of SNOMED Clinical Terms (SNOMED CT) to ICD-10 (International Classification of Diseases, Tenth Revision) is provided for two concepts: “COVID-19” and “Exposure to SARS-CoV-2,” as described in Table 5.

Table 5. SNOMED CT (SNOMED Clinical Terms) to ICD-10 (International Classification of Diseases, Tenth Revision) map.

Preferred term	Source SNOMED CT identifier	Target ICD-10 identifier
COVID-19	840539006	U07.1
Exposure to SARS-CoV-2	840546002	Z20.8

Summary of Tertiary Resources

This section provides an inexhaustive list of initiatives that have contributed to the creation of tertiary resources. As shown in Table 6, the initiatives are categorized into three categories: standard, guidelines, and terminologies. Information on the group or organization has been provided to support future applications to catalogue these resources in their services.

Table 6. Summary of tertiary resources related to COVID-19–based standards, guidelines, and terminologies.

Category and organization/group	Initiatives
Standards	
Health Level Seven (HL7)	HL7 is a health information exchange standard. Using its current standard—Fast Healthcare Interoperability Resources (FHIR)—different initiatives have been taken place related to COVID-19 that include COVID-19 Knowledge Accelerator (COKA) [43] and the Situational Awareness for Novel Epidemic Response (SANER) Project using HL7 FHIR to enable easier reporting for public health [52].
International Organization for Standardization (ISO)	The ISO has compiled a list of freely available standards to support global efforts in dealing with the COVID-19 crisis [53]. It also features a list of national resources developed by ISO members in different countries to support the fight against COVID-19 [54].
American National Standards Institute (ANSI)	In response to the COVID-19 pandemic, the ANSI has initiated the Standards Alliance Phase 2 (SA2) [55], which aims to reduce importation and regulatory barriers of COVID-19 testing kits and training resources on the use of medical devices and testing equipment.
Guidelines and recommendations	
National Institutes of Health (NIH)	The NIH has developed a comprehensive set of COVID-19 treatment guidelines [48].
American College of Surgeons (ACS)	The ACS Elective Case Triage Guidelines for Surgical Care [49] aims to develop recommendations to help surgeons identify which procedures should be curtailed.
World Health Organization (WHO)	The WHO is perhaps the largest source of information, guidance, and recommendations to support the fight against COVID-19. In addition to general public health recommendations, it provides technical guidance on different topics [39].
Centers for Disease Control and Prevention (CDC)	Like the WHO, the CDC offers advice, recommendations, and guidelines for different stakeholders. For health workers alone, it provides guidance on 12 categories that include testing, clinical care, infection control, etc [37].
American Gastroenterological Association (AGA)	The AGA has developed recommendations based on the systematic review and meta-analysis of 47 studies and 10,890 unique patients with gastrointestinal symptoms [56].
US Food and Drug Administration (FDA)	The FDA provides guidance related to drug development programs and the food industry impacted by COVID-19, such as donating COVID-19 plasma and facilitating the development and availability of medical device therapeutics to combat COVID-19 [57].
Vocabularies and terminologies	
SNOMED Clinical Terms (SNOMED CT)	As of August 11, 2020, SNOMED International has added 49 records related to COVID-19 [50].
International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM)	The ICD-10-CM is an official coding and reporting guideline that provides important information needed to understand the usage of ICD codes in the context of COVID-19 [58]. These codes can be searched in a newly released user-friendly browser [59].
Unified Modeling Language System (UMLS)	The UMLS provides a set of COVID-19–related terms [60] mostly mapped to SNOMED CT and Medical Subject Headings.
Medical Subject Headings (MeSH)	A new MeSH Supplementary Concept Record (SCR Class 3-Disease) was added on February 13, 2020, to the 2020 MeSH Browser in response to COVID-19 [61]. The most current updates are found on the MeSH Browser [62]. Using MeSH terms, the recommended search strategy for retrieving COVID-19–related biomedical studies is “2019-nCoV OR 2019nCoV OR COVID-19 OR SARS-CoV-2 OR ((Wuhan AND coronavirus) AND 2019/12[PDAT]:2030[PDAT]).”
Logical Observation Identifiers Names and Codes (LOINC)	LOINC introduced 264 codes in response to COVID-19 [63]. These codes are distributed in 5 categories: SARS-CoV-2 lab tests (84 terms), LOINC terms for SARS-CoV-2 ask-at-order-entry questions (9 terms), convalescent plasma (2 terms), LOINC terms related to public health case reporting (63 terms), and COVID-19 or telehealth documents (106 terms).

COVID-19 Dashboard Applications

An array of dashboards has been proposed and implemented to portray the influx of data and information related to COVID-19. Here, we first discuss a set of well-known dashboards in use and provide information on different forms that include structured, unstructured, plane, and graphical.

Johns Hopkins University Interactive COVID-19 Dashboard

In response to the COVID-19 emergency, the CSSE at Johns Hopkins University (JHU), in the United States, developed an online interactive dashboard to visualize and track coronavirus cases in real time [51,64]. Starting on January 22, 2020, the dashboard data were updated manually, but with the increase in the number of cases, the manual reporting process became unsustainable and a semiautomated living data stream strategy has been used since February 1. This dashboard relies on several data sources (eg, for the identification of new cases) and seeks data from DXY China (it was initially the only data source), Twitter feeds, online news, and direct communication sent to the dashboard. The case numbers are duly confirmed with regional and local health departments, including the respective CDCs, health departments, and the WHO. This dashboard's main feature is real-time interactivity, which enables users to see cumulative cases, active cases, and other information like incidence rate on a global map. Users can click and select a region on the map and see that region's statistics. A US map is provided separately with county-wise confirmed cases and deaths. Moreover, it supports data in motion that show daily trends of cases and deaths in different regions.

WHO COVID-19 Dashboard

Like the JHU CSSE interactive dashboard, the WHO provides a live dashboard with COVID-19 case numbers and deaths where users can use their mouse to hover over a map to obtain an overview of cases across the world [16]. It provides two kinds of maps: a bubble map and a choropleth map. Alongside the maps are data tables detailing country-wise cumulative confirmed cases, deaths, as well as newly reported cases and deaths in the last 24 hours. It facilitates region-wise searches (eg, Europe, Asia, and Africa) as well.

Worldometer Coronavirus Updates

Run by an international team of developers, researchers, and volunteers, Worldometer provides global COVID-19 real-time statistics on data collected, analyzed, and validated from thousands of sources worldwide [65]. The data are claimed to be trusted and used by different governments (eg, the United Kingdom, Thailand, Pakistan, Sri Lanka, Vietnam, etc) and private organizations (eg, JHU CSSE, the BBC, the New York Times, etc). It provides country-wise statistics of new cases, deaths, recovered cases, critical cases, tests per million, and other important information. The most informative feature is the searchable and clickable country-wise data table that can be customized to include or exclude columns such as new cases, total cases, deaths, and tests per million, which are presented along with the total population of that country.

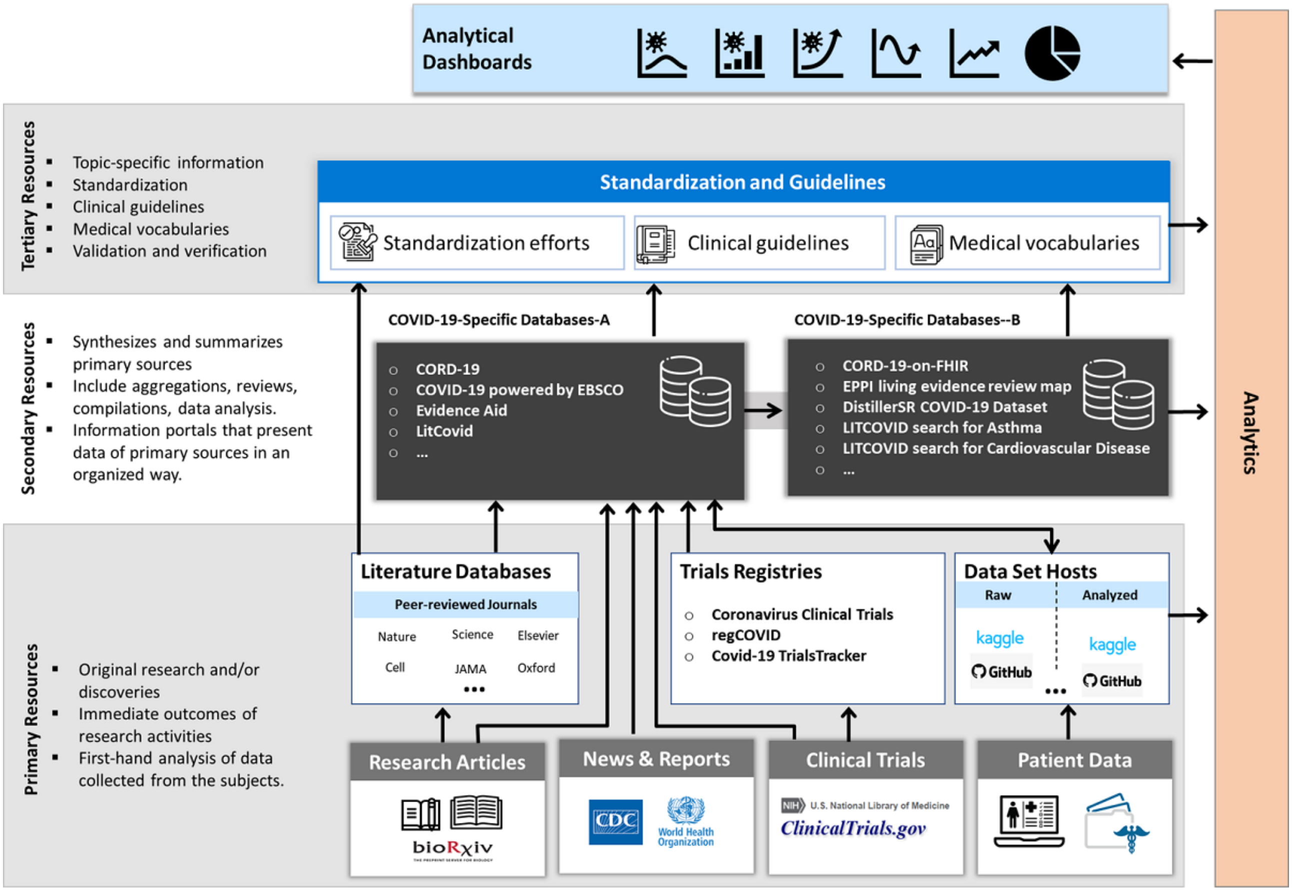
Other Efforts

Other than the dashboards mentioned above, dozens of dashboards are available for use scoped by a specific country, territory, or region. Coronaboard [66] provides COVID-19 statistics globally for the United States and three other countries (the Netherlands, France, and South Korea) in their respective languages. Almost all countries affected by the COVID-19 pandemic have put forth efforts to keep their populace informed via easy-to-use and understandable communication methods. For instance, Japan has developed its own dashboard [67], which supports the Japanese language and other languages such as English, German, French, and Arabic. Moreover, different media groups such as CNN, the BBC, and the New York Times have devised sophisticated dashboards, which rely heavily on JHU data.

A Conceptual Framework COVID-19–Related Knowledge Resources

Investigating diverse information at the three levels discussed earlier enabled us to develop an enterprise architecture framework for COVID-19–related knowledge resources. As illustrated in Figure 9, the framework comprises the categorization of efforts and initiatives, and organizes resources at the primary, secondary, and tertiary levels, demonstrating resource interconnectedness and flow of information.

Figure 9. An enterprise architecture framework for COVID-19–related efforts and initiatives involving primary, secondary, and tertiary knowledge resources. CORD-19: COVID-19 Open Research Dataset, FHIR: Fast Healthcare Interoperability Resources, EPPI: Evidence for Policy and Practice Information and Co-ordinating Centre, JAMA: Journal of the American Medical Association.



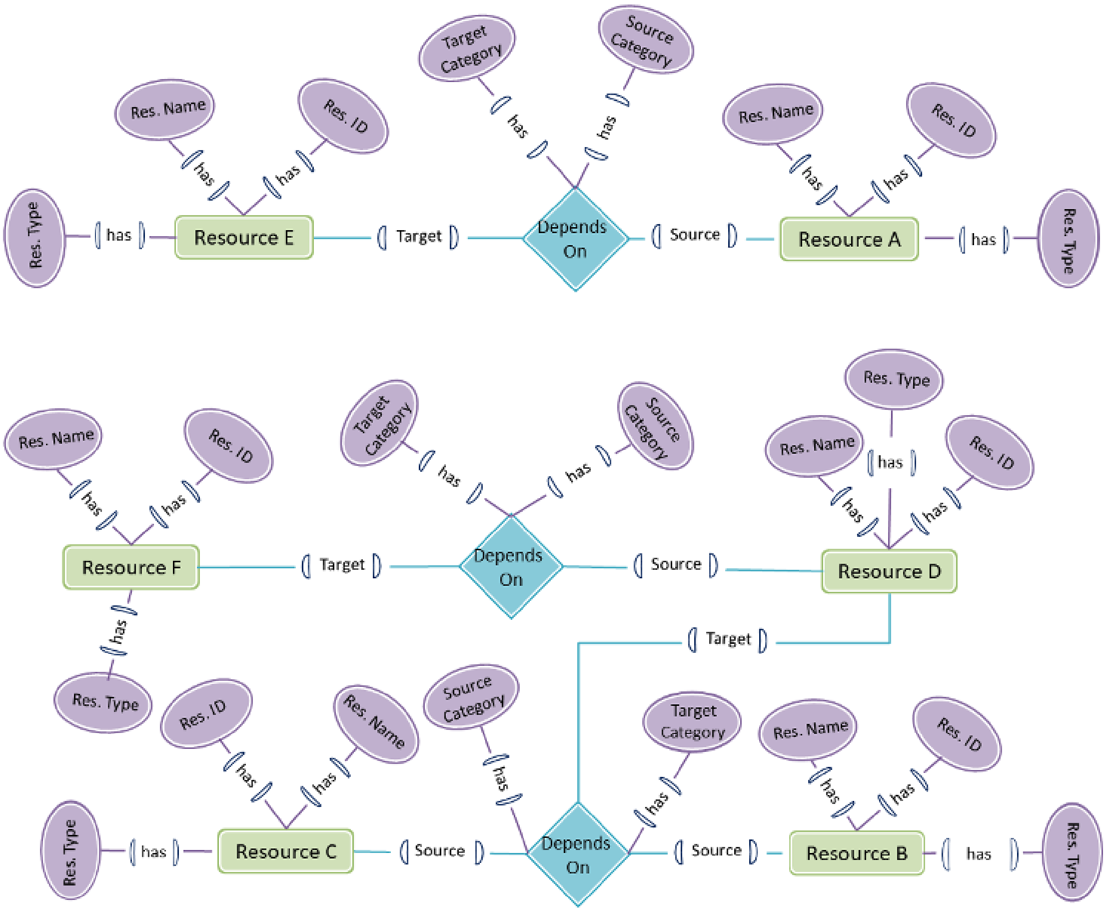
The framework's key feature is to enable tracking of a context in terms of information resources at different levels. For instance, if a user is interested in information that is an outcome of a secondary-level initiative, the dashboard will provide the required information resource(s) along with the dependent resource(s) at the primary level. The resources are then visualized in the form of dependency graphs generated automatically in response to the user query.

Figure 9 is a high-level conceptual illustration of the organization of COVID-19 resources in three logical layers connected to analytics that enable the creation of user applications such as analytical dashboards. In the following sections, we discuss the physical design of resources at different levels with relationships and properties, which demonstrates the approach's practicality.

Conceptual Modeling Using Knowledge Graphs

A robust and semantically enriched model is needed to manage the highly interlinked COVID-19 information resources and metadata. Based on the proposed framework, we created a knowledge graph design to represent interlinked resources to put data in context via linking and semantic information. An example scenario is presented in Figure 10 to display the suitability of the knowledge graph. Let us have 6 resources named A, B, C, D, E, and F, where three resources (A, B, and C) belong to primary, two resources (D and E) to secondary, and one (F) to tertiary. Let resource F be dependent on resource D, which depends on resources B and C. Similarly, let resource E be dependent on resource A. The corresponding nodes in the knowledge graph to represent the dependency among resources is shown using the relationship node *depends on*, which has two attributes, *source category* and *target category*. The source refers to the category of resources it depends on, and the target refers to the category of resource created as a result.

Figure 10. A knowledge graph representation reflecting an example scenario of 5 resources A, B, C, D, and E with their mutual dependencies.



Each resource has at least three attributes—identifiers, name, and type—where the type represents the subcategory within the primary, secondary, or tertiary category. For instance, resources whose type is data resources are research publication resources in the primary category.

Maintenance of Knowledge Graphs

The rich feature set of knowledge graphs that include classes, relationship types, and categorization support greatly help to resolve the resource maintenance challenge. Adding a new resource to the database by assigning the correct class of primary, secondary, and tertiary requires the users to input metadata about the resource. The input data may consist of dichotomous questions to support structured queries run on the underlying graph database to infer the target class for the resource, and saving a new resource must look for duplication by checking multiple parameters.

Visualization Using Knowledge Graphs

Current COVID-19 dashboards typically represent time-series visuals and geographic maps, with exceptions of dashboards that respond to the pandemic by showing clinical trials, policy- and finance-related interventions, and social distancing directives [68]. Some dashboards include contact tracing data; however, resource dependency–tracking dashboards are not seen in the literature. Novel knowledge graph visualization algorithms are emerging, customized to support resource tracking with their dependencies and metadata semantics.

Discussion

We conducted this study to classify COVID-19 resources into a three-level structure. We designed a two-phase research design approach to locate COVID-19 resources and their placement, and conceptualize the architecture in the first phase while developing and testing the contextual dashboards in the second phase. We surveyed various efforts and initiatives worldwide, provided descriptive statistics, and classified them into primary, secondary, and tertiary categories. The proposed categorization led us to design knowledge graph–based models for developing contextual dashboards. A dependency graph theory was incorporated to visualize the results of information resources and their interdependence. The proposed work enables other applications such as search engines, interactive dashboards, and tracking systems to capture contextual information of COVID-19–related resources. Using knowledge graph models for application development will add transparency to the information infrastructure, thus increasing the trust factor. Moreover, the semantics captured in subgraphs of the whole COVID-19 resource categorization knowledge graph can provide more domain information and thus significantly improve the performance of machine and deep learning models [69].

The knowledge graph has the capabilities to store a resource and associated metadata about the resource. The metadata is linked to the resources via a well-established relationship mechanism defined in the knowledge graph. These relationships provide a baseline context to the stored resources, making them more explicit and distinctive from each other. Using existing relationships in the knowledge graph could create new types of relations in the knowledge graph. Using reasoning on these extended contextual relationships could help recognize and classify the COVID-19 resources into three explicit categories. In addition, we can seek help from human experts to create an initial set of resources with explicit categorization, which can be used as a seed input to develop a machine learning model. The learned machine learning model can be used as a classification model for resource categorization, and the feature set can be used to create entities and relationships in the knowledge graph.

Moreover, knowledge graph–based representation will be a great source of assistance in data preparation for machine learning models. For instance, the source and target entities associated with each other through a relation communicate a context that is useful in word embeddings. Using machine learning over other graph databases lacks two main components: (1) the metadata related to data, which is coined as lacking a piece of contextual information; and (2) the lack of a functional module, also called the reasoning module, to interpret or transform the actual data in the presence of metadata. The knowledge graph as a source to machine learning exposes the actual data, metadata, and contextual relationships. The additional meta information and contextual relationship improve machine learning outcomes in three main ways. First, the model created from actual data associated with contextual information provides more intelligent predictions or accurate classification. Second, based on the learning patterns of machine learning, the knowledge graph reasoning capability enhances the model with additional rules and generates other contextual relationships. Third, if required (and this depends on the design of the knowledge graph), some information may be inferred by the knowledge graph during modeling and embedded to the learning phase of the machine learning method.

This study’s resource categorization can help develop applications for various purposes for combatting the novel coronavirus. First, it provides a baseline for the further categorization of resources in each level. Further classifications can be introduced in each level to make its use more specialized and customized. Second, it allows for the development of customized search engines for users to obtain results more precisely. Third, it enables specialized dashboards constructed on the information to be structured into three levels. Finally, the proposed framework is extendable to bring clinical and genomic resources together by highlighting their associations to help disease monitoring and tracking.

Acknowledgments

This work was supported in part by the Ministry of Science and ICT (MSIT), South Korea, through the Information Technology Research Center (ITRC) Support Program (IITP-2021-2017-0-01629), and in part by the Institute for Information & Communications Technology Promotion (IITP), through the Korea Government (MSIT) (2017-0-00655, IITP-2021-2020-0-01489, and NRF-2019R1A2C2090504).

Abstract

Background: Simulation study results suggest that COVID-19 contact tracing apps have the potential to achieve pandemic control. Concordantly, high app adoption rates were a stipulated prerequisite for success. Early studies on potential adoption were encouraging. Several factors predicting adoption rates were investigated, especially pertaining to user characteristics. Since then, several countries have released COVID-19 contact tracing apps.

Objective: This study's primary aim is to investigate the quality characteristics of national European COVID-19 contact tracing apps, thereby shifting attention from user to app characteristics. The secondary aim is to investigate associations between app quality and adoption. Finally, app features contributing to higher app quality were identified.

Methods: Eligible COVID-19 contact tracing apps were those released by national health authorities of European Union member states, former member states, and countries of the European Free Trade Association, all countries with comparable legal standards concerning personal data protection and app use voluntariness. The Mobile App Rating Scale was used to assess app quality. An interdisciplinary team, consisting of two health and two human–computer interaction scientists, independently conducted Mobile App Rating Scale ratings. To investigate associations between app quality and adoption rates and infection rates, Bayesian linear regression analyses were conducted.

Results: We discovered 21 national COVID-19 contact tracing apps, all demonstrating high quality overall and high-level functionality, aesthetics, and information quality. However, the average app adoption rate of 22.9% (SD 12.5%) was below the level recommended by simulation studies. Lower levels of engagement-oriented app design were detected, with substantial variations between apps. By regression analyses, the best-case adoption rate was calculated by assuming apps achieve the highest ratings. The mean best-case adoption rates for engagement and overall app quality were 39.5% and 43.6%, respectively. Higher adoption rates were associated with lower cumulative infection rates. Overall, we identified 5 feature categories (symptom assessment and monitoring, regularly updated information, individualization, tracing, and communication) and 14 individual features that contributed to higher app quality. These 14 features were a symptom checker, a symptom diary, statistics on COVID-19, app use, public health instructions and restrictions, information of burden on health care system, assigning personal data, regional updates, control over tracing activity, contact diary, venue check-in, chats, helplines, and app-sharing capacity.

Conclusions: European national health authorities have generally released high quality COVID-19 contact tracing apps, with regard to functionality, aesthetics, and information quality. However, the app's engagement-oriented design generally was of lower quality, even though regression analyses results identify engagement as a promising optimization target to increase adoption rates. Associations between higher app adoption and lower infection rates are consistent with simulation study results, albeit acknowledging that app use might be part of a broader set of protective attitudes and behaviors for self and others. Various features were identified that could guide further engagement-enhancing app development.

KEYWORDS

COVID-19; contact tracing; app-based tracing; Mobile App Rating Scale; user engagement; human–computer interaction

Introduction

COVID-19 Contact Tracing Apps

For the first time, digital technology could play a key role in fighting a global health crisis. Particularly, COVID-19 contact tracing apps have been advocated as a way to achieve pandemic control, avoid or leave lockdowns [1], and return to normalcy [2]. Contact tracing and other nonpharmaceutical measures—like testing, case isolation, quarantining, hygiene, decontamination, and physical distancing—are especially important in situations where vaccinations and effective treatment are not widely available. Even in light of achievements in developing the first available vaccines [3], several countries will have been locked down twice or even three times (eg, Germany and Austria both as of December 2020) before pandemic control is expected to be reached through vaccination dissemination.

The potential advantage of contact tracing apps consists in shared characteristics of digital technology and the SARS-CoV-2 virus: speed and spread. SARS-CoV-2 is being transmitted between people at a high speed. Hinch and colleagues [4] have assumed a generation time for virus transmission of just 6 days and an epidemic doubling time of 3-3.5 days, resulting in a large proportion of the population potentially becoming infected within short periods of time in the absence of any effective intervention. For this reason, modeling study results have continuously suggested that manual contact tracing might be too slow, largely due to personnel limitations, and only feasible in locations with low incidence rates [1,2,5]. Briefly, manual contact tracing is a process by which some index person with confirmed infection reaches out to contact health authority personnel to provide information about other people with whom they have come in contact with and whom they, thereby, might have infected. The health authorities then trace those people to inform them about their possible infection and the necessity that they seek testing or quarantine themselves [5].

Major advantages of digital technology are its large scalability and its potential to speed up the tracing process. Key features of contact tracing apps for COVID-19 consist of informing others immediately of having been in contact with a person who is infected, thus speeding up isolation, testing, and quarantining. Moreover, contact tracing apps with symptom checkers can also reduce testing delay (ie, the time duration between symptom onset and subsequent testing) by immediately referring people to testing facilities [5] and reduce the time of uncertainty by providing test results more quickly. Moreover, digital contact tracing might be more reliable than manual tracing, as it is not affected by recall bias [2], especially of casual contacts, and allows for anonymous contacts to be traced [5]. Finally, once released, contact tracing apps may reach the majority of the population within a short period of time. It is estimated that 3.6 billion people worldwide already had access to a mobile device in 2020 [6]. In Europe alone, 540 million people (72% of the population) are currently in possession of a functional smartphone [6].

App Adoption and Effectiveness

Acceptance by the potential users is the major challenge for COVID-19 contact tracing apps reaching their potential. Simulation studies concordantly emphasize the importance of high rates of app adoption in the population. In a best-case scenario, Xia and Lee [2] found that 90%-95% of the population must use a contact tracing app to stop the spread of COVID-19 and allow normalcy without physical distancing. Based on data for the United Kingdom, Hinch and colleagues [4] found that the pandemic could effectively be suppressed if 80% of smartphone users, or 56% of the population, use a contact tracing app. Kretzschmar and colleagues [5] used data from the Netherlands and investigated different scenarios including adoption rates. In a best-case scenario in which the app adoption rate is 80%, almost 80% of forward transmission could be prevented. Interestingly, even with an adoption rate of 20%, contact tracing apps were more effective than manual tracing, and just 40% of the population needed to use the app to control the pandemic. Yasaka and colleagues [7] found the best results for an adoption rate of 75%, but even a rate 25% could provide some suppression of the infection curve. Similarly, Moreno López and colleagues [8] reported that a 30% adoption rate of tracing apps could be sufficient to reduce the pandemic to a manageable level if the dynamics of infection are moderate. Braithwaite and colleagues [9] presumed a quadratic relationship between a population's app adoption rate (ie, 80% adoption rate) and associated reductions in transmission (ie, 64% of contacts notified). However, assuming an adoption rate of 53%, Kucharski and colleagues [10] suggested that manual tracing is more effective than digital tracing. It should be noted that no empirical data have yet been published, with all the aforementioned numbers merely the result of modeling studies whose parameter settings might be debated (eg, assumptions made by Kucharski and colleagues [10] about the capacity of manual tracing in high incidence situations might be too optimistic). In a recent combined simulation and observational study, Wymant and colleagues [11] found that every 1% increase in app adoption lead to a decrease of 0.8% up to 2.3% in infections. To summarize, these studies suggest that high adoption rates are vital for contact tracing apps to play a key role in fighting COVID-19 but that "lower numbers of app users [would] also have a positive effect" [4].

Initial studies on the intention to download and use a contact tracing app were encouraging. In a large multinational study in Western countries (France, Germany, Italy, the United Kingdom, and the United States), the intention to use a contact tracing app ranged from 68% to 75% [12]. In a Belgian study, 49% of participants intended to use a contact tracing app [13]. In a large study in Ireland, 83% claimed that they would either definitely or probably install a contact tracing app on their smartphone [14]. Additionally, in a Dutch sample, app adoption rates varied between 59% and 66%, depending on the app's features [15].

Numerous factors have been investigated as potential predictors of app adoption. They have included potential users' age, gender, comorbid illness, smartphone use, trust in the government, opt-in installation [12], belonging to a higher risk group, general trust in others, privacy concerns [16], the presence of serious health conditions, level of education, fear of infection, expected general adoption rate in the society [15], attitudes toward protecting family members and friends, feeling responsible to the community, COVID-19–related worry [14], perceived benefits, cues to use the app in the media, and self-efficacy toward properly using the app [13].

Quality Characteristics

Although such personal characteristics, individual expectations, and societal variables are important, quality-related characteristics of contact tracing apps might also play an important role in their acceptance and adoption rates. According to Stoyanov and colleagues [17], a health app's quality characteristics can be subcategorized into those pertaining to engagement, functionality, aesthetics, and information quality. These four dimensions of COVID-19–related app quality were investigated in an early review published by Davalbhakta and colleagues [18], focusing on India, the United States, and the United Kingdom. Most apps provided information on COVID-19 or included symptom checkers. In general, the quality of COVID-19 apps was above average, and apps were designed to achieve higher scores in functionality, while features to make apps engaging and important to the user were not as highly considered. Interestingly, adoption rate (measured through the number of app downloads as a proxy for adoption) was not correlated with app quality. For Europe, Davalbhakta and colleagues [18] claimed that apps generally focus on providing high quality information from credible sources but often lack creative and interactive methods to provide this information. At the time of their review, only two COVID-19 contact tracing apps from national health authorities had been launched in the European Union. Since then, almost all European countries have developed and launched COVID-19 contact tracing apps. To the best of our knowledge, their quality characteristics and actual adoption rates have not been yet systematically investigated.

The primary aim of this study is, therefore, to investigate the quality characteristics of European national COVID-19 contact tracing apps, in terms of their engagement, functionality, aesthetics, and information quality. A secondary aim is to examine quality characteristics and their associations with app adoption rates. Likewise, we will investigate adoption rates and associated numbers of confirmed COVID-19 cases as a measure of pandemic control. Furthermore, we also will analyze features embedded within COVID-19 contact tracing apps. Finally, based on our results and the identification of apps with the highest quality scores, we will provide recommendations for optimizing contact tracing apps and increasing adoption rates.

Methods

Search Strategy

Eligible countries were member states of the European Union, former members (the United Kingdom), and countries of the European Free Trade Association (Switzerland, Iceland, Norway, and Liechtenstein). These countries share similar standards of voluntariness of app use, data protection, and privacy regulations, namely the European General Data Protection Regulation (GDPR) or regulations that are equivalent to these standards. Further inclusion criteria were a tracing app launched by a national health authority, voluntary app use, unrestricted access to the app, English version available, and app launch at least 4 weeks before the review was conducted. To identify all relevant national COVID-19 contact tracing apps, an English Google search was performed using the keywords "corona tracing app," "corona app," and "covid app" combined with the name of each country. For the United Kingdom, we considered England, Scotland, Wales, and Northern Ireland separately. For some countries, no national tracing apps were identified directly; therefore, the search was repeated in each country's main language using translation software. The apps were then downloaded through the Google Play Store or Apple App Store.

Interdisciplinary Quality Rating

Quality characteristics were assessed with the Mobile App Rating Scale (MARS) [17] using the German version [19]. The MARS quality section consists of four subscales: engagement, functionality, aesthetics, and information quality. These scales collectively contain 19 questions that reviewers are asked to respond to using a 5-point response scale (1: inadequate; 2: poor; 3: acceptable; 4: good; 5: excellent). One item directed at the level of evidence of treatments (item 19) was excluded. For each scale, the mean score was calculated, ranging from 1 to 5. The MARS has been shown to exhibit very good internal consistency (α=.90) and interrater reliability (intraclass correlation coefficient [ICC] 0.79) [17].

Four reviewers were used in this study: two researchers with a background in e–mental health and two researchers from the human–computer interaction field. All experts rated the apps independently of each other, after each rater finished the rater training proposed by Messner and colleagues [19] and practiced ratings on 3 apps for depression. The scores were combined and ICCs calculated for each app. In cases of ICCs below 0.75, discrepancies in ratings were discussed until consensus about the rating was reached, as proposed by Messner and colleagues [19]. For the ratings, two devices operating with iOS and two with Android were used.

Adoption Rates

All app developers were asked, via email, to provide the numbers of downloads. In cases of no reply, a reminder was sent after 1 week. If answers from developers could not be attained personally, the number of downloads was extracted from published statistics by national health authorities, app developers, or other publicly available sources. We calculated the percentual of the download count within the population in each country to obtain the overall adoption rate. The total download numbers, numbers of inhabitants, and data of retrieval are available in Multimedia Appendix 1.

Infection Rates

For each country, the number of infected people were obtained from publicly available data from the COVID-19 Dashboard by the Center for Systems and Engineering at Johns Hopkins University [20]. The time span from app release to the date of measuring adoption rate was considered. Numbers are reported in Multimedia Appendix 1.

Statistical Analysis

A mixed methods approach was used for this review. For the MARS total score and each subscale, the mean score was calculated and reported, ranging from 1 to 5. ICCs were calculated using a two-way mixed effects average measures model with absolute agreement [17]. To explore associations between contact tracing app quality characteristics and adoption rates, scatterplots and trend lines were presented together with univariate ordinary least squares (OLS) and Bayesian regression analysis [21]. Due to the expected low sample size of European contact tracing apps, any significance testing and relying on *P* values are highly likely to miss existing associations (type II error). Therefore, we focused on effect sizes and reported all associations exceeding a medium effect size, as recommended by Cohen [22].

Additionally, we calculated adoption rates for best-case scenarios (best-case adoption rate [BCAR]), assuming that app quality characteristics were optimized (five points on the MARS). The same analyses were conducted to investigate associations between adoption rates and measures of pandemic control.

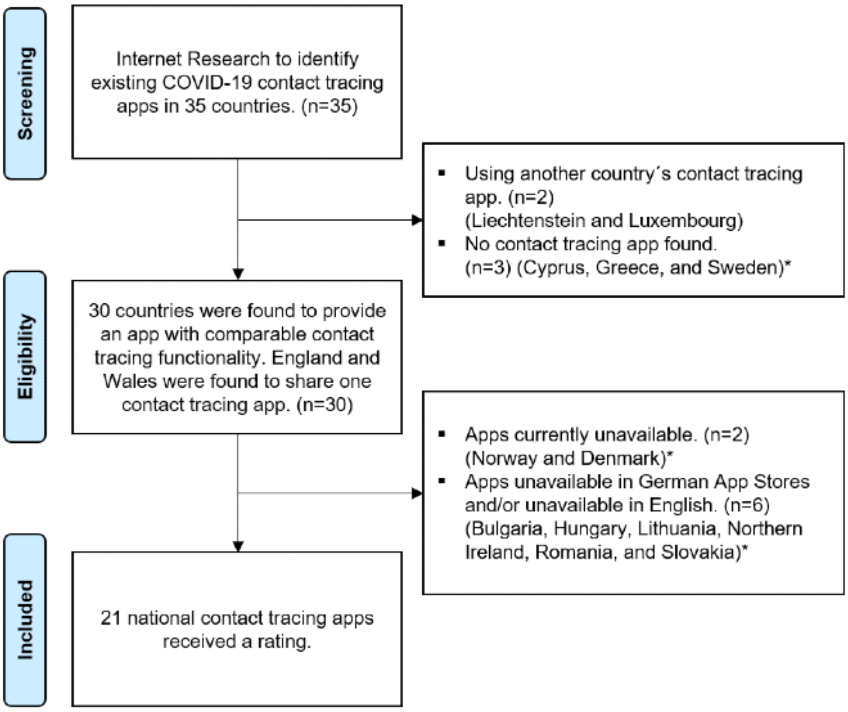
As part of our qualitative analysis, all raters were instructed to identify features of the tracing apps that, in their opinion, might increase user engagement and adoption rates. Features were identified by all raters and then discussed and classified by all authors. As a result, all apps were analyzed with respect to the features they offered. Additionally, apps with high scores on the various MARS items were presented as examples of best practice. Finally, MARS ratings, identified features, and best practice guided recommendations for optimizing acceptance and adoption of COVID-19 contact tracing apps are proposed.

Results

Search

We identified 21 contact tracing apps that we then included in our quality review. For a detailed description of the search process, see Figure 1.

Figure 1. App selection process flowchart.



*Screening was finished 1st of November 2020; Apps / English versions may be available by now.

Interdisciplinary Quality Rating

For 17 apps, ICCs between 0.75 and 0.89 were detected, indicating good interrater reliability, while excellent interrater reliability (ICC>0.90) was observed for 2 apps. Due to low ICCs, ratings for 2 apps needed to be discussed, resulting in moderate ICCs of 0.70 (France) and 0.65 (Poland) [23].

In general, the average MARS total score was 3.97, indicating above average app quality, with mean scores ranging from 3.53 to 4.42 (see Table 1 and Figure 2). The Irish app was rated best (MARS ∅=4.42), almost 1 SD above the app with the second highest rating (Finland; MARS ∅=4.24). With regard to app quality characteristics, functionality, aesthetics, and information quality scored over 4 points. High scores for information quality and functionality were especially associated with low variance, indicating small differences between the apps (Table 1). The scores for engagement were lower, on average, and the differences between apps larger. Although high scores for functionality reflect a ceiling effect and scores for aesthetics and information quality a close-to-ceiling effect, lower scores for engagement indicate opportunities for improvement.

Table 1. MARS rating scores on all apps (N=21).

Country	App name	MARS[a] total	Engagement	Functionality	Aesthetics	Information	Downloads, n	Adoption rate (%)
All, mean (SD)	N/A[b]	3.97 (0.22)	3.34 (0.45)	4.43 (0.28)	4.16 (0.37)	4.09 (0.18)	97,097,051	22.92 (12.51)

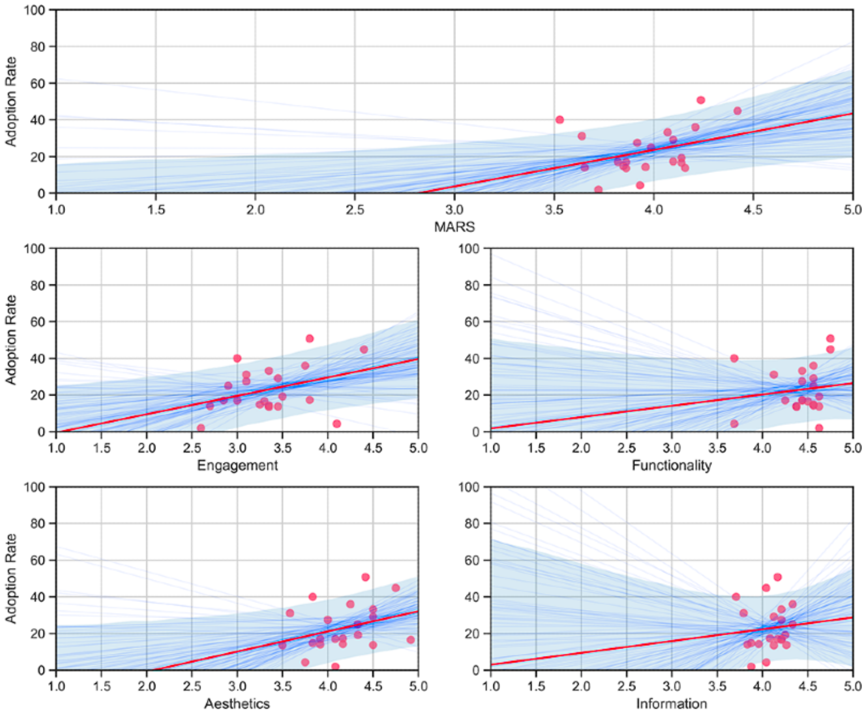
[a] MARS: Mobile App Rating Scale.

[b] N/A: not applicable.

Figure 2. Bayesian regression with trend lines and 80% CIs (blue shaded area) for app characteristics and adoption of COVID-19 contact tracing apps. MARS: Mobile App Rating Scale.



Adoption Rate

European COVID-19 contact tracing apps had an average population adoption rate of 23%, with high variation between countries, indicated by an SD of 12.5%. Taking different population sizes into account, the overall adoption rate was estimated at 22%. Adoption varied between the highest rates for Finland (51%), Ireland (45%), and Iceland (40%), and the lowest for the Czech Republic (14%). Poland (4%) and Croatia (2%) were considered low adoption outliers. Data on app release are summarized in Multimedia Appendix 1.

App Quality Characteristics and Adoption Rates

The MARS total score and two dimensions of quality characteristics exceeded the minimum threshold for an intermediate strength correlation: general app quality (MARS total score; R=0.35), engagement (R=0.35), and aesthetics (R=0.31). To calculate the BCAR, we conducted a univariate Bayesian linear regression using 20,000 Markov chain Monte Carlo draws for each app characteristic. Results are presented in Table 2 and Figure 2. This analysis yielded one BCAR distribution per app characteristic (Figure 3), resulting in a mean BCAR of 44% for apps with maximum general app quality, 40% for apps designed in the most engaging way, and 32% for apps with maximum scores for aesthetic design. Among app quality characteristics with high average scores—functionality and information quality—no associations exceeded the minimum threshold.

Table 2. Regression analysis app characteristics correlated with moderate-effect sizes for adoption of COVID-19 tracing apps (results for Bayesian regression are based on 20,000 draws).

Predictor	R	Intercept, mean (SD)	*t* test (*df*)	Slope, mean (SD)	*t* test (*df*)	BCAR[a,b] 10% percentile	BCAR	BCAR 90% percentile
MARS[c] total score	0.349	–55.68 (50.43)	1.10 (19)	19.82 (12.69)	1.56 (19)	25.28	43.56	61.21
Quality characteristics (dimensions)

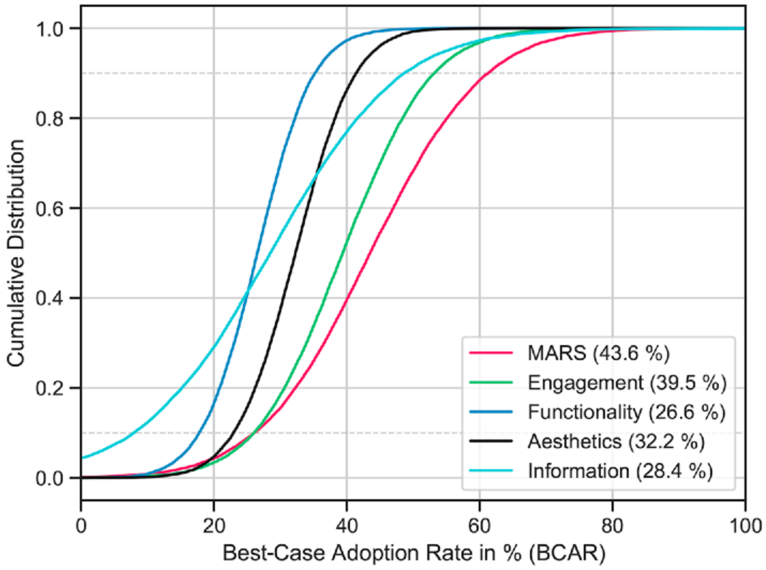
[a] BCAR: best-case adoption rate.

[b] BCARs are assuming maximum MARS scores.

[c] MARS: Mobile App Rating Scale.

Figure 3. Cumulative distribution of the BCAR; numbers in brackets indicate the mean BCAR for specific app characteristics. BCAR: best-case adoption rate; MARS: Mobile App Rating Scale.

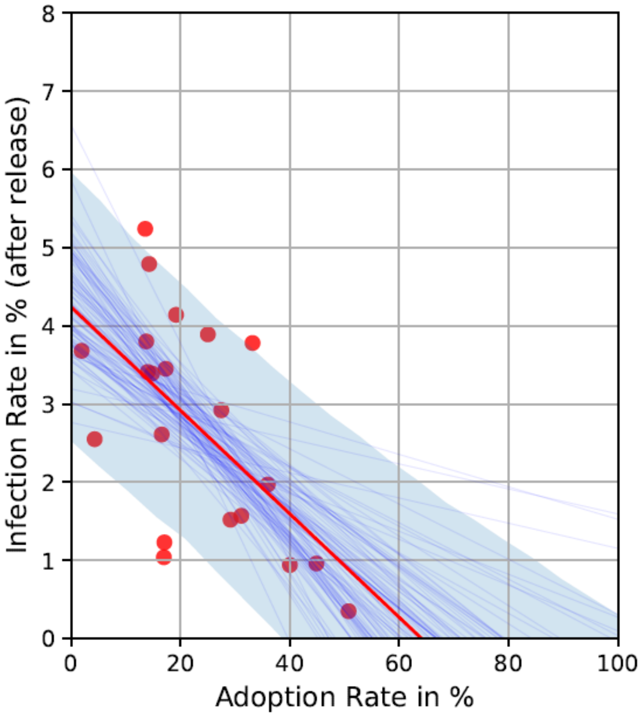


For 18 specific quality characteristics, six MARS items were correlated with higher adoption rates with at least a medium level effect (Table 2). Higher ratings for interesting use facilitating frequent engagement correlated with higher adoption (item 2; R=0.41) and an above average BCAR of 33%. More interactive apps—allowing user input, providing feedback, and containing prompts (item 4)—were directly correlated with app adoption (R=0.30; BCAR 40%). Likewise, appropriate app design for the target group (item 5) was correlated with the app adoption rate (item 5; R=0.49, BCAR 32%). These three specific app characteristics are part of the engagement dimension. Item 11 considers the quality of graphics and visual design of buttons, icons, menus, and content as part of the aesthetic dimension. Higher scores were correlated with higher adoption rates (R=0.32; BCAR 29%). The accuracy of the app description in app stores (item 13) and the quantity of information (item 16) represent facets of the information quality dimension. A highly accurate description of the components and functions of the app was correlated with higher adoption rates (R=0.42; BCAR 28%). Likewise, comprehensive and concise information with links to more information and resources was correlated positively with adoption (R=0.41; BCAR 28%). The regression model for the target group was the only one with significant effects.

App Adoption and Infection Rates

Next, the associations between app adoption rates and infection rates due to COVID-19 were investigated (see Figure 4). Results for Bayesian regression based on 20,000 draws suggested an inverse correlation between app adoption and infection rates after app release: the higher the adoption rate, the lower the rate of infections (r=–0.606; *P*=.004). Based on numbers at the time of assessing adoption (mean 22.92) and infection (mean 3.05) rates, the results indicated that a 1-point increase in adoption is associated with a 0.07 percentage points decrease in infection rate, representing a change in infection rate of 2.30%. According to the OLS regression (y = 4.23 + –0.07 * x), a zero rate of infections (trend line intersects x-axis) is reached if the adoption rate equals 60.43%. The SD of the intercept was 0.57 (t_{19}=7.36), and for the slope, it was 0.02 (t_{19}=2.99). Excluding low adopting outliers, the effects were even more pronounced for infection rates (r=–0.656; *P*=.002).

Figure 4. Bayesian regression with trend lines and 80% CI for app adoption of COVID-19 contact tracing apps and infection rate after app release.



Features of COVID-19 Contact Tracing Apps

On qualitative analysis, various features of the COVID-19 contact tracing apps were identified that might contribute to higher adoption rates. This section gives an overview of features implemented by presenting best practice examples. We focus on features that contributed to higher ratings in each MARS dimension.

Engagement

Most features aimed to increase users' engagement with the app. Table 3 provides an overview of features believed to enhance engagement beyond the core functionality of contact tracing. Apps with high scores on engagement—like those in Ireland, Poland, Finland, France, and England and Wales (see Table 1)—provided best practice examples.

Table 3. Features of COVID-19 contact tracing apps contributing to engagement.

[q] MT: Malta.

[r] NL: Netherlands.

[s] PL: Poland.

[t] PT: Portugal.

[u] SC: Scotland.

[v] SI: Slovenia.

[w] Symptom checker: symptom checker is used only if required.

[x] Included in this app.

[y] Not included in this app.

[z] Indicates that features are displayed on an external website.

[aa] Symptom diary: symptoms are monitored daily and symptom history is saved.

[ab] Statistics on COVID-19: numerical information regarding infections, deaths, tested, etc.

[ac] App use: numbers of app downloads, transferred positive COVID-19 tests, warnings from the app, etc.

[ad] Public health instructions/restrictions: app links to current information on the pandemic, for example, on how to protect oneself from the virus or which restrictions are currently in place.

[ae] Burden on health care system: numerical information on available intensive care units, numbers of COVID-19 cases hospitalized, etc.

[af] Assigning personal data: potential to provide personal data (telephone number, nickname, postal code).

[ag] Updates on assigned region: updates on the status of assigned region of residence.

[ah] Control over tracing activity: potential to disable tracing in app settings.

[ai] Contact diary: users can document their contacts.

[aj] Venue check-in: using a Quick Response code, users check into venues.

[ak] Chat: app provides a chat function.

[al] COVID-19–related helplines: app provides telephone numbers to seek help (medical).

[am] Sharing: app has a (prominently displayed) button so the app can be shared.

Interest

Several apps provided a *symptom checker.* They included a series of COVID-19–specific questions and provided individual feedback and recommendations. Typically, users could assess the occurrence and intensity of symptoms and receive recommendations for appropriate action (eg, scheduling an appointment at a test center). Users were free to check symptoms as often as they wished. Some apps addressed the benefits of checking symptoms by providing a link to an external website. Accordingly, users had to leave the app, and those apps could not make use of any data on the external website. However, most symptom checkers saved symptomatic data and included a history of symptoms within the app. In this case, a *symptom diary* was coded. The symptom diary enabled users to monitor symptoms that were displayed using a numeric and text-based design. Graphic displays to present the course of symptoms were not observed. Noteworthy is that the checking feature implemented in the Polish app was a combined *risk group checker* and symptom checker. Therefore, users must indicate age and any pre-existing illness (eg, obesity along with current symptoms), and feedback probably was provided by taking all this information into account. A separate risk group checker informing users about, for example, any increased risk of severe COVID-19 symptoms, was not identified in any app. Besides the symptom diary, a *contact diary* was observed in 1 app (Poland). Users can take written notes on each contact, which helps them to remember contacts and give more detailed information in case of infection. Other modes of contact diary input or output—like speech, picture, or location-based notes—were not found. All these checking and monitoring features lead to higher scores for engagement, as they provide added value and invite users to interact with the app more often.

Features providing new and relevant information contributed to higher scores in engagement as well. First, several apps informed the users about current numbers of newly infected people and the number of infected people who had died (see Table 3). Second, some apps provided information on public health measures, like current restrictions during a lockdown. Third, users receive information on the capacity of and burden on the health care system (eg, current number of hospitalized patients or occupied beds in intensive care units, as done with the French app). Fourth, some have features informing users about the number of downloads, thereby informing them about the size of the app-using community and motivating them to share the app with others. Fifth, a few apps additionally informed users about the protective behaviors of other users (eg, number of shared positive test results; see Swiss app) or about others' self-protective behaviors, like the number of users that conducted a symptom check that day (see Irish app). Such features were rated positively, as they can strengthen a sense of belonging to a community of people who take the pandemic seriously and care for one another. However, it should be noted that apps provided this information differently: sometimes directly included in the app, while others provided a link to an external website, thereby, interrupting users' engagement with the app.

Although paper-and-pencil lists were used in several countries to document visitors (eg, museums) or customers (eg, restaurants), the *venue check-in* (see English and Welsh app) offered a digital solution as part of their tracing app by scanning the QR (Quick Response) codes of pertinent venues. As all visitors are registered with a time stamp, it is possible to exchange information on infections quickly and reliably.

Customization

Several features were identified that contributed to higher customization ratings. First, with regard to visual customization, the Portuguese app offered users the opportunity to switch between different themes: dark mode, light mode, and automatic. In this way, users can choose the mode that appeals most to them, as opposed to most other apps, which were designed using a one-size-fits-all strategy. Second, there was one example of a customized welcome message (Polish app); with this, users could voluntarily assign themselves a nickname to receive a personalized welcome while using the app. Third, some apps provide regional customization, like the English and Welsh app, so users can receive news about the status of COVID-19 in their own region of residence. To facilitate the identification of COVID-19 hot spots, the Italian app asked users to indicate their region of residence. Fourth, users can customize the channel of support by voluntarily providing their phone number as a callback option (Irish and Latvian apps). Fifth, most apps offer to customize tracing functionality, meaning that users can pause contact tracing. Most of these customization options were voluntary. However, to be able to use the app, it was sometimes mandatory for users to indicate their postal code (England and Wales) or provide their telephone number (Iceland).

Interactivity

High interactivity facilitates interactions between users or considers the interaction between the user and the app. First, interactive symptom diaries and checkers were rated higher than noninteractive versions of these features (eg, the app links to a symptom checker on an external website). A high level of interactivity also is achieved if symptoms can be checked within the app and feedback provided based on the results, for example, with recommendations regarding self-isolation and taking a test (English and Welsh app) or friendly, encouraging feedback when no symptoms are reported (Irish app). Likewise, the interactive risk group checker provided individual feedback. Lower interactivity was deemed present in apps that merely included links to external websites to assess potential symptoms of COVID-19. Second, features that allow users to share the app with their family and friends in an easy and comfortable way contributed to higher ratings for interactivity (eg, the Dutch app). Third, 1 app provided users the option of interacting directly with health officials via chat (Iceland).

Target Group

Adequate consideration of the target group relates to intended users' sociodemographic characteristics, preferences, and needs. First, all reviewed apps were rated to be designed for the average user and the whole population, irrespective of user age, gender, or socioeconomic background. Apps received higher scores when the language used was easy to understand. Within most apps' illustrations, the icons and images supported textual information and contributed to better understanding. Likewise, almost all the apps were designed according to current trends and standards. Noteworthy is that illustrations within the English and Welsh app were designed to represent a diverse society with people from different cultures. Second, the target group can also be characterized by their needs and expectations (eg, the need for predictability, users feeling well prepared when they receive an alert, or using the app to share one's own positive test result with others). The Dutch app provides a good example for a preview on how the app will alert the user in the event of a detected encounter with a person who has tested positive. To do so, this app uses explanatory text paired with graphic support.

Functionality, Aesthetics, and Information

In general, the functionality, aesthetics, and information quality of all the apps were rated highly, with minimal variance between the ratings. Therefore, only a few features were identified that could make a difference and potentially increase users' adoption of the app. According to their MARS ratings, the rater team identified best practice examples of app features for each dimension: the Finish and Irish apps provide good examples for functionality, the Italian for aesthetics, and the Dutch and English/Welsh apps for information.

High scores for functionality were achieved by most of the apps, as they performed very well. Their structure was easy to understand because content areas were often clearly separated by card-based layouts and marked with headings. Additionally, all the apps were easy to use. In terms of navigation, some differences appeared. For example, tab navigation with icons and text in the footer and metanavigation integrated into the header was rated highly, as this configuration allows easy orientation (ie, Irish and Portuguese apps).

Most apps were rated highly with regard to aesthetics, with the graphic design of most corresponding to design trends of the years 2020 and 2021 (based on research by creative platforms, creative experts, and agencies), thereby making them attractive for most people. All apps used sans serif fonts and almost all preferred illustrations over photos. Most apps and almost all illustrations appeared in flat design, sometimes in combination with light background gradients or background circles. The character designs often appeared on monochrome backgrounds (eg, Belgium, Germany, and Slovenia) in analogue color schemes (eg, Italy and Finland) or with complementary color schemes (eg, Germany and the Netherlands), presumably to focus on the content or the message of the illustrations, rather than to illustrate the app's functionality. Disproportionate body parts embodied the character design of some apps (eg, Italy), for example, with small heads on large bodies with large limbs, while detailed facial features were largely avoided. The modern line art style was used especially for icons in most apps (eg, Finland's navigation tabs). Meanwhile, with the Estonian app, this style was used for the entire app's appearance. The use of curved lines was an exception only observed with the Latvian app. Buttons often appeared haptic, with drop shadows compared to illustrations, making it easier for users to identify elements of the interface that they can interact with.

Apps with the highest aesthetics ratings used different font styles with high contrast and strong, saturated colors for components of the interface design. Visual information groups were formed using the law of proximity, in the form of cards, spaces between components, and white space in general. Based on our assessment of the apps, visual appeal was mostly characterized by flawless graphics and a uniform and professional design. Small animations bring graphics to life (eg, Italy), stimulating positive feelings in users.

High ratings for information quality were achieved by high-level accuracy in app descriptions in app stores, reflecting the app's actual functionality. Likewise, the apps' goals were well described in the stores or within the apps. Some differences were observed in the extent to which illustrations and visualizations (tables, images, graphics) were used to deliver information. Generally, apps with more illustrations and visualizations were rated higher. Credibility of information was rated high, as all apps were published by the health authorities in their country of use. Noteworthy is the Dutch app, a good example of providing concise and helpful information on how to use the app. For example, users can easily understand how the app will warn them if they ever come in contact with a person testing positive for COVID-19.

Discussion

General Findings

This study investigated quality characteristics among European COVID-19 contact tracing apps and explored these characteristics' associations with user adoption rates. In general, scores for functionality, aesthetics, and information quality were high, and differences between the apps were minor. However, the quality of features aiming to increase users' engagement with the app was lower, on average, with substantial differences between the apps that reflected large differences in adoption rates. Alongside quality ratings, we identified engagement-friendly features implemented in tracing apps that contribute to the higher quality of those apps, may guide further development, and could increase the acceptance and adoption of contact tracing apps in the general population. These engagement-friendly features are presented within nine recommendations for an engagement-oriented design for COVID-19 contact tracing apps.

Findings in Context

Comparing the level of quality observed in our study to the earlier review by Davalbhakta and colleagues [18], there is increased quality of the COVID-19 contact tracing apps, with an overall MARS rating 0.52 points higher, a 13% increase. Especially with regard to information quality (+0.83) and aesthetics (+0.68), apps achieved higher ratings, while scores for functionality were almost unchanged. This overall improvement is probably because the apps assessed in this study were in place later in 2020, meaning that developers simply had more time to improve features like aesthetics and engagement beyond tracing core functionality. Differences in information quality might be explained by all the apps in this study having been released by the countries' own national health authorities. Interestingly, the relative order in tracing apps' quality—with functionality scoring highest, followed by aesthetics and information quality, and engagement lowest—found both in our study and the study conducted by Davalbhakta and colleagues [18] has also been observed in apps for other health conditions, like rheumatism [24], heart failure [25], and posttraumatic stress disorder [26], and for health behaviors, like physical activity [27], and might indicate a general underemphasize of engagement-friendly designs for health-targeted apps. Overall, adoption rates were substantially lower than anticipated, based on the results of early acceptability studies [12,15], and lower than several simulation studies found to achieve pandemic control [2,4,7]. However, the observed average adoption rate was close to 25%, which was a lower threshold for a suppressive effect of tracing apps on the infection curve in the study of Yasaka and colleagues [7], while Wymant and colleagues [11] highlighted that every 1% increase in app adoption leads to a meaningful decrease in infections. With regard to acceptability studies, the discrepancy might be explained by the gap between intention to use a tracing app and actual behavior, a phenomenon known as the intention–behavior gap [28]. Another explanation is the reliance on nonrepresentative samples and the use of digital surveys that might be preferred by people with positive attitudes toward digital apps [29].

App Design and App Adoption

Low adoption rates may also be the result of app design. To the best of our knowledge, this is the first study to investigate the association between app quality characteristics and actual adoption rates for national COVID-19 contact tracing apps. Bayesian regression analyses suggest that adoption rates can be increased by optimizing app quality characteristics. In our analysis, optimizing engagement features appeared to be associated with higher adoption rates, relative to strategies focused on functionality, aesthetics, or information quality. This finding has several implications. First, one promising strategy, from an app design perspective, appears to be to focus on engagement. Second, the app's level of engagement is a modifiable factor that can quickly be made the target of developers and public health actions. Other factors that are associated with the acceptance of tracing apps are either not or minimally modifiable, like potential users' age, gender, comorbidities, medical preconditions, level of education, household income, and trust in the government [12,30]. Third, it is not enough for tracing apps to trace and warn users properly. They should also be designed in a way that makes them interesting to use, stimulate repeated engagement with the app, offer customization and tailoring to personal preferences, allow user input, and provide feedback. Fourth, the predicted adoption rate in the case of optimal engagement was 40%. This potential increase is comparable or even larger than the 17% increase in adoption recently identified for monetary incentives for installing a COVID-19 contact tracing app [30]. Although it might be speculated that such different adoption-increasing interventions have an additional effect on adoption rates, a compensatory effect is possible. Finally, given the importance and potential impact on user rates of engagement-friendly app designs, this topic might deserve as much attention as data security and privacy issues.

App Adoption and Infection Rates

Another important finding of this study was the association between higher app adoption rates and lower infection rates. As association is not necessarily causation and confounders have to be considered, results should be discussed and interpreted from different perspectives. First, following the line of reasoning that using tracing apps leads to lower infection, it is of interest that the predicted adoption rate of 60% in this empirical observational study required achieving a zero infection rate that was between the adoption rates reported for simulation studies by Hinch and colleagues [4] and Xia and Lee [2]. Congruent with simulation studies, our results may indicate a beneficial effect of COVID-19 contact tracing apps, in terms of controlling the pandemic. Similarly, in a combined empirical observational and modeling study, Wymant and colleagues [11] found that app adoption as measured by downloads is an indicator of active use, and higher app use leads to lower infections. Interestingly, compared to the findings of Wymant and colleagues [11], in our study, we observed almost the same effect of app adoption, namely, a 1% increase in app adoption was associated with a 2.3% reduction in infections. Second, the association might also be explained by reverse causality. Growing infection rates (eg, in the beginning of the second wave) could trigger fear, which in turn may increase app adoption. Building on the well-investigated effects of fear on health behavior change, it is possible that some individuals adopted tracings apps as a consequence of an increased perceived threat. However, it was found that the effect of fear on behavior is rather limited [31], and sometimes fear could also lead to undesired consequences (eg, avoidance) [32]. Therefore, the association between adoption and infection may partly but not largely be explained by reverse causality. In line with our results on the importance of engagement-friendly app design, it is also possible that spikes in incidences may raise awareness for the existence of tracing apps and motivate individuals to download apps given the precondition that apps are perceived as beneficial and engaging. Third, it seems likely that third variables play a considerable role in explaining the overserved association, as we found no country using tracing apps as the only nonpharmaceutical measure. In fact, they are used in concert with a multitude of other nonpharmaceutical interventions [33]. For example, app users are also more likely to adhere to other public health measures, like adherence to social distancing recommendations, wearing a mask, and washing hands [30]. Accordingly, tracing app use probably represents one specific health behavior that is part of a broader set of protective attitudes and behaviors for self and others. Depending on the respective national policy, app use could facilitate and boost other measures (eg, testing as a consequence on exposure notification or results from an app symptom checker) [11]. In this case COVID-19 tracing apps could also be considered as a hub for a multitude of measures to fight the pandemic. Accordingly, it is difficult to disentangle the unique contribution of tracing apps, and interactions between measures should be considered when interpreting the considerable strong association between app adoption and infection.

Features and Recommendations

The features identified in this study using MARS as a guiding framework include those mentioned in prior reviews, such as self-monitoring, symptom checking [18,34], and contacts to helplines [35]. Although information or news related to COVID-19 represent broad categories [18,35], this study provides a more detailed description of existing features; for example, by differentiating between information content and purpose. Moreover, new features were observed like venue check-in, contact diary, and providing users control over tracing activity within the app. Generally, we observed a tendency toward multifeature COVID-19 contact tracing apps. Although apps evaluated earlier generally were limited to specific functionalities and features (eg, separate apps for tracing, symptom checking, and information dissemination [18]), apps reviewed later in 2020 seem to incorporate different features, thereby making the COVID-19 contact tracing app a broader hub for preventing COVID-19 transmission. Likewise, Collado-Borrell and colleagues [35] found that most apps had more than one purpose.

Based on best practice examples and the features observed in existing apps, recommendations were derived to foster an engagement-oriented app design (see Textbox 1).

Textbox 1. Recommendations for an engagement-oriented design for COVID-19 contact tracing apps.

- Strive for a multifeature tracing app and avoid a trace-and-warn functionality only app. Offer additional features that make daily living during the pandemic more convenient and secure (eg, by replacing paper contact lists with a digital venue check-in).
- Make the app interesting and relevant to stimulate daily use by providing useful information (eg, current infection rates; intensive care unit capacities; lockdown rules; and legal regulations pertaining to schools, work, commuting, etc)
- Make the app as regionally targeted as possible, indicating the region most relevant to each particular user's daily life, since public health measures (eg, regional lockdown rules) might only apply to certain regions. Matching the app's level of regionality to local applied public health measures might increase user acceptance and adherence.
- Address the need of relatedness and create a virtual community of people who are committed to protecting themselves and others (eg, by making sharing the app as easy and obvious as possible). Provide feedback on other users' protective behaviors toward self and others (eg, indicating the number of people using the app or sharing a positive test result).
- Include interactive and personalized features, like risk group and symptom checkers, and a symptom diary with individual feedback and recommendations. Such features encourage protective behaviors for both self and others, including early testing. They provide additional beneficial features to the user, stimulating frequent use, while personalization makes the app more relevant to users.
- Account for suboptimal connectivity between app users and extend the benefits of the digital solution to those not using a tracing app. For example, a venue check-in serves as a double safeguard, while a contact diary helps to inform those not using an app, thereby increasing the app's overall effectiveness.
- Reduce uncertainty and provide users with a clear picture of what will happen in case of infection. Succinctly and clearly describe what exactly the app will do if the user comes in contact with a person who is infected and how infected users can inform others.
- Adhere to current design trends to make the app visually appealing to as many as possible. Allow customized layouts or consider different graphic layouts for different target groups—like younger children, teenagers, and older adults—to better meet their needs and expectations. Prefer the currently widely employed tab navigation, hamburger menu, and card-based layout.
- Address the need of autonomy by providing users with full information and control over data. Settings should be customizable in both directions, allowing users to either pause and delete or share more detailed personal data than currently required.

Recommendations based on the reviewed best practice examples are consistent with other studies on features designed to increase user engagement with mobile health apps [36], especially those providing diary or note-taking functionality, health monitoring features, personalized feedback, personalized information matched to user characteristics (like their region of residence), providing autonomy through customizable settings, and screen design and navigation. Besides inspiration from existing apps and features, recommendations for further development could be driven by either the literature [36-38] or upcoming challenges over the course of the pandemic. First, rewards should be used more intensively (eg, for opening the app, sharing a positive test result with others, or recommending the app to others). Second, notifications and reminders on, for example, updated information or keeping a diary are likely to increase engagement with the app. Third, the perception of personal benefits is a facilitator of contact tracing and may be achieved by providing feedback on what the app has done for the user. Likewise, addressing collective responsibility is likely to facilitate engagement, for example, by providing feedback and rewards on what the user has done for the community and what the community has contributed to pandemic control, or by setting collective goals, for example, pertaining to the number of app recommendations or downloaded apps. Fourth, rewards and incentives could also be linked to the national health policy (eg, access to free of charge testing could be offered to users that received an alert or obtained critical results from a symptom checker). Likewise, using a venue check-in could be rewarded by easier access to social events. Such rewarding *health policy–related app characteristics* seem to have the potential to further increase app adoption. However, those health policy–related characteristics should be developed and implemented in close collaboration with lay publics such as civil society representatives, advocacy groups, and nongovernmental organizations [39]. Fifth, as greater interactivity and personalized features of tracing apps require more personal information (eg, information on regional lockdown rules require information on the user's location), it is even more important to implement the highest standards of transparency, data privacy, and control over personal data. Nevertheless, implementing those features seems important, as a recent study by Meier and colleagues [40] found that the perceived benefits of tracing apps are more important for the intention to use an app than privacy concerns from a user perspective.

As the percentage of people who have been vaccinated increases, two strategies are possible: tracing app promotion can be slowed or their functionality adapted to the changing situation. The latter should be considered an adaptive strategy, capitalizing on the observation that millions have downloaded the app and the premise that digital solutions to upcoming challenges could be useful. Such an adaptive strategy consists of slowly stepping down tracing features while stepping up the number of features designed to manage the pandemic's next phase, starting with the option of informing others if they have had contact with a vaccinated and, hence, potentially less infectious person [41] or one who has not yet been vaccinated. The adaptive strategy could include features designed to increase the rate of vaccinations, shifting the target behavior from tracing to undergoing vaccination. It might provide useful and personalized information; support users making appointments for health assessments, treatment, or vaccinations; report adverse or long-term effects; or aid users wanting to contact health care professionals. Designing adaptive tracing apps that are capable of changing their focus depending on a pandemic's life cycle appears feasible, of benefit to protecting public health, and worthy of further investigation.

Study Strengths

First, to evaluate quality characteristics, we systematically used an interdisciplinary approach by gathering a team of experts providing both digital health and human–computer interaction perspectives. All the apps were evaluated by four independent raters with two experts from digital health science and two from human–computer interaction research. Second, we included national apps from countries with similar identical legal regulations on voluntariness, privacy, and data protection. By the time this study was conducted, all countries adhered to the European GDPR or equivalent regulations. Therefore, confounding factors related to voluntariness, privacy, and data protection standards are unlikely to affect results to a greater extent. Nevertheless, differences in the integration of tracing apps into the respective health care system and national strategy to fight the pandemic exist.

Third, we investigated associations between app quality characteristics, actual national adoption rates, and infection rates. For the first time, results indicated a direct association between app quality characteristics and adoption rates that were, in turn, associated with lower infection rates. Although causality cannot be inferred from observational data, these results are consistent with prior simulation studies. Unless contradictory experimental data become available, our results should encourage app developers and policy makers to focus more on developing engagement-friendly designs for COVID-19 contact tracing apps to potentially enhance pandemic control. Third, prior reviews investigated all kinds of COVID-19–related apps, including apps with nontracing functionality (eg, only providing information to patients or health care professionals) and apps developed by both governmental and nongovernmental (eg, private technology) agencies [18,34,35]. This study focused entirely on COVID-19 contact tracing apps released by national health authorities, rendering the results especially important to public health officials and policy makers. Fourth, this study provides an estimation on potentially achievable adoption rates in case of optimal app design. For an optimistic outlook, the upper bound of the BCAR 80% highest density interval suggested an adoption rate of 61% for maximum MARS total scores and 54% for maximum engagement scores. However, these estimates also point to the necessity of additional measures beyond app-based digital contact tracing, as adoption rates are still below the thresholds indicated by simulation studies. Especially for younger children or older adults (eg, those with dementia), wearables may be an option to increase the overall adoption of digital contract tracing in the population [2].

Study Limitations

Several study limitations must be considered. First, app development is an ongoing and dynamic process. Consequently, this review merely provides a snapshot of the current status of app quality. The study is not a final report investigating the success or failure of specific national apps or digital contact tracing in general. Instead, it aims to support developers and public health policy makers striving to improve COVID-19 contact tracing apps, focusing on a predetermined set of important, yet limited, app quality characteristics evaluated by the MARS. Second, the number of downloaded apps was used as our measure of app adoption, and more precise measures exist, like the number of times a user opens the app, how long an app is used, and how many positive test results are shared. Moreover, we do not know the percentage of users who uninstalled the app. In one Swiss study, the uninstallation rate was 5% [29]. On the other hand, more precise measures conflict with data privacy, and the number of downloads was the only measure that was widely available to us. Third, item 15 of the MARS indicates that the correctness of information and scores might be biased toward more positive ratings. In cases of uncertainty, we assumed higher values, mainly because all the apps were released by credible sources: national health authorities. From a technical perspective, we were unable to determine if sensors worked properly and, therefore, if the information on contacts was reliable and accurate. From a medical perspective, COVID-19–related information was not reviewed by an independent board of virologists. However, we are not aware of any leading virologists who have criticized the information provided by any of the tracing apps we reviewed. Likewise, we had no information on diagnostic accuracy (ie, the sensitivity, specificity, and positive and negative predictive values of personal risk evaluations or symptom checkers). App developers should strive to include validated tools, since one study by Munsch and colleagues [42] found that some symptom checkers performed no better than random guessing, while some were highly sensitive, others highly specific, and only two both adequately sensitive and specific. Fourth, MARS, the instrument used in this study, does not include a section on privacy and security, a topic that was widely discussed in the media in the early phases of tracing app development [43]. Vokinger and colleagues [44] recently provided a framework for evaluating this issue in COVID-19 tracing apps.

Fifth, we focused exclusively on the characteristics of tracing apps and were unable to assess how these apps were embedded in the overall health care system or whether there were changes over time in the way tracing apps were embedded. Finally, we only assessed the international English version of each app and did not rule out the possibility that app versions in the language of the app's country of origin might include more information or features.

Conclusions

The member states of the European Union, associated countries, and former members with almost identical legal regulations on the voluntariness of use and data protection regulations serve as an excellent real-life laboratory for investigating tracing apps that have been released by the various national health authorities. All 21 national COVID-19 contact tracing apps that we evaluated demonstrated high levels of functionality, aesthetics, and information quality. Although, adoption rates were below the desired levels recommended by several simulation studies investigating the impact of digital contract tracing, while other research indicates that every additional percent app adoption is important. Our results suggest that engagement-friendly app design has the potential to gain those additional percentages. We found a lower level of an engagement-friendly app design, with substantial variations between the various apps. Moreover, app designs that raters considered more engagement-oriented were generally linked to higher app adoption rates, which makes developing more engagement-friendly app designs a promising target as countries strive to optimize their COVID-19 contact tracing apps. Several specific recommendations based on best practice examples were provided. The association we observed between higher app adoption rates and lower infection rates are consistent with predictions from simulation studies and—despite limitations—could indicate that COVID-19 contact tracing apps could contribute to flattening COVID-19 curves.

Abstract

Background: Before the advent of an effective vaccine, nonpharmaceutical interventions, such as mask-wearing, social distancing, and lockdowns, have been the primary measures to combat the COVID-19 pandemic. Such measures are highly effective when there is high population-wide adherence, which requires information on current risks posed by the pandemic alongside a clear exposition of the rules and guidelines in place.

Objective: Here we analyzed online news media coverage of COVID-19. We quantified the total volume of COVID-19 articles, their sentiment polarization, and leading subtopics to act as a reference to inform future communication strategies.

Methods: We collected 26 million news articles from the front pages of 172 major online news sources in 11 countries (available online at SciRide). Using topic detection, we identified COVID-19–related content to quantify the proportion of total coverage the pandemic received in 2020. The sentiment analysis tool Vader was employed to stratify the emotional polarity of COVID-19 reporting. Further topic detection and sentiment analysis was performed on COVID-19 coverage to reveal the leading themes in pandemic reporting and their respective emotional polarizations.

Results: We found that COVID-19 coverage accounted for approximately 25.3% of all front-page online news articles between January and October 2020. Sentiment analysis of English-language sources revealed that overall COVID-19 coverage was not exclusively negatively polarized, suggesting wide heterogeneous reporting of the pandemic. Within this heterogenous coverage, 16% of COVID-19 news articles (or 4% of all English-language articles) can be classified as highly negatively polarized, citing issues such as death, fear, or crisis.

Conclusions: The goal of COVID-19 public health communication is to increase understanding of distancing rules and to maximize the impact of governmental policy. The extent to which the quantity and quality of information from different communication channels (eg, social media, government pages, and news) influence public understanding of public health measures remains to be established. Here we conclude that a quarter of all reporting in 2020 covered COVID-19, which is indicative of information overload. In this capacity, our data and analysis form a quantitative basis for informing health communication strategies along traditional news media channels to minimize the risks of COVID-19 while vaccination is rolled out.

Introduction

The emergence of the novel coronavirus SARS-CoV-2 and the resultant disease COVID-19 has resulted in an estimated 2.4 million deaths [1,2]. Due to the initial lack of pharmaceutical measures targeting COVID-19, many governments resorted to nonpharmaceutical interventions (NPIs) to control the spread of the pandemic [3,4]. The introduction of NPIs, such as social distancing, mask-wearing, or so-called *lockdowns*, significantly reduced SARS-CoV-2 transmission [5-8]. Therefore, in the absence of effective treatments or widespread rollout of vaccines, NPIs remain an important tool in COVID-19 control [9].

The effectiveness of NPIs is dependent on population-wide adherence to government mandates (eg, social distancing rules, stay-at-home orders, and mask-wearing). Adherence, in turn, is dependent on society’s perception of such measures [9,10], which are shaped by print and digital media. Since adherence to NPIs is linked to public understanding of the guidelines, it is crucial for news sources shaping such knowledge to effectively expound the rules to maximize public response. As evidence accumulates, it is expected that guidelines will shift and be clarified. In the digital age, one of the primary information sources for society is online news [11,12]. Effective communication on the current state of the pandemic and prevention guidelines affects how society adheres to and responds to NPIs and, therefore, influences the severity of the pandemic.

News articles have been previously shown to be an effective way of tracking disease outbreaks, with services such as HealthMap contributing to detecting and tracking disease outbreaks [13,14]. Even if only by virtue of its unprecedented scale, news media has been particularly important in the COVID-19 pandemic [15]. There have been an estimated 38 million English-language articles on COVID-19 [16]. It has further been demonstrated that misinformation on COVID-19 has been widespread and influential, both on social media [17] and in traditional news sources [16]. This can lead to an overload of information that hinders societal response to the pandemic [18].

A particular difficulty of the pandemic is its emotional toll, both from the disease itself and from social distancing measures [19-21]. Emotional toll can be investigated quantitatively by sentiment analysis, which calculates emotional polarization of text from negative, through neutral, to positive. Three previous studies have attempted to quantify emotional toll using sentiment analysis of social media conversations on COVID-19 [22-24]. Counterintuitively, given pandemic subject matter, all three studies of sentiments from COVID-19 conversations on social media showed a higher proportion of positive rather than negative emotions. In contrast, analysis of COVID-19 headlines from 25 English news media sources indicated that 52% of them evoked negative emotions, 30% evoked positive emotions, and 18% evoked neutral emotions [25]. News media can shape behavior toward the pandemic and adherence to control measures. Therefore, extensive negative coverage or contradictory information (ie, information overload) could have detrimental effects to both the mental health of individuals and how effectively society responds to control measures [26].

An earlier study on COVID-19 news coverage by Evanega et al [16] sourced 38 million English-language COVID-19 articles by keyword search from LexisNexis, which indexes 7 million sources. Quantifying the extent of COVID-19 information requires normalizing the absolute number of articles with respect to the number of contributing sources. Likewise, sentiment of COVID-19 coverage also needs to be analyzed in the context of overall negativity of consumed information. Aslam et al [25] analyzed 141,208 COVID-19 headlines, showing that 52% carried negative sentiment. Similar results were reported by Chakraborty and Bose, who collected COVID-19 news articles from GDELT (Global Database of Events, Language, and Tone) and found that pandemic coverage was mostly associated with negative sentiment polarization [27]. Though informative, these studies did not contrast COVID-19 sentiment distribution with the sentiment distribution of the sources they originated from. By contextualizing the sentiment distribution of pandemic reporting within that of the overall coverage, it is possible to draw meaningful conclusions on whether the amount of COVID-19 information is indeed more negatively polarized than what news media consumers are exposed to.

To address the above issues, we collected over 26 million articles from the front pages of 172 major online news sources from 11 countries and compiled these into a reusable database available at SciRide [28]. Firstly, we investigated trends in COVID-19 news with respect to all articles that appeared on the front pages in 2020. Secondly, we analyzed whether articles on COVID-19 were more sentiment-polarized compared with other articles. Finally, we analyzed the leading subtopics in COVID-19 coverage and assessed their sentiment polarization. Overall, our work aimed to elucidate the volume and content of news coverage of COVID-19 in traditional media as a basis for data-driven discussion regarding policy communication in the pandemic.

Methods

Curation of a Database of Front-Page News Articles

To assess coverage of COVID-19 and the sentiment it evoked, we analyzed the landing pages from major online news sources in countries with robust media presence. We selected the major online news sources from 11 countries: the United States, the United Kingdom, Canada, Australia, New Zealand, Ireland, Germany, France, Italy, Spain, and Russia. We included an additional *international* category to better reflect the global focus of certain online news sources.

For each country, the major online news sources were identified by reference to profiles in BBC Media, which is an authority in curating global news source information and lists of news sites with the most traffic and is curated by SimilarWeb. Focusing on major national online news sources, as defined by online visibility, captures some of the main sources in shaping societal knowledge and opinions [29]. It should be noted that the focus on online news sources excludes the impact of social media, epistemic communities, and other influences on public perception. However, due to their depth of penetration, political heterogeneity, and reliability, major online news sources provide an excellent proxy of overall public perception.

