Abstract

Background: eHealth has the potential to improve outcomes such as physical activity or balance in older adults receiving geriatric rehabilitation. However, several challenges such as scarce evidence on effectiveness, feasibility, and usability hinder the successful implementation of eHealth in geriatric rehabilitation.

Objective: The aim of this systematic review was to assess evidence on the effectiveness, feasibility, and usability of eHealth interventions in older adults in geriatric rehabilitation.

Methods: We searched 7 databases for randomized controlled trials, nonrandomized studies, quantitative descriptive studies, qualitative research, and mixed methods studies that applied eHealth interventions during geriatric rehabilitation. Included studies investigated a combination of effectiveness, usability, and feasibility of eHealth in older patients who received geriatric rehabilitation, with a mean age of ≥ 70 years. Quality was assessed using the Mixed Methods Appraisal Tool and a narrative synthesis was conducted using a harvest plot.

Results: In total, 40 studies were selected, with clinical heterogeneity across studies. Of 40 studies, 15 studies (38%) found eHealth was at least as effective as non-eHealth interventions (56% of the 27 studies with a control group), 11 studies (41%) found eHealth interventions were more effective than non-eHealth interventions, and 1 study (4%) reported beneficial outcomes in favor of the non-eHealth interventions. Of 17 studies, 16 (94%) concluded that eHealth was feasible. However, high exclusion rates were reported in 7 studies of 40 (18%). Of 40 studies, 4 (10%) included outcomes related to usability and indicated that there were certain aging-related barriers to cognitive ability, physical ability, or perception, which led to difficulties in using eHealth.

Conclusions: eHealth can potentially improve rehabilitation outcomes for older patients receiving geriatric rehabilitation. Simple eHealth interventions were more likely to be feasible for older patients receiving geriatric rehabilitation, especially, in combination with another non-eHealth intervention. However, a lack of evidence on usability might hamper the implementation of eHealth. eHealth applications in geriatric rehabilitation show promise, but more research is required, including research with a focus on usability and participation.

geriatric rehabilitation; eHealth; mHealth; digital health; effectiveness; feasibility; usability; systematic review

Introduction

The world's population is aging rapidly. Currently, 143 million people are aged 80 years or older, and this number is expected to rise to around 426 million in 2050 [1]. Although many older adults are relatively fit, functional decline, multimorbidity, and geriatric syndromes such as frailty or falls are common in older adults [2,3]. A combination of these age-associated conditions triggers an increased risk of adverse outcomes such as hospitalization, functional impairments, and even mortality [4]. Postacute care such as geriatric rehabilitation aims to diminish these age-associated risks. Evidence shows that geriatric rehabilitation can improve functional outcomes and reduce nursing home admissions and mortality [5,6]. On the other hand, the rapidly aging populations and lack of staff are putting pressure on the quality, accessibility, and affordability of geriatric rehabilitation. In regard to these problems, the use of eHealth can be seen as important and promising, as it has the potential to simultaneously improve both rehabilitation outcomes and efficiency.

eHealth can be defined as “the use of digital information and communication to support and/or improve health and health care” [7]. Some examples of eHealth are video communication, exergames (ie, active video games), and mobile apps. Although eHealth can be seen as important and promising, successful implementation of eHealth interventions in geriatric rehabilitation is complex, can be time consuming, and involves a variety of determinants on multiple levels [8-10]. To safely and successfully implement eHealth in geriatric rehabilitation, scientific evaluation of eHealth is key [11,12]. Three important outcome measures for the evaluation of eHealth in geriatric rehabilitation can be identified: effectiveness, feasibility, and usability [9,13].

In terms of effectiveness, previous reviews show that eHealth can improve physical activity, gait, and balance in community-dwelling older adults [14-17]. However, the evidence on effective eHealth in geriatric rehabilitation is scarce and fragmented. To our knowledge, no prior reviews have examined the effectiveness of eHealth in geriatric rehabilitation.

To better understand how eHealth can be used safely, feasibility testing is an important first step [18,19]. The aim of feasibility testing is to “determine whether an intervention is appropriate for further testing” [20,21], but a general accepted standard on feasibility testing is lacking. Examples of factors that can be addressed in feasibility testing are adverse events, adherence, and acceptability [10].

Additionally, usable eHealth is also an important prerequisite for successful implementation [13,19,22]. Usability can be defined as “the extent to which a system, product, or service can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use” [23]. For older adults receiving geriatric rehabilitation, usability is especially crucial, since there are certain age-related barriers that may hamper the usability of eHealth [24-26]. These barriers can be categorized into 4 patient-related domains: cognition, physical ability, perception, and motivation [27]. For example, poor vision can make it harder to distinguish certain

icons on screens, or cognitive impairment might lead to problems understanding certain eHealth interventions. Often, eHealth is insufficiently tailored to these age-related barriers [28].

Therefore, a systematic review of eHealth in geriatric rehabilitation including the concepts feasibility, usability, and effectiveness was needed. This systematic review can help speed up the implementation process of eHealth and ensure successful adoption of eHealth overall. The aim of this review was to assess evidence on the effectiveness, feasibility, and usability of eHealth interventions in older adults in geriatric rehabilitation.

Methods

Study Registration and Protocol

This systematic review is registered at PROSPERO, with registration number CRD42019133192 [29]. This systematic review was based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) statement, which is an evidence-based minimum set of items used for reporting in systematic reviews and meta-analyses [30]. The complete checklist for this review can be found in [Multimedia Appendix 1](#).

Types of Studies and Participants

In this review, we included randomized controlled trials, nonrandomized studies, quantitative descriptive studies, qualitative research, and mixed methods studies. We excluded systematic reviews, abstracts, editorials, and non-English and nonpeer-reviewed studies. Studies were included that examined older patients with a mean age of ≥ 70 years who received geriatric rehabilitation, which is in line with consensus statements on the organization and delivery of geriatric rehabilitation across Europe [31]. Because there is variability between countries' health care systems and consequently also between countries' provisions of geriatric rehabilitation [31,32], we included studies in different types of settings such as (geriatric) rehabilitation centers, skilled nursing facilities, hospitals, or ambulatory settings. Studies that included patients with a chronic disease with no acute functional decline were excluded.

Interventions and Outcomes

Studies investigated eHealth interventions applied during postacute geriatric rehabilitation. Outcome measures related to the effectiveness of interventions were included if they could be classified based on the World Health Organization's International Classification of Functioning, Disability, and Health (ICF) model [33], which covers the following domains: body functions and structure, activities, participation, environmental factors, and personal factors. For the purpose of this review, we chose to specify feasibility within the following domains: adverse events, adherence, and exclusion rates. Usability outcome measures were classified based on the MOLD-US framework, which is an evidence-based framework of aging barriers that influence the usability of eHealth in older adults and includes 4 categories: cognition, motivation, physical ability, and perception [27]. We included both primary and secondary outcome measures.

Sources and Search Strategy

On March 9, 2019, March 10, 2019, and January 11, 2021, we searched the following databases: MEDLINE, PsycINFO, EMBASE, EMCARE, Cochrane Library, Web of Science, and Central databases. For this review, 3 separate search strings were compiled. The first focused on the effectiveness, the second focused on the feasibility, and the third focused on the usability of eHealth interventions in geriatric rehabilitation. The search string focusing on effectiveness included keywords related to older adults, rehabilitation, and eHealth interventions. Studies were identified when at least 2 of 3 keywords were present. The search strings focusing on feasibility and usability included an additional keyword related to feasibility or usability. In both search strings, keywords were combined using MeSH terms using the Boolean operations “or” and “and.” The complete search strings can be found in [Multimedia Appendix 2](#).

Selection of Studies and Data Extraction

We first screened titles of the identified studies. The abstracts of all potentially relevant studies were then screened by 2 authors independently. Next, full texts were obtained and reviewed by the same authors. We excluded studies that did not meet the inclusion criteria. Disagreements between the 2 authors were discussed until a consensus was reached. If a disagreement could not be resolved, a third reviewer was consulted. Data extraction was performed using Covidence, which is an online systematic review management tool [34]. In Covidence, a data extraction form was constructed that included details of publication (ie, author, year, title, country of study, and funding), study design, methods (ie, inclusion and exclusion criteria, population, randomization, statistical analysis, and outcome measures), sample characteristics (ie, age, number of participants, gender, and diagnosis), eHealth intervention (ie, name of intervention, goal of intervention, delivery of intervention, and application of intervention), and primary and secondary outcomes. As the complexity of eHealth interventions influences implementation, we sorted eHealth interventions ranging from simple (ie, video communications, health sensors, or gateways) to complex (ie, robotics, exergames, or virtual reality) [9,35]. One author then extracted the data. A subset of the data (10% of included studies) was also extracted by a second author to check interrater reliability.

Quality Appraisal

The quality of included studies was assessed using the Mixed Methods Appraisal Tool (MMAT) [36], which allowed quality assessment across different study designs. The MMAT is a critical appraisal tool specifically designed to assess the quality

of 5 types of study designs: qualitative research, randomized controlled trials, nonrandomized studies, quantitative descriptive studies, and mixed methods studies. For each study design, the MMAT provides 5 quality criteria that must be rated with “Yes,” “No,” or “Can’t tell.” Since the calculation of an overall score from the ratings of each criterion is discouraged [36,37], we reported a separate score for each rating. Nevertheless, an overall score was reported, because it provides a general picture of study quality. Studies were not excluded based on study quality [36]. For the randomized controlled trials and nonrandomized designs, we rated the criterion “Are there complete outcome data?” as “No” when the drop-out rate was over 20% [38]. In nonrandomized designs, we rated the criterion “Are the confounders accounted for in the design and analysis?” as “No” when there was no description of additional therapy offered during the study, functional status, or cognitive status. Quality assessment was carried out by one author, and 10% of the included studies were selected at random and additionally assessed by a second author to check interrater reliability.

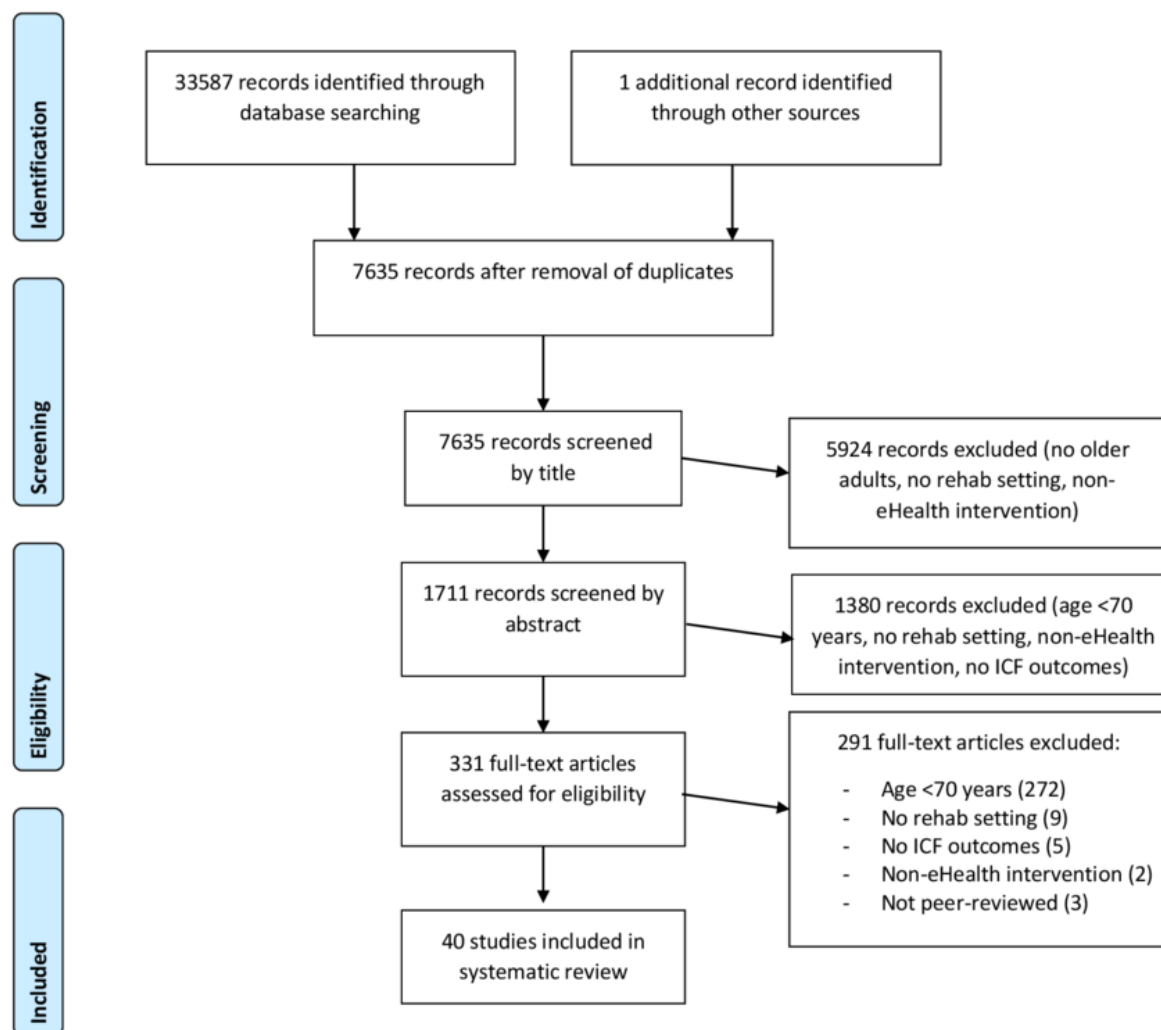

Data Analysis and Data Synthesis

In studies that reported outcomes related to effectiveness and included a control group, a narrative synthesis was conducted using a harvest plot [39]. In the harvest plot, primary and secondary outcomes were described and color coded based on ICF domain. For each study, the bars in the harvest plot indicated the total results for the different ICF domains, and the height of the bars represented the methodical quality based on the MMAT. When a study reported multiple consistent results within the same ICF domain, the results were combined in 1 bar. If a study reported conflicting results within the same ICF domain, both results were presented. Randomized controlled trials were represented by a thick contour around bars. A meta-analysis was not feasible since the included studies were too heterogeneous with regard to population, intervention, and outcome measures.

Results

Study Selection

The search strategy identified a total of 7635 unique records. After exclusion of records based on title and abstract, 331 records remained. During full-text screening, a further 291 records were excluded, resulting in the inclusion of 40 studies in this review. Reasons for exclusion are presented in the study flowchart shown in [Figure 1](#). In 12 cases, a third reviewer was needed to achieve consensus during the process of study selection.

Figure 1. PRISMA flow diagram of search strategy results. ICF: International Classification of Functioning, Disability, and Health.

Study Characteristics

Study characteristics are shown in [Table 1](#). Of the 40 included studies, 18 (45%) were randomized controlled trials [40-57], 2 (5%) had a mixed methods design [58,59], 1 was a qualitative study [60], and 19 (48%) had a quantitative nonrandomized design [61-79], of which 9 studies (of 19, 47%) included a control group [53,61-68,79]. Of 40 studies, 17 studies (43%) were conducted in a hospital setting [41-44,46,50,51,55-57,62,64-66,68,71,79]. Of the 17

hospital-setting studies, 12 (71%) were conducted in a dedicated hospital-rehabilitation unit [41-44,46,50,51,55,56,64,71,79], 2 (12%) were in a hospital-stroke unit [57,68], and 1 (6%) was conducted in a geriatric day hospital [62]. Of the 40 studies, 10 (25%) were conducted in an ambulatory setting [47,48,52-54,60,69,75,76,78], 9 studies (23%) took place in a geriatric rehabilitation setting [40,45,49,58,59,61,63,70,74], 2 studies (5%) were at a tertiary rehabilitation center [60,73], 1 study (3%) was at a skilled nursing facility [77], and 2 studies (5%) did not report the setting [67,72].

Table 1. Study characteristics.

Author, year, country	Design	Diagnosis; n; setting	Age (SD); female (%)	Intervention	Use of intervention	Primary outcome domain (primary outcome measure)	Secondary outcome domain(s)
Barnason [53], 2009, United States	RCT ^a	Cardiac; n=55; Ambulatory	71.6 (5.1); 16	Video communication in combination with non-eHealth vs usual care	Daily use, subjects responded to assessment queries, were provided with strategies	Effectiveness, activities (other)	Effectiveness, participation
Backman [59], 2020, United Kingdom	Mixed methods	Orthopedic; n=30; Geriatric rehabilitation	81 (67-96); 63	Mobile apps	Providing access to discharge records during transition to home	Usability	__ ^b
Bernocchi [52], 2018, Italy	RCT	Multiple diagnoses; n=146; Ambulatory	79 (6.5); 84	Video communication in combination with non-eHealth vs usual care	Weekly calls; video communication 2×/month; fall prevention program provided by therapist	Effectiveness, activities (other)	Feasibility, effectiveness, activities, participation
Bernocchi [69], 2016, Italy	Quantitative; nonrandomized	Stroke; n=15; Ambulatory	71 (11); 47	Video communication in combination with health sensors	Weekly calls with nurse; weekly video communication with physiotherapist	Feasibility (n completed, n sessions)	Effectiveness, body functions, activities
Cannell [44], 2017, Australia	RCT	Stroke; n=40; Hospital, rehabilitation unit	74 (10); 37.5	Exergames in combination with virtual reality vs usual care	1 hour/session, 5 days/week, in addition to conventional therapy	Effectiveness, activities (maintaining body position)	Effectiveness, activities
Chan [62], 2012, China	Quantitative nonrandomized	Multiple diagnoses; n=90; Geriatric Day hospital	80 (7.1); 73	Exergames vs usual care	10 min/session, 8 sessions total, in addition to conventional therapy	Feasibility (total time spent, average BS ^c and %MHR ^d)	Effectiveness, activities
Cimaroli [77], 2017, United States	Quantitative; nonrandomized	Multiple diagnoses; n=237; Skilled nurse facility	76 (10.7); 59	Exergames	Recommended use: 2 sessions/week for 15 min, in addition to conventional therapy	Feasibility (time spent, predictors of intense use)	Effectiveness, external factors
Dakin [61], 2011, Australia	Quantitative; nonrandomized	Multiple diagnoses; n=34; Geriatric rehabilitation	77; 47	Health sensors vs usual care	Wore health sensor daily during admission	Effectiveness activities (ADL ^e)	Effectiveness, external factors
Da-Silva [57], 2019, United Kingdom	RCT	Stroke; n=33; Hospital, stroke unit	71; 60.6	Health sensors with reminders vs health sensors without reminders	Wore health sensor for 4 weeks, health sensor vibrated to remind patients to use affected arm	Effectiveness, activities (hand and arm use)	Feasibility, adherence
Doornebosch [70], 2007, Netherlands	Quantitative; nonrandomized	Stroke; n=10; Geriatric rehabilitation	72 (53-94); 80	Robotics	20 minutes/session, 8 sessions total, in addition to conventional therapy	Personal factors (patient's experience)	Effectiveness, body functions
Edmans [68], 2009, United Kingdom	Quantitative; nonrandomized	Stroke; n=13; Hospital, stroke unit	73; 23	Virtual reality vs usual care	1 hour/session, 5 days/week	Effectiveness, activities (other)	Effectiveness, activities
Franceschini [56], 2020, Italy	RCT	Stroke; n=48; Hospital, rehabilitation unit	72 (64.3); 45.8	Robotics vs usual care	30 minutes/session, 5 days/week over 6 weeks, in addition to conventional therapy	Effectiveness, body functions (muscle power, tone, and reflexes)	Effectiveness, (muscle power, tone, and reflexes)
Gandolfi [71], 2017, Italy	Quantitative; nonrandomized	Stroke; n=2; Hospital, rehabilitation unit	74; 100	Robotics	20 minutes/session, 5 days/week, 10 sessions total, in addition to conventional therapy	Feasibility (compliance, time to set device)	Effectiveness, body functions
Goto [65], 2017, Japan	Quantitative; nonrandomized	Orthopedic; n=20; Hospital	74 (7.5); 90	Robotics vs usual care	Every other day, in addition to conventional therapy	Effectiveness, body functions (mobility of joints)	Effectiveness, body functions

Author, year, country	Design	Diagnosis; n; setting	Age (SD); female (%)	Intervention	Use of intervention	Primary outcome domain (primary outcome measure)	Secondary outcome domain(s)
Hesse [42], 2014, Germany	RCT	Stroke; n=50; Hospital, rehabilitation unit	70 (16); 44	Robotics vs usual care	30 minutes/session, 4 days/week, in addition to conventional therapy	Effectiveness, body functions (muscle power, tone, and reflexes)	Effectiveness, body functions, activities, external factors
Hesse [72], 2010, Germany	Quantitative; nonrandomized	Stroke; n=1; Not reported	72; 0	Robotics	25 minutes/session, 5 days/week, 25 sessions in total, in addition to conventional therapy	Effectiveness, body functions (ADL)	—
Hicks [63], 2016, United States	Quantitative; nonrandomized	Cardiac; n=285; Geriatric rehabilitation	79 (48-99); 54.3	Health gateway vs usual care	Encouraged daily use, in addition to conventional therapy	Effectiveness, activities (ADL)	Effectiveness, external factors
Iosa [46], 2015, Italy	RCT	Stroke; n=4; Hospital, rehabilitation unit	71.5 (4.51); 50	Exergames in combination with virtual reality vs usual care	30 minutes/session, 3 days/week, in addition to conventional therapy	Feasibility (motivation, time spent, adverse events)	Effectiveness, body functions, activities
Karner [55], 2019, Germany	RCT	Stroke; n=56.4%; Hospital, rehabilitation unit	73.7 (7.33); 56.4	Robotics vs book reading	30 minutes/session 3 days/week over 3 weeks	Effectiveness, body functions (visual)	—
Koneva [67], 2018, Russia	Quantitative; nonrandomized	Stroke; n=40; Not reported	84 (1.2); 30	Virtual reality vs usual care	Task-specific training	Effectiveness, body functions (neurological)	Effectiveness, body functions, activities, participation
Laver [50], 2012, Australia	RCT	Multiple diagnoses; n=44; Hospital, rehabilitation unit	84.9 (4.5); 80	Exergames vs usual care	25 minutes/session, 5 days/week for duration of stay	Effectiveness, activities (mobility)	Effectiveness, body functions, activities, participation
Levinger [64], 2016, Italy	Quantitative; nonrandomized	Orthopedic; n=4; Hospital, rehabilitation unit	70; 76	Exergames vs usual care	2 sessions/week, in addition to conventional therapy	Effectiveness, activities (mobility)	Effectiveness, body functions, activities, participation
Li [54], 2020, Hong Kong	RCT	Orthopedic; n=31; Ambulatory	79.3 (9.1); 80.6	Mobile apps vs usual care	Use of app based on rehabilitation goals, in addition to conventional therapy	Effectiveness, activities (mobility)	Effectiveness, feasibility, body functions, activities,
Ling [58], 2017, Netherlands	Mixed methods	Orthopedic; n=7; Geriatric rehabilitation	70 (8); 71	Exergames	30 minutes/session, in addition to conventional therapy	Usability (ease of use)	—
Marschollek [75], 2014, Germany	Quantitative; nonrandomized	Orthopedic; n=14; Ambulatory	83.5 (71-90)	Health sensors	Sensors placed at home for monitoring ADL	Feasibility (installation time, downtimes)	Acceptability
Oesch [49], 2017, Switzerland	RCT	Multiple diagnoses; n=54; Geriatric rehabilitation	74 (67-79); 45	Exergames vs self-regulated exercises	30 minutes/session, twice a day	Effectiveness (personal factors)	Effectiveness personal factors, activities
Peel [40], 2016, Australia	RCT	Multiple diagnoses; n=270; Geriatric rehabilitation	81 (8); 58	Health sensors with goal-setting vs health sensors without goal-setting	Daily feedback and goal-setting by therapists, in addition to conventional therapy	Effectiveness, activities (mobility)	Effectiveness, activities, participation, external factors
Peel [78], 2011, Australia	Quantitative; nonrandomized	Multiple diagnoses; n=0; Ambulatory	—	Video communication	All communication conducted through intervention	Feasibility	—
Piqueras [47], 2013, Spain	RCT	Orthopedic; n=142; Ambulatory	73.3 (6.5); 72.4	Video communication in combination with health sensors vs usual care	1 hour/session over 10 days	Effectiveness, body functions (mobility of joints)	Effectiveness, body functions, activities

Author, year, country	Design	Diagnosis; n; setting	Age (SD); female (%)	Intervention	Use of intervention	Primary outcome domain (primary outcome measure)	Secondary outcome domain(s)
Pol [48], 2019, Netherlands	RCT	Orthopedic; n=240; Ambulatory	83 (6.9); 79.6	Health sensors in combination with non-eHealth intervention vs non-eHealth intervention vs usual care	Sensors placed at home for monitoring ADL, 4 home visits and 4 telephone consultations	Effectiveness, activities (other)	Effectiveness, participation
Sampson [73], 2012, New Zealand	Quantitative; nonrandomized	Stroke; n=1; Rehabilitation center	76; 100	Robotics in combination with virtual reality	45 minutes/session, 4 sessions/week over 6 weeks, in addition to conventional therapy	Effectiveness, body functions (muscle power, tone, and reflexes)	Effectiveness body functions
Schoone [45], 2011, Netherlands	RCT	Stroke; n=24; Geriatric rehabilitation	71.3 (8.2); 33	Robotics	10-30 minutes/sessions, 3 sessions/week over 6 weeks, in addition to conventional therapy	Effectiveness, body functions, activities (hand and arm use)	Effectiveness participation, external factors
Schwicker [74], 2011, Germany	Quantitative; nonrandomized	Orthopedic; n=8; Geriatric rehabilitation	79.5; 50	Robotics, virtual reality	30-45 minutes/session, 2-3 sessions/week for 2-4 weeks, in addition to conventional therapy	Feasibility (adherence, satisfaction)	Effectiveness, body functions, activities, participation
Takano [79], 2020, Japan	Quantitative; nonrandomized	Orthopedic; n=27; Hospital, rehabilitation unit	81 (6.3); 89	Robotics in combination with exergames	20 min/session 6 sessions/week for 2 weeks in addition to conventional therapy	Effectiveness activities (mobility)	Effectiveness, activities,
Taveggia [43], 2016, Italy	RCT	Stroke; n=28; Hospital, rehabilitation unit	72 (6); 39	Robotics vs usual care	30 minutes/session, 5 sessions/week over 5 weeks, in addition to conventional therapy	Effectiveness, activities (mobility)	Effectiveness, activities, participation
Tousignant [76], 2006, Canada	Quantitative; nonrandomized	Multiple diagnoses; n=4; Ambulatory	70,75; 50	Video communication	1 hour/session, 3 sessions/week over 4 weeks	Effectiveness, activities (ADL)	Effectiveness, body functions, activities
Van den Berg [51], 2015, Australia	RCT	Multiple diagnoses; n=58; Hospital, rehabilitation unit	80 (12); 62	Exergames vs usual care	1 hour/session, 5 session/week, in addition to conventional therapy	Effectiveness, activities (mobility)	Usability; Effectiveness, activities, participation
Vanoglio [41], 2017, Italy	RCT	Stroke; n= 30; Hospital, rehabilitation unit	71 (12); 53	Robotics vs usual care	40 minutes/session, 5 sessions/week over 6 weeks	Feasibility (n completed, adverse events, difficulty)	Effectiveness, body functions, external factors
White [60], 2015, Australia	Qualitative	Stroke; N=12; Rehabilitation center, ambulatory	73 (53-83); 33	Mobile apps	Therapist installed apps; patients encouraged to explore iPad	Usability	—
Yoshikawa [66], 2018, Japan	Quantitative; nonrandomized	Orthopedic; n=19; Hospital	76 (6.85); 81	Robotics vs usual care	14 minutes/session, 12-14 session in 4 weeks, in addition to conventional therapy	Effectiveness, activities (mobility)	Effectiveness, body functions

^aRCT: randomized controlled trial.

^bNot available.

^cBS: Borg Perceived Exertion Scale.

^d%MHR: maximum heart rate.

^eADL: activities of daily living.

Of 40 studies, 17 (43%) included participants who were diagnosed with stroke [41-46,55-57,60,67-73], 10 (25%) included participants with multiple diagnoses [40,49-52,59,61,62,76-78], 11 (28%) included participants with orthopedic problems [47,48,54,58,59,64-66,74,75,79], and 2 studies (5%) included participants with cardiac-related diagnoses

[53,63]. Across all studies, the included sample size ranged from 1 to 285 participants.

Various types of eHealth interventions were used. Of 40 studies, 11 studies (28%) delivered the intervention via robotics [41-43,45,55,56,65,66,70-72], 2 studies (5%) combined robotics with virtual reality [73,74], and 1 study (3%) combined robotics

with exergames [79]. Additionally, 9 studies (of 40, 23%) investigated exergames [44,46,49-51,58,62,64,77], of which 2 (of 9, 22%) combined exergames with virtual reality [44,46] and 1 (of 9, 11%) combined exergames with health sensors [51]. Of 40 studies, 2 (5%) examined video communication [76,78], 3 (8%) combined video communication with health sensors [47,53,69], and 1 (3%) combined video communication with a non-eHealth intervention [52]. Of 40 studies, health sensors were used in 6 studies (15%) [40,48,57,61,63,75], including 1 (of 6, 17%) in combination with a health gateway [63] and 1 (of 6, 17%) in combination with a non-eHealth intervention [48]. Of 40 studies, 3 studies (8%) investigated mobile apps [54,59,60], and 2 studies (5%) examined virtual reality [67,68].

Outcome measures related to effectiveness were reported in 24 of 40 studies (60%) [40,42-45,47-50,53,55,56,61,63-68,70,72,73,76,79], and 10 of 40 studies (25%) included outcome measures related to effectiveness and feasibility [41,46,52,54,57,62,69,71,74,77]. Of 40 studies, 2 studies (5%) included outcomes related to usability [58,60], 2 studies (5%) included outcomes related only to feasibility [75,78], 1 study (3%) included outcomes related to effectiveness and usability

[51], and 1 study (3%) included outcomes related to feasibility and usability [59]. A detailed description of all included studies can be found in Multimedia Appendix 3.

Study Quality

Results of the quality assessment are presented in Figure 2 and Figure 3. The quality of the included studies ranged from -3 to 5 (on a scale ranging from -5 to 5). The mean overall score was 3 for randomized controlled trails, 1 for quantitative nonrandomized studies, 1 for a mixed methods studies, and 5 for a qualitative study (based on 1 study). In quantitative nonrandomized studies, the most frequent shortcoming was insufficient reporting of confounders; only 2 of 19 studies (11%) accounted for confounders in design and analysis [73,79]. The representativeness of the target population in quantitative nonrandomized studies was also often insufficient; 9 of the 19 studies (47%) reported insufficient information, lacking either adequate explanation of why certain eligible participants chose not to participate or a clear description of the target population [53,61,65,67,69,71,75,76,78]. Additionally, 6 of the 19 studies (32%) included a sample size of less than 20 [64,66,70,72-74].

Effectiveness

Main Results for Effectiveness

Across all studies with a control group (n=27; 27/40, 68%), 73 different outcome measures were reported that were related to effectiveness, including 16 (22%) within the ICF domain “body functions,” 40 (55%) in the domain “activities,” 11 (15%) in the domain “participation,” 4 (5%) in the domain “external factors,” and 2 (3%) in the domain “personal factors” (Figure

4). In 15 studies (of 27, 56%), eHealth interventions were found to be at least as effective as non-eHealth interventions when focusing on the primary outcome measure, and 11 studies (of 27, 41%) reported eHealth interventions to be more effective than non-eHealth interventions. Of 27 studies, 1 study (4%) reported beneficial outcomes in favor of the non-eHealth interventions. Results for each ICF domain are described in detail below. A harvest plot illustrating the evidence regarding effectiveness is presented in Figure 5.

Figure 4. Outcome measures classified by the International Classification of Functioning, Disability, and Health model.

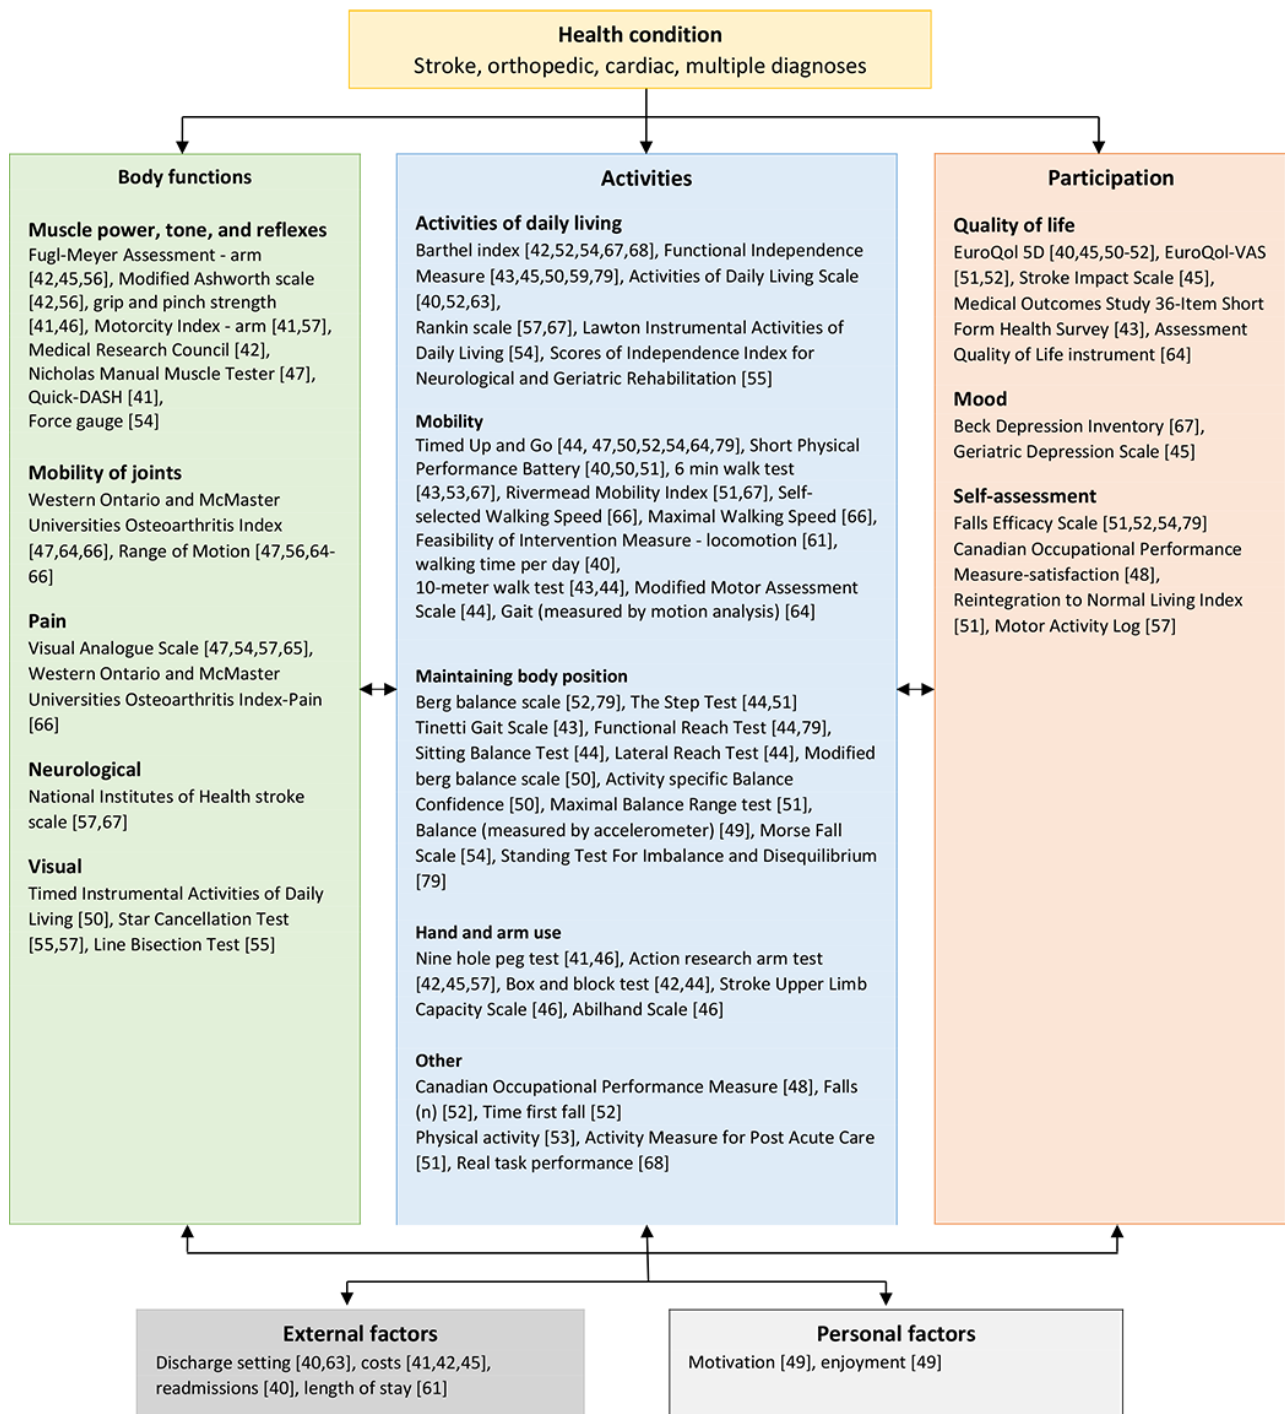

Figure 5. Harvest plot: effectiveness of eHealth interventions. MMAT: Mixed Methods Appraisal Tool.

Body Functions

Of 40 total studies, 14 studies (35%) included 16 outcomes related to body functions [41,42,45-47,50,54-57,64-67]. Of these 14 studies, 9 studies (64%) found, in 7 outcome measures, significant improvements in favor of the intervention group (Figure 5) [41,46,47,54-56,65-67]. Of 14 studies, 4 studies (29%) reported improved muscle power through robotics [56,65], exergames [46], or mobile apps [54]. Of 14 studies, 4 studies (29%) found that the addition of robotics [56,65,66] or video communication in combination with health sensors [47] improved the mobility of joints when compared with physical

therapy alone. Another 2 studies (of 14, 14%) reported that the use of robotics could decrease pain when compared with conventional physiotherapy [65,66]. Koneva and colleagues [67] reported that the use of virtual reality improved neurological status, as measured by the National Institutes of Health stroke scale, when compared with usual care (5.2±0.4 vs 6.3±0.5; P<.001).

Activities

Of all 40 included studies, 25 studies (63%) reported 40 outcomes related to activities [40-55,57,61-64,66-68,79], and 13 studies (33%) found, in 17 outcomes, a significant outcome

in favor of the intervention group [40,41,46,48,50-53,62,63,66,67,79]. Of 40 studies, 5 studies (13%) demonstrated that eHealth was effective in improving activities of daily living when the intervention was delivered via video communication in combination with health sensors and a non-eHealth intervention [52] or when the intervention was delivered via health sensors in combination with health gateways [63], exergames [62], robotics [79], or virtual reality [67]. In these studies, eHealth was compared with usual care [52,67], physiotherapy [62,79], or no intervention [63]. Another 6 studies (of 40, 15%) found that eHealth could contribute to improved mobility through the use of robotics [52,79], exergames [50], virtual reality [67], video communication in combination with health sensors [52], or health sensors in combination with goal setting [40]. These interventions were compared with physiotherapy [50,66,79], usual care [52,67], or health sensors without goal setting [40]. Of 40 studies, 4 studies (10%) reported improvements in balance when the intervention was delivered via robotics [79], exergames [50], exergames in combination with health sensors [51], or video communication in combination with health sensors [52], when compared with physiotherapy [50,51,79] or usual care [52]. Another 2 studies (of 40, 5%) reported that either robotics [41] or exergames in combination with health sensors [46] could improve hand and arm function when compared with physiotherapy [41] or no intervention [46]. Pol and colleagues [48] found that patient-reported daily functioning significantly improved with the use of health sensors in combination with cognitive behavioral treatment, compared with cognitive behavioral treatment alone, reporting a difference of 1.17 (95% CI 0.47-1.87; $P < .001$). Bernocchi and colleagues [52] reported that the use of video communication in combination with health sensors and a non-eHealth intervention was effective in preventing falls in patients who were at high risk of falling, when compared with usual care (29 falls vs 56 falls; $P < .001$). Of 40 studies, 1 study (3%) demonstrated that the use of video communication in combination with health sensors improved physical activity when compared with usual care [53].

Participation

Of 40 studies, 12 studies (30%) included 11 outcome measures within the participation domain [40,43,45,48,50-53,57,64,67,79]. Of these 12 studies, 3 studies (27%) reported a significant difference in quality of life [52], mood [67], or self-assessment [48] when the intervention was delivered via the use of video communication in combination with health sensors and a non-eHealth intervention [52], virtual reality [67], or the use of health sensors in combination with a non-eHealth intervention [48]. Particularly, Bernocchi and colleagues [52] demonstrated that the use of video communication in combination with health sensors and a non-eHealth intervention significantly improved scores on the EuroQol Visual Analog Scale at 6 months, when compared with usual care (mean 63.8 vs mean 53.5; $P < .001$). Koneva and colleagues [67] reported that the use of virtual reality decreased the severity of depression as measured by the Beck Depression Inventory, when compared with usual care (mean 9.5, SD 5.52 vs mean 10.3, SD 6.03; $P < .05$). Additionally, Pol and colleagues [48] found that the use of health sensors in combination with a non-eHealth intervention

significantly improved the performance satisfaction in daily functioning at 6 months, when compared with usual care, reporting a difference of 0.94 (95% CI 0.37-1.52; $P < .001$).

External Factors

Across all 40 studies, 5 studies (13%) included outcome measures related to external factors [40,42,45,61,63]. Of these 5 studies, 2 studies (40%) included robotics as interventions and found significant differences in cost, in favor of the intervention group [41,42]. Of the 5 studies, 1 study (20%) included robotics as an intervention and found a difference in favor of the control group [45]. Hesse and colleagues [42] and Vanoglio and colleagues [41] reported decreases in cost with the use of robotics in comparison with either regular arm therapy (€4.15 [US \$4.92] for robotic interventions vs €0.00 [US \$11.85] for regular arm therapy, for each patient per session) [42] or physiotherapy (€237 [US \$280.73] for robotic intervention vs €480 [US \$568.57] for physiotherapy, for each patient per 30 days) [41]. In contrast, Schoone and colleagues [45] reported an increase in total costs when compared with physiotherapy (€644.14 [US \$762.99] for robotic interventions vs €23.74 [US \$501.93] for physiotherapy). Across all studies, no differences were found with regard to discharge settings [40,63], readmissions [40], or lengths of stay [61].

Personal Factors

Oesch and colleagues [49] found that self-regulated exercise using instruction leaflets was superior to exergames in terms of enjoyment (effect size: 0.88, range 0.32-1.44; $P < .001$) and motivation (effect size: 0.59, range 0.05-1.14; $P = .046$).

Feasibility

Main Results for Feasibility

Of the 40 included studies, 20 studies (50%) evaluated the feasibility of the eHealth intervention used [41,46,50-52,54,57,59,60,62,64,65,69,71,72,74-78], of which 19 (of 20, 95%) concluded that the eHealth intervention was feasible when it was delivered via robotics [41,65,71,72], robotics in combination with exergames [74], exergames [50,62,64,77], exergames in combination with health sensors [46,51], video communication [76], video communication in combination with health sensors [52,69], health sensors [57], health gateways in combination with health sensors [75], or mobile apps [54,59,60]. Peel and colleagues [78] reported that the use of video communication was not feasible due to problems related to patient limitations, staff issues, and the logistics of the system.

The outcome measures applied to evaluate feasibility varied considerably among studies, and a total of 19 different outcome measures were used. Of the 20 studies that reported feasibility, 6 studies (30%) reported outcomes related to “adverse events,” 7 studies (35%) reported outcomes related to “adherence,” and 7 studies (35%) reported outcomes related to “exclusion rate.” Another 4 studies (of 20, 20%) did not specify the outcome measure used to evaluate feasibility but used outcomes related to effectiveness to establish feasibility [54,64,65,72].

Adverse Events

None of the included studies reported serious adverse events during the study period [41,46,50,51,74,76]. However, 2 studies (of 40, 5%) reported that some participants experienced discomfort during exergames [49,50].

Adherence

Of 40 studies, adherence was reported in 7 studies (18%) [49-52,57,74], and 5 studies (13%) reported information regarding the number of completed sessions [41,50-52,69]. Of the 7 studies reporting adherence, 5 studies (71%) reported high levels of adherence, ranging from 76% [52] to 100% [74]. Of the 7 studies, 2 studies (29%) reported low adherence in patients assigned to an exergame intervention when compared with either a non-eHealth intervention [49] or use of the exergame intervention below the recommended level (<30 minutes per week) [77].

Exclusion Rate

Of 40 studies, high exclusion rates were found in 7 studies (18%). Specifically, of these 7 studies, 1 study (14%) reported an exclusion rate of 64% [47], 2 studies (29%) reported an exclusion rate of 75% [49,51], and 4 studies (57%) reported an exclusion rate over 80% [42,45,50,68]. In these latter studies, eHealth was delivered through complex eHealth interventions: robotics [42,45], exergames [50], and virtual reality [68]. The most commonly reported reasons for exclusion were cognitive impairment [45,47,49,51], physical impairment [45,49], and refusal to participate [42,47,49-51,68]. Of these 7 studies, in 2 studies (29%), the reason given for declining to participate was “no interest” in eHealth [50,51].

Usability

Main Results for Usability

Of 40 studies, outcomes related to the usability of eHealth interventions were addressed in 4 studies (10%): 2 studies (5%) evaluated the usability of exergames [51,58], and another 2 studies (5%) evaluated mobile apps [59,60]. Evaluation of usability consisted of a system usability scale [51], a survey of patients and therapists [58,59], or semistructured interviews [59,60]. Of the 4 studies that reported usability, 2 studies (50%) included outcomes related to the barrier “cognition,” 4 studies (100%) included outcomes related to the aging barrier “motivation,” and 1 study (25%) included outcomes related to the barrier “physical ability.” None of the studies included outcomes related to the barrier “perception.”

Cognition

Ling and colleagues [58] reported that some patients found exergames too complicated because of the requirement to engage in multiple activities simultaneously, and they experienced difficulties in following instructions. To tailor the exergames to older patients with cognitive impairments, the authors advised to minimize the amount of information presented on the screen, which might help older patients to perceive the information better [58]. Additionally, White and colleagues [60] reported that patients with cognitive impairments experienced difficulties in operating mobile apps and needed their partner for support.

Motivation

Van den Berg and colleagues [51] reported a mean score of 62 (SD 21), on the system usability scale (scores ranging from 0 to 100), indicating that participants were generally comfortable with exergames and that they would like to use exergames more frequently. Similar findings were reported by Ling and colleagues [58], who concluded that patients and therapists both found exergames easy to use and therapists intended to use the exergame in the future. Therapists rated the exergame as highly satisfactory for motor rehabilitation in older patients after hip surgery. Findings regarding mobile apps indicated that patients readily grasped the skills required for use and that this was a beneficial source of extrinsic motivation [59,60].

Physical Ability

Ling and colleagues [58] reported that some patients with physical disabilities had difficulties playing certain exergames that required stepping exercises because these patients were unable to maintain balance during exergames.

Discussion

Principal Findings

This review aimed to provide an overview of the effectiveness, feasibility, and usability of eHealth in geriatric rehabilitation. The review included 40 studies that applied eHealth interventions in older patients receiving geriatric rehabilitation. The majority of the included studies showed that eHealth interventions in geriatric rehabilitation are at least as effective as non-eHealth interventions. All studies that delivered eHealth in combination with another non-eHealth intervention reported positive outcomes. Most studies included outcome measures related to the ICF domain “activities.” Very few studies included outcomes related to the ICF domain “participation.” eHealth seems to be feasible in geriatric rehabilitation, since no serious adverse events were reported and most studies reported high levels of adherence. However, high exclusion rates were found in some studies. Results related to usability indicate that there are certain age-related barriers, such as cognition and physical ability, that lead to difficulties in using eHealth. Very few studies included outcomes related to feasibility and usability. However, these are important prerequisites to maximize the likelihood of successful implementation, and they thereby influence the effectiveness of eHealth.

Comparison With Prior Work

Our findings suggest that eHealth delivered via robotics, exergames, or health sensors is often found to be at least as effective as non-eHealth. Previous reviews that examined robotics [80], exergames [16], or health sensors [81,82] often found more beneficial results in favor of the intervention group. These reviews did not focus on older adults who were admitted for geriatric rehabilitation, and this could indicate that there are certain age-related barriers that affect the effectiveness of eHealth in older adults receiving geriatric rehabilitation. All of the included studies that delivered eHealth in combination with a non-eHealth intervention reported beneficial outcomes in favor of the intervention group. This is in line with other studies in which eHealth was delivered in combination with a non-eHealth

intervention [83-85]. This indicates that eHealth is more beneficial when provided through blended care, where eHealth is delivered in combination with face-to-face treatment. This may provide a better quality of care by combining the best of the two types of interventions. This seems to especially be the case when blended care is delivered via video communication [52] or health sensors [48], since it offers the possibility to monitor and treat patients remotely.

Almost all of the studies that included outcomes related to feasibility concluded that eHealth was feasible in older adults receiving geriatric rehabilitation. None of the studies reported serious adverse events, which is in line with other reviews concerning feasibility of exergames [15,86]. The majority of the studies that included outcomes related to adherence or completed sessions reported high levels of adherence. Previous reviews that examined exergames also reported high adherence rates [86]. Some studies where eHealth was delivered via robotics or exergames reported a high exclusion rate (up to 88%). All studies with exclusion rates of $\geq 75\%$ were conducted in a geriatric rehabilitation setting [45,49] or in a hospital with a dedicated rehabilitation unit [50,51]. Reasons for exclusion were mostly cognitive or physical impairments, problems that are often present in older patients receiving geriatric rehabilitation. These findings indicate that eHealth in geriatric rehabilitation is safe to use and overall adherence is expected to be high, but complex eHealth interventions such as robotics and exergames might only be feasible in a selective group of older patients receiving geriatric rehabilitation.

There is limited available evidence on the usability of eHealth interventions. The studies included in our review indicate that exergames and mobile apps are usable once older patients have been trained in their use. However, there were certain age-related barriers associated with cognitive or physical ability that led to difficulties in using eHealth. While we did not find studies that reported problems in the use of eHealth due to problems in perception, 2 of 4 studies (50%) that included usability outcome measures explicitly excluded patients with visual impairments [51,58]. This might suggest that poor usability was expected in patients with visual impairments; this is in line with findings from other studies [27]. These findings suggest that usability problems are expected in older patients receiving geriatric rehabilitation, since they often suffer from cognitive, physical, or visual impairments. eHealth should be tailored to these specific age-related barriers to maximize the probability of successful use and implementation [22,27]. Furthermore, most studies did not incorporate clear usability endpoints, and the evaluation of usability varied considerably among studies. The lack of using clear endpoints or reliable and validated questionnaires combined with task metrics (preferably, task completion) to evaluate usability hampers the ability to pinpoint usability issues and prevents comparisons across different eHealth types [25,87].

Strengths and Limitations

The first strength of this review is the extensive search strategy that covered a broad range of search databases and included all types of research designs. Another strength of this review is the categorization of outcome measures based on the ICF model, providing a clear overview of different types of outcome domains evaluated in the included studies. Nonetheless, several limitations of this systematic review should be noted. While this review provides a broad overview of the literature on 3 different concepts, our study design led to a vast variety of different outcome measures related to effectiveness. The inclusion of various outcomes measures, in combination with various eHealth interventions and diagnoses, limited our ability to draw definitive conclusions. Since a meta-analysis was not feasible, we were unable to report an effect size and publication bias. We instead provided an overview of the effectiveness of eHealth interventions using a harvest plot. Lastly, while we used a separate search string that included keywords related to usability, we only found 4 studies that included outcomes on usability. A possible explanation might be that we did not include specific Computer Science search databases, which might include more studies that are related to usability [88]. Furthermore, despite the massive growth in eHealth studies, only a small portion publish their usability results [89].

Conclusions

In conclusion, eHealth can improve rehabilitation outcomes in older adults receiving geriatric rehabilitation. Based on our findings, comparisons to literature, and the strengths and limitations of our review, our main results and recommendations for further research and the use of eHealth in clinical practice are (1) keep it simple, (2) include evidence on usability, (3) focus on participation, and (4) ensure consensus. First, simple interventions have the most potential to improve rehabilitation outcomes in older adults receiving geriatric rehabilitation, especially, when they are provided as blended care. Additionally, simple eHealth interventions have a higher chance of feasibility in older patients receiving geriatric rehabilitation who often suffer from cognitive or physical impairments. Second, scarce evidence on the usability of eHealth might hamper the implementation of eHealth in older patients receiving geriatric rehabilitation and could negatively influence effectiveness and feasibility. Further research on this topic with clear endpoints is needed. Health care professionals need to be aware of the usability of eHealth interventions they are providing. Third, participation is a key concept in geriatric rehabilitation and plays an important role in enabling older patients to continue living as independently as possible. Future research on eHealth interventions should consider including outcome measures related to participation. Fourth, current evidence on the use and evaluation of eHealth in geriatric rehabilitation is diverse, making it hard to compare outcomes and draw evident conclusions. Consensus on the use and evaluation of eHealth is needed for further development and implementation of eHealth in geriatric rehabilitation.

Authors' Contributions

JJMK screened titles of the identified studies. JJMK and AV screened the abstracts of all potentially relevant studies and obtained and reviewed the full texts. Disagreements between JJMK and AV were discussed until a consensus was reached. If a disagreement could not be resolved, EFvDvI was consulted. JJMK extracted the data. AV also extracted a subset of the data (10% of included studies) to check interrater reliability. JJMK performed quality assessment, and 10% of the included studies were selected at random and additionally assessed by AV to check interrater reliability. In 12 cases, a third reviewer, EFvDvI, was needed to achieve consensus during the process of study selection.

Abstract

Background: Delirium prevention is crucial, especially in critically ill patients. Nonpharmacological multicomponent interventions for preventing delirium are increasingly recommended and technology-based interventions have been developed to support them. Despite the increasing number and diversity in technology-based interventions, there has been no systematic effort to create an overview of these interventions for in-hospital delirium prevention and reduction.

Objective: This systematic scoping review was carried out to answer the following questions: (1) what are the technologies currently used in nonpharmacological technology-based interventions for preventing and reducing delirium? and (2) what are the strategies underlying these currently used technologies?

Methods: A systematic search was conducted in Scopus and Embase between 2015 and 2020. A selection was made in line with the Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR). Studies were eligible if they contained any type of technology-based interventions and assessed delirium-/risk factor-related outcome measures in a hospital setting. Data extraction and quality assessment were performed using a predesigned data form.

Results: A total of 31 studies were included and analyzed focusing on the types of technology and the strategies used in the interventions. Our review revealed 8 different technology types and 14 strategies that were categorized into the following 7 pathways: (1) restore circadian rhythm, (2) activate the body, (3) activate the mind, (4) induce relaxation, (5) provide a sense of security, (6) provide a sense of control, and (7) provide a sense of being connected. For all technology types, significant positive effects were found on either or both direct and indirect delirium outcomes. Several similarities were found across effective interventions: using a multicomponent approach or including components comforting the psychological needs of patients (eg, familiarity, distraction, soothing elements).

Conclusions: Technology-based interventions have a high potential when multidimensional needs of patients (eg, physical, cognitive, emotional) are incorporated. The 7 pathways pinpoint starting points for building more effective technology-based interventions. Opportunities were discussed for transforming the intensive care unit into a healing environment as a powerful tool to prevent delirium.

Introduction

Background

Delirium is an acute brain dysfunction with a disturbance in attention, awareness, and cognition [1], which is common, especially in critically ill patients. It occurs in about 40% of patients in the intensive care unit (ICU) [2], and in case of ventilated patients, the proportion goes up to about 65%-80% [2,3]. Nonetheless, delirium can be often underestimated due to differences in the severity of illness in populations and underrecognition of delirium [4,5]. Delirium is frequently associated with a significant increase in the ICU length of stay [6], risk of long-term cognitive impairments [7], and 6-month mortality rates after leaving the ICU [8]. At the organizational level, delirium is associated with an increase in the cost of ICU care [9], ICU readmission [10], and mental stress of ICU nurses who take care of patients with delirium [11]. At the societal level, delirium costs up to \$152 billion per year in health care in the United States [12]. Prevention of delirium may be the most effective way to avoid these negative outcomes. In case of in-hospital patients, at least 30%-40% of delirium cases are preventable by reducing the risk factors of delirium [13,14]. There are 2 types of interventions used for preventing delirium: pharmacological and nonpharmacological interventions (eg, reorientation).

Nonpharmacological multicomponent interventions are recommended over pharmacological interventions as a safe and promising way of preventing delirium [15]. Nonpharmacological multicomponent interventions aim at reducing delirium risk factors that are modifiable by, for instance, promoting better sleep, early mobilization, and cognitive training/stimulation [15]. In order to support the implementation of nonpharmacological interventions, several methods [16,17] have been introduced. As an example, the ABCDEF bundle provides practical ways to provide optimal care of ICU patients [16]. Despite the benefits of using these methods [18], there are still barriers, as the way in which nonpharmacological interventions are applied is often highly dependent on the medical staff. Technology-based interventions might help to overcome these barriers. In this review, “technology” is defined as equipment that is used or developed based on scientific knowledge for practical purposes. Ironically, while the ICU room has been one of the most technology-intensive places in hospitals, when it comes to delirium prevention, the use of technology-based interventions in the ICU room often remains limited to, for example, the use of earplugs [19].

With recent developments in technology, there is large potential for the diversity of technology-based interventions. Examples include a modified ICU room design providing, among others, a personalized light therapy system and noise reduction to support cognitive stimulation and a normal sleep-wake cycle of patients [20]. Another example is an interactive app using a

conversational agent, which provides patients social interactions and medical advice [21]. The app enables personalized care for patients without frequent physical visits of bedside nurses. These examples showcase some of the possibilities that recent developments in technology can bring. However, understanding how to optimize technology-based interventions is limited, and therefore, it is worthwhile to further and more systematically study the topic.

Prior Work

Recently, several (systematic) reviews have been performed to provide overviews and to highlight the potential of existing nonpharmacological interventions for preventing delirium [18,22-28]. However, none of the existing reviews focused exclusively on technology-based interventions for preventing delirium. Moreover, none of the previous reviews [25-27] provided information necessary for improving the design and development of new technology-based interventions. For instance, a vision outlining what is needed to build a better care environment for patients in the context of intensive care and clear guidance for technology-supported improvements are lacking.

Goal of This Study

To close this gap, this paper will provide a comprehensive review of technology-based interventions used for preventing and reducing in-hospital delirium. To our knowledge, this is the first systematic effort to provide such an overview. Taking a bottom-up approach, we will first investigate what types of technologies are used in current nonpharmacological interventions and how these interventions contribute to delirium prevention and reduction in hospitalized patients. Second, we will identify underlying strategies of technologies applied in the technology-based interventions. Finally, following our analysis, we will discuss the limitations of the current technology use and the opportunities for further research and development of technology-based interventions aimed at delirium prevention in the ICU and for other hospitalized patients. This systematic scoping review was conducted to answer the following questions: (1) what are the technologies currently used in nonpharmacological technology-based interventions for preventing and reducing in-hospital delirium? and (2) what are the strategies underlying these currently used technologies? This review will provide insights into technologies that can be used for in-hospital delirium prevention and reduction and suggest directions for future design and development of innovative technology-based interventions. We propose that incorporating these insights will optimize the use of technologies and enhance the effectiveness of technology-based interventions.

Methods

Search Strategy

This systematic scoping review was conducted complying with the Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) guidelines [29]. The study protocol was registered on the international prospective register of systematic reviews (PROSPERO, CRD42020175874). The search was conducted from the Scopus and Embase databases for studies that are written in English and were published between January 1, 2015 and January 6, 2020 (Scopus)/January 13, 2020 (Embase). This time period was set to focus on the state-of-the-art technologies used following our scope for this review. The initial search was conducted with the terms delirium (deliri*) and technology (technolog*) but it did not result in a sufficient number of relevant studies. Samples of search terms were identified through previous studies and extended through the search of index terms, medical subject headings, and other technological terms used

for other medical purposes. The following terms were used for the final search: (1) deliri*, (2) technolog*, (3) intelligen* OR automat* OR digital* OR computer OR computing OR robot*, (4) mobile OR app, (5) visual OR virtual OR VR OR video, (6) light* OR ambien* OR aroma* OR architect*, (7) sound* OR music* OR voice OR alarm, (8) cognitive training OR tracking OR game*, and (9) 1 AND 2 OR 3 OR 4 OR 5 OR 6 OR 7 OR 8 (see [Multimedia Appendix 1](#) for the full search strategy). Additional studies were sought through communication with experts. Only studies that were peer reviewed and conducted with human subjects were included. The title-abstract screening and the full-text review were performed by 2 reviewers (CMK and EMvdH) independently. Disagreements were discussed and reevaluated based on the main goal of the study. The reasons for excluding were recorded.

Eligibility Criteria and Study Selection

The studies were included based on the eligibility criteria (See [Table 1](#)).

Table 1. Eligibility criteria.

Criterion	Inclusion criteria	Exclusion criteria
Study type	All types of original research published in peer-reviewed journals and conferences	Letters, comments, editorials, conference abstracts, or any type of review
Period	January 1, 2015 until January 6 (Scopus) and 13 (Embase) 2020	Before January 1, 2015 and after January 6 (Scopus), 2020 and January 13 (Embase), 2020
Language	English	All other languages
Population	In-hospital patients in all age groups	Patients who are not in-hospital patients, healthy participants
Intervention	Nonpharmacological interventions using any type of technology either as a single intervention or as a part of multicomponent intervention aiming at preventing or reducing delirium	Pharmacological interventions, interventions only focusing on detecting/screening delirium
Comparator	Any comparator, including no comparator	N/A ^a
Outcome	Delirium-related data (eg, occurrence, duration of delirium) or risk factor-related data that indirectly influence delirium (eg, anxiety)	Neither delirium-related data nor risk factor-related data

^aN/A: not applicable.

The main goal of this review was to find papers dealing with the prevention and reduction of delirium in the ICU, but in order to not overlook the potential of a greater range of technology-based interventions, the search scope was not limited to the ICU department but included also other hospital departments (eg, pediatric ICU, geriatric ward). We also included delirium from all age groups: from acute pediatric delirium to geriatric delirium because they share a similar range of delirium symptoms [30]. Moreover, the risk factors and recommended interventions across delirium in these groups are more or less the same [31]. Although delirium consists of 3 subtypes, each of which have their own symptoms and courses [32], these subtypes were not applied in the eligibility criteria and the study selection, as most studies did not specify them. We included studies focusing on incident delirium as well as prevalent delirium in order to address the full scope of delirium interventions. As we intended to explore all existing technology-based interventions supported by scientific evidence, we did not place any inclusion restrictions on the study design.

Data Extraction and Quality Assessment

Data extracted from the studies included the primary author, year of publication, country of origin, publisher, summary of intervention content, applied technology, intervention goal, study design, type and number of participants, outcome measure, intervention outcomes, key findings, and limitations of the study. The primary data extraction was performed by CMK using the predesigned data extraction form, and the extracted data were reviewed and confirmed by EMvdH. Disagreements were resolved by discussions between CMK and EMvdH, which included revisits of the relevant data by both authors. To distinguish differences in the strength of evidence in the studies, a quality assessment was performed by CMK using a predesigned assessment form ([Multimedia Appendix 2](#)) and reviewed and confirmed by EMvdH. Disagreements were resolved by follow-up discussions. However, none of the studies were excluded based on the quality assessment in our analysis as our goal in this review was to create an overview of the existing technology-based interventions.

Data Analysis

First, all technologies used in the technology-based interventions were looked into and clustered per technology type; a total of 8 categories was identified. Clustering was performed by CMK and reviewed and confirmed by EMvdH. Next, to summarize the strategies used in the technology-based interventions, goals and content summaries of each intervention were looked into, and 14 strategies were identified. These strategies were clustered and labelled based on the overarching theme: this led to the identification of 7 pathways to delirium prevention. An extraction of 14 elements from each intervention was carried out by CMK and clustering was performed independently by

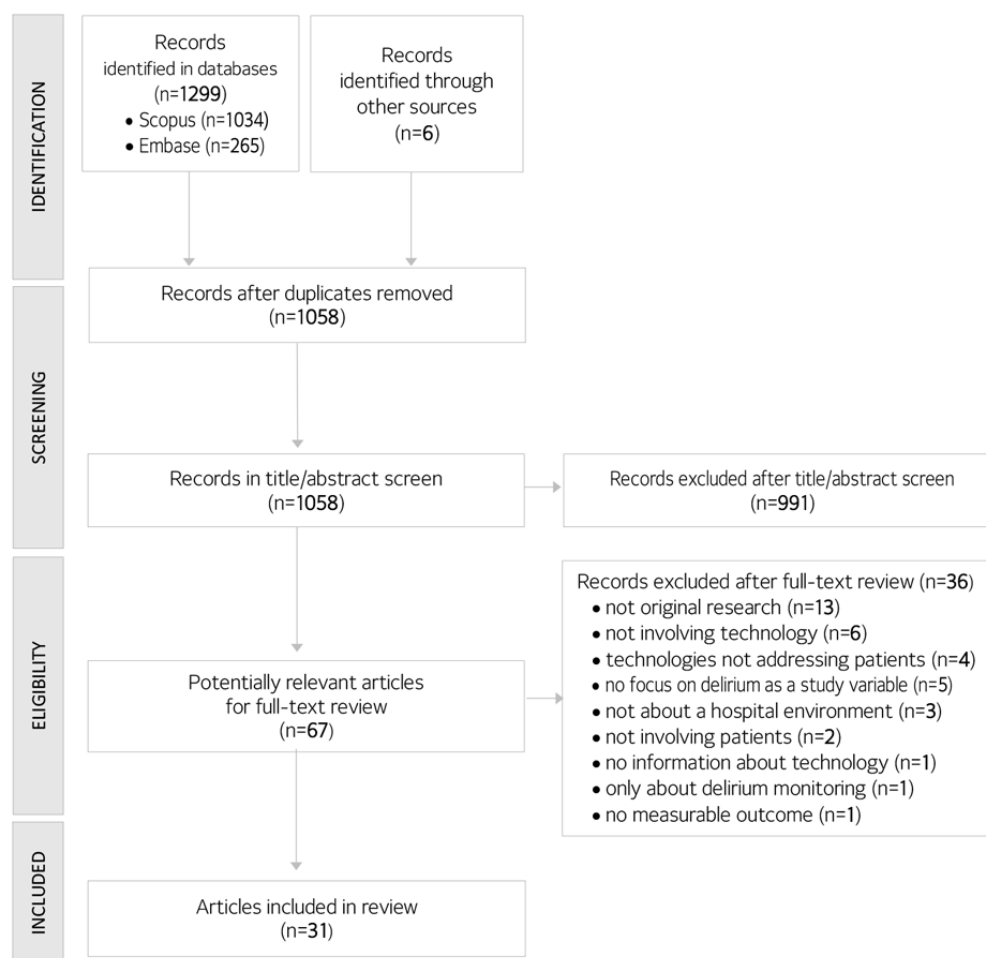

CMK and 2 other experienced researchers. After each session, the results and disagreements were discussed by CMK with the other experienced researchers, and then the synthesis was finalized by CMK.

Results

Study Selection

The process of literature screening and selection is presented in the flow diagram (Figure 1). After removing the duplicates, a total of 1058 studies were screened. Among these, 67 studies were examined based on the full text and 31 studies met inclusion for the review.

Figure 1. Flow diagram of study selection.

Study Characteristics

The characteristics of the 31 included studies are listed in Table 2. Most of the studies were conducted in the ICU (15/31, 48%) followed by hospital wards (13/31, 42%) and both ICU and hospital wards (3/31, 10%). The most common study population was adult patients (23/31, 74%). Seven studies were conducted

with pediatric patients [33-39] and 1 study was conducted with both adult and pediatric patients [40]. Most studies were prospective studies (28/31, 90%), including randomized trials [33-49], pretest-posttest/experimental [19,21,24,50-52], organizational case study [53], observational cohort [54], and pilot studies [55-57]. There were 3 retrospective studies [58-60] (See Table 2 for further specifications).

Table 2. Characteristics of the included studies classified into 8 different technology types.

Technology type, study	Main goal of intervention	Study design	Patient type ^a	Total number of patients (per group)
Audio: music/voice message				
Damshens et al [40]	To improve mental state ^b	Randomized clinical trial	ICU ^c (pediatric and adult)	80 (I ^d : 40, C ^e : 40)

Bott et al [21]	To provide companionship, social support, and health information to decrease loneliness and depression ^b	Case control quasi-experimental pre-post (for randomized controlled trial)	Medical and surgical unit	95 (I: 41, C: 54)
Others				
Lin et al [46]	To make the children adapt to the experience of visual disturbance	Prospective blinded randomized trial	PACU (pediatric)	179 (I: 89, C: 90)
Giraud et al [45]	To support mental status, earlier physical mobilization, and multisensory feedback/integration	Pilot time-cluster randomized controlled study	ICU	223 (I: 115, C: 108)
Multiple components				
Arbabi et al [51]	To support reorientation, cognitive/physical activation, human interaction ^b	Quasi-experimental	ICU	148 (I: 78, C: 69)
Tovar et al [52]	To reduce environmental precipitating factors, which impair sleep and to support maintenance of circadian cycle.	Prospective pre-experimental	ICU	49
Rivosecchi et al [24]	To provide cognitive stimuli and to support reorientation ^b	Prospective, observational quality improvement project pre-post	Medical ICU	483 (I: 253, C: 230)
Mitchell et al [47]	To support orientation and to provide cognitive stimulation	Single center randomized controlled trial	ICU	61 (I: 29, C: 32)
Zachary et al [59]	To prevent functional/cognitive, sleep and visual/hearing impairment, and dehydration	Retrospective	Medical, surgical/telemetry units ⁱ	4850 (I: 2146, C: 2704)

^aAll patients are adults unless mentioned as pediatric patients.

^bWith our minimal interpretation.

^cICU: intensive care unit.

^dI: intervention group.

^eC: control group.

^fPACU: post anesthesia care unit.

^gAbout 10% was delirious at admission.

^hOnly delirious patients.

ⁱExcluding intensive care unit patients.

Quality Scores of the Included Studies

The assessed quality scores ranged from 1 [24,56] to 5 [32,36-39,46,48] (Multimedia Appendix 2). The average score was 3.258 (SD 1.264). A score lower than 3 was found in 10 studies [21,24,51-53,55-58,60]. Seven studies reached the maximum score of 5 [33,36-39,46,48]. The included studies were analyzed in 2 ways: first, by focusing on extracting the different types of technologies in the interventions, and second, by focusing on identifying strategies underlying these interventions.

Types of Technologies Currently Used for Preventing Delirium

A total of 31 technology-based interventions were identified (Table 2 and Table 3). Eight categories were distinguished based

on the type of technology used. These categories are audio (7 studies), light (5 studies), video/video game (5 studies), virtual reality (VR) (3 studies), sleep aids (2 studies), communication support (2 studies), and others (2 studies). Technologies used as part of a multicomponent approach were grouped into a category called multiple components (5 studies). The identified technologies varied from simple (eg, earplugs, window blinds) to more advanced (eg, dynamic light, VR) ones. These technologies were used to complement conventional delirium treatments rather than replace them by reducing the negative (psychosocial) consequences of environmental factors and their effects on patient experiences.

Table 3. The content and effects of technology-based nonpharmacological interventions.

Study	Summary of the intervention	Incidence of delirium, <i>P</i> value	Duration of delirium (days)	Effectiveness		Key findings
				Direct ^a	Indirect ^b	
Audio: music/voice message						
Damshens et al [40]	<i>Music therapy:</i> Listening to light instrumental music selected by a music expert for 45 minutes twice (once in the morning and once at night) for a day.	I ^c : 15 (37.5%) C ^d : 16 (40%) (<i>P</i> =.82)	N/A ^e	No ^f	Yes ^g	No significant difference between the control and test group in terms of incidence of delirium. Significantly lower use of 2 pain relievers (acetaminophen and diclofenac) in the test group.
Lee et al [39]	<i>Music intervention:</i> A single 30-minute session of listening to slow-beat music (60-80 bpm) selected by patients from predefined playlists through headphones in the presence of a nurse at the bedside. The study was conducted to explore the anxiety-reducing effect of the intervention.	N/A	N/A	N/A	Yes	Music intervention significantly reduced anxiety and stress-related measures (serum cortisol level, heart rate, visual analog scale for anxiety, etc) of mechanically ventilated intensive care unit patients.
Johnson et al [48]	<i>Music intervention:</i> Listening to simple repetitive, self-selected music with slow tempo (60-80 bpm), low pitch, and repetitive rhythms for 60 minutes using an iPod and headsets, twice a day, over 3 days following admission.	I: 0 C: 0	N/A	N/A	Yes	No delirium incidence in both the control and test group. Music intervention significantly improved the pathophysiological mechanisms that contribute to delirium, neurotransmitter imbalance, inflammation, and acute physiological stressors in the test group.
Sharda et al [53]	<i>Confusion avoidance led by music program:</i> On postoperative day 1, patients got a music player and headphones with a personalized playlist based on a music assessment. Listening for at least 20 minutes twice a day was recommended, but patients had autonomy over the ultimate dose and frequency.	I: 17.8% C: 28.7% (<i>P</i> =.14)	N/A	No	No	This program may impact incident delirium and optimize postoperative pain and anxiety.
Cheong et al [55]	<i>Creative music therapy:</i> Spontaneous music making with musical instruments, playing familiar songs of patient's choice and music listening for 30 minutes once a day over 2 days. Based on individual's profile and response to music, a certified music therapist modified techniques to meet patients' need.	N/A	N/A	N/A	Yes	This therapy can improve mood/emotion and engagement of patients with dementia and delirium.
Byun et al [33]	<i>Mother's recorded voice:</i> Listening to either the recorded a voice of mother (I1) or a stranger (I2) through noise-cancelling headphones at the end of a surgery. The prerecorded message with standardized text was repeated with 10-second intervals and was continued until entering the postanesthesia care unit.	I1: 8 (24.2%) I2: 20 (60.6%) (<i>P</i> =.006)	N/A	Yes	N/A	Letting children listen to the sound of their mother in the recovery room reduced the incidence of emergence delirium.
Munro et al [49]	<i>Automated reorientation:</i> During the first 3 days at the intensive care unit, patients either received automated reorientation messages with a familiar (I1) or unfamiliar voice (I2) or no reorientation message at all (C). The message containing patient's name and information about the intensive care unit environment (<2 minutes long) was played during the day (9 AM to 4 PM).	Delirium-free day I1: 1.9 days (0.99) I2: 1.6 days (1.07) C: 1.6 days (1.13) (<i>P</i> =.04)	I1:0.3 (0.48) I2:0.6 (0.84) C: 0.9 (1.28) (not significant)	Yes	N/A	Reorientation through automated messages increased the number of delirium-free days. A familiar voice was more effective than an unfamiliar voice in reducing delirium.

Study	Summary of the intervention	Incidence of delirium, <i>P</i> value	Duration of delirium (days)	Effectiveness		Key findings
				Direct ^a	Indirect ^b	
Light: dynamic light/natural light						
Estrup et al [58]	<i>Circadian light</i> : Exposure to the circadian light in which the amount of blue light (460-480 nm) changes over time like natural light. The light intensity varied from 50 lux to 4000 lux during daytime (between 6:00 and 20:30) and there was no blue light between 23:00 and 6:00. The exposure time of patients was varied from at least 24 hours to their total stay.	I: 30 C: 28	I: 2.5 (1-7) C: 1.5 (1-3) (<i>P</i> =.41)	No	N/A	Circadian light did not have an effect on the development of delirium.
Pustjens et al [60]	<i>Dynamic light</i> : Exposure to an artificial daylight system with light intensity peak values of 750 lux at the eye level and a color temperature ranging from 2700 K to 6550 K. Patients were exposed as long as possible during daytime. The overall period varied from 20 hours to 42.7 hours depending on the patient.	I: 20 (5.4%) C: 19 (5.0%) (<i>P</i> =.80)	N/A	No	N/A	Exposure to dynamic light did not reduce the incidence of delirium nor total hospital length of stay.
Simons et al [41]	<i>Dynamic light</i> : Exposure to the circadian light system with light intensity and color temperature peaks of 1700 lux and 4300 K via conventional fluorescent tubes between 9:00 and 16:00 except for 11:30 and 13:30 (intervention group) and to the standard lighting settings of 300 lux and 3000 K (control group) during the intensive care unit stay of patients (3-9 days).	I: 137 (38%) C: 123 (33%) (<i>P</i> =.16)	I: 2 (2-5) C: 2 (1-5) (<i>P</i> =.87)	No	N/A	Dynamic light as a single intervention did not reduce the cumulative incidence and duration of delirium in the test group.
Potharajaroen et al [42]	<i>Bright light</i> : Treatment with bright light therapy consisting of 5000 lux at 1.4-m distance from patient's face between 9:00 and 11:00 for 3 days. Other treatment data (nasal cannula oxygen, drugs etc) were analyzed.	I: 2 (6.45%) C: 11 (35.48%) (<i>P</i> =.005)	N/A	Yes	N/A	Bright light therapy reduced the incidence of delirium in the test group.
Smonig et al [54]	<i>Natural light exposure</i> : Exposure to natural light via windows from admission to the intensive care unit until discharge (3-7 days).	I: 65 (64%) C: 55 (71%) (<i>P</i> =.28)	I:3 (1-6) C:3 (1-7) (<i>P</i> =.43)	No	Yes	Admission to a single room with natural light via windows did not reduce the incidence of delirium but a risk of agitation episodes and hallucinations
Video/video game: information/distraction						
Lee et al [50]	<i>Preoperative video information</i> : Informative videos that explain preoperative procedures, operating room environment, and intensive care unit environment on the day prior to surgery.	I: 3 (12%) C: 5 (20%) (<i>P</i> =.26)	N/A	No	Yes	The intervention was not effective in reducing delirium incidence but decreased the anxiety levels.
Kim et al [34]	<i>Video distraction and parental presence</i> : In the preoperative holding room before surgery, provision of a 4-minute animated cartoon video (I1), parental presence (I2), or a video plus parental presence (I3). The primary study goal was to compare the effect of video distraction, parental presence, or combination of both on the preoperative anxiety reduction.	I1: 13 (38.2%) I2: 13 (39.4%) I3 ^c : 20 (43.5%) (<i>P</i> =.32)	N/A	No	N/A	All groups showed similar effect on the preoperative anxiety and none of them significantly reduced emergence delirium.

Study	Summary of the intervention	Incidence of delirium, <i>P</i> value	Duration of delirium (days)	Effectiveness		Key findings
				Direct ^a	Indirect ^b	
Rodriguez et al [35]	<i>Video distraction using varying screen size</i> : Watching a movie in the preoperative area and through the induction of anesthesia. Patients chose from one of the 5 preselected age-appropriate movies using either a large bedside screen (I1) or a small tablet (I2). One parent accompanied a patient. The average time spent was 3.8 minutes (I1) and 4.5 minutes (I2). The primary study goal was to compare the effect of video distractions in different screen sizes on anxiety reduction.	I1: 29.16% I2: 30.8% (not significant)	N/A	No	Yes	The video distractions decreased the preoperative anxiety, regardless of the size, with parental presence at induction of anesthesia. No effect was found for the emergence delirium rate.
Waszynski et al [43]	<i>Simulated family presence and nature scene</i> : Two types of video intervention for when agitation is present and the family is not: watching a 1-minute family video message plus usual care (I1) or watching a 1-minute nature video plus usual care (I2). The study goal was to examine the effect of family video message on agitation level.	N/A	N/A	N/A	Yes	Both family video message and nature video can decrease agitation in delirious patients.
Dwairej et al [36]	<i>Video game distraction and anesthesia mask practice</i> : Combination of video distraction using a handheld video game (1-2 minutes) before the transfer to operation room, anesthesia mask exposure, and shaping intervention. During anesthesia induction, parental presence is allowed but not standardized. In the operating room, nonmedical talks occurred to distract the child. The study goal was to evaluate the effectiveness of the intervention on the preoperative anxiety.	I: mean 11.06, SD 3.97 C: mean 10.25, SD 4.81 (<i>P</i> =.30)	N/A	No	Yes	The intervention significantly reduced anxiety. Yet, the results did not reveal statistically significant difference in emergence delirium scores.
Virtual reality: information/distraction						
Eijlers et al [37]	<i>Virtual reality exposure</i> : Provision of a 15-minute highly immersive virtual reality experience of the operating theatre to get familiarized with the environment and general anesthesia procedures. The virtual environment was computer-generated, interactive, and child-friendly.	I: 7.0 (5.0-9.0) ^f C: 6.0 (5.0-9.0) (<i>P</i> =.27)	N/A	No	No	This did not have a beneficial effect on anxiety, pain, emergence delirium, or parental anxiety.
Ryu et al [38]	<i>Preoperative immersive virtual reality tour of operating theater</i> : Provision of a 4-minute virtual reality video for pediatric patients showing the operating theater and explaining the perioperative process by using a popular animal character as a patient. The intervention was provided 1 hour prior to entering the operating room. The study goal was to examine the effect of the intervention on reducing the preoperative anxiety.	I: 16 (39%) C: 14 (36%) (<i>P</i> =.77)	N/A	No	Yes	The intervention did not reduce the incidence and severity of emergence delirium, although it was effective in alleviating preoperative anxiety in children.

Study	Summary of the intervention	Incidence of delirium, <i>P</i> value	Duration of delirium (days)	Effectiveness		Key findings
				Direct ^a	Indirect ^b	
Suvajdzic et al [57]	<i>Patient-centered virtual reality system:</i> Intervention consisting of 2 sessions (session 2 was held at least 24 hours after session 1): (1) a video instructing patients to enjoy the movie by moving their heads to look around, followed by a 5-10-minute guided meditation in virtual nature scenes for breath control (Relax VR), (2) playing either Relax VR or fishing game (Bait!).	I: 0 (0%) C: 2 (6%) (<i>P</i> >.99)	N/A	N/A	No	The interventions did not result in clinically significant changes in pain, sleep, or vital signs. It seems likely that greater exposure to virtual reality is more likely to produce a meaningful effect on patient physiology and sleep quality.
Sleep aids						
Demoule et al [44]	<i>Earplugs and eye masks:</i> Use of earplugs and eye masks every night between 10 PM and 8 AM from inclusion until ICU discharge (average 7 days). The study goal was to evaluate the impact of the intervention on sleep architecture in intensive care unit patients.	I: 2 (7%) C: 2 (6%) (<i>P</i> >.99)	N/A	N/A	Yes	Interventions resulted in reduced long awakenings and increased deep sleep duration. Possibly the effect was at least partially counteracted by the discomfort of wearing the devices.
Van de Pol et al [19]	<i>Nocturnal sound-reduction protocol:</i> A protocol focusing on reducing noise in the night, for example, speaking and laughing quietly in the lobby, minimizing alarm volume, closing the door when the patient is not delirious, and providing earplugs at night. One month of implementation phase.	Slope of delirium incidence I: -2.79% (<i>P</i> =.02) C: 0.91% (<i>P</i> =.37) Difference: -3.70% per time period (<i>P</i> =.02)	N/A	Yes	Yes	The protocol reduced the incidence of delirium. It significantly reduced delirium risk factors such as perceived nighttime noise and the use of sleep medication. Reported sleep quality was not improved.
Communication aids						
Garry et al [56]	<i>Eye-tracking devices:</i> Usage sessions (45 min/session, 5 sessions on consecutive weekdays) were given, during which patients were prompted to spell out notes, indicate their needs via picture sets, and play simple memory games. Patients were permitted to communicate with family, nursing staff, and physicians outside the training sessions.	Day 1: 4 (33%) Day 2: 1 (8%) Day 3/onward: 0	N/A	N/A	Yes	The use of an eye-tracking device positively affected patients' happiness and ability to participate; however, it did not show a significant effect on patients' confusion level or frustration.
Bott et al [21]	<i>Bedside digital care coach avatar:</i> 24-hour psychosocial and health care support through an embodied conversational agent with an appearance of animated animal avatar. It checks patient status, assists communication, and offers psychological support during their stay at medical and surgical units (3-6 days). The average time spent with the embodied conversational agent was 61 minutes per day.	I: pre12 (41%)/post1 (3%) C: pre6 (13%)/post3 (6%) (<i>P</i> <.01/.25)	N/A	Yes	Yes	The use of the care coach avatar during hospitalization can reduce the frequency of delirium, loneliness, and falls among diverse hospitalized older adults.
Others						
Lin et al [46]	<i>Eyepatch for visual preconditioning:</i> Preventive treatment for pediatric patients undergoing ophthalmic surgery consisted of covering the eye with an eyepatch for at least 3 hours one day before surgery.	I: 15 (16.9%) C: 40 (44.4%) (<i>P</i> <.001)	N/A	Yes	Yes	The intervention significantly reduced preoperative anxiety and emergence delirium. Preoperative anxiety was found to be an independent risk factor of emergence delirium.

Study	Summary of the intervention	Incidence of delirium, <i>P</i> value	Duration of delirium (days)	Effectiveness		Key findings
				Direct ^a	Indirect ^b	
Giraud et al [45]	<i>Structured mirrors intervention</i> : Protocol-driven mirrors intervention consisting of different mirrors to provide visual feedback about the environment as a re-orientation tool and to support self-awareness and explanation of medical/nursing procedures. The unit of randomization was a 2-week time period cluster.	I: 20 (17%) C: 17 (16%) (<i>P</i> =.71)	I: 1 (IQR 1-3 [range 1-25]) C: 2 (IQR 1-8 [range 1-13]) (<i>P</i> =.40)	No	Yes	Use of the mirror intervention did not reduce delirium but improved factual memory encoding.
Multiple components						
Arbabi et al [51]	<i>Environmental changes and liaison education</i> : Environment with proper time cues, appropriate lighting for the time of the day during intensive unit care stay (average about 5 days). Further, allowing interactions with family members and medical staff, giving vision and hearing aids, preventing dehydration, and encouraging early mobilization. Training for medical staff on delirium management.	I: 30 (37.97%) C: 50 (72.46%) (<i>P</i> =.01)	I: 26.18 (SD 35.38) C: 35.84 (SD 39.31) (<i>P</i> =.001)	Yes	N/A	Multifactorial intervention (educational and environmental changes) was effective in reducing the delirium rate in the intensive care unit and the duration of delirium.
Tovar et al [52]	<i>Environment with reduced environmental stressors</i> : Nursing care guide to reduce environmental stressors such as noise and continuous artificial light. Provision of active interactions with family members and medical staff, cognitive/sensory stimuli, and information about the environment. The posttest was performed after the guideline had been applied for 5 days.	I: 3 (6.12%)	N/A	Yes	N/A	Multicomponent intervention focusing on reducing precipitating environmental factors was effective in reducing delirium incidence and improving sleep.
Rivosecchi et al [24]	<i>Nonpharmacological protocol</i> : Nursing education bundled into the protocol consisting of music, opening blinds, re-orientation and cognitive stimulation, eye and ear protocol during intensive care unit stay (median 188.3 hours-control group, and 153.5 hours-intervention group).	I: 24 (9.4%) C: 36 (15.7%) (<i>P</i> =.04)	I: 16 h (IQR 8-24) C: 20 h (IQR 9.5-37) (<i>P</i> <.001)	Yes	N/A	The protocol reduced both duration and incidence of delirium.
Mitchell et al [47]	<i>Multicomponent family-delivered intervention</i> : Family intervention consisting of orientation (memory clues: family pictures etc), therapeutic engagement (cognitive stimulation: discussing current family life events etc), and sensory (glasses, hearing aids in place/working). The intervention group was enrolled for a median of 5 days and the family members were asked to deliver the intervention at least once a day. The study goal was to assess the feasibility and acceptability of the intervention for designing a larger randomized controlled trial.	I: 17 (59%) C: 18 (56%) (<i>P</i> =.87)	I: 1.0 (2) C: 1.0 (2) (<i>P</i> =.60)	No	N/A	Multicomponent family-delivered intervention was not effective in reducing delirium incidence nor days of delirium.

Study	Summary of the intervention	Incidence of delirium, <i>P</i> value	Duration of delirium (days)	Effectiveness		Key findings
				Direct ^a	Indirect ^b	
Zachary et al [59]	<i>Hospital elder life program interventions</i> : Geriatric intervention program consisting of reorientation, social stimulation, music therapy, games, mindfulness relaxation, mobilization, visual/hearing aids, sleep aids, and nutrition support. Volunteer interventions were 3 times a day, which took 20-30 minutes each time.	N/A	N/A	N/A	Yes	This program reduced 30-day readmissions and hospital length of stay in the 70-85 years age group.

^aDirect effects: incidence and duration of delirium.

^bIndirect effects: length of stay or delirium risk factors, including but not limited to pain, anxiety, stress, mood, agitation, and sleep deprivation.

^cI: intervention group.

^dC: control group.

^eN/A: not applicable.

^fNo significant positive effect.

^gSignificant positive effect.

Of the 31 identified studies, 23 studies analyzed the effect of the interventions on direct delirium-related outcome measures (incidence and duration of delirium). The other 8 studies only assessed indirect outcome measures (eg, length of stay, precipitating risk factors of delirium such as anxiety). Of the 23 studies that evaluated direct delirium-related outcome measures, 9 studies showed a significant effect on decreasing either or both incidence and frequency of delirium. The interventions in these studies involved diverse technologies across the categories, that is, audio [33,49], light [42], sleep aids [19], communication support [21], others [46], and multiple components [24,51,52]. Of the 14 studies without significant effect on direct outcome measures, 8 studies, however, showed significant effects on delirium risk factors or symptoms, including pain [40], anxiety [35,36,38,50], agitation [54], hallucination [54], and factual memory encoding [45]. Six of the 8 studies using diverse technology-based interventions showed a significant effect on indirect outcome measures, including anxiety [39], agitation [43], sleep deprivation [44], or ICU readmission [59]. The technologies used in these studies were audio [39,48,55], video/video game [43], sleep aids [44], and multiple components [59]. It is notable that across all technology categories, significant positive effects were found on either or both direct and indirect delirium outcome measures. An explanation and further analysis of each category is given as follows.

Audio

The interventions using audio had either music or prerecorded voice messages. Music interventions involved, in general, slow tempo music with a duration of 20 minutes to 1 hour. The music was provided 2 or 3 times a day by using a television audio system or headset. These interventions aimed at addressing anxiety [39,53], mood [55], pain [40,53], and engagement [55] for adult patients. Across these interventions, we found differences in the level of personalization and autonomy: the level of personalization varied from the provision of music preselected by a music expert to the creation of a music playlist based on a patient's own choice and the level of autonomy

ranged from patients listening to music with dose and frequency predecided by a researcher to patients deciding on dose and frequency. Interestingly, delirium incidence was reduced in the study with personalized music allowing patients autonomy [53]. While the majority of studies used a passive format such as music listening, 1 study used a participatory format providing an interactive music therapy and showed significant improvement in mood and engagement [55]. Prerecorded voice messages contained mainly patient's name and information about the care environment using either a familiar or unfamiliar voice. These interventions aimed to provide reorientation and a feeling of comfort. Two studies were carried out with different patient age groups: one with pediatric patients and the other with adult patients. The use of a prerecorded voice message reduced direct delirium outcome in both groups [33,49]. Likewise, one of the studies showed that a familiar voice was more effective than an unfamiliar one [49].

Light

The interventions involving light used either a specially made light therapy system for dynamic/bright light or natural light through windows. Dynamic light interventions provided light consisting of diverse intensities (ranging from 50 lux to 4000 lux) and color temperatures (ranging from 2700 K to 6550 K) in the environment of patients [41,58,60]. The bright light intervention used high intensity of light (5000 lux) for 2 hours a day [42] while the natural light intervention used natural light coming through windows [54]. All studies aimed at improving the patients' circadian rhythm and were only tested on adult patients. Only the bright light intervention showed an effect on reducing the incidence of delirium [42]. Possibly, most of the current light interventions are not effective in reducing direct delirium outcomes. Another possible explanation for why few studies found an effect on reducing incidence of delirium might relate to the amount of light (intervention) that patients actually received. In most studies, for example, the actual light intensity at patients' eye level was not specified or the definite exposure time to light of each patient was not guaranteed as sedative patients were included who had their eyes closed [54,58,60].

Video/Video game

The interventions using video/video games were used for providing either information about the medical procedure prior to a surgery or distractions with various contents, including age-appropriate programs (eg, cartoons), family messages, or nature scenes through a handheld tablet or a specially made bedside screen. These interventions aimed to address anxiety or agitation and were effective in decreasing anxiety or agitation in all studies with either pediatric or adult patients [34-36,43,50]. Regarding direct delirium outcome measures, none of the studies showed a significant effect [34-36,50].

VR Technology

The interventions using VR technology provided either information about medical procedures, distraction, or sensory stimulation for patients. VR interventions used a head-mounted device and the VR content varied from a guided tour to the operating theatre, to the virtual scenes of real-world locations. The interventions were mainly used to address anxiety or to support restorative effect for both pediatric and adult patients [37,38,57]. The effects of using VR to provide information (a preoperative VR tour to the operating theatre) differed in the studies. Of the two, 1 study showed a significant effect on reducing the anxiety of pediatric patients [38]. For none of these studies, the use of VR resulted in any effect on delirium-related outcome measures [37,38,57].

Sleep Aids

The interventions related to sleep aids were wearable devices such as earplugs and eye masks [19,44], and environmental modifications such as closing doors and window blinds were applied [19]. They aimed at reducing noise and light during nighttime to improve the sleep quality of adult patients. The application of both wearables and environmental modifications showed an effect on reducing the incidence of delirium [19]. Moreover, the use of a wearable showed an improvement in sleep quality [44]. It is notable that this study also highlights the potential negative side-effects of using wearables due to discomfort experienced by vulnerable patients.

Communication Supports

The technologies used for communication supports were a conversational agent [21] and an eye-tracking device [56]. They assisted adult patients to express their needs or to participate in psychosocial activities. Both types improved the psychological well-being of patients by increasing happiness and the ability to participate and by reducing loneliness. The conversational agent was used as a digital care coach providing communication means, human interactions, and companionship. This intervention reduced the frequency of delirium [21].

Others

In this category, we found rather simple forms of technologies used for diverse purposes: an eyepatch for experiencing what will happen after surgery [46] and a structured mirror to provide patients cognitive stimuli as a means to support mobilization and communication [45]. The eyepatch was used for pediatric patients and was effective in reducing emergence delirium [46]. The structured mirror intervention was for adult patients and improved their factual memory encoding [45].

Multiple Components

Some interventions involved more than one technology as part of a nonpharmacological bundle for adult patients. Environmental modifications for noise reduction, cognitive stimulation, and reorientation reduced delirium incidences in 3 studies [24,51,52]. Zachary et al [59] had a similar focus and showed an effect on reducing the 30-day readmission. In a small feasibility study, no significant effect was found on direct delirium outcome measures for the simple technology-based intervention involving families throughout different therapies such as orientation and cognitive stimulation [47].

Seven Pathways to Delirium Prevention

Fourteen strategies to prevent delirium were identified from the technology-based interventions of the included studies (see [Multimedia Appendix 3](#) for the 14 strategies used in the included studies and see [Table 4](#) for full description of the 14 strategies).

Table 4. Descriptions of the 14 strategies.

Strategy	Explanation	Example
Cognitive stimulation and training	Stimulating patient's brain activity to maintain and improve their cognitive capability and executive functions such as attention, memory, reasoning, and language.	Music, book
Companionship	Providing patients a sense of consistent social presence as a means to combat social isolation and loneliness.	Digital agent
Contextual cue (reorientation)	Providing patients contextual information such as time, date, and place to minimize confusion and anxiety coming from not knowing what's going on and feeling lost	Automated voice message, clock
Daytime awakening	Supporting patients to stay physically and mentally activated during day so they can become tired enough to sleep at night	Dynamic light
Distraction	Redirecting patient's focus away from distressing situations/conditions such as pain, discomfort, fear, and anxiety	Music, video, virtual reality
Early mobilization	Encouraging patients to move their bodies early enough to prevent muscle loss and other complications caused by lack of physical movement	Structured mirror
Easier communication	Providing a means for patients to better express their needs especially when they are mechanically ventilated	Eye-tracking device
Engagement	Encouraging patients to be interested in and to be involved with what is happening	Participatory music therapy
Familiarity	Providing something that patients feel familiar with to help them feel safe, at ease, and calm	Mother's voice, personalized music list
Good night sleep	Providing an environment that facilitates sleeping by removing disturbing elements such as sound and light noise and by adding elements enhancing patient comfort and relaxation	Ear plugs
Human (social) interaction	Providing patients warm human (-like) interactions to stimulate them socially and to help them feel being involved and being cared for	Digital agent
Personalization	Providing an option that reflects patient's preference	Personalized music list
Psychological preparation	Helping patients to feel prepared and confident by informing them what will happen in advance.	Virtual tour to the operation room
Soothing elements	Helping patients to calm down and to manage stress and anxiety by providing an activity or environment that is soothing	Music, nature video

Subsequently, the 14 strategies were clustered into 7 pathways by using a thematic analysis approach (Figure 2). As such, the 7 pathways might provide directions toward technology-based interventions for delirium prevention. The 7 pathways and a short description of each pathway are as follows:

1. Restore the circadian rhythm: helping patients to find a normal sleep-wake cycle to prevent sleep deprivation.
2. Activate the body: supporting patients to regain physical strength and endurance.
3. Activate the mind: supporting patients to prevent cognitive decline, restore cognitive function, and minimize confusion, which can cause negative emotions such as anxiety, agitation, and aggression.
4. Induce relaxation: helping patients to stay in a positive psychological state, which prevents emotional distress, makes it easier to cope with their situation, and improves the patients' physical state (eg, through better sleep).
5. Provide a sense of security: supporting patients in feeling reassured and safe so that they can easily handle stress and

emotional distress such as anxiety and fear that originate mainly from uncertainty and unfamiliarity.

6. Provide a sense of control: supporting patients by enhancing autonomy, empowerment, and control over anxiety.
7. Provide a sense of being connected: supporting patients to feel connected and socially engaged to prevent loneliness, depression, and anxiety.

Three of the 7 pathways outlined above, that is, *Restore the Circadian Rhythm*, *Activate the Body*, and *Activate the Mind*, are in line with strategies recommended in the ABCDEF bundle [16]. The other pathways are not directly linked, yet are associated with important predictors of well-being used in psychology: *Induce Relaxation* links to coping strategies [61] and *Provide a Sense of Security, Control, and Being Connected* are related to the universal psychological needs, which are security [62], dominance [63], and relatedness [62]. The 7 pathways, therefore, cover a broad range of delirium prevention strategies correlating physical, cognitive, and emotional aspects as shown in Figure 2.

Figure 2. Overview of the 14 strategies grouped into 7 pathways of delirium prevention that are used in technology-based interventions.

Discussion

Overview

The results of this review provided an overview and characteristics of technology-based interventions that have been used to prevent and reduce delirium. We also summarized the related strategies into 7 pathways. These 7 pathways include key elements for developing technology-based interventions for delirium prevention. From our analysis of the included studies and technologies, we next discuss the limitations and opportunities for future research.

Limitations in the Current Technology Use for Preventing Delirium

First, most technology-based interventions addressed only one or a few delirium risk factors. For instance, interventions that used a dynamic light system [41,60] aimed to improve the patients' sleep-wake cycle while interventions, including video distraction [34,35,43], aimed to reduce the anxiety of the patients. Such approaches are not in line with the frequently recommended multicomponent approach, which effectively targets the multifactorial origin of delirium [15]. Second, most technology-based interventions were more momentary than continuous solutions. Although the length of stay in the ICU should be kept as short as possible, it can last from days to

weeks. During this period, depending on the severity of their illness, patients are going through various clinical and emotional phases and their needs are changing respectively. During various activities (eg, clinical checkup, therapy session, cleaning, resting, family visit), patients can experience diverse feelings (eg, anxiety, fear, tiredness, worrying, relaxed, cheerful) and have different corresponding needs. In contrast to the heterogeneity of activities and patients' needs throughout their ICU stay, the majority of the included studies focused on a short period of time. For instance, the video and video game interventions were usually planned for less than 5 minutes [34-36,43,50], and the VR interventions were used for less than 15 minutes [37,38,57]. In order to minimize delirium risk factors, it is important to understand the needs and concerns of patients throughout their whole ICU stay and to develop preventive solutions that are more continuous and seamless. Importantly, knowledge as how to develop and implement a continuous solution throughout the ICU stay of patients is missing as none of the reviewed studies evaluated it. Third, only a limited number of studies focused on the use of technology for improving the patients' environment. Despite the negative influences of the stressors in the current ICU environment, such as overload of light and noise [64,65] on patients' clinical progress, only a few studies [41,51,52,58,60] aim at optimizing the ICU environment. In contrast, most technologies used as interventions added extra sensory burden to the patients. Last,

the effect of some technologies can be improved by a more thorough understanding of (vulnerable) patients and context-dependent needs. Understanding the patient's needs is crucial for delivering high-quality care. However, sometimes, the implementation of technology can be challenging and might result in a suboptimal match with the patients and context. For instance, in the study of bright light therapy, patients were sedated and had their eyes closed and this resulted in insufficient amount of light exposure [41]. The use of wearable sleep-aid devices (earplugs and eye masks) by ICU patients can lead to potential discomfort, thereby limiting the effectiveness of the intervention [44].

Further Development of Technology-Based Interventions for Preventing Delirium

Despite the limitations of current technology-based interventions, the potential of technology in delirium prevention is promising [20]. Reflecting on the identified limitations, the following recommendations are proposed for the future design and development of technology-based interventions for delirium prevention. First of all, technology should not only support physical and cognitive functions but also support psychological and emotional needs. In the analysis, the proposed 7 pathways described existing approaches for delirium prevention, which cover multifaceted needs of patients. Yet, comparing the number of related strategies and studies included in each pathway, it is notable that, in general, there are far more technology-based interventions aiming to support functions than to support needs. To take a more comprehensive approach, further development of technologies should aim at meeting patients' needs by, for instance, providing a means to allow them more control over their situation, feel relaxed, safe, and connected. Some examples are an interaction device to enable ventilated patients to easily express their needs using gestures [66], a robotic pet that lets patients cuddle and helps them feel calm [67], or an intelligent alarm system contributing to a relaxing environment for ICU patients by controlling and harmonizing alarm sounds [68]. Another way to meet patients' emotional and psychological needs can be found in the provision of (multi-) sensorial and cognitive stimuli. For instance, aromatherapy can be a way to support patients to feel relaxed through sensorial stimuli combining pleasant tactile pressure and aromatic fragrance [69]. For the stimuli, using nature elements can be an interesting candidate as exemplified by previous cases [43,57] and other applications: examples are a VR therapy showing various nature sceneries [70] and a geriatric care environment adapting nature elements [71] to generate relaxation [70,71], increase social engagement, and reduce restlessness [71]. Second, technology could create a healing environment for patients: a more context-aware, personalized, and adaptive ICU. Despite emerging interest in patient-centered care, this review showed that such interactive technology is rare in the current ICU environment. Patient-centered care recognizes a patient as a

unique individual and stresses the importance of care tailored to patients' specific preferences, needs, and values [72-74]. In order to better adapt patient-centered care, technology should be evolved in a way that (1) it allows patients to take a more active role in their care process, for instance, by enabling them to be explicit about their specific needs and (2) enables a care environment and service system to provide real-time interventions adapted to the patients' profiles and their changing status/needs. Advances in technologies have made this feasible. Next to the modified ICU room [20] and the conversational agent [21] described in the introduction, the intelligent ICU concept enables autonomous monitoring of patients and the ICU environment over time by using pervasive sensing [75]. Previously we pointed out that there were too few technologies aiming at improving patients' environment despite its significant influence on patients. Luetz et al [20] emphasized the potential of environment-related innovations, arguing that the ICU should be considered as a treatment tool. In order to design a healing environment, future technology-based interventions should reinforce the main ingredients of patient-centered care: context-awareness, personalization, and adaptability.

Study Limitations

This study has some limitations. First, this review was conducted between 2015 and 2020 to focus on state-of-the-art technologies used for preventing and reducing delirium. Therefore, some technologies that might have been introduced in the studies published before 2015 and have not been studied since then were not included in this review. Second, the search strategy made use of the combination of keywords describing different types of technologies and not the keyword "technology" as this was not widely used in literature on delirium prevention and reduction. Although we tried to cover all the existing technology-related keywords, this search strategy might have left out some very rare types of technologies. Third, the 7 pathways were made based on the included studies only. Therefore, some approaches and strategies from the studies, which did not meet our criteria, were not included, such as approaches and strategies related to pharmacological interventions or delirium detection only.

Conclusions

In this review, we provided an overview of technology-based interventions and proposed the 7 pathways to delirium prevention based on evidence-based studies. These insights can be considered as starting points for transforming ICUs into a healing environment, which might be well one of the most powerful nonpharmacological technology-based interventions for preventing delirium. Further research should generate a more in-depth and complete understanding of the key components of a healing environment for patients and on designing and developing technologies that can actualize it.

Acknowledgments

We would like to thank Thomas Falck, MSc (Philips Research) and Dr Ir Hanneke Becht (University of Twente) for helping with the development of the search strategy, Prof Dr Sophia de Rooij (University Medical Center Groningen) for advising on the

formulation of the search scope, and Meyke Roosink (Philips) and Benedetta Lusi (University of Twente) for participating in the clustering session.

Authors' Contributions

CMK contributed to planning, screening, reading full text, and acquiring/analyzing/interpreting data. EMvdH contributed to screening, acquiring data, reading full text, and revising the results of data analysis/interpretation. TJLvR and GJV reviewed the results of data analysis/interpretation. GDSL conceptualized and reviewed the results of data analysis/interpretation. All authors contributed to drafting the manuscript or revising it critically for important intellectual content. All authors read and confirmed the final version of the manuscript and agreed to be accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of the work are appropriately investigated and resolved.

Conflicts of Interest

This study is part of the Digital Nature project that received funding from the Top Technology Twente Connecting Industry program (TKI Topsector HTSM), which is partially funded (paid to institution) by Philips. CMK is employed by the University of Twente through this fund. EMvdH is employed fully by Philips. The remaining authors do not have a conflict of interest to declare.

Abstract

Background: Pregnant adolescent women increasingly seek support during pregnancy and the puerperium through digital platforms instead of the traditional support system of family, friends, and the community. However, it is uncertain whether digital, web-based tools are reliable and effective in providing information to the user on a variety of topics such as fetal development, pregnancy outcomes, delivery, and breastfeeding to improve maternal and infant outcomes.

Objective: We aimed to identify web-based tools designed to promote knowledge, attitudes, and skills of pregnant adolescents or adolescent mothers and determine the efficacy of such web-based tools compared with conventional resources in promoting good pregnancy and infant outcomes.

Methods: A systematic search was conducted using Medline, Scopus, CINAHL, and PsycINFO for articles published from January 2004 to November 2020 to identify randomized trials and observational studies that evaluated digital, web-based platforms to deliver resources to pregnant adolescents. All articles written in the author's languages were included. Two authors independently reviewed abstracts and full-text articles for inclusion and assessed study quality. Risk of bias in each study was assessed using appropriate tools recommended by PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) and the Joanna Briggs Institute. We adopted a qualitative synthesis and presented the results in a narrative format due to the heterogenous nature of the studies.

Results: Seven articles met the inclusion criteria and were analyzed. The majority of the studies were graded to be of low to moderate risk for bias. The research methodologies represented were varied, ranging from randomized (n=1) and nonrandomized controlled trials (n=1) and prospective cohort studies (n=1) to mixed methods studies (n=1) and longitudinal surveys (n=3). Four studies included active web-based interventions, and 3 described exposure to web-based tools, including the use of social media and/or other internet content. Web-based tools positively influenced treatment-seeking intentions (intervention 17.1%, control 11.5%, $P=.003$) and actual treatment-seeking behavior for depression among postpartum adolescents (intervention 14.1%, control 6.5%, $P<.001$). In contrast, readily available information on the internet may leave adolescents with increased anxiety. The critical difference lies in information curated by health care professionals specifically to address targeted concerns versus self-acquired data sourced from various websites.

Conclusions: Despite almost universal web use, few studies have used this platform for health promotion and disease prevention. Social media interventions or web-based tools have the potential to positively influence both maternal and infant outcomes in adolescent pregnancy, but there is a need for more well-conducted studies to demonstrate the effectiveness of these support programs. The vastness of the information available on the web limits the ability of health care professionals to monitor or control

sources of information sought by patients. Thus, it is important to create professionally curated platforms to prevent or limit exposure to potentially misleading or harmful information on the internet while imparting useful knowledge to the user.

Introduction

Pregnant adolescents are an especially vulnerable population. Despite the significant decline of adolescent pregnancies in recent decades [1], the World Health Organization estimates that 12 million girls aged 15 to 19 years give birth yearly in developing countries [2]. These adolescents are at increased risk of prenatal and perinatal complications including gestational hypertension, preterm delivery, low infant birth weight, and other neonatal complications [3-5]. Adolescent pregnancies are more prevalent in socioeconomically disadvantaged communities, on a background of disrupted family structures and limited educational opportunities [6]. Poor pregnancy outcomes are more frequent among socioeconomically disadvantaged adolescents, largely due to the complex social and cultural factors that result in lower or delayed maternal engagement with health care services [7,8].

The transition from child-free adolescence to motherhood is daunting. Traditionally, those who are pregnant or postpartum turn to their family, friends, and partners for support [9]. More recently, community-based and home-visit programs have also been established to support adolescent mothers. Home-visit programs may offer better outcomes in adolescents who are difficult to engage due to close bonds formed [10]. These programs aim to provide access to information, resources, and social support in order to maximize coping strategies and eventual reintegration into society [11,12]. The Teenage Pregnancy Strategy is an example of a successful, multicomponent intervention that has reduced adolescent conceptions and improved outcomes for adolescent mothers by providing support for mothers targeted at completion of education and securing appropriate housing [13].

With increasing access to technology, expectant mothers may seek pregnancy-related information or support from social media [14,15] or internet-based platforms [16,17] instead of traditional sources. Due to shifts in contemporary social structure, many women find themselves geographically and emotionally isolated from their support system of family and friends [14,15]. Alternative support systems on digital platforms provide opportunities for like-minded women to exchange experiences and gain social support. Web-based support systems are available regardless of time and location and allow for anonymity of use, reducing stigma and facilitating the discussion of sensitive topics [18]. Furthermore, the majority of expectant mothers perceive the internet to be a reliable source of information and access information on a large variety of topics including fetal development, delivery, and breastfeeding [16].

As such, information found on the internet has the potential to influence the mother's decisions surrounding her pregnancy care [19].

While the definition of social media is dynamic and constantly evolving [20], in general, a social media site is an interactive online platform that facilitates the exchange of user-generated content [21,22]. In our study, we defined social media as any online platform that enables users to exchange content (eg, Facebook or Instagram), while internet content was defined as any online platform that does not facilitate content exchange among users (eg, websites or online reading materials) [21,22]. We defined web-based tools broadly as describing all services and technologies found on online platforms and consider both social media and internet content to be subsets of web-based tools [23]. Despite their convenience and easy access [24], these tools have limitations. Information found online may not be verified and may provide pregnant women with inaccurate, unreliable, or unsupported knowledge [25]. A meta-analysis evaluating the quality of online health information found that 70% of the included studies concluded that information sources on the internet were of low quality [26] and often provided advice with limited or no scientific evidence [27-29]. Specifically regarding women's health, inaccurate celebrity-based advice has been highlighted [30]. Low-quality pregnancy-related information may be harmful or conflicting [29] and is often not discussed with health care providers to clarify misconceptions [24,31], all of which have the potential to negatively influence pregnancy outcomes. The unregulated online community can also produce negative experiences for the naïve user [32]. As the use of social media or internet resources during pregnancy is a relatively recent phenomenon, there is an opportunity to explore the association between its use among at-risk adolescents and perinatal outcomes.

The aims of this systematic review were to assess the impact of web-based tools used by pregnant adolescents or adolescent mothers on maternal and infant outcomes to compare these to conventional resources and critically appraise the evidence from relevant quantitative and qualitative studies. The research questions addressed were as follows:

- What types of available web-based tools are designed to promote knowledge, attitudes, and skills of pregnant adolescents or adolescent mothers?
- How effective are these web-based tools in promoting good pregnancy and infant outcomes compared with conventional resources?

Methods

Search Strategy

The protocol was registered with the International Prospective Register of Systematic Reviews (PROSPERO) [CRD42020195854]. We followed the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines [33] and conducted a systematic search of PubMed, Scopus, CINAHL, and PsycINFO electronic databases for articles published from January 2008 to November 2020. We restricted publications to the last 12 years to ensure studies promoted updated practices relating to pregnancy care. The search was initially conducted on May 15, 2020, and updated on December 5, 2020. The process of updating the search was guided by methods described by Bramer et al [34]. We also conducted a secondary search to identify studies published between 2004 and 2007 as the first concept of Web 2.0, which is defined as a network platform that spans across all devices, was introduced in 2004 [35]. No further studies met our inclusion criteria. Two librarians from the National University of Singapore Medical Library were consulted on the finalization of the search strategy. Search terms included “pregnant,” “adolescents,” “social media,” and “internet,” and the full search strategy can be found in [Multimedia Appendix 1](#).

Selection of Studies

The study selection was conducted in two phases. During level 1 screening, two authors (JW, NA) independently screened all studies retrieved by electronic database searches based on key terms and resolved discrepancies by discussion with a third author until a list of studies for level 2 screening was agreed upon. During level 2 screening, the full texts of studies selected in level 1 were retrieved and independently reviewed by the same 2 authors to determine the eligibility of each study; discrepancies were again resolved by discussion with the third author until a final list of studies was agreed on. The reasons for exclusion were coded and recorded systematically.

Eligibility Criteria

All inclusion and exclusion criteria were defined a priori. We included both quantitative and qualitative studies that explored the association between the use of web-based tools by pregnant adolescents or adolescent mothers and maternal and neonatal outcomes. Studies that defined their population as adolescents or studied women aged 21 years and younger were included. Social media was defined as online platforms providing avenues to exchange content with other users (eg, Facebook, Instagram, Twitter, blogs, vlogs, forums, chatrooms) while internet content was defined as online platforms that did not provide direct opportunities to interact with other users (eg, websites, online reading materials, internet programs). Conventional tools developed to support adolescent mothers such as brochures, school-based counseling, community-based counseling, and group and personal counseling were the comparison of interest. Maternal outcomes measured were physical (nutrition, physical activity, breastfeeding practices, birth complications, and risky behaviors such as smoking and alcohol consumption) and psychosocial (mental health, depression, anxiety, loneliness and stress, self-esteem, birth preparedness, and parenting outcomes)

factors. Infant or child outcomes included preterm birth, low birth weight, sudden infant death syndrome, and obesity. All outcomes collected met the inclusion criteria. We included studies with or without a comparison group that were relevant to answering our research questions and excluded reviews, abstracts, conference proceedings, letters, editorials, comments, opinions, and book chapters. We excluded studies that were not in English, Chinese, Malay, or French, the languages of the authors. Studies that only examined the use of social media or internet content with no quantitative or qualitative outcomes were also excluded.

Data Extraction

We extracted relevant evidence using a standard proforma including study design, settings, observational period, sample size, participant characteristics, description of intervention and comparison tools, maternal outcomes, infant or child outcomes, adjusted factors, findings, and limitations.

Risk of Bias Assessment

We conducted a mixed methods systematic review to assess the relevant studies using various critical appraisal tools that are validated and widely used. Qualitative studies [36] and nonrandomized controlled trials [37] were evaluated using the Joanna Briggs Institute instrument, which appraises articles as “included,” “excluded,” or “seek further info” based on 10- and 9-question checklists, respectively. Cohort or case-control studies were evaluated using the Newcastle-Ottawa Quality Assessment Scale [38], which rates articles according to selection, comparability, and exposure categories using a star system. Randomized controlled trials (RCT) were evaluated using the Cochrane Risk of Bias 2 describing a “fixed set of domains of bias, focusing on different aspects of trial design, conduct, and reporting” [39]. It appraises articles as low risk of bias, some concerns, and high risk of bias. Studies using mixed methodologies were evaluated using the Mixed Methods Appraisal Tool [40] based on a qualitative and quantitative scoring system. Four authors (JW, NA, SL, CM) independently and critically appraised each study for quality and potential bias. We resolved discrepancies by discussion until a consensus was reached.

Synthesis of Results

We categorized included studies into 2 groups to answer our research questions. To explore the variety and effectiveness of web-based tools in promoting knowledge, we analyzed and compared all 7 studies [41-47]. To determine their influence on pregnancy outcomes compared to conventional resources, we assessed 2 studies [41,42]. The studies analyzed were too heterogeneous to enable a formal meta-analysis, thus we adopted a qualitative synthesis and presented the results in a narrative format.

Results

Search Results

The search in the various medical databases (Medline [using PubMed platform], Scopus, CINAHL [using EbscoHost platform], and PsycINFO) for articles published from January

2008 to November 2020 yielded a total of 6157 records. After removing the duplicates, 4722 records were eligible for further screening. After 2 reviewers screened all titles and abstracts, 135 records met the inclusion criteria and were eligible for

further full-text screening. Following the full text review, we excluded 128 articles based on the predefined exclusion criteria, and 7 articles were finally included in the systematic review for analysis (Figure 1).

Figure 1. PRISMA flow diagram.

Study Characteristics

Characteristics of the 7 studies are summarized in Table 1. Six were conducted in the United States [41-44,46,47], and one was conducted in Western Australia [45]. The research methodologies represented were varied—the most common study design was qualitative (n=3) [43,45,46], while the remaining studies were an RCT [41], a non-RCT [47], a prospective cohort study [42], and a mixed methods study [44]. Study sizes ranged from 7 [43,45] to 292 participants [42]. Despite limiting our inclusion criteria to adolescents, the participant age range was large, from age 13 years [42] to a participant aged 22 years, who was included as she was

considered an adolescent by the authors [42,46]. Most participants were defined as adolescents in 6 studies [41,42,44-47], while 1 study defined participants as first-time mothers [43]. Participants were currently pregnant (n=1) [44], already mothers (n=5) [41-43,45,47], or both (n=1) [46]. Various methods were used to encourage participation: 5 studies recruited participants from established institutions such as prenatal clinics or organizations offering services for adolescents [41,42,44,46,47], while the remaining 2 studies recruited participants by posting public advertisements or through personal and professional contacts [43,45]. Two studies included a control group, which received conventional care [41,42].

Table 1. Descriptive characteristics.

Author, country	Study design	Participants	Intervention/exposure	Control group (if any)	Outcomes evaluated	Key findings
Hudson et al [41], US	Quantitative; RCT ^a	Adolescents: 16-21 years (mean 18.3 [SD 1.7] years); 1-week postpartum; single, low-income, African Americans	n=15; NMN ^b website: internet-based education resource, discussion forum, direct email contact with nurses (6 months)	n=19; usual care: hospital parenting instructions, parent's own resources	Maternal: <ul style="list-style-type: none"> • Mental health • Parenting outcomes • Birth complications Infant: <ul style="list-style-type: none"> • Health care use • Breastfeeding 	The NMN website is well poised for nursing-driven social support intervention. The social support component was identified as a key strength with positive qualitative comments.
Logsdon et al [42], US	Quantitative; matched prospective cohort study	Adolescents: 13-21 years; up to 1-year postpartum; living in urban, suburban and rural counties, mixture of White (8.6%), Black (88.0%) and others (3.4%)	n=154 (mean 17.9 [SD 2.1] years); internet intervention website: internet-based education resources (2 weeks)	n=138 (mean 18.2 [SD 1.9] years); home visitation program	Maternal: <ul style="list-style-type: none"> • Mental health 	The internet intervention was successful in changing attitudes, perceived control, intention to seek treatment, and actually seeking treatment. The intervention effect was equal in adolescents regardless of where they lived, but the impact on changing attitudes may be dose dependent.
Fleming et al [43], US	Qualitative	First-time mothers; mean 18-21 [SD 19.5] years); 6-8 weeks postpartum; single (85.7%), low-income	n=7; personal electronic media use: websites, internet blogs, internet chat rooms, online shows (duration not specified)	— ^c	Maternal: <ul style="list-style-type: none"> • Birth preparedness • Mental health 	This study demonstrated adolescents' desire and need for clear, accurate, and easily accessible information about birthing. Providing credible electronic sources will educate the mothers and increase their confidence and birthing preparedness levels.
Vander Wyst et al [44], US	Mixed methods; non-RCT	Adolescents: 14-18 years; 12-28 weeks pregnant; low-income, mixture of Black (70%), Hispanic White (20%), and non-Hispanic White (10%)	n=10 (median 17.0 [IQR ^d 16.4, 17.7] years); social media intervention: private Facebook group with interactive activities and dissemination of health information (18 weeks)	n=12 (median 29.2 [IQR 23.7, 33.8] years); adult participants ^e	Maternal <ul style="list-style-type: none"> • Physical anthropometric data • Nutrition knowledge • Nutrition behavior • Physical activity • Attitudes and beliefs on prenatal health • Social support Infant <ul style="list-style-type: none"> • Birth weight • Gestational age • Breastfeeding 	Poor diet quality persists among both adolescent and adult low-income pregnant women. Although social media-based education was well received by the participants, this did not result in significant changes in dietary intake and knowledge.
Nolan et al [45], WA ^f	Qualitative	Adolescents; 16-19 years; 3-17 months postpartum; single, living with parents (71.4%), extended relatives (14.3%), or partner/friend (14.3%)	n=7; personal social network site use: website that enables users to create public profiles and form relationships with other users (duration not specified)	—	Maternal: <ul style="list-style-type: none"> • Social support • Mental health • Parenting outcomes 	The use of social network sites affords adolescent mothers access to tangible, informational, and emotional support. There is a potential role for midwives to use such platforms to provide additional social support.

Author, country	Study design	Participants	Intervention/exposure	Control group (if any)	Outcomes evaluated	Key findings
Rueda et al [46], US	Qualitative	Adolescents; 14-22 years; currently pregnant or mothers; single, living in residential foster care home, mixture of ethnic minorities: Hispanic (43.5%), Black (30.4%), Mixed race (10.9%)	n=13; personal electronic media use: social media websites, phone apps that facilitate communication between individuals (duration not specified)	—	Maternal: <ul style="list-style-type: none"> Relationship with intimate partners Mental health Infant: <ul style="list-style-type: none"> Child protection 	The use of technology among adolescent mothers living in foster homes is associated with multiple social issues. Technology should be included in various models of care to increase understanding between professionals and adolescents.
Logsdon et al [47], US	Quantitative; non-RCT	Adolescents; mean 16.8 years; mothers; single, students of a public school-based program for adolescent parents; mixture of African American (48.6%), White (34.1%), and others (17.3%)	n=138; internet intervention website: internet-based education resources (single class period)	—	Maternal <ul style="list-style-type: none"> Mental health 	The testing of a prototype website for adolescent mothers with postpartum depression showed promising results. Attitudes related to depression and seeking treatment improved after viewing the website.

Risk of Bias Within Studies

Table 2 illustrates an overview of the studies' risk of bias. A detailed assessment of the relevant studies using various critical appraisal tools is found in Multimedia Appendix 2, as the criteria for each study differed by study design. All 7 studies were included, and 6 were judged to have a low risk of bias [41-46]. Of note, 2 out of 7 studies [42,47] were conducted by Logsdon

et al [47]. The earlier study in 2013 was conducted as a pilot to test the prototype of a web-based intervention. Although included, it was rated as a poor-quality study due to the lack of a control group, the one-off nature of outcome sampling, lack of meaningful clinical outcome, and an inadequate description of statistical analysis used. This was subsequently followed by a more robust prospective cohort study in 2018 [42].

Table 2. Overview of the studies' risk of bias.

Author	Study design	Quality assessment instrument	Rating
Hudson et al [41]	Quantitative; RCT ^a	Cochrane Risk of Bias 2	Include; risk of bias: low
Logsdon et al [42]	Quantitative; matched prospective cohort study	Newcastle-Ottawa Quality Assessment Scale (Cohort studies)	Include; selection: ***; comparability: **; outcome: **; risk of bias: low

Synthesis of Results

The study results are summarized in Tables 3 and 4. Adolescents in 4 studies [41,42,44,47] received an active intervention. Of these studies, 1 included adolescent–health care professional interactions [41], 2 described adolescent-adolescent interactions

[41,44], and the remaining 2 studies described purely internet content [42,47]. The adolescents in the remaining 3 studies [43,45,46] were exposed to various web-based tools. Of these studies, the duration of exposure to the web-based tools was not known for all [43,45,46], and resources accessed by the adolescents include informative [43] and social media websites

[43,45,46]. Various outcomes were collected during and after the intervention, measured via self-reports, postintervention surveys, corroboration with medical records, validated tools (if available), and general anthropometric data. The outcomes are

discussed as maternal and infant outcomes. We further categorized maternal outcomes into physical, mental well-being, parenting outcomes, and others.

Table 3. Synthesis of quantitative results.

Author, country	Statistically significant outcomes with intervention ($P < .05$, unless stated otherwise)	Non-statistically significant trends following intervention
Hudson et al [41], US	Assuming $\alpha = .10$, $P < .10$; <ul style="list-style-type: none"> Intervention group had lower self-esteem than control group at 6 months; scale: RSE^a Intervention group had higher levels of perceived competence after 6 months; scale: PPS^b Intervention group had higher parenting satisfaction levels after 6 months; scale: WPBL-R^c ER^d use reduced >50% in intervention group compared to control group (35.7% vs 70.6%); data collection: questionnaire Intervention group was less likely to exclusively breastfeed compared to control group; data collection: questionnaire 	Increasing: <ul style="list-style-type: none"> Social support No differences in: <ul style="list-style-type: none"> Depression symptoms Loneliness Perceived stress Birth complications

Table 4. Synthesis of qualitative results.

Study, country	Outcomes
Fleming et al [43], US	<ul style="list-style-type: none"> Increased anxiety due to graphic media, birthing process, potential complications, and neonatal care Birth preparedness: suboptimal birth preparedness due to fragmented, inconsistent, weakly linked, and poorly referenced information although a small subset of women developed improved or enhanced understanding Social support: platform allowed connection with others and peer support
Vander Wyst et al [44], US	<ul style="list-style-type: none"> Nutrition behavior: adolescents had improved attitudes toward nutrition with dietary changes (eg, limiting high fat fast food, increasing vegetable and fruit intake), motivated by time, convenience, and food preferences Physical activity: adolescents had an increased tendency to exercise during pregnancy as they believed it to help with labor Breastfeeding: adolescents tended to be less likely to breastfeed compared to adults Social support: both adolescents and adults had both good and poor sources of social support
Nolan et al [45], WA ^a	<ul style="list-style-type: none"> Increased social support and connectedness: participants had unlimited access to relationships, minimizing feelings of exclusion, and social isolation. They could maintain both old and new friendships. Social network sites provide valuable tangible, emotional, and informational support for adolescent mothers, contributing to mothers' social capital Parental stress and anxiety: social network sites served as a medium for problem sharing and helped to reduce parental stress and anxiety. Drawbacks were the absence of adequate privacy controls and negative comments that could potentially threaten emotional well-being Increased parenting confidence: peer support and positive affirmations significantly increased adolescents' confidence levels
Rueda et al [46], US	<ul style="list-style-type: none"> Social media tools provided positive experiences in: <ul style="list-style-type: none"> Interacting with a potentially intimate partner Maintaining contact and fostering feelings of closeness with their child's father Social media tools provided negative experiences in: <ul style="list-style-type: none"> Unwanted sexual solicitations Child protection, as meetings with strangers in offline spaces place both the adolescent and their children at risk Cyber abuse (eg, cyber bullying, stalking) of which adolescents were both victims and perpetrators Adverse emotional side effects fueled by jealousy and mistrust

^aWA: Western Australia.

Maternal Outcomes

Maternal mental well-being was explored in 5 studies [41-43,45,47]. Hudson et al [41] conducted an RCT comparing participants who were exposed to the New Mothers Network website with those who received typical parenting instructions provided by the hospital. The New Mothers Network intervention provided parenting information through their electronic library and via communications with other mothers and nurses. The authors found that self-esteem levels measured via the Rosenberg Self-Esteem scale were significantly lower in the intervention group over the 6-month period ($P=.04$), although the authors found no clear explanation for this trend. In the 2 studies conducted by Logsdon et al [42,47], the earlier prospective pilot study [47] explored the efficacy of a website showcasing pictures and stories of other adolescent mothers' experiences, county and national mental health resources, and a frequently asked questions segment. The evidence from this study suggests that attitudes toward seeking psychological help, measured via the Attitude Toward Seeking Psychological Help scale, were significantly higher postintervention ($P=.02$). A similar result was observed in their prospective cohort study [42] of participants who received exposure to the website and home visits by volunteers as part of a home visitation program. Compared to the earlier pilot study [47], the intervention was adapted slightly to showcase video vignettes instead of pictures and stories based on user feedback. Mental health community resources and the frequently asked questions segment remained. The earlier results of improved attitudes toward seeking

psychological help ($P=.04$) were successfully replicated, with additional data demonstrating that perceived behavior control ($P=.007$), intention to seek treatment for depression ($P=.003$), and seeking treatment for depression ($P<.001$) were significantly higher after 2 weeks in the intervention group compared to the controls. Data was measured using the Attitude Toward Seeking Psychological Help scale, Health Self Determination Index scale, Mental Health Intention scale, and a questionnaire on the outcomes of seeking treatment, respectively. Fleming et al [43] conducted qualitative interviews of participants who had prepared for childbirth through a variety of web-based tools including websites, blogs, chatrooms, and mass media. The findings suggested that access to electronic media did not necessarily prepare adolescents for pregnancy and childbirth but instead increased anxiety levels. Nolan et al [45] also conducted qualitative interviews on participants who used social media and reported that communicating with other adolescent mothers via social network sites helped reduce loneliness, parental stress, and anxiety.

Only one study by Vander Wyst et al [44] explored maternal physical outcomes. In this 18-week longitudinal study, participants were added into a private Facebook group where health information (pregnancy fitness, healthy recipes, nutrition, pregnancy fun facts, and stress management) were disseminated and interactive group activities were conducted. The authors compared adolescent and adult mothers and found dietary sugar distribution among both groups to be significantly increased after 18 weeks, with a greater increase in the adolescent group (7.4 [SD 0.2] vs 6.3 [SD 0.1] g/d, $P=.005$). Adolescent mothers

were less likely to shop for groceries (postintervention; 14.0% vs 89.0%, $P=.002$) or cook at home (postintervention; 14.0% vs 67.0%, $P=.054$) compared to adult mothers and had significantly less knowledge regarding nutrition (identifying fiber rich foods, recommended daily consumption of wholegrains, fruit and vegetable varieties, and fat) before and after the intervention. There were no significant differences concerning anthropometric data, mean caloric consumption, or macronutrient distribution of food.

Parenting outcomes were explored in 3 studies [41,43,45]. Hudson et al [41] found that both intervention and control groups had significantly higher perceived competence ($P<.01$) and parenting satisfaction ($P<.01$) measured by the How I Deal With Problems Regarding Care of My Baby and evaluation subscale of the What Being the Parent of a Baby is Like–Revised, respectively. Fleming et al [43] concluded that although many young mothers had acquired knowledge on what to expect during childbirth, much of this was fragmented, inconsistent, weakly linked, poorly referenced, not always beneficial, and potentially a greater source of confusion. In contrast, Nolan et al [45] found that using social network sites increased young mothers' confidence levels in parenting roles and with parenting strategies through positive affirmations, reassurance by other parents, and the collective sharing of experiences. Regarding social support to adolescent mothers, Hudson et al [41] observed a positive trend in social support levels following intervention supported by the qualitative comments submitted by participants. Nolan et al [45] described valuable tangible, emotional, and information support from social networks. Additionally, Rueda et al [46] explored the role of technology and social network sites on intimate relationships among adolescents living in residential foster homes. They determined these tools to be critical to the adolescent mothers' ability to maintain or initiate intimate relationships with the fathers of their children or with new partners, facilitating both communication and in person meetings.

Infant Outcomes

Infant outcomes were studied less. None of the studies investigated putative associations between the use of web-based tools and premature birth, low birth weight, infant obesity, or sudden infant death syndrome. Hudson et al [41] found that emergency services use for postpartum problems in the first 6 months decreased significantly following intervention compared to no intervention, as 70.6% of mothers who did not receive intervention brought their child to the emergency room at least once compared to 35.7% of mothers who received the intervention ($P=.052$). In each group, there was one visit to the emergency room that was appropriate, with one infant hospitalized and a mother-infant pair treated for smoke inhalation. Vander Wyst et al [44] described adolescents as less likely to breastfeed compared to adults. Hudson et al [41] observed that adolescents in the intervention group were less likely to exclusively breastfeed compared to those who received usual care ($P=.06$ [assuming $\alpha=.10$, $P<.10$]). Rueda et al [46] reported that residential foster home staff were concerned about adolescent mothers bringing their children to meetings arranged over social media with unknown partners, potentially placing

their children at risk. While this topic was not discussed with the adolescent mothers, their dialogue suggests that they are aware of such risks. This belies an important knowledge and perception gap of program staff on how adolescent mothers use technology and social networks, as meeting strangers offline was either not as common as program staff believed or was regarded as shameful and not openly discussed by the adolescents.

Discussion

Principal Findings

Based on current available literature, there is much that needs to be explored concerning the potential benefits and harms of social media for pregnant and postnatal adolescents. This is despite most adolescent participants having grown up in the presence of advanced technology and with extensive social media use. We have systematically studied the impact of web-based tools used by adolescents on various maternal and infant outcomes to address our research questions. We found that available web-based tools include professionally curated programs (via websites or social media), readily available information on the internet, and personal use of various social media platforms.

While the limited evidence shows mixed and conflicting findings, we observe that web-based tools may be useful in improving mental health outcomes, positively influencing treatment-seeking intentions, and actual treatment-seeking behavior for depression among postpartum adolescents [42,47]. Conversely, readily available information on the internet may increase anxiety among adolescent recipients [43]. The difference appears to lie in the source of information, whether curated by health care professionals specifically to address common concerns of the target group and presented in a controlled setting or self-acquired data sourced from various websites initiated by the adolescent recipients themselves. RCTs using similar platforms, not limited to adolescent mothers, yield similar results, with postpartum mothers with depressive symptoms describing significantly improved parenting competence and decreased depression severity following social media interventions compared to unexposed mothers [48-51]. The presence of a professionally moderated program may be a key differentiating factor in mental health outcomes. Web-based tools may also be more influential on mental health outcomes due to the users' relative anonymity compared to conventional care. A systematic review found that although online services did not significantly facilitate mental help-seeking behavior in youths, many youths regularly use online services and recommend them to peers as they are easily accessible, anonymous, and less stigmatizing [52].

Aside from mental health outcomes, there may be other benefits for adolescent mothers, including fewer emergency room visits (with increased knowledge and confidence in postpartum care) [41] and positive, albeit limited, dietary and behavioral changes [44]. Vulnerable populations like low-income adolescent mothers do not have ready access to health care professionals or services, but frequently have questions regarding childcare. These require rapid attention and resolution, resulting in

unnecessary emergency room visits. Despite a lack of theoretical knowledge, structured interventions can motivate both adolescents and adults to seek healthier lifestyles. Furthermore, professional support via web-based tools has demonstrated positive impact on both infants [53,54] and older mothers [55-57] in the general prenatal population.

Preexisting social media platforms and internet-based tools play an integral role in an adolescent's life and are associated with positive and negative outcomes, particularly with maintaining beneficial friendships and fostering precarious and potentially dangerous relationships, respectively [45,46]. Despite some negative consequences, Sherman et al [32] found online adolescent pregnancy communities such as online support groups and discussion forums to be largely supportive and to serve an important role for those who use them. The authors noted that adolescents should choose their online community carefully to reduce additional psychological distress. Social media platforms may thus fill an unmet need to engage adolescent pregnant women, given the substantial use of social media globally [58].

Only 2 studies compared the efficacy of web-based tools and conventional methods in influencing maternal and neonatal outcomes in the adolescent population [41,42]. Mental health was the only common outcome that both studies evaluated, in which Logsdon et al [42] had a greater focus on depression compared to Hudson et al [41]. As such, no meaningful conclusions can be drawn to address our second research question.

A Singaporean study described increased risks of perinatal complications like anemia and preterm births and reduced likelihood of regular clinic attendance and sexually transmitted infection screening in a group of younger, vulnerable, predominantly Malay parturients with poorer access to prenatal care [59]. This highlights the importance of increasing accessibility to prenatal care and making a concerted effort to improve outreach [59]. Such young women are vulnerable to poor health literacy [60], closely related to eHealth literacy, which involves the use of digital technology [61], and are less likely to gain positive outcomes from internet searches [62]. eHealth interventions have proven effective in reaching out to populations with low levels of literacy [63], enabling health care professionals to facilitate behavioral change, personalize management, and improve education surrounding their health [64]. Aside from designing interventions to reach out to adolescents, it is also important to educate them and fill in the skill gap in eHealth literacy so they can access and evaluate health information accurately [65]. The use of professionally curated web-based tools incorporating online resources, communication services with health care professionals and peers, and social support may hold the key to reduce this important health inequality gap. However, larger age and culturally appropriate RCTs are necessary to validate the efficacy of these nontraditional methods.

Overall, our findings demonstrate a paucity of studies in this important aspect of managing adolescent pregnancies and

highlight the effectiveness of web-based tools to reach pregnant and postpartum adolescents who may be more comfortable seeking help on online platforms. These tools allow health care professionals and policy makers to spread valuable pregnancy-related information to this vulnerable population in an age and peer acceptable way. Local or regional governments can potentially harness internet platforms and social media to drive public health policies. It may prove to be a more efficient allocation of resources, improving compliance to prenatal follow-ups and reducing pregnancy-related complications. Aside from antenatal care, governments can broaden their focus and cover topics pertaining to general women's health and, importantly, contraception use.

Strengths and Limitations

Our systematic review is timely as advanced technology and social media use are pervasive in modern societies, particularly among youth. Including both quantitative and qualitative studies in the review allowed for a broader interpretation of both statistical outcomes and adolescents' qualitative feedback.

Key limitations of this systematic review are the weaknesses inherent in the included studies and the lack of research in this important area, particularly in Asian societies, despite being the most connected globally. Notwithstanding the extensive internet and social media use among adolescents, few studies have been conducted to directly establish the relationship between technology use in pregnant adolescents or adolescent mothers and pregnancy outcomes. Across the 7 studies there was great variability in measurement scales and reported outcomes, contributing to the heterogeneity of our results, and making it challenging to draw well-grounded conclusions. For this reason, we were not able to conduct a meta-analysis and were only able to provide a descriptive narrative of the studies. These studies were based in the United States and Western Australia, and findings may not be directly applicable to more ethnically diverse populations given the cultural differences in family traditions, community infrastructure, and child-raising practices [66]. Babes Pregnancy, a charity based in Singapore [67], has used social media to support these vulnerable youth, although the impact of this program is not known.

Conclusion

The vastness of the information available on the web limits the ability of health care professionals to monitor or control sources of information sought by patients. It is important to create professionally curated platforms that patients can be directed to in order to prevent or limit exposure to potentially misleading or inaccurate information. Although our study is limited by the scope of the included studies, it is evident that web-based tools have the potential to improve outcomes in adolescent pregnancies. This review highlights the potential for web-based tools to target this vulnerable population, which is usually excluded from public health policies. The data presented can be highly informative to local health care policy makers. Overall, community-specific research is urgently needed to explore the potential of social media to guide novel interventions for this important vulnerable group.

Acknowledgments

We would like to thank the medical librarians Ms Wong Swei Nee and Ms Wong Huey Lih Winnifred from the National University of Singapore for their valuable feedback in the search strategy.

Authors' Contributions

JYW conceptualized the research, conducted the database search, screened records, performed data extraction, critically appraised studies, analyzed the data, wrote the first draft of the paper, and reviewed the paper. NA conceptualized the research, screened articles, critically appraised studies, analyzed the data, and wrote and reviewed the paper. MS wrote and reviewed the paper. SL and CNZM conceptualized the research, critically appraised studies, and wrote and reviewed the paper.

Conflicts of Interest

None declared.

Abstract

Background: Alternative approaches to analyzing and evaluating health care investments in state-of-the-art technologies are being increasingly discussed in the literature, especially with the advent of Healthcare 4.0 (H4.0) technologies or eHealth. Such investments generally involve computer hardware and software that deal with the storage, retrieval, sharing, and use of health care information, data, and knowledge for communication and decision-making. Besides, the use of these technologies significantly increases when addressed in bundles. However, a structured and holistic approach to analyzing investments in H4.0 technologies is not available in the literature.

Objective: This study aims to analyze previous research related to the evaluation of H4.0 technologies in hospitals and characterize the most common investment approaches used. We propose a framework that organizes the research associated with hospitals' H4.0 technology investment decisions and suggest five main research directions on the topic.

Methods: To achieve our goal, we followed the standard procedure for scoping reviews. We performed a search in the Crossref, PubMed, Scopus, and Web of Science databases with the keywords *investment, health, industry 4.0, investment, health technology assessment, healthcare 4.0, and smart* in the title, abstract, and keywords of research papers. We retrieved 5701 publications from all the databases. After removing papers published before 2011 as well as duplicates and performing further screening, we were left with 244 articles, from which 33 were selected after in-depth analysis to compose the final publication portfolio.

Results: Our findings show the multidisciplinary nature of the research related to evaluating hospital investments in H4.0 technologies. We found that the most common investment approaches focused on cost analysis, single technology, and single decision-maker involvement, which dominate bundle analysis, H4.0 technology value considerations, and multiple decision-maker involvement.

Conclusions: Some of our findings were unexpected, given the interrelated nature of H4.0 technologies and their multidimensional impact. Owing to the absence of a more holistic approach to H4.0 technology investment decisions, we identified five promising research directions for the topic: development of economic valuation methodologies tailored for H4.0 technologies; accounting for technology interrelations in the form of bundles; accounting for uncertainties in the process of evaluating such technologies;

integration of administrative, medical, and patient perspectives into the evaluation process; and balancing and handling complexity in the decision-making process.

Introduction

Background

How do health care organizations manage and determine their investment decisions in Industry 4.0 (known as Healthcare 4.0 [H4.0]) technologies? Having the right answer to this question is essential because the health care value chain is increasingly applying H4.0 technologies [1]. In addition, the rising demand for more efficient, qualified, and less expensive health services has motivated novel technological solutions [2]. Health care organizations have incorporated innovative technologies around the internet to facilitate and support more efficient and flexible processes, services, and products [3,4]. Such technologies started playing a pivotal role as enhancers of efficiency and quality in health care systems in the 1990s, culminating in what is currently known as *eHealth* [5]. Health care institutions extend the emerging principles and technologies belonging to the Industry 4.0 realm to health care as a continuous and disruptive process of innovation and transformation of the entire health care value chain [6].

The magnitude of the technological shift, the scope of activities affected, and their interrelationships expose health care decision-makers to large and complex investment decision problems [7,8]. The scope of activities encompasses procedures, equipment, and processes used to deliver medical care [9]. The range of such investments usually involves computer hardware and software that deal with the storage, retrieval, sharing, and use of health care information, data, and knowledge for communication and decision-making [10]. Although it is possible to identify stand-alone technologies under the H4.0 umbrella, they tend to be highly interrelated, generating the need to assess them in bundles. In addition, there is significant uncertainty regarding which technology will be the industry standard, adding an extra level of complexity to financial evaluations.

As the level of investment required to stay competitive with these new technologies is massive, the financial budgets of health institutions and countries are constantly stressed. For instance, data from the BRICS nations (ie, Brazil, Russia, India, China, and South Africa) indicate that their average health expenditure grew from 5.41% of their gross domestic product in 1995 to 6.94% in 2013 and is forecast to reach an average of 7.86% by 2025 [11]. Hence, there is an increasing need for massive and interconnected investments that will impose nontrivial challenges in determining their value, optimum level, and implementation sequence.

Several different theoretical lenses help to enlighten managers in their technological investments. The Health Technology Assessment International Policy Forum recently concluded that the assessment paradigms need to be more agile, helping health care systems to understand the potential of innovations and ensure that their potential value is realized [12]. However, although the literature has suffered from balkanization because multiple alternative approaches have grown significantly in recent years, hospitals rarely have, or use, a systematic decision process for H4.0 technology investments, accounting for all organizational objectives and using objective data [13,14].

This paper aims to address the current gap between the literature and practice by examining trends, challenges, and research opportunities in hospital investment valuations of H4.0 technologies. To achieve this goal, we opted to carry out a scoping review of the literature, which is appropriate for identifying and mapping critical concepts that underpin a specific research topic, especially in the absence of previous comprehensive studies [15,16]. More importantly, the scoping review approach is also suggested as an alternative to a systematic review when the literature is vast, sparse, and complex [17,18], which is the case of investments in H4.0 technologies [19].

The paper has been structured as follows. First, we motivate the study, present the protocol for the scoping review (ie, the research method section), and summarize the manuscript selection process. Second, we define the research questions, identify the relevant studies, and select the final list. Third, we present the main findings in a section devoted to the analysis of results, addressing the first two research questions. Fourth, we develop a framework that synthesizes the analysis and identifies promising research directions regarding the most crucial characteristics for evaluating investments in H4.0 technologies, addressing the third research question.

Hospital Investments, the Fourth Industrial Revolution, and Alternative Evaluation Approaches

The advent of Industry 4.0 technologies has significantly affected the global health care value chain. The recent integration of disruptive technologies derived from Industry 4.0 into health care systems aims at achieving virtualization to provide care in real time [20]. Health care institutions have incorporated cyberphysical systems, cloud computing, the Internet of Things, and big data, among others, into health care processes, services, equipment, material, and people. H4.0 technologies allowed the establishment of a smart system to monitor, track, and store patient records for ongoing care and analysis [21,22]. The combination of new technologies has

expanded the scope of hospital activities. Economically, H4.0 technologies come with a value proposition of simultaneously improving efficiency and quality of care while reducing operating costs [23].

However, health care institutions need to carry out substantial investments to achieve the economic gains associated with H4.0 technologies. In 2014, US health care expenditure was US \$3 trillion and is forecast to rise to US \$5.1 trillion in 2023, outpacing the expected gross domestic product growth rate in the corresponding period [24,25]. These expenditures imply multiple investments that are not free of uncertainties because evaluating the impact on patient care is extremely difficult [26].

The unique characteristics of H4.0 technologies add a layer of evaluation complexity in an industry where assessing economic value is already challenging. For instance, studies on health technology assessment have primarily recognized that not every technological development results in net health gains [27]. The history of medicine and health includes many examples of technologies that did not produce the expected benefits or even proved harmful. At the same time, proving the effectiveness of technologies creates a continuous challenge for health systems because their application may require additional resources or compel health systems to choose from competing alternatives within the health system.

Studies have examined how health care organizations struggle to benefit from investments in H4.0 technologies [28,29]. Therefore, the dramatic increase in firms' technology investments in recent years has not necessarily resulted in a significant increase in productivity [30]. The complexity involved in understanding the economic impact of H4.0 technologies resulted in nontrivial challenges in determining the policy and practice implications associated with them [31].

Organizations contribute significant financial resources to developing and implementing H4.0 technologies, and the potential for a negative return on investments or total implementation failure is a worrisome possibility [32]. Assessing technological investments is of great interest to hospital managers when they seek to raise capital to expand services [33]. With the rapid growth of eHealth in developing countries, there is an urgent need for substantial evidence of its impact on justifying and guiding the investment of resources in such systems [26].

Studies evaluating H4.0 technology investments have taken different approaches. A wide array of manuscripts focus on cost reduction evaluation. For instance, a study by Galani and Rutten [34] reported that health care decision-makers base their adoption decisions on cost-effectiveness and cost-minimization analyses. The main limitation of this approach is the focus on just one aspect of the decision (cost), underemphasizing value considerations.

The real-options approach to decision-making has been useful in capturing and valuing uncertainty in many operating decisions that decision-makers face [35]. Its utility lies in the fact that real options are contingent on future discretionary investment. The magnitude, timing, and schedule of the investment outlay affect the value of firms' growth opportunities. Apart from

correcting limitations from the cost perspective, the real-options approach increases the analytical effort that organizations need to carry out economic evaluations.

In addition, investing in H4.0 technologies requires multilateral stakeholder dialog and collaboration that address health needs and product conceptualization [12]. The nature of H4.0 technologies imposes challenges on how to assess the various aspects of technological value in the decision-making processes so that the assessment simultaneously accounts for the input of physicians, patients, and society [36].

Unsurprisingly, despite the expected benefits of H4.0 technologies and the interest from hospitals and policy makers in implementing them, the uptake and adoption of these technologies have not always been consistent within the health care practice, and adoption of these technologies has lagged [37]. There is a need to synthesize research activities and evidence to clarify the evaluation process of H4.0 technology investment in hospitals. Our scoping review explores this knowledge gap by mapping the extent and nature of the available literature and focusing on literature-based evidence that examined the integration of H4.0 technology investments into hospitals.

Methods

Overview

The scoping review design represents a methodology that allows the assessment of emerging evidence; therefore, it is the first step in research development [16]. It is a relatively new approach to evidence synthesis and differs from systematic reviews in its purpose and aims. The purpose of a scoping review is to provide an overview of the available research evidence without producing a summary answer to a discrete research question [38]. The methodology can help answer broad questions and gather and assess information before conducting a systematic review. It is suitable for achieving several objectives such as identifying the types of existing evidence in a given field, clarifying key concepts or definitions in the literature, surveying how research is conducted on a specific topic, identifying key characteristics related to a particular topic, and identifying knowledge gaps. Compared with systematic literature reviews and meta-analyses, a scoping review provides more flexibility and allows for diverse, relevant studies that use different methodologies [17,39,40]. Our research domain is adequate for performing a scoping review because studies regarding H4.0 technologies are multidisciplinary and relatively new.

To achieve our goal, we followed a standard scoping study procedure comprising five steps: (1) identify the research questions; (2) identify relevant studies; (3) select studies; (4) chart the data; and (5) collate, summarize, and report the results. In the following sections, we detail each stage and the outcomes of our study.

Identify the Research Questions

As with most systematic literature reviews, scoping reviews start with a primary research question to focus the inquiry [15,16], guiding researchers to build the search strategies [17]. Our broad initial research question was "How have health care

institutions assessed their H4.0 technology investments?" However, given the multidisciplinary nature of the subject and the comprehensive sources of the reports, we narrowed the main research question into three more specific research questions:

Research question 1: What methodologies do health care institutions use for evaluating investments in H4.0 technologies?

Research question 2: What are the main challenges faced by health care institutions when evaluating investments in H4.0 technologies?

Research question 3: Which are the most important characteristics that the methodologies for evaluating investments in H4.0 technologies must have?

To answer these questions, we developed a rigorously structured and sufficiently documented method to provide robust evidence and arguments.

Identify Relevant Studies

A scoping review requires the identification of all relevant studies, regardless of the methodological design [16]. This step aims to find all available published and unpublished studies that address the research questions, operationalized through the search terms. As familiarity with the research topic is likely to increase as the review advances, we searched for relevant studies in two stages. In the first stage of identification, to include as many relevant studies as possible, we defined the set of keywords that best represented the scope of the study. In the second inclusion stage, we randomly selected a group of papers from each database and analyzed their keywords to determine the need to add more keywords to our inquiry. This two-stage process allowed us to address the search string's potential problem of being overly specific or entailing (partially) misleading buzzwords.

In the first stage, we defined the three research dimensions or keywords that best reflected our research questions: investment, health, and Industry 4.0. Subsequently, we combined an initial

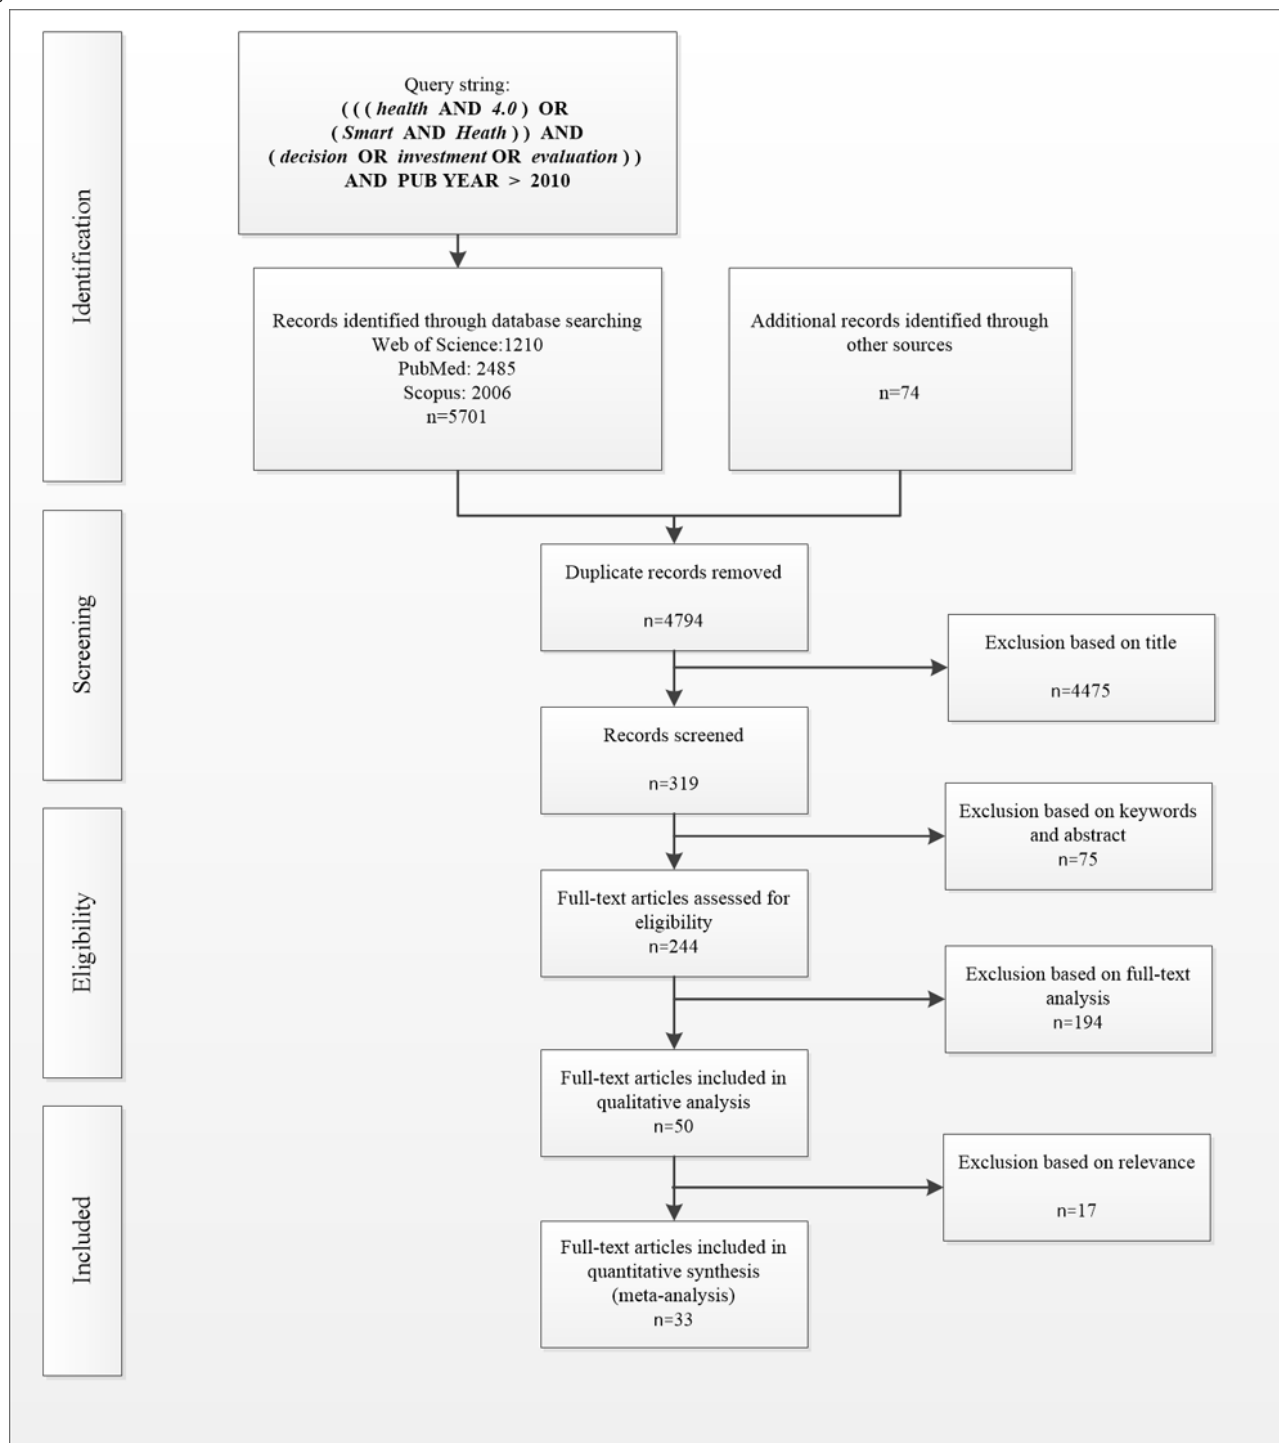

set of keywords using the AND and OR Boolean search operators (*investment AND health, health AND industry 4.0, investment AND industry 4.0, health technology assessment AND industry 4.0*) to retrieve publications that used them in the title, abstract, and keywords. The use of the AND operator in the search process significantly reduced misleading results, especially in the case of the 4.0 string. We searched for scientific articles in the following databases: Crossref, PubMed, Scopus, and Web of Science (which comprises biomedical literature from MEDLINE, life science journals, and web-based books).

As H4.0 derives from principles and technologies from Industry 4.0, whose concept was formally acknowledged in 2011 [41], we only considered publications after that year. Furthermore, in the widely referenced literature review by Liao et al [3], the authors indicated that, although the announcement of the Industry 4.0 concept traces back to April 2011, it began to attract attention only after it became one of the ten official projects within the *High-Tech Strategy 2020* action plan in March 2012. In fact, no study was identified before that date, supporting the choice of the cut-off year of 2011 for our scoping review.

We applied the query string to the indicated databases and retrieved a total of 5701 publications from these databases.

In the second stage, we randomly selected five articles from each database to compare their keywords with those from the research dimensions used in the first stage [42]. The objective was to take into account the fact that different taxonomies may be associated with a given subject, potentially compromising the search. From the comparisons, we identified the need to add the keyword *smart* to our inquiry. A new search, with this keyword included, generated 74 additional papers, giving us a total of 5775 publications scattered among the databases, as shown in Figure 1. We conducted both search stages from July 2000 to August 2020. Figure 1 charts the process of the identification of relevant studies and the final selection of the studies included in the review.

Figure 1. Selection of studies for the review.

Selected Studies

The definition of different inclusion and exclusion criteria was post hoc because the researchers' familiarity with the studies increased. In the first exclusion process (screening), we considered only articles in English published in peer-reviewed journals. We removed duplicate publications from the portfolio, reducing the number of articles from the initial 5775 to 4794. In the next exclusion step, the paper titles were individually verified to determine their alignment with the research topic. This resulted in 4475 papers being deemed irrelevant to the research. The remaining 319 articles that passed the title

screening were then checked for the alignment of keywords and abstracts with the research topic. A total of 75 articles were excluded, resulting in 244 articles being considered in the eligibility step.

The next step was to determine the eligibility of the papers. Best practice guidelines for conducting scoping reviews recommend that 2 separate reviewers carry out the literature search and sifting process. They must both agree before the study can be included. Therefore, we took special care to ensure interrater reliability, with at least two separate reviewers involved in the process.

We carried out the two separate review processes and performed a full-text analysis of the 244 articles to determine their eligibility. In all, 50 articles were identified by both reviewers as fully aligned with our research interests. We then evaluated the papers keeping in mind the criteria of relevance and methodological rigor. In this process, we added a third reviewer, and a majority vote determined the inclusion of a paper. By the end of this stage, 30 articles were considered appropriate for inclusion in the review. We also analyzed the references of these articles to identify relevant studies not yet included in the portfolio, but none were found. However, based on experts' recommendations (qualitative analysis), three articles were added to the portfolio, resulting in a final number of 33 studies in the publication portfolio, as displayed in [Figure 1](#).

Results

Overview

We charted and interpreted critical data from the publication portfolio to establish the grounds for the subsequent analytical

step [39]. We followed a descriptive-analytical method [17,43], providing a broader and meaningful view of all papers and collecting standard information from each study. Driven by our investigation's research questions, we organized the articles in a spreadsheet that included the following information: authors, year of publication, journal, aims, type of technology, application focus (eg, hospital processes or health treatments), valuation methods, decision-makers, users, challenges, and opportunities.

[Table 1](#) shows a basic descriptive numerical summary of the publication count per year. Three main characteristics are noteworthy. First, as expected, studies on the financial evaluations of H4.0 technologies are recent. Second, there has been a slight increase in the number of publications in recent years (2018-2020). Finally, the number of included articles is relatively small (n=33), which may be due to the novelty of H4.0 technologies and the multidisciplinary nature of the investment evaluation requirements and its complexity. These findings reinforce the convenience of using a scoping review approach.

Table 1. Number of publications per year.

Year	Number of publications
2011	2
2012	1
2013	2
2014	4
2015	4
2016	3
2017	3
2018	6
2019	5
2020	3

Collate, Summarize, and Report Results

In this step, the results were collated, summarized, and reported based on a thematic framework such that a narrative account of the publication portfolio became available. Following the study by Levac et al [39], we carried out three complementary analyses to increase the consistency of this step. First, we performed a descriptive thematic analysis to collate and summarize the results. Second, based on the reported results, we developed a detailed analysis of the characteristics, contributions, and challenges of H4.0 technology evaluation tools. We report this analysis in the *Analysis of Results* section. In the *Classification Framework* section, we describe an emerging framework that synthesizes the empirical patterns of the analyzed papers. Finally, we discuss our findings' implications in a broader context, ensuring the scoping study methodology's legitimacy for both theory and practice [39]. In this discussion, we have also listed the research gaps and proposed research alternatives for future studies.

We now expand on the first step, providing detailed information on the characteristics of key publications. We conducted a word

cloud analysis using the titles, keywords, and abstracts of papers in the portfolio. [Multimedia Appendices 1-3](#) and [Table 2](#) include the results, which provide initial evidence to answer the research questions. *Health* was the most frequent word, followed by *cost*, *cost-effectiveness*, *study*, *evaluation*, *care*, *patients*, and *data*.

The word cloud analysis anticipates the interdisciplinary nature of the manuscripts in the portfolio, allowing us to identify cost-effectiveness evaluation as the most recurrent. In addition, the incidence of the words *management*, *clinical*, and *patient* anticipates the need for health care institutions to incorporate a broad set of players in the investment decision process. We emphasize the absence of words such as *quality*, *value*, and *bundle*, which anticipate challenges and opportunities in current research on H4.0 technology investment analysis.

[Table 3](#) reports the top 15 most frequent authors in the portfolio and the number of documents they authored, showing some of those who authored just one paper and the entire list of those who authored two or more. From the list of 146 authors, 1 participated in three studies, 2 participated in two studies, and the remaining 143 appeared in only one article. A large number

of authors with small authoring prominence is typical of research topics about which knowledge is still incipient, such as H4.0 technology investment evaluation, reinforcing the convenience of adopting a scoping review as the methodological approach. We also observed a large average number of authors per publication (mean value of 4.33, SD 2.24), which is typical of publications in the medical field.

The journals' analysis also reinforced the topic's multidisciplinary nature. [Table 4](#) reports the number of papers

by category, and [Table 5](#) reports the number of papers by journal. The Web of Science category *Health Care Sciences & Services* has the highest frequency of 16, followed by *Medical Informatics* (n=10), and *Pharmacology & Pharmacy* (n=2). The remaining categories displayed a frequency of 1 (6/9, 67% of the sample). Two journals published four manuscripts each: *Journal of Medical Internet Research* and *JMIR MHealth and UHealth*.

Analysis of Results

Tables 6 and 7 summarize the papers listed in the rows by year of publication and their different content characteristics. We started by reporting the type of technology analyzed, grouping them according to their role within the health care organization. The study by Aceto et al [5] proposed four interrelated subsets: (1) communication, (2) sensing, (3) processing, and (4) actuation. Communication involves different interactions and disseminating health-related information, supporting patient-professional relationships, and providing collaborative

care. Related H4.0 technologies provide support to increase accessibility, exchange, and sharing of information. Sensing refers to acquiring information about a patient, equipment, material, or process without necessarily making physical contact with them. Processing refers to technologies that may change or process the acquired data, producing actual information in any manner detectable by an observer. Finally, actuation refers to technologies responsible for moving and controlling a system, mechanism (electronic or mechanical), or software based on the information and signals received.

^aPresent in study.

There may be overlaps among the technology subsets. Following the classification in the study by Tortorella et al [1], we further grouped H4.0 technologies into two bundles according to their role within the hospital: sensing-communication (reported under the column labeled *sensing and communication*) and processing-actuation (reported under the column labeled *processing and actuation*; Table 6). Consistent with previous studies' reports on the incidence of technological applications

(eg, the study by Tortorella et al [1]), the number of articles evaluating sensing-communication is significantly greater than those analyzing processing-actuation. In addition, and somewhat paradoxically, given the nature of H4.0 technologies, most studies focus on just one technology, with only six manuscripts addressing bundles of technologies.

Regarding the thematic analysis (data not included in Table 6 because of space limitations), we observed two groups of studies

on H4.0 technology evaluation in health care organizations: those related to health treatments and those related to hospitals' supporting and administrative processes. Articles in the former group were relatively more frequent than those in the latter group.

The evaluation of different technologies contributes to health improvement in various ways. H4.0 technologies contribute to reductions in diseases such as cancer [44,59] and allow for better connectedness that manages individual and community health holistically by leveraging various technologies [70]. Connectedness can also incorporate telehealth and integrated care services, covering the entire spectrum of health-related services that address healthy individuals and patients with chronic conditions [70]. In addition, neural networks improve decision-making, improving care delivery at a reduced cost [68].

The aforementioned analysis allowed us to describe the types of technology and the health improvement sought from their use. Next, we addressed the first research question. For this purpose, we surveyed the methodologies that health care institutions reportedly use for evaluating investments in H4.0 technologies.

With regard to the different methodologies for evaluating investments in H4.0 technologies, of the 33 papers analyzed, only 14 (42%) presented valuation methods, whereas 7 (21%) focused on cost valuation methods and 7 (21%) focused on value methods. Regarding forms of considering uncertainty in the analysis, of the 33 papers analyzed, 2 (6%) used deterministic techniques that disregarded uncertainties, 5 (15%) accounted for uncertainty but did not use real options, and 7 (21%) accounted for uncertainty using a real-options approach.

As we can observe, studies that consider the cost implications of investing in H4.0 technologies focus on economic analysis, adopting a cost-effectiveness and cost-minimization perspective. These studies were complemented by the application of a Bayesian sequential economic evaluation model for health technologies in which an investigator has flexibility over the timing of a decision to stop carrying out research and conclude that one technology is preferred over another on cost-effectiveness grounds [49]. A total of five manuscripts took a real-options perspective that incorporates value considerations but refers to past work, mainly published at the beginning of the time window of analysis.