For each online news source, we collected the archived front-page snapshots dating back to 2015 via Internet Archive [30], cutting off coverage in 2020 at October 15. We used the pre-2020 articles to fine-tune the accuracy of article collection and provide statistics on reporting of certain topics pre–COVID-19. Each front page was sourced for potential news items using a custom-based pipeline we developed (Section 1 in Multimedia Appendix 1). We defined each article as the combination of the metadata elements title and description—sometimes referred to as headline and subheading—that are broadly akin to titles and abstracts in scientific publications [31]. Such metadata are reasonably standardized among online news sources and they offer a headline-like summary of the article, typically designed for sharing on social media, making them suitable for topic detection and sentiment analysis. In total, we collected 26,077,939 articles from front pages of 172 online news sources (Table 1), with the full list of contributing sources in Table S1 in Multimedia Appendix 1.

Contemporary news sites rapidly change their content, which is spread through multiple sections, so it is difficult to gauge the level of attention received by particular articles. Front pages of news sites should be reliable reflections of the information many users are exposed to, since they are the main points of entry. This is opposed to other article collection strategies, such as RSS (Really Simple Syndication) or downloading the entire website content, that can provide limited control over assessing how many people have actually read any given article [16,32]. Focusing our efforts on articles from landing pages of major online news sources enabled us to assess the number of COVID-19–related articles that a large proportion of online news consumers were exposed to.

Table 1. Number of online news sources and collected articles per country.

Country	Online news sources (N=172), n (%)	Collected articles (N=26,077,939), n (%)
Canada	13 (7.5)	1,269,200 (4.8)
Australia	8 (4.6)	1,124,859 (4.3)
Italy	13 (7.5)	1,526,521 (5.8)
The United Kingdom	21 (12.2)	4,977,792 (19.0)
The United States	33 (19.1)	4,388,383 (16.8)
France	9 (5.2)	1,951,608 (7.4)
Germany	18 (10.4)	2,348,403 (9.0)
Ireland	8 (4.6)	905,598 (3.4)
International	6 (3.4)	462,989 (1.7)
New Zealand	5 (2.9)	651,050 (2.4)
Russia	19 (11.0)	3,348,825 (12.8)
Spain	19 (11.0)	3,122,711 (11.9)

Topic Models

For each article we extracted, we analyzed the text content of the metadata title and description to determine whether the article could be associated with one of the following topics: cat, sport, Merkel, Putin, Johnson, Biden, Trump, cancer, climate, or COVID-19. Non–COVID-19 topics were selected to provide a reference with large expected volumes of coverage (ie, politicians) that cover a wide range of sentiments (e g, *cat* as nonnegative and *cancer* as negative). Each topic was identified on the basis of the keywords presented in Table 2. The only normalization we applied to the words for topic identification was case folding, otherwise the words were not stemmed nor lemmatized. Topics that were used solely for sentiment analysis—cat, sport, climate, and cancer—were not identified for non-English online news sources.

We chose keywords for each topic in order to maximize the precision of topic identification. Because we focused on titles and descriptions, mentions of specific keywords here made it unlikely that they were only tangentially relevant to the article at hand (eg, explicit mentions of politicians' names). In the case of COVID-19, we tested the extent to which our topic detection misclassified the topic by identifying COVID-19 articles in the pre–COVID-19 era of 2015 to 2019. Out of 21,693,591 articles, only 7375 (0.03%) were erroneously identified as related to COVID-19, demonstrating high precision of the selected keywords. In the majority of cases, misclassifications stemmed from mentions of lockdowns, which were chiefly gun related, but in the case of the United Kingdom, they were even related to a seagull attack on a school. Subsequent subtopic identification stratified the different threads of COVID-19 coverage, providing a wider set of keywords.

Table 2. Keywords employed for topic detection.

Topic	Keywords by language					
	English	German	French	Spanish	Italian	Russian
COVID-19						
	coronavirus	coronavirus	coronavirus	coronavirus	coronavirus	коронавирус
	covid	covid	covid	covid	covid	covid ковид
	lockdown	lockdown	lockdown couvre-feu	lockdown confinamiento	lockdown contenimento	lockdown локдаун
	quarantine	quarantäne	quarantaine	cuarantena	quarantena	карантин
	pandemic	pandemie	pandémie	pandemia	pandemia	пандемиа
	N/A[a]	corona-	N/A	N/A	N/A	N/A
Merkel	merkel	merkel	merkel	merkel	merkel	merkel меркел
Trump	trump	trump	trump	trump	trump	trump трамп
Biden	biden	biden	biden	biden	biden	biden байден
Johnson	boris johnson	boris johnson	boris johnson	boris johnson	boris johnson	boris johnson борис джонсон
Putin	putin	putin	putin	putin	putin	putin путин
Climate						
	global warming	—[b]	—	—	—	—
	climate change	—	—	—	—	—
	climate crisis	—	—	—	—	—
Cat						
	cat	—	—	—	—	—
	kitten	—	—	—	—	—
Sport						
	baseball	—	—	—	—	—
	major league	—	—	—	—	—
	champion's league	—	—	—	—	—
	football	—	—	—	—	—
	nfl	—	—	—	—	—
	premier league	—	—	—	—	—
	basketball	—	—	—	—	—
	soccer	—	—	—	—	—
	nba	—	—	—	—	—
Cancer	cancer	—	—	—	—	—

[a] N/A: not applicable; this keyword, which is specific to the German language because of its compound nature, was only found in German news sources.

[b] The topics *climate*, *cat*, *sport*, and *cancer* were not identified in non–English-language online news sources, as these were solely employed for sentiment analysis.

We further identified subtopics within COVID-19 news coverage by a similar keyword-based approach. Since many subtopic words can have several forms (eg, dead, died, and dies), we stemmed the words associated with each subtopic (eg, healthy and healthier are both stemmed to health); these are presented in Table 3. An article was identified as pertaining to a subtopic if, after stemming its title and description, a token corresponding to a stemmed keyword in Table 3 was identified.

Table 3. COVID-19 news subtopics.

Subtopic[a]	Stemmed keywords
Case	case
Crisis	crisi
Death	die, death
Disease	diseas
Distancing	distanc
Fear	fear
Health	health
Home	home
Hospital	hospit
Infection	infect
Isolation	isol
Lockdown	lockdown
Mask	mask
Outbreak	outbreak
Quarantine	quarantin
Spread	spread
Symptom	symptom
Test	test
Treatment	treatment
Vaccine	vaccin

[a] Each of the subtopics was identified by the stemmed keywords (ie, stemming).

Sentiment Analysis of News Articles Using Vader

We used a well-established sentiment analysis tool, Vader [33], to identify emotionally polarized content, which has previously been applied to news media. It is suitable for short snippets of text, such as the titles and descriptions in our metadata. For a given piece of text, Vader provides a compound score between –1 and 1, with –1 being entirely negative, 0 being neutral, and 1 being entirely positive. For instance, the phrase “I find your lack of faith disturbing” offers a Vader score of –0.42, whereas the phrase “I find your lack of faith encouraging” gives a score of 0.5994. In our case, a sentiment score for a single article consists of a Vader compound score for the concatenation of the article title and description.

Novel topics are associated with many subject-specific keywords and phrases (eg “social distancing” and “lockdown” for COVID-19). Applying sentiment analysis to text with novel keywords can result in software being unable to correctly annotate polarization. We assessed Vader sentiment annotations on articles identified as one of the subtopics in Table 3. This revealed an artifact of the tool, wherein “positive coronavirus test” was labeled as emotionally polarized in the positive direction by virtue of the word “positive.” In order to mitigate the effect of this subject-specific misclassification, the words “positive” and “negative,” for symmetry, were removed from articles related to coronavirus testing prior to applying Vader annotation.

Estimating Topic Polarization: Relative Sentiment Skew

We examined whether coverage of a given topic was more emotionally polarized than another topic by contrasting their sentiment distributions. Directly comparing topic sentiment distributions between different online news sources is not sound. Different online news sources can be more sensational and negative or toned-down and neutral, which gives radically different sentiment distributions. To address this issue, we calculated whether specific topic coverage was more negative, positive, or neutral relative to other articles within a particular online news source.

For each article “*a*” (ie, that article’s title and description metadata) in English-language online news sources, we calculated the Vader compound sentiment score *sent(a)*. For all 2020 articles and topics, in a given online news source, we calculated the mean of the Vader compound sentiment scores, denoted as $\mu_{ONS,TOPIC}$ (online news source [ONS]; equation 1). As a reference statistic for the distribution of sentiment scores not relating to a topic, we calculated the mean Vader score of the articles from a given online news source that were not identified as a given topic, denoted as $\mu_{ONS,TOPIC}$ (equation 2):

where *ONS* is a particular online news source, *TOPIC* is a topic from Table 2 or Table 3, *ONS(TOPIC)* is the set of articles on a given topic from a particular online news source, and $|ONS_{TOPIC}|$ is the total number of articles on a given topic in that online news source. A set of articles not identified as a given topic from a particular online news source is denoted as ONS_{TOPIC}.

For each topic in each online news source, we calculated the relative sentiment skew ($rsskew_{ONS,TOPIC}$) between topic mean sentiment and the mean of all other articles in the given online news source (equation 3).

Relative sentiment skew is designed to indicate whether the sentiment score distribution of a particular topic is negatively or positively polarized, compared to other articles, for example, where a topic has one positive (score +1) and two negative articles (each with score −1), and there are seven other nontopic articles that are all positive (each with score +1). In this instance, the relative sentiment skew metric $rsskew_{ONS,TOPIC}$ is –1/3 – 7/7 = –1.33, which indicates greater negativity. Note, we do not account for sample size variation, as the denominator is generally very large (ie, in the thousands).

Results

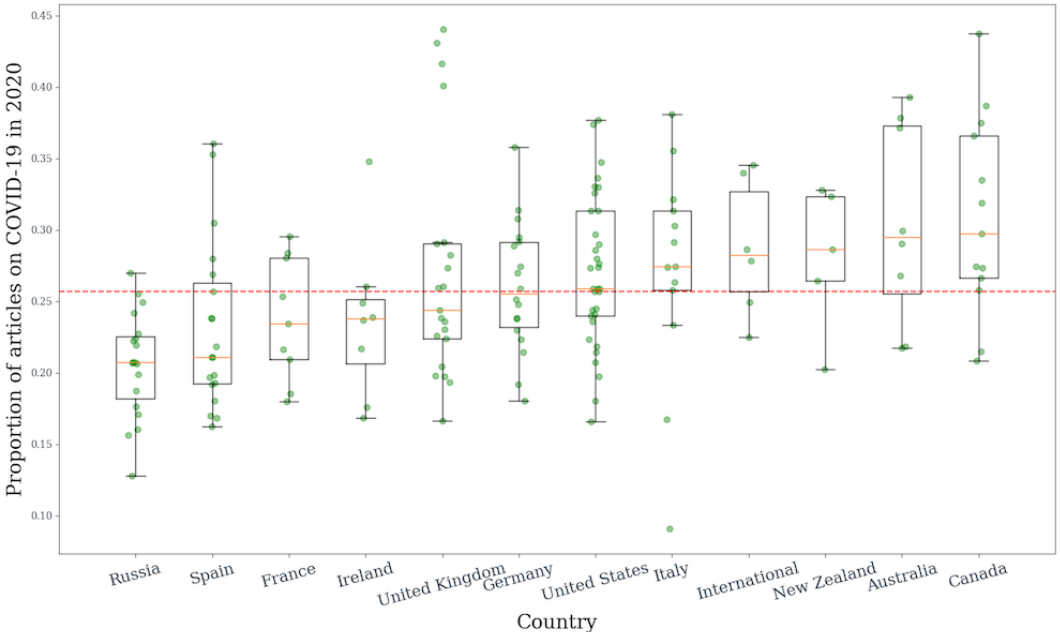
One-Quarter of 2020 News Coverage Was Pandemic Related, Suggesting Information Overload

We estimated the extent of COVID-19 coverage in online news media by identifying articles relating to the pandemic and comparing this number to the total number of articles between January and October 2020.

For each online news source, we performed topic detection, categorizing each article title and description as relating to the coronavirus—topic called COVID-19—if the title and description contained any keyword of a specific set, given in Table 2. Keywords for this simplified topic detection model were chosen to maximize the precision and accuracy of content identification in order to avoid cross-contamination with other topics. In English, these keywords included *covid*, *coronavirus*, *lockdown*, *quarantine*, and *pandemic*, but not, for example, *hospital* and *death*. The keywords were adjusted for the six languages that we used in this study: English, German, French, Spanish, Italian, and Russian (Table 2).

COVID-19 featured in 25.3% of the news articles (1,135,561/4,477,867) across the online news sources (Figure 1). While this proportion varied between countries, it was consistently large, with the lower bound at 20% and the upper bound at 30%. Thus, even using our relatively simple topic detection model, we were able to demonstrate that 2020 online news coverage was dominated by COVID-19.

Figure 1. The extent of coronavirus coverage in 2020. We calculated the proportion of all COVID-19 articles as the proportion of all front-page articles. Proportions were calculated for each online news source separately and then aggregated at the national level. The green points represent the individual coverage of each online news source. The yellow line in each box represents the median; the upper and lower whiskers represent the 75th and 25th percentiles, respectively. The red dotted line indicates mean proportion across all online news sources.



To provide a point of reference to coverage of COVID-19, we identified other global topics with regular and topical media presence (Table 2). We selected topics such as Donald Trump (Trump), Joe Biden (Biden), Boris Johnson (Johnson), Angela Merkel (Merkel), and Vladimir Putin (Putin). Unsurprisingly, mentions of politicians are most common in their home countries

(Figures S1-S5 in Section 2 of Multimedia Appendix 1) (eg, Vladimir Putin in Russia). Nonetheless, each politician received an order of magnitude less media attention than COVID-19 in 2020. Specifically, mean coverage of COVID-19 across 11 countries was 25.66%, whereas politicians received 2.50% for Trump, 0.45% for Biden, 0.18% for Putin, 0.17% for Johnson, and 0.09% for Merkel. Higher coverage of COVID-19 was also reflected at the national level. Although 2020 was an election year in the United States, *Trump* received a mean of 15.29% of 2020 media mentions in US online news sources, as opposed to 25.91% of mean mentions for COVID-19. Furthermore, US articles in 2020 mentioning both Trump and COVID-19 accounted for a mean coverage of 3.82%.

To provide temporal perspective on the media attention of COVID-19, we plotted the proportions of global coverage in the period from January to October 2020 (Figure S6 in Section 2 of Multimedia Appendix 1). COVID-19 attention in 2020 spiked between March and May, coinciding with many countries following the Chinese strategy of lockdown and other distancing measures. Proportion coverage leading up to the second COVID-19 wave in Europe and the United States did not reach levels seen from March to May but did stay above 20% in the regions we considered. These results provide a quantification of the extent of media attention received by COVID-19 across countries and languages, reflecting the global and protracted impact of the pandemic.

COVID-19 News Sentiment Analysis Suggests Heterogeneity of Coverage

The emotion that news coverage of COVID-19 evokes is an important factor in a society’s response to the pandemic [25]. We addressed this issue by sentiment analysis contrasting emotional polarization of COVID-19 news with that of certain reference topics and all non–COVID-19 articles for each online news source. Such contrast allows us to determine whether sentiment distribution of COVID-19 coverage was polarized compared to reference topics and other online news for a given online news source.

To quantify the emotional content of news article text, we employed Vader, which has been previously applied to news article analysis [33,34] (see Methods section). For each online news source whose primary language was English (91/172, 52.9%), we created Vader annotations for both the title and description of each of its articles. We grouped articles by their annotated topics (Table 2) to provide a comparison with COVID-19 sentiments. Politicians—Merkel, Trump, Johnson, Biden, and Putin—were used as reference points for subjects with frequent coverage. We selected four additional topics to offer intuitive reference points on the positive and negative sentiment spectrum: cat, sport, climate, and cancer. The topics *cat* and *sport* were used, as they would not necessarily be associated with negative sentiments. Likewise, the topics of *climate*—identified by the key phrases global warming, climate crisis, and climate change—and *cancer* were used as references that we would expect to be associated with negative emotions. Altogether, individual sentiment annotations for each online news source were grouped by one of the topics: cat, sport, Merkel, Johnson, Biden, Trump, COVID-19, and cancer.

For each online news source and topic, we calculated the relative sentiment skew statistic ($rsskew_{ONS,TOPIC}$; see Methods section), which measures the polarization of a given topic within an online news source. We noted how many topics had a negative or positive relative sentiment skew value (Table 4). For the nonpolitician non–COVID-19 topics (ie, cat, sport, and cancer), skew was in the expected direction, suggesting that they are appropriate references for assessing sentiment of COVID-19 articles. We noted negative relative sentiment skew values for 74 out of 91 (81%) English-language online news sources. Nonetheless, this observation cannot be taken as evidence of significant negative polarization, as these relative sentiment skew values are not substantially different than $rsskew=0$, which indicates no polarization. The mean relative sentiment skew for COVID was –0.04 (SD 0.07) (Table 4). Since cancer and COVID-19 are both diseases and exert a large burden on public health, one might expect their sentiment distributions from online news to be similar. However, COVID-19 sentiment distribution was not as extreme as that of cancer, which was 100% negative per online news source, and had a mean relative sentiment skew of –0.53 (SD 0.12). Perhaps surprisingly, the sentiment distribution for COVID-19 articles was more akin to coverage of climate, which was *a priori* expected to be negative, akin to cancer, or to subjects covering heterogenous topics by virtue of their wide-ranging implications for society, such as politicians (Figure 2). This, however, can be an indicator of topics being intertwined: since heads of state are responsible for the pandemic response, they can be expected to be mentioned in relation to COVID-19.

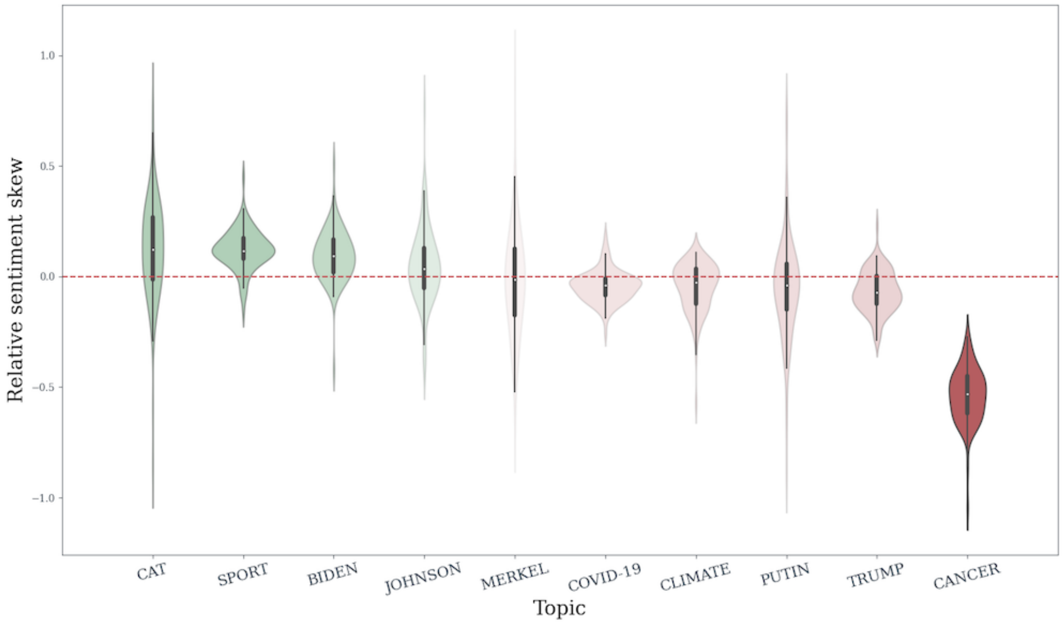
Table 4. English-language online news sources[a], with positive (≥0) or negative (<0) relative sentiment skew of 2020 articles on a given topic.

Topic	Positive online news sources, n (%)	Negative online news sources, n (%)	Relative sentiment skew, mean (SD)	Total articles[b], n
Cat (n=87)	64 (74)	23 (26)	0.12 (0.23)	2746
Sport (N=91)	84 (92)	7 (8)	0.12 (0.08)	63,155
Biden (n=90)	75 (83)	15 (17)	0.09 (0.11)	38,949
Johnson (n=90)	57 (63)	33 (37)	0.04 (0.17)	22,613
Merkel (n=79)	38 (48)	41 (52)	–0.01 (0.25)	2011
COVID-19 (N=91)	17 (19)	74 (81)	–0.04 (0.07)	589,701
Climate (N=91)	38 (42)	53 (58)	–0.04 (0.11)	7195
Putin (n=88)	33 (38)	55 (63)	–0.05 (0.23)	5179
Trump (N=91)	24 (26)	67 (74)	–0.06 (0.09)	157,702
Cancer (N=91)	0 (0)	91 (100)	–0.53 (0.12)	9548

[a] We had 91 English-language online news sources in total; however, in cases where it was impossible to identify a certain topic in a given source, it was left out.

[b] The total number of articles we identified as being associated with a given topic across all online news sources.

Figure 2. Relative sentiment skew (*rrskew*) of COVID-19 coverage. Each article title and description from each English-language online news source (ONS) received a Vader sentiment compound score between –1 and 1 (most negative and most positive, respectively). We noted the difference in mean sentiment for a specific topic and mean sentiment for other 2020 articles in a given online news source ($rsskew_{ONS,TOPIC}$; see Methods section). The density of the relative sentiment skew is plotted for each topic. Distributions are colored green if their relative sentiment skew was predominantly positive or red if predominantly negative (Table 4). Intensity of the color is scaled by the distance from the red dotted line at 0, which indicates a lack of difference between topic sentiment and all other articles in a given online news source.



These results suggest that the sentiment of COVID-19 coverage in online news media is heterogeneous and is certainly not as clearly polarized as cancer, though the volume of coverage might play a role (Figure S7 in Section 3 in Multimedia Appendix 1). One explanation could be the all-permeating nature of the pandemic, where it becomes background to most reporting. Therefore, COVID-19 articles cannot all be categorized as fully negative, contrary to the expectation of pandemic subject matter. In fact, on average, they appear to not be polarized in either the positive or negative direction, especially when compared to reference topics. This suggests that coverage of COVID-19 was highly heterogeneous, with many themes contributing to the totality of messaging.

Highly Sentiment-Negative Subtopics Account for 16% of COVID-19 Coverage, Suggesting Emotional Pressure

We studied the text content of COVID-19–related title and description metadata to reveal the leading themes associated with heterogeneous pandemic reporting.

We investigated article subtopics and calculated the most commonly used words and bigrams (ie, consecutive combinations of two words) to demonstrate the most frequent mentions in COVID-19 coverage. For each of the 91 English-language online news sources, we calculated the ranks of single words and bigrams in articles that pertained to COVID-19. The articles were further subdivided within each online news source as negative (Vader score <–0.2; 247,542 articles), positive (Vader score >0.2; 192,643 articles), or all (any Vader score; 589,709 articles). This subdivision aimed to reveal whether certain keywords or bigrams were more frequently associated with differently polarized text. For each subdivision, we averaged the individual online news source ranks of each word and bigram found across all 91 online news sources. In Table 5 we present the top 20 highest-ranking words and bigrams across all 91 online news sources. Words and bigrams in Table 5 reveal many themes that are intuitively associated with the coronavirus, such as testing, vaccine, death, etc. In particular, negative articles had unique top words and bigrams that are intuitively associated with negative emotions. In the singletons, these were *death*, *crisi*, and *fear*, while in bigrams these were *covid_crisi*, *covid_death*, *coronavirus_death*, and *death_toll*—note that words are stemmed.

To calculate the news coverage proportion related to these top themes, we created a constrained set of COVID-19 subtopics, based on the highest-ranking words and bigrams from Table 5. We removed terms that pointed to nonspecific coronavirus coverage, such as *COVID*, *coronavirus*, *pandemic*, or *news*. We extended the list of subtopics to include those we did not find in Table 5 but considered as strongly related to COVID-19 coverage, such as *hospital*, *quarantine*, *symptom*, or *isolation*, with a full list of subtopics in Table 3. For each subtopic, we calculated the proportion of COVID-19 coverage per online news source (Figure S8 in Section 4 of Multimedia Appendix 1) and relative sentiment skew per online news source for the subtopic (Figure S9 in Section 4 of Multimedia Appendix 1). The means of coverage and sentiments per online news source are plotted against each other in Figure 3. The subtopics in Table 3 account for a mean of 67.14% of all COVID-19 articles across English-language online news sources. Of these, the top three are *case*, *lockdown*, and *death*, which account for a mean of 9.29%, 8.56%, and 8.08% of COVID-19 articles, respectively. Figure 3 and Figure S9 in Multimedia Appendix 1 suggest that out of *case*, *death*, and *lockdown*, only *death* carried a firmly polarized sentiment, with *case* and *lockdown* not being significantly skewed in either positive or negative directions. The words *fear*, *crisis*, and *death* unsurprisingly indicated substantial negative polarization (Figure 3).

We analyzed the impact on news sentiment in 2020 of the three most negative subtopics, *fear*, *crisis*, and *death* (Figure 3). For each online news source, we calculated the mean sentiment of all the 2020 articles after removing articles that mentioned one of those three topics. For all 91 online news sources, removing articles mentioning one of the top three negative topics resulted in a statistically significant—at the level of .05 with Bonferroni correction—shift toward mean positive sentiment (Section 5 in Multimedia Appendix 1). By contrast, removal of all the sentiment-heterogeneous (Figure 2) articles from all 2020 articles resulted in a significant shift toward mean positive sentiment in 40 out of 91 (44%) online news sources, a significant shift toward mean negative sentiment for 11 out of 91 (12%) online news sources, and no statistically significant result for 39 out of 91 (43%) online news sources. Altogether, articles mentioning *fear, crisis*, and *death* accounted for a mean of 16% of COVID-19 articles across 91 online news sources; due to their highly polarizing nature, they may play a significant role in shaping societal perception of the pandemic.

Of the three most negative topics, *fear*, *crisis*, or *death*, the latter was the most frequently mentioned for COVID-19 (Figure 3). In total, *death* was mentioned in the context of COVID-19 in 2.33% of all coverage in 91 English-language online news sources. All *death* mentions in 2020 in 91 English-language online news sources accounted for a mean coverage of 5.74%, whereas in the pre–COVID-19 period of 2015 to 2019, they accounted for 4.07%. Therefore, we can identify that *death* in the context of COVID-19 constituted a significant proportion of negatively associated coverage that appears to have contributed to overall death reporting in the news.

These results demonstrate that even though the overall coverage of COVID-19 in 2020 was not significantly polarized by sentiment, there was a nontrivial proportion of negative news that contributed to overall reporting negativity in 2020.

Table 5. Top words and bigrams in English-language countries.

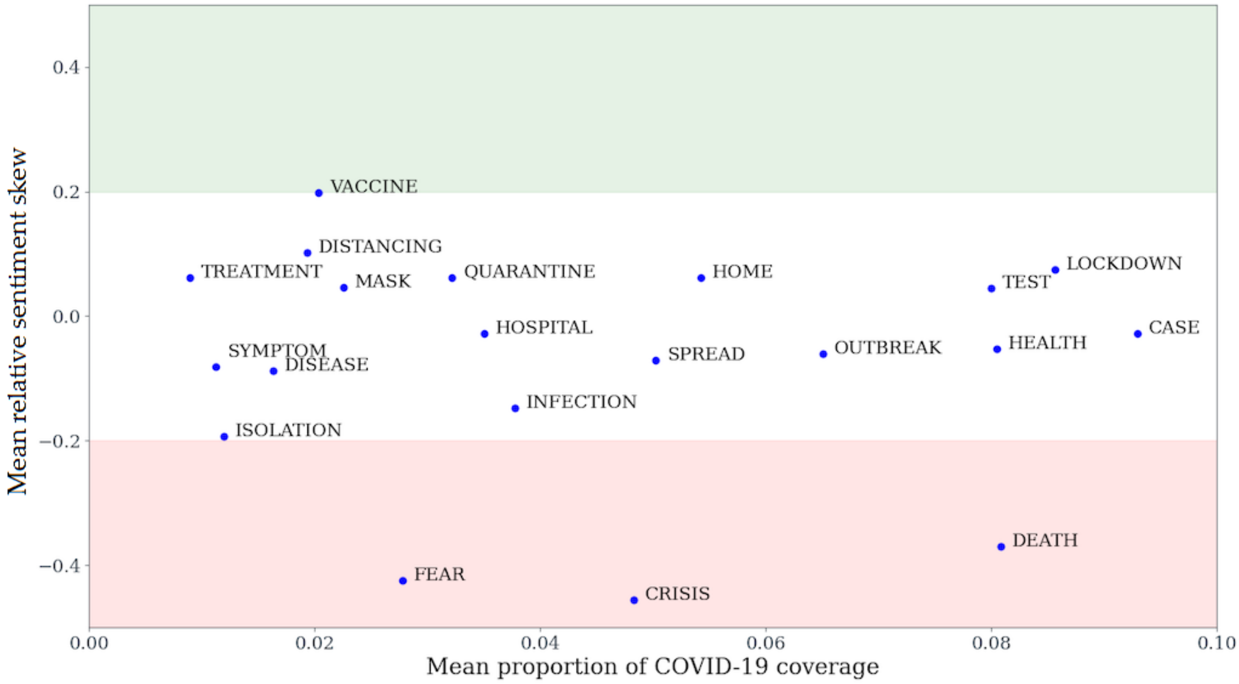
Rank	Words and bigrams by polarization[a]		
	Negative	All	Positive
Single words			
1	coronavirus	coronavirus	coronavirus
2	covid	covid	covid
3	pandem	pandem	pandem
4	new	new	new
5	peopl	peopl	help[b]
6	say	case	say
7	crisi[b]	say	peopl
8	health	health	test
9	case	test	health
10	death[b]	outbreak	case
11	outbreak	week	us
12	virus	us	home
13	test	virus	week
14	could	could	one
15	govern	day	time
16	us	one	day
17	countri	govern	govern
18	one	home	could
19	week	countri	work[b]
20	fear[b]	time	outbreak
Bigrams			
1	coronavirus_pandem	coronavirus_pandem	case_covid
2	coronavirus_crisi	case_coronavirus	coronavirus_pandem
3	coronavirus_outbreak	case_covid	posit_test
4	health_public	coronavirus_spread	health_public
5	posit_test	distanc_social	coronavirus_outbreak
6	case_coronavirus	health_public	case_coronavirus
7	coronavirus_spread	covid_test	covid_pandem
8	coronavirus_new	coronavirus_outbreak	distanc_social
9	case_covid	covid_pandem	coronavirus_lockdown[b]
10	distanc_social	coronavirus_new	coronavirus_spread
11	covid_crisi[b]	coronavirus_crisi	covid_test
12	covid_test	case_new[b]	covid_vaccin[b]
13	covid_pandem	covid_outbreak	home_stay
14	coronavirus_due[b]	posit_test	coronavirus_test[b]
15	covid_death[b]	minist_prime	covid_posit[b]
16	second_wave[b]	home_stay	minist_prime
17	death_toll[b]	first_time[b]	like_look[b]

Rank	Words and bigrams by polarization[a]		
	Negative	All	Positive
18	coronavirus_death[b]	around_world[b]	covid_outbreak
19	amid_coronavirus[b]	covid_spread[b]	coronavirus_new
20	two_week	two_week	coronavirus_vaccin[b]

[a] For each of the 91 English-language online news sources, we calculated the most common words and bigrams and grouped these by Vader scores: >0.2 for positive, <–0.2 for negative, and any score for all. We averaged the ranks of words and bigrams across all online news sources, and here we present the top 20 for each subdivision. The words in the table are stemmed.

[b] These entries indicate elements that can be found in the top 20, only in the specific subdivisions of *positive*, *all*, or *negative*.

Figure 3. COVID-19 subtopic coverage and sentiment means. We calculated the mean coverage and mean sentiment of each subtopic. Coverage is expressed as the mean of ratios of subtopics in a given online news source against all COVID-19 articles in the same online news source. Sentiment is the mean of the subtopic relative sentiment skew for all online news sources. The shaded areas illustrate regions with relative sentiment skew above 0.2 (green), between 0.2 and –0.2 (white), and below –0.2 (green).



Discussion

In this work, we compiled the largest data set on COVID-19 news, collating over 26 million articles from the front pages of 172 major online news sources from 11 countries. We have made this database publicly available at SciRide [28]. We first investigated trends in COVID-19–related news with respect to all front-page articles in 2020. We next used sentiment analysis to determine whether COVID-19 coverage was more polarized than other topics. Finally, we analyzed the leading subtopics in COVID-19 coverage and assessed their sentiment polarization. We demonstrated that 25% of front-page articles in traditional news media between January and October 2020 concerned COVID-19. Sentiment analysis demonstrated that pandemic coverage cannot be simply categorized as negatively polarized by virtue of disease association, pointing to heterogenous reporting. However, there was an increased incidence in reporting of negatively associated topics, in particular concerning *death*. Our results provide a data-driven foundation on policy communication surrounding distancing measures.

NPIs are drastic measures that reduce casualties before vaccinations and/or treatment regimens become widespread. Such methods, however, are only effective with societal adherence. Information received by a population in times of a pandemic shapes collective adherence to policies introduced to stem its spread. Currently, the internet is the primary source of health information for people in developed countries [35].

Comprehensive analysis of COVID-19 information received by a population would require thorough analysis of all possible internet news sources and all users' exposure to each piece of information received. The online ecosystem is extremely heterogeneous, with channels of information discovery spread across traditional news sites, blogs, social media, and many others. Within each of such platforms, information itself can take different forms (eg, text length and format). How users interact with the information also has a great effect on the amount of attention a given piece of information receives and the degree of influence it has (eg, extent of sharing on social media or a more visible position on a website). Analysis of COVID-19 information from all online sources is not tractable.

Direct access to major news sites accounts for 76% of media consumption online [29]. The landing pages of such outlets implicitly capture articles that might have been seen by online users. Thus, our analysis of content from front pages of major news sites should encompass a significant proportion of sources shaping knowledge of the pandemic covering reporting across different languages and geographies. In total, we curated a data set of 26 million articles from 172 major web traffic–generating online news sources in 11 countries.

We identified COVID-19–relevant articles as well as a selection of other topics to serve as reference points for both coverage volume and sentiment analysis. As a standardized common denominator among articles, we analyzed the metadata titles and descriptions, where the main subject matter can be expected to be referenced. We employed a facile topic identification method using a limited set of keyword mentions. We chose a limited number of keywords to make it unlikely that an article would not make the corresponding topic its subject matter if it were referenced in its metadata title and description (eg, politician’s name). This avoided the caveat of tangential references to certain topics mentioned in the full article body or ambiguities that might arise by using more sophisticated topic modeling algorithms [36]. Unlike more complex topic modeling methods, or even using a wider set of keywords, our approach did not capture much more subtle references to these topics, and so we will have underestimated total coverage.

Nonetheless, even using our simple approach, we still identified a nontrivial number of COVID-19 articles on the front pages of our online news sources. We estimate that a mean of 25% of our sample of front-page articles from 11 countries in 2020 mentioned COVID-19 in their titles and descriptions. Our method had reduced topic identification recall by not accounting for more subtle references to COVID-19, and the totality of the articles was certainly contaminated by retrieval of erroneous links that were not actual news articles. Therefore, the actual proportion of articles on the front pages of news sources referencing COVID-19 might have indeed been higher. We envision that the amount of reporting on a topic of general interest like COVID-19 needs to be balanced. Too little information might leave the population underinformed and ill-equipped to respond appropriately. Too much coverage risks obscuring information that is crucial for individuals to understand the pandemic and how to stay safe.

Reporting on the pandemic could have wider implications than only its basic informative function. It is unknown what effect regular reporting on cases, casualties, and containment methods could have on adherence to distancing rules or mental health [19,37-40]. Though current sentiment analysis methods fall short of identifying complex nuance, they offer a good approximation for the position of text on the emotional spectrum (ie, negative, neutral, or positive). By employing sentiment analysis, we found that overall COVID-19 reporting was not markedly polarized in either a positive or negative direction, as opposed to cancer. It is contrary to what might be expected by virtue of the pandemic subject matter, suggesting heterogeneity in reporting. Such heterogeneity might be due to the sheer scale of the pandemic, the consequences of which have permeated much of everyday life. Nevertheless, we found that negatively polarized COVID-19 articles mentioning death, fear, and crisis accounted for 16% of pandemic articles, with death being most widely referenced. Such a nontrivial volume of negatively associated articles significantly skews the sentiment of 2020 reporting toward the negative direction.

Our results offer a quantification of COVID-19 reporting that substantiates widespread qualitative observations (eg, the pandemic received an unprecedented amount of media attention). Our analysis offers insights for shaping discussion on health communication in order to maximize the effect of control policies. Our retrospective analysis of health communication during the first two waves indicates signs of information and emotional overload that might have obscured understanding of policy. We hope that our findings will inform how best to communicate so as to minimize the risk of subsequent waves while vaccination regimens are introduced.

Abstract

Background: As policy makers continue to shape the national and local responses to the COVID-19 pandemic, the information they choose to share and how they frame their content provide key insights into the public and health care systems.

Objective: We examined the language used by the members of the US House and Senate during the first 10 months of the COVID-19 pandemic and measured content and sentiment based on the tweets that they shared.

Methods: We used Quorum (Quorum Analytics Inc) to access more than 300,000 tweets posted by US legislators from January 1 to October 10, 2020. We used differential language analyses to compare the content and sentiment of tweets posted by legislators based on their party affiliation.

Results: We found that health care–related themes in Democratic legislators' tweets focused on racial disparities in care (odds ratio [OR] 2.24, 95% CI 2.22-2.27; *P*<.001), health care and insurance (OR 1.74, 95% CI 1.7-1.77; *P*<.001), COVID-19 testing (OR 1.15, 95% CI 1.12-1.19; *P*<.001), and public health guidelines (OR 1.25, 95% CI 1.22-1.29; *P*<.001). The dominant themes in the Republican legislators' discourse included vaccine development (OR 1.51, 95% CI 1.47-1.55; *P*<.001) and hospital resources and equipment (OR 1.22, 95% CI 1.18-1.25). Nonhealth care–related topics associated with a Democratic affiliation included protections for essential workers (OR 1.55, 95% CI 1.52-1.59), the 2020 election and voting (OR 1.31, 95% CI 1.27-1.35), unemployment and housing (OR 1.27, 95% CI 1.24-1.31), crime and racism (OR 1.22, 95% CI 1.18-1.26), public town halls (OR 1.2, 95% CI 1.16-1.23), the Trump Administration (OR 1.22, 95% CI 1.19-1.26), immigration (OR 1.16, 95% CI 1.12-1.19), and the loss of life (OR 1.38, 95% CI 1.35-1.42). The themes associated with the Republican affiliation included China (OR 1.89, 95% CI 1.85-1.92), small business assistance (OR 1.27, 95% CI 1.23-1.3), congressional relief bills (OR 1.23, 95% CI 1.2-1.27), press briefings (OR 1.22, 95% CI 1.19-1.26), and economic recovery (OR 1.2, 95% CI 1.16-1.23).

Conclusions: Divergent language use on social media corresponds to the partisan divide in the first several months of the course of the COVID-19 public health crisis.

(J Med Internet Res 2021;23(6):e27300) doi:10.2196/27300

KEYWORDS

Twitter; COVID-19; digital health; US legislators; natural language processing; policy makers; social media; policy; politics; language; cross-sectional; content; sentiment; infodemiology; infoveillance

Introduction

The novel COVID-19 pandemic continues to surge throughout the world. The United States' federal and state policy responses continue to shift and vary throughout the stages of the pandemic [1]. Notable divisions related to public health measures and frameworks for closing and reopening local economies have proliferated [2]. A unique aspect of the COVID-19 pandemic is the role that social media plays in housing, disseminating, and amplifying information and opinions [3,4]. US legislators have also taken to social media to connect with their constituents, comment on the pandemic, and provide information across a spectrum of pandemic-related content to individuals.

Understanding what content US legislators are sharing through social media posts (eg, Twitter) and how they are relaying COVID-19–related information is important, as these issues guide public knowledge and public opinion and inform policy change. By using social media data, prior studies have identified growing partisan differences among Republican and Democrat legislators as the pandemic has progressed [5]. It has also been found that tweets about specific topics (eg, social distancing) from legislators are often associated with the time when policies are put into action, and the effect of such tweets are larger in democratic counties [6].

The objective of this study was to analyze the language in posts on Twitter—a leading social media platform—that were posted by US legislators over the course of the pandemic to identify potential health care–related themes in COVID-19–related posts and to analyze the associated sentiment within tweet language across partisans.

Methods

Data

We identified state legislators' Twitter posts that were related to COVID-19 and posted from January 1 to October 10, 2020, by using Quorum (Quorum Analytics Inc) [7], a software platform that collects policy-related documents, including social media posts from politicians that were posted during their time in office. This study was considered exempt from review by the University of Pennsylvania Institutional Review Board, as it involves the analysis of public-facing data.

Language Feature Extraction

We extracted the relative frequency of single words and phrases from tweets by using the Differential Language Analysis ToolKit package [8] and created two sets of features—(1) an open vocabulary that was defined by using latent Dirichlet allocation [9], an unsupervised clustering algorithm, to create 50 data-driven word clusters (topics) and (2) sentiment, which was measured by using the National Research Council (NRC) Canada lexicon [10], a data-driven dictionary containing words associated with positive and negative valence. The NRC lexicon was developed by using a corpus of 77,500 positive and negative tweets, and consists of 54,129 weighted unigrams and 316,531 bigrams in which the weight corresponds to the degree of association between a token and sentiment [10].

Statistical Analyses

To distinguish linguistic differences across political parties (coded as a dichotomous outcome), each feature set was input in a logistic regression model, and those that were significantly different according to a cutoff Benjamini-Hochberg–corrected P value of <.001 were reported [11]. Two authors independently evaluated each topic for thematic meanings by reviewing the top 10 posts per topic and coded them into health care–related and nonhealth care–related themes.

Data on changes in the prevalence and sentiment of topics that were significantly associated with either party and occurred over time were obtained by calculating the mean scores across all posts per week, stratified by party, and visualized via locally estimated scatterplot smoothing [12].

Results

US Legislators' Tweets

We identified 309,438 COVID-19–related tweets from the 4224 unique accounts of US legislators. The descriptive statistics of the data set are in Table 1. The number of tweets per legislator over the selected time period is shown in Multimedia Appendix 1. Tweet language that correlated with US legislature party affiliation is displayed in Figure 1. Of the statistically significant topics, we identified 7 health care–related themes and 14 nonhealth care–related themes associated with the two major party affiliations.

Figure 1. Words and phrases that were significantly associated with tweets from Democratic legislators (blue) and Republican legislators (red). Bar length indicates effect size and shade indicates relative word frequency (*P*<.001; Benjamini-Hochberg p-correction). CCP: Chinese Communist Party.

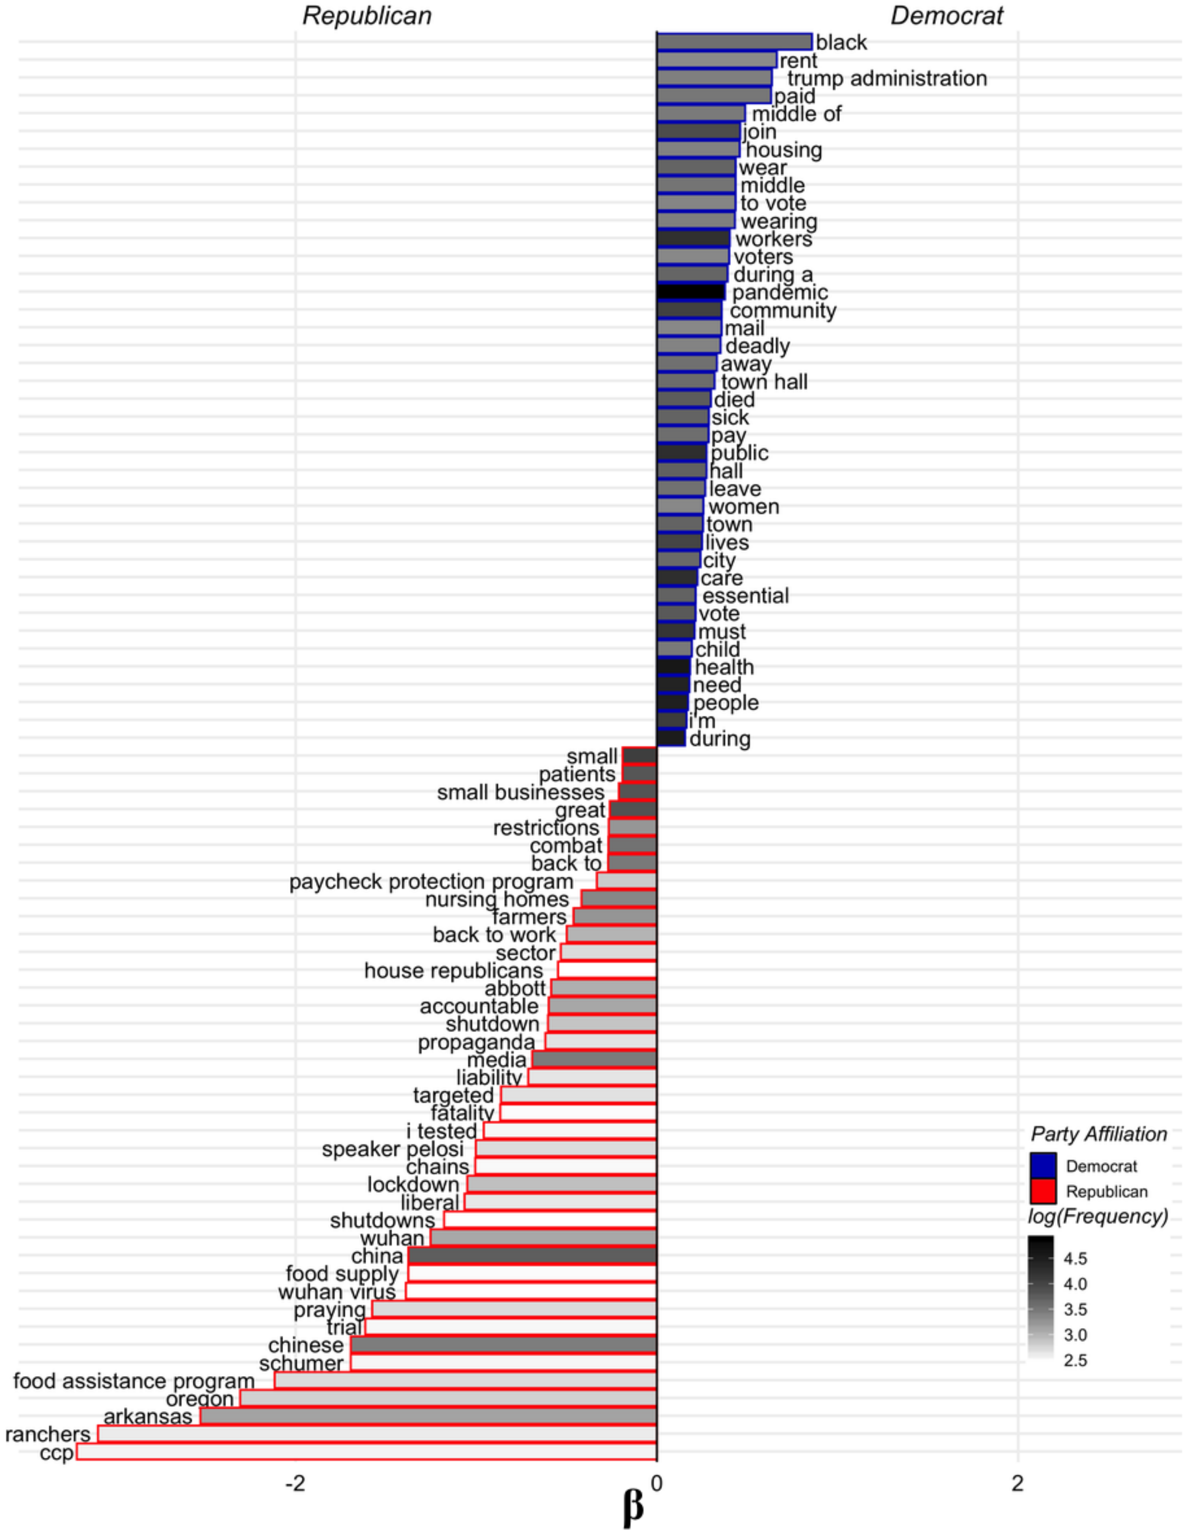

Table 1. Descriptive statistics of the data collected from Quorum from January 1 to October 10, 2020.

Category	Value, n (%)
Number of tweets	
All legislators	309,438 (100)
Republican legislators	88,146 (28.4)
Democrat legislators	221,292 (71.5)
Number of retweets	
Republican retweets	38,120 (12.3)
Democrat retweets	96,469 (31.1)
Number of individual accounts	
All legislators	4224 (100)
Democrat legislators	2432 (57.6)
Republican legislators	1792 (42.4)

Thematic Differences by Party Affiliation

Health care–related themes (Table 2) associated with a Democratic party affiliation included the following: racial disparities in care (odds ratio [OR] 2.24, 95% CI 2.22-2.27), health care and insurance (OR 1.74, 95% CI 1.70-1.77), public health guidelines (OR 1.25, 95% CI 1.22-1.29), and COVID-19 testing (OR, 1.15, 95% CI 1.12-1.19). Health care–related themes associated with a Republican party affiliation included the following: vaccine development (OR 1.51, 95% CI 1.47-1.55) and hospital resources and equipment (OR 1.22, 95% CI 1.18-1.25).

Nonhealth care–related topics were also identified across parities. The themes associated with a Democratic affiliation included the following: protections for essential workers, the 2020 election and voting, unemployment and housing, crime and racism, public town halls, the Trump Administration, immigration, and the loss of life. The themes associated with a Republican affiliation included the following: China, congressional relief bills, small business assistance, press briefings, and economic recovery (Table 3). The prevalence of the themes over time stratified by affiliation is shown in Multimedia Appendices 2 and 3. The set of topics that did not significantly correlate with affiliation are shown in Multimedia Appendix 4.

Table 2. Health care–related topics that are more likely to be posted by Democrat legislators and Republican legislators. Effect size is shown by using odds ratios (ORs) along with 95% CIs. Only significant topics after Benjamini-Hochberg p-correction (*P*<.001) are shown.

Affiliation and topic theme	Top words	ORs (95% CI)	Example tweets
Democrat			
Racial disparities	“communities,” “black,” “color,” “racial,” “disparities,” “disproportionately,” “impact,” “hit,” “women,” and “latino”	2.24 (2.22-2.27)	“COVID-19 is disproportionately harming communities of color and exposing generations of systemic racism. We need to collect racial and ethnic data for coronavirus testing and treatment so we can address these health disparities and begin rectifying decades of injustice.”
Health care and insurance	“healthcare,” “americans,” “access,” “insurance,” “coverage,” “affordable,” “millions,” “medicaid,” and “court”	1.74 (1.70-1.77)	“The #MedicareCrisisProgram would: Expand Medicare to the recently unemployed & cap out-of-pocket costs Expand Medicaid to cover even more people Ensure no out-of-pocket costs for COVID-19 testing/treatment for everyone”
Public health guidelines	“mask,” “social,” “distancing,” “wear,” “spread,” “hands,” “stay,” “home,” “wash,” “practice,” and “stop”	1.25 (1.22-1.29)	“The pandemic is nowhere near over. Continue practicing social distancing & WEAR A MASK”
COVID-19 testing	“testing,” “free,” “county,” “sites,” “appointment,” “center,” “residents,” “open,” “city,” “visit,” and “symptoms”	1.15 (1.12-1.19)	“New COVID-19 mobile testing site opens. Scheduled Locations for Free Drive-Through COVID-19 Testing” [retweet]
Republican			
Vaccine development	“vaccine,” “research,” “drug,” “production,” “effective,” “vaccines,” “treatments,” “development,” and “defense”	1.51 (1.47-1.55)	“Three Coronavirus Vaccine Developers Report Promising Initial Results” [retweet]
Hospital resources and equipment	“medical,” “patients,” “hospitals,” “masks,” “equipment,” “supplies,” “ppe,”[a] “donate,” “blood,” “needed,” and “plasma”	1.22 (1.18-1.25)	“Kansans everywhere are stepping up to fight the #Coronavirus.…,which manufactures aircraft parts in…, is using their 3D printing capabilities to work with local area hospitals on prototypes of N-95 surgical masks and protective face shields.”

[a] PPE: personal protective equipment.

Table 3. Nonhealth care–related topics that are more likely to be posted by Democratic legislators and Republican legislators. Effect size is shown by using odds ratios (ORs) along with 95% CIs. Only significant topics after Benjamini-Hochberg p-correction (*P*<.001) are shown.

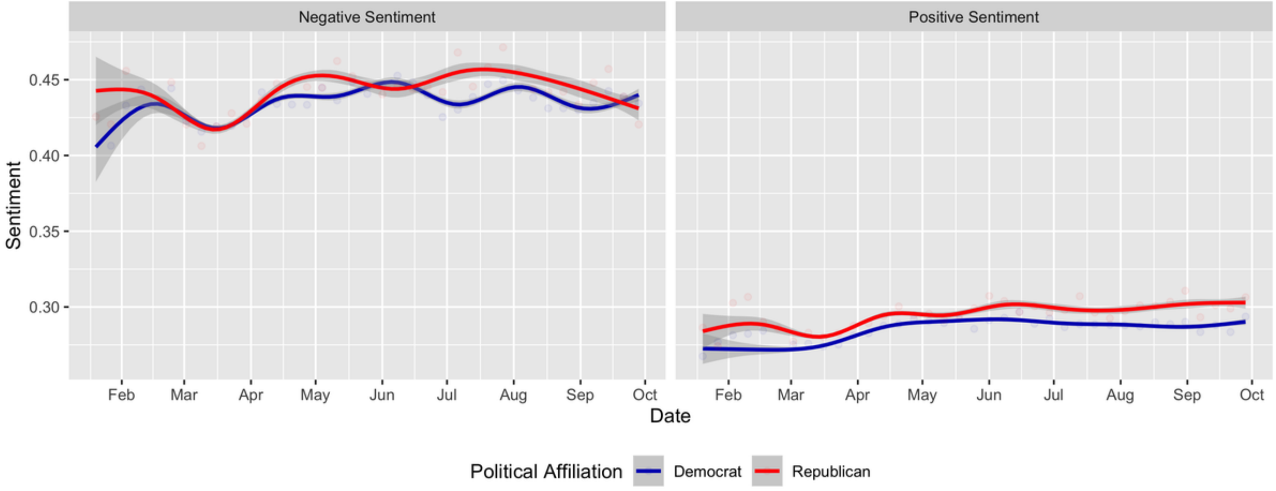
Sentiment Differences by Party Affiliation

We performed an analysis of sentiment for the language used in tweets and found that overall, Republican-affiliated tweets used more positive sentiment, which increased over time. The variation in overall sentiment is shown in Figure 2. Negative sentiment was associated with content from both parties across the following themes: health care and insurance, COVID-19 testing, and racial disparities. Positive sentiment was associated with content within the theme of government public health expertise. Sentiment within themes over time and across parities is identified in Multimedia Appendices 5 and 6.

Figure 2. Sentiment analysis of US legislators' language on Twitter across party affiliations.



Discussion

By using machine learning techniques, we investigated narrative content in over 300,000 twitter posts from US legislators over the course of the COVID-19 pandemic to date. Investigating the language within posts on social media platforms has become more common and has been specifically used to study aspects of health and health care. This study is among the first to analyze US legislators' Twitter-based language to identify the COVID-19–related themes that policy makers are discussing on Twitter with a specific focus on health care–related topics. Additionally, this study deployed advanced language assessments that use machine learning to analyze how legislators are talking about these themes by conducting sentiment analyses throughout the phases of the pandemic.

We noted key differences across the two major US political parties. Health care–related themes that correlated with a Democratic party affiliation focused on the health care access and disparities across race. The themes that correlated with a Republican party affiliation focused on initial and persistent vaccine progress, access to equipment (eg, personal protective equipment), and government expertise. Furthermore, in the language analysis, we identified that across content posted by Republican legislators, there was considerably more content about the pandemic and approaches for managing the pandemic across health care topics. Language analysis was also used to detect thematic differences in narrative content within Twitter posts across the two major political parties. In this study, our results indicated that legislators with a Democratic party affiliation focused their COVID-19 content more toward social services and racial disparities. Content from Republican-affiliated legislators focused thematically on government relief and economic aid. This finding is consistent with surveys of elected officials and the general public, which suggests that awareness and concern about health disparities among Democrats are greater than those among Republicans [13,14].

There are limitations to this study, including the fact that content was collected from publicly available Twitter posts; thus, legislators who do not post content were not included. If a legislator did not have a party affiliation (as noted by the Quorum database), we could not include them in this analysis. We also did not control for demographic or health access data, as our analysis was performed on the language of individual legislators. Further, a topic's significant association with a particular affiliation does not imply that other party legislators did not tweet about it; it only indicates the relative frequency of tweets containing the words that were associated with each topic.

This study highlights the ability to understand how legislators use social media (eg, Twitter); what information they choose to share; and how they frame their content, which was determined through sentiment analysis [15]. These are key insights that will remain important to the public and health care systems as policy makers continue to shape the national and local responses to the pandemic [16].

Abstract

Background: Since late 2019, the lives of people across the globe have been disrupted by COVID-19. Millions of people have become infected with the disease, while billions of people have been continually asked or required by local and national governments to change their behavioral patterns. Previous research on the COVID-19 pandemic suggests that it is associated with large-scale behavioral and mental health changes; however, few studies have been able to track these changes with frequent, near real-time sampling or compare these changes to previous years of data for the same individuals.

Objective: By combining mobile phone sensing and self-reported mental health data in a cohort of college-aged students enrolled in a longitudinal study, we seek to understand the behavioral and mental health impacts associated with the COVID-19 pandemic, measured by interest across the United States in the search terms *coronavirus* and *COVID fatigue*.

Methods: Behaviors such as the number of locations visited, distance traveled, duration of phone use, number of phone unlocks, sleep duration, and sedentary time were measured using the StudentLife mobile smartphone sensing app. Depression and anxiety were assessed using weekly self-reported ecological momentary assessments, including the Patient Health Questionnaire-4. The participants were 217 undergraduate students. Differences in behaviors and self-reported mental health collected during the Spring 2020 term, as compared to previous terms in the same cohort, were modeled using mixed linear models.

Results: Linear mixed models demonstrated differences in phone use, sleep, sedentary time and number of locations visited associated with the COVID-19 pandemic. In further models, these behaviors were strongly associated with increased interest in *COVID fatigue*. When mental health metrics (eg, depression and anxiety) were added to the previous measures (week of term, number of locations visited, phone use, sedentary time), both anxiety and depression (*P*<.001) were significantly associated with interest in *COVID fatigue*. Notably, these behavioral and mental health changes are consistent with those observed around the initial implementation of COVID-19 lockdowns in the spring of 2020.

Conclusions: In the initial lockdown phase of the COVID-19 pandemic, people spent more time on their phones, were more sedentary, visited fewer locations, and exhibited increased symptoms of anxiety and depression. As the pandemic persisted through the spring, people continued to exhibit very similar changes in both mental health and behaviors. Although these large-scale shifts in mental health and behaviors are unsurprising, understanding them is critical in disrupting the negative consequences to mental health during the ongoing pandemic.

Introduction

The COVID-19 Pandemic

COVID-19 has drastically changed life for people worldwide. The World Health Organization (WHO) declared COVID-19 a pandemic on March 11, 2020 [1]. In this work, we extend our previous research beyond the initial phases of the pandemic to June 25, 2020. By this time, the world had seen over 2,000,000 confirmed COVID-19 cases and 100,000 deaths [2], and the severe long-term political, economic, educational, and social ramifications of COVID-19 had grown increasingly acute. Understanding the behavioral and mental health implications for individuals during the spring of 2020, an unprecedented period of high stress, is critical for the upkeep of mental health during the pandemic.

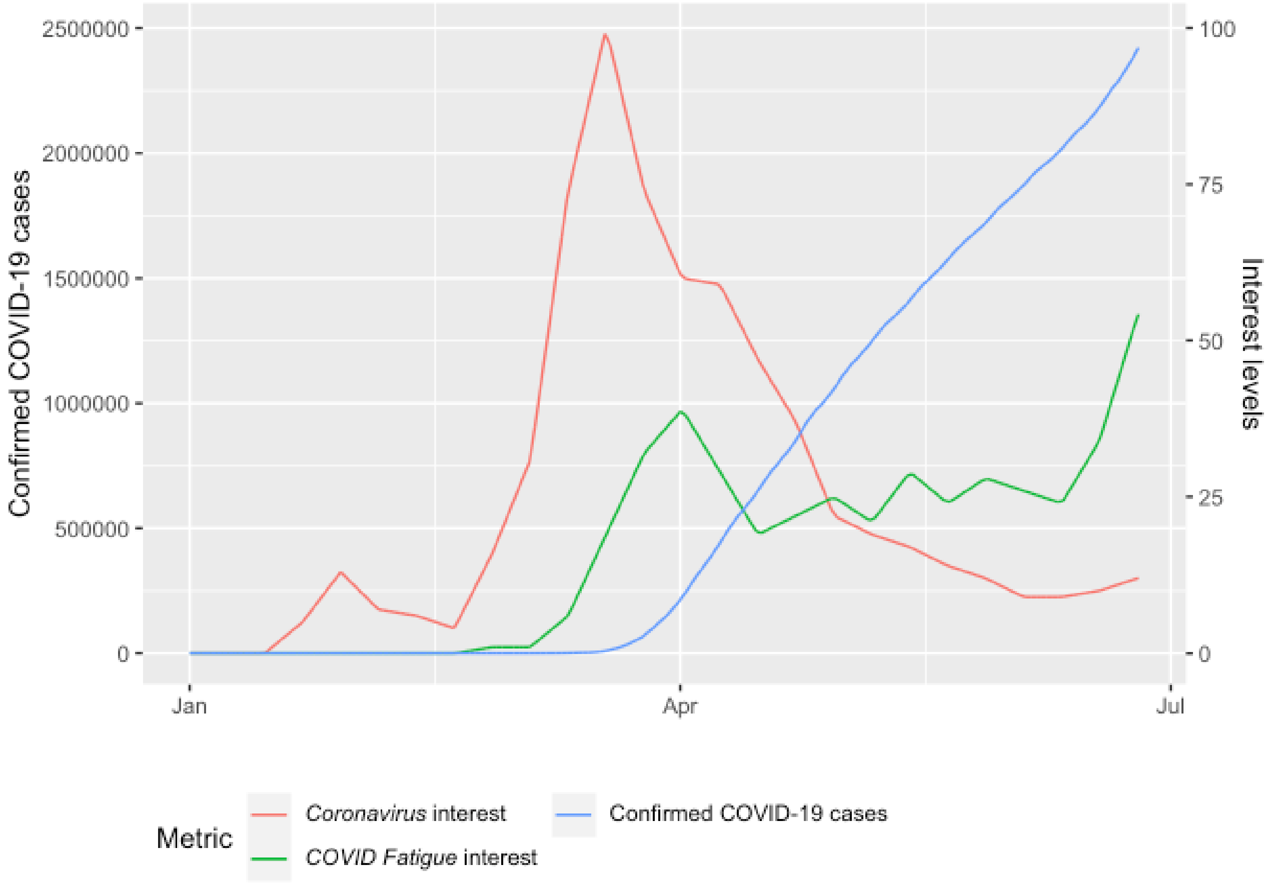
College students seem to be vulnerable to the impact of COVID-19 on mental health [3-5]. In the spring of 2020, global health measures forced many colleges to shut down in an effort to mitigate the spread of the virus. On March 12, 2020, Dartmouth College requested that students leave the campus, with hope that the campus could resume normal operations in 5 weeks. At that time, it was believed that the COVID-19 situation would end rather quickly; however, by March 17, the severity of the virus became more apparent, and Dartmouth College announced that all classes and office hours would be held remotely during the Spring 2020 academic term. Students were asked to leave campus and not return until further notice. Following changes in school, local, and federal policies, drastic alterations in students' behavior were observed. Prior research found that during the initial stages of the pandemic, this cohort of students visited fewer locations, spent more time sedentary, and increased its phone use [6]. All these behavioral changes were linked with increased levels of anxiety and depression [6], a trend observed by other researchers among various groups of college students [7,8]. Despite the negative impact on their mental health, many students continued to practice physical distancing with the hope of a swift return to normalcy. Unfortunately, improved knowledge about the ways in which COVID-19 spreads made it increasingly clear that physical distancing and other measures needed to continue for the sake of public health. Although some localities began to ease their restrictions and reopen in April 2020, it was still widely suggested that people avoid public gatherings and maintain physical distance from others.

COVID-19 Restrictions Over the Long Term

Towns and cities across the United States were forced to sustain COVID-19 "Stay Home, Stay Safe" restrictions in an effort to stem the spread of COVID-19. The effort of adhering to these restrictions seems to have bred fatigue among people nationwide. Although there is evidence that these stay-at-home-orders resulted in an immediate suppression of negative changes in mental health brought on during this time [9], people grew weary of the effort required to maintain constant vigilance. For many, staying at home began to feel like a monotonous rut—many referred to this feeling as "COVID fatigue." Search term interest in *COVID fatigue* is seen alongside interest in *coronavirus* and the total number of confirmed COVID-19 cases [2] (Figure 1). Interest in *COVID fatigue* began to grow about a month into the pandemic (spiking in April) and continued to grow throughout the spring, while interest in *coronavirus* peaked around the time when policy changes were implemented in March before sharply and steadily declining. Therefore, *COVID fatigue* became an appropriate metric for measuring pandemic intensity at a given moment in time, while interest in the search term *coronavirus* seemed to capture the initial pandemic-related changes, reaching peak interest levels in late March. because many students continued to live under "Stay Home, Stay Safe" restrictions throughout the spring, it is necessary to understand how the sustenance of these behaviors is related to mental health.

Over the last year, the COVID-19 pandemic has prompted multiple lockdowns, which have brought about increased interest in the search term *COVID fatigue*, a term that has quickly become the subject of much discussion in public health research [10-13]. Cross-sectional research in Istanbul, Turkey, suggests that those with higher education levels experience more COVID-19–based fatigue [14], which may be attributable to a greater likelihood of this population to adhere to virus protocols and practice physical distancing [14,15]. Recent work proposes that college students may experience increases in depression due to COVID fatigue [16]. Most work measuring COVID fatigue has been limited to the use of web-based surveys. Using smartphone mobile sensing for digital phenotyping enables increased sampling frequency [17] and an ecologically valid approach [18,19], particularly when paired with ecological momentary assessments (EMAs). How behavioral and mental health changes related to COVID fatigue among populations at high risk for mental health issues (eg, college students) remains an unresolved question that we investigate in this work.

Figure 1. Number of confirmed COVID-19 cases graphed alongside search term interest (scaled from 0-100) during the winter and spring of 2020. COVID-19 case data were taken from the COVID-19 Data Repository by the Center for Systems Science and Engineering (CSSE) at Johns Hopkins University [2]. Search term interest was taken from Google Trends.



Modeling Stages of the Pandemic With Changes in Behavior and Mental Health

Using previously successful methods, this work seeks to infer the behavioral and mental health impacts of the initial onset and duration of the COVID-19 pandemic among a cohort of Dartmouth College undergraduate students. Search query–related data are a promising metric in gathering population-based interest, which can be used to successfully identify changes in mental health [9,20,21]. Prior work has shown EMAs to be an excellent tool for gathering real-time assessments of mental health [22]. Notably, researchers have also used EMAs to assess mental health changes during the COVID-19 pandemic [6,23]. Interest in the search terms *coronavirus* and *COVID fatigue* was gathered from Google Trends to quantify the initial and ongoing phases of the pandemic (Figure 1). Interest levels were linearly inferred based on smartphone behavioral sensing data (gathered via passive sensing) and reported levels of anxiety and depression. Linear models are a useful tool in understanding the impact of the COVID-19 pandemic on daily behaviors and mental health in previous work, as a nearly identical method using COVID-19 media presence was previously successful [6]. Previously, we observed that the early media presence of COVID-19 was associated with increased levels of anxiety and depression as well as increased sedentary time and phone use [6]. This work seeks to build on prior work conducted by this and other groups to gain further insight into the ways in which COVID-19 has impacted daily life and mental health. We hypothesized that over nearly 3 months, students would continue to exhibit changes in depression, anxiety, and daily behaviors similar to those seen in the initial response to the COVID-19 pandemic.

Objective

In this work, we seek to understand the behaviors and mental health changes associated with the continuing phases of the pandemic, as inferred by interest in the search terms *COVID fatigue* and *coronavirus*.

Methods

Study Design

All data from this study were obtained from the StudentLife study [24], which is a longitudinal multimodal study designed to follow the experiences of undergraduate students throughout their academic tenure with a focus on mental health. Study components include smartphone mobile sensing through the StudentLife app [25], EMAs, and surveys focusing on a variety of college experience components and functional neuroimaging [26].

Participants

Data were collected from 219 participants who agreed to provide mobile sensing data via the StudentLife app [25]. One participant was removed from the study for having a phone incompatible with the app, and one participant withdrew within a week of starting the study. Data for both participants were excluded from further analyses. Of the remaining 217 participants, 67.8% (147) were female, with an age range of 18-22 years at the time of enrollment. Recruitment for this study began in August 2017 and concluded in November 2018. This study was reviewed and approved by Dartmouth College's Committee for the Protection of Human Subjects. All data analyzed were collected from September 9, 2017, through June 25, 2020.

Academic Terms

At Dartmouth College, the academic schedule consists of a flexible, year-round calendar that is roughly divided into 4 10-week academic terms (quarters), typically followed by 2 or more weeks of break. COVID-19 was first discovered in the United States during Dartmouth College's Winter 2020 term, which began on January 6, 2020. The Spring 2020 academic term (March 30 start date) was the first complete academic term that occurred during the COVID-19 pandemic. To graphically show differences in anxiety and depression related to COVID-19, academic terms, including the subsequent 2 weeks of break prior to the Winter 2020 term, were included as control terms.

Mobile Sensing and Ecological Momentary Assessments

Smartphone sensing data and EMA surveys were administered using the StudentLife application (iOS and Android) [25]. The StudentLife app collects data from several of the phone's sensors, including but not limited to GPS, accelerometer, and lock/unlock status. Anonymized data from the StudentLife app are uploaded to a secure server whenever a participant is both connected to a Wi-Fi network and charging their phone. Data from these sensors are used to assess items such as the day-to-day and week-by-week impact of workload on stress, sleep, activity, mood, sociability, mental well-being, and academic performance [25]. Students are prompted weekly by the StudentLife application to complete a few short surveys, administered as EMAs [22]. These EMAs include the Patient Health Questionnaire-4 (PHQ-4), which combines a brief measure of depressive and anxious symptoms [27] that assesses how often individuals were bothered by specific symptoms over the last 2 weeks with values ranging from 0 to 6 for each subscale. The PHQ-4 combines the Patient Health Questionnaire-2 (PHQ-2) and the Generalized Anxiety Disorder-2 (GAD-2) tool.

Sedentary Time

Sedentary time, or stationary duration, is computed with algorithms that detect a lack of movement based on accelerometer data from a phone's sensors. This enables us to measure students' activity or, more precisely, their lack of activity level. The StudentLife app continuously infers physical activities using the Android activity recognition application programming interface [28,29] or iOS Core Motion [30].

Sleep

Sleep was inferred through a combination of passive sensing features (ambient light, movement activity, screen on/off). In this way, three features were computed: sleep onset, wake time, and sleep duration. These measures of sleep have been shown to be accurate within ±30 minutes of total sleep duration [25].

Location

Density-based spatial clustering of applications with noise (DBSCAN) [31] was used to cluster GPS coordinates to determine the number of locations visited and distance traveled during a given time period. Locations were detected when 3 GPS samples (sampled every 10 minutes) were within a radius of 30 meters. Distance was calculated in meters traveled between all locations throughout the day.

Phone Use

Unlock duration is a measurement of time during which a user's phone is unlocked and the screen is on, calculated as the time between the user unlocking the phone and the user either manually relocking the phone or autolocking due to disuse (the iOS default is 30 seconds, Android defaults vary by manufacturer, and users can alter this time through their phone settings). Notification and system services do not influence the measurement of unlock duration. For the iOS app (189 users), from the start of the study in September 2017 until September 2018, unlock duration was measured by remotely triggering phones every 10 minutes, sampling 1 minute every 10 minute period (minimum 10% temporal coverage). After September 2018, phones were remotely triggered every 3 minutes, with subsequent sampling for 1 minute. Lock/unlock behaviors within that minute are recorded in real time, while locks/unlocks for the remaining 2 minutes are logged during the next remote trigger. The Android phone app natively supports phone use tracking and does not need to be triggered (28 users).

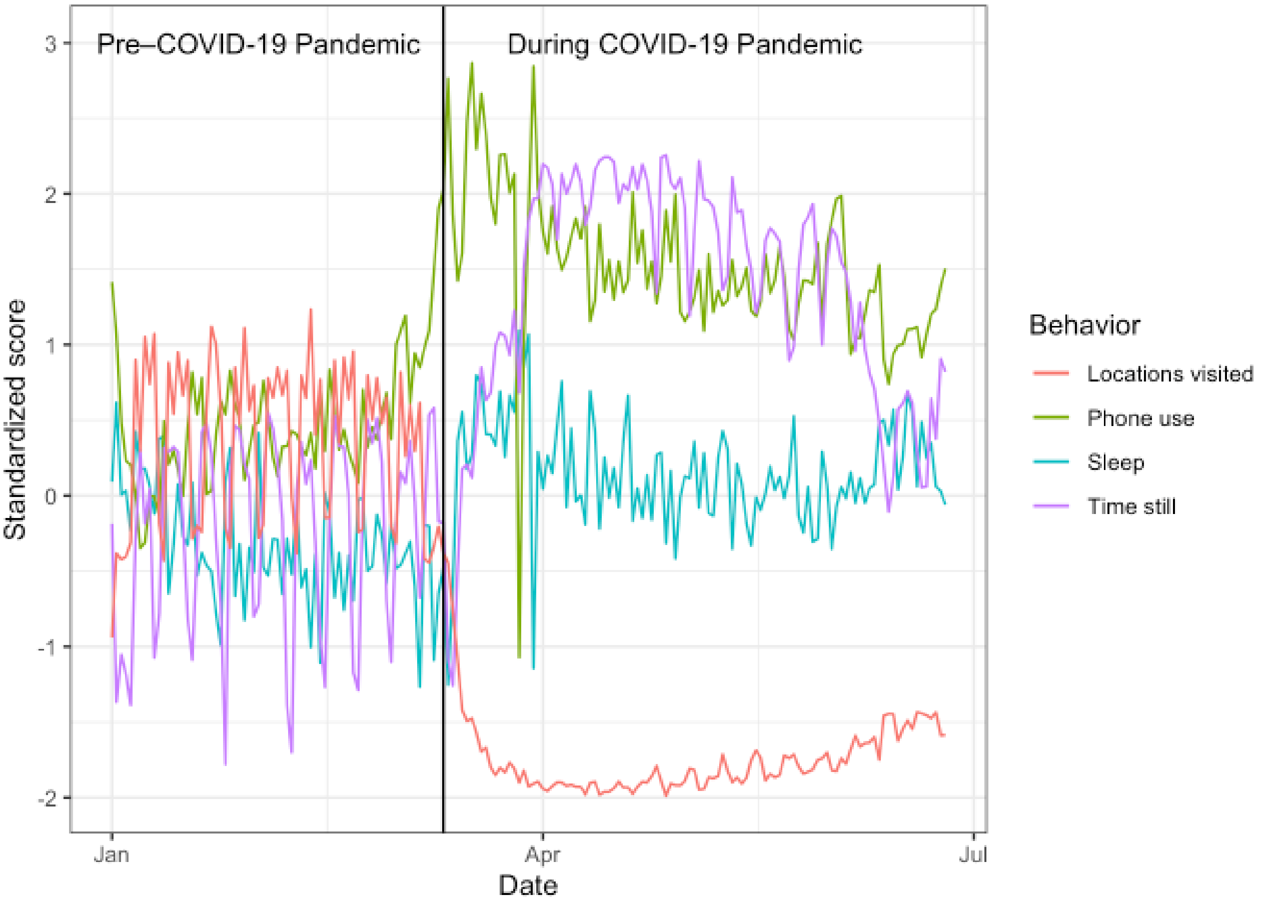
Google Trends

Google is the world's leading search engine, and Google Trends is an excellent tool to quantify topic interest. In turn, interest data from Google Trends have been successfully used to quantify changes in mental health [9,20,21]. Google data are posted publicly, and data can be downloaded directly through Google's web portals or through freely available software. Google normalizes search data by region (in this case, the United States). To normalize the data, each data point is divided by the total searches of the geographic and time range it represents to compare relative popularity; the results are then scaled from a range of 0 to 100 based on a topic's proportion to all searches on all topics [32]. Search terms with low interest appear as "0," while "100" reflects peak interest during a given period. To obtain an unbiased measurement of interest in *coronavirus* and *COVID fatigue*, interest in both search terms was pulled for the duration of the entire study (September 7, 2017, to June 25, 2020). Data received from Google Trends were reported on a weekly scale; interest was reported for each Sunday. To gather a more finely grained real-time view of interest, the data was linearly interpolated using the "approxm" function from the Freqprof package in RStudio.

Data Processing, Modeling, and Visualization in RStudio

Modeling was implemented in lme4 [33] and lmerTest [34]. All plots were generated using ggplot2 [35]. Result tables were produced using stargazer [36]. On average, 164/217 participants (75.6%) reported mobile sensing data each day. For all participants with data, for the following behaviors, inferred through mobile sensing, daily group-level averages were calculated, standardized, and plotted over the time course of January to July 2020: locations visited, phone use, sleep, and time still (Figure 2). The objective of the analyses was to determine how the shock and sustained nature of the pandemic impacted the participants' behaviors and mental health. The term week was modeled as linear and quadratic factors. To obtain a variable mirroring interest in *coronavirus* and *COVID fatigue*, topic interest in both *coronavirus* and *COVID fatigue* was gathered from Google Trends. Interest levels were modeled with fixed effects of reported depression and anxiety levels, unlock duration, unlock number, sedentary time, sleep duration, number of locations visited, and term week (linear and quadratic) variables, as well as random intercepts for each participant. For each variable, any days with missing data (14.47%) were excluded from the analysis. Each variable except participant was scaled to aid model convergence. *P* values were calculated using the Satterthwaite method as implemented in lmerModLmerTest as part of lmerTest.

Figure 2. Standardized daily scores of the number of locations visited, duration of time phone unlocked, sleep duration, and sedentary time before and after the World Health Organization declared COVID-19 a global pandemic (March 11, 2020). All behaviors were calculated using data from the StudentLife app.

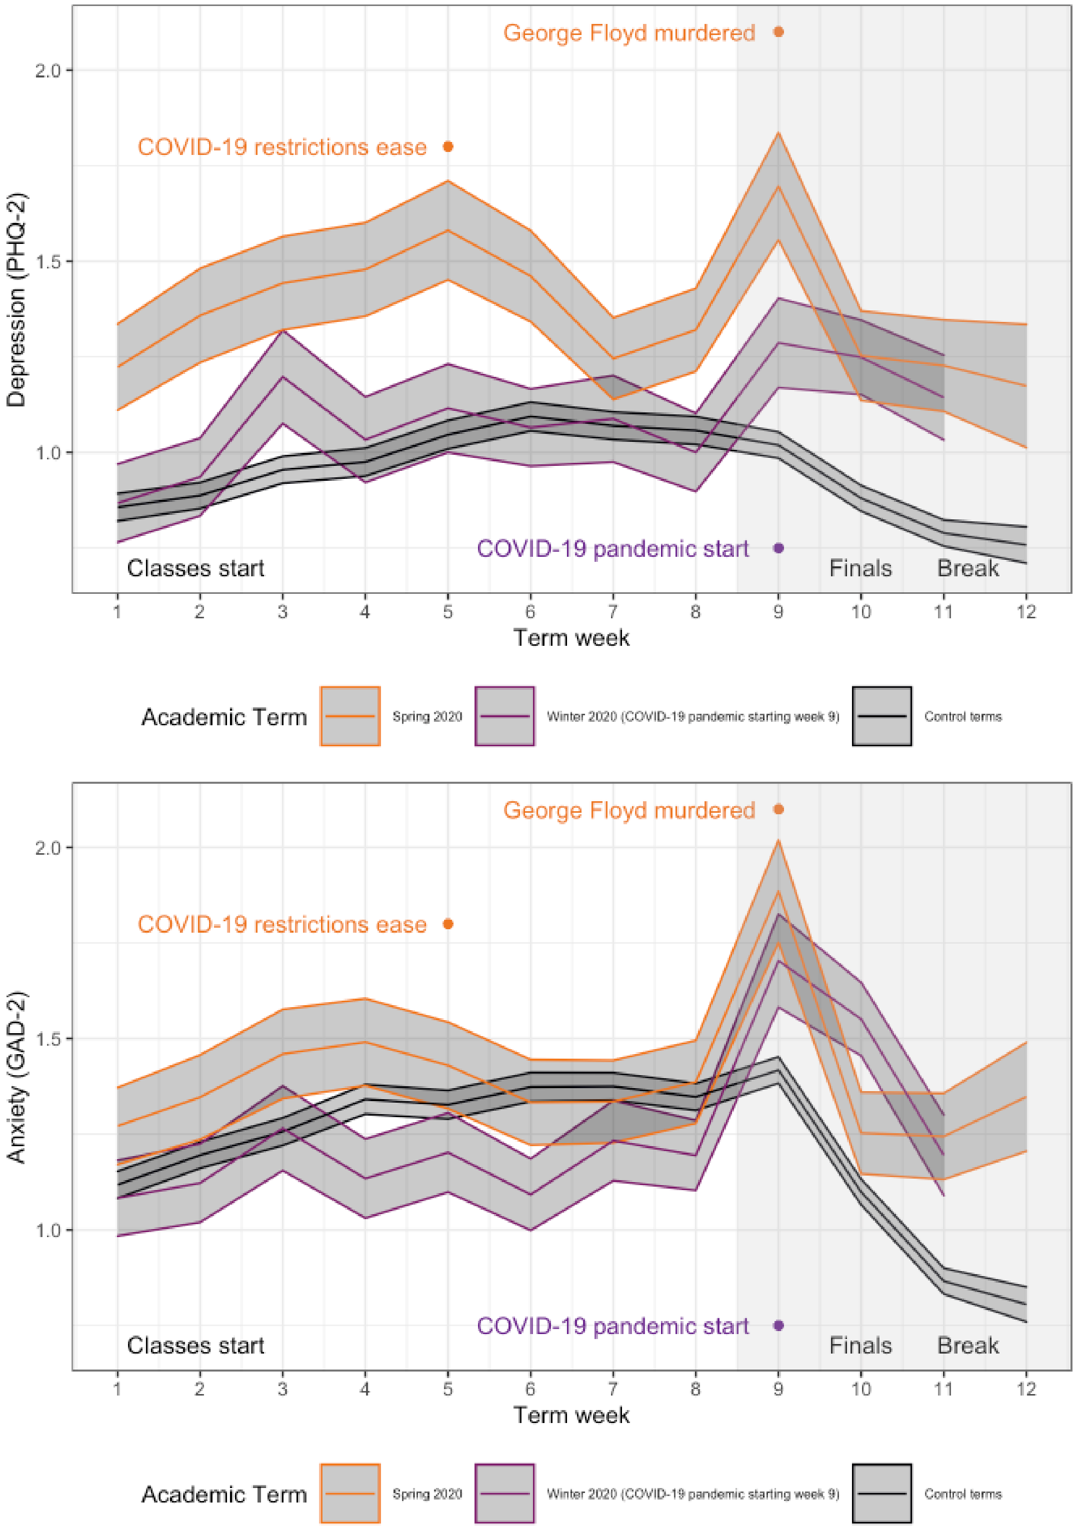


Results

Behavioral and Mental Health Changes Associated With the COVID-19 Pandemic

To visually observe shifts in behaviors due to the COVID-19 pandemic, standardized scores were produced for each behavior plotted with a vertical line marking the date on which the WHO named COVID-19 a pandemic (Figure 2). Students visited fewer locations, used their phones more, spent more time sedentary, and initially exhibited increases in sleep before a sustained decrease in sleep. Notably, the graph shows less extreme peaks and valleys, suggesting that differences in behavior between weekdays and weekends were less pronounced during the COVID-19 pandemic. The mean values of depression and anxiety were plotted by week of the term; data were combined from all study participants from all terms prior to the Winter 2020 term, which was plotted as a separate line along with the Spring 2020 term. Standard error was plotted as a shaded ribbon surrounding the mean. Sustained increased levels of depression and anxiety throughout the Spring 2020 academic term compared to Winter 2020 and control terms were plotted (Figure 3). Peak self-reported anxiety and depression symptoms were observed during the ninth week of the Spring term, corresponding to the time before final examinations, increases in COVID-19 cases, and the murder of George Floyd. Linear models were produced to better assess these differences in a more quantitative manner.

Figure 3. Depression (top) and anxiety (bottom) scores across an academic term and the first 2 weeks of break, with the term influenced by the outbreak of the COVID-19 pandemic as a separate line. The shaded ribbons represent the standard error for each week. Winter 2020 weeks influenced by policy changes related to COVID-19 are represented with a shaded box from weeks 9 to 12. Colored text corresponds to the term in which the event took place. Depression and anxiety were measured with the PHQ-2 and GAD-2 scales through the StudentLife app. Control terms include data from the same group of individuals across previous academic terms. Finals: final examinations; GAD-2: Generalized Anxiety Disorder-2; PHQ-2: Patient Health Questionnaire-2.



Multiple models for sedentary time, phone use, sleep, locations visited, depression, and anxiety were tested (see the *Methods* section for specific details). For all mobile sensing variables except phone use, superior fit was observed with the most complex model that included the COVID-19 academic term, linear and quadratic term week trends, the interaction of the COVID-19 academic term with each of the term week trends, and allowance for random intercepts for each participant's data (random effects). For phone use, superior fit (measured by lowest deviance) was observed with the model including the COVID-19 academic term, linear and quadratic term week trends, and the interaction between the linear term week variable and the COVID-19 academic term. Modeling of the COVID-19 academic term compared with non–COVID-19 academic terms identified significantly increased sedentary time, phone use, sleep, depression, and anxiety, along with a decrease in locations visited (*P*<.001; Table 1). Significant interactions of the COVID-19 term and quadratic term week regressor for sedentary time, locations visited, and anxiety (*P*<.001), as well as sleep and depression (*P*=.05), were observed. Significant interactions between the COVID-19 term and the linear term week regressor for locations visited, phone use, and anxiety (*P*<.001) as well as sedentary time (*P*=.01) and depression (*P*=.05) were also observed.

Table 1. Models of sedentary time, locations visited, sleep duration, phone use, depression, and anxiety by week and by presence of COVID-19 during the academic term.

Variable	Sedentary time (1) (91,541 observations)		Locations visited (2) (85,148 observations)		Sleep duration (3) (91,541 observations)		Phone use (4) (91,541 observations)		Depression (5) (21,284 observations)		Anxiety (6) (21,284 observations)

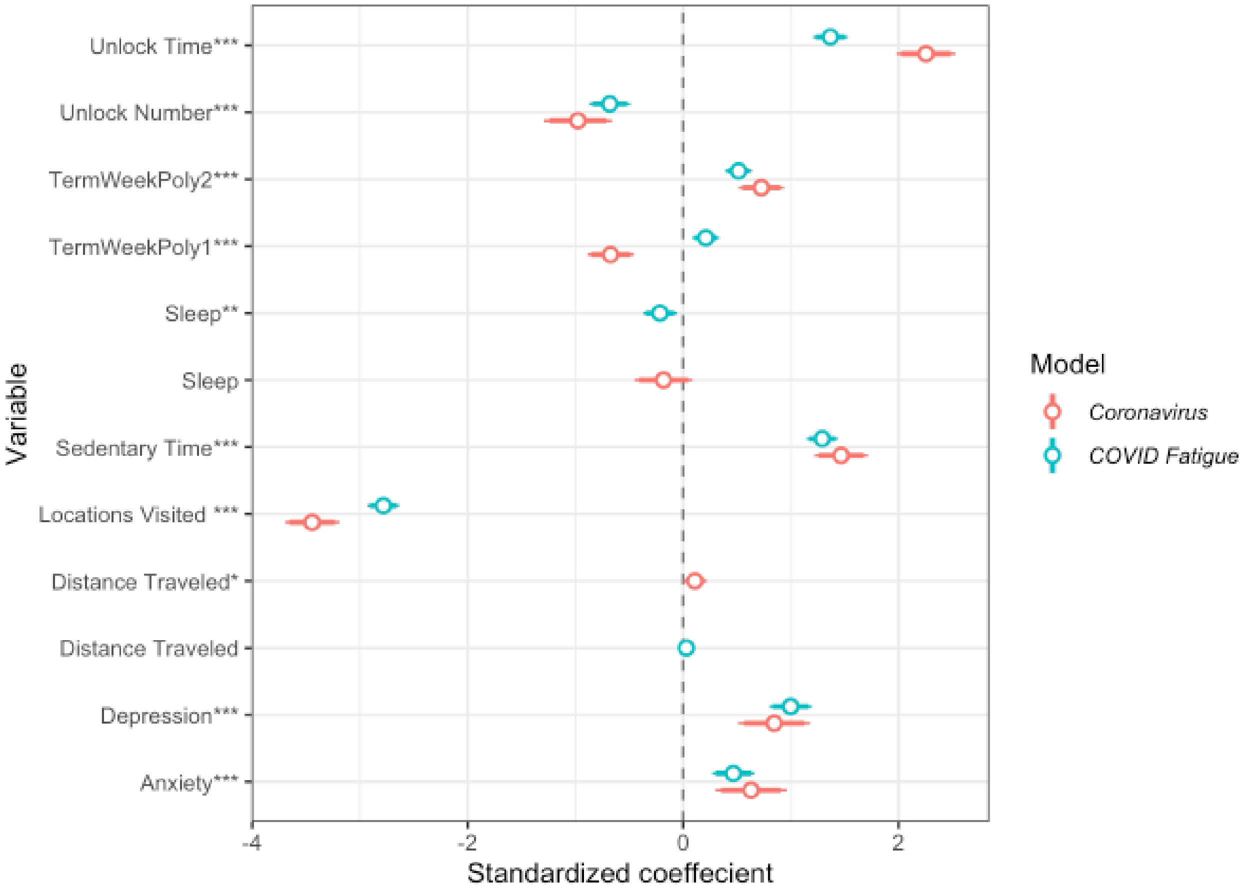
COVID-19 Interest, Mental Health, and Mobile Sensing

After observing broad differences in sleep, phone use, locations visited, sedentary time, depression, and anxiety between the Winter 2020 term and previous terms, the next goal was to see if these behaviors changed on a daily scale, particularly mirroring the relative interests in *coronavirus* and *COVID fatigue* over the duration of the study. Interest in both variables was at zero until March 2020 (Figure 1). To gather what behaviors changed with *coronavirus* interest and how they changed, we included fixed effects for phone use (unlock duration and unlock number), sedentary time, sleep duration, number of locations visited, and linear and quadratic academic term week regressors. Random intercepts per participant were included in the model. Each variable was scaled to help with convergence of the restricted maximum likelihood model and to obtain regression coefficients that can be compared for relative importance. Models inferring interest in *COVID fatigue* had a better fit (lower deviance) than models of *coronavirus* interest. All variables were significantly associated with interest in the search term *coronavirus*, and all variables except distance traveled were significantly associated with interest in *COVID fatigue*. In both models, phone use (unlock duration) had the largest positive standardized coefficient, followed by sedentary time. The number of locations visited had the largest magnitude of negative standardized coefficient, followed by the number of phone unlocks and sleep duration (*P*<.001).

In the second set of models of interest data, we again made inferences with mobile sensing features, this time with the addition of self-reported anxiety and depression scores. Again, all variables seemed to produce a better fit when inferring interest in COVID fatigue. When anxiety and depression were added to the previously used sensing model, our model demonstrated that increased anxiety and depression were significantly associated with rising interest in *coronavirus* and *COVID fatigue* (*P*<.001). Again, we observed increased phone use (unlock duration), increased sedentary time, and decreased number of locations visited, with standardized beta weights stable across both models. Sleep was negatively associated with interest in *COVID fatigue* (*P*=.05) but no longer had a significant association with *coronavirus* interest, perhaps due to the weekly measured mental health metrics accounting for variance. Notably, both the linear and quadratic term week variables were positively associated with *COVID fatigue* interest, though only the quadratic term week variables were positively associated with *coronavirus* interest. A coefficient plot depicting the relative impacts on behaviors and mental health is shown in Figure 4.

Figure 4. Coefficient plots from mixed linear models of interest in the search terms *coronavirus* and *COVID fatigue*, inferred by mobile smartphone features and self-reported mental health. Intercepts and random intercepts per participant are not plotted. **P*<.05; ***P*<.01; ****P*<.001.



Discussion

Principal Findings

As in our previous work, we found increased interest in COVID-19 to be associated with increased depression and anxiety alongside stark behavioral changes. Further linear models showed that as initial interest in the search term *coronavirus* increased, a cohort of 217 Dartmouth College undergraduate students became more sedentary, visited fewer locations, slept less, used their phones more, and showed increases in anxiety and depression. Although initial models suggested an increase in sleep during academic terms affected by COVID-19, controlling for other sensing variables revealed that students exhibited decreases in sleep as the pandemic endured. Although we observed an increase in distance traveled as *coronavirus* interest rose, we attribute this finding to students returning home, as it coincides with Dartmouth College closing its campus. We found that the search term *coronavirus* had a stronger relationship with changes in behaviors and mental health, with the exception of levels of depression. With sustained adherence to "Stay Home and Stay Safe" guidelines implemented by many national and international governments, we found that as the pandemic endured, students were more sedentary, visited fewer locations (as inferred from GPS tracking), slept less, used their phones more, and exhibited increases in anxiety and depression. Notably, over the entire course of the study, self-reported anxiety and depression levels were highest in the week after George Floyd was murdered. Future digital phenotyping work should investigate the impact of current events on mental health and behavior.

Our models revealed that behaviors and mental health changed in response to the pandemic over a sustained period of time. Although this work is descriptive by nature, behavioral changes sometimes drive changes in mental health in a lagged manner. Notably, a comparison of contemporaneous correlations of data collected prior to and during the COVID-19 pandemic revealed a decrease in the strength of the correlations between sedentary time and mental health (anxiety and depression). Notably, the correlation between locations visited and anxiety also became weaker. Future COVID-19–related work investigating causal relationships between general daily travel, particular sedentary behaviors, and changes in mental health would be of high interest.

Unfortunately, we remain engaged in a battle against the continued spread of COVID-19, necessitating long-term adherence to physical distancing and other mitigation protocols. Although the initial impact of these unprecedented shifts in behavior has been documented, the effects of the longevity of the pandemic are less known. This work uses longitudinal data from a cohort of 217 college students to observe what behavioral and mental health changes are associated with the enduring pandemic. As in previous work, we found increased interest in COVID-19 to be associated with increased depression and behavioral changes. Further linear models showed that as initial interest in *coronavirus* increased, participants became more sedentary, visited fewer locations, slept less, used their phones more, and showed increases in anxiety and depression. Although initial models suggested an increase in sleep during academic terms affected by the COVID-19 pandemic, controlling for other sensing variables revealed that students exhibited decreases in sleep as the pandemic endured.

As in previous work [6], we again observed that COVID-19 is associated with decreased sleep, increased sedentary time, and negative mental health outcomes. Recent work, collected prepandemic, suggests that sleep may mediate a relationship between physical activity and stress [37]. An overwhelming body of research supports the claim that increased physical activity is associated with longer, better quality sleep [38-40]. On the other hand, physical inactivity tends to be associated with increased stress [41], and recent work suggests that exercising during the pandemic may help reduce levels of stress [42]. Stress has been implicated in changes in mental health [43,44] and poor sleep [45-47]. Importantly, other work identifies disturbances in sleep and physical activity that coincide with COVID-19 fatigue [12]. Although the observed prolonged decreases in sleep may potentially mediate a relationship between sustained decreased physical activity and mental well-being during the pandemic, mental health research currently remains uncertain.

Our finding of sustained increased phone use during the COVID-19 pandemic presents a quandary. Work prior to the pandemic suggests that smartphone overuse is associated with negative changes in mental health [48]. However, at a time of widespread social distancing, it seems that smartphones may have a more complex relationship with mental health. Recent research has shown that using smartphones to connect with friends and colleagues may be associated with increased well-being during the pandemic [49]. Moreover, social connection may provide resilience in battling COVID-19 fatigue [50]. Simultaneously, increased phone use during the pandemic may reflect increased social media use and negative changes in mental health [49,51]. Given the observance of increased phone use among college students during the COVID-19 pandemic, future work may seek to uncover the various impacts of phone use during the pandemic.

Primary takeaways from the models are that individuals are maintaining previously seen changes in behavior and mental health. This finding suggests the importance of prioritizing communication with loved ones, and it emphasizes the benefit of maintaining a regular sleep schedule and physical activity to help improve mental health.

Study Limitations and Future Directions

One possible limitation of this study is the search terms used. Although other literature reports use the term “COVID fatigue” to refer to behavioral exhaustion, it is worth noting that similar search terms listed on Google Trends are related to the symptomatology of COVID-19 (ie, fatigue related to virus contraction) rather than to behavioral fatigue. Our graphs show that interest in *COVID fatigue* begins to increase well into the pandemic, but after interest in *coronavirus* increases; however, it is possible that we are partially capturing interest in symptoms. Still, we observed that behaviors and mental health model interest in *covid fatigue* with a better fit than with interest in the term *coronavirus*; this finding suggests that the gradually building interest in COVID-19 fatigue accurately reflects the continuing phases, while interest in the disease itself reflects the initial phase. Future work may consider identifying trending search terms such as *covid mutation* or *covid vaccine* to help quantify the interest in the continuation of the pandemic and how that interest may be impacting mental health. Similarly, as vaccines are more widely distributed, using the terms *covid vaccine* and *herd immunity* along with the terms used in this work could be an effective way to model the impacts of later and (hopefully) final stages of the COVID-19 pandemic on mental health.

Although the mobile smartphone sensing data gathered by the StudentLife app are quite robust, they too have potential limitations. When mobility is decreased, such as during a stay-at-home order, people may not always have their phones with them, which could lead to an overestimation of sedentary time and sleep. Our moderate sample size of 217 total participants across all terms and 212 participants during the COVID-19 pandemic (97.6%) limits the generalizability of the findings. Further, participants may be preferentially accessing larger screens (eg, tablets, laptops, or televisions). Because the app was only installed on the students’ mobile phones, our metric of phone use (as measured by screen unlock duration or number of unlocks) may underestimate the total amount of screen time. However, we did observe increased phone use, suggesting that the effect sizes we observe are underestimated. Future digital phenotyping work capable of distinguishing different types of screen time during the pandemic would be of high interest, as would work that distinguishes the purposes (ie, working, watching Netflix, reading) and proportions of screen use. Further work could also use smartwatches to improve the measurement of behaviors such as sedentary time and allow for more frequent sampling of phone use, location and other measures. Additionally, the use of smartwatches could facilitate highly accurate inferences of time spent exercising, sleep and sedentary time, as these watches typically track heart rate. Despite the moderate sample size and potential data inaccuracies, strong significant effects on mental health and behaviors were observed, suggesting robust effects.

Although finding ways to combat COVID-19 fatigue is beyond the scope of this work, we encourage more research on the subject. In our work, we were unable to infer daily changes in mental health, as to maximize long-term retention, the StudentLife app prompted participants to respond to weekly, not daily, EMAs. Although we presume that college students are likely to be more susceptible to experiencing pandemic fatigue, we do not directly gather fatigue-related feedback. Future studies may consider addressing fatigue more directly, although one should be cautious when choosing metrics of fatigue, as they may also be symptoms of depression (eg, physical exhaustion, anhedonia, trouble sleeping). Administering EMAs on a daily, rather than weekly, basis could help parse day-to-day changes in mental health related to fatigue. In light of the drastic changes in sedentary time, it is critical to find day-to-day activities or routines that may help prevent or reduce fatigue levels. There may be differences in the degree of reported mental health changes between those who spend more time watching television compared to those using social media. Although gathering enough participants may be challenging, using questionnaires to investigate specific behaviors that drive or reduce fatigue levels is critical.

Comparison With Prior Work

In the initial stage of the COVID-19 pandemic, as the media presence of COVID-19 increased, individuals exhibited increased levels of depression and anxiety alongside increased sedentary time, phone use, and a decrease in the number of locations visited. This work examined if the same cohort of individuals exhibited the same changes in behaviors and mental health over the course of a 12-week academic term. Rather than using media presence, this work uses search term interest gathered from Google Trends, a tactic that has recently proved fruitful during the pandemic [9,20]. In this work, we chose the search term *COVID fatigue* to measure the intensity of the pandemic at a given moment to add to the prior knowledge gained during the initial phases of the pandemic. This tactic enabled us to observe what behavioral and mental health changes were associated with the ongoing COVID-19 pandemic, as opposed to focusing on the initial phase, as in prior work. In addition to previously observed shifts in mental health and behaviors, we observed significant decreases in sleep as the COVID-19 pandemic endured.

Conclusions

While the long fight against COVID-19 continues, we must further our understanding of its impacts on mental health. This study provides additional insight into mental health and related behaviors during the ongoing COVID-19 pandemic. Using mixed linear models of smartphone mobile sensing and self-reported mental health questions, we were able to infer the initial and ongoing phases of the COVID-19 pandemic, as measured by search term interest in *coronavirus* and *COVID fatigue*; moreover, we were able to validate that the participants' mental health and related behaviors changed contemporaneously with relative interest levels in these terms. Increases in depression, anxiety, sedentary time, and phone use, alongside decreases in sleep and the number of locations visited, are significantly associated with the ongoing pandemic. All of these changes seem very similar to those seen during the initial phases of the pandemic. As the virus continues to mutate, in future work, we may attempt to identify behaviors as resilience factors for changes in mental health. Similarly, work tracking the distribution of vaccines may elucidate a return to pre–COVID-19 pandemic levels of behavior and mental health.

Abstract

Background: Due to strict, nationwide, comprehensive COVID-19 protective measures, including home quarantine, all Chinese medical students began taking web-based classes beginning in the spring semester of 2020. Home quarantine, web-based classes, and the stress surrounding the COVID-19 pandemic may have triggered an increased incidence of mental health problems among medical students. Although there have been increasing amounts of literature on depression among medical students, studies focusing on positive psychological resources, such as resilience during the COVID-19 pandemic, still need to be expanded.

Objective: This study aims to assess depression among medical students who are taking web-based classes during the COVID-19 pandemic and to investigate the role of coping styles as mediators between resilience and depression.

Methods: A cross-sectional study of 666 medical students involving stratified sampling in Shenyang, Liaoning Province, China, was completed between March 20 and April 10, 2020. The participants responded to a self-administered, smartphone-based questionnaire, which included the Patient Health Questionnaire-9, Simplified Coping Style Questionnaire, and Ego Resilience 89 Scale. Hierarchical linear regression and structural equation modeling were used in this study.

Results: The prevalence of depression among the participants was 9.6% (64/666) in this study. The regression analysis revealed that grade (the year in which the medical student was in training) (P=.013), how well students adapted to web-based classes (P<.001), their levels of resilience (P=.04), and their coping styles were independent predictors for depression (P<.001). Resilience and positive coping styles were negatively related to depression (resilience: P=.04; positive coping styles: P<.001), and negative coping styles were positively related to depression (P<.001). The structural equation modeling analysis showed that the effect of resilience on depression was partially mediated by coping styles (P=.007).

Conclusions: In this study, it was found that the prevalence of depression was slightly low and coping styles mediated the association between resilience and depression among medical students during the COVID-19 pandemic. These findings have significant implications for future studies. Future studies and interventions should aim to improve resilience and promote positive coping styles.

Introduction

The COVID-19 pandemic has deeply affected peoples’ lives all over the world since its emergence in 2019. Both isolation and economic pressure have had a profound impact on the psychosocial environment in each affected country. The pandemic has also increased the public’s susceptibility to detrimental psychological consequences [1]. According to a Chinese study, more than half the study population reported moderate or severe psychological impacts resulting from the COVID-19 pandemic [2]. Quarantine-associated mental health issues involve depression, anxiety, and irritability [3].

School lockdowns were implemented in many countries [4]. In order to better prevent and control the further spread of COVID-19, many universities in China began conducting web-based classes in February 2020. With the unprecedented number of web-based classes, home-quarantined medical students' psychological status is an important area of investigation. It has been reported that the rate of anxiety and depression among medical students is high [5], and the COVID-19 pandemic might bring about further risks to their mental health. Medical courses usually involve practice and experiments. However, web-based classes cannot provide such opportunities, which may add to medical students' worries about their academic achievements and result in high amounts of mental stress. Students have been reported to prefer studying in classrooms over having web-based classes due to the feeling of being together during classroom learning and the ability to share perspectives [6]. Therefore, the lack of peer contact and face-to-face communication with teachers in web-based classes may increase the risk of developing worry, anxiety, or even depression among medical students.

Depression—a mood disorder defined by sadness, inactivity, the loss of appetite or overeating, and difficulty in concentrating—can result in the reduced ability to perform daily activities among some people. Depression is one of the most often identified health issues among college undergraduates [7,8] and is especially common among medical undergraduates [9,10]. Previous studies have found that approximately 30% of medical undergraduates in Europe experience anxiety or depression [11,12]. Mental health disorders among home-quarantined university students have also been found in a previous study, which reported that the prevalence of depression was as high as 9% among university students about 1 month after COVID-19 outbreak in China [13]. A large cross-sectional study that included 44,447 Chinese college students reported an overall prevalence of depression symptoms of 12.2% during the COVID-19 pandemic [14]. The increased prevalence of depression was also observed in the winter 2020 academic semester in a US study [15].

The cognitive-behavioral model of health anxiety [16] suggests that some individuals have maladaptive assumptions about their health and, consequently, tend to overconsume health information, which could lead to high levels of anxiety [17]. Based on this model, individuals who have high levels of anxiety tend to be more anxious during a pandemic [18,19]. The transactional stress model theory [20] states that the responses of individuals who are faced with stress are affected by the coping process during a stressful experience [21] and that situation appraisal and coping can be influenced by positive personal resources.

There are many recent, positive psychology [22,23] studies that focus on depression, and resilience—a positive capability—is a topic of wide concern [24,25]. Resilience refers to one’s capability to adjust to challenges and adverse events [26,27] such as trauma, threats, or other major stresses, and resilience may prevent depression [28-30]. People who are less resilient are more susceptible to pathological reactions to adversities, while people who are more resilient are more likely to be protected against adversities [31].

According to the transactional stress model theory, the process of coping plays a significant role in individuals’ responses to stress [21]. Coping presents strategies of cognition and behavior that individuals can use to master, decrease, or stand up to the inward or outward demands of stressful situations [32]. Dynamic reactions to adversities aid individuals in preventing themselves from developing psychological impairments. Coping styles generally consist of two categories—positive coping and negative coping. Positive coping involves managing problems, adjusting quickly to stressors, and allaying pressure, whereas negative coping includes avoidance, social withdrawal, and the pitying of oneself, which all exacerbate anxiety. Studies have shown the significant correlation between negative coping styles and depression [33,34]. Positive coping styles help individuals to cope with adversities actively. This may involve seeking others’ advice and finding out solutions to problems, which is beneficial for mental well-being. Previous studies have indicated that coping styles play a mediating role in the relationship between perfectionism and depression among undergraduate students [35] and mediate the association between depression and eating disorders among Chinese female undergraduates [36]. Thus, it has been speculated that coping styles would mediate the relationship between resilience and depression.

This study assessed the prevalence of depression among medical students and determined whether coping styles play a mediating role in the relationship between resilience and depression among medical students during the COVID-19 pandemic. This study examined the following three hypotheses: (1) higher levels of resilience predict lower depression scores; (2) coping exerts a positive effect on relieving depression; and (3) coping styles mediate the relationship between resilience and depression.

Methods

Study Design and Participants

A cross-sectional study involving stratified sampling was carried out by conducting a self-administered questionnaire on Wenjuanxing—a smartphone- and web-based questionnaire platform—between March 20 and April 10, 2020. Wenjuanxing is a widely used, open, web-based questionnaire platform that was developed by Changsha Ranxing Information and Technology Limited Company. The free and self-design version was used in this study. The validity and reliability of the questionnaire that we designed and used in this study were examined.

Medical students who were home-quarantined in their first, second, or third year at China Medical University were eligible for this study. In total, 8 classes from each grade in which the medical students were in training were randomly selected. The medical students from 24 classes in their first, second, or third year at China Medical University were selected as the participants and finished the questionnaire. Of the total 720 medical students who were recruited in this study, 666 participants responded completely to the questionnaire, resulting in a valid response rate of 92.5% (666/720).

Ethics Statement

All participants were fully informed of the study protocol and provided informed consent prior to taking the web-based questionnaire. Participation was voluntary and anonymous. The study protocol was approved by the Ethics Committee of China Medical University.

Demographic Characteristics of Participants

Demographic information, including grade (the year in which the medical student was in training; ie, freshman, sophomore, and junior year), gender, age (<20 years and ≥20 years), fathers' education (junior middle school and below and specialized secondary school and above), mothers' education (junior middle school and below and specialized secondary school and above), monthly income (≤RMB 5000 [US $778.30] and >RMB 5000 [US $778.30]), major (clinical medicine and others), and whether students adapted to web-based classes (yes or no), was collected.

Measurement of Depression

Depression was measured with the Patient Health Questionnaire-9 (PHQ-9), which is commonly used for the measurement of depression based on the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition criteria, is comparably sensitive and specific, and includes 9 items [37]. A score of ≥10 on the PHQ-9 was considered as the indicator for the existence of depression. The PHQ-9 has been widely used in previous studies among the Chinese population [38]. Many previous studies have confirmed that the PHQ-9 has good reliability, ranging from 0.749 to 0.92 [38-41], and the Cronbach α coefficient of the PHQ-9 was .927 in this study.

Measurement of Coping Styles

Coping styles were assessed with the Simplified Coping Style Questionnaire, which included 20 items using a Likert scale of 0 (never) to 3 (frequently). In this study, the Cronbach α coefficient of the Simplified Coping Style Questionnaire was .862.

Measurement of Resilience

Resilience was measured with the Ego Resilience 89 Scale, which has good internal reliability [42] as well as superior construct validity [43]. Participants completed the 14-item, 4-point scale by indicating the degree to which they approved of each statement, with scores ranging from 1 to 4 (1="does not apply at all"; 2="applies slightly, if at all"; 3="applies somewhat"; 4="applies quite strongly"). In this study, the Cronbach α coefficient of the Ego Resilience 89 Scale was .935.

Statistical Analysis

SPSS 17.0 (IBM Corporation) and AMOS (Analysis of Moment Structures) 24.0 (IBM Corporation) were used for statistical analyses in the present study. The comparison of differences among classified groups was conducted with *t* tests (two-tailed) and one-way analysis of variance tests, and a two-tailed *P* value of less than .05 considered statistically significant.

In order to examine the incremental variance of any given set of independent variables and to assess the mediating role of coping styles in the association between resilience and depression, hierarchical linear regression analysis was used. Depression was used as the dependent variable. Resilience and coping styles were used as the independent variables. The variables were entered into models via the following step-by-step process: in step 1, the demographic characteristics of the medical students were entered; in step 2, resilience was entered; and in step 3, coping styles were entered. The following criteria for establishing the mediating effects, according to Baron and Kenny [44] in their approach to analyzing mediation, are supposed to be met: (1) the independent variable (resilience) is significantly related to both the dependent variable (depression) and the mediator (coping styles); (2) the mediator (coping styles) is significantly related to the dependent variable (depression); and (3) the adding of the mediator (coping styles) in the model significantly lessens or clears away the independent variable's (resilience's) impact on the dependent variable (depression).

To prove that coping styles played a mediating role in the relationship between resilience and depression, structural equation modeling was used. Bootstrapping strategies were used to examine the mediating role (a×b product) of coping styles in the relationship between resilience and depression. The bootstrap estimate was based on 5000 bootstrap samples, and the bias-corrected and accelerated (BCa) 95% CI for each a×b product was examined. The goodness of fit was determined by the following: a chi-square to df ratio of <5, a goodness-of-fit index (GFI) of >0.90, a comparative fit index (CFI) of >0.90, a root mean square error of approximation (RMSEA) of <0.08, and a Tucker-Lewis Index (TLI) of >0.90.

Ethical Approval

The study protocol conformed to the ethical standards of and was approved by the Ethic Committee of China Medical University. All participants gave their consent after being informed of the purpose and procedure of the study via a web-based platform. The confidentiality and anonymity of all participants' collected information were ensured.

Informed Consent

The informed consent of every participant was acquired before the launch of the procedures of this research.

Results

Demographic Characteristics and Depression Distribution Among the Participants

The demographic characteristics and their respective mean depression scores are shown in Table 1. Approximately 41.7% (278/666) of study participants were freshmen. The average age of the participants was 20 years. Approximately 39.3% (262/666) of the participants were males. The students reported their fathers' education and mothers' education as junior middle school or below, accounting for 55.4% (369/666) and 59.9% (399/666) of the responses, respectively. About 49.2% (328/666) of the participants reported their family's monthly income as more than RMB 5000 (US $778.30). Most students were studying clinical medicine (460/666, 69.1%). With respect to gender, the depression scores of the male students were significantly higher than those of the female students (*P*=.045). Up to 88.9% (592/666) of the participants were adapting to web-based classes, while 11.1% (74/666) were not. The depression scores among the students who were not adapting to web-based classes were significantly higher than those among the students who were adapting to web-based classes (*P*<.001).

Table 1. Demographic characteristics and the distributions of depression among students (N=666).

Variables	Value, n (%)	Depression score, mean (SD)
Grade		
Freshman	278 (41.7)	4.31 (4.83)
Sophomore and junior	388 (58.3)	3.67 (4.20)
Gender		
Male	262 (39.3)	4.37 (5.12)[a]
Female	404 (60.7)	3.66 (3.98)
Age (years)		
<20	315 (47.3)	3.84 (4.48)
≥20	351 (52.7)	4.02 (4.48)
Fathers' education		
Junior middle school and below	369 (55.4)	4.02 (4.69)
Specialized secondary school and above	297 (44.6)	3.84 (4.21)
Mothers' education		
Junior middle school and below	399 (59.9)	3.99 (4.47)
Specialized secondary school and above	267 (40.1)	3.86 (4.50)
Monthly income (RMB [US $])		
≤5000 (US $778.30)	338 (50.8)	3.84 (4.16)
>5000 (US $778.30)	328 (49.2)	4.04 (4.79)
Major		
Clinical medicine	460 (69.1)	3.91 (4.54)
Others	206 (30.9)	4.00 (4.35)
Adapting to web-based classes		
Yes	592 (88.9)	3.44 (4.07)
No	74 (11.1)	7.88 (5.54)[b]

[a] Significant at the .05 level (two-tailed).

[b] Significant at the .01 level (two-tailed).

Correlations Between Depression and Continuous Variables

The correlations between depression and the continuous variables are shown in Table 2. Depression among medical students was significantly and negatively associated with both resilience (*P*<.001) and positive coping styles (*P*<.001), while depression was significantly and positively associated with negative coping styles among medical students (*P*<.001).

Table 2. The correlations among depression and continuous variables.

Variables[a]	Depression	Resilience	Positive coping styles	Negative coping styles
Depression				
r	1	−0.288[b]	−0.332[b]	0.356[b]
P value	—[c]	<.001	<.001	<.001
Resilience				
r	−0.288[b]	1	0.558[b]	−0.089[b]
P value	<.001	—	<.001	<.001
Positive coping styles				
r	−0.332[b]	0.558[b]	1	0.078[b]
P value	<.001	<.001	—	<.001
Negative coping styles				
r	0.356[b]	−0.089[b]	0.078[b]	1
P value	<.001	<.001	<.001	—

[a] The mean scores for depression, resilience, positive coping styles, and negative coping styles are 3.94 (SD 4.48), 43.88 (SD 7.77), 38.80 (SD 6.76), and 17.79 (SD 4.83), respectively.

[b] Significant at the .01 level (two-tailed).

[c] Not applicable.

The linear regression models of depression among medical students are presented in Table 3. The final regression model (model 3) explained 31% of the total variance in depression scores. Resilience and coping styles explained 7% and 13.5% of the total variance in depression scores, respectively. Grade (*P*=.013), resilience (*P*=.04), positive coping styles (*P*<.001), and negative coping styles (*P*<.001) were significant predictors for depression. Grade, resilience, and positive coping styles were negatively associated with depression, while negative coping styles were positively associated with depression.

Table 3. The hierarchical linear regression analysis of depression.

Variables	Depression, standardized β		
	Model 1[a]	Model 2[b]	Model 3[c]
Block 1: demographic characteristics			
Grade (freshman vs sophomore and junior)	−.088	−.112[d]	−.103[d]
Gender (male vs female)	−.029	−.040	.000

The Mediating Role of Coping Styles in the Relationship Between Resilience and Depression

Figure 1 presents the direct effect of resilience on depression (c=−.34; *P*<.001) before coping styles were entered as a mediator. The model revealed that resilience had a significant negative effect on depression (*P*<.001), and this model had good model fit indices (chi-square to df ratio<5; RMSEA=0.052; CFI=0.962; GFI=0.928; adjusted GFI=0.904; TLI=0.954; Figure 1).

Figure 1. Standardized solutions for the structural equation model of resilience and depression. The standardized path coefficient is shown on the unidirectional arrow path. *The coefficient of the path is significant at the *P*<.05 level.

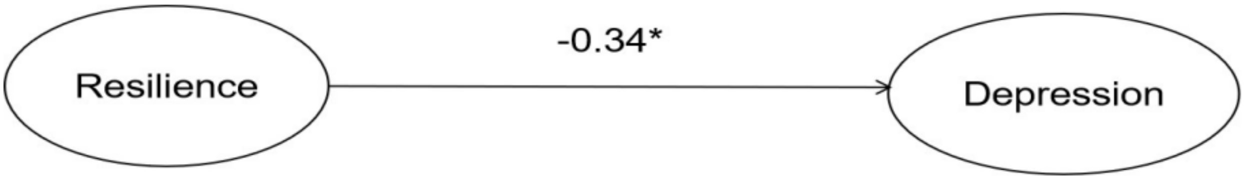

Figure 2 represents the structural equation modeling of the mediating role of coping styles in the relationship between resilience and depression, and the standardized path coefficients are presented on the unidirectional arrow paths. When coping styles were used as the mediator, the path coefficient between resilience and depression decreased significantly (from −.34 in Figure 1 to −.12 in Figure 2; *P*=.007), which confirmed coping styles' partial mediating role in the association between resilience and depression. This model yielded a good model fit (chi-square to df ratio<5; RMSEA=0.051; CFI=0.957; GFI=0.923; adjusted GFI=0.900; TLI=0.949). According to the BCa bootstrap test, coping styles played a significant mediating role in the association between resilience and depression (*P*=.007; a×b=−0.22; BCa 95% CI −0.324 to −0.153), which proved that coping styles had a significant role as a mediator between resilience and depression.

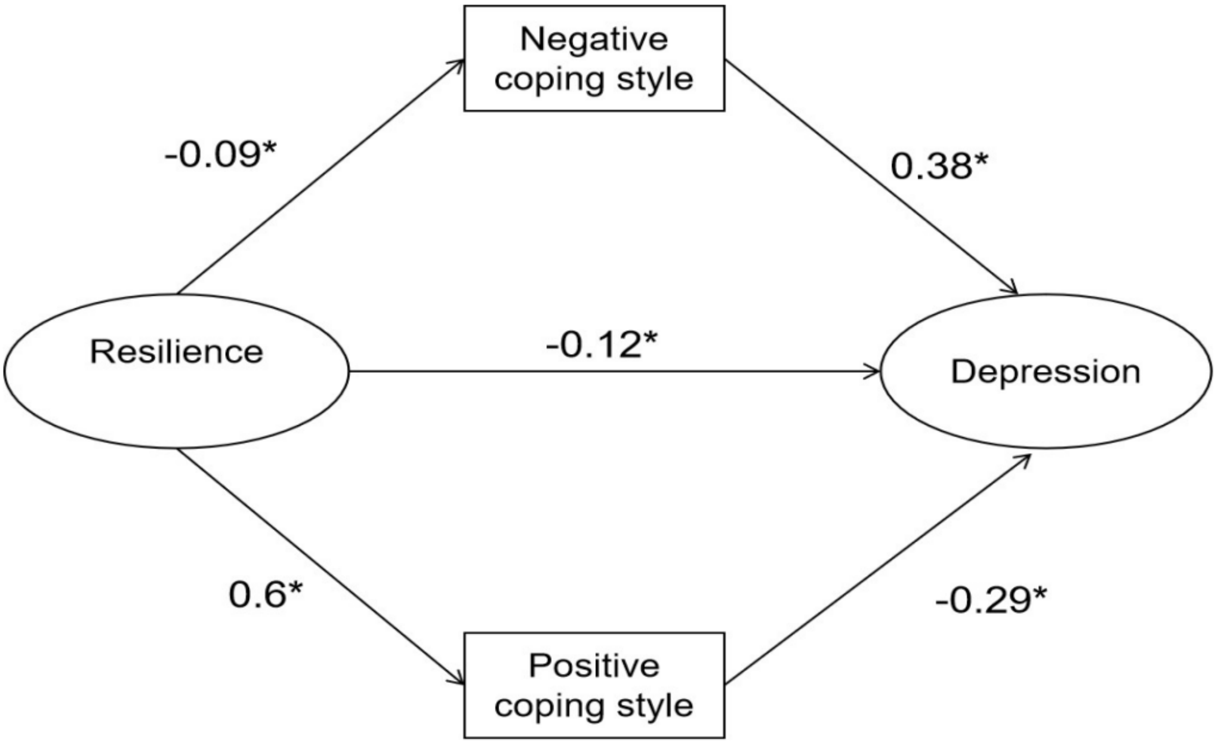
Figure 2. Structural equation modeling of the mediating role of coping styles in the relationship between resilience and depression. Standardized path coefficients are shown on the unidirectional arrow paths. *The coefficient of the path is significant at the *P*<.05 level.



Discussion

As far as we know, this study presents the first attempt to investigate the relationship among resilience, coping styles, and depression among Chinese medical students in the context of web-based classes during the COVID-19 pandemic. In this study, 64 out of the 666 (9.6%) participants reported depression, which was slightly higher than the depression prevalence of 9% in a study of home-quarantined Chinese college students that was conducted during the COVID-19 pandemic [13] but lower than the prevalence rates in most previous studies. Such studies have indicated high prevalence rates of depression among college students (ranging from 12.2% to 25.3%) during the COVID-19 pandemic [14,45,46]. Depression is one of the most commonly occurring mental health issues among college students [47-49], and the prevalence of depression is especially high among medical students [10,50-52]. However, the prevalence of depression among medical students in this study was slightly lower than that of a Swedish study (12.9%) [53] and much lower than that of a study (25%) on US and Canadian medical students [10,54]. One possible reason why this study found lower rates of depression among Chinese medical students may be that staying with family helped ease symptoms of depression. This is good for mental health, and web-based classes provided the students with more opportunities to use available resources at home for entertainment, which might have helped with easing symptoms of depression. Furthermore, due to their medical knowledge, medical students may be more likely to perceive the pandemic objectively, which might prevent depression.

In this study, grade (*P*=.013) and whether students adapted to web-based classes (*P*<.001) had significant impacts on depression. With the national requirement of “suspending classes without suspension of learning” in China during the COVID-19 pandemic, web-based studying at home provided the only feasible method for keeping up with the learning schedule. The results in this study showed that the 11.1% (74/666) of participants who did not adapt to web-based classes had significantly higher depression scores (*P*<.001). This may be because the students who failed to adapt to web-based classes were more accustomed to face-to-face instruction and web-based classes added to their stress, which could result in increased levels of depression.

It was found that resilience was negatively related to depression in this study. With regard to our hypotheses, which were based on the transactional stress model theory [20], the findings from this study indicated that higher levels of resilience were predictive of lower levels of depression. This is in line with a substantial number of previous studies [55-58]. A prospective, multi-institutional study focusing on US medical students reported that resilient students were less susceptible to depression [59]. It was clarified in previous studies that resilience played a role in attenuating depression in different populations [56,57], such as college students and medical and nursing students [60,61]. Our study indicated that resilience played a protective role against depression, which is in line with prior studies [62,63]. Higher levels of resilience have been found to correlate with better subjective health [60], less distress [64], and more optimism among medical students [65]. Previous studies have also found that resilience among medical students might play a critical role in maintaining mental well-being during the COVID-19 pandemic. Web-based classes have been viewed as an intervention that plays a role in decreasing levels of anxiety associated with the pandemic [66]. However, there have been some students who might have had low resilience and failed to adapt to web-based classes well. Lower resilience has been found to be related to higher incidence rates for psychological issues [67,68]. Home-quarantined medical students who transitioned from learning in classrooms on campus to web-based learning at home might have experienced added stress, which might trigger depression. Resilience might help medical students adapt to uncertainty and maintain mental well-being while taking web-based classes at home during the COVID-19 pandemic. First, high resilience might help medical students combat the stressful situations of web-based classes, thus relieving the symptoms of depression. However, students with low resilience might be less likely to adapt to web-based classes well and, consequently, could be more susceptible to anxiety or even depression. Second, students with high levels of resilience might recover more quickly from adversities and cope with problems more actively, which could help with lowering their susceptibility to depression during the pandemic. Third, students who have high levels of resilience might be more likely to have successful experiences of coping with and recovering from adversities, including the pandemic.

The findings from this study showed that coping styles had a significant effect on relieving depression ($P<.001$), which is in line with previous studies [69,70]. Our study also showed that positive coping was inversely related to depression, while negative coping was positively related to depression among Chinese medical students. A positive coping style could help students cope with problems (eg, web-based classes) more rationally and might reduce stress, which in turn might prevent depression. This study also indicated that coping styles mediated the effect of resilience on depression. The coefficient of the resilience to depression path decreased after the coping style variables were added to the model, which indicated that coping styles had a partial mediating role in the relationship between resilience and depression. It is possible that individuals who are more resilient might be more likely to adopt a positive coping style, which might increase their likelihood of perceiving stressful situations, such as being quarantined at home while taking web-based classes during the COVID-19 pandemic, as surmountable. Therefore, they might be less likely to experience depression. Such individuals are also more likely to have better control over their emotions and be more motivated to figure out the solutions to problems, thus allowing them adapt to adverse situations. This could be beneficial for their mental well-being. Our results implied that positive coping and resilience training would be beneficial to medical students in terms of confronting the COVID-19 pandemic more positively and adapting to web-based classes more easily, which might help them to fight stress, reduce depression levels, and maintain mental well-being.

A few limitations exist in this study. First, this study is cross-sectional, which limits its ability to identify causal associations between variables. Second, self-reported measures may have resulted in response bias in this study. Third, the study sample only included medical students in years 1 to 3 from 1 university in northeastern China, which might limit the generalizability of our results.

Conclusion

This study found that Chinese medical students in web-based classes experienced slightly low levels of depression during the COVID-19 pandemic. Resilience ($P=.04$) and coping styles ($P<.001$) were significantly related to depression. Positive coping styles played an essential role in decreasing depression levels among medical students, while negative coping styles were positively related to depression. It was also found that coping styles mediated the association between resilience and depression. This study indicates that interventions that aim to enable the development of positive coping styles among individuals and improve their resilience are of great practical importance to decreasing depression levels among medical students while they are taking web-based classes during the large-scale COVID-19 pandemic.

Abstract

Background: Overcoming the COVID-19 crisis requires new ideas and strategies for online communication of personal medical information and patient empowerment. Rapid testing of a large number of subjects is essential for monitoring and delaying the spread of SARS-CoV-2 in order to mitigate the pandemic’s consequences. People who do not know that they are infected may not stay in quarantine and, thus, risk infecting others. Unfortunately, the massive number of COVID-19 tests performed is challenging for both laboratories and the units that conduct throat swabs and communicate the results.

Objective: The goal of this study was to reduce the communication burden for health care professionals. We developed a secure and easy-to-use tracking system to report COVID-19 test results online that is simple to understand for the tested subjects as soon as these results become available. Instead of personal calls, the system updates the status and the results of the tests automatically. This aims to reduce the delay when informing testees about their results and, consequently, to slow down the virus spread.

Methods: The application in this study draws on an existing tracking tool. With this open-source and browser-based online tracking system, we aim to minimize the time required to inform the tested person and the testing units (eg, hospitals or the public health care system). The system can be integrated into the clinical workflow with very modest effort and avoids excessive load to telephone hotlines.

Results: The test statuses and results are published on a secured webpage, enabling regular status checks by patients; status checks are performed without the use of smartphones, which has some importance, as smartphone usage diminishes with age. Stress tests and statistics show the performance of our software. CTest is currently running at two university hospitals in Germany—University Hospital Ulm and University Hospital Tübingen—with thousands of tests being performed each week. Results show a mean number of 10 (SD 2.8) views per testee.

Conclusions: CTest runs independently of existing infrastructures, aims at straightforward integration, and aims for the safe transmission of information. The system is easy to use for testees. QR (Quick Response) code links allow for quick access to the test results. The mean number of views per entry indicates a reduced amount of time for both health care professionals and testees. The system is quite generic and can be extended and adapted to other communication tasks.

Introduction

After the first outbreak of SARS-CoV-2 in December 2019 in Wuhan, Hubei province, China, the virus spread rapidly worldwide [1,2]. Thus, the management of its induced crisis has become a ubiquitous topic [3]. Each day, the number of new infections increases worldwide, and reached 107,021,165 confirmed cases globally on February 10, 2021, at 4:22 PM [4].

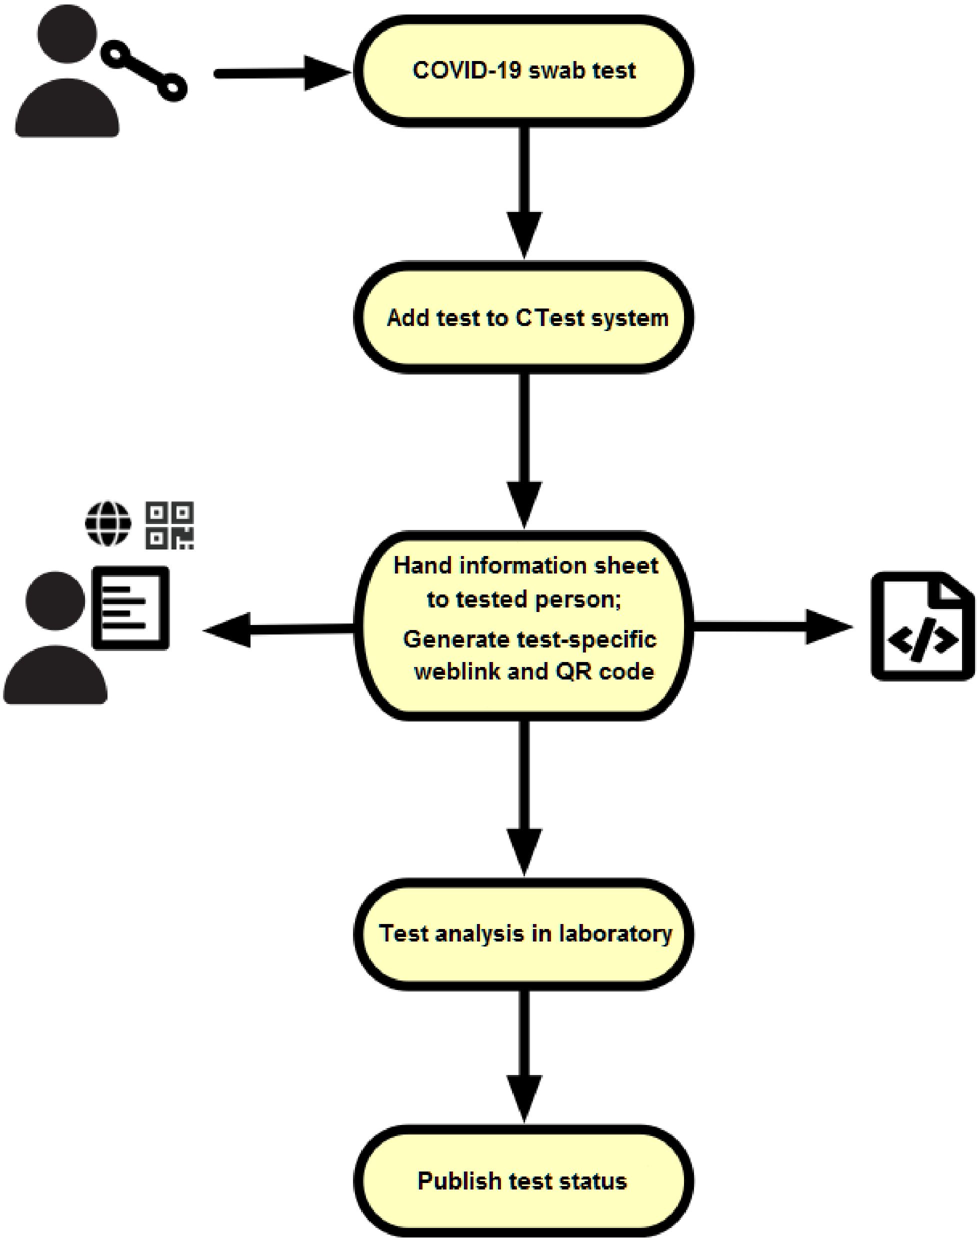
The current pandemic has significantly affected the possibility of direct interpersonal communication, together with a massive overload of the public health care system. In this context, digital technologies have become crucial sources of support. While surveys and data collection have empowered the evaluation of the first lockdown measures [5], the development of apps and dashboards is paramount in controlling the virus's spread [6]. Here, rapid case identification is one of the demanding tasks in controlling its spread. The most common available test for COVID-19 infections is to take a throat swab and test by real-time reverse transcription–polymerase chain reaction (RT-PCR) [7-9]. While speeding up this diagnostic test itself has limited feasibility, the time lag between administration of the test and the communication of results can be improved to ensure adequate isolation of positive cases. For ensuring maximal containment of spread, different digital solutions have been applied: (1) rapid identification of cases has been supported by apps concerning contact tracing and tracking of self-reported symptoms [10-14] and (2) special attention has been paid to artificial intelligence approaches supporting home-based self-testing and diagnosis [10,14]. In the case of Germany, available official apps to support health management have been developed and are provided in Table 1 [15-25]. Nevertheless, given the lack of standardization of home-based testing and self-made diagnosis [26,27], empowering the communication between testees and public health institutions is crucial in overcoming the current pandemic crisis. Here, the natural delay between hospital-based tests and the resulting communication with testees has not yet been addressed. Timely communication of results is essential for taking appropriate action; however, it is challenging, due to the high throughput and the high demand under the circumstances in which the tests are carried out. In most European countries, the current practice is to call the respective clinic or laboratory for information about test results [28]. This process ties up considerable resources and does not scale well for large numbers of tests [28]. Communication channels become overloaded and time-consuming for medical staff due to the testees' repeated calls, as waiting times and anxiety of the testees increases, altogether affecting patient empowerment.

Table 1. Official COVID-19–associated apps released in Germany.

App	Institution of release in Germany	Function
Corona-Warn-App [15]	Federal Government, Robert Koch Institute	Anonymized contact tracking Incidence and case reporting Personalized contact tracking
Corona-Datenspende [16]	Robert Koch Institute	Collection of provided health data from fitness trackers and smartwatches
CovApp [17]	Charité and Data4Life	Anonymized questionnaire providing contacts and guidance
Warn-App NINA [18]	Federal Department of Civil Protection and Disaster Assistance	Basic information about the COVID-19 crisis Local valid regulations
CoCoV app [19]	University Hospital Ulm	Private diary on the tolerability of COVID-19 vaccination based on a standardized questionnaire Aggregated analysis and presentation of events that have occurred on a public dashboard
Corona Check [20]	University Hospital Würzburg	Self-screening of symptoms with recommendations for action based on the results Live ticker with official regulations Recommendations on how to protect oneself and others
Corona Health app [21]	University Hospital Würzburg	Anonymized questionnaires on the psychological and physical health-related impacts of COVID-19 Screening analysis News
Safe Vac 2.0 [22]	Paul-Ehrlich-Institut	Anonymized tracking of tolerability of COVID-19 vaccination
WHO Academy: Covid-19 Learning [23]	World Health Organization	Guidance for case management, infection prevention control, and laboratory testing Epidemiology Regional and international information and regulations Research and development
Gutenberg COVID-19 Studien app [24]	University Medical Center Mainz	Survey of study participants
CoronaBoXX [25]	Charité	Health documentation of people in quarantine Hygiene checklist

We set up a framework to ensure fast and secure communication of health-related results to testees. This was applied to accelerate the COVID-19 testing procedure. Therefore, we implemented an online query system, called CTest, that provides convenient digital access to the status and results of the respective COVID-19 tests to testees (Figure 1). This approach avoids unnecessary and repeated phone calls, avoids manual transcription errors, limits language-associated barriers, and, consequently, reduces the burden on the clinical staff. CTest empowers testees, since they can check their test results and statuses independently through a secure online system [29].

Figure 1. Workflow of the COVID-19 test process using CTest. First, a COVID-19 swab test is performed. The test is then added to the CTest system via an order number. Based on this order number, CTest generates a cryptographically secure tracking ID. An information sheet with a test-specific weblink and QR (Quick Response) code is generated by CTest and handed over to the person tested. After laboratory analysis is complete, the results are sent to CTest. CTest updates the test results, which can be queried via the individual weblink.



The CTest system extends the functionalities of the previously developed online tracking tool TraqBio [30]. We created this application to simplify and standardize communication between users and core facilities. Its clean design and its open-source license allow for the development (ie, refactoring), deployment, establishment, and integration of CTest within a short period.

CTest runs on Java Virtual Machine [30,31]. The web application can be deployed independently of the operating system and platform.

Methods

Implementation and Setup

We based the CTest application on the TraqBio software [30]. The back-end functionality of the CTest server was implemented in the Lisp dialect Clojure. Clojure runs on Java Virtual Machine (Oracle) [31] and is, thus, platform independent. The back end comprises a database that stores the scheduled COVID-19 tests and corresponding results. Clojure supports different databases and connectors. We chose to use SQLite, version 3.29.0 [32], to keep the setup independent of additional database servers. A local database file holds the data. Additionally, CTest provides functionality for user management and data backup.

Every new order number entered and supplied by the laboratory staff in the CTest system generates a database entry with a unique identifier and unique tracking number. Here, this order number is used as the primary unambiguous identifier. CTest can be configured to append the current date to the order number to create a primary unambiguous identifier in setups where order numbers are only guaranteed to be unique within the same day. Using a secure random number generator, we generate a corresponding tracking number for each new entry [33]. This random number generator generates 6 bytes, which are then translated into a sequence of 12 characters containing numbers from 0 to 9 and letters from A to F. This sequence of characters is unique and is not created in sequential order. Every tracking number generated is checked for uniqueness prior to use (ie, there is no link between the tracking number and the order number).

Web-based front-end functionality is implemented using JavaScript and HTML templates. We used freely available standard web frameworks, such as Bootstrap v3 (Twitter) [34,35], jQuery (OpenJS Foundation) [36], and extensions to these frameworks. Using these state-of-the-art frameworks, we aim to enable a straightforward adaptation of the front end for integration at other institutions. The front end features a responsive graphical user interface for the management functions, the creation of tests, and accessibility for users to their test results. Persons may query their test status and results via a unique weblink without requiring an account or log-in. As an alternative to the weblink, a QR (Quick Response) code is provided for easy access.

To secure web communication, creation of new entries, and queuing of test results, our setup consists of different security layers. Only Secure Sockets Layer (SSL)–certified access to the websites is allowed via HTTP Secure (HTTPS). Connection and transferred data are encrypted, and the certificate authority–signed server certificates are used. A reverse-proxy setup forwards the external hostname to a virtual machine within the hospital's secure network infrastructure. On the virtual server, another reverse proxy is in place to allow for running of the Java application as a nonprivileged user. As the standard HTTP port 80 is privileged, it can only be used by a system user, so running the application as a user with system-wide rights is a security risk. Therefore, proxy settings forward the privileged port to a high port (above 1024) that normal users can control. Hence, no system rights are necessary for managing the application at the operating system level. For the clinical environment setup, we also set up a firewall with specific ban rules—iptables and fail2ban service on a Linux operating system—to prevent brute force attacks on log-in or tracking numbers. Also, network Internet Protocols (IPs) and subnets can be white-listed to allow access to management functions of the application. Thus, other computers and devices are blocked from accessing these functions after failed attempts. For the tracking interface, a brute force attack, such as trying all combinations of possible tracking numbers, is shielded by blocking IPs after too many failed attempts with wrong or nonexistent tracking numbers.

Query Performance Test

We first performed 1024 simultaneous requests for our performance test using a single machine and a single network connection. Next, we created a mixed data set (ie, interleaved_urls), including 758 available database entries (ie, available_urls) and the same number of unavailable tracking numbers (ie, notavailable_urls). Furthermore, we measured repeated queries of a single available URL, repeated queries of a single unavailable URL, as well as repeats of these two URLs consecutively. That makes six data sets in total, each of which was accessed 1516 times. Queries were carried out once in sequence (ie, ordered) and randomly (ie, random). Also, we tested the two-scenario caching function of the browser (ie, 1filePerRequest) and complete reloading (ie, 23or1filesPerRequest). This means that unchanged files are not reloaded (caching), whereas in the other scenario, all required files and displayed images (eg, flag graphics or Cascading Style Sheets) are reloaded.

For the second scenario, one file is loaded if the tracking number is not available and 23 files are loaded if the tracking number is available. Stress tests were measured using Siege 4.0.4 (JoeDog Software) [37].

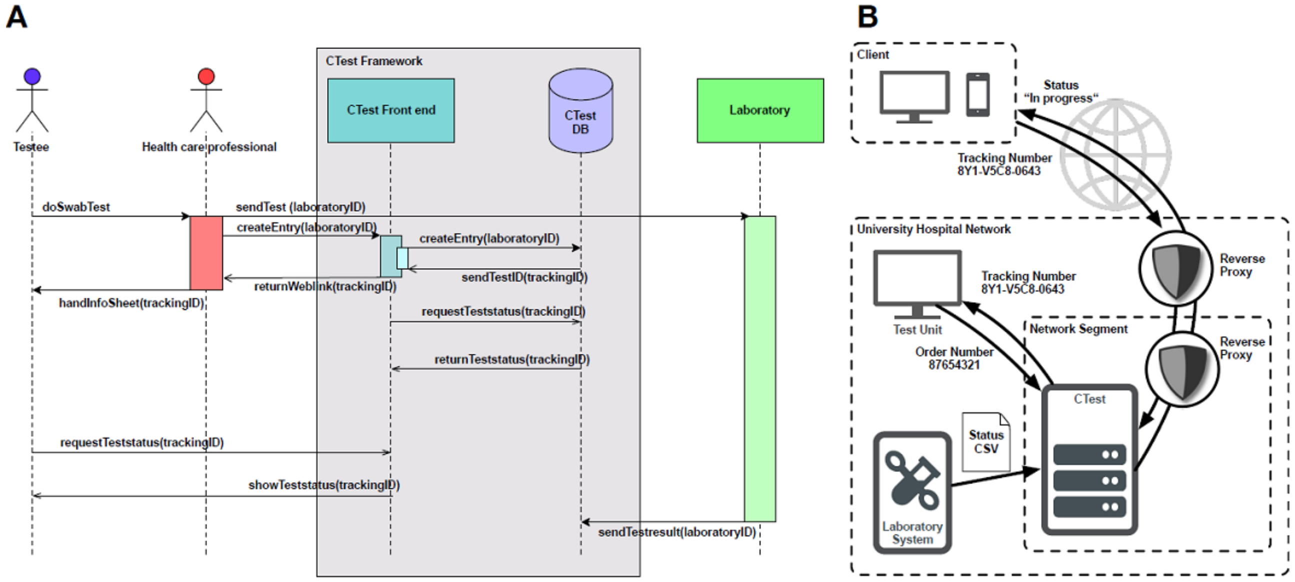
Data Availability

The source code, documentation, and an installation guide are freely available from GitHub [38] under the Eclipse Public License v2.0.

Results

CTest was built based on an existing, proven software stack: TraqBio [30]. It extends TraqBio to the functionality required for COVID-19 tests. We were able to successfully integrate it into the existing clinical testing workflows for SARS-CoV-2 infections in two major German university medical centers—University Hospital Ulm and University Hospital Tübingen—within a few days (Figure 2).

Figure 2. COVID-19 test procedure and setup. (A) The left-hand panel shows the detailed process flow of the COVID-19 tests. CTest (gray) is tightly integrated into the test process. The test framework comprises a web-based front end (turquoise) and a Clojure back end, including a mySQL (Structured Query Language) database (DB) (purple). After the swab test for COVID-19, the health care professional creates a CTest entry via entering the laboratory ID in the CTest front end. Based on that, a secure tracking ID is created by the back end and a corresponding personalized URL is created. CTest then automatically creates a test-specific information sheet for each testee. This sheet contains the test-specific weblink and a QR (Quick Response) code, both based on the tracking ID. The URL does not provide any information to track back the test results to the corresponding testee (blue). Via this URL, a testee can request the corresponding test status at any time. After the analysis in the laboratory, results are transmitted to the CTest database. The CTest front end automatically updates the status on the test-specific weblink based on the corresponding test results. (B) In the right-hand panel, a possible integration scenario of CTest into a clinical infrastructure is shown. CTest runs on a virtual machine within the secured network of a university hospital. The external hostname, with weblinks to the testee's status, is forwarded via reverse proxy. A second reverse proxy forwards the port to the application to a nonprivileged port. Thus, the application does not need to run with a system user. Inside the hospital's network, the test unit communicates to the CTest server to create new test cases via an order number. The CTest server returns back the tracking number and the corresponding weblink and QR code. The laboratory pushes test results as comma-separated values (CSV) files to the CTest server. The test-specific webpage content is then updated according to the test result.



The workflow starts with taking a sample for testing. In the first step, an order number is generated by the testing lab and added as a barcode label to the sample. Analogous to other medical applications, order numbers within the clinical or laboratory information system are unique but do not contain personal information about the patient [39]. This order number is transferred to the CTest system via scanning or typing the number into the dialogue window’s input field. We implemented format restrictions via regular expressions to the input field to minimize incorrect entries. Afterward, CTest generates an unambiguous, nonconsecutive tracking number. Therefore, a cryptographically strong pseudo-random number generator [33] creates 6 bytes that are transferred into a 12-digit character code, including letters from A to F and numbers from 0 to 9. Using this tracking number ensures that no personal information about any testee can be inferred.

After taking the sample, the tracking number is given to each testee on a printed sheet, including information on how to access the status of their COVID-19 test (Figure 3, A). After the sample has been processed, the lab system sends updated files as comma-separated values (CSV) files via an encrypted Secure File Transfer Protocol (SFTP) connection to the CTest server. Results in the CSV file are then automatically parsed, backed up, and imported into the CTest database, which leads to an automatic status update of each processed test.

Figure 3. Information for testees. Information concerning access to the test status and its results are given in eight languages. (A) The information sheet handed over to testees informs them of how to access the COVID-19 test results online. (B) The test-specific URL links to a page that includes information about the test result (eg, negative test result) or (C) information stating that the test is still in progress. (D) Scanning the QR (Quick Response) code with a smartphone link takes the testee directly to the current test status or its result.

Tracking Nr.
48Y1-V5C8-0643

Status

Test negativ
Hinweis: ein negatives Ergebnis schließt die Möglichkeit einer Coronavirus-Infektion nicht vollständig aus (z.B. bei Probenabnahme zu früh während des Infektionsverlaufs).

Result negative
Information: a negative test result does not entirely exclude a coronavirus infection (e.g. in case samples were obtained too early after infection).

Test négatif
Remarque: un résultat négatif n'éxclut pas entièrement la possibilité d'une infection avec le coronavirus (par example, si des échantillons sont prélevés trop tôt au cours de l'infection).

Negatif test
Not: negatif bir sonuç, koronavirüs enfeksiyonu olasılığını tamamen dışlamaz (örneğin, enfeksiyon sırasında örnek çok erken alınırsa).

Test negativo
Nota: un risultato negativo non esclude completamente la possibilità di un'infezione da coronavirus (ad es. Se il campione viene prelevato troppo presto nel corso dell'infezione).

Тест отрицательный
Примечание: отрицательный результат не полностью исключает возможность коронавирусной инфекции (например, если образец был взят слишком рано в течение инфекции).

测试结果阴性
注意：阴性结果并未完全排除冠状病毒感染的可能性（例如，在感染过程中过早取样）。

النتيجة سلبية
ملاحظة: النتيجة السلبية لا تلغي تمامًا احتمالية الإصابة بالفيروس كورونا (على سبيل المثال إذا تم أخذ العينة في وقت مبكر جدًا من تقدم الإصابة)

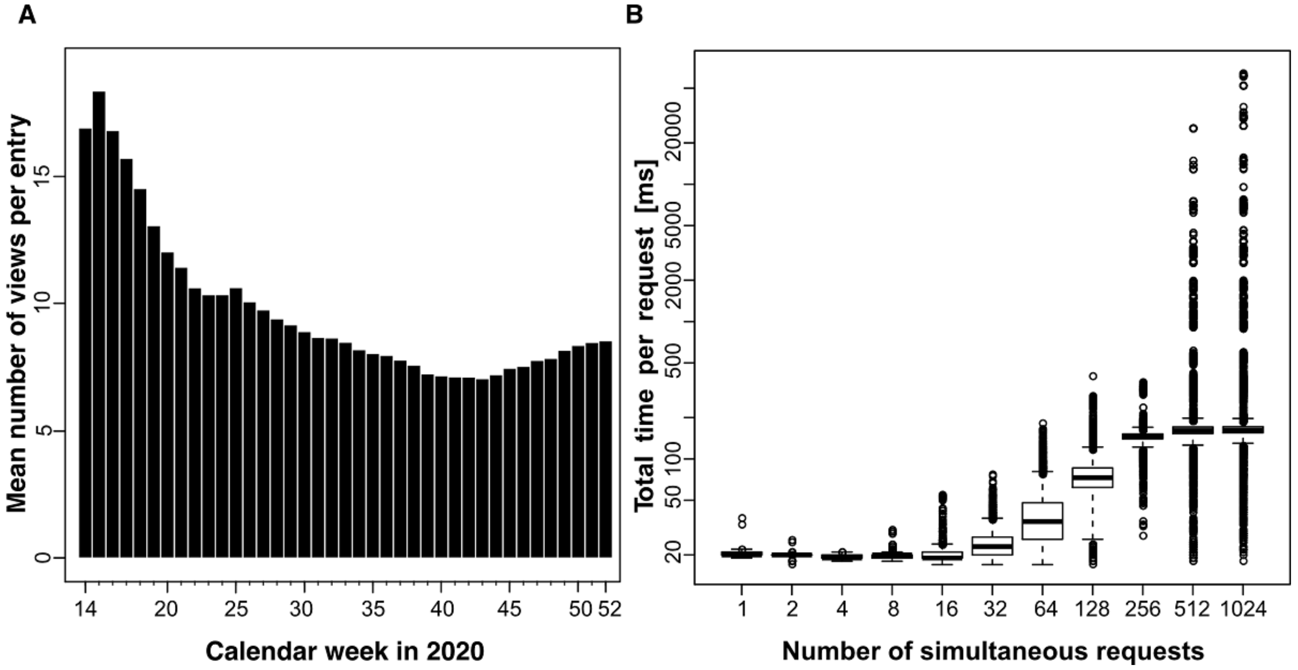
Currently, the CTest system distinguishes multiple potential outcomes: (1) the COVID-19 test is negative (Figure 3, B), (2) the COVID-19 test is still in progress (Figure 3, C), (3) the COVID-19 test is positive, or (4) the COVID-19 test is flawed. As the software is generic, one can implement other outcomes. Phone calls from the health department still inform people who have tested positive for COVID-19. Thereby, officials can inform them about health arrangements and how to avoid further spreading of the virus.

We provide two possibilities to query the status of the COVID-19 test. Testees can either scan a QR code on the information letter they received with a smartphone and get redirected to a test status webpage (Figure 3, D) or they can enter the weblink from the information letter into a web browser directly. The status of the individual test result is automatically displayed in a responsive form on the device (Figure 3, D). We have observed that both possibilities for requesting test results have been used. A total of 30.6% (64,201/209,808) of people preferred to query the test results via a web browser, while the rest of the testees preferred to scan the provided QR code.

To overcome language barriers, we translated information concerning the procedure to obtain test results, and the results themselves, into eight languages: German, English, French, Turkish, Italian, Russian, Chinese, and Arabic. Here, native-language speakers were asked to translate the information and kindly supported the translation process to ensure correct translations. Additionally, in the context of accessibility for medical information and patient empowerment, we paid particular attention to the use of easily understandable language and integration of behavioral recommendations.

Highlighting the reduced burden for clinical staff during the pandemic and the potential scalability of this approach in general, we estimate that there will be a personnel expense according to the derived data. On the one hand, we assume a mean of 10 (SD 2.8) views per entry, as shown in our data (Figure 4, A), and a duration of 30 seconds per access event via CTest. These numbers result in a total time consumption of 5 minutes via the use of CTest. On the other hand, a telephone inquiry is estimated to take 3 minutes if the lines are not busy. Using the number of times that CTest was accessed as the number of phone calls, the estimated amount of time per entry increases to 30 minutes. However, as a more realistic approach, we assume three calls per entry per day, which, at best, would lead to around 9 minutes of inquiry time for the patient.

Figure 4. Requests to the CTest server. (A) Since its introduction into the routine at the University Hospital Ulm (Germany) in week 14 (2020), a mean of about 10 (SD 2.8) views per test entry was recorded. The plot shows the mean number of views per entry per calendar week in 2020 as bars. (B) The server can respond within 200 ms to >80% of requests when responding to up to 1024 simultaneous requests. In this simulation, requests were made using a single machine and a single network connection.



Furthermore, we checked its performance and robustness in load tests (Figure 4, B, and Figures S1-S6 in Multimedia Appendix 1). Our CTest server can respond within 200 milliseconds to over 80% of requests and within 500 milliseconds to over 90% of requests when responding to up to 1024 simultaneous requests (Figure 4, B). Additionally, we performed stress tests with available and unavailable tracking numbers (Figures S1-S6 in Multimedia Appendix 1). Based on these tests, we are confident that CTest is well-suited to rapid testing demands even if deployed in an ad hoc manner on standard hardware. Its platform independence allows for its deployment on a wide variety of existing infrastructures.

Due to the high number of tests being administered during the peak times of COVID-19 infection waves, CTest was designed to handle large numbers of queries in a short amount of time. At Ulm University Hospital, a maximum of 394 laboratory tests were added to CTest per day. In total, 24,643 tests were added to CTest in 2020. In contrast, we registered up to 5263 access events to the website within one day and 209,808 in total in 2020. Since the introduction of CTest into the clinical routine, there have been around 12 queries performed per test (Figure 4, A). The handling of all these requests via phone calls would lead to communication overload. Consequently, CTest can reduce the burden on clinical staff. On top of that, CTest data at Ulm University Hospital shows that test results are provided to testees within one day.

Another feature of CTest is its functionality for error reporting and statistics. A dedicated *reporter* account is required to access the reporting data. Here, all data are provided in the machine-readable JavaScript Object Notation (JSON) format and the path “/reports/list” can be accessed to get a list of information and error reports. The included information is about the successful backup runs and successful test status imports from the CSV files. Also, the number of test result views per day can be accessed at “/reports/views.” General system information, such as memory consumption and central processing unit usage, is available at “/reports/system.” Furthermore, the sample collection dates are available at “/reports/test-dates” for analysis.

We present CTest as a web interface. In addition to its web interface, CTest facilitates third-party software (ie, apps) access if the testee decides to use it. These apps can query the status using the tracking link with appended “?app=true,” which returns only the test status instead of the complete HTML document.

Discussion

Fast and efficient communication with patients is the key to effective treatments and avoidance of health-related misunderstandings [40-42]. The COVID-19 crisis has brought a greater level of attention to this topic. In particular, hospital overload and lack of possibilities for direct and in-person communication have highlighted huge limitations for patient empowerment and compliance. On these grounds, we developed a framework to reduce the communication burden and to empower patients. The CTest framework enables an automated system that is always available and that does not require continuous human supervision and office hours. This framework thus reduces the burden on clinical staff involved in the COVID-19 crisis and slows down the spread of the virus by quickly and easily informing people who have been tested with concrete recommendations for action. Furthermore, we wanted to empower testees to obtain their results in a facile and easy-to-access way while, at the same time, ensuring efficient and almost instantaneous and exclusive communication. In the same way, other applications have tried to address patient empowerment and rapid isolation of positive cases [10-14]. Here, home-based self-tests and diagnoses, together with contact tracking, are major pillars that attempt to relieve the burden on public health. These approaches are meant to reduce the number of people with potential COVID-19 infections coming to hospitals for testing and to empower patients by providing insights into their health status [6]. Nevertheless, they still lack reliability and sensitivity [6]. For this reason, it is of relevance to support the information process in the public health context. In general, both aspects together are crucial in the effort to contain the spread of COVID-19. With our approach, we provide a unique workflow to support communication. Even if our implementation attempts to speed up hospital-related processing, we are aware that other steps, from testing to communicating results, are affected by delays. Nevertheless, the presented approach has the potential to support multiple testing locations, therefore, synergistically complementing the effort to provide reliable testing for patients. In this context, our results encourage the application of CTest.

CTest has already been successfully integrated into the hospital information system and captures thousands of COVID-19 tests per week at the University Hospital Ulm and at the University Hospital Tübingen in Germany. As part of the clinical routine, the first analyses of CTest showed a mean of 10 queries per test performed. Even half of that number of telephone inquiries would lead to communication overload. Consequently, the introduction of CTest into the clinical routine could achieve our primary goal of reducing the burden on clinical staff. The open-source license of TraqBio and its clean and simple setup were beneficial for this purpose [30]. This made it possible to implement and integrate the CTest system within a very short period (4 days) into the clinical workflow. Another advantage is that users do not have to create an account to request their test results. Besides, we provide two possibilities for querying the status of the test results. The fact that 30.6% of users queried their test results via QR codes encourages us in this implementation.

Our workload tests demonstrated the ability of CTest to deal with a massive number of parallel access events. These could not be processed via telephone calls. With the numbers estimated in our Results section, one employee could handle around 50 phone calls per 8-hour shift. This fact highlights the potential for increasing the speed of informing testees and for slowing down the virus spread. Using CTest, test results at Ulm University Hospital are available within a mean of one day. In contrast to that, for instance, Omar et al [43] imputed an average delay of 5.56 days in notifying testees with COVID-19–positive results using the conventional way. The estimated results from this study emphasize the reduced amount of time for testees to receive results regardless of business hours and, accordingly, the increasing potential for self-empowerment. Additionally, modeling approaches highlighted the relevance of rapid testing in flattening the infection curve [44,45].

Reducing public health burden is crucial in the final aim of providing digital health support for patient empowerment. In fact, the first consequence for patients of a rapid test response is an overall effect on their stress levels. After being tested, people are worried until they know the result of their test [46]. Notably, in the oncological context, it was shown that stress levels of patients waiting for their diagnosis were comparable to the ones of patients receiving severe diagnostic results [47]. Moreover, not knowing the outcome might tempt testees not to act according to recommendations and, thus, increase the risk of infecting others. Another crucial point we wanted to address with our workflow is ensuring comprehensible and secure communication. For this reason, we implemented translations in eight different languages in CTest to avoid language barriers as much as possible. To ensure the correct understanding of the provided information, we contacted native-language speakers who kindly provided translations. Previous studies outside of the pandemic context already showed that nonnative speakers experienced more stress and uncertainty in communicating with local health care providers. Steinberg and colleagues [42] reported a case study on safe and high-quality health care for children whose parents have limited English proficiencies in the United States. By performing 48 interviews with Latina mothers from two independent cities, they were able to show that these mothers experienced frustration with health care providers. Similar results were obtained from a South African study from Hunter-Adams and Rother [41]. Here, they investigated language barriers between local health care providers and cross-border migrants. Again, interviewed subjects reported frustration in understanding health care indications. Strikingly, some of the participants reported invasive medical procedures performed without explicit consent. Overall, not understanding indications increases fears over unwanted procedures and inaccessibility of health care, which, in the end, affects patient compliance. In the context of the COVID-19 pandemic, these issues would lead to increased communication overload and, consequently, to uncontrolled viral spread. For this reason, we tried to maximize the availability of translation options. The presented workflow also limits the occurrence of third-party translation that would affect patient privacy. In addition, it was shown that partners that try to play the role of interpreter caused additional nonprofessional nonmedical interpretations, again affecting patient empowerment and compliance [41].