The portfolio of 33 studies lists three types of decision-makers, who may be consulted individually or in groups: doctors, administrative staff, and patients. Doctors appear in 82% (27/33) of the studies; 39% (13/33) incorporate the administrative perspective; and 21% (7/33) contain the patient perspective. Although there is a dominance of expert opinion based on medical advice, the variety of decision-makers is a positive result that further claims support for a multidisciplinary analysis that incorporates the different types of users affected when evaluating investments in H4.0 technologies. Users of the information derived from the evaluations are also doctors, administrative staff, and patients; however, administrative users are predominant because they are direct users of the economic information.

A relevant aspect of the 33 studies analyzed in the portfolio is that 48% (16/33) of them present results of scoping or systematic literature reviews and meta-analyses (1 meta-analysis present among the 16 papers). However, they focused on the medical convenience of H4.0 technology investments, not on exploring specific economic evaluation tools, and mainly assessed a particular technology (eg, physicians' adoption of eHealth technology or smart device apps for older adults).

We were able to consolidate several relevant propositions for the economic evaluation of H4.0 technologies. A fundamental contribution of our review is the identification of the main antecedents of hospital investment decisions in technology, such as the health care system, the socioeconomic and cultural context, and its mission [13,14]. Regarding the health care system, the findings emphasize the role of health insurance coverage, financing methods, reimbursement methods for hospitals, methods used to make payments to physicians, and hospital ownership as antecedents of H4.0 technology investments. The existence of these antecedents anticipates the challenges of investment evaluations [14,37,44-74].

The appropriate deployment of medical technology should help to contribute to the quality of health care delivered, improve access to information, and contain costs [52]. Among the most promising evaluation alternatives is the framework in the study by Greenhalgh et al [60] to assist implementation teams in identifying, understanding, and addressing the interacting challenges to achieving sustained adoption, local scale-up, distant spread, and long-term sustainability of their technology investments in hospitals. Complementing this analysis is the call for applying a simple, multiattribute rate technique in the valuation process, as proposed in the study by Wernz and Zhang [13].

We identified four main challenges faced by health care institutions when evaluating investments in H4.0 technologies. First, H4.0 technologies should be analyzed as a bundle of technologies rather than individual solutions. As proposed in the study by Aceto et al [5], there are four overlapping groups of technologies based on their roles and applicability within the hospital. In our portfolio, of the 33 papers, only 6 (18.1%) analyzed H4.0 technologies as a bundle. Second, as mentioned earlier, there is a research gap in valuation methodologies for H4.0 technologies, especially in the realm of real-options analysis. Third, regarding who makes the decision to acquire the technology (medical personnel, administrative staff, or patient), 82% (27/33) of studies focused on the medical personnel as the main decision-makers. In contrast, only 24% (8/33) focused on patients, and a single paper integrated the 3 actors in the process [54]. Fourth, regarding the user of the technologies, 67% (22/33) of studies focused on medical personnel, whereas 24% (8/33) indicated that the main user was the patient.

Real-options strategies offer a transparent method for weighing the costs and benefits of adopting and further researching new and expensive technologies [44,45]. Such valuation methodologies incorporate the value of future new information in the current analyses. The articles in the portfolio report real-options applications in proton therapy adoption analysis

[44,45] and help formulate better human papillomavirus vaccination strategies [47]. Surprisingly, none of the articles using real-options analysis incorporated uncertainty correlations among the bundles of technologies. This is a critical shortcoming given the antecedents that report the importance of taking broader portfolio considerations when evaluating related and uncertain investments in areas such as biotechnology research and development [75].

Health care managers often make purchasing decisions without adequately assessing the resource demands, up-front costs (including integration costs), workflow impact, reimbursement potential, and other factors needed to fully understand the value added by new medical technology [52]. Consequently, health care authorities may risk failing to conduct thorough due diligence before purchasing medical technology. Under these circumstances, organizations might add unnecessary costs to their budget without adding significant clinical or operational value.

Selecting new medical technology for a health care organization can be a daunting task. It is crucial to implement a systematic approach for evaluating the latest medical technology, starting with a clearly articulated need for the technology. If organization authorities are unwilling to assess and redesign processes to fully use the new medical technology, investment withholding may be the most suitable course of action. Moreover, there is a risk of bias in purchasing the latest technology simply because it is available [52]. Overall, health care organizations rarely assess a systematic decision process that considers all organizational objectives and analyzes and integrates comprehensive data [52].

Providing universal access to innovative, high-cost technologies has led to tensions in today's health care systems. The stress becomes particularly evident in the context of scarce resources, where the risk of taking contentious coverage decisions increases rapidly. If health care institutions intend to maintain sustainable access to H4.0 technologies in the future, new approaches are needed to reconcile these different perspectives [48]. Overall, although policy makers request rapid and at-scale technology implementation, the reality is that when dealing with the multiple complexities of health and care, it is challenging to go beyond small-scale demonstration projects [52]. To address the need for new approaches, we propose in the next section a framework for the evaluation of H4.0 technologies in hospitals.

Classification Framework

Scientific research presents frameworks because managers use them to support their analysis and provide validity to the decision-making process [76]. We developed an emerging framework from the study we conducted on the research on hospital evaluations of H4.0 technologies.

Frameworks have multiple advantages. They decrease the number of uncertainties when addressing a new phenomenon, as is the case with H4.0 technologies. Frameworks can support the selection of investment strategies. In addition, frameworks can depict features of various phenomena [77], compare and guide numerous organizational practices [78], support the

execution of tasks [79], and refute or confirm a particular management approach [80].

When developing the framework, it is fundamental to determine the rationale that validates the theoretical process. Given the scoping review's multidisciplinary and integrative nature, we have chosen a process of abstraction, that is, we obtain higher-order themes from lower-order elements [81]. Therefore, we follow the most common abstraction process, in which lower-order themes are a function of the findings of individual studies, and higher-order structures link and organize the lower-order themes [81]. Such a method should result in the advancement of knowledge rather than a simple overview or description of a research area [82], that is, it should not be descriptive or historical but should preferably generate a new conceptual framework. In addition, we checked the reliability of higher-order themes using a focus group of experts. It is worth noting that the higher-order themes respond to taxonomy and not from a typological process [82,83].

Figure 2 presents the proposed classification framework. It focuses on the most fundamental tensions that organizations face when analyzing H4.0 technology investments and reflects the most prominent features of our publication portfolio. We categorized the type of technology analyzed based on its focus, sensing-communication or processing-actuation, following the classification in the study by Tortorella et al [1]. In this process, we classify lower-order themes into higher-order classification. We describe the number of technologies evaluated, depending on whether the analysis refers to stand-alone technologies or bundles. We also report the evaluation method, stating whether it is based only on cost or also takes into account value considerations. We considered whether the analysis does not incorporate flexibility in the valuation process or explicitly incorporates it using a real-options approach. We also examine the portfolio of manuscripts regarding the variety of decision-makers included and the type of technology users. For all these cases, we propose higher-order themes for the portfolio of manuscripts.

The framework not only helps to classify a particular research paper but also has utility for practice. It may allow hospital authorities to understand what type of organizational process they have in place to analyze investment decisions in H4.0 technologies. In addition, it helps to anticipate the complexity of the task. When reflecting on the most critical tensions that hospitals face, the structure would allow authorities to detect the underlying leadership and change-management challenges.

When categorizing the portfolio of manuscripts using the proposed framework, we identified a significant concentration of studies on the left side. It seems reasonable to observe such an unbalanced distribution, given the developing nature of H4.0 technologies. However, it also signals an essential shortcoming of the current studies, directing further research propositions. There is a risk that hospitals might have been making decisions by following isomorphic behavior [84], which is not necessarily the best rational approach. Research concentration might reflect herding behavior in which hospitals imitate one another instead of following a robust, innovative path.

We further analyzed the framework and developed a research opportunity map, displayed in Figure 3, focusing on two dimensions of the framework: the complexity of the analysis and the number of technologies considered.

From the research map, it is possible to indicate that there is a research opportunity related to analyzing bundles of technologies

with complex relationships that incorporates uncertainty correlations. It is important to emphasize that complex relationships do not necessarily imply more complex analyses. The challenge is to integrate a higher level of complexity with straightforward analytical tools. We will return to this point at the end of the following section.

Figure 2. Classification framework.

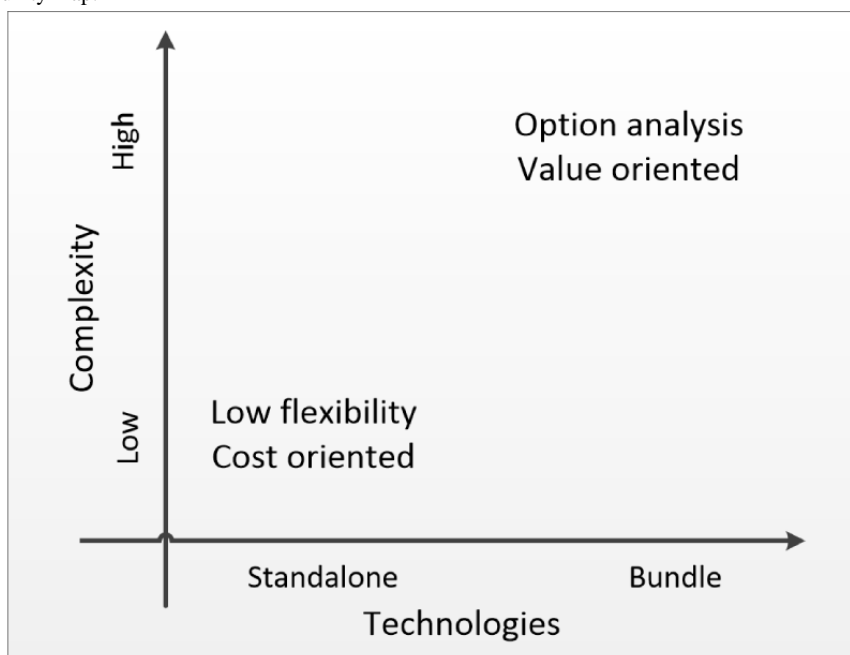

Figure 3. Research opportunity map.

Discussion

Principal Findings

This section addresses the third research question, that is, we identify the crucial characteristics that methodologies for evaluating investments in H4.0 technologies should have. These characteristics also represent research gaps that should be addressed in future research.

Overall, we anticipate that the evaluation of H4.0 technologies presents challenges and opportunities that are similar to those related to general technology investments, although the evaluation is more complex because of the nature of H4.0 technologies. We also observe that the existing research does not entirely succeed in helping hospitals in the investment decision-making process, leading to promising research opportunities.

Insufficient Economic Valuation of H4.0 Technology Investments

Decades of research on health technology assessment have resulted in a framework that includes economic evaluation as a fundamental pillar. However, studies that rigorously integrate this economic perspective are still scarce. Advancements focus more on cost-effectiveness than economic value at the public policy level rather than at the hospital level. In addition, studies have confirmed that health care institutions rarely apply a systematic analysis that considers all organizational objectives and integrates comprehensive data [13]. For instance, the relatively low commercial externality valuation is one of the shortcomings of economic analysis.

Although some older studies on real options include cost and value considerations, more recent propositions tend to overfocus on cost analysis, imposing a challenging bias on investment decisions. Among propositions that incorporate value, the net present value analysis is the most frequently used, often resulting in a suboptimal decision because it does not consider the value of future options and managerial flexibility [13]. Usually, simple cost-benefit analysis and subjective assessment replace sophisticated analytical methods and objective data at the risk of not investing in more expensive technologies with higher health impacts because of their investment requirements. The development of real-options approaches that include value considerations targeted at evaluating investments in H4.0 technologies is a promising research opportunity that should resonate positively among practitioners.

Explicit Assessment of Technological Interrelationships

The literature provides evidence that for maximizing the return on H4.0 technology investments, hospitals should consider them in bundles. Studies have proposed distinct bundles (or groupings) of H4.0 technologies. Sharma et al [55] categorized technologies into three bundles according to the extent of patient-centered integration and caregiver interaction. The study by Aceto et al [5] conceptually proposed four overlapping groups of technologies based on their roles and applicability within the hospital. The study by Gastaldi and Corso [85] proposed another categorization of H4.0 technologies, dividing them into four macroareas, further subdivided into 14 solutions

provided by each technology. Finally, the study by Alrige and Chatterjee [86] suggested a taxonomy to classify wearable technologies in health care systems according to three major dimensions: application, form, and functionality.

Although the literature still lacks consensus on the correct taxonomy of bundles of H4.0 technologies and how to combine them to act synergistically, it is clear that the valuation should incorporate the bundling of technologies. Therefore, researchers and institutions need to assess portfolio effects explicitly [75]. The literature on real options includes several studies that explicitly address portfolio considerations [75,87-89], providing a potential area of extension to H4.0 technology investments. In analyzing hospital investments, research incorporating portfolio considerations is scarce (eg, the study by Wernz and Zhang [13]) and does not include real-options valuations. It is fundamental to understand whether investing in technology bundles creates super- and subadditivity [75], altering the net economic contribution of different alternatives and eventually changing the suggested priorities.

We detected recent efforts to provide an accessible and usable framework that would enable multiple objectives, mainly developed by authors seeking to design, develop, implement, scale-up, spread, and sustain technology-supported health or social care programs to identify and help address the critical challenges in different domains and the interactions among them [51,60,67]. However, the developments only start to address the shortcomings identified in our scoping review, opening opportunities for future research.

Incorporate Fundamental Uncertainties

H4.0 technologies enhance efficiency and quality in health care systems. However, fundamental uncertainties exist in the definition of industry standards for many of these technologies, creating uncertainty when evaluating investments. Factors that add additional complexities to technological advancements relate to uncertainty regarding patient demands and competition [13].

To reduce the risk of investing in a technology that ends up being crowded out and not adopted as the standard, hospitals have several alternatives; further research is needed to explore their viability. Surprisingly, the discussion about standards is scarce in the economic evaluation of H4.0 technologies, with the main focus continuing to be on their efficacy.

Integrating Administrative, Medical, and Patient Perspectives in the Evaluation Process

The fourth research opportunity relates to integrating medical, patient, and administrative considerations in the valuation process. We have already stressed that the interrelationships among technology bundles incorporate nontrivial challenges. In addition, institutions should consider the risk of investing in technologies that fail to establish the industry standard. The final layer should adequately balance medical benefits with economic costs. It is still unclear how to achieve such reconciliation [48]. The central problem concerns the resolution of the economic logic versus medical logic debate. On the one hand, doctors favor technologies with the most promising medical effects, regardless of uncertainty and varying

requirements of investment and cost. On the other hand, the administrative staff need to ensure the hospital's economic viability. Amid high levels of uncertainty, the amount of investment and the operating costs, that is, the economic logic, might contradict the medical logic. Research is needed to explore the most suitable ways in which hospitals can coordinate both perspectives.

In integrating the different perspectives into the valuation process, hospitals need to include those of the patient for at least three reasons [48]. First, a comprehensive assessment should consider patients' views on the satisfaction and acceptability of health technologies. Second, with chronic forms of disease and disability, patients and their families play a more active role in health care decisions. Patients' lifestyles and behaviors may dramatically influence long-term prognoses of chronic conditions. Third, the involvement of patients increases transparency and openness in public policy [48]. We acknowledge that incorporating the patient's view in the investment decision analysis adds a layer of complexity to a process that is already difficult to manage. However, any valuation analysis that considers costs and value without including the patient perspective will be incomplete.

The integration of different perspectives provides an opportunity to cross-fertilize research on H4.0 technology investments with adaptive leadership tools [90]. Alternatively, the incorporation of H4.0 technologies equals establishing a dynamic organizational capability that demands from employees the ability to leverage interpersonal relationships conducive to productive dialog [91].

Remain Manageable in the Decision-Making Process

Previous studies describe hospitals' investment decisions as ad hoc, informal, political, without sufficient data analysis, and not aligned with the institutions' mission and strategy [13]. We argue in favor of assessments that explicitly consider technological interrelationships, incorporate fundamental uncertainties, and integrate administrative and medical insights. However, our argument comes with an essential caveat: analytical methods should avoid introducing complex evaluation tools that hamper the hospital's decision-making process.

At first, such a requirement seems to be challenging. We have suggested incorporating bundles of technologies, mapping multiple uncertainties, considering value implications and not exclusively cost aspects, and including different stakeholders' perspectives. A priori, these requirements go against the simplification of the decision-making process. However, it might be possible to solve this tension by articulating the valuation process in different stages. We envision a lean financial valuation that combines these competing demands without drastically complicating the decision process.

The lean financial valuation of H4.0 technology investments involves simplifying, streamlining, and harmonizing essential valuation processes to create a leaner, more efficient valuation operation. The current research opportunity relates to developing lean organizations that incorporate valuation tools that simultaneously address challenges such as complex uncertainty

relationships and bundle effects into organizational structures that adjust to lean principles.

Limitations and Final Remarks

This study examined how hospitals approach investment decisions in H4.0 technologies by using a scoping review of the existing literature. We performed a search for journal articles in four databases and screened relevant contributions to consolidate a publication portfolio on the topic, following predefined criteria. The results of the scoping review were explored using the following stepwise approach:

1. A descriptive numerical summary and thematic analysis.
2. Identification of trends and challenges in H4.0 technology investment evaluation.
3. Proposal of a classification framework for H4.0 technology investment evaluation.
4. Identification of research opportunities and proposals for future research directions from a hospital investment management point of view.

Despite the topic's recency, we observed that research in H4.0 technologies expands interdisciplinarily with a diversified set of applications and functionalities. In terms of the economic evaluation, studies on H4.0 technologies tend to overfocus on cost considerations and underemphasize cost-value relationships. Studies that consider both sides of the economic valuation (ie, value and cost) use real-options analysis and tend to be older in the sample of studies analyzed. Although the impacts of H4.0 technology adoption substantially increase when hospitals adopt technologies in bundles, research mainly focuses on the analysis of single technologies. Finally, recent studies have called for the integration of different actors in the decision process by developing a comprehensive, consistent, and data-driven framework for evaluating hospitals' investment decisions. We have proposed a framework that serves as a starting point.

Our study includes some noteworthy limitations, mostly related to its nature and methodological choices. As Industry 4.0 was formally acknowledged in 2011 and H4.0 is a concept derived from it, our scoping study only encompassed studies after that year. However, it is worth mentioning the existence of initiatives aimed at valuing Industry 4.0 technologies in health care systems not characterized as such and dating earlier than 2011, which is a limitation of our research. Nevertheless, because studies before 2011 were scarce and scattered, and the number of publications on the topic has significantly increased in the past few years, we believe that our choice of the search period returned all relevant studies on H4.0 technologies.

A second limitation is that we focused our literature analysis and discussion on H4.0 technology evaluation within hospitals. However, the concept of health care has expanded beyond the limits of health care organizations (ie, hospitals and clinics). In fact, with the advent of *smart cities*, complementary aspects of health care have been integrated because of the increased level of interconnectivity and data acquisition, allowing health care services to be demanded remotely. Our study did not analyze these aspects and exclusively considered hospitals the units of analysis.

Third, it is worth emphasizing that we combined insights from two perspectives to develop the proposed framework: the state of the practice at hospitals and the state of the art in the literature. However, our main focus was on research, and we did not include a specific survey of empirical studies mapping hospital tools. This is simultaneously a limitation of our investigation and a research opportunity.

Finally, identifying trends, challenges, and theoretical gaps through this scoping review allowed us to develop a framework. However, we acknowledge that this is the first step toward the proposal of an in-depth framework. Future studies could use the theoretical consolidation of the studies in our paper as a conceptual baseline for developing such a detailed H4.0 technology evaluation framework. We hope that our classification framework will act as a solid starting point for future developments in evaluating H4.0 technology investments.

Abstract

Background: Significant morbidity, mortality, and financial burden are associated with cardiac rhythm abnormalities. Conventional investigative tools are often unsuccessful in detecting cardiac arrhythmias because of their episodic nature. Smartwatches have gained popularity in recent years as a health tool for the detection of cardiac rhythms.

Objective: This study aims to systematically review and meta-analyze the diagnostic accuracy of smartwatches in the detection of cardiac arrhythmias.

Methods: A systematic literature search of the Embase, MEDLINE, and Cochrane Library databases was performed in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines to identify studies reporting the use of a smartwatch for the detection of cardiac arrhythmia. Summary estimates of sensitivity, specificity, and area under the curve were attempted using a bivariate model for the diagnostic meta-analysis. Studies were examined for quality using the Quality Assessment of Diagnostic Accuracy Studies 2 tool.

Results: A total of 18 studies examining atrial fibrillation detection, bradyarrhythmias and tachyarrhythmias, and premature contractions were analyzed, measuring diagnostic accuracy in 424,371 subjects in total. The signals analyzed by smartwatches were based on photoplethysmography. The overall sensitivity, specificity, and accuracy of smartwatches for detecting cardiac arrhythmias were 100% (95% CI 0.99-1.00), 95% (95% CI 0.93-0.97), and 97% (95% CI 0.96-0.99), respectively. The pooled positive predictive value and negative predictive value for detecting cardiac arrhythmias were 85% (95% CI 0.79-0.90) and 100% (95% CI 1.0-1.0), respectively.

Conclusions: This review demonstrates the evolving field of digital disease detection. The current diagnostic accuracy of smartwatch technology for the detection of cardiac arrhythmias is high. Although the innovative drive of digital devices in health care will continue to gain momentum toward screening, the process of accurate evidence accrual and regulatory standards ready to accept their introduction is strongly needed.

Trial Registration: PROSPERO International Prospective Register of Systematic Reviews CRD42020213237; https://www.crd.york.ac.uk/prospero/display_record.php?RecordID=213237.

Introduction

Background

Cardiac arrhythmia encompasses a group of conditions in which the heart beats too quickly, too slowly, or in an irregular pattern. Significant morbidity, mortality, and financial burden are associated with cardiac rhythm abnormalities [1]. Of these cardiac rhythm abnormalities, atrial fibrillation (AF) is the most common type of cardiac arrhythmia [2], and its prevalence increases sharply with age, reaching 17.8% in a European population for those aged >85 years [3,4]. The presence of AF increases the risk of ischemic stroke by five-fold [5] and can lead to other thromboembolic events. It is well recognized that AF often remains asymptomatic, and therefore, by the time of screening, the patient may have already suffered the consequences.

Although AF is the most common type of cardiac arrhythmia, other arrhythmias, such as premature cardiac contractions, are responsible for significant symptomatic burden. Premature atrial contractions have been shown to be an independent risk factor for all strokes in a longitudinal study [6]. Similarly, a cohort study found that having premature ventricular contractions resulted in a higher rate of ischemic stroke than those without contractions [7].

Conventional screening tools, in the form of 12-lead electrocardiograms (ECGs) and ambulatory electrocardiography monitors, are often unsuccessful in detecting AF or other cardiac arrhythmias, such as bradyarrhythmias or tachyarrhythmias, because of the transient nature of episodes. The episodic and infrequent nature of cardiac arrhythmias means that they are not captured within the investigation period, making diagnosis very difficult.

Recent advances in mobile health technology and wearable electronic devices allow heart rhythm monitoring to be undertaken in real time with greater comfort, ease, and engagement [8]. Wearable devices such as smartwatches show great potential for the detection of cardiac arrhythmias. Timely diagnosis of AF ensures that management is commenced early to prevent ensuing events that impact the quality of life while also relieving the burden that this poses on the health care system.

Smartwatches have gained popularity in recent years, especially as a health tool for the detection of heart rhythms. Patients with a smartwatch can self-diagnose their heart rhythm within 30 seconds using one finger [9]. These apps use photoplethysmography (PPG) from an optical sensor to analyze the pulse rate from the wrist [10]. However, adoption of the technology by both clinicians and patients requires that these devices are accurate and provide clinically applicable information in a manner that is compatible with workflow in the health setting.

Objectives

This study aims to systematically review and meta-analyze the diagnostic accuracy of smartwatches in the detection of cardiac arrhythmias.

Methods

Overview

This review was carried out and reported in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [11]. The review was registered at the International Prospective Register of Systematic Reviews (PROSPERO ID: CRD42020213237).

Search Strategy

A thorough literature search was performed using the Embase, MEDLINE, and Cochrane Library databases. All articles published until February 2021 were included in the study. The appropriate MeSH (Medical Subject Headings) terms and free text all field searches were performed and combined with appropriate Boolean operator terms for *arrhythmias*, *cardiac OR irregular pulse** OR *atrial fibrillation*, *wearable electronic devices OR smartwatch** OR *wristband**, *diagnosis*, *computer-assisted OR diagnos**, and *detect** in Embase and Ovid in MEDLINE. Search terms in the Cochrane Library included *arrhythmias*, *cardiac OR atrial fibrillation OR irregular pulse** OR *arrhythmia**, *smartwatch** OR *wearable electronic device**, and *diagnosis*, *computer-assisted OR detect** OR *diagnos**. The full search strategy is provided in [Multimedia Appendix 1](#).

Inclusion and Exclusion Criteria

Inclusion criteria were as follows:

- studies reporting detection of cardiac arrhythmias using smartwatches;
- studies reporting sensitivity, specificity and diagnostic accuracy; or studies with adequate information to calculate these data; and
- studies published or translated into English.

Exclusion criteria were as follows:

- studies with no original data present (eg, review article, letter);
- studies with no full text available;
- studies >20 years; and
- studies without adequate data to calculate sensitivity, specificity and diagnostic accuracy data.

Study Selection

Studies obtained from the literature search were analyzed, and duplicates were removed. Title, abstract, and full-text review were performed by 2 reviewers independently, and irrelevant studies were excluded. Disagreements were settled by consensus among the reviewers.

Data Extraction

Data were extracted onto a standard spreadsheet template. Information regarding the journal, author, study design, type of smartwatch, number of subjects, and diagnostic accuracy data (sensitivity, specificity, accuracy, positive predictive value [PPV], and negative predictive value [NPV]) was selected from each paper.

Study Quality Assessment

The Quality Assessment of Diagnostic Accuracy Studies 2 tool was used to assess the risk of bias of the included studies [12]. Each domain was classified as low risk, high risk, or unclear risk of bias.

Statistical Analysis

Summary estimates of sensitivity, specificity, and area under the curve data were attempted using a bivariate model for diagnostic meta-analysis. Independent proportions and their differences were calculated and pooled using DerSimonian and Laird random effects modeling [13]. This considered both between-study and within-study variances, which contributed to study weighting. Study-specific estimates and 95% CIs were computed and represented in forest plots. Statistical heterogeneity was determined by the I^2 statistic, where <30% was low, 30%-60% was moderate, and >60% was high. Analyses were performed using Stata version 15 (StataCorp). *P* values of $\leq .05$ were considered statistically significant.

Results

Search Results and Characteristics

The database searches identified 292 studies that matched the criteria. Duplicates were removed, and 215 studies were eligible for title and abstract screening. Following this, a full-text review

was undertaken, and a total of 18 studies were included in this review. Studies that failed to satisfy the inclusion criteria were excluded, and the reasons for exclusion of these articles included wrong intervention (such as the lack of use of a smartwatch) or wrong outcomes (such as studies that did not involve the detection of cardiac arrhythmias or reports on diagnostic accuracy). The study screening and selection process is shown in Figure 1.

The studies included in this systematic review were all published between 2017 and 2021. The outcome measure in the studies was mainly AF detection but also included bradyarrhythmias, tachyarrhythmias, and premature contractions. The studies measured diagnostic accuracy using smartwatches in 424,371 subjects in total. The Apple watch was used in 7 studies, Samsung smartwatches were used in 5 studies, and the remaining studies used a Huawei, Huami, or Empatica smartwatch. One study used the Wavelet wristband. Three different types of Huawei smartwatches were used in 2 studies to assess the diagnostic accuracy [14,15].

The reference standard was an ECG in most studies in the form of a 12-lead ECG, a Holter monitor, an ECG patch, telemetry, or an internet-enabled mobile ECG. In one study, an implantable cardiac monitor was used as the standard [16]. Almost all studies, except for 2 that did not specify, used PPG-based sensors to assess pulse rate. Table 1 provides the characteristics of the included studies.

Sensitivity, Specificity, and Accuracy

The diagnostic accuracy of the smartwatch in detecting cardiac arrhythmias was analyzed, reporting a pooled sensitivity of 100% (95% CI 0.99-1.00; Figure 2) in 17 studies with 5074 subjects and a pooled specificity of 95% (95% CI 0.93-0.97; Figure 3) in 16 studies with 5050 subjects. The sensitivity ranged

from 25% (95% CI 0.14-0.36) to 100% (95% CI 1.00-1.00), whereas the specificity ranged from 68% (95% CI 0.65-0.70) to 100% (95% CI 1.00-1.00).

Of the 18 studies, 7 (39%) reported data on accuracy. Among the 1769 subjects, the pooled accuracy for arrhythmia detection was 97% (95% CI 0.96-0.99; Figure 4).

Figure 2. Pooled analysis for sensitivity of cardiac arrhythmia detection by smartwatches. Effect sizes are shown with 95% CIs. A random effects model was used. ES: effect sizes.

Figure 3. Pooled analysis for specificity of cardiac arrhythmia detection by smartwatches. Effect sizes are shown with 95% CIs. A random effects model was used. ES: effect sizes.

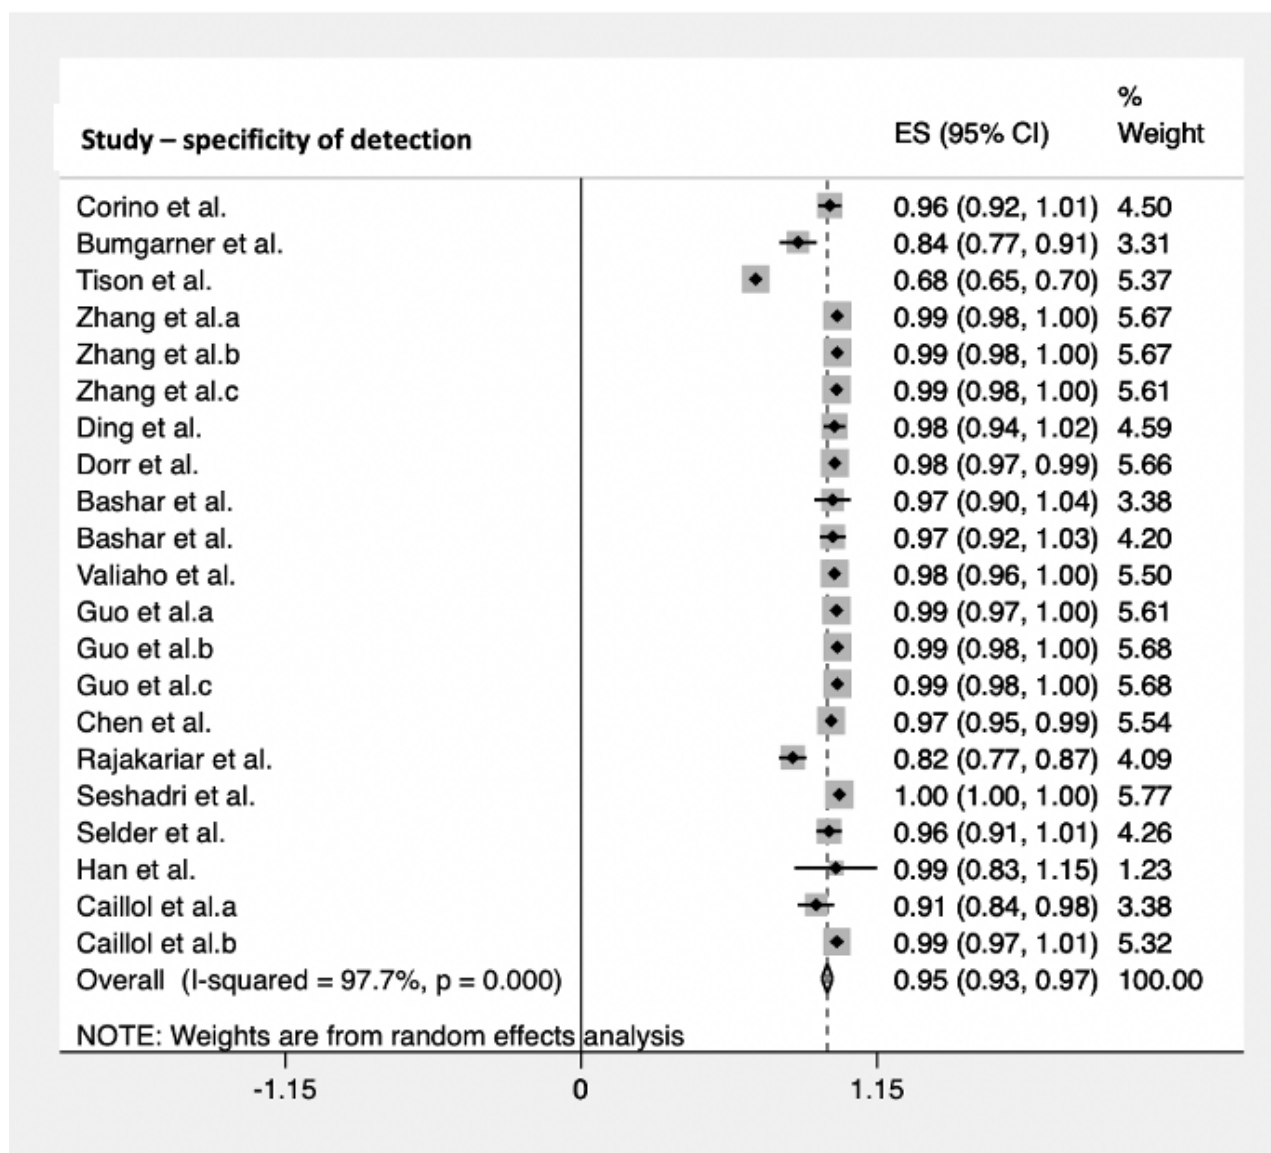

Figure 4. Pooled analysis for accuracy of cardiac arrhythmia detection by smartwatches. Effect sizes are shown with 95% CIs. A random effects model was used. ES: effect sizes.

PPV and NPV Analysis

The PPV for cardiac arrhythmia detection was assessed in 9 studies using a smartwatch. These included a total of 421,267

subjects and reported a PPV of 85% (95% CI 0.79-0.90; Figure 5). The pooled NPV was reported in 6 studies as 100% (95% CI 1.0-1.0; Figure 6), taking into consideration 3323 subjects.

Figure 5. Pooled analysis for PPV of cardiac arrhythmia detection by smartwatches. Effect sizes are shown with 95% CIs. A random effects model was used. ES: effect sizes; PPV: positive predictive value.

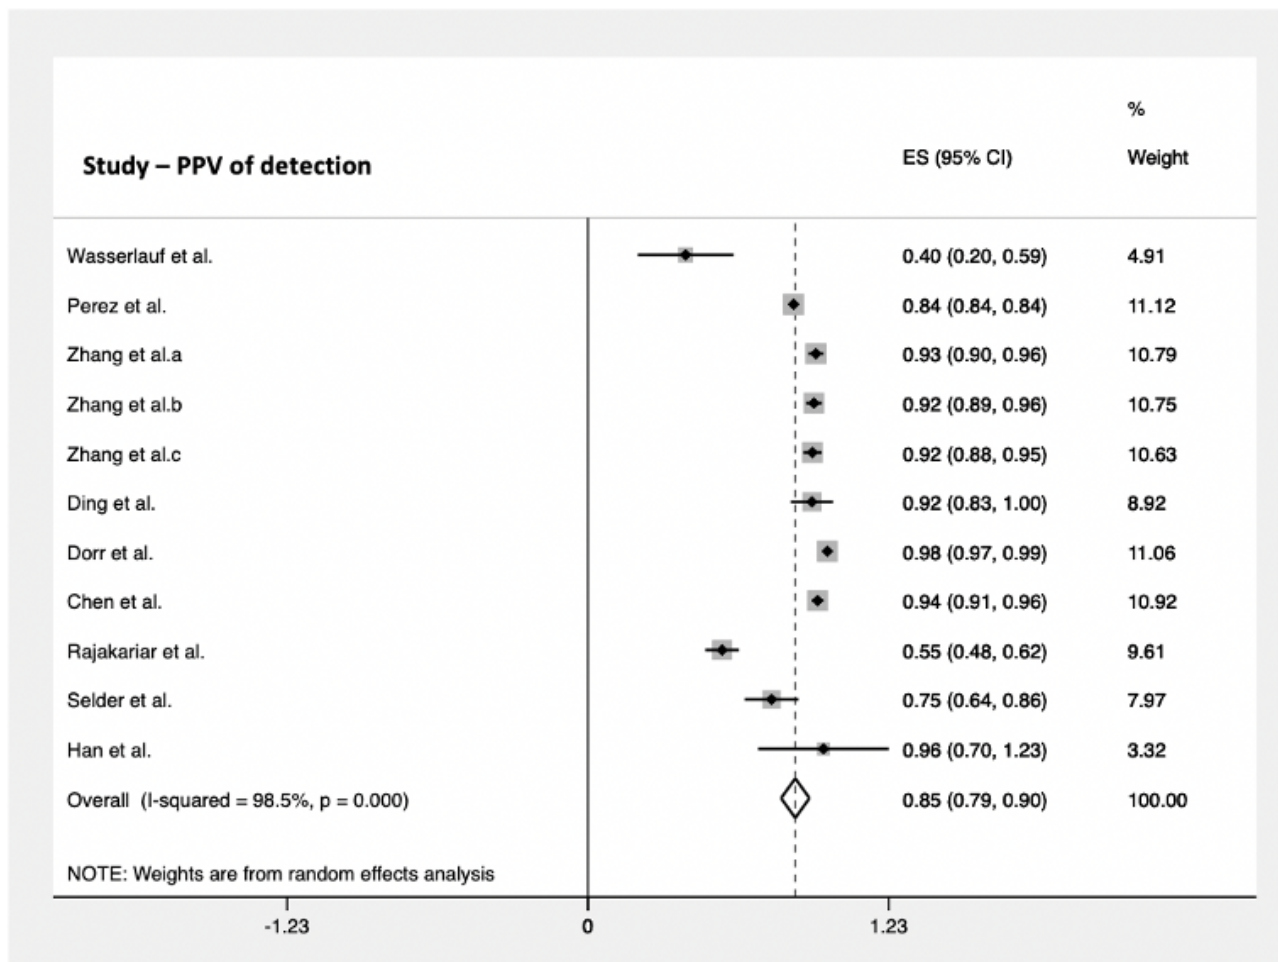

Figure 6. Pooled analysis for NPV of cardiac arrhythmia detection by smartwatches. Effect sizes are shown with 95% CIs. A random effects model was used. ES: effect sizes; NPV: negative predictive value.

Heterogeneity of Studies

There was a high degree of variation between studies assessing cardiac arrhythmia detection using a smartwatch. The heterogeneity was statistically significant when all the studies were compared ($P < .05$). The lowest variation among studies was seen when reporting the accuracy of smart devices to detect arrhythmias ($I^2 = 81.1\%$), whereas heterogeneity was highest in studies when assessing PPV ($I^2 = 98.5\%$).

Quality Assessment

The assessment of bias using the Quality Assessment of Diagnostic Accuracy Studies 2 tool for the included studies is highlighted in [Multimedia Appendix 2](#) [14-31].

Discussion

Principal Findings

To the best of our knowledge, this systematic review and meta-analysis is the first to investigate the diagnostic accuracy of smartwatches for all cardiac arrhythmias. We have shown that the detection of cardiac arrhythmias using commercially available smartwatches is possible, with very high diagnostic accuracy. The overall sensitivity, specificity, and accuracy of these digital systems were 100%, 95%, and 97%, respectively. The pooled PPV and NPV for detecting cardiac arrhythmias

were 85% and 100%, respectively. These values may offer clinicians a quantifiable appreciation for the use of smartwatches in a health care setting.

Although the aim of this study is to review the diagnostic accuracy of smartwatches in detecting cardiac arrhythmias, it is clear from the results that there are currently very few studies that assess the ability of PPG technology on smartwatches to detect non-AF arrhythmias.

Smartwatches

A wide variety of smartwatches are commercially available, and this is reflected in the diverse range of smartwatches used in these studies ([Table 2](#)). These devices range from fitness trackers to more medically oriented watches with prices between US \$40 and US \$1700. Although all devices use PPG sensors ([Figure 7](#)), there is diversity in functionality beyond this point. Several smartwatches are capable of recording a single-lead ECG, and others, such as the Empatica E4, have electrodermal activity sensors capable of recording sympathetic nervous system activity. The Samsung Simband is unique within these studies in that it is the only device designed for developers and is not commercially available, allowing custom adaption of sensor inclusion. Of the studies included, only the Apple Smartwatch has Food and Drug Administration (FDA) clearance for its ECG tracking functionality.

Table 2. Characteristics of smartwatches used in included studies.

Smartwatch	Company	Country	Approximate price ^a , £ (US \$)	Type	Photoplethysmography	Single-lead ECG ^b	Food and Drug Administration clearance ECG tracking	Electrodermal activity sensor

Figure 7. Overview of photoplethysmography sensor detection of arrhythmia. PPG: photoplethysmography.

The Impact of Improving AF Detection

The incidence of AF increases annually with an increase in the prevalence of risk factors, such as advancing age, obesity, hypertension, and type 2 diabetes. The challenge with detection is the ability of AF to remain asymptomatic or intermittent before eventually revealing itself. This poses a huge economic burden, accounting for 1%-2% of health care expenditure [32]. A new technology that is promising for reducing or preventing AF-related morbidity, and in doing so, addressing this burden, is welcomed. Machine learning coupled with smartwatches provides the opportunity to detect asymptomatic arrhythmias in a timely manner, allowing appropriate management to be

initiated early. A recent study showed that a trained deep neural network was able to outperform single cardiologists by accurately classifying a broad range of rhythm classes and distinguishing between artifacts and arrhythmias [33]. This method could reduce the rate of misdiagnosed rhythms by digital ECG machines and improve the efficiency of expert human ECG interpretation by accurately prioritizing the most urgent conditions.

The detection of cardiac arrhythmias using smartwatches has multiple functionalities. It can be used to diagnose an abnormal rhythm, for monitoring of an arrhythmia, for example, in those with known paroxysmal AF, or for screening. Current methods

of AF detection are criticized for their periodic investigative approach, during which an irregular pulse may be absent [34-36]. Using smartwatches, users can diagnose an irregular pulse by placing a finger on their device at any point. Smartwatch devices that detect cardiac arrhythmias are a simple, noninvasive, and user-friendly alternative to current ECG monitoring tools, such as 24-hour Holter monitoring or implantable cardioverter defibrillators [37,38]. The novel devices provide users with prospective information in real time, with relatively high sensitivity and specificity, as shown in our study, and are cost-effective [39]. However, the adoption of this technology by clinicians and patients requires clinically meaningful results in a manner that is compatible with the workflow of clinicians. Therefore, an optimal strategy for their implementation must be in place.

What Are the Next Steps?

Wearable devices for *wellness* are viewed as low-risk fitness monitors by the FDA, which does not apply the same stringent regulations as it would when considering medical devices. The FDA has introduced its Digital Health Precertification Program, in which companies are able to gain expedited clearance for ECG analysis and heart rate sensing software [40]. This process leads to companies producing technology that is confirmed to be *safe* but not necessarily of good quality because they have bypassed the conventional workflow for research discovery. Large clinical trials are lacking, and as a result, no expert consensus recommends screening for all occult AF [41].

Furthermore, there is insufficient evidence on the burden of smartwatch-detected AF, which would prompt further evaluation and treatment. Guidance on what the clinician is expected to do with an episode of AF detected by a smartwatch is lacking. We suggest that this should be a critical prerequisite before introducing a digital detection tool into the general population; otherwise, overdiagnosis and an expectant role of clinicians from the public to assess their device-detected condition will become an even bigger burden on the health care system. A recent study evaluating the clinical outcome of the Apple smartwatch concluded that false-positive screening results may lead to overutilization of the health care system [42]. Preparation for the problems that a new generation of smartwatch technology, which attempts to bridge the gap between disease and the health care system, brings is key.

With evolving technology in the field of health care applications, there is a move to a more personalized and *patient-centric* approach, where patients have an increasing number of tools at their disposal to assess risk and diagnose disease. Although frequent and active screening using a smartwatch is potentially feasible, few studies have examined the long-term adherence to this system. This user-involved measurement could too easily miss minimally symptomatic and brief paroxysms of arrhythmia. Long-term commitment and adherence from the user or the ability of continuous monitoring by the device is required for an accurate and worthwhile outcome.

Limitations

There are many limitations to the studies in our review. At present, most studies have assessed the use of a PPG sensor and

an accompanying algorithm to detect cardiac arrhythmias. However, they have not gone further to assess the use of such systems in health care. The largest study within our systematic review did not go beyond the participants' self-reporting of an irregular pulse [20]. Several factors must be controlled to produce unbiased data that are clinically applicable. The published papers included observational and case-control studies, which did not evaluate the efficacy of smartwatch-based screening for clinical outcomes nor reflect real-life conditions [21,22]. Moreover, the sample sizes of some studies were small, with data sets of less than 50 in 5 of the papers [16,21,23,24,30]. One study had a very low sensitivity compared with others when assessing atrial flutter or tachycardia, which could likely be because of the small sample size for this group [31]. Finally, most studies were conducted in controlled research environments as opposed to a real-life setting, which may call into question the diagnostic accuracy of these smartwatches in an uncontrolled environment. Therefore, the interpretation of a sensitivity of 100%, effectively ruling out the presence of a cardiac arrhythmia with a negative result and the interpretation of an NPV of 100%, suggesting the return of no false negatives, should be interpreted with caution. The significant heterogeneity between studies is likely a result of different study settings, different patient group sizes, and different devices, based on personalized algorithms, having been used. Although the presence of this heterogeneity demands caution in interpreting our results, it also stresses the need for randomized controlled trials in this field using large data sets.

Many studies had a large proportion of data excluded because of insufficient PPG signal quality [14,18,22,24]. Some studies took place in settings where patients were supervised and provided instructions on the technique [22,27]. Thus, generalizing these findings to the *real world* could weaken the diagnostic accuracy. PPG technology recognizes the cardiac cycle by the pulsatile pattern of the change in light absorption, which reflects the volumetric alteration in the microvascular beds underneath the skin. With an accurate estimation, each episode of maximum reflected light absorption translates into an R wave. Although previous research has questioned the use of PPG sensors in darker skin, a recently published study showed no statistically significant differences in wearable heart rate measurement accuracy across skin tones [43]. However, a number of studies have shown that PPG sensors are less reliable at higher heart rates and during exercise [44,45]. As some studies in this review did not report the average heart rate of participants, it may add a level of bias to the results. In addition, PPG technology cannot detect myocardial ischemia or arrhythmias with a ventricular origin and therefore, at present, cannot completely replace 12-lead ECGs. Therefore, one must question whether the application of PPG-based sensors for cardiac arrhythmia detection is premature.

Finally, for smartwatch devices to be used as a screening tool for cardiac arrhythmias, such as AF detection, the value is highly dependent on disease prevalence. The estimated prevalence of AF in adults is between 2% and 4%. The prevalence increases with age, especially for those aged >65 years [46]. However, only 4.6% of smartwatch users in the United States are aged >65 years, and among those that are current smartwatch users,

the prevalence of AF is low [47]. The studies in this review used estimated disease prevalence rates, which have been age adjusted, when assessing diagnostic accuracy values. Subjects were not limited to age groups, and as a result, some studies overestimated AF prevalence among smartwatch users [19,22]. This means that the PPV value of 85% in our review may be higher than expected for cardiac arrhythmia detection in smartwatch users. Either way, there is a high number of false positives, which leads to unnecessary anxiety among those in whom the device detects AF and may have the downstream consequences of inappropriate initiation of treatment in these patients. Treatment with anticoagulants can cause bleeding, which may be harmful. False positives may improve if the device is targeted to those most at risk of AF, but larger studies are needed to evaluate smartwatches as a tool for long-term AF screening in selected at-risk patient groups.

Regardless of the current studies, the future of health technology is undeniably advancing. Thus, measures should be taken early to ensure that such smartwatch technology supports ongoing national public health programs rather than having it run in parallel. Given the lack of recent success with the national NHS test and trace program in the United Kingdom, in which it fell short of its uptake aims when reaching contacts of people who tested positive for SARS-CoV-2 [48], the wider use of machine

learning smartwatch technology should be considered in such circumstances. It may be more efficient and effective to integrate the need for health programs at the population level with existing devices. Governments should consider this, where applicable, in their decision-making processes.

Conclusions

This systematic review and meta-analysis demonstrates the evolving field of digital disease detection and the increased role of machine learning in health care. The current diagnostic accuracy of smartwatch technology for the detection of cardiac arrhythmias is high. This shift signals a new direction in the field, allowing patients to play a greater role in disease diagnosis. However, before the use of these devices as a screening tool in health care is widely adopted, more studies are needed to clearly define the ideal population for the use of these systems, as well as to help form specific guidance on the conduct of device-detected disease. Consideration should also be placed for the wider use of smartwatch technology and similar digital tools in policy making decisions by health care departments in the future. Although the innovative drive of digital devices in health care will continue to gain momentum toward screening, the process of accurate evidence accrual and regulatory standards ready to accept their introduction is strongly needed.

Abstract

The effective use of geospatial data and technologies to collect, manage, analyze, model, and visualize geographic data has great potential to improve data-driven decision-making for immunization programs. This article presents a theory of change for the use of geospatial technologies for immunization programming—a framework to illustrate the ways in which geospatial data and technologies can contribute to improved immunization outcomes and have a positive impact on childhood immunization coverage rates in low- and middle-income countries. The theory of change is the result of a review of the state of the evidence and literature; consultation with implementers, donors, and immunization and geospatial technology experts; and a review of country-level implementation experiences. The framework illustrates how the effective use of geospatial data and technologies can help immunization programs realize improvements in the number of children immunized by producing reliable estimates of target populations, identifying chronically missed settlements and locations with the highest number of zero-dose and under-immunized children, and guiding immunization managers with solutions to optimize resource distribution and location of health services. Through these direct effects on service delivery, geospatial data and technologies can contribute to the strengthening of the overall health system with equity in immunization coverage. Recent implementation of integrated geospatial data and technologies for the immunization program in Myanmar demonstrate the process that countries may experience on the path to achieving lasting systematic improvements. The theory of change presented here may serve as a guide for country program managers, implementers, donors, and other stakeholders to better understand how geospatial tools can support immunization programs and facilitate integrated service planning and equitable delivery through the unifying role of geography and geospatial data.

Introduction

Maps are powerful tools for public health decision-makers to better understand the relationship between the location of populations and health system resources, indicators or predictors of health status, and their patterns over space and time. The

visual power of the map is aided by modern advances in technology, computing, and handheld devices that can record the location of any place on the earth and transmit geospatial data for analysis, sharing, and use. The use of geography to analyze patterns of disease, distribution of populations, and

inventories and locations of health services come together to create a catalyst for improving health systems.

Immunization programs in low- and middle-income countries are beginning to harness digital maps and geospatial data to display and analyze complex information for program improvements [1-6]. The effective use of geospatial data can show program managers which locations have not received adequate immunization services, provide more accurate denominators, and inform what vaccination delivery strategies should be used to optimize coverage and equity. It can also improve monitoring of immunization programs.

Applications of geospatial technologies for immunization are often approached as simple solutions to system challenges without careful consideration of the greater ecosystem or planning for widespread adoption and sustainability [7]. Interventions are often deployed as pilot technology-focused projects without sustained resources or commitment to support the underlying enabling environment, human capacities, and governance systems that will contribute to a long-lasting impact on decision-making and health outcomes [8]. Gavi, the Vaccine Alliance, supports a systematic approach to understanding the range of geospatial data and technology implementation experiences to guide sustainable and effective systems and governance for improving immunization services that can reach every child with life-saving vaccines while strengthening primary health care systems [9]. Geospatial data and technology applications for immunization align with GAVI’s 2021-2025 strategy and the global Immunization Agenda 2030 strategy [9,10]. In order to provide life-saving services to children who

default on the vaccination schedule and “zero-dose” children who have never received a vaccine, new geo-enabled approaches to planning and delivering services are needed to expand the reach of effective vaccination for all children.

Theory of Change

Complex interventions benefit from collaborative efforts to understand the underlying series of events and changes that will lead to the desired result [11]. A *theory of change* is a process and framework to help describe this causal pathway and to support critical thinking throughout the project design, implementation, and evaluation cycle [11]. A *theory of change for the use of geospatial technologies for immunization programming* describes the potential for geospatial technologies to contribute to real-world impacts by optimizing routine immunization program design, implementation, and monitoring to reach all children with immunization services (Figure 1). It was developed as part of a collaboration between GAVI and UNICEF (United Nations Children’s Emergency Fund) to review the state of evidence in the published and grey literature and through consultations with implementers, donors, immunization, and geospatial technology experts, as well as country-level implementation teams [12]. The theory of change is meant to guide future investment and planning of geospatial technologies and systems for immunization programs within a broader context of health system strengthening, to coordinate donor and partner collaboration, and optimize investments in foundations and systems for long-term sustainability and effective use of immunization data for decision-making.

Figure 1. Theory of change for the use of geospatial technologies for immunization programming (originally published and adapted from [12]), with permission from Gavi, UNICEF, and HealthEnabled.

Health Impact	Reduction in Childhood Disability and Mortality Due to Vaccine-Preventable Diseases		
Immunization Impact	≥80% of children fully immunized in all districts and equitable coverage across population subgroups based on geographic, socio-economic and cultural differences		
Improved immunization campaigns and routine immunization programs			
Immunization Outcomes	Increased number of children immunized through improved target setting	Optimized immunization resource distribution and location of services	Improved quality, timeliness, and perception of immunization services with equity in coverage between communities
Geospatial Data and Technologies Outputs	Improved identification of zero dose and under-immunized children through more accurate microplanning and identification of missed settlements to implement appropriate vaccination strategy	Improved planning and allocation of immunization resources through strengthened use of geospatial data, analysis and visualisation	Improved service delivery through better planning, monitoring and tracking of immunization activities for rapid problem identification and corrective action
Geospatial Data and Technologies Inputs	Produce and regularly update digital maps for health area planning based on health resources mapping through a participatory process involving local health staff to map immunization resources	Optimize distribution of resources (workforce, funding, vaccines and supplies) based on more accurate target population distribution and identification of gaps in coverage and immunization service accessibility based on geospatial accessibility analysis, coverage modelling, forecasting and other new innovations and applications	Track service delivery by location of vaccinator activities and geographically-linked notifications, immunization sessions, supervision and allocation of financial resources
Geospatial Data & Immunization Foundations	Health System Mapping (essential): Develop and maintain master lists and data standards for health facilities, vaccination delivery sites and cold chain, settlements, infrastructure, health area boundaries and other core geographic objects Population Estimation (essential): Generate and use accurate population estimates (human density and distribution) to establish targets (denominators) in immunization program planning Analytics & Modeling for Accessibility, Coverage, and Surveillance Planning and Monitoring (when possible): Use modeling to understand geographic accessibility to services, vaccine distribution, and immunization coverage with links to data (through HIS, IHRIS, and eLMIS) on vaccine-preventable diseases and adverse events following immunization (AEFI)		
Enablers	<ul style="list-style-type: none"> Clearly defined vision, strategy and plan for a geo-enabled HIS/immunization program Information system governance structure including custodianship of geospatial data and technologies Policies supporting and enforcing the strategy and governance, including data accessibility Necessary human and financial resources to ensure effective use and sustainability of geospatial data and incorporation of new technologies and innovations over the long-term 		

Evidence From Research and Implementation Experiences

Overview

Geospatial data and technologies contribute to the following three interrelated immunization outcomes in the theory of change that together strengthen immunization campaigns and routine immunization program coverage and equity:

1. Increase the number of children immunized through improved target setting
2. Optimize immunization resource distribution and location of services
3. Improve the quality, timeliness, and perception of immunization services with equity in coverage between communities

These three outcome pillars are supported by foundations and enablers in the health system and a foundation of essential data that serve to guide the collection, management, and sustainable use of geospatial data and technologies for health. The theory of change is based on evidence and implementation experiences described for each of the three expected outcomes below.

Increase the Number of Children Immunized Through Improved Target Setting

Despite years of improvements in global vaccination coverage and strengthening systems for service delivery, many children remain underimmunized or never come in contact with routine immunization programs [13]. Delivering life-saving immunization services to all children requires an enormous amount of coordination, planning, and resources; microplans are the local-level operational workplans used by immunization managers to systematically compile relevant local data, prioritize activities, maintain adequate stock, and find solutions to service delivery barriers [14]. UNICEF and the World Health Organization (WHO)'s Reach Every District (RED) strategy encourages the use of maps for local-level microplanning activities, which are traditionally hand-drawn sketches of the catchment area based on local knowledge [15]. These sketch maps are often not to scale; inaccurate or incomplete; and do not contain crucial information for microplanning such as distances, road conditions, or geographic barriers that may delay or discourage vaccinator teams from reaching remote areas during door-to-door campaign activities [3,16]. Health system data may contain overlapping borders; settlements that fall outside health boundaries; and inconsistencies in naming, spelling, and classification of service delivery units and settlements [2,4]. The planning tools and delivery strategies to reach all children with immunization services need to expand beyond the current methods to incorporate new digital tools that support local immunization managers to identify and reach areas that have been historically left off maps and microplans [17].

Children who have never received a vaccination can be clustered in settlements or neighborhoods, increasing their risk of contracting a vaccine-preventable disease without the benefit of herd immunity in their communities [18,19]. Due to a variety of socioeconomic and geographic barriers, these children are left "off the map" both literally and figuratively. Geospatial

data and technologies for immunization programming can help identify these underreached communities by pinpointing the physical location of all settlements relative to the area's immunization service delivery locations. Spatially accurate maps are created through a combination of satellite images and field-based data collection to georeference and validate landmarks, inhabited settlements, and infrastructure through a participatory process with district and local immunization managers. They are then used to plan and execute realistic action plans that include outreach activities. Microplans developed with geospatial technologies and data are a cost-effective way to identify settlements missed with traditional microplanning activities that rely on hand-drawn paper maps [2,5,6,16]. With more accurate and reliable information about the locations, characteristics, and number of settlements within their catchment area, managers can plan and prioritize their activities to vaccinate more children and monitor progress both from the local and central levels.

Optimize Immunization Resource Distribution and Location of Services

Deciding how many vaccinators are needed for each catchment area, how many vaccines to send, and where to deploy fixed and outreach vaccination services depends on the number of people being served in each area, their distribution in the area, and the current unmet need for immunization services. The target population, or denominator, is often estimated from the most recent national census, adjusted each year by adding a fixed rate of growth [16]. Unfortunately, outdated census data, variation in growth rates, and population migration and mobility contribute to overestimation of the target population, leading to wasted resources, or underestimation with subsequent shortages and unvaccinated children [16,20,21]. Even with good population estimates, the location of settlements in relation to services measured by distance or travel time impact access and coverage. There is a relationship between complete and timely vaccination status and shorter distance or travel time to the nearest vaccination service, demonstrating how important the location of immunization services and geographic accessibility is for maximal immunization coverage [1,22-25]. To calculate unmet need, aggregate vaccination coverage data for the entire country or province can hide pockets of low coverage and settlements with unvaccinated children, leaving these communities vulnerable to vaccine-preventable diseases [26,27]. These data limitations impact immunization program planning and resource distribution, thereby preventing the timely delivery of life-saving vaccines to all children.

Tools and approaches that utilize geospatial technologies can help immunization managers make more targeted decisions for where and how to focus activities and resources. Precise estimates of population density and distribution for small geographic areas can be generated with a combination of satellite image data, statistical modelling, and sampled survey information to create accurate program targets for planning and monitoring purposes [28,29]. Population distribution estimates can be combined with spatial data on the location of vaccine service posts, road and transportation infrastructure, and geographic barriers to quantify the movement opportunity for people to reach existing services, inform new strategies and

location of services, and prioritize outreach activities to remote communities [30,31]. Modelled vaccination coverage for small subnational units of measurement can be generated using multiple sources of data to identify pockets with low coverage and, when combined with data on other socioeconomic indicators, can help suggest solutions to overcome the social, gender-related, economic, geographic, or other factors that are preventing access to immunization services [32]. Improved granular data that is visualized to show geographic trends for local populations can help target delivery strategies and resources to increase immunization coverage in the areas that need it the most [33,34].

Improve the Quality, Timeliness, and Perception of Immunization Services With Equity in Coverage Between Communities

A number of underlying factors contribute to nonvaccination—from service delivery challenges in the immunization program to community demand, including the caregiver's perceived quality of immunization services, trust, and respect within the community [35,36]. Pockets of communities that do not receive quality and timely immunization services are susceptible to vaccine-preventable disease outbreaks. Measuring and monitoring these geographic and socioeconomic pockets of inequality is the first step toward promoting equality in coverage [37,38]. Timely and accurate data on program performance such as tracking supply and logistics, frequency of outreach services, and drop-out-rates can be used to improve the quality of services by providing entry points for supportive supervision, improve planning, identify problems, and initiate rapid corrective action for better overall service delivery [8,39]. Vaccine-preventable disease surveillance systems require rapid communication of data that facilitate feedback up and down the surveillance chain for coordinated and appropriate investigation and response [40]. In order to respond quickly to gaps and challenges, local and subnational immunization managers need to have the skills to use data that is collected accurately, transferred quickly, and presented in a way that can trigger action [8].

Mobile technologies and cellular networks provide opportunities to improve data collection, transfer, analysis, and use [41]. The combination of near real-time communication with automatic collection of accurate location data enables field-based teams of vaccinators to report on the number and location of doses delivered and any barriers encountered during immunization campaigns into an integrated dashboard where managers can monitor progress and respond appropriately to challenges and missed communities [42-45]. These daily reports of progress during campaign activities can help inform the next day's strategy or provide evidence to extend or alter activities to reach all children in the target area [43-45]. For routine immunization services, supervisors can track the progress of mobile vaccination sessions as part of a geo-enabled digital microplan to identify and respond to missed settlements and improve monitoring of the microplan implementation [3,46]. The collection of geographic information linked to reports of suspected vaccine preventable diseases can facilitate rapid and coordinated action to prevent outbreaks, identify high-risk areas

that need vaccination services, and facilitate risk-mapping to predict future outbreaks [40,47]. The transparent sharing of data can promote a common understanding of expectations and challenges between vaccinators and supervisors.

Implementation Experiences: Myanmar Case Study

The current knowledge base shows that geospatial data and technology applications for immunization have the potential to stimulate programmatic improvements and increase immunization coverage. However, real-life examples of comprehensive and sustainable systems using geospatial data and technologies for immunization are rare. Myanmar provides an example of how the process of integrating geospatial data and technology for immunization microplanning validates the progression of incremental steps outlined in the theory of change.

In 2016, the national immunization program in Myanmar undertook a review as part of a health system commitment to creating a geo-enabled health information system. The assessment uncovered gaps in immunization coverage for children living in geographically and socially hard-to-reach communities, such as migrant worker settlements, remote villages, ethnic minority communities, and conflict-affected areas [48]. The local-level operational immunization workplans lacked reliable population information, and boundaries were out of date. This limited the ability of health workers to plan and undertake the daily logistics of immunization service delivery. In response to these gaps in coverage, the program took steps to support the microplanning process with geospatial data and technologies.

A phased pilot approach began in late 2017 in one township to begin building foundations, local capacity, and standard procedures and to demonstrate the benefits of using geospatial data and technologies for local-level immunization microplanning [48]. Subsequent expansion to a larger region in 2018 built on the foundations and lessons learned from the first pilot, as well as made improvements in the processes and implementation approach. Each expansion phase to a new area lasted 6 to 9 months to ensure that local capacity and systems were strengthened along the way.

The field implementation process created an up-to-date geo-referenced master list of facilities, settlements, and health area boundaries. A master list establishes a standardized, complete, up-to-date, and uniquely coded list of all features essential to the delivery of immunization services. Through this collaborative process, standard definitions were established for the geographic objects relevant to the microplanning process (eg, vaccination sites, facilities, and communities), and procedures were established for standard data collection. Every location where people lived, including temporary migrant settlements, were identified, defined, and included in the master list. Satellite images aided in settlement identification and catchment area delineation. Health workers were important stakeholders in the process to validate and review the maps and make necessary adjustments to their immunization microplans based on available transportation routes, distances, and geographic features in coordination with their supervisors. Online and printed maps showing accurate spatial relationships

between key immunization assets and communities were produced and made available for national immunization program staff to plan vaccination campaigns and routine service delivery.

The interim results from Myanmar's phased implementation approach include immediate effects of the collaborative process, map production, and distribution. With settlements and communities well defined, including characteristics and locations of temporary settlements, health workers were able to include these previously overlooked populations in their immunization microplans. The addition of missed settlements improved target population estimates, allowing for improvements in service delivery planning. The transparency and sharing of microplans and maps enabled supervisors to provide better support to health workers and encouraged accountability at all levels. Health officials were able to see the

need for expanded health facility distribution with a clear visualization and accurate distances displayed in new microplanning maps.

These experiences validate the expected outputs for the integration of geospatial data and technologies in the theory of change (Table 1). Myanmar's process of integrating geospatial data and technologies for immunization microplanning demonstrates how the complex challenge of delivering effective vaccinations to every child in countries with underlying health system challenges can benefit from these applications. Based on the implementation experiences in Myanmar's program, it seems likely that continued expansion and improvements in the geo-enablement of their immunization program will lead to the desired immunization outcomes and overall expanded coverage as the theory of change suggests.

Table 1. Summary of geo-enabled microplanning implementation results from the Myanmar Central Expanded Program on Immunization.

Myanmar's geo-enabled microplanning experiences	Corresponding geospatial data and technology theory of change output
<ul style="list-style-type: none"> Settlements that were previously missed are defined, identified, and included in the microplan Visualization of accurate geospatial relationships in catchment areas serve as a tool to plan vaccination sessions 	Improved identification of zero-dose and underimmunized children through more accurate microplanning and identification of missed settlements to implement appropriate vaccination strategy
<ul style="list-style-type: none"> Target population denominator is closer to actual community density and distribution Standardized definitions and categorization of settlements and immunization resources help streamline planning process Visualization serves as an advocacy tool to demonstrate to senior health officials the need for improvements in the equitable distribution and allocation of resources 	Improved planning and allocation of immunization resources through strengthened use of geospatial data, analysis, and visualization
<ul style="list-style-type: none"> Enhanced geo-enabled microplanning process encourages accountability of health workers and supervisors with transparency and shared expectations and service delivery plans 	Improved service delivery through better planning, monitoring, and tracking of immunization activities for rapid problem identification and corrective action

Additional lessons from Myanmar's experience reinforce the importance of the enabling environment and foundations in the theory of change, built on UNICEF's guidelines and detailed approach to support the enabling environment for geospatial data and technologies in immunization programs [49]. The high-level commitment to transition to a geo-enabled national health information system in the Department of Public Health in Myanmar, with support and technical guidance from the WHO, GAVI, UNICEF, and the Health GeoLab Collaborative (a center of excellence for the Asia-Pacific region) laid a strong foundation of advocacy, governance, policies, and capacity for the management and use of geospatial data and technologies in the broader health sector [50]. The geo-enhanced microplanning process was further supported by the creation of common master lists for the geographic objects essential to the immunization program, an element recommended in the theory of change as an essential foundation to the sustained and effective use of geospatial data and technologies for immunization programs. A commitment to improving the supportive environment with a dedicated plan and resources to address needs and gaps in these enablers and foundations will promote the sustainable and effective use of geospatial data and technologies and the application of future geospatial innovations for immunization programs.

Discussion: Applying the Theory of Change

As more immunization programs begin to incorporate geospatial data and technologies to help achieve and measure improvements in equitable immunization service delivery, the *theory of change for the use of geospatial technologies for immunization programming* can guide discussions, decision-making, and consensus building for investment, development, and coordination. The theory of change represents a thought process aimed at understanding the underlying sequence of events that can contribute to sustained and effective improvements and should be considered a roadmap that is subject to change, improvements, and fine-tuning as more country-level experiences bring insights into best practices and real-world challenges. The three pillars and supportive foundations and enablers can help initiate conversations and identify needs and gaps in country immunization programs to make sound decisions for short-term and long-term planning and contribute to improving the broader health system through shared geospatial data, technologies, and resources.

The theory of change may also serve as a framework for operational research and evaluations by suggesting quantifiable

research objectives that will contribute to the evidence base and help clarify the relationships and determinants of effective application and use of geospatial data and technologies. The use of geospatial data and technologies within immunization programs can improve not only the systematic collection and use of quality and transparent data for programming but also for measuring improvements and incremental achievements throughout the project cycle.

The framework presented here is grounded in lessons from a handful of implementation experiences and existing evidence from the literature. As more countries gain practical experiences in integrating geospatial data and technologies into national immunization programs, best practices will suggest improvements to this theory of change and will help guide other programs on the incremental steps, foundations, planning, and budgeting recommendations that contribute to the sustainable integration of spatial data for immunization programming. A number of global and regional centers are developing and testing practical guidance and also providing technical support, resources, and training to help national programs apply geospatial data and technologies for immunization and other health systems [49,51,52].

Conclusions

Effective data use will be necessary to make additional gains in global immunization coverage. Technology can help improve the collection, visualization, and use of data to detect and address inequalities in coverage [8,38]. However, the quality and value of immunization data ultimately depends on the people who are collecting, analyzing, and using the data, not just the technology they are using [8]. Geospatial data and technologies are a means to an end. They can strengthen data-driven decision-making if they are aligned with immunization outcomes in ways that address program needs and reinforce people's confidence and trust in the resulting data products and analyses. Optimizing the deployment of immunization services to make them accessible for newly identified communities will pave the way for anchoring primary health care services in underserved areas. A focus on investing in and building sustainable and equitable health and immunization systems with strong leadership and capacity to use the geospatial tools and technologies that are appropriate for each country program will be critical for delivering life-saving vaccines to all children.

Acknowledgments

The authors thank the Monitoring and Evaluation team at the GAVI Secretariat and all the key informants for providing guidance on the original landscape and theory of change. Special thanks to Rocco Panceira at UNICEF for providing insights and suggestions on the manuscript. The research was supported by Gavi, the Vaccine Alliance (contract no. M&E88730520).

Authors' Contributions

SCC led landscape analysis, evidence review, cases study development, and primary author of paper. PM led framing and co-authoring of the landscape; led development of theory of change; and contributed to the structure, review, and revision of the manuscript. NMT provided content for the case study on Myanmar experiences and performed an overall review of the manuscript. MSD provided technical guidance and reviewed and revised the manuscript. CG provided guidance, framing, and input for the landscape and theory of change, as well as technical guidance, review, and revision of the manuscript.

Conflicts of Interest

None declared.

Abstract

Podcasts are increasingly being recognized as an effective platform to facilitate the continuous professional development (CPD) of health care professionals (HCPs). Compared with face-to-face meetings and other more traditional forms of CPD, podcasts allow for flexible learning and are less expensive to develop. Podcasts are at the cutting edge of digital education and can be an important element of a pharmaceutical company's multichannel communications plan to improve HCP engagement and CPD in specific therapy areas. However, developing a successful podcast can have significant challenges. In this viewpoint paper, we provide our perspectives on medical podcasts as a medium for educating HCPs in the digital age. We describe our experience in developing an HIV-focused podcast for Australian HCPs, creating a series that has now expanded to other therapy areas in several countries. Practical considerations and unique challenges associated with industry-sponsored podcasts are outlined. Overall, we believe that the process of developing a podcast can be a challenging but rewarding experience, and CPD delivered via podcasting should be more routinely considered by pharmaceutical companies.

Introduction

Podcasts have gained in popularity during the mid-2000s and are now widely available on the internet and on various on-demand channels [1]. Although many podcasts have been developed for entertainment, they are increasingly being used as a platform for medical education [2-5], and recent review articles have shown that a wide variety of medical podcasts covering numerous medical specialties are available [2,6,7]. Medical journals such as *The New England Journal of Medicine* [8] and *The Lancet* [9] are using podcasts to discuss contemporary topics in medicine, further supporting the idea that medical podcasts can supplement more traditional forms of learning, such as peer-reviewed journal articles.

This rise in the popularity of podcasts among the medical community is probably due to several factors. Podcasts allow for rapid dissemination of up-to-date data [10] and provide a range of perspectives to listeners (eg, patient perspectives). The availability of on-demand content helps listeners to learn on the go, which is especially important for busy health care professionals (HCPs) [10]. Unlike face-to-face lectures or congress presentations, podcasts avoid the need for and the expense of travel and give opportunities to HCPs from resource-limited settings to access new perspectives and data. Medical podcasts typically cater to a wide audience with different levels of knowledge (eg, clinicians, medical students, and other HCPs, nurses, pharmacists, and allied HCPs).

Medical podcasts can be grouped into two broad categories: industry-sponsored and general medical podcasts.

Industry-sponsored podcasts are developed by (or in collaboration with) pharmaceutical companies, are typically developed exclusively for the continuing professional development (CPD) of HCPs, and focus on a particular therapy area or product. General medical podcasts are often developed by individuals or medical societies for a wider audience (eg, medical students or the general public, as well as HCPs) and cover a wide range of topics [2].

We noted that there were very few digitally based CPD resources available circa 2018 for Australian HCPs who care for people living with HIV. In response, we launched *HIV in*

Podcast Australia, a podcast that provides the latest insights into HIV care from leading experts. *HIV in Podcast Australia* was initially hosted on a web-based platform exclusive to HCPs [11] and in July 2019, we launched a dedicated app to house the podcast. Since then, the series has expanded to include additional therapy areas and regions, and now comprises the following: *HIV in Podcast Australia*, *Hepatology in Podcast Australia*, *Virology in Podcast Nordics*, *HCV in Podcast Russia*, and *HIV in Podcast Russia* (Figure 1). As appropriate, content was tailored to region-specific health challenges. Apart from the 2 Russian series, all podcasts were recorded in English.

Figure 1. Overview of the *in Podcast* series and podcast metrics provided by the hosting platform. ^aAs of May 31, 2021. ^bAudio file download to app or live stream across series.

In this paper, based on our own experience with the *in Podcast* program, we describe practical considerations and challenges associated with developing, distributing, and measuring the success of industry-sponsored podcasts. Several guides on creating effective general medical podcasts have been published [12-15]. However, to the best of our knowledge, there are no publications that discuss the unique challenges associated with developing industry-sponsored podcasts. Overcoming some of these challenges could contribute to an increase in the use of this CPD tool for HCPs.

Practical Considerations for Industry-Sponsored Podcasts

To develop high-quality and engaging medical podcasts, a few basic elements are implicit. In short, these include the recruitment of a suitably qualified host with medical training

and therapy area experience, ideally with medical journalism experience. Equally, interviewees should be regional or international experts in their field and be able to discuss contemporary topics concisely. Podcasts should be “bite-sized,” with recommended lengths of 10-20 minutes [3], and recorded and produced by professional sound engineers.

In our experience, development of industry-sponsored podcasts often present other unique challenges and considerations, which we describe in further detail below.

Podcast Hosting Platforms

Podcast episodes need to be hosted on an appropriate digital platform for access by listeners [12]. A myriad of hosting options are available (eg, custom-built websites or apps and paid and free platforms) [12], and choosing a platform will depend on budgets, compliance requirements, and timelines. An ideal hosting platform should be secure and easy to use,

provide reliable and standardized metrics, and be adaptable for local and regional regulatory requirements regarding distribution of content to HCPs. In general, access to podcast episodes can be achieved via the webpage of the hosting platform or a dedicated mobile app. Such apps should be easy to download, have intuitive interfaces, be compatible with both Apple and Android operating systems, and allow download and storage of episodes for offline listening. Based on these considerations, we chose a specialist podcast hosting platform [16] for the *in Podcast* series that is free of charge to the end user, with an optional associated app to provide HCPs with the convenience of accessing content via their mobile device. The app is available in multiple languages (to mirror the podcasts). It is important to note that developing such an app requires significant investment, likely including partnering with companies or individuals with app development expertise.

Regulatory Considerations

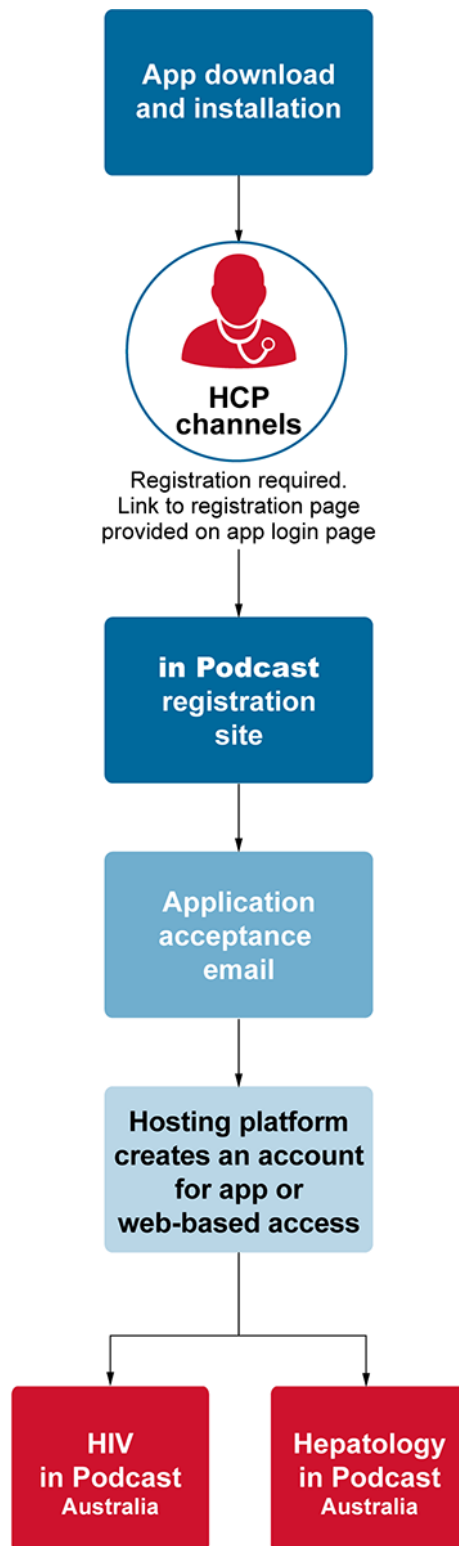

A challenge encountered with industry-sponsored podcasts is ensuring that the discussions related to medications or clinical practice are in line with the approved indication for that region, fair, balanced, and consistent with local and regional guidelines governing communication with HCPs. For example, guests might describe treatments that are not approved in the country where the podcast is released, or they might discuss data from studies of unlicensed uses for approved agents; thus, content could be deemed promotional or noncompliant with local guidelines [17,18]. Medical writers, together with regulatory personnel of the sponsor company, play an important role in managing content development. In the *in Podcast* program, the medical writing team were involved in all aspects of episode development, including podcast recording sessions, to ensure that discussions between the podcast host and guests were accurate and reflected the approved indications for any treatment discussed (“on label”). The medical writing team were also responsible for postrecording activities such as transcribing the

recording and ensuring that all scientific claims were supported by current evidence from peer-reviewed journal papers or government guidelines, with a reference list available for every podcast episode. We believe that medical writers play a crucial role, in partnership with the regulatory team, in ensuring that all podcast content is fair and balanced.

The *in Podcast* series has been launched across different regions; therefore, we had to ensure compliance with regulatory and privacy requirements for each of the relevant countries. The introduction of the European Union General Data Protection Regulation (GDPR) in 2018 implied ensuring the protection of personal data, privacy, and consent of podcast users. To achieve this, we engaged medical, regulatory, business compliance, and legal stakeholders in the region and therapy area when planning each series. Some hosting platforms collect personal data (eg, email addresses) for metrics analysis, so it is important to utilize a GDPR-compliant hosting platform.

In some countries, discussion or promotion of prescription medicines is only permitted among HCPs. As such, industry-sponsored podcast topics may only be appropriate for an HCP audience (eg, content that could be perceived as promotion of a pharmaceutical product to a non-HCP audience). To ensure that only HCPs could access the content, we created a registration webpage that allowed us to verify a user’s HCP status via their medical/professional registration numbers, or enabled the HCP to self-verify their status, depending on local regulatory requirements. Once a user’s HCP status is verified, they are sent detailed instructions on how to download the podcasting app, create a personal podcast account, and access episodes via the app or a web browser. A summary of the user registration process we used is shown in [Figure 2](#). Because HCPs register through a country-specific registration page, they are given access to content available in their region only. This system enables 1 platform and mobile app to be used across multiple regions.

Figure 2. Podcast registration flow for Australian HCPs accessing *HIV in Podcast Australia* or *Hepatology in Podcast Australia* episodes. Channel access is determined by geographical location upon registration, so that Australian HCPs will only have access to Australian channels. HCP: health care professional.

Accreditation of Podcasts

The credibility of industry-sponsored podcasts can be enhanced through accreditation by a professional body (a medical society or college), thereby allowing HCPs to use the podcasts for CPD. Medical practitioners registered with the Medical Board of Australia, for example, need to complete a minimum number of CPD hours that are relevant to their practice [19].

Accreditation of podcasts may thus help to increase their uptake by the target audience. To gain accreditation, podcast transcripts and supporting references for each episode of *HIV in Podcast Australia* were reviewed by the Australasian Society of HIV Medicine [20]. Users were encouraged to self-report their listening activity to Australasian Society of HIV Medicine to claim CPD points and maintain their registration as prescribers

of HIV treatment. It is important to note that the role of CPD points in continuing professional medical education and accreditation requirements varies across regions. The medical writing team plays an important role in ensuring that all podcast materials meet the accreditation standards of the relevant accrediting society.

Audience Recruitment

Recruiting an appropriate and sizable audience can be challenging. Promoting general medical podcasts typically involves the use of social media platforms (eg, blogs, Facebook, and Twitter) [13] or joining a podcast network [21]. However, if applied to industry-sponsored podcasts, this approach may be considered an untargeted promotional activity and tends to be avoided by pharmaceutical sponsors. Instead, we employed several focused strategies to increase the awareness of the podcasts among HCPs, including the use of hard copy and electronic mailouts to HCPs on subscriber lists provided by industry partners, publishing printed advertisements in peer-reviewed journals or scientific magazines, and conducting promotional activities at scientific meetings (setting up booths, handing out flyers, and conducting in-person registrations). We found that electronic mailouts reach a wider, more targeted audience than the other methods but may require the use of external platforms (eg, Mailchimp) or third parties (eg, advertising or event management agencies who have access to lists of potential subscribers). We found that an advantage of promoting podcasts at scientific meetings was that it provided us with opportunities to gain valuable feedback on the podcasts. We recommend that multichannel promotional strategies be used, if possible, to maximize podcast uptake.

Measuring the “Success” of Podcasts

Regularly measuring the uptake of podcasts by HCPs is essential for evaluating the performance of a podcast and can be an indicator of the success of the strategies used to attract listeners. The number of downloads is one of the most frequently used digital performance metrics [3], although other metrics are available (eg, the number of podcast users) [22]. At the time of writing (May 31, 2021), *HIV in Podcast Australia* had achieved the largest number of total downloads and unique users (993 downloads; 115 unique users) followed by *Hepatology in Podcast Australia* (608 downloads; 88 unique users; Figure 1). In Europe and Russia, *HIV in Podcast Russia* achieved the largest number of total downloads (455 downloads), whereas *HCV in Podcast Russia* had the highest number of unique users (52 users). Relative to the small number of unique users, the large number of downloads suggests that users likely downloaded multiple podcast episodes, which indicates continued engagement with content over time. In our experience, the number of downloads can be influenced by various factors including therapy area, size of the target audience, geographical region, and how readily the target audience can access the podcast. This makes direct comparisons of podcast performance difficult. For example, average monthly downloads for the *in Podcast* series, housed on our app in which HCPs must register to gain access, were between 56 downloads per month for *Hepatology in Podcast Australia* and 11 downloads per month for *Virology in Podcast Nordics* (Figure 1). In contrast, publicly

available medical podcasts have been reported to achieve between 217 and 10,000 downloads per month [10,23,24]. Comparisons with other industry-sponsored podcasts are challenging owing to a lack of published data.

Another important consideration is that download metrics provided by GDPR-compliant hosting platforms contain anonymized user identifications. This makes it difficult to profile podcast users by HCP type (eg, proportion of physicians vs nurses), which may be of specific interest to the sponsor. Additional qualitative measures of success may therefore add value. For example, short surveys can be included in electronic mailouts or conducted via face-to-face interviews with the target audience [10]. These qualitative data can be used to understand if, and the extent to which, listeners are enjoying the series and whether it may be changing their clinical practice. Additionally, podcast performance metrics should be codeveloped with industry partners and realistic goals set for measuring “success” (eg, a prespecified proportion of licensed prescribers within a therapy area in 1 country). We believe that combining both quantitative and qualitative metrics provides more holistic insights into the overall performance of the podcast.

Viewpoint

There is a growing interest from the pharmaceutical industry to invest in digital innovation, such as podcasts, to increase awareness of diseases, clinical practice updates, and available therapies. At present, most medical podcasts have been created by individuals and academic societies rather than pharmaceutical companies. Medical podcasts are an important medium for delivering specific and targeted CPD to HCPs and could be considered more routinely by the pharmaceutical industry as part of multichannel communication plans to improve HCP engagement and education. However, very little published information is available on the considerations and challenges associated with creating industry-sponsored podcasts.

In our opinion, one key challenge is the limitation around granular metrics data on industry-sponsored podcasts, making it difficult to demonstrate a return on investment. Close collaboration with industry partners will be needed to define the target audience and to help ensure that meaningful metrics are collected. The inclusion of qualitative measures (eg, user surveys) is also recommended to determine if podcast uptake is associated with changes in clinical practice.

The requirement for users to register and be verified as HCPs before being able to access the podcasts may also be a significant “digital barrier” to the uptake of industry-sponsored podcasts. We suspect that multistep registration processes (Figure 2) and the need to create a personal podcast account may act as a deterrent for busy HCPs to quickly access podcast content. However, these are necessary steps from an industry compliance perspective in many jurisdictions. Possible options for overcoming this challenge could include setting up preregistrations and involving medical science liaison officers of companies to help users with the registration process. If regulations allow, creating podcast apps that support single-click access from an invitation email for HCPs who have been preregistered and verified could reduce the steps required for

authentication and prevent possible “password fatigue,” which may result from users needing to manage multiple passwords and accounts.

Overcoming these barriers could help increase the use of this flexible and versatile educational platform among the medical community. Indeed, recent innovations have highlighted that podcasting will be an important medium for educating HCPs in the future. For example, several Adis-affiliated journals allow the publication of peer-reviewed podcast articles on clinically-relevant topics (eg, conference data, treatment innovations, and expert opinions on drugs and disease therapies) [25]. We believe that the challenges and potential solutions we have outlined are not only relevant for podcasting but also broadly applicable to the various forms of industry-sponsored

digital education (eg, webinars and education modules) that are increasingly being used.

Conclusions

Podcasting is a novel method for delivering medical education and can be a suitable alternative to traditional face-to-face and print-based education and incorporated into CPD programs. Careful planning is needed to ensure the success of industry-sponsored podcasts. With further uptake and optimization of this form of medical education, industry-sponsored podcasts may play an important role in shaping change in clinical practice and improving patient care in the future.

Acknowledgments

We thank the members of the *in Podcast* team at Oxford PharmaGenesis (Vanessa Bateman, Lucy Eberhard, Robert Goodwin, Cara Kingston, Svetha Sankar, Tanya Stezhka, and Vanessa Wielgosz) and Gilead Sciences (Hassan Aladdin, Mike Elliott, Damien Fagan, Aurelie Freismuth, Janniche Hammer, Geraldine Reilly, Natalia Tikhonova, and Tatiana Usacheva) for their contributions to the series. We also thank the speakers and series hosts for contributing to the podcasts, especially Dr Brad McKay at East Sydney Doctors (Sydney, New South Wales, Australia), for playing a key role in the development and success of the inaugural *HIV in Podcast* Australia series. We are also grateful to Svetha Sankar for critical review of this manuscript.

Conflicts of Interest

JN is an employee of Gilead Sciences. JB, SI, AL, and KS are employees of Oxford PharmaGenesis, which has received funding to support development of the *in Podcast* series and this article, from Gilead Sciences.

Abstract

Background: Providing patient-centered fertility care is known to improve quality of life and can reduce anxiety and depression. In a previous study, we established the need for a web-based app providing personalized information and interactive functionalities among couples undergoing intracytoplasmic sperm injection with surgically retrieved sperm.

Objective: This study aimed to design, develop, and qualitatively evaluate a multifaceted web-based app for infertile couples undergoing intracytoplasmic sperm injection with surgically retrieved sperm during their treatment trajectory.

Methods: The web-based app was developed in three phases: (1) we established a patient-centered functional design, (2) developed the app in collaboration with medical and technical professionals, and (3) qualitatively evaluated the app among couples using a think-aloud method.

Results: The basis of the app is the couple's visualized treatment trajectory. The app provides personalized and interactive functionalities; for example, customized information and communication options. During qualitative evaluation, myFertiCare was highly appreciated and received a median score of 8 out of 10. The main improvements made upon conclusion of the think-aloud sessions were related to faster login and easier app navigation.

Conclusions: A patient-centered web-based app aimed at guiding couples through their fertility treatment course was systematically designed, developed, and positively evaluated by patients and medical and technical professionals.

Introduction

According to the Institute of Medicine, health care should be safe, effective, timely, efficient, equitable, and patient-centered [1]. Patient-centeredness is described as “providing care respectful of and responsive to individual patient preferences, needs and values, and ensuring that patient values guide all clinical decisions” [1]. Providing patient-centered fertility care

can improve quality of life and can reduce anxiety and depression [2]. It has been reported that patient-centeredness in fertility care needs improvement [3,4]. Crucial aspects of patient-centeredness in fertility care are provision of adequate information, continuity of care, and active involvement of patients in their treatment course [5-8]. The internet is known to be an important source of information and support for infertile couples [9-11]. A possible instrument for improving

patient-centeredness is the use of eHealth tools; that is, web-based apps in health care [12]. Previous eHealth initiatives in fertility care aimed mainly at information provision, support, and mental health promotion [13]. These initiatives only contained few interactive web-based components. Aarts et al [13] concluded that these initiatives could be improved by including more interactive and dynamic elements as their key components. Infertile couples are known to specifically prefer personalized information and appreciate being able to communicate with both their treatment team and fellow patients [3,10]. eHealth tools are a promising strategy to empower patients in managing their own treatment trajectory.

In a previous study [14], we established the need for a web-based app providing personalized information and interactive functionalities among couples undergoing intracytoplasmic sperm injection (ICSI) with surgically retrieved sperm. We hypothesized that a web-based app is specifically suitable for this group of patients because of the psychological and physical burden of the multidisciplinary treatment on both partners. Therefore, the aim of this study was to design, develop, and qualitatively evaluate a multifaceted web-based app for use by couples undergoing ICSI with surgically retrieved sperm during their treatment trajectory.

Methods

Systematic Approach

myFertiCare was developed in three phases: (1) we established a patient-centered, functional design for the app; (2) developed myFertiCare in collaboration with medical and technical professionals; and (3) had myFertiCare qualitatively evaluated for usability, with a think-aloud method.

Phase 1: Establishment of a Patient-Centered Functional Design

The functional design of myFertiCare is based on (1) literature review; (2) interviews with an expert panel comprising a gynecologist, a urologist, an embryologist, an expert in patient-centered innovation, and a board member of Freya, the Dutch association for infertility problems; and (3) interviews with a patient panel. This was part of our previous study [14] on the informational needs of couples undergoing ICSI with surgical sperm retrieval. The patient panel consisted of 11 couples, a number that was determined through data saturation. We conducted semistructured interviews with each couple individually. The data were analyzed using a constant comparative method. The functional design that followed from this process was verified by the clinic's fertility treatment team and supplemented with their suggestions. Both the expert and the patient panels were enthusiastic about the idea of a web-based app to guide couples through their treatment trajectory. The overall opinion was that the more functionalities an app provides, the better the app, so that people are motivated to use it. The participants specifically valued personalized and interactive functionalities. Various functionalities were suggested, such as being able to view appointments, test results, and information about lifestyle advice; information about the clinic's fertility treatment team; and communication with

physicians and peers. The interviewees also highlighted the safeguarding of confidential information, which they stated should be at the core of app development [14].

Phase 2: Development of myFertiCare

Based on the preferences of the expert and the patient panels, myFertiCare was developed in close collaboration with medical professionals from the department of Reproductive Medicine, Radboud University Medical Center (RUMC), and technical experts from a Dutch company specializing in eHealth. Together, they formed the project team. Development was an iterative process. The desired functionalities of myFertiCare were categorized by the medical professionals as must-have functionalities that had to be available before the app could be made available on the internet, or as nice-to-have functionalities that could be developed later. Subsequently, the must-have functionalities were developed by the technical experts and tested in a test environment by both the technical experts and the medical professionals. Technical adjustments were made as necessary, and the testing cycle was started over again. Once all the must-have functionalities were developed and tested by the technical and medical experts, myFertiCare was made available through the hospital website, the App Store, and Google Play Store to couples undergoing ICSI with surgical sperm retrieval. myFertiCare was also incorporated in the existing hospital information systems. After the app was live, all the nice-to-have functionalities were developed through the same development cycle. After each functionality was iteratively developed and tested, it was immediately made available to all myFertiCare users. The duration of the whole development trajectory was approximately 1.5 years.

Phase 3: Qualitative Evaluation of myFertiCare for Usability Through the Think-Aloud Method

After all the must-have and nice-to-have functionalities were implemented, we began the qualitative evaluation of myFertiCare. In total, 21 couples, who consecutively visited the fertility clinic, were invited by their physicians to participate in the think-aloud sessions. Six couples agreed to participate, which accounted for 9 participants (4 men and 5 women) (Tables 1 and 2). Reasons for nonparticipation were being too busy, already having too much going on, or simply not wanting to participate. Think-aloud is a research method in which participants verbalize their thought processes while interacting with a tool [15]. It provides a valid source of data about participants' thought processes and can be used effectively in qualitative studies [15]. Our aim was to identify usability flaws and to provide suggestions for design modification.

The participants were individually provided with 16 tasks to perform using myFertiCare while thinking out loud (Figure 1). Of these tasks, 11 were the same for every participant and 5 focused on the specific phase of treatment that an individual was in. By completing these tasks, the participants explored all the functionalities of myFertiCare. The researcher observed the participants and asked questions for clarification where needed. The researcher took notes, also focusing on nonverbal communication of participants. In addition, the sessions were audio-taped. After completing each task, the participants answered 3 task-linked questions ("I find this task easy," "I find

this information useful,” and “I find this information is in a logical spot”) with a 5-point Likert scale to rate responses. They could also add free comments.

Immediately after each think-aloud session, the participants completed a self-developed questionnaire on their experiences using myFertiCare (Figure 2). The questions were about

participants’ attitudes toward usability, privacy, understandability of information, and the usefulness of various functionalities of myFertiCare. The questionnaire consisted of 20 questions: 17 with responses rated on a 5-point Likert scale, 2 to be answered with “yes” or “no,” and 1 open question. Again, the participants could also write free comments.

Table 1. Demographic characteristics of the study participants (N=9).

Characteristic	Men (n=4)	Women (n=5)
Age (years), median (range)	33 (27-47)	30 (28-36)
Daily internet usage in a private setting (minutes), median (range)	60 (45-60)	90 (60-180)
Treatment-related use of the internet, n	3	5
Use of myFertiCare prior to the think-aloud session, n	1	2
Educational status,^a n		
Low	0	0
Medium	1	2
High	3	3
Ethnic background, n		
Caucasian	3	4
Non-Caucasian ^b	1	1
Those who already have children, n		
Yes	0	0
No	4	5

^aLow educational status includes no education and lower general secondary education. Medium educational status includes higher general secondary education and intermediate vocational education. High educational status includes higher vocational education and a university degree.

^bOne man from Indonesia and 1 woman from Suriname.

Table 2. Demographic characteristics of the couples who participated in the study (N=6).

Characteristic	Couples
Socioeconomic status,^a n	
Low	3
Medium	3
High	0
Stage of treatment, n	
Before surgical sperm retrieval	1
After surgical sperm retrieval and before ICSI ^b	2
During first ICSI cycle	2
After at least one full ICSI cycle	1
Duration of infertility (months), median (range)	28 (16-47)

^aAccording to the Dutch Social and Cultural Planning Office: Low socioeconomic status included a status score of ≤ -1 ; medium socioeconomic status included a status score between -1 and $+1$; high socioeconomic status included a status score of >1 .

^bICSI: intracytoplasmic sperm injection.

Figure 1. Results obtained from think-aloud sessions.

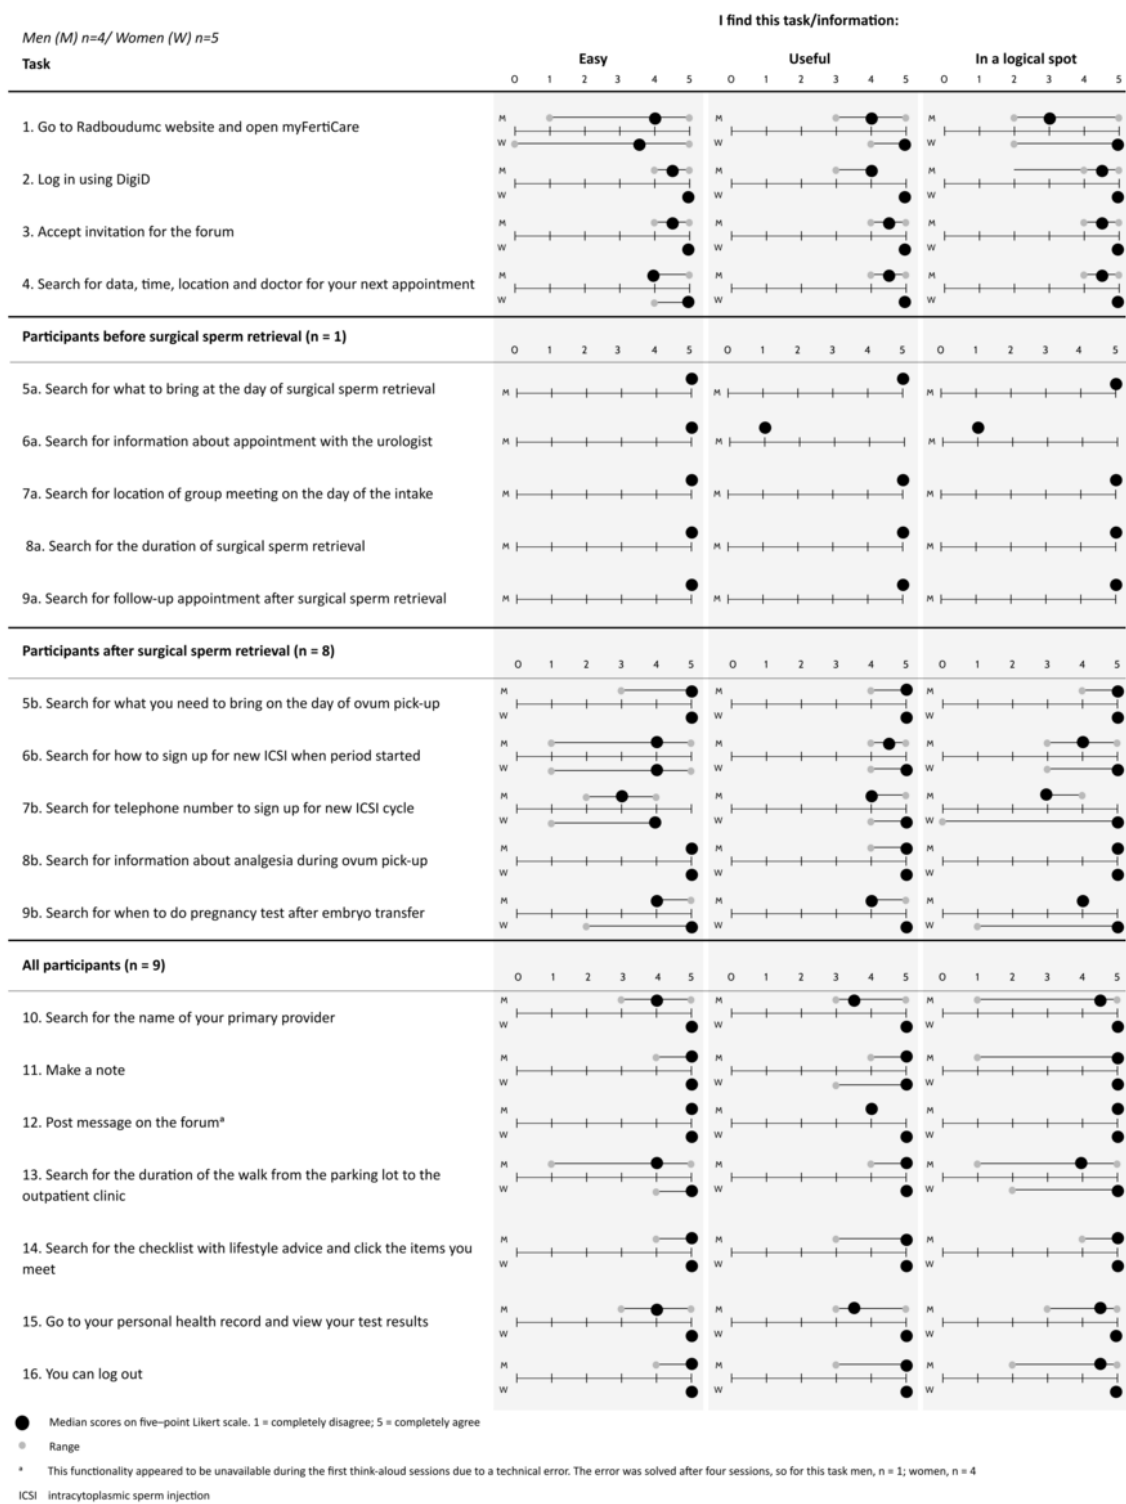

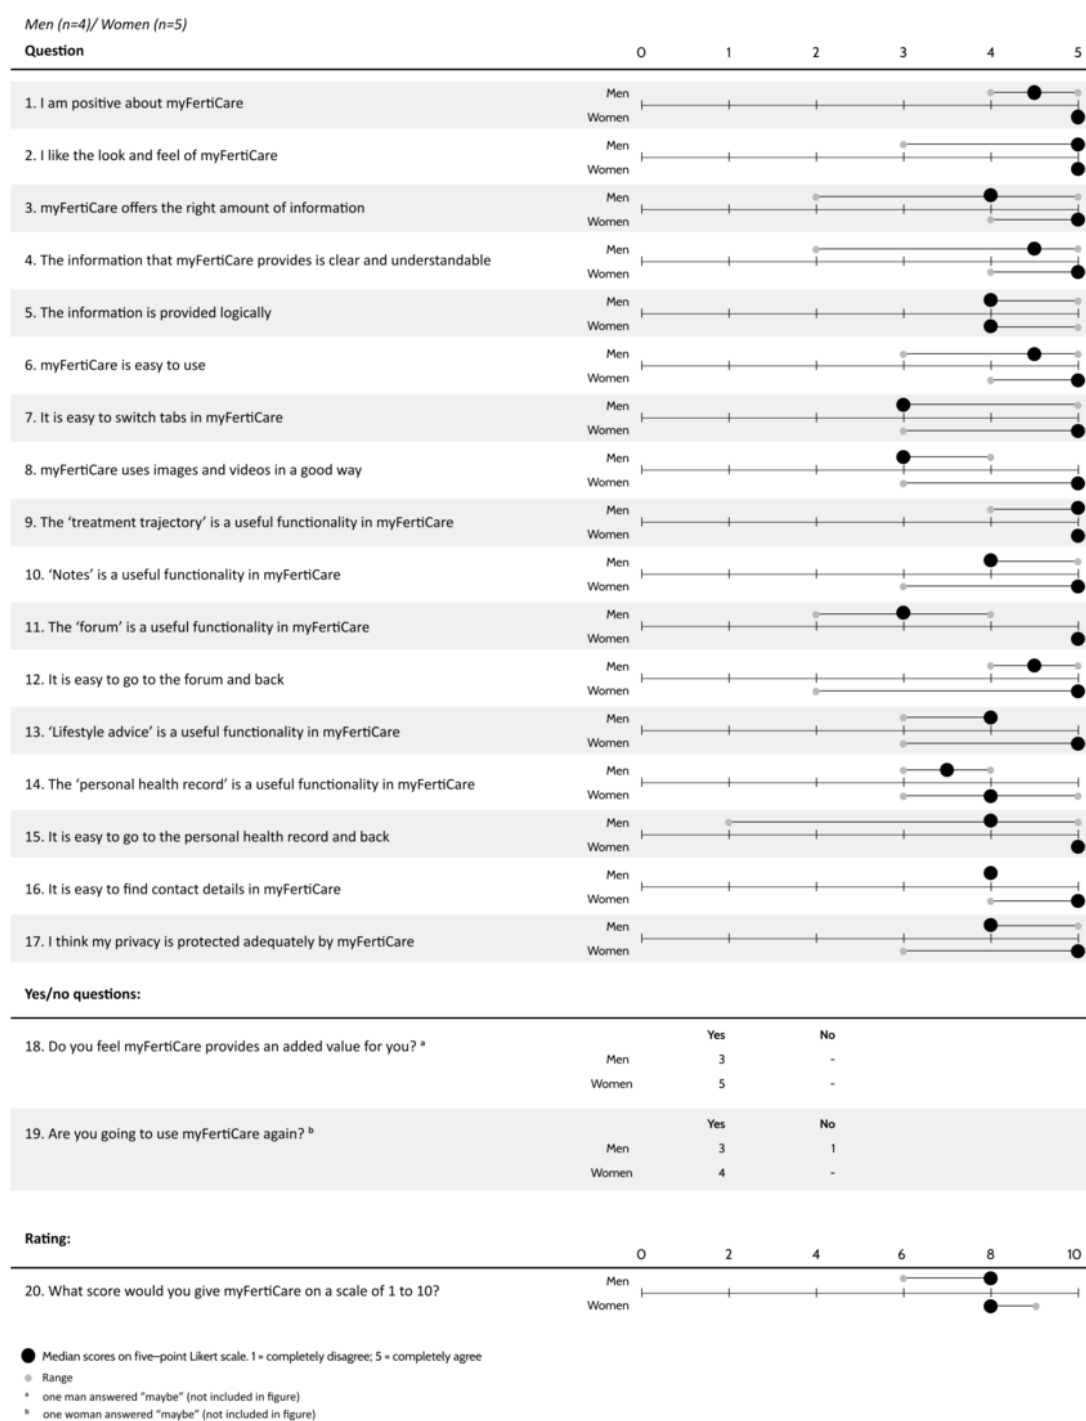

Figure 2. Results obtained from the questionnaire on users' experience with myFertiCare.

The think-aloud sessions were conducted until saturation was reached. The duration of a session was approximately 15 to 20 minutes. The audio-taped sessions were transcribed verbatim. Data were analyzed anonymously. An open coding method was applied. We coded quotes that identified usability flaws or provided suggestions for modification of the app's design. A second researcher verified the coding process. Differences were discussed until consensus was reached. Ethical approval was proposed but was not required according to the local research ethics committee (CMO Arnhem Nijmegen, file# 2016-2485). All participants provided written informed consent.

Results

Phases 1 and 2: Design and Development of myFertiCare

Based on the results of phase 1 [14], myFertiCare was developed as a web-based app available on the RUMC website, Google Play Store, and Apple App Store for couples undergoing ICSI with surgical sperm retrieval at the RUMC. Patients log in using their digital identity (DigiD), which is provided by the government of the Netherlands to assure safe access to all

governmental institutions. This guarantees the safety of couples' medical data. The apps of both partners are synchronized, so that individuals can also see their spouse's information.

myFertiCare is free for use and is offered in addition to usual care. A screenshot of the app is provided in Figure 3.

Figure 3. Screenshot of the myFertiCare app.

myFertiCare contains personalized and interactive functionalities that are divided over 5 tabs:

1. Treatment trajectory: this is the basis of the app. The treatment trajectory is visualized as a subway map in which every stop stands for one of the appointments a couple must have in order to move forward. Couples can see their past appointments and future scheduled appointments with the corresponding data, time, physician, and location, but they can also see future appointments that are not scheduled yet. Thus, couples are better prepared for the upcoming trajectory and know what to expect. Each stop on the subway map provides information about the specific phase of the treatment trajectory and provides advice on how to prepare for the appointment, and, if applicable, informs them of anything they should bring with them for the appointment. Furthermore, users receive support messages before or after certain appointments to comfort them or provide some advice. These support messages are sent via the app or via text message.
2. Notes: users can write notes that are synchronized with their spouse's notes. For example, couples can compose a topic list with questions they want to ask during their upcoming physician's appointment.
3. Care providers: an overview of the whole treatment team is provided through photographs, with an individual's primary care provider on top. Users can ask medical questions to the treatment team, and they are answered within 24 hours.
4. Forum: patients can communicate with peers on the forum. The forum is supervised by a clinician.
5. Lifestyle advice: this is provided as separate checklists for men and women. The aim is to improve treatment outcomes; that is, to improve the chance of retrieving semen through

percutaneous epididymal sperm extraction or testicular sperm extraction and concomitantly the probability of conception. Users can click the boxes of the checklist, which are also synchronized with those of their partner.

In addition to the 5 tabs, myFertiCare provides a main menu with general information (eg, contact details and app settings) and a link to the user's personal health record. In the personal health record, users can see their own test results and read the correspondence between their primary care provider and their family physician.

Finally, for couples who are not yet being treated at RUMC and thus do not have login details, a preview version of myFertiCare is available. In this version, they can view the general treatment trajectory and consult the checklist with lifestyle advice. Thus, they can prepare themselves for their intake appointment.

Phase 3: Qualitative Evaluation of myFertiCare for Usability With the Think-Aloud Method

The think-aloud sessions yielded both positive and negative feedback. Given the aim of the study, we focused on opportunities to improve the app. As described earlier, every participant completed 16 tasks (11 generic and 5 personalized). This resulted in 21 different tasks. After each task, the participants answered 3 task-linked questions ("I find this task easy," "I find this information useful," "I find this information is in a logical spot") on a 5-point Likert scale (1="totally disagree," 5="totally agree"). Figure 1 shows a summary of the results. In general, participants considered the tasks (ie, the functionalities that myFertiCare provides) easy and useful. They also considered that the information was provided logically.

Although the scores for all tasks were high, the participants named some discomforts and suggestions for improving the app

design. They commented that logging in with their DigiD was too cumbersome, since it consists of a username, password, and verification via text message. It was also noted that moving along the visualized treatment trajectory was difficult. The participants attempted to slide through the treatment trajectory, which was not possible. Instead, they had to click on stops to move to this specific stop. Furthermore, they noticed that the app did not open with the most recent appointment, which was the mode they preferred. When using the forum, participants regretted that they could not delete an erroneous message they had posted. Finally, participants expressed the need for a home button to lead them to the home screen of the app.

At the end of each think-aloud session, the participants completed a questionnaire about their experience using myFertiCare. Figure 2 shows a summary of the results. The participants allocated high scores to all surveyed items that related to usability, understandability of information, the usefulness of various functionalities, and privacy. The men were consistently slightly more critical than the women. The space for writing free comments revealed no additional information. All participants felt that myFertiCare provides an added value to them. All but 1 participant intended to use myFertiCare in the future. In conclusion, myFertiCare was rated 8 out of 10 (Figure 2).

Guided by the think-aloud sessions, we made various improvements in app design. We made it possible for myFertiCare users to create a 4-digit entry code after the first login with DigiD, so that fast but equally safe access was enabled for future use. Furthermore, opening myFertiCare with the most recent appointment was made possible, while proceeding through the treatment trajectory. We added an option to remove a message from the forum after it has been posted as well. A home button was incorporated, which leads users to the app's home screen.

Discussion

Principal Findings

We designed, developed, and qualitatively evaluated an eHealth app for fertility care in accordance with a methodological framework, based on couples' information needs and input provided by health care providers. The basis of the app is the visualized treatment trajectory. The app provides both personalized and interactive functionalities, including customized information and communication options. On thorough qualitative evaluation, myFertiCare received high usability ratings. The participants felt that myFertiCare provides an added value during their treatment. The app was rated with a median score of 8 out of 10. The most important improvements after the think-aloud sessions were related to faster login and easier navigation through the app.

A large part of research in fertility care is aimed at the female partner. We chose to include both partners when developing the app, since it is recognized that men should have a well-defined role as an equal partner during fertility treatment, particularly in cases of male infertility [16]. A previous study by Sylvest et al [11] reported that men registered a marked time

lag between diagnosis and treatment initiation. They felt "they were in a maze without a map" and expressed the need for detailed information about the treatment plan, including a timetable, so that they could control and manage their lives [11]. With a visualized treatment trajectory as the basis of myFertiCare, we aimed to meet this need and guide couples through their entire treatment trajectory. In our opinion, patient satisfaction with information provided by the clinic is an important indicator of the quality of fertility care, although in fertility care, the focus is often on live birth rates. Alper et al [17] further endorsed this idea.

There is literature available on eHealth initiatives in fertility care [13], primarily on online support groups. In general, there is a lack of initiatives that provide interactive and dynamic elements, and there is a lack of methodological standards for these complex interventions [13]. There has been 1 web-based initiative that provides both information and peer support, which showed high patient appreciation [18]. Furthermore, a web-based community has been reported in which couples could communicate and share information with professionals and peers [19].

Compared to previous initiatives, a strength of myFertiCare is that it provides a large variety of personalized and interactive functionalities centered around the visualized treatment trajectory of the couple. Another methodological strength of our study is its 3-phase systematic approach: first, a functional design for the app was developed through a qualitative assessment of the informational needs of patients; second, myFertiCare was actually developed; and third, myFertiCare was qualitatively evaluated for usability through the think-aloud method. All 3 phases were carried out in collaboration with patients and medical and technical professionals, which is important for successful eHealth development and implementation [20]. Our qualitative evaluation of myFertiCare for usability is crucial since usability evaluations are critical to the success of adopting an interactive eHealth app [20,21]. The think-aloud method is preferred for uncovering usability problems, and it provides understanding of how users interact with myFertiCare [22]. Furthermore, the think-aloud method is especially suitable since we used both a concurrent method (ie, while performing the task) and a retrospective method (ie, immediately after performing the task) to report participants' thinking, a method that has been suggested for producing optimal data quality [23].

Limitations

Our study also has some limitations. It could be argued that the study population for the think-aloud sessions was relatively small. However, studies have shown that for a think-aloud test, 5 participants are enough for success in identifying usability problems in a user interface [24]. Since we included 9 participants and achieved data saturation, we are confident that we have identified all the possible usability problems. Furthermore, it is known to be a challenge for a researcher to remain consistent when it is necessary to intervene in a think-aloud session; for example, when a participant is unable to complete a task, clarification on a participant's comment is required, or a participant sidesteps the functionality of interest

[25]. In these situations, it is important to explain to a participant that it is the aim of the study to identify problems and to invite them to approach the problem otherwise. It has been reported that researchers often unintentionally intervene in theoretically inconsistent ways [25]. We made a conscious effort to achieve a reliable data set by being aware of these limitations and through triangulation of research methods (namely the think-aloud, task-linked questions, and researcher's observations) and the recording, transcribing, and coding of the interviews.

Practical Implications

This study provides a framework for patient-centered design, development, and evaluation of an eHealth app. Our systematic approach, in which patients and professionals participated in every phase of the process, is particularly suitable in the current era where patient-centeredness is highly valued. Furthermore, we obtained insight into the various functionalities that patients appreciate in a web-based app. The framework we developed for myFertiCare supports professionals in fertility care for

guiding patients through their treatment trajectory and delivering patient-centered care. In the near future, myFertiCare will also be evaluated quantitatively. Expansion of eHealth tools to cover the whole fertility care journey and expansion to other medical disciplines is considered of high value. Development of eHealth tools from a patient's viewpoint is an opportunity to empower patients in managing their own treatment trajectories in the current era of patient-centered care.

Conclusions

We designed, developed, and qualitatively evaluated a multifaceted web-based app, myFertiCare, through a systematic approach in which patients and medical and technical professionals participated in every phase. This app aims to guide couples undergoing ICSI with surgically retrieved sperm through their treatment trajectory. myFertiCare provides personalized and interactive functionalities, facilitating the provision of patient-centered care and empowering patients to manage their own treatment trajectory. The app had a high usability rating and was highly appreciated by both male and female partners.

Acknowledgments

The authors wish to thank all study participants and the medical and technical experts, who contributed to the development and evaluation of myFertiCare. This study did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Authors' Contributions

All authors contributed to the design of the study. EMS performed data collection and analysis, which was supervised by WLDMN and KF. EMS drafted the manuscript. All authors critically revised the manuscript and approved the final version for submission for publication.

Abstract

Background: The *Cracks in the Ice* (CITI) community toolkit was developed to provide evidence-based, up-to-date information and resources about crystal methamphetamine to Australians. Given the high rates of internet use in the community and the potential for misinformation, CITI has the potential to play an important role in improving knowledge and challenging misconceptions surrounding crystal methamphetamine.

Objective: This study aims to determine (1) whether the CITI toolkit is achieving its aim of disseminating evidence-based information and resources to people who use crystal methamphetamine, their family and friends, health professionals, and the general community and (2) examine the association between the use of CITI and the knowledge and attitudes about crystal methamphetamine.

Methods: A cross-sectional web-based survey, open to Australian residents (aged ≥ 18 years), was conducted from November 2018 to March 2019. People who had previously visited the website (referred to as “website visitors” in this study) and those who had not (“naïve”) were recruited. At baseline, knowledge, attitudes, and demographics were assessed. CITI website visitors then completed a series of site evaluation questions, including the System Usability Scale (SUS), and naïve participants were asked to undertake a guided site tour of a replicated version of the site before completing the evaluation questions and repeating knowledge and attitude scales.

Results: Of a total 2108 participants, 564 (26.7%) reported lifetime use of crystal methamphetamine, 434 (20.6%) were family/friends, 288 (13.7%) were health professionals, and 822 (38.9%) were community members. The average SUS score was 73.49 (SD 13.30), indicating good site usability. Health professionals reported significantly higher SUS scores than community members ($P=.02$) and people who used crystal methamphetamine ($P<.001$). Website visitors had significantly higher baseline knowledge than naïve participants ($P<.001$). Among naïve participants, knowledge scores increased following exposure to the website (mean 15.2, SE 0.05) compared to baseline (mean 14.4, SE 0.05; $P<.001$). The largest shifts in knowledge were observed for items related to prevalence, legal issues, and the effects of the drug. Stigmatizing attitude scores among the naïve group were significantly lower following exposure to CITI (mean 41.97, SE 0.21) compared to baseline (mean 44.3, SE 0.21; $P<.001$).

Conclusions: This study provides an innovative evaluation of a national eHealth resource. CITI is achieving its aim of disseminating evidence-based, nonstigmatizing, and useful information and resources about crystal methamphetamine to key end user groups and has received good usability scores across its target groups. Interaction with CITI led to immediate improvements in knowledge about crystal methamphetamine and a decrease in stigmatizing attitudes. CITI demonstrates the important role of digital information and support platforms for translating evidence into practice and improving knowledge and reducing stigma.

Introduction

Background

Internationally, there continues to be a widespread concern about the use of methamphetamine, particularly with respect to the most potent form, crystal methamphetamine. Crystal methamphetamine produces stronger and longer-lasting effects than other forms of methamphetamine, thereby increasing the risk of serious long-term health issues, including dependence [1,2]. The use of crystal methamphetamine has been associated with considerable harms not only in individuals who use the drug but also in their families and communities [3]. Crystal methamphetamine has attracted a high level of negative attention compared with other drugs, particularly in Australia. In the 2019 National Drug Strategy Household Survey, the Australian community ranked meth/amphetamines as the drug of most serious concern and the drug most likely to be associated with a *drug problem* [4]. Its public ranking overtook alcohol in 2016 for the first time in the history of the survey [5]. Concerningly, crystal methamphetamine use has been frequently labeled as a national *crisis* or *epidemic*, with people who use crystal methamphetamine being negatively stereotyped in the media and being framed as criminal, deviant, or dangerous [6]. This is despite the prevalence of methamphetamine use being low, with only 1% of Australians reporting use in the previous 12 months [4].

In response to growing concern and negative attention around the drug, the Australian Government's Department of Health funded the development of the *Cracks in the Ice* (CITI) community toolkit as an easily accessible, evidence-based, and up-to-date information resource [7]. The website was launched in 2017 and includes information about the prevalence, effects of the drug, treatment options, and support programs as well as tailored resources for families or friends, health professionals, and the community. The codevelopment process of CITI was broad-reaching and iterative, with the involvement of more than 450 community members across Australia (all states and territories), including people with lived experience, their families and friends, health professionals, and researchers [8]. CITI currently has 107 resources including factsheets, guidelines, animations or videos, and training and support programs and has reached more than 625,000 unique end users from across the globe (70% from Australia) with more than 1.2 million page views (Google Analytics as of March 22, 2021) and 2 national awards (Rotary Health Australia, 2017; The Mental Health Services Learning Network, 2020). A companion smartphone app, which allows users to access content offline, was launched in January 2018 to extend the reach and engagement of the toolkit, particularly for people in areas where internet access may be unreliable (ie, remote or regional areas) [9]. This is essential in a geographically diverse country such as Australia,

where several data sources have indicated that the use of methamphetamine is higher, access to face-to-face services is lower, and unreliable internet connections are more common in regional and remote areas than in urban areas [10-12].

The internet has become a leading source of health information for the public, with eHealth platforms such as CITI offering a high level of accessibility and potential reach [13]. eHealth programs and websites have demonstrated an increase in empowerment and knowledge among health seekers on the internet [14] along with improved quality of care through the translation of evidence-based research into practice [15,16]. In Australia, it is estimated that 86.5% of the population are internet users, and 80% of Australians reported using the internet to search for health information in 2019 [17]. Indeed, during the development of CITI, the most commonly endorsed reasons given by participants for visiting a website about crystal methamphetamine were to "seek information for myself" (41.0%) and "to find out how to get help for a friend or a family member" (30.2%) [8]. However, there are risks associated with using the internet as a source of information, with many websites containing low-quality, irrelevant, inaccurate, or inappropriate health information [18,19]. Thus, a rigorous methodology is needed for both the development and evaluation of websites and eHealth resources. However, a recent systematic review found that although there are many toolkits for digital health, evaluations of these toolkits are uncommon [20]. This study aims to fill this gap. This evaluation is also one of the first to examine the relationship between knowledge and its impact on attitudes, an element not often looked at in website evaluations.

Given the large proportion of Australians who use the internet, the potential for misinformation, and the high level of interest in crystal methamphetamine use, initiatives such as CITI play an important role in not only disseminating accurate evidence-based information but also reducing the stigma and discrimination surrounding crystal methamphetamine use. Recent research by our team indicates that stigma toward people who use crystal methamphetamine is common in Australia, with 1 in 3 people who use crystal methamphetamine reporting that they have been discriminated against because of their drug use [21]. Stigma is a source of immense psychological distress and has been associated with feelings of self-blame, low self-worth, shame, and higher rates of drug dependence and lower rates of treatment seeking for substance use problems and other health conditions such as mental illness, trauma, and infections [22-24]. Importantly, our previous study also demonstrated that higher levels of accurate knowledge about crystal methamphetamine were associated with less stigmatizing attitudes [21]. Thus, by improving knowledge about crystal methamphetamine, CITI has the potential to influence public attitudes toward those affected by the drug and support people to seek help when they need it (Figure 1).

Figure 1. Proposed conceptual model of how providing evidence-based information can lead to increased knowledge and decreased stigma and ultimately improve help-seeking behaviors among people who use crystal methamphetamine.

Objectives

This study presents a large community evaluation of an innovative centralized eHealth resource for evidence-based information and resources on crystal methamphetamine. The aims of this study were to (1) determine whether the CITI toolkit is achieving its aim of disseminating evidence-based, nonstigmatizing, and useful information and resources about crystal methamphetamine to key end user groups (people who use crystal methamphetamine, affected family members and friends, health professionals, and the general Australian community) and (2) examine the association between the use of CITI and improvements in knowledge and attitudes about crystal methamphetamine and harms.

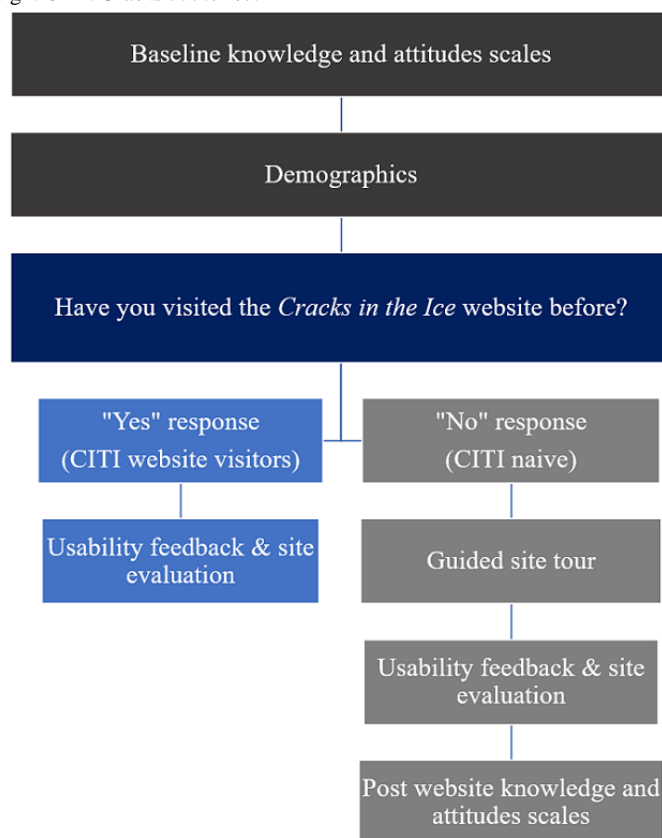

Methods

Design and Procedure

Between November 2018 and March 2019, participants were recruited via convenience sampling methods, including advertising on the CITI website, Facebook page, Twitter page, e-newsletter, and through paid public advertising on Facebook. The eligible participants provided informed consent before completing a web-based cross-sectional survey that was open to all Australian residents aged ≥ 18 years. At the end of the survey, all participants were given the opportunity to provide their email address to enter a draw to win an Apple iPad. Ethics

approval was obtained from the University of New South Wales (HC# HC180735) and the University of Sydney (Project 2018/844) human research ethics committees.

To address both aims of the study, people who had previously visited the website (CITI website visitors) and people who had not previously visited the website (CITI naïve) were recruited (Figure 2). At baseline, all participants completed a series of knowledge and attitude scales, along with standard demographic questions. Participants were then divided into 2 groups depending on their answer to the question “Have you visited the CITI website before?” (yes, no, or unsure). CITI website visitors completed a series of site evaluation questions, whereas CITI-naïve participants were asked to undertake a guided site tour of a replicated version of the live CITI site before completing the site evaluation questions and repeating the knowledge and attitude scales. This methodology permitted the assessment of any change in these constructs associated with viewing the website. As a part of the guided site tour, CITI-naïve participants were encouraged to view the homepage and key webpages featuring content on the prevalence and physical and mental health effects of crystal methamphetamine use along with treatment and support options. As CITI is a live responsive website, the entire site was replicated to allow measurement of usage behavior by study participants. Participants who selected *unsure* were assigned to the CITI-naïve group; however, they were excluded from group comparison analyses to reduce any possible confounding of results.

Figure 2. Flow chart of the study design. CITI: *Cracks in the Ice*.

Measures

Information collected included age (in years), gender, residential postcode, and region (metropolitan, regional, or rural or remote). Participants were asked to identify whether they had previously used crystal methamphetamine, had a family member or friend who used (or who they thought might be using) crystal methamphetamine, or were a health professional. All participants were asked to indicate whether they had previously viewed the CITI website.

The System Usability Scale (SUS) is a reliable scale for measuring usability, including 10 items about several facets such as the complexity of the website and ease of use. The 10 items were scored on a 5-point Likert scale ranging from 0 (strongly disagree) to 5 (strongly agree), with scores calculated as validated in the literature [25]. Scale scores ranged from 0 to 100, with higher scores indicating enhanced usability. The average SUS score based on more than 500 studies was 68, with scores of 80 or above indicating a strong performance [26].

Participants also responded to an additional 4 items about the website's purpose, goals, and evidence base adapted from previous research by our team [8] with items being (1) "The support options listed on *Cracks in the Ice* are useful," (2) "The primary goal/purpose of *Cracks in the Ice* is clear," (3) "The information and resources on *Cracks in the Ice* have been informed by evidence," and (4) "The terminology on *Cracks in the Ice* is nonstigmatizing." These statements were scored on a 5-point Likert scale, ranging from 0 (strongly disagree) to 5 (strongly agree). In addition, participants were asked on a 7-point Likert scale, ranging from 0 (strongly disagree) to 7

(strongly agree), "I am confident in helping someone who has a problem with ice" and on a 5-point Likert scale, "If I knew someone who was using ice, I would help them." Participants were given the opportunity throughout the questionnaire to provide open-ended feedback about the website. The term "ice" was used instead of "crystal methamphetamine" as it is a more commonly known term for crystal methamphetamine among the Australian community.

To assess knowledge of crystal methamphetamine, participants completed a series of 18 *true or false* questions (each with three response options: 1=true, 2=false, and 3=unsure). Questions included knowledge of its effects on the brain and body (eg, "Ice will cause psychosis in all people"), rates of use (eg, "Methamphetamines [including ice] are the most popular illicit drugs in Australia"), and legal status in Australia. The total knowledge score was calculated by summing the number of correctly answered items (min=0 and max=18). *Unsure* responses were coded as incorrect for the purposes of analysis. This measure was developed by the authors as part of the development of CITI to assess key areas of knowledge and potential misconceptions about crystal methamphetamine among a lay audience [8] and has been used in other analyses by our group [21].

To assess attitudes toward people who use methamphetamine, participants responded to a 14-item, 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree). Ten items were adapted from the Brener and Von Hippel scale to measure attitudes toward people who inject drugs. The reliability and validity of the original scale have been previously demonstrated [27]. Mentions of "people who inject drugs" in the original scale

were replaced with “people who use ice.” Four additional items were adapted from the Depression Stigma Scale (DSS) with mention of mental health issues being replaced with “people who use ice” to assess perceptions of personal blame or control (“A person using ice could recover if they just stopped using” or “Using ice is a sign of personal weakness”), danger (“People who use ice are dangerous”), and shame (“If I had a problem with ice, I would not tell anyone”) [28]. Although the DSS was originally designed to measure stigma attached to depression, it has also been used to assess stigma attached to other disorders [29,30]. The reliability and validity of the DSS have been demonstrated in prior studies [28,30]. Positive statements were reverse coded before the total score was calculated (min=14 and max=70), with higher scores indicating more negative attitudes. The adapted scale demonstrated good internal consistency in the current sample (Cronbach α =.86).

Data Analysis

Data were analyzed using the IBM SPSS Statistics version 24. Analysis of variance was conducted to assess differences in system usability scores of end user groups and the impact of CITI on knowledge and attitudes about crystal methamphetamine. Chi-square tests were used to compare ratings on Likert scale statements among the 4 end user groups, with “strongly disagree” and “disagree” ratings combined for the purpose of analyses, as the count was too low among the health professional end user group. Two-tailed *t* tests were also conducted to assess whether knowledge was different between the CITI website visitors and CITI-naïve groups and within the

CITI-naïve group before and after visiting the CITI website. Content analysis of open-ended feedback using general inductive analysis [31] was also performed to identify core themes.

Results

Participants

A total of 2125 participants completed the survey. Among them, 17 participants were excluded from the analysis owing to invalid responses (eg, rapid responding or inconsistent responses), leaving a total of 2108 participants in the final sample. The mean age was 36 (SD 13) years, and 58.6% (1235/2108) of the participants identified as female. More than half of the participants were from metropolitan areas (1190/2108, 56.5%), a third (691/2108, 32.8%) were from regional locations, and 10.8% (227/2108) were from rural or remote locations. The sample’s age, gender, and state or territory of residence aligned closely with national population statistics from the 2018 Australian Bureau of Statistics [32]. A total of 26.7% (564/2108) of participants reported lifetime use of crystal methamphetamine (any use of the drug either current or in the past). Table 1 summarizes the descriptive statistics of gender, age, and region for each of the target end user groups (people who use crystal methamphetamine, affected family and friends, health professionals, and the general Australian community). The respondents in the “people who use crystal methamphetamine” group included both people who were currently using and those who reported using it in the past.

Table 1. Demographics by end user groups (N=2108).

Demographics	End user group			
	People who use crystal methamphetamine (n=564)	Family and friends (n=434)	Health professionals (n=288)	Community members (n=822)
Gender, n (%)				
Female	278 (49.3)	306 (70.5)	212 (73.6)	439 (53.4)
Male	270 (47.9)	113 (26.0)	75 (26.0)	368 (44.8)
Nonbinary or gender fluid	5 (0.9)	11 (2.5)	0 (0)	13 (1.6)
Different identity or prefer not to say	11 (1.9)	4 (1.0)	1 (0.3)	2 (0.2)
Age (years), mean (SD)	35.76 (9.42)	39.45 (14.55)	40.42 (12.72)	33.57 (13.64)
Region, n (%)				
Metro	343 (60.8)	215 (49.5)	146 (50.7)	486 (59.1)
Regional	176 (31.2)	161 (37.1)	92 (31.9)	262 (31.9)
Rural or remote	45 (8.0)	58 (13.4)	50 (17.4)	74 (9.0)

Usability and Site Evaluation

The average SUS score for the CITI website was 73.49 (SD 13.30), indicating good usability. Table 2 provides the average SUS score for each end user group. SUS scores were significantly higher in the health professionals group than in

the community ($F_{3,2062}=6.8$; $P=.02$) and people who use crystal methamphetamine ($F_{3,2062}=6.8$; $P<.001$) end user groups. SUS scores were also significantly higher in the family and friends group than in the people who used crystal methamphetamine group ($F_{3,2062}=6.8$; $P=.04$).

Table 2. System Usability Scale scores for each end user group (N=2066)^a.

End user group	Participants, n (%)	SUS ^b , mean (SD)
Community members	809 (39.1)	73.53 (13.43)
People who use crystal methamphetamine	553 (26.7)	71.73 (13.31)
Family and friends	419 (20.2)	74.12 (13.92) ^c
Health professionals	285 (13.7)	75.91 (11.41) ^d

^aA total of 42 participants were excluded from the analyses because they selected unsure when asked if they had visited the *Cracks in the Ice* website.

^bSUS: System Usability Scale.

^cP=.02.

^dP<.01.

Participants had an overall positive response to the website’s purpose, goals, and evidence base (Figure 3), with most participants providing a rating of *agree* or *strongly agree* for statements such as “The information and resources has been

informed by evidence” (1839/2066, 87.2%), “The terminology is nonstigmatizing (1825/2066, 86.6%), “The primary goal/purpose is clear” (1907/2066, 90.5%), and “The support options listed are useful” (1836/2066, 87.1%).

Figure 3. Participant feedback of the *Cracks in the Ice* website’s purpose, goals and, evidence base on a 5-point Likert scale.

Ratings for each statement were compared, with significant associations observed between the end user group and ratings for each of the statements (χ^2 , range 43.79-67.05; $P<.001$). Agreement was generally higher among the community, health professional, and family and friends groups compared with people who use crystal methamphetamine; however, the differences were small (between 5% and 12%). Further descriptive information for each statement by the end user group is detailed in Multimedia Appendix 1.

Open-ended comments left by survey respondents at the end of the survey were mostly positive, stating that the website was evidence-based, informative, easy to use, and presented information in a nonjudgmental or nonstigmatizing way. Other comments related to improving the user experience or

navigation, creating more resources such as lived experience stories, and specific resources to support regional or rural areas along with Aboriginal and Torres Strait Islander peoples. Several examples of the comments are provided in Multimedia Appendix 2.

Knowledge and Attitudes About Crystal Methamphetamine and Harms

Overview

There were 277 participants who had previously visited the website (CITI website visitors) and 1789 participants who had not previously visited the website (CITI-naïve group). An additional 42 participants were excluded from further analyses

as they selected the response *unsure* when asked if they had visited the website.

The CITI-naïve group spent an average of 2.16 minutes on the replicated website, visiting 2.17 pages, spending an average of 82.63 (SD 189.5) seconds on relevant content pages (Google Analytics November 19, 2018, to March 31, 2019). This is in line with the average session duration of between 2 and 3 minutes for large websites, such as many health care sites [33].

Previous experience with the website resulted in significantly higher SUS scores in the CITI website group ($t_1=8.36$; $P=.004$) compared with the CITI-naïve group.

On average, CITI website visitors had higher total baseline knowledge scores (mean 15.2, SE 0.1) than those who had not previously visited the website (mean 14.4, SE 0.05) (Table 3). This difference was significant ($t_{2064}=5.54$; $P<.001$), with a small to medium-sized effect (Cohen $d=0.44$).

Table 3. Comparison of knowledge between *Cracks in the Ice* (CITI) visitors and the CITI-naïve group at baseline, indicating the numbers and percentages of participants who gave correct answers to the knowledge statement (N=2108)^a.

Knowledge statement	Total sample (n=2108), n (%)	CITI ^b visitors (n=277), n (%)	CITI-naïve (n=1789), n (%)
It is illegal to drive while under the influence of ice	2069 (98.1)	271 (97.8)	1756 (98.15)
Ice use can lead to serious long-term physical effects	2056 (97.5)	270 (97.5)	1745 (97.54)
Using ice can affect your sleep	2019 (95.8)	273 (98.6)	1705 (95.30)
Ice use can make you feel paranoid	2017 (95.7)	272 (98.2)	1705 (95.30)
Ice use can make you feel agitated or distressed	2013 (95.5)	272 (98.2)	1701 (95.08)
You always know what you're taking when you use ice	1962 (93.1)	259 (93.5)	1663 (92.95)
Taking ice with other drugs can reduce the risks of harm	1910 (90.6)	253 (91.3)	1620 (90.55)
Low doses of ice will not impair driving skills	1908 (90.5)	258 (93.1)	1611 (90.05)
It is legal to share ice with friends	1818 (86.2)	238 (85.9)	1544 (86.30)
It is impossible to break an ice dependence	1771 (84.0)	249 (89.9)	1490 (83.28)
The effects of ice are short-lived	1731 (82.1)	235 (84.8)	1464 (81.83)
Ice is generally more potent (strong) than speed	1718 (81.5)	239 (86.3)	1445 (80.77)
You can go to jail for using methamphetamines, including ice	1578 (74.9)	215 (77.6)	1334 (74.56)
Most teenagers have used ice	1570 (74.5)	220 (79.4)	1325 (74.06)
Ice will cause psychosis in all people	1408 (66.8)	216 (78.0)	1172 (65.51)
Legal penalties for drug offences relating to methamphetamine in Australia are different in each of the states and territories	1310 (62.1)	196 (70.8)	1087 (60.76)
Methamphetamines (including ice) are the most popular illicit drugs in Australia	899 (42.6)	144 (52.0)	743 (41.53)
Most of the time, police will not be called when an ambulance is attending a drug overdose	808 (38.3)	126 (45.5)	668 (37.33)

^aStatements are ordered from most to least correctly answered among the total sample.

Change in Knowledge and Attitudes After Viewing the Website

The CITI-naïve group was assessed on knowledge both before and after website viewing, with results showing that, on average, knowledge scores significantly increased following exposure to the website (mean 15.2, SE 0.05) compared with baseline (mean 14.4, SE 0.05; $t_{1788}=17.893$; $P<.001$), as displayed in Table 4. The largest shifts in knowledge were observed for items related to the prevalence of crystal methamphetamine use, legal

issues, and the physical and mental effects of the drug. There was a 35.1% change (n=261) for “Methamphetamines (including ice) are the most popular illicit drugs in Australia,” a 24.0% change (n=160) for “Most of the time, police will not be called when an ambulance is attending a drug overdose,” 22.0% change (n=239) for “Legal penalties for drug offences relating to methamphetamine in Australia are different in each of the states and territories,” 16.8% change (n=197) for “Ice will cause psychosis in all people,” and 10.8% change (n=161) for “It is impossible to break an ice dependence” following exposure to the CITI website.

Table 4. Knowledge among the *Cracks in the Ice*-naïve sample at baseline and after website exposure, indicating the number and percentage of people giving correct answers to knowledge statements (N=1789).

Knowledge statement	Baseline, n (%)	Postexposure ^a , n (%)
Methamphetamines (including ice) are the most popular illicit drugs in Australia	743 (41.53)	1004 (56.12)
Most teenagers have used ice	1325 (74.06)	1418 (79.26)
Ice is generally more potent (strong) than speed	1445 (80.77)	1561 (87.25)
You always know what you're taking when you use ice	1663 (92.95)	1702 (95.13)
Using ice can affect your sleep	1705 (95.30)	1759 (98.32)
Taking ice with other drugs can reduce the risks of harm	1620 (90.55)	1660 (92.78)
Ice use can lead to serious long-term physical effects	1745 (97.54)	1757 (98.21)
It is impossible to break an ice dependence	1490 (83.28)	1651 (92.28)
You can go to jail for using methamphetamines, including ice	1334 (74.56)	1342 (75.01)
It is legal to share ice with friends	1544 (86.30)	1473 (82.33)
Most of the time, police will not be called when an ambulance is attending a drug overdose	668 (37.33)	828 (46.28)
It is illegal to drive while under the influence of ice	1756 (98.15)	1732 (96.81)
The effects of ice are short-lived	1464 (81.83)	1542 (86.19)
Low doses of ice will not impair driving skills	1611 (90.05)	1647 (92.06)
Ice will cause psychosis in all people	1172 (65.51)	1369 (76.52)
Ice use can make you feel agitated or distressed	1701 (95.08)	1761 (98.43)
Ice use can make you feel paranoid	1705 (95.30)	1756 (98.15)
Legal penalties for drug offences relating to methamphetamine in Australia are different in each of the states and territories	1087 (60.76)	1326 (74.11)

^aAverage knowledge scores increased following exposure to the website (mean 15.2, SE 0.05) compared to the baseline (mean 14.4, SE 0.05; $t_{1788}=17.893$; $P<.001$).

On average, the total attitude score among the CITI-naïve group was significantly lower following exposure to the CITI website (mean 41.97, SE 0.21) compared with the baseline (mean 44.3, SE 0.21; $t_{1788}=23.91$; $P<.001$), with lower scores indicating less

negative or stigmatizing attitudes (Table 5). Follow-up analyses indicated that significant before and after changes in knowledge and attitude scores were observed in all 4 end user groups.

Table 5. Endorsement of attitudes toward people who use crystal methamphetamine of the *Cracks in the Ice*–naïve sample at baseline and after website exposure (N=1789)^a.

Attitude statement	Baseline, n (%)	Postexposure ^b , n (%)
Negative attitudes		
I won't associate with people who use ice if I can help it	1233 (68.92)	986 (55.11)
I avoid people who use ice whenever possible	1232 (68.88)	1103 (61.65)
Use of ice is just plain wrong	986 (55.11)	863 (48.23)
People who use ice are dangerous	821 (45.89)	588 (32.86)
A person using ice could recover if they just stopped using	737 (41.19)	621 (34.71)
If I had a problem with ice, I would not tell anyone	597 (33.37)	395 (22.07)
Use of ice is immoral	470 (26.27)	408 (22.80)
Using ice is a sign of personal weakness	251 (14.03)	182 (10.17)
People who use ice should be locked up to protect society	241 (13.47)	173 (9.67)
Positive attitudes		
People should feel sympathetic and understanding of people who use ice	821 (45.89)	924 (51.64)
People who use ice are mistreated in our society	716 (40.02)	837 (46.78)
People who use ice have a perfect right to their lifestyle, if that's the way they want to live	260 (14.53)	237 (13.24)
People who use ice should be accepted completely into our society	251 (14.03)	317 (17.71)
The use of ice is merely a different kind of lifestyle that should not be condemned	185 (10.34)	186 (10.39)

^aParticipant selected *agree* or *strongly agree* on 5-point Likert scale.

^bTotal attitude score was significantly lower following exposure to the *Cracks in the Ice* website (Mean 41.97, SE 0.21) compared with the baseline (mean 44.3, SE 0.21; $t_{1788}=23.91$; $P<.001$).

In addition, among the CITI-naïve group, exposure to the CITI website resulted in minor improvements (eg, selecting neutral or agree responses) to the two additional statements “If I knew someone who was using ice, I would help them” and “I am confident in helping someone who has a problem with ice” (Table 6).

For the “If I knew someone who was using ice, I would help them” statement, measured on a 7-point Likert scale from

strongly disagree to strongly agree, 25.1% (n=448) increased their rating, 16.3% (n=292) decreased their rating, whereas 58.6% (n=1049) made no change in their rating after viewing the website. For the statement “I am confident in helping someone who has a problem with ice,” measured on a 5-point Likert scale from strongly disagree to strongly agree, 44.1% (n=790) reported an increase in rating, 3.6% (n=64) decreased their rating, whereas 52.3% (n=935) made no change in their rating after viewing the website.

Table 6. Rates of agreement with helping statements before and after website exposure among *Cracks in the Ice*-naïve group (N=1789).

Statement	Baseline, n (%)	Postexposure, n (%)
If I knew someone who was using ice, I would help them		
Strongly disagree	33 (1.8)	30 (1.7)
Mostly disagree	47 (2.6)	47 (2.6)
Somewhat disagree	65 (3.6)	33 (1.8)
Neither agree nor disagree	151 (8.4)	140 (7.8)
Somewhat agree	490 (27.4)	479 (26.8)
Mostly agree	561 (31.4)	543 (30.4)
Strongly agree	442 (24.7)	517 (28.9)
I am confident in helping someone who has a problem with ice		
Not at all	543 (30.4)	191 (10.7)
A little bit	448 (25.0)	448 (25.0)
Moderately	451 (25.2)	596 (33.3)
Quite a bit	234 (13.1)	399 (22.3)
Extremely	113 (6.3)	155 (8.7)

Discussion

Principal Findings

This study evaluated CITI, the first centralized Australian eHealth resource to provide information and resources about crystal methamphetamine to support the community [8]. This evaluation is one of the most rigorous evaluations of eHealth resources to date, conducted among a large sample of more than 2000 Australians. This website evaluation was also one of the first studies to examine the effect of an eHealth resource on knowledge and attitudes regarding illicit substance use. Overall, the results indicated that CITI is achieving its aim of disseminating evidence-based, nonstigmatizing information and resources about crystal methamphetamine to key end user groups (people who use the drug, affected family members and friends, health professionals, and the general Australian community). This is evidenced by more than 80% of participants endorsing statements about the clarity of the website's purpose, goals, and evidence base. Endorsement of the website's purpose and goals was generally higher among the community, health professional, and family and friends groups compared with people who use crystal methamphetamine; however, differences were small (between 5% and 12%). It is a challenge for CITI to cater to different end user groups that have differing needs and has been addressed by providing user-specific sections in addition to general information. Therefore, it was important to check whether these key end user groups had been adequately catered for and identify any improvements that might be needed for the tailored resources.

The average SUS score for CITI was 73.49 (SD 13.30), indicating good usability, which is above the average of 68, based on >500 studies [26]. An SUS of 80 or above is an indication of strong performance, and future iterations of CITI will aim to further improve user experience on the site to reach this level. The differences in SUS scores between different stakeholder groups is a key point of interest, with health

professionals reporting significantly higher SUS scores than general community members or people who use crystal methamphetamine. This may be because of health professionals having high digital literacy levels [34] and having higher general levels of education. We also observed higher SUS scores among family and friends than among people who used crystal methamphetamine. This may reflect the fact that the support of families and friends was a priority area in site development, with fewer resources available for people who use crystal methamphetamine. Creating and tailoring information and resources for people who use crystal methamphetamine is an area of growth for the website, and several such resources are currently in development. Unsurprisingly, familiarity with the website (measured by visiting the website before the evaluation) was associated with significantly higher SUS scores.

The finding that the use of CITI led to improvements in knowledge and attitudes about crystal methamphetamine and harms in the naïve group, despite the average time spent on the replicated website being 2 minutes, is encouraging. The average knowledge scores significantly increased after viewing the site, although the effects were small. Examination of individual items showed some promising shifts, particularly for items that are often common misconceptions about the drug (eg, prevalence of use, legal issues, and the physical and mental effects of the drug). Thus, providing some support that the shifts could be meaningful in areas where knowledge is lacking or incorrect. These changes in knowledge are of particular salience given the misconceptions often portrayed in the Australian media about the methamphetamine *epidemic* and the framing of people who use the drug as criminal, deviant, or dangerous [6]. Unsurprisingly, those already familiar with the website before the study had higher total baseline knowledge scores. This may reflect the fact that they had previously reviewed the key informational pages or the possibility that those who had sought out the CITI website of their own volition previously had more knowledge about the drug.

The decrease in total attitude score among the CITI-naïve group (indicating less negative or stigmatizing attitudes) following exposure to the website is also promising. We have previously found that increased knowledge about the drug is associated with less stigmatizing attitudes [21]. This also aligns with what has been found in mental health research, where improvements in knowledge have led to increased positive attitudes or less stigmatizing beliefs [35-38]. Through CITI's dissemination of evidence-based information about crystal methamphetamine, it has the potential to change public attitudes and reduce the stigma associated with the drug. This is potentially an important shift, given that stigma is consistently cited as one of the main barriers to care among people who use methamphetamine [39].

Comparison With Previous Work

eHealth resources are a low-cost way to increase public awareness of important issues and have the potential to reach a large number of people [40]. However, they must respond to rapidly changing population trends and evidence. In areas such as new and emerging drugs, this is particularly important [41]. Therefore, it is important for eHealth resources to be living resources that are adequately funded to respond to emerging research evidence. Consumer health websites need to be not only evidence-based and trustworthy sources of information but also user friendly and meet the health information-seeking needs of their target groups [42,43]. Therefore, website evaluations commonly use a variety of methodologies, including measures of usability (SUS and task performance), self-reports (surveys), qualitative interview-based methods, or Google Analytics to investigate website behaviors (use and interaction) [44-47]. Similar to a recent study, we did not find published recommendations for procedures to conduct a review of a live website in a systematic manner [48]. A recent systematic review found that despite there being many published toolkits, very few were evaluated, and the authors concluded that this is an area where greater attention and rigorous methodology are needed [20]. Although review criteria [49] and a possible framework (Reach, Effectiveness, Adoption, Implementation, Maintenance) from implementation science [50] have been proposed as useful avenues for evaluation, they are more appropriate for web-based intervention-based studies on behavior change. Within this context, we note that this website evaluation is one of the most rigorous evaluations in the field and is a solid starting point, with the potential for future experimental designs. This evaluation also involved the examination of knowledge and its impact on attitudes, an element not often looked at in website evaluations.

It is generally assumed that the longer a visitor spends on a website, the more engaged they are. However, it is difficult to find or estimate a benchmark for the average time spent on health-related websites, as time spent visiting sites depends on the scope and purpose of the actual site. It has been reported that for large websites, such as many health care sites, the average session duration is between 2 and 3 minutes [33]. However, it is difficult to find a benchmark for comparison with public health websites such as CITI because of the large variability across sites and industries. In this study, the CITI-naïve group that undertook the site tour spent an average time of 2.16 minutes, visiting 2.17 pages, in line with the

average session duration of health care sites. This is slightly higher than the average time for website users of the live website, which has an average session time of 1.42 minutes with people visiting an average of 1.65 pages (April 3, 2017, to December 31, 2020). It would be useful for future studies to examine the impact of time spent on the site and to determine whether strategies to increase the length of time users engage with the site would be useful to encourage knowledge or attitude change.

The CITI eHealth resource also caters to several different end user populations (eg, health professionals, community members, family and friends, and people who use crystal methamphetamine). As such, similar to other websites, challenges remain in distinguishing between and meeting the needs of different groups [40]. This was evident in this study with people who use crystal methamphetamine having slightly lower endorsement of the website's purpose and goals. Therefore, more in-depth investigation is needed to understand the information needs of people who use crystal methamphetamine. Another avenue for future evaluation is to ensure that the information provided on CITI is suitable to people from diverse backgrounds and varying levels of health literacy, an important consideration that has been noted in the literature [51].

Limitations

This study is not without its limitations, and its findings should be interpreted with these in mind. As CITI is a live website, which can be accessed at any time, this study used a quasi-experimental design. Future evaluations may consider creating beta versions of the site that could be tested in an A/B test with a control group. Another limitation is that although the CITI-naïve group was directed to specific pages during the site tour, there was no minimum time to stay on each page enforced, and participants could also review pages other than those specifically mentioned. Therefore, although changes in knowledge were significant, it is difficult to ascertain the direct cause of this change and whether, for example, it was related to the amount of time participants spent on the site or the specific pages they visited. Similarly, as this study is not longitudinal in its design, it is unclear whether these knowledge shifts are maintained over time or whether changes in knowledge and attitudes lead to behavior change.

This study used convenience sampling methods; therefore, the sample was not nationally representative. However, the sample's age, gender, and state or territory of residence aligned closely with national population statistics from the Australian Bureau of Statistics [32]. Similarly, the use of paid Facebook advertising may have attracted individuals with an interest in the drug crystal methamphetamine; thus, the knowledge and attitude findings may not be representative of the general population. The use of paid advertising also resulted in the sample of CITI-naïve participants being 6 times larger than the group already familiar with CITI; however, the sample sizes achieved in each group were large for studies of this kind.

It should also be noted that the measure used to assess knowledge about crystal methamphetamine was developed by the research team in response to a lack of published measures

for this purpose. As such, the psychometric properties of the measure are unknown, including whether knowledge as measured in this study is a multidimensional or unidimensional construct. Therefore, direct conclusions about improving which aspects of knowledge (or knowledge in general) might reduce stigmatizing attitudes cannot be made.

Conclusions

This study is one of the most comprehensive and rigorous evaluations of a centralized national eHealth resource for the general public, focusing on substance use. CITI, an innovative portal for evidence-based information and resources about crystal methamphetamine, was found to achieve its aim of

disseminating evidence-based, nonstigmatizing, and useful information and resources about crystal methamphetamine to key end user groups. Furthermore, it received good usability scores across its target groups and was found to be easy to use. In addition, interaction with CITI led to immediate improvements in knowledge and a decrease in stigmatizing attitudes about the drug, which is promising given the links among knowledge, stigma, and help-seeking. CITI demonstrates the important role of digital information and support platforms for translating evidence into practice as well as improving knowledge and reducing stigma around crystal methamphetamine. It is hoped that this will ultimately lead to an increase in help-seeking and evidence-based service use.

Acknowledgments

CITI is supported by funding from the Australian Government Department of Health. This study was also supported by the Australian National Health and Medical Research Council via Fellowships (NN, APP1166377; LS, APP1132853; KC, APP1120641; FKL, GNT1110371; and MT, APP1078407) and the Centre of Research Excellence in the Prevention and Early Intervention in Mental Illness and Substance Use (APP11349009). The funders had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript. The authors would like to thank the individuals who generously shared their experiences with them and allowed them to use their stories on the CITI website and many community members from around the country who provided their input and feedback during the development and evaluation of this resource. CITI was developed by researchers at the Matilda Centre for Research in Mental Health and Substance Use at the University of Sydney (SK, LB, HD, NN, LS, KC, FKL, MT, and CC). The authors received no financial or other benefits from the CITI website.

Abstract

Background: Internet-based cognitive behavior therapy (I-CBT) for adolescents with chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) has been shown to be effective in a randomized controlled trial (RCT; Fatigue in Teenagers on the Internet [FITNET]). FITNET can cause a significant reduction in fatigue and disability.

Objective: We aimed to investigate whether FITNET treatment implemented in routine clinical care (IMP-FITNET) was as effective, using the outcomes of the FITNET RCT as the benchmark.

Methods: Outcomes of CFS/ME adolescents who started IMP-FITNET between October 2012 and March 2018 as part of routine clinical care were compared to the outcomes in the FITNET RCT. The primary outcome was fatigue severity assessed posttreatment. The secondary outcomes were self-reported physical functioning, school attendance, and recovery rates. Clinically relevant deterioration was assessed posttreatment, and for this outcome, a face-to-face CBT trial was used as the benchmark. The attitude of therapists toward the usability of IMP-FITNET was assessed through semistructured interviews. The number of face-to-face consultations during IMP-FITNET was registered.

Results: Of the 384 referred adolescents with CFS/ME, 244 (63.5%) started IMP-FITNET, 84 (21.9%) started face-to-face CBT, and 56 (14.6%) were not eligible for CBT. Posttreatment scores for fatigue severity (mean 26.0, SD 13.8), physical functioning (mean 88.2, SD 15.0), and full school attendance (mean 84.3, SD 26.5) fell within the 95% CIs of the FITNET RCT. Deterioration of fatigue and physical functioning after IMP-FITNET was observed at rates of 1.2% (n=3) and 4.1% (n=10), respectively, which is comparable to a waiting list condition (fatigue: 1.2% vs 5.7%, $\chi^2_1=3.5$, $P=.06$; physical functioning: 4.1% vs 11.4%, $\chi^2_1=3.3$, $P=.07$). Moreover, 41 (16.8%) IMP-FITNET patients made use of face-to-face consultations.

Conclusions: IMP-FITNET is an effective and safe treatment for adolescents with CFS/ME in routine clinical care.

KEYWORDS

Fatigue in Teenagers on the Internet; cognitive behavior therapy; fatigue; chronic fatigue syndrome; adolescents; implementation

Introduction

Chronic fatigue syndrome/myalgic encephalomyelitis (CFS/ME) is a disabling condition in which patients have severe, medically unexplained, and persistent (>6 months) fatigue, resulting in impairment of functioning [1]. The prevalence of CFS/ME in adolescents is 0.11% to 1.29% in Dutch and British adolescent populations, with a female-to-male ratio of 2:1 to 5:1 [2,3]. In adolescents, CFS/ME often has a chronic course, leading to school absence, and has long-term detrimental effects on social and academic development [4,5].

The etiology of CFS/ME is unknown. The context of the biopsychosocial model defines individual predisposing, precipitating, and perpetuating factors that provoke and maintain severe fatigue and disability [6]. Face-to-face cognitive behavior therapy (CBT) aimed at fatigue-maintaining factors has been tested in several randomized controlled trials (RCTs) and leads to a significant reduction in fatigue and an improvement in physical functioning and school attendance [4,7,8]. An internet-based format of CBT for adolescents with CFS/ME, named *Fatigue in Teenagers on the Internet (FITNET)*, was found to be effective in an RCT, leading to significant reduction of fatigue and fatigue-related disabilities [4]. Two-thirds of patients reported fatigue levels and physical functioning within the normal limits, as well as full school attendance following treatment [4]. Currently, in the United Kingdom, an RCT is investigating the feasibility, clinical effectiveness, and cost-effectiveness of FITNET delivered in the context of the National Health Service (FITNET_NHS) [9,10]. FITNET is easily accessible since it is not bound to the geographic location of the therapist delivering the intervention [4]. Patients do not need to travel to a treatment center and can follow the treatment at home, making the intervention easy to follow. Importantly, adolescents with CFS preferred FITNET over face-to-face treatment [4]. It is not self-evident that outcomes of an RCT can be extrapolated to routine clinical care (RCC), since the effectiveness of an RCT may be overestimated due to strict inclusion criteria and close monitoring of the intervention [11,12]. Thus far, the effectiveness of FITNET delivered in RCC has not been shown. Recently, concerns have been raised about the safety of behavioral interventions for CFS/ME. It has been suggested that CBT leads to deterioration of symptoms and functioning [13]. Analyses of RCTs testing the efficacy of CBT for CFS have thus far not shown a higher prevalence of deterioration or more adverse events following or during CBT compared to control conditions [4,14,15]. However, this has not yet been determined for internet-based cognitive behavior therapy (I-CBT) delivered in RCC for adolescents, which uses less strict inclusion criteria and less stringent monitoring of the treatment process.

The primary aim of this study was to determine whether FITNET implemented in RCC (IMP-FITNET) is as effective as in a research context with respect to the outcomes of fatigue severity, physical functioning, school attendance, and recovery rates, using the outcomes of the previous RCT as the benchmark [4]. The secondary aim was to investigate the safety of IMP-FITNET by assessing the frequency of deterioration of fatigue and physical functioning in comparison to a waiting list

condition of another benchmark RCT in adolescents [14]. Lastly, the attitude of therapists toward the usability of IMP-FITNET was assessed through semistructured interviews.

Methods

Design and Participants

This was an observational study of RCC. Data were collected retrospectively from adolescents who finished treatment in RCC after implementation.

All patients were referred to the Expert Centre for Chronic Fatigue (ECCF), a national referral center for IMP-FITNET and face-to-face CBT for adolescents with CFS/ME, and were retrospectively included in the study between October 2012 and March 2018.

The inclusion criteria were as follows: (1) CFS according to the US Centers for Disease Control (CDC) criteria revised in 2003 [1,16]; (2) 12-18 years of age at baseline; (3) severe fatigue, operationalized as a score of 40 or higher on the fatigue severity subscale of the Checklist Individual Strength-20 (CIS-20) [17]; (4) self-reported substantial disabilities in daily functioning; (5) access to the internet; and (6) no psychiatric comorbidity that could explain the presence of fatigue, ruled out by the Mini International Neuropsychiatric Interview for children (M.I.N.I. KID) [18].

Posttreatment effectiveness in terms of fatigue severity, physical functioning, school attendance, and recovery rates were compared with results derived from the previously published RCT on FITNET [4]. The safety of IMP-FITNET was determined by comparing the prevalence of the deterioration of fatigue and physical functioning with the results of a benchmark study that reported on deterioration rates in a waitlist condition of an RCT testing the efficacy of face-to-face CBT for CFS/ME in adolescents [14]. In RCC, patients received either IMP-FITNET or face-to-face CBT as decided in a shared decision process, in which patients/parents and therapists worked together to choose the best suitable therapy, reflecting both evidence and patient priorities and preferences.

The Dutch Medical Research Involving Human Subjects Act did not apply to our study, as the collected data were part of RCC. Therefore, no formal ethical approval from the medical ethics committee was needed for this study.

Treatment

CBT for CFS/ME is developed on the basis of a cognitive behavioral model of CFS, assuming that behavior and beliefs can perpetuate symptoms [19]. In this study, two formats of CBT for adolescents with CFS/ME were used. A face-to-face CBT treatment manual for adolescents was applied, which was found to be efficacious in previous research [7]. The second format was an implemented version of the online CBT intervention FITNET with the same content and similar layout, but using a different software package, referred to as IMP-FITNET. FITNET is an internet-based CBT program developed on the basis of the face-to-face CBT treatment manual for adolescents. FITNET has been found to be efficacious in the context of research [4]. The FITNET program consists, aside

from psychoeducation on CFS, of 21 interactive treatment modules, with content in line with face-to-face CBT treatment for adolescents and a program for care givers. Each module includes assignments and mandatory e-consultations with the therapist [4,9,20]. IMP-FITNET has the same 21 interactive modules for patients with e-consultations and caregivers. In IMP-FITNET, therapists were however allowed to offer face-to-face consultations or phone calls if deemed necessary, and for patients starting treatment in 2017, videoconferencing was possible.

Eleven trained cognitive behavioral therapists who received weekly supervision from experienced clinical psychologists delivered face-to-face CBT and IMP-FITNET.

Outcome Variables

Primary Outcome Posttreatment

All outcome variables were self-reported. The primary outcome was fatigue severity assessed with the subscale fatigue severity of the CIS-20. This subscale consists of eight items scored on a 7-point Likert scale, resulting in a fatigue severity score ranging from 8 to 56. A score ≥ 40 indicates the presence of severe fatigue [17]. The internal consistency and discriminative validity of the CIS are excellent [7,17].

Secondary Outcomes Posttreatment

Physical functioning was measured with the subscale physical functioning (nine items, range 0%-100%) of the Child Health Questionnaire-87 (CHQ-87). The questionnaire is validated and has good internal consistency [21].

School presence was assessed using a diary and reported as the percentage of classes attended over the past 2 weeks divided by the scheduled number of classes for peers [4].

Recovery was defined in relation to healthy peers by having a CIS-fatigue score < 40 [2], a CHQ-87 physical score $\geq 85\%$ [21], and school absence $\leq 10\%$ in the past 2 weeks [2]. These recovery criteria were derived from the FITNET RCT [4].

Deterioration of fatigue was defined as an increase of more than six points in CIS-fatigue, and deterioration of physical functioning was defined as a decrease of more than 10 points in CHQ-physical [9,22].

The benchmark for deterioration, as a proxy for safety, was the waiting list condition in a prior RCT on the efficacy of face-to-face CBT [14]. Instead of the CHQ-87 subscale physical functioning, the SF-36 (short-form) of the RAND was used in this study [23].

Semistructured Interviews

Using a semistructured telephone interview, 11 therapists were asked which criteria they used to propose to start with either IMP-FITNET or face-to-face CBT for the individual adolescent or face-to-face consultations during IMP-FITNET. Nine therapists participated. Interviews with the therapist were recorded and transcribed by one researcher (EA). The themes were independently synthesized by two researchers (EA and LNN) based on the interviews [24]. Discrepancies were resolved

through discussion with the principal investigator (HK) to reach consensus. In addition, the number of face-to-face consultations during IMP-FITNET was registered.

Procedure

After referral, adolescents had two diagnostic face-to-face sessions with a psychologist. The results of the baseline assessment were discussed with the adolescent and parents, and this was followed by a shared decision for either IMP-FITNET or face-to-face CBT. Following treatment, adolescents completed an online posttreatment assessment, which was discussed in a face-to-face session.

Statistical Analysis

The demographic characteristics of the adolescents and baseline scores were compared using a benchmark strategy, in which the baseline scores of RCC were compared with the 95% CIs of corresponding values in the FITNET RCT. If the mean value in RCC was outside the 95% CI of the RCT, it was considered divergent. The same procedure was used to compare the post-treatment outcomes of RCC with the RCT. Baseline characteristics of patients lost to follow-up were compared with those who were assessed posttreatment using a *t* test for independent groups.

Analyses were based on intention to treat, using the summary estimate of five imputations for 15 missing observations in the primary outcome, with the assumption that data were missing at random [25]. All baseline and posttreatment scores were entered as predictors. The posttreatment score of fatigue severity was entered as a variable to impute. Moreover, analyses were repeated with only those patients who met all the inclusion criteria of the benchmark FITNET RCT (baseline score for physical activity $< 85\%$ and/or school presence $\leq 85\%$). The within-group Cohen *d* was reported as the effect size. For the main outcome fatigue severity, we calculated the percentage of patients who scored below the cutoff of severe fatigue (CIS < 40) and reported a reliable change index (*z*) score greater than $+1.96$ [26]. To test differences in deterioration, chi-square tests were performed. Percentages of adolescents who were lost to follow-up in the RCT and in RCC were compared with chi-square tests. Lastly, the number of face-to-face consultations during IMP-FITNET were registered.