In the interest of privacy protection, tracking numbers for test results in our workflow are created based on nonpersonalized order numbers. Based on this implementation, we address big data challenges in personalized medicine [29] and respect the German and European data protection laws. To tackle these data protection issues, clinical or laboratory information systems are often closed-source systems. Therefore, development or integration of new interfaces can be time-consuming. To overcome these barriers, we developed an independent, stand-alone software solution without storing personalized data. Nevertheless, this has the limitation wherein CTest alone cannot automatically transfer positive case results to the public health department. Since this transfer is compulsory in Germany, additional communication still has to be made by employees. In addition, a required step is the input of test results from external sources. Consequently, CTest is independent of existing infrastructures, such as specific laboratory information systems. Data import interfaces can be adapted for a broad range of scenarios (eg, hospitals, independent test centers, or resident physicians).

Currently, CTest is specialized for the query of COVID-19 test results and their status. However, it is a generic framework that can readily be adapted to other queries or to the distribution of different types of test results in all medical fields. Even integrating the CTest system into apps is possible if the HTML view presented here is not desired. For this purpose, the token “?app=true” has to be added after the tracking number. All in all, the idea of CTest is a generalizable approach that can be adapted to various uses in medical communication, such as blood analysis for resident physicians. In this context, an outlook for further development of the software is to have a user interface for configuration. Respective requirements for results, the connected database, and other parameters could be set via a graphic user interface to ease a roll-out into other domains. This might become interesting in the context of electronic prior authorization processes.

Acknowledgments

We thank the COVID-19 task force of the University Hospital Ulm, the Department of Clinical Chemistry, the Comprehensive Cancer Center Ulm, the Zentrum für Information und Kommunikation (ZIK), and all our supporters at University Medicine Ulm—Martin Loose, Thomas Baur, Robert Mahnke, and others—who supported the development of the tool and allowed its rapid integration into the clinical processes. We also thank Yessin Yahia, William Ferdinand, Cagatay Günes, and Xenia Kirgis for their help in translating the texts. The rapid implementation, deployment, and integration of the application were also made possible by support from different digitization initiatives.

KK, HK, and OK acknowledge funding from the Germany Federal Ministry of Education and Research (BMBF) as part of the DIFUTURE project, Medical Informatics Initiative (grants 01ZZ1804I and 01ZZ1804D). OK and HK acknowledge funding from the Ministry of Science and Art Baden-Württemberg (Zentrum für Innovative Versorgung [ZIV]). OK and TS acknowledge funding from the Ministry of Social Affairs of the state of Baden-Württemberg (Zentren für Personalisierte Medizin [ZPM]). HK acknowledges funding from the German Science Foundation (DFG) (grant 217328187). HK and UK acknowledge funding from the German BMBF (Nationales Forschungs Netzwerk [NFN] COVID-19) (grant 01KX2021).

Authors' Contributions

KK, OK, PK, UK, TS, and HK were responsible for funding acquisition. HK was responsible for project administration. GV, AF, TG, JK, AG, and JS were responsible for software development. HK was responsible for supervision of the project. GV, AF, JS, and SW were responsible for visualization of the results and for the development of software graphics. JS, SW, AF, PK, OK, GV, NI, and HK were responsible for writing the original draft of the manuscript. JS, GV, KK, SW, NI, JB, FJ, MH, OK, TS, and HK were responsible for writing, reviewing, and editing the manuscript.

Abstract

Background: Studies have highlighted that fear and anxiety generated by COVID-19 are important psychological factors that affect all populations. There currently remains a lack of research on specific amplification factors regarding fear and anxiety in the context of the COVID-19 pandemic. Despite established associations between anxiety sensitivity, intolerance of uncertainty, and cyberchondria, empirical data investigating the associations between these three variables, particularly in the context of the COVID-19 pandemic, are currently lacking. Urgent research is needed to better understand the role of repeated media consumption concerning COVID-19 in amplifying fear and anxiety related to COVID-19.

Objective: This study investigated the associations between fear of COVID-19, COVID-19 anxiety, and cyberchondria.

Methods: Convenience sampling was used to recruit respondents to participate in an online survey. The survey, which was distributed via social media and academic forums, comprised the Cyberchondria Severity Scale, Fear of COVID-19 Scale, Coronavirus Anxiety Scale, Anxiety Sensitivity Index, and Intolerance of Uncertainty Scale. Multiple mediation analyses were conducted using structural equation modeling.

Results: A total of 694 respondents (males: n=343, females: n=351) completed the online survey. The results showed that fear and anxiety generated by COVID-19 predicted cyberchondria (fear: β=.39, SE 0.04, *P*<.001, *t*=11.16, 95% CI 0.31-0.45; anxiety: β=.25, SE 0.03, *P*<.001, *t*=7.67, 95% CI 0.19-0.32). In addition, intolerance of uncertainty and anxiety sensitivity mediated the relationship between fear and anxiety generated by COVID-19 with cyberchondria. In a reciprocal model, the standardized total effects of cyberchondria on fear of COVID-19 (β=.45, SE 0.04, *P*<.001, *t*=15.31, 95% CI 0.39-0.51) and COVID-19 anxiety (β=.36, SE 0.03, *P*<.001, *t*=11.29, 95% CI 0.30-0.41) were statistically significant, with moderate effect sizes. Compared to males, females obtained significantly higher scores for cyberchondria ($t_{1,692}$=–2.85, *P*=.004, Cohen *d*=0.22), COVID-19 anxiety ($t_{1,692}$=–3.32, *P*<.001, Cohen *d*=0.26), and anxiety sensitivity ($t_{1,692}$=–3.69, *P*<.001, Cohen *d*=0.29).

Conclusions: The findings provide a better understanding of the role of COVID-19 in amplifying cyberchondria. Based on these results, cyberchondria must be viewed as a significant public health issue. Importantly, increasing awareness about cyberchondria and online behavior at both the individual and collective levels must be prioritized to enhance preparedness and to reduce the adverse effects of current and future medical crises.

Introduction

Background

The COVID-19 outbreak is more of a global emergency than a medical challenge. Research highlights the intense and broad spectrum of psychosocial ramifications that pandemics can inflict on the general population [1]. Fear of COVID-19 and COVID-19 anxiety, coupled with quarantine and isolation [2], can generate specific negative psychological responses such as maladaptive behaviors, emotional distress, and avoidance reactions among both general and patient populations [3,4]. Compared with previous pandemics (eg, severe acute respiratory syndrome [SARS]), psychological distress and anxiety disorders related to the increasingly widespread use of the internet are relatively novel problems in psychiatric and medical settings. The internet can be a useful source of health information [5] and has become increasingly prevalent among all members of the public. However, repeated media exposure to pandemic-related information and excessive searching for health-related information on the internet can significantly exacerbate anxiety and create an escalating pattern of psychological distress that is difficult to break. This has been termed “cyberchondria” [6,7].

Cyberchondria in the Context of the COVID-19 Pandemic

Cyberchondria has been defined as “anxiety resulting from a health-related search online” [8,9]. Cyberchondria is conceptualized as a multidimensional construct, including repetitive (excessive) online searching for health-related information, distress (increased negative affect), compulsion (interruption of daily routine), and reassurance seeking. Seeking health-related information on the internet to reduce anxiety may result in more anxiety or distress [10]. In the latest (fifth) edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5), individuals can receive one of two anxiety-related diagnoses. Somatic symptom disorder refers to anxiety concerning health diagnoses in the context of significant somatic symptoms whereas illness anxiety disorder refers to a health anxiety diagnosis without somatic symptoms. Individuals affected by these mental health problems tend to misinterpret minor bodily sensations or symptoms as if they were severe illnesses [11]. When individuals with these diagnoses use online networks to search for health-related information, they are classified as having cyberchondria [12]. As a safety behavior, cyberchondria (ie, anxiety when searching online for health-related information) may fuel psychopathological vulnerabilities [12]. This indicates a strong relationship between health anxiety and cyberchondria [13,14]. Individuals with elevated health anxiety exhibit higher anxiety levels during and after online health-related searches and report more frequent and longer online searches than those with lower levels of health anxiety [15,16]. These discrepancies between the purpose and outcome of cyberchondria may complicate our understanding of patterns of cyberchondria. In addition to anxiety, fear is a substantial motivating factor in seeking health-related information [17]. Cyberchondria may also exacerbate fear of illness and have a negative impact on relationships with primary care physicians. Cyberchondria is also associated with accessing increased health resources, as measured by the number of visits to general practitioners and other health professionals [18].

Fear in the Context of the COVID-19 Pandemic

Fear, generated by trauma-related stimuli, is a prominent emotion in psychopathology [19]. Fear can be viewed as an adaptive response to threat, which can be a motivating factor that facilitates protective and preventive behavior among individuals to avoid infection and follow pandemic-related health instructions. However, for individuals who experience fear intensely, it may result in an elevated risk perception. Consequently, this adaptive response to fear becomes maladaptive when these emotional responses fail to provide accurate information. Prior experience, cognitive and attentional biases, and mental disorders can all generate faulty appraisals of the physical and social environment, leading to maladaptive emotional reactions. In the context of the current COVID-19 pandemic, fear and anxiety can elicit additional media consumption [20]. In addition, the consumption of pandemic-related media coverage may be an important factor that is associated with anxiety and psychological distress [7,21]. For example, exposure to warning messages, as well as inaccurate and misleading information concerning life-threatening aspects of COVID-19 during online searching, can exacerbate anxiety and worries related to the pandemic [22]. Moreover, a significant positive association has been found between anxiety resulting from online health searches for oneself and anxiety resulting from online health searches for others [8]. Fear of self-infection or infecting family members is one of the most common reactions to pandemics [23,24] and can result in health anxiety, worries, specific phobias, and psychological distress [25-27]. There is also a strong relationship between cyberchondria and health anxiety [28]. Health anxiety can motivate excessive or repeated health-related information seeking on the internet, which can amplify anxiety or distress (eg, fear) [9,15,29]. Therefore, individuals with cyberchondria may be anxious about the health of family members, attempt to diagnose them online, and/or take additional measures as a consequence of their fear of COVID-19.

Uncertainty and Anxiety Sensitivity During the COVID-19 Pandemic

The current pandemic has caused much uncertainty about many different aspects of daily life. Intolerance of uncertainty is recognized as a strong predictor of cyberchondria. In times of uncertainty, reducing uncertainty has a central role in motivating searching for health information on the internet [30]. In addition, individuals with a higher level of intolerance of uncertainty exhibit prospective anxiety due to dispositional fear of unknown future events [31,32]. Individuals with a higher intolerance of uncertainty levels may perceive uncertain situations as both threatening and aversive. Therefore, individuals engage in uncertainty-reducing behaviors (eg, repeatedly seeking reassurance due to worries) to moderate the perceptions of uncertainty and threat [33].

Anxiety sensitivity, defined as “the fear of sensations of anxious arousal based on beliefs about their harmful consequences,” is conceptualized as a cognitive-emotional individual difference factor of the fear related to bodily sensations [34]. Experimental studies have demonstrated a positive association between anxiety sensitivity and oversearching of medical information. Compared to individuals with generalized anxiety disorder, anxiety sensitivity is recognized as a potential risk factor for increased anxiety related to COVID-19 [35]. Research also indicates that accurate knowledge about pandemics may be associated with anxiety. During the COVID-19 pandemic, it is possible that such individuals search for information and medical news related to COVID-19 with high sensitivity to anxiety, which leads to an increase in their fear.

Purpose of This Study

Understanding COVID-19 pandemic–related psychopathology development is limited due to numerous individual and contextual factors. There is currently a lack of research on specific amplification factors regarding fear and anxiety in the context of the COVID-19 pandemic. Cyberchondria is a maladaptive behavioral pattern, more likely during public health crises such as the COVID-19 pandemic. Research is urgently needed to better understand the role of repeated media consumption concerning COVID-19 [36]. Despite established associations between anxiety sensitivity, intolerance of uncertainty, and online medical information seeking [37-39], there is currently a lack of empirical data concerning the associations between anxiety sensitivity, intolerance of uncertainty, and cyberchondria, particularly in the context of the COVID-19 pandemic.

Therefore, this study investigated the associations between fear of COVID-19, COVID-19 anxiety, and cyberchondria. Using structural equation modeling (SEM), a mediation analysis was carried out to investigate the underlying mechanism between cyberchondria and fear of COVID-19, COVID-19 anxiety, intolerance of uncertainty, and anxiety sensitivity. In addition, an evaluation of the reverse mediation model of the association between the study variables was also carried out. The study may potentially contribute to a better understanding of the pandemic in relation to cyberchondria. Moreover, the findings provide additional insight into cyberchondria and the pandemic, providing important information to clinical practitioners and policymakers. It was hypothesized that intolerance of uncertainty and anxiety sensitivity would mediate the association between fear of COVID-19 and COVID-19 anxiety on cyberchondria.

Methods

Inclusion Criteria

The eligibility criteria included (1) age >18 years, (2) not hospitalized or quarantined in the current or a past viral pandemic due to infection, (3) not having (or suspect as having) COVID-19, (4) being able to read and complete an online survey and provide informed consent, (5) fluency in the Persian language, and (6) currently living in Iran. Only completed questionnaires were analyzed.

Measures

The survey comprised the Cyberchondria Severity Scale, Fear of COVID-19 Scale, Coronavirus Anxiety Scale, Anxiety Sensitivity Index, and Intolerance of Uncertainty Scale.

Cyberchondria Severity Scale–Short Form

The Cyberchondria Severity Scale–Short Form (CSS-12) [40] is a 12-item self-report scale designed to assess anxiety attributable to health-related online searches. The items (eg, “If I notice an unexplained bodily sensation, I will search for it on the Internet”) are rated on 5-point scale from 1 (never) to 5 (always). The scale comprises three subscales: compulsion, distress, and mistrust of medical professionals. Higher scores indicate greater cyberchondria. The internal consistency of the CSS-12 in this study was excellent (Cronbach α=.90).

Fear of COVID-19 Scale

The Fear of COVID-19 Scale (FCV-19S) [41] is a 7-item unidimensional scale that assesses fear of COVID-19. The items (eg, “I am afraid of losing my life because of COVID-19”) are rated on a 5-point scale ranging from 1 (strongly disagree) to 5 (strongly agree). Higher scores indicate a greater fear of COVID-19. The internal consistency of the FCV-19S in this study was very good (Cronbach α=.83).

Coronavirus Anxiety Scale

The 5-item Coronavirus Anxiety Scale (CAS) [42] assesses dysfunctional anxiety associated with COVID-19. The items (eg, “I had trouble falling or staying asleep because I was thinking about the coronavirus”) are rated on a 5-point scale, ranging from 1 (strongly disagree) to 5 (strongly agree). Higher scores are associated with a COVID-19 anxiety diagnosis, impairment, maladaptive coping, and suicidal ideation. The internal consistency of the CAS in this study was excellent (Cronbach α=.90).

The Anxiety Sensitivity Index-3

The Anxiety Sensitivity Index-3 (ASI-3) [43] is an 18-item self-report scale that assesses anxiety-related symptoms. Items (eg, “It scares me when my heart beats rapidly”) are rated on a 5-point scale from 0 (not at all) to 4 (very much). Higher scores indicate a more severe anxiety sensitivity level. The internal consistency of the ASI-3 in this study was very good (Cronbach α=.85).

Intolerance of Uncertainty Scale-12

The Intolerance of Uncertainty Scale-12 (IUS-12) [44] is a 12-item scale that assesses individuals’ responses to uncertainty. The items (eg, “It frustrates me not having all the information I need”) are rated on a 5-point scale from 1 (not at all characteristic of me) to 5 (entirely characteristic of me). Higher scores indicate greater uncertainty. The internal consistency of the IUS-12 in this study was very good (Cronbach α=.82).

Participant Recruitment

The study was conducted during the COVID-19 pandemic (October and November 2020) via convenience sampling; hence, all data were collected online because face-to-face data collection was not possible. The participants were recruited over a 6-week period using an online platform to complete the survey. The recruitment process included advertising the study via social media platforms (Instagram, WhatsApp) with links to the survey. In addition, the link was distributed on several academic forums. Once the link was clicked, it led to an informed consent page to be read and agreed upon before proceeding to the survey. Only those who provided informed consent were able to access the survey. The informed consent page included information about the study goals, such as the study's objectives and confidentiality.

Sample Size

A priori power analysis for multiple linear regression was calculated using G*Power (Heinrich-Heine-Universität Düsseldorf) to determine the sample size, with an alpha of .025, a power of 0.80, Cohen f^2 of 0.02, and two predictors [45]. The effect size value (Cohen f^2=0.02) signifies small effect sizes, according to Cohen's guidelines [46]. The desired total sample size was 576. In total, 694 participants were recruited in this study, which allowed for a 20% data attrition.

Ethics

The study, including all assessments and procedures for the study, were reviewed by the National Institute for Medical Research and Development and the Institutional Human Research Ethics Committee. The corresponding author's institutional review board also approved the research protocol to ensure participant confidentiality, sampling, and informed consent.

Data Analysis

Descriptive Statistics

Descriptive statistics were used to calculate the sample characteristics. Absolute skewness and kurtosis values assessed the normality assumption [47]. Variance inflation factor (VIF) was utilized to examine multicollinearity (1<VIF<3) [48]. Pearson coefficient correlation analysis was carried out to calculate the association between cyberchondria and the study variables. There were no missing values in the assessed variables. Therefore, no imputation method was implemented.

Multiple Mediation Analysis

Parallel multiple mediation analysis was conducted using SEM with a 95% CI for indirect effects and 5000 bootstrapping [49]. Once the measurement models were fitted to the data, 2 SEM models were examined. The first SEM investigated the relationships between fear of COVID-19 and COVID-19 anxiety (as independent variables) with cyberchondria. Anxiety sensitivity and intolerance of uncertainty were potential mediators. In the second SEM, the reverse model was examined. An indirect effect was considered statistically significant when the bias-corrected CI does not include zero [50,51]. Cohen f^2 values of ≥0.15 and ≥0.35 signified approximately moderate to large effect sizes, according to Cohen's guidelines [46]. SPSS (version 25, IBM Corp) and AMOS (version 24, IBM Corp) were utilized to test hypothesizes (two-tailed), and an alpha level of .05 was used to indicate statistical significance.

Results

Descriptive Statistics

Of the 820 returned surveys, 694 met the inclusion criteria and were included in the analysis. Therefore, the sample comprised 694 adults from the general population (males: n=343, 49.4%; females: n=351, 50.6%) , with a mean age of 27.92 years (SD 5.22, range 19-41 years). The demographic characteristics of the sample are shown in Table 1.

There was no significant difference between males and females (χ^2=0.09, *P*=.76). The participants were well educated and young. With respect to educational level, 25.8% (n=179) had completed high school, 49.2% (n=341) had a bachelor's degree, and 25% (n=174) had a master's and/or higher degree. Compared to males, females had significantly higher scores for cyberchondria ($t_{1,692}$=–2.85, *P*=.004, Cohen *d*=0.22), COVID-19 anxiety ($t_{1,692}$=–3.32, *P*<.001, Cohen *d*=0.26), and anxiety sensitivity ($t_{1,692}$=–3.69, *P*<.001, Cohen *d*=0.29). Compared to females, males had significantly higher scores for intolerance of uncertainty ($t_{1,692}$=2.29, *P*=.02, Cohen *d*=0.18). Gender differences for other variables were nonsignificant (*P*>.05) (Table 1).

The univariate normality of the data was checked. Values of skewness and kurtosis were within <|1|, suggesting the absence of severe normality. The VIF values demonstrated no violation of multicollinearity (Table 2). The Pearson coefficient correlation analyses showed a moderate to large correlations between variables (Table 2). Correlation analysis revealed a moderate to large correlation between cyberchondria and fear of COVID-19, COVID-19 anxiety, anxiety sensitivity, and intolerance of uncertainty.

Table 1. Demographic characteristics and descriptive statistics of the sample (N=694).

Characteristic	Participants	Statistics[a]	*P* value
Gender, n (%)		χ^2=0.09	.76
Male	343 (49.4)		
Female	351 (50.6)		
Age group, n (%)		χ^2=11.60	.003
19-25 years	193 (27.8)		
26-31 years	266 (38.3)		
>31 years	235 (33.9)		
Age (years), mean (SD)	27.92 (5.29)	$t_{1,692}$=0.82	.41
Cyberchondria, mean (SD)	33.17 (8.04)	$t_{1,692}$=–2.85	004
Coronavirus anxiety, mean (SD)	11.91 (2.51)	$t_{1,692}$=–3.32	.001
Fear of COVID-19, mean (SD)	15.21 (4.93)	$t_{1,692}$=–1.70	.09
Intolerance of uncertainty, mean (SD)	38.82 (9.52)	$t_{1,692}$=2.29	.02
Anxiety sensitivity, mean (SD)	28.52 (8.29)	$t_{1,692}$= –3.69	<.001

[a] Negative *t* values indicate that females obtained higher scores.

Table 2. Correlation matrix of main variables (N=694).

Item	1	2	3	4	5	6	Skewness	Kurtosis	VIF[a]
1. Age	1.00						0.49	–0.99	—[b]
2. Cyberchondria	–0.09[c]	1.00					0.38	0.85	2.51
3. Coronavirus anxiety	0.04	0.36[d]	1.00				0.70	–0.69	1.82
4. Fear of COVID-19	–0.06	0.46[d]	0.29[d]	1.00			0.39	0.75	1.35
5. Intolerance of uncertainty	0.26[d]	0.43[d]	0.31[d]	0.29[d]	1.00		0.65	–0.96	2.23
6. Anxiety sensitivity	–0.03	0.31[d]	0.27[d]	0.44[d]	0.36[d]	1.00	0.22	–1.02	1.92

[a] VIF: variance inflation factor.

[b] Not applicable.

[c] Correlation significant at the *P*<.05 level (two-tailed).

[d] Correlation significant at the *P*<.01 level (two-tailed).

Multiple Mediation Analysis

The first SEM mediation analysis showed that fear of COVID-19 and COVID-19 anxiety were significantly associated with cyberchondria via both direct and indirect paths. The standardized total effects for fear of COVID-19 and COVID-19 anxiety on cyberchondria were both statistically significant (fear: β=.39, SE 0.04, *P*<.001, *t*=11.16, 95% CI 0.31-0.45; anxiety: β=.25, SE 0.03, *P*<.001, *t*=7.67, 95% CI 0.19-0.32). Anxiety sensitivity and intolerance of uncertainty were also positively associated with cyberchondria (Figure 1). In addition, for fear of COVID-19 and COVID-19 anxiety, the indirect effects of anxiety sensitivity and intolerance of uncertainty on cyberchondria were significant (Table 3).

In the reciprocal model, the standardized total effects of cyberchondria on both fear of COVID-19 and COVID-19 anxiety were statistically significant (fear: β=.45, SE 0.04, *P*<.001, *t*=15.31, 95% CI 0.39-0.51; anxiety: β=.36, SE 0.03, *P*<.001, *t*=11.29, 95% CI 0.30-0.41. The indirect effects of cyberchondria on COVID-19 anxiety via anxiety sensitivity and intolerance of uncertainty were both significant. However, only cyberchondria's indirect effect on fear of COVID-19 via anxiety sensitivity was significant (Figure 2). The effect sizes for associations in both mediation models are reported in Table 4.

Figure 1. The multiple mediation model. Path coefficient: standardized coefficient (*t* value). ****P*<.001 level (two-tailed).

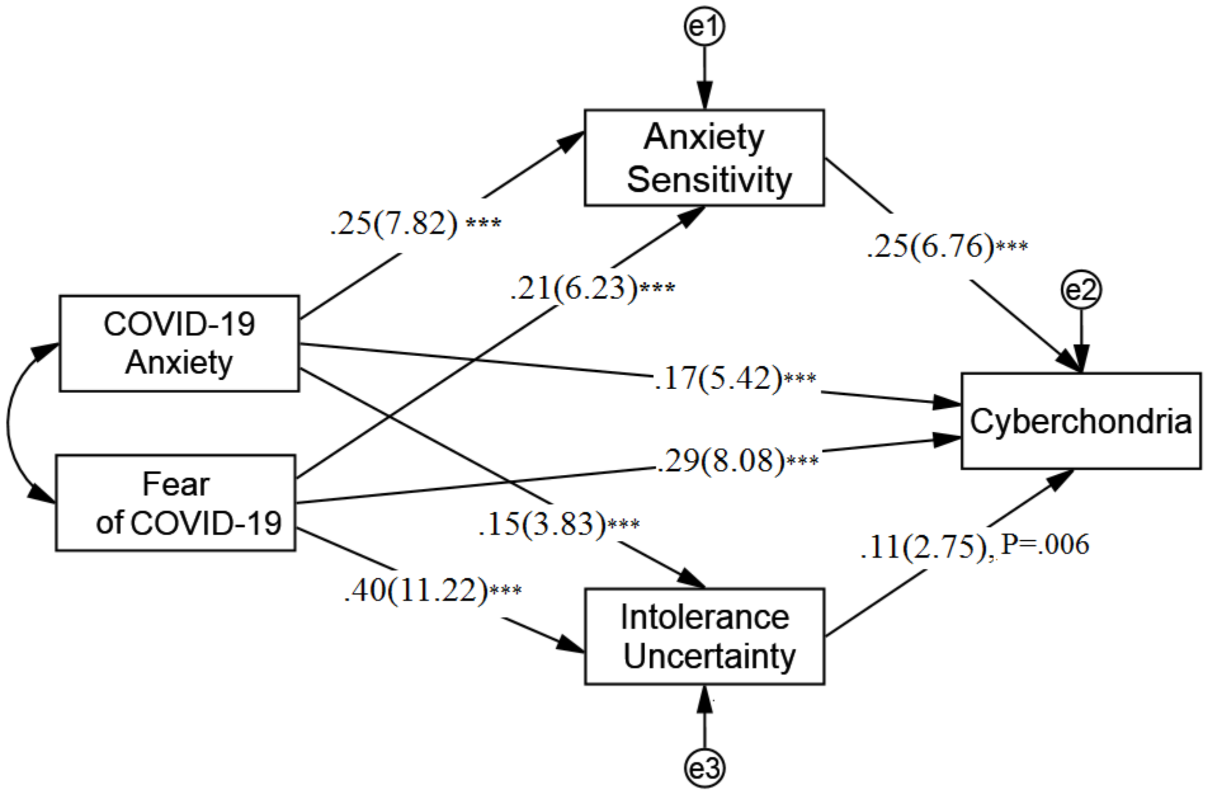

Table 3. Standardized indirect effects of model paths.

Model and indirect path[a]	Beta[b]	SE	*t* value	*P* value	95% CI
Model 1					
Coronavirus anxiety –> intolerance of uncertainty –> cyberchondria	.06	0.02	4.98	<.001	0.04 to 0.09
Fear of COVID-19 –> intolerance of uncertainty –> cyberchondria	.06	0.01	4.52	<.001	0.03 to 0.08
Coronavirus anxiety –> anxiety sensitivity –> cyberchondria	.02	0.01	2.23	.03	0.004 to 0.03
Fear of COVID-19 –> anxiety sensitivity –> cyberchondria	.04	0.02	2.67	.01	0.01 to 0.07
Model 2 (reciprocal model)					
Cyberchondria –> intolerance of uncertainty –> coronavirus anxiety	.07	0.02	4.26	<.001	0.04 to 0.11
Cyberchondria –> anxiety sensitivity –> coronavirus anxiety	.04	0.01	2.98	.004	0.01 to 0.07
Cyberchondria –> intolerance of uncertainty –> fear of COVID-19	.02	0.02	1.15	.25	–0.01 to 0.05
Cyberchondria –> anxiety sensitivity –> fear of COVID-19	.11	0.02	6.99	<.001	0.08 to 0.15

Discussion

Principal Findings

Understanding COVID-19 pandemic–related psychopathological development has been limited due to numerous individual and contextual factors. There is concern that individuals affected by fear and anxiety generated by the pandemic will rapidly outnumber infected cases. This study investigated the impact of the relationship between cyberchondria and the fear and anxiety generated by COVID-19. The study also explored whether the relationships would be mediated by the intolerance of uncertainty and anxiety sensitivity. Results indicated that greater fear and anxiety related to COVID-19 directly predicted cyberchondria [52-54] and indirectly via the mediator variables. Cyberchondria and anxiety generated by COVID-19 was bidirectional. A higher level of cyberchondria directly predicted a higher level of fear and anxiety generated by COVID-19, and indirectly via the mediators.

The mediation analysis empirically showed that intolerance of uncertainty and anxiety sensitivity mediated the associations between fear and anxiety generated by COVID-19 on cyberchondria. In the context of COVID-19, individuals with a higher intolerance of uncertainty levels may search for medical information to reduce uncertainty that results in additional negative experience [55-57]. Intolerance of uncertainty amplifies both threat perception and uncertainty perception [58], which can lead to more engagement in safety behaviors (eg, checking behavior) [59]. Like a vicious circle, seeking health-related information on the internet to reduce uncertainty may be associated with greater levels of uncertainty and therefore amplify health anxiety. These safety-seeking behaviors to reduce uncertainty are often not long lasting. In addition, most uncertainty reduction attempts meet with information that is overly brief and inaccurate, which can lead to greater levels of uncertainty. Moreover, uncertainty-reducing behaviors can lead to greater uncertainty perceptions and/or higher perceived threat severity. During a pandemic, individuals with a high intolerance of uncertainty perceive low-risk situations as highly threatening and report higher anxiety levels [34].

Individuals with high anxiety sensitivity (1) are more afraid of pain and more likely to seek unnecessary treatment for minor pain symptoms [60]; and (2) may misinterpret symptoms, which can result in bodily sensations related to anxiety (eg, sweating, shaky hands) that may be interpreted as severe physical symptoms or illness [61]. Since individuals with elevated anxiety sensitivity interpret anxiety-related bodily sensations to be dangerous, they exhibit increased online medical information-seeking behaviors in an attempt to placate concerns about the origins of anxiety-related bodily sensations. Specifically, this cognitive-affective condition is considered conceptually distinct from anxiety and reflects the fear of anxious arousal symptoms. Anxiety sensitivity is a more robust predictor of posttraumatic symptoms with a moderate to large effect size [62]. On the other hand, the reduction in anxiety sensitivity positively predicts a reduction in the severity of anxiety symptoms [63,64]. This theoretical process is consistent with research that has found the engagement in safety behaviors, including using medical websites to investigate medical symptoms, results in increased levels of health anxiety. With respect to the bidirectional associations between intolerance of uncertainty and anxiety sensitivity, findings suggest that evaluation of both conditions can add to the diagnosis process for individuals with cyberchondria.

This study also found some gender differences. In line with the few studies to date, females reported a higher levels for cyberchondria than males [65]. Females also reported higher levels of COVID-19 anxiety and anxiety sensitivity than males in this study. In line with recent studies, females reported more psychological problems associated with COVID-19 than males [66-68]. Our findings concur with previous studies indicating that females report greater psychological problems and are more likely to develop anxiety symptoms than males [69]. Regarding age, the results suggest that behaviors related to cyberchondria appear to be more prevalent among younger individuals [70,71].

Limitations

The findings of this study should be interpreted in light of several limitations. This study was conducted during October 2020 at the height of the COVID-19 pandemic in Iran. Therefore, to minimize infection risk, online data collection was utilized rather than a traditional face-to-face method. Online data collection may limit the participation of specific relevant population groups (eg, disadvantaged groups such as those living in poverty who may not have internet access). Therefore, the data do not represent all groups' views, affecting the generalizability of the study's findings. However, online data collection tends to provide more honest and truthful responses than offline methods [72]. Moreover, all data were self-reported and are therefore subject to well-established method biases. It should also be noted that the data collected did not include some potentially important variables such as whether (1) the participants were currently working or whether they had lost their job as a result of the pandemic, (2) they and/or their family members had experienced COVID-19, and (3) whether they had financial problems as a result of the pandemic. These are all variables that could be considered in future research when reexamining the variables of this study. Finally, the data were cross-sectional; therefore, determining the true relationships and directions of causality between the study variables is not possible. Future studies would need longitudinal designs to determine true causality.

Conclusion

Despite these limitations, the findings of the first SEM suggest that anxiety sensitivity and/or intolerance of uncertainty may lead to the development of cyberchondria in the context of the COVID-19 pandemic, with small to moderate effect sizes. In this study, greater fear and anxiety of COVID-19 were associated with greater cyberchondria. However, the reverse SEM demonstrated that cyberchondria is also associated with the study construct, with moderate to large effect sizes. In addition to the pandemic, anxiety sensitivity and intolerance of uncertainty can be critical in increasing or maintaining psychopathological development, as well as physical and psychological dysfunctions [73-75]. Given the co-occurring nature of mental health problems during the current pandemic, disorder-specific interventions may be difficult to justify when the clinical reality is complex and comorbidities are the norm [76]. Many clinical studies have recommended shifting from the traditional specific disorder–focused approach toward a transdiagnostic treatment as an alternative approach. Despite some scholars' assertions [77], the findings of this study do not justify cyberchondria as a transdiagnostic condition. However, the transdiagnostic treatments or application of the relative modules may be effective in treatment for cyberchondria. For example, higher self-awareness and contextual awareness enable individuals to clearly identify the triggering of negative responses and can help reduce maladaptive cognitive patterns by facilitating awareness or attention toward an object (eg, heartbeat, breathing) in a mindful manner [78,79]. To provide adaptive emotional responding to anxiety-related bodily sensations, self-awareness can be promoted by the mindfulness-based stress reduction therapy or other unified protocols [80].

This study's findings help to explain how the consequences of the pandemic can be associated with cyberchondria. The role of cyberchondria in the exacerbation of pandemic-related psychological distress can provide further evidence that maladaptive new age issues related to human-internet interaction need further attention from scholars, policymakers, and health care practitioners. Finally, based on the findings here, cyberchondria must be viewed as a significant public health issue. Importantly, increasing awareness about cyberchondria and online behavior at both the individual and collective levels must be prioritized to enhance preparedness and reduce adverse effects associated with the current pandemic and future medical crises.

Abstract

Background: Monitoring public confidence and hesitancy is crucial for the COVID-19 vaccine rollout. Social media listening (infoveillance) can not only monitor public attitudes on COVID-19 vaccines but also assess the dissemination of and public engagement with these opinions.

Objective: This study aims to assess global hesitancy, confidence, and public engagement toward COVID-19 vaccination.

Methods: We collected posts mentioning the COVID-19 vaccine between June and July 2020 on Twitter from New York (United States), London (United Kingdom), Mumbai (India), and Sao Paulo (Brazil), and Sina Weibo posts from Beijing (China). In total, we manually coded 12,886 posts from the five global metropolises with high COVID-19 burdens, and after assessment, 7032 posts were included in the analysis. We manually double-coded these posts using a coding framework developed according to the World Health Organization's Confidence, Complacency, and Convenience model of vaccine hesitancy, and conducted engagement analysis to investigate public communication about COVID-19 vaccines on social media.

Results: Among social media users, 36.4% (571/1568) in New York, 51.3% (738/1440) in London, 67.3% (144/214) in Sao Paulo, 69.8% (726/1040) in Mumbai, and 76.8% (2128/2770) in Beijing indicated that they intended to accept a COVID-19 vaccination. With a high perceived risk of getting COVID-19, more tweeters in New York and London expressed a lack of confidence in vaccine safety, distrust in governments and experts, and widespread misinformation or rumors. Tweeters from Mumbai, Sao Paulo, and Beijing worried more about vaccine production and supply, whereas tweeters from New York and London had more concerns about vaccine distribution and inequity. Negative tweets expressing lack of vaccine confidence and misinformation or rumors had more followers and attracted more public engagement online.

Conclusions: COVID-19 vaccine hesitancy is prevalent worldwide, and negative tweets attract higher engagement on social media. It is urgent to develop an effective vaccine campaign that boosts public confidence and addresses hesitancy for COVID-19 vaccine rollouts.

Introduction

As of January 2021, the COVID-19 pandemic has led to more than 100 million cases and 2 million deaths worldwide [1]. Although personal prevention measures such as mask wearing and social distancing have been shown to be effective in curbing the spread of COVID-19 [2], vaccination is expected to be the key to the long-term prevention and control of the pandemic [3,4]. The COVID-19 pandemic has triggered intense global research and development (R&D) of vaccines against the disease. Several candidate vaccines advanced to Phase III clinical trials in mid-2020, including the Oxford/AstraZeneca, Sinopharm, Sinovac, BioNTech/Pfizer, and Moderna vaccines, and had finished clinical trials at the end of 2020. These vaccines have been approved for use by December 2020 in some countries such as the United Kingdom, the United States, and China [5]. To ensure universal vaccination coverage, governments must enhance public confidence, address the issue of vaccine hesitancy, and design community engagement strategies for COVID-19 vaccine rollouts.

Although immunization has proved successful in reducing the global burden of illness and death, a range of concerns have converged to affect public confidence in vaccines. When vaccine confidence breaks down, hesitancy can cause serious consequences such as delays, refusals, and disruptions to research and delivery programs, and sometimes leads to the resurgence of disease outbreaks [6]. Vaccine hesitancy has proliferated over the decades and was cited by the World Health Organization (WHO) as one of the top 10 global health threats in 2019 [7,8]. Vaccine hesitancy is complex, multifactorial, and influenced by a combination of emotional, cultural, social, spiritual, and political factors. It can vary across countries, vaccines, and time. Reports have indicated that hesitancy toward general vaccines is prevalent among caregivers of children worldwide, at rates such as 45.8% in France (2016) [7], 31.8% in the United States (2014) [9], 24.6% in Italy (2017) [10], and 23% in Brazil (2016) [11]. The prevalence of vaccine hesitancy among health care providers ranges from 2% to 16% across different countries [12]. The accelerated R&D process of the COVID-19 vaccine may further exacerbate public concern on its safety and effectiveness [13]. Similarly, the novelty of the disease, politicization of the vaccine, and distrust in experts and governments have increased uncertainty about COVID-19 vaccination [3]. Therefore, it is necessary to assess public confidence and acceptance toward the COVID-19 vaccine to prepare for vaccine introduction.

Social media has become a source of data for detecting outbreaks and understanding public attitudes and behaviors during public health emergencies [14-16]. Large amounts of real-time data posted on social media platforms can be used to quickly identify public attitudes on COVID-19 vaccines as a way to support health communication and health promotion messaging. A growing body of literature has used social media platforms such as Twitter and Facebook for public health research [15]. Compared with traditional surveys, social media listening can not only monitor public attitudes in a timely manner but also assess the dissemination of and public engagement with these opinions [17]. Individuals are increasingly using social media to communicate with each other, and public engagement can assess how various messages around COVID-19 vaccines spread on social media. Although several previous studies investigated public acceptance toward COVID-19 vaccines using questionnaire surveys, it is unknown how these opinions spread among the public.

By using social media listening data from the largest metropolises worldwide, this study aimed to assess global vaccine hesitancy and confidence toward COVID-19 vaccination and public engagement in communications about COVID-19 vaccines.

Methods

Data Collection

Twitter is one of the most popular social media platforms in the world; Sina Weibo, Twitter in China, is the most influential social media platform in China, with over 500 million users. Users can share information or opinions by tweets or posts on these platforms. Using the Meltwater platform [18], we collected posts mentioning COVID-19 vaccines on Twitter from New York (United States), London (United Kingdom), Mumbai (India), Sao Paulo (Brazil), and Sina Weibo posts from Beijing (China). The five metropolises were selected due to their high disease burden of COVID-19. The data covered the period from June 13 to July 31, 2020, when five COVID-19 vaccines started their Phase III clinical trials worldwide, including the Oxford/AstraZeneca, Sinopharm, Sinovac, BioNTech/Pfizer, and Moderna vaccines [19]. The keywords included “COVID vaccin*” OR “COVID-19 vaccin*” OR “COVID19 vaccin*” OR “coronavirus vaccin*” OR “vaccin* for coronavirus” OR “vaccin* for COVID.” Each post record comprised account name, contents, post time, the number of followers, and engagement data. Since our study aimed to assess public attitudes toward COVID-19 vaccination, we only included tweets or Weibo posts from individual accounts and excluded those from news and organizational accounts. Duplicate tweets, tweets with identical text but different tweet identifications, retweets, quotes without comments, and irrelevant tweets were removed [20]. This study was exempt from ethical review because it examined retrospective publicly available data.

Content Analysis

We identified and classified posts describing personal opinions or discussion of COVID-19 vaccines from Twitter and Sina Weibo. A coding framework (Multimedia Appendix 1) was developed for content analysis according to the WHO’s Confidence, Complacency, and Convenience (“3 Cs”) model of vaccine hesitancy [21] and validated through manual annotation of the subset with 500 posts. All posts were double-coded independently, and a third coder resolved disagreements. Posts were initially classified as relevant or irrelevant to personal opinions toward COVID-19 vaccines, and relevant posts were further classified to the predefined categories in Multimedia Appendix 1. Predefined categories included attitudes toward COVID-19 vaccination (accept, neutral, doubt, or refuse), expectations of COVID-19 vaccine R&D and introduction (positive, neutral, or negative), confidence in COVID-19 vaccine importance (important or not), confidence in COVID-19 vaccine effectiveness (effective or not), confidence in COVID-19 vaccine safety (safe or not), trust in governments (trust or not), trust in experts (trust or not), misinformation or rumors about all vaccines, complacency (perceived risk of getting COVID-19: high or low), COVID-19 vaccine convenience (accessibility, distribution, or affordability), COVID-19 vaccine types (AstraZeneca, Moderna, Pfizer, or Chinese vaccines), and others. Each post could be classified as one category, multiple categories, or no category. We described simple counts and percentages of posts for each topic on COVID-19 vaccination.

Social Media Engagement Analysis

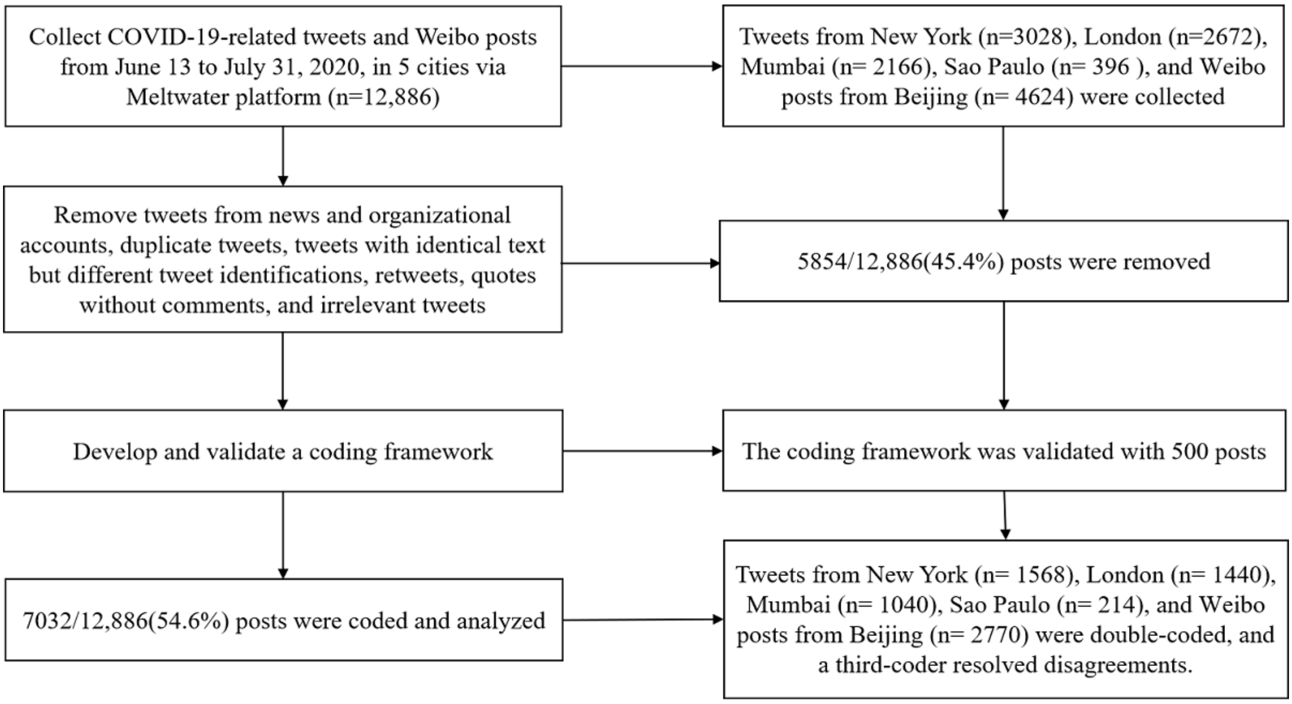
We also conducted social media engagement analysis to investigate public communication and interaction about various topics relating to the COVID-19 vaccine online. In Twitter, the engagement metric measures all actions viewers have taken as a result of seeing tweets and engaging with tweets [22]. At the level of public engagement and interaction, Twitter engagement refers to retweets, follows, replies, favorites, and clicks on the tweets. It covers the three metrics of social media engagement: popularity based on the number of likes for tweets, commitment based on the number of comments for tweets, and virality based on the number of shares for tweets [22]. The mean number and SD of engagement with and followers of tweeters were presented for each topic of COVID-19 vaccines.

Results

Description of Analyzed Social Media Posts

Figure 1 shows the process of data selection and analysis. In total, we collected 12,886 social media posts mentioning a COVID-19 vaccine. There were 3028 tweets on Twitter from New York, 2672 tweets from London, 2166 tweets from Mumbai, 396 tweets from Sao Paulo, and 4624 Sina Weibo posts from Beijing. After assessment, 7032 posts met the inclusion criteria and were included in our content analysis, including 1568 tweets from New York, 1440 tweets from London, 1040 tweets from Mumbai, 214 tweets from Sao Paulo, and 2770 Sina Weibo posts from Beijing.

Figure 1. Flowchart of data process and analysis.



COVID-19 Vaccine Hesitancy and Confidence

Figure 2 presents social media users' attitudes toward COVID-19 vaccination. Among social media users, 36.4% (571/1568) in New York and 51.3% (738/1440) in London reported willingness to accept COVID-19 vaccines, much lower than observed in metropolises in lower- and middle-income countries (LMICs), such as 69.8% (726/1040) in Mumbai, 67.3% (144/214) in Sao Paulo, and 76.8% (2128/2770) in Beijing. Although about 10% to 20% of users doubted the safety or effectiveness of COVID-19 vaccines in each metropolis, 20% (313/1568) in New York and 15.1% (218/1440) in London expressed refusal, much higher than other metropolises (<5%), leading to prevalent vaccine hesitancy. About 50% to 80% of users discussed the R&D and introduction of the COVID-19 vaccine globally, with most showing positive expectations, and the remaining users did not mention the R&D and introduction of COVID-19 vaccines (Figure 3). The discussion levels on the R&D and introduction of the COVID-19 vaccine in New York and London were lower than those in Mumbai, Beijing, and Sao Paulo.

Figure 2. Social media users' attitudes toward COVID-19 vaccination.

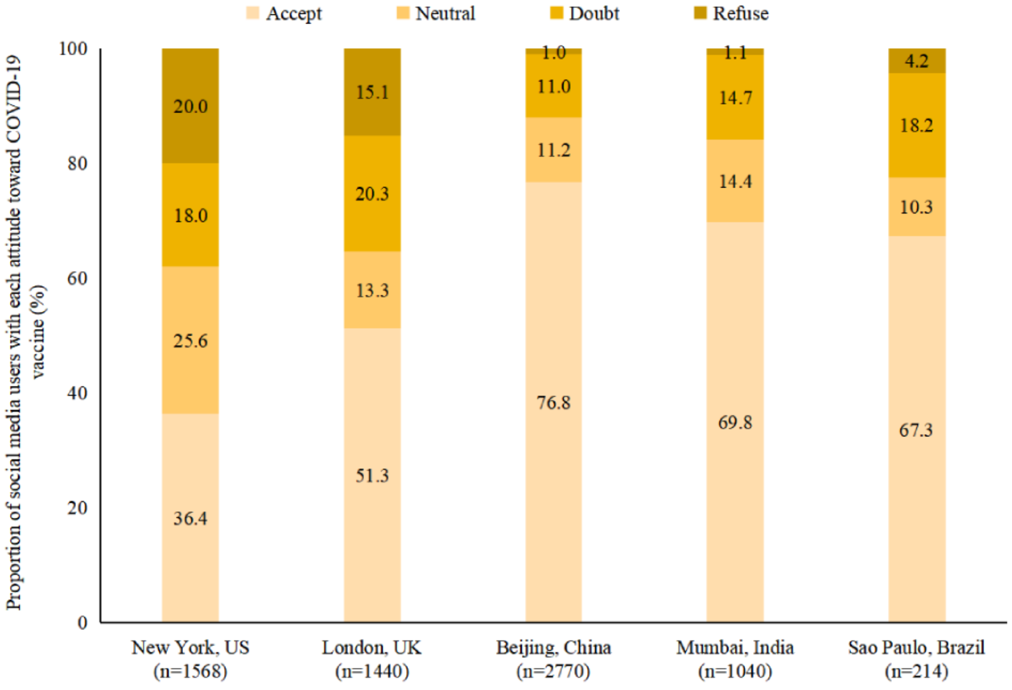


Figure 3. Expectations of COVID-19 vaccine R&D and introduction. R&D: research and development.

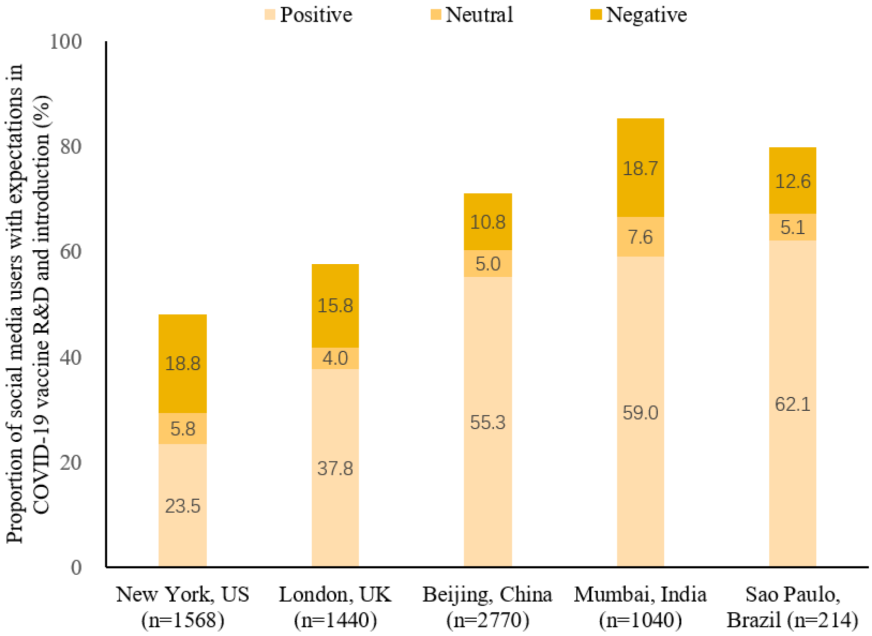

Table 1 conveys confidence, complacency, and convenience related to COVID-19 vaccination on social media. Although most tweets in each metropolis regarded COVID-19 vaccination as important and effective, proportions of tweets perceiving COVID-19 vaccines as unsafe in high-income countries (HICs; 133/1568, 8.5% in New York and 157/1440, 10.9% in London) were much higher than those in other metropolises (<4%). These HIC users expressed distrust in governments (>10%) and experts (around 5%). Furthermore, 11.8% (185/1568) and 11% (158/1440) of users in New York and London, respectively, mentioned misinformation, rumors, or antivaccine campaigns, but few users in LMIC metropolises (<7%) shared these concerns.

Table 1. Confidence, complacency, and convenience related to COVID-19 vaccines on social media in 2020.

Topics	New York, US	London, UK	Beijing, China	Mumbai, India	Sao Paulo, Brazil

[a] We assessed 50% random samples from New York and London due to the large sample size, and full samples in Beijing, Mumbai, and Sao Paulo.

[b] Topics are calculated among relevant posts.

[c] Trust in experts is not measured specifically for Sina Weibo posts from Beijing.

Regarding complacency, most social media users perceived the risk of getting COVID-19 to be high despite only a small number of them (around 5% except Beijing) directly mentioning the risk of getting COVID-19. For vaccination convenience, approximately 5% of HIC users mentioned vaccine accessibility, whereas more users in LMIC metropolises (10%-20%) worried about vaccine accessibility, including production and supply capacity for COVID-19 vaccines. Nearly 20% of HIC users worried about vaccine distribution, including priority vaccination groups, whereas less users in LMIC metropolises (around 10%) mentioned this subject. Few users (about 5%) considered vaccine affordability in mid-2020. There were differential concerns on vaccine accessibility worldwide.

The proportion of tweets mentioning specific vaccine types was 16.5% (259/1568) in New York, 57% (122/214) in Sao Paulo, and around 30% in the remaining three metropolises. Tweets in New York mainly discussed COVID-19 vaccines produced in the United States, and tweets in other metropolises discussed vaccines produced worldwide. In terms of specific COVID-19 vaccines that had started Phase III clinical trials, social media users in metropolises except for Beijing mostly mentioned the Oxford/AstraZeneca vaccine, followed by the BioNTech/Pfizer and Moderna vaccines; the Chinese vaccine was the least frequently mentioned. This indicated that public attention was consistent to the development progress of specific vaccines.

Engagement Levels of COVID-19 Vaccine–Related Tweets

Table 2 presents the engagement metrics of COVID-19 vaccine–related tweets by topic. On average, tweeters who posted COVID-19 vaccine–related tweets had 3634 followers, and their followers ranged from 1637 (expressing COVID-19 vaccination is important) to 4778 followers (expressing COVID-19 vaccination is unsafe) and 7430 followers (expressing COVID-19 vaccination is ineffective). Overall, tweeters expressing negative attitudes toward COVID-19 vaccines, such as doubt or refusal to vaccinate, lack of confidence in vaccines (importance, effectiveness, and safety), and misinformation or rumors, had more followers than those expressing positive attitudes.

COVID-19 vaccine–related tweets attracted 6.1 engagement values on average. When comparing engagement levels on different topics regarding COVID-19 vaccines, we found that the most active topics were misinformation (engagement value 14.0), followed by confidence in vaccine safety (13.1), vaccine effectiveness (10.9), and governments (9.7), whereas the least active topics were vaccine convenience (2.6-5.8), confidence in vaccine importance (3.6) and experts (3.8), and complacency (5.4). For topics on vaccine hesitancy and expectations in vaccine R&D and introduction, tweets with clear attitudes attracted more engagement than neutral tweets, but there was little difference in public engagement between tweets with positive and negative attitudes. For each topic regarding vaccine confidence except distrust in governments, lack of confidence propagated more than having confidence, especially for vaccine safety (16.7 engagement for tweets expressing vaccine is unsafe vs 10.3 engagement for tweets expressing vaccine is safe); trust in governments attracted much more engagement than distrust (52.8 vs 5.4), representing the public's common expectations of governments taking an active role in controlling the epidemic.

Table 2. Followers and engagements of COVID-19 vaccine–related tweets in 2020.

Topics	Followers, mean (SD)	Engagements, mean (SD)
Vaccine hesitancy		
Attitudes toward COVID-19 vaccination	3633.6 (12,614.4)	6.1 (61.4)
Accept	2448.8 (8614.6)	7.9 (93.3)
Neutral	4333.0 (16,250.7)	5.8 (28.5)
Doubt	4593.3 (18,245.7)	10.0 (93.4)
Refuse	2708.4 (12,504.3)	6.4 (35.4)
Expectations of COVID-19 vaccine R&D[a] and introduction	3011.0 (11,759.4)	8.4 (94.4)
Positive	2527.7 (9083.2)	8.8 (104.3)
Neutral	4449.8 (16,399.9)	5.9 (31.9)
Negative	3629.4 (14,833.2)	8.2 (84.0)
Vaccine confidence		
Perceived importance of vaccines	1763.6 (3727.9)	3.6 (10.7)
Important	1636.5 (3167.2)	3.4 (9.9)
Unimportant	2843.1 (6811.7)	5.4 (16.5)
Perceived effectiveness of vaccines	3373.4 (13,960.7)	10.9 (115.5)
Effective	2505.6 (8366.8)	10.6 (119.5)
Ineffective	7430.1 (27,615.6)	12.2 (94.7)
Perceived safety of vaccines	3274.3 (14,058.0)	13.1 (137.2)
Safe	2086.2 (6191.7)	10.3 (137.4)
Unsafe	4778.0 (19,897.0)	16.7 (137.1)
Trust in governments	3865.2 (16,363.8)	9.7 (111.8)
Trust	3055.6 (6573.5)	52.8 (360.4)
Distrust	3946.0 (17,036.6)	5.4 (28.7)
Trust in experts	1887.9 (4812.1)	3.8 (14.7)
Trust	2029.1 (4076.9)	3.0 (6.5)
Distrust	1827.7 (5102.0)	4.1 (17.1)
Information around vaccines		
Misinformation or rumors	3127.7 (11,610.5)	14.0 (121.2)
Vaccine complacency		
Perceived risk of getting COVID-19	3017.9 (8282.9)	5.4 (15.6)
High	2909.7 (7848.9)	5.1 (15.5)
Low	3937.6 (11,554.1)	8.1 (16.5)
Vaccine convenience		
Vaccine accessibility	2351.5 (8915.4)	2.6 (7.8)
Vaccine distribution	3531.5 (12,541.6)	5.8 (26.2)
Vaccine affordability	2525.3 (4895.6)	3.1 (8.3)

Discussion

Principal Findings

This social listening study in large metropolitan areas in five countries examined hesitancy toward COVID-19 vaccination; perceptions of vaccine confidence, complacency, and convenience; and level of online public engagement. We found that COVID-19 vaccine hesitancy was prevalent worldwide, with the highest prevalence in New York and London, followed by Sao Paulo and Mumbai, and the lowest in Beijing. With high perceived risk of getting COVID-19, social media users in HICs, including the United States and the United Kingdom, expressed low acceptance of COVID-19 vaccines, serious concerns regarding vaccine safety, and distrust in governments and experts. There were different concerns about vaccination convenience and accessibility between HICs and LMICs. Negative tweets expressing lack of vaccine confidence and misinformation or rumors had more followers and attracted more online public engagement.

Overall, social media users expressed relatively high hesitancy toward COVID-19 vaccination across metropolises with high COVID-19 burdens. There were no metropolises where willingness to accept a COVID-19 vaccine exceeded 80%, and only between 36% to 50% of tweeters accepted the COVID-19 vaccine especially in New York and London. These social listening results were similar to global survey studies [13,23], which showed that COVID-19 vaccine acceptance was higher in China, India, and Brazil but lower in the United States and the United Kingdom. Over the past decade, vaccine refusal has accelerated worldwide, and antivaccine activities have been amplified through political activities and social media [24]. The prevalent hesitancy toward COVID-19 vaccines could potentially lead to low vaccination coverage, which will further delay global control of the pandemic and societal and economic recovery. Recent studies estimated a COVID-19 R_0 of around 3.87 for Europe and around 3.45 for the United States [25,26], implying herd immunity thresholds of 74% and 71%, respectively. The current acceptance levels among tweeters in New York, London, Mumbai, and Sao Paulo is insufficient to reach this 71% to 74% threshold; one exception is Beijing with an acceptance level at 76.8%. As governments are preparing to introduce COVID-19 vaccines and initiate postpandemic recovery, the need to develop an effective vaccine campaign for the rollout that boosts public confidence and addresses hesitancy is urgent.

A previous study showed that confidence in vaccines and governments was strongly associated with vaccine acceptance and uptake [13]. However, our findings showed lack of confidence in vaccine safety, distrust in governments and experts, and widespread misinformation or rumors, especially in HICs. Public confidence in the safety and effectiveness of COVID-19 vaccines was far lower than the confidence level in general vaccines. In the 2018 Global Monitor Survey, 79% and 84% of the public agreed that vaccines were safe and effective globally [27]. During COVID-19, the development of a vaccine for a new pathogen has been pushed much faster than ever before, and new bioscience technologies (eg, mRNA vaccine) are being used in humans for the first time [5,28]. In light of the accelerated R&D process, any negative news related to vaccine failure may weaken public confidence in its safety and effectiveness [13,29]. Therefore, effective communication campaigns should be designed to explain the safety of COVID-19 vaccines to the public and clarify misinformation or rumors, especially in HICs. Communication campaigns should be supported by the scientific community to address public concerns in COVID-19 vaccines. Through creating a space for a collaborative dialogue between the scientific community and the public, these campaigns would aim to not only provide the public with the latest information but also build public confidence in vaccine programs.

Social media users in HICs and LMICs expressed different concerns about vaccination convenience and accessibility. HIC users had less concerns about production and supply capacity of COVID-19 vaccines but more concerns on vaccine distribution and inequity. In contrast, LMIC users worried more about vaccine production and supply instead of vaccine distribution. Although HICs can ensure the supply of COVID-19 vaccines, systemic racial and economic disparities have existed for a long time in many fields, including health care and vaccination. The COVID-19 pandemic has disproportionately affected low-income groups and communities of color [24]. Disparities in access to COVID-19 vaccines possibly still occur and may be a point of concern that needs to be addressed in HICs. There is also much concern regarding access to COVID-19 vaccines and rollout gaps in LMICs compared with HICs. Many HICs have sought to gain priority access to COVID-19 vaccines by striking advance purchase agreements with vaccine manufacturers, instead of through WHO's global allocation mechanism, leaving few vaccine doses for LMICs [23,30]. Therefore, vaccine campaigns should be tailored to each context to address local concerns: LMICs should take efforts to address vaccine supply issues and HICs should focus more on equitable distribution within countries. This study calls for strengthened international partnerships and coordination to address the equitable access to COVID-19 vaccines worldwide, and the WHO should be empowered to take a leading role in guiding more preparedness actions to control the epidemic [31].

According to social media engagement analysis, we found that negative tweets had more followers and higher engagement than positive tweets. This finding might demonstrate that users on Twitter are more interested in communicating and disseminating negative messages such as those expressing misinformation or rumors and lack of vaccine confidence. Previous studies showed that Twitter users sharing misinformation tend to be more connected and clustered [32], and false information travels faster than true information does in social networks [33]. Although scientific experts received considerable attention early on in the COVID-19 pandemic, online attention shifted toward political communities as the pandemic developed [34]. During the evolution of the pandemic, scientific experts lost some of their influence, and it became harder for scientific information to reach a broad audience. In addition, the spread of misinformation or rumors on social media has been found to be significantly associated with vaccine hesitancy [35]. Social media is therefore a double-edged sword that not only can help disseminate public health knowledge directly to the public but also that can, through inappropriate use, be destructive to public health efforts, especially during a public health emergency [36-38]. Therefore, more efforts are needed to build a more proactive public health presence on social media, and health systems should *listen* to tweets from the public to help inform policies related to public health response.

Limitations

This study captured routine populations who may not be represented in traditional research designs, and social media data can eliminate reporting bias that occurs from speaking with a researcher [20]. However, this study has some limitations. First, there is an inherent bias shared among all social media studies, where users might present themselves differently online or represent a skewed-younger population [39]. Second, we did not extract demographic data because of difficulty to refer to users' profiles. Third, we used manual coding methods rather than automated annotation, which increased the length of time taken to annotate. Therefore, we only assessed vaccine hesitancy in large metropolises in a short period, and it reduced the generalizability of our findings. In the future, based on our coding data set from this study, we plan to develop a machine learning program to continuously track public attitudes toward COVID-19 vaccination.

Abstract

Background: In recent years, medical journals have emphasized the increasingly critical role that social media plays in the dissemination of public health information and disease prevention guidelines. However, platforms such as Facebook and Twitter continue to pose unique challenges for clinical health care providers and public health officials alike. In order to effectively communicate during public health emergencies, such as the COVID-19 pandemic, it is increasingly critical for health care providers and public health officials to understand how patients gather health-related information on the internet and adjudicate the merits of such information.

Objective: With that goal in mind, we conducted a survey of 1003 US-based adults to better understand how health consumers have used social media to learn and stay informed about the COVID-19 pandemic, the extent to which they have relied on credible scientific information sources, and how they have gone about fact-checking pandemic-related information.

Methods: A web-based survey was conducted with a sample that was purchased through an industry-leading market research provider. The results were reported with a 95% confidence level and a margin of error of 3. Participants included 1003 US-based adults (aged ≥18 years). Participants were selected via a stratified quota sampling approach to ensure that the sample was representative of the US population. Balanced quotas were determined (by region of the country) for gender, age, race, and ethnicity.

Results: The results showed a heavy reliance on social media during the COVID-19 pandemic; more than three-quarters of respondents (762/1003, 76%) reported that they have relied on social media at least “a little,” and 59.2% (594/1003) of respondents indicated that they read information about COVID-19 on social media at least once per week. According to the findings, most social media users (638/1003, 63.6%) were unlikely to fact-check what they see on the internet with a health professional, despite the high levels of mistrust in the accuracy of COVID-19–related information on social media. We also found a greater likelihood of undergoing vaccination among those following more credible scientific sources on social media during the pandemic (χ^2_{16}=50.790; ϕ=0.258; P<.001).

Conclusions: The findings suggest that health professionals will need to be both strategic and proactive when engaging with health consumers on social media if they hope to counteract the deleterious effects of misinformation and disinformation. Effective training, institutional support, and proactive collaboration can help health professionals adapt to the evolving patterns of health information seeking.

Introduction

In recent years, medical journals have emphasized the increasingly critical role that social networking sites (SNSs) play in the dissemination of public health information and disease prevention guidelines [1,2]. Still, platforms such as Facebook and Twitter continue to pose unique challenges for clinical health care providers and public health officials alike. Although the public has grown more reliant on social media to stay informed during times of crisis [3], the information they receive comes from a variety of sources that are not always official or objective in nature. Health professionals often lack the time and resources that are necessary to keep pace with the rapidity of these web-based information environments. Moreover, effective health communications are increasingly complicated by factors such as politicization, antiscientific sentiments, and the potential that social networks have in rapidly spreading false information [4-6]. These challenges are perhaps the most acute under crisis conditions, which place unique strains on both health care systems and traditional information networks [7,8].

Although these concerns extend beyond the COVID-19 pandemic, their urgency has been underscored by the ongoing crisis. From the outset of the pandemic, public health officials noted an alarming volume of erroneous misinformation (as well as malicious disinformation) associated with COVID-19 on social media. Estimates from early studies have suggested that as much as 25% of the COVID-19–related information circulating on platforms like Twitter may contain some degree of misinformation [9]. The World Health Organization labeled this phenomenon as an “infodemic” and suggested that such misinformation can “lead to poor observance of public health measures, thus reducing their effectiveness and endangering countries’ ability to stop the pandemic” [10].

In order to effectively communicate during public health emergencies, it is increasingly critical for health professionals to understand how patients gather health-related information on the internet and adjudicate the merits of such information. However, while much has been written about social media’s expanding role in health communications, very little empirical data have been collected to examine how the public actually uses social media to learn and stay informed about ongoing health emergencies. To that end, we conducted a survey of 1003 American adults in order to better understand how heavily they have relied on social media and the specific ways in which they have used social media to learn about the COVID-19 pandemic. In light of the growing concerns over the proliferation of misinformation on social media, this study also aims to aid both health care practitioners and researchers in understanding how SNS users interact with and rely on credible scientific sources and how they have gone about fact-checking pandemic-related information. Collectively, this study seeks to better inform health communications through an enriched understanding of social media’s evolving role in health information seeking.

Methods

A web-based survey of 1003 US-based adults was conducted (January 9 to January 12, 2021) through Prodege MR, an industry-leading market research provider. This survey was funded by Florida’s Center for Cybersecurity at the University of South Florida. Survey respondents were selected by using a stratified quota sampling approach to ensure that the sample was representative. Balanced quotas were determined (by region of the country) for gender, age, race, ethnicity, and education based on the US Census Bureau’s 2019 American Community Survey (ACS). Table 1 provides a summary of the comparison between sample respondents and the 2019 ACS data.

The initial sampling target was a total of 1067 individuals (which represents a margin of error 3.0 for the US population). However, data cleaning revealed a small number of incomplete and unusable responses, resulting in a total sample size of 1003 (a margin of error 3.09 for the US population). The results were reported with a 95% confidence level and a margin of error of 3.09. It is worth noting that the data collection method necessarily excluded those who lack internet access. However, given that the focus of the study was on social media users, this did not represent a serious threat to validity. Perhaps more importantly, the method naturally underrepresented those with lower levels of education. We made deliberate attempts to target this group during survey administration, though a gap persisted for those lacking a high school diploma (Table 1).

Table 1. Sample comparison.[a]

Characteristic	Sample in this study, %	2019 American Community Survey, %
Gender		
Female	51.2	51.1
Male	48.8	48.9
Age (years)		
18-24	11.3	11.9
25-34	17.8	17.8
35-44	17	16.5
45-54	16	16
55-64	17.1	16.6
≥65	20.8	21.2
Race		
Black or African American	15.7	15.1

Graduate or professional degree	11.7	11.4

[a] Data are from the Florida Center for Cybersecurity’s January 2021 COVID-19 survey.

Results

Summary of Results

Although the growing importance of social media in health communications has been widely discussed, our understanding of these trends, particularly those at the consumer level, has been largely anecdotal. The results reported below add some empirical context to our general understanding of these trends while also contributing important new data to enhance our understanding of how SNS users seek out and fact-check medical information during a public health emergency. The results are reported in subsections that follow the organization of the survey.

Reliance and Confidence

The results from the survey affirm that Americans have relied heavily on social media to stay informed about COVID-19. Among the survey respondents, more than three-quarters (762/1003, 76%) stated that they have relied on social media at least “a little” to stay informed about the COVID-19 pandemic, while just under half (458/1003, 45.6%) reported that they have relied on social media “a lot” (Table 2). Further, 59.2% (594/1003) of respondents indicated that they read information about COVID-19 on social media at least once per week, while roughly one-third (323/1003, 32.2%) do so every day. These responses highlight the extent to which social media has become a primary source of health information for Americans; a large number of users (762/1003, 76%) reported that they do not merely encounter such content on the internet but also rely on platforms such as Facebook and Twitter for health information.

Table 2. Reliance on social media for pandemic-related information.[a]

Questions and responses	Respondents, n (%)
How much have you relied on social media to stay informed about the COVID-19 pandemic?	
A great deal	208 (20.7)
A lot	250 (24.9)
A little	304 (30.3)
Not at all	241 (24)
On average, how often do you read information about COVID-19 on social media?	
Every day	323 (32.2)
A few days a week	271 (27)
Once a week	112 (11.2)
Less often	297 (29.6)
I am confident in the accuracy of the information I see about COVID-19 on social media	
Strongly agree	73 (7.3)
Somewhat agree	250 (24.9)
Neither agree nor disagree	252 (25.1)
Somewhat disagree	188 (18.7)
Strongly disagree	240 (23.9)

[a] Data are from the Florida Center for Cybersecurity's January 2021 COVID-19 survey.

Although people's reliance on SNSs has been remarkably high throughout the pandemic, only about one-third of respondents (323/1003, 32.2%) expressed confidence in the accuracy of the information that they receive about COVID-19 on social media. Although paradoxical, this finding is consistent with prior studies that have shown a similar lack of confidence in the accuracy of news and political information on the internet, despite the increased reliance on such web-based media for information seeking [11]. In our study, this may, at least in part, reflect the sharp politicization of the COVID-19 pandemic [12]. Among the survey respondents, more three-quarters (761/1003, 76.1%) agreed that "politics has made it harder to learn the truth about Covid-19." For health professionals, this highlights the extent to which the politicization of public health efforts can obscure scientific guidance and complicate health communications, especially when treatment and mitigation become matters of public policy.

Fact-checking Social Media

It has been recently been noted in medical literature that identifying and mitigating misinformation on social media is a growing priority for health professionals [4]. It has also been pointed out that doing so will require proactive steps, such as "meeting people where they are and through the information networks and devices they use for day-to-day interactions" [13]. With these goals in mind, it is important for health professionals to understand the propensity of social media users to validate and verify (ie, fact-check) potential misinformation that they encounter on the internet and to understand the types of sources that social media users are turning to for guidance during public health crises. Prior research has suggested that rigorous fact-checking is less common on social media [14], and the survey responses appear to affirm this suggestion. Only about one-third of respondents (365/1003, 36.4%) indicated that they have "talked to a doctor or healthcare professional about the accuracy of something they saw on social media related to Covid-19" (Table 3). In contrast, respondents were almost twice as likely to have "talked to friends, family, or coworkers" about such information (686/1003, 68.4%), and 22% of respondents were more likely to have conducted their own internet research (578/1003, 57.6%) to fact-check COVID-19–related information on social media.

Table 3. Fact-checking pandemic-related information on social media.[a]

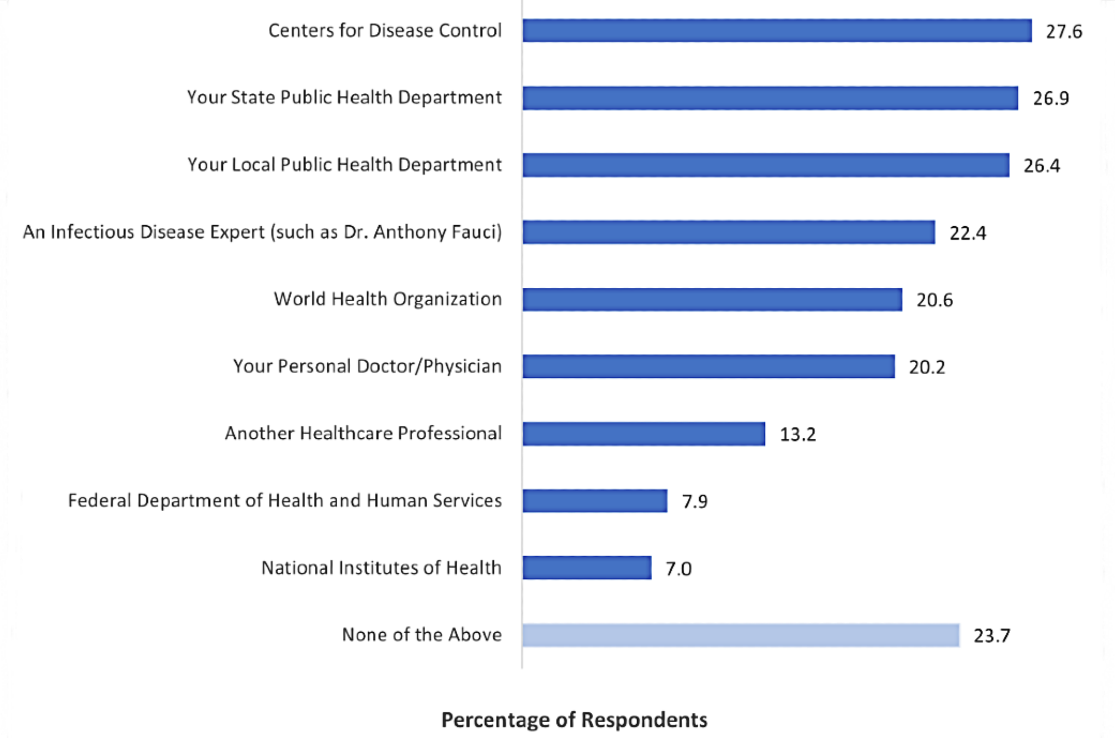
Responses to the following question: "Please indicate whether or not you've done each of the following since the start of the pandemic?"	Respondents, n (%)
"…done internet research to fact-check something that I saw on social media related to COVID-19"	578 (57.6)
"…talked to friends, family, or coworkers about the accuracy of something I saw on social media related to COVID-19"	686 (68.4)
"…talked to my doctor or a healthcare professional about the accuracy of something that I saw on social media related to COVID-19"	365 (36.4)

[a] Data are from the Florida Center for Cybersecurity's January 2021 COVID-19 survey.

Following Scientific Sources

Although only about one-third of respondents reported actively fact-checking information with a medical professional, 581/762 (76.2%) reported that they followed at least 1 authoritative scientific source on social media during the pandemic (Figure 1). The data in Figure 1 only represent those who reported at least “a little” reliance on social media to stay informed about COVID-19 (n=762). More than one-quarter of respondents began following the Centers for Disease Control (210/762, 27.6%), their state public health department (205/762, 26.9%), or their local public health department (201/762, 26.4%). Just under one-quarter of respondents reported following an infectious disease expert such as Dr Anthony Fauci (171/762, 22.4%). Further, one-fifth of respondents (154/762, 20.2%) reported following their own personal doctor or physician, while 101/762 (13.2%) began following “another healthcare professional.”

Figure 1. Health Information Sources "Followed" (As % of Respondents).



Perhaps surprisingly, the data showed that respondents were slightly more likely to have followed institutional actors on social media (ie, the Centers for Disease Control and Prevention or a public health department) than they were to have followed individual health experts (ie, their personal physician or an infectious disease expert). This is somewhat inconsistent with findings from prior research, which have suggested that individual actors are typically more influential on social media [15,16]. The nature and severity of the COVID-19 pandemic may account for this difference, though additional research into this topic is warranted in order to better inform professional best practices.

On one hand, the responses were promising in the sense that most social media users did appear to have intentionally expanded their web-based networks during the pandemic to include credible institutional and individual medical and scientific sources (ie, 581/762 [76.2%] have followed at least 1 authoritative scientific source). On the other hand, it was noteworthy that nearly one-quarter of those who relied on social media for pandemic-related information (181/762, 23.8%) did not choose to follow such sources, and only one-fifth of respondents (154/762, 20.2%) began engaging with their own personal physician (ie, the health care provider whom they are most likely to trust for personalized health guidance) on social media.

Scientific Credibility and Vaccine Intentions

As previous literature has suggested, the dissemination of credible scientific information on social media is necessary for disease prevention and effective public health management. The crosstabs from our survey highlighted one specific example of this; those who opted to follow credible scientific sources were significantly more likely to indicate that they will accept a COVID-19 vaccine ($P<.001$). When asked, 588/1003 (58.6%) of respondents to the survey reported that they would definitely or probably undergo vaccination [17]. Those who followed at least 2 credible public health or medical sources were 10% more likely to indicate that they would “definitely get vaccinated” than those who did not follow any such sources (Table 4). Those who followed 4 or more such sources were over 25% more likely to report the same response.

Table 4. Medical sources and vaccine intentions.[a]

Intentions	Number of medical sources followed				
	None	1	2-3	4-5	≥6
Will definitely undergo vaccination, %	28.2	31.7	38.8	55	55.6
Will probably undergo vaccination, %	24.9	23	24.9	17.5	14.8
May or may not undergo vaccination, %	16.6	15.5	19.6	23.8	18.5
Will probably not undergo vaccination, %	14.4	11.7	6.2	0	3.7
Will definitely not undergo vaccination, %	16	18.1	10.5	3.8	7.4

[a] Chi-square test results: χ^2_{16}=50.790; ϕ=0.258; P<.001.

In contrast, nearly one-third (55/181, 30.4%) of those who did not follow any public health or medical sources said that they would either "probably not" or "definitely not" undergo vaccination. This number fell by roughly 50% among those following at least 2 of the aforementioned sources. A chi-square test showed that the differences were statistically significant (χ^2_{16}=50.790; ϕ=0.258; P<.001). This observed relationship likely reflects some degree of simultaneity. However, the data did suggest that exposure to credible scientific information on the internet is positively related to compliance with pandemic mitigation measures. Given the high vaccination levels needed to achieve herd immunity, closing even small informational gaps could prove critical to ending the COVID-19 pandemic.

Discussion

Data from the Pew Research Center show that social media is slowly but steadily supplanting traditional information mediums as a primary source of news and information for many Americans [18]. It has become increasingly clear from existing literature (including our own research) that this trend includes personal and public health information seeking behaviors as well. In this study, we surveyed 1003 American adults on their use of social media to learn about the COVID-19 pandemic. The survey responses confirmed that health consumers have relied heavily on social media to stay up to date with and informed about the COVID-19 pandemic. More than three-quarters (762/1003, 76%) of respondents stated that they have relied on social media at least "a little," and 59.2% (594/1003) of respondents indicated that they read information about COVID-19 on social media at least once per week. The heavy reliance on social media observed among US-based SNS users is consistent with findings from recent research conducted in various international settings, including China [19] and Europe [20].

Our findings also showed that only about one-third of SNS users (365/1003, 36.4%) have fact-checked pandemic-related information with a medical professional, despite the widespread distrust in the accuracy of COVID-19–related information that is shared on social media. Although disconcerting, this observation is consistent with the previous finding that rigorous fact-checking is relatively uncommon on social media [14]. We also found a greater likelihood of undergoing vaccination among those following more credible scientific sources on social media (χ^2_{16}=50.790; ϕ=0.258; P<.001), suggesting that scientific credibility may be crucial when promoting compliance with public health guidelines. Recent research has suggested that social media has been instrumental in the spread of vaccine hesitancy [21,22], thereby underscoring the need for health professionals and scientific experts to actively engage with patients and health consumers on social networks in order to address common misconceptions about vaccine safety and efficacy.