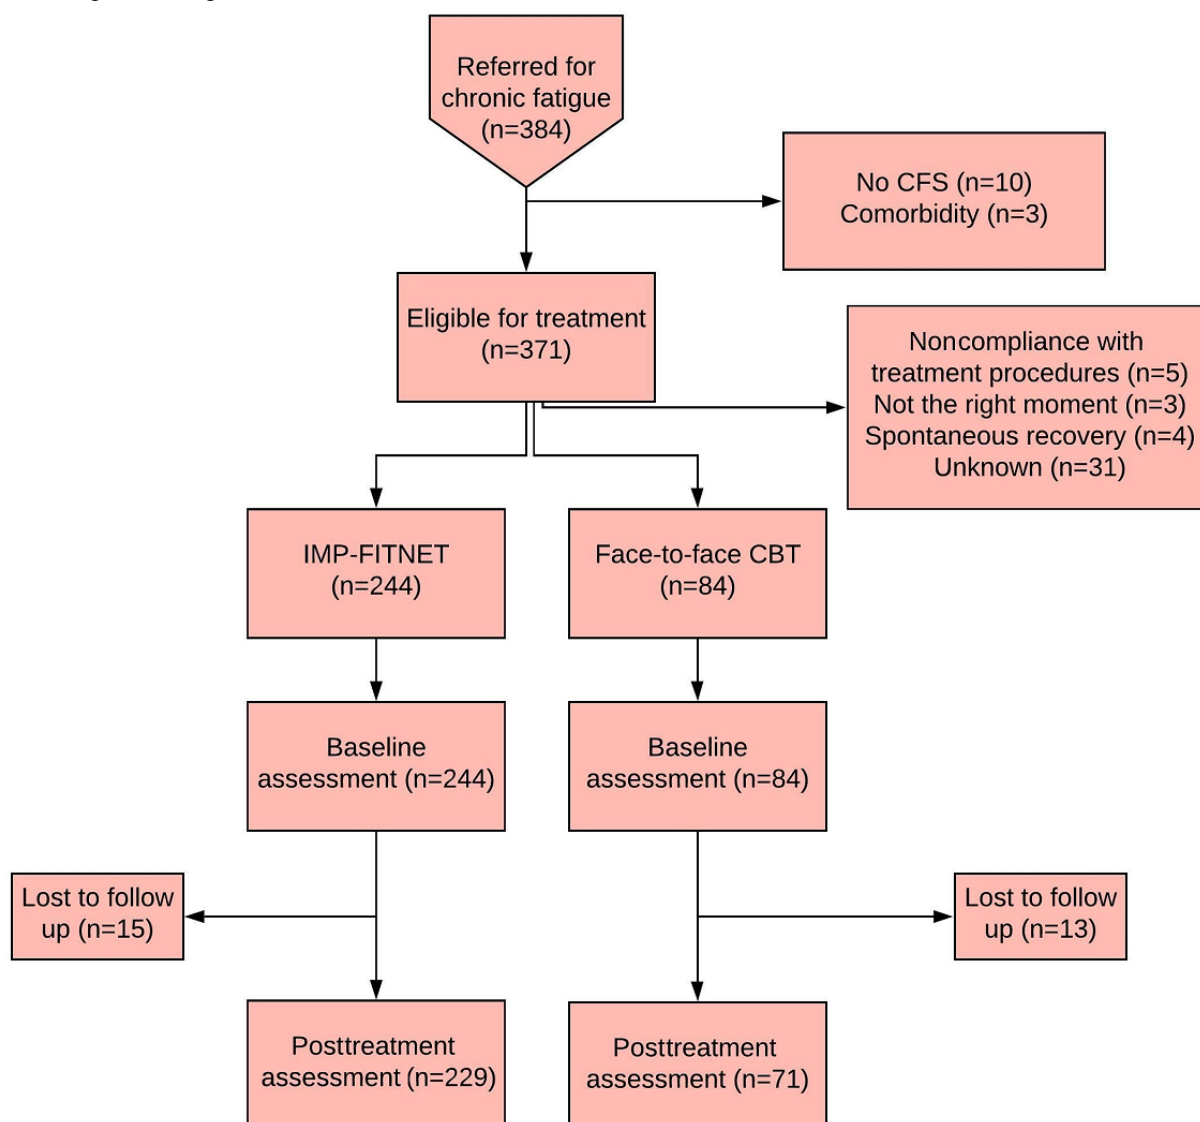

SPSS version 25 (IBM Corp) was used for statistical analyses, and significance was set at $P < .05$.

Results

Study Population

Of the 384 referred adolescents, 371 were eligible for treatment, of which 328 (88.4%) started treatment. Of the 328 patients, 244 (74.4%) received IMP-FITNET and 84 (25.6%) received face-to-face CBT. All 328 adolescents filled out the baseline assessment, 229 of the 244 patients (93.8%) who received IMP-FITNET completed the posttreatment assessment, and 71 of the 84 patients (84.5%) who received face-to-face CBT completed the posttreatment assessment (Figure 1).

Figure 1. Study flow of the patients in routine clinical care. CBT: cognitive behavioral therapy; CFS: chronic fatigue syndrome; IMP-FITNET: implemented Fatigue in Teenagers on the Internet.

Baseline Characteristics

Adolescents lost to follow-up differed significantly in physical functioning at baseline (mean score 64.7, SD 16.4 vs mean score [lost to follow-up] 73.0, SD 19.4; $t_{241} = -2.04$, $P = .04$).

Table 1 provides the baseline characteristics of the adolescents in RCC (IMP-FITNET and face-to-face CBT) compared with the baseline characteristics of the patients from the benchmark FITNET RCT. The duration of symptoms was significantly lower in patients who received IMP-FITNET and significantly higher in patients who received face-to-face CBT compared to the FITNET RCT. Both were outside the 95% CI of the FITNET RCT. The duration of symptoms between IMP-FITNET and

face-to-face CBT did not significantly differ ($t_{306} = 0.984$, $P = .33$). Fatigue severity of the adolescents following either IMP-FITNET or face-to-face CBT was lower and their physical functioning was higher than in the benchmark study, as was their school participation. Moreover, adolescents receiving face-to-face CBT were younger and more often male than in the benchmark study. The analyses were repeated with the subset of patients in RCC who met all the inclusion criteria of the benchmark study. This analysis showed the same pattern of results (data not shown).

The percentage of adolescents lost to follow-up was significantly higher in IMP-FITNET than in the FITNET RCT (8.5% [n=28] vs 3.0% [n=4], $N = 463$, $\chi^2_1 = 3.3$, $P = .03$).

Primary and Secondary Outcomes Posttreatment

The CIS-fatigue severity score after IMP-FITNET and face-to-face CBT in RCC fell within the 95% CI of the benchmark FITNET study. Additionally, 173 of the 229 adolescents (75.5%) with a posttreatment fatigue score had a reliable change index score greater than +1.96 and a score lower than 40 on the CIS. All secondary outcomes (Table 2) fell within the 95% CIs of the benchmark study. The analyses were repeated with the subset of patients in RCC who fulfilled all the inclusion criteria of the benchmark study. This analysis showed the same pattern of results (data shown in Multimedia Appendix 1).

In RCC, 3 of the 244 patients (1.2%) reported a clinically significant deterioration of fatigue severity after IMP-FITNET. In the waiting list condition of a face-to-face CBT benchmark study, 2 out of 35 patients (5.7%) showed clinically significant deterioration in fatigue severity [15]. This did not significantly differ (N=279; $\chi^2_1=3.5$, $P=.06$). Nine of the 244 patients (3.7%)

following IMP-FITNET had a baseline score for fatigue severity above 50 and did not show improvement. They could not be identified as patients showing clinically significant deterioration of fatigue due to the ceiling effect of the CIS-20 questionnaire (maximum score of 56).

In RCC, 10 of the 244 patients (4.1%) reported clinically significant deterioration of physical functioning after IMP-FITNET. In the benchmark study [14], 4 of 35 patients (11.4%) showed clinically significant deterioration of physical functioning. Deterioration of physical functioning did not significantly differ between the waiting list condition of the benchmark and IMP-FITNET (N=279; $\chi^2_1=3.3$, $P=.07$) (Table 3).

The within-treatment group effect size of FITNET in the RCT was large (Cohen $d=2.73$), with a 95% CI of 2.26 to 3.21. The effect size of IMP-FITNET was also large (Cohen $d=2.28$) and fell within the 95% CI of the FITNET RCT.

Semistructured Interviews and Number of Face-to-Face Consultations

Nine of the 11 therapists were interviewed. Face-to-face CBT was preferred to IMP-FITNET when there were interaction problems in the family or when the patient had psychiatric or somatic comorbidities. Therapists decided to make use of face-to-face consultations during IMP-FITNET treatment in the case of perceived inability of the patient to benefit from solely IMP-FITNET or anticipated problems with adherence and motivation. In general, therapists preferred blended therapy with combinations of IMP-FITNET.

Of the 244 adolescents who started IMP-FITNET, 116 (47.5%) followed only IMP-FITNET without face-to-face consultations and 102 (41.8%) had at least one face-to-face consultation with their therapist, and of these, 41 adolescents (16.8%) had over 3 face-to-face consultations. Adolescents who used face-to-face consultations had on average about three face-to-face consultations (mean 3.2, SD 3.81, modus 1). Moreover, videoconferencing became an additional feature during IMP-FITNET treatment for 50 patients, of which 23 patients (46.0%) used videoconferencing, with an average of 5.1

conferences (SD 3.48) lasting on average 24.3 minutes (SD 20.7).

Discussion

The posttreatment outcomes of adolescents with CFS/ME treated with I-CBT implemented in RCC (IMP-FITNET) were within the CIs of the outcomes from the benchmark with respect to levels of fatigue severity, physical functioning, school attendance, and recovery rates at posttreatment. Additionally, 133 of the 229 (58.1%) adolescents treated with IMP-FITNET met the recovery criteria posttreatment. The within-treatment group effect size of the decrease in fatigue severity with IMP-FITNET was also within the CI of the benchmark. At baseline, patients had an average fatigue severity score of 49.8 (SD 5.0), and after treatment, their fatigue severity score reduced on average by 23.8 points to 26.0 (SD 13.8). We conclude from this that IMP-FITNET applied in RCC is an effective intervention. Our findings are in line with the results of studies in adult patients with CFS/ME, in which blended CBT implemented in RCC was as effective as in a research context [27,28].

The primary and secondary outcomes of adolescents following face-to-face CBT were also within the CIs of the FITNET RCT.

A quarter of the referred patients eligible for IMP-FITNET started with face-to-face CBT after a shared decision process. This was more often the case when patients were young, were male, had a long symptom duration, and were anxious. Therapists indicated preferring face-to-face CBT in case of family interaction problems, psychiatric or somatic comorbidities, and problems with motivation.

The prevalence of a clinically significant deterioration following IMP-FITNET was low in general and comparable with a waiting list condition of a prior CBT study [14]. Therefore, we consider IMP-FITNET safe for application in RCC, without evidence of an increased risk of deterioration in fatigue and physical functioning. This replicates similar findings in previous studies of the safety of CBT for CFS/ME conducted in a research context [14].

At baseline, differences existed between adolescents who received IMP-FITNET and those in the benchmark FITNET RCT. Adolescents in RCC were less severely fatigued, were less physically impaired, had less school absence, and had a shorter symptom duration compared with patients from the benchmark RCT. This may be the result of the increased availability of an evidence-based and internet-based treatment for this patient group after nationwide implementation of I-CBT that followed the publication of the FITNET RCT results. Moreover, for these less severely affected adolescents with CFS/ME, IMP-FITNET is effective. IMP-FITNET has the advantage that adolescents do not need to travel for treatment. The nationwide availability of an effective intervention favors earlier referral.

This clinical observational study was not designed to investigate the difference in effectiveness of IMP-FITNET versus face-to-face CBT in relation to specific patient populations. Nevertheless, we found that even with a less strict treatment protocol and a more blended form of treatment, IMP-FITNET is effective. Although CBT for adolescents with CFS/ME (FITNET, face-to-face CBT, or IMP-FITNET) is considered effective, one-third of patients do not recover. To further improve the treatment and prognosis of adolescent CFS/ME, it is important to identify the factors that contribute to treatment effectiveness and assess which factors are associated with nonrecovery. Some issues need further consideration. First, in this observational study design, the choice of the treatment form (face to face vs IMP-FITNET) was determined by health care providers taking into account the patient's preference. For this reason, there are methodological limitations, and the most

important one is the risk of confounding by indication [29]. Second, the inclusion criteria of the FITNET RCT were stricter than those of IMP-FITNET, applying cutoff scores for physical functioning or school participation [4]. We did not find evidence that this influenced the outcomes of IMP-FITNET as the pattern of results was similar in the subgroup of patients who followed IMP-FITNET and met the stricter inclusion criteria. Next, the average time between pretreatment and posttreatment assessments in RCC was much longer than in the FITNET RCT, owing to the waiting list, holidays, and breaks. Third, not all results of the RCT could be compared with the findings of this study since some data were obtained with a different method or were not systematically assessed in the implementation study (eg, self-reported recovery). Fourth, although still relatively low, the dropout rate in RCC was significantly higher than in the FITNET RCT. This could, despite imputation of missing data, have led to selection bias. Lastly, the benchmark used to compare deterioration of physical functioning did not use the exact same questionnaire. As this study reported on data from patients who were treated with an evidence-based treatment in RCC, we do attribute the reduction in symptoms to the treatment with IMP-FITNET. Moreover, the advantage of retrospective data from RCC is the unbiased representation of the patient population.

IMP-FITNET in RCC was adapted according to therapist and patient preferences for video or face-to-face consultations. A substantial number of adolescents who followed IMP-FITNET had one or more face-to-face consultations. A blended form of IMP-FITNET, in which different modalities of communication can be used, may have advantages and is in line with the current practice to combine internet interventions with face-to-face interaction with a therapist. One limitation is that during implementation of the FITNET treatment, technical options were expanded, for example, video consultations were integrated in the portal. The increasingly rapid development within software systems makes it more difficult to compare treatments designed at different time points. More research is necessary to inform when blended CBT is more effective than internet-based treatment alone. Further research also has to show whether blended care, with video consultations, is as cost-effective as FITNET with only email contact.

In conclusion, this study showed that IMP-FITNET is an effective and safe treatment for adolescents with CFS/ME in RCC. In RCC, the therapist can tailor the mode of delivery of the intervention to the needs of the individual patient.

Authors' Contributions

HK was the principal investigator of this study. EA and LNN were responsible for data gathering. EA, LNN, EEBVDS, and HK were responsible for the data analysis and for drafting the report. HK, SLN, and EMVDP designed and supervised the study, and revised the manuscript critically. All authors have read and approved the final submitted manuscript.

Abstract

Background: Mechanical heart valve replacement (MHVR) is an effective method for the treatment of severe heart valve disease; however, it subjects patient to lifelong warfarin therapy after MHVR with the attendant risk of bleeding and thrombosis. Whether internet-based warfarin management reduces complications and improves patient quality of life remains unknown.

Objective: This study aimed to compare the effects of internet-based warfarin management and the conventional approach in patients who received MHVR in order to provide evidence regarding alternative strategies for long-term anticoagulation.

Methods: This was a prospective, multicenter, randomized, open-label, controlled clinical trial with a 1-year follow-up. Patients who needed long-term warfarin anticoagulation after MHVR were enrolled and then randomly divided into conventional and internet-based management groups. The percentage of time in the therapeutic range (TTR) was used as the primary outcome, while bleeding, thrombosis, and other events were the secondary outcomes.

Results: A total of 721 patients were enrolled. The baseline characteristics did not reach statistical differences between the 2 groups, suggesting the random assignment was successful. As a result, the internet-based group showed a significantly higher TTR (mean 0.53, SD 0.24 vs mean 0.46, SD 0.21; $P<.001$) and fraction of time in the therapeutic range (mean 0.48, SD 0.22 vs mean 0.42, SD 0.19; $P<.001$) than did those in the conventional group. Furthermore, as expected, the anticoagulation complications, including the bleeding and embolic events had a lower frequency in the internet-based group than in the conventional group (6.94% vs 12.74%; $P=.01$). Logistic regression showed that internet-based management increased the TTR by 7% (odds ratio

[OR] 1.07, 95% CI 1.05-1.09; $P < .001$) and reduced the bleeding and embolic risk by 6% (OR 0.94, 95% CI 0.92-0.96; $P = .01$). Moreover, low TTR was found to be a risk factor for bleeding and embolic events (OR 0.87, 95% CI 0.83-0.91; $P = .005$).

Conclusions: The internet-based warfarin management is superior to the conventional method, as it can reduce the anticoagulation complications in patients who receive long-term warfarin anticoagulation after MHVR.

KEYWORDS

RCT; warfarin; telemedicine; TTR; complication

Introduction

Heart valve replacement is recommended for patients with severe heart valve disease and is performed in several hundred thousand patients worldwide each year [1]. As a replacement valve for humans, a mechanical valve is more durable than a bioprosthetic valve but requires lifelong anticoagulation therapy [2]. Over 98% of young Chinese patients who need heart valve replacement receive mechanical valves [3] but face the risk of thrombosis on the valves and ensuing embolism [4]; thus, lifelong anticoagulation is required and recommended by guidelines [5]. Warfarin, as an anticoagulation drug, is widely used in the prevention of various thromboembolic events [6], but it is not easy to control due to the narrow therapeutic range and patients' heterogeneity. Therefore, the dosage of warfarin needs to be adjusted accordingly by the international normalized ratio (INR) [7,8]. Time in therapeutic range (TTR), as the percentage of time the patient's INR is within the target range, has been used in clinical research to measure the adequacy of warfarin therapy and shows a significant correlation with anticoagulation outcomes [9,10]. Well-managed warfarin anticoagulation is effective in reducing complications, such as bleeding and thrombosis, in patients with a mechanical heart valve [11]. However, in clinical practice, patients' anticoagulation management is not conducted in ideal fashion.

The conventional way to manage anticoagulation is face to face [12], but the quality of this approach depends highly on the patients' compliance, resulting in difficulty in management and increased risk of adverse events [13,14]. Chinese cardiac surgeons tend to focus more on inpatient treatment, but follow-up is often ignored, especially in central and western China, where there is a lack of professional cardiac surgery-related health care [15]. Furthermore, the extensive

follow-up required for warfarin management adds to the workload of specialist hospitals [16,17]. Therefore, current warfarin management needs to be urgently improved.

The internet provides fast and convenient communication, with integration into health care delivery systems presenting exciting opportunities for improving care promotion, disease prevention, and value-based clinical medicine [18]. Previous studies have reported several online warfarin management systems and have demonstrated their benefits for patients after heart valve surgery [19-21]. However, the capacity of these telemedicine apps to improve the quality of anticoagulation remains unclear, and carefully designed prospective trials are needed to provide reliable evidence. Therefore, in this large scale, prospective, multicenter, randomized controlled trial, we aimed to study if internet-based warfarin management increases TTR and reduces the risk of anticoagulation complications in patients after mechanical heart valve replacement. Our study is the first randomized controlled trial to explore the effectiveness of internet-based warfarin anticoagulation management in patients after mechanical heart valve replacement.

Methods

Study Design

The clinical trial design has been described previously [16]. In brief, the study was a prospective, multicenter, randomized, open-label, controlled trial. The patient flow chart is shown in Figure 1. The project was organized and implemented by Beijing Anshan Hospital affiliated with Capital Medical University. Five top cardiac centers in China participated in the clinical trial. The Peking University Clinical Research Institute has created a data committee to evaluate the data quality and supervise data collecting.

Figure 1. Patient flow chart. MHVR mechanical heart valve replacement.

All participants provided written informed consent. The study protocol was approved by the Ethics Committee of Beijing Anshan Hospital, Capital Medical University, and all other centers accepted the central ethics approval or obtained local approval by internal ethics committees.

Participants

Inclusion criteria were as follows: patients had a normal psychological state and were aged 18 to 65 years, patients or guardians agreed to the study plan and signed the informed consent form, long-term anticoagulation was required after mechanical heart valve replacement, and patients and their families could effectively operate smartphones. The exclusion criteria were the following: patients with emergency surgery; patients treated with cardiac bypass surgery; patients with severe chronic diseases, such as malignant tumors, hepatic cirrhosis, diabetes, cerebral hemorrhage (cerebral infarction), convalescence, thyroid dysfunction, and respiratory failure; patients with severe renal insufficiency (endogenous creatinine clearance rate ≤ 20 mL/min); patients with severe hepatic insufficiency (Child-Pugh ≥ 10); patients with severe heart failure (cardiac function New York Heart Association grade IV); patients with postoperative infective endocarditis; patients with severe postoperative complications and poor prognosis; and patients who were unable to comply with this study.

Intervention

In our study, the conventional management was conducted by laboratory testing and drug dose adjustment at the hospital as instructed by a doctor, while internet-based management was performed via a mobile user interface medical network follow-up platform. All patients in both groups received training and education on warfarin anticoagulation before discharge, which included information on drug interactions, diet, compliance with dosing, and the importance of INR testing.

In the conventional anticoagulation management model, patients underwent INR tests at the local hospital. After reviewing the laboratory results, the outpatient cardiologist evaluated the INR results and decided whether to adjust the warfarin dosage until

the next patient visit. Patients were asked to record the results of every examination and note the physical symptoms related to warfarin anticoagulation, such as bleeding and embolism, to prepare for follow-up discharge.

In the early stages of the study, we developed an internet-based follow-up system for clinical use after cardiac surgery [22]. In the new warfarin management group, online registration information was generated by researchers and sent to patients, who completed the rest of the follow-up registration. The app software for the internet-based follow-up management system has been described previously [16]. All patients and their families attended at least 3 follow-up training sessions, including watching an educational video and installation and simulation of the follow-up software and mobile apps. Patients were asked to upload the INR and other laboratory test results to the apps.

Randomization, Blinding, and Grouping

The central stratified randomization method was used in this study. Patients who met the inclusion and not exclusion criteria and consented to participate in this study were randomized in a 1:1 ratio into the conventional and internet-based management groups. Patients were aware of their grouping, whereas the researchers conducting the end point evaluations were blinded to the groupings.

Anticoagulation Treatment Strategies and Follow-Up

The INR was measured every 3 to 5 days for 1 month after discharge. After the patient's INR results stabilized, the INR was measured every 10 to 14 days from 1 to 3 months after discharge, once a month from 3 to 6 months, and once every 2 months from 6 to 12 months after discharge. The target INR window ranged from 1.8 to 2.5 (1.8-2.2 for aortic valve replacement, 2.0-2.5 for mitral valve replacement, and 2.0-2.5 for double valve replacement).

Patients were followed up at 3 months (30 days before and after), 6 months (30 days before and after), 9 months (30 days before and after), and 12 months (30 days before and after) after discharge.

At each follow-up point, patients in the traditional group were asked to bring their original hospitalization records and all medical examination results after discharge, and the researchers completed the case report form. Patients were followed up by telephone if they could not return to the hospital at the scheduled time points.

For patients in the new warfarin group, the researchers checked the data results uploaded by the patients in the new follow-up system app and completed the case report form at the follow-up time points.

End Point

The primary end point of this study was the TTR. The TTR was measured by Roosendaal linear interpolation [10]. The secondary end point was the incidence of anticoagulation-related embolism and bleeding. Embolism includes any embolic event that occurs in the absence of infection after the immediate perioperative period. Embolism may manifest as a neurologic event or a noncerebral embolic event. Severe bleeding associated with anticoagulation includes any episode of major internal or external bleeding that causes death, hospitalization, or permanent injury or that necessitates transfusion. General bleeding related to anticoagulation refers to bleeding of the nasal cavity and gums, skin ecchymosis, menorrhagia, hematuria, melena, and so on.

Statistical Analyses

Continuous variables are expressed as the mean and SD or median and IQR; meanwhile, categorical variables are expressed as frequencies and percentages. Baseline characteristics were compared between the 2 groups by the chi-square, *t*, and Mann-Whitney tests as appropriate. The Mann-Whitney test was used to determine the difference in the TTR between the conventional anticoagulation management model group and the internet-based anticoagulation model group. The incidence of adverse events (bleeding or thrombosis) was compared by the chi-square test. A 2-sided *P* value <0.05 was regarded as statistically significant. All analyses were performed using R version 3.4.2 (The R Foundation).

Results

Characteristics of the Patients

A total of 721 patients from 5 top Chinese cardiovascular centers were enrolled between July 2018 and September 2019 and then randomly assigned to a conventional group (n=361) or an internet-based warfarin management group (n=360). The average ages of the conventional and internet-based group were 49.59 (SD 9.46) and 50.6 (SD 9.65), respectively (*P*=0.16); the percentage of female patients in the 2 groups was 38.9% (140/360) and 39.1% (141/361), respectively (*P*=0.96). The other baseline characteristics also did not reach statistical differences between the 2 groups (Table 1), suggesting the patients' random assignment was successful.

Internet-Based Warfarin Management Increased TTR

In order to study the effect of internet-based management on warfarin anticoagulation, we used TTR as the primary end point. The TTR was significantly higher in the internet-based group than in the conventional group (internet: mean 0.53, SD 0.24; conventional: mean 0.46, SD 0.21; $P<.001$). Of the 360 patients in the internet-based group, the number of patients with a TTR in the range of 0%-30%, 30%-60%, and 60%-100% was 61 (16.94%), 156 (43.33%), and 143 (39.72%), respectively; meanwhile, of the 361 patients in the conventional group, the number was 77 (21.33%), 189 (52.35%), and 95 (26.32%),

respectively. As expected, the internet-based group yielded a higher fraction of TTR than did the traditional group (internet: mean 0.48, SD 0.22; conventional: mean 0.42, SD 0.19; $P<.001$). Logistic regression indicated that the internet-based management increased the TTR by 7% (odds ratio [OR] 1.07, 95% CI 1.05-1.09; $P<.001$; [Table 2](#)). Our results suggest that internet-based warfarin management is better than the conventional method according to increased TTR, while the mean INR values (internet: mean 2.13, SD 0.87; conventional: mean 2.14, SD 1.10; $P=0.87$) were not different between the 2 groups ([Table 3](#)).

Table 2. Logistic regression of time in the therapeutic range.

Internet-Based Warfarin Management Reduced the Risk of Adverse Events

A lower risk of stroke and bleeding can be reached by maximizing the TTR. We further used the bleeding and embolic events as a secondary end point to investigate the difference between the internet-based and conventional groups. The incidence of all bleeding and embolic events (6.94% vs 12.74%; $P=.009$) was lower in the internet-based group than in the conventional group

(Table 4). Logistic regression showed that internet-based management reduced the bleeding and embolic risk by 6% (OR 0.94, 95% CI 0.92-0.96; $P=.01$). Moreover, low TTR was a risk factor for bleeding and embolic events (OR 0.87, 95% CI 0.83-0.91; $P=.005$; Table 5). The results showed that internet-based warfarin management not only increased TTR but also reduced the risk of adverse events of warfarin anticoagulation.

Table 4. Adverse events.

Adverse event	Internet-based group (n=360)	Traditional group (n=361)	P value

Discussion

In this study, there was a significantly higher level of TTR in the population that was administered with the internet-based anticoagulation management than in the population treated with conventional warfarin management (0.53 vs 0.46; $P < .001$) in a real-world medical setting. Management of warfarin anticoagulation by a specialized, telemedicine-based service was able to substantially improve the quality of anticoagulation therapy. Our research findings showed that the new telemedical

warfarin management had lower incidences of general bleeding events (22/260, 6.11% vs 40/361, 11.08%; $P = .02$), all bleeding events (24/360, 6.67% vs 44/361, 12.19%; $P = .01$), and all bleeding and embolic events than did the conventional group. In addition, single factor logistic regression of TTR and all bleeding and embolic events demonstrated the superiority of the new internet-based warfarin management as well as the relationship between TTR and anticoagulation complications in the 2 groups.

Patients who receive mechanical heart valve replacement need lifelong anticoagulation therapy, and their INR is conventionally measured to adjust the anticoagulation strength and the dose of anticoagulation drugs. However, adjusting the warfarin dosage is a challenging task since there is heterogeneity in patients' warfarin dosing [23]. It has been reported that Chinese patients require a lower dose of warfarin than do White patients although the intensity of the anticoagulation is comparable [24,25]. As Chinese patients have a lower warfarin requirement, there are concerns about whether the target INR range for Western populations also provides optional anticoagulation in Chinese patients. In one study, You et al concluded that an INR of 1.8 to 2.4 appeared to be associated with the lowest incidence of major bleeding or thromboembolic events in a cohort of Chinese patients receiving warfarin therapy for moderate-intensity anticoagulation [26]. Unfortunately, there is no guideline for the target value of INR in China. At the seminar before the start of the project, after rigorous discussion, the researchers from all subcenters finally determined the target INR window of 1.8 to 2.5 (1.8-2.2 for aortic valve replacement, 2.0-2.5 for mitral valve replacement, and 2.0-2.5 for a double valve replacement) according to the actual clinical situation and previous studies in our centers [23,27-30]. The effectiveness of warfarin anticoagulation therapy is usually expressed as TTR. Due to the relatively narrow INR window, the TTR in the 2 groups was correspondingly lower than that reported in other warfarin management studies [19,20,31,32].

The finding of high levels of TTR and low incidences of anticoagulation complications in the internet-based management group might be, at least in part, attributable to the education, reminders, and convenient doctor-patient communication of the new management platform, which has been described previously [16,22]. Led by the director of surgery and including surgeons, trained physician assistants, staff nurses, and pharmacists, the new anticoagulation management model was developed and combined health science promotion and education, portable coagulation indicator monitoring, warfarin-related gene monitoring, warfarin dosage predication, access to a professional outpatient clinic, and a publicity manual. Unlike other studies in which only the patients use the app, our mobile apps are specific to doctors and patients. The app for doctors was distributed to cardiovascular surgeons from the collaborating units participating in the study by the lead unit of this study; the app for patients was distributed to patients enrolled in this study by doctors participating in this study. The doctor's app contained a patient management module and a professional learning module that allowed timely patient contact. The patient's app contained the patients' personal information, including hospitalization information and discharge matters requiring attention. The patient's app was mainly divided into

a health management module, doctor consultation module, and medical science popularization module. The app regularly reminded the patients of the time of the INR test. If patients missed the test, the software would warn them. This new platform completed the collection of clinical data and provided reliable and quality follow-up services and warfarin management for patients undergoing lifelong warfarin coagulation.

Telemedicine, a term used interchangeably with telehealth, is the distribution of health-related services and information via electronic information and telecommunication technologies [33]. Over the past four decades, telemedicine has become an increasingly effective alternative to traditional medicine and has evolved into an integrated technology used in hospitals and clinics [34]. As the public becomes more adept at using the internet and smartphone in all aspects of daily life, evolving app in health care will change the way in which patients and doctors interact [35]. A few previous studies explored several internet-based warfarin management approaches and showed the advantages of the new anticoagulation model [32,36-38]. However, their conclusions were not completely consistent.

Based on the modern communication technologies, a new type of anticoagulation mode for cardiac surgery was established via the "Internet+Medical" management mode, supported by knowledge-based clinical medical diagnosis and treatment. This prospective, multicenter, randomized, open-label, controlled trial fills a deficit in research and adds to the solid evidence which exists regarding optimal strategies for patients with an extended period of warfarin anticoagulation. The new internet-based anticoagulation management model has the potential to provide considerable social and economic benefits in terms of further improving the long-term survival and quality of life of patients undergoing lifelong anticoagulation therapy.

There were also some limitations to this study. First, for the anticoagulation complications, the sample size was relevantly small, and the results may not be representative of all populations with anticoagulation therapy; thus, more prospective, large sample, randomized studies are needed to confirm our findings. Second, patients' age, education level, and disease severity might have affected their compliance, which also might have influenced the quality of anticoagulation after surgery. Third, we did not compare the cost in the 2 management groups or the difference between urban and rural patients. In future studies and follow-up research, we will compare the associated medical costs during follow-up and rehabilitation under the 2 warfarin management models.

Internet-based warfarin management is superior to conventional management, as it can reduce the anticoagulation complications in patients who receive long-term warfarin anticoagulation after mechanical heart valve replacement.

Acknowledgments

The work is supported by the Beijing Science and Technology Commission of China (New warfarin anticoagulation management model after heart valve surgery; #D171100002917003). The authors are thankful for all the researchers from the 4 participating centers, Peking University Clinical Research Institute, and the technical support of Digital Health China Technologies Co, Ltd.

Authors' Contributions

HZ, ZZ, and YL conceived the study idea. CL, JS, KW, KL, FZ, ZZ, YL, JH, YQ, YY, GF, HZ, ZD, DX, YC, RW, YZ, ZZ, and XM made substantial contributions to the development of the study. ZZ and HZ drafted the manuscript, and all the authors contributed to the critical revisions of the paper. The final manuscript was read and approved by all the authors.

Abstract

Background: Routine HIV testing accompanied with pre-exposure prophylaxis (PrEP) requires innovative support in a real-world setting.

Objective: This study aimed to determine the usage of HIV self-testing (HIVST) kits and their secondary distribution to partners among men who have sex with men (MSM) in China, who use PrEP, in an observational study between 2018 and 2019.

Methods: In 4 major cities in China, we prospectively followed-up MSM from the China Real-world oral PrEP demonstration study, which provides daily or on-demand PrEP for 12 months, to assess the usage and secondary distribution of HIVST on quarterly follow-ups. Half of the PrEP users were randomized to receive 2 HIVSTs per month in addition to quarterly facility-based HIV testing. We evaluated the feasibility of providing HIVST to PrEP users.

Results: We recruited 939 MSM and randomized 471 to receive HIVST, among whom 235 (49.9%) were daily and 236 (50.1%) were on-demand PrEP users. At baseline, the median age was 29 years, 390 (82.0%) men had at least college-level education, and 119 (25.3%) had never undergone facility-based HIV testing before. Three months after PrEP initiation, 341 (74.5%) men had used the HIVST provided to them and found it very easy to use. Among them, 180 of 341 (52.8%) men had distributed the HIVST kits to other MSM, and 132 (51.6%) among the 256 men who returned HIVST results reported that used it with their

sexual partners at the onset of intercourse. Participants on daily PrEP were more likely to use HIVST (adjusted hazard ratio=1.3, 95% CI 1.0-1.6) and distribute HIVST kits (adjusted hazard ratio=1.3, 95% CI 1.1-1.7) than those using on-demand PrEP.

Conclusions: MSM who used PrEP had a high rate of usage and secondary distribution of HIVST kits, especially among those on daily PrEP, which suggested high feasibility and necessity for HIVST after PrEP initiation. Assuming that fourth-generation HIVST kits are available, HIVST may be able to replace facility-based HIV testing to a certain extent.

HIV self-testing; men who have sex with men; pre-exposure prophylaxis; secondary distribution; usage

Introduction

Oral pre-exposure prophylaxis (PrEP) can reduce HIV infections among adherent men who have sex with men (MSM) [1-3]. While the adherence to PrEP is only approximately 60% in the real-world setting [4], it is crucial for all PrEP users to undergo quarterly HIV testing to avoid a breakthrough infection and acquiring resistance to antiretroviral therapy [5].

However, the implementation of PrEP has increased the rate of missing facility-based testing. Almost 30% of PrEP users did not show up for their first quarterly clinical visits [6], and approximately 40% of them missed their 6-monthly appointment [7]. Difficulty attending clinical visits and missing laboratory testing has become one of the main reasons for the interruption [8] and discontinuation [9] in PrEP use in clinical settings. Since the outbreak of COVID-19, attendance at facility-based HIV testing became more difficult because of clinic closure, challenges with social distancing, and related difficulties [10]. It is crucial to identify strategies to ensure frequent HIV testing among individuals on PrEP.

In order to improve and expand PrEP uptake, nonclinical PrEP approaches are being piloted, such as central dispensing at pharmacies [11], community venues (eg, automated teller machines in shopping malls) [12], schools, and prisons or jails [13]. These approaches still require periodic HIV testing, often through HIV self-testing (HIVST), and be supplemented with internet-based support, which is a convenient and confidential option for HIV testing, allowing people to take an HIV test and learn the outcome in their own home or at other private locations [14], while mailing and application of the test kit, support consultations during testing, uploading of testing outcomes, and follow-ups can be conducted over the internet [15,16].

HIVST can also promote partner testing through secondary distribution of test kits [17]; that is, an individual who is provided multiple self-test kits can distribute them to sexual partners or to others in their social network [18]. Peers within the key HIV-infected population play an important role in facilitating HIV prevention in that population; for example, by promoting the uptake of HIV testing [19] and linkage to care [20]. Providing multiple HIVST kits to PrEP users and encouraging their secondary distribution would potentially empower MSM using PrEP and the promote HIV prevention within the MSM community.

HIVST technology has advanced in recent years. Third-generation HIVST technology has a testing period of 3 weeks, with high sensitivity and specificity [21]. PrEP recipients can easily administer HIVST at home and know their HIV status at least 4-8 weeks ahead of their next quarterly HIV facility-based test, as recommended by World Health Organization and Centers for Disease Control and Prevention [5]. In such a scenario, HIVST can be used to identify a breakthrough infection earlier and prevent 4-8 weeks of antiretroviral therapy in PrEP that could lead to resistance.

We aimed to assess the usage and secondary distribution of internet-based HIVST kits and their correlates among MSM using PrEP, prospectively. This information can provide evidence regarding the utility of HIVST in the era of PrEP and support a better paired and targeted HIV-testing strategy among PrEP users in the future.

Methods

Study Design, Setting, and Participants

We conducted a randomized control trial of HIV self-testing among MSM who are PrEP users (Chinese Clinical Trial Registry# ChiCTR1800020374). Participants were recruited from among MSM in the ongoing PrEP pragmatic trial (CROPrEP, ChiCTR-IIN-17013762), which provides regimens of daily and on-demand PrEP, in 4 major Chinese cities (Beijing, Shenyang, Chongqing, and Shenzhen) from December 2018 to September 2019. CROPrEP provides all participants standard care of PrEP, including quarterly facility-based HIV testing. Given the well-documented protective effect of PrEP, the sample size of the CROPrEP study at each site was not determined through power calculations. The sample size at each site was increased maximally by fully considering the human resources and capability of each study site [22].

We randomized half of the enrolled PrEP recipients to provide them 2 HIV self-tests per month, in addition to the standard care. The study team has generated a service account on one of the most popular social media in China (WeChat) to provide web-based services on the application of extra testing kits, instructions on self-testing, real-time consultation with the staff, uploading of test outcomes, and follow-up questionnaires. All HIVST kits distributed or secondarily distributed were marked with a serial number. Participants who received HIVST were also encouraged to share them with their male sexual partners.

All participants were prospectively followed up quarterly. This study adhered to the STROBE (Strengthening the Reporting of Observational studies in Epidemiology) checklist ([Multimedia Appendix 1](#)).

The study sites are general hospitals equipped with HIV voluntary counseling and testing clinics and HIV treatment clinics with physicians specialized in infectious diseases in 4 major cities in China: The Youan Hospital of Capital Medical University, Beijing; The First Affiliated Hospital of China Medical University, Shenyang; The Chongqing Public Health Medical Center of Southwest University, Chongqing; and The Third People's Hospital, Shenzhen.

Participants were eligible to participate in this study if they (1) were designated male at birth; (2) have sex with male partners; (3) are aged 18-65 years; (4) report having ≥ 1 of the following risk factors in the last 6 months: (a) had condomless receptive anal sex with a male partner, (b) had more than 2 male sexual partners, (c) had self-reported sexually transmitted infections (STIs) such as syphilis, gonorrhea, chlamydia, chancroid, or lymphogranuloma venereum, or (d) have ever used postexposure prophylaxis medication, but have not received postexposure prophylaxis medication in the previous month; (5) have a nonreactive outcome on a fourth-generation HIV enzyme-linked immunosorbent assay test at baseline screening and undetectable HIV-1 RNA; (6) have no evidence of severe liver or kidney dysfunction on a comprehensive evaluation (including physical examination, urine test, and blood biochemical examination); and (7) indicate willingness to participate and sign an informed consent form. Individuals were excluded if they (1) are deemed ineligible on eligibility evaluation for the CROPrEP trial, (2) refuse to accept or use the HIVST kits (with reasons recorded), or (3) refuse to sign the informed consent form.

To prevent loss to follow-up bias, the clinicians and study staff provided one-on-one personalized compliance support, counseling, and cohort maintenance during the follow-up period. Furthermore, community-based organizations and the weekly internet-based retention strategies were used to strengthen group- and individual-level supervision of retention and cohort management. This internet-based strategy included interactive peer counseling focusing on study retention; a short message providing routine follow-up visit reminders, along with a live chat.

Measures

Information on demographic characteristics (including age, education level, marital status, and monthly income), HIV-related risk behavior in the past 3 months (frequency of anal intercourse, and instances of condomless anal intercourse, substance abuse, etc), and testing history for HIV and STIs in the past were collected at baseline through self-administrated questionnaires distributed on each participants' smartphone. The aforementioned information was obtained in accordance with a systematic review that analyzed studies on HIV testing behaviors among MSM in China [23]. Participants were grouped into <25-year-old and ≥ 25 -year-old age groups in accordance with the definition of youth of the United Nations [24]. Participants were also grouped by their median monthly income. Measures of monthly income were separated by the median

income. Usage of HIVST and secondary distribution of HIVST to male sexual partners and other MSM were recorded at quarterly follow-up among all participants through self-administrated questionnaires on each participants' smartphone. The returned results of photographs of used HIVST were uploaded by participants after they used HIVST kits, and information regarding the place, occasion, and ease of using HIVST was collected. The proportion of HIVST usage was calculated among participants retained at the third month follow-up visit. Furthermore, the proportion of HIVST secondary distribution was calculated among participants who had self-reported usage of HIVST at the third month follow-up visit.

Statistical Analyses

Statistical analysis was conducted using SPSS (version 20.0, IBM Corp). Demographics, the PrEP regimen, and HIV-related risk behavior in the past 3 months among all participants were expressed as numbers and percentages. Follow-up time was determined as the number of days from the date of enrollment to the date of quarterly follow-up. Univariable and multivariable Cox regression analyses were performed to assess the predictors of self-reported usage of HIVST and secondary distribution of HIVST at the first quarterly follow-up. Variables with $P < .20$ on univariable analysis were included in the multivariable model to avoid the omission of clinically relevant variables, which had an underestimated effect in univariable analysis [25,26]. Variables in the final model were selected with a forward stepwise procedure. Hazard ratios (HRs) and adjusted HRs (aHRs) were calculated. On multivariate analysis, $P < .05$ was considered the cut-off for a significant difference. We plotted Kaplan–Meier survival curves for predictors for HIVST usage and their secondary distribution during multivariable Cox regression analysis with $P < .05$ indicating significance.

Ethics Approval

The study protocol was approved by the ethics review board of the First Affiliated Hospital of China Medical University (IRB-2018-273), Shenyang. Written informed consent was obtained from each participant before collecting study information or blood samples. Participants voluntarily participated in the study and had the right to refuse to answer any question. Participants had the right to withdraw from the study without penalty. The protocols for the CROPrEP trial [25] and this study [27] have been published. This HIVST study among PrEP recipients was registered on the Chinese Clinical Trial Registry (trial ID ChiCTR1800020374).

Results

Baseline Demographics and Behavioral Characteristics

A total of 939 MSM were recruited from the CROPrEP trial, with 470 daily PrEP users and 469 on-demand PrEP users. In total, 471 men were randomized to receive 2 HIV self-tests per month, in addition to the standard care, which included 235 (49.0%) daily PrEP users and 236 (50.1%) on-demand PrEP users.

The median age of these 471 participants at baseline was 29 years (quantile 25-35 years); among them, 390 (82.0%) had an

education level of undergraduate and above, 241 (51.2%) had a monthly income of less than US \$857, and 266 (56.5%) were single. Regarding HIV-related risk behavior in the past 3 months, 165 (35.0%) individuals had had anal intercourse every week and 234 (49.7%) had had anal intercourse every month, 312 (66.2%) of them had condomless anal intercourse with male sexual partners, 226 (48.0%) used Poppers in the previous 3

months, and 103 (22.5%) had participated in group sex. In total, 39 (8.3%) of them self-reported having STI-related symptoms in the previous 12 months. Further, 375 (79.6%) participants self-reported having used HIVST in the past, and 352 (74.7%) reported having undergone facility-based HIV testing in the past ([Table 1](#)).

Table 1. Baseline characteristics of pre-exposure prophylaxis recipients carrying out HIV self-testing in 4 major cities of China (N=471).

Variable	Participants, n (%)
Pre-exposure prophylaxis regimen	
Daily	235 (49.9)
On-demand	236 (50.1)
Age (median 29.0 years, quantiles 25.0-35.0 years)	
<25	84 (17.8)
≥25	387 (82.2)
Education level	
Senior high and below	81 (17.2)
Undergraduate and above	390 (82.8)
Monthly income (US \$)	
≤857	241 (51.2)
≥858	230 (48.8)
Marital status	
Single	266 (56.5)
Married or cohabiting with a female	30 (6.4)
In a relationship or cohabiting with a male	175 (37.2)
Frequency of anal intercourse in the past 3 months	
Every day	8 (1.7)
Every week	165 (35.0)
Every month	234 (49.7)
Less than once a month	64 (13.6)
Had condomless anal intercourse in the previous 3 months	
Yes	312 (66.2)
No	159 (33.8)
Had used Poppers in the previous 3 months	
Yes	226 (48.0)
No	245 (52.0)
Had group sex in the previous 3 months^a	
Yes	103 (22.5)
No	354 (77.5)
Had sexually transmitted infection–related symptoms in the previous 12 months	
Yes	39 (8.3)
No	432 (91.7)
Have ever used HIV self-testing in the past	
Yes	375 (79.6)
No	96 (20.4)
Have ever undergone facility-based HIV testing in the past	
Yes	352 (74.7)
No	119 (25.3)

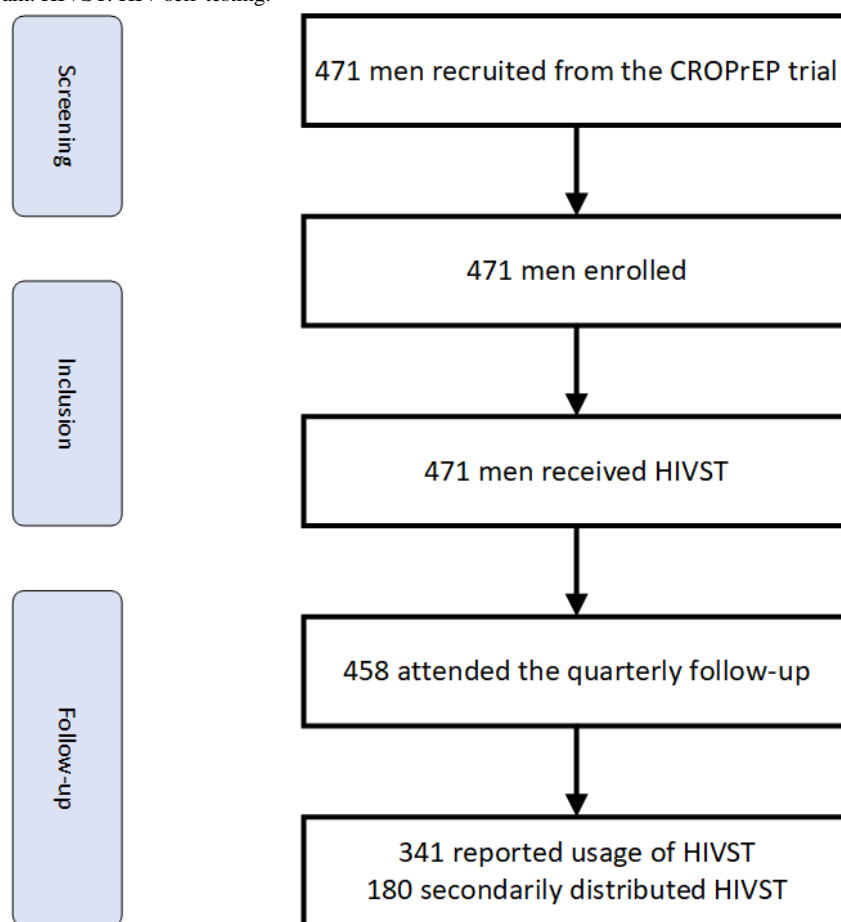

^aThere were 14 missing data.

Usage, Returning Results, and Sharing of HIVST at the First Quarterly Follow-ups

Among these 471 men, 458 men were retained at the first quarterly follow-up, resulting in a retention rate of 97.2%. At the first quarterly of PrEP initiation, a total of 341 (74.5%) participants self-reported that they had used the HIVST in the past 3 months, among whom 256 (75.1%) returned HIVST testing outcomes by uploading photographs of the used HIVST

kits marked with a serial number. In total, 260 (76.2%) men self-reported that they had recommended HIVST to their male sexual partners or gay friends, and 180 (52.8%) participants self-reported that they had shared their HIVST kits with the male sexual partners or gay friends. Among the 256 participants who had returned HIVST outcomes, the most frequent place of using HIVST was at home ($n=218$, 85.2%). In total, 132 (51.6%) men reported that HIVST was used immediately before or after sexual intercourse with their male sexual partners (Figure 1).

Figure 1. Study flow diagram. HIVST: HIV self-testing.

Correlation of Self-Reported Usage of HIVST on Quarterly Follow-up

On univariable Cox regression analysis, men with the following variables were more likely to use HIVST during follow-up: being on daily PrEP (vs on-demand PrEP, HR=1.273, 95% CI 1.028-1.576; $P=.03$), having an education level of senior high or below (vs college and above, HR=1.393, 95% CI 1.054-1.841; $P=.02$), having STI-related symptoms in the previous 12 months (vs not having symptoms, HR=1.384, 95% CI 0.956-2.004; $P=.09$), having ever used HIVST in the past (vs having used HIVST in the past, HR=1.492, 95% CI 1.102-2.020; $P=.01$). Participants with the following variables were less likely to use HIVST: having had anal intercourse every day in the past 3 months (vs less than once a month, HR=0.396, 95% CI 0.143-1.101; $P=.08$), having had condomless anal intercourse

in the past 3 months (vs not having had condomless anal intercourse, HR=0.825, 95% CI 0.687-0.990; $P=.04$) (Table 2).

After the forward stepwise procedure, all variables with $P<.20$ on univariable regression analysis were included in the multivariable regression model, and participants with the following variables were more likely to use HIVST during follow-ups: being on daily PrEP (vs on-demand PrEP, aHR=1.298, 95% CI 1.047-1.608; $P=.02$), having an education level of senior high or below (vs undergraduate and above, aHR=1.482, 95% CI 1.119-1.964; $P=.006$), and having used HIVST in the past (vs not having used HIVST in the past, aHR=1.642, 95% CI 1.205-2.242; $P=.002$). Furthermore, participants who self-reported having used Poppers in the past 3 months (vs those not having used Poppers in the past 3 months, aHR=0.788, 95% CI 0.633-9.981; $P=.03$) were less likely to use HIVST (Table 2 and Figure 2).

Table 2. Cox regression model of correlates of usage of HIV self-testing among pre-exposure prophylaxis recipients within 3 months of treatment initiation in 4 major cities in China (N=471).

Variable	Usage of HIV self-testing				Secondary distribution of HIV self-test kits

^aVariables with $P < .20$ on univariable analysis were included in the multivariable Cox regression model.

^b—: not determined.

Figure 2. Kaplan–Meier survival curves for predictors of HIVST usage. HIVST: HIV self-testing, PrEP: pre-exposure prophylaxis.

Correlation of Secondary Distribution of HIVST Kits at Quarterly Follow-up

On univariable Cox regression analysis, participants with the following variables were more likely to secondarily distribute HIVST kits during follow-up: being on daily PrEP (vs on-demand PrEP, HR=1.343, 95% CI 1.072-1.682; $P=.01$), being currently married (vs being single, HR=1.523, 95% CI 0.963-2.408; $P=.07$), having ever used HIVST in the past (vs having never used HIVST in the past, HR=1.415, 95% CI 1.034-1.937; $P=.03$) (Table 2).

After the stepwise forward procedure, all variables with $P<.20$ on univariable regression were included in the multivariable regression model, and participants with following variables were more likely to secondarily distribute HIVST during follow-ups: being on daily PrEP (vs on-demand PrEP, aHR=1.352, 95% CI 1.079-1.694; $P=.009$), being currently married (vs single, aHR=1.706, 95% CI 1.074-2.709; $P=.02$), and having used HIVST in the past (vs not having used HIVST in the past, aHR=1.464, 95% CI 1.066-2.009 $P=.02$) (Figure 3).

Figure 3. Kaplan–Meier survival curves for predictors of HIVST secondary distribution. HIVST: HIV self-testing; PrEP: pre-exposure prophylaxis.

Discussion

Principal Findings

We prospectively identified a high rate of usage and secondary distribution of the internet-based HIVST among MSM who are using PrEP in a multicenter pragmatic trial in China, especially among the daily PrEP users. This result warrants the internet-based HIVST as a crucial part of the HIV testing strategy paired with PrEP among the MSM population. Furthermore, the high rate of secondary distribution of HIVST kits and self-testing among sexual partners among PrEP users assures a promising future for peer-initiated expanded HIV testing and maximization of the HIV prevention among the MSM community.

Approximately 80% of PrEP users have used HIVST within 3 months after PrEP initiation and found it easy to use, reflecting HIV testing behavior among PrEP recipients. Every 4 of 5 of these PrEP users had used HIVST before the initiation of PrEP, which is much higher than the level among the general MSM population in China (20%-40%) [28,29]. Since difficulty attending facility-based testing was one of the main reasons for discontinuing PrEP during implementation [8,9], this high usage of HIVST among PrEP users warrants future consideration of substituting some facility-based HIV testing during PrEP and provides evidence in support of HIVST to support PrEP users during the COVID-19 pandemic in the future, since

facility-based services and in-person patient-clinician contact has been limited because of the pandemic [30].

Notably, there was a high rate of secondary distribution of HIVST and testing of sexual partners among those who had used HIVST after PrEP initiation. Half of the HIVST was used to test together with their sexual partners immediately before or after intercourse. This is significant because of the limited success and high cost of accessing MSM at clinics or provider-initiated expanded HIV testing strategies [31,32]. According to previous studies, MSM who accept or uptake PrEP were more concerned about their partners' HIV status [33] and had more sexual partners [34], which makes them excellent facilitators for expanded HIV testing among the MSM population. Empowering them with HIVST as a tool to undertake secondary distribution and partner testing can maximize the impact of PrEP on the MSM community via peer-initiated HIV prevention campaigns. Future studies should vigorously pursue and explore the critical role of PrEP users in HIV prevention within the key populations.

Factors promoting the usage and secondary distribution of HIVST among PrEP users were also identified. Men on daily PrEP were more likely to use and secondarily distribute HIVST after PrEP initiation than those on the on-demand regimen. Since most of the HIVST was used immediately before or after sexual intercourse, this correlation can be explained by the fact that MSM on daily PrEP displayed more frequent HIV-related risk behavior and a higher number of sexual partners [35,36].

According to HIV transmission network studies, MSM with a higher number of sexual partners are associated more firmly with other MSM and had a crucial impact on the network of HIV transmission within the population. This correlation illustrates that MSM on daily PrEP play a more critical role in expanded HIV testing and HIV prevention campaigns as peers among the MSM community. Studies on the social network of PrEP recipients built through HIVST distribution should be actively pursued in the future.

An inhibitor of the use of HIVST among PrEP users is the use of Poppers, which is one of the most popular recreational drugs among MSM worldwide [37]. According to previous studies, Poppers users are more likely to consider themselves PrEP candidates and more likely to be a current PrEP user [38]. However, Poppers usage among MSM is associated with an increased risk of HIV infection [39,40] and a higher probability of participating in group sex [40], which indicates the necessity of timely HIV testing. This inhibitor should draw attention from PrEP providers to address timely HIV testing for PrEP users.

Limitations

This study has several limitations. First, there is no fourth-generation HIVST kit available currently in China. These are available in the United Kingdom and in other countries and would potentially allow this model to replace some of the facility-based testing. Second, this study was conducted before the COVID-19 pandemic, which might underestimate the usage of HIVST among PrEP users. Third, this study only assessed the usage and secondary distribution within the first 3 months after PrEP initiation, which requires a longer follow-up period to illustrate its long-term usage. Finally, this study only included participants from 4 major cities in China, which did not represent the general MSM population in China.

Conclusions

Within a pragmatic setting, MSM who are using PrEP had a high rate of usage and secondary distribution of HIVST kits, especially among those on daily PrEP. Offering multiple HIVST to PrEP users to replace some of the facility-based HIV testing and to facilitate expanded HIV testing is feasible and necessary, especially during the COVID-19 pandemic.

Acknowledgments

The authors would like to thank the community-based organizations of *Sunshine*, Shenyang; *YouAn-Tian Yuan Studio*, Beijing; *Chongqing Red Ribbon AIDS Care Center*, Chongqing; and *258 Rainbow Workshop*, Shenzhen, for their help with recruiting and maintaining the participants. We would also like to thank all of the participants for being involved in our study. This work was supported by the Mega-Projects of national science research (13rd Five-Year Plan [2017ZX10201101-002-007]), the Mega-Projects of national science research (12th Five-Year Plan [2012ZX10001006-001-010]), National Natural Science Foundation of China (81872674), and Mega-Projects of national science research (2018ZX10101001-001-003).

Authors' Contributions

JZ, JJX, and HS conceived and designed the study. JZ, HYW, ZXC, QHH, XJH, YKC, HW, XQH, YL, LKZ, ZLH, RTB, SCL, HL, HBD, YJJ, and WQG performed the study and experiments. JZ, JJX, JDT, and WMT drafted the manuscript. All authors reviewed and approved the final manuscript.

Abstract

Background: Given the scarcity of alcohol prevention and use disorder treatments in many low- and middle-income countries (LMICs), the World Health Organization has launched an eHealth portal that includes the web-based self-help program “Alcohol e-Health.”

Objective: We aimed to test the effectiveness of the Alcohol e-Health program in a randomized controlled trial.

Methods: This was a two-arm, individually randomized, and controlled trial across four LMICs comparing the self-help program and a psychoeducation and internet access as usual waiting list. Participants were broadly recruited from community samples in Belarus, Brazil, India, and Mexico from January 2016 through January 2019. The primary outcome measure was change in the Alcohol Use Disorders Identification Test (AUDIT) score with a time frame of 6 months between baseline and follow-up. Secondary outcomes included self-reported numbers of standard drinks over the previous week and cessation of harmful or hazardous drinking (AUDIT score <8).

Results: For this study, we recruited 1400 predominantly male (n=982, 70.1%) at least harmful or hazardous alcohol drinkers. The mean age was 37.6 years (SD 10.5). The participants were recruited from Brazil (n=587), Mexico (n=509), India (n=212), and Belarus (n=92). Overall, complete case analysis identified higher AUDIT changes in the intervention group ($B=-4.18$, 95% CI -5.42 to -2.93 , $P<.001$, $d=0.56$) that were mirrored by changes in weekly standard drinks ($B=-9.34$, 95% CI -15.90 to -2.77 , $P=.005$, $d=0.28$) and cessation rates for harmful or hazardous drinking ($\chi^2_1=14.56$, $N=561$, $P<.001$). The supplementary intention-to-treat analyses largely confirmed these initial results.

Conclusions: The expansion of the Alcohol e-Health program to other LMICs with underdeveloped alcohol prevention and treatment systems for alcohol use disorders should be considered after successful replication of the present results.

KEYWORDS

alcohol; internet; public health; self-help; World Health Organization

Introduction

There is increasing interest in differences in patterns of alcohol use between low- and middle-income countries (LMICs) and high-income countries (HICs). Although alcohol use might be less common in LMICs, its risks are often more pronounced as mainly adults of low socioeconomic status [1] in these countries

engage more in drinking of spirits to intoxication, a pattern very harmful to health [2]. Moreover, while alcohol is consumed by most middle-aged men and women in HICs, most users (83%) in LMICs are younger men [2]. Typical countries that follow these patterns, according to the World Health Organization (WHO) global status report on alcohol and health 2018 [3], are Belarus, Brazil, Mexico, and India (Table 1).

Table 1. Alcohol use and use disorder indicators for the four low- and middle-income countries of interest in 2016, according to the World Health Organization global status report on alcohol and health 2018 [3].

Country	Consumption of spirits as a proportion (%) of total alcoholic beverages recorded per capita in the last 12 months ^a	Heavy episodic drinking in the last 30 days (%) ^a		Alcohol use disorder prevalence (%) ^b	
		Male	Female	Male	Female
Belarus	49.0	40.5	12.2	33.9	6.2
Brazil	34.0	32.6	6.9	6.9	1.6
Mexico	20.0	30.6	6.1	4.3	0.4
India	92.0	28.4	5.4	9.1	0.5

^aAge 15+ years.

^b12-month prevalence estimates including alcohol dependence and harmful use of alcohol (age 15+ years).

There are insufficient studies summarizing treatment coverage and treatment demand for alcohol use disorders in LMICs. In a systematic review, only five of the 84 low-income countries or LMICs (applying the World Bank classification) provided sufficient epidemiological data regarding harmful alcohol use [1]. According to the World Mental Health Survey, failure and delays in treatment for substance use disorders were significantly greater in LMICs compared to HICs [4]. Treatment in LMICs mainly focuses on tertiary care services for alcohol dependence with often poor outcomes [5]. Research among brief alcohol interventions in LMICs suggests that brief interventions, mainly motivational interviewing (MI) following positive screening with a standardized instrument, can help reduce self-reported hazardous or harmful alcohol use in primary care populations [6]. However, implementing brief alcohol interventions in practice and scaling them up is challenging, given a number of factors like fear of stigmatization for the patient, time pressure on the practitioner, and lack of funding for adequate training at the system level [7], which makes internet-based interventions so attractive [8].

Internet interventions that target harmful or hazardous alcohol use have been developed for HICs. In meta-analyses, the largest effect sizes were reported for studies integrating different treatment principles such as cognitive behavioral therapy (CBT), principles of self-control (PSC), and personalized normative feedback (PNF) [9,10]. These studies were superior to interventions employing elements of PNF as stand-alone

interventions [9]. As expected, the first cost-effectiveness studies on internet programs for alcohol abuse were very positive. A study in a treatment center demonstrated the superiority of internet-based therapy over internet-based self-help regarding value for money when considering quality-adjusted life years gained [11]. Access to an alcohol reduction website via a brochure resulted in less costs with no worse outcome when compared to a standard face-to-face brief intervention in primary care settings [12]. However, there is a paucity of research among internet-based preventative and treatment self-help programs targeting hazardous or harmful alcohol use and alcohol use disorders [9] and mental health in general [13] in LMICs.

On December 6, 2012, the WHO launched the WHO eHealth portal for alcohol and alcohol-related consequences on health, as part of activities to reduce hazardous and harmful drinking in populations, following the objectives of the WHO's global strategy to reduce the harmful use of alcohol [14]. The portal includes the web-based self-help program called "Alcohol e-Health," an evidence-based intervention initially developed in the Netherlands [15] as a means to reduce harmful or hazardous alcohol use and use suggestive of dependence. This program has been completely revised and implemented by the WHO Department of Mental Health and Substance Use, with institutes and organizations in Belarus, Brazil, India, and Mexico. The revised intervention's effectiveness was tested in a randomized controlled trial (RCT) across the four involved countries [16]. The study's primary hypothesis was that Alcohol

e-Health program participants would exhibit greater reductions in their Alcohol Use Disorders Identification Test (AUDIT) score (primary outcome [17]) between baseline and a 6-month follow-up than control subjects allocated to psychoeducation and access to the internet as usual.

Methods

Design

This study compared the Alcohol e-Health program, based on CBT, MI, and PSC, with an assessment, psychoeducation, and access to the internet as usual control group for reducing alcohol use disorder (AUDIT score) in an individually randomized controlled four LMIC trial.

The trial was executed in compliance with the Helsinki Declaration, and approved by the WHO Ethics Review Committee in October 2015 (RPC756) and four country-specific

ethics committees. The study has been registered at Current Controlled Trials (registration number: ISRCTN14037475), and the detailed study protocol was published on October 26, 2017 [16].

Participants and the Inclusion and Exclusion Criteria

Participants were broadly recruited in community samples from Belarus, Brazil, India, and Mexico via information flyers and newspapers, magazines, radio, social media, websites, and informational events related to alcohol and health from January 2016 through January 2019. This broad recruitment strategy allowed for different recruitment conditions in the participating countries. However, there were considerable delays initiating recruitment in India due to official study approval procedures and changes in the study team. Moreover, continuous recruitment in Belarus proceeded very slowly. The study inclusion and exclusion criteria, and the rationale behind them are summarized in [Table 2](#).

Table 2. Overview of the study inclusion and exclusion criteria, and the rationale behind them.

Criteria	Rationale
Inclusion criteria	
Age between 18 and 75 years	To ensure a minimal age of participation
A resident of one of the participating pilot countries	To be covered by local ethics board approval
At least weekly internet access	To ensure at least minimal program access
A screening AUDIT ^a score ≥8	To include adults with potentially hazardous or harmful alcohol consumption, and those whose drinking habits are suggestive of dependence
Exclusion criteria	
Current substance abuse treatment	To avoid confounding treatment effects
Use of opioids, inhalants, cocaine/crack or amphetamine/amphetamine-like stimulants, sedatives over the past month, or cannabis/synthetic cannabinoids for more than 4 days over the past month	To prevent confounding effects with other frequently used mind-altering drugs

^aAUDIT: Alcohol Use Disorders Identification Test.

Intervention and Comparator

Subjects in the active study arm participated in the Alcohol e-Health program, while controls were assigned to a “waiting list,” where they were offered general information on alcohol and its effects on health, and access to the internet as usual. Program access was granted 6 months later.

The Alcohol e-Health program is an accessible interactive self-help tool for people seeking to reduce or discontinue their use of alcohol ([Multimedia Appendix 1](#)). Participants can register and use the program in their own time and free of charge. Alcohol e-Health provides support to encourage individuals to think about their drinking habits, decide whether to change their drinking behaviors, set goals regarding their drinking, take action toward reducing or stopping their drinking, measure their progress, and deal with relapses.

The core element of the program was a comprehensive diary, where participants could record every consumption occasion in terms of when, where, what, and how much they drank; with whom and how they feel about it; and other comments. Consumption of alcoholic beverages was measured in standard

drinks as per the WHO Audit definition (10 g of alcohol), and a calculator assisted participants to convert their drinks into standard drinks. The drinking diary was filled out daily by dragging and dropping icons representing country-specific common drinks. Furthermore, participants could set goals for maximum number of standard drinks each day. Diary data were used for tailored weekly feedback with respect to meeting these drinking goals. Feedback was generated automatically based on individual drinking goals and country standards for low-risk drinking.

After having set baseline benchmarks regarding drinking, participants could explore the advantages and disadvantages of drinking and subsequently analyze their motivation to change. Furthermore, they were encouraged to identify risky situations with suggestions to deal with them and motivational strategies to help them maintain higher levels of resistance under such circumstances (development of alternative action plans). A relapse module allowed participants to analyze these situations (where and when, with whom, thoughts, personal feelings and thoughts, and consequences) and to cope with potential relapse (development of alternative helpful thoughts and actions in

these situations). Graphical summaries of entries supported users to quickly identify core elements of risky situations. In the persistence module, users explored how they could resist social pressures to drink excessively. To address technical problems that occurred during their participation in the program, participants were permitted to contact, by email in their native language, a technician qualified to deliver technical assistance. A detailed program description is provided in the study protocol paper ([Multimedia Appendix 2](#)) [16].

Conversely, those within the psychoeducation and internet access as usual control group were told that they would be provided access to the program in 6 months, and referred to a web page containing information about the various types of alcoholic beverages, standard drink definitions, effects of alcohol on the mind and body, social effects of drinking alcohol, risk factors for alcohol dependence, women and alcohol, and adolescent alcohol use.

Throughout the 6-week program, all participants were encouraged to see a health professional if they experienced acute alcohol withdrawal or other severe physical or mental symptoms,

and were afforded access to a country-specific medical advisory and emergency list.

Measurement Instruments

The main outcome was change in the adjusted AUDIT [17] score between baseline and a 6-month follow-up. Corresponding AUDIT versions were provided in English, Portuguese, Russian, and Spanish. Since the follow-up period was limited to 6 months, the AUDIT was assessed for the last 6 months instead of the last 12 for items 9 and 10, both at baseline and follow-up [17].

Secondary outcomes were as follows ([Table 3](#)): (1) falling below the cutoff of hazardous or harmful alcohol use (AUDIT score <8); (2) weekly number of standard drinks (based on a single question with seven answering fields asking about alcohol use, in standard drinks, on each day of a typical week); and (3) program satisfaction, rated using the 8-item Client Satisfaction Questionnaire (CSQ-8) [18] (assessed 6 weeks after baseline). At the 6-month follow-up, participants were asked to grade any negative effects they had experienced, as per the report by Rozental et al [19], and if they had received any external help.

Table 3. Overview of the study measurements.

Assessments/instruments	Baseline ^a	Week 6 follow-up	Month 6 follow-up ^a
Sociodemographics	Yes	No	No
AUDIT ^b score	Yes	No	Yes
Weekly number of standard drinks ^c	Yes	No	Yes
8-item Client Satisfaction Questionnaire	No	Yes	No
Adverse effects	No	No	Yes

^aWhere “Yes” is indicated both at baseline and the 6-month follow-up, the outcome of interest is the change between baseline and the 6-month follow-up.

^bAUDIT: Alcohol Use Disorders Identification Test.

^cBased on a single question with seven answering fields asking about alcohol use, in standard drinks, on each day of a typical week.

Sample Size

The initial sample size estimate (Cohen $d=0.40$ [14], 95% confidence [$\alpha=.05$], and 95% power [$1-\beta=0.95$]) for analysis of covariance with one covariate (country) was 708 overall, when controlling for cluster effects [16]. However, as we met considerable follow-up problems in Brazil (see [Multimedia Appendix 3](#) for country-specific trial flows) and as study implementation in India was delayed for technical reasons, we started to recruit only in Brazil and Mexico, with over-recruitment by 50% for the increased missing follow-up data (achieved N with 52% over-recruitment for Brazil and Mexico, including some data from Belarus [$n=92$], equaling 1188). However, recruitment started in India in January 2019 ($n=212$). Finally, the study team decided to include participants from India to increase validity for a LMIC. This resulted in a total N of 1400.

Study Procedures, Screening, and Consent

Once potential participants arrived on the Alcohol e-Health program home page, they were asked to complete the AUDIT and subsequently received personalized feedback, according to their individual drinking level concerning nonrisky drinking

(<8 drinks/week), potentially harmful or hazardous drinking (8-19 drinks/week), and drinking suggestive of dependence (≥ 20 drinks/week). Those with an AUDIT score ≥ 8 were given details about the study, including (1) study aims and duration; (2) inclusion and exclusion criteria ([Table 2](#)); (3) two different study conditions; (4) potential risks of participation and safety agreements; (5) information that Alcohol e-Health cannot replace face-to-face interventions; (6) information on how participation was entirely voluntary and on their right to withdraw from the study at any time without consequences; and (7) information that the study had been approved by the WHO Research Ethics Committee and the four country-specific ethics committees. Informed consent was assumed when they selected all the necessary fields on the online informed consent form and clicked the submission icon. After having consented, participants filled out baseline questionnaires and were randomized, by a computer, to either the Alcohol e-Health program or control group, in a 1:1 ratio in each country [16]. This nonblinded assignment was registered automatically in the background database.

Follow-Up Procedure and Compensation

The 6-month follow-up assessment was performed using a step-wise procedure including electronic follow-up and reminders, as well as telephone interviews by study collaborators in their own language. Completion of all follow-up assessments qualified subjects for participation in a raffle to win a tablet or corresponding donation to a charitable organization in each country, except Brazil owing to Ethics Committee restrictions.

Statistical Analysis

For the baseline analysis between centers, we used chi-square analysis, analysis of variance (ANOVA), or the Kruskal-Wallis test, depending on the type of variable. The main analysis was based on complete case analyses (CCAs) and supplemented with intention-to-treat (ITT) analyses. Multiple linear models using regression analysis predicting the variable change score (baseline – follow-up) were used with baseline variables and the treatment condition as predictors. The missing data for ITT analyses were supplemented with multiple imputations and the R package MICE [20]. MICE specifies a multivariate distribution for missing data and draws imputations from their conditional distributions employing Markov chain Monte Carlo techniques. The missing data were assumed to be at random, and a total of 20 data sets were imputed in the supplemental ITT analyses. The effect sizes of the program were calculated using pooled results of linear model analysis. Sociodemographic (group, sex, age, country, and treatment center), and primary (AUDIT) and secondary (standard drinks in the last 7 days) outcome variables were included in the ITT imputation model. Treatment center was not used as a covariable in the overall

analysis as the explained variance was less than 4%. Secondary analysis was based on complete cases, as the imputation of satisfaction scores and adverse effects was deemed unreasonable with the exception of the analysis of the number of standard drinks consumed in the last 7 days, which was additionally performed with imputed data.

Dealing With Invalid Data/Outlier Data

Outlier data were removed to increase data validity, based on the number of standard drinks consumed in the last 7 days, as there were no upper limits for self-reported data. Values above three standard deviations from the mean were considered unlikely and potentially wrong; 18 data points were set to null based on this criterion. [Multimedia Appendix 4](#) shows a sensitivity analysis with setting of the 18 data points to the maximum remaining value in the data set.

Results

Demographics and Baseline Characteristics

Of the 1422 persons who signed up, 22 failed to complete the baseline survey. Thus, a total of 1400 participants (418 female, 29.9%) were randomly allocated to two study arms ([Figure 1](#)). [Table 4](#) summarizes the demographic characteristics and baseline screening data of and statistical comparisons between the four study centers. The average age of participants was 37.6 years (SD 10.5). Participants consumed an average of 43.7 (SD 41.4) standard drinks per week and had an average of 2.6 (SD 2.0) alcohol-free days per week at baseline. The average AUDIT score at baseline was 23.0 (SD 7.7), with significant differences between the four centers for all variables.

Study Attrition and Dropout Analysis

In total, 562 (40.1%) participants completed follow-up. Dropout analysis showed a significant difference by country of enrolment ($\chi^2_3=36.88$, N=1400, $P<.001$), assigned study condition ($\chi^2_1=16.11$, N=1400, $P<.001$), baseline AUDIT score ($F_1=9.69$, N=1400, $P=.002$), and baseline drink-free days over the last 7 days ($F_1=6.94$, N=701, $P=.009$). The follow-up rate ranged from 27.6% (n=80) in the intervention group in Brazil to 56.2% (n=26) in the control group in Belarus, and in total, 34.9% (n=239) of the intervention group could be followed compared to 45.3% (n=323) of the control group. The average AUDIT score and number of drinking-free days were 22.18 (SD 7.92) and 2.35 (SD 2.07), respectively, for participants who could be followed up, and 23.48 (SD 7.49) and 2.77 (SD 2.02), respectively, for dropouts. Dropouts were not different in gender

($\chi^2_1=0.13$, N=1400, $P=.72$), age ($F_1=2.50$, N=1398, $P=.11$), baseline standard drinks over the preceding 7 days ($F_1=3.32$, N=1380, $P=.069$), or adherence ($t_{417.5}=1.76$, $P=.08$). Detailed follow-up rates are listed in [Multimedia Appendix 3](#).

Main Effects

[Table 5](#) shows the detailed outcome analysis of changes in the AUDIT score (main outcome) and changes in the number of standard drinks in the last 7 days across all countries. Regression analysis based on the complete case data showed a significant decrease in the AUDIT score in the intervention group (mean 7.4, SD 7.8) compared with that in the control group (mean 3.2, SD 7.1) ($B=-4.18$, 95% CI -5.42 to -2.93, $P<.001$, $d=0.56$). [Table 6](#) shows detailed values between baseline and follow-up from complete cases, and [Multimedia Appendix 5](#) and [Multimedia Appendix 6](#) show values from supplemental imputed data that confirmed the CCA results.

Table 5. Regression analysis results.

Variable	Intervention versus control after 6 months (complete cases) (N=562)		
	B ^a	95% CI	P value

Secondary Outcomes

Standard Drinks

There was a significantly higher decrease in standard drinks in the intervention group (mean 24.7, SD 39.6) compared with that in the control group (mean 15.4, SD 28.4) ($B=-9.34$, 95% CI -15.90 to -2.77 , $P=.005$, $d=0.28$). Results were confirmed in the supplemental ITT analysis (see [Multimedia Appendix 5](#) and [Multimedia Appendix 6](#)).

Harmful or Hazardous Alcohol Use

A total of 102 (18.2%) participants had a total AUDIT score below 8 after 6 months and could therefore be classified as no more harmful or hazardous alcohol use. There was a significant difference in the assigned group, with 57 (25.6%) in the intervention group versus 41 (12.7%) in the control group achieving a score below 8 after 6 months ($\chi^2_1=14.56$, $N=561$, $P<.001$).

CSQ-8

Participants in the intervention group were significantly more satisfied with their study participation (mean CSQ-8 score 21.56, SD 4.1) compared with those allocated to the control group (mean score 18.92, SD 4.7) ($t_{415,39}=6.18$, $P<.001$).

Adherence

Of the 687 participants in the intervention group, 258 (37.6%) had at least one diary entry, 159 (23.1%) completed the tools to maintain their targets for alcohol consumption and to resist social pressure, and 41 (6.0%) completed the relapse tool.

Adverse Effects

A total of 188 participants completed the Rozenal adverse side effects questionnaire [17]. Of these, 136 (71.9%) answered that they had not experienced any negative effects during the study, while 33 (17.5%) claimed that an adverse effect had affected them "somewhat negatively," 7 (3.7%) claimed "quite negatively," and 13 (6.9%) claimed "to a great extent." There was no significant intergroup difference ($t_{151,93}=1.35$, $P=.18$).

Discussion

Principal Findings

To our knowledge, this is the first RCT to investigate the effectiveness of an international web-based self-help program for at least harmful or hazardous drinkers in LMICs. The observed changes in AUDIT scores (main outcome) were mirrored by all of the secondary outcomes in the CCA and mostly confirmed in the supplemental ITT analyses. Adverse effects credited to the intervention were few. Thus, expanding this program to other LMICs with underdeveloped alcohol prevention and alcohol use disorder treatment systems should be considered after successful replication of these initial findings. The achieved effect strength for ITT changes in the weekly number of standard drinks ($d=0.27$) in this study is only slightly smaller than that reported for meta-analyses from HICs ($d=0.40$) [9] and evaluation of the initial Dutch program ($d=0.40$) [15] from which development of the Alcohol e-Help program started [16]. However, effects on the main outcome, change in the AUDIT score, were even higher (CCA: $d=0.55$; ITT: $d=0.51$). Presumably, in this study, the standardized AUDIT scores [17] with validated translations were more appropriate as an outcome measure than the number of weekly standard drinks, despite country-specific adaptation of the standard drink examples.

The achieved effects were mainly grounded in the Brazilian and Mexican middle-income country data, but were also observed in data from India, the only low-income country involved. Moreover, the program attracted subjects with a high probability of alcohol dependence (mean AUDIT score above 22) in these countries. In India, the baseline AUDIT score was 30. Our Indian collaborators noted that recruitment was difficult in the general population and that some of the participants might have been reached through community clinic settings where recruitment posters were sometimes hung, which may partially explain their higher baseline scores. The only country where we failed to demonstrate program effectiveness was Belarus, the middle-income country with the highest spirit use and clearly the highest alcohol use disorder prevalence. Unfortunately, we only reached few Belarusian participants with, contrary to our expectations, a comparatively low level of alcohol use and very few with an AUDIT level suggestive of dependence. Our

Belarusian collaborators have advised us that there is no sense of harmful and hazardous alcohol use in the general Belarusian population and spirit use is culturally still very accepted. Unless a medical doctor refers someone for inpatient detoxification, many Belarussians with high levels of spirit use still seem to feel they do not have a health problem warranting changes in their alcohol drinking behaviors. Thus, a comprehensive prevention campaign to make the Belarussian drinking population aware of potential health problems and the consequences of their drinking behaviors might be a required preliminary step before implementation of the Alcohol e-Help program or similar interventions. In addition, a cultural adaptation of the program to reflect these values and attitudes toward excessive alcohol consumption could also be important. This could also apply to other former Soviet Union regions with similar drinking cultures and, thus, limits the generalizability of our study results. Generalizability is further limited to individuals with sufficient reading and writing skills in the corresponding study languages, those with at least weekly internet access, and those without frequent use of illicit drugs.

Despite the typical gender gap in heavy episodic drinking and prevalence of alcohol use disorders in LMICs compared to HICs [1,2], the Alcohol e-Help program still reached a population that was almost 30.0% female, and dropout rates were similar in the two genders. It is possible that similar to HICs, relatively more women will be reached by online interventions compared to face-to-face interventions. A detailed analysis of the outcome predictors in the near future could clarify the relevance of gender and other predictors for the program's effectiveness.

On one hand, the decision to over-recruit made it possible to include data from the delayed recruitment in India in this study. On the other hand, over-recruitment increases the chance of detecting an intervention effect. Since the effect strengths determined were analogous or, in the case of the main outcome, significantly higher than originally calculated, most of the results would probably have been significant even with the originally calculated sample size. For this reason, we have not subsequently adjusted our power calculation.

Study recruitment was set as broad as possible to encourage people from the respective general populations with at least harmful or hazardous alcohol consumption, who otherwise would not receive adequate support, to participate. In this way, we also wanted to optimize the study results' generalizability. However, this strategy probably also led to recruitment distortions between the participating countries. In Brazil, for example, a large proportion of participants were recruited through television coverage, as the Brazilian media displayed great interest in the study. Conversely, in India, the only truly successful recruitment strategies were newspaper advertisements and hanging posters, since the Indian media would have reported on the study only if financially compensated.

One difficulty that arose due to the comparatively long study preparation and study phase was that the underlying content management system (CMS) was outdated and an update during

the study phase in the four country-specific portals turned out to be tricky for reasons of methodological and data loss risks. Before the Alcohol e-Help program can be adapted for other LMICs and widely implemented, its content must be transferred to the latest CMS in a time-consuming process. However, measured against the public health impact potential and increasing spread of broadband internet access in LMICs [21], this seems to be a worthwhile investment.

A major limitation of this study is the high attrition rate of nearly 60%, which was larger than for studies in HICs [9]. In addition, selective attrition was a concern with higher dropout rates in the intervention group and more severe baseline AUDIT scores reported by noncompleters. These difficulties might compromise the stability and reliability of effects. Therefore, we based our results on the CCA and added the ITT analyses only supplementally. Up to which missing level and under which conditions data can still be imputed for ITT analysis is part of ongoing discussions [22,23]. Particularly for internet-based programs in the alcohol field, this discussion is still pending. Since follow-up surveys are obviously more difficult to conduct in low-income countries, this discussion must be held as soon as possible and a consensus should be reached in this regard. The transfer of successful programs from HICs should not be hindered merely by lack of consensus in these discussions. However, since we have carried out the first transfer of a program to reduce alcohol misuse to LMICs, there is certainly room for improvement to increase the follow-up rate. Higher financial compensation would be an obvious solution. However, we deliberately decided against this because we saw a risk of an imbalance, and thus, an uncontrollable confounder, between the different countries involved. Another possibility would be to link the follow-up survey with a content booster module, in which, for example, short personalized feedback using the AUDIT strategies for the long-term success of alcohol consumption reduction is addressed. A follow-up survey would then make more sense to some participants, and they would be more likely to participate. In addition, better imputation programs, especially for data sets with a high missing proportion, are hoped to be available soon.

Other limitations of this study are as follows: (1) self-reported use of standard drinks that might particularly be susceptible to retrospective bias, due to inclusion of individuals suggestive of dependence (AUDIT score ≥ 21); (2) skewed country distribution of participants with an underrepresentation of individuals from Belarus and India, which made some of the ITT analyses in these two countries impossible (Multimedia Appendix 7); and (3) incorrect programing of the originally planned adherence assessments [16]. As such, no adequate sensitivity analysis could be performed.

Conclusions

Based on the results reported here, expansion of the program to other LMICs with underdeveloped alcohol prevention and treatment systems for alcohol use disorders should be considered after successful replication of the initial results.

Acknowledgments

We thank the following additional members of the World Health Organization (WHO) e-Health project on Alcohol and Health Investigators Group from Brazil: Ana Regina Noto, Denise De Micheli, Ana Paula L Carneiro, Roseli Boerngen-Lacerda, Telmo M Ronzani, Laisa M A Sartes, and Leonardo F Martins. We thank the following members from India: Rajat Ray, Sudhir Khandelwal, Rakesh Chadda, and Urvashi Singh. We thank the following members from Mexico: María Asunción Lara, Silvia Carreño García, and Morise Fernández Torres. We thank Isy Vromans who managed the project at the initial stages and managed the development of the intervention in collaboration with the Trimbos Institute. We would also like to thank Otavio J E Pereira, Gabrielle A Cunha, Marcia Omori, and Denise Silva for their technical support. This study was funded by the WHO (APW 2018/806239-0). MLOSF received additional funding from the Associação Fundo de Incentivo à Pesquisa, CNPq (315769/2018-1), CAPES, and the São Paulo Research Foundation FAPESP (2015/19472-5).

Authors' Contributions

MPS, MT, NMV, AA, RB, AW, DP, SO, FLM, ALMA, and MLOSF significantly contributed to the development of the portal and adaptation of the intervention and/or were substantially involved in subject recruitment and data collection. MPS was the overall principal investigator, wrote the first draft of the manuscript, and analyzed the data together with AW and CB. DR and VP were the project leaders at the World Health Organization and had the overall project lead. The WHO e-Health Project on Alcohol and Health Investigators Group includes Michael P Schaub, Marcela Tiburcio, Nora Martínez-Vélez, Atul Ambekar, Yatan Pal Singh Balhara, Andreas Wenger, André Luiz Monezi Andrade, Dzianis Padruchny, Sergey Osipchik, Elise Gehring, Vladimir Poznyak, Dag Rekve, Maria Lucia Oliveira Souza-Formigoni, Ekaterina Lapushinskaya, Pavel Rynkov, Dmitry Statkevich, Roseli Boerngen Lacerda, Telmo Ronzani, Laisa M A Sartes, María Asunción Lara, Morise Fernández, Anubha Dhall, Monica Mongia, Roshan Bad, and Urvashi Raj. All authors discussed the results and contributed to the final manuscript.

Abstract

Background: Due to the increasing use of shared decision-making, patients with esophagogastric cancer play an increasingly important role in the decision-making process. To be able to make well-informed decisions, patients need to be adequately informed about treatment options and their outcomes, namely survival, side effects or complications, and health-related quality of life. Web-based tools and training programs can aid physicians in this complex task. However, to date, none of these instruments are available for use in informing patients with esophagogastric cancer about treatment outcomes.

Objective: This study aims to develop and evaluate the feasibility of using a web-based prediction tool and supporting communication skills training to improve how physicians inform patients with esophagogastric cancer about treatment outcomes. By improving the provision of treatment outcome information, we aim to stimulate the use of information that is evidence-based, precise, and personalized to patient and tumor characteristics and is communicated in a way that is tailored to individual information needs.

Methods: We designed a web-based, physician-assisted prediction tool—Source—to be used during consultations by using an iterative, user-centered approach. The accompanying communication skills training was developed based on specific learning objectives, literature, and expert opinions. The Source tool was tested in several rounds—a face-to-face focus group with 6 patients and survivors, semistructured interviews with 5 patients, think-aloud sessions with 3 medical oncologists, and interviews with 6 field experts. In a final pilot study, the Source tool and training were tested as a combined intervention by 5 medical oncology fellows and 3 esophagogastric outpatients.

Results: The Source tool contains personalized prediction models and data from meta-analyses regarding survival, treatment side effects and complications, and health-related quality of life. The treatment outcomes were visualized in a patient-friendly manner by using pictographs and bar and line graphs. The communication skills training consisted of blended learning for clinicians comprising e-learning and 2 face-to-face sessions. Adjustments to improve both training and the Source tool were made according to feedback from all testing rounds.

Conclusions: The Source tool and training could play an important role in informing patients with esophagogastric cancer about treatment outcomes in an evidence-based, precise, personalized, and tailored manner. The preliminary evaluation results are

promising and provide valuable input for the further development and testing of both elements. However, the remaining uncertainty about treatment outcomes in patients and established habits in doctors, in addition to the varying trust in the prediction models, might influence the effectiveness of the tool and training in daily practice. We are currently conducting a multicenter clinical trial to investigate the impact that the combined tool and training have on the provision of information in the context of treatment decision-making.

KEYWORDS

prediction tool; communication skills training; shared decision-making; risk communication; treatment outcomes; esophageal cancer; gastric cancer; patient-physician communication

Introduction

Background

Esophageal and gastric cancers rank eighth and fifth, respectively, in incidence worldwide [1]. The mortality rate is high and, even in the curative setting, the 5-year survival rates do not exceed 50% [2,3]. Over the years, several treatment regimens have come into use, resulting in an array of treatments varying in their effectiveness regarding survival, health-related quality of life (HRQoL), and side effects and complications. For example, localized esophageal cancer can be treated with resection, with or without neoadjuvant chemotherapy or chemoradiotherapy, or with definitive chemoradiation, and localized gastric cancer can be treated with resection with or without adjuvant or neoadjuvant chemotherapy [4-6]. Various options exist for metastasized cancers, with chemotherapy yielding the best survival rates. However, palliative radiotherapy and best supportive care may also be valuable options for specific groups of patients [4,5,7-10].

Often, the choice between treatment options is based on preferences; the personal weighing of the pros and cons of the options plays a decisive role in the final decision made, and therefore, shared decision-making is needed [11,12]. For shared decision-making to be effective, patients need to be well-informed and thus be offered evidence-based and precise information on treatment outcomes. Evidence-based information refers to the best available, most accurate, and up-to-date evidence. Precise information is concrete, clear, and substantially detailed, such as “In 5 years, 45 out of 100 patients like you that are given this treatment will still be alive.” However, treatment outcomes can differ according to specific patient characteristics (such as age and performance status) and tumor characteristics (such as tumor–node–metastasis [TNM] staging and the number of metastases) [13,14]. Thus, physicians face the challenge of having to inform patients on treatment-related outcomes in a manner that is not only evidence-based and precise but also personalized to the individual patient.

Physicians may face many other challenges when informing patients with cancer on treatment and related outcomes. A vast amount of information on the possible treatment options, including their procedures and associated risks and benefits, must be communicated within the time restrictions of a consultation [15]. Moreover, this information, including schedules, numbers, and probabilities, is often complex and therefore difficult for patients to process [16,17]. Patients’

emotions can complicate information processing even further, especially as esophagogastric cancer is a life-threatening disease [18,19]. Physicians consider dealing with these emotions as a difficult-to-acquire skill [20]. They often worry that their information might even increase a patient’s anxiety or take away a patient’s hope [21-25]. Therefore, physicians may have conflicting opinions and doubts about how to provide precise and numerical information regarding treatment risks and benefits.

Furthermore, tailoring the type and amount of information to the individual patient’s information needs, interests, and concerns (eg, one patient wants to be informed using exact percentages, whereas another would rather get a general description) has also been shown to be a difficult skill for physicians [26]. These challenges impede the ability to meet the information needs of patients with cancer [27-29]. Physicians rarely use clinical outcome data to systematically inform patients, given a certain treatment, on their chances of survival, the most likely side effects, and the consequences on their quality of life [30,31]. However, it has been established that many patients want to receive more information on their treatment-related outcomes and want this information to be more precise [32-36].

Several tools have been developed to aid physicians in this task by using prediction models to generate clarifying visualizations of personalized outcome data, such as the *Predict* and *Adjuvant Online* tools for breast cancer [37,38]. To achieve personalized prediction, these models use multiple characteristics of the patient and the disease to create bar plots and Kaplan-Meier curves displaying survival data. However, to date, no web-based prediction tool exists for use in clinical consultations targeted at patients with esophageal and gastric cancer [39]. Moreover, the probabilities of side effects and HRQoL related to the treatment options are not addressed in the current tools, although patients express information needs related to these outcomes [32,40]. Furthermore, several training programs are available to improve the communication skills of cancer care providers [41,42]. However, these often do not specifically address how to inform patients about treatment options and their particular outcomes, for instance, by using a prediction tool. Combining a prediction tool with communication skills training to address knowledge, attitudes, and skills might increase the usage and adoption of the new tool in clinical practice, improve the overall communication of outcome information by physicians, and stimulate shared decision-making.

Objectives

Therefore, we aim to develop a web-based prediction tool and supporting communication skills training to improve how physicians inform patients with esophagogastric cancer on treatment outcomes, namely, survival, side effects or complications, and HRQoL. To improve the provision of treatment outcome information, we aim for information that is evidence-based, precise, and personalized to the patient and tumor characteristics, and that is communicated in a way tailored to the individual information needs.

Introducing a change in physician-patient communication by adding a new instrument might initially result in resistance from users, as suggested by behavior change theories [43]. For example, physicians might be reluctant to use the tool because it does not fit into their consultation routine or because they might lack trust in the prediction models. Therefore, our secondary aim is to evaluate the feasibility of the tool and training in practice by consulting physicians, patients, survivors, and experts and to iteratively improve the tool and training.

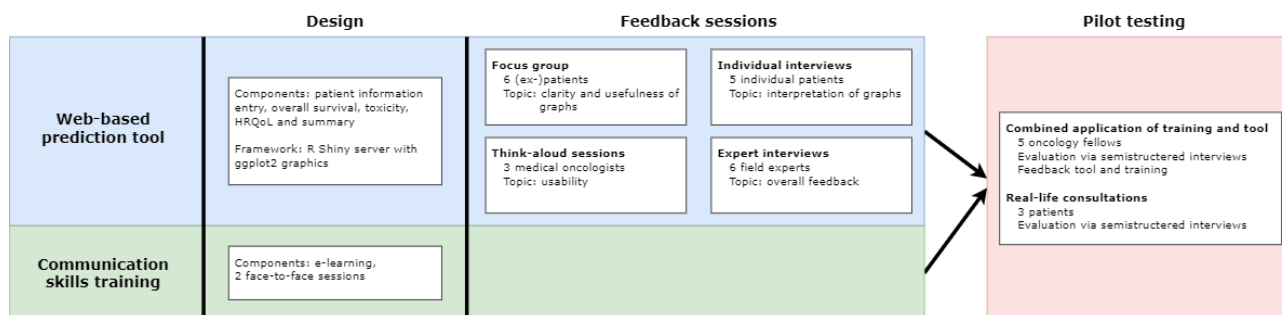

Methods

Overview

Both the tool and training were targeted at physicians in oncology who regularly conduct treatment decision-making consultations. In the development of the tool and training, we focused on patients with metastatic esophageal and gastric cancer. With regard to shared decision-making, this group is confronted with the most complex decision-making process, where personal values and preferences play a large role in deciding among multiple relevant treatment options.

The iterative development and testing of this two-part intervention occurred in several phases following the 2008 Medical Research Council framework [44]. This framework provides guidance for developing complex interventions and presents several steps and elements necessary for the successful implementation of the intervention. The framework is divided into the following four phases: (1) development, (2) piloting, (3) evaluation, and (4) implementation. This study describes the first two phases: development and piloting. The development phase is described separately for the tool and training. Both elements of the intervention are joined in the piloting phase as a combined pilot study (see Figure 1 for an overview).

Figure 1. Schematic representation of the development process of the tool and training. HRQoL: health-related quality of life.

The Web-Based Prediction Tool: Source

The web-based, physician-assisted prediction tool named *Source*, which contains visualizations of evidence-based, precise, and personalized outcome information, was developed using an iterative, user-centered approach. The tool was designed to be used by oncology health care providers for decision-making consultations. The *Source* tool, unlike other prediction tools such as *Predict* and *Adjuvant Online*, was not designed for unsupervised use by patients at home to prevent incorrect use, misunderstanding, and lack of emotional support.

First, prediction models were developed to ensure that the *Source* tool's treatment outcome information (survival, side effects and complications, and HRQoL) was evidence-based, precise, and personalized to the individual patient and tumor characteristics. Personalized predictions for survival using this tool are based on the *SOURCE* prediction models [45,46], which predict survival based on the individual patient and tumor characteristics and are regularly updated when new data become available. Depending on the tumor location, either nine variables (for gastric cancer) or 13 variables (for esophageal cancer) are required for predictions. These variables include age, tumor

staging, and metastasis characteristics. The model output is the probability of survival up to 2 years following diagnosis and allows for the comparison of multiple treatments.

The side effects (toxicity) of chemotherapy treatment are based on TOXView meta-analyses [7]. These models establish the probability of adverse events such as nausea, alopecia, and neuropathy, stratified by mild or severe grade toxicity (according to the Common Terminology Criteria for Adverse Events [47]), for various chemotherapy regimens. These probabilities are not personalized to the individual characteristics and do not vary over time, as this was not possible with the available data.

Finally, predictions of HRQoL are available from a meta-analysis and describe the change in the EORTC QLQ-C30 (European Organisation for Research and Treatment of Cancer quality of life questionnaire C30) on the global health scale for best supportive care and chemotherapy in metastatic patients up to 6 months after diagnosis [10].

Next, these models and meta-analyses were used to visualize treatment outcomes. For the visualizations to be easy to understand for patients, a previous systematic literature review on visual risk communication was consulted [48]. Furthermore,

the literature about usability and usability guidelines for web-based applications [49-52] and existing prediction tools, such as *Predict* and *Adjuvant Online*, were consulted [37,38]. On the basis of the literature, the first set of requirements for

the tool was created according to the MoSCoW (Must Have, Should Have, Could Have, Won't Have) system [53]. This process resulted in the requirements listed in [Textbox 1](#).

Textbox 1. Overview of the requirements of the web interface according to the MoSCoW (Must Have, Should Have, Could Have, Won't Have) system.

Must Have

1. After opening the tool, a data entry form is shown to enter the variables needed for the prediction models.
2. The data entry form is dynamic and shows only relevant variables.
3. Survival, adverse events, and health-related quality of life outcomes are displayed in their own tabs, and only one outcome is displayed at a time.
4. The outcomes are displayed graphically in a screen-filling image.

Should Have

1. The data entry form contains input validation to avoid mistakes during entry.
2. The data entry contains explanations of the variables.
3. The plots can be tailored to the patients' and physicians' preferences (eg, time frame and treatments to be compared).

Could Have

1. The tool's display language can be set to Dutch or English.
2. A textual summary accompanying the plots can be generated and printed so the patient can review the information at a later time.
3. A help function for physicians is incorporated.

A prototype of the web interface was created based on the literature guidelines and first requirements. The web-based tool was developed using the RShiny software (version 1.2.0; RStudio) supplemented with ggplot2 (version 3.2.1) to create graphs [54,55]. The creation, evaluation, and improvement of the tool followed an iterative user-centered design framework, where feedback was gathered from end users (patients and physicians) and experts. By iteratively updating the tool, we aim to provide improvements for the tool after each feedback session and avoid receiving the same feedback after each feedback round. A total of 4 feedback sessions were conducted from January 2018 to July 2018.

First, a face-to-face focus group was conducted with 6 patients with esophageal and gastric cancer and survivors from the Foundation for Patients with Cancer in the Digestive system after verbal informed consent was provided. The aim of this focus group was to obtain feedback on the tool in a group setting and promote discussions among the group members. One of the researchers acted as a moderator and presented the participants with each of the tool's graphs. Each displayed graph was accompanied by a short oral explanation, after which the participants were asked for their opinions. Feedback on the web interface and suggestions for improvement supported by multiple participants were used to create an improved version of the tool. The focus group session was audio-recorded and analyzed according to microinterlocutor analysis to systematically evaluate the participants' remarks [56].

In a second feedback round, 30-minute, semistructured, face-to-face interviews were conducted with individual patients with esophageal and gastric cancer. The main focus of these audio-recorded interviews was to determine whether the patient interpretation of the revised graphs was adequate. By conducting

interviews with individual patients rather than in a group, the aim was to review patient interpretations without the influence of other patients. The interviews were conducted using a piloted script. A total of 5 outpatient participants were recruited by an oncologist at the Amsterdam University Medical Centers. Following the participants' informed consent, 2 researchers presented the tool to patients by using fictitious predictions of treatment outcomes. Patients were asked to interpret the presented graphs and describe their meaning to assess their understanding. Thereafter, the researcher provided the correct description of the graph, and the patients' subsequent feedback was gathered. Feedback was registered in a response matrix, including the frequency of different remarks, to establish which possible improvements could be implemented.

The third feedback round aimed to evaluate the usability of the tool when used by medical oncologists, and 3 medical oncologists at the Amsterdam University Medical Centers participated in individual face-to-face think-aloud sessions. After providing informed consent, they were asked to use the tool for two paper patient cases while stating out loud whatever came to mind. The cases described fictitious patients with esophageal or gastric cancer, including some of their clinical characteristics. Several tasks and questions about specific outcomes (eg, "What is the 1-year survival probability with best supportive care?" and "Which treatment has the best quality of life after 6 months?") were posed to guide the use of the tool by medical oncologists. At the beginning of the think-aloud session, a video explaining the think-aloud method [57] was presented and the participants were asked to complete a short practice exercise to ensure that they understood the think-aloud method before starting the task. After the think-aloud session, participants completed the System Usability Scale (SUS) to measure the ease of use and overall likeability of the web-based

tool [52]. Both screen captures and audio recordings were registered during the think-aloud session. One of the researchers (FH) used both recordings to register whether the oncologists successfully completed the tasks, how many mouse clicks they used to complete a task, and which buttons they clicked on the web interface. The median SUS scores were calculated to provide a quantitative indication of usability.

In the fourth and last round, feedback from experts was gathered by conducting semistructured interviews with 6 researchers with expertise in patient-physician interaction, shared decision-making, risk communication, medical informatics, and clinical decision support software. The experts were presented with a walkthrough of the tool and its options. Interviews were recorded and summarized to determine which possible improvements were brought forward.

The Source Supportive Communication Skills Training

Overview

Communication skills training was developed to educate physicians on informing patients with cancer in a treatment decision-making consultation using the Source tool. Due to the complexity of the skills needed, it was important to specify clear learning goals. As stated in complex learning theory, when training complex skills, the desired learning outcomes must address the following domains: knowledge, attitudes, and skills [58-60]. The training aimed for physicians to be able to name the most important tips and tricks for adequately informing patients on treatment outcomes and communicating treatment risks and benefits (knowledge). Furthermore, the training aimed for physicians to have a positive outlook on using numbers to inform patients about treatment outcomes and their ability to inform patients in an evidence-based, precise, personalized, and tailored manner (attitude). Moreover, the training aimed for physicians to be able to use the Source tool and to incorporate the tool to inform patients during consultations (skills). Finally, the training aimed to increase physicians' ability to provide information tailored to patients' informational needs and level of understanding (skills). A team (n=5) of experts in medical communication and psycho-oncology and experienced trainers in medical communication discussed the context and content of the training and set learning objectives. In addition, the literature on training and shared decision-making frameworks was reviewed.

As physicians value time-efficient and flexible training [16], the training was designed as blended learning, encompassing preparatory e-learning and a face-to-face component. The 4-step shared decision-making model proposed by Stiggelbout et al [12] was used as a framework. This model distinguishes the following four essential steps for shared decision-making: (1) setting the agenda, (2) informing about treatment options, (3) exploring patients' values, and (4) making a decision in agreement [61]. The outline of the training was based on previous communication skills training for skills in shared decision-making, as designed for and proven to be effective in the CHOICE (Choosing Treatment Together in Cancer at the End of Life) trial [61] and the literature on the guidelines for effective communication skills training [42,62]. The focus of the Source training is the second step of this model, that is,

informing patients about treatment options and the pros and cons thereof.

e-Learning

First, e-learning was targeted at summarizing the evidence base for effective information provision and providing physicians with tips and tricks for clinical practice. To this end, we consulted the literature related to theories, evidence, and guidelines on the provision of information in medical practice [12,63-67]. The assembled literature and theories were summarized into short chapters, each covering a different subtopic. The expert team discussed the scripts in these chapters to obtain a consensus on the frameworks and models used. Interactive elements, such as exercises, were added to the e-learning to enable the learner to actively process the information. Second, the e-learning aimed to introduce the Source tool, thereby addressing the use and functionalities of the tool and the underlying prediction models.

An earlier study concluded that physicians value both visual attractiveness and variation between learning activities in e-learning [16]; therefore, the layout, animations, and videos were developed in cooperation with a small visual design company, Public Cinema.

Face-to-Face Sessions

Face-to-face sessions were developed based on previous experience in developing and evaluating communication skills training in oncology [42,61,68]. The most important recommendations from these earlier studies were to role-play with an actor to practice the lessons learned during the training and provide the trainee with personal feedback [42]. Development took place in multiple sessions with the expert team. The basic assumptions for effective information provision, as incorporated in the e-learning, served as a starting point for the training content. Derived ideas were written down and discussed to create a training script and a supportive PowerPoint presentation. The casuistry for the training actors was developed together with a clinical expert (HWMVL). These multiple development sessions led to a conceptual version of the training.

Pilot Study Tool and Training

A pilot study was conducted from December 2018 to March 2019 to test both the tool and training in a real-life setting. As this pilot study targeted patients with advanced disease only, we included medical oncologists and metastatic cancer patients as study participants. The pilot study was evaluated by the Medical Ethics Review Committee of the Academic Medical Center Amsterdam (reference number: W18_278). In total, 5 medical oncology fellows (2 men and 3 women) from two university medical centers were invited to use the tool and trained according to the concept training format. After completion of the training, participating fellows were individually interviewed via telephone in a semistructured manner to gather feedback to improve both the Source tool and training. For the tool, the focus of the feedback was on opinions and experiences regarding usability and willingness to use the tool. Regarding training, feedbacks on the different components, training as a whole, and perceived utility were collected.

In addition, an experienced medical oncologist (HWMVL) conducted three treatment decision-making consultations with outpatients using the Source tool for information provision and in line with the training principles. These consultations were recorded on video after obtaining written informed consent from the patients and oncologists. To comply with ethical standards and according to the training, only information that the patient wanted to receive was disclosed to the patient. One-on-one semistructured interviews were conducted with the 3 patients by one of the researchers (LFVDW) to gather their experiences with the physician’s outcome information and the use of the Source tool.

Results

The Web-Based Prediction Tool: Source

A prototype web interface was created based on the findings of a systematic review of the effects of different types of risk

communication on patients with cancer [48]. Following this review, we decided to use clear and precise risk information (eg, percentages or frequencies) and simple graphs with a limited amount of information displayed. As the review did not yield consistent guidelines on which types of graphs to use, it was decided to visualize the outcomes in multiple ways. In this way, graphs can be used according to the preferences of individual patients, and the amount and presentation format of the information displayed can be tailored to their needs and preferences. The resulting RShiny web interface runs on an x64 Linux server (version 3.10.0).

Source Tool Components

The final tool, Source 1.103, contains five main components. The first component, the patient information entry component, allows the oncologist to enter the patient characteristics necessary for the prediction models and meta-analyses, using supporting information, such as the definitions of TNM variables (Figure 2).

Figure 2. A screenshot of patient data entry. The data entry screen displays the fields that are necessary for the prediction models and meta-analyses. Additional information on variables such as the World Health Organization performance status is provided with a mouse-over.

The survival component outcome was visualized in two ways: an icon array displaying the survival probability at a given point in time by coloring a subset of 100 figures and a Kaplan-Meier curve (line graph) displaying the survival probability over time (Figure 3). The survival component incorporates the possibility of switching between the two presentation formats. From the options menu, it is possible to select specific treatments for

comparison (eg, best supportive care and chemotherapy) and change the time frame of the prediction (from 6 to 24 months) to show a per treatment CI and three survival scenarios (indicating the best-case scenario comprising the top 25%, the worst-case scenario comprising the bottom 25%, and the typical outcome comprising the middle 50% [63,64]).

Figure 3. A screenshot of survival graphs. On the left, a pictograph displaying the predicted survival for best supportive care and chemotherapy after 1 year is shown. On the right, the Kaplan-Meier curve for the best supportive care is shown. The optional shaded area displays the so-called typical outcome scenario (with survival ranging from 25% to 75%).

The side effects component displays bar charts for various toxicities (Figure 4), as the meta-analysis provided static probabilities for each of the adverse events [7]. Each side effect was visualized by two stacked bars, one for mild side effects and one for severe side effects on the Common Terminology Criteria for Adverse Events scale [69]. The side effects of multiple chemotherapy regimens can also be compared. To avoid information overload, only the three most frequently occurring side effects are shown initially, although it is possible to select all side effects.

HRQoL is displayed in a line graph and shows the EORTC QLQ-C30 global health score over time (Figure 5). There are options to compare HRQoL in best supportive care with chemotherapy and display a CI and reference value (obtained from the European Organisation for Research and Treatment of Cancer reference values manual [70]). The final component is a summary that can be printed as a handout for the patient or saved as a PDF file. This feature enables physicians to show the aforementioned graphs accompanied by an explanatory text. This text is dynamically generated using the selected treatment data and explains the content of the graphs.

Figure 4. A screenshot of the side effects bar chart. This displays the three most commonly occurring toxicities for both 5FU and CAPOX. The darker bars indicate severe toxicities, and the lighter bars indicate mild toxicities. 5FU: 5-Fluorouracil; CAPOX: capecitabine combined with oxaliplatin.

Figure 5. A screenshot of the HRQoL (health-related quality of life) line graph. The graph displays the HRQoL following definitive chemoradiation. The shaded area optionally displays the CI of the HRQoL line.

Evaluation Round Feedback

The four evaluation rounds of the tool resulted in several minor visual and functional adjustments to the web interface, as described in [Multimedia Appendix 1](#). Major adjustments to the tool resulting from the gathered feedback were mostly adjustments regarding usability, such as increasing the font size and positioning of the legend. For the survival outcome, the icon array was found to be the most comprehensible, whereas the line graph provided the most insight for survival over time. Therefore, it was decided to keep both formats for the survival outcome, as the graphs supplemented each other. The line graph also remained in the tool as it incorporated the scenario's functionality (indicating worst-case, typical, and best-case survival), a feature that was found important by most patients. For side effects, it was found that the patients did not correctly interpret the meaning of the stacked bar charts. The bars were changed into two nonstacked bars with 90% overlap to display mild and severe adverse events for the same side effects to increase clarity on the meaning of the graph ([Figure 4](#)). Furthermore, it was decided to remove bar charts as a display option for HRQoL data, as both patients and oncologists found the graph unclear and wanted the data to be displayed over time, as HRQoL may increase and decrease over time. Showing the predictions at a single time point may therefore not provide sufficient insight. In the final design, various options are available to personalize the displayed graphs. Regarding the usability of the tool, it received a median SUS score of 90.0 out of 3 ratings (above the *Excellent* threshold of 80.3 points [52]) during the think-aloud sessions.

In the pilot study, 4 of the 5 oncology fellows participated in an evaluative semistructured interview following the training. The fifth fellow did not respond to repeated invitations. All 4 oncology fellows reported that the tool was highly usable overall. Some minor suggestions were provided for improving the display of certain options, graphs, and buttons. Of the 4 oncologists, 3 reported that they would use the tool in their clinical practice. They especially valued the personalized nature

of the tool's predictions and the clear and easy-to-understand visualizations for patients. Furthermore, the inclusion of HRQoL data and the option to print a summary for the patient were found useful. The fourth fellow would like the prediction models to be further developed before using the tool. For instance, during the pilot training and interviews, several critical remarks on the prediction models were expressed, such as the lack of World Health Organization performance status as a predictor of overall survival. These comments likely reflect a possible lack of trust in the underlying models and analyses of the tool. Another barrier to using the tool that one of the fellows addressed was the fear of emotionally confronting the patient with the exact numbers. This fellow did indicate that this fear was overcome through the tailoring skills that he had acquired during the training.

The Source Supportive Communication Skills Training

The e-Learning Module

A short and to-the-point e-learning module was developed to provide an overview of the theoretical background on the provision of information in a treatment decision context and introduce a web-based prediction tool. The e-learning module starts with a short peer endorsement video of the training of physicians that discusses the Source tool. Subsequently, physicians can navigate through 4 chapters. The first chapter provides an overview of the principles of effective information provision in the context of a shared decision. The second chapter introduces the physicians to the Source tool by presenting them with a tailor-made instructional video of its use and functions. Furthermore, a summary of the tool's models and their underlying data is provided. The third chapter provides an overview of tips and tricks for informing patients about the risks and benefits of treatment ([Multimedia Appendix 2](#)). The final chapter consists of a short and practical summary of key take-home messages. In all chapters, textual information and short assignments are alternated by instructional videos and animated knowledge clips. A simple and appealing visual design is applied.

Face-to-Face Training Sessions

The face-to-face component of the training consisted of two group sessions of 3.5 hours each, provided by an experienced trainer, with approximately 2 to 3 weeks in between to facilitate intermediate practice. The sessions were aimed at small groups of 2 to 6 participants, as this approach enables every participant to practice and receive personal feedback. Such a setting can also promote interactivity [71]. Both sessions involved individual role-play exercises with a professional actor in which feedback was provided by the trainer, the actor, and peers to learn additional skills [62]. Furthermore, group discussions were stimulated and led by the trainers. This approach was used to encourage physicians to discuss their attitudes toward using numbers and the tool in the context of the provision of information to patients [62,72].

The first session covered the skills of setting the agenda of the decision-making consultation, introducing the tool and informing patients on survival outcomes. Physicians were asked to practice separate parts of the consultation while receiving feedback from other physicians and the trainer. Physicians were instructed to use the acquired knowledge and skills during their outpatient consultations before the next training session. The second session allowed for the repetition of issues addressed during the first session and sharing experiences of applying the lessons learned of the first session in clinical practice. Next, skills were addressed, again with role-play and feedback, to inform patients about treatment outcomes in terms of side effects and complications and HRQoL. This session also addressed how to conclude decision-making consultations.

In both sessions, tailoring of the amount and type of outcome information to specific patients played a significant role in both role-play practice and group discussions. Tips and tricks were discussed regarding how to determine an individual's information needs and wants, how to fit these needs with the informational needs of the physician, and whether and how the tool could contribute to tailored information giving.

The total duration of the blended learning was 7.5 study hours, which consisted of 0.5 hours of e-learning and 7 hours of face-to-face training.

Feedback and Major Adjustments

Medical Oncology Fellows

Fellows reported that they enjoyed participating in the training and specifically valued personal coaching and practical tips. Furthermore, fellows appreciated the trainers and actors. In their opinion, there was a good balance between the information provided by trainers and practical exercises. Fellows especially appreciated the feedback during the training from the actor and trainer on their role-play with the actor. Overall, the training was described as useful, and specific improvements were suggested.

A point of improvement that was brought up was the substantial time investment in the training. In particular, the pace of the e-learning and instructional video was considered too slow. Furthermore, the timing of the face-to-face sessions following a day of work was considered inconvenient. The most important

adjustments to the training as a result of the fellows' feedback were related to accelerating the pace and adding an individual booster session to the training in which the physician could receive personal feedback from one of the trainers on a full, recorded consultation.

Patients With Metastatic Cancer

Despite their emotions on the subject, 2 out of the 3 patients were willing to participate in a short interview about their experiences with the consultation. Both appreciated the use of the Source tool and the physicians' explanations of possible treatment outcomes. Patients expressed differences in their experiences regarding the amount of information about treatment options and outcomes. Although one patient reported being satisfied with the amount of information, the other indicated that the amount of information was too extensive for him to memorize it all. He needed a printed summary of the tool for support. Both patients mentioned their struggle with the meaning of risk or benefit for themselves, as great uncertainty remains about their own future, despite the information provided.

Discussion

Findings

Our study shows the iterative development and pilot testing of the Source tool and training. This combined intervention was developed using scientific evidence and input from physicians, patients, and experts. This process resulted in the first web-based prediction tool to inform patients with esophagogastric cancer during consultations on survival, side effects, and HRQoL of different treatment options. Furthermore, we created a supporting training to teach physicians the communication skills needed to use the tool and to provide patients with information in an evidence-based, precise, personalized, and tailored manner. Preliminary evaluation results are promising and provide valuable input for further development and testing of both elements.

Both the tool and training were valued by participating physicians and patients. Physicians especially appreciated the practical approach of the training; the multiple practice opportunities and personal feedback helped them use the tool. Nevertheless, despite their positive attitudes toward the tool and training, old habits could stand in the way of using the tool and may impede the use of learned communication techniques in clinical practice. Behavioral change theories show that many factors can contribute to but also stand in the way of learning new behaviors. Resistance could, for instance, arise as a result of a different expected outcome of the tool or because of a low tolerance for change [43]. The *transfer* of training describes the possible behavioral change resulting of an educational intervention such as training. From the literature, we know that although certain trainee characteristics (such as the perceived utility of the training) and training design factors (such as a realistic training environment) can promote the transfer of training, they are also strongly influenced by characteristics of the work environment, such as situational cues (eg, social support from peers or supervisors) or consequences (eg, negative or strong emotional reactions from patients) [73]. These characteristics can be difficult to control in the setting of

everyday hospital care. However, concerning the training design factors, the distribution of the training sessions might be an important factor contributing to the transfer of this tool and training for daily clinical practice. Indeed, the so-called *spacing* between the two face-to-face sessions and the booster session of the training might help increase task performance [74-79].

During the pilot training, it was noted that in some cases, the fellows lacked trust in the prediction models used in the tool. Further steps were taken to increase the physicians' trust. For instance, details about the underlying data and publications were added to the tool to provide more information about the methodology and sources. Model updates (such as the 2020 version of the survival model), which increases the model's performance and sample size and includes, for instance, World Health Organization performance status as a predictor, may also increase trust in the tool [39]. Finally, external validation of the models can also generate trust in the validity and applicability of the tool [80].

The use of the Source tool could also be influenced by the application's usability and how well the tool solves the patient-informing problem as perceived by patients and physicians. Therefore, iterative usability testing is necessary to achieve an acceptable level of usability. As the number of testing rounds in this study is limited compared with other studies [37,38], the tool's usability may be further improved. This issue will be an ongoing point of attention that we will address during future testing and development of the tool. From a patient's perspective, some uncertainties regarding treatment outcomes may be reduced during the consultation, whereas other uncertainties remain. For example, the tool might support patients in participating in shared decision-making, but active participation in this difficult choice might also overwhelm them [81]. These issues can be addressed in medical education and training by dealing with a broad spectrum of patient uncertainty.

On the basis of our experiences, we can provide several recommendations to aid future research in creating and evaluating web-based prediction tools with training. First, we advise involving end users, such as patients and physicians, in the early stages of development. Assumptions and implementations are often made from the perspective of developers, which may not coincide with the needs and wishes of patients or physicians. By evaluating at an early stage, it is possible to adjust the tool and training, and subsequent improvements can be implemented more seamlessly. Although not formally evaluated in this study, user research to investigate patients' and physicians' ideas and expectations regarding such a tool could also contribute to the usability and adoption of the tool in clinical practice. Second, evaluation by physicians may be complicated because of their busy schedules. We recommend making the feedback rounds with physicians as short as possible, planning them sufficiently in advance, and having them take place on education days. Third, as insights on data visualization and risk communication may change constantly, we recommend facilitating ongoing updates of a designed prediction tool. We also suggest that future research should use the current state of the art when designing a new tool or training. Fourth, we advise that communication on outcomes with subjective interpretations, such as HRQoL, deserves a more prominent place in

communication skills training. We noticed in our training that physicians often had trouble explaining outcomes such as HRQoL. Finally, it was observed that end users sometimes had conflicting opinions regarding improvements to the tool or training. As it is not possible to cater to everyone's wishes, we recommend weighing the pros and cons of suggestions and deciding whether a personalization option will be implemented (such as displaying survival as a pictograph and a line graph) or whether a single option will be implemented (such as the background color of the web interface).

Most of the patients and physicians who participated in this study agreed that the tool and training added value to clinical practice. However, bias may have played a role in the evaluation of the tool and training, as the evaluation only partly took place in clinical practice. To investigate this potential bias and the extent to which the combined tool and training aid in information provision in the context of treatment decision-making, we are currently performing the third phase of the Medical Research Council framework: evaluation, a multicenter effect study (registered under NCT04232735, the SOURCE trial). In this stepped-wedge trial, physicians receive training and use the Source tool both in simulated patient assessments and with outpatients. The effect that the intervention has on the outcome information provided by oncology physicians was quantitatively investigated by recording these consultations before and after the intervention and analyzing physicians' outcome-related remarks. The primary outcome of this study is the provision of precise outcome information; secondary outcomes include the amount of tailoring to the information needs of patients, the patients' own knowledge and opinions on the communicated outcome information, and the influence that the consultation has on patients' emotions. As trust in the SOURCE models was found to be a potential barrier to using the tool in the pilot study, physicians' trust in the models will be closely monitored and specifically addressed during the trial. The models included in the Source tool are being continuously improved and updated, in part, to address these issues.

In this trial, both palliative and curative patients will participate, and models aimed at potentially curable patients (cM0) will be added to the Source tool. The survival models are based on the 2020 version of the models, which include updated palliative prediction models and newly developed curative prediction models for both esophageal and gastric cancer [39]. The HRQoL model for curatively treated patients originates from a systematic review and meta-analysis, and treatment side effects for curatively treated patients were provided by the COMplot study [82,83]. The addition of these models to the Source tool enables evidence-based and precise information personalized to the individual's characteristics in the full spectrum of patients with esophagogastric cancer. As the tool is currently being tested in a trial, access is currently restricted to trial participants. However, after the conclusion of the trial, the tool will be freely available in both Dutch and English, enabling the use of the Source tool in clinical practice [84].

Conclusions

We developed and evaluated a web-based tool and training to inform patients with esophageal or gastric cancer regarding treatment outcomes. Through evaluation and a pilot study,

patients and physicians indicated the added value of the tool and training, and both were improved based on their feedback. The tool and training are currently being evaluated in a multicenter trial to determine their added value in clinical practice.

Acknowledgments

Financial support for this study was provided entirely by a grant from the Dutch Cancer Society (grant UVA 2014-7000). The funding agreement ensured the authors' independence in designing the study, interpreting the data, and writing and publishing the report. The funder had no role in the design and conduct of the study; the collection, management, analysis, and interpretation of the data; the preparation, review, or approval of the manuscript; or the decision to submit the manuscript for publication.

Conflicts of Interest

The authors developed and evaluated the web-based tool Source and the accompanying training described in this study. HWMVL reports grants from the Dutch Cancer Society during the conduct of the study and personal fees from Bristol Myers Squibb, Lilly, and Nordic Pharma; and grants and nonfinancial support from Bayer, Bristol Myers Squibb, Celgene, Jansen, Lilly, Nordic Pharma, Philips, Roche, and Servier outside this work. In addition, HWMVL has a consultant or advisory role with Bristol Myers Squibb, Lilly, MSD, Nordic Pharma, and Servier.

Abstract

Background: Secondary prevention strategies after acute coronary syndrome (ACS) presentation with the use of drug combinations are essential to reduce the recurrence of cardiovascular events. However, lack of drug adherence is known to be common in this population and to be related to treatment failure. To improve drug adherence, we developed the “Mon Coeur, Mon BASIC” video. This online video has been specifically designed to inform patients about their disease and their current medications. Interactivity has been used to increase patient attention, and the video can also be viewed on smartphones and tablets.

Objective: The objective of this study was to assess the long-term impact of an informative web-based video on drug adherence in patients admitted for an ACS.

Methods: This randomized study was conducted with consecutive patients admitted to University Hospital of Lausanne for ACS. We randomized patients to an intervention group, which had access to the web-based video and a short interview with the pharmacist, and a control group receiving usual care. The primary outcome was the difference in drug adherence, assessed with the Adherence to Refills and Medication Scale (ARMS; 9 multiple-choice questions, scores ranging from 12 for perfect adherence to 48 for lack of adherence), between groups at 1, 3, and 6 months. We assessed the difference in ARMS score between both groups with the Wilcoxon rank sum test. Secondary outcomes were differences in knowledge, readmissions, and emergency room visits between groups and patients’ satisfaction with the video.

Results: Sixty patients were included at baseline. The median age of the participants was 59 years (IQR 49-69), and 85% (51/60) were male. At 1 month, 51 patients participated in the follow-up, 50 patients participated at 3 months, and 47 patients participated at 6 months. The mean ARMS scores at 1 and 6 months did not differ between the intervention and control groups (13.24 vs 13.15, 13.52 vs 13.68, respectively). At 3 months, this score was significantly lower in the intervention group than in the control group (12.54 vs 13.75; $P=.03$). We observed significant increases in knowledge from baseline to 1 and 3 months, but not to 6 months, in the intervention group. Readmissions and emergency room visits have been very rare, and the proportion was not different among groups. Patients in the intervention group were highly satisfied with the video.

Conclusions: Despite a lower sample size than we expected to reach, we observed that the “Mon Coeur, Mon BASIC” web-based interactive video improved patients’ knowledge and seemed to have an impact on drug adherence. These results are encouraging, and the video will be offered to all patients admitted to our hospital with ACS.

Introduction

Cardiovascular disease is a major cause of morbi-mortality in Europe, with a substantial contribution from acute coronary syndrome (ACS) [1]. Secondary prevention strategies, such as risk factor control through lifestyle modifications and the use of medication combinations, have greatly reduced the recurrence of ACS [2]. European guidelines have been developed to enhance evidence-based medicine prescriptions for patients with myocardial infarction (MI) [3,4], and we previously showed that physicians at our hospital in Switzerland predominantly issued prescriptions of this type [5]. However, poor patient self-adherence to cardiac medications has been documented worldwide [6-8] and has been associated with increased morbi-mortality [9-11]. The discontinuation of antiplatelet drugs has been related to fatal consequences such as stent thrombosis, particularly soon after ACS onset [12].

Poor drug adherence is related to many factors associated with health care systems (eg, cost, access to care), socioeconomic (ie, poverty), therapy (ie, treatment complexity, cost), and patients (ie, health literacy, willingness to change, knowledge, education) [13]. In Switzerland, the health care system offers high-quality care to all residents, and less social inequality exists than in other countries; we thus believe that patient adherence in this country is more likely related to treatment and patient factors. The provision of sufficient and effective information to patients with chronic diseases has been shown to increase patient satisfaction [14], reduce psychological distress [15], enhance patients' perceived control [16], and improve patient adherence to medication prescriptions [13]. Thus, the offering of such information and knowledge to all patients with ACS is very important.

Various interventions have been shown to promote drug adherence in the context of cardiovascular health. These strategies range from the simple, such as the distribution of written material about medications [17] and the regular mailing of informational letters [18,19], to multifaceted interventions (eg, medication reconciliation, therapeutic education) involving clinical pharmacists [20,21] and nurses specialized in therapeutic education [22].

The length of hospital stays after MI has shortened in recent years, which has reduced the number of opportunities to inform patients about their disease during hospitalization. Cardio-rehabilitation (CR) centers are meant to fill this gap, but not all patients participate in CR programs. In addition, depending on the type of program chosen (ie, stationary or ambulatory), the objective may be oriented more toward cardiovascular reeducation than to patient education. Moreover, very few sessions are devoted to educating patients about their drug treatments.

Different kinds of mobile health (mHealth) technologies have been developed to support cardiovascular health, like eHealth

diaries [23], apps supporting cardiac rehabilitation [24,25], and complete e-learning platforms [26]. However, none of these technologies were available in French, and only a few studies have evaluated the impact of mHealth technologies on therapeutic adherence [27,28]. As we were convinced that mHealth technologies have an impact on drug adherence, we wanted to test it with our study. Therefore, we developed a new approach using a video tool for the provision of information and patient education. The tool we developed is interactive, web-based, smartphone- and tablet-compatible, and it is designed to be offered to patients with ACS during their hospital stays. We tested whether this tool has impacts on drug adherence and patient knowledge after ACS. Our study is therefore expected to fill some important gaps in the current literature.

Methods

Study Design and Population

The Secondary Prevention of ACS With Beta-Blockers, Antiaggregants, Statins, Angiotensin-Converting Enzyme Inhibitors, and Risk Factor Control (BASIC) study was a single-center randomized trial. The objective of the study was to assess if a new web-based and interactive video could increase long-term drug adherence, as well as the knowledge of the patients about their disease and their current medications, in patients admitted in hospital for an ACS.

The patients were screened between February 1 and September 1, 2019, on admission to the University Hospital of Lausanne. The intervention for this study was added to usual care, in which all patients with ACS watched a 20-minute video called ELIPS during their hospital stays [29]. ELIPS explains acute infarction, acute care, and the drugs prescribed. Patients also received a booklet about coronary artery disease. All patients admitted to our hospital for ACS are encouraged to participate in a CR program after discharge; the program chosen depends on each patient's willingness and home location. Two types of programs are offered (a 3-week stationary program and an ambulatory program), and both are reimbursed by health insurance.

Participants eligible for the study were men and women older than 18 years who were diagnosed with ST-segment elevation myocardial infarction (STEMI) or non-ST-segment elevation myocardial infarction (NSTEMI) treated with percutaneous coronary intervention (PCI). Other requirements were total discernment capacity; possession of a digital tablet, smartphone, or home computer; and satisfactory French language skills. Exclusion criteria were the inability to follow the study procedure (eg, due to language problems, psychological disorders, dementia), refugee claimant status, homelessness or incarceration (because of the impossibility of contacting such individuals after discharge), and life expectancy <6 months due to another disease.

Eligible participants were randomized to the intervention and control groups using a 1:1 allocation ratio after providing oral

and written informed consent. The randomization was conducted by a clinical study specialist who was not involved in the study. The randomization process was made by week and block of 4. Each week was randomized as intervention or control in order to avoid having two patients in different groups next to each other in the intermediate care unit.

“Mon Coeur, Mon BASIC” Web-Hosted Video

“Mon Coeur, Mon BASIC” is an interactive web-hosted video that is smartphone- and tablet-compatible. It is freely available online [30]. It is a simple animated cartoon (Figure 1) with narration in French. It consists of three parts providing information about heart function and the physiopathology of

ACS, acute care for ACS (coronarography and PCI), and the medications prescribed after ACS (usefulness and side effects), with a total length of about 15 minutes. The viewer can click on the video using a mouse or finger to obtain information about a particular point or to jump directly to another subject. The video was developed by a working group consisting of a pharmacist, a graphic designer, a specialist in patient communication, and a cardiologist. It was designed using Illustrator and InDesign (both from Adobe Inc, San José, California), and the interactivity was created using Storyline 360 (Articulate, New York). It was tested with several patients, and all bugs were eliminated before the beginning of the study.

Figure 1. Screenshots from the “Mon Coeur, Mon BASIC” video.

Intervention and Control Condition

The pharmacist participating in the study met all patients in the intervention group during their hospital stays and gave each of them a medication card with his or her current prescriptions ([Multimedia Appendix 1](#)). The medication card contained all the medications currently prescribed to the patient, classified by type of medication according to the acronym BASIC for Beta-blocker, Antiaggrégant, Statin, angiotensin-converting enzyme Inhibitor, and Control of risk factors (ie, smoke cessation, limitation of fatty meals, etc), and was the size of a

credit card. She then connected to the e-learning website on the patient's tablet or smartphone and created a shortcut. Tablets from the institution were lent to patients with no tablet, smartphone, or computer. The pharmacist asked the patients to watch the video at their convenience. After the patients had watched the video, the pharmacist visited to answer questions and distribute study questionnaires (described below). The postvideo visit was short, and the aim of the visit was to check if the patients had watched the video and to answer patients' questions if they had any. The duration of this visit was around 10 minutes per patient.

The control group received usual care. In usual care, the patient has no meeting with the pharmacist at all, and the information about medications and the disease are provided by the nurses and the physician in charge of the patient during hospitalization. All the patients (in control and intervention group) also watched a short film developed in the Geneva University Hospitals [29]. For the purpose of the study, the pharmacist only met patients randomized to the control group to give them the study questionnaires.

Primary Outcome

The primary outcome was the difference in medication adherence between groups at 1, 3, and 6 months after ACS for the assessment of postdischarge treatment initiation, treatment implementation in daily life, and long-term treatment persistence, respectively. Adherence was assessed using the Adherence to Refills and Medication Scale (ARMS; [Multimedia Appendix 2](#)). This self-report questionnaire was chosen due to its strong internal consistency (Cronbach $\alpha=.814$), good correlation with other subjective and objective measures, and validation for use with patients with coronary heart disease [32]. It consists of 12 items assessing adherence to taking medication ($n=8$) and refilling prescriptions ($n=4$). The questionnaire is made up of affirmations that can be answered with “none of the time,” “some of the time,” “most of the time,” or “all of the time,” varying from 1 to 4 points, respectively. Final scores range from 12 (most adherence) to 48 (least adherence) and can be treated as continuous measures or dichotomized as 12 and >12 . We translated the validated English version of the ARMS into French according to guidelines developed for health care research [33].

Secondary Outcomes

The first secondary outcome was the difference in ACS-related knowledge (basics of heart function, ACS pathophysiology, and usefulness of prescribed medications) between groups, assessed using a questionnaire developed specifically for this study ([Multimedia Appendix 3](#)). The questionnaire has 9 items, and scores range from 0 to 9 (most knowledge). The questionnaire was given to the intervention group as a pretest (before the video viewing) and posttest (after viewing), to the control group 1 day after study inclusion, and to all participants at 1, 3, and 6 months. We also assessed whether the groups differed in a composite measure of cardiovascular mortality, first occurrence of reinfarction, recurrence of ACS, cardiovascular death, and readmission and emergency room visitation over the 6-month study period. Finally, we assessed patients' satisfaction with the video using a questionnaire of 11 multiple-choice questions.

Data Collection

Most baseline data (eg, demographic characteristics, laboratory values, and vital parameters on day 2 after ACS; ACS type and therapeutic strategy; cardiovascular risk factors; drug prescribed at discharge) were collected from computerized patient records generated during hospitalization. Other data were collected through patient interviews; they included patients' email addresses, educational levels (graduation of primary, secondary, or tertiary school), employment statuses (full time, part time,

retired, or unemployed), spoken French levels (native, near native, highly proficient, very good working knowledge, or basic communication skills), general practitioners' names, types of device used at home (smartphone, tablet, or computer), information and communications technology (ICT) use levels (low: short message service or telephone only, medium: also maps and basic online research, or high: many applications in daily life), and health literacy scores, assessed with the validated French translation of the Functional, Communicative and Critical Health Literacy (FCCHL) tool [34]. FCCHL scores range from 14 (least literacy) to 70 (most literacy). All data were collected and managed using REDCap (Research Electronic Data Capture) tools hosted in the University Hospital of Lausanne [35,36]. REDCap is a secure, web-based software platform designed to support data capture for research studies.

An email with a link to the study questionnaires (hosted by REDCap) was sent to the participants at 1, 3, and 6 months after study inclusion. For participants who did not provide any email address, the questionnaires were mailed with postage-paid return envelopes.

Statistical Analysis

An intention-to-treat analysis including all study participants was performed. The characteristics of patients randomized to the intervention and control groups were expressed as medians with 25th and 75th percentiles for continuous variables, and as numbers and percentages for categorical variables. They were compared using the Pearson chi-square test for categorical variables and the t test for continuous variables.

The ARMS scores at 1, 3, and 6 months were compared between groups using the Wilcoxon rank sum test. This test was also used to compare pretest and posttest knowledge scores and those at 1, 3, and 6 months between groups. The Wilcoxon rank sum test for paired data was used to assess differences in knowledge within groups between study timepoints. Descriptive statistics (numbers and percentages) were calculated for the composite outcome, satisfaction scores, and video reuse. The level of significance for all analyses was set at two-sided $\alpha<.05$. All analyses were performed using Stata software (version 14; StataCorp, College Station, Texas).

We performed a power analysis to estimate the sample size required to detect a significant difference in medication adherence between the intervention and control groups. We based the calculation on the mean ARMS score of 16.32 (SD 4.06) for chronically ill patients [32]. We determined that a sample of 128 patients (64 per group) was needed to detect a difference of 0.5 SD (ie, 2.03) between the intervention and control groups at a two-sided 5% significance level with a power of 0.8 and an allocation ratio of 1:1. Assuming 10% loss to follow-up, the target sample size was 142 patients. Based on our hospital's annual admission rate of 500 patients with NSTEMI and 300 patients with STEMI, we initially believed that study enrollment would be completed within 20 weeks, but because many patients were discharged before we could conduct baseline assessment, and an unexpectedly large number of patients refused to participate, we extended the enrollment period to 37 weeks. However, because the investigator was not available for a longer period of time than planned, we had to

terminate the study before the target sample size had been reached. The results presented in this article must therefore be interpreted with caution because the study was underpowered.

Ethical Considerations

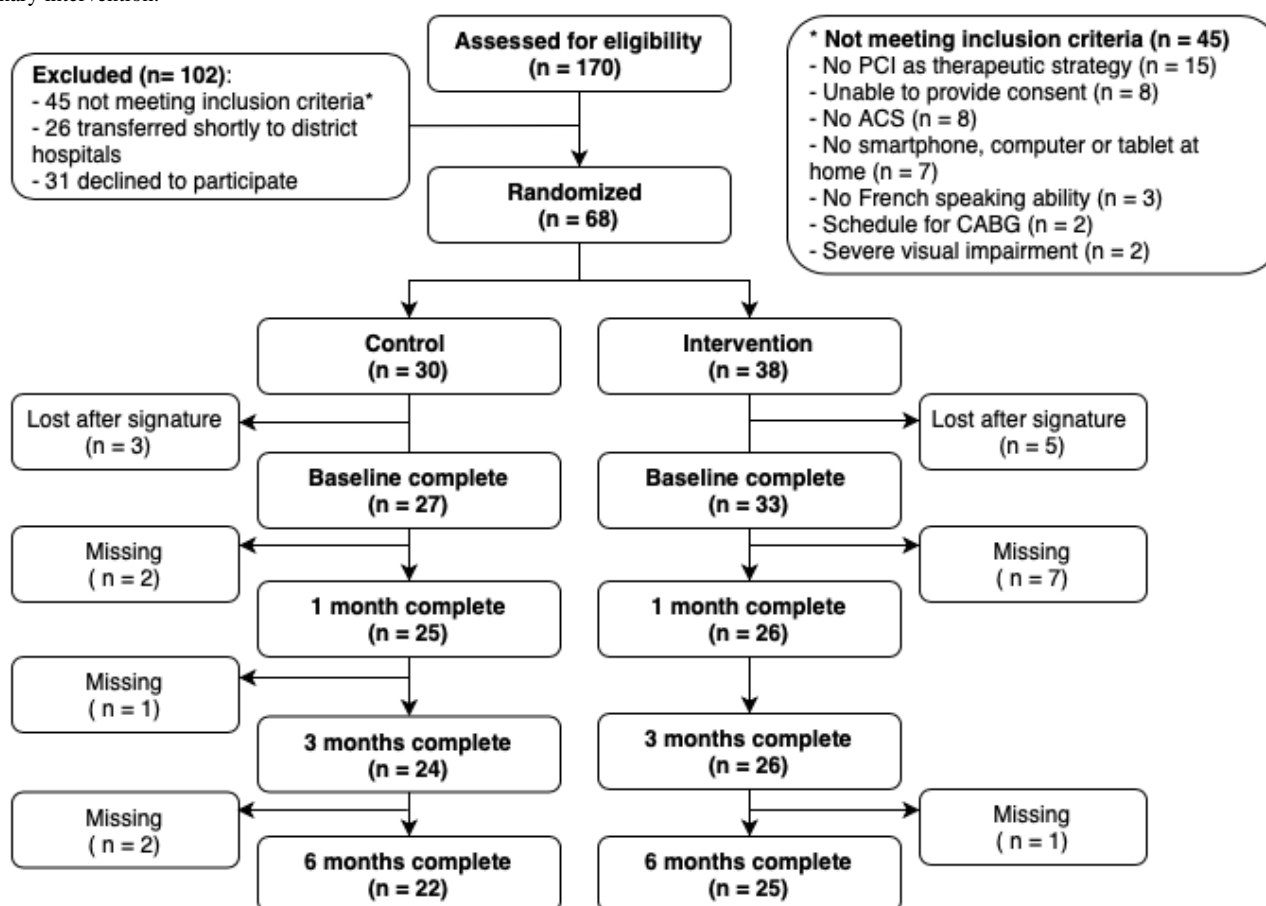

This study was approved by the local ethics committee (*Commission cantonale d'éthique de la Recherche sur l'être humain du Canton de Vaud*; number 2018-02223) and registered at ClinicalTrials.gov (number NCT03949608). It complied with the principles of good clinical practice and the Declaration of Helsinki.

Results

Study Population and Baseline Characteristics

In total, 170 patients were screened during the study period, and 125 patients were asked to participate (Figure 2). Of these, 31 (24.8%) patients declined participation, and 26 (20.8%) were transferred to district hospitals shortly thereafter and were not enrolled. We randomized 68 patients to the control (n=30) and intervention (n=38) groups. Of these, 8 patients were transferred unexpectedly to district hospitals, did not watch the video, or did not complete the baseline questionnaires; thus, the final baseline sample consisted of 60 patients (33 in the intervention group and 27 in the control group) with complete baseline data. An additional 21 of the 68 randomized patients (31%) did not complete the follow-up questionnaires.

Figure 2. Patient flowchart within the study period. ACS: acute coronary syndrome; CABG: coronary artery bypass grafting; PCI: percutaneous coronary intervention.

The median age of the 60 patients included was 59 years; 85% (51/60) of the patients were men, 19% (11/59) had diabetes, and about 45% (25/56) were active smokers (Table 1). Patients in the control group were slightly older and more often retired than patients in the intervention group were. They also had more

comorbidities and more often had NSTEMI than did patients in the intervention group. However, the groups were well matched, with no significant difference in baseline characteristics.

Table 1. Baseline patient characteristics (N=60). Categorical data are presented as n (%) and continuous data are presented as median (interquartile range). *P* values were estimated with the chi-square test for categorical variables and *t* test for continuous variables.

^mN/A: not applicable.

Primary Outcome: ARMS Score

At 1 month, the mean ARMS score did not differ significantly between the intervention and control groups (13.15, 95% CI 12.56-13.74 and 13.24, 95% CI 12.52-13.96, respectively; $P=.99$). At 3 months, the ARMS score was significantly lower in the intervention group than in the control group (12.54, 95%

CI 12.08-13.00 vs 13.75, 95% CI 12.74-14.76; $P=.03$). At 6 months, this score did not differ between the intervention and control groups (13.52, 95% CI 12.63-14.41 and 13.68, 95% CI 12.96-14.76, respectively; $P=.33$; [Figure 3](#)). The median ARMS score increased from 1 to 6 months in the control group but remained more stable (at ~12) in the intervention group, despite a change in distribution.

Figure 3. ARMS scores at 1, 3, and 6 months. In the box plots, the boundary of the box closest to zero indicates the 25th percentile, the line within the box represents the median, and the boundary of the box farthest from zero indicates the 75th percentile. Whiskers above the box indicate the 90th percentile. Points above the whiskers represent the outliers outside the 90th percentile. The *P* values represent statistics made with the nonparametric Wilcoxon test. *n* represents the number of participants per group. ARMS: Adherence to Refills and Medication Scale.

Of 13 participants whose ARMS scores increased between 1 and 3 months, 10 were in the intervention group, and 3 were in the control group. In 7 (54%) cases, scores increased because patients provided different responses to the last item about prescription refills (Multimedia Appendix 2).

Secondary Outcomes

Knowledge Score

The mean knowledge score did not differ significantly between the intervention and control groups at baseline or at 1, 3, or 6

months (7.22, 95% CI 6.64-7.81 and 7.03, 95% CI 6.46-7.60; 8.19, 95% CI 7.66-8.72 and 7.72, 95% CI 7.06-8.38; 8.36, 95% CI 8.03-8.69 and 8.00, 95% CI 7.44-8.56; and 8.04, 95% CI 7.54-8.54 and 7.72, 95% CI 7.00-8.45, respectively; all *P*_s>.05; Figure 4). Within each group, knowledge increased from baseline to 6 months; increases were significant in the intervention group between baseline and 3 months, but not at 6 months (Table 2).

Figure 4. Knowledge scores (0-9) at baseline (pretest), 1 day after ACS (posttest), and 1, 3, and 6 months after ACS. In the box plots, the boundary of the box closest to zero indicates the 25th percentile, the line within the box represents the median, and the boundary of the box farthest from zero indicates the 75th percentile. Whiskers above the box indicate the 90th percentile. Points above the whiskers represent the outliers outside the 90th percentile. n represents the number of participants per group. ACS: acute coronary syndrome.

Table 2. Differences in knowledge scores from baseline.

Timepoint	Control, median (95% CI)	P value ^a	Intervention, median (95% CI)	P value ^a
Baseline score	7.22 (6.64 to 7.81)	N/A ^b	7.03 (6.46 to 7.60)	N/A
Difference from baseline				
Posttest (1 day)	0.33 (-0.16 to 0.82)	.14	1.00 (0.48 to 1.52)	.001
1 month	0.48 (-1.13 to 1.19)	.17	1.04 (0.35 to 1.73)	.03
3 months	0.63 (-0.02 to 1.27)	.06	1.40 (0.68 to 2.12)	.008
6 months	0.32 (-0.30 to 0.94)	.27	0.88 (0.25 to 1.51)	.144

^aWilcoxon rank sum test for paired data.

^bN/A: not applicable.

Composite Endpoint of Mortality, Reinfarction, Rehospitalization, and Emergency Room Visits

No death occurred in the cohort. Five patients visited the emergency room and were subsequently hospitalized. Overall, 7 of 46 (15%) patients (2 in the intervention group, 5 in the control group) were hospitalized for cardiovascular reasons (heart rhythm disorders: 1 tachycardia, 1 bradycardia; vagal discomfort: n=2; chest pain that was determined to be noncardiac: n=1; elective stent placement: n=1; and coronary artery bypass grafting: n=1). No patient had a new infarct during

the follow-up period and no difference was observed between groups.

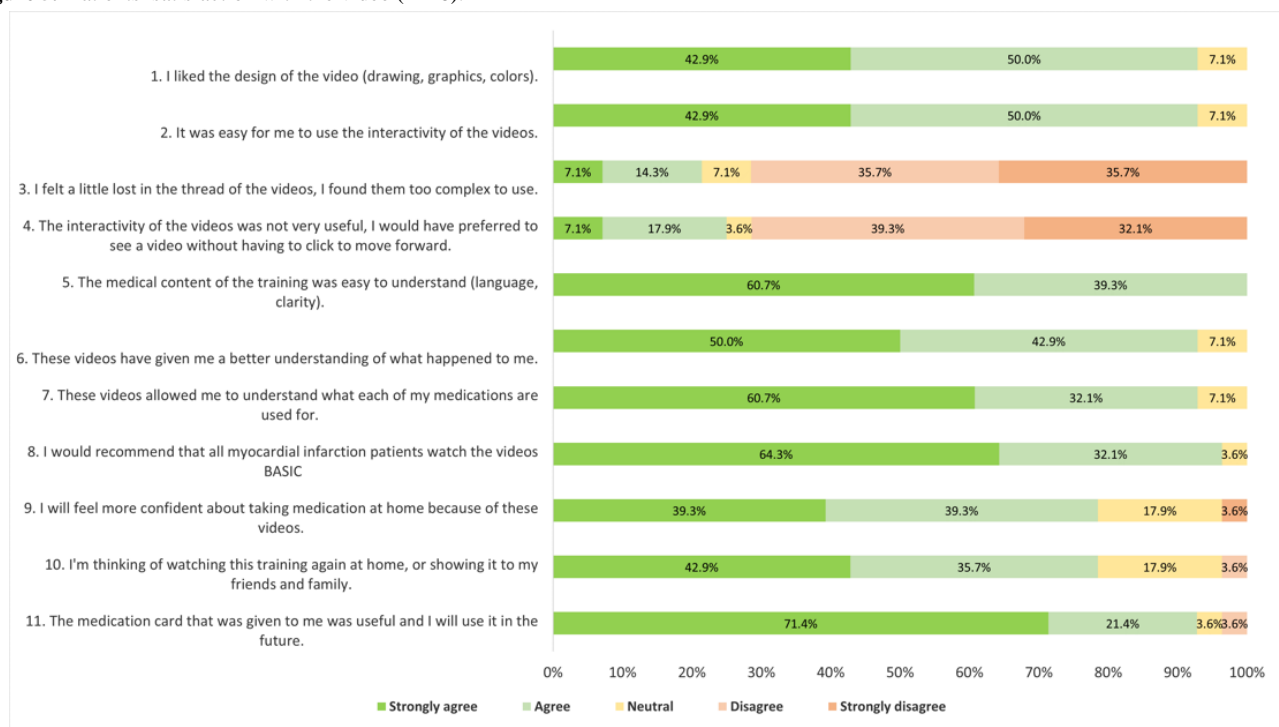

Satisfaction With and Reuse of the Video and Medication Card

Overall, the patients were highly satisfied with the design, use, and medical content of the video (Figure 5). The majority of patients felt that the video helped them to better understand their disease and medications and indicated that they would recommend it to other patients with ACS. As questions 3 and 4 were negatively worded, some patients may have answered

them incorrectly. Despite this potential issue, the majority of patients felt comfortable with the interactivity of the video and did not lose the thread of the presentation. Responses regarding whether patients thought they would watch the video again at

home were the most mitigated. We found that 18 of 30 (60%) patients viewed the video again at home. The majority of patients strongly appreciated the medication cards, and 22 of 30 (73%) patients reused the cards after discharge.

Figure 5. Patients' satisfaction with the video (n=28).

Discussion

Principal Findings

The “Mon Coeur, Mon BASIC” web-hosted video seemed to significantly improve the drug adherence of patients with ACS for a few months after treatment initiation: a significant effect was observed at 3 months, but not at 1 or 6 months. Moreover, patients from the intervention group showed significant improvement in their knowledge about ACS and their medications from baseline to 3 months; no such effect was seen in the control group. In addition, patients were generally very satisfied with the information provided in the video and with the medication cards given to them.

The rate of drug adherence was high in both groups at 1 month after ACS. As expected, the median ARMS score tended to increase over time in the control group, reflecting decreasing adherence. At 3 months, the intervention group showed much better drug adherence than did the control group. At 6 months, the median score remained lower in the intervention group, but this difference was not significant. Although the observed trends may not all be attributable to the effect of the video alone, we can state with strong confidence that patients in the intervention group were more likely to refill their prescriptions at 3 months than at 1 month.

In the intervention group, patients' knowledge about ACS and their medications increased significantly from baseline to 1 day (after video viewing) and 3 months after ACS. Thus, the intervention appeared to effectively improve patients'

cardiovascular knowledge over the first 3 months after ACS presentation.

Overall, our results are encouraging but must be interpreted with caution. The sample size initially calculated could not be reached, and our study is therefore underpowered. However, our results are still interesting and show a great tendency for improvement of drug adherence and knowledge.

Comparison With Previous Work

App use has been demonstrated to improve drug adherence. For example, use of the “My Interventional Drug-Eluting Stent Education” app, developed in the United States with a similar goal as the “Mon Coeur, Mon BASIC” video, increased patients' antiplatelet drug adherence and knowledge about PCI in a pilot study [27]. Use of another patient support app increased ticagrelor adherence and tended to improve cardiovascular-related lifestyle changes [28]. mHealth technologies seem to have an impact in drug adherence and should be part of future developments in the cardiology field.

Place of mHealth Technology for ACS Patients

Most currently available mHealth technologies were developed to support cardiovascular health; products include eHealth diaries [23], apps supporting cardiac rehabilitation [24,25], and complete e-learning platforms [26]. We are convinced that these strategies will make up a large part of future patient care, but their use will likely remain limited for a large proportion of current cardiac patients. The median age of our patients at admission was 59 years, and 20% (12/60) of patients reported low levels of ICT use. Moreover, we had to exclude patients

with no ICT device or internet connection at home. For these reasons, we sought to develop a tool that is easy to use, even for patients who are not familiar with ICT use. We developed pocket-sized medication cards instead of digital cards for the same reasons, and patients appreciated these cards even more than the video. mHealth cannot replace the face-to-face approach, but it can be used as a complementary tool to increase patients' self-efficacy. In this study, the pharmacist talked with patients and answered their questions after they had watched the video, which may have affected their satisfaction. We will continuously update the content and enhance the interactivity of our web-based video, and we plan to develop a complete app with an easily updated medication plan, a frequently asked questions module, and quizzes to help patients develop even more knowledge.

Limitations

This study has some limitations. The ARMS is not the gold standard for the assessment of drug adherence; such assessment should include the direct measurement of drug consumption. Unfortunately, patients' drug consumption cannot be determined accurately using data from the Swiss health care system, as drugs are delivered by packs containing a prespecified number of tablets (eg, ticagrelor is available in blister packs of 56 tablets, whereas aspirin is delivered by packs of 98 tablets) and are not delivered by drug unit (for example, 30 tablets for 30 days of treatment). In addition, we did not adjust for some baseline characteristics (eg, age, sex, and educational level), which may have resulted in bias. Nevertheless, all baseline characteristics were similar in the two study groups, which reduced the risk of statistical errors; we thus believe that the intervention had an impact on drug adherence. Another limitation is the small sample, which together with the high degree of variance resulted

in the loss of statistical power and the inability to perform subgroup analyses. We had difficulties in recruiting patients because many of them were transferred within 24 hours to a peripheral hospital, and we lost several of them to follow-up. We unfortunately could not continue the recruitment further, and we had to analyze the results with the small sample. The exclusion of patients without home internet access also may have biased the results. Finally, our findings may have been affected by attrition bias, as we lost about 20% (13/60) of patients between baseline and study completion. Despite these limitations, our results are very encouraging and suggest that the provision of an interactive informational video to patients has positive effects. These results should be confirmed in larger clinical studies that include subgroup analyses to identify the populations that would benefit most from such interventions.

Conclusions

Despite our study being underpowered, we were still able to show that the "Mon Coeur, Mon BASIC" web-hosted interactive video improved drug adherence and enhanced patients' cardiovascular knowledge. The video will be available at no charge from a webpage constructed by our hospital's cardiology department staff and will be offered to all patients hospitalized for ACS at our institution in the future. Our findings reflect patients' need for and appreciation of medical information; the most appropriate means of providing such information needs to be determined. Such tools should be developed for patients with a wide range of chronic diseases, and their content should be continuously improved. Over time, increasing numbers of patients will be able to use smartphone apps, which provides the opportunity to develop this type of support to improve the management of patients with chronic diseases.

Acknowledgments

This work was supported by an "e-learning commission" from the University Hospital of Lausanne. The funder had no role in the design of the study; collection, analysis, or interpretation of data; or writing of the manuscript. We sincerely thank all individuals who participated in the development of the "Mon Coeur, Mon BASIC" video, including Alienor Held, Pierre-Antoine Dubois, Ana Loureiro Soares, Anaëlle Morf, and Anne-Sylvie Diezi; we thank Marc Sohrmann for his advice on video content and Laurence Iseli for video narration.

Abstract

Background: Ecological momentary assessment (EMA) is a research design that allows for the measurement of nearly instantaneous experiences within the participant's natural environment. Using EMA can help improve recall bias, ecological validity, and patient engagement while enhancing personalization and the ubiquity of interventions. People that can benefit from the use of EMA are men who have sex with men (MSM). Previous EMA studies have been successful in capturing patterns of depression, anxiety, substance use, and risky sexual behavior. These findings are directly relevant to MSM, who have high rates of each of these psychological and behavioral outcomes. Although there is a driving force behind the growing literature surrounding EMAs among MSM, no synthesizing reviews yet exist.

Objective: The aims of this study were to (1) synthesize the literature across fields on how EMA methods have been used among MSM, (2) better understand the feasibility and acceptability of EMA interventions among MSM, and (3) inform designs for future research studies on best evidence-based practices for EMA interventions.

Methods: Based on 4 library databases, we conducted a scoping review of EMAs used within interventions among MSM. The eligibility criteria included peer-reviewed studies conducted in the United States and the use of EMA methodology in an intervention for MSM. Modeling after the Centers for Disease Control and Prevention's Compendium of Evidence-Based Interventions as the framework, we applied a typology that used 8 distinct review criteria, for example, sample size, design of the intervention, random assignment, design of the follow-up investigation, rate of retention, and rate of engagement.

Results: Our results ($k=15$, $N=952$) indicated a range of sample sizes; the smallest sample size was 12, while the largest sample size was 120. Of the 15 studies, 7 (47%) focused on outcomes related to substance use or outcomes related to psychological experiences. Of the 15 studies, 5 (33%) implemented an EMA intervention across 30 days. Of the 15 studies, 2 studies (13%) used random assignment, and 2 studies (13%) had quasi-experimental designs. Of the 15 studies, 10 studies (67%) reported acceptable retention rates greater than 70%. The outcomes that had event-contingent prompts (ie, prompts after engaging in substance use) were not as effective in engaging participants, with overall engagement rates as low as 37%.

Conclusions: Our systematic scoping review indicates strong evidence that the EMA methodology is both feasible and acceptable at high rates among MSM, especially, when examining psychological and behavioral outcomes such as negative or positive affect, risky sexual behavior, or substance use. Further research on optimal designs of EMA interventions for MSM is warranted.

Introduction

Ecological Momentary Assessment

Developed originally from the field of personality and social psychology, ecological momentary assessment (EMA) is a research design with methodological components that allow researchers to measure experiences as close to that moment as possible and within the participant's natural environment [1]. Methodological strategies in EMAs have included prompting participants at various time intervals using self-report surveys or triggers specific to locations, events, or both [2]. Researchers have indicated that recall-based self-reports can be inaccurate or unreliable measurements of participants' actual lived experiences [2]. The goal of EMA is to minimize retrospective recall issues and enhance researchers' ability to measure lived experiences of people in the moment [1].

The ability to measure and potentially intervene in lived experiences in the moment is especially important to impact dysfunctional thoughts, capture psychological distress, or even intervene in harmful behavior [2]. In addition, one of the key benefits and goals of EMA is to provide high levels of ecological validity, or validity that comes from collecting data and implementing an experiment in a participant's natural setting in real-world contexts. High ecological validity can enhance the ability for research findings to be applied to real-world scenarios, increasing the likelihood of generalizability [3]. Research has also found EMA methods to outperform traditional paper-pencil measurements in the ability to determine needs of clinical interventions more precisely. A primary reason that EMA measurements outperform traditional paper-pencil measurements is that repeated measurements minimize the effect of participants' current state on results [4]. Finally, technology-based interventions incorporating EMA methods have shown promise in terms of feasibility and acceptability of enhancing intervention outcomes [5].

Men Who Have Sex With Men

Men who have sex with men (MSM) have been found to show high rates of both psychological distress and engagement in various risky behaviors [6]. Specifically, studies have found MSM to endure higher levels of depression, anxiety, substance use, and risk of contracting HIV [7,8]. EMAs have been used among MSM in daily diaries since 2007 [7] and have evolved tremendously into the realm of internet use [9], smartphone technology [10], and interventions [11]. Use of EMAs among MSM is a growing area of research. EMAs have been shown to be highly effective in reaching people who have a history of substance use or other risky behavior, due to the minimization of stigma and enhancement of self-control over privacy, confidentiality, and anonymity [10,12,13].

Scoping Review

The primary purpose of a scoping review is to synthesize current literature surrounding a topic area. Thus, the synthesis produced from a scoping review acts as a summary of available literature, a means to identify key concepts, and a precursor to a systematic

review [14]. To the best of the authors' knowledge, neither a scoping review nor a systematic review has yet been produced on the topic of EMA use among MSM, due to the limited literature surrounding the topic. As a result, the authors intended to conduct a scoping review by applying the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses-Extension for Scoping Reviews) [15], as a contribution toward a future systematic review based on an increase in literature. Authors also acknowledge the limitations of a scoping review, mainly, an inability to make quality assurances, a lack of strong validity, and an inability to hypothesize based on the review.

Scoping Review for EMAs Among MSM

Despite the benefits and clinical implications of using EMA methods for at-risk populations, there have been no reviews compiling the literature of how EMAs have been used among MSM. One growing method for synthesizing theoretical and empirical evidence in the literature is the scoping review [16]. Scoping reviews are considered as means to describe key findings across literature, identify gaps in research, and inform the design of future research studies [16]. Two major benefits of conducting a scoping review are the ability to examine the breadth of the topic of EMA methodologies that are applied to MSM, specifically, within interventions, and the ability to identify knowledge gaps and future directions for the expansion of this area of research. The aims of this study were to: (1) synthesize the literature across fields on how EMA methods have been used among MSM, (2) better understand the feasibility and acceptability of EMA interventions among MSM, and (3) to inform designs for future research studies on best evidence-based practices for EMA interventions.

Methods

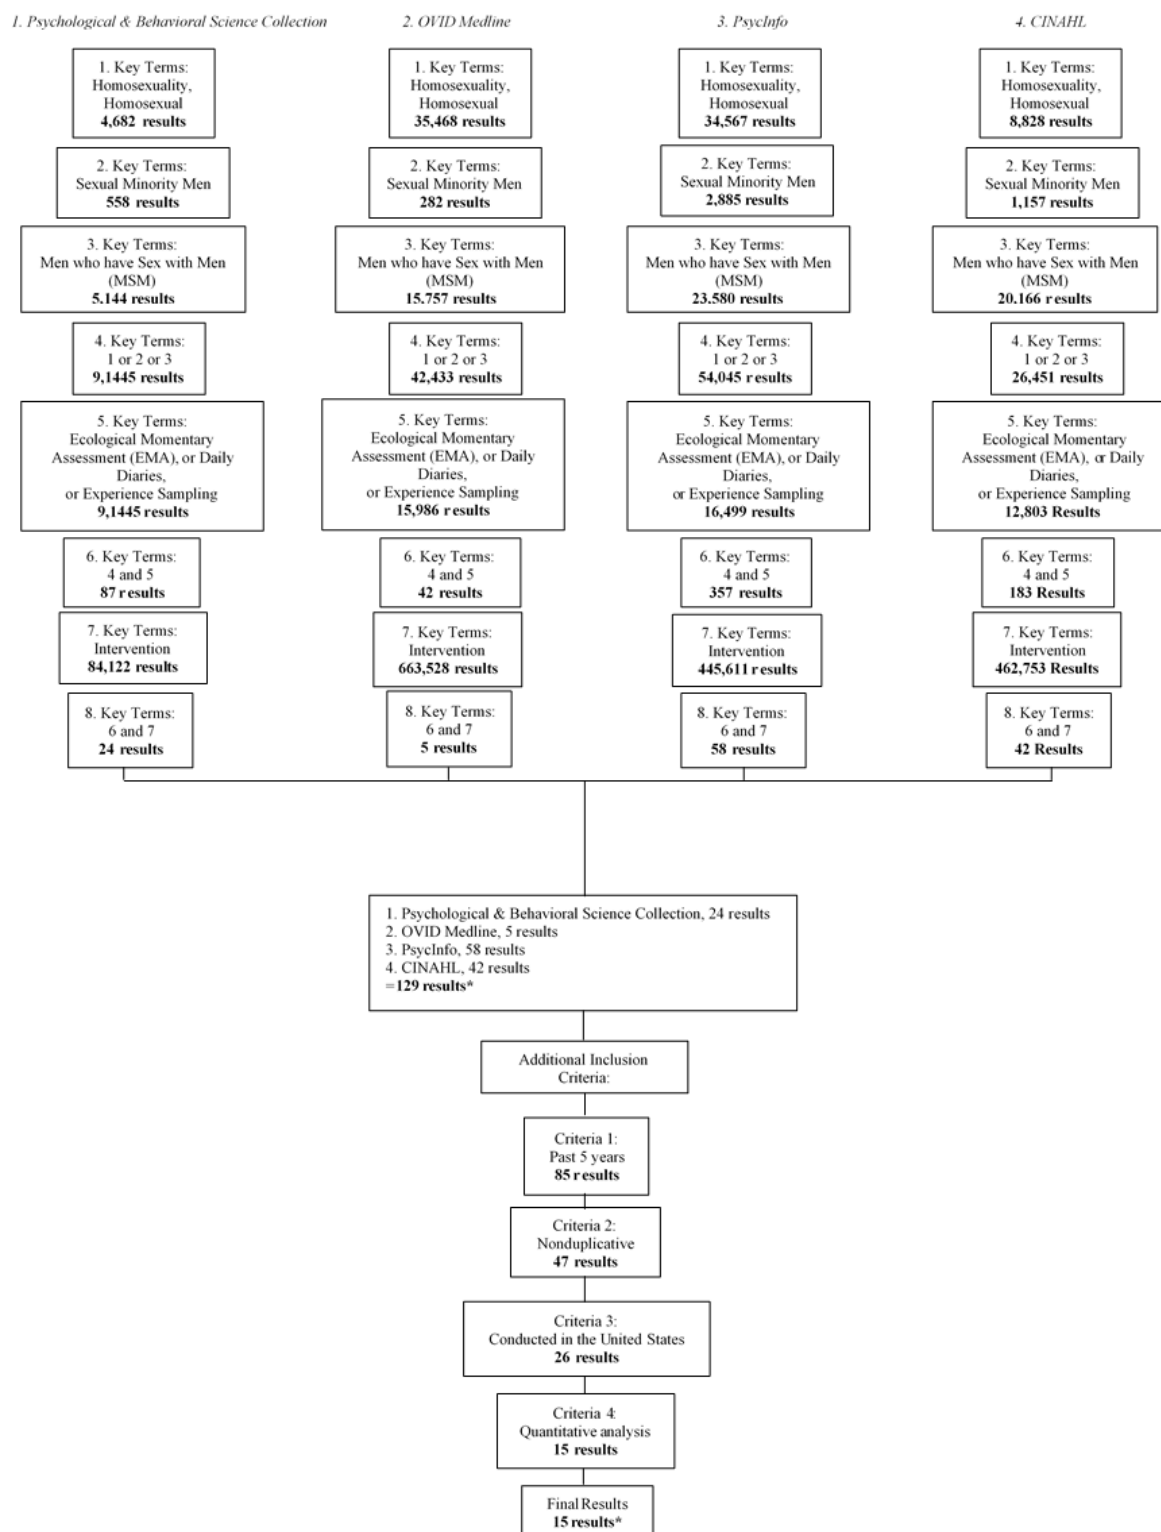

Eligibility Criteria

We identified several eligibility criteria that needed to be met for a publication to be included in this scoping review. The eligibility criteria included MSM samples; EMA interventions or assessments or determinations of EMA's efficacy, acceptability, and feasibility; a publication date within the past 5 years; peer-reviewed studies conducted in the United States; and quantitative data analyses.

Information Sources

We chose 4 prominent databases to retain studies from: Ovid Medline, which focuses on biomedical scholarly literature; Psychological and Behavioral Science Collection, which focuses on mental processes and emotional and behavioral experiences; PsycInfo, which focuses on behavioral and social science research; and Cumulative Index to Nursing and Allied Health Literature, which provides access to health research, specifically, in nursing and other allied health. EMAs have predominately been applied to behavioral or psychological health [17,18] and physical health [19,20]. Therefore, these databases were determined as most relevant and applicable to the specific topic of this scoping review (Figure 1).

Figure 1. Flow diagram of study selection process. CINAHL: Cumulative Index to Nursing and Allied Health Literature; *Peer-reviewed articles.

Keywords and Search Process

To ensure that we conducted an inclusive review of the literature across databases, we used multiple search terms for our target populations. Step 1 involved searching the terms “homosexuality” and “homosexual.” In step 2, we used the search term “sexual minority men.” Finally, in step 3, we used the search terms “men who have sex with men” and “MSM.” In step 4, we combined all these terms to achieve the most

comprehensive review of literature pertaining to our target population of MSM. In step 5, we added the keywords “ecological momentary assessment” or “EMA,” “daily diaries,” and “experience sampling” to identify all EMA-related literature from these databases. In step 6, we combined our MSM search terms with the EMA terms to narrow down to only the most directly relevant articles. Upon reaching step 7, we applied the term “intervention” to further narrow the articles included in this review. Step 8 was comprised of combining all search terms

from our MSM terms, EMA terms, and intervention terms, which resulted in a total of 129 articles.

Inclusion Criteria, Exclusion Criteria, and the Iterative Process

Once we had the initial studies from our database searches, we combined all the study titles and previewed the articles. Articles were further narrowed based on 2 additional inclusion criteria and 2 additional exclusion criteria; studies were excluded if they were not published in the past 5 years and if they were duplicative across databases. Studies were included if they were conducted in the United States and included quantitative data and analyses (Figure 1).

As suggested by the clarity of guidelines in scoping reviews [21], our search and review were conducted in an iterative manner over time. We conducted our first search in January 2020, our second search in May 2020, our third search in September 2020, and the last search in March 2021, as presented, to examine quarterly changes in the literature.

Analysis

Modeling after the Centers for Disease Control and Prevention (CDC) Compendium of Evidence-Based Interventions (EBIs) [22], we primarily used 8 distinct criteria to review the final set of eligible publications [9,11,13,23-34]. The EBI criteria and best practices in the compendium, developed and defined by the CDC's Prevention Research Synthesis project, posit a series of systematic review components for interventions. EBI criteria have been shown to generate significant effects and strong evidence of efficacy in HIV-related outcomes [22]. Based on the compendium of EBIs, our review criteria included (1) citation, sample size, and duration of study; (2) location; (3) random assignment (yes or no); (4) key aspects of the intervention; (5) follow-up (yes or no); (6) occurrence of follow-up after intervention; (7) rate of retention; and (8) rate of engagement (Multimedia Appendix 1). We also conducted a secondary analysis comprised of additional review criteria: recruitment strategy, description of intervention and comparison of arms, specific measurement tools, outcomes of interest, and outcome results (Multimedia Appendix 2).