Our findings highlight the increasing importance of social media in health information seeking and thus highlight its potential value to health professionals as a conduit for personal and public health communications. However, the growing popularity of SNS platforms for health information seeking is not without its potential drawbacks. Among such drawbacks is the noted propensity for SNSs to facilitate the rapid and widespread dissemination of misinformation and disinformation [4,5,23]. Several studies have examined the presence and effects of misinformation related to COVID-19 since the start of the pandemic. One early analysis of pandemic-related messaging on Twitter suggested that as much as 25% of COVID-19–related information that is being circulated on the platform may contain some degree of misinformation [9]. Recent studies have found that exposure to misinformation on the internet is linked to decreases in the awareness of and compliance with preventative and mitigation measures [24,25]. Although the anonymous and instantaneous nature of social networks can contribute to the rapid spread of health-related misinformation, some research has suggested that social media may also offer an effective avenue for health professionals to counter speculation and misinformation. For example, in a recent experimental study, corrective infographics circulated by the World Health Organization were found to reduce scientific misperceptions about COVID-19 prevention [26].

Another potential drawback of people's increasing reliance on SNS platforms is the potential for social media overload to increase anxiety and adversely impact the psychological well-being of patients and SNS users. Several recent studies have documented this propensity during the COVID-19 pandemic, though these concerns are likely to be germane to any sustained public health or emergency scenario. One study of young SNS users in the United Kingdom found that information overload related to the COVID-19 pandemic resulted in diminished psychological well-being, including unhealthy levels of the fear of COVID-19 [27]. A similar study that was conducted in Hong Kong during 2020 found a correlation between social media usage and pandemic-related anxiety as well as diminished social trust in information [28]. Although our results showed an increased reliance on social media for health information seeking, these previous findings have suggested that this trend may have adverse mental health impacts for some SNS users—a fact that health professionals will need to be increasingly cognizant of when considering best practices for health communications.

When put into context with the emerging body of literature, our findings suggest that health professionals will need to become increasingly savvy when it comes to social media usage—not just reactively (ie, “setting the record straight”) but also proactively. Given the fact that 76% (762/1003) of health consumers in this survey have relied on social media at least “a little” as a source of health information during the pandemic, accurate and consistent messaging by credible public health organizations is just a start. Based on our research, we believe that this will require more active engagement between health professionals and patients and consumers. To achieve this degree of engagement, health professionals and public health organizations will need to cultivate and customize state-of-the-art social engineering skills to include data mining and natural language processing skills as well as skills that can only be called “active measures” (ie, those for monitoring, anticipating, and responding to misinformation and disinformation on social media platforms), especially during a public health crisis [29]. Furthermore, future research should explore recommendations for institutional policies regarding social media use by government and public health institutions [30].

At the patient level, given the apparent reticence of many social media users to connect with health professionals when fact-checking web-based information, it may be necessary for providers to more deliberately engage patients in conversations about the medical information that they are encountering on social media. Along with raising these issues individually in clinical settings, health care providers can also leverage the evolving functionality of platforms such as Twitter and Facebook to organize live question-and-answer sessions or fact-checking sessions for their patients and communities. For example, during the Zika virus outbreak, the US Department of Health and Human Services held digital town halls via social media. These were routinely advertised through posts such as the following:

> *Don't miss the @HHSGov #AtoZika Twitter Town Hall tomorrow, Aug. 30, 10 a.m. Submit questions using #AtoZika. #Zika* [31]

More deliberate networking efforts between local providers and public health agencies may be an effective means of organizing and promoting such events in order to counter misinformation on the internet.

Although these types of broadly targeted communications are critical to effective pandemic management, recent research has also suggested that for many SNS users, personal appeals from reputable practicing physicians may be a more effective means of public health messaging via social media [32]. This type of messaging may be of particular importance in the case of politicized public health emergencies, such as the COVID-19 pandemic. For example, one recent study found that reliance and trust in institutional information sources declined between March and April of 2020 as the pandemic became increasingly politicized [33]. However, our findings suggest that even during the COVID-19 pandemic, a notably low number of Americans have chosen to follow their own clinical providers on social media. Although this may be due to personal choice, the lack of a health care provider presence on social media could be a factor of that choice. For example, a prior survey of physicians indicated that confidentiality, organizational support, and time are all significant barriers to social media adoption [30]. Physicians, physician assistants, and nurse practitioners may need more training on how to effectively use social media to engage with and inform their patient populations. Among other things, such training should address health care providers’ concerns regarding governance, ethics, trust, and patient privacy [34,35]. Notably, prominent organizations such as the Mayo Clinic have already begun incorporating social media literacy into the academic training of health professionals [36].

It is important to acknowledge that adding social media–related duties to the duties of an already overextended health care workforce may further exacerbate the burnout that is experienced by many care providers [37]. However, these data underscore the increasing tendency of patients and consumers to rely on SNS platforms for health-related information. We believe that effective training, institutional support, and proactive collaboration can help health professionals adapt to the evolving patterns of health information seeking behaviors while also protecting the well-being of providers, especially in the midst of an already taxing pandemic.

Abstract

Background: Advanced prediction of the daily incidence of COVID-19 can aid policy making on the prevention of disease spread, which can profoundly affect people's livelihood. In previous studies, predictions were investigated for single or several countries and territories.

Objective: We aimed to develop models that can be applied for real-time prediction of COVID-19 activity in all individual countries and territories worldwide.

Methods: Data of the previous daily incidence and infoveillance data (search volume data via Google Trends) from 215 individual countries and territories were collected. A random forest regression algorithm was used to train models to predict the daily new confirmed cases 7 days ahead. Several methods were used to optimize the models, including clustering the countries and territories, selecting features according to the importance scores, performing multiple-step forecasting, and upgrading the models at regular intervals. The performance of the models was assessed using the mean absolute error (MAE), root mean square error (RMSE), Pearson correlation coefficient, and Spearman correlation coefficient.

Results: Our models can accurately predict the daily new confirmed cases of COVID-19 in most countries and territories. Of the 215 countries and territories under study, 198 (92.1%) had MAEs <10 and 187 (87.0%) had Pearson correlation coefficients >0.8. For the 215 countries and territories, the mean MAE was 5.42 (range 0.26-15.32), the mean RMSE was 9.27 (range 1.81-24.40), the mean Pearson correlation coefficient was 0.89 (range 0.08-0.99), and the mean Spearman correlation coefficient was 0.84 (range 0.2-1.00).

Conclusions: By integrating previous incidence and Google Trends data, our machine learning algorithm was able to predict the incidence of COVID-19 in most individual countries and territories accurately 7 days ahead.

(J Med Internet Res 2021;23(6):e24285) doi:10.2196/24285

Introduction

COVID-19, a highly infectious disease with serious clinical manifestations, was first reported in China in late 2019 and spread to other countries within weeks [1,2]. It was announced as a public health emergency of international concern by the World Health Organization (WHO) on January 30, 2020, and declared a pandemic on March 11, 2020 [3]. As of August 21, 2020, COVID-19 has been reported in 215 countries and territories, with 22,876,009 confirmed cases and 797,289 deaths [4]. The severity of the pandemic is variable in individual countries and territories. In some regions, severe outbreaks, occurred and case numbers took a long time to decrease. In other regions, it took more time for the spread of the disease to affect people. Even in places where the spread has been brought under control, there have been second or third waves of outbreaks, with variable severities of morbidities and mortalities.

Prediction of the incidence of COVID-19 in individual countries and territories is extremely important to provide reference for governments, health care providers, and the general public to prepare management measures to combat the disease. In the early months of 2020, prediction was useful to inform the countries and territories at risk of outbreak to take action for prevention. Currently, although the COVID-19 outbreak has already occurred in almost all regions globally, prediction has merits in monitoring the severity of spreading and recovery and assessing the likelihood of a secondary or tertiary epidemic. COVID-19 may become a seasonal or persistent epidemic in future years, like influenza. Thus, predicting and monitoring COVID-19 activity is needed at present and in the future. As a typical example, Google search data can predict the incidence of influenza effectively [5].

There are reported studies on the prediction of the incidence of COVID-19. A susceptible-exposed-infectious-recovered metapopulation model was used to simulate the epidemic in major cities in China [1]. Our previous study showed that data from internet search engines and social media platforms could predict the incidence of COVID-19 in China [6]. Later, data mining and machine learning techniques were used to predict the incidence of COVID-19 using data from the previous incidence or internet search volumes [7,8]. In these studies, only a few countries were investigated or the world was considered as one region. Furthermore, as the pandemic continues, increasing amounts of data are available for modeling and calibration. The actual situation may be different from previous predictions. For example, Tuli et al [9] predicted that the total number of new cases would reach 97% of the total expected cases on August 14 in the United States; however, actually, there were still tens of thousands of new cases daily. Therefore, an up-to-date and evolving prediction method is needed.

In this study, we aim to develop an efficient and novel methodology for real-time prediction of COVID-19 activity based on the previous daily incidence of COVID-19 and infoveillance data (search volume data via Google Trends) in all individual countries and territories worldwide.

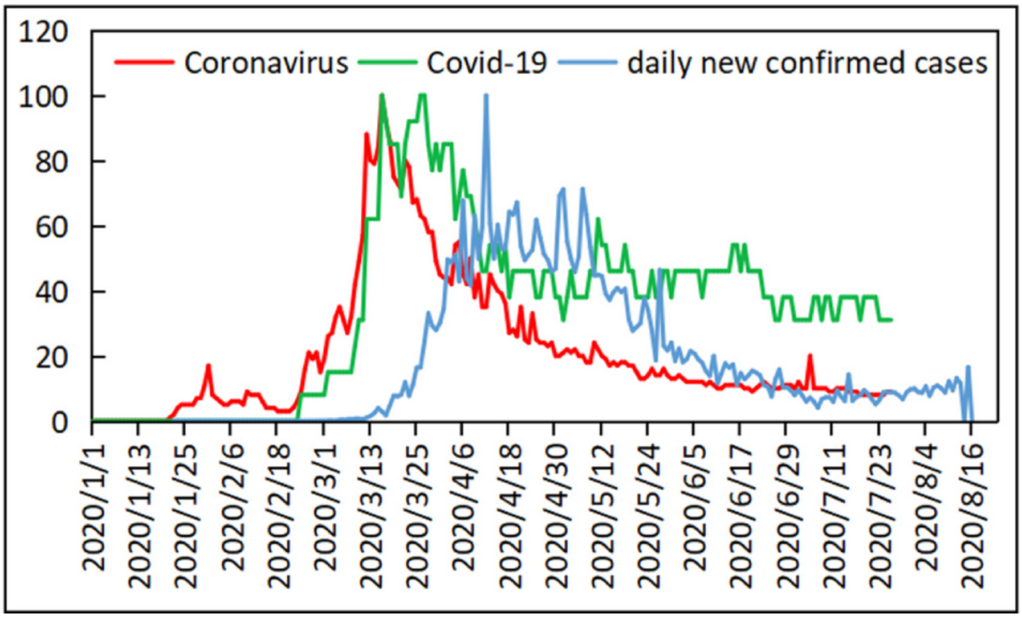
Methods

Data Source

Two sets of data were collected. The first data set was the search volume data obtained from the Google Trends service. We collected the Google search volumes of 28 candidate features related to COVID-19 from January 1 to July 26, 2020, in 215 countries and territories. We used 14 terms, including *coronavirus*, *pneumonia*, and *Covid-19*; 6 symptom-related terms [10] (*cough*, *diarrhea*, *fatigue*, *fever*, *nasal congestion*, and *rhinorrhea*); and 5 prevention-related terms (*hand washing*, *hand sanitizer*, *mask*, *social distance*, and *social isolation*. There were two main reasons for selecting these 14 terms for Google Trends data collection: (1) Previous studies [6,10-13] have shown that the internet search data for these terms were correlated with the incidence of COVID-19. (2) These 14 terms are related to COVID-19 in different aspects, such as topics, symptoms, and prevention; therefore, they can reflect its incidence. Two types of Google Trends data were retrieved. The first type was the data of interest over time, defined as the search interest relative to the highest point for the specific term, region, and time interval. Values were calculated on a scale from 0 to 100, where 100 is the peak popularity for the time period. The second type of data, data of interest by region, was retrieved by setting the region to “worldwide” for the given term and time. The values were calculated on a scale from 0 to 100, where 100 is the location with the most popularity as a fraction of total searches in that location. It is notable that we included low search volume regions to obtain data for more regions.

The second data set was the daily number of new COVID-19 cases from January 10 to August 16, 2020, in 215 countries and territories, obtained from the WHO website [14]. For consistency, the values of the daily number of new COVID-19 cases in the 215 countries and territories were normalized to a scale from 0 to 100. An example showing the search volumes of the terms *coronavirus* and *Covid-19* and the daily incidence of COVID-19 in the United Kingdom is shown in Figure 1.

Figure 1. The Google Trends search volumes for the topics *coronavirus* (red line) and *Covid-19* (green line) and the number of daily new confirmed cases (blue line) in the United Kingdom. All values are scaled from 1 to 100.



Correlation Analysis and Feature Engineering

We conducted two types of correlation analyses in each country or territory to find the right combination of input features. The first analysis was the Spearman correlation between the Google volume data of each feature and daily new confirmed cases with n days of lag (n=7, 14, 21, 28). We obtained the average and maximum Spearman correlation coefficients for different lag days between each Google volume data feature and daily newly confirmed cases in the 215 countries and territories (Multimedia Appendix 1). Each Google volume data feature was related to the daily new confirmed cases in the 215 countries and territories. The top related item was the interest over time in *coronavirus*. We found a better correlation with the 21-day lag than with the other days of lag. Therefore, we combined 28 Google volume data features with daily new confirmed cases of 21-day lag and formed 29 input features.

We calculated the Spearman correlation among 28 independent Google Trends volume data features in the 215 countries and territories to assess the independence of the features. We obtained the average results of the Spearman correlation coefficients between the top 10 cross-correlation Google volume data features in the 215 countries and territories. The highest correlation coefficient, between *coronavirus* interest over time and interest by region, was 0.59, which is lower than the criterion of strong correlation (0.8). Additionally, the cross-correlation between the remaining 18 Google volume data features was less than 0.1. Therefore, the correlation analysis results showed that the 28 Google volume data features were independent.

Cluster Analysis

The internet search patterns and the management of COVID-19 vary among countries and territories. We used a hierarchical clustering technique to cluster the 215 countries and territories into several groups, and we built a model for each group. Two types of data were used for clustering. One type was the related metrics of the importance scores of 29 input features resulting from the random forest regression algorithm in 215 countries and territories. The other type was the correlation of the development trend of daily new confirmed cases in the 215 countries and territories. Finally, the 215 countries and territories were clustered into 8 groups (Multimedia Appendix 2). There were 150 countries and territories in the first group, 38 in the second group, 11 in the third group, 7 in the fourth group, 6 in the fifth group, and 1 country or territory each in the sixth, seventh, and eighth groups.

In addition, to explore the internal relationships between the countries and territories in each cluster, two types of Spearman correlation coefficients were calculated. The first was the Spearman correlation between the daily new confirmed cases among the countries in the first five groups, which contain more than one country or territory. The second was the Spearman correlation between the search volume of the term *coronavirus* among the countries in the first five groups. These two correlations were also calculated in the sixth, seventh, and eighth groups with a single country or territory. The average Spearman correlation coefficients are shown in Table 1. There were two findings. The first was a correlation between the incidence of COVID-19 among the countries and territories in each group, especially in the first group, which contains 150 countries and territories. The second was that the correlation of Google search data among countries and territories in the first five groups was high. These findings also showed the reliability of our clustering method.

Table 1. Average Spearman correlation coefficients in each group of countries/territories for the 2 data sets.

Data set	Average Spearman correlation coefficient							
	Group 1 (n=150)	Group 2 (n=38)	Group 3 (n=11)	Group 4 (n=7)	Group 5 (n=6)	Group 6 (n=1)	Group 7 (n=1)	Group 8 (n=1)
Daily new cases	0.46	0.18	0.35	0.26	0.38	0.23	0.04	0.15
Coronavirus search volume	0.76	0.68	0.71	0.74	0.69	0.52	0.00	0.43

Modeling and Evaluation

We built a model for each group of countries/territories separately according to the clustering results and produced a 7-day-ahead incidence prediction of COVID-19 for the 215 countries and territories. The random forest regression algorithm has many decision trees; therefore, it has good robustness and a strong ability to resist overfitting. In addition, the random forest regression (RFR) algorithm gave the importance score of the features, which was helpful for feature selection. Therefore, the RFR algorithm was used to forecast the daily new confirmed cases of COVID-19 over the time series data set, which consisted of Google Trends data and the incidence of COVID-19 with 21-day lag provided by the WHO. Python 3.7.6 was used for the modeling and evaluation.

To quantitatively evaluate the performance of the models, we calculated four metrics: the mean absolute error (MAE), root mean square error (RMSE), Pearson correlation coefficient, and Spearman correlation coefficient.

where p_i, t_i, and M represent the predicted value, true value, and total number of days; X and Y are two independent time series; and σ_X and σ_Y are the standard deviations of X and Y, respectively. x_i and y_i are the ith value of X and Y and and are the mean values of X and Y, respectively, and n is the length of the time series. The P values of the Pearson correlations were calculated to assess the statistical significance.

Optimization and Validation

Several experiments were conducted to optimize and validate the results. First, to evaluate the role of each input feature in the prediction, we calculated the importance score of each input feature. To validate the features included in this study, a series of ablation studies, in which the top n features (n=1, 2, ..., 29) were used as inputs in turn, were conducted on different groups of countries/territories according to the clustering results. The Pearson correlation coefficient was averaged for the 8 groups of countries/territories based on the sum of the input features (Figure 2). According to the results, the top 13, 10, 10, 25, 2, 5, 1, and 3 features were used for the respective 8 groups in further experiments. The models using previous daily incidence with and without Google Trends data as input features were compared (Table 2). Adding Google search volume features as input improved the MAE, RMSE, Pearson correlation, and Spearman correlation by 0.28, 0.88, 0.06, and 0.08, respectively, in terms of average results in 215 countries and territories. These results confirmed that the Google Trends data played a positive role in predicting the incidence of COVID-19.

Second, to reduce the influence of random noise, we used multiple-step forecasting (5-step, 6-step, 7-step, 8-step, 9-step, and 10-step), which used the data over the past n days (n=5, 6, 7, 8, 9, 10) to predict the daily new confirmed cases of COVID-19. The average quantitative results of the different steps of the second period in the 215 countries and territories are shown in Table 3. The performance of the 7-step prediction was slightly better than that obtained using other numbers of steps in terms of 4 of 5 quantitative metrics in our study. Therefore, we selected the 7-step prediction.

Third, the proposed RFR algorithm was compared with two other mainstream algorithms. One was decision tree regression (DTR), which is a traditional machine learning algorithm. The other was long short-term memory (LSTM), which is a deep learning algorithm. Especially, LSTM, an artificial recurrent neural network, was used as a 3-layer model in our study. TensorFlow and Keras were used as frameworks for training the LSTM models. Table 4 shows the average quantitative results of the different methods for the 215 countries and territories. The random forest regression algorithm achieved better performance in terms of all quantitative metrics compared to DTR and LSTM.

Fourth, we trained the models with as much data as possible. Therefore, we updated the models and repeated the experiments at regular intervals. The effectiveness of the models at 3 time periods was compared.

Fifth, we predicted the incidence of COVID-19 2 days and 7 days ahead. Table 5 shows the average quantitative results of different time windows of the second period in the 215 countries and territories. We found the predictive power of the 7-day window to be less accurate than that of the 2-day window. It was noted that the 2-day window prediction may not be sufficiently informative for policy making, and the 7-day window would be more useful to enable a responsible authority to respond proactively and impose interventions in time. Therefore, we used the 7-day window for the prediction of the incidence of COVID-19.

Figure 2. The average Pearson correlation coefficients of the number of top-scoring features included in the prediction of the incidence of COVID-19 in different groups of countries. The red, blue, green, orange, purple, yellow, black, and brown lines represent groups 1 to 8, respectively.

Results

We produced 7-day-ahead and real-time COVID-19 forecasts for 215 countries and territories. Our final models performed well in predicting the daily new confirmed cases of COVID-19 in most of the countries and territories examined. Of the 215 countries and territories, 198 (92.1%) had MAEs <10 (Figure 3a), and 187 (87.0%) had Pearson correlation coefficients >0.8 (Figure 3b). In all 215 countries/territories, the mean MAE was 5.42 (range 0.26-15.32), the mean RMSE was 9.27 (range 1.81-24.40), the mean Pearson correlation coefficient 0.89 (range 0.08-0.99) and mean Spearman correlation coefficient 0.84 (range 0.21-1.00), with *P*<.001 in most of the countries and territories. Detailed results of the individual countries and territories are listed in Multimedia Appendix 3. The average results for each group are shown in Table 6. Generally, the models performed well in the first, second, third, and fifth groups, which contained 150, 38, 11, and 6 countries and territories, respectively. The Pearson correlation coefficients were >0.80 in most of these countries and territories. In contrast, the performance was poorer in groups 4, 6, 7, and 8. The Pearson correlation coefficients were <0.80 in most of these countries.

The performance of the models in 3 different time periods is shown in Table 7. As the training data increased, the overall prediction performance of the model improved. In addition, we randomly selected 4 countries from the 150 countries in the first group for further analysis. The predicted and actual daily new confirmed cases of the 3 different time periods in these 4 countries are shown in Figure 4. For example, our models can predict the increase in daily new confirmed cases in China from July 18 to July 31 and the decrease of daily new confirmed cases in China from August 3 to August 16. Our models were able to predict the daily new confirmed case numbers consistently.

Figure 3. Heat maps of the (a) mean absolute error and (b) Pearson correlation coefficients of the predicted and actual daily new confirmed case numbers in different countries worldwide. The deeper the color, the lower the mean absolute error (a) and the higher the correlation coefficient (b).

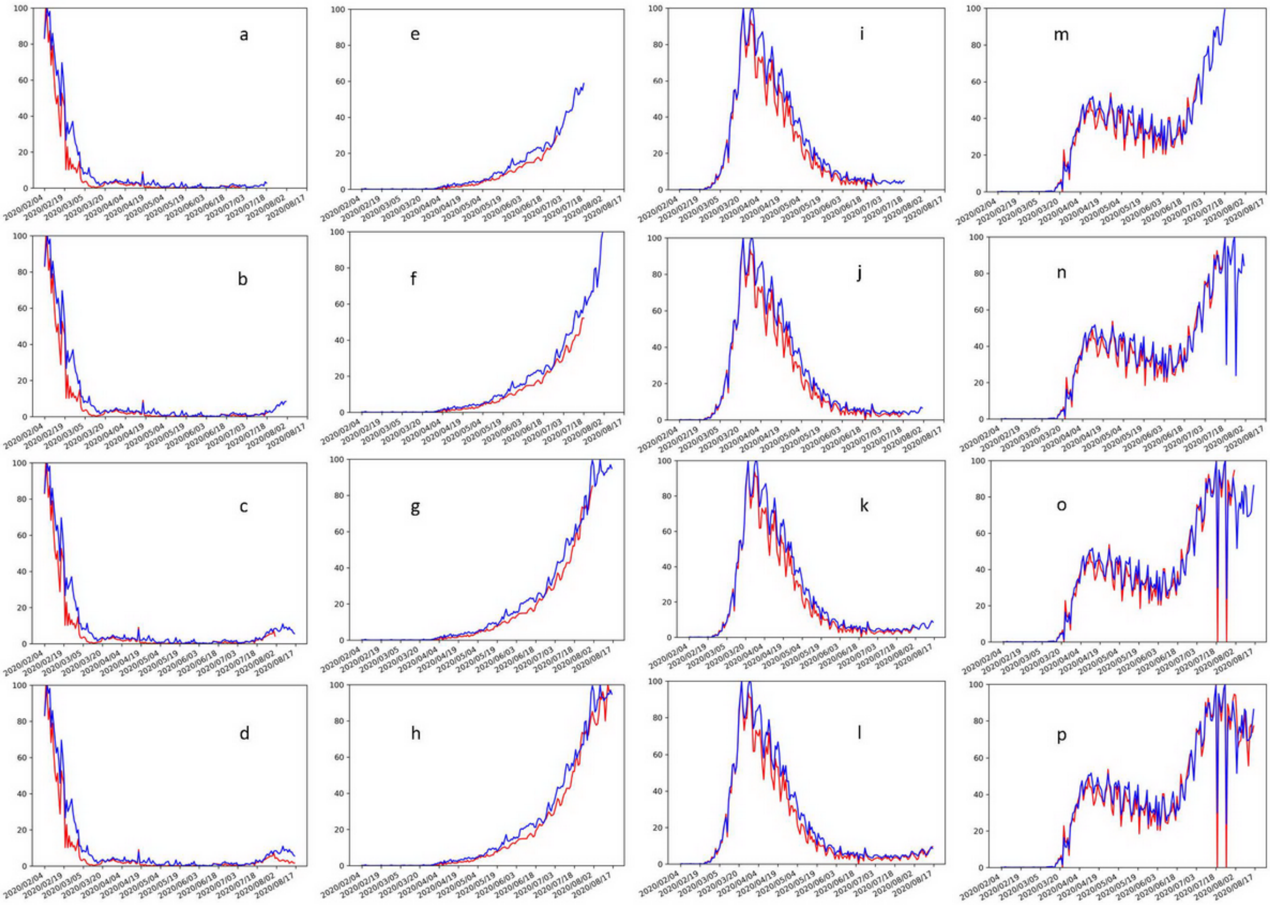
Figure 4. The prediction curves in China (a-d), India (e-h), Italy (i-l), and the United States (m-p). The blue and red lines indicate the predicted and real daily new cases, respectively. The first panels in each country (a, e, i, m) show the prediction for July 3 to July 17. The second panels (b, f, j, n) show the actual number of daily new cases for July 3 to July 17 and the prediction for July 18 to July 31. The third panels (c, g, k, o) show the actual number of daily new cases for July 18 to July 31 and the prediction for August 1 to August 16. The fourth panels (d, h, l, p) show the actual number of daily new cases from August 1 to August 16.



Discussion

Principal Results

In this study, we have established a method to obtain a 7-day-ahead prediction of COVID-19 activity by combining the previous incidence of COVID-19 and Google search volume data at the country or territory level in the real world. The models performed well in most countries. In a total of 215 countries and territories, the mean MAE, RMSE, Pearson correlation and Spearman correlation values were 5.42, 9.27, 0.89, and 0.878, respectively. The *P* value was <.001 in most countries and territories, which shows the significance of the Pearson correlation coefficient. The results show that the longer the training time and the greater the amount of available data, the higher the prediction accuracy.

Comparison With Prior Work

Our study has several advantages compared to other reported studies on similar topics. First, we investigated 215 individual countries and territories. Other studies only investigated a single country [15] or several countries [16], or they considered the world as one whole region [11,17]. Our method performed well in most of the countries and territories. Second, we used clustering methods to pool data with similar patterns together. The advantage of large amounts of data improved the performance of the models. Our results show that the groups with a large number of countries and territories had better results compared to those with a limited number of countries. There has been a report on clustering of provinces in China [12], but not clustering of countries. In another study, countries were grouped into 4 clusters; however, this clustering was not used for prediction [18]. Third, we combined data regarding both previous incidence of COVID-19 and Google Trends search volumes for prediction. Both of these data sources have been used individually in forecasting COVID-19 incidence. Our results showed that adding the Google Trends data improved the performance of the models developed from the previous incidence data. Fourth, we used machine learning methods for modeling. Many previous studies [13,19,20] indicated that Google Trends data are correlated with the incidence of COVID-19. Machine learning has been used to manage some large data sets and develop models to predict the incidence of COVID-19 in only a few countries [20]. Our models can produce useful and reliable predictions in most countries. Some studies used epidemical models such as susceptible-infected-recovered-dead (SIRD) for prediction. However, the spread of COVID-19 is affected by many factors, including public health management, traveling, and other social activities, which are not taken into account in the SIRD model. In Iran, COVID-19 was expected to subside at the beginning of May 2020 according to the SIRD model. However, at the time of writing this manuscript, thousands of new cases were still being reported daily in Iran [21]. Fifth, our models used the most up-to-date data and were updated three times. As more data become available, the performance of the models can be further improved. Some models developed several months ago may have severe errors. For example, Tuli et al [9] predicted that the total number of new cases would reach 97% of the total expected cases on August 14, 2020, in the United States [9]; however, tens of thousands of new cases were reported daily in July and August.

The high accuracy of our models enables real-time forecasting of the short-term trends of COVID-19, not only during the outbreak but also during the recovery period and subsequent second or third epidemic in individual countries. The methods can also be adapted to predict the incidence of subregions. Real-time digital surveillance of COVID-19 is provided, which would save time and resources in data collection. As the COVID-19 pandemic is changing rapidly, digital health systems should provide an effective solution to address the challenges to public health and consequential socioeconomical complications with high efficiency. The epidemic of COVID-19 is likely to persist in the future, and it may even become a seasonal infectious disease like influenza. Therefore, accurate surveillance and prediction of its activity would help governments, health care providers and the general population to take appropriate actions to compact the disruptive effects of COVID-19 [5].

Limitations

We recognize some limitations of the current study. First, the models did not predict well in some countries, which were clustered into independent groups and had limited periods of data for training. Second, the occurrence of COVID-19 in some countries would have increased the awareness of other countries, especially those with a close relationship, consequently resulting in a large Google search volume for terms related to COVID-19. Third, there is a limitation in applying our models in countries and territories where Google is not the mainstream search engine. Thus, predictions of COVID-19 incidence in regions with limited internet access or prohibited Google access may not be accurate. Fourth, COVID-19 and influenza share some common symptoms and even prevention methods. Therefore, the Google Trends data of these terms may not be able to differentiate COVID-19 and influenza. Further studies are needed to develop an algorithm to differentiate these two infectious diseases using Google Trends.

Conclusions

In this study, we integrated the Google Trends data and previous daily incidence of 215 individual countries and territories using the techniques of features engineering, country clustering, and machine learning. We are able to achieve prediction 7 days ahead of time of the daily incidence of COVID-19 in real time in most countries and territories.

Acknowledgments

This study was supported in part by the National Key R&D Program of China (2018YFA0701700), the Department of Education of Guangdong Province (2020KZDZX1086), the National Natural Science Foundation of China (61971298), and the Grant for Key Disciplinary Project of Clinical Medicine under the Guangdong High-level University Development Program.

Authors' Contributions

YP and YR analyzed the data. YP drafted the manuscript. CL collected the data. CL, CPP, HC, and XC interpreted the data. HC and XC designed the study. CP and HC revised the manuscript. All authors agreed on the final version for submission to the journal.

Abstract

Background: On January 21, 2020, the World Health Organization reported the first case of severe acute respiratory syndrome coronavirus 2, which rapidly evolved to the COVID-19 pandemic. Since then, the virus has also rapidly spread among Latin American, Caribbean, and African countries.

Objective: The first aim of this study is to identify new emerging COVID-19 clusters over time and space (from January 21 to mid-May 2020) in Latin American, Caribbean, and African regions, using a prospective space–time scan measurement approach. The second aim is to assess the impact of real-time population mobility patterns between January 21 and May 18, 2020, under the implemented government interventions, measurements, and policy restrictions on COVID-19 spread among those regions and worldwide.

Methods: We created a global COVID-19 database, of 218 countries and territories, merging the World Health Organization daily case reports with other measures such as population density and country income levels for January 21 to May 18, 2020. A score of government policy interventions was created for *low*, *intermediate*, *high*, and *very high* interventions. The population’s mobility patterns at the country level were obtained from Google community mobility reports. The prospective space–time scan statistic method was applied in five time periods between January and May 2020, and a regression mixed model analysis was used.

Results: We found that COVID-19 emerging clusters within these five periods of time increased from 7 emerging clusters to 28 by mid-May 2020. We also detected various increasing and decreasing relative risk estimates of COVID-19 spread among Latin American, Caribbean, and African countries within the period of analysis. Globally, population mobility to parks and similar leisure areas during at least a minimum of implemented intermediate-level control policies (when compared to low-level control policies) was related to accelerated COVID-19 spread. Results were almost consistent when regional stratified analysis was applied. In addition, worldwide population mobility due to working during high implemented control policies and very high implemented control policies, when compared to low-level control policies, was related to positive COVID-19 spread.

Conclusions: The prospective space–time scan is an approach that low-income and middle-income countries could use to detect emerging clusters in a timely manner and implement specific control policies and interventions to slow down COVID-19 transmission. In addition, real-time population mobility obtained from crowdsourced digital data could be useful for current and future targeted public health and mitigation policies at a global and regional level.

Introduction

On January 30, 2020, the World Health Organization (WHO) declared COVID-19 as a Public Health Emergency of International Concern and later characterized it as a pandemic [1]. On January 21, 2020, the WHO published the first situation report, announcing the first cases of pneumonia of unknown etiology detected in Wuhan City on December 31, 2019 [2]. By May 18, 2020, more than 200 countries reported confirmed cases of COVID-19 [2,3]. Among them, there were several Latin American, Caribbean, and African countries with limited resources to monitor, manage, and treat COVID-19. The first signs of virus spread were delayed among these regions compared with Europe, Asia, and North America [2,4].

Several government interventions have already been implemented to prevent and contain the alarming propagation of COVID-19 [5,6]. Each country has applied its own disease control measures, which vary by specific policy and implementation timing. Some countries initially implement a *lower* level of measures and policies, while others are adopting *stricter* ones. Government health and social distancing policies are evolving rapidly based on the COVID-19 transmission in each region. Policies range from traveler's temperature checks and medical screening at each country's entry point and public school closures to quarantining an entire country. Various Latin American and African countries adopted COVID-19 restriction policies rapidly [7]. Barriers such as the effectiveness of social distancing measures among low-income and middle-income countries (LMICs) have been pointed out [8]. For these reasons, global and local health policy makers and international organizations have said that the lack of health and government resources among these regions would pose barriers and challenges to halt virus spread.

Space–time surveillance is a methodology [9] that could be of use among Latin American and African regions to identify and list locations in an emergency, apply the strictest public health measures, and allocate resources. The space–time scan statistic technique is able to detect *dynamic* or emerging clusters of COVID-19, which can be used for targeted monitoring during the outbreak [10]. Since COVID-19 data are updated daily, this method could contribute to timely monitoring of the pandemic among various areas such as Latin American and African regions. In addition to statistical approaches, digital technology [11,12] could be used to understand population mobility and to assess the effectiveness of government policies or the re-evaluation of specific strategies. During the COVID-19 outbreak, smartphone software can provide information (in an anonymous way and at the country level) [13] on various characteristics of population mobility (eg, workplaces or parks). This information could be of use among countries and specifically in resource-limited settings to understand rapidly whether the government restrictions need enhancements or corrections.

In the early stage of the COVID-19 spread in the United States, prospective scan statistic methodology detected the *active* cluster in New York State, marking the area that needed specific attention [10]. To the best of our knowledge during COVID-19, except in the United States, the prospective scan method has not been applied elsewhere, though it could be a useful monitoring and intervention–decision tool. In addition, the collective effect sizes of population mobility patterns under the social distancing government policies are empirically unknown, particularly in low-income countries (LICs) and middle-income countries (MICs) with differential population vulnerability (ie, poverty, lack of resources, and health infrastructure). Given the information regarding effective treatment schemes and population vaccination going forward slowly and taking into account the delays in deliveries among countries, detection of emerging clusters among these regions will make a substantial contribution [14] to the field facilitating the translation of knowledge and implementation of evidence into COVID-19 practice and policy at the country level. In addition, it will guide authorities globally and among low- and middle-income countries (LMICs) to enhance and update if necessary the applied COVID-19 containment policies based on real-time population mobility. The first aim of this study, therefore, is to identify new emerging space–time COVID-19 clusters implementing space–time surveillance among Latin American, Caribbean, and African countries, applying a prospective space–time scan statistic methodology. This technique is a well-known method for detecting clusters of health-related events in the space–time dimension [10]. Our available data extends until May 18, 2020. Thus, we report results applying the prospective space–time scan statistic in five time periods to monitor the emerging clusters when adding updated case data: (1) January 21 to March 15, (2) January 21 to March 31, (3) January 21 to April 15, (4) January 21to April 30, and (5) January 21 to May 15. The second aim is to assess the impact of real-time population mobility patterns between January 21 and May 18 under the implemented government interventions, measurements, and policy restrictions on COVID-19 spread among Latin American, Caribbean, and African countries as well as globally. This study focuses its analysis on Latin American, Caribbean, and African countries (as a sample of LMICs) among other Asian-Pacific regions due to the excessive COVID-19 transmission in these areas. This study could serve as a learning tool presenting new information on virus surveillance and its timely detection among countries and regions with limited resources at their disposal, while population mobility patterns will facilitate public health authorities to design targeted social distancing strategies instead of *horizontal* lockdowns or social distancing measures. Results of this study in combination with lessons from other countries' experiences [15] could be helpful for policy makers at regional and international level.

Methods

Study Design

We conducted a retrospective observational longitudinal study. We obtained data on COVID-19 propagation and related risk factors from 218 countries and territories (as reported by the WHO). We compiled a data set of COVID-19 daily cases and deaths spanning the period January 21 to May 18, 2020, based on the most recent publicly available population-level information (by country), as reported by the WHO [2]. This study was approved by Parc Sanitari Sant Joan de Déu, Ethics Committee (PIC-67-20, Barcelona, Spain) and conformed to the ethical guidelines of the 1975 Declaration of Helsinki.

COVID-19 International Data

The WHO daily situation reports were used from January 21 to May 18, 2020, to assess disease transmission internationally [2]. Data on daily confirmed cases, total confirmed cases, daily confirmed deaths, total confirmed deaths, transmission classification, and time since the last reported case were compiled for 218 countries and territories. Case classifications were based on the WHO case definitions for COVID-19. Transmission was classified into three distinct groups to capture changes in the classification that the WHO applied during these 4 months: community transmission, transmission under investigation, and sporadic clusters transmission (includes sporadic transmission, clusters, and local transmission) [2]. Cases identified in cruise ships were excluded from the analysis, while cases among China's provinces were grouped together. Cases in Hong Kong, Macao, and Taiwan special administrative regions of China were classified separately since they applied different government interventions and policy measures than mainland China. Based on the WHO database, Puerto Rico was classified separately from the United States as was the case for other territories.

Countries' Government Interventions, Health Policy, and Restriction Measures

Each country's health and government policy measures were obtained as announced from each country's official source after January 21, 2020. If this was not feasible, the information was obtained from local media sources and was cross-checked with at least two sources (where possible). Additionally, two researchers cross-validated the obtained information to ensure the highest accuracy. This information was then validated using the WHO global tracking database on governments' COVID-19 response as the gold standard database [16]. Based on this information, a four-level health and government policy interventions and measures score was created, ranging from 0 to 3, which represented *low*, *intermediate*, *high*, and *very high* intervention levels [17]. These intervention and control policy categories were formed following already announced alert classification systems [18] and other international COVID-19 government response data and methodologies [19,20].

Other Baseline Assessments by Country

Index for Risk Management and World Bank Income Classification

Information regarding threat detection and risk assessment were obtained from the Index for Risk Management (INFORM) Epidemic Risk Index [21], developed by the EU Joint Research Centre in collaboration with the WHO, and was used as a measure of each country's epidemic preparedness. The INFORM index ranged from 0 to 10, and higher scores corresponded to a lower epidemic preparedness risk of a country. More detail about the development of this index can be found elsewhere [21].

The World Bank income classification system was also used to classify each of the 218 countries' income (high-income countries, upper-income countries, lower middle–income countries, and low-income countries) [22]. COVID-19 testing policy in each country was assessed as the number of days that each country started implementing COVID-19 tests in the population and as the number of days that each country implemented tracing strategies for COVID-19 cases. Information on these items was obtained from publicly available sources [20].

Cell Phones and Community Mobility Reports

The population's mobility patterns at the country level were obtained from Google community mobility reports. These reports are publicly available [23] and present movement trends over time by geography and across different place categorization such as retail and recreation places, groceries and pharmacies, parks and other similar places, transit stations, workplaces, and residential areas. Specifically, as described by Google reports, retail and recreation grouping correspond to mobility trends for places such as restaurants, cafés, shopping centers, theme parks, museums, libraries, and movie theaters. Groceries and pharmacies reports mobility trends for places such as grocery markets, food warehouses, farmers markets, specialty food shops, drug stores, and pharmacies. The parks category encompasses mobility trends for places such as national parks, public beaches, marinas, dog parks, plazas, and public gardens. In addition, transit station cluster marks mobility trends for places such as public transport hubs (eg, subway, bus, and train stations). The workplace classification corresponds to the mobility trend for places of work. Finally, the residential cluster encompasses mobility trends for staying at home. These reports show how visits and length of stay at different places change compared to a specific reference period (a reference period defined by Google as, for example, January 3 to February 6, 2020). Data in these reports are generated using aggregated anonymized sets of data from users that turned on the location history setting.

Of the 218 countries and territories, 179 had complete data and were selected for the adjusted analysis. In this analysis, only COVID-19 daily new cases were analyzed. Analysis was applied globally only between real-time population mobility patterns and COVID-19 spread, while the rest of the analysis was restricted for the regions of Latin America, the Caribbean, and Africa. By May 15, 2020, we calculated the standardized incidence ratios (SIRs) [24] for 4 countries (Brazil, Peru, Uganda, and Nigeria) to compare and validate the accuracy of our prospective space–time models. COVID-19 SIR estimations were calculated as the ratio of observed counts to the expected counts.

Statistical Analysis

Based on the literature review, government interventions are not having an immediate effect on COVID-19 spread; for this reason, we considered their time scheduling based on a starting time point t0, with the addition of a seven-day lag [25]. These time lag effects only concern the modeling process via a mixed model approach, as it is when our analysis tested the government control policies.

Prospective Space–Time Scan Statistic

The early detection of emerging COVID-19 space–time clusters was determined using a prospective version of the space–time scan statistic approach [9]. The method helps to identify COVID-19 clusters in the space–time dimension, which have a significant relative risk (RR) at the end of the study period [10]. The general assumption is that the number of COVID-19 cases follows a Poisson distribution with a constant risk, which is proportional to the at-risk population of each corresponding country or territory over the geographic region under study.

This approach works using cylinders that move and scan the region of interest looking for potential space–time clusters of COVID-19 cases. The center of the cylinder is defined as the centroid of each country in the region of interest. The general working function of this technique can be summarized as follows: an unknown large number of cylinders of different spatial and temporal sizes are generated around each centroid until the maximum spatial and temporal thresholds are reached; the observed and expected case counts are computed within each cylinder, which is derived from the total number of centroids captured in each cylinder.

In this manner, the RR is defined as having more observed than expected COVID-19 cases within each cylinder. We determined the elevated RR of COVID-19 calculating maximum log-likelihood ratio tests. Furthermore, 100 runs of Monte Carlo testing were used to depict the empirical distribution of the log-likelihood ratio, assuming constant risk. This distribution allows us to assess the statistical significance of space–time clusters (*P* value <.05), and the cylinder with the largest log-likelihood ratio is the most likely cluster.

In our study, we reported the significant emerging clusters of COVID-19 at the country level for the Latin American, Caribbean, and African regions, and computed the estimated RR, which identifies the risk for the population to COVID-19 within a cluster in comparison with the risk outside of the cluster. Moreover, five time periods were monitored: (1) January 21 to March 15; (2) January 21 to March 31; (3) January 21 to April 15; (4) January 21 to April 30; and (5) January 21 to May 15, 2020.

This analysis was carried out using the R package *scanstatistics* in R version 3.6.3 (R Foundation for Statistical Computing) and follows previous prospective scan statistic work [9,10,26].

Mixed Models Analysis

We also fitted a negative binomial (NB) mixed model, with daily new COVID-19 cases as the outcome. The model accounts for a linear trend with respect to time since the appearance of the first COVID-19 case, taking into account the varying secular trends across regions and the treatment–effect heterogeneity across time, and was adjusted for the countries' preparedness in epidemics (INFORM index), COVID-19 testing policy, COVID-19 type of transmission for each country through time, populations' real-time mobility patterns, their interaction with each level of government control policy, and the country's income level. In this mixed model, all the predictors are assumed to be fixed effects; however, the intercept includes a country-level random effect term. As offset, the natural logarithm of the total population was added to the generalized linear predictor function of the NB component to account for the variable number of daily new COVID-19 cases per country population. Models were tested globally and regionally (for Latin American, Caribbean, and African countries). The maximum likelihood estimation procedure was used to fit all multilevel analysis models. In this mixed model, only three out of five real-time mobility patterns for workplaces, parks, and similar places as well as mobility for food and drug supplies were applied to avoid collinearity, as the correlation among the mobility variables was higher than 0.70. Mixed model analysis was carried out using the R package g*lmmTMB* in R Version 3.6.3 [27].

Validation Analysis

First, the predicted validity of the prospective scan statistic model was tested evaluating the relation between the RRs of the prospective scan statistic and the SIR estimations using Pearson rho coefficients. Second, we used the Man-Whitney *U* test to explore the increase in mean COVID-19 cases before and after April 15, 2020, and then, we checked if the prospective scan had predicted a potential COVID-19 cluster. We followed classical reported criteria to classify a correlation as weak (≤0.3), moderate (0.4-0.6), and strong (≥0.7; coefficients are presented as absolute values) [28]. All *P* values are based on two-sided tests. A *P* value ≤.05 was considered as significant.

Results

Prospective Scan Statistics and Emerging Country-Level Results Between January 21 and May 15 for Latin America, the Caribbean, and Africa

Tables 1 and 2 provide the characteristics of the significant COVID-19 emerging space–time clusters at the country level among LMICs, from January 21 to May 15, 2020. Analyzing COVID-19 spread between January 21 to March 15, 7 major clusters among Latin American, Caribbean, and African countries were revealed. For the Latin American and Caribbean countries, cluster 1 included 15 countries with a RR>1 (ie, having more observed than expected COVID-19 cases). Saint Kitts and Nevis (cluster 3) showed an extremely elevated RR of 19.31 (*P*<.001). Exploring the African region during the same period, cluster 4 integrated most of the countries with a RR of 9.46 (*P*<.001), and cluster 5 encompassed Madagascar, Mauritius, Mayotte, Reunion, and Seychelles with a RR of 21.35 (*P*<.001). Rwanda and Uganda were grouped in cluster 6 and Sudan in cluster 7. Both these clusters marked the most elevated RR (cluster 6: RR 37.75, *P*<.001; cluster 7, RR 45.75, *P*<.001; Figures S1 and S2 in Multimedia Appendix 1).

Using data for the period of January 21 to March 31, 2020, allowed us to assess the evolution of COVID-19 spread among LMICs. It was shown that the initial 7 emerging COVID-19 country clusters among Latin America, the Caribbean, and Africa, when the period of analysis extended for 15 days, were spread to 20 clusters. Cluster 5 that included only Antigua and Barbuda Island had the most elevated relative risk (RR 60.48; *P*<.001) followed by cluster 6 (Puerto Rico, Saint Maarten, and Virgin Islands) with a RR of 23.27 (*P*<.001) and cluster 8 (Dominica) with a RR of 21.85 (*P*<.001; Figures S3 and S4 in Multimedia Appendix 1).

Analyzing data from January 21 to April 15-30 and to May 15, 2020, it was shown that the spread was further extended with the evolution of time. Specifically, when the period of analysis extended to April 15, the virus spread was reported to 27 clusters among Latin America, the Caribbean, and Africa, and by April 30 and May 15, the emerging clusters were 29 and 28, respectively. For the period between January 21 to April 15 for Latin America and the Caribbean, the cluster with the highest RR was Chile (RR 18.02; *P*<.001), followed by Antigua and Barbuda (RR 14.22; *P*<.001), and Mexico (RR 14.07; *P*<.001). For Africa, the emerging clusters were Djibouti (RR 165.84; *P*<.001), followed by Mauritius (RR 136.05; *P*<.001) and Egypt (RR 52.20; *P*<.001). Focusing on the period between January 21 to April 30 and to May 15, we showed extended COVID-19 spread following similar patterns as previously mentioned (Figures S5-S10 in Multimedia Appendix 1).

Table 1. Emerging COVID-19 space–time clusters and their RR for having more observed than expected COVID-19 cases, from January 21 to March 15 and March 31, 2020, at the country level within the Latin American, Caribbean, and African regions.

[a] RR: relative risk estimate.

[b] All RRs have a *P* value <.001.

Predictive Validity of the Prospective Scan Model

To evaluate the predictive validity of the prospective scan statistic approach, we used Brazil, Peru, Uganda, and Nigeria as country examples. Figure S11 in Multimedia Appendix 1 illustrates the RRs of the prospective scan approach and the SIR estimations. The correlation of both models for all 4 countries was strong and significant (Uganda: ρ=0.78, *P*=.04; Nigeria: ρ=0.98, *P*=.002; Brazil: ρ=0.95, *P*=.01; and Peru: ρ=0.86, *P*=.03). In addition, among all 4 countries that prospective scan modelling predicted a potential outbreak after April 15, 2020, we found a significant increase in the comparison of the COVID-19 mean new cases before and after April 15 (Uganda: W=697, *P*=.008; Nigeria: W=1280, *P*<.001; Brazil: W=1596, *P*<.001; and Peru: W=1246, *P*<.001).

COVID-19 Spread in Relation to Real-time Population Mobility Patterns Between January 21 and May 18 Globally and Regionally for Latin America, the Caribbean, and Africa

Population Mobility Patterns and COVID-19 Spread at the Global Level

COVID-19 daily new cases and real-time population mobility changes by region are presented in Figure S12 in Multimedia Appendix 1. Among the 3 population mobility patterns, a reduced change in comparison with the reference period of time was observed. Population mobility patterns and COVID-19 spread worldwide and by the Latin American, Caribbean, and African region are reported in Table 3. Worldwide, between January and May 2020, population mobility to all kinds of food places, drug stores, and pharmacies was not associated with COVID-19 spread, while the use of park places (ie, national and city parks, public beaches, and dog parks) and mobility to workplaces were negatively related with COVID-19 spread (mobility to parks and similar places: *b*=–0.03, 95% CI –0.04 to –0.02); workplaces mobility: *b*=–0.03, 95% CI –0.05 to –0.02). However, when the interaction effect between government control policies (intermediate, high, and very high) and population's mobility patterns was applied and compared with that of low-level government control policies, different trends were extracted regarding COVID-19 spread. It was observed that COVID-19 spread changes significantly throughout mobility confounders depending on the degree of the implemented control policies. Specifically, with the implementation of intermediate, high, and very high control policies, mobility to parks and other similar places (like beaches, dog parks, and others) were related with increased COVID-19 spread (*b*=0.02, 95% CI 0.01-0.03; high-level interventions: *b*=0.02, 95% CI 0.01-0.03; very high–level interventions: *b*=0.02, 95% CI 0.01-0.03) when compared with the population mobility in parks during the implementation of low-level government control policies. Similar increased COVID-19 spread estimates were shown for population mobility to workplaces during high-level and very high–level movement restrictions (high-level interventions: *b*=0.02, 95% CI 0.01-0.04; very high–level interventions: *b*=0.03, 95% CI 0.01-0.04) when compared with population mobility to workplaces during the implementation of low-level government policies.

Table 3. Results from mixed model analysis that evaluated the COVID-19 spread with government interventions, their interaction with population mobility patterns, and other factors during the first 4 months of the outbreak.[a]

[a] Models were also adjusted by country income level; preparedness in epidemics (Index for Risk Management); COVID-19 type of transmission (ie, community transmission or local transmission); and COVID-19 testing and tracing policies (in days).

[b] These are values less than 0.005 in absolute numbers.

[c] N/A: not applicable.

Population Mobility Patterns and COVID-19 Spread for Latin America, the Caribbean, and Africa

When the analysis was stratified by Latin American, Caribbean, and African countries, specific trends in COVID-19 spread were shown due to distinct population's mobility patterns (Table 3). As noted, the coefficients of the interaction between the populations' mobility to parks and similar places and social distancing measures were consistent at the regional level, apart from the region of Africa. Specifically, when high-level and very high–level control policies were applied in comparison with those at a low level, only people's mobility to parks and similar places was related with increased COVID-19 spread (exception was the African countries where the results were not significant; ie, Latin America, the Caribbean, and Africa: high-level interventions concurrently with mobility to parks and similar places *b*=0.05, 95% CI 0.02-0.07; very high–level interventions concurrently with mobility to parks and similar places *b*=0.05, 95% CI 0.03-0.07). Moreover, the interaction between populations' mobility to workplaces and social distancing measures showed heterogeneity among the tested regions. However, apart from the global analysis, results were not significant for the Latin American, Caribbean, or African regions.

Finally, we conducted a sensitivity analysis to assess our inferences for large countries in terms of area extension (due to possible subnational mitigation policies) and to avoid a possible bias effect toward big country areas, taking into account our analytical sample of countries (n=179). For the sensitivity analysis, we fitted all models again for data on COVID-19 spread removing the 5 top countries with the largest area worldwide (ie, Russia, Canada, China, the United States, and Brazil) and the top 3 countries with the largest area regionally for Latin America and for Africa (Brazil, Angola, Argentina, etc). Again, the observed results remained in the same direction at the global and regional level, as was previously mentioned (data not shown in the text).

Discussion

Principal Findings

This study analyzed the geographical and temporal COVID-19 spread among LMICs in Latin America, the Caribbean, and Africa using the prospective space–time scan statistical methodology and the impact of real-time population mobility patterns during the implemented government interventions in the area of interest between January 21 and May 18, 2020. First, analyzing the current data with scan statistics at five prospective time periods, it was shown that virus spread was rapid and at alarming rates since March 15, where we detected 7 emerging COVID-19 clusters, which at May 15 had spread to 28, among the regions of Latin America, the Caribbean, and Africa. As governments decide their strategies in response to the pandemic, surveillance is of importance especially among LMICs that have limited resources at their disposal; hence, the prospective scan statistic could be used as a useful surveillance tool at the international, national, and subnational levels. Second, as presented in 4 country-specific examples, the prospective scan statistic showed high predictive validity with classic surveillance technics. Third, when the real-time mobility to parks, beaches, and other similar places as well as the mobility to workplaces were tested as individual factors, it was shown that these patterns were related with reduced COVID-19 spread. However, worldwide, the population movement to parks, beaches, and other similar places (although more reduced than the reference period) seemed to be related with increased virus spread with all levels (intermediate, high, very high) of government control policies activated (when compared with the low-level government control policies). Fourth, similar trends were shown for population mobility to workplaces when high and very high–level control policies (after comparing them with low-level government interventions) were implemented worldwide. Fifth, stratified analysis for the Latin American, Caribbean, and African regions showed a variety of patterns mostly following the entire samples' tendency (ie, real-time mobility to parks when the social distancing measures were implemented). Governments are applying social and mobility restriction measures to slowdown the COVID-19 spread, but there is limited information about the real-time population mobility patterns, and based on our analysis, this information could help public health authorities to design effective strategies to slow down virus transmission.

The major strength of the prospective space–time scan methodology is the ability to add dynamically updated data sets and reapply the analysis to extract new emerging COVID-19 clusters, while it also has the ability to monitor the growing or shrinking COVID-19 evolution among initial detected clusters. Our analysis showed that Antigua and Barbuda had an emerging COVID-19 cluster with one of the highest RRs in Latin America and the Caribbean by the end of March 2020 and continues with a shrinking magnitude by mid-May. Similar trends were reported for Mexico and Chile. The same tool could be used subnationally among these countries to detect emerging clusters at the cross-national level (as has been done for the United States [10]). Regarding African regions, Djibouti, Mauritius, and Egypt showed growing and reducing magnitudes in COVID-19 spread from January 21 to May 15, 2020. This kind of information could be helpful to the relative stakeholders since it gives the opportunity to the public health authorities to evaluate constantly the effectiveness of the implemented mitigation and control strategies. Our comparative analysis between prospective scan and SIR modeling among 4 areas showed similar predictive results in virus spread. As has recently been reported, effective COVID-19 surveillance and monitoring need to include additional information on suspected, probable, and negative COVID-19 tests for a holistic understanding of COVID-19 transmission patterns [29], something that is often not possible for LMICs and could be marked as a barrier. Thus, future studies, data sets, and research funding are needed [30]. Health policy research showed that countries should not phase out social distancing policies until they establish strong systems that could effectively monitor the COVID-19 spread [15]. For this reason, at the early stages of the virus spread, the prospective scan methodology could serve as a useful public health surveillance tool especially among LMICs that are facing substantial limitations to monitor and detect virus transmission.

A lot of discussion has happened about the role of government interventions and control policies on COVID-19 spread. Until today, there is limited information on the impact of social restrictions and control policies at the global, regional, and national levels [15,25]. In Europe, the strictest government policy measures are related with less virus spread [31]. Targeted national health policies with effective screening and isolation tools as well as support systems are needed [15]. Based on that, real-time population mobility patterns during this intervention and social distancing period could be useful to stakeholders and policy makers to plan current and future public health–targeted strategies. Recent studies showed the important role of COVID-19–targeted strategies at the national level [32,33]. Moreover, this kind of information could serve among LMICs with limited resources in social distancing implementation, allowing them to plan targeted mobility control activities [34].

To date, although this kind of information is publicly available from well-known crowdsource applications, analyses at a national, regional, or global level are lacking. Our study used the publicly available crowdsource mobility information and showed that at the global level, when all kinds of government control policies were implemented, mobility to parks, beaches, and other leisure places was related with accelerated COVID-19 spread when compared with places where low-level control policies were effective. At a global level, peoples' mobility for work was also related to increased virus spread when high-level and very high–level government interventions were active, after comparing with the reference category of low-level government interventions. However, at the regional level (LMICs among Latin America, the Caribbean, and Africa), the results were not significant, showing that the aforementioned relation is mainly driven from the rest of the areas around the world. At this point, it has to be noted that, when we did not take into account the interaction with governmental social distancing interventions, the aforementioned mobility patterns were related with reduced virus transmission.

During the period that a region is facing increased dynamics of COVID-19 spread, social activities and engagement are associated with increased risk for virus spread [35]. For this reason, the WHO and other public health organizations are recommending avoiding crowded conditions [36]. Recent data from the United States showed that lower mobility to workplace and retail locations is related with lower virus transmission [35]. Our entire sample analysis showed a positive relation between mobility to places like parks and workplaces while governments applied social distancing measures. Similar findings were also reported by other researchers for the United States [35]. In addition, our regional stratified analysis showed consistent findings with the global one, except from the region of Africa. Taking into account that human mobility is a complicated concept (and at this point is analyzed collectively by using crowdsource data), we may hypothesize that individuals' behavior (use of face mask) [32], people's dynamic network [33] when visiting these places, and seasonality could be potential explaining mechanisms of virus spread [35,37]. The aforementioned findings could guide stakeholders on specific social distancing implementations and enforcement planning [38]. In the past months, countries are introducing various nonpharmaceutical intervention strategies in their local health policy agendas. These results can be used as *roadmap* indicators for specific social distancing planning. Targeted implemented policies could lead to further suppressed levels of virus spread, with less negative effects on the economy and citizens [39]. To this extent, a recent study noted that, during the phasing out of government social distancing policies, higher mobility at workplaces was correlated with increasing virus spread [40].

Effectiveness of the Current Measures and Current and Future Challenges

To date, countries have adopted divergent restriction strategies to suppress and halt COVID-19 transmission. Stricter social distancing policies seem effective in suppressing virus spread [31]. Differences in innovative surveillance techniques, virus transmission monitoring, COVID-19 cases tracing, systematic population testing, and isolating practices have been shown [15]. Regions with previous experiences in infectious diseases (eg, severe acute respiratory syndrome) have invested in their public health care system's reformation to efficiently handle the current outbreak [15]. Western societies (eg, the European Union and the United States) seem to lack this kind of planning [41]. In addition, recent studies showed that COVID-19 spread could be more rapid among more prosperous countries [15,42]. Countries need to organize their health systems [15,41], establishing effective infectious diseases and crisis management planning [43] (eg, enhance monitoring techniques and screening tools) to prevent virus spread in the community. Future longitudinal studies may be needed to better describe the relation of real-time mobility data with COVID-19 transmission.

Strengths and Limitations

This is among the first studies using COVID-19 prospective surveillance analysis among LMICs, exploring COIVD-19 spread in relation with real-time population mobility patterns. However, this study shares common limitations with previous studies of this kind [17,25]. Specifically, there were challenges in capturing uncertainty (completeness of the WHO COVID-19 data set or government interventions being announced on one day but only being applied after several days) and lags in data availability, which may not fully capture temporal trends of COVID-19 spread. We extracted only mobility patterns from smartphones using Google software to ensure homogeneity of the used information. In addition, this study had only the ability to analyze data from regions in which mobile phone information was obtainable [35]. For example, the use of crowdsourcing digital data for the extraction of real-time population trends through mobile phones may be limited particularly in Africa (data for selected African countries reported that about one-third of adults own smartphones) [44]. This may have altered the findings of this study. In addition, certain large countries applied subnational control policies at different time points, which could have affected our findings. In that manner, we applied a sensitivity analysis excluding large countries from the global and regional sample, and testing whether those countries had an impact on the inferential analyses. The applied aforementioned analysis showed that the results remained similar. Additionally, our investigation focused on data variations in the COVID-19 spread from January to May 2020.

Therefore, the results of this paper should be interpreted with caution, as they only relate to the underlying data collection conditions and period. As COVID-19 is an infection with dynamic transmission and all the variables we use may variate in the future, we do not think it would be appropriate to make conclusions beyond May, as further data and analysis would be required. To this extent, it should also be noted that this mixed model analysis assumes that the impact of each relative mobility pattern change has the equal relative impact among countries and across time (as an additional adjustment to this extent was not possible). Next, although our study adjusted for various confounders, we could not consider physical distancing recommendations (ie, 1 or 2 meters) or other precautionary measures and conditions due to lack of data. In addition, some of the mobility variables used in this analysis (eg, parks) may be also affected from weather seasonality. The prospective space–time scan statistic used case data for confirmed cases, so suspected and probable cases were not considered due to the unavailability of the WHO COVID-19 data set. In addition, the prospective scan methodology does not allow for adjustment of age and other covariates. These limitations may alter the true magnitude of the COVID-19 spread as presented by using the prospective scan statistic.

Conclusions

We used publicly available WHO daily reports to identify emerging space–time clusters of COVID-19 at the country level among Latin America, the Caribbean, and Africa for five separate time periods. It was shown that the prospective scan is a tool that LMICs could use to detect emerging clusters and implement specific control policies and interventions to slowdown COVID-19 transmission. In addition, we found that different kinds of real-time population mobility patterns were related with different magnitudes of COVID-19 spread worldwide. The findings of this study give insights that may help in COVID-19 screening and detection strategies as well as in government–specific COVID-19 control planning.

Acknowledgments

All data generated or analyzed during this study are included in this paper and its supplementary information files.

ST was supported by the Foundation for Education and European Culture, the Miguel Servet programme (reference CP18/00006), and the Fondos Europeos de Desarrollo Regional. DF is a Serra Húnter Fellow and was supported by Marsden grant E2987-3648 administrated by the Royal Society of New Zealand, and by grant 2017 SGR 622 (GRBIO) administrated by the Departament d'Economia i Coneixement de la Generalitat de Catalunya (Spain). Abstract

Background: The novel coronavirus pandemic continues to ravage communities across the United States. Opinion surveys identified the importance of political ideology in shaping perceptions of the pandemic and compliance with preventive measures.

Objective: The aim of this study was to measure political partisanship and antiscience attitudes in the discussions about the pandemic on social media, as well as their geographic and temporal distributions.

Methods: We analyzed a large set of tweets from Twitter related to the pandemic, collected between January and May 2020, and developed methods to classify the ideological alignment of users along the moderacy (hardline vs moderate), political (liberal vs conservative), and science (antiscience vs proscience) dimensions.

Results: We found a significant correlation in polarized views along the science and political dimensions. Moreover, politically moderate users were more aligned with proscience views, while hardline users were more aligned with antiscience views. Contrary to expectations, we did not find that polarization grew over time; instead, we saw increasing activity by moderate proscience users. We also show that antiscience conservatives in the United States tended to tweet from the southern and northwestern states, while antiscience moderates tended to tweet from the western states. The proportion of antiscience conservatives was found to correlate with COVID-19 cases.

Conclusions: Our findings shed light on the multidimensional nature of polarization and the feasibility of tracking polarized opinions about the pandemic across time and space through social media data.

Introduction

Effective response to a health crisis requires society to forge a consensus on many levels: scientists and doctors have to learn about the disease and quickly and accurately communicate their research findings to others, public health professionals and policy experts have to translate the research into policies and regulations for the public to follow, and the public has to follow guidelines to reduce infection spread. However, the fast-moving COVID-19 pandemic has exposed our critical vulnerabilities at all these levels. Instead of orderly consensus-building, we have seen disagreement and controversy that exacerbated the toll of the disease. Research papers are rushed through the review process, with results sometimes being disputed or retracted [1], policy makers giving conflicting advice [2], and scientists and many in the public disagreeing on many issues, from the benefits of therapeutics [3] to the need for lockdowns and face-covering [4]. The conflicting viewpoints create conditions for polarization to color perceptions of the pandemic [5-8] and attitudes toward mitigation measures.

Surveys have identified a partisan gulf in the attitudes about COVID-19 and the costs and benefits of mitigation strategies, with the public's opinion polarized into sharply contrasting positions. According to a Pew Research Center report [9], political partisanship significantly affects perceptions of public health measures and might explain regional differences in the pandemic's toll in the United States [10]. Polarization has colored the messages of US political leaders about the pandemic [7] as well as discussions of ordinary social media users [8]. Coupled with a distrust of science and institutions, polarization can have a real human cost if it leads the public to minimize the benefits of face coverings or reject the COVID-19 vaccine when it becomes available. Dr Anthony Fauci, the nation's top infectious diseases expert, attributed many of the disease's 500,000 deaths (and counting) to political divisions in the country [11]. This further affirms the need to investigate the presence, and unravel the ill effects, of polarization in scientific and political discourse.

Current research measures polarization as divergence of opinions along the political dimension and its effect on other opinions, for example, discussion of scientific topics [12]. However, opinions on controversial issues are often correlated [13]; for example, those who support transgender rights also believe in marriage equality, and those who oppose lockdowns also resist universal face-covering. Inspired by this idea, we capture some of the complexity of polarization by projecting opinions in a multidimensional space, with different axes corresponding to different semantic dimensions. Once we identify the dimensions of polarization and define how to measure them, we can study the dynamics of polarized opinions, their interactions, and regional differences.

Our work analyzed tweets posted on Twitter related to the COVID-19 pandemic collected between January 21 and May 1, 2020 [5]. We studied polarization along three dimensions: political (liberal vs conservative), science (proscience vs antiscience), and moderacy (hardline vs moderate). User polarization along the science axis identifies whether users align with scientific and factual sources of information or whether they are characterized by mistrust of science and preference for pseudoscientific and conspiracy sources. A user's political ideology is defined in a 2D space. Working in tandem with the political axis, the moderacy dimension recognizes the intensity of partisanship from hardline to moderate. For the hardliners identified along the moderacy dimension, we leveraged the political axis to identify their partisanship as liberal or conservative.

Cinelli et al [14] and Weld et al [15] showed that sharing of URLs annotated by Media Bias/Fact Check is a reliable proxy of one's political polarity. Inspired by the findings and conclusions made in these works, we used media sources that have been classified by nonpartisan sites along these dimensions to define the poles of each dimension of polarization. These media sources include both mainstream news and a large variety of other sources, such as government agencies, nongovernmental organizations, crowdsourced content, and alternative medicine news and health sites. Users were given a score reflecting how often they shared information from each set of polarized sources. These users served as training data to train machine learning algorithms to classify remaining users along the multiple dimensions of polarization based on the content of their posts. Inferring the polarization of users discussing COVID-19 allowed us to study the relationships between polarized ideologies and their temporal and geographic distributions. We showed that political and science dimensions were highly correlated and that politically hardline users were more likely to be antiscience, while politically moderate users were more often proscience. We also identified regions of the United States and time points where the different ideological subgroups were comparably more active and we identified their topics of conversation. We found that areas of heightened antiscience activity corresponded to US states with large COVID-19 outbreaks. Our work, therefore, provides insights into potential reasons for geographic heterogeneity of outbreak intensity.

The contributions of this work are as follows:

- We described a framework to infer the multidimensional polarization of social media users, allowing us to track political partisanship and attitudes toward science at scale.
- We showed that political and science dimensions were highly correlated, with hardline right and antiscience attitudes closely aligned.
- We studied the geographical distribution of polarized opinions and found that regional differences can correlate with the pandemic's toll.

As the amount of COVID-19 information explodes, we need the ability to proactively identify emerging areas of polarization and controversy. Early identification could lead to more effective interventions to reduce polarization and also improve the efficacy of disease mitigation strategies. Vaccine hesitancy was shown in past research to be associated with antiscience attitudes [16]; therefore, our approach may help identify regions of the country that will be more resistant to COVID-19 vaccination. This may better prepare public health workers to target their messages.

Methods

Here, we describe the data and methods we used for measuring polarization and also inferred it from text and online interactions.

Data Set

In this study, we used a public data set of COVID-19 tweets from Twitter [5]. This data set comprises 115 million tweets from users across the globe, collected over a period of 101 days from January 21 to May 1, 2020. These tweets contain at least one keyword from a predetermined set of COVID-19–related keywords (eg, coronavirus, pandemic, and Wuhan).

Fewer than 1% of the tweets in the original corpus have geographic coordinates associated with them. We specifically focused on tweets from users located in the United States, at state-level granularity, based on geolocated tweets and fuzzy matching of user profile text [8]. Specifically, we used a fuzzy text matching algorithm to detect state names and abbreviations, as well as names of populous cities. The user profile text extracted from the *description* attribute of the *user* object was passed on to the *loc_to_state* function of the georeferencing code [17] to extract the user's location at the state level. A manual review of this approach found it to be effective in identifying the user's home state. This methodology provided location information for 65% of users in the data set. The georeferenced data set consisted of 27 million tweets posted by 2.4 million users over the entire time period.

Measuring Polarization Using Domain Scores

We characterized individual attitudes along three dimensions of polarization. The *political* dimension, the standard dimension for characterizing partisanship, captured the difference between *left* (*liberal*) and *right* (*conservative*) stances for users with strong hardline political opinions. The *science* dimension captured an individual's acceptance of evidence-based *proscience* views or the propensity to hold *antiscience* views. People believing and promoting conspiracies, especially health-related and pseudoscientific conspiracies, were often grouped in the antiscience camp. Finally, the *moderacy* dimension described the intensity of partisanship, from *moderate* or nonpartisan opinions to politically *hardline* opinions.

We inferred polarized attitudes of users from the content of their posts. While previous work [18] inferred polarization from user hashtags, we instead relied on user-tweeted URLs. The key idea that motivated our approach is that online social networks tend to be ideologically similar, with users more closely linked (eg, through follower relationships) to others who share their beliefs [19,20]. While we did not have follow links in our data, we used URLs as evidence [21] of a homophilic link. We extended this approach beyond political ideology [22] to label other dimensions of polarization. Specifically, we used a curated list of information sources, whose partisan leanings were classified by neutral websites, to infer the polarization of Twitter users at scale. We used lists compiled by Media Bias/Fact Check, AllSides, and NewsGuard, which tracks coronavirus misinformation (see data folder at GitHub [23]). Table 1 lists exemplar domains, hereinafter referred to as pay-level domains (PLDs), in each category. PLDs listed under *conspiracy* and *questionable sources* were mapped to our antiscience category. For the *moderacy* axis, we considered the union of left and right PLDs as a proxy for the *hardline* category, while the union of least-biased, left-moderate, and right-moderate PLDs formed the proxy *moderate* category.

We quantified a user's position along the dimensions of polarization by tracking the number of links to curated PLDs the user shared. Specifically, we extracted PLDs that were shared by users in the data set and filtered for relevant PLDs that were present in our curated lists (Table 1). This gave us a set of 136,000 users who shared *science* PLDs, 169,000 users who shared *political* PLDs, and 234,000 users who shared PLDs along the *moderacy* dimension. There was a wide distribution in the number of tweets, and therefore PLDs, shared between users (Figure S1 in Multimedia Appendix 1), with some users tweeting many PLDs and many users tweeting one or none. We, therefore, filtered out users who shared fewer than *three* relevant PLDs in each dimension (ie, fewer than three in the science dimension, fewer than three in the partisan dimension, and fewer than three in the moderacy dimension), which resulted in 18,700 users. For each user, we computed a *domain score* δ along each of the three dimensions, as the average of mapped domain values of a dimension:

where δ_i is the domain score of $user_i$ and $D_{i,d}$ represents the set of PLDs shared by $user_i$ relevant to dimension d.

Table 1. Curated information and news pay-level domains (PLDs) with their polarization.

Dimension and polarization dimension	PLDs, n	Examples of PLDs
Science[a]		
Proscience (+1)	150+	cdc.gov, who.int, thelancet.com, mayoclinic.org, nature.com, and newscientist.com
Antiscience (−1)	450+	911truth.org, althealth-works.com, naturalcures.com, shoebat.com, and prison-planet.com
Political[b]		
Liberal (−1)	300+	democracynow.org, huffingtonpost.com, newyorker.com, occupy.com, and rawstory.com
Conservative (+1)	250+	nationalreview.com, newsmax.com, oann.com, theepochtimes.com, and bluelivesmatter.blue
Moderacy[c]		
Moderate (+1)	400+	ballotpedia.org, c-span.org, hbr.org, wikipedia.org, weforum.org, snopes.com, and reuters.com
Hardline (−1)	500+	gopusa.com, cnn.com, democracynow.org, huffingtonpost.com, oann.com, and theepochtimes.com

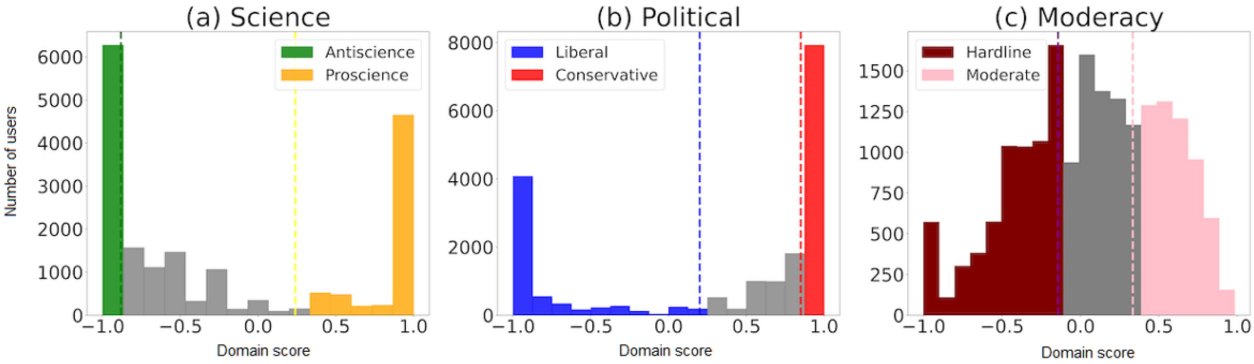
[a] Proscience PLDs are mapped to +1 along the science axis, while antiscience PLDs are mapped to −1.

[b] Along the political axis, liberal PLDs are mapped to −1, while conservative PLDs are mapped to +1.

[c] Along the moderacy axis, hardline PLDs are mapped to −1, while moderate PLDs are mapped to +1.

Figure 1 shows the distribution of domain scores for users who shared links to information sources across all dimensions. The distributions were peaked at their extreme values, showing more users sharing information from antiscience than proscience PLDs and more conservative than liberal PLDs. In Figure S2 in Multimedia Appendix 1, we show that these extremes were robust to how we filtered users and were, therefore, not a product of, for example, sharing a single link.

Figure 1. The distribution of domain scores along science, political, and moderacy dimensions. (a) The vertical lines at 0.42 and −1 mark the top and bottom 30% cutoffs of distribution along the science dimension, which are binned as proscience (+1) and antiscience (−1), respectively. (b) The vertical lines at 1 and −0.33 mark the top and bottom 30% cutoffs of distribution along the political dimension, which are binned as conservative (+1) and liberal (−1), respectively. (c) The vertical lines at 0.38 and −0.18 mark the top and bottom 30% cutoffs of distribution along the moderacy dimension, which are binned as moderate (+1) and hardline (−1), respectively.



For network-level analysis, we then built a web scraper that mapped PLDs to their respective Twitter handles. The scraper initiated a simple Google query of the form "*Domain Name Twitter Handle*." This tool relied on the search engine to rank results based on relevance and picked out the title of the first result containing the substring "|*Twitter*." This substring was of the form "*Account Name* (*@handle*) | *Twitter*," which was parsed to retrieve the domain's corresponding handle. We manually verified the mapped PLDs. The mapped dimension-wise PLDs are available on our GitHub repository under the data folder.

Recall that along each of the three dimensions, we mapped the dimension's constituent domain names to their respective Twitter handles. The mapped Twitter handles formed our seed sets for semisupervised learning at the network level. Each dimension's seed set comprised key-value pairs of Twitter handles and their corresponding orientation along the dimension.

Table 2 illustrates the number of seeds along each polarization axis.

To investigate the presence of bias stemming from an uneven distribution of PLDs along each ideological dimension's polarized ends, we sampled an equal number of PLDs along each of the dimension's two polarities. More specifically, we performed random downsampling of the majority ideological polarity along each dimension. Upon ensuring that each dimension's polarized ends were now represented by an equal number of PLDs, we calculated domain scores for each user along the ideological dimensions (Figure S3 in Multimedia Appendix 1). Leveraging these domain scores, we then rebuilt prediction models. We found that the performance of this modified procedure did not differ significantly from our results (see Table S1 in Multimedia Appendix 1 for more details). This robustness check demonstrated the versatility of our approach to differences in the sampling of PLDs along each dimension.

Table 2. Description of the retweet network.

Dimension and polarization	Seeds[a], n (%)
Science (n=158)	
Proscience	81 (51.3)
Antiscience	77 (48.7)
Political (n=195)	
Liberal	96 (49.2)
Conservative	99 (50.8)
Moderacy (n=558)	
Hardline	195 (34.9)
Moderate	363 (65.1)

[a] Number of seed handles along each polarization axis for initial node assignment in the label propagation algorithm.

Inferring Polarization

Overview

Using domain scores, we were able to quantify the polarization of just a small fraction (18,700/2,400,000, 0.78%) of users who generated PLDs in the data set. In this section, we describe how we leveraged this data to infer the polarization of the remaining users in our data set. In the Results section, we compare the performance of these inference methods. Two methods, label propagation algorithm (LPA) and latent Dirichlet allocation (LDA), act as baselines against our state-of-the-art text embedding method. Our study focused on investigating content generated by users over the entire period rather than at the noisier tweet level. Investigating a user's content, tweet by tweet, may or may not provide sufficient information to gauge their ideological polarity, whereas analyzing all tweets generated by a user over time would facilitate this.

We classified users according to the binned domain scores along each dimension. We found that classification worked better than regression in this data set. We binned domain scores by thresholding the distribution into two classes along each dimension, as shown in Figure 1. Using other threshold values to bin the domain score distribution into two classes did not qualitatively change results (Multimedia Appendix 1). Additionally, we released a GitHub repository [23] for readers to reproduce this work upon careful rehydration of tweet data, instructions for which have also been provided in the repository.

Label Propagation Algorithm

LPA was used in the past to label user ideology based on the ideology of accounts the user retweets (eg, see Badawy et al [22]). The idea behind label propagation is that people prefer to connect to, and retweet content posted by, others who share their opinions [24,25]. This gives us an opportunity to leverage topological information from the retweet network to infer users' propensity to orient themselves along ideological dimensions.

The geocoded Twitter data set provides fields named *screen_name* and *rt_user*, which allowed us to identify the user being retweeted and the user retweeting, respectively. To this end, we built a network from 9.8 million retweet interactions between 1.9 million users sourced from the data set. In the retweet network, an edge runs from *A* to *B* if user *A* retweets user *B*. Descriptive statistics of the retweet network are shown in Table 3. We then used the semisupervised greedy learning algorithm (ie, the LPA) to identify clusters in the retweet network.

LPA, as proposed by Raghavan et al [26], is a widely used near-linear time node classification algorithm. This greedy learning method started off with a small set of labeled nodes also known as seeds, with the remaining nodes assigned labels at random. The number of seeds for each polarization dimension is shown in Table 2. The algorithm then iteratively updated the labels of nonseed nodes to the majority label of their neighbors, with ties broken at random, until converging to an equilibrium where the labels no longer changed. However, owing to stochasticity of tie-breaking, a certain amount of randomness crept into the results produced by this algorithm. As the result, LPA tended to generate slightly differing classifications of user polarization for the same network each time it was run. To address the stochasticity, we ran the LPA in 5-fold cross-validation and averaged the results.