Results

Risk of Quality in Individual Studies

Using the CDC compendium of best evidence-based risk reduction for individual-level interventions, we evaluated the strength of each study. None of the studies reviewed met full criteria for best standards of risk reduction in individual-level interventions. However, we continued evaluating based off CDC compendium criteria to determine study designs, intervention elements, and highest standards currently achieved.

Study Selection

A total of 129 articles were identified in the preliminary search: 24 from the Psychology and Behavioral Science Collection, 5 from OVID Medline, 58 from PsycInfo, and 42 from Cumulative Index to Nursing and Allied Health Literature. Among these 129 articles, we excluded 114 studies for not meeting additional screening criteria. These 4 criteria that the studies had to meet

were: (1) the study was published in the past 5 years, eliminating 44 studies; (2) not a duplicative study, eliminating 38 studies; (3) a US-based study, eliminating 12 studies; and (4) the study used a quantitative analysis, eliminating 9 studies. The qualifying criteria led to a final set of 15 studies in this review [9,11,13,23-34].

Sample Sizes

The average sample size across the 15 studies reviewed was 63.5 (SD 31.85). The CDC recommends that each sample is greater than 50 participants per study arm. Among the 15 studies reviewed, 10 (67%) had sample sizes >50, and 4 (27%) had sample sizes ≥ 100 [9,31,33,34]. The largest sample size was 120, in a study that had a single intervention arm [31]. Of 15 studies, 4 (27%) had multiple intervention arms [11,26,27,30].

Demographics

The only 2 demographic measurements reported by all 15 articles were race/ethnicity and age [9,11,13,23-34]. Within the total sample of 952 participants that was developed from a composite of all article samples, the majority of participants (476/952, 50%) were white, and this sample had a mean age of 38.75 years (SD 8.5). Of 15 studies, across 9 studies (60%), income was also reported, with the majority of the composite sample making <\$40,000 annually [9,11,13,25,26,31-34]. The final demographic measurement that was majorly reported, across 12 of the 15 studies (80%), was education; the majority (420/952, 44.1%) of this composite sample had at least some college education [9,11,13,24-26,28,29,31-34]. A detailed synopsis of demographics can be found in Multimedia Appendix 3.

Key Aspects of the Interventions

From this review, we determined that multiple studies had similar key aspects across the interventions implemented. First, 7 of the 15 studies (47%) focused on multiple types of substance use, including nicotine use, alcohol use, or other substance use (eg, cocaine, methamphetamine, and cannabis). Second, affect and stigma were discussed as primary outcomes for 5 of 15 studies (33%) [11,28-30,34] and secondary outcomes for 3 additional studies of the 15 studies (20%) [27,32,33]. Among 15 studies reviewed, 6 (40%) of them focused on examining feasibility or acceptability of EMA methodologies within the intervention [11,13,23,25,31]. Finally, 60% (9/15) of the studies focused on sexual behavior among men who have sex with men [9,11,23,25,28,30,32-34].

Random Assignment

Random assignment occurred in 2 of the 15 studies (13%) included in our review [11,26]. The CDC recommends random assignment as a gold standard, to rule out biases in a systematic way across multiple intervention arms. Since the majority of the studies (11/15, 73%) included in this review had only 1 arm, random assignment was not implemented [9,13,23-25,28,29,32-34]. In the remaining 2 studies that had nonrandomized designs with multiple arms, one study used a quasi-experimental design implementing clinical cutoffs for hypersexuality to determine group membership [30], while the other study assigned groups based on whether participants were recruited in-person or online [9]. Random assignment was considered as

potentially unethical in many of these studies due to their focus on substance use and sexual behavior; thus, a quasi-experimental design was better suited.

Description of Intervention and Comparison Arms

Across the articles, there were a wide variety of intervention strategies used for implementation, for example, impacting the duration, mechanism for the intervention, and tasks for intervention participants. The average duration of the intervention was 31.5 days; the shortest intervention was a single-day cross-sectional survey [13], and the longest was a 90-day intervention [31]. Interventions were conducted primarily via mobile devices (14/15, 94%) [9,11,23-34]. Among the interventions conducted through mobile devices, 11 of 14 studies (79%) used texting prompts [13,28-30]. Tasks to be completed were predominately surveys (10/15, 67%) [11,13,24-31] administered through text message (6/15, 40%) [11,24-27,31]. The second-most used modality for data collection was daily diaries (5/15, 33%) [9,23,32-34]. The CDC recommends a clear intervention description, which we found across all the included studies [22].

Follow-up and Occurrence of Follow-up

Follow-up assessments were administered in 2 studies of the 15 (13%) [11,31], one of which included follow-ups at 3 different time points: 60 days, 90 days, and 120 days [31], while the other followed up with participants after 4 weeks [11]. According to the CDC compendium, there should be a follow-up, and it should, specifically, occur more than 30 days after completion of the intervention [22].

Rate of Retention

Rate of retention was measured in 33% (5/15) of the included studies [11,25-27,31]. Among those that measured retention, the average retention rate was 77.58%, the lowest retention rate was 29.2% [31], and the highest retention rate was 93% [26]. For a high-quality intervention, the CDC recommends a 70% study retention rate [22].

Rate of Engagement

Of the 15 studies, 13 (87%) reported rate of engagement [9,13,23-29,31-34]. Engagement rate was defined as an overall rate of completion for text or online surveys, text prompts, or daily diaries, depending on the study modality and was reported consistently across all studies. The average overall engagement rate was 76.93%, the lowest overall engagement rate was 37.3% [9], and the highest was 98.7% [13]. Engagement is a key component of retention, and the 70% retention rate is recommended as the benchmark for an acceptable engagement rate [22].

Location

The location of the catchment areas and study sites varied. The majority of studies (9/15, 60%) were conducted on the East Coast [9,13,23,25,28,29,32-34]. Within those conducted on the East Coast, the majority of these studies (5/9, 56%) were concentrated in the Northeast [9,23,32-34]. The second-most researched area was the West Coast (4/15, 27%) [11,26,27,31], with a focus on San Francisco (3/15, 20%) [26,27,31]. Of the

15 studies, 1 (7%) was conducted in the Northwest [24] and 1 (7%), in the upper Midwest [29].

Recruitment Strategies

Of the 15 studies, 12 (80%) used more than 2 recruitment strategies. Of those that used at least 2 recruitment strategies, 14/15 (93%) studies paired their strategies with social media (e.g., Instagram or Facebook) [9,11,23-34]. Of the 15 studies, 3 (20%) used cohorts from larger or alternative study sites [11,13,30], one of which used multiple recruitment strategies, including social media [30]. The most popular recruitment strategy that was paired with social media was the use of community-based organizations with in-person recruitment (6/15, 40%) [11,25-27,30,31].

Specific Measurement Tools

The majority of the studies (10/15, 67%) were conducted with EMA surveys [11,13,24-31]. Of these 10 studies, 2 (20%) used the same scale to measure affect, the Positive and Negative Affect Scale [9,30]. Of these 10 studies, 2 others (20%) administered the Difficulties with Emotion Regulation Scale to measure emotion dysregulation [28,29]. Many studies used questions such as how many partners a participant engaged in sex with over the past 24 hours (9/15, 60%) [9,11,23,25,30-34], how many standard alcoholic drinks a participant consumed in the past 24 hours (6/15, 40%) [9,24,26,32-34], and what types of drugs were used over the past 24 hours (11/15, 73%) [9,23,24,26,27,29-34].

Outcomes of Interest

There were 3 prominent outcomes of interest across the included studies: risky sexual behavior, substance use, and acceptability. Of the 15 studies, 7 (47%) measured substance use status, including use of nicotine, alcohol, and other nonprescription drugs [9,11,24,27,29,33,34]. Of the 15 studies, 6 (40%) measured sexual behavior, especially, risky, unprotected sexual behavior defined by condomless sex or sex with partners who were of unknown HIV status [11,23,30,32-34]. Of the 15 studies, 4 (27%) assessed the acceptability of EMAs implemented in an intervention by measuring response rates, completion rates, and study retention rates [9,25,26,31].

Outcome Results

Intervention studies using EMA methods have demonstrated success in longitudinally measuring substance use, compared with studies that relied on non-EMA measurements such as timeline follow-back surveys [9,23,32]. Additionally, EMA methods generated greater acceptability than other methods: daily diaries had high rates of response completion. The highest response rate was 97.3% [9,34], and the lowest was only 84% [23].

Discussion

Principal Findings

In our scoping review, we aimed to provide an overview of the growing literature on a relatively novel measurement: ecological momentary assessment (EMA). We found that among men who have sex with men (MSM), the majority of EMAs have been

used to intervene on risk-taking behaviors such as alcohol and drug use or unprotected sex with multiple partners. Although risk-taking behaviors have often been stigmatized, the use of EMA through smartphone technology has been seen as a highly effective way to safely assess risk-taking behaviors [10,12,13]. Overall, EMA was seen as an acceptable and feasible method, with daily diaries as the most acceptable tool [9,23,32-34] to collect the experiences of MSM. A unique facet of MSM research was the successful use of recruitment strategies beyond technology-based recruitment, which included assistance in initiation and engagement from community-based organizations [11,25-27,30,31]. This scoping review was used as a synthesizing method with a wide array of review dimensions and criteria such as quantitative interventions among MSM. This allowed our results to provide a comprehensive set of typological frameworks that may be useful in designing and implementing an EMA-integrated intervention for behavioral change. Basing typographic dimensions off preexisting frameworks offered by the CDC [22], we incorporated the most salient components for intervention research. This allowed for a better assessment of the strength of existing EMA interventions among MSM. Also, we conducted 4 time points of literature searches (ie, January 2020, June 2020, September 2020, and March 2021), for inclusion of more studies, which increased the comprehensiveness of this scoping review.

Our study determined that there were limited psychometrically sound EMA measurements that were fully validated. Given the growing research attention on EMAs within the context of behavioral intervention, future studies may aim to develop and validate EMA measurements. EMA has been widely used as a just-in-time assessment and monitoring tool, but it also can be a great measurement resource to predict behavioral outcomes. We suggest future research should focus on developing predictive models and analytic methods, using intensive longitudinal data from EMAs to understand behavioral changes or outcomes over time. In terms of an analytic perspective, since EMAs lead to extensive longitudinal data, the risk of missingness and the handling of missing data will become more prevalent. Therefore, studies on appropriate analytic approaches to manage missing data from EMAs will be essential.

Although EMAs may reduce recall bias, due to the repetitiveness of measurement, they can also increase participant bias and burden [35,36]. Future research should take into consideration EMA designs that are engaging but protective of data anonymity

and confidentiality, to prevent participant biases such as the social desirability effect and the halo or devil effect. To avoid priming of such participant biases, details and information in EMA-based interventions should be presented in a judgment-free manner. In order to reduce psychological reactions, future research should consider developing EMAs as self-motivated mechanisms, with use options such as event-contingent prompts, daily diaries, text prompts, or other mechanisms. Additionally, future studies should examine putative mechanism factors such as resilience and social support, to develop a comprehensive, integrative intervention program for MSM [37].

Limitations

There were limitations imposed by the scope and design of the study. First, the inclusion of the major library databases focused on studies most relevant to the population and methodological strategy of interest, but we excluded other minor library databases. Therefore, a future direction may include an inclusion of minor databases in the review for EMA interventions among MSM. Second, many of the studies included in this review were feasibility and acceptability tests as well as pilot studies with inconsistent assessments of outcomes, thus minimizing the effectiveness of a meta-analysis or systematic review. Although we presented results from a scoping review to provide an overview and the state of EMA in behavioral medicine, future research may conduct a systematic review or meta-analysis, as the prevalence of empirical evidence from randomized controlled trials using EMAs in this area is likely to increase [38].

Conclusions

Leveraging evidence-based intervention designs with validated ecological momentary assessments can advance our understanding of factors and processes in behavioral changes and health outcomes. These approaches can be further empowered through technology-based behavioral medicine and social medicine. In this scoping review paper, we provided a typology of EMA-based intervention research that was designed to promote health behavior and psychological well-being. Advancements in psychometric tests to validate EMAs will be critical. As the empirical evidence and theories in this field are emerging, we hope our review offers some guidance and synthesis of the literature to develop and evaluate technology-based EMA health interventions.

Authors' Contributions

VC conceived the study. VC and SJK were responsible for the study design and concept. SJK was responsible for accurate implementation of scoping review methodology. VC was responsible for the literature search and literature review. SJK supervised the study design and the review process. VC was responsible for constructing figures and multimedia appendices. VC and SJK collaborated on the discussion and study impact. VC and SJK drafted the first draft of the manuscript. All authors extensively reviewed and approved the manuscript before submission for peer review.

Abstract

Background: Despite the availability of thousands of health apps worldwide, when considering those addressing children's first 1000 days of life, most apps fail to consider the continuity between the prenatal and postnatal stages, and their joint impact on maternal and child health. The reliability, quality, and effectiveness of these apps are largely unknown, and the provided content seems questionable in terms of completeness, updating, and trustworthiness.

Objective: This study evaluates available Italian pregnancy and postnatal care apps to highlight the main gaps to be overcome and the resulting future challenges to be met in this mobile health-related field.

Methods: A systematic search was conducted on the Apple App Store and Google Play Store, and basic information was collected for all identified apps. After deduplication and further selection based on the exclusion criteria, an in-depth analysis of each app was performed by two researchers independently. A 71-item six-domain questionnaire about the desirable features of apps was used to assess information, functionalities, and technical features, while the Mobile Application Rating Scale (MARS) was employed for app quality evaluation.

Results: From an initial sample of 684 apps, 22 were deeply analyzed. Most apps did not fulfill the expectations, as just one achieved 50% of all desirable aspects. Postnatal care and counselling for both the mother and child was the least accomplished domain. Moreover, the quality of app information was generally rated more negatively than the quality of their functionality and esthetic features. The lacking aspects were information about methods for postpartum family planning and birth spacing (1/22, 5%) and immunization (2/22, 9%).

Conclusions: The identified gaps could serve as a basis for designing and implementing increasingly high-quality, targeted, and effective apps for pregnancy and postnatal health care, which provide comprehensive, reliable, and evidence-based information, as well as appropriate esthetic and functional characteristics, with relevant implications in terms of maternal and newborn health prevention and promotion.

KEYWORDS

pregnancy; postnatal care; app; mHealth; mobile health; newborn

Introduction

Recent development in information and communication technologies has enabled the disruptive expansion of electronic health (eHealth) and mobile health (mHealth). These developments, along with the introduction in clinical practice of technological innovations, such as telemedicine, telemonitoring, and remote screening, are considered essential elements of “game-changing innovations” in the next 25 years [1].

In fact, the widespread distribution of networked devices, which are estimated to reach 29.3 billion in 2023 [2], offers a promising but challenging opportunity of mHealth use for health information seeking, with an important role in health behavior formation [3-5]. In 2017, more than 325,000 health apps were available worldwide [6], and among them, to the best of our knowledge, there were more apps available to support pregnancy than for any other medical domain [7]. These mobile technologies in support of pregnancy have also increased the possibility for both parents and parents-to-be to self-manage health issues, as shown by a recent study conducted in 2019 in Switzerland reporting that 91% of parents declared using digital media for seeking information about their child’s health and development [8]. Moreover, a recent meta-analysis showed that social media and mHealth have the potential to be effective in promoting maternal physical health (eg, weight management), mental health, and knowledge about pregnancy [3]. However, when considering apps addressing children’s first 1000 days of life, from conception through age 24 months, many of them just focus on the prenatal or postnatal stage [9], failing to consider the continuity between the two phases and their joint impact on maternal and child health.

Furthermore, the reliability, quality, and effectiveness of current available pregnancy and postnatal care apps are unclear, and this could become an obstacle to health promotion, since during pregnancy women are more sensitive to external influences, and misleading information on health care and lifestyle could lead to unnecessary worrying or stress during pregnancy [10].

Considering the large variability among available apps in terms of property, responsibility of information accuracy, level of trustworthiness, and updating of content [11], as well as the lack of a certification system or their classification as a medical device [11,12], the limited evidence of their effectiveness is not a surprise [10]. In addition to this, standard app development and evaluation do not take into account the health literacy level of the target population [12,13], leaving to users the choice of mHealth to use, which therefore may be driven by popularity or esthetic, functional, and engagement aspects. In this regard, the literature suggests that many users do not critically assess the validity of the content provided by apps or consider issues concerning the privacy and security of their personal information and data [14].

Investigating previous research related to the impact of mHealth on maternal and child health care during pregnancy and in the postnatal period, the following two points have come to the forefront: (1) the consideration of children’s first 1000 days of life as a crucial developmental window for the children, where

it is essential for mothers to receive accurate health information [3] and (2) the critical influence of the health information source on maternal well-being, lifestyle, and decision-making about pregnancy and child health during children’s first 1000 days of life [15]. Given these aspects and considering the striking gaps in the current literature, it is an ideal time to conduct an in-depth analysis on pregnancy and postnatal care apps currently in use.

The aim of this review was therefore to critically evaluate available Italian pregnancy and postnatal care apps and to highlight the main shortcomings and resulting future challenges about the apps for the health care of mothers and children in the first 1000 days of life.

Methods

Research on Italian Pregnancy and Postnatal Care Apps

A systematic search was conducted by six independent researchers from Trieste University, IRCCS (Istituto di Ricovero e Cura a Carattere Scientifico) Burlo Garofolo, and Area Science Park for the selection, data extraction, and functional evaluation of the available pregnancy and postnatal care apps on the Apple App Store and Google Play Store. The whole research team included public health specialists, psychologists, sociologists, clinical engineers, and a specialist in ergonomics (all under 45 years of age). The search was conducted for both the Apple App Store and Google Play Store using as keywords the Italian words for *pregnant, mother, 9/nine months, birth, newborn, baby, obstetrics, pregnancy, new baby, my baby, and child* (the last four keywords were used with their English translation as well). The exclusion criteria for the research were as follows: gaming, photo and video, shopping, and commercial apps; calculator apps; apps specifically developed for health care professionals; fertility or menstrual tracking apps; and apps whose names were not available with Latin alphabets. A basic information set was collected for all resulting apps, including app name, operating system (iOS/Android), free/upon payment availability, availability of further contents upon payment, number of languages, availability of an Italian version, store category, dimension (MB), age restriction, number of downloads, position in download rankings, user rating, first release date, latest update, assistance responsibility, copyright, privacy policy, advertisement, and eventual presence of a medical device European mark (CE). The search was independently conducted between June 15 and July 3, 2020, by six researchers (three working on iOS and three on Android); any inconsistent information collected by the researchers was discussed until consensus was reached. Next, results were merged, and app deduplication was performed.

In-Depth Analysis of Italian Pregnancy and Postnatal Care Apps

Further selection was made among identified apps according to additional exclusion criteria referring to apps not available in the Italian language and in both the Apple App Store and Google Play Store. The apps resulting from this selection were downloaded and installed on both iOS and Android devices for in-depth analysis. The six independent researchers were

attributed the same number of apps each. For each app, two independent researchers registered and logged in to evaluate all app contents and functionalities, thus ensuring that each app would be evaluated on both the Apple App Store and Google Play Store. When relevant, a simulation of required input data, such as expected birth date and the starting date of the last menstrual period, was set to fully evaluate app potential. Pursuing this last aim, two evaluators simulated being in the first trimester of pregnancy, another two in the second trimester, and the last two in the third trimester to cover the entire pregnancy period. All investigators were able to consider and evaluate contents related to the postpartum period.

The analysis of the information, functionalities, and technical features of the apps was performed between September 1, 2020, and November 16, 2020, according to a 71-item assessment questionnaire investigating the desirable criteria of apps, developed based on the scientific literature [16], and multiprofessional discussion and agreement (Table 1).

As shown in Table 1, data items referred to six domains corresponding to pregnancy care and counselling, postnatal care and counselling for both the mother and child, reminders and push notifications, notes and records, social support, and app technical features. Each app was evaluated separately for all 71 questions. The answers were attributed as follows: yes (y) if

the app provided the information/functionality/feature specified in the question; no (n) if the app did not provide the information/functionality/feature specified in the question; inconsistent information (i) in the case of inconsistent information derived from the operating system (iOS/Android) for the two researchers; and partially (p) if the app only partly provided the information/functionality/feature specified in the question. The Mobile Application Rating Scale (MARS) was used for app quality evaluation regarding four dimensions of objective app quality, including engagement, functionality, esthetics, and information quality. The subjective quality subscale and perceived impact section of the MARS were not included in the evaluation due to possible interresearched biases, as already reported in previous studies [17,18]. All MARS items were rated on a 5-point scale from 1 (inadequate) to 5 (excellent) and required the researcher to circle the number that most accurately represented the quality of the app component under evaluation. The means of the MARS scores judged by the six researchers were calculated for each app. Data were then merged and analyzed using Microsoft Excel for Office 365 ProPlus (Microsoft Corp). Fulfillment of the desirable criteria by each app was expressed as number and percentage on the specific domain and on the total of 71 questions. Responses to the questions by the group of apps was reported as number and percentage with descriptive statistics.

Table 1. Assessment questionnaire.

Domain	Questions
Pregnancy care and counselling	<ol style="list-style-type: none"> 1. Does the app provide information about pregnancy? 2. Does the app provide information about the woman's rights during pregnancy (eg, at work, at school, and economical support)? 3. Are prenatal risks and life-threatening conditions identified in the app? 4. Does the app inform about maternal physiological and metabolic changes occurring during pregnancy? 5. Does the app inform about the immunizations that the mother needs to receive? 6. Does the app provide information about maternal or child services accessibility and contacts? 7. Does the app provide information about available prenatal diagnostic tests? 8. Does the app include physical exercises and workouts for women during pregnancy? 9. Does the app provide pregnancy nutritional counselling for mothers? 10. Does the app include personal hygiene practices for women during pregnancy? 11. Does the app provide information about delivery? 12. Does the app provide information about predelivery courses? 13. Does the app provide month/trimester-related tips for pregnant women? 14. Does the app provide a list of essentials for the hospital luggage? 15. Does the app provide a list of free-of-charge and upon payment examinations during pregnancy?
Postnatal care and counselling for both mother and child	<ol style="list-style-type: none"> 1. Does the app provide a list of essentials for the first welcome of the mother and baby at home? 2. Does the app inform about maternal physiological and metabolic changes occurring during the postpartum period? 3. Does the app include information about manifest neonatal complications and warning signs? 4. Does the app offer information about postpartum mental disorders, such as postpartum depression and baby blues (eg, symptoms and coping strategies)? 5. Does the app inform about the immunizations that mothers or newborns need during the first 1000 days? 6. Does the app provide tips for the postpartum recovery process? 7. Does the app provide practical tips on how to take care of the newborn (eg, hygiene, diapers' changing, and burping)? 8. Does the app provide postnatal nutritional counselling for mothers? 9. Does the app provide a breastfeeding guide and support? 10. Does the app report personal hygiene practices in the postnatal period? 11. Does the app encompass methods for postpartum family planning and birth spacing?
Reminders and push notifications	<ol style="list-style-type: none"> 1. Does the app allow to set reminders for medical appointments (eg, prenatal and postnatal check-ups, pediatric visits, and immunizations)? 2. Does the app include push notification reminders for scheduled medications/immunizations? 3. Does the app include push notification reminders when the pregnancy month/trimester begins? 4. Does the app allow to schedule reminders for routine activities (eg, drinking, diapering, feeding, pumping, and sleeping)? 5. Does the app allow users to change reminders and notifications settings?
Notes and records	<ol style="list-style-type: none"> 1. Does the app require specifying the latest period date or the expected delivery date? 2. Does the app allow the user to modify the expected delivery date following medical re-evaluation? 3. Does the app allow to record physiological values of the mother (eg, pressure, temperature, and mood)? 4. Does the app allow to record contractions or kicks? 5. Does the app allow to record routine activities of the mother or the newborn (eg, drinking, steps, diapers changes, bottle feeding, and sleeping patterns/times)? 6. Does the app allow to take note of the medical care the mother or the newborn has received (eg, medications and vaccination shots)? 7. Does the app allow to track the newborn's developmental milestones? 8. Does the app record anthropometric measurements of the fetus (eg, height, weight, and head circumference)? 9. Does the app record anthropometric measurements of the newborn (eg, height, weight, and head circumference)? 10. Does the app record measurements of the mother's weight at baseline and during pregnancy? 11. Does the app record measurements of the mother's weight in the postnatal period? 12. Does the app allow the mother to create a sleep diary for herself? 13. Does the app allow the mother to create a sleep diary for the newborn?
Social support	<ol style="list-style-type: none"> 1. Is the app integrated with social networks (eg, Facebook and Twitter)? 2. Is there a FAQ (frequently asked questions) page in the app? 3. Does the app provide users with social mechanisms to interact with each other and share experiences (eg, community, forum, and chat)? 4. Does the app provide users with social mechanisms to interact with health care staff (eg, community, forum, and chat)?

Domain	Questions
App technical features	<ol style="list-style-type: none"> 1. Does the app ask users for authentication? 2. Does the app present a privacy policy? 3. If present, is that privacy policy properly written in Italian? 4. Are all app contents freely available to the users (without any payment)? 5. Are there specific inclusion criteria for full app usage (eg, national health service card, place of living, and certification by a health professional)? 6. Does the app require to “sign” an informed consent for app usage? 7. Does the app provide references about the provided contents? 8. Does the app include a glossary of the most used medical terms? 9. Does the app identify the scientific responsibility of the provided contents? 10. Is there a possibility to back-up/restore data within the app? 11. Is there a possibility to download data collected through the app? 12. Does the app have multilanguage support? 13. Does the app geolocalize the user to provide more detailed information? 14. Does the app allow users to book visits, vaccinations, and checkups? 15. Does the app allow users to update their account preferences? 16. Does the app use a tone that is simple, informal, and friendly? 17. Does the app adapt to screen orientation (both portrait and landscape)? 18. Does the app learn user’s preferences over time? 19. Does the app implement intuitive and predictable navigation patterns? 20. Are the app contents validated by an institutional source (local, regional, or national)? 21. Is the app a certified medical device according to Italian law? 22. Does the app provide contents through different ways (eg, text, video, and audio)? 23. Does the app ask about user satisfaction?

Results

In total, 684 apps were initially identified; after deduplication, the number reduced to 285. Based on the exclusion criteria, 35 apps were downloaded and installed for in-depth analysis. The flow diagram illustrating the results of the selection process of apps is reported in [Figure 1](#). Following the download of the apps and their further analysis, researchers excluded 13 additional apps as they met at least one of the exclusion criteria or had limitations in content or access that prevented their evaluation. In more detail, one app was not freely available, one was a photo and video app, two were only calculators, one was specifically developed for health professionals, two were menstrual tracking apps (one of which was the only app marked as a medical device among the 35 downloaded and installed apps), two were commercial apps, two contained only physical exercise suggestions, one contained information accessible through a premium account, and one did not work. At the end

of the eligibility selection procedure, 22 Italian pregnancy and postnatal care apps underwent in-depth analysis.

There were 180 apps available in the Apple App Store and 148 available in the Google Play Store. Most of these apps (148/180, 82.2% and 146/148, 98.6% for iOS and Android, respectively) were freely available, but many offered extra content upon payment (95/180, 52.8% for iOS and 50/148, 33.8% for Android). Around half of them were available in Italian in both stores, and the majority presented any type of privacy policy. The distributions of the declared presence of advertisements within the app and some age usage restriction were quite different between the two stores. There were significant differences in dimensions among the two as well ([Table 2](#)). The mean user rating was well above the average value of 2.5 out of 5 in both stores, being greater in the Google Play Store. Finally, only one app was characterized by the presence of a medical device European mark (CE). The evaluated characteristics are reported in [Table 2](#).

Figure 1. Results of the selection process of apps.

Table 2. Characteristics of the initial 285 apps for pregnancy and postnatal care identified after deduplication.

App characteristics	Apple App Store (n=180), n (%) or value	Google Play Store (n=148), n (%) or value
Freely available (yes)	148 (82.2%)	146 (98.6%)
Further content upon payment (yes)	95 (52.8%)	50 (33.8%)
Available in Italian (yes)	103 (57.2%)	62 (41.9%)
Privacy policy (yes)	141 (78.3%)	122 (82.4%)
Advertisement (yes)	10 (5.5%)	89 (60.1%)
Mean dimension (MB)	52.3	20.5
Some age restriction (yes)	106 (58.9%)	11 (7.4%)
Mean user rating (stars/5)	3.85	4.22
Medical device European mark (yes)	1	1

In [Multimedia Appendix 1](#), data of in-depth analysis for the 22 evaluated apps are reported. Most apps did not fulfill the expectations, as just one met 50% of all desirable aspects while four met at least 40% of the expected requirements.

As reported in [Table 3](#), the most accomplished domains were pregnancy care and counselling (124/330, 37.6%) and app technical features (160/506, 31.6%), followed by notes and records (77/286, 26.9%), social support (20/88, 22.7%), and postnatal care and counselling for both mother and child (54/242, 22.3%). The least accomplished domain was reminders and push notifications (24/110, 21.8%).

For pregnancy care and counselling, in addition to the general information about pregnancy provided in 14 (64%) cases, other information most frequently given included nutritional

counselling for mothers (11/22, 50%), month/trimester-related tips for pregnant women (10/22, 46%), and information about delivery (10/22, 46%). Considering app technical features, a simple, informal, and friendly tone (22/22, 100%), and an intuitive and predictable navigation pattern (19/22, 86%) were the most frequently included features along with the presence of a privacy policy (17/22, 77%). Relating to the various domains, other aspects characterized at least half of the apps, including the presence of a properly written Italian privacy policy (13/22, 59%), as well as a frequently asked questions (FAQ) page (12/22, 55%), the requirement of the latest period date or the expected delivery date (12/22, 55%) and possibility of its eventual modification following medical re-evaluation (12/22, 55%), and the requirement of authentication for app usage (11/22, 50%).

Table 3. Level of accomplishment for each domain.

Domains	Yes ^a , n (%)	No ^b , n (%)	Inconsistent information ^c , n (%)	Partially ^d , n (%)
Pregnancy care and counselling (n=330)	124 (37.6%)	188 (57.0%)	3 (0.9%)	15 (4.5%)
Postnatal care and counselling for both mother and child (n=242)	54 (22.3%)	173 (71.5%)	3 (1.2%)	12 (5.0%)
Reminders and push notifications (n=110)	24 (21.8%)	83 (75.5%)	2 (1.8%)	1 (0.9%)
Notes and records (n=286)	77 (26.9%)	200 (69.9%)	0 (0.0%)	9 (3.1%)
Social support (n=88)	20 (22.7%)	67 (76.1%)	0 (0.0%)	1 (1.1%)
App technical features (n=506) ^e	160 (31.6%)	329 (65.0%)	14 (2.8%)	1 (0.2%)

^aIf the app provided the information/functionality/feature.

^bIf the app did not provide the information/functionality/feature.

^cIn the case of inconsistent information derived from the operating system (iOS/Android) of the two researchers.

^dIf the app only partly provided the information/functionality/feature.

^eNot applicable for two apps.

Aspects that were particularly lacking included information about methods for postpartum family planning and birth spacing (1/22, 5%), immunizations that mothers or newborns need to be administered (2/22, 9%), and postnatal personal hygiene practices for the mother (2/22, 9%). Notably, information about free-of-charge and upon payment examinations during pregnancy was present in only 14% (3/22) of apps, but partial information was given by 32% (7/22) of apps.

Few apps have push notification reminders for scheduled medications/immunizations (3/22, 14%) or when the pregnancy month/trimester begins (3/22, 14%), and a minority of them allow mothers to schedule reminders for routine activities (2/22, 9%) or to take notes of medical care received by both the mother and newborn (2/22, 9%), as well as to monitor the mother's sleep (1/22, 5%). Furthermore, a limited number of apps allow users to record physiological values of the mother (3/22, 14%), routine activities of both the mother and newborn (3/22, 14%), or the newborn's developmental milestones (3/22, 14%). Almost all apps do not provide users with social mechanisms to interact and share experiences with each other (21/22, 96%) or with the health care staff (21/22, 96%). Regarding app technical features, only in a few cases, data collected through the app can be downloaded (3/22, 14%), and a minority of apps have multilanguage support (3/22, 14%) or geolocalize the user to provide more detailed information (3/22, 14%). Just one app requires the habilitation of the pregnant women by the regional health care system as a specific inclusion criterion (1/22, 5%). Only two apps learn user preferences over time (2/22, 9%), but none of them directly allows the mother to book visits, vaccinations, or checkups. Moreover, no app is marked as a medical device according to the medical device directive 93/42/EEC, and subsequent modifications and integrations.

The MARS scores for global app quality ranged from a minimum score of 1.9 to a maximum of 4.5, with most apps (16/22, 73%) achieving a score greater than 3. The engagement score ranged from 1.6 to 4.1 (median 3.0), functionality score ranged from 2.5 to 4.9 (median 4.0), esthetics score ranged from 1.8 to 4.3 (median 3.7), and information score ranged from 1.7 to 4.8 (median 3.5). The mean MARS scores for all 22 analyzed apps are reported in [Multimedia Appendix 2](#).

Discussion

Principal Findings

This systematic search aimed to evaluate the available Italian pregnancy and postnatal care apps, providing an overview of their main characteristics with specific focuses on shortcomings and gaps to be filled with future developments in the eHealth-related field. We believe that such an assessment is indeed crucial for the implementation of increasingly effective apps for pregnancy and postnatal health care. Overall, the presence of a single app containing more than half of the investigated desirable aspects suggests considerable room for improvement in developing apps targeted at the needs of pregnant women and new mothers.

Since during pregnancy women are more sensitive to misleading information [10] and considering the potential of mHealth to be effective in promoting maternal health and knowledge about pregnancy and child health and development [3,8], the importance of developing apps able to provide the most complete, truthful, and reliable information on pregnancy and the postnatal period is unquestionable. In this regard, less than a third of the analyzed apps provided references about included contents or identified their scientific responsibility. Furthermore, the quality of information included in the examined apps was rated more negatively than the quality of their functionality and esthetic features. This aspect can prove to be a double-edged sword, since, as suggested in the literature, the choice of mHealth to be used may be driven by popularity, esthetic features, and functional features rather than the validity, veracity, and reliability of the provided content [14]. Similarly, the use of a simple, informal, and friendly tone, as well as the presence of intuitive and predictable navigation patterns, which are the most frequently included features in the analyzed apps, may pose a threat. While these aspects make an app intuitive, user friendly, and pleasant to use, they may also attract attention and prompt mothers and mothers-to-be to use the app even in the absence of reliable health-related information. In this regard, the tendency to be driven by esthetic or engagement aspects could be particularly detrimental to mothers with low health literacy who lack critical capacity and awareness of the

information they receive [12,13]. The development of apps that are both esthetically pleasing and sources of accurate, valid, and comprehensive information, providing indications about the reliability of content, is therefore highly desirable [19].

Moreover, the fact that no app is marked as a medical device denotes a serious shortcoming, which needs to be addressed through the development of apps that are not only information or entertainment tools, but also the subject of a specific regulatory regime, the new medical device regulation. The latter underlines the importance of medical device apps in terms of their predictive utilization for mothers and children, and the control or support of conception.

Regarding provided content, postnatal care and counselling for both the mother and child represented the thematic domain least covered by the analyzed apps, pointing out that most of the available apps focus on pregnancy and neglect the postpartum period. It would therefore be advisable for an app to provide more balanced information on the stages of the mother's life and newborn infant's life, thus paying attention to both prenatal and postnatal care. This point is in line with the literature suggesting that most of the currently available apps just focus on the prenatal or postnatal stage [9], neglecting the continuity between the two phases and their joint impact on the health of both the mother and child.

Surprisingly, information about free-of-charge and upon payment clinical examinations during pregnancy and about immunizations that mothers and newborns need to receive is absent in most apps. This highlights a gap that should be filled through new mobile apps that encourage the promotion of disease prevention for mothers, newborns, and infants and facilitate early intervention in case of problems or complications during pregnancy. An app that provides correct and up-to-date medical information related to preventive or diagnostic medical practices, such as immunizations and examinations, can be a tool to support the health care system by guiding women to the most appropriate screening and therapeutic paths.

Moreover, most of the evaluated apps do not seem to encourage interaction, communication, and confrontation of pregnant women either with other women in the same condition or with health professionals, not taking into consideration the dimension of sociability and the importance of support from both peers and competent professionals. This deficiency, especially in certain periods (eg, during the COVID-19 pandemic), could be burdensome for the woman, potentially generating a sense of loneliness and disorientation.

Very few apps include push notification reminders for scheduled medical appointments, and a minority of apps allow mothers to schedule reminders for routine activities. It follows that the examined apps are not particularly interactive, giving mothers and mothers-to-be few opportunities to rely on them as reference and guidance tools throughout the day or during the pregnancy and postnatal periods. Furthermore, no app directly allows the mother to book visits, vaccinations, or checkups, highlighting the absence of a direct link between the app and reservation systems, and therefore, a lack of integration of this tool within the wider public national or regional health care system. This major gap could be filled by the development of more

interconnected and institutional apps that could streamline booking procedures by reducing the number of phone calls or other request modes from patients and the staff involved in managing them.

Furthermore, only two apps could learn user preferences over time, denoting a poor ability of the analyzed apps to adapt to the type of user. Greater "intelligence" of the tool and the consequent possibility of greater customization and profiling of the app system would be desirable, thus resulting in a more tailored option for each woman.

Longitudinal studies, focused on the use of apps by mothers and mothers-to-be over time, could be very useful to highlight which technical features, functionalities, and contents of apps (and to what extent) may be most effective in promoting pregnancy and postnatal health care. The results of such longitudinal research may provide evidence-based guidelines based on which increasingly effective apps could be developed and implemented, thus becoming effective tools for improving health.

Limitations

This study has some limitations, which include only analysis of apps available in Italian and available on both the Apple App Store and Google Play Store without charge. Even if this prevented the researchers from including all apps, this choice was driven by the need to analyze apps with a potentially large user base aiming at equity and equality, and the need for researchers to fully understand the content proposed by the apps. Second, we did not directly involve pregnant women or mothers during the postnatal period as evaluators. Third, even if developed following previous research available in the scientific literature, the definitions of the 71 items for the app evaluation were in part the result of original work of multiprofessional comparison and agreement based on the experience and expertise of the research team. Finally, considering the nature of the dimensions investigated by the MARS, subjectivity in awarding its scores cannot be ruled out. Nevertheless, our research team included members under 45 years of age (mostly women), and some of the women had been pregnant; therefore, we can assume that no biases were there for the assessment procedure. Moreover, in the case of one app, we were prevented from accessing full contents and features, so our evaluation could present some undesired bias in this specific case.

Conclusion

People are increasingly using the internet and specific apps to find health information thanks to the ease of access and the speed of communication that digital solutions offer. While this creates a wide range of advantages and new opportunities, it can pose a threat to public health in terms of prevention and promotion, with exposure to risks, such as lack of content control and misinformation. Within this framework, this study aimed to highlight the main shortcomings in available Italian pregnancy and postnatal care apps to serve as a basis for designing and implementing increasingly high-quality apps that provide comprehensive, reliable, and evidence-based information, and have appropriate esthetic and functional characteristics. Further developments are desirable in the

eHealth-related field, with a view to encourage increasingly conscious and effective use of apps by mothers and mothers-to-be for pregnancy and postnatal care.

Acknowledgments

The work has been partially supported by “ARGO system,” a protocol agreement signed in 2018 among the Friuli Venezia Giulia Region, the Italian Ministry of Education University and Research, and the Italian Ministry of Economic Development.

Authors' Contributions

LB designed the research; LB, MDC, FC, MC, MP, FS, and CDV collected data; LB, MDC, FC, MC, MP, FS, AS, CDV, MB, and SZ discussed the investigation methodology and contributed to result interpretation; LB and CDV performed data analysis; LB and SZ supervised the study conduction; LB and CDV wrote the original draft; and TS revised contents. All authors revised the paper and agreed with the final version of the manuscript.

Abstract

Background: Excessive muscle loss is an important prognostic factor in esophageal cancer patients undergoing neoadjuvant chemoradiotherapy (NACRT), as reported in our previous research.

Objective: In this pilot study, we prospectively tested the feasibility of a health coaching mobile app for preventing malnutrition and muscle loss in this patient population.

Methods: Between July 2019 and May 2020, we enrolled 38 male patients with esophageal cancer scheduled for NACRT. For 8 weeks from the start of radiotherapy (RT), the patients used Noom, a health coaching mobile app that interactively provided online advice about food intake, exercise, and weight changes. The skeletal muscle index (SMI) measured based on computed tomography and nutrition-related laboratory markers were assessed before and after RT. We evaluated the changes in the SMI, nutrition, and inflammatory factors between the patient group that used the mobile app (mHealth group) and our previous study cohort (usual care group). Additionally, we analyzed the factors associated with walk steps recorded in the app.

Results: Two patients dropped out of the study (no app usage; treatment changed to a definitive aim). The use (or activation) of the app was noted in approximately 70% (25/36) of the patients until the end of the trial. Compared to the 1:2 matched usual care group by propensity scores balanced with their age, primary tumor location, tumor stage, pre-RT BMI, and pre-RT SMI level, 30 operable patients showed less aggravation of the prognostic nutritional index (PNI) (−6.7 vs −9.8; $P=.04$). However, there was no significant difference in the SMI change or the number of patients with excessive muscle loss (Δ SMI/50 days >10%). In patients with excessive muscle loss, the walk steps significantly decreased in the last 4 weeks compared to those in the first 4

weeks. Age affected the absolute number of walk steps ($P=.01$), whereas pre-RT sarcopenia was related to the recovery of the reduced walk steps ($P=.03$).

Conclusions: For esophageal cancer patients receiving NACRT, a health care mobile app helped nutritional self-care with less decrease in the PNI, although it did not prevent excessive muscle loss. An individualized care model with proper exercise as well as nutritional support may be required to reduce muscle loss and malnutrition.

KEYWORDS

esophageal cancer; malnutrition; muscle loss; sarcopenia; mobile app; mHealth

Introduction

Esophageal cancer is one of the most aggressive malignancies and is ranked as the sixth leading cause of cancer-related death worldwide [1]. Recent advances in treatment including radiotherapy (RT), chemotherapy, and surgery, and their combinations have led to improved clinical outcomes; however, patients continue to experience high mortality [2]. Patients with esophageal cancer commonly have symptoms such as dysphagia and weight loss even before a confirmed diagnosis of the disease, and up to 80% of patients are nutritionally compromised [3,4]. Malnutrition, cachexia, and sarcopenia are reported as poor prognostic factors associated with treatment compliance and clinical outcomes in esophageal cancer and various cancers other as well [5,6].

Previously, we conducted a retrospective review among 248 esophageal cancer patients who underwent surgery and reported excessive muscle loss after neoadjuvant concurrent chemoradiotherapy (NACRT) as a significant poor prognostic factor for disease recurrence and overall survival [7]. In that study, many patients experienced malnutrition before and after NACRT; 62.9% of the patients were assigned the status of sarcopenia before the start of the treatment, and 28.2% showed more than 10% deterioration in the skeletal muscle index (SMI) after NACRT. To reduce muscle loss, more active support toward the patient's nutrition and physical activity was needed than education from a physician or nutrition specialist. Additionally, most patients were managed in the outpatient setting.

Noom (Noom Inc) [8] is one of the most popular commercial health care mobile apps. This app has been mainly used by obese people for weight control [9,10]. In addition to losing

weight, the company also provides paramedical experience for patients with diabetes or eating disorders, and pregnant women [11-14]. It provides interactive health coaching on various aspects of nutrition, exercise, and weight control. Although there is little evidence for the usage of this app, it can be applied to the self-management of nutrition for cancer patients.

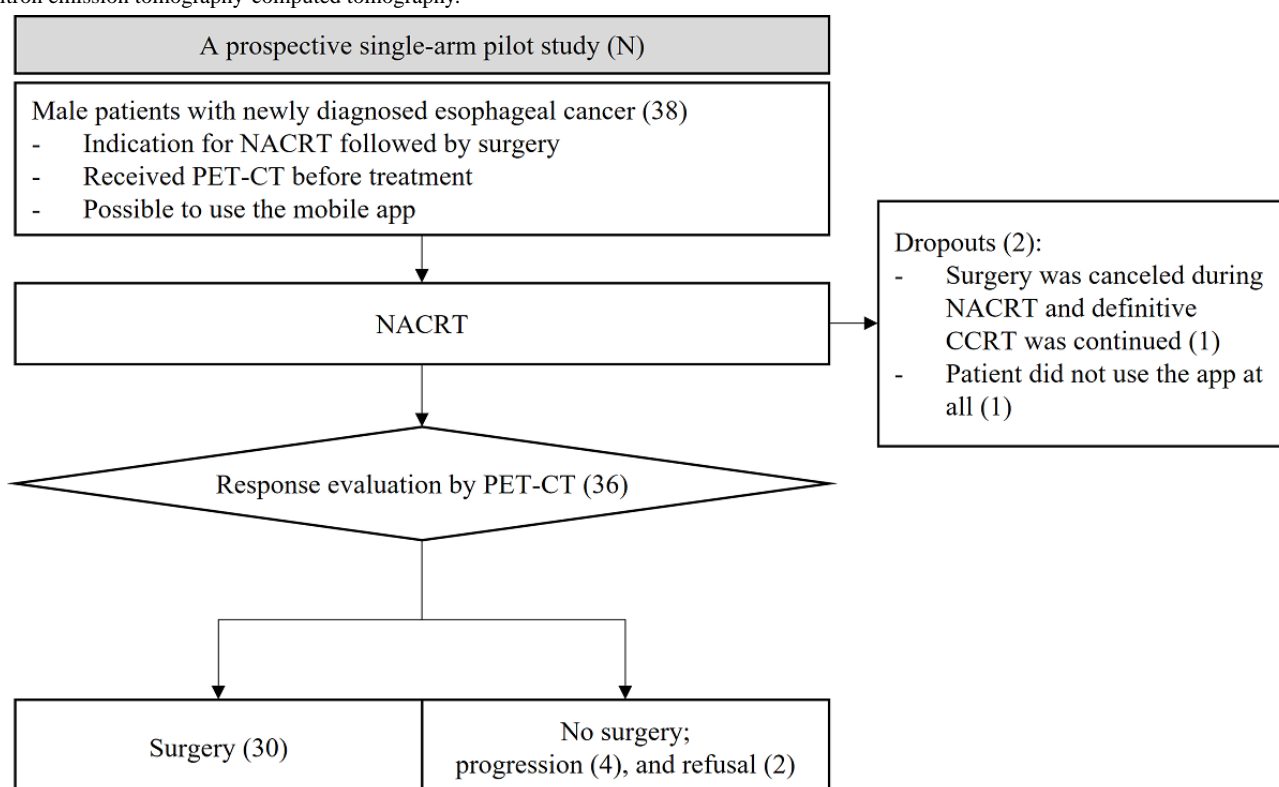

This prospective pilot study aimed to evaluate the usefulness of a health care mobile app in preventing malnutrition and excessive muscle loss in patients with esophageal cancer receiving NACRT.

Methods

Study Design

The inclusion criteria for this study were as follows: adult male patients (1) newly diagnosed with esophageal cancer, (2) scheduled for NACRT followed by radical surgery as per the authors' institutional protocol, and (3) undergoing positron emission tomography-computed tomography (PET-CT) as part of the diagnostic workup (Figure 1). Patients with synchronous distant metastasis, previous history of thoracic irradiation, or having difficulty using an app on a smartphone were excluded. Between July 2019 and May 2020, totally 38 patients were enrolled in this study. Data regarding the app usage were gathered for 8 weeks from the beginning of NACRT. During the trial, two patients dropped out; one did not use the app at all, and the other decided not to undergo surgery during NACRT and continued RT with a definitive aim for 6 weeks. Finally, 36 patients analyzed to evaluate the feasibility and effectiveness of using the app. This study was approved by the Institutional Review Board of Samsung Medical Center, and all participants provided written informed consent.

Figure 1. Flowchart of the study design. CCRT: concomitant radiotherapy and chemotherapy; NACRT: neoadjuvant chemoradiotherapy; PET-CT: positron emission tomography-computed tomography.

Treatment Scheme

Details of the treatment scheme, which includes RT and chemotherapy for NACRT, are described in our previous research [7]. The dose prescriptions for RT were 44 Gy in 22 fractions (2.0 Gy per fraction) for 18 patients and 43 Gy in 20 fractions (2.15 Gy per fraction) for 18 patients. All patients underwent intensity-modulated RT. All the patients completed NACRT as scheduled without grade 4 or higher complications. The concurrent chemotherapeutic regimen involved 2 cycles of cisplatin-based therapy in combination with 5-fluorouracil or capecitabine during RT. For response evaluation of NACRT, PET-CT was performed 3-4 weeks after the completion of NACRT, before surgery. The median time interval between pre-RT and post-RT PET-CTs was 73 days, ranging from 54 to 103 days. Patients underwent radical thoracic surgery, and the mean interval between the beginning of RT and completion of surgery was 10.5 weeks (range 9.1-14 weeks). Finally, surgery was not performed in 6 patients; 4 patients showed progressive disease after NACRT, not to assure curative surgery, and 2 patients did not want to undergo surgery after NACRT. Before NACRT, prophylactic feeding tube insertion was not performed in all patients except 1. During the trial, all patients received the best supportive care for their symptoms, such as painkillers and antacid drugs if needed.

Mobile App for Health Coaching

Before the start of NACRT, patients were informed about the trial and app usage by a study instructor and attended an online meeting with the app manager. The app provided services following enrollment, and the patients used it autonomously. The app setting was similar to that used in previous studies [9].

During the first sign-in, patients set their information including age, sex, height, and current and target weight. Users could record their food intake, exercise, and weight on a daily basis. In addition, the activity monitor in the app automatically measured the number of walk steps. Based on these records, the app provided summaries on calorie balance and weight trends. Additionally, experts in nutrition and exercise therapy provided feedback messages and encouraged the users through the app. The number of active records and messages from patients was counted each week in terms of nutrition, weight, and exercise. If any active data were recorded by the patient in a certain week, then the app was considered “activated” for that week. Based on previous experiences of the app users, as the compliance for this trial, the activation level of the app per 8 weeks was categorized as follows: “high,” activated for 6-8 weeks; “moderate,” activated for 4-5 weeks; and “low,” activated for 1-3 weeks.

Muscle Loss and Malnutrition Assessment

Similar to our previous study, the skeletal muscle area (cm^2) at the level of the third lumbar vertebra (L3) in the two CT image sets from PET-CT before and after NACRT was measured using an in-house software program [15]. The SMI (cm^2/m^2) was calculated from the skeletal muscle area divided by the square of the height (m^2). We also used the cutoff value of $52.4 \text{ cm}^2/\text{m}^2$ for sarcopenia from our previous study [7] and a population-based study [16]. ΔSMI (%), which is the percentage of SMI change based on the pre-RT SMI, was adjusted with various time intervals between 2 PET-CT measurements, and unified in 50 days per interval between 2 PET-CT measurements for each patient ($\Delta\text{SMI}/50 \text{ days}$, %). Excessive muscle loss was defined when $\Delta\text{SMI}/50 \text{ days}$ was more than 10%.

Other information regarding nutritional status was obtained from the laboratory tests on the day closest to that before the start of RT (pre-RT) and those as preoperative workups (post-RT), which were the first blood tests in most patients performed after the end of RT. Data were collected for the following laboratory parameters: absolute counts of white blood cells (WBC, / μ L), absolute neutrophil count (ANC, / μ L), absolute lymphocyte count (ALC, / μ L), platelet count (/ μ L), and albumin level (g/dL). From these results, the neutrophil-to-lymphocyte ratio (NLR, ANC/ALC), platelet-to-lymphocyte ratio (platelet/ALC), and prognostic nutritional index (PNI, $10 \times$ albumin + $0.005 \times$ ALC) [17] were calculated.

Statistical Analyses

The purpose of this study was to evaluate whether Δ SMI (%/50 days) was reduced in patients who used the mobile app (mHealth group) compared with that in our previous study cohort (usual care group). Additionally, changes in nutritional and inflammatory factors were also analyzed between the two groups. To compare the two groups, propensity score matching was used to balance characteristics such as the age, primary tumor location, tumor stage, pre-RT BMI, and pre-RT SMI level. Fisher tests for discrete variables and *t* tests (or Mann-Whitney *U* test) for continuous variables were conducted

for comparing the characteristics. To identify significant factors associated with excessive muscle loss in this study, logistic regression was performed with the quantified app data. Additionally, we performed mixed model analysis for repeated measures of walk steps counted by the app for 8 weeks. R 4.0.3 (version 4.0.3, R Development Core Team) [18] and SPSS Statistics (version 27.0, IBM Corp) were used for statistical analyses with $P < .05$ suggesting statistical significance.

Results

Compliance With the App

For 8 weeks of the trial, 80.6% (29/36), 77.8% (28/36), 75.0% (27/36), 77.8% (28/36), 72.2% (26/36), 66.7% (24/36), and 72.2% (26/36) of the patients had been active on the app from the second week to the 8th week. In addition, the activation levels were as follows: high, moderate, and low levels in 25 (69.4%), 3 (8.3%), and 8 (22.2%) patients, respectively. However, the patients selectively used parts of the app (Table 1). The most activated records were for the nutritional part. However, in the exercise records, only one was moderately activated, and there was no highly activated patient. Walk steps were passively gathered and had a pattern similar to that of the total activation level.

Table 1. Activation level based on the number of activated weeks.

Activated part of the app	Activation level ^a , n (%) (N=36)		
	Low	Moderate	High
At least one activation in any part of the app	8 (22.2)	3 (8.3)	25 (69.4)
Nutrition	14 (38.8)	7 (19.4)	15 (41.7)
Weight	20 (55.6)	4 (11.1)	12 (33.3)
Exercise	35 (97.2)	1 (2.8)	0 (0)
Walking ^b	6 (16.7)	5 (13.9)	25 (69.4)

^aActivation level was determined depending on the number of activated weeks—low: activated for 1 to 3 weeks; moderate: activated for 4 to 5 weeks; high: activated for 6 to 8 weeks.

^bThe number of walk steps was automatically recorded by the activated app.

Patient Characteristics and Comparison With the Usual Care Group

The median patient age was 59 years, and all patients had an Eastern Cooperative Oncology Group Performance Status (ECOG PS) of 0 to 1. The details of the patient characteristics are summarized in Table 2. Compared to the previous study cohort (usual care group), the age, tumor location, and some of the laboratory markers were significantly different in this study cohort (mHealth group) (Supplement table). As a result, Δ SMI/50 days (%) and the proportion of patients with excessive muscle loss (Δ SMI/50 days >10%) were not significantly

different between the two groups. However, in the mHealth group, the PNI decreased to a lesser extent after NACRT.

After 1:2 propensity score matching to adjust for variables such as the age, primary tumor location, tumor stage, pre-RT BMI, and pre-RT SMI level, we compared 30 patients in the mHealth group with those of the usual care group (Table 2). Even after propensity score matching, Δ SMI/50 days (%) and the proportion of patients with excessive muscle loss (Δ SMI/50 days >10%) were not significantly different (−8.1% vs 7.4%, $P = .57$ and 33.3% vs 30.0%, $P = .94$, respectively). The PNI decreased to a lesser extent in the mHealth group than in the usual care group (−6.7 vs −9.8, $P = .04$).

Use of the App and the Associated Excessive Muscle Loss

In this study, there was excessive muscle loss in 12 of the 36 patients (33.3%) (Table 3). Regarding the app usage, there was

no significant difference in the activation level, but walk steps decreased more in the excessive muscle loss group. More patients with a 70% or more decrease in walk steps between the first and the last 4 weeks were in the excessive muscle loss group (66.7% (6/9) vs 14.3% (3/21), $P=.02$).

Mixed Model Analysis for Weekly Walk Steps

Repeatedly measured walk steps appeared to have a pattern (Figure 2A), which decreased at the 5th and 6th weeks and slightly recovered at the 7th and 8th weeks. Discrete variables such as age, BMI, SMI, and surgery were used for this analysis (Table 4). When the variables were fixed, time (week) was commonly significant. In contrast, when time was fixed, only the age was significantly different ($P=.01$), which showed a

gap in the absolute number of walk steps in the two age groups (Figure 2B). For the interaction between time and each variable, only pre-RT sarcopenia was significantly different ($P=.03$), which showed different recovery patterns at the 6th and 8th weeks between the pre-RT sarcopenia and nonsarcopenia groups (Figure 2C). Although not significant, excessive muscle loss seemed to affect the trend in the number of walk steps (Figure 2D).

Figure 2. Weekly trends in walk steps recorded automatically by the application for 8 weeks (N=33): all patients (A), patient groups according to age (B), pre-RT sarcopenia (C), and excessive muscle loss ($-\Delta\text{SMI}/50$ days $>10\%$), during neoadjuvant concurrent chemoradiotherapy. RT: radiotherapy; SMI: skeletal muscle index.

Table 4. Mixed model analysis with walk steps for 8 weeks.

For 8 weeks	<i>P</i> value for weeks	<i>P</i> value for variables	<i>P</i> value for interaction
Age (<60 vs ≥60 years)	<.001	.006	.39
Pre-RT ^a BMI (≥20 vs <20 kg/m ²)	.001	.17	.98
Post-RT BMI (≥20 vs <20 kg/m ²)	.001	.67	.47
$-\Delta\text{BMI}$ (>5% vs <5% kg/m ²)	<.001	.98	.096
Pre-RT sarcopenia (yes vs no)	<.001	.55	.03
Post-RT sarcopenia (yes vs no)	.001	.44	.64
$-\Delta\text{SMI}^{\text{b}}/50$ days $>10\%$ (>10% vs <10%)	<.001	.42	.43
Surgery (Yes vs No)	.007	.08	.96

^aRT: radiotherapy.

^bSMI: skeletal muscle index.

Discussion

Principal Findings

Sarcopenia is a syndrome characterized by a progressive decrease in skeletal muscle mass and strength, leading to a risk of worse outcomes in terms of physical ability, quality of life, and survival, although there are various definitions for this term provided by the European Working Group on Sarcopenia in Older People (EWGSOP), the European Society for Clinical Nutrition and Metabolism Special Interest Groups (ESPEN-SIG), and the International Working Group on Sarcopenia (IWGS) [19]. It was first considered an age-related disease by Rosenberg [20]. However, in recent years, it is clinically noticeable that sarcopenia can be caused by malignancy or inflammatory diseases and adversely affects their treatment. The mechanism of sarcopenia is not clear but seems multifactorial; its risk factors are old age; female sex; low level of physical activity; and comorbidities including malignancy, obesity, osteoporosis, and diabetes [21]. Focusing on malignancy, higher metabolism, and inflammation by aggressive cancer cells, cancer treatments including surgery, chemotherapy, and RT; anorexia or poor oral intake; and low physical activity make patients more susceptible to sarcopenia [22]. Moreover, gastrointestinal malignancy easily causes malnutrition, and most esophageal cancer patients experience cachexia or sarcopenia. Furthermore, the presence of sarcopenia in cancer patients has been accepted clinically as one of the important predictors of survival and treatment outcomes [6,22]. In addition to clinical evidence, the muscle loss is gaining interest in biochemical research, including the anti-inflammatory or anticancer effects of myokines [23]. We previously analyzed the effect of sarcopenia in patients with esophageal cancer receiving NACRT [7]. NACRT itself has risk factors for sarcopenia; symptoms or complications such as nausea/vomiting and anorexia induced by chemotherapy and acute esophagitis by RT can deplete nutrition and physical energy [22]. We revealed that the changes in the muscle index (Δ SMI/50 days) were the prognostic factors for disease recurrence and survival and not the presence of sarcopenia before the treatment [7]. Additionally, sarcopenia is related to nutritional and inflammatory markers [7,24]. Therefore, we suggest that appropriate intervention for nutrition and physical activity could be beneficial for these patients.

Numerous interventions to overcome malnutrition in patients with various cancers have been attempted [3,25,26]. Unfortunately, interventions to improve cancer patients' malnutrition or muscle loss have been rare. Malnutrition is still considered insurmountable, and most esophageal cancer patients find it difficult to overcome malnutrition or often experience worsened conditions. This study, which used an interactive health coaching mobile app as an intervention for nutrition and physical activity, found similar negative results in terms of preventing muscle loss in esophageal cancer patients receiving NACRT compared to that in the usual care group. As a secondary endpoint, however, the use of the mobile app could improve nutritional indicators such as PNI, which is also known to be a prognostic factor for gastrointestinal cancers [17]. The compliance of the mobile app was as good because 70% (20/36) of the patients used it until the end of the trial, especially in

nutrition and weight items. This could be because the patients were concerned about maintaining their oral intake and weight.

Guidelines for nutritional support suggest that appropriate interventions have to be selected depending on each patient's nutritional status, from basic nutritional modification and oral nutritional supplements to enteral or parenteral nutrition for severe cases [3,5]. However, it might be difficult by only through nutritional interventions to improve or prevent sarcopenia. The benefit of physical activity and exercise is well known for sarcopenia, and the international clinical practice guidelines for sarcopenia in 2018 strongly recommend physical activity for the treatment of sarcopenia [27]. Any single intervention in the aspect of nutrition, exercise, or medication is less effective for the management of sarcopenia, and proper dietary intake and exercise should be combined [28]. Resistance exercise has been shown to improve muscle mass and strength [29,30].

An interesting result was the number of weekly walk steps. The mean of the walk steps reached a maximum of 20,000 in the second week and a minimum of 7000 in the 6th week. It is assumed that the limited physical activity during the fourth to the 6th week could cause muscle loss. This pattern is associated with the severity of radiation esophagitis. In general, RT esophagitis begins at week 2 of RT, its severity increases over time, and peaks at the end of RT. It takes approximately 3 weeks for the symptoms to resolve. Detailed analyses of the walking steps showed that patients with excessive muscle loss during NACRT significantly decreased the number of steps in the last half of the trial period. Furthermore, age affected the number of walking steps, and pre-RT sarcopenia showed a difference in the recovery of the decreased walking steps after NACRT. This means that older patients and those with sarcopenia at the start of the treatment have difficulty maintaining physical activity during the treatment and recovering decreased physical activity after NACRT. Some studies suggested that the number of walking steps was related to performance status [31]. As performance status is also one of the important factors for surgical indication and outcome [32], the pattern of the decrease and recovery in walking steps after NACRT is likely to be an indicator for the continuation of follow-up surgery or a predictor for postoperative mortality in patients with esophageal cancer.

To prevent malnutrition and muscle loss in esophageal cancer patients receiving NACRT, comprehensive supportive care including nutritional care as well as exercise might be needed. In addition, the status of nutrition and muscle mass needs to be evaluated individually before the start of treatment. For example, patients without malnutrition and sarcopenia can be managed with the mobile interactive coaching app used in this study. However, patients with old age, malnutrition, and sarcopenia might need to be managed differently. Physical activity guidelines for cancer patients from the American Cancer Society recommend avoiding inactivity, continuing normal daily activity as much as possible, and performing exercise adapted for the disease and the patients' condition, particularly if patients experience severe symptoms such as extreme fatigue or ataxia, or have cardiovascular and pulmonary contraindications [33]. However, exercise programs targeting patients with sarcopenia or extremely low physical activity are not well established, and

high-intensity exercise might be not good for patients undergoing cancer treatment. It is necessary to develop a customized and intensity-modified physical program for patients with malnutrition and sarcopenia.

As a limitation, this prospective study was a small pilot test, thus limiting detailed analyses. We used the SMI from CT to diagnose sarcopenia, but muscle strength, which is one of the criteria for the definition of sarcopenia, could not be evaluated. In addition, all enrolled patients were male for comparison with our previous study, which predominantly involved esophageal cancer patients for ensuring study homogeneity. Finally, we focused on the app usage such as the activation or automatically recorded walk steps, but more specific nutritional factors such as calories during oral intake were missing. Although the app was not highly effective in preventing muscle loss and further

research using more detailed information is needed, we expect that it can be used as a self-managing nutritional support for cancer patients and possibly expanded for cancer survivors after treatment.

Conclusion

For esophageal cancer patients receiving NACRT, an interactive health coaching mobile app helped nutritional self-care with a significantly less decrease in PNI, although it did not prevent excessive muscle loss. Low physical activity estimated by the number of walking steps did not recover even a few weeks after the end of NACRT in patients with old age or pretreatment sarcopenia. An individualized care model with proper exercise as well as nutritional support may be required to reduce muscle loss and malnutrition.

Acknowledgments

Noom Inc provided full range of services in the Noom app during this trial.

Conflicts of Interest

Although HK, JL, and YK are affiliated to the company providing the app, this study was based on only objective measures such as patient activities using the app, walk steps, and clinical data. The other authors have no conflict of interest to disclose.

Abstract

Background: There is growing interest in using social media data to detect and address nonsuicidal self-injury (NSSI) among adolescents. Adolescents often do not seek clinical help for NSSI and may adopt strategies to obscure detection; therefore, social media platforms may be able to facilitate early detection and treatment by using machine learning models to screen posts for harmful content and subsequently alert adults. However, such efforts have raised privacy and ethical concerns among health researchers. Little is currently known about how adolescents perceive these efforts.

Objective: The aim of this study is to examine perceptions of automated alerts for NSSI posts on social media among Latinx adolescents, who are at risk for NSSI yet are underrepresented in both NSSI and health informatics research. In addition, we considered their perspectives on preferred recipients of automated alerts.

Methods: We conducted semistructured, qualitative interviews with 42 Latinx adolescents between the ages of 13 and 17 years who were recruited from a nonprofit organization serving the Latinx community in Milwaukee, Wisconsin. The Latinx population in Milwaukee is largely of Mexican descent. All interviews were conducted between June and July 2019. Transcripts were analyzed using framework analysis to discern their perceptions of automated alerts sent by social media platforms and potential alert recipients.

Results: Participants felt that automated alerts would make adolescents safer and expedite aid before the situation escalated. However, some worried that hyperbolic statements would generate false alerts and instigate conflicts. Interviews revealed strong opinions about ideal alert recipients. Parents were most commonly endorsed, but support was conditional on perceptions that the parent would respond appropriately. Emergency services were judged as safer but inappropriate for situations considered lower risk. Alerts sent to school staff generated the strongest privacy concerns. Altogether, the preferred alert recipients varied by individual adolescents and perceived risks in the situation. None raised ethical concerns about the collection, analysis, or storage of personal information regarding their mental health status.

Conclusions: Overall, Latinx adolescents expressed broad support for automated alerts for NSSI on social media, which indicates opportunities to address NSSI. However, these efforts should be co-constructed with adolescents to ensure that preferences and needs are met, as well as embedded within broader approaches for addressing structural and cultural barriers to care.

Introduction

Background

The rates of nonsuicidal self-injury (NSSI) and suicidal ideation have been rising among adolescents in the United States, with Latinx adolescents experiencing high rates of both [1-3]. NSSI, also known as self-harm or self-injury, is defined as “deliberate, self-inflicted damage of body tissue without suicidal intent and for purposes not socially or culturally sanctioned” [4]. Although distinct in intent, NSSI is a risk factor for suicidality [5,6]. There is evidence that social media users share web-based NSSI content [7,8], creating interest in approaches using social media data to detect and address NSSI and prevent suicidality [9-13].

One approach, termed digital phenotyping, suggests that analysis (usually via machine learning) of data generated from interactions with digital technologies and devices, including social media, can be used to “identify and diagnose health conditions” [14-16]. Although initially envisioned to include clinician-generated inputs, such as medical records, the approach is now regularly applied to social media data without further inputs [10,16-19]. As adolescents often do not seek clinical help for NSSI [20] and may adopt strategies to obscure detection [7,21-23], the creation of alerts informed by digital phenotyping of social media data could provide new opportunities for early detection and treatment.

Although a potentially promising intervention, digital phenotyping alerts based on machine learning algorithms to detect mental health concerns raise questions about consent, efficacy, and privacy risks [14,24]. For example, Facebook uses digital phenotyping to detect suicidal ideation in posts made by US users and then alerts local emergency responders when the staff deems it is appropriate [13]. There is no way to opt into or out of this feature, even for minors [25]. Some have also raised questions about the accuracy of the underlying machine learning model analyzing posts to infer mental health status, particularly in cases where predictions are primarily built using data from adults [26]. Both false negatives and false positives weaken the efficacy of the intervention and may pose risks to adolescents. Although adults have shown little support for these efforts [27], adolescents’ perceptions of both alerts based on their social media posts and the commercial and institutional uses of personal data remain largely unknown [28]. Given the initial evidence that youth are less likely than adults to view their health information as sensitive and the collection of their personal data by companies as a privacy violation [29], they may be apathetic toward these interventions. However, the only prior study of the perceptions of young adults of digital phenotyping (which focused on assessing mental health via cellphone sensor data) demonstrated that they had concerns about privacy and autonomy and rejected the monitoring of text message content [30].

As interventions informed by social media data are already deployed and will likely spread to an increasing number of settings, it is an ethical and design imperative to understand how adolescents perceive these efforts and how mental health alerts based on digital phenotyping can best be tailored to meet their preferences and needs [12]. Prior research has stressed the

importance of user-centered design and the cocreation of digital mental health tools with youth [25,30]. Moving ahead without considering youth perspectives may result in both rights violations and backlash against existing and future interventions [25]. For example, the only way adolescents may opt out of Facebook’s suicide intervention efforts is to discontinue using the Facebook and Instagram platforms, which may have negative implications for adolescents and would limit the completeness of data used to inform subsequent interventions. Accordingly, assessing youth perspectives on how interventions are designed may help improve their efficacy and accuracy.

Study Aims

We address this gap in the literature by qualitatively examining how Latinx adolescents perceive social media platforms automatically detecting posts about NSSI and alerting an authority figure in response (*automated alerts*). We focus on Latinx adolescents because although they engage in NSSI, they are underrepresented in research on NSSI and are more likely to be undiagnosed than White adolescents [31]. Latinx adolescents also experience higher rates of depression, which is a risk factor for NSSI [32,33], than non-Hispanic White adolescents [2,32-34]. The actual rates of depression may be higher because clinicians may miss cultural differences in the expression of symptoms [35]. Thus, population-level models may introduce cultural bias into digital phenotyping efforts to infer NSSI [36]. At the same time, Latinx adolescents may stand to benefit from such tools because of socioeconomic and cultural barriers to receiving mental health screening [37]. Moreover, the Latinx community is underrepresented in studies of privacy on social media [38-40] despite factors such as documentation status and larger household sizes, potentially creating unique privacy needs and ethical concerns [41]. In the context of mental health, potential stigmatization shapes who they are likely to approach for mental health support [42] and thus may also influence their preferences for who should receive an alert. Accordingly, it is critical to engage with Latinx adolescents to study how they perceive interventions that automatically alert a third party to obtain help when adolescents make concerning social media posts and their preferences for alert recipients.

Methods

Data Collection

Eligible participants were Latinx adolescents aged 13 to 17 years who used social media, defined as posting at least once per week. We collaborated with a community organization serving the Latinx community in Milwaukee, Wisconsin, which hosts a summer youth program to recruit and screen participants based on the eligibility criteria. Adolescents gave assent, and guardians provided consent before data collection proceeded. Both assent and consent documents were available in English and Spanish. Although the family origin of students at the community organization was not available, Milwaukee’s Latinx population is largely of Mexican descent [43]. Participants who were enrolled in the study received a US \$40 incentive. The institutional review board at the University of Wisconsin-Milwaukee approved the research protocol.

Between June and July 2019, 60- to 90-minute semistructured, in-person interviews were held with 43 Latinx adolescents in a quiet room at the community organization. Although a Spanish-speaking interviewer was available, all interviews were conducted in English at the request of the adolescents. At the start of the interview, participants provided demographic information and selected a study pseudonym. As part of a broader line of questioning about how adolescents handle mental health disclosures from peers on social media [44], participants were asked the following question: “How would you feel if a social media app sent an automatic alert to an adult when you or your friends made a post about self-harm?” The term self-harm was chosen over NSSI to reflect common use [7]. The participants were then asked who should receive such alerts. We probed about emergency services, which the Facebook suicide intervention alerts, and *trusted adults* (parents or guardians and school staff or teachers) frequently identified in prior literature [44,45]. Participants were also probed about why they endorsed or opposed these alert recipients. One interview concluded without asking about automated alerts because of time constraints, resulting in a sample size of 42 participants.

Data Analysis

Following professional verbatim transcription, the interdisciplinary team, consisting of a senior qualitative researcher in public health, a senior sociologist who is Latinx, and 2 graduate students trained in qualitative methods, analyzed the transcripts using framework analysis [46] to identify perceptions of automated NSSI alerts and alert recipients. The 2 senior members performed open coding on the transcripts for the first 12 interviews to identify the initial codes and develop the codebook. The codebook captured perceptions for and against automated alerts. Transcripts were then split among team members and coded using MAXQDA 2018 (VERBI Software GmbH). Throughout the final coding process, an additional 11 transcripts were coded by 2 to 3 members and discussed code by code to allow new codes to arise and ensure a shared understanding of code definitions. Any discrepancies were resolved through consensus, with prior coding updated as needed using an iterative process [47]. Coded transcripts were then charted into a framework analysis matrix [46] using MAXQDA 2018 to summarize data by category from each transcript, with a focus on identifying favorable and unfavorable perceptions of automated alerts and alert recipients. In addition, memos were written to aid in the data interpretation and identification of representative quotes [48].

Results

Overview

Of the 42 participants, 24 (57%) self-identified as girls and 18 (43%) as boys. The ages ranged from 13 to 17 years, with a mean age of 15. Over 61% (26/42) of the participants indicated that both of their parents were immigrants in the United States. The participants most frequently used Snapchat (42/42, 100%), followed by Instagram (39/42, 93%). We present findings on the perceptions of automated alerts for NSSI, followed by the preferred recipient of such alerts. The majority of participants felt that automated alerts would make adolescents safer, but

also expressed strong concerns about alert accuracy and the efficacy of alert recipients. The representative quotes below are presented using the pseudonyms selected by the participants.

How do Latinx Adolescents Perceive Automated Alerts for NSSI?

Participants worried about whether digital phenotyping tools could accurately detect NSSI, specifically mentioning false positives due to (1) the frequent use of jokes, sarcasm, and hyperbole by adolescents, and (2) situations that were seen as posing only minor levels of risk that did not necessitate intervention. For example, Dahlia (age 14) supported alerts but worried about social media posts being misinterpreted, and alerts sent inappropriately:

I think I would be okay with that because in the end they're just trying to help, but at the same time if like you were saying that but you didn't really mean that and someone were to find out, that would be like embarrassing.

Ariona (age 14) similarly worried about common turns of speech being taken literally and parents overreacting to an alert:

...if it was just joking around, your parents might take it way too seriously. [Ariona]

So what's an example of someone joking around about self-harm? [Interviewer]

Like sometimes when we have a bad test that was really hard and we'll be like, "I want to kill myself," but it's just joking. We're not being for real about it. [Ariona]

Fears also included getting in trouble with authorities if emergency services were summoned without an emergency being present.

Pablo (age 17) explained as follows:

Don't you get like fined and stuff like that like if the ambulance comes?...What if the algorithm gets it wrong for some reason then you get some ambulances outside your house?

Broad privacy concerns were relatively rare and focused primarily on the desire for adolescents to tell adults themselves rather than an impersonal alert being sent on their behalf. Although none of the participants indicated that they would stop posting to regain control of their privacy, a small number anticipated that other adolescents may do so. More commonly, participants dismissed privacy concerns as minor relative to the severe risks posed by NSSI. Although the interview questions about automated alerts focused on self-harm, participants often linked NSSI with suicidality, both conceptually (as with the quote from Ariona above) and with regard to the importance of timely intervention to curtail escalation. Perceptions of urgency were the primary drivers of support for automated alerts. Ashley (age 15) explained as follows:

Like it's good for [parents] to get that alert just so you don't do anything more stupid than trying to self-harm yourself, and so that way your parents can know on time to like hurry and like tell you before you do anything else.

Similarly, David (age 17) felt alerts would “probably be a good thing because it’d probably alert the parent or guardian before the harmful thought got too serious.”

Participants also noted that adolescents often post about mental health struggles without anyone acting on it and expressed a strong sentiment that parents or guardians are commonly unaware of how their children are feeling. Bri (age 17) felt that alerts were as follows:

pretty smart, because so many people tend to stay quiet. They tend to keep it on social media. They usually don't tell their parents, hey, this person that I know is feeling like this. And it's just better to be safe than sorry...It's better to do that than say that and then no one says anything, and then it just stays in that toxic state. Like it's just there. You keep saying you're depressed, and no one says anything. And something could happen.

Consequently, participants felt that adolescents struggling with NSSI may experience barriers to timely help. Automated alerts were seen as faster and more reliable for obtaining aid than waiting on friends to take action or parents or guardians to notice. Alerts were mentioned as a means of improving communication among adults and children. Once notified, participants generally anticipated that adults would offer adolescents some form of mental health support. Monse Marie (age 13) explained this as follows:

I think that would be a good thing for the social media to do because if you're going through something then the parent will try to help you like oh, maybe therapy or something, you know, besides like because sometimes parents are blinded, like they don't know what's going on with the kid.

Who Should Receive Automated Alerts for NSSI?

Despite strong support for automated alerts because they could yield adult help, participants were cognizant of adults differing in their efficacy and desire to help. An alert sent to the wrong person could fail to generate help and instead cause negative repercussions if sent to someone who would punish rather than help the adolescent. Although most participants suggested that alerts should be sent to parents or guardians because of their close bonds to their children, parents or guardians also stood out in interviews as both unpredictable and occasionally hurtful. Lucy (age 14) recalled the example of a friend who illustrated this as follows:

...my friend, she's felt sad before and she even mentioned depression once, and her parents got really mad at her, and they blamed it on her that she was feeling sad and that she mentioned it. So I think that it would be best to tell a teacher versus a parent, or tell emergency services...

John (age 14) similarly noted that “if it were an abusive parent or something like that it wouldn't be good.” A small number of participants also expressed fear of how their own parents would respond to the alerts.

One common concern was that parents or guardians would not take mental health concerns seriously and may not know how to respond. Lilo (age 17) preferred emergency services over parents since:

self-harm is something that somebody should get treated for and their parent might...be passive about it. Like you never know how serious a parent is going to take it.

Bri (age 17) felt that Latinx families specifically may have limited efficacy in handling mental health concerns:

I feel like it's different, because of the fact that I know, for Latinos, when there's mental health included, it's really hard to talk about it with your parents, especially if your parent is not educated in that, or if your parents is—they've grown up in certain ways, and so they will believe that what we think is kind of dumb. Because I know, for some families, they can't even talk about that type of thing, because it's seen as a weakness.

Emergency services were more uniformly seen as safe and knowledgeable, but participants felt that not all posts indicating NSSI merited intervention from emergency services. Some participants mentioned a hotline number as an alternative. No participant worried about emergency services introducing risks to their families, although one stated “you wouldn't want the FBI knocking on your door” [John, age 14].

School staff and teachers were occasionally mentioned as preferable substitutions when participants thought parents or guardians would be unsupportive, but these adults were not immune from concerns about unhelpful responses and punishment. Although privacy concerns for automated alerts in general were minimal, privacy concerns specific to alerts sent to schools were more common. Specifically, some participants worried about other students finding out or that school staff and teachers would judge adolescents for their mental health struggles. Jaden (age 16) explained as follows:

I wouldn't want that business out there to my school if, you know, right away. Because if they don't understand the context of the situation, that could just also do the whole labeling thing where it's like you feel like everyone's kind of just watching out for you...I wouldn't want that business there with my school because it's just, it's a big place and you're there for a long time, so it's kind of like it could have lasting effects on you while you're there.

Although preferred alert recipients differed across individual adolescents and across perceived severity of situations, participants shared a desire that alerts should be sent to “someone who cares and who wants them to get better” [Sara, age 14]. Overall, the alert recipient was viewed as critical to the efficacy and desirability of alerts derived from social media posts.

Discussion

Principal Findings

This study examined the perceptions of Latinx adolescents toward automated alerts for NSSI based on digital phenotyping using social media platforms. Diverging from adult perceptions [27], participants were largely positive toward automated alerts, suggesting that alerts could help overcome the lack of responsiveness from peers and parents. In particular, participants felt that alerts could connect adolescents to help before situations escalated. Notably, the perception that social media users often ignore posts with concerning content rather than report it is among the reasons that Facebook launched its digital phenotyping efforts [13]. Adolescents stressed that alerts must be accurate and directed toward someone able and willing to help. The efficacy of alerts as a mental health intervention is partially contingent on the efficacy of the alert recipient, suggesting the need to adopt practices that accommodate and support the social fabric surrounding adolescents.

The findings reveal opportunities to improve the ethics and efficacy of mental health interventions based on digital phenotyping. With respect to the machine learning algorithms that underpin alerts, the findings show that these must be sensitive to the specific linguistic patterns of adolescents to account for the use of sarcasm, jokes, and hyperbole used for dramatic effect. Furthermore, algorithms must be sensitive to variation across adolescents, including those rooted in cultural differences in the expression of depression and NSSI [35]. Although participants did not suggest that they had concerns unique to their status as Latinx youth, attention should be paid to the specific subpopulations included in the data to train algorithms [36]. Although continued manual screening of posts identified through machine learning, similar to the efforts of Facebook, may help reduce the number of alerts being sent inappropriately, poorly trained machine learning tools are still likely to miss concerning posts. In line with prior research showing that depression can co-occur with NSSI [32,33], interviewees relayed how detecting depression early could offer timely help to limit adolescent harm.

With regard to the actual alerts, the selection of an appropriate recipient is crucial to the adolescent receiving assistance. NSSI represents a particularly interesting scenario for alerts because, unlike suicidality, emergency services are not always the obvious or appropriate choice. Although many participants either conflated NSSI with suicidality or worried about NSSI leading to something more serious, which accords with prior research on Latinx adolescents [31], they felt that emergency services may be an excessive response for NSSI. However, not all adolescents reported access to supportive school staff, teachers, parents, or guardians, and some worried adults would respond in detrimental ways. These concerns are consistent with those found in prior research on adolescents who engage in NSSI and highlight the importance of increased education for adults who surround adolescents [49].

As there was no uniformly appropriate alert recipient across all participants and levels of need, researchers and social media platform developers should consider the development of alerts

that take into account the privacy preferences of *individual* adolescents. The lack of uniformly appropriate alert recipients is consistent with a contextual view of privacy [50] and suggests that interventions should be co-designed with adolescents providing feedback to ensure that efforts meet their preferences and needs [51]. In the implementation stage, adolescents should be asked whether they want alerts to be sent for NSSI and, if so, to whom. Engagement is ideally an ongoing process, as privacy preferences and trusted adults may change over time. Allowing participants to opt in to alerts would address one of the major ethical concerns with the current approach of Facebook to digital phenotyping [25].

At the time of writing, we were not aware of any platforms that allow social media users to choose in advance who should receive alerts sent by platforms. Facebook makes use of a two-tiered system in which their machine learning tool identifies users who may be at risk of imminent harm. In the event that Facebook's Community Operations team agrees with the assessment, the user is shown *support options* [52], including a prompt to reach out to a Facebook friend using prepopulated text. However, the user must decide in that moment to send the message themselves. In the event that the risk to the user is deemed high, the Facebook team instead notifies local emergency services. It should be noted, however, that this system was designed for suicidality rather than NSSI. Furthermore, other platforms popular with adolescents do not have an official alert policy at all, even for suicidality. TikTok, for example, simply states that those considering harming themselves should "please contact [their] local emergency services, a suicide-prevention helpline, or expert listening service for help" [53]. Platforms have room for significant growth in the area of co-designing responses for both NSSI and suicidality. It will also be critical to engage parents, teachers, and emergency service managers in this co-design process to examine their preferences for alerts. In addition, further research is needed to examine and support the capacity of these actors to manage alerts in a constructive manner, especially with respect to recognizing when and how to seek mental health treatment. As noted by the participants themselves, the notification of an adult is not a guarantee that an adolescent will receive mental health services.