Table 3. Statistics of the network.

Statistic	Value, n
Nodes	1,857,028
Maximum in-degree	39,149
Maximum out-degree	1450
Retweets	9,788,251
Unique retweets	7,745,533
Size of the strongly connected component	1,818,657

Latent Dirichlet Allocation

We used LDA [27] to identify topics, or groups of hashtags, and represented users as vectors in this topic space. We considered the set of *all* hashtags in the COVID-19 data set generated by a user over time as a document representing that user—after ignoring hashtags used by fewer than 10 users or more than 75% of the users—leaving 25,200 hashtags. The choice of 75% was arbitrary, but a hashtag that appeared at a lower threshold (eg, within roughly 50% of the users) could be highly prevalent in one domain and not another. We used a more lenient threshold to avoid this issue. We also used 20 topics, as that gave a higher coherence score. Given the enormity of the geocoded Twitter data set we leveraged in this study, conducting LDA experiments to validate these thresholds proved to be computationally prohibitive and it was unlikely that tuning would have achieved significantly better results than the one seen in this study.

We used the document-topic affinity matrix generated by LDA to represent users. An *affinity vector* was composed of 20 likelihood scores corresponding to 20 topics, adding up to 1, with each score indicating the probability of the corresponding topic being a suitable representation for the set of hashtags generated by the user. Using these affinity vectors, we generated feature vector matrices for each of the three dimensions of interest. In doing so, we were able to represent over 900,000 users who used some hashtag in their tweets with a dense vector of length 20.

Text Embedding Using fastText

Previous methods—see Conover et al [28]—classified a user's political polarization based on the text of their tweets by generating term frequency–inverse document frequency–weighted unigram vectors for each user. However, the advent of more powerful text-embedding techniques [29-31] allowed us to generate sentence-embedding vectors to better represent content.

We grouped the tweets generated by each of the 2.4 million users from January to May 2020. More specifically, we collected all COVID-19–related tweets generated by a user in this time period and concatenated them to form a text document for each user. After preprocessing the 2.4 million documents to lowercase and removing hashtags, URLs, mentions, handles, and stop words, we used the fastText sentence-embedding model pretrained on Twitter data to generate tweet embeddings for each user. Preprocessing of tweets was performed by leveraging the regular expression (*re*) package in Python, version 3.7 (Python Software Foundation); the Natural Language Toolkit; and the *Gensim* natural language processing library. The *Sent2vec* Python package [32] provided us with a Python interface to quickly leverage the pretrained model and generate 700-dimension feature vectors representing each user's discourse.

Results

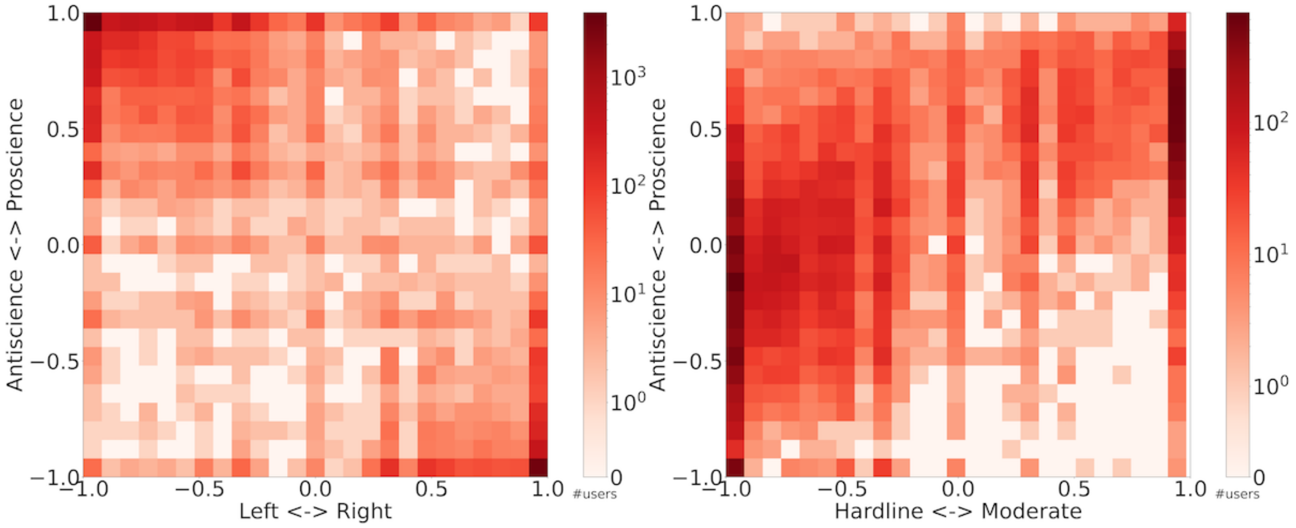
Overview

First, we visualized the domain scores of the 18,700 users, showing the relationship between the science, moderacy, and political dimensions. Then we compared the performance of algorithms for classifying users along the three dimensions of polarization, using domain scores as ground truth data. We used the inferred scores to study the dynamics and spatial distribution of polarized opinions of users engaged in online discussions about COVID-19.

Visualizing Polarization

Figure 2 shows the relationship between dimensions of polarization, leveraging domain scores of 18,700 users who shared information from curated PLDs. The heat map shows the density of users with specific domain scores. Large numbers of users are aligned with proscience-left extreme (top-left corner) or antiscience-right extreme (bottom-right corner), with lower densities along the diagonal between these extremes (Figure 2, left-hand side). This illustrates the strong correlation between political partisanship and scientific polarization, thereby highlighting the influence of pernicious political divisions on evidence-based discourse during the pandemic, with conservatives being more likely to share antiscience information than proscience sources. The heat map on the right-hand side in Figure 2 highlights the interplay between the science and moderacy axes. The white region in the bottom-right corner shows there are few antiscience users who are politically moderate, thus demonstrating an asymmetry in these ideologies. The shading also highlights a higher density of proscience users identifying as politically moderate. These results are robust to how data are filtered, as shown in Figure S4 in Multimedia Appendix 1.

Figure 2. Polarization of COVID-19 tweets. On the left is the heat map of polarization (domain scores) along the science-partisanship dimensions. On the right is the heat map of polarization (domain scores) along the science-moderacy dimensions. Each bin within the heat map represents the number of users with domain scores falling within that bin.



Classifying Polarization

To run the LPA, we started from a set of labeled seeds: Twitter handles corresponding to PLDs categorized along the dimensions of interest (Tables 1 and 2). We reserved some of the seeds along each dimension for testing LPA predictions and reported accuracy of 5-fold cross-validation.

For content-based approaches, we used binned domain scores of 18,700 users as ground truth data to train logistic regression models to classify user polarization along the three dimensions. We represented each user as a vector of features generated by different content-based approaches: topic vectors for LDA and sentence embeddings for the fastText approach. We reserved a subset of users for testing performance.

Table 4 compares the performance of polarization classification methods. LPA worked well when it tried to identify user alignment along the political and science dimensions. However, it failed to capture the subtler distinctions along the moderacy axis. Training was further hampered by the low number of retweet interactions with moderate PLDs in comparison to hardline ones. Of the 1.8 million retweet interactions, only 250,000 involved some moderate seed nodes, whereas over 1 million interactions involved some hardline seed nodes. Moreover, poor classification performance with LPA revealed an important pattern: that moderates surrounded themselves with diverse opinions and, thus, a clear distinction could not be made by observing who they retweeted.

LDA modeling on hashtags allowed us to generate reduced-dimension, dense feature vectors for over 900,000 users who used hashtags in their tweets. This representation allowed us to design better learning models that significantly outperformed the LPA model.

A logistic regression model trained on fastText outperformed all other models described in this study. Coupled with fastText's ability to better handle out-of-vocabulary terms, the model's access to finer levels of detail at the tweet-text level, culminated in it being able to better predict dimensions of polarization. Given the model's superior performance across all three dimensions, we leveraged its predictions in subsequent analyses. We classified users along the three polarization dimensions. However, since the definition of the hardline extreme of the moderacy dimension overlapped with the political dimension, we needed to report only six ideological groups, rather than all eight combinations.

Table 4. Performance of polarization classification.[a]

Method and dimension	Data set size, n	Accuracy, %	Precision, %	Recall, %	F1 score, %
Label propagation algorithm					
Science	158	92.6	*100* [b]	80	88.9
Political	195	92.3	86.9	*100*	93.0
Moderacy	1205	20.1	72	1.4	2.74
Latent Dirichlet allocation					
Science	9983	92.2	91.6	92.4	91.9
Political	11,020	93.5	95.1	93.3	94.2
Moderacy	9565	86.4	85.6	85.0	85.4
fastText					
Science	11,202	*93.8*	93.9	*93.7*	*93.8*
Political	12,425	*95.1*	*96.5*	94.6	*95.5*
Moderacy	11,197	*90.2*	*90.1*	*90.5*	*90.2*

[a] Results compare classification performance of the label propagation algorithm and content-based methods, including topic modeling (latent Dirichlet allocation) and full-text embedding (fastText). Results are averages of 5-fold cross-validation. Data set sizes are the number of users in model validation data sets and are composed of users with strong polarization scores (top or bottom 30% as defined previously) in the filtered 18,700-user data set.

[b] Values in italics indicate the best-performing models.

Discussion

Dynamics of Polarization

Research shows that opinions of Twitter users about controversial topics do not change over time [33]. To investigate whether user alignments along the three polarization dimensions changed over time, we grouped tweets by time into seven biweekly intervals: January 21 to 31, 2020; February 1 to 15, 2020; February 16 to 29, 2020; March 1 to 16, 2020; March 17 to 31, 2020; April 1 to 15, 2020; and April 16 to May 1, 2020. There were 3000 users who tweeted consistently in all seven biweekly intervals. For each of the N users, we computed cumulative domain scores along science, political, and moderacy dimensions for all time intervals t and computed the average absolute change in domain score from biweekly period $t-1$ along each dimension given by the following:

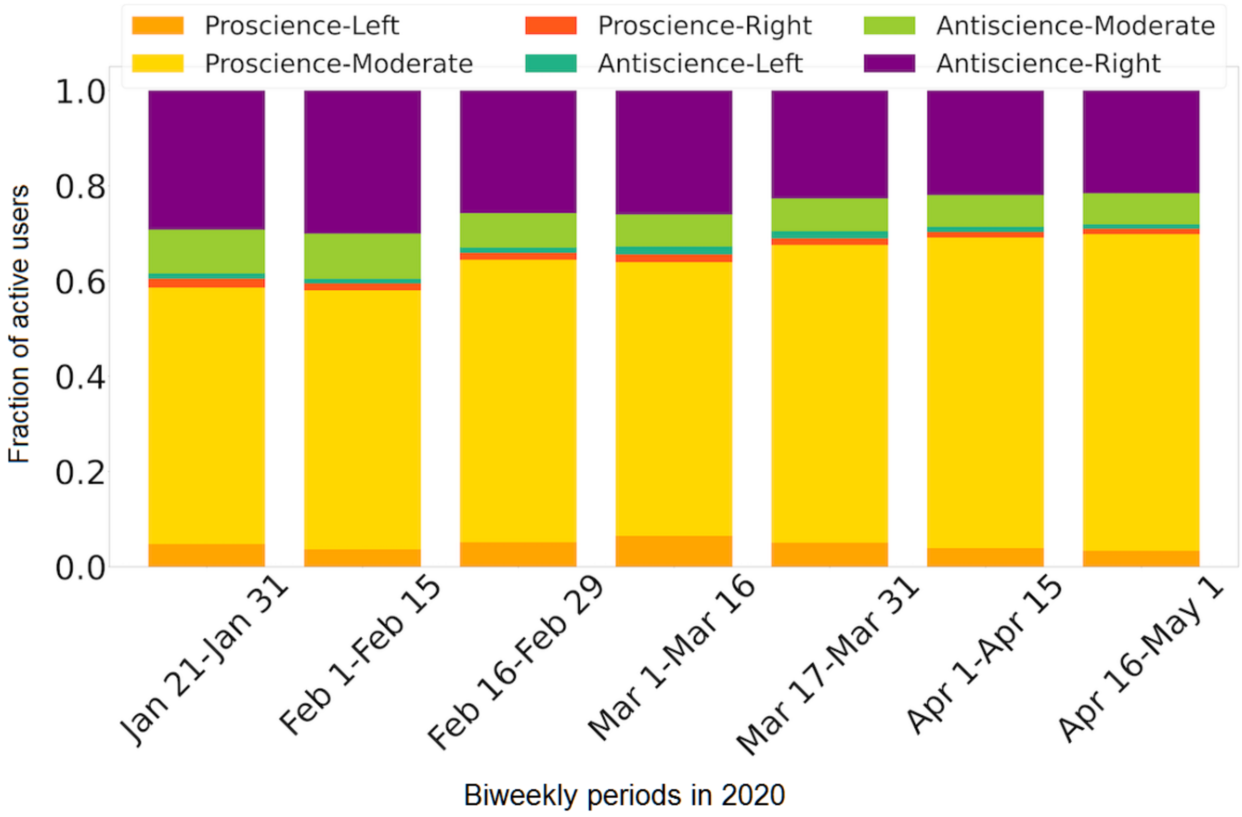
where $\delta_{i,t}$ represents the domain score for a user i in biweekly period t. The small values of in Table 5 confirm that user alignments do not change significantly over time.

Table 5. Average absolute change in domain score along consecutive biweekly intervals.

Dimension	Average absolute change () per biweekly interval numbers					
	2,1	3,2	4,3	5,4	6,5	7,6
Political	0.09	0.05	0.03	0.02	0.03	0.02
Science	0.13	0.07	0.04	0.02	0.02	0.02
Moderacy	0.21	0.11	0.07	0.04	0.04	0.03

Although each individual's alignments did not change, the number of users within each ideological group did change over time. User alignments did not change; therefore, we leveraged polarization classification results to show biweekly fractions of active users per ideological category. Figure 3 shows the composition of active users in all categories. As time progressed, we could clearly see the growth in the proscience-moderate category accompanied by a corresponding decline in antiscience-right users. This was consistently found over a variety of data filters, as seen in Figure S5 in Multimedia Appendix 1.

Figure 3. Fraction of active users per ideological group in biweekly periods. For completeness, this plot shows all users in the data set and not the filtered 18,700 users.



Topics of Polarization

To better understand what each of the six groups tweeted about, we collected the 50 most frequent hashtags used by each group, after removing hashtags common to all six groups. Figure 4 shows the word clouds of the most common hashtags within each group, sized by the frequency of their occurrence. Most striking was the use of topics related to conspiracy theories, such as *#qanon* and *#wwg1wga* by the antiscience-right group, along with politically charged references to the *#ccpvirus* and *#chinavirus*. This group also used hashtags related to former US President Donald Trump’s re-election campaign, showing the hyper-partisan nature of COVID-19 discussions. Another partisan issue appeared to be *#hydroxychloroquine*, a drug promoted by Donald Trump. It showed up in both proscience-right and antiscience-right groups but was not discussed by other groups. Overall, these intuitive results highlight the overall accuracy of our polarization inference model.

Figure 4. Topics of discussion within the six ideological groups. The top row (from left to right) illustrates topics for proscience-left, proscience-moderate, and proscience-right groups. The bottom row (from left to right) illustrates topics for antiscience-left, antiscience-moderate, and antiscience-right groups.

(a) Proscience-Left (b) Proscience-Moderate (c) Proscience-Right

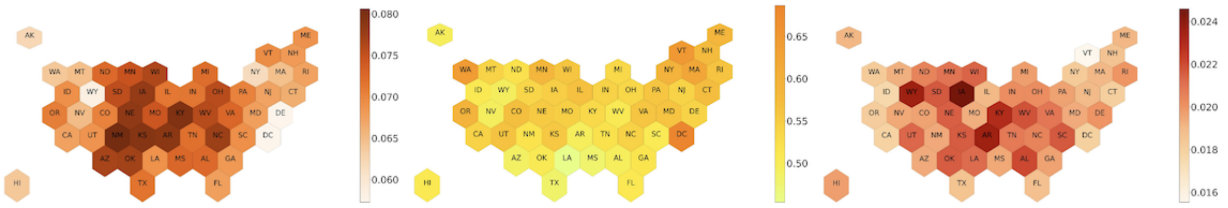
(d) Antiscience-Left (e) Antiscience-Moderate (f) Antiscience-Right

The polarized nature of the discussions could be seen in the users of the hashtags *#trumppandemic* and *#trumpvirus* by the left and proscience groups. However, in contrast to antiscience groups, proscience groups talked about COVID-19 mitigation strategies, using hashtags such as *#stayhomesavelives*, *#staysafe*, and *#flattenthecurve*.

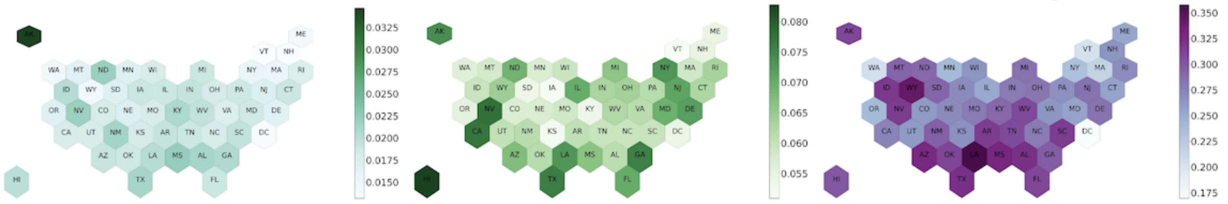
Geography of Polarization

Responses to the coronavirus pandemic in the United States have varied greatly by state. While the governors of New York, California, Ohio, and Washington reacted early by ordering lockdowns, the governors of Florida and Mississippi have downplayed the gravity of the situation for a longer time. To explore the geographical variation in ideological alignments, we grouped users by the state from which they tweeted and computed the fraction of their respective state's Twitter users belonging to an ideological group. We then generated geo-plots, shown in Figure 5, to highlight the ideological composition of each state.

Figure 5. Fraction of US states' Twitter users per ideological category. Plots (a) to (c) (top row, left to right) show the fraction of states' Twitter users who were classified as proscience-left, proscience-moderate, and proscience-right, respectively. Plots (d) to (f) (bottom row, left to right) show the fraction of states' Twitter users who were classified as antiscience-left, antiscience-moderate, and antiscience-right, respectively. The vertical bars next to the maps indicate the fraction of Twitter users in the state belonging to the ideological group. Two-letter abbreviations are used for each state.



(a) Proscience-Left (b) Proscience-Moderate (c) Proscience-Right



(d) Antiscience-Left (e) Antiscience-Moderate (f) Antiscience-Right

We saw a higher composition of proscience-moderates, as seen in Figure 5 (b), in Washington, Oregon, DC, and Vermont. As expected, these states had a lower fraction of antiscience users, as can be seen from Figure 5 (d), (e), and (f). Governors of these states were quick to enforce lockdowns and spread pandemic awareness among the general public.

Over the course of the pandemic, we have seen the strong opposition to masking mandates and closing down of businesses in California, Nevada, Hawaii, Georgia, and Texas. These antiscience sentiments are reflected in Figure 5 (e), which shows that these states had a comparatively higher proportion of their Twitter users in the antiscience-moderate ideology group.

Southern states—South Carolina, Mississippi, Louisiana, Texas, and Arizona—and northwestern states—Wyoming, North Dakota, South Dakota, and Montana—have experienced COVID-19 surges, with southern states becoming overwhelmed during the summer of 2020 and northwestern states becoming overwhelmed in the fall of 2020 (Figure S6 in Multimedia Appendix 1 shows the cumulative COVID-19 cases per state). The political and religious leaders in these states have also consistently downplayed the pandemic and resisted mitigation strategies. Our results are consistent with this, showing that these states also had more conservative Twitter users who mistrust science, as manifested by sharing information from antiscience sources. The antiscience attitudes in these states may also spell trouble for vaccination plans. The statistically significant positive correlation (Figure S7 in Multimedia Appendix 1) between state-wise cumulative COVID-19 case counts and antiscience-right users, as well as the negative correlation between the former and proscience-moderate users, affirms the significance of scientific beliefs in mitigating the spread of virus.

Limitations and Future Directions

Our novel approach to identify ideological alignments of users on Twitter comes with certain limitations. Akin to other studies involving Twitter data, our study worked under the caveat that the behaviors of the subset of users being considered in our data set may not be representative of population behavior. The use of geolocation techniques and subsequent consideration of users with a geolocation could introduce certain biases, which necessitate further investigation.

Thresholds that were used in our LDA analysis of user hashtags have been set intuitively due to LDA's prohibitive computation needs when dealing with over 900,000 hashtags. It is unlikely that we would have observed significant improvements in classification results with different thresholds. However, we encourage readers to investigate this further.

Additionally, the seed sets (Table 2) employed for our label propagation experiments may have had room for bias, as not all PLDs collected had a corresponding Twitter account. The cross-section of PLDs that have a Twitter account could be biased by political orientation, age group that the PLD caters to, etc. Investigation of bias stemming from this is a promising prospect for future work. Furthermore, our analyses worked under the assumption that media bias ratings provided by Media Bias/Fact Check accurately exhibited ideological biases of media sources. Leveraging these ratings, we assumed that generating tweets consisting of PLDs was an expression or reflection of one's ideological polarity. Future studies can build on these assumptions, and interesting avenues can be explored by incorporating other indicators of user polarity.

Verification of agreement or disagreement of user viewpoint and content in PLDs being shared was not in the purview of this study, and we encourage our readers to explore these avenues in future research. Furthermore, although we showed good performance on classifying polarized opinions, additional work is required to infer finer-grained opinions. Namely, by predicting fine-grained polarization among users, we could better infer, for example, network effects, such as whether users prefer to interact with more polarized neighbors, which may adversely impact provaccine mitigation strategies. Moreover, longer-term trends need to be explored in order to better understand how opinions change dynamically. This will better test whether social influence or selective formations of ties are the drivers of echo chambers and polarization. Finally, there is a need to explore polarization across countries to understand how different societies and governments are able to address polarization and how these polarized dimensions relate to one another across the world.

Conclusions

Our analysis of a large corpus of online discussions about COVID-19 confirms and extends the findings of opinion polls and surveys [9]: opinions about COVID-19 are strongly polarized along partisan lines. Political polarization strongly interacts with attitudes toward science: conservatives are more likely to share antiscience information related to COVID-19, while liberal and more moderate users are more likely to share information from proscience sources. On the positive side, we found that the number of proscience, politically moderate users dwarfed other ideological groups, especially antiscience groups. This is reassuring from the public health point of view, suggesting that a plurality of people are ready to accept scientific evidence and trust scientists to lead the way out of the pandemic. The geographical analysis of polarization identified regions of the country, particularly in the south and the west where antiscience attitudes are more common, that correlate to areas with particularly high COVID-19 cases, as seen in Figure S6 in Multimedia Appendix 1. Messaging strategies should be tailored in these regions to communicate with science skeptics. Overall, we found that analysis of tweets, while less representative than surveys, offers inexpensive, fine-grained, and real-time analysis of polarization and partisanship.

Abstract

Background: The COVID-19 pandemic has changed work life profoundly and concerns regarding the mental well-being of employees' have arisen. Organizations have made rapid digital advancements and have started to use new collaborative tools such as social media platforms overnight.

Objective: Our study aimed to investigate how professional social media communication has affected work engagement before and during the COVID-19 pandemic and the role of perceived social support, task resources, and psychological distress as predictors and moderators of work engagement.

Methods: Nationally representative longitudinal survey data were collected in 2019-2020, and 965 respondents participated in all 4 surveys. Measures included work engagement, perceived social support and task resources, and psychological distress. The data were analyzed using a hybrid linear regression model.

Results: Work engagement remained stable and only decreased in autumn 2020. Within-person changes in social media communication at work, social support, task resources, and psychological distress were all associated with work engagement. The negative association between psychological distress and work engagement was stronger in autumn 2020 than before the COVID-19 outbreak.

Conclusions: The COVID-19 pandemic has exerted pressure on mental health at work. Fostering social support and task resources at work is important in maintaining work engagement. Social media communication could help maintain a supportive work environment.

Introduction

The rapid spread of the COVID-19 pandemic has affected our lives and work profoundly [1,2]. The COVID-19 pandemic has pressurized organizations to make a rapid digital leap to remote work and thus challenged and cultivated employees' well-being [3,4]. In Europe, 37% of the employees began working remotely in March and April 2020, with Finland having the largest proportion of remote workers (59%) [3]. In 2019, prior to the COVID-19 pandemic, only 23% of people in Finland worked remotely from home or other locations regularly, and 14% did so occasionally; therefore, the leap has been enormous [5].

In remote work conditions during the COVID-19 pandemic, the use of digital tools and social media platforms has increased at work for information and document creation, sharing, and exchange and for video meetings and discussions [6]. These tools are often used for both work and nonwork purposes among colleagues and have been found to enhance ways of working, foster innovation, allow for learning new skills, enhance performance, foster social relationships and social support, organizational identification, enable job satisfaction, and work engagement [6-11]. However, there is currently a lack of research on their role during the pandemic.

Work engagement, a key positive motivational state of well-being at work, is a comprehensive and enduring positive mental state that employees experience at their workplace and consists of three dimensions: vigor (ie, high energy levels, mental resilience, and persistence), dedication (ie, a sense of significance and pride), and absorption (ie, deep concentration on work and challenges detaching from work) [12,13]. Work engagement among employees in Finland was favorable before the COVID-19 crisis: 63% experienced vigor, 64% experienced dedication, and 56% experienced absorption in their work often or always [5].

According to job demands-resources model, work engagement is particularly driven by job resources, which are positive psychological, physical, social, and organizational characteristics of work, such as a good organizational climate and social support from colleagues and supervisors, which help employees accomplish work goals and foster learning and personal growth [13,14]. Social support defined as emotional, informational, and instrumental support, which describes not only the functional importance of relationships, but also the quality of those relationships and social belonging, can be a great reciprocal resource, for example, in coping stress and enhancing self-efficacy [15-18]. Engaged employees are more likely to be proactive and productive in their work [19]. Furthermore, autonomy, possibility to engage in meaningful work, and opportunities to leverage their strengths and experience at work are important factors influencing employee engagement [20-21].

Based on the Conservation of Resources (COR) theory, people tend to obtain and protect valuable resources, and loss of resources plays a significant role in the development of psychological stress [22]. Work engagement, as an energetic resource that employees may possess, should be a key priority in organizations, as it can increase life satisfaction and can prevent employees from psychological distress, depression, anxiety, sickness absenteeism, and burnout [23-26]. Furthermore, work engagement has been associated with healthy cardiac autonomic activity and a low likelihood of disability pensions [27,28]. Notably, high levels of work engagement have also been associated with increased short-term psychological distress and with decreased psychological stress over time [29]. At the societal level, work engagement predicts less unemployment in the general population [27].

The COVID-19 pandemic, along with its associated increase in digital and remote work, has potentially transformed ways of working for good [30]. Prior literature indicates that in the digital work environment, employees appreciate the opportunity to influence their work and enjoy the freedom and flexibility to complete their tasks; thus, they experience agency and higher self-esteem [31]. Resources such as support from managers received on social media can prevent work-related psychological distress [32,33]. Recent studies on the COVID-19 pandemic have reported that personal resilience and organizational and social support can sustain employee well-being and prevent anxiety [34]. Low supervisor support can, in turn, predict lower well-being, including stress, exhaustion, and burnout [35]. Furthermore, a study on adults in the United States reported that psychological distress increased from 3.9% in 2018 to 13.6% in 2020 during the COVID-19 pandemic [36]. Indeed, employees in the medical field have reported increased psychological distress and decreased well-being owing to heightened demands and workloads [34,37].

According to the COR theory [22] resource gains (such as supervisor support) in themselves have only a modest effect on well-being, but instead acquire saliency in the context of resource loss. Thus, prolongation of the COVID-19 pandemic can be considered a resource threat for employees. It can be argued that perceived social support and task resources have been particularly important in autumn 2020 as social distancing policies had been implemented since spring 2020 [1,2], and normal social interactions and working practices have been highly limited for a prolonged time. Among the basic psychological needs, particularly relatedness (lack of social contacts) and competence (eg, reduced possibilities to effectively bring about desired effects and outcomes) have been affected [38].

Social media communication at work has increased during the COVID-19 pandemic [6], and prior evidence has shown that work-related social media communication can enhance occupational resources such as social support and organizational identification and moreover work engagement [8]. However, previous studies have also indicated that psychological distress is associated with decreased work engagement before [39] and during the COVID-19 pandemic in spring 2020 [40]. Thus far, little is known about the longitudinal associations between professional social media communication and work engagement or how professional social media communication has affected work engagement and employees' mental well-being during the COVID-19 pandemic.

This longitudinal study analyzed changes in work engagement among employees in Finland before and during the COVID-19 pandemic. Our study investigated whether changes in social media communication at work, perceived social support, task resources, and psychological distress are related to changes in employees' work engagement, especially at a time of a prolonged pandemic. We proposed the following hypotheses: (1) increased social media communication predicts an increase in work engagement; (2) increased perceived social support and task resources at work predict an increase in work engagement; (3) increased psychological distress predicts decreased work engagement; and (4) the association between work engagement and (i) social media communication, (ii) social support, and (iii) psychological distress have been stronger during rather than before the COVID-19 pandemic.

Methods

Participants and Procedure

Data from a 4-timepoint longitudinal survey on social media usage at work in Finland from 2019 to 2020 were acquired to represent the working population in Finland. The first survey was conducted in March to April 2019 (timepoint 1 [T1]; n=1817). The participants were recontacted in September to October 2019 (timepoint 2 [T2]; n=1318), March to April 2020 (timepoint 3 [T3]; n=1081), and September to October 2020 (timepoint 4 [T4]; n=1152). The fourth survey was sent to all original respondents, whereas the third survey was sent only to those who had responded to the second survey.

The final sample in this study (n=965; 45.08% female; mean age 44.97 years, SD 11.36 years) included respondents who answered all 4 surveys, and the response rate was 53.11%. We found no major bias when conducting nonresponse analyses and when comparing the sample with official census figures of the working population in Finland [8]. The sample encompassed all major occupational fields and covered all prominent areas of Finland [6]. Analyses focused on employees of working age (18-66 years) and those respondents who remained employed (n=868). Only those respondents who finished the whole survey were included in the final data set. The survey study involved no ethical issues according to the assessment of the Academic Ethics Committee of Tampere region in Finland. The survey was conducted in Finnish, and participation was voluntary. The research group designed the survey and collected data in collaboration with Norstat, whose web-based research panel was used to recruit participants.

Measures

Work-Related and Nonwork-Related Social Media Communication

We measured the frequency of social media usage for work-related communication by asking the question, "How often do you use social media to keep in touch with your colleagues or work community regarding work-related matters (eg, sharing information or agreeing on timetables)?" We measured the frequency of social media usage for nonwork-related communication by asking the question, "How often do you use social media to keep in touch with your colleagues or work community regarding nonwork-related matters?" Possible answers were 0="I don't use it," 1="less than weekly," 2="weekly," 3="daily," and 4="many times a day." Both social media communications were measured at every time point; that is, every 6 months.

Work Engagement

Work engagement is most often measured using the Utrecht Work Engagement Scale (UWES) [41]. The 9-item version of this scale, UWES-9, is used most often owing to its construct validity [42]. Example questionnaire items include the following: "At my work, I feel that I am bursting with energy" and "I feel happy when I am working intensely." Responses are scored on a scale ranging from 0="never" to 6="always/every day." All 3 dimensions of the UWES were summed up to create a composite variable with a range of 0-54 and the Cronbach α coefficient was measured for all timepoints, ranging from .95 to .96. Work engagement was measured at every timepoint; that is, every 6 months.

Perceived Social Support

Perceived social support at work was measured using 4 questions on social support received from colleagues, supervisors, and the work community in general. These questions originate from the second version of the Copenhagen Psychosocial Questionnaire (Multimedia Appendix 1) [43], and they have been previously validated as a measure for social support at work [8]. Scores associated with these 4 items were summed to obtain a composite variable with a range of 4-20. Higher figures indicate higher perceived social support. The scale showed high reliability (Cronbach α=.74-.79). Perceived social support was measured at every timepoint; that is, every 6 months.

Task Resources

Task resources were measured using 4 questions from the work organization and job content dimension of the second version of the Copenhagen Psychosocial Questionnaire (Multimedia Appendix 2) [43]. Scores associated with the 4 questions were summed to obtain a composite variable with a range of 4-20. The scale showed adequately high internal consistency (Cronbach α=.67-.69). Task resources were measured at every time point; that is, every 6 months.

Psychological Distress

We measured psychological distress using the 12-item General Health Questionnaire [44]. Example questions included the following: "Have you recently felt constantly under strain?" and "Have you recently felt capable of making decisions about things?" Scores associated with all items were summed to obtain a composite variable with a range of 0-36. Higher scores indicate higher psychological distress. The scale showed high reliability (Cronbach α=.89-.92) between measurement points. Psychological distress was measured at every timepoint; that is, every 6 months.

Background Variables

Sociodemographic variables considered herein included age, gender, and education. All background variables were assessed at every timepoint; that is, every 6 months.

Statistical Analyses

As descriptive statistics, we expressed data as mean (SD) values for continuous study variables and frequencies and proportions for categorical variables (Tables 1 and 2). In addition, SD values between measurements were calculated for the within-person–level variables. We also assessed correlations among our study variables measured at different timepoints (Multimedia Appendix 3).

For all our hypotheses, we analyzed whether the within-person variation in social media communication, perceived social support, task resources, and psychological distress predicted changes in work engagement. We tested our hypotheses using a hybrid (or within-between) linear regression model [45]. This method decomposes the association between the dependent variables and time-variant independent variables into within-person and between-person effects. This is carried out by adding the individual means of dependent variables (between-person effects) and individual deviations from the person means (within-person effects) into the model simultaneously. Between-person effects are then estimated as associations between the individual means of the dependent and independent variables. Within-person effects are estimated as associations between the dependent variable and the observed deviation from the individual means. Thus, the between-person effects describe static differences between individuals, whereas within-person effects describe a dynamic relationship between the timely fluctuations in both the dependent and independent variables.

Table 1. Descriptive statistics of the study variables: continuous variables.

Variables		Time				Within-person differences, SD
	Range	T1, mean (SD)	T2, mean (SD)	T3, mean (SD)	T4, mean (SD)	
Work engagement	0-54	38.78 (12.13)	39.08 (12.15)	39.29 (11.64)	38.42 (12.04)	5.35
Work-related social media communication	0-4	1.27 (1.21)	1.31 (1.19)	1.52 (1.21)	1.51 (1.25)	0.69
Nonwork-related social media communication	0-4	1.16 (1.06)	1.10 (0.99)	1.24 (1.06)	1.18 (1.01)	0.59
Social support	4-20	14.65 (2.86)	14.56 (2.87)	14.68 (2.91)	14.65 (3.01)	1.49
Task resources	4-20	13.89 (2.76)	13.98 (2.74)	14.03 (2.63)	13.90 (2.70)	1.31
Psychological distress	12-48	24.89 (6.21)	24.14 (5.60)	24.26 (5.29)	24.19 (5.53)	3.32
Age in T1 (years)	18-64	43.52 (10.86)	N/A[a]	N/A	N/A	N/A

[a] N/A: not applicable.

Table 2. Descriptive statistics of the study variables: categorical variables.

Variables	Values	
	Coding	Number of participants, n (%)
Females[a]	0/1	379 (43.7)
Basic education	0/1	26 (3.0)
Secondary degree	0/1	429 (49.4)

[a] Number of participants at each time point (T1-T4)=868; total number of observations (T1+T2+T3+T4)=3472.

Our analysis proceeded in 2 steps. Model 1 included all our within-person and between-person main effects and a random intercept. For work-related and nonwork-related social media communication, perceived social support, task resources, and psychological distress, the effects were estimated as within- and between-person effects. For time, we estimated only within-person effects. Time was included as binary variables (T2-T4) with T1 as a reference category. Gender, age, and education at T1 were added to the model as between-person variables, as they varied only between persons.

To test our hypothesized moderation effects, within-person interaction terms including work-related and nonwork-related social media communication, perceived social support, task resources, and psychological distress at T4 were added to the model; Schunck [46] has described the estimation of within-person interaction terms. The significant interaction terms (95% CI) are reported in Model 2 in Tables 3 and 4. We report unstandardized regression coefficients (B), their estimated SE values, significance (*P* value), the variance of random intercept, and a log pseudolikelihood estimate in Tables 3 and 4. For effect size estimates, we reported Cohen f^2 coefficients for all the significant predictors. These coefficients were calculated using the approach described by Selya et al [47] and they can be interpreted as the proportion of explained variance associated with certain independent variables [48].

Table 3. Within-between models predicting changes in work engagement with time: fixed effects.

Variables	Model 1		Model 2	
	B (SE)	*P* value	B (SE)	*P* value
Constant	4.84 (3.82)	.21	3.99 (3.89)	.31

Variables	Model 1	Model 2
Intercept, variance (95% CI)	52.49 (45.37-60.73)	52.52 (45.40-60.76)
Log pseudolikelihood	–11753.96	–11748.44

Results

The results of descriptive statistical analysis are shown in Tables 1 and 2. There were no significant changes in work engagement in T1-T3; however, in T4, work engagement decreased (B=–0.66; *P*=.02) (Table 3). The effect size of this change was low (Cohen f^2<.01). Among the other within-person variables, an increase in work-related social media communication (B=0.38; *P*=.009), social support (B=0.82; *P*<.001), and task resources (B=0.91; *P*<.001) were associated with increased work engagement. Increased psychological distress, in turn, was associated with reduced work engagement (B=–0.28; *P*<.001). The variance in work engagement was mainly explained by social support (Cohen f^2=.06), task resources (Cohen f^2=.05), and psychological distress (Cohen's f^2=.04), and the effect size for work-related social media communication was low (Cohen f^2<.01).

Between-person differences in nonwork-related social media communication (B=1.35; Cohen f^2<.01; *P*=.003), social support (B=0.72; Cohen f^2<.01; *P*<.001), and task resources (B=1.89; Cohen f^2=.01; *P*<.001) were positively associated with average work engagement, yet they only explained a marginal share of the variance in work engagement. Between-person differences in psychological distress, in turn, were negatively associated with work engagement (B=–0.57; *P*<.001). The effect size for this association was low (Cohen f^2<.01). In addition, female gender (B=4.02; *P*<.001) and age (B=0.08; *P*=.003) were associated with between-person differences in work engagement.

This implies that females reported higher work engagement on average than males, and older respondents also had higher work engagement on average. However, the effect size was low both for gender (Cohen $f^2<.01$) and age (Cohen $f^2<.01$).

Among our moderations (model 2), only the interaction effect between T4 and psychological distress was significantly related to work engagement (B=–0.14; *P*=.012). As expected, the negative association between within-person differences in work engagement and psychological distress was stronger in autumn 2020 (B=–0.39) than at T1 (B=–0.25; *P*<.001). However, the overall proportion of the variance in work engagement explained by this interaction was low (Cohen $f^2<.01$).

Discussion

Principal Findings

This study longitudinally investigated how social media communication at work predicts work engagement. Our theoretical and empirical model was based on the job demands-resources model and COR theory and considered the role of social support and task resources at work, along with psychological distress. Our results show that work engagement remained stable and only decreased in autumn 2020. Within-person changes in social media communication at work, social support, task resources, and psychological distress were associated with work engagement. Moreover, work engagement decreased during autumn 2020 when psychological distress had a stronger negative association with work engagement compared to that before the COVID-19 outbreak.

Our findings partly support hypothesis 1 and fully support hypothesis 2, thus demonstrating that more intensive work-related social media communication and higher perceived social support and task resources are associated with higher within-person work engagement. Nonwork-related communication with colleagues, perceived social support, and task resources were associated with between-person work engagement. However, within-person changes in nonwork-related social media communication did not predict changes in work engagement. Women and older people experienced higher work engagement, as reported previously for individuals in Finland and Europe [49,50].

Increased psychological distress was associated with reduced within-person work engagement, thus supporting hypothesis 3. Our results do not support hypotheses 4-i and 4-ii as the associations between work engagement and social media communication, perceived social support, and task resources did not change during the COVID-19 pandemic. The results partly support hypothesis 4-iii because the within-person association between psychological distress and work engagement was stronger during the COVID-19 pandemic (ie, autumn 2020).

Comparison With Prior Work

Our study is timely and the first one to offer longitudinal evidence regarding internal and external social media communication, both work-related and nonwork-related, in organizations and the related well-being implications, before and during the COVID-19 pandemic. Our findings revealed that work engagement remained considerably state at the onset of the COVID-19 pandemic during spring 2020. Hence, our results provide interesting insights and are in contrast with those of prior studies reporting that major disasters usually provoke stress and reduce resources [22,51]. However, prolonged uncertain situations have detrimental effects on well-being [52], which our results also confirm.

Increased psychological distress was associated with reduced work engagement in the within-person model, which is in line with prior reports on stress and social media use [53,54]. Individuals experienced higher psychological distress and lower work engagement during the autumn 2020, when COVID-19 was already well-known, and the crisis was underway. Therefore, our results contribute to the current literature on crises and the use of information and communication technologies [55,56], which indicate that a continued crisis has a negative influence on employee well-being and provides further knowledge, especially on professional social media use during the COVID-19 pandemic.

The significant role of various job resources in work engagement construction has been established in prior studies and in the context of social media [8,13,14]. Our findings strengthen the role of job resources in boosting work engagement during the pandemic by demonstrating that an increase in perceived social support and task resources fosters within-person and between-person work engagement.

Our findings have practical implications for organizations by demonstrating that work engagement decreased during autumn 2020, while psychological distress was stronger at that timepoint. Employees continued to work under uncertain conditions in autumn 2020 with no certain signs of future relief. Thus, providing mental health support for employees in such situations is crucial. The importance of supervisor support in alleviating employees' emotional exhaustion and feelings of uncertainty regarding COVID-19 has been previously reported [57], which our findings also emphasize. Furthermore, our results indicate that work-related social media communication is associated with enhanced work engagement, thus explaining within-person variation. Hence, communication with colleagues via social media can also serve as an important job resource that supports employees' resources and vigor, as well as their dedication to and absorption in their work.

Increased nonwork-related social media communication did not explain within-person variation in work engagement. We observed only between-person differences because those with high nonwork-related social media communication also had a higher level of work engagement on average. Employees who use social media actively for informal communication are also the ones who engage more in their work. This is because when engaged, employees invest energy into their work-related roles and therefore behave more proactively [58] and have higher contextual performance; that is, an individual's propensity to behave in ways that facilitate the social and psychological context of an organization [59]. Furthermore, the association between informal social media communication and work engagement might be more complex. For example, prior literature has reported that the association between informal social media communication and work engagement is mediated through other factors such as social support and organizational identification [8].

Moreover, increased social support and task resources were related to enhanced within-person and between-person work engagement. The results emphasize the importance of supporting employees in using their expertise, maintaining a sense of meaningfulness, providing possibilities to influence their work content and load, and offering and receiving social support.

Strengths and Limitations

We used a longitudinal, nationally representative sample, which enabled the analysis of timepoints before and during the COVID-19 crisis and the related effects on well-being, which can regard as one of the strengths of this study. The response rate was high, and our survey included a very limited number of missing observations. The study design with work-related and nonwork-related social media communication was novel, and a similar longitudinal study has not been performed before. The study was conducted with employed people in Finland and did not examine the COVID-19 crisis cross-nationally. Because this was an observational study, the associations reported herein should not be directly interpreted as causal relationships. Some effect sizes were low, but effect sizes for the main results remained significant even though our model was adjusted for a number of factors. This study was also limited to self-reported information.

Conclusions

Work engagement decreased during autumn 2020 at a time when psychological distress had a stronger negative association with work engagement. Social media communication at work, perceived social support, and task resources were also associated with higher work engagement. Overall, work engagement remained relatively stable during the COVID-19 crisis. However, providing mental health support during a prolonged crisis is crucial for organizations. Moreover, supporting employees' resources at work is important in maintaining employee work engagement, in which social media communication can be of help.

Abstract

Background: The COVID-19 pandemic has highlighted the importance of rapid dissemination of scientific and medical discoveries. Current platforms available for the distribution of scientific and clinical research data and information include preprint repositories and traditional peer-reviewed journals. In recent times, social media has emerged as a helpful platform to share scientific and medical discoveries.

Objective: This study aimed to comparatively analyze activity on social media (specifically, Twitter) and that related to publications in the form of preprint and peer-reviewed journal articles in the context of COVID-19 and gastroenterology during the early stages of the COVID-19 pandemic.

Methods: COVID-19–related data from Twitter (tweets and user data) and articles published in preprint servers (bioRxiv and medRxiv) as well as in the PubMed database were collected and analyzed during the first 6 months of the pandemic, from December 2019 through May 2020. Global and regional geographic and gastrointestinal organ–specific social media trends were compared to preprint and publication activity. Any relationship between Twitter activity and preprint articles published and that between Twitter activity and PubMed articles published overall, by organ system, and by geographic location were identified using Spearman's rank-order correlation.

Results: Over the 6-month period, 73,079 tweets from 44,609 users, 7164 journal publications, and 4702 preprint publications were retrieved. Twitter activity (ie, number of tweets) peaked in March 2020, whereas preprint and publication activity (ie, number of articles published) peaked in April 2020. Overall, strong correlations were identified between trends in Twitter activity and preprint and publication activity ($P<.001$ for both). COVID-19 data across the three platforms mainly concentrated on pulmonology or critical care, but when analyzing the field of gastroenterology specifically, most tweets pertained to pancreatology, most publications focused on hepatology, and most preprints covered hepatology and luminal gastroenterology. Furthermore, there were significant positive associations between trends in Twitter and publication activity for all gastroenterology topics (luminal gastroenterology: $P=.009$; hepatology and inflammatory bowel disease: $P=.006$; gastrointestinal endoscopy: $P=.007$), except pancreatology ($P=.20$), suggesting that Twitter activity did not correlate with publication activity for this topic. Finally, Twitter activity was the highest in the United States (7331 tweets), whereas PubMed activity was the highest in China (1768 publications).

Conclusions: The COVID-19 pandemic has highlighted the potential of social media as a vehicle for disseminating scientific information during a public health crisis. Sharing and spreading information on COVID-19 in a timely manner during the pandemic has been paramount; this was achieved at a much faster pace on social media, particularly on Twitter. Future investigation could demonstrate how social media can be used to augment and promote scholarly activity, especially as the world begins to increasingly rely on digital or virtual platforms. Scientists and clinicians should consider the use of social media in augmenting public awareness regarding their scholarly pursuits.

coronavirus; COVID-19; social media; gastroenterology; SARS-CoV-2; research; literature; dissemination; Twitter; preprint

Introduction

COVID-19, caused by the novel coronavirus SARS-CoV-2 (severe acute respiratory syndrome coronavirus), emerged into public view in December 2019 and resulted in a pandemic that has affected six continents, and it continues to indiscriminately affect individuals of all ages, races, and ethnicities. According to the World Health Organization, there have been more than 33,000,000 confirmed cases of COVID-19 globally, including more than 1,000,000 deaths reported by the end of September 2020—only 9 months after its emergence [1]. With time, different countries faced surges in cases straining their health care systems in unprecedented ways. It is during these times that the rapid dissemination of information related to this highly contagious virus and its management has been crucial.

Even though initial experiences related to COVID-19 primarily described respiratory complications, reports of gastrointestinal/gastroenterology (GI) involvement became more evident with increased clinical experience [2]. Although the extent of GI involvement with COVID-19 was uncertain based on early published experiences, it was postulated that this could be substantial due to the identification of the entry mechanism of SARS-CoV-2 that utilizes the angiotensin-2 (ACE2) receptor pathway, which is found throughout the GI tract, liver, and pancreas. Given the pathogen's similarities to the coronavirus known to cause severe acute respiratory syndrome (SARS) and Middle East Respiratory Syndrome (MERS), investigators suspected that prior experiences with these preceding viruses could provide insight into the current COVID-19 pandemic. Thus, GI luminal manifestations, the involvement of the liver and pancreas, and the management of unique GI patient populations were all considered areas of clinical and research interest [3-5]. Considering the rapid spread of COVID-19 and the consequent interruption of health care services across multiple fronts, the publishing of international experience with COVID-19 along with frequent updates in clinical guidance documents have assisted the GI community in managing this novel disease [6-9]. Furthermore, in an effort to mitigate the spread of infection, endoscopists have encountered significant changes to endoscopic practices by adopting new preprocedure regulations, use of enhanced personal protective equipment, and the rearrangement of endoscopy units to facilitate social distancing [10,11]. Additionally, with the implementation of national "lockdowns," the ability to share clinical experiences, analyze medical data, and disseminate management strategies for COVID-19 has become reliant on electronic media [12]. During these unprecedented times, the medical community has increasingly utilized social media (eg, Twitter, Facebook, TikTok) for communication and to facilitate interdisciplinary discussion [13,14].

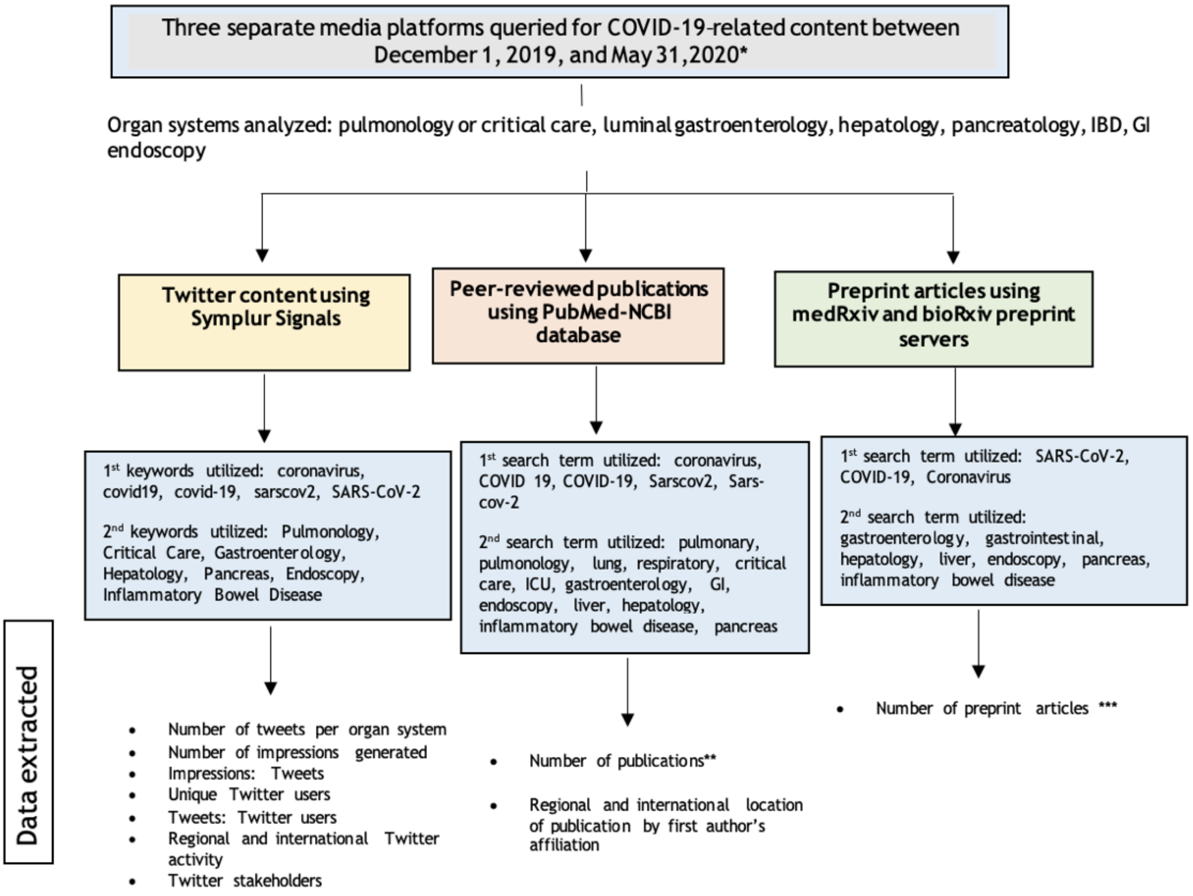
Social media platforms such as Twitter are social networking services through which any user or organization with an account, including those belonging to the scientific and medical communities, can share information and achievements. Compared to other professions, the health care community has been relatively reluctant in utilizing social media for professional purposes related to concerns on its potential impact on employment, medicolegal liability, and relationships among patients and colleagues [15-17]. Nonetheless, as these platforms continue to gain global acceptance and utilization, the ability to collect and analyze data from social media platforms has become essential in understanding health care–related needs, shifting public health interests, and highlighting areas for further medical study [18]. In this study, we aimed to explore COVID-19–related social media activity pertaining to the fields of gastroenterology and hepatology during the initial 6-month period of the COVID-19 pandemic, when knowledge about the virus was new and limited. Furthermore, we aimed to compare activity on social media—specifically Twitter—with that via more traditional channels of medical information sharing and distribution such as publications in medical journals and preprint repositories.

Methods

Data Collection for COVID-19–Related Twitter Activity

Data were collected using the publicly available Twitter analytics platform Symplur Signals [19]—a health care social media analytics platform that utilizes algorithms with natural language processing to provide in-depth information on Twitter activity. Data on topics related to COVID-19 were collected by performing specific searches categorizing the topics by organ system (Multimedia Appendix 1). Data were captured over the first 6 months of the COVID-19 pandemic, from December 1, 2019, to May 31, 2020. In an effort to capture the longitudinal evolution of social media use during this period, each month was split into half (ie, day 1-15 and day 16 to the end of the month). Data collected included total number of tweets and retweets, total number of impressions, total number of users, and user data, including the place of origin—by country (globally) and by state (within the United States). The ratios of tweets per Twitter user and impressions per tweet were also calculated (Figure 1). Definitions of these terms can be found in Multimedia Appendix 1.

Figure 1. Study flow diagram outlining the data extraction method from 3 media platforms analyzed (Twitter, PubMed-NCBI, and medRxiv or bioRxiv). *Each month of the specific study period was split into half-month intervals for the purposes of analysis. **Duplicate publications from separate searches were individually reviewed and reorganized into the most appropriate subject group in order to eliminate potential for publications to be accounted for more than once. ***A follow-up review of preprint articles pertaining to COVID-19 and gastroenterology that ultimately resulted in formal peer-reviewed journal publications was performed for July 2020. IBD: inflammatory bowel disease; GI: gastrointestinal.



Data Collection for COVID-19–Related Preprints and Publications

Preprint articles are research manuscripts shared publicly before peer review, which allows for rapid dissemination of information, thereby helping to inform policy and clinical practice in a timely manner. Preprint repositories have gained considerable attention over the course of the COVID-19 pandemic and have been increasingly utilized for the dissemination of crucial pandemic-related research. For our analysis, preprint articles related to COVID-19 biomedical research were identified using two popular preprint servers: medRxiv and bioRxiv. Specific search terms (see Multimedia Appendix 1) were used to identify and extract COVID-19 preprint articles for each half-month period across the 6-month study period for comparison with Twitter data. Furthermore, a follow-up review of the preprint articles pertaining to COVID-19 and gastroenterology that ultimately resulted in formal peer-reviewed journal publications was performed for the month of July 2020. This was done to account for the delay associated with the formal publication of a preprint article.

For the analysis of peer-reviewed publications, the PubMed–NCBI database was used to search for all publications pertaining to COVID-19 over the 6-month study period. The specific search terms used are detailed in Multimedia Appendix 1. All citations resulting from PubMed searches were recorded, and the search results were further filtered by half-month time intervals, identical to the search methods used for Twitter content and preprint articles for the purposes of comparison. For both preprints and publications, articles were further subgrouped by organ system topic. Duplicate publications from separate searches were individually reviewed and recategorized into the most appropriate subject group, thereby eliminating the potential for publications to be accounted for more than once. Finally, for each publication, the geographic location of the first author's institution was recorded.

Analysis of Social Media, Preprint, and Publication Activity

The primary outcome of the analysis was to identify the peak activity across the 3 platforms, as this shows how efficiently one platform could disseminate information as compared to the others. "Activity" was defined by the number of tweets (via Twitter), or publications (when referring to preprint or publication databases, such as bioRxiv and medRxiv or PubMed, respectively) produced. "Dissemination" could be defined in different ways as referenced by a previous systemic review report published by the Agency for Healthcare Research and Quality (AHRQ); however, for the purpose of this study, it was defined as “the active and targeted distribution of information or interventions via determined channels using planned strategies to a specific public health or clinical practice audience” [20]. In this study, the information distributed is the content of tweets or articles published in preprint repositories or accessible via the PubMed database. Of note, Twitter impressions is a convenient way to measure the exact distribution of the tweet content, as it calculates how many users would have been sent a particular tweet based on the number of followers the user who posted the tweet originally had. Secondary outcomes included (1) peak activity in each platform overall and then by GI subtopic, (2) peak activity in each platform by geographic location, and (3) comparison of trends between the different platforms overall, as well as by GI subtopic (see Multimedia Appendix 1).

Summary statistics of baseline data for tweets, impressions, preprints and PubMed publications are presented as frequencies for categorical data unless otherwise specified. Spearman’s rank-order correlation was performed to determine the relationship between Twitter activity (ie, tweets and impressions) and PubMed publications overall, by organ system and geographic location, as well as by Twitter activity and preprint articles overall and by organ system. Analysis was performed using STATA 15 (StataCorp, LLC) software. Statistical significance was set at *P*<.05. All authors had access to the study data and reviewed and approved the final manuscript.

Results

COVID-19–Related Publications and Twitter Activity Trends

Over the 6-month study period from December 1, 2019, through May 31, 2020, 73,079 tweets were identified from a total of 44,609 users, generating 207,039,610 impressions on the topic of COVID-19. During this same period, 7164 publications pertaining to COVID-19 were found to be indexed in PubMed along with 4702 preprints archived in medRxiv and bioRxiv repositories. The overall summary of Twitter and research publication activity by half-month time interval is shown in Table 1. Twitter activity, with regard to original tweets on the topic of COVID-19 did not appear until the latter half of January 2020, which resulted in 245 original tweets. This activity progressively increased thereafter and peaked during March 16-31, 2020, with 20,660 original tweets before gradually decreasing over the remaining study interval (Figure 2).

Table 1. A comparison of productivity trends by half-month intervals of COVID-19–related publication, preprint, and Twitter activity from December 2019 through May 2020.

Informational sources	December 2019		January 2020		February 2020		March 2020		April 2020		May 2020

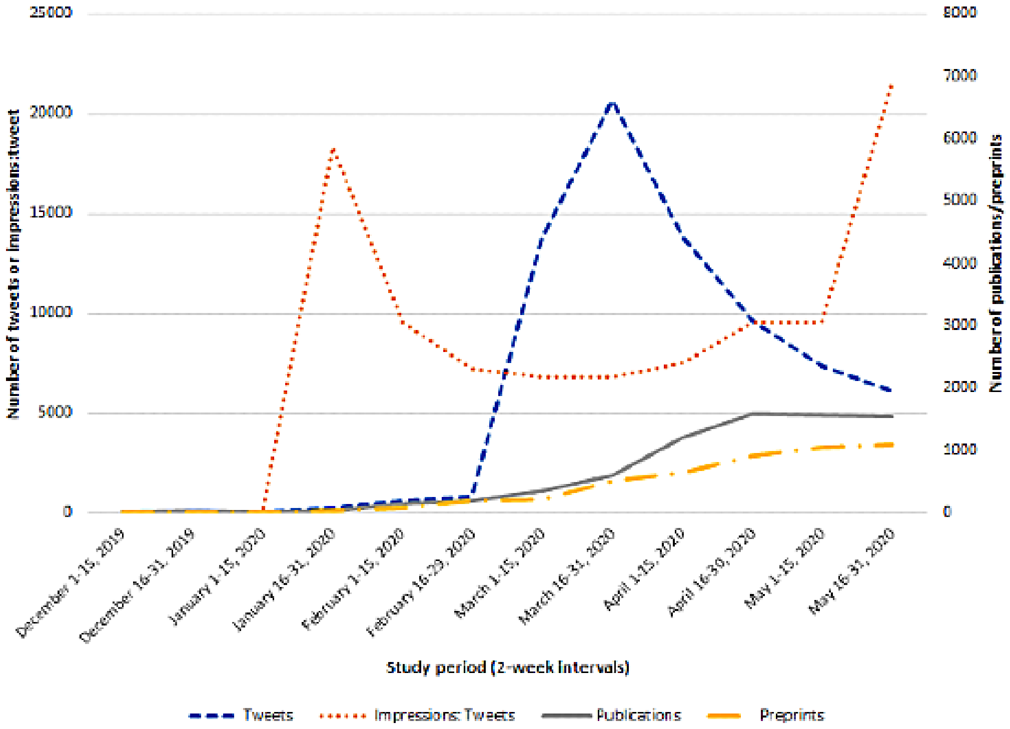
[a] Publications indexed in PubMed–NCBI database.

[b] Preprints located in the medRxiv and bioRxiv repositories.

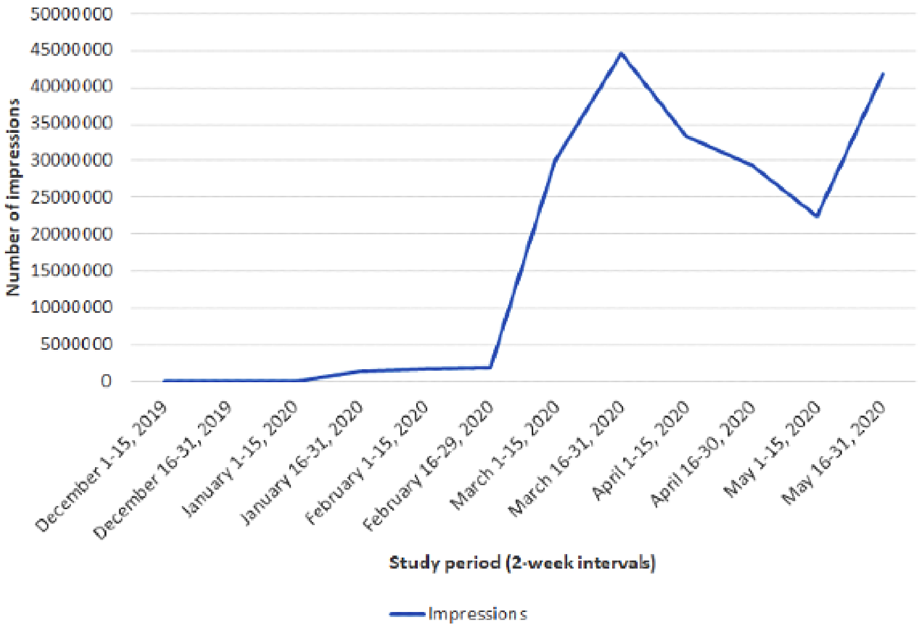
[c] Tweets and associated variables extracted using Symplur Signals search engine.

Figure 2. Trend of COVID-19–related tweets, ratio of impressions to tweets, publications and preprints. Twitter activity from December 1, 2019, through May 31, 2020, captured at half-month intervals by using the Twitter analytics platform Symplur Signals. Preprints from medRxiv and bioRxiv repositories were also abstracted during this time period along with publications indexed in the PubMed-NCBI database.



A similar pattern of activity was observed among the number of Twitter users who posted tweets related to COVID-19, which increased from 165 users to 13,034 users between January and the latter half of March 2020. Twitter impressions followed a similar pattern, with a peak observed during the second half of March 2020. Interestingly, a second peak in impressions was apparent during the latter half of May 2020, which was not observed with regard to the number of tweets and Twitter users (Figure 3). On average, the number of tweets per Twitter user ranged from 1.48 to 1.97. Impressions generated per tweet were initially high (5874 impressions/tweet) in the latter half of January 2020 but did not peak until the latter half of May 2020 (6880 impressions/tweet). Temporal trends are further detailed in Figure 2.

Figure 3. Trend of COVID-19 Twitter impressions. Number of impressions generated from Twitter from December 1, 2019, through May 31, 2020, captured at half-month intervals by using the Twitter analytics platform Symplur Signals.



Scientific COVID-19–related articles indexed in PubMed as well as preprints in medRxiv and bioRxiv servers followed a similar trajectory as Twitter activity, with both the first peer-reviewed articles and the first preprints becoming available during the second half of January 2020 [21]. However, unlike Twitter activity that peaked in the second half of March 2020, publications and preprints reached peak activity around the second half of April 2020. Notably, we observed a parallel rise in the number of preprints and PubMed publications (Table 1 and Figure 2).

A moderately strong correlation was demonstrated between Twitter activity (ie, number of tweets) and number of PubMed publications (ρ=0.58), as well as between Twitter activity and number of preprints (ρ=0.57) across the study duration (*P*<.001 for both; Table 2).

Similarly, there was a moderately strong association between the number of Twitter impressions and PubMed publications (ρ=0.56, *P*<.001), as well as between the number of Twitter impressions and preprints (ρ=0.54, *P*<.001; Table 3).

Table 2. Correlation between Twitter activity (tweets) and PubMed publications and between Twitter activity (tweets) and preprints by organ system. Italicized values indicate statistical significance.

Organ system	Tweets and PubMed publications (ρ)	*P* value	Tweets and preprints (ρ)	*P* value
Overall trend	0.58	*<.001*	0.57	*<.001*

COVID-19–Related Twitter, Publication, and Preprint Content Classified by Organ System Topic

Overview

Analysis of Twitter, publication, and preprint data pertaining to the effects of COVID-19 on specific organ system topics are outlined in Table S1 of Multimedia Appendix 2, and trends are illustrated in Figure 4 and Figure 5. The majority of COVID-19–related tweets (58,792/73,079, 80.4%), publications (6713/7164, 93.7%), and preprint articles (4567/4702, 97.1%) covered the topic of pulmonology or critical care. Gastroenterology was a small subset of these topics; however, within the field, the majority of tweets were on the topics of pancreatology (5804/73,079, 7.9%), followed by luminal gastroenterology (3318/73,079, 4.5%), inflammatory bowel disease (2818/73,079, 3.9%), GI endoscopy (1764/73,079, 2.4%), and hepatology (583/73,079, 0.8%). With regard to gastroenterology-related publications, the majority of articles were on the topic of hepatology (236/7250, 3.3%) followed by GI endoscopy (111/7250, 1.5%), luminal gastroenterology (64/7250, 0.9%), IBD (30/7250, 0.4%), and pancreatology (10/7250, 0.1%). Preprint publications were primarily on the topics of luminal gastroenterology (21/4702, 0.4%), hepatology (18/4702, 0.4%), and IBD (3/4702, 0.1%) (see Table S1 in Multimedia Appendix 2).

Figure 4. Trend of Twitter, publication, and preprint activity related to COVID-19 and pulmonary or critical care topics. Comparison of the number of tweets posted with articles published in peer-reviewed journals and preprints published pertaining to COVID 19 and pulmonary or critical care at half-month intervals between December 2019 and May 2020.

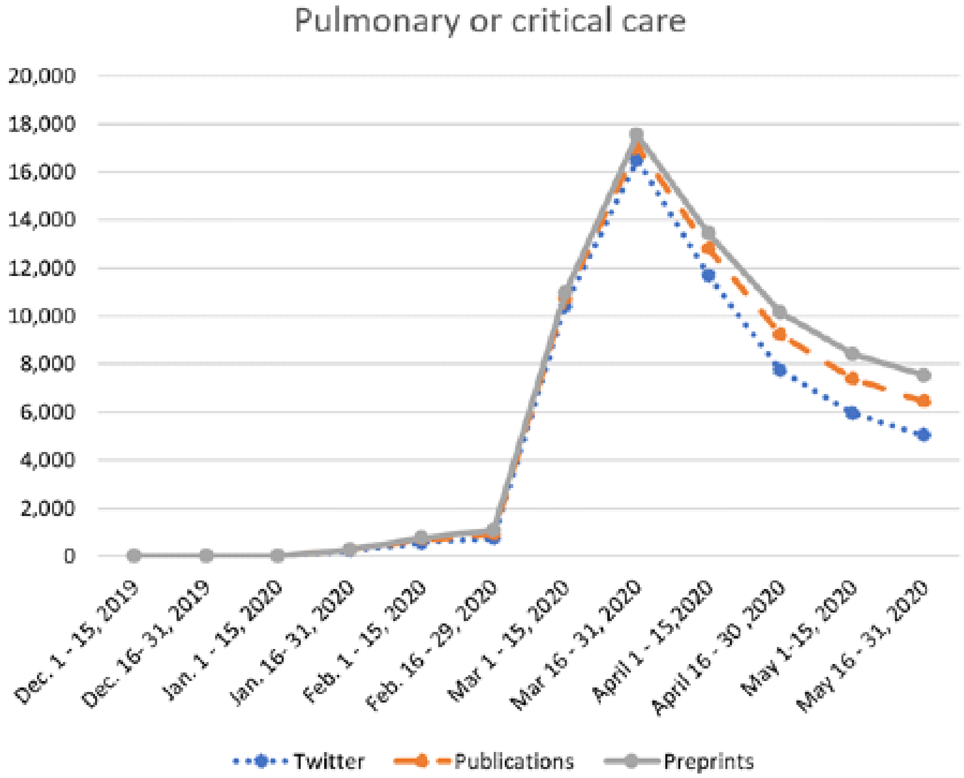

Figure 5. Trend of COVID-19 and gastroenterology subspecialty–related Twitter, publication, and preprint activity. Trend in the number of (A) tweets, (B) publications, and (C) preprints published pertaining to COVID 19 and gastroenterology subspecialty topics at half-month intervals between December 2019 and May 2020. GI: gastrointestinal; IBD: inflammatory bowel disease.

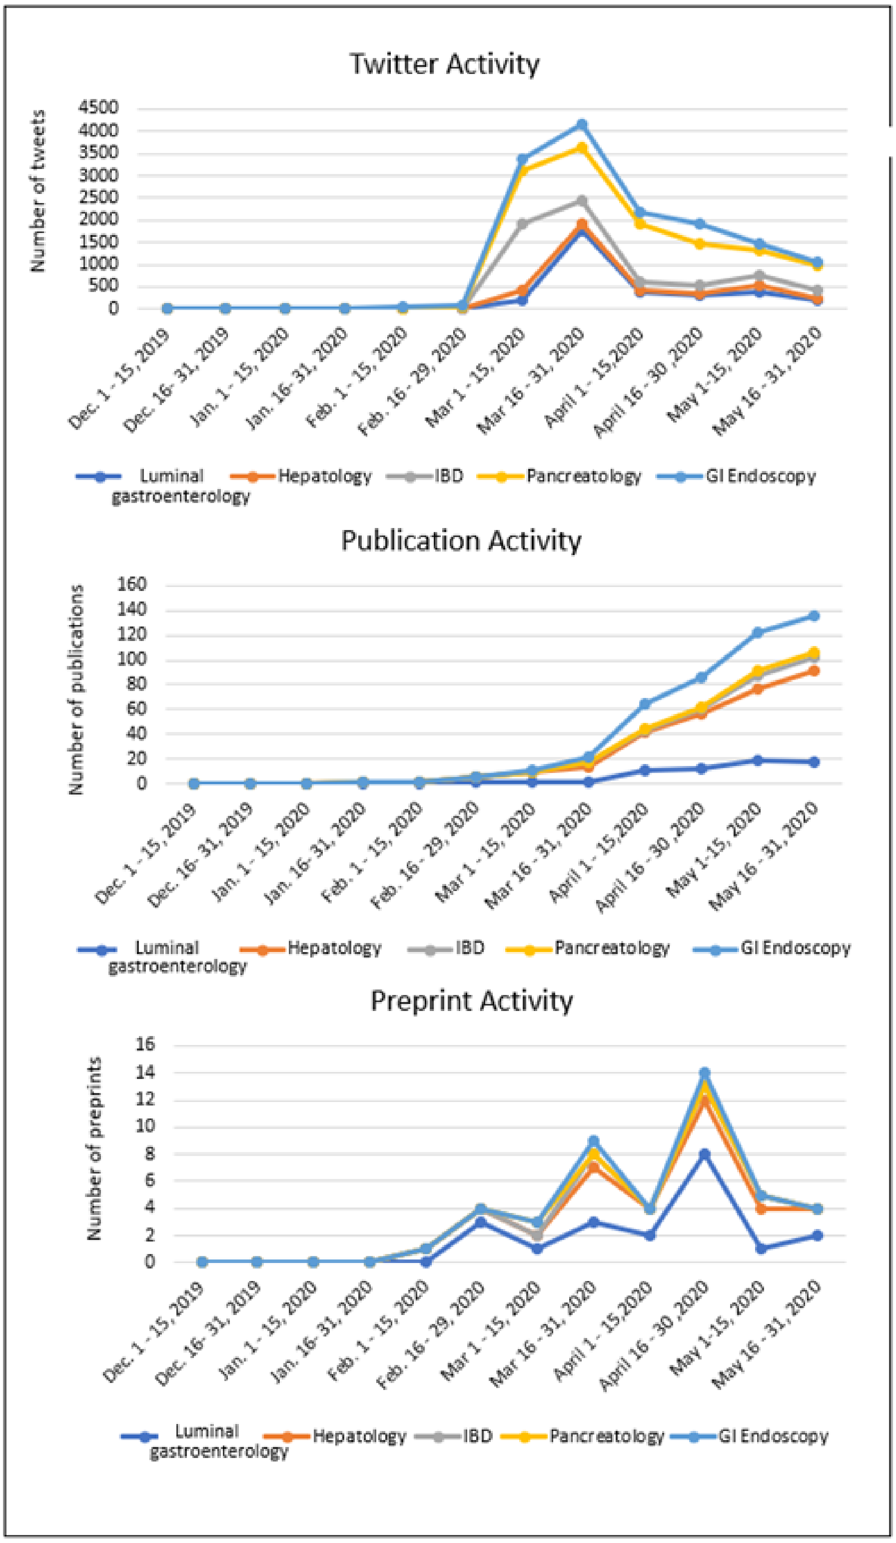


Pulmonology and Critical Care

Approximately 59,000 COVID-19–related tweets analyzed across the study period were on the topic of pulmonology or critical care. The most significant increase in tweets on this topic occurred between February and March 2020, with a nearly 22-fold increase, and an ultimate peak in activity (n=16,489) was observed in the latter half of March (Figure 4 and Table S1 in Multimedia Appendix 2).

A total of 6713 peer-reviewed articles on the topic of pulmonology or critical care and COVID-19 were indexed in PubMed during the 6-month study period, and these first appeared in January 2020. The most significant increase (ie, 2-fold) in the number of publications on COVID-19 and pulmonology or critical care was observed between the latter half of March 2020 and the start of April 2020. As compared to peer-reviewed publications, there were approximately one-third fewer preprint articles (n=4567) in medRxiv and bioRxiv related to COVID-19 and pulmonology or critical care identified during the study period. Moreover, on the topic of pulmonology or critical care and COVID-19, the longitudinal trend in preprint article availability appears to have paralleled publications indexed in PubMed; however, for preprint articles, the most significant rise was observed 2 weeks prior to that observed with PubMed publications, specifically between the first and second half of March (Figure 4 and Table S1 in Multimedia Appendix 2).

There was a strong correlation between both the number of COVID-19–related tweets and peer-reviewed publications (ρ=0.8, *P*=.002) as well as between the number of COVID-19–related tweets and preprints (ρ=0.8, *P*=.003, respectively; Table 2) on the topic of pulmonology or critical care. Similarly, there was a strong correlation between both pulmonology or critical care–related Twitter impressions and publications (ρ=0.8, *P*=.001) as well as between Twitter impressions and preprints (ρ=0.8, *P*=.002; Table 3).

Gastroenterology

A total of 14,285 tweets concerning the field of gastroenterology and COVID-19 (encompassing subspecialty fields of luminal gastroenterology, IBD, hepatology, GI endoscopy, and pancreatology) were identified during the study period (Figure 5 and Table S1 in Multimedia Appendix 2). Among all tweets recorded during the 6-month study period, 19.6% (14,287/73,079) were on the topic of COVID-19 and gastroenterology. The longitudinal trend in number of gastroenterology-related tweets (including subspecialty gastroenterology fields) paralleled that observed with pulmonology or critical care–related tweets, with an approximate 45-fold increase in the number of tweets spanning the latter half of February 2020 (n=75) and peaking in the second half of March 2020 (n=4171). When further stratified by subspecialty field, the majority of COVID-19 and gastroenterology–related tweets were on the topic of pancreatology (5804/14,287, 40.6%), followed by luminal gastroenterology (3318/14,287, 23.2%), IBD (2647/14,287, 19.7%), GI endoscopy (1764/14,287, 12.3%), and hepatology (583/14,287, 4.1%).

A total of 449 peer-reviewed publications related to COVID-19 and gastroenterology were identified in PubMed during the study period. In contrast to Twitter activity, the majority of these publications were on the topic of hepatology (235/449, 52.3%) followed by GI endoscopy (111/449, 24.6%), luminal gastroenterology (64/449, 14.2%), IBD (30/449, 6.7%), and pancreatology (10/449, 2.2%). Similar to Twitter activity, PubMed publications on the topics of luminal gastroenterology and hepatology first appeared in the latter half of January 2020. The most significant increase in COVID-19 and liver–related publications was observed between the latter half of March (n=12) and early April 2020 (n=31), with an over 2.5-fold increase in the number of publications on this topic. Luminal gastroenterology–related publications, which first appeared in the latter half of February 2020, significantly increased between the second half of March and early April 2020, with a 5-fold increase as detailed in Table S1 in Multimedia Appendix 2.

A total of 45 COVID-19 and gastroenterology–related preprints were archived in medRxiv and bioRxiv servers over the study period. Longitudinal analysis showed that the number of preprints on the topic of gastroenterology peaked in the latter half of April 2020. When further stratified by subspecialty, unlike that observed with peer-reviewed publications, the majority of preprints covered luminal gastroenterology (21/45, 46.7%), followed by hepatology (18/45, 40%), IBD (3/45, 6.7%), GI endoscopy (2/45, 4.4%), and pancreatology (1/45, 2.2%) (Table S1 in Multimedia Appendix 2).

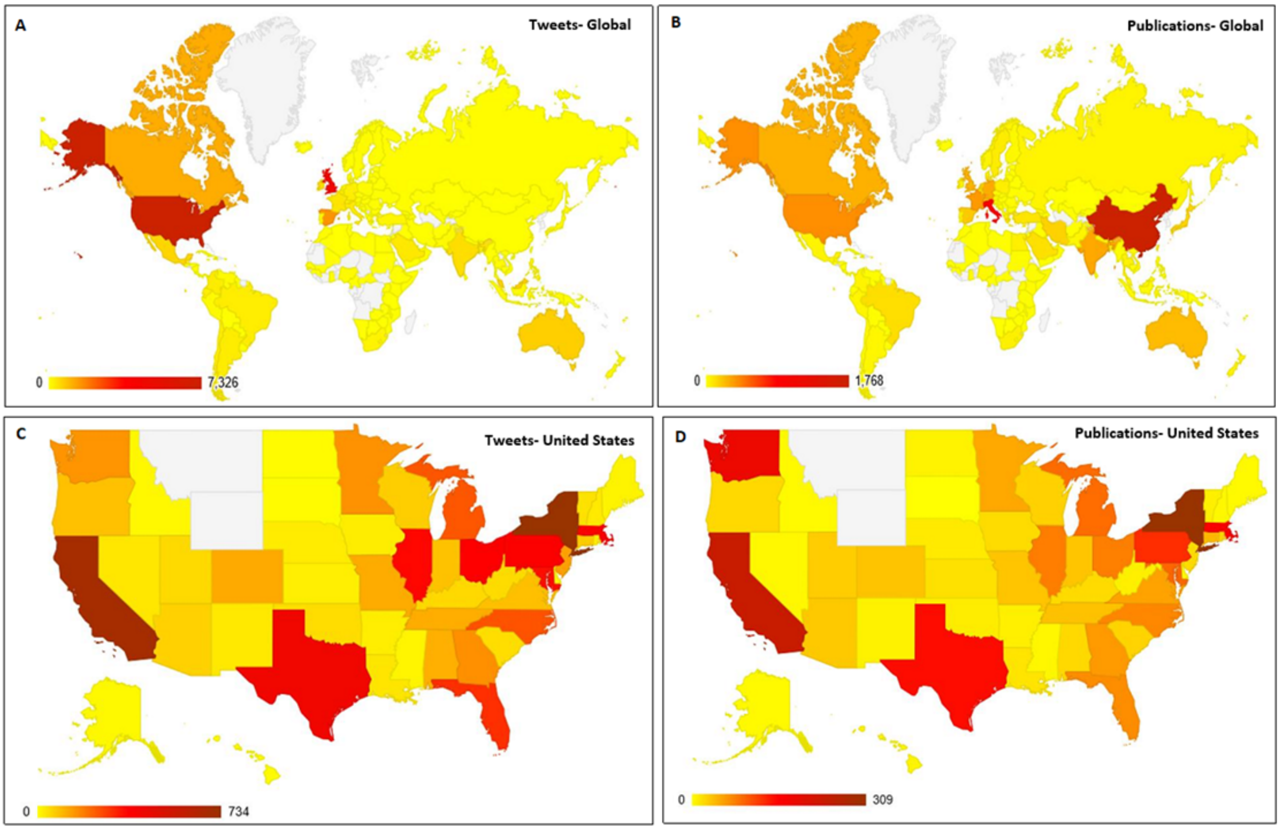
Similar to pulmonology or critical care–related content, there was a strong correlation between tweets and peer-reviewed publications (ρ=0.6, *P*=.03) as well as between tweets and preprints (ρ=0.7, *P*=.009) on the topic of luminal gastroenterology. Additionally, a strong correlation was identified between both the number of tweets and peer-reviewed publications (ρ=0.7, *P*=.006) as well as between tweets and preprints (ρ=0.7, *P*=.009) on the topic of COVID-19 and hepatology. A similarly strong correlation was observed between the number of tweets and PubMed publications on the topic of GI endoscopy (ρ=0.7, *P*=.007), the number of tweets and preprints on the topic of GI endoscopy (ρ=0.7, *P*=.02), and the number of tweets and peer-reviewed publications on the topic of COVID-19 and IBD (ρ=0.7, *P*=.008). In contrast, no significant correlation was identified between tweets and peer-reviewed publications or preprints on the topic of COVID-19 and pancreatology (Table 2).

Regarding COVID-19 and luminal gastroenterology content, a strong correlation was observed between both Twitter impressions and peer-reviewed publications (ρ=0.7, *P*=.009) as well as between Twitter impressions and preprints (ρ=0.7, *P*=.006). Similarly, strong correlations were identified between Twitter impressions and peer-reviewed publications on the topics of COVID-19 and hepatology (ρ=0.7, *P*=.005), IBD (ρ=0.8, *P*=.004), and GI endoscopy (ρ=0.8, *P*=.004). There was no significant correlation between Twitter impressions and publications on the topic of COVID-19 and pancreatology. In evaluating the association between Twitter impressions and preprints, strong associations were found on the topics of hepatology (ρ=0.7, *P*=.006) and GI endoscopy (ρ=0.7, *P*=.02), whereas no associations were found pertaining to the topics of IBD and pancreatology (Table 3).

COVID-19 Twitter and Publication Content by Geographic Location

The top 5 countries with the highest number of COVID-19–related tweets posted globally over the 6-month study period included the United States (7331/22,215, 33.0%), followed by the United Kingdom (4229/22,215, 19.3%), Spain (1527/22,215, 6.8%), Canada (1174/22,215, 5.3%), and Australia (673/22,215, 3.0%). China generated the highest number of peer-reviewed publications indexed in PubMed (1768/6352, 27.8%) throughout the study period, followed by Italy (915/6352, 14.4%), the United States (389/6352, 6.1%), France (348/6352, 5.5%), and India (303/6352, 4.8%). Figure 6 illustrates the countries with the highest Twitter activity and peer-reviewed publication activity. The top 20 countries with the highest number of tweets and the highest number of peer-reviewed publications are listed in Tables S3 and S4, respectively, in Multimedia Appendix 2. There was a strong correlation between the number of tweets and peer-reviewed publications in both the United States (ρ=0.8, *P*=.005) and the United Kingdom (ρ=0.8, *P*=.01; see Table S2 in in Multimedia Appendix 2).

Figure 6. Heat maps illustrating the total number of COVID-19–related tweets (A) across the globe and (C) in the United States, as well as publications indexed in the PubMed-NCBI represented (B) across the globe and (D) in the United States, over the 6-month study period (December 2019 through May 2020). Numbers are represented on the spectrum from the least (yellow) to the highest amount (maroon), as detailed in the legend accompanying each map. Countries or US states shaded white indicate the absence of data for those regions.



Within the United States, when analyzing both Twitter activity and peer-reviewed publications, the state of New York had the highest COVID-19–related activity (11% of tweets and 39.1% of publications) during the study period, followed closely by California (10.3% of tweets and 36.6% of publications). Figure 6 illustrates the Twitter activity and publication activity in the US states. The top 20 US states with the highest number of tweets and peer-reviewed publications are listed in Tables S5 and S6, respectively, in Multimedia Appendix 2.

COVID-19 Twitter Content by User Stakeholder Designation or Category

Twitter user data entered as the Twitter user's self-designated health care stakeholder role was analyzed. For the topics of pulmonology or critical care, luminal gastroenterology, hepatology, IBD, and GI endoscopy, the top 2 most active stakeholder categories were doctors/physicians and researchers/academic users. Furthermore, for the topic of pancreatology, advocacy organizations and patient advocates were the most active stakeholder users. The top 15 most active users and their stakeholder roles categorized by Twitter activity for each organ system topic are further detailed in Table S7 in Multimedia Appendix 2.

Discussion

Principal Findings

Since its emergence in December 2019, the novel coronavirus SARS-CoV-2 has triggered an unparalleled global response in the fields of science, medicine, public health, and technology. Considering its highly contagious nature, along with the paucity of knowledge and current lack of effective treatment modalities to combat the infection, the need for rapid sharing and dissemination of information has been paramount. In this study, we assessed the dissemination of COVID-19–related information via preprint services, formal peer-reviewed publications, and through the global reach of the social media platform Twitter.

Specifically, we observed that during the second half of March 2020, when COVID-19 was continuing to spread rapidly prompting various nations, including the United States, to enter a state of lockdown, social media activity on Twitter was at its peak, with almost 7000 impressions per tweet analyzed. Furthermore, we observed that Twitter activity was strongly correlated with the published scientific data available to the general public. Although COVID-19 has been predominantly linked with severe pulmonary complications, approximately 20% of the conversations on social media was related to the field of gastroenterology with specific discussions related to hepatology, GI endoscopy, luminal gastroenterology, IBD, and pancreatology. Social media activity was strongly associated with the availability of published data pertaining to all gastroenterology topics with the exception of pancreatology. Finally, in our analysis of data by geographic region of publication, social media activity was most prominent in the regions most affected by the pandemic both globally (in regions where social media via Twitter is not banned) and within the United States, with strong associations between social media and publication data.

In the longitudinal assessment of publication activity, the authors observed that peak social media activity predated peak PubMed publications by approximately 30 days. One possible explanation for this lag interval is the technical delay that typically occurs after acceptance of a peer-reviewed manuscript by a journal and prior to indexing in PubMed. It is worth highlighting that around the peak of PubMed publication activity, we also witnessed a parallel rise in the preprint repository activity. Historically, the use of preprint repositories has allowed researchers to “claim the space” or even to “publish first” in contentious fields of science and research. However, in the face of an evolving pandemic, preprint repositories are serving as a new mode of scientific communication, bypassing the typical lengthy peer-review process and thus allowing for faster dissemination and communication of research and clinical findings related to COVID-19. In fact, in March 2020, when the World Health Organization officially declared COVID-19 a pandemic, 8830 biomedical preprints were published, a 142% increase from the previous year, and medRxiv page views had increased to 15 million a month, as compared to 1 million a month prior to the start of the pandemic [22]. As of July 1, 2020, we were able to document that nearly half of all preprint articles related to COVID-19 and gastroenterology have subsequently made their way into reputable scientific journals, further supporting this theory.

Notably, we observed that physicians, nonmedical doctors, and scientific researchers constituted the lead stakeholder activity for social media use overall during the COVID-19 pandemic. This observation suggests that even during the early stages of the COVID-19 pandemic, social media became an increasingly sought-after tool, likely for the purpose of communicating medical and scientific information. This study confirms—by documenting health care stakeholder activity—that the scientific and medical communities leveraged social media platforms during the early stages of the COVID-19 pandemic more so than other health care stakeholders such as patients or advocacy groups. Previous studies performed during nonpandemic times have demonstrated conflicting evidence regarding the impact of social media on scientific publications related to citation impact, metrics, and viewability [23-26]. This study clearly illustrated that social media activity was greater and also peaked earlier than any of the publication modalities, which is important to consider when investigating how social media could potentially impact research and scientific work in future.

The gastroenterology subtopic of pancreatology is a good example of this potential influence, or rather, the lack thereof. Although pancreatic manifestations (eg, acute pancreatitis) of COVID-19 have been less commonly reported in the literature as compared to other GI symptoms, we unexpectedly observed that Twitter activity on the topic of pancreatology was the highest among all gastroenterology subtopics. However, there was no statistically significant correlation between Twitter and publication activity or between Twitter and preprint activity on the topic of pancreatology, thus implying that the rise of social media activity did not necessarily reflect the same rise in activity in bioRxiv, medRxiv, or PubMed activity. This could possibly be explained by reviewing the stakeholder data for pancreatology-related tweets. For each of the other gastroenterology subfields, stakeholder demographics fell largely under the categories of physicians, nonmedical doctors, or researchers and academic users; however, for the topic of “pancreas,” the most active stakeholders appeared to be advocacy organizations or patient advocates. Upon further review of the top 50 associated hashtags used for the “pancreas” topic, those related to cystic fibrosis support and awareness groups were the most common. Patient advocacy organizations not only play an important part in espousing awareness of specific diseases and patient populations, but they also serve an essential role in the dissemination of information on their behalf, typically in the form or raising awareness on the internet, lobbying directly for change within the government of other institutions, and via marketing and outreach, but likely only indirectly in the context of research activity. Therefore, this increase in Twitter activity may not translate to a proportionate increase in research publication activity on the topic of COVID-19 and pancreatology as demonstrated in this study. Using this topic as an example, further investigation diving deeper into the content of tweets, specific users, and how they translate directly into published work would be helpful to document the direct impact social media has on research activity.

Limitations

There are several limitations to this study that are worth noting. The first major limitation is that social media platforms, such as Twitter, are not available in several countries, including China. This could help to explain China’s lead in research publication activity as compared with other regions, as publication is likely one of the primary modalities used in this country for disseminating information. Other social media platforms, including WeChat and Sina Weibo, are used in China; however, information regarding the use of these other social media platforms within China is limited to date. Future studies are needed to assess social media activity on these alternative platforms and their association with publications as well as how they compared to the use of Twitter in other nations, such as the United States (where Twitter is not banned). Second, although we were able to account for and reassign duplicate publications for the various categorizations performed, a similar approach could not be guaranteed for Twitter data. The very nature of tweets allows for other users to publish an original tweet to their account generating additional impressions as it is sent to their followers (also known as a “retweet”). Therefore, limiting duplicate tweets may artificially decrease activity. More importantly, certain tweets, or even retweets, may have been assigned to more than one topic area owing to limitations of the Symplur software. Hence, we were unable to limit tweets to a single topic, and as such, this may have artificially boosted the overall number in certain organ system topics, thereby potentially skewing the results of this study.

Conclusions

In conclusion, this study demonstrates patterns in the utility of social media and publications—both in preprint repositories as well as peer-reviewed journals—for the rapid dissemination of information during a global pandemic of infectious disease. As the world faces this unprecedented public health emergency, this study has reflected on shifting worldwide trends from solely traditional methods of disseminating information (ie, via publications) to more contemporary methods, specifically among the GI community. social media tools like Twitter can be an effective method for educating and informing audiences in real time and via an interactive approach, a feat that cannot always be achieved with more conventional methods (ie, scientific publications). The new media age has resulted in a number of novel avenues for the distribution of information, including Twitter. Utilizing a single modality for dissemination of health care discoveries or information has been shown by the AHRQ to not be as effective as utilizing multiple modalities. It may therefore be time for the medical and scientific communities to cultivate formal social media platforms as effective tools for data sharing and collaboration to augment existing modalities of archival publication.

Abstract

Background: The COVID-19 pandemic has necessitated a rapid shift in how individuals interact with and receive fundamental services, including health care. Although telemedicine is not a novel technology, previous studies have offered mixed opinions surrounding its utilization. However, there exists a dearth of research on how these opinions have evolved over the course of the current pandemic.

Objective: This study aims to evaluate how the language and sentiment surrounding telemedicine has evolved throughout the COVID-19 pandemic.

Methods: Tweets published between January 1, 2020, and April 24, 2021, containing at least one telemedicine-related and one COVID-19–related search term (“telemedicine-COVID”) were collected from the Twitter full archive search (N=351,718). A comparator sample containing only COVID-19 terms (“general-COVID”) was collected and sampled based on the daily distribution of telemedicine-COVID tweets. In addition to analyses of retweets and favorites, sentiment analysis was performed on both data sets in aggregate and within a subset of tweets receiving the top 100 most and least retweets.

Results: Telemedicine gained prominence during the early stages of the pandemic (ie, March through May 2020) before leveling off and reaching a steady state from June 2020 onward. Telemedicine-COVID tweets had a 21% lower average number of retweets than general-COVID tweets (incidence rate ratio 0.79, 95% CI 0.63-0.99; *P*=.04), but there was no difference in favorites. A majority of telemedicine-COVID tweets (180,295/351,718, 51.3%) were characterized as “positive,” compared to only 38.5% (135,434/351,401) of general-COVID tweets (*P*<.001). This trend was also true on a monthly level from March 2020 through April 2021. The most retweeted posts in both telemedicine-COVID and general-COVID data sets were authored by journalists and politicians. Whereas the majority of the most retweeted posts within the telemedicine-COVID data set were positive (55/101, 54.5%), a plurality of the most retweeted posts within the general-COVID data set were negative (44/89, 49.4%; *P*=.01).

Conclusions: During the COVID-19 pandemic, opinions surrounding telemedicine evolved to become more positive, especially when compared to the larger pool of COVID-19–related tweets. Decision makers should capitalize on these shifting public opinions to invest in telemedicine infrastructure and ensure its accessibility and success in a postpandemic world.

Introduction

The COVID-19 public health crisis has transformed how individuals interact with critical services. This is particularly true of health care systems, which have been overwhelmed by patients with COVID-19 in both inpatient and intensive care units [1]. The sudden disruption in the ability to receive medical care has had widespread consequences for millions of Americans, and a survey by the US Centers for Disease Control and Prevention estimated that 40.9% of adults have delayed receiving medical care (including both emergency and routine care) due to concerns surrounding COVID-19 [2]. The new burdens placed on health care systems by the global pandemic have demonstrated the urgent need for the implementation of technologies to facilitate enhanced connectivity between patients and providers.

Telemedicine, defined as the delivery of health care services through electronic, audiovisual telecommunication systems, is not a novel concept—in fact, it has proven to be successful across a myriad of health domains [3]. The increased use of telemedicine during an emergency situation is also not new, and an increased uptake of telemedicine technologies has been observed during local, national, and international crises [4]. The implementation of telemedicine during a global pandemic is of particular value—not only can it be used to screen, diagnose, and triage patients from the comfort of their own homes, but it can also limit the need for physicians to use personal protective equipment that may be in low supply, facilitate rapid follow-up with diverse patient populations (particularly older patients or those living in a rural environment), reduce exposure to the infectious agent, and decrease the risk for intrahospital infection [5,6].

Despite its promise, prepandemic uptake of telemedicine in the United States was limited largely due to a lack of physician acceptance, stringent and heterogeneous licensing and reimbursement policies, and the upfront monetary costs of investing in the necessary infrastructure [4,5]. Nevertheless, shifts in policies in the peripandemic period have led to a surge in the uptake of telemedicine technologies. After the US Centers for Medicare & Medicaid Services revised their telemedicine reimbursement policies to include over 135 services (including emergency department visits, inpatient and nursing facility visits, and "discharge day management services"), over 36% of Medicare beneficiaries received at least one telemedicine service. Similarly, Medicaid and the Children's Health Insurance Program reported a 2600% increase in the use of telemedicine services in March through June 2020 compared to the same period in 2019 [7]. Thus, there exists a clear demand for heterogeneous patient populations to receive care digitally. However, these utilization metrics may not directly correlate to patient satisfaction, willingness to engage in telemedicine, or their ability to do so. Thus, additional work is needed to quantify patients' perceptions of the enhanced accessibility of telemedicine services.

Social media has increasingly been used as a surveillance tool by public health researchers to answer diverse health-related questions, including detecting disease outbreaks, situational awareness of humanitarian crises (such as natural disasters), and understanding a population's reaction towards certain messaging or events [8]. This is particularly vital during an ongoing public health pandemic, wherein social media can provide insights more rapidly than traditional data collection methodologies such as surveys [9]. One of the more commonly used social media platforms for this purpose is Twitter, owing to the abundance of daily content and the widespread (although not necessarily representative) demographic reach of this platform [10]. A previous study evaluating telemedicine discourse on Twitter during the COVID-19 pandemic has identified distinct user networks that bridge content domains and user types (including educational, promotional, and political materials) [11], whereas another study found that the geographic distribution of telemedicine tweets in the United States was significantly correlated to the number of confirmed COVID-19 cases within a state [12]. However, both studies only evaluated a 1- to 2-week period, leaving a gap in understanding how conversations surrounding telemedicine may have changed over the course of the pandemic.

Furthermore, neither study considered the sentiment content of the tweets, which could provide more precise insights into how Twitter users perceive telemedicine. A separate evaluation of the sentiment of telemedicine-related tweets within a subpopulation of health care providers found overall positive opinions that focused on safety, accessibility, and implementation strategies [13]. However, because this study only focused on providers, there exists a dearth of research on the sentiment toward telemedicine expressed by the general Twitter population. Thus, the purpose of this study was to characterize how the content of telemedicine-related tweets has evolved during the COVID-19 pandemic, with a particular focus on changes in sentiment types. It was hypothesized that the frequency of telemedicine-related content on Twitter increased throughout the COVID-19 pandemic and that the sentiment of tweets became more positive across this period.

Methods

Data Collection

The characterization of telemedicine content in relation to COVID-19 was evaluated across 4 components of tweets: the number of favorites and retweets, language used within the tweet, sentiment of the tweet, and authorship. Tweets in English language posted between January 1, 2020, and April 24, 2021, containing at least one of a series of telemedicine-related terms and at least one of a series of COVID-19–related terms were curated from the Twitter full-archive search available via the Academic Research product track [14]. Search terms were derived from the literature and the Medical Subject Headings thesaurus established by the National Library of Medicine (NLM) of the National Institutes of Health (NIH) (Multimedia Appendix 1) [11,15]. A random sample of tweets containing only COVID-19–related terms was extracted for the same period for comparison with the distribution of sampled tweets matched with the daily distribution of telemedicine-related COVID-19 tweets. No geographic restrictions regarding the location of the tweet were implemented, and all tweets beginning with “RT @” (indicating retweet status) were removed prior to analysis.

Text Processing

Standard natural language processing preprocessing procedures were performed prior to textual analysis of the tweets. First, links, mentions, hashtags, and HTML escape characters were removed from all tweets. Next, tweet-level sentiment was calculated using the Valence Aware Dictionary and sEntiment Reasoner (VADER), which was designed specifically for use on a social media corpus and has been validated in other Twitter-based studies, including one on telemedicine [16,17]. In addition to the compound sentiment score, a categorical sentiment was assigned to each tweet based on prespecified cutoffs within the literature (ie, *positive* if the compound sentiment was greater than 0.05, *negative* if the compound sentiment was lesser than –0.05, and *neutral* if the compound sentiment was between these values) [16]. After determining the sentiment, other preprocessing included tokenizing and lemmatizing the text and removing traditional English and Spanish stop words. In addition, words with an inverse document frequency in the 0.05th percentile were removed given their high frequency across all tweets (eg, “covid19”). Other words removed included non-English words (as determined by the GradyAugmented dataset [18]), as well as words with alternative connotations that may have skewed any analysis (eg, “trump” could refer to the verb or the 45th President of the United States; “patient” could refer to the adjective or a person receiving medical treatment). This processing was performed for both single words as well as bigrams (ie, two-word phrases) and trigrams (ie, three-word phrases).

Author Analysis

In addition to evaluating all telemedicine-related COVID-19 tweets (“telemedicine-COVID”) relative to a general COVID-19 sample (“general-COVID”), the authors of tweets with the 100 most and the 100 fewest retweets were extracted and manually labeled with a domain (eg, “news,” “political,” “health and medicine”) and account type (ie, “organization” or “individual”). Domains were created by reviewing the author description information and, for verified users, confirming their identity through an independent Google search. Individual authors who represented a nonverified person were automatically labeled as “private citizen,” whereas all organizations were labeled with a domain regardless of the verification status. This process was completed by one member of the research team for both the telemedicine-COVID and general-COVID data sets to compare outcomes within these tweet subpopulations. A second member of the research team independently labeled 10% of the authors as a “validity check” [19]. This subsequentially resulted in Cohen κ=0.66 (percent agreement: 77.3%) for domain type and κ= 0.75 (percent agreement: 86.4%) for the account type.

Statistical Analysis

A comparative analysis of retweets and favorites by month and by data set (ie, telemedicine-COVID vs general-COVID) was conducted using zero-inflated Poisson regression to accommodate for the preponderance of tweets receiving no favorites or retweets and the count nature of the outcome variable. Sentiment analysis was also performed to assess the distribution of positive, negative, and neutral tweets both overall and by month and compared using chi-square tests. This analysis was repeated to compare sentiment in the telemedicine-COVID data set with that in the general-COVID data set. Chi-square tests were also used to compare the distribution of sentiment between the top 100 most and least retweeted posts both within each data set and between them. All analyses were conducted in Python (version 3.7.4) within the Jupyter Notebook graphical user interface (GUI) (version 7.19.0) and R (version 3.6.3) within the RStudio GUI (version 1.3.959). Code is available on GitHub [20]; tweet IDs are available upon request. Given the public nature of social media data, institutional review board approval was not required as specified in Regulation 45 CFR 46 as authored by the US Department of Health and Human Services Office for Human Research Protections [21].

Results

After removing duplicate tweets and retweets from analysis, 351,718 tweets related to telemedicine and COVID-19 were used in the analytic data set (telemedicine-COVID). A sample comparator data set (general-COVID) of 351,401 tweets was collected with a similar daily distribution for comparison.

Telemedicine-COVID tweets spiked in the early stages of the pandemic (eg, March 2020 to May 2020) before leveling off in the following months (Figure 1). There were significant monthly variations in the number of retweets of telemedicine-COVID tweets (Figure 2). Retweets peaked in March 2020, with April, May, July, September, October, and December 2020 and January through April 2021 having significantly fewer retweets by comparison (Table S1 in Multimedia Appendix 2). Tweets from the telemedicine-COVID data set had a 21% lower average number of retweets than tweets from the general-COVID data set (incidence rate ratio [IRR] 0.79, 95% CI 0.63-0.99; *P*=.04; Table S2 in Multimedia Appendix 2). In terms of favorites, telemedicine-COVID tweets in April, May, July, August, September, October, and December 2020, and tweets from January through April 2021 had a significantly lower average number of favorites than those in March 2020 (Table S3 in Multimedia Appendix 2). Telemedicine-COVID tweets had a 14% lower average number of favorites than did general-COVID tweets, but this value was not statistically significant (IRR 0.86, 95% CI 0.58-1.28; *P*=.45) (Table S4 in Multimedia Appendix 2).

When broken down by sentiment, the percentage of telemedicine-COVID tweets with an overall sentiment of positive or neutral generally increased over the period of interest, whereas the percentage of negative tweets decreased (Figure 3). There were significant monthly variations in the percentage of tweets with each sentiment (*P*<.001). The months with the highest percentage of positive telemedicine-COVID tweets were August 2020 (14,371/24,543, 58.6%), September 2020 (10,475/18,758, 55.8%), and March 2020 (19,851/36,478, 54.4%), whereas the months with the highest percentage of negative tweets were February 2020 (453/1274, 35.6%), January 2020 (13/43, 30.2%), and January 2021 (3695/16,613, 22.2%). There were also significant differences in the distribution of positive, negative, and neutral tweets between the telemedicine-COVID and general-COVID data sets (*P*<.001; Figure 4). Although sentiments were evenly distributed among general-COVID tweets (38.5% positive, 31.4% neutral, and 30.0% negative), a majority of telemedicine-COVID tweets (N=351,718) were positive (n=180,295, 51.3%), followed by neutral (n=100,870, 28.7%). There were also significant variations between data sets on a month-to-month basis for March 2020 through April 2021, with a significantly higher proportion of positive tweets in the telemedicine-COVID data set relative to the general-COVID data set (Multimedia Appendix 3).

Figure 1. Frequency of tweets mentioning telemedicine and COVID-19 between January 1, 2020, and April 24, 2021 (N=351,718).

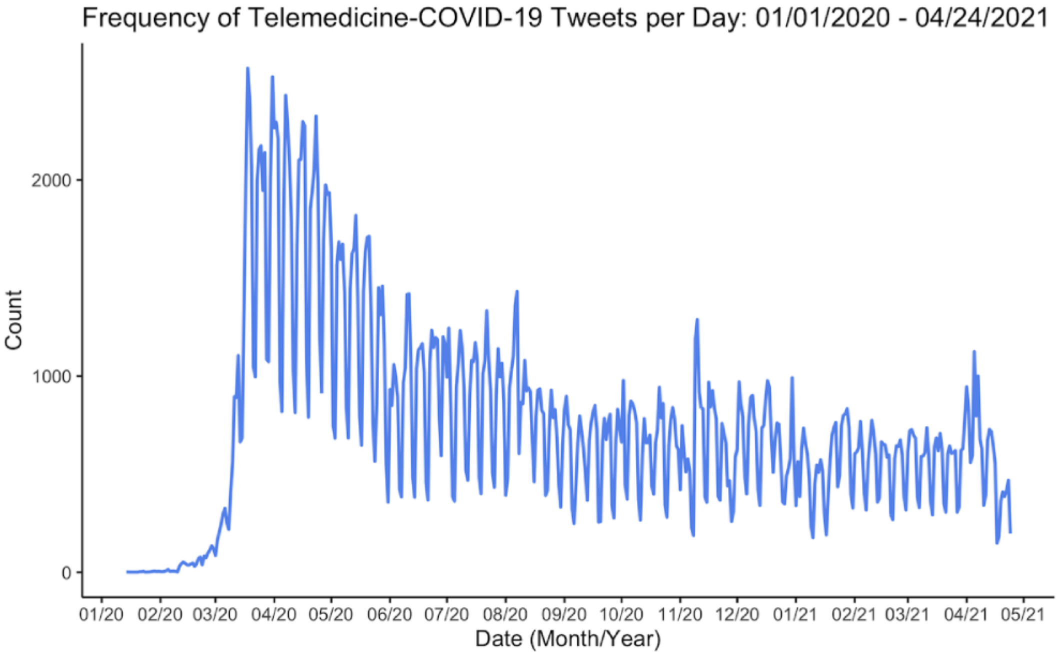

Figure 2. Monthly variations in the base 10 log number of retweets for tweets mentioning COVID-19 and telemedicine. Note that 219,212 tweets (62.2%) had no retweets and are not included in this visualization.

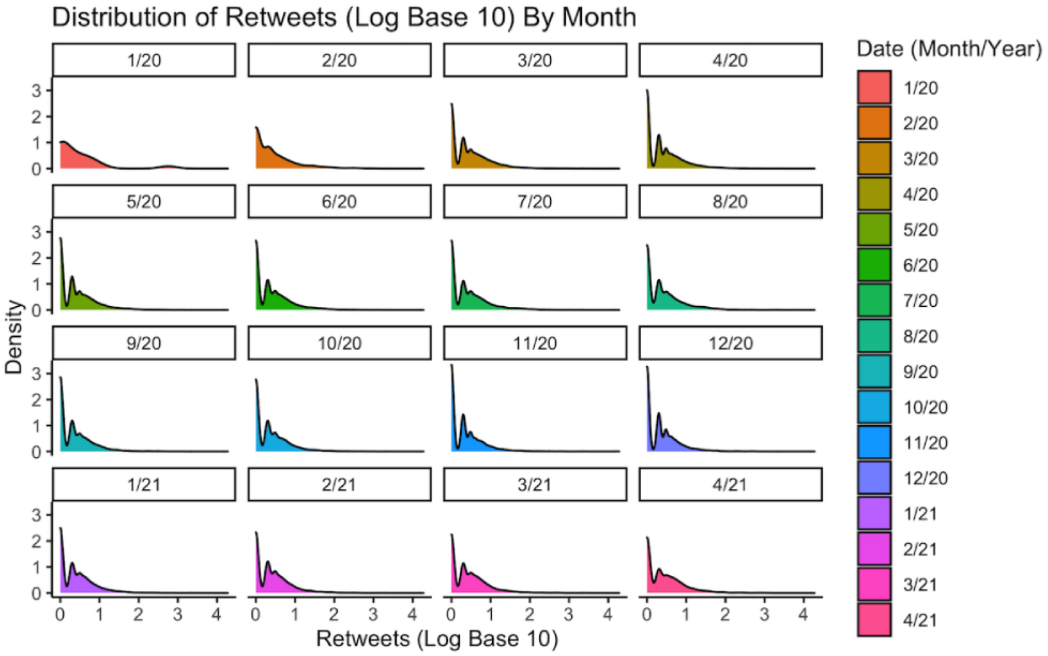

Figure 3. Changes in the frequency of positive, negative, and neutral tweets mentioning telemedicine and COVID-19 posted between January 1, 2020, and April 24, 2021 (N=351,718).

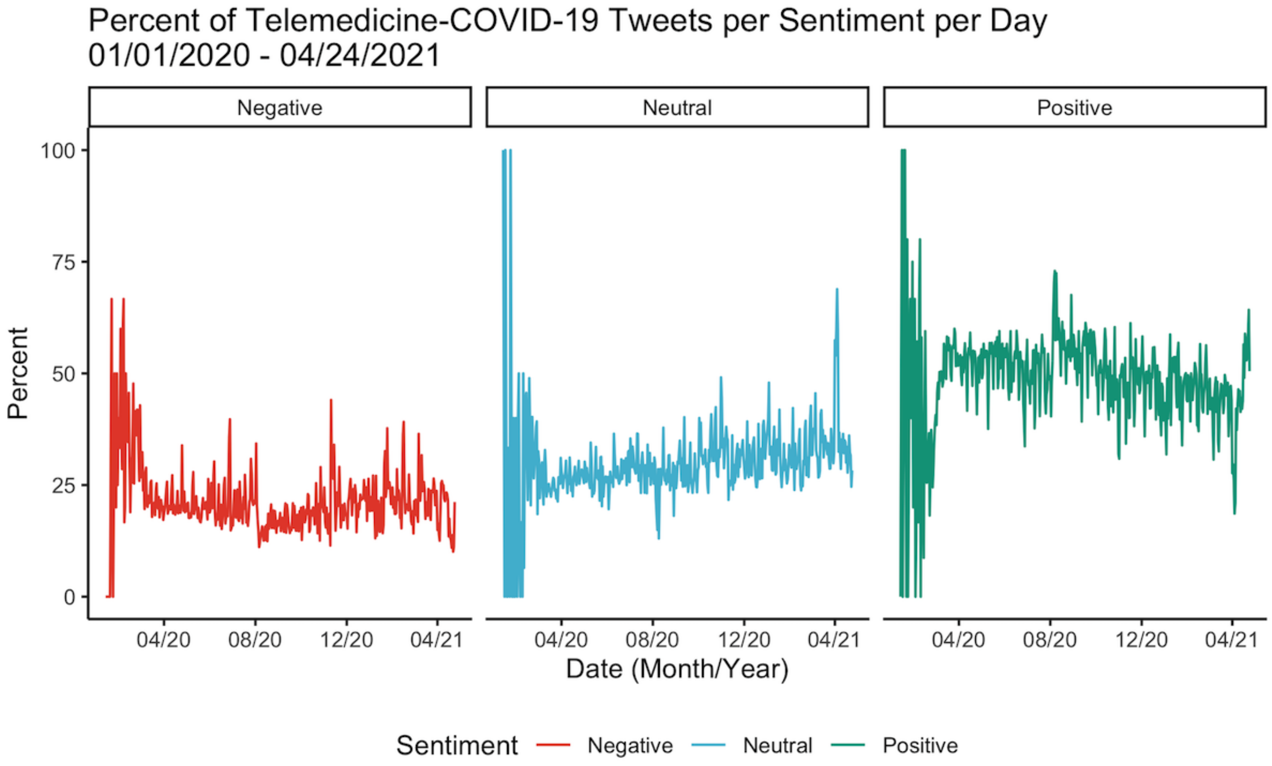

Figure 4. Variations in sentiment by tweet type (ie, telemedicine and COVID-19 vs COVID-19 only). A significantly higher proportion of tweets with a positive sentiment was found in the telemedicine-COVID data set than in the general-COVID data set (*P*<.001).

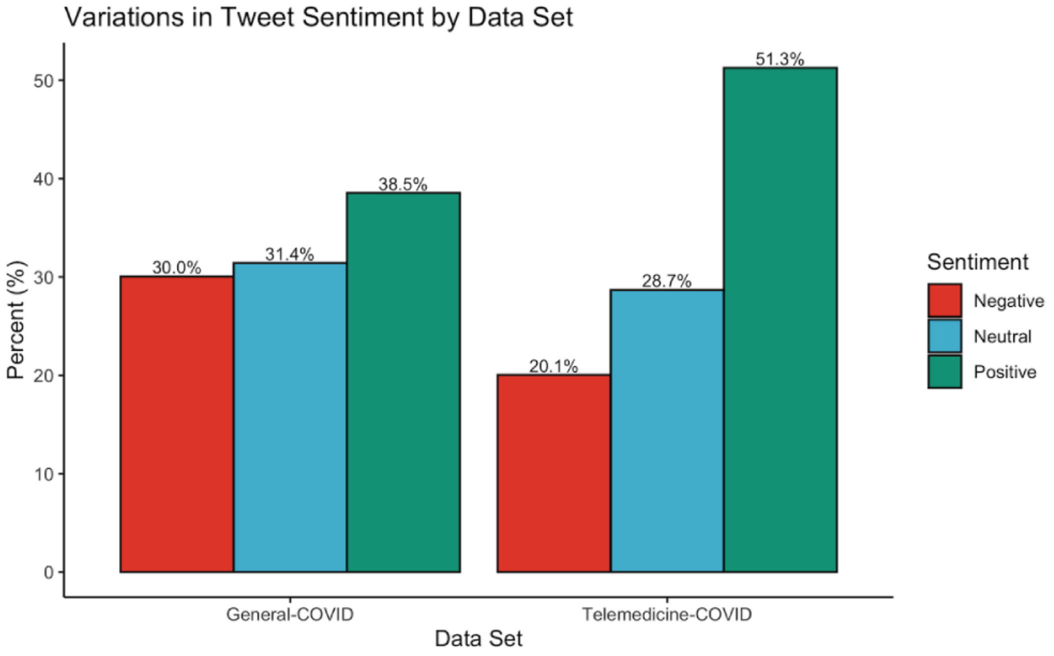

Within the telemedicine-COVID tweet data set (N=351,718), the most frequently used bigrams were “town hall” (n=1411, 0.40%); “white house” (n=848, 0.24%), “san diego” (n=757, 0.22%), “mask wearing” (n=670, 0.19%), “lessons learned” (n=610, 0.17%), and “artificial intelligence” (n=562, 0.16%). The most frequently used trigrams were “widespread mask wearing” (n=385, 0.11%), “feeling helpless hopeless” (n=301, 0.09%), “fast track vital” (n=199, 0.06%), “cancer sooner simply” (n=191, 0.05%), “thermal imaging cameras” (n=188, 0.05%), and “list refresh page” (n=176, 0.05%).

In contrast, within the general-COVID sample (N=351,401), the most frequently used bigrams were “ill [*sic*] deliver” (n=1195, 0.34%), “nursing homes” (n=693, 0.20%), “task force” (n=597, 0.17%), “herd immunity” (n=563, 0.16%), “prime minister” (n=508, 0.14%), and “town hall” (n=439, 0.12%).

The most frequently used trigrams were “appointment detected provider” (n=214, 0.06%), “personal protective equipment” (n=205, 0.06%), “complete project chapter” (n=181, 0.05%), “wall street journal” (n=101, 0.03%), “operation warp speed” (n=68, 0.02%), and “midnight mm rain” (n=67, 0.02%). A word cloud of unigrams is presented in Multimedia Appendix 4.

When broken down by authorship, the top 100 most retweeted telemedicine-COVID tweets were predominantly authored by politicians (20/93, 21.5%) and private citizens (20/93, 21.5%), followed by journalists (14/93, 15.1%). Similarly, the top 100 most retweeted general-COVID sample tweets were predominantly authored by private citizens (23/89, 25.8%), journalists (16/89, 18.0%), and politicians (13/89, 14.6%). Of the sample of tweets without any retweets, 82.8% (72/87) of those from the general-COVID sample and 61.1% (55/90) from the telemedicine-COVID sample were authored by private citizens. There was a small subset of authors within each data set that did not have available account information (7 authors of the top 100 telemedicine-COVID retweets, 10 authors of the bottom 100 telemedicine-COVID retweets, 11 authors of the top 100 general-COVID retweets, and 13 authors of the bottom 100 general-COVID retweets). In terms of sentiment, of the most retweeted tweets within the telemedicine-COVID data set, 54.5% (55/101) were positive and 30.7% (31/101) were negative. In contrast, of the fewest retweeted tweets, 51.3% (40/78) were positive and 19.2% (15/78) were negative (*P*=.03). Within the general-COVID data set, 49.4% (44/89) of the top retweeted tweets were negative and 33.7% (30/89) were positive. This was not significantly different from the fewest retweeted general-COVID posts (*P*=.16), but it was significantly different from the most retweeted telemedicine-COVID tweets (*P*=.01). The sentiment of the fewest retweeted general-COVID did not significantly differ from the sentiment of the fewest retweeted telemedicine-COVID tweets (*P*=.07).

Discussion

Principal Findings

To the best of our knowledge, this study is the first to comprehensively evaluate tweets pertaining to telemedicine and COVID-19 posted between January 2020 and April 2021 compared to a general COVID-19 data set. Analysis of retweets and favorites suggested monthly variations in the “attention” received by telemedicine-COVID tweets, and these tweets had a significantly lower average number of retweets than the general-COVID data set. Telemedicine-COVID tweets were predominantly positive both overall and by month, especially compared to the general-COVID data set. There were also variations in the frequency and sentiment of tweets made by entities in various domains, including private citizens, politicians, and journalists, and a higher proportion of the most retweeted tweets in the telemedicine-COVID data set were positive than those in the general-COVID data set. The findings presented here demonstrate how social media can be leveraged to perform surveillance of shifting opinions surrounding critical health technologies, including telemedicine.

The number of tweets that mentioned telemedicine and COVID-19 drastically increased between February and March 2020, coinciding with the declaration of the COVID-19 pandemic by the World Health Organization on March 11, 2020 [22]. As stay-at-home orders continued throughout April and May 2020, telemedicine became more prominent within the COVID-19 dialogue on Twitter, and health systems began to adapt to the use of this technology. Discussions surrounding telemedicine decreased through June 2020 and remained relatively constant thereafter, perhaps reflecting the achievement of “steady state.” This leveling off coincides with previous studies that have found that the weekly rate of telemedicine consults in a Medicare population peaked in April before declining in June 2020 [23].

As the volume of telemedicine-COVID tweets evolved, so did the sentiment of these tweets. Over half of all months between March 2020 and April 2021 had a majority of telemedicine-COVID tweets labeled as positive, and all months during this period had a significantly higher proportion of positive tweets compared to the general-COVID data set. Although this finding aligns with a study prior to the pandemic that found a higher number of positive telemedicine tweets than negative and neutral tweets, it contrasts with another study that found that 59% of individuals were either unsure of telemedicine or considered it subpar to traditional care delivery mechanisms [17,24]. The positive results found in this study may be reflective of increasing acceptance toward telemedicine—while patients may have viewed telemedicine as just an alternative to in-person care before the pandemic, telemedicine may now be viewed as an alternative to no care whatsoever. This finding aligns with recent patient surveys on their opinion of telemedicine, which found that 79% of patients were “satisfied” with their experience with telemedicine and 78% felt that they had a health problem that could be addressed virtually [25]. Furthermore, increased positivity in the middle stages of the pandemic (particularly in August and September 2020) reflects the evolving understanding of the Twitter population that reduced contact during a telemedicine visit can provide a safer experience during a highly contagious disease outbreak. The increase in positivity in this period in particular also corresponds to the signing of the Executive Order 13941 on August 3, 2020, which aimed to “improve rural health and telehealth access” to Medicare beneficiaries during the postpandemic period [26,27].

The most followed accounts within both the telemedicine-COVID and general-COVID data sets predominantly consisted of journalists and politicians. These groups present stark contrasts in content veracity—journalists likely provide neutral content with minimal bias (depending on the agency), whereas politicians likely share more polarized content that reflect their own views. Prior work evaluating tweets on telemedicine during the COVID-19 pandemic (but not necessarily related to it) found that private citizens frequently retweeted content from both sources, although politicians were retweeted more frequently [11]. Thus, there is a chance that a larger number of Twitter users’ opinions on telemedicine and COVID-19 may be limited to “echo chambers” that reinforce their own opinion and, in a worst-case scenario, spread misinformation with deleterious consequences. However, the fact that a majority of tweets within the telemedicine-COVID data set were positive suggests that this may not necessarily be the case for tweets pertaining to telemedicine or other novel technologies. Conjecturally, this may reflect that positive news and experiences on telemedicine were amplified during the COVID-19 pandemic, which could lead to more widespread adoption and uptake of this technology.

Policy Implications

Telemedicine is the pinnacle "21st century approach" to deliver convenient and less expensive care, and over 50 large US health systems have integrated it into their standard operating procedures [5]. Although the surge in telemedicine visits during the early phases of the pandemic have waned to some extent, evidence shows a high (but geographically variable) degree of persistence of telemedicine, from 8% to almost 48% [23]. This can likely be attributed to relaxations in policies that presented major challenges to telemedicine uptake, including reimbursement parity, interstate licensing, prescribing practices, the use of Health Insurance Portability and Accountability Act (HIPAA)-compliant technologies, and the definition of an "originating site" (ie, where the patient is located), to name a few [28,29]. The overwhelming and consistent positive nature of conversations surrounding telemedicine on Twitter as presented here, coupled with a surge in uptake throughout the pandemic, demonstrate that diverse, heterogeneous populations view telemedicine favorably, including patients, providers, and politicians. These findings provide clear evidence for policymakers that replacing restrictive policies with long-term, systematic favorable toward telemedicine would be met with support from numerous, diverse communities.

Limitations and Future Directions

Despite the promise of this study, it is not without its limitations. Although the list of search terms was comprehensive and based on prior literature, it may have missed tweets that used other terminology to describe telemedicine-related services. Similarly, it is possible that some of the included tweets may not have directly been related to telemedicine. The analysis also does not include telemedicine-related tweets that were made during the study period that did not contain a direct mention of COVID-19. Although this ensured that the data specifically focused on the impacts of telemedicine as they related to COVID-19, future work could analyze how telemedicine tweets that directly mentioned COVID-19 varied from those that did not during the same time. Furthermore, future work could evaluate whether the trends observed in the varied from tweets made during the same period in the prior year. In addition, the present work does not include geospatial data, which has previously been shown to be an influential component of tweet sentiment [30,31]. Thus, future work could evaluate geospatial variations in telemedicine sentiment, including whether it is associated with uptake of the technology in local medical facilities. In addition, only the top 100 most and least retweeted posts were included in the author-level analysis, and future work could expand on this to label more accounts, improve the classification of labels (eg, labeling fewer accounts as "private citizens"), or analyze only a subset of these accounts (eg, politicians or "influencers"). Lastly, the Twitter population of predominantly 18-24 years old, well-educated individuals is not representative of a US or broader population [32]. Thus, future work is needed to characterize the change in sentiment within other populations, especially those that may not be technologically literate and may therefore encounter barriers when attempting to utilize telemedicine.

Conclusions

Opinions on telemedicine and COVID-19 on Twitter have increased in popularity and were largely positive throughout 2020 and the beginning of 2021. These telemedicine-COVID tweets were generally more positive than general-COVID tweets both overall and within the subset of the most followed authors, suggesting an amplification of discussion surrounding the benefits of telemedicine. Given the relative positivity with which individuals seemed to view telemedicine during the COVID-19 pandemic, shifts in policies stemming from the COVID-19 pandemic that support telemedicine are likely to be well received.

Abstract

Background: COVID-19 has continued to spread in the United States and globally. Closely monitoring public engagement and perceptions of COVID-19 and preventive measures using social media data could provide important information for understanding the progress of current interventions and planning future programs.

Objective: The aim of this study is to measure the public's behaviors and perceptions regarding COVID-19 and its effects on daily life during 5 months of the pandemic.

Methods: Natural language processing (NLP) algorithms were used to identify COVID-19–related and unrelated topics in over 300 million online data sources from June 15 to November 15, 2020. Posts in the sample were geotagged by NetBase, a third-party data provider, and sensitivity and positive predictive value were both calculated to validate the classification of posts. Each post may have included discussion of multiple topics. The prevalence of discussion regarding these topics was measured over this time period and compared to daily case rates in the United States.

Results: The final sample size included 9,065,733 posts, 70% of which were sourced from the United States. In October and November, discussion including mentions of COVID-19 and related health behaviors did not increase as it had from June to September, despite an increase in COVID-19 daily cases in the United States beginning in October. Additionally, discussion was more focused on daily life topics (n=6,210,255, 69%), compared with COVID-19 in general (n=3,390,139, 37%) and COVID-19 public health measures (n=1,836,200, 20%).

Conclusions: There was a decline in COVID-19–related social media discussion sourced mainly from the United States, even as COVID-19 cases in the United States increased to the highest rate since the beginning of the pandemic. Targeted public health messaging may be needed to ensure engagement in public health prevention measures as global vaccination efforts continue.

Introduction

As COVID-19 continues its spread in the United States, a key to controlling the spread while vaccination efforts continue is to enlist the public in risk-mitigation behaviors [1,2]. Studying the public's social media posts regarding COVID-19 public health measures may provide information about targets of interventions, progress toward behavior goals, and the risk of future outbreaks [3-9]. Although real-time reports on pandemic-related tests and mortality are widely available, there are fewer opportunities to gain near real-time insight into behaviors and beliefs about the pandemic.

Social media, which people are using now more than ever to communicate, has served as a useful data source for providing rapid insight into the public's behaviors and beliefs during the pandemic [10-13]. Studies have noted a high prevalence of COVID-19–related discussion—including such topics as hygiene, shortages, and the spread of misinformation—and an increase in COVID-19–related discussion as COVID-19 cases increase [5,14,15]. However, existing findings are based on evidence during only the beginning of the outbreak, from December 2019 to April 2020, and the range of topics and keywords explored is also limited [7,14-19]. Additionally, studies analyzing COVID-19 behaviors and beliefs on social media have primarily used Twitter as their source, which has several limitations [14-16,19]. Most notably, highly rated retweets are more likely to come from spam and bot accounts, which are also actively posting about COVID-19, and can obscure the targeting of signals from human discussions [20-22]. Further, previous studies each focused on a particular aspect of the pandemic, such as misinformation relating to the pandemic, without comparing the volume of discussion related to multiple aspects to determine the public's relative focus on particular pandemic-related issues and behaviors. Therefore, there is a need to assess how the public's current reaction to the pandemic has changed since the early stages, by examining broad online discussion from more diverse sources.

Accordingly, we measured the prevalence of online discussion that included topics in the categories of daily life, which may or may not be related to COVID-19, and COVID-19–related public health, from June through November 2020. We also assessed the correlation between prevalence of discussion topics and US COVID-19 new daily case rates (incidence). In measuring these trends in social media data and the COVID-19 incidence rate in the United States, we sought to elucidate the US public's engagement with COVID-19–related public health measures, which are crucial to addressing the current pandemic.

Methods

Data Sources

The data sample consisted of unstructured, English-language posts from forums, such as Reddit, Facebook public pages, and 4Chan, and comments from news sites (Table S1 in Multimedia Appendix 1) [23]. We defined forums as thread lists or topic-specific pages, and excluded social media sites including Twitter, YouTube, Instagram, and LinkedIn [24]. Signals Analytics, an advanced analytics consulting firm that conducted the analysis, accessed these data sources through a third-party data vendor, NetBase [25,26]. These social media posts were geotagged by NetBase both directly, by using geolocation data from posts, and indirectly, by using author profiles and unique domain codes (such as .uk). All data were deidentified by NetBase before being transferred to Signals Analytics.

In addition to the social data, the study included US COVID-19 case data from the COVID-19 Dashboard by the Center for Systems Science and Engineering at Johns Hopkins University [27]. These data were updated daily using a public application programming interface (API) and included total number of deaths, new daily deaths, total active cases, and daily new cases [28].

No personal identifying information (eg, usernames, emails, or IP addresses) was shared as part of the analysis or reporting process. This study was exempted from Institutional Review Board review by Yale University as it did not engage in research involving human subjects.

Approach

To determine trends in social media discussion during the COVID-19 pandemic, we collected data posts from all internet sources and applied natural language processing (NLP) algorithms to identify and classify mentions of COVID-19, COVID-19–related public health measures, and daily life topics (Table S2 in Multimedia Appendix 1).

NetBase ran a daily query that we designed based on our project scope on over 300 million online data sources from June 15 to November 15, 2020 (Methods 1 in Multimedia Appendix 1). There were several steps to narrow the sample retrieved from the query to include only posts relevant to our research question (Figure S1 in Multimedia Appendix 1). First, NLP algorithms were run to remove advertisements and pornography-related sites and posts (Methods 2 in Multimedia Appendix 1). Next, a taxonomy of topics was applied (Methods 3 in Multimedia Appendix 1). The posts that did not include discussion of topics from the taxonomy were deleted. Finally, all news articles and blog posts were deleted from the sample, so that the only remaining data posts were from social outlets (forums and comments on news sites).

The taxonomy was comprised of two categories, COVID-19–related public health measures and daily life behaviors, each of which included multiple topics (Methods 4 in Multimedia Appendix 1). COVID-19 mentions was also an individual topic in the taxonomy, independent of either category. Any post that directly mentioned COVID-19 by name or synonym, including slang such as "Miss Rona," was classified as including a COVID-19 mention (Table S2 in Multimedia Appendix 1). Taxonomy categories and topics were not exclusive, so that a post was classified as belonging to each taxonomy topic and category that it contained mention of (Table S2 in Multimedia Appendix 1).

Once all posts were classified according to the topics in the taxonomy, we measured trends in these topics over time by tracking the total number of posts that included mentions of each taxonomy topic and category. Classifications of topics and categories were not mutually exclusive, so the same post was able to be classified into multiple topics across any category. Trends were visualized by taxonomy category, COVID-19 mentions, and by the most commonly mentioned taxonomy topics. These trends were visualized with the COVID-19 incidence rate in the United States. We chose to correlate the trends in taxonomy topics with trends in the COVID-19 incidence rate rather than the COVID-19 death rate based on previous literature, which found a correlation between trends in online social chatter and COVID-19 incidence [3,5].

This approach allowed us to identify changes in both topics that prior research in the early stage of the outbreak had shown to be prevalent in COVID-19 discussion, and topics from daily life and COVID-19 literature reviews that were not previously known to be found in COVID-19 discussion, but that may have become apparent as COVID-19 cases or current events changed [15,16,29-33]. Additionally, our approach removed redundant posts, limiting the effect of bots and reposts (Methods 3 in Multimedia Appendix 1). The taxonomy classification was validated by calculating positive predictive value and sensitivity (Methods 5 in Multimedia Appendix 1). We also validated the methodology by applying it to US-specific current events and found that the approach revealed an increase in online social discussion when the given current event topic was most relevant (Figure S2 in Multimedia Appendix 1). This methodology was shown to reveal insights into outbreak characterization and event prediction for the e-cigarette or vaping use–associated lung injury outbreak [34].

Results

The final data sample consisted of 9,065,733 online social posts that mentioned at least one of the topics in our taxonomy from June 15 to November 15, 2020 (Table 1). The majority (87%) of posts in our sample came from sources that were categorized as forums, including Reddit, Facebook, and 4Chan (Table 2; Table S1 in Multimedia Appendix 1) [23]. The minority of posts (13%) in our sample were derived from comment sections on news sites, including The Hill, a media source focused on politics and business, and Breitbart, a right-leaning media source (Table 2; Table S1 in Multimedia Appendix 1) [35,36]. Most posts in the sample were not able to be directly geotagged due to sources' data privacy measures and restrictions. A minority were geotagged as from the United States, with the remaining geotagged as from a country other than the United States (Table S3 in Multimedia Appendix 1). Using indirect geotagging provided by NetBase, it was estimated that about 70% of all initial posts collected by the search query were from the United States. In an independent data sample of 100 posts classified by manual review, the algorithm had a positive predictive value of over 80%, which was calculated as the number of posts correctly classified by the taxonomy using NLP algorithms divided by the number of all posts classified by the taxonomy. This was a higher accuracy measure than is found in comparable social media research [30]. Sensitivity was calculated as the number of correct classifications of a topic using the NLP algorithms divided by the total number of posts for the topic identified by manual screening, and we found that our taxonomy approach led to an average classification rate of 92% sensitivity.

Within the data sample, 6,210,255 (69%) posts were classified as including discussion of daily life topics, while 3,390,139 (37%) contained mentions of COVID-19, and 1,836,200 (20%) posts were classified as including discussion of COVID-19–related public health topics (Table 1). The most prevalent topics among the daily life posts were sex life (n=887,457, 14%), food (n=838,513, 14%), and financial concerns (n=710,757, 11%). The most prevalent topic in COVID-19–related public health behaviors posts was wearing face masks (n=1,120,344, 61%), followed by lockdowns (n=457,705, 25%), and social distancing (n=242,105, 13%).

Online social posts including COVID-19 mentions and discussion of COVID-19–related public health behaviors increased in June 2020, as COVID-19 cases also increased, but remained stagnant as cases began to increase in October (Figure 1). Discussion about wearing face masks was most prevalent in mid-July, during the summer wave (mid-June to early September) of COVID-19 cases, and remained at pre-June levels in October and November, with the exception of a sharp increase on October 2, 2020 (Figure 2).

Table 1. Number of posts by taxonomy topic from June 15 to November 15, 2020 (N=9,065,733)[a].

Relevant taxonomy categories (percent classified within all posts) and topics	Number of posts with mentions (percent classified within category)
COVID-19–related public health topics (20)	1,836,200
Wearing face mask	1,120,344 (61)
Lockdown	457,705 (25)
Social distancing	242,105 (13)
Quarantine	94,301 (5)
Testing	87,712 (5)
Excessive handwashing	64,679 (4)
Contact tracing	31,775 (2)
Reopening	16,681 (1)
Screening	14,569 (1)
Wearing gloves	11,531 (1)
Disinfection	11,076 (1)
Wearing face shield	10,104 (1)
Daily life taxonomy topics (69)	6,210,255
Sex life	887,457 (14)
Food	838,513 (14)
Financial	710,757 (11)
Travel	651,426 (10)
Smoking/vaping	476,468 (8)
Mass gatherings	451,815 (7)
Virtual communication	414,549 (7)
Alcohol consumption	398,229 (6)
Religion	285,538 (5)
New skills/hobbies acquisition/DIY	280,155 (5)
Drug use	257,819 (4)
News/media consumption	257,415 (4)
Reading	246,074 (4)
Physical activity	205,116 (3)
Work from home	198,057 (3)
Socializing in person	177,522 (3)
Stockpiling	171,421 (3)
Relaxation techniques	164,262 (3)
Excess sleep	127,623 (2)
Pets	109,510 (2)
Postponing plans	98,626 (2)
Childcare	97,735 (2)
Public transportation	94,414 (2)
Reduced sleep quality	88,196 (1)
Home school	80,153 (1)
Non–COVID-19 hospital visits	77,278 (1)
Doctor well visit	72,235 (1)
Funerals	45,394 (1)

Relevant taxonomy categories (percent classified within all posts) and topics	Number of posts with mentions (percent classified within category)
Family-centered time	28,106 (0)
Outdoor culture	21,546 (0)
Births	17,283 (0)
Telehealth	11,574 (0)
Smokeless tobacco consumption	2136 (0)
COVID-19 mentions (37)	3,390,139

[a] Percentages do not sum to 100 because each post may have included discussion of multiple topics, including topics in different categories.

Table 2. Number of posts by source type from June 15 to November 15, 2020.

Category of COVID-19 discussion topic	Posts with mentions of COVID-19–related public health behavior (N=1,836,200), n (%)	Posts with mentions of daily life (N=6,210,255), n (%)	Posts with mentions of COVID-19 (N=3,390,139), n (%)	Total data sample (N=9,065,733), n (%)
Forums	1,494,401 (81)	5,714,446 (92)	2,749,451 (81)	7,928,599 (87)
Comments	341,799 (19)	495,809 (8)	640,688 (19)	1,137,134 (13)

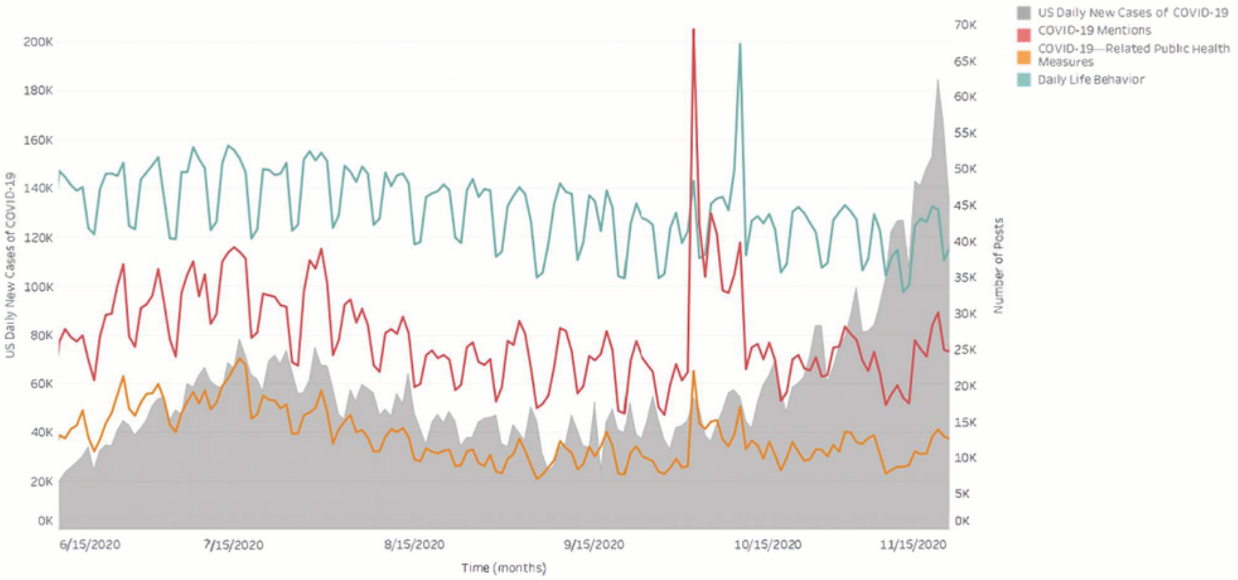

Figure 2. Public health measures online social discussion versus US daily new COVID-19 cases (June 15 to November 15, 2020).

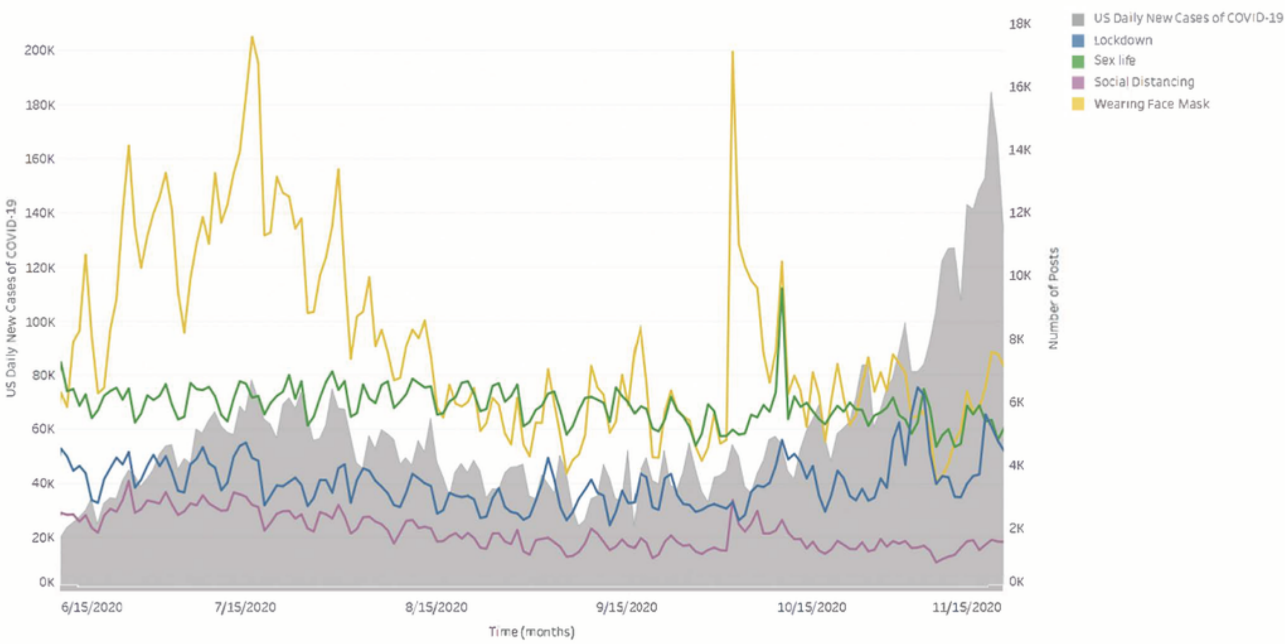

Discussion

Principal Findings

Our study had several important findings. From June to November 2020, predominantly US-based online social chatter was more focused on daily life than it was on public health behaviors relating to COVID-19. In addition, although discussion relating to COVID-19 and related public health behaviors appeared to increase with rising US cases in the summer wave (early June to early September), the volume of COVID-19–related discussion was lower in the wave that began in the fall (mid-October), despite the fact that, during the fall wave, COVID-19 cases increased to their highest rates since the pandemic began [37]. In particular, discussion of wearing face masks, the most prevalent of any COVID-19 public health behavior we studied, declined in mid-July despite the pandemic continuing and evidence that wearing face masks has not been universally adopted in the United States, and increased only minimally once cases began to increase again in early October [38,39]. One exception to this finding was the brief but stark increase in COVID-19–related discussion on October 2, 2020, which coincided with the announcement that President Donald Trump had contracted COVID-19 [40]. Our finding that daily life topics were more prevalent in social media chatter than COVID-19–related public health behaviors and mentions of COVID-19 is not immediately surprising given the differences in scope. Nevertheless, we applied consistent methods over time, and the decrease of COVID-19–related discussion in the context of the fall rise in COVID-19 cases differs from the pattern we visualized in the summer wave.

Our study expanded upon previous COVID-19–related social media analyses in that our sources used forums and comments on news sites instead of Twitter and our study was conducted in later phases of the pandemic. Our study sources included forums and comments on news sites, which we believe was an advantage for a few reasons. First, forums are unique to other forms of social media in that they tend to include more text, with greater character allowances and less frequent use of hashtags. This allows the NLP algorithms to be more accurately applied, because forum users include more context to which inclusion and exclusion criteria can be applied. Reddit has also been found to include more discussion than links to external sources, again providing more context to analyze [41]. Second, forums, such as Reddit and public Facebook pages, and comments on news sites, are already focused on specific topics and therefore have more in-depth discussions on the same topic, as opposed to other social media sites, which more often share updates from individual users or links to other sites. The added context from in-depth discussions also allows for more accurate NLP classification. Third, as discussed earlier, retweets driven by spam and bot accounts on Twitter can obscure the targeting of signals from human discussion [20-22].

Due to these differences in study design and time period, our findings may not be consistent with those of previous studies from the first wave of the COVID-19 pandemic. However, future research may investigate whether the cause of the different findings is a significant difference between the type of social chatter found on forums and that found on Twitter and other social media platforms, or whether the different findings are due to a temporal trend of a decreased focus on COVID-19. Although we found that online social chatter was more focused on daily life than it was on COVID-19 public health behaviors, previous research found the opposite. For instance, one study from March 2020 that used data from Twitter found that social media discussion about COVID-19–related health topics was more common than discussion about daily life topics such as socializing, the economy, or politics [42]. Earlier research also found that COVID-19–related public health measures were discussed not only more often than social topics, but also more often than other COVID-19–related topics [7,15]. Thus, our finding that online social chatter from June to November was more focused on daily life than it was on COVID-19 public health behaviors may indicate that the public's focus on COVID-19 preventative health behaviors had decreased since previous studies were conducted in March and April, or our results may have differed from these earlier studies because our study used different data sources and excluded Twitter. There have been related studies that have analyzed social media data on Reddit—a major source of data in our analysis—during the pandemic; however, none of these studies addressed our research question directly, which was how levels of COVID-19–related public health discussion compared to levels of daily life and COVID-19–related discussion over time. We noted three studies conducted during the time period from January to May 2020 discovered and measured common COVID-19–related topics among online Reddit posts without determining the relative prevalence of COVID-19–related public health discussion to daily life discussion [43-45]. One additional study found that, from February to May 2020, there was a positive correlation between COVID-19–related news coverage and COVID-19–related discussion on the r/Coronavirus subreddit, but that the COVID-19–related discussion declined after sustained media coverage, showing that public attention saturates [46].

Although our results cannot be compared to previous studies to show that public perception changed from the spring wave to the summer and fall waves, there is precedent for the interpretation that the public's focus on COVID-19 public health measures waned during the fall months. As public health experts warned against relaxing preventive behaviors as pandemic fatigue grew, activity and traffic data indicated that people may have stopped adhering to public health recommendations to stay home and avoid close contact with people outside their household [47-50]. The decline of chatter regarding wearing face masks, and the relative low rates of discussions on other COVID-19–related public health behaviors, may reflect that social media engagement with these issues decreased as the pandemic progressed, and remained low among the US population as the pandemic continued to confront a high COVID-19 daily case rate.

Our study has several limitations. First, although our third-party data provider, NetBase, reported that about 70% of posts were from the United States based on indirect geotagging methods, we do not know the location for most posts according to our direct geotagging methods, which were only able to tag about 20% of posts (Table S3 in Multimedia Appendix 1). As a result, we cannot make international comparisons, but our data set is more representative of the United States than of any other country. Second, the number of posts included in our data set was much lower than previous studies, likely due to the types of data sources used, which excluded social media sites such as Twitter in order to exclude noise that might have obscured signals in data, and our methodology, which included removing posts not relevant to our more refined taxonomy. We used a stringent exclusion criterion with a list of prespecified keywords that may also have led to a smaller sample size, but our approach aimed to create a sample with high accuracy levels. Third, we were not able to include sentiment analysis or other content analysis in our study, which is an area for further exploration. Finally, there is no demographic information available from the data posts directly due to privacy considerations and data use agreements. Thus, we cannot determine whether our data sample contains biases due to the demographics of the people who posted. For instance, Reddit, which was the most common forum source for our data sample, has been found to be used by a younger, male audience [51,52].

Conclusion

In this study of predominantly US-based COVID-19 social media data from June to November 2020, we observed that COVID-19 and relevant public health measures were discussed less than daily life behaviors on social media, and that discussion on wearing face masks decreased throughout the summer and into the fall, while cases increased. These discussion rates may reveal a need for increased public health messaging as the pandemic continues.

Abstract

Background: Vaccination is a cornerstone of the prevention of communicable infectious diseases; however, vaccines have traditionally met with public fear and hesitancy, and COVID-19 vaccines are no exception. Social media use has been demonstrated to play a role in the low acceptance of vaccines.

Objective: The aim of this study is to identify the topics and sentiments in the public COVID-19 vaccine–related discussion on social media and discern the salient changes in topics and sentiments over time to better understand the public perceptions, concerns, and emotions that may influence the achievement of herd immunity goals.

Methods: Tweets were downloaded from a large-scale COVID-19 Twitter chatter data set from March 11, 2020, the day the World Health Organization declared COVID-19 a pandemic, to January 31, 2021. We used R software to clean the tweets and retain tweets that contained the keywords *vaccination*, *vaccinations*, *vaccine*, *vaccines*, *immunization*, *vaccinate*, and *vaccinated*. The final data set included in the analysis consisted of 1,499,421 unique tweets from 583,499 different users. We used R to perform latent Dirichlet allocation for topic modeling as well as sentiment and emotion analysis using the National Research Council of Canada Emotion Lexicon.

Results: Topic modeling of tweets related to COVID-19 vaccines yielded 16 topics, which were grouped into 5 overarching themes. Opinions about vaccination (227,840/1,499,421 tweets, 15.2%) was the most tweeted topic and remained a highly discussed topic during the majority of the period of our examination. Vaccine progress around the world became the most discussed topic around August 11, 2020, when Russia approved the world's first COVID-19 vaccine. With the advancement of vaccine administration, the topic of instruction on getting vaccines gradually became more salient and became the most discussed topic after the first week of January 2021. Weekly mean sentiment scores showed that despite fluctuations, the sentiment was increasingly positive in general. Emotion analysis further showed that trust was the most predominant emotion, followed by anticipation, fear, sadness, etc. The trust emotion reached its peak on November 9, 2020, when Pfizer announced that its vaccine is 90% effective.

Conclusions: Public COVID-19 vaccine–related discussion on Twitter was largely driven by major events about COVID-19 vaccines and mirrored the active news topics in mainstream media. The discussion also demonstrated a global perspective. The increasingly positive sentiment around COVID-19 vaccines and the dominant emotion of trust shown in the social media discussion may imply higher acceptance of COVID-19 vaccines compared with previous vaccines.

Introduction

As the COVID-19 pandemic spread globally, COVID-19 vaccine-related issues received increasing public attention. Multiple research teams in major pharmaceutical companies and research institutions across various nations have been developing vaccines [1,2]. Although vaccination is a cornerstone of the prevention of communicable infectious diseases [3], the practice has traditionally faced public fears, hesitancy, and even opposition [4,5]. During the COVID-19 pandemic, it is estimated that 55% to 85% of the population, depending on the country and the infection rate, needs to receive the COVID-19 vaccine to provide herd immunity [6,7]. However, a survey about COVID-19 vaccine intentions in September 2020 suggested that 21% of the public in the United States would definitely get vaccinated and 24% would definitely not get vaccinated [8]. One factor leading to the low acceptance of vaccines is poor health literacy, which is significantly influenced by social media use [9]. Therefore, there is a pressing need to understand how COVID-19 vaccines have been discussed on social media to better understand the public perceptions, concerns, and sentiments that may influence the achievement of herd immunity goals.

Although social media data analysis has been widely performed for both health-related issues and emerging public health crises [10-14], analysis of big data of social media discussion on COVID-19 vaccines is limited [15,16]. To the best of our knowledge, in the most recently published work about COVID-19 vaccine–related social media discussion, the study period ended in November 2020 [16]. However, many significant events related to COVID-19 vaccines have occurred since that date, such as the confirmation of more COVID-19 variant cases in North America by the US Centers for Disease Control and Prevention (CDC), rollout of vaccines, and increased numbers of vaccines showing high efficacy. Previous studies found that changes in social media discussion about vaccine-related topics correspond to the changing reality [15,17]. Thus, research involving recent social media data is needed to fully understand the public discussion on COVID-19 vaccines during the pandemic. In addition, knowledge of the content of COVID-19 vaccine discussion on social media will provide a possible explanation for users' attitudes toward COVID-19 vaccines and COVID-19 vaccine acceptance or hesitancy. However, previous research on COVID-19 vaccines did not touch on these topics [16,18-21]. To fill this gap, in this study, we will examine the public discourse about COVID-19 vaccines on Twitter since the World Health Organization announced it to be a global pandemic on March 11, 2020, up to January 31, 2021, to identify the topics, overarching themes, and sentiments around COVID-19 vaccines and vaccination. This is the first study to include data from almost one year of the pandemic. This long time span will allow us not only to observe a bigger picture of the public discussion and concerns regarding COVID-19 vaccines but also discern the salient changes in major topics and sentiments during the course of the pandemic and further inform public health education and campaigns for increasing COVID-19 vaccine acceptance. Also, our results may provide insight that will be useful in the promotion of other vaccines.

Methods

Data Extraction and Preprocessing

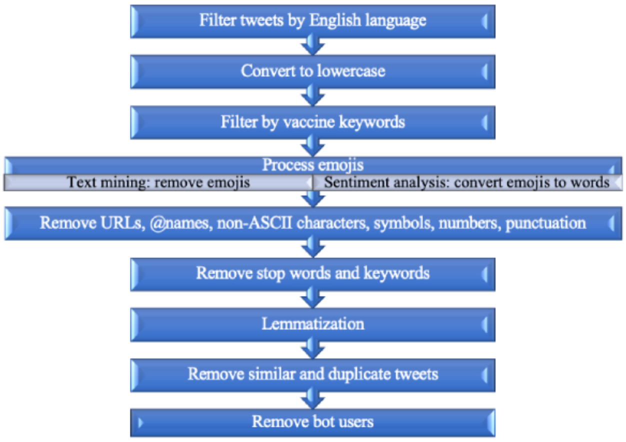
The IDs from a total of 1,499,421 tweets, without retweets, from March 11, 2020, through January 31, 2021, were obtained using the data set maintained by Georgia State University's Panacea Lab [22]. These tweets were collected by the Panacea Lab using the following 13 keywords: *COVID19*, *CoronavirusPandemic*, *COVID-19*, *2019nCoV*, *CoronaOutbreak*, *coronavirus*, *WuhanVirus*, *covid19*, *coronaviruspandemic*, *covid-19*, *2019ncov*, *coronaoutbreak*, and *wuhanvirus*. The Panacea Lab can only provide the tweet IDs [23], which need to be hydrated to recover the full tweet data.

During the tokenizing stage, we used the *gsub* function in R (R Foundation for Statistical Computing) to extract the tweets whose language field in the tweets' metadata was specified as English. All text mining was performed using RStudio Version 1.4.1103 on a Mac computer (Apple Inc) running Big Sur, version 11.2.2. We converted the text of all the tweets to lowercase. We further filtered the tweets by the following keywords: *vaccination*, *vaccinations*, *vaccine*, *vaccines*, *immunization*, *vaccinate*, and *vaccinated*. We prepared 2 batches of tweets, 1 for text mining and 1 for sentiment/emotion analysis. The data processing procedures for the 2 batches are almost the same except at the beginning: for sentiment analysis, we converted all the emojis to words, whereas for text mining, we removed all the emojis. Next, we created a script to remove the URLs, mentioned names, non–American Standard Code for Information Interchange (ASCII) characters, and anything other than English letters or spaces (eg, "1" and "?"). Using the R package *dplyr*, version 1.0.2, we cleaned the tweets by removing duplicates. To filter tweets created by fake or bot accounts, we used the document-term matrix (DTM), which contains rows corresponding to the tweets and columns corresponding to the terms. Each entry in the DTM denotes the number of times a term appears in a tweet. The similarity matrix $S=[S_{ij}]$, which measures how similar the i-th tweet is to the j-th tweet, is obtained by computing the dot product between the i-th row vector and the j-th row vector R_j in the DTM, which geometrically represents the cosine of the angle between the row vectors R_i, R_j:

Therefore, if the i-th and the j-th tweets are identical, then $S_{ij}=1$; if they are completely different (ie, the angle between the corresponding row vectors is 90°), then $S_{ij}=0$. For tweets that were 80% similar, we retained the most representative one (measured by the magnitude of the row vector in the DTM). Furthermore, we used the *tweetornot* package [24], version 0.1.0, to remove users that were identified as bots with a 95% probability or higher.

The final cleaned data set consisted of 1,499,421 unique tweets from 583,499 different users. We further cleaned the tweets by removing words and characters that were of little or no analytical value (eg, “the”, “very”, “&”). We performed this task by creating our own list of stop words by appending the 13 keywords related to *COVID-19* and the 7 keywords related to *vaccine* to the English stop words list from the R package *tidytext*, version 0.2.6; this step was performed because we already knew that every tweet would contain one or more of those keywords, and retaining them in the tweets would not further our understanding of the main content of the tweets. Finally, we stemmed and lemmatized the words to their root forms using the R package *textstem*, version 0.1.4 (eg, *vaccinating*, *vaccinates*, and *vaccinated* were changed to *vaccinate*). Figure 1 shows a summary of our data preprocessing procedure.

Figure 1. Data preprocessing procedure. ASCII: American Standard Code for Information Interchange.



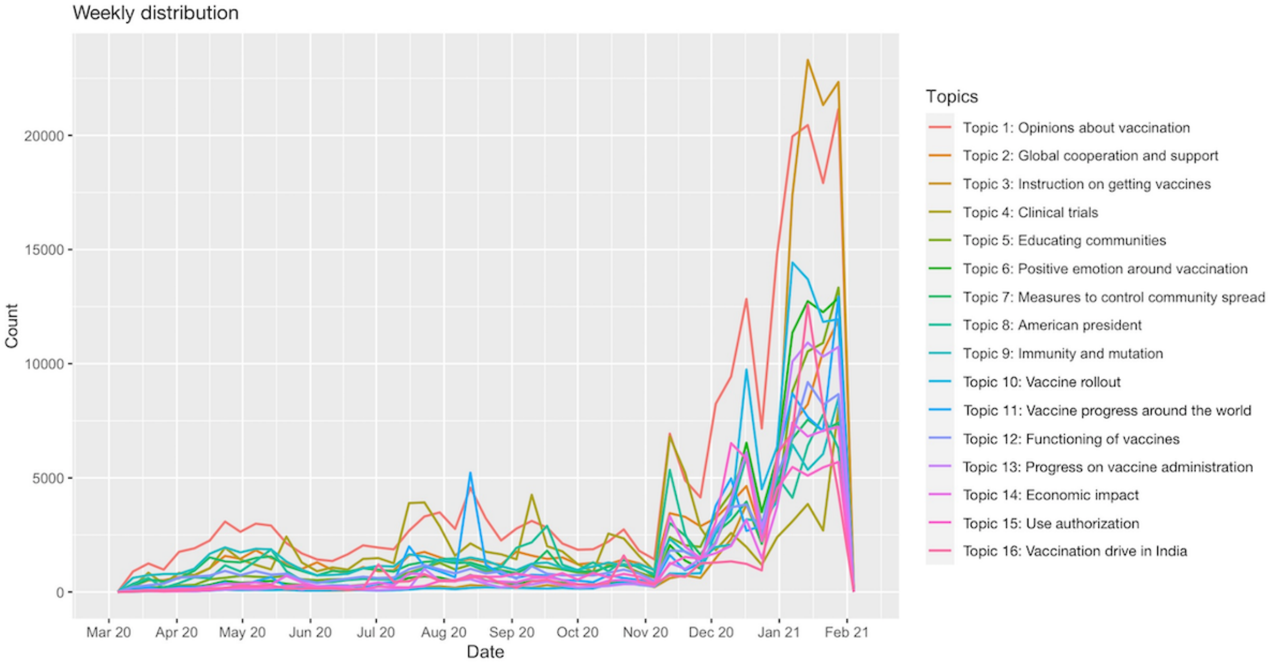
Topic Modeling

Topic modeling can help organize a large collection of documents by grouping documents into different themes. Topic modeling is often referred to as a probabilistic clustering. It is more robust and usually provides more realistic results than hard clustering (eg, k-mean clustering) [25]. A typical clustering algorithm assumes a distance measure between topics and assigns one topic to each document, whereas topic modeling assigns a document to a collection of topics with different weights or probabilities without any assumption of the distance measured between topics. Many topic models are available, of which the most widely used is the latent Dirichlet allocation (LDA) model [25], developed by David Blei, Andrew Ng, and Michael I Jordan in 2002 [26].

To extract common topics from this very high number of tweets, we used the LDA algorithm for topic modeling. We performed the LDA algorithm on the data using the R *textmineR* package, version 3.0.4. The LDA algorithm requires manual input of the number of expected topics. We ran the LDA algorithm on the data by varying the topic number from 2 through 40. For each topic number, we calculated the coherence score using the *textmineR* package. We chose 16 as the topic number for our final topic model, based on two considerations: first, the topic number 16 corresponded to the highest coherence score (see Multimedia Appendix 1); second, in comparison with topics that appeared in the other topic models, the topic model with 16 topics strikes a balance between one too narrow that the model would risk excluding important topics and one so broad that it would dilute the main focus.

The top 8 terms from each of the 16 topics were generated. We also used the *geo_freqpoly* function in the R package *ggplot2*, version 3.3.2, to generate the frequency polygons (see Figure 2) to visualize the weekly frequency of the 16 topics from March 11, 2020, to January 31, 2021. For each tweet, the LDA assigned a probability to each of the 16 topics. We assigned the topic with the highest probability to each tweet, and we grouped the tweets according to the most prevalent topics. To obtain representative tweets for each topic, we randomly sampled 100 tweets from each topic; two of the authors then independently examined the sampled tweets, followed by a group discussion to select the most representative ones. If one of the authors thought that no conspicuous topics had emerged from the first 100 sampled tweets, another 100 tweets would be sampled and further reviewed; the authors continued this process until they judged that there was a clear common topic and they reached a consensus (see our previous paper [27] for more details). We used the *textmineR* package’s topic label function to generate an initial labeling for the topics. After carefully reading through the sampled tweets from each topic, the two authors refined the machine-generated labeling to give each topic the most accurate, concise, and coherent description (see Table 1 in the *Results* section). Through discussions, the authors further grouped the topics into 5 overarching themes. Specifically, two of the authors first independently grouped the topics into the number of themes that made the most sense to them and resolved conflicting views through discussion. The third author was involved by providing additional comments on both the agreements and disagreements between the two authors. The final decision of the grouping was made together by all three authors. For example, whether the topic of “vaccination drive in India” should be grouped into the theme of “vaccine administration” or “vaccines as a global issue” was unresolved after the two-author discussion. By rereading tweets and discussing among the three authors, we finally placed the topic under the theme of vaccines as a global issue.

Figure 2. Weekly frequency of each topic on Twitter from March 11, 2020, to January 31, 2021.



Sentiment and Emotion Analyses

Sentiment analysis can be used to classify the polarity of a given document; it can assign a score to a document to indicate whether the expressed opinion is positive, negative, or neutral. Emotion analysis goes beyond simple polarity and can give scores to different emotions, such as anger, fear, anticipation, trust, surprise, sadness, joy, and disgust (the so-called Plutchik wheel of emotions) [28]. The *syuzhet* package (Jockers, 2017) [29] is the most popular and efficient R package for sentiment/emotion analysis. To perform the emotion analysis, we used the National Research Council of Canada Emotion Lexicon developed by Turney and Mohammad in 2010 [30]. It is the most comprehensive dictionary for this task [31]. In Figure 3, we show the weekly average polarity (sentiment) scores from March 11, 2020, to January 31, 2021; we fitted the data points with the best linear fit and obtained a slope of 0.003764 with a *P* value <.001 and an intercept of 0.1653927 with a *P* value <.001. In Figure 4, we plot the weekly percentage of emotions.

Figure 3. Weekly average polarity (sentiment) scores from March 11, 2020, to January 31, 2021. The slope of the best fit is 0.003764.

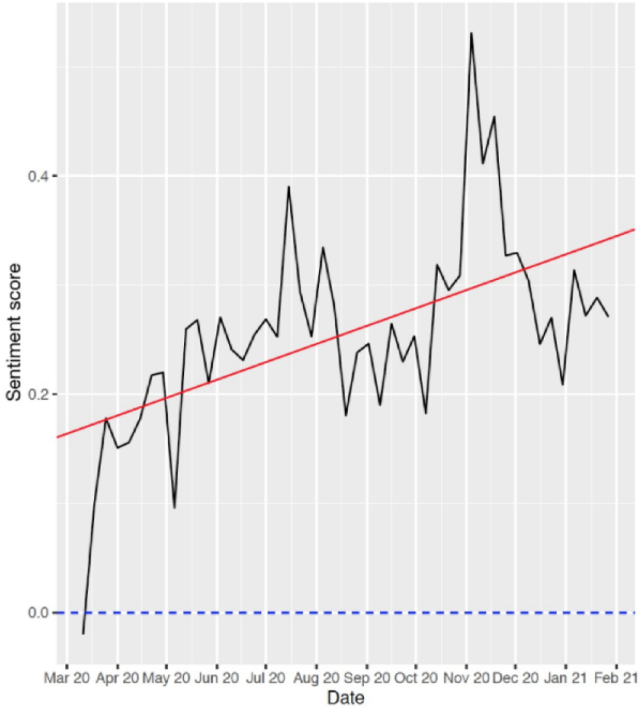


Figure 4. Weekly percentages of emotions from March 11, 2020, to January 31, 2021.

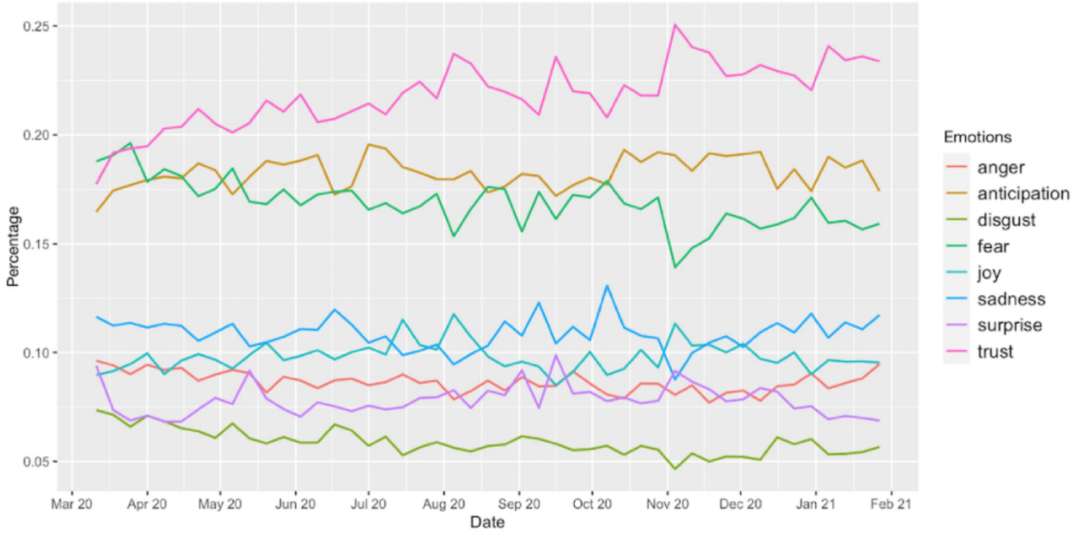
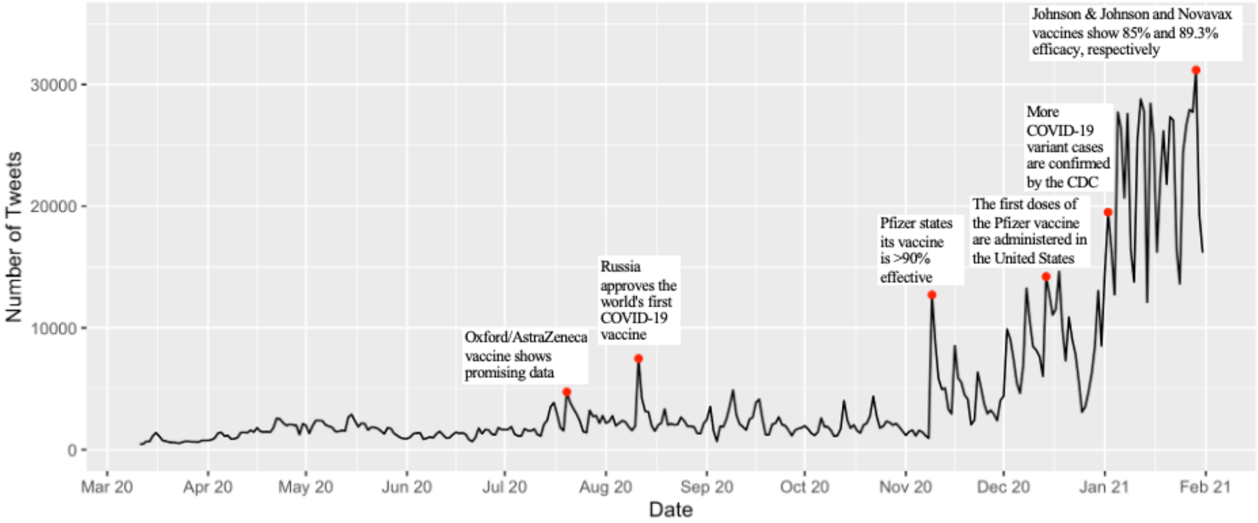


Results

Numbers of Tweets

We downloaded 144,332,894 tweets posted from March 11, 2020, through January 31, 2021 (for a total of 327 days) using the Panacea Lab database. After cleaning, a total of 1,499,421 tweets from 583,499 different users were included in the analysis. As shown in Figure 5, the number of daily tweets continually increased; the daily average for the month of January 2021 was 22,202 tweets. Before November 9, 2020, the number of daily tweets was around or below 5000, with only one exception, on August 11, 2020 (n=7486), when Russia approved the world's first COVID-19 vaccine [32]. The first wave of an exponential increase in the number of daily tweets started on November 9, 2020 (n=12,720), when Pfizer stated that its vaccine is 90% effective [33]. The second wave of a surge in the number of daily tweets started around January 3, 2021, when more COVID-19 variant cases were confirmed in North America by the CDC, and the highest number of tweets in a single day (n=31,197) occurred on January 29, 2021, when Johnson & Johnson's and Novavax's vaccines showed 85% and 89.3% efficacy, respectively [34].

Figure 5. Daily numbers of COVID-19–related tweets from March 11, 2020, to January 31, 2021.



Topic Modeling of COVID-19 Vaccine–Related Tweets

Analysis of the tweets yielded 16 topics, which were grouped into 5 overarching themes. In descending order of quantity of tweets (N=1,499,421), the themes are opinions and emotions around vaccines and vaccination (405,397 tweets, 27.04%), knowledge around vaccines and vaccination (355,305 tweets, 23.7%), vaccines as a global issue (311,251 tweets, 20.76%), vaccine administration (266,744 tweets, 17.79%), and progress on vaccine development and authorization (160,724 tweets, 10.72%). Table 1 summarizes the 16 topics, top terms in the topics, and the number and percentage of each topic; it also provides a tweet example for each topic. More details about the themes and topics, including the salient temporal variance of topics (see Figure 2), are elaborated in the following subsections.

Table 1. Numbers and percentages of tweets related to each COVID-19 vaccine topic (N=1,499,421).

Theme and topics	Top terms contributing to the topic model	Total tweets, n (%)	Example paraphrased tweet[a] (date posted)
Theme 1: Opinions and emotions around vaccines and vaccination			
Opinions about vaccination	*people*, *get*, *take*, *go*, *want*, *make*, *like*, *think*	227,840 (15.20)	"It is pathetic to see the low trust in science and the government. People need to see leaders and politicians on TV to receive the vaccine to convince them that the vaccine is safe." (December 18, 2020)
Positive emotion around vaccination	*get*, *good*, *first*, *day*, *today*, *work*, *one*, *feel*	89,117 (5.94)	"After getting the first dose of the covid-19 vaccine today, I can finally breath some fresh air and feel there is hope in life." (January 23, 2021)
American president	*Trump*, *Biden*, *American*, *president*, *gate*, *bill*, *plan*, *administration*	88,440 (5.90)	"There are more lies than usual in today's press. Biden is being portraited as anti-vaccine. This is not correct. In fact, he said on Wednesday he trusted the vaccines and the scientists, while accusing President Trump of playing politics with a potential covid-19 vaccine." (September 16, 2020)
Theme 2: Knowledge about vaccines			
Educating communities	*question*, *read*, *answer*, *expert*, *article*, *community*, *immunity*, *black*	96,532 (6.44)	"You can learn more about the covid-19 vaccines in our upcoming town hall meeting. We will address any questions and concerns on January 13, 2021, 2-3:30 PM (EST)." (January 7, 2021)
Measures to control community spread	*mask*, *get*, *need*, *go*, *still*, *available*, *end*, *life*	89,008 (5.94)	"Even though covid-19 vaccines are an important step in slowing down the spread of the virus, people still need to continue taking all precautions: wear a mask, maintain physical distance from others, and keep your hands clean." (January 19, 2021)
Immunity and mutation	*flu*, *year*, *new*, *may*, *variant*, *work*, *effective*, *strain*	88,327 (5.89)	"They say that coronavirus resembles the flu virus. As we know, the flu virus mutates. Therefore, they need to create different flu shot every year into order to fight off the virus, but there hasn't been a flu vaccine that is 100% effective. So good luck with making the covid-19 vaccine." (May 11, 2020)
Functioning of vaccines	*people*, *effect*, *test*, *risk*, *side*, *side effect*, *immune*, *death*	81,438 (5.43)	"Both vaccines use mRNA technology which contains instructions that tell our cells how to make a protein that triggers an immune response inside our bodies." (December 21, 2020)
Theme 3: Vaccines as a global issue			
Global cooperation and support	*world*, *country*, *global*, *pandemic*, *access*, *need*, *develop*, *effort*	108,366 (7.23)	"On Thursday, WHO [the World Health Organization] warns against 'vaccine nationalism.' No one country is safe if poor countries can't get access to the vaccines." (August, 9, 2020)
Vaccine progress around the world	*UK*, *China*, *EU*, *Russia*, *first*, *country*, *approve*, *news*	83,156 (5.55)	"On Tuesday, German health minister Jens Spahn joined EU [the European Union] to place restriction on exporting covid-19 vaccines. This came amid discontent over the delay in rolling out the AstraZeneca vaccine to member countries." (January 26, 2021)
Economic impact	*new*, *case*, *death*, *news*, *rollout*, *rate*, *high*, *report*	61,360 (4.09)	"A rise in new covid-19 cases outweigh positive vaccine news. Shutdown fears sink global markets. US coronavirus deaths are above 250,000." (November 9, 2020)
Vaccination drive in India	*India*, *drive*, *minister*, *Indian*, *speed*, *warp*, *health*, *warp speed*	58,369 (3.89)	"India clears covid-19 vaccine makers Serum Institute of India (SII) and Bharat Biotech to start the world's largest immunization drive." (January 3, 2021)
Theme 4: Vaccine administration			
Instruction on getting vaccines	*county*, *health*, *state*, *appointment*, *update*, *plan*, *site*, *distribution*	106,544 (7.11)	"Health departments will each announce their vaccine availability and locations. Eligible individuals at the federally qualified health center will be contacted regarding access to a covid-19 vaccine." (December 30, 2020)

Theme and topics	Top terms contributing to the topic model	Total tweets, n (%)	Example paraphrased tweet[a] (date posted)
Vaccine rollout	*worker*, *care*, *health*, *first*, *receive*, *healthcare*, *hospital*, *staff*	85,623 (5.71)	"We have many sites delivering the covid-19 vaccines to the top priority group. Please be patient and if you are in the top priority group, you will be contacted." (January 17, 2021)
Progress on vaccine administration	*dose*, *million*, *first*, *receive*, *week*, *Pfizer*, *people*, *first dose*	74,577 (4.97)	"Since Tuesday's update, Louisiana has administered 25,133 additional covid-19 vaccines. The second doses started being administered this week. 7,068 people have been fully vaccinated. In total, since mid-December, 81,585 doses have been administered." (January 7, 2021)
Theme 5: Progress on vaccine development and authorization			
Clinical trials	*trial*, *clinical*, *Pfizer*, *Moderna*, *phase*, *effective*, *clinical trial*, *oxford*	99,754 (6.65)	"There are 70 covid-vaccines under development. Moderna is one of the first to test their covid-19 vaccine on humans. If the trial is successful, Moderna could reach the final stage of testing by Fall 2020." (April 26, 2020)
Use authorization	*use*, *FDA*, *approve*, *emergency*, *approval*, *Pfizer*, *emergencyuse*, *health*	60,970 (4.07)	"The FDA's [US Food and Drug Administration's] vaccine advisory committee has unanimously approved an emergency use of the covid-19 vaccine made by Pfizer and by Moderna." (January 19, 2021)

[a] The tweets are paraphrased to protect users' privacy.

Theme 1: Opinions and Emotions Around Vaccines and Vaccination

This theme contained 3 topics, among which the topic of opinions about vaccination (227,840/1,499,421 tweets, 15.2%) was the most tweeted of all the 16 topics and remained the most discussed topic in the majority of the period of our examination (see Figure 2). This theme reflected the mixed opinions of Twitter users about vaccination, including their doubt, hesitancy, trust, and advocacy. Some Twitter users also asked for freedom about vaccination. The second topic, positive emotion around vaccination, featured happiness, hope, relief and other positive emotions that the public showed in their tweets. Many emotions were based on their direct or indirect experiences with vaccination. The third topic was named "American president." The public's opinions and emotions were expressed through their comments on US President Trump and President Biden's vaccine-related words and actions.

Theme 2: Knowledge Around Vaccines and Vaccination

This theme consisted of 4 topics focusing on understanding and facilitating understanding of COVID-19 vaccines and vaccination. The most frequently discussed topic under this theme was educating communities, with a considerable number of tweets spreading information about the live webinars where health professionals would provide important information about COVID-19 vaccines and answer questions. The topic of measures to control community spread featured the recommendation of taking measures such as wearing a mask, washing hands, and social distancing both before and after getting vaccinated. The topics of immunity and mutation centered around the immunity of vaccines and mutation of the coronavirus, which was frequently discussed in comparison with *flu virus*. Functioning of vaccines, as a topic, introduced how vaccines work and the subsequent symptoms and side effects after vaccination.

Theme 3: Vaccines as a Global Issue

The theme of vaccines as a global issue consisted of 4 topics related to the globality of SARS-CoV-2 and the COVID-19 vaccines; therefore, the topics under this theme were not centered on the United States. These topics involved active news about vaccine progress and updates around the world, such as international vaccine supplies, delivery, and purchases in many countries (ie, the topic of vaccine progress around the world), the impact of vaccines on the global economy (ie, the topic of economic impact), and the world's largest inoculation drive (ie, the topic of the vaccination drive in India). The topic of vaccine progress around the world became the most discussed topic around August 11, 2020, because Russia approved the world's first COVID-19 vaccine (see Figure 2). The most salient topic under this theme was global cooperation and support, which called for global cooperation to accelerate the vaccine development and equitable access and advocated no vaccination nationalism. This was also the second most tweeted topic (108,366/1,499,421 tweets, 7.23%) among the 16 topics, only after the topic of opinions about vaccination.

Theme 4: Vaccine Administration

This theme consisted of 3 topics covering several aspects of vaccine administration. The topic of vaccine rollout mainly centered around vaccination to the top priority groups, including health care providers being the first in line. After the first doses of Pfizer vaccine were administered in the United States on December 14, this topic remained one of the 3 most discussed topics for approximately 5 weeks (see Figure 2). The second topic focused on the progress of the vaccine administration, including the shipment and supply of vaccines that directly relate to the progression of vaccine administration. The third topic under this theme was instruction on obtaining vaccines, which included spreading of information from health authorities at various levels to guide the public to obtain their vaccine shots. More detailed information was mentioned in the tweets in this topic, such as “If anyone is 75 and older, does not have internet access, and needs help to schedule an appointment, please call the central appointment desk for help at 1-866-960-0633” (a tweet posted on January 20, 2021). With the advancement of vaccine administration, this topic gradually became more salient and leaped to the rank of most discussed topic, surpassing the topic of opinions about vaccination, after the first week of January; it then remained at the top rank until the end of January (see Figure 2).

Theme 5: Progress on Vaccine Development and Authorization

There are 2 topics under this theme, which focused on the development of COVID-19 vaccines and authorization by the US Food and Drug Administration (FDA). The topic of clinical trials centered around the plan and process of clinical trials, mainly from Pfizer and Moderna, and the updated results of the clinical trials. This topic remained the most discussed topic for a week around July 20, when the first human trial of the Oxford/AstraZeneca coronavirus vaccine showed promise [35], and became 1 of the 2 most discussed topics, together with the topic of opinions about vaccination, for 3 weeks after Pfizer stated its vaccine is 90% effective on November 9, 2020 (see Figure 2). The topic of use authorization centered on FDA approval of an emergency use authorization for COVID-19 vaccines.

Sentiment and Emotion Analyses of COVID-19 Vaccine Tweets

Weekly mean sentiment scores showed that despite fluctuations, in general, the sentiment was increasingly positive from March 11, 2020, to January 31, 2021, with the linear best fit slope of 0.003764 (with a *P* value <.001, which indicates that it is statistically significant) (see Figure 3). Moreover, the positive emotion reached its peak around November 9, 2020, when Pfizer announced that its vaccine is 90% effective; on the same day, the number of daily tweets became historically high before January, as mentioned above. Emotion analysis further showed that trust was the most predominant emotion, accounting for 22.78% of the 8 emotions (anger, anticipation, disgust, fear, joy, sadness, surprise, and trust), followed by anticipation (18.34%), fear (16.29%), sadness (10.97%), joy (9.76%), anger (8.63%), surprise (7.60%), and disgust (5.63%). Noticeably, the most dominant emotion shown in COVID-19 vaccine tweets before April was fear; however, it changed to trust from the week of April 1, 2020 (Figure 4). Trust remained the most dominant emotion after that, and the number of tweets expressing trust continued to grow. In addition, it was observed that when the emotion of trust increased, the emotion of fear decreased. The trust emotion reached its peak on November 9, 2020, when Pfizer announced that its vaccine is 90% effective; on the same day, the fear emotion was expressed the least throughout the time period of our examination. It was also noted that apart from the obvious changes in the emotions of trust and fear over time, the other emotions were relatively stable in the period of March 11, 2020, to January 31, 2021 (see Figure 4).

Discussion

Principal Findings

In this study, we examined sentiments and topics over a long time span, covering the discussions about COVID-19 vaccines from when COVID-19 became a global pandemic (March 11, 2020) to January 31, 2021, when multiple vaccines become available and mass vaccination had begun in the United States and many other countries. This study adds to the latest research about the social impact of the COVID-19 vaccine. For example, there are surveys addressing sociodemographic social media user characteristics and the social determinants of vaccine acceptance [18,36]. Our research supplements studies like these by providing the discourse patterns on social media, that is, how people actually talked about their vaccination intentions and other related issues. Researchers have taken a similar approach to studying very specific vaccine-related topics, such as side effects and the type of vaccines in the context of China. This study could provide a comparison in different cultural contexts, as the corpus was pulled from a global data set and English tweets were analyzed. The specific topics and public sentiments identified could be used for further studies about specific vaccine-related topics among English language social media users. Many of the current studies about COVID-19 vaccination focus on vaccine hesitancy and antivaccine messages [19], and some used survey methods to gather data [37]. As the vaccines for COVID-19 are still very new, and they were developed in a very short period of time due to the urgent need, we would expect the expression of vaccine hesitancy in the public media channels. This study would help contextualize the major concerns about vaccine efficacy and safety.

This study has found some changing patterns of the discussion on Twitter along with the progress. Similar patterns of sentiments and topics found in another research using natural language processing and deep learning techniques on Facebook and Twitter posts [16]. The results of this research show that the patterns are valid across platforms. The number of tweets regarding COVID-19 vaccination is largely driven by major events—mainly the milestones in vaccine development and the new variants of the virus. Major spikes in the number of tweets correspond closely to these events. The analysis of each topic also shows such patterns. For example, from the weekly distribution of topics, a sudden overall increase is noticeable starting from early November, also right at the time of the Pfizer announcement. Scholars have studied how information flows from social media to mainstream news. In today’s media ecology, the boundary between social and mainstream media is no longer clear; however, here we can see that social media discourse is largely mirroring what is happening in the news. Future studies could detect to what extent the social media discussion is shaped by mainstream media.

The sentiment analysis shows that the general sentiment toward COVID-19 vaccination is becoming more positive over time. The overall sentiment score reached the maximum in early November 2020, which also corresponded to the report of the high efficacy of the Pfizer vaccine. As for the emotions, trust continually dominated the discussion; it reached the highest point around early November, following Pfizer's announcement about the efficacy of its vaccine. The percentage of tweets increased overall, showing that more people were expressing their trust in the discussion of COVID-19 vaccine. The change of the percentage of tweets expressing fear mirrors that of tweets expressing trust. The overall percentage is decreasing, showing that as the vaccine development progressed, people's fear about the pandemic decreased. The highest point was in mid-March 2020, after the declaration of the global pandemic, and the lowest point was in early November, at the time of Pfizer's announcement. As vaccine research and testing moved closer to a promising result, the expression of fear declined. Other emotions, in terms of their percentages of the overall tweets, remained more or less stable over time. Trust is the dominant emotion, which can be understood as a reflection of the vaccination as the only option. Unlike other types of vaccines, which people can choose to take or not, vaccination has been increasingly viewed as the only promising way to end the pandemic given the prevalence of COVID-19, the speed of its community spread, the disruption of normal life, and the lack of other options proved to be efficient.

The topics related to opinions and emotions were the most common, and among the 3 topics in this theme, the topic on opinions about vaccination represented the largest proportion. The development of COVID-19 vaccines has progressed along with the spread of the virus and the appearance of variants, together with our increasing knowledge about the disease, all of which have become active topics in public discourse. With many uncertainties remaining about vaccines and other options, we would expect mixed opinions to surface on the platform. This mixed opinion about vaccination should also be situated in the larger context of the antivaccine movement in the United States and other countries as well. Our results show that doubts, vaccine hesitancy, conspiracy theories, and the argument that vaccination is an individual freedom are all common themes in the antivaccine discourse. However, as mentioned earlier, as COVID-19 has affected people's day-to-day life, a vaccine is crucial for returning to normal life; people still have much hope in vaccines, leading to the sharing of positive emotions. Finally, with the political climate and the ongoing presidential election, both candidates included vaccination on their agenda; thus, the discussion about the vaccine was very politicized.

As COVID-19 is an ongoing crisis with a global scale, the discussion about the vaccine is also global. The pandemic has revealed how much the world is now connected, and thus vaccination has become a global issue—if a country cannot reach a certain level of vaccination of its population, it has a high risk of contagion and virus mutation; thus, it is difficult for the country to return to its role in the global economy, and global cooperation is needed to defeat the disease. Therefore, the economic impact of the pandemic and the development of vaccines are salient issues.

The currently available vaccines are also results of cross-national collaboration, which is why "vaccine nationalism" is frequently mentioned in tweets as an issue that would impede the progress of fighting the pandemic. In a global crisis, information-seeking needs increase, particularly as vaccines become available and people need instructive information regarding the vaccine rollout, obtaining vaccines, and the vaccine administration. As COVID-19 is a new disease that is still being studied, and the vaccines also became available after a short period of research and development, there are numerous uncertainties facing public acceptance of these vaccines. For laypeople, the science behind the vaccines is still not well understood, particularly because COVID-19 is such a new disease and many things are still unknown. These uncertainties have provoked people to seek and share information about the vaccines, which is reflected in the topic of knowledge around vaccines, such as the science behind the vaccines (immunity and mutation), the techniques used, and results of clinical trials. These uncertainties have also provoked people to seek information about the vaccine rollout and administration because these topics are are closely connected to when and how people will be vaccinated.

The results of this study show that the discussions about COVID-19 vaccines are multifaceted, and the public are actively seeking and sharing information about them. It is important for public health agencies to understand the major public interests and concerns regarding vaccination, that is, the major factors that would affect vaccine acceptance and hesitancy. In this way, they could establish appropriate strategies to facilitate public communication. Our study shows that the major spikes in vaccine discussions corresponded to reports of the breakthroughs of vaccine development as they appeared in the news. Public health agencies need to pay attention to this pattern and monitor the discussions on the web on days when major news is reported about vaccine development or other significant events, such as a report of severe adverse events from a particular vaccine. These agencies could develop immediate responses based on identifying the instant reactions—and the dominant emotions and topics—on social media. In this study, we found that trust is the predominant emotion regarding vaccines, which is promising and reassuring for the public health agencies promoting vaccination. For individual themes and topics, public health agencies should pay close attention to the discussions about vaccine knowledge and administration to close the information gap between the needs of the public and the information the agencies have provided.

Limitations

By examining how topics and sentiments evolve along the timeline of the pandemic and vaccine development, one can see the correspondence of the volume of tweets and major research breakthroughs in the news. Although it is clear that the number of tweets shows a major spike at the news of Pfizer reporting its high vaccine efficacy in early November, a statistical analysis may provide more details about whether there are significant differences. Although it is not the focus of this study, close examination of Twitter users may provide more meaningful information, such as how the contents shared by different kinds of users vary and whether certain types of users are more likely to post or comment on certain topics. In addition, this study may have geographic bias in the examined tweets, as is observed in many other studies of unstructured textual data [38]. As a result, a given data set could overrepresent some geographic areas. Last but not least, because Twitter users are not representative of the US population [39], our data set could be overly representing a subset of the population with specific characteristics. Therefore, the findings of this study should be generalized with great caution.

Conclusion

This study identifies the major topics and sentiments about COVID-19 vaccine–related issues discussed on social media. It also examines the changes in these topics and sentiments over time to better understand the larger trend. Among the 16 distinct topics, opinions about vaccination was the most common and remained so over time. As vaccine development progressed around the world, the dominant topics also shifted. Instructions on getting the vaccine became the most discussed topic around early January 2021. The discussion of COVID-19 vaccination on social media was largely driven by major news events about COVID-19 vaccines and mirrored the active new topics in mainstream media. Also, the discussion has a global perspective. The overall sentiment was increasingly positive over time, and trust was the predominant emotion, which shows that social media discussions may imply higher acceptance of COVID-19 vaccines compared with previous vaccines. Due to the timeline of our data set, in this study, we did not further examine the sentiments about specific brands of vaccines. We would expect the discussions to be different when using different brand names to search for tweets and conduct sentiment analysis. Particularly, after administration of the Johnson & Johnson vaccine was paused by the CDC, there could be a surge of related discussions, and a topic about the side effects of the vaccines could emerge. Therefore, further study in this line is highly recommended.

Abstract

The ability of remote research tools to collect granular, high-frequency data on symptoms and digital biomarkers is an important strength because it circumvents many limitations of traditional clinical trials and improves the ability to capture clinically relevant data. This approach allows researchers to capture more robust baselines and derive novel phenotypes for improved precision in diagnosis and accuracy in outcomes. The process for developing these tools however is complex because data need to be collected at a frequency that is meaningful but not burdensome for the participant or patient. Furthermore, traditional techniques, which rely on fixed conditions to validate assessments, may be inappropriate for validating tools that are designed to capture data under flexible conditions. This paper discusses the process for determining whether a digital assessment is suitable for remote research and offers suggestions on how to validate these novel tools.

digital assessment; remote research; measurement validity; clinical outcomes; ecological momentary assessment; mobile phone

Introduction

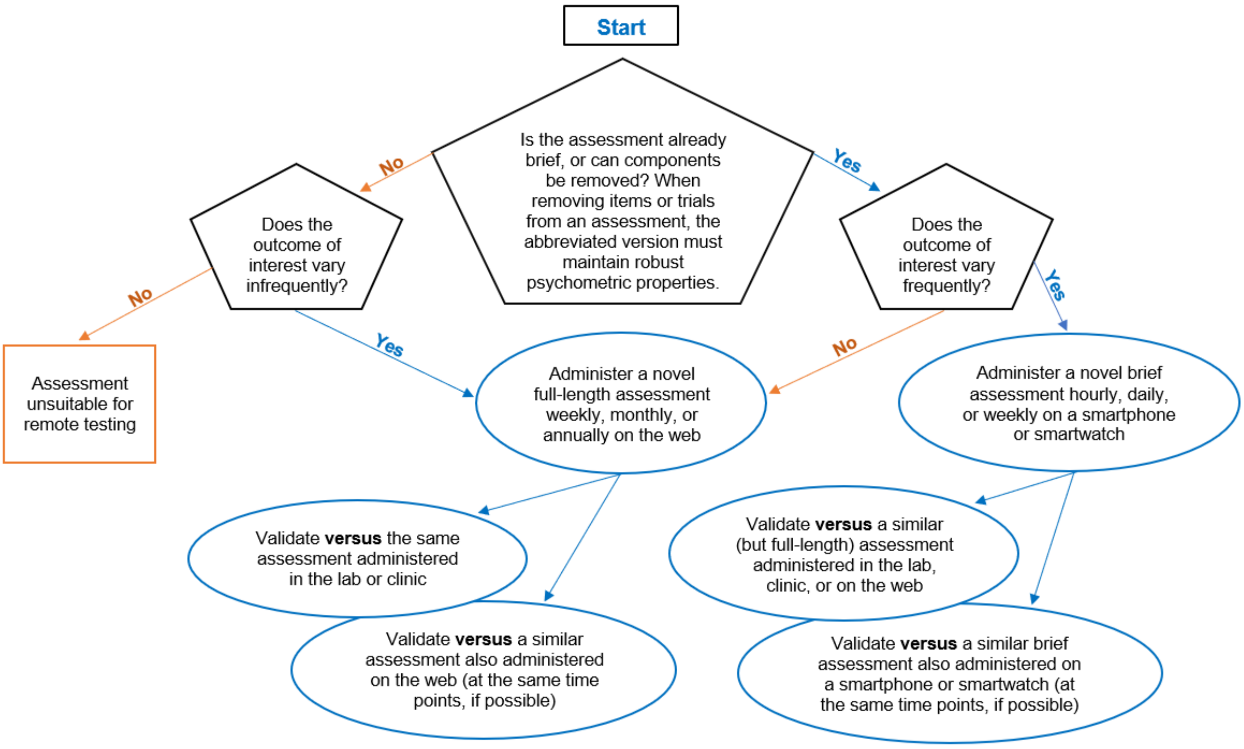
The emergence of SARS-CoV-2 at the turn of 2020 demonstrates how abruptly life—and research—can change. The global response to the resulting pandemic also demonstrates how quickly the world can use technology to adapt to these changes. The physical closure of organizations has less impact now than it would have had even 10 years ago; thanks to technological advances, many formerly in-person activities can now be conducted virtually. For some organizations, this way of operating was already familiar, whereas for others it is novel and challenging. Overall, most organizations are being compelled to adapt and create innovative ways to enhance remote working.

Scientific research has also had to adapt to these unforeseen circumstances. Fortunately, a great deal of psychological research was routinely conducted remotely before the SARS-CoV-2 outbreak [1], primarily in an attempt to produce more externally valid research [2,3]. Remote data collection offers an opportunity for researchers to broaden the diversity of their samples, both in terms of whom they recruit and when and where data collection occurs. Remote data collection is facilitated through web-based recruitment platforms (eg, *Amazon Mechanical Turk*, *Prolific*, and *Call for Participants*), web-based survey and experiment builders (eg, *Qualtrics* and *Gorilla*), and personal devices (eg, smartphones and smartwatches) that can be used to collect data on a range of behaviors (eg, location, movement, social interactions, travel behavior, energy intake, energy expenditure, vital signs, sleep patterns, menstrual cycles, mood, cognition, and pain) [1,3,4]. Smart devices are used for both active and passive data collection, and users can manually input self-report data, whereas built-in sensors allow for continuous collection of objective data [3].

Although much cognitive and behavioral research was already moving toward remote testing before the SARS-CoV-2 outbreak, progress in this field needs to be accelerated. Once social distancing measures are relaxed, it is reasonable to expect a gradual return to normality. However, it is unrealistic to expect our way of life to be wholly unchanged. With the world turning to technologies that facilitate virtual interactions, there are likely to be technical improvements made to these tools, as well as increased availability. The discovery that certain virtual experiences are equally efficient as, or more efficient than, their real-world counterparts may change the way that many of us operate. Considering the widespread effects of the current pandemic and the potential for similar infectious disease pandemics in the future, it is realistic to expect that virtual research will become increasingly popular and, perhaps, even the new norm [5]. Now, more than ever, resources need to be invested in the development of remote research assessments.

Here, we discuss the benefits of conducting remote clinical research, how to determine the suitability of an assessment for remote research, and various approaches to validating such assessments based on where and how frequently data collection occurs. We focus on the validation process of active assessments, including both objective and subjective measures (neuropsychological tests and patient-reported outcomes, respectively). However, the principles outlined here should also apply to the validation process of some passive assessments, such as those designed to detect cigarette smoking [6]. We have included a flowchart (Figure 1) to illustrate the decision-making process. We discuss traditional validation techniques (ie, the comparison of a single assessment between controlled and uncontrolled settings and comparison between two different assessments in the same setting), as well as innovative methods that account for the measurement of constructs across time and location (eg, improving signal-to-noise detection to capture more robust baselines and develop novel phenotypes for improved precision in diagnosis and accuracy in outcomes). We have included case studies to illustrate the breadth of approaches and techniques that may be necessary to consider when designing a validation process for novel assessments. However, it is important to note that these individual pilot studies are only presented here for example purposes and should not be considered comprehensive empirical studies in their entirety.

Figure 1. The decision process for validating digital assessments for remote research.



The Benefits of Conducting Clinical Research Remotely

In a conventional clinical trial, researchers ask patients to complete comprehensive assessments to monitor their symptoms. The assessments can be extensive and may require trained personnel to administer and score them. As the assessments are burdensome for both parties [7], the frequency with which they can be administered is limited and, as a result, they only provide snapshots of treatment efficacy. In other words, assessments may only be administered monthly or even less frequently. However, symptoms can fluctuate from week to week, day to day, and even within a single day. At the time of assessment, a patient's symptoms might improve or be exacerbated by chance because of factors unrelated to treatment efficacy (eg, a stressful event occurring in the morning before an afternoon assessment). Therefore, it can be difficult to ascertain whether changes in patients' symptoms are due to treatment or extraneous factors. Researchers might test patients on the same day of the week or at the same time of the day throughout the trial to account for fluctuations in symptoms. However, this strategy operates on the assumption that symptom changes occur in a predictable manner.

Many psychiatric disorders are characterized by irregular circadian rhythms. Therefore, these patient groups might have, in particular, stochastic fluctuations in cognitive function and mood that cannot be easily predicted [8]. Researchers may attempt to evaluate symptoms during the intervals between assessments by relying on retrospective subjective reports from patients [3]. However, self-report measures can be unreliable indications of actual behavior [9-12], especially when a patient's condition affects their insight or their memory [13,14], impairing their ability to accurately recall past events and symptoms. In addition, there is a limit to how much detail can be recalled. Retrospective subjective reports usually ask patients to reflect on symptom changes over a week or month because recalling hourly or daily changes would be unfeasible [15]. To account for confounders that coincide with test days and avoid relying on biased reports of symptoms, researchers may measure the symptoms of interest before and after an experimental manipulation in the laboratory. This design is assumed to act as a proxy for what might occur in the real world. However, it is not clear how well the trigger and resulting behavior in an artificial setting will translate into those occurring in the real world [16]. An alternative is to conduct the trial remotely, using a phone or wearable device to administer assessments in natural settings at regular intervals or in response to state changes, also known as ecological momentary assessment [2,3]. This methodology reduces user burden while increasing the likelihood of the measurements capturing clinically relevant symptoms when they occur in real time, and such approaches will help to revolutionize clinical trials [3,17].

Determining the Suitability of an Assessment for Remote Research

When developing any assessment tool, there needs to be a trade-off between the length or duration of an assessment and the frequency at which it can be administered. On the one hand, the testing time should be kept to a minimum. Increased testing time can cause participants to tire of the assessments [18], which could decrease the accuracy of responses and compliance, thereby increasing attrition. Similarly, knowing that one will need to complete frequent lengthy assessments during a research study may negatively affect recruitment to that study. On the other hand, there needs to be a sufficient amount of data to maximize the precision of the measurements and ensure their accuracy (ie, effectiveness at detecting the presence or absence of the symptom of interest) [19]. These considerations are especially crucial when the research study requires participants to interrupt their normal routines to complete assessments [20,21] and even more so when conducting clinical research with patients who may have a low threshold for burdensome research procedures because of their symptoms (eg, lack of concentration, fatigue, or motivational fluctuations). Therefore, for the most part, remote assessments should be either *brief and frequent* or *lengthy and infrequent* to be successfully implemented and to reliably capture valid data. However, there are exceptions to this rule, which we discuss herein.

Assessments that require a substantial amount of time to complete cannot be easily incorporated into daily routines or administered frequently without overly inconveniencing users. The inclusion of these assessments in real-world trials is likely to decrease compliance and increase attrition. Therefore, lengthy assessments will need to be abbreviated to be administered at high frequencies.

However, some assessments cannot be abbreviated, such as those that cannot sacrifice items or trials without degrading the assessment's psychometric properties. As long as lengthy assessments can be administered at relatively low frequencies (eg, once a day or once a week) and have some flexibility regarding when they can be completed (within reason), they can be administered remotely (ie, on the web). Administering a lengthy assessment remotely (as opposed to administering it at a testing facility) provides a more naturalistic context for data collection and may reduce confounding factors associated with artificial test settings. It also reduces the intervals between events of interest and subsequent measurements, which may improve symptom recall accuracy. In addition to these benefits, there are temporal and spatial limitations within this context that should be considered. Users will need to find an appropriate space as well as time to engage with the assessment. Therefore, administering lengthy assessments remotely is not a suitable method for capturing clinically relevant data in real time. However, depending on the research question and clinical population, it might be preferable for participants to complete an extensive assessment less frequently and retrospectively, rather than complete a less comprehensive assessment more frequently and in real time (eg, when qualitative data are needed, for the purposes of a clinical diagnostic interview, etc).

Assessments that are brief (or can be abbreviated), track dynamic changes, and are not limited by specific technical requirements are appropriate for high-frequency remote testing. This approach captures high-resolution data that allow for the interpretation of outcomes in relation to time and location. This increased level of detail can be incorporated into the statistical analyses to improve the signal-to-noise ratio. As a result, high-frequency assessments can be used to achieve more representative baselines and develop novel digital phenotypes to improve the precision and accuracy of diagnosis and outcomes [22]. It should be noted that brief assessments do not necessarily have to be administered at high frequencies to be valid measurement tools. For example, the 2-item Patient Health Questionnaire (PHQ) is an abbreviated version of the 9-item PHQ, which is widely used to evaluate depression and demonstrates sufficient diagnostic sensitivity when administered at the same low frequency as the full-length version [23]. Administering the abbreviated version infrequently is likely to be less sensitive than both administering the full-length version infrequently and administering the abbreviated version frequently. However, the latter options may not always be feasible (eg, when the other study procedures are already time consuming and effortful) or sensible (eg, when increasing the response rate or completion rate is key).

Sampling frequency matters—both over- and undersampling can have negative consequences. It may be inefficient to use hourly sampling to capture diurnally varying symptoms [24] or to use time-based sampling to capture symptoms that occur in response to specific (eg, clinically relevant) events [3]. This is particularly true if the frequency and regularity of the relevant event vary considerably among individuals (eg, panic attacks can occur several times per week or a couple of times per year) [25-27]. Sampling more than necessary risks burdening participants, wasting resources, and ultimately degrading data quality (eg, by decreasing compliance) [24]. The sampling frequency should align with the fluctuations of the symptoms of interest as much as possible so that each measurement is informative. This may mean that low-frequency sampling is the most appropriate, circumventing the need for brief assessments. However, compliance may be low if participants are required to self-initiate assessments after the occurrence of relevant events. Alternatively, high-frequency sampling can be used to continuously monitor relevant events (eg, through a watch that passively detects smoking) and trigger an assessment when appropriate [6,28,29]. There are also cases in which the relevant events may occur irregularly or infrequently, but continuous monitoring of the symptoms of interest outside of the event window is useful; for example, measuring positive and negative affect regularly as well as whenever self-harm occurs [30]. Continuous monitoring of symptoms provides a clearer picture of baseline functioning, which can be used to better characterize changes in functioning. Furthermore, continuous monitoring of symptoms of interest, relevant events, or related factors can help identify patterns in behavior that can be used to predict changes, increasing sampling accuracy and reducing participant burden [31,32]. Of course, the feasibility of continuous monitoring will depend on the effort required by the participant to complete the assessment and the capacities and constraints of the specific participant group.

There are also assessments that are appropriate to abbreviate and administer at high frequencies but may not be suitable for remote testing for other reasons (eg, if researcher supervision or a specialist device is required). Furthermore, if the assessment is susceptible to practice effects, mitigating solutions will need to be developed [33]. Some considerations may not be directly related to the assessment itself but to the context in which it is used. For example, an assessment may be designed to evaluate outcomes after a pharmacological challenge and, in this case, whether or not the pharmacological challenge can be delivered remotely needs to be considered. It may be possible, if appropriate precautions are taken, to instruct participants to self-administer certain substances, such as caffeine, alcohol, nicotine, etc, but this would clearly not be possible in other cases (eg, controlled substances).

A Process for Evaluating Tools for Remote Research

As research transitions from operating in testing facilities to the field, it is vital that remote research assessments are developed to a high standard. A remote research assessment needs to be both a valid measure of the construct being evaluated and practical to implement. One of the difficulties in transitioning to remote data collection lies in defining the process for validating remote assessments. For a novel assessment to be valid, it must be reliable and a true measure of the construct of interest. Reliability can be verified by measuring the internal consistency of items or trials or by investigating whether the assessment produces consistent results under similar conditions (ie, test-retest reliability) [34]. To demonstrate internal validity, a reliable assessment is compared with a gold standard (ie, a tool that has been demonstrated to consistently and accurately measure the construct of interest) under controlled conditions to reduce extraneous influences. To demonstrate external validity or generalizability, the assessment is administered and compared across different testing conditions (ie, at different times, in different settings, and in different people) [35,36].

However, this paradigm for evaluating internal validity is not necessarily useful for validating remote research assessments, which are not designed to be administered under controlled conditions. This is not necessarily a limitation because using a traditional validation paradigm may not be ideal when the focus is on real-world behavior, as is the case in applied research. Testing under controlled conditions can introduce temporal and spatial biases into the data. Unlike traditional research assessment, remote research assessment is far more flexible in terms of when and where it can be administered. This increased flexibility in data collection can improve the external validity of the assessment but also means less standardization because assessments are completed without researcher supervision and in contexts that can vary within and across participants. Therefore, the framework for evaluating the *internal* validity of remote research assessments may need to be different from traditional methods that assume spatiotemporal consistency.

How to Validate Low-Frequency Assessments for Remote Research

The internal validity of an assessment includes face, content, criterion, and construct validity [36,37]. Criterion validity is useful to assess when evaluating the construct validity of an assessment, abbreviating an already existing assessment, or planning to use an assessment in a new environment. To assess the criterion validity of any new assessment (either a completely new assessment or an amended version of an already validated assessment), the validity assessment needs to be administered (concurrent validity) or after (predictive validity) an established assessment. An established assessment is one that has already been validated to measure the same construct or a similar constructs (to evaluate criterion and construct validity, respectively) [36]. The outcomes generated by the new assessment need to be compared with those generated by an established assessment. To validate a new low-frequency assessment for data collection in a clinical or laboratory setting, both the new and established assessments need to be administered under standardized conditions at the testing facility to confirm that the assessments are equivalent. To validate a new low-frequency assessment for remote data collection, the new assessment needs to be administered remotely and the resulting outcomes compared with those generated by the established assessment. The established assessment can either be administered in a clinical or laboratory setting or remotely (depending on whether the assessment has already been validated for remote data collection) [38-40]. When validating assessments remotely, the unsupervised and uncontrolled nature of the study environment and the potential for selection bias need to be considered. Table 1 illustrates not only some limitations of remote data collection but also the advantages that remote data collection offers over data collection at testing facilities. The advantages may offset the disadvantages of remote data collection because research suggests that data collected remotely and in-person are comparable [1,39,41-45].

Table 1. Key factors to consider when validating assessments for remote research.

Factors	Limitations	Advantages
Absence of rater or supervision	• The researcher cannot observe participants to determine whether participants are incapacitated, disengaged, or require clarification and intervene if necessary [46].	• Participants may be less influenced by social facilitation or impairment and behave more naturally [47].
No central testing location and testing can occur at unspecified times	• There may be a higher likelihood of distractions during data collection [48]. • The sample might be biased toward individuals with technology and internet access and technology proficiency [1,39,48,49].	• Being outside of the laboratory or clinic may reduce evaluation apprehension and cause participants to behave more naturally [50]. • Depending on the study design, participants may be reporting on behaviors, mood states, etc when and where they naturally occur [3]. • Participation in the study is accessible to individuals who are unwilling or unable to travel to a central testing location or to be tested in person [1,48].
Differences in device, computer hardware, software, processing speed, screen resolution, display characteristics, internet connection, and response input method	• May bias stimulus presentation and response measures, especially reaction time [1,40,45,48,51,52] • Differences in the ownership of certain devices (eg, smartphones) may be patterned by sociodemographic factors [53].	• Having participants use their personal devices to input data may reduce study costs (devices do not need to be purchased and supplied to participants). In addition, the use of a familiar device may improve performance and compliance [54].

Evaluating behavior under controlled (ie, laboratory or clinic) or quasi-controlled (ie, on the web) conditions may suffer from poor external validity because the findings will not necessarily represent natural behavior. External validity refers to the degree to which the measurements generated by an assessment generalize to other people (population validity) and settings (ecological validity) [35] and across time [55]. In field research, behavior can be evaluated at frequent intervals, in natural settings, and in real time. This avoids experimenter and recall biases, increasing the ecological and temporal validity of the research. The population validity of field research is less straightforward (Textbox 1).

Textbox 1. Taking a closer look at the external validity of remote assessments.

Selection biases

- Both remote and in-person studies are subject to selection biases [49,56-60]. Whether a study is conducted remotely or in-person, participants are motivated to take part for a variety of reasons. For example, a common motivation for taking part in in-person studies is financial reward; other reported motivations include the desire to help science and medicine, help other people, learn, and socialize [60]. Differences in participation motivation can have downstream effects such as affecting engagement with the study procedures. In turn, data quality may suffer, resulting in misleading findings. Previous research demonstrates that there are systematic differences in engagement between paid and course-credit participants in in-person studies [59] and between web-based participants looking for paid work (eg, *Amazon Mechanical Turk* users) and those recruited through paid advertisements [56].
- A large proportion of the participants in in-person studies are Western, educated, affluent, and democratic individuals from industrialized countries [61] and primarily students [1,48]. The resulting lack of diversity of the sample can weaken population validity [1,48,61]. For example, there is evidence of systematic differences in data obtained from student samples and the general population [57]. When conducting research with clinical populations, there are additional barriers associated with poor health that can bias trial recruitment and retention [62]. Individuals with the lowest levels of functioning may be the least likely to participate in, or the first to drop out from, clinical trials because participation might be too burdensome [63]. Conversely, when recruitment for clinical trials primarily occurs at health care facilities, individuals who do not visit doctors' offices and hospitals (perhaps those with the highest levels of functioning or those that dislike or fear health care settings) are likely to be underrepresented in the clinical research [64]. Collecting data through remote assessments may increase sample diversity, for instance, by making participation more accessible to nonstudent populations (such as individuals who work during normal operating hours, who have care responsibilities, who live and work far from the university, who are unfamiliar with research, etc). Collecting data through remote assessments can also increase sample diversity for clinical research by making participation more accessible to individuals with varying disease severity and to those reluctant to seek out treatment. Remote methodology also allows individuals who might not otherwise participate in research because of disapproval from family or friends [65] to participate discretely.
- However, although this approach mitigates certain selection pressures, it is likely to induce different selection effects relating to, for instance, internet and device access [49,54,66,67]. Although it is commonly accepted that this may affect generalizability, it may also bias exposure-outcome relationships within the study of interest owing to collider bias. For example, say we enroll participants in a remote study on cognitive performance in which assessment necessitates using an iPhone. It has been demonstrated that ownership of an iPhone is associated with educational attainment, age, and health [68]. If we assume that educational attainment is related to cognitive performance, then any relationship we see between the predictors of iPhone use (eg, age and health) and cognition may be distorted by collider bias [69].
- Instead, researchers may allow participants to complete the assessments on any smartphone to increase the inclusivity of the research. If large variations in responses due to software or hardware differences are anticipated, the analysis may include device type as a covariate to control for this variability. Doing so, however, can again introduce collider bias, where, for example, an association between socioeconomic status and cognitive performance may appear weaker than the true population value [54]. This selection bias poses a risk to generalizability of the findings. Therefore, researchers must carefully consider their recruitment strategy and implement statistical tools such as weighted and sensitivity analyses to avoid and correct for selection biases [58,70].

How to Validate High-Frequency Assessments for Remote Research

Field assessments cannot feasibly be administered in controlled settings at fixed times in an attempt to avoid interference from the outside world. As a result, it can be challenging to empirically evaluate the impact of extraneous factors and thus demonstrate robust internal validity, especially because there can be substantial intraindividual variability in many important symptoms and behaviors. One solution is to exploit the ability of these tools to capture high-resolution data [22]. High intraindividual variability can inflate the sample SD; increasing the number of data points per participant can increase the precision of estimates and improve statistical power [71-74]. However, the feasibility of increased sampling needs to be considered because it can exacerbate practice and fatigue effects [33].

To validate any new high-frequency assessment, the procedure is broadly the same as that for a low-frequency assessment: outcomes from a high-frequency assessment can be compared with those generated by an established low-frequency assessment. As high-frequency assessments are administered under flexible conditions, they exhibit greater external validity at the expense of internal validity. Likewise, because low-frequency assessments are administered under stricter conditions, they exhibit greater internal validity at the expense of external validity (Textbox 1). Therefore, equivalence in the outcomes generated by these complementary measures suggests that high-frequency assessments are likely to possess robust external and internal validity.

However, to make a comparison between two complementary measures, any methodological differences in how the measures are implemented need to be taken into account. When validating an assessment for high-frequency testing, the new assessment is often a brief assessment, whereas the established assessment may be a full-length assessment. When validating a brief assessment against a full-length assessment, there is often a temporal mismatch. A full-length assessment needs to be administered only once to provide meaningful data. However, because a brief assessment is less comprehensive than a full-length assessment, a single data point may be less likely to be informative. Instead, the brief assessment needs to be administered repeatedly across a range of time points, with the resulting multiple data points taken together to provide useful information.

An exception might be when a full-length assessment is not particularly lengthy to begin with; therefore, the abbreviated version is not considerably shorter than the full-length version, and the psychometric properties of the assessment are not drastically affected. The reason for shortening the assessment might be to coadminister it alongside other assessments while keeping the total testing time brief. Alternatively, it might be beneficial to remove a component that may be problematic when delivering assessments remotely. For example, the 8-item PHQ is equivalent to the 9-item PHQ except that it excludes the item on suicidal ideation. It is useful for screening for depression in environments where it would not be feasible to implement safeguarding procedures for participants who indicate suicidal thoughts or intentions [75]. In these cases, the assessment may still be administered at high frequencies, but not because increased sampling is necessary to compensate for a reduction in trials or items. Therefore, in these cases, the outcomes from a single abbreviated assessment would be meaningful and could be directly compared with the outcomes from a single full-length assessment.

When validating a brief assessment against a full-length assessment, there is often a spatial mismatch. Brief assessments are often implemented to facilitate field research, whereas full-length assessments are best suited to more controlled environments where participants can dedicate a substantial amount of time to attend to the assessment (ie, in a clinical or laboratory setting). Therefore, when comparing outcomes between the two it is useful to compare high-frequency measurements collected in the field with low-frequency measurements collected in a controlled environment. For example, a recent study evaluated the feasibility and validity of high-frequency cognitive assessments in patients with schizophrenia. Patients and healthy controls completed a traditional neuropsychological battery at the clinic, followed by an ecological momentary assessment (hosted on a mobile phone) to measure cognitive function remotely for 7 days. Compliance was high, fatigue effects were not observed, and practice effects occurred as a function of study duration, but this relationship was observed for both the patient and control groups. Outcomes for the high-frequency abbreviated assessments correlated considerably with the outcomes from the validated full-length assessments in both patients and controls, demonstrating convergent validity for the high-frequency assessments [76]. However, the full-length assessment, against which the abbreviated assessment is validated, does not necessarily need to be administered at a testing facility. It can instead be administered remotely if it has been validated for remote administration and can feasibly be administered at moderately high frequencies (eg, once a week or once a day). This approach is illustrated in Textbox 2 [77].

Textbox 2. Comparing high-frequency abbreviated assessments with low-frequency full-length assessments.

Aim

- To evaluate the feasibility and validity of high-frequency assessments to capture fluctuations in cognition and mood

Methods

- Ecological momentary assessment was used to measure cognition and mood remotely for 2 weeks in 10 healthy participants in a pilot study.
- Cognitive function was assessed remotely by using the following:
    - Validated full-length assessments from the Cambridge Neuropsychological Test Automated Battery (CANTAB): spatial working memory, rapid visual information processing, attention switching task, and emotion recognition task. The assessments were hosted on a web page and administered after 5 PM each day.
    - An abbreviated assessment (hosted on a smartwatch: Microsoft Band 2) of working memory (A-prime: the ratio of hits [correct detection of an n-back match] to false alarms [response during no match] 2-back task). The assessments were administered once per hour between 9 AM and 7 PM.
- Mood was assessed remotely by the following methods:
    - A validated full-length assessment: positive and negative affect schedule. The assessment was hosted on a web page and administered after 5 PM each day.
    - A brief assessment (hosted on a smartwatch: Microsoft Band 2) of emotional state (through the selection of the participant's current emotion and rated intensity of this emotion) probed immediately after cognitive testing each day.

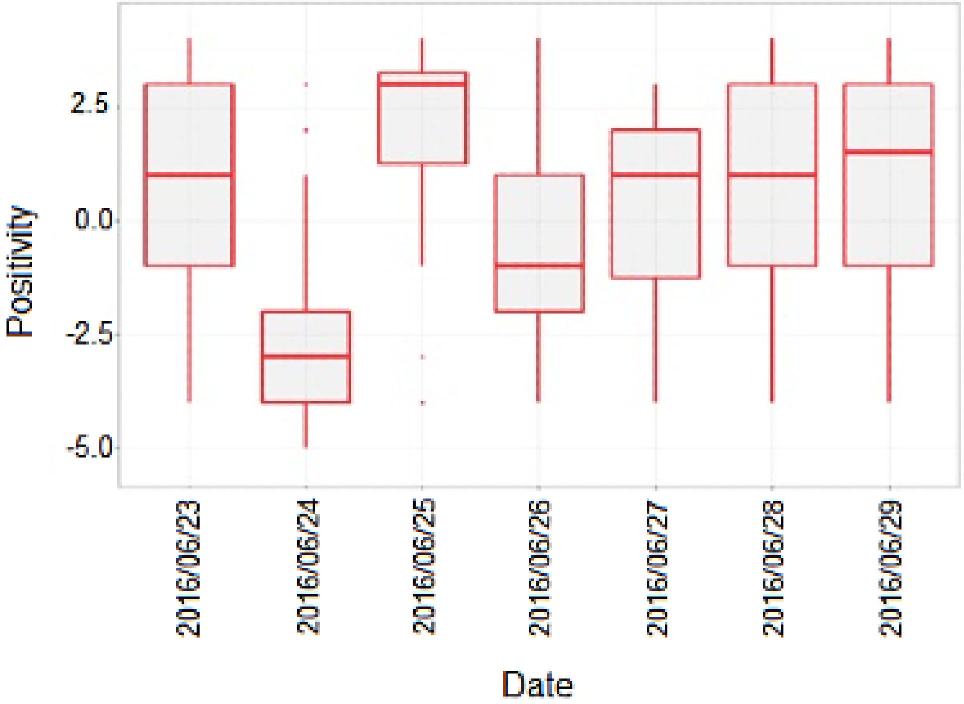
Key findings

- The feasibility of the high-frequency methodology was evaluated by measuring compliance with data collection. The high-frequency 2-back task was completed on 64% (9/14) of the study days, with an average of 3.6 tests completed on those days. More assessments were completed on weekdays than on weekends and outside of commuting hours (9 AM and 6 PM).
- The convergent validity of the high-frequency 2-back task was evaluated by correlating its outcomes with the outcomes from the CANTAB tests. A-prime was significantly correlated with measures of spatial working memory (r=−0.8) and attention switching task (r=−0.45), and moderate but not statistically significant correlations were observed with performance on a measure of sustained attention (rapid visual information processing A-prime r=−0.33). On the high-frequency assessments of mood, this nonclinical sample rated the mood as generally positive and of a low intensity. Participants were first asked to rate their emotion by choosing 1 of 6 canonical emotions (happiness, sadness, disgust, fear, surprise, and anger) and then the intensity of that emotion on a 6-point scale where 6 was the most intense. As negative emotions (sadness, disgust, fear, and anger) were much less frequently reported than positive emotions (happiness and surprise) in this healthy sample, daily intensity reports across positive and negative emotions were aggregated to produce a single scale representing the overall balance of reports of positive or negative emotional intensities over a day. Notably, a reduction in mood positivity was observed on the day of the results of the 2016 United Kingdom European Union membership referendum (June 24, 2016; Figure 2).

Key conclusions

- A full-length assessment allows for comprehensive data collection at a single time point and allows for researchers to exert greater control over the testing environment. Yet, the data might be distorted owing to low-sampling frequency or use of an artificial environment. In this case study, it was feasible to administer the full-length assessments daily in natural settings. However, many full-length assessments might be too long to administer as frequently as once a day [78] or need to be administered at a testing facility [76] (eg, when specialist equipment or a trained administrator is required). The results in this case study demonstrate how extraneous factors (eg, the referendum) can affect outcomes. Outcomes that are measured infrequently are more vulnerable to confounding bias (ie, the outcomes may differ dramatically depending on the day or time when they were measured). Measuring outcomes at high frequencies, instead, allows researchers to detect confounding effects and control for, or investigate, them as appropriate.
- To feasibly measure outcomes at high frequencies, assessments must be brief, which means the comprehensiveness of data collected at a single time point is drastically reduced. Therefore, to ensure that abbreviated assessments are sensitive to what they are intended to measure, they need to be administered more frequently than, say, once per week or once per day. This often requires sampling to occur in real-world environments because it is impractical to collect data in a laboratory or clinic at such high frequencies. Using field assessments comes with its own set of challenges; therefore, study designs should account for times when engagement may be low (eg, weekends or during commuting).
- Although it is unfeasible to validate field assessments under tightly controlled conditions, they can be compared with assessments that have reliably exhibited internal validity in both healthy participants and patient groups, such as the CANTAB tests portrayed in this case study [79-83]. Field assessments benefit from sampling phenomena within natural settings and in real time over extended periods of time. When outcomes generated by the field assessments are comparable with those generated by validated full-length assessments, it is reasonable to assume that the field assessments also exhibit strong internal validity or, at the very least, are sufficiently valid measures owing to robust external validity and extensive sampling.

Figure 2. Daily mood positivity across all participants over a 7-day period.



One disadvantage of validating a high-frequency assessment against a low-frequency assessment is that it seeks equivalence between outcomes captured at different times and in different locations. An alternative approach is to compare 2 assessments that take measurements in equivalent ways (ie, at high frequencies in the field). This approach is only possible when a brief assessment (validated to measure the same or an empirically similar construct of interest) already exists. This approach allows for a new brief assessment to be validated against an established assessment in real time, evaluating construct and criterion validity. As the assessments are completed concurrently, both assessments will be subject to similar influences (eg, common confounding structures). However, this threat to internal validity is likely to be offset by the richer and more granular data produced by high-frequency assessments. It allows for in-depth exploration of interindividual and intraindividual variability, which is key to identifying a signal in a noisy setting. This validation approach is illustrated in Textbox 3. Although one of the strengths of high-frequency testing is increased external validity (Textbox 1), it is worth thinking critically about the degree to which it increases generalizability (population validity) specifically, with special consideration given to recruitment strategy and analytical approaches [58,70].

Textbox 3. Comparing different high-frequency assessments.

Aim

- To evaluate the feasibility and validity of a high-frequency assessment of vigilant attention and explore how reducing task length affects both factors

Methods

- Ecological momentary assessment was used to measure vigilant attention remotely for 2 weeks in 13 healthy participants in a pilot study.
- Vigilant attention (which is sensitive to sleep deprivation) was assessed remotely by using the following:
  - An abbreviated version of the psychomotor vigilant task (PVT), an objective measure of vigilant attention. The PVT measured reaction time after stimulus onset across approximately 50 trials. It was hosted on a mobile phone and was administered up to 2 times per day (morning and afternoon).
  - A subjective, validated measure of sleepiness or alertness, the Karolinska Sleepiness Scale (KSS). The KSS consists of a single rating of sleepiness or alertness on a 9-point scale. The KSS (hosted on a mobile phone) was administered immediately after each administration of the PVT.

Key findings

- Compliance was poor; of the 13 participants who took part, 10 completed at least 50% (14/28) of the assessments. However, it should be noted that the PVT and KSS measures were administered as part of a longer battery (approximately 10 min), which many of the participants felt was burdensome. Therefore, it is probable that compliance would have been higher if the PVT and KSS measures were administered on their own. Overall, mean PVT reaction times were correlated moderately with KSS scores (r=0.37; 95% CI 0.25-0.48). As the outcome measures were captured in real time and sampled frequently, they were not influenced by retrospective recall bias and were less susceptible to coincidental factors. In addition, the granularity of the data allowed for in-depth analysis of how compliance, task performance, and task sensitivity changed as a result of repeated assessments, the time of day, the day of the week, task length, and individual differences.
- For example, to assess if the PVT's sensitivity to sleep deprivation changed as a result of task length, the association between PVT reaction times and KSS scores across all time points for the full 50 trials can be compared with the first 45, 40, and so on, trials. As there are multiple observations for each individual, a mixed model can be used to account for the dependency of observations, where observations (level 1) are nested within participants (level 2). Below, we have plotted the proportion of variance explained by the model based on the number of trials included in the analysis (Figure 3).
- The plot illustrates that the amount of variation in PVT reaction time explained by KSS scores does not change when fewer trials are included in the analysis. However, this plot depicts aggregate data across all participants. Owing to the granular nature of the data, several data points exist for each measure for each participant. Therefore, it is possible to calculate an intraindividual correlation between 2 variables (such as PVT reaction times and KSS scores) for each participant to allow for the interpretation of interindividual and intraindividual variability. Below, we show the association between PVT reaction times and KSS scores across all time points for each participant with more than 50% (14/28) compliance (n=10) based on the number of trials included in the analysis (Figure 4).
- In addition, owing to the granular nature of the data, sources of variability such as temporal influences on PVT performance (eg, time of day, repetition of assessments) can be explored and accounted for in the modeling. Below, we show how mean PVT reaction time (averaged across all participants) varies based on time of day (morning vs evening assessments) and over the 14-day testing period (Figure 5).

Key conclusions

- The rich, granular data produced by the high-frequency assessments allow for in-depth exploration of interindividual and intraindividual variability. Furthermore, sources of random variability can be accounted for in the analysis, increasing the signal-to-noise ratio.

Figure 3. The proportion of variance explained by the model (conditional R^2) across all participants based on the number of trials that were included in the analysis.

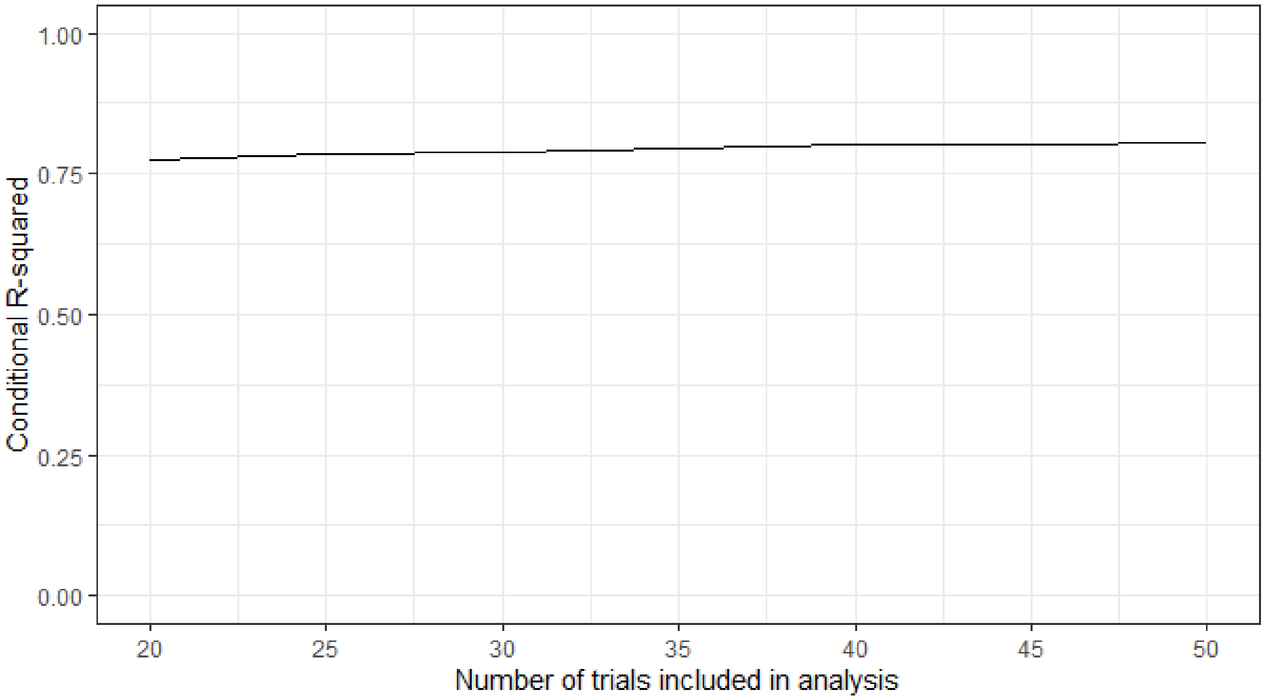


Figure 4. The correlation (Pearson *r*) between psychomotor vigilance task reaction times and Karolinska Sleepiness Scale scores across all time points within participants. Only participants with more than 50% compliance (ie, completed at least 14 of the 28 possible assessments) are included (n=10).

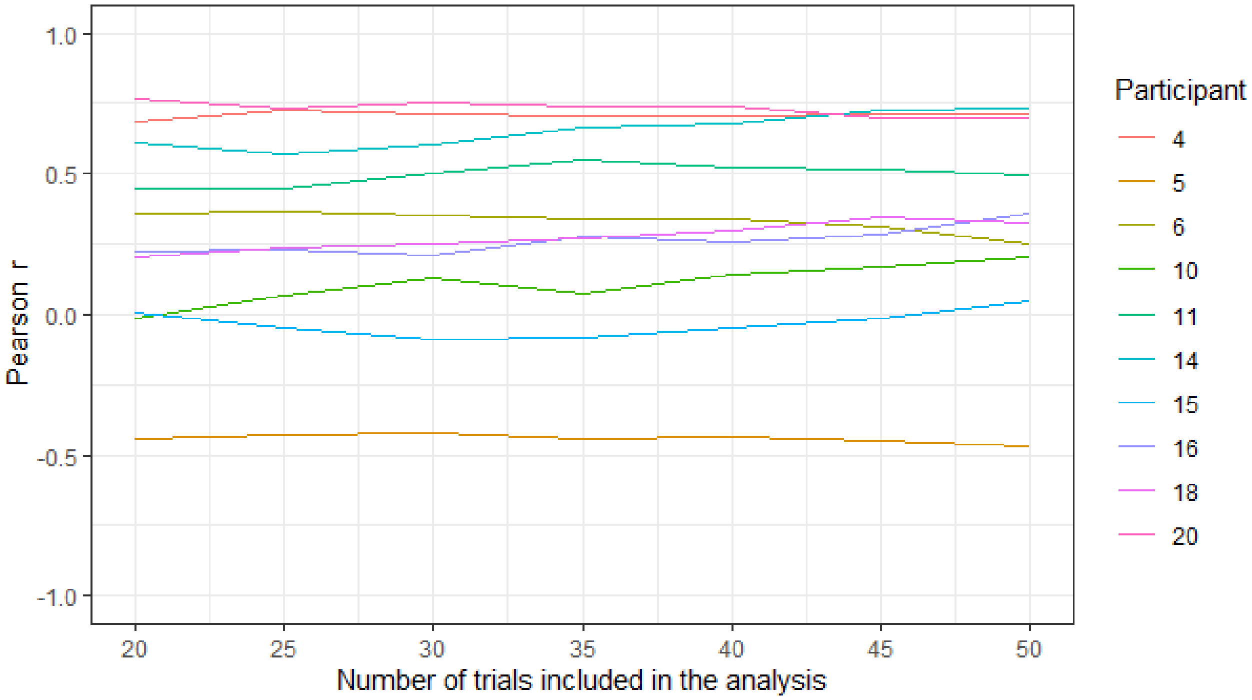

Figure 5. Mean psychomotor vigilance task reaction time (across all participants) as a function of the time of day (morning vs evening) and study day (day 1 to day 14). PVT: psychomotor vigilance task.

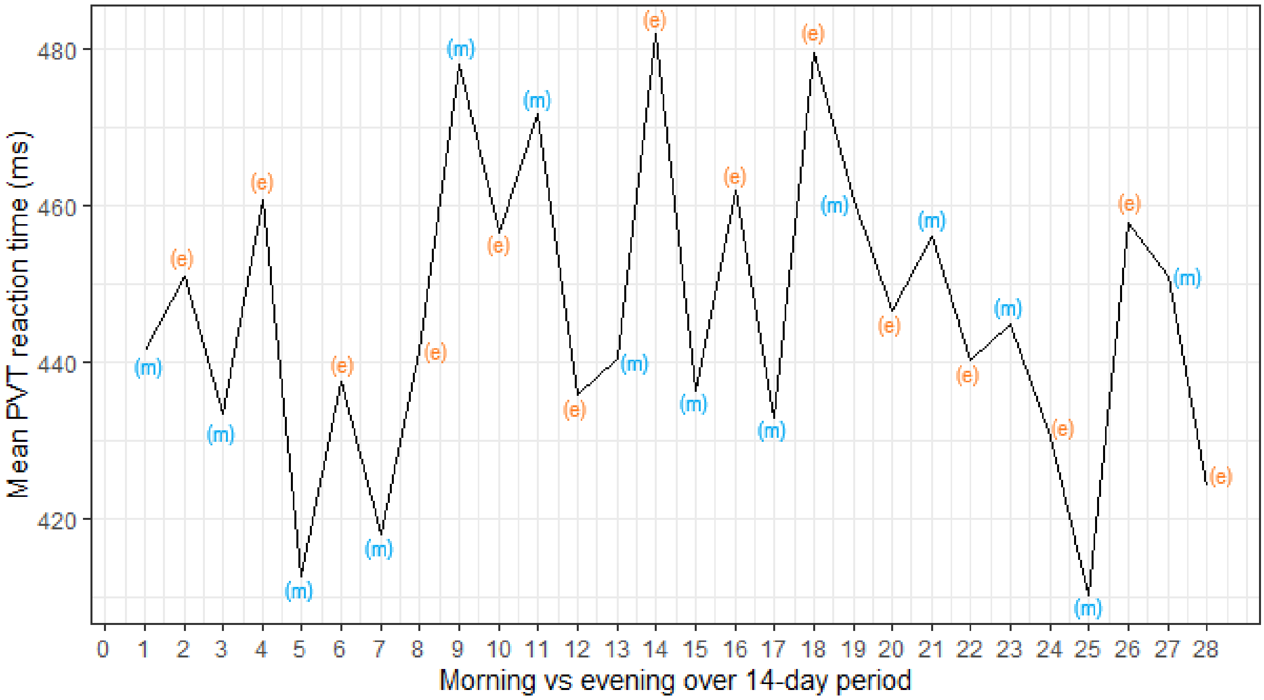


Longitudinal data sets, such as those presented in Textbox 2 and Textbox 3, can be analyzed using mixed-effect models, which allow for both fixed and random effects to be included in the modeling. The benefits of using mixed-effects models are that they can tolerate missing data and evaluate changes over time. Furthermore, changes over time can be explored with respect to how each individual changes over time and how this differs among individuals [84,85]. New approaches to mixed-effects modeling are being developed that allow for close investigation of within-individual volatility. This approach is illustrated in Textbox 4.

Textbox 4. Deriving novel phenotypes using fine-grained repeated observations.

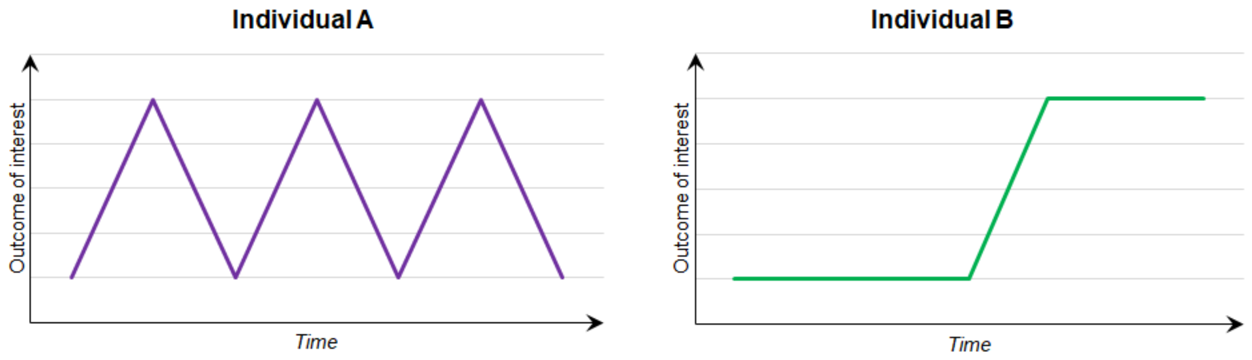
Measuring response volatility

- Fine-grained temporal data such as those offered by the more rapidly reflexive nature of remote research assessments allow researchers to test hypotheses that could not be tested with coarser temporal coverage. For instance, ecological momentary assessment studies can be deployed more rapidly than traditional surveys owing to their electronic distribution—meaning they also allow researchers to ask more reflexive questions, for instance, about the mental health impact of rapidly evolving events such as COVID-19 lockdown policies [86].
- There are further benefits to the use of remote research assessments in the generation of higher-order individual-level characteristics. Repeated measures collected from an individual over time allow for inference about not only the nature of a static response characteristic, but also the within-individual heterogeneity within the response of interest. This is clearly of particular interest in psychological research if it is hypothesized that the variability itself is of substantive interest. For instance, work on borderline personality disorder can require the characterization of affective dysregulation through response volatility [87]. Similarly, studies have investigated associations of affective volatility with mental health and alcohol consumption mediated by mean positive affect in mothers [88].
- Broadly, further increases in temporal granularity allow more complex parameterizations of volatility. We may start with something relatively commonplace such as SD or variance. However, consider the example below: intuitively we can see that individuals A and B have different levels of *volatility*; yet, simply considering the SD or variance of measures will yield identical values for both participants (Figure 6).
- If the researcher wants to distinguish between these individuals, then variance or SD is clearly insufficient. We must include further consideration of, say, autocorrelation or stability [89], or even something more bespoke. For instance, researchers monitoring continuous blood glucose levels from wearable technologies derived a measure of "variability from one moment to the next," operationalized as the length of the line on a graph between 2 adjacent time points [90].
- The fine-grained data afforded to researchers by remote research assessments allow the generation of more complex research questions. For example, take the data presented in Textbox 3. Novel mixed-effect models could be specified to further explore the association between sleep quality and alertness. This would allow for analysis of not only whether sleep quality informs mean levels of alertness, but also whether the variability of the responses of a given individual are predicted by their indicated sleep quality.

Key conclusions

- Fine grained, repeated temporal measures allow researchers to derive novel phenotypes from repeated observations of a given outcome. Extracting and modelling higher order observational phenomena will, in turn, enable better understanding of underlying, within-individual processes underpinning effects in traditional observational enquiry.

Figure 6. Within-individual repeated observations of an outcome of interest with identical means and SDs but different volatility.



Conclusions

Remote research assessments can be used to study cognition and behavior in unconventional and innovative ways while carefully adhering to established research principles. As a result, the use and further development of these assessments will reshape psychological and clinical research in the near future.

These tools are not without their own set of unique challenges and require the careful consideration of the optimal approach, particularly approaches for increasing generalizability, for any given research question. This presents an opportunity for discoveries that, without creative thinking, technological advancements, and flexibility, might otherwise have remained undiscovered. There is always room to improve research tools, and it is vital that the methods to evaluate these tools keep pace.

Acknowledgments

This project was hosted by the Cambridge Cognition Research Hub at the University of Bristol, a collaborative partnership between researchers at Cambridge Cognition Ltd and the University of Bristol. This project falls within the scope of the established collaboration, which is recognized by the University of Bristol through a contract that includes agreed intellectual property terms. All authors contributed to the conceptualization of this work. JF wrote the original draft, and GJG, CS, NC, FKC, JHB, and MRM contributed to the critical revision of this paper. All authors approved the final version of the manuscript for publication.

Conflicts of Interest

MRM provides consultancy to Cambridge Cognition Ltd and is a codirector of Jericoe Ltd, which produces software for the assessment and modification of emotion recognition. JF's post at the University of Bristol is funded by Cambridge Cognition Ltd. CS, NC, NT, JD, FC, and FKC are employees of Cambridge Cognition Ltd. JHB is an employee and shareholder of Cambridge Cognition Ltd.