Although participants mentioned concerns about their privacy within school settings, none voiced concerns related to social media platforms analyzing or storing mental health relevant information, or ethical concerns about this occurring without their awareness or explicit consent. Furthermore, none expressed concerns about the implications of these data for future employment or insurability [24]. Although there is little research on adolescent perceptions of commercial and institutional privacy [28], these findings are consistent with initial evidence that adolescents are less likely than adults to view their health information as sensitive [29]. It is also possible that the absence of concerns reflects a lack of awareness of risks. Adolescents in the United States may be at particular risk for harms stemming from the intentional or inadvertent disclosure of private health-related information by platforms in light of the power of the private health insurance industry. Although the Affordable Care Act of 2010 currently prevents insurers from denying

coverage or charging higher rates due to preexisting conditions, these provisions are currently in jeopardy because of legal challenges [54]. Future research should provide participants with risk information and assess whether support changes for social media platforms engaging in digital phenotyping. Any effort by social media companies to expand current efforts should adopt a digital literacy component to achieve meaningful informed consent. More broadly, it is notable that Facebook's automated suicide-prevention feature is not available in the European Union because the General Data Protection Regulation provides social media users greater control over their *data concerning health* [12,55]. The United States currently has no equivalent law, and the Health Insurance Portability and Accountability Act applies only to health care providers, plans, and clearinghouses [55]. Further work is needed to ensure that social media platforms protect the health-related information they gather and analyze, particularly concerning minors.

Overall, the findings suggest that automated alerts based on digital phenotyping of social media data may offer opportunities to address NSSI among Latinx adolescents and prevent further harm. This is a significant finding given the high rates of NSSI and barriers to receiving mental health treatment among Latinx adolescents [2,35,56]. Further, Latinx adolescents have a high rate of smartphone access and report high levels of social media use [57], indicating a wide range of opportunities for deployment. However, the implementation of alerts without addressing underlying disparities in access to mental health services in the United States may exacerbate disparities because such interventions risk being more effective for populations with access to care [37,58-60]. In addition to practical concerns with regard to algorithms and alert recipients, developers should also be mindful of the broader socioeconomic implications of their efforts.

Limitations

With regard to limitations, the transferability of findings should be considered in light of the fact that this study was conducted with English-speaking Latinx adolescents drawn from a summer program in a midsized US city that is largely of Mexican origin

[43]. The homogeneous sample helps address the underrepresentation of Latinx groups in privacy research and their disproportionate risk of NSSI. Further research is needed to reveal how concerns and preferences may be distinct across populations. In addition, as this study was one element within a larger project, time constraints prevented additional questions prompting participants to reflect explicitly on questions of commercial privacy. However, the absence of probing allowed us to capture the degree to which participants readily reflected on these concerns. It should also be stressed that participants were not selected based on prior experiences with NSSI, which allows findings to be transferable to a broader pool of adolescents but may fail to capture the unique preferences of those engaging in NSSI. In light of prior research indicating that many adolescents choose to seek help for NSSI on the internet [61], and that these adolescents may experience more suicidality than those who do not seek help on the internet [62], there is a strong need for additional work exploring whether the benefits of NSSI alerts would offset any potential chilling effects on help seeking via social media. Finally, future research should also expand beyond adolescents to consider the capacity and preferences of adults and institutions who could serve as alert recipients.

Conclusions

This research finds broad support among Latinx adolescents for automated alerts issued in response to NSSI posts on social media, indicating an opportunity for deploying interventions grounded in digital phenotyping to address mental health on the internet. Latinx adolescents described pragmatic concerns about the accuracy of these tools and who should receive alerts but had few ethical concerns and expressed little awareness of the risks posed by the collection and storage of health-related information by commercial entities. Researchers and social media platforms should collaborate with adolescents to co-design interventions that accurately and appropriately alert a chosen recipient when they are at risk for NSSI. Any such effort should consider the implications for adolescent privacy. Ensuring access to appropriate mental health services following detection will be critical to avoid exacerbating disparities.

Abstract

Background: Social media provides women with varying platforms to express themselves, show their talents, communicate and expand their social relationships, and break the shackles imposed by their societies. Theoretically, social media can play a significant role in developing women's freedom and decreasing social pressures; nonetheless, women continue to face violence during the social media era mainly in the form of psychological violence.

Objective: This study aims to conduct an empirical in-depth analysis of how the digital space, particularly social media, provides men with new opportunities to surveil, restrict, harass, and intimidate feminists in Arab countries.

Methods: This study includes an empirical survey to investigate what Arab women think are the causes and types of violence wielded against them and their perspectives on the impact of that violence. This study used a web-based questionnaire administered through Google Forms (n=1312) with responses from Arab women aged 15 years and above from all Arab countries.

Results: We found that most Arab women feared posting an actual photograph of themselves on their social media accounts and only approximately one-third (490/1312, 37.3%) did so. Most women indicated that they encountered sexual harassment regardless of their age. Furthermore, most women were not aware of the legal aspects of this crime and even those who were aware indicated that they would not press charges for several reasons, including bringing dishonor upon their families, the time-consuming nature of litigation, and fear of revenge.

Conclusions: This study shows that young and less educated women are more vulnerable to abuse from either social media users or being condemned by their families. This has several effects, including lower self-esteem and hesitancy in seeking a job, feelings of mistrust and fear, cynicism, anxiety, depression, and sleep disorders. These issues hold women back from using social media in positive ways and some consider leaving social media.

Introduction

Background

Social media provides women with a variety of platforms to express themselves [1-3] and show their talents, communicate, expand their social relationships, and break the shackles imposed by their societies. Theoretically, social media can play a significant role in developing women's freedom and decreasing social pressures on them [4]; nonetheless, women face high levels of violence on social media, particularly sexual harassment [5-9]. According to an Amnesty International report in 2018 [10], women are subjected to scorn, disrespect, and abuse on the internet, and they encounter a staggering amount of violent or aggressive behavior from their relatives and other individuals. Women in Arab countries use social media with fear and extreme caution. The behavior on the part of others that elicits this fear can be considered violence against women. Moreover, it can be seen as restricting freedom of speech and freedom of thought because of social media's encompassing role that extends beyond entertainment and leisure and into work and political life as well. Therefore, any kind of violence on social media directed against women negatively affects the physical, mental, financial, and social aspects of their lives.

As a phenomenon, violence against women on social media has not been studied sufficiently to understand this kind of violence better, the reasons for it, and the outcomes of that violence across the Arab region, with the majority of studies focusing on individual countries. This study aims to conduct an empirical in-depth analysis to investigate how the digital space negatively impacts women in Arab countries, using questionnaire surveys. We speculate that social media provides men with new opportunities to surveil, restrict, harass, and intimidate women in Arab countries.

Conceptual Framework

The intersection of women, feminism, and technology is addressed in many social science disciplines, particularly media and communications political science, sociology, and philosophy [9,11,12]. In order to examine Arab women's relationship with technology, particularly social media, which theoretically deliberates and empowers women, the dominant feminist approaches must be outlined. However, in this study, the liberal feminist approach will be highlighted to focus on the aspect of women's self-expression. The conceptual framework considers violence against women across social media, a phenomenon that is more emphasized by radical feminists. Besides the two approaches, *liberal feminist* and *radical feminist*, related studies in Arab countries will be considered.

Liberal Feminism and Social Media

The internet, particularly social media, is highly connected to the liberal feminist perspective and ambition. In this context, Megarry argues that "liberal feminism attempts to harness the liberal values of justice, equality, and fairness to fight for women's rights within the patriarchal state system" [9]. The liberal approach looks positively on the role played by technology, including social media, as a way to enhance women's lives. Although women face violence across digital

technologies, they argue that social media can still bolster women's interests and rights [13]. The connection between social media and feminism has been examined in several interdisciplinary studies [14-19], in which researchers highlighted the positive aspects of social media that allow women to engage globally [16], contribute to social movements that reflect feminist goals [20], and expand and raise awareness about issues related to sexism, misogyny [21], inequality, and gendered violence [17]. In a similar context, Crossley argues that social media facilitates understanding of women's issues and enhances feminist ideas across societies [18]. Facebook, Twitter, Snapchat, and Instagram are described as interactive and participatory platforms, which allow for the dissemination of information through the creation, sharing, and consumption of text, audio, and video content [22-24]. From this standpoint, social media enables feminist activists and groups to build and create interactive networks to achieve their goals and shape positive ideas about women and their interests in the face of beliefs and ideas that oppose equality for women.

Radical Feminism and Social Media

The radical feminist perspective tends to view the digital space more negatively, seeing women as exposed to abuse and domination of the male perspective [25-27]. Social media enhances radical feminism, which ideologically becomes fragmented and less geographically bound [28]. In other words, radical feminism as a universal approach has been negatively affected because of social media. Even before the emergence of social media, the radical feminist approach rejected the argument that the developments in technology resulted in positive outcomes for women [29-32] because they believe that social institutions are dominated by men [33] and new technology, including social media, is developed in the interest of men [9]. Many studies emphasize this dark side of social media with relation to women. In this regard, Stubbs-Richardson et al [14] show that women are often pathologized or trolled either on the internet or offline and cyberspace is a sexist and gendered space [14] controlled by the logic of power, ideology, and a market-oriented approach. Other studies argue that social media as a commercial platform aims to generate revenue [34]. Other studies, focused on Tinder and dating apps, show that gendered discourses have implications on hidden harassment and abuse of women [35]. From the radical feminist perspective, women face violence and are pathologized or trolled and exploited by men.

Status of Arab Women

Like all women, Arab women are affected by cultural factors such as religious beliefs, social systems, education, and the media [36]. Religious beliefs play a remarkable role in social and cultural socialization, working to determine women's relationship with others, even within the realm of social media [37]. The education system has also portrayed Arab women negatively, and they are directed to deal with men sensitively and with fear [38]. In turn, this results in a tendency for them to adopt conservative values because they still follow the traditional Arab culture where their relationships are limited. While liberal feminists might argue that, in the age of satellite television channels there is opportunity for openness, Arab

media tends to focus on women's bodies as a commodity and promotes women as key to the labor market and in constructing the family and society. Other studies have found that social media has worked to expand the social circles of Arab women [39]. However, they tend to face high levels of violence, with the Arab League releasing a report that Arab women tend to be faced with a lack of real political participation, education, job opportunities, and health care and are vulnerable to violence as a consequence of regional war and conflict [40]. Similarly, the Economic and Social Commission for Western Asia has released reports that corroborate the Arab League's findings [40]. Overall, there is a lack of studies on violence on social media against Arab women, with these 2 reports failing to address the issue. Hence, this study seeks to examine this issue to understand the present dynamics and identify possible solutions in a better manner.

Research Questions and Hypotheses

On the basis of this literature review and our study objectives, 4 questions and 8 hypotheses were developed.

Research Questions

1. How do Arab women use social media?
2. Do Arab women use social media freely?
3. How do Arab women face sexual harassment via social media?
4. Do Arab women have legal awareness about sexual harassment on social media?

Hypotheses

Along with the research questions shown above, this study tests 8 hypotheses to shed light on the study's underlying arguments.

1. Level of education is positively associated with posting personal photographs on social media accounts.
2. Age is negatively associated with posting personal photographs on social media accounts.
3. Level of education is negatively associated with being condemned for posting a photograph or about a topic on social media.
4. Age is negatively associated with being condemned for posting a photograph or about a topic on social media.
5. Level of education is associated with being sexually harassed via social media.

6. Age is not associated with being sexually harassed via social media.
7. Level of education is associated with legal awareness about sexual harassment on social media.
8. Level of education is associated with willingness to press charges against sexual harassers.

Methods

Methods Overview

This study includes an empirical survey to investigate what Arab women think of the types and causes of violence against them and their perspectives about the impact of that violence. This study used a web-based questionnaire administered through Google Forms (n=1312) with responses from Arab women aged 15 years and older from all Arab countries. The random sampling method is considered one of the best methods since everyone in the research context had an opportunity to participate [41,42]. Consequently, the results represented the population as a whole [43]. Data collection was carried out starting during the last week of October through mid-December 2020. The participants were categorized into five age groups: 15-18 years (134/1312, 10.2%); 19-25 years (608/1312, 46.3%), which was the largest group; 26-35 years (250/1312, 19.1%); 36-50 years (264/1312, 20.1%); and ≥51 years (56/1312, 4.3%). The 19-25-year-old participants comprised the largest group because they are mainly college students, a cohort that actively uses social media. The survey also considered the marital status of the participants. Single women comprised the largest number with 858 (of 1312, 65.4%) participants, married women comprised the second-largest group with 414 (of 1312, 31.6%) participants, and widowed/divorced women comprised the smallest group with 40 (of 1312, 3.0%) participants. The participants were from different educational levels: those who only have reading and writing skills (8/1312, 0.6%), high school students (138/1312, 10.5%), university students (454/1312, 34.6%), those with a bachelor's degree (446/1312, 34.0%), those with a master's or PhD degree (244/1312, 18.6%), and activists (22/1312, 1.7%)—referring to those working in political parties and organizations. The demographic characteristics of the study participants are summarized in Table 1. A Spearman correlation model was used to test the aforementioned 8 hypotheses.

Table 1. Demographic backgrounds of women (N=1312).

Characteristics	Women, n (%)
Age (years)	
15-18	134 (10.2)
19-25	608 (46.3)
26-35	250 (19.1)
36-50	264 (20.1)
≥51	56 (4.3)
Education levels	
Reading and writing skills	8 (0.6)
High school	138 (10.5)
University students	454 (34.6)
Bachelor's degree	446 (34.0)
Master's or PhD degree	244 (18.6)
Activists	22 (1.7)
Marital status	
Single	858 (65.4)
Married	414 (31.6)
Widowed/divorced	40 (3.0)

Procedure for Measuring Hypotheses

The data were analyzed by using SPSS (version 22, IBM Corp). Considering the nature and aim of this study, several questions were presented in the questionnaire to measure psychological violence against Arab women through binary scale (“yes/no”) and triple scale (“yes/no/do not know”) modes. “Do not know” was used for some questions, which we predicted that some of the participants would answer with “do not know” to express their views. Furthermore, a triple scale mode “no/somewhat/yes” was used. The “somewhat” response was included to know how many women face sexual harassment or whether they face it rarely. The second model was a Spearman correlation model with Sig. (2-tailed) *P* values, which was processed in SPSS to test the 8 hypotheses through 2 levels of public engagement.

Table 2. Popular social media platform among Arab women (N=1312).

Social media platforms	Women, n (%)
Facebook	770 (58.7)
Instagram	272 (20.7)
Snapchat	128 (9.8)
TikTok	94 (7.2)
WhatsApp	48 (3.7)

Results

Social Media Use by Arab Women

This section examines the first research question, which asked the women who participated to identify their preferred social media platform. [Table 2](#) shows that the majority (770/1312, 58.7%) prefer Facebook and one-fifth (272/1312, 20.7%) prefer Instagram. The third-most popular platform among Arab women is Snapchat, which was used by 128 (9.8%) participants. As shown in [Table 3](#), the user-friendliness of a social media platform was most important to them, which 808 (61.6%) participants selected as the most important reason they chose their preferred platform. The second-most cited reason was cybersecurity, chosen by 138 (10.5%) participants. This reason is important for Arab women, but the majority of them did not highlight this issue because hacking a social media account is not easy and women tend to use social media cautiously ([Table 3](#)). In total, 122 (9.3%) Arab women use social media for promotions and personal branding.

Table 3. Reasons for using such social media platforms among Arab women (N=1312).

Reasons	Women, n (%)
Cybersecurity	138 (10.5)
User-friendly	808 (61.6)
Most popular	124 (9.5)
Entertainment	120 (9.1)
Useful for promotion and personal branding	122 (9.3)

Freedom of Using Social Media by Arab Women

This section examines the second research question, which looks at the freedom with which Arab women use social media. [Table 4](#) shows that most women are cautious about posting photographs of themselves on their social media accounts and only approximately one-third (490/1312, 37.3%) do so. Approximately half (628/1312, 47.9%) of respondents post general photographs, such as those of a public figure, an image of nature, a city, or text with an image instead. Thus, they feel that they cannot post a photograph of themselves, but still seek to represent their personal identity. [Table 4](#) shows that 180 (13.7%) participants post group photographs of family members that include themselves, which indicates that they would like

to post personal photographs but are under pressure not to do so alone. As shown in [Table 5](#), the main reason expressed by the 726 women who did not post their personal photograph on their social media accounts was fear that it would be misused (488/1312, 67.2%). This represents a major issue for women because they feel that it can affect their reputation. [Table 5](#) shows that 112 (15.4%) respondents claim that they feel ashamed to show their photograph because Arab society is generally conservative, and women cannot express themselves even on social media. Seventy-four (10.1%) women revealed that their families do not allow them to post their personal photographs on social media. Their families fear the misuse of the photograph, which can affect reputation and honor.

Table 4. Types of images on social media accounts of Arab women (N=1312).

Type of image	Women, n (%)
Personal photograph	490 (37.3)
Photograph that contains me and my family	180 (13.7)
Photograph that contains me and my friends	14 (1.1)
General images such as those of a public figure, nature, a city, or a text with an image	628 (47.9)

Table 5. Reasons for not posting personal photographs on social media accounts.

Reasons	Women, n (%)
Fear of misusing my photograph by other people	488 (67.2)
My family does not allow me to post my photograph on my social media account	74 (10.1)
Society and cultural pressure	52 (7.1)
Feeling shameful	112 (15.4)
Total	726 (100)

Sexual Harassment via Social Media

This section examines the third research question, which addresses how Arab women face sexual harassment via social media. As shown in [Table 6](#), at total of 494 (37.7%) participants stated that they encountered sexual harassment, and 508 (38.7%) stated that they somewhat encountered sexual harassment. Less than one-fourth (310/1312, 23.6%) of respondents claimed that

they have not been sexually harassed via social media ([Table 6](#)). Thus, men are given yet another opportunity to engage in violence against women, beyond the public setting, workplace, and at home. Moreover, sexual harassment is often a disturbing experience. Survivors can be subjected to significant harm that not only inflicts emotional distress but also raises substantial problems in their family situations.

Table 6. Sexual harassment of Arab women via social media (N=1312).

Sexually harassed via social media	Women, n (%)
Yes	494 (37.7)
Somewhat	508 (38.7)
No	310 (23.6)

Women's Legal Awareness of Sexual Harassment on Social Media

This section examines the fourth research question, which addresses legal awareness about sexual harassment on social media. Table 7 indicates that only half of the participants (646/1298, 49.8%) were aware that charges could be pressed against sexual harassment on the internet, and 222 (17.1%) were unaware. Approximately all 1264 (98.3%) participants would not take legal action against sexual harassers. As shown in Table

8, half (642/1298, 49.9%) of the participants did not want to take legal action against sexual harassers because they believe that it could affect their reputation. Another reason stated by many women (373/1298, 29%) was that they thought that the process of a sexual harassment lawsuit would take too long. Another 271 (21.1%) participants feared acts of revenge by sexual harassers. These findings indicate that women do not have complete confidence in judicial power and the police to protect them.

Table 7. Perceptions of sexual harassment as a punishable offense and willingness to press charges against harassers (N=1298).

Perception of sexual harassment being a punishable offence	Women, n (%)
Do you think sexual harassers can be punished?	
Yes	646 (49.8)
No	222 (17.1)
Do not know	646 (49.8)
Would you take sexual harassers to court ?	
Yes	22 (1.7)
No	1264 (98.3)

Table 8. Reasons of not pressing charges against sexual harassers among Arab women (N=1286).

Reasons	Women, n (%)
It takes my time in the court	373 (29.0)
It affects my reputation	642 (49.9)
I fear that the accused will take revenge	271 (21.1)

Results of Our Study Hypotheses

This section is focused on testing and interpreting the 8 study hypotheses. The first hypothesis predicted a positive correlation between the level of education of Arab women and posting their personal photograph on social media. Table 9 shows that this hypothesis ($R_s = -0.085$; $P < .001$) is negatively correlated, which implies that women with lower education levels were more likely than those with higher education levels to post their personal photograph on social media.

The second hypothesis predicted that older Arab women were more likely to post the personal photograph on their social media accounts than younger women. This hypothesis ($R_s = -0.134$; $P < .001$) was negatively correlated, similar to the first hypothesis. We assumed that educated and older women would understand and recognize problems such as sexual harassment better than relatively lesser educated and younger women and would therefore be more reluctant to post their photograph on social media.

The third hypothesis predicted that Arab women with higher levels of education would be less likely to face pressure for posting a photograph or a topic on social media than those who are relatively less educated because it is a common prediction that education empowers women to become more independent and respected among families, which this present study confirmed ($R_s = -0.076$; $P = .02$).

The fourth hypothesis predicted that age is negatively associated with being condemned for posting a photograph or topic on social media. This hypothesis ($R_s = -0.053$; $P = .06$) is not confirmed, which implies that Arab women are more likely being condemned for posting a photograph or topic on social media regardless of age.

The fifth hypothesis predicted a positive correlation between the education level of women and being sexually harassed via social media. This hypothesis ($R_s = 0.083$; $P = .04$) was confirmed, which implies that educated women face more sexual harassment via social media. It is assumed that they are more active in the public sphere, have wider relationships, and are more popular than lesser educated women, the latter probably spending more time within their families.

The sixth hypothesis predicted that age is negatively associated with being sexually harassed via social media, which implies that younger women more face sexual harassment. However, Table 9 shows that this hypothesis ($R_s = 0.036$; $P = .003$) was not confirmed, which implies that Arab women are likely to face sexual harassment on social media irrespective of their age. Table 9 shows that 494 (37.7%) participants stated that they encountered sexual harassment, and 508 (38.7%) stated that they somewhat encountered it.

The seventh hypothesis predicted that the education level of women is associated with legal awareness about sexual

harassment on social media, and this hypothesis ($R_s=0-125$; $P<.001$) was confirmed.

The eighth hypothesis predicted that the education level of women is associated with a willingness to press charges against sexual harassers. This hypothesis predicted that educated women have more power and realize that the sexual harassment can be

legally prosecuted and will be more likely to confront their harassers in court. However, this hypothesis ($R_s=0.014$; $P=.62$) was not confirmed because the vast majority of participants (1264/1286, 98.3%) were not willing to press charges against their sexual harassers irrespective of their educational background (Table 7).

Table 9. The Spearman correlation model reports the associations between age and education levels of Arab women with posting their personal photographs on social media, being condemned for using social media, experiencing sexual harassment, and having legal awareness of sexual harassment on social media (N=1312).

Hypothesis	Variables	R_s value	Sig. (2-tailed) P value
1	Level of education is positively associated with posting a personal photograph on social media.	-0.085 ^a	.002
2	Age is associated negatively with posting a personal photograph on social media.	-0.134 ^a	<.001
3	Level of education is negatively associated with being condemned for posting a photograph or topic on social media.	-0.076 ^a	.02
4	Age is negatively associated negatively with being condemned for posting a photograph or topic on social media.	-0.053	.06
5	Education level of women is positively associated with being sexually harassed via social media.	0.083 ^a	.06
6	Age of women is not associated with being sexually harassed via social media.	0.036	.19
7	Education level of women is associated with legal awareness of sexual harassment on social media.	0.125 ^a	<.001
8	Education level of women is associated with willingness to pressing charges against sexual harassers.	0.014	.62

^aThe correlation is significant when R_s values range from -1 to +1.

Discussion

Principal Findings

There is a lack of studies examining the positive and negative aspects of social media in the lives of Arab women [39]. Previous studies at the global level have referred to a number of positive aspects of social media platforms, such as their role in facilitating interaction and participation and disseminating information [22-24]. Other studies have highlighted the positive aspects of social media in boosting the feminist movement [20], understanding women's issues [18], and raising awareness about sexism and misogyny [21]. In this study, only 122 (9.3%) participants indicated that they used social media for promotions and personal branding (Table 3) [44,45]. These positive aspects of social media help women to become entrepreneurs and launch web-based businesses and other positive ventures. Besides this, 120 (9.1%) participants indicated that social media is an entertainment platform for them and social media lets them access global culture, even if they live in a relatively conservative society (Table 3). Fear of image-based abuse, blackmailing, and interference in their private lives were reasons that motivated half of the participants to refrain from posting personal photographs on their social media profiles. For instance, Table 4 indicates that most Arab women were reluctant to post their personal photographs on their social media accounts and only approximately one-third (490/1312, 37.3%) did so. Alternatively, they posted images of local or international celebrities, nature, or family group photographs, which are more difficult to alter or use maliciously. This situation counters the

liberal notion that women can express themselves on social media and use social media as a platform to play influential roles in society [1-3,16]. Even though laws in many Arab countries clearly define harassment on social media as a crime, many women encounter some level of sexual harassment (Table 6) irrespective of their age. Although some women knew that this is a crime (Table 7), they indicated that they would not come forward and press charges against their harassers for several reasons, including bringing dishonor upon their families, the time-consuming nature of litigation, and the fear of revenge.

Limitations

The majority of previous studies have focused on individual Arab countries rather than adopting a regional approach, and have used descriptive rather than data-based approaches. This does not allow for extensive comparison with this study's outcomes. Regarding data collection, doing so in-person across all Arab countries representationally is difficult and costly. This was also prevented by the COVID-19 pandemic in 2020. Therefore, this study adopted a survey method using a web-based questionnaire administered through Google Forms (N=1312) with responses from Arab women aged ≥ 15 years from all Arab countries. More extensive data collection would further improve our results.

Conclusions

This study predicts that women's endurance of the vast majority of sexual harassment without taking legal action against sexual harassers could motivate harassers to continue engaging in abusive behavior. This harms women and creates a climate of

intimidation and repression in social and economic life, particularly among young women, as this study shows that age is negatively associated with being condemned for posting a photograph or topic on social media (Table 9). Conversely, the education level of women plays a positive role in independence within the family. Our third hypothesis predicts that Arab women with lower levels of education might face more pressure for posting a photograph or topic on social media than those with higher education levels. This study found that young women and the relatively lesser educated are more likely to face

abuse. This leads to several issues including lower self-esteem and hesitancy in looking for a job, feelings mistrust and fear, cynicism, anxiety, depression, and sleep disorders. These issues constrain women from using social media and some of them think about disengaging from social media. This issue needs governments' consideration to develop laws to reduce violence and empower women to take legal action. Hence, future studies should address the violence against women with regard to legal and psychological perspectives.

Abstract

Background: The use of social media in communications regarding cancer prevention is rapidly growing. However, less is known about the general population's social media use related to cancer screening awareness and behavior for different cancers.

Objective: We aimed to examine the relationship between social media use and cancer screening awareness and behavior among people without a cancer diagnosis.

Methods: Data were collected from the Health Information National Trends Survey 5 Cycle 1 to 3 in the United States (n=12,227). Our study included 10,124 participants without a cancer diagnosis and 3 measures of screening awareness (those who had heard of hepatitis C virus [HCV], human papillomavirus [HPV], and the HPV vaccine) and 4 measures of behavior (those who had prostate-specific antigen tests, Papanicolaou tests for cervical cancer, as well as breast cancer and colon cancer tests). Propensity-score matching was conducted to adjust for the sociodemographic variables between the social media user and nonuser participants. Multivariable logistic regression was used to assess the association of social media use by gender. Jackknife replicate weights were incorporated into the analyses.

Results: Of the 3794 matched participants, 1861 (57.6% weighted) were male, and the mean age was 55.5 (SD 0.42) years. Compared to social media nonusers, users were more likely to have heard of HCV (adjusted odds ratio [aOR]=2.27, 95% CI, 1.29-3.98 and aOR=2.86, 95% CI, 1.51-5.40, for male and female users, respectively) and HPV (aOR=1.82, 95% CI, 1.29-2.58 and aOR=2.35, 95% CI, 1.65-3.33, for male and female users, respectively). In addition, female users were more likely to have heard of the HPV vaccine (aOR=2.06, 95% CI, 1.41-3.00). No significant associations were found between social media use and

prostate-specific antigen tests in males, Papanicolaou tests and breast cancer tests in females, or colon cancer tests in both male and female users.

Conclusions: While social media services can potentially promote cancer screening awareness in the general population, but they did not improve screening behavior after adjusting for socioeconomic status. These findings strengthened our understanding of social media use in targeting health communications for different cancers.

KEYWORDS

social media; cancer screening awareness; cancer screening behavior; gender-specific effects; propensity-score matching; general population

Introduction

The introduction of screening for early prostate, colorectal, breast, and cervical cancer detection has significantly reduced mortality rates over the past few decades [1]. However, cancer remains the second leading cause of death in the United States [2], and premature cancer deaths resulted in US \$94.4 billion lost earnings among people aged 16 to 84 years in 2015 [3]. Therefore, there is growing concern regarding the low proportion of cancer screening awareness and behavior in the general population and the relative disparities in cancer screening awareness and behavior due to race and ethnicity and socioeconomic status.

A recent National Health Interview Survey reported that the utilization of recommended cancer screenings is far lower than the Healthy People 2020 targets for the nation [4]. However, cancer screening awareness and behavior disparities exist according to cancer types, race and ethnicity, socioeconomic status, and other health care access factors [1,4,5]. For example, from 2005 to 2015, colorectal cancer screenings have increased steadily, but prostate, breast, and cervical cancer screenings have declined [6]. In addition, prostate, cervical, breast, and colon cancer screening rates are lower among Hispanic and Asian groups than non-Hispanic White and Black groups, declining with decreasing education levels [6]. Therefore, new channels for informing target populations are needed to improve the cancer screening awareness and behavior regarding different cancers and reduce the relative disparities.

The use of social media has increased over the past decade and has become a new channel for promoting cancer prevention [7]. Compared to older approaches to cancer interventions with unidirectional and paternalistic outreach barriers, contemporary social media is easy to access, bidirectional, interactive, and patient-driven [7,8]. Social media services are widely used, varied, and continually innovating, offering substantial opportunities for health communication [9]. Given these inherent advantages of social media, there has been rapid growth in the use of different social media services by health care providers and the general population to communicate information regarding cancer prevention, such as basic cancer knowledge, healthy lifestyles, and the importance of cancer screenings.

Previous research on the use of social media in cancer prevention has primarily focused on educational material [7]. In most previous studies, general information regarding cancer screening has been reported as a key component of cancer

prevention education. However, a single study has addressed the detailed descriptions of bowel preparation for colorectal cancer screening [7,10]. Among these studies, cancer screening awareness and behavior for different cancers were not thoroughly examined [7]. Thus, more insight is needed to understand better the effects of social media on peoples' awareness and behavior concerning the screening for different cancers.

Despite the diversity of social media services, the previous studies mainly used specific types of social media, including Facebook, Twitter, and WeChat (a widely used social media app in China) [10-12]. Although one qualitative study reported that Facebook use helped promote breast cancer screening awareness [12], inconsistent effects of different social media services were found for the screening behavior for different cancer types [10,11]. Rosemary et al [11] showed that using Twitter did not improve specific behaviors regarding breast cancer prevention, including screening. In contrast, one study revealed an improvement in colorectal screening behavior through the use of WeChat [10]. However, the discussions are still too limited to provide comprehensive information to determine and compare the effects of social media on cancer screening awareness and behavior for different cancer types.

The variety of evolving social media services makes it necessary to examine how the general use of social media impacts cancer screening awareness and behavior for different cancer types. Moreover, most users of different social media services vary across racial and ethnic minority and socioeconomic groups. Only certain populations were included in previous prevention studies using specific types of social media [7,10-12]. Even less is known about the general population's social media use related to cancer screening awareness and behavior for different types of cancer.

This study aimed to assess how the general use of social media impacted people's cancer screening awareness and behavior for different cancer types in a nationally representative sample of US adults without a cancer diagnosis. In addition, because of the inherent heterogeneity of different cancer types between males and females, the gender-specific effects of social media use were examined. By evaluating social media use in the general population, this study furthers our understanding of the relationship between health communications using social media and health-promoting behaviors.

Methods

Data Sources

This study adopted data from the National Cancer Institute (NCI) Health Information National Trends Survey (HINTS), including HINTS 5 Cycle 1 (2017, n=3285), HINTS 5 Cycle 2 (2018, n=3504), and HINTS 5 Cycle 3 (2019, n=5438). The HINTS is a nationwide survey of noninstitutionalized individuals aged 18 years and older in the United States and has been conducted every 1 to 2 years by the NCI since 2003. It uses a probability-based sampling with a 2-level stratified design, considering areas with high or low concentrations of minorities. Data from the 3 surveys were collected by mail or Web Pilot from January to May 2017, 2018, and 2019, respectively. Data were available in a publicly accessible repository that does not issue DOIs. Publicly available data sets were analyzed in this study. More detailed information on the study design and high-quality HINTS data have been published elsewhere [13]. After excluding those individuals with a cancer diagnosis, 10,124 participants remained. Participants with missing data for any variables were excluded from the final analyses, resulting in a sample of 7090 social media users and 2775 social media nonusers.

Measurements

Social Media Use

Social media use was assessed using all 5 subquestions of the B14 question in the HINTS questionnaire (“Sometimes people use the internet to connect with other people online through social networks like Facebook or Twitter. This is often called ‘social media.’”). The 5 subquestions asked, “In the past 12 months, have you used the internet for any of the following reasons: (1) to visit a social networking site, such as Facebook or LinkedIn; (2) to share health information on social networking sites, such as Facebook or Twitter; (3) to write in an online diary or blog (ie, weblog); (4) to participate in an online forum or support group for people with similar health or medical issues; or (5) to watch a health-related video on YouTube?” The participants answered either “yes” or “no,” and those using social media were defined by a “yes” response to any of the 5 questions.

Cancer Screening Awareness and Behavior

The measures of cancer screening awareness consisted of 3 dependent variables, which were assessed by 3 questions: (1) “Have you ever heard of the hepatitis C virus (also known as Hep C or HCV)?”; (2) “Have you ever heard of HPV?”; (3) “Before today, have you ever heard of the cervical cancer vaccine or HPV shot?” Participants indicated their response with either a “yes” (1) or “no” (0).

Cancer screening behavior measures contained 4 dependent variables defined by 4 questions: (1) “Have you ever had a prostate-specific antigen (PSA) test?” (1=yes; 0=no); (2) “How long ago did you have your most recent Papanicolaou (Pap) test to check for cervical cancer?” (1=I have had a Pap test [a year ago or less, 1 to 2 years ago, 2 to 3 years ago, 3 to 5 years ago, or more than 5 years ago]; 0=I have never had a Pap test); (3) “When did you have your most recent mammogram to check

for breast cancer, if ever?” (1=I have had a mammogram [a year ago or less, 1 to 2 years ago, 2 to 3 years ago, 3 to 5 years ago, or more than 5 years ago]; 0=I have never had a mammogram); (4) “Have you ever had one of these tests, including colonoscopy, sigmoidoscopy, and stool blood test to check for colon cancer?” (1=yes; 0=no).

Due to the differences in the survey content between the different Cycles, the data for HCV were from Cycle 2 (2018) and Cycle 3 (2019), the data for HPV and the HPV vaccine were from Cycles 1 to 3 (2017-2019), the data for PSA testing were from Cycle 1 (2017) and Cycle 3 (2019), the data for Pap and breast cancer testing were from Cycles 1 to 3 (2017-2019), and the data for colon cancer testing were from Cycle 2 (2018) and Cycle 3 (2019).

Sociodemographic Covariates

The sociodemographic characteristics in this study included self-reported measures of gender (male or female), age, race and ethnicity (non-Hispanic White or racial and ethnic minority), education level (high school or less or more than high school), income (less than US \$20,000 or US \$20,000 or more annually), and geographic area (nonmetropolitan or metropolitan). Measurements of the geographic area were obtained by 9 metropolitan codes corresponding to the Rural-Urban Continuum Codes with a range of 1 to 9 [14]. Based on the cutoff points adopted by the United States Department of Agriculture and previous HINTS studies, this study divided the geographic areas into metropolitan (codes 1 to 3) and nonmetropolitan (codes 4 to 9) areas [14-16].

Statistical Analysis

This study compared the sociodemographic characteristics of social media users and nonusers via chi-squared tests for categorical variables and 2-tailed *t*-tests for continuous variables. Propensity-score matched analysis was carried out to adjust the sociodemographic variables between the social media users and nonusers. Confounders used for matching social media users and nonusers included gender, age, race and ethnicity, education, income, and geographic area. Given the gender differences for different cancer types, the differences in cancer screening awareness and behavior were compared by the social media use of males and females. Crude odds ratios (cOR), adjusted odds ratios (aOR), and their 95% CIs stratified by gender were computed using univariate and multivariable logistic regression analyses to clarify the impact of social media use on each dependent variable. This study adjusted the multivariable analyses for potential confounders, including gender, age, race and ethnicity, education, income, and geographic area.

All statistical analyses were carried out using SAS (version 9.4; SAS Institute). Given the complex survey design of the HINTS, jackknife replicate weights were incorporated into the analyses to obtain population-level estimates. The jackknife method creates a set of replicate samples from the original sample and provides an estimate of the variable and its variance of interest [17,18]. A *P*<.05 was considered statistically significant.

Results

Sociodemographic Characteristics and Social Media Use

All percentages, means, and standard errors reported in this section are the weighted values. Among 10,124 participants without a diagnosis of cancer, 50% (n=4103) were male, and the average age was 48 (SD 0.20) years (Table 1). Nearly two-thirds (n=5551, 59%) of the participants were non-Hispanic White, and about one-third (n=2496, 31%) had a high school education or less. The income of about 18% (n=1715) of the

participants was less than US \$20,000 annually. In addition, 14% (n=1246) of the population lived in nonmetropolitan areas. Among the 9868 participants with complete information, 72% (n=7093) used social media. There were statistically significant differences in all sociodemographic characteristics between the social media user versus nonuser participants (all $P<.001$). Compared to social media nonusers, the social media users were more likely to be female (56%, n=1291), tended to be younger (mean age 44 years vs 59 years), non-Hispanic White (n=4129, 61% vs n=1344, 54%), were educated above a high school level (76%, n=5765 vs n=1580, 50%), and were more likely to live in metropolitan areas (n=6298, 88% vs n=2361, 83%).

Table 1. Sociodemographic characteristics for social media users and nonusers. All percentages, means, and standard errors reported in the table are the weighted values.

Characteristics	Total (N=10,124)	Social media use (n=9868)		P value ^a
		Use (n=7093)	Nonuse (n=2775)

Sociodemographics of Participants After Propensity-Score Matching

After propensity-score matching, a total of 3794 (33%) participants (1897 social media users and nonusers each) remained (Table 2). Of those 1864 (58%) were male, 2110

(59%) were non-Hispanic white, 1278 (45%) had a high school education or less, 907 (24%) had an annual income below US \$20,000, and 528 (16%) lived in nonmetropolitan areas. No statistically significant differences between social media users and nonusers were found in any of the sociodemographic characteristics.

Table 2. Sociodemographic characteristics between social media users and nonusers matched by the propensity-score method. All percentages, means, and standard errors reported in the table are the weighted values.

Characteristics	Total (n=3794)	Social media use (n=3794)		P value ^a
		Use (n=1897)	Nonuse (n=1897)

^aChi-squared tests for categorical variables and t-tests for continuous variables.

Cancer Screening Awareness and Behavior by Social Media Use and Gender

Male social media users, compared to nonusers, were more likely to have heard of HCV (n=394, 92% vs n=321, 84%; $P=.02$) and HPV (n=502, 56% vs n=398, 43%; $P=.003$). However, awareness of the HPV vaccine was not significantly different between male social media users and nonusers (n=420, 48% vs n=369, 41%, respectively; $P=.12$). For all 1861 male participants, including both social media users and nonusers, about 815 (49%) had taken PSA tests ($P=.97$), and 488 (55%)

of the social media users had taken colon cancer tests compared to 433 (47%) social media nonusers ($P=.09$; [Table 3](#)).

For the 1933 female participants, the social media users, compared to nonusers, were more likely to have heard of HCV (89%, n=402 vs 75%, n=336; $P<.001$), and HPV (72%, n=683 vs 56%, n=566; $P\le.001$), and HPV vaccine (72%, n=664 vs 58%, n=577; $P\le.001$). In addition, 97% (n=913) social media users and 94% (n=921) nonusers had taken Pap tests ($P=.31$), 87% (n=849) social media users and 85% (n=874) nonusers had taken breast cancer tests ($P=.43$), and 66% (n=514) social media users and 64% (n=479) nonusers had taken colon cancer tests ($P=.61$).

Table 3. Differences in cancer screening awareness and behavior by social media use and gender. All percentages, means, and standard errors reported in the table are the weighted values.

Characteristics	Social media use					
	Male (n=1861)			Female (n=1933)		
	Use (n=941)	Nonuse (n=920)	P value ^a	Use (n=956)	Nonuse (n=977)	P value
Awareness						
Heard of HCV ^b (yes), n (%)	394 (91.7)	321 (83.5)	.02	402 (89.3)	336 (75.0)	.002
Heard of HPV ^c (yes), n (%)	502 (56.4)	398 (43.4)	.003	683 (72.3)	566 (55.5)	<.001
Heard of HPV vaccine (yes), n (%)	420 (48.0)	369 (40.5)	.12	664 (71.7)	577 (57.7)	<.001

Impact of Social Media Use on Awareness and Behavior of Cancer Screening

Table 4 reports the relationship between social media use and cancer screening awareness and behavior in male and female participants presented by weighted analyses. Male social media

users were more likely to have heard of HCV (cOR 2.17, 95% CI 1.25-3.77; aOR 2.27, 95% CI 1.29-3.98) and HPV (cOR 1.68, 95% CI 1.20-2.36; aOR 1.82, 95% CI 1.29-2.58) compared to nonusers. No statistically significant effects of social media use on awareness of the HPV vaccine and taking PSA tests or colon cancer tests were observed in males.

Table 4. Univariate and multivariable logistic regression assessing the impact of social media use on cancer screening awareness and behavior. Weighted analyses are presented.

Characteristics	Male (n=1861)				Female (n=1933)			
	cOR ^a (95% CI)	P value	aOR ^b (95% CI)	P value	cOR (95% CI)	P value	aOR (95%CI)	P value
Awareness								
Heard of HCV ^c	2.17 (1.25-3.77)	.007	2.27 (1.29-3.98)	.005	2.80 (1.57-4.99)	<.001	2.86 (1.51-5.40)	.002
Heard of HPV ^d	1.68 (1.20-2.36)	.003	1.82 (1.29-2.58)	.001	2.10 (1.53-2.87)	<.001	2.35 (1.65-3.33)	<.001
Heard of HPV vaccine	1.35 (0.92-1.98)	.12	1.42 (0.98-2.06)	.07	1.85 (1.34-2.57)	<.001	2.06 (1.41-3.00)	<.001

Had Pap ^f Test	N/A		N/A		1.72 (0.57-5.19)	.33	1.54 (0.58-4.10)	.38
Had breast cancer test	N/A		N/A		1.20 (0.76-1.88)	.43	1.06 (0.70-1.60)	.78
Had colon cancer test	1.38 (0.95-2.02)	.09	1.58 (0.98-2.54)	.06	1.08 (0.80-1.45)	.62	1.24 (0.88-1.74)	.21

^acOR: crude odds ratio.

^baOR: adjusted odds ratio.

^cHCV: hepatitis C virus.

^dHPV: human papillomavirus.

^ePSA: prostate-specific antigen.

^fPap: Papanicolaou.

Female social media users were more than twice as likely to have heard of HCV (cOR 2.80, 95% CI 1.57-4.99; aOR 2.86, 95% CI 1.51-5.40), HPV (cOR 2.10, 95% CI 1.53-2.87; aOR 2.35, 95% CI 1.65-3.33) or the HPV vaccine (cOR 1.85, 95% CI 1.34-2.57; aOR 2.06, 95% CI 1.41-3.00) compared to nonusers. There was no statistically significant impact of social media use on taking Pap tests, breast cancer tests, and colon cancer tests.

Discussion

Principal Results

Our study conducted a comprehensive evaluation of the effects of general social media use on cancer screening awareness and behavior among US adults without a cancer diagnosis. Although the impact of social media on screening awareness varied across different cancer types and genders, we showed social media could promote cancer screening awareness in the general population. However, it did not improve screening behavior after adjusting for race and ethnicity and socioeconomic status. In light of the growing use of social media by health care providers and the general population, the findings of this study can contribute to targeted messaging for cancer prevention and reduce disparities between the different groups.

After matching and controlling for sociodemographic characteristics, we found that the general social media use had a significant impact on the awareness of HPV in both male and female adults. In contrast, its effect on HPV vaccine awareness was only significant in female adults. Similar to an online cervical cancer prevention study, HPV awareness can be increased through social media [19]. Persistent infection with specific HPV subtypes accounts for almost all cervical cancers in women, practically all anal cancers (over 9 out of 10), most vaginal, oropharyngeal, vulvar, and penile cancers (between two-thirds and three-quarters), and some oral cavity and laryngeal cancers in both men and women [20]. In addition to cervical cancer, most HPV-associated cancers could be reduced by current vaccines [20]. Hence, HPV vaccination is recommended for both males and females at specific ages. The American Cancer Society suggests that all children aged 11 or 12 years should be vaccinated against HPV infections. HPV vaccination with Gardasil 9 (Merck) has been approved for men and women aged 26 to 45 years by the United States Food and Drug Administration since 2018 [1,21]. An Australian study suggested that Twitter-derived measures of information exposure were associated with HPV vaccine coverage for both adolescent males and females [22]. Hence, in addition to communicating about HPV vaccination and cervical cancer prevention, social media can provide additional health information about other HPV-associated cancers and target the male population.

A significant impact of social media use on HCV awareness was also found for both male and female adults in this study. A southeast Michigan study on health disparities in hepatitis C revealed a suboptimal impact of multiple sociodemographic factors on hepatitis C screening and care [23]. Through the internet and a personal health record training program, health-related internet use increased among low-income patients with HCV, and their self-efficacy and patient activation were

also improved [24]. As a patient-driven internet service, social media emerges as a tool linking the general population with HCV awareness. However, its impact on improving hepatitis C screening and care among specific groups at high risk of HCV requires further research.

Social media use did not significantly impact cancer screening behavior, including taking PSA tests in male adults, Pap tests and breast cancer tests in female adults, or colon cancer tests in both male and female adults. In contrast, previous studies regarding specific social media services in the United States or China showed inconsistent effects of social media on cancer screening behavior [10-12]. These results may be due partly to misinformation in cancer communications commonly shared via social media.

There are increasing concerns about misleading or inaccurate medical science information on social media [25-27]. For example, a recent study on the accuracy of genitourinary malignancy articles shared on social media showed inaccurate and misleading articles were shared at a significantly higher rate on average than accurate articles, and 1 in 10 articles about PSA testing contained misinformation [28].

In addition, a lack of consensus on the clinical use of cancer screening and treatment may cause unnecessary panic when shared via social media. The so-called gray area of PSA testing with a high rate of false positives has resulted in its questionable clinical usefulness in Italy [29]. Prostate cancer tends to develop slowly, and its overdiagnosis and overtreatment are controversial [30]. Overdiagnosis and overtreatment have the potential for unnecessary side effects, including physical and psychological harms. The decrements in quality of life from side effects may offset some of the gains in length of life obtained from screening [31,32].

Given that social media amplifies scientific information and misinformation [25], a Japanese study [33] has revealed the information war for and against cancer screening messages has begun online. Therefore, accurate information with more engagement from scientists or professional institutions on social media is urgently needed to prevent misinformation about cancer screening from expanding and to achieve the screening target rates recommended in Healthy People 2030. In addition, collaboration with celebrities diagnosed with cancer may trigger substantial social media interest compared to traditional efforts for raising cancer screening awareness and affect screen behaviors, allowing health care providers to leverage social media methods like celebrities.

In terms of routine cancer care, PSA or colon cancer tests for males and Pap tests and breast cancer tests for females are part of routine check-ups. However, it may not be easy to change the behavior of people with negative perceptions regarding cancer screenings. As several HPV vaccine studies have pointed out, prior exposure to negative information was correlated with the later expression of negative opinions [34], and among Twitter users in Canada, the United Kingdom, and Australia, those with negative or opposing views about vaccinations were more likely to be better connected than those with positive views [35], leading to more barriers to improving routine cancer screening. As for cancers and tests that are not part of routine

care, such as skin cancer [31], social media could be used to increase prior exposure to positive views for targeted populations to raise screening rates.

The findings in this study also suggest that among social media users, increased health information awareness did not lead to increased cancer screening behavior. The gap between “knowing” and “doing” in cancer screening behavior may be associated with the social characteristics of social media. Vaterlaus et al [36] reported a significant impact of social media on diet and exercise, which are commonly shared on social media. Compared to diet and exercise, health communication about cancer screening targets relatively small groups and has less engagement. Breast Cancer Awareness Month and associated events on Twitter revealed that a strategic communication plan calls for ongoing social media conversations on breast cancer and screening mammograms to help increase breast cancer screening rates [11].

The reach of social media is substantial, and the demographics of health-related users vary across different social media platforms [37]. It is valuable to promote cancer screening through various social media platforms according to the demographics of their health-related users to increase cancer screening rates for certain socioeconomic groups and hard-to-reach populations. Combined with ads targeted toward specific audiences, social media platforms could provide potentially innovative and effective ways to communicate positive health information.

Limitations

This study had several limitations. First, this study was based on the general use of social media rather than health-related use, which may result in measurement errors. Given the wide

use of social media, it is difficult to separate health communications from the general use of social media. For instance, COVID-19 dominated social media communications at the beginning of 2020. Furthermore, the degree of social network use (eg, frequency and duration) was not quantified, and thus, the time-dependent effects of social media use could not be measured. Second, this study defined the use of Pap tests and breast cancer tests via “yes” or “no” responses among all the participants, without considering the recommended screening frequency by age. Moreover, the patterns of social media use vary across different age groups. Further studies on the effects of social media use on the frequency of cancer screening awareness and behavior at different ages should be conducted.

Conclusions

This study identified the association between social media use and cancer screening awareness and behavior among people without a cancer diagnosis after matching and controlling for sociodemographic factors. Social media use was associated with HPV and HCV awareness among both male and female participants, and the awareness of the HPV vaccine among female participants. No significant correlation was observed between social media use and screening behavior, including PSA, Pap, breast cancer, or colon cancer test-taking. This study provided a comprehensive assessment of the association between general social media use and cancer screening awareness and behavior for different types of cancer in the general population. Our study suggests that health communication using social media can effectively impact the awareness of specific cancers. Still, a more innovative and targeted approach is needed, including accurately delivering messages to hard-to-reach populations and improving specific screening behaviors.

Abstract

Background: Web-based social media provides common people with a platform to express their emotions conveniently and anonymously. There have been nearly 2 million messages in a particular Chinese social media data source, and several thousands more are generated each day. Therefore, it has become impossible to analyze these messages manually. However, these messages have been identified as an important data source for the prevention of suicide related to depression disorder.

Objective: We proposed in this paper a distant supervision approach to developing a system that can automatically identify textual comments that are indicative of a high suicide risk.

Methods: To avoid expensive manual data annotations, we used a knowledge graph method to produce approximate annotations for distant supervision, which provided a basis for a deep learning architecture that was built and refined by interactions with psychology experts. There were three annotation levels, as follows: free annotations (zero cost), easy annotations (by psychology students), and hard annotations (by psychology experts).

Results: Our system was evaluated accordingly and showed that its performance at each level was promising. By combining our system with several important psychology features from user blogs, we obtained a precision of 80.75%, a recall of 75.41%, and an F1 score of 77.98% for the hardest test data.

Conclusions: In this paper, we proposed a distant supervision approach to develop an automatic system that can classify high and low suicide risk based on social media comments. The model can therefore provide volunteers with early warnings to prevent social media users from committing suicide.

deep learning; distant supervision; mental health; crisis prevention

Introduction

Background

Mental disorders have become a serious problem worldwide, with over 264 million people experiencing depression disorders [1]. A recent large-scale survey in China showed that the lifetime prevalence of depression and anxiety is 6.9% and 7.6%, respectively [2]. Depression is a leading cause of disability worldwide and contributes greatly to the global burden of diseases [3]. Suicide is the most serious consequence of depression [4]. The latest World Health Organization report showed that close to 800,000 people die by suicide every year. Furthermore, for each suicide, there are more than 20 suicide attempts. Suicides and suicide attempts have a ripple effect that impacts families, friends, colleagues, communities, and societies [5]. Stopping suicides before they are successful is a top priority. With the widespread popularity of the internet and the lack of immediate support in life, people are more inclined to express their emotions—even suicidal thoughts—in web-based communities, such as Weibo (Sina Corporation) and Twitter. Social media users favor these communities due to the anonymity and real-time advantages that they provide [6]. The data from web-based communities are huge in quantity, and it is difficult to analyze these data manually.

Traditional suicide risk assessment studies mainly conduct psychological tests, interviews, and questionnaires, which cost a lot of money. If computer technology can be used to assist suicide risk assessments, we can greatly improve the coverage and efficiency of screening and therefore reduce the number of suicide attempts. In recent years, many deep learning methods have been used for text sentiment analysis. However, these methods require large amounts of labeled data. With regard to the topic of our study, several thousands of comments are generated every day, but only a few (typically, less than 10) are indicative of high suicide risk. It is very time consuming to label so much data, and analyzing low and high suicide risk requires professional knowledge and special training.

In this context, we propose a distant supervision model to reduce the workload of domain experts. We integrated interesting scientific findings from the psychology field into our model. We developed a system that requires no manual annotations and takes into account the feedback of experts to better classify people's suicide risk levels based on the textual comments published on a Chinese social media platform. To avoid expensive manual data annotations, we used a knowledge graph method to produce approximate annotations, which provided a basis for building a deep learning model. The learning model was further refined by interactions with people with different experiences in psychology (beginners and experts) to generate our three data sets—the free annotation (zero cost), easy annotation (labeled by psychology students), and hard annotation (labeled by psychologists) data sets. We built the following three progressive models to fit these data sets: a bidirectional encoder representations from transformers (BERT)-based model, a fine-tuning model, and the psychology+ model. We obtained a precision of 80.75%, a recall of 75.41%, and an F1 score of 77.98% for the hard annotation data set, which was the

hardest data set among the three data sets. This system reports on suicide risk assessments to volunteers from the Tree Hole Rescue Team [7] for web-based crisis prevention in China.

We first introduce the background of our research and discuss related work in the *Introduction* section. In the *Methods* section, we describe the task and introduce our workflow. In the *Results* section, we describe our data sets and a series of experimental results to prove the performance of our method. In the *Discussion* section, we summarize a series of open problems in this study and put forward some thoughts on future research directions. We summarize the whole paper in the final *Conclusion* section.

Related Work

Distant Supervision

Distant supervision is a method for using prior knowledge to generate noise labels (data containing wrong labels), which can help with avoiding a lot of manual labeling. In 2009, Mintz et al [8] first proposed the distant supervision method and used it for relation extraction. They generated a large amount of noise labels by mapping an existing knowledge base to rich unstructured text. Thus, they were able to train a good relationship extractor. Some sentiment classification methods also involve the distant supervision method. Go et al [9] proposed a method for automatically classifying sentiment in Twitter messages. They first used the emoticons in the text to generate labels and then used machine learning algorithms for classification. Purver and Battersby [10] and Suttles and Ide [11] used emoticons and hashtags or emojis in Twitter data to generate noise labels. Sahni et al [12] used half of a data set for comparisons with a baseline model and achieved a 2% to 3% higher accuracy than the baseline model. Camacho-Collados et al [13] proposed a simple, distant, supervision-based postprocessing step for using noisy, user-generated text to learn cross-lingual embeddings. They used English data to train classifiers for other languages. Purver and Battersby [10] used tag symbols and topic tags as weak tag training models. Without human intervention, the models were used to detect multiple types of emotions in Twitter messages. Mohammed et al [14] proposed a novel distant supervision technique for automatically gathering noisy topic category annotations from topically focused streams.

Most related research is based on the same annotation standard and eliminates the differences between different data through distance supervision. In our study, different levels of annotators (from nonprofessional to professional) provided different standards. Our method can be used with different levels of annotators (from basic algorithms to domain experts) to train models and obtain performance improvements to deal with real scenarios.

Deep Learning-Based Text Sentiment Analysis

Text sentiment analysis is the task of detecting sentiment information contained in text through a computer program. A basic task in sentiment analysis is classifying the polarity of a given text, that is, whether the expressed opinion in the text is positive, negative, or neutral. In advanced cases, polarity can refer to emotional states such as anger, sadness, and happiness.

Sentiment analyses have been applied in marketing, customer service, and clinical medicine. Different from classical text sentiment analysis, our task of classifying high and low suicide risk on the basis of a given text was mainly based on whether users had decided a specific suicide method and a determinate suicide plan. Negative polarity and the emotional states of sadness and anger unnecessarily imply a high risk.

In recent years, many deep learning methods have been used for text sentiment analysis. Kim [15] used the word2vec method to convert sentences into sentence vectors and input the vectors into a convolutional neural network for sentiment analysis and question classification. Kalchbrenr et al [16] designed a dynamic convolutional neural network for binary and multi-class sentiment prediction. The model can handle input sentences of different lengths and can explicitly capture short and long relationships. Dieng et al [17] proposed a recurrent neural

network for the sentiment analysis of movie reviews, which could capture the long-term dependency of text sentiment analysis. However, these methods all use word embedding for word vector representation, which cannot solve the problem of polysemy in reality. In 2018, Devlin et al [18] proposed a BERT-based, pretrained language model for dynamically obtaining encoded word vectors according to context. The BERT-based, pretrained language model uses a bidirectional transformer [19] as a feature extractor. Compared to traditional word embedding methods, such as Word2Vec [20-22] and Glove [23], the BERT method is better for capturing the representation of word and sentence levels. The BERT model is one of the most state-of-the-art pretraining models. Our final model was modified based on BERT, integrated the psychology features (Textbox 1) of users, and provided a more comprehensive suicide risk detection system.

Methods

Study Design

As previously mentioned, the information for classifying high and low suicide risk in our task is different from those used in the classical sentiment analysis tasks. In this study, to avoid the high cost of creating manually annotated data, we used a distant

supervision approach that does not require manual annotations. Domain experts can use this approach to provide a small amount of annotations, which provides a basis for further improving a model by taking into account the experts' feedback. The flowchart of our method is shown in [Figure 1](#).

The method was divided into two parts—automated annotation generation (via the knowledge graph rules in Figure 1) and deep learning–based classification (the three models in Figure 1).

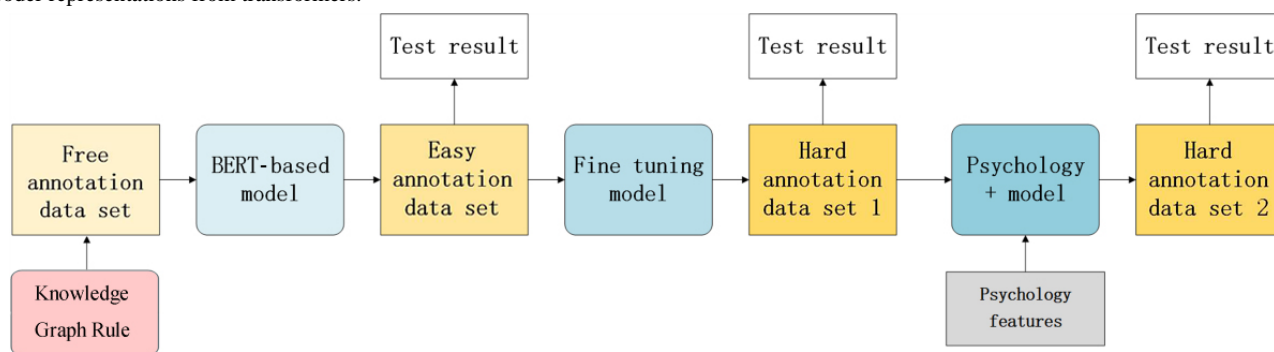

For automated annotation generation, a set of semantic rules was constructed based on an ontology for the field of crisis prevention to generate the free annotation data set. These automated (possibly erroneous) annotations were then used to supervise the deep learning models.

We then build a BERT-based model based on the free annotation data set. This model was used to classify new texts that were further corrected by psychology students to generate the easy annotation data set. This data set had comparable amounts of high and low crisis risk data. It should be noted that without the assistance of a computer algorithm, it would have been a massive challenge for humans to provide such a balanced data set because the percentage of high-risk messages was quite low,

as mentioned above. We used the easy annotation data set to fine-tune this basic learning model and develop the fine-tuning model, which took into account the knowledge in the easy annotations. In parallel, a psychology expert assisted with providing the hard annotation data set, which is of much smaller size than the easy annotation data set due to its cost. Finally, we improved our model by using the hard annotation data set and extra psychology features to obtain the final psychology+ model.

Our models continually fitted 3 data sets. These three data sets were labeled by psychology practitioners of different levels. As the standards for the labeling process gradually became stricter, the models became more accurate. The final model (psychology+ model) combined the prior knowledge obtained from the precedent models and fused prior domain knowledge. Improved performance was achieved under the premise of using a small amount of manually annotated data.

Figure 1. Flowchart of our method. As the labeling process became stricter, we continued to improve our model's performance. BERT: bidirectional encoder representations from transformers.

Task Definition

Given a textual sentence (*s*) published on a web-based media platform by a user (*u*), our task was to predict if the user (*u*) has a high suicide risk. If this is the case, a crisis intervention will be provided to save the user’s life. This is a challenging task, and even a person with professional knowledge has to be careful to avoid mistakes. Furthermore, the huge amount of comments produced daily makes manual analysis impossible and costly.

With regard to the definitions of high and low risk, Huang et al [24] proposed a grading standard based on the certainty of planned suicide methods and the urgency of the action, thereby obtaining 10 risk levels, as shown in Textbox 2. We defined level 6 and above as “high risk” and the rest as “low risk.” Furthermore, social media may contain a lot of irrelevant comments. Therefore, we created level 0 and defined it as “no risk.”

Textbox 2. Suicide risk levels and judgement criteria.

Knowledge Graph and Reasoning Rules

We created a knowledge graph that was used to construct a free annotation data set. The Tree Hole knowledge graph contains four independent ontologies—the suicide ontology, time ontology, space ontology, and wish ontology. The suicide ontology consists of two major categories—suicide methods (eg, cutting the wrist and burning charcoal) and suicide plans (eg, buying drugs and meeting with suicide partners). The time

ontology covers absolute time concepts, such as calendar days and holidays, and relative time concepts, such as the present, future, and past. The space ontology describes related concepts of spatial geography. The wish ontology was mainly used to analyze the subjective suicidal wishes of a specific group of people and to exclude them from people without subjective suicidal wishes. An excerpt of the Tree Hole knowledge graph can be found in [Figure 2](#).

Figure 2. An excerpt of the Tree Hole knowledge graph.

Once the knowledge graph was created, we constructed prolog rules based on the definite clause grammar (DCG) and DCG transformation rules. To take into account the domain knowledge for reasoning and determining the risk level, the DCG rules integrate the relevant conceptual information from the Tree Hole knowledge graph. For example, the definition for suicide risk level 8 is that the suicide plan has been determined and the suicide date has been roughly determined. This can be formally

described by the logic program rules in [Textbox 3](#), which use two predicates—*rdfsSubClassOf* and *uninterestedText*. The predicate *rdfsSubClassOf* was used to decide if a textual fragment mentions some sort of suicide method (or time) concept of *suicideOntology* (or *timeOntology*) in the Tree Hole knowledge graph, and *uninterestedText* was used to verify that such a mention was not negated by a negative expression in the text. More details can be found in other studies [24,25].

BERT-Based Model

We used the data set generated by Tree Hole knowledge graph method to build the BERT-based model. We used BERT to obtain sentence vectors from free annotation data. The size of each sentence vector was 768 dimensions. We added a dropout function to this sentence vector to avoid overfitting. Afterward,

we added a fully connected layer to classify comments that were indicative of high and low suicide probabilities. We used the sigmoid function as the activation function of the output layer. The parameters of the BERT layer and the fully connected layer participated in the training at the same time. The architecture of model 1 is shown in [Figure 3](#).

Figure 3. Architecture of our BERT-based model. BERT: bidirectional encoder representations from transformers .

Fine-Tuning Model

We used BERT-trained (the first model) to obtain 768D sentence vectors from the easy annotation data set. We added 3 fully connected layers to the sentence vectors. The input and output of the first 2 fully connected layers had 768 dimensions, and we used the ReLU function [26] as their activation function.

We also added a dropout function and batch normalization function [27] after each activation function to prevent overfitting. We used the sigmoid function as the activation function of the output layer. Different from the first model, the fine-tuning model did not train the BERT layer but only trained the previous fully connected layer. The structure of model 2 is shown in Figure 4.

Figure 4. Architecture of our fine-tuning model. BERT: bidirectional encoder representations from transformers.

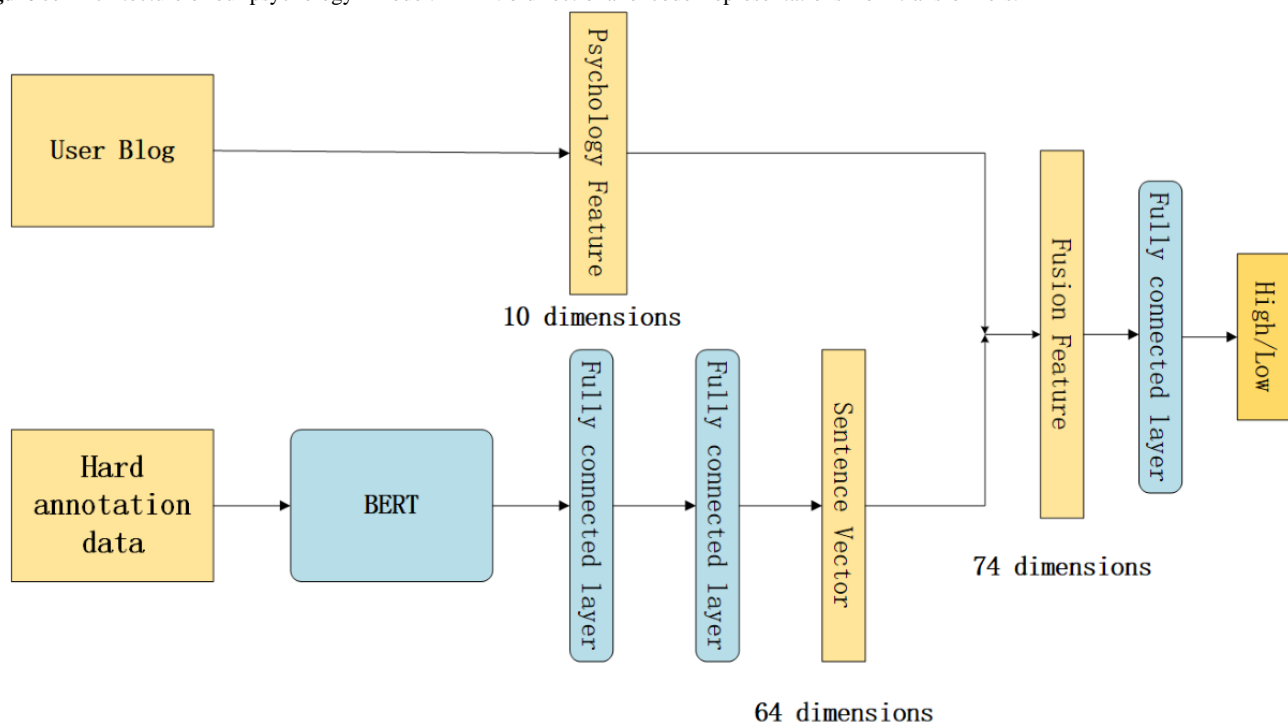

Psychology+ Model

This model combined deep learning and psychology features. According to a psychology study, people with a high suicide risk have a higher degree of self-concern than those with a low suicide risk, that is, they may be more focused on themselves rather than their surroundings [28]. Social network behaviors can reflect individuals' personality traits [29]. Gosling et al [30] found that people with extraverted personality traits use social networks more frequently, have higher engagement, and are more active compared to introverts. To take advantage of these scientific findings, we built the psychology+ model, as described below.

We analyzed the 10 psychology features defined in Textbox 1. According to psychological research, people with a high and

low suicide risk have significantly different behaviors with regard to these 10D features [28-32]. We further analyzed and obtained Weibo users' psychology features and integrated them into our final model. These 10 features were represented as a 10D vector. Afterward, we used the BERT-trained model (the first model) to obtain 768D sentence vectors from hard annotation data. We used 2 fully connected layers to reduce the sentence vector to 64 dimensions. Our choice of using a 64D vector was based on experiments. We experimented with 256, 128, 64, 32 dimensions, and the best results were obtained with 64 dimensions. We combined the 64D sentence vector and 10D psychological feature vector to form a 74D vector. Finally, we used the fully connected layer as a classifier and the sigmoid function as the activation function to classify high and low suicide risk. This model structure is shown in Figure 5.

Figure 5. Architecture of our psychology+ model. BERT: bidirectional encoder representations from transformers.

Results

Data Set

In this study, data were obtained from the comments of the Zoufan Weibo account [33]. In addition, we performed the following preprocessing methods for the data sets: the removal of duplicate data, the removal of meaningless emojis, and the removal of too short sentences (≤ 5 words). As previously explained, we constructed the following four data sets (our annotation data sets can be made available upon request for research purposes):

- the free annotation data set, which was generated by using knowledge graph method
- the easy annotation data set, which was labeled by a psychology student
- hard annotation data sets 1 and 2, which were labeled by a psychologist

These data sets were used to train and test our models. The data distribution can be seen in Table 1.

For the psychology+ model, the psychology features were extracted from each user’s Weibo page [34].

Table 1. Comment distributions in each data set.

Data set	Comments indicating a high suicide risk, n	Comments indicating a low suicide risk, n
Free annotation data set	3630	3220
Easy annotation data set	6659	8657
Hard annotation data set 1	813	645
Hard annotation data set 2	599	601

Evaluation

We evaluated the three learning models that were built based on the automatically generated annotation data set. We found that the free and easy annotation data sets resulted in a simple classification task that could be solved well by the BERT-based model and the fine-tuning model, respectively. However, the hard annotation data set resulted in a much harder task for which our psychology+ model could achieve a promising performance.

Experimental Setup

For the basic BERT-based model, we used the pretrained Chinese model released by Google. The model uses a 12-layer transformer with about 110 million parameters. The optimizer

uses the Adam method [35], and the learning rate was set to 0.00002. The maximum length of inputted characters is 128. The batch sizes of the training set, validation set, and test set were 8, 16, and 16, respectively. At the fully connected layer, the dropout was set to 0.1. We built our model by using a GTX 2080Ti graphics processing unit, and the deep learning framework we used was PyTorch [36]. In the evaluation experiments, we used F1 scores, precision, recall, and the accuracy of high-risk classifications as the evaluation metrics. The F1 score is the harmonic mean of precision and recall, and it was the most important evaluation metric in our study.

Evaluation of the BERT-Based Model

We performed fivefold cross-validation for 6850 comments (3630 comments indicating a high suicide risk and 3220 indicating a low suicide risk; [Table 1](#)) and thus obtained 5480 comments for training and 1370 comments for testing. We report in [Table 2](#) the evaluation results of the model that was based on the free annotation data set and the easy annotation data set.

We found that the values of all evaluations metrics for the free annotation data set were higher than 0.98. This shows that this simple model can simulate the knowledge graph-based approach well. The model's performance based on the easy annotation data set was lower, particularly in terms of precision (0.9899 vs 0.8367), indicating that the model needs further improvement to analyze behavior just as well as psychology students for the annotation task.

Table 2. Bidirectional encoder representations from transformers-based model.

Data set	F1 score	Precision	Recall	Accuracy
Free annotation data set	0.9864	0.9899	0.9829	0.9862
Easy annotation data set	0.9111	0.8367	0.9998	0.9151

Evaluation of the Fine-Tuning Model

According to the fivefold cross-validation, we separated 15,316 comments (6659 comments indicating a high suicide risk and 8657 indicating a low suicide risk; [Table 1](#)) into the training set or the test set, which contained 12,252 and 3064 comments, respectively. We also evaluated the performance of the model based on hard annotation data sets 1 and 2.

The results can be seen in [Table 3](#). Clearly, by fine-tuning the model, the performance of the model improved (compared to the BERT-based model) in terms of F1 score (0.9111 vs 0.9214), precision (0.8367 vs 0.9241), and accuracy (0.9151 vs 0.9218). However, the recall value dropped a little bit (0.9998 vs 0.9282).

In contrast to the performance of the model based on the easy annotation data set, the results for the 2 hard annotation data sets were unsatisfactory (<0.6 in most cases). This meant that the model needed further improvement. Intuitively, we could have performed a similar fine-tuning process with the hard annotations. However, as seen in [Table 1](#), the hard annotation data sets were much smaller than the easy annotation data set. This was due to the high cost of the hard annotations. Therefore, we created the psychology+ model by taking into account certain psychological knowledge in order to avoid the requirement of large amounts of annotated data.

Table 3. Fine-tuning model.

Data set	F1 score	Precision	Recall	Accuracy
Easy annotation data set	0.9214	0.9241	0.9282	0.9218
Hard annotation data set 1	0.7281	0.5815	0.9734	0.5942
Hard annotation data set 2	0.6753	0.5131	0.9877	0.5239

Evaluation of the Psychology+ Model

According to fivefold cross-validation, we separated 1458 comments (813 comments indicating a high suicide risk and 645 indicating a low suicide risk from hard annotation data set 1; [Table 1](#)) into the training set or the validation set, which contained 1167 and 291 comments, respectively. Hard

annotation data set 2 was reserved mainly for testing. We report the evaluation results for these two hard annotation data sets in [Table 4](#). We obtained an accuracy of 78.68% for hard annotation data set 2. Compared to the fine-tuning model, the F1 score of the psychology+ model based on hard annotation data sets 1 and 2 improved by 7.88% and 10.45%, respectively.

Table 4. Psychology+ model.

Data set	F1 score	Precision	Recall	Accuracy
Hard annotation data set 1	0.8069	0.8067	0.8072	0.8105
Hard annotation data set 2	0.7798	0.8075	0.7541	0.7868

Discussion

Principal Findings

Summary of Findings

In this study, we examined three types of annotation data sets—the free annotation, easy annotation, and hard annotation data sets. As seen in [Table 2](#) and [Table 3](#), free annotations and easy annotations can be generated by deep learning models of

high quality. Even though we achieved promising results from the hard annotation data sets, the quality of the results is still imperfect. Indeed, our task was exposed to some challenges due to several characteristics of the data.

We consider the F1 score to be the most important evaluation metric. In follow-up work, we will invite more volunteers to manually evaluate our model based on actual situations.

Obscure Expression

With regard to the two sentences in [Figure 6](#), without considering the context of the task, neither of these two statements are indicative of a high risk of suicide. However, due to the nature of our data source, both sentences were classified as high risk by psychological experts. The first sentence expresses the result of someone cutting their wrist, but

in terms of our context, the sentence was used to comment on a suicide attempt (cutting wrist), indicating that the attempt has been taken. Therefore, a prevention intervention should be provided. The second sentence is about making an appointment with other people to die together. In the context of our data source, it can be considered that the date of the suicide was about to be determined, resulting in a high risk level of between 7 and 8.

Figure 6. Examples of comments that express a high suicide risk in an obscure way.

别割了，很疼的，又死不了
Don't cut yourself. It hurts and you won't die.

去哪个城市一起?
Which city shall we go together?

Ultrashort Text

Short texts can also indicate a high suicide risk. For example, for the three short sentences in [Figure 7](#), the first two are indicative of a low suicide risk, but the third is indicative of a high suicide risk. This is because the first two expressions

indicate that the plan is still under consideration. However, the third indicates that the plan has been restricted to two possible suicide methods. Such ultrashort texts are difficult to classify, and successful classification needs the combination of more specific context and domain knowledge.

Figure 7. Ultrashort texts that are indicative of different suicide risk levels.

跳楼?
Jump off the building?

烧炭?
Burn charcoal?

跳河还是跳楼呢?
Jumping into the river or jumping off the building?

Long Text With Contradictions

Some people express their feelings by telling their own stories, as illustrated by the examples given in [Figure 8](#). These long,

contradictory, redundant, and possibly incomprehensible expressions and sentences also make classification difficult.

Figure 8. Examples of long texts for which the suicide intention level is hard to capture.

天天在耳边听着想死两个字。我真的也熬不住了。明知道一个是无病呻吟，一个是真的想死...可是就是忍不住的烦，忍不住就想离开，想死。但是现实却又一切是那么美满，让我不能死，不敢死。怕让那些看重我的人伤心难过，我不能自私白发人送黑发人，但是又真的熬不住觉得自己活着就是个过错没活着的意义。
Every day I heard the words "going to die" in my head. I really can't take it anymore. I know that on the one side, I am moaning about imaginary illness, and on the other hand, I really want to die... I can't help being bored and I am willing to leave the world. But the reality is also so wonderful, the fact that makes me barely dare to die. I'm afraid to make my beloved ones sad. I can't be so selfish to let my parents watch my death. But I can't help feeling that it's meaningless for me to be alive.

最近在绝食，整天整天地让自己躺在床上不动已经快半个月了，不想跟我妈妈说话也不想跟我妹妹说话，所以我也不能吃饭，但是我仍旧守着洗碗的承诺，每天晚上9点过去洗碗，今天是绝食的第三天。我腿好疼，快要站不起来了，第二天洗碗的时候感觉我的腿一直在打颤，我好难过又好愤怒。
I have been on a hunger strike recently. I have been lying in bed all day long for almost half a month. I don't want to talk to my mother or my sister. I don't want to eat, but I still keep my promise to wash dishes. I go to wash dishes every night at 9pm. Today is the third day of my hunger strike. My leg hurts and I can't stand up anymore. When I was washing the dishes on the second day, I felt my legs trembling all the time. I am so sad and angry.

Conclusion

In this paper, we proposed a distant supervision approach to develop an automatic system that can classify high and low

suicide risk based on social media comments. We constructed 3 data sets of different levels (free, easy, and hard) via interactions with psychologists who were assisted by our models.

Although a deep learning model has excellent performance in different domains, it requires a lot of annotations to train a reliable model. Per our study, ordinary people cannot accurately label data. Only people who have been professional trained can accurately classify the suicide risk expressed in comments in accordance with standard methods. This makes it difficult to obtain large-scale annotations. Per our processing steps, we first used a basic algorithm to generate annotations for training the baseline model. Afterward, we invited people with different psychology knowledge levels to provide a small number of annotations. Then, based on domain knowledge, we extracted users' multidimensional psychological features and integrated them into our final model (the psychology+ model). Our operating steps greatly improved the efficiency of our model.

Only 1458 professional labels were required to train a model that could analyze real situations. It would have been impossible to train a reliable model with just over 1000 data points if we did not conduct the previous steps.

In future work, we will combine actual work experiences and cooperate with psychologists to propose more suitable suicide classification standards and provide immediate warnings for upcoming emergencies. Although our model could meet actual standard requirements, its run time was relatively slow (274 comments/minute) due to the large number of model parameters. Further, although the model's efficiency could meet people's daily needs, we still hope to develop a more lightweight model for dealing with certain data produced in special situations, such as short-term, large-scale comments.

Abstract

Background: Digital prevention programs that are delivered in a school environment can inoculate young people against depression. However, little is known about the school-based factors that help and hinder the implementation of these programs. Staff members are integral for supporting mental health programs in schools and are likely to have a wealth of expertise and knowledge about the factors that affect implementation.

Objective: The primary objective of this study was to explore the barriers and facilitators to implementing a digital depression prevention program in Australian secondary schools with teachers, counselors, and principals. The secondary objective was to explore variations in these factors across different school contexts, including the school type (government or nongovernment), location (capital city, regional/or rural areas), and socioeconomic status (SES) (low, medium, high).

Methods: This quantitative cross-sectional survey study assessed the barriers and facilitators to implementing a hypothetical digital prevention program in Australian schools. The survey was taken by 97 teachers (average age 38.3 years), 93 counselors (average age 39.5 years), and 11 principals (average age 50.9 years) across Australia between November 2017 and July 2018.

Results: A range of barriers and facilitators relating to logistics and resources, staff support, and program factors were endorsed by the surveyed staff. Consistent with prior research, common barriers included a lack of time and resources (ie, staff and rooms). These barriers were particularly evident in government, rural/regional, and low socioeconomic schools. Other barriers were specific to digital delivery, including privacy issues and a lack of clarity around staff roles and responsibilities. Facilitators included upskilling staff through training, embedding the program into the curriculum, and other program factors including universal delivery, screening of students' mental health, and clear referral pathways. Knowledge about the program efficacy was also perceived as important by a large proportion of the respondents.

Conclusions: The digital depression prevention program was perceived as suitable for use within different schools in Australia, although certain factors need to be considered to enable effective implementation. Logistics and resources, support, and program factors were identified as particularly important for school-based implementation. To maximize the effectiveness in delivering digital programs, implementation may need to be tailored to the staff roles and school types.

Introduction

Depression is a debilitating problem in young people. An earlier onset is associated with a more severe clinical course and greater risk of recurrence, impairments in academic performance, social problems, and increased risk of comorbid physical and mental health problems [1,2]. Access to evidence-based treatment for depression is often limited, and even among those who do obtain access, relapse rates remain high [3]. Therefore, depression is a prime target for prevention. To increase access to and effectiveness of prevention efforts, a proactive approach is needed whereby programs are delivered in contexts frequented by young people using methods in which they are already engaged. One way to increase access and effectiveness is by delivering psychological prevention programs in schools.

Schools are ideally placed to address the mental health problems of young people. Young people spend much of their waking time at school and have reported a greater willingness to access mental health services at school than in other settings [4,5]. Among young people who do receive mental health care services, more than 50% have indicated that the first access was driven by their school [4]. Schools in many countries, including Australia, Canada, and the United Kingdom, typically have designated mental health and well-being staff (eg, counselors, psychologists, or well-being officers). Although there are variations across schools, these staff members are well positioned to support mental health programs and create meaningful impact for students.

School-based depression prevention programs are already available. Two meta-analyses have found that school-based prevention programs had a small preventive effect on depressive symptoms, regardless of whether the program was delivered to all students (ie, universal) or to a targeted sample [6,7]. Most of the studies involved programs that were delivered in person, an approach that places high demand on the already limited resources in schools (eg, staff availability, infrastructure, time, financial cost). Only two studies from this review reported on programs that were delivered online via a website [8,9]. More recent randomized controlled trials have investigated the effectiveness of online or telephone-based prevention programs delivered in schools, with mixed results [10-13]. Given that there is some indication of the effectiveness of school-based digital programs, using technology to deliver prevention programs may be a promising way forward in addressing student depression in schools.

Barriers and Facilitators to Delivering Mental Health Programs in Schools

Digital Programs

Little is known about the factors affecting the implementation of digital mental health programs in schools. Research has typically focused on the factors that generally affect the acceptability of and engagement with digital mental health programs, or on settings other than schools [14,15]. Schools are complex environments for delivering digital mental health programs, and many factors will affect their implementation and uptake by students. Given that school staff and school

leaders decide what programs are implemented, and are often involved in supporting program delivery, it is important to consider their perspectives about what will work in their schools. Research investigating the barriers and facilitators of specific digital mental health programs as perceived by school staff is currently lacking [16], with more focus on face-to-face delivery methods.

Face-to-Face Programs

Studies have identified school-specific factors that affect implementation of face-to-face evidence-based mental health programs. One early qualitative study involved interviews with the developers of multiple evidence-based school mental health interventions [17]. Results identified the following seven factors as being important for effective implementation: (1) principal and other administrative support; (2) teacher support; (3) adequate financial resources; (4) high-quality training and consultation to ensure fidelity to the intervention components; (5) alignment of the intervention with the philosophy, culture, and approach to mental health of the schools; (6) visibility of the intervention outcomes to key stakeholders; and (7) adequate ways to address turnover of the staff involved in program support and delivery. Another study was conducted based on these results by incorporating the perspectives of program directors and clinicians working within schools [18]. In this study, Langley and colleagues found that the four main barriers to implementation included competing responsibilities, parent engagement, logistics, and support from administrators and teachers. Facilitators included having a professional network and being able to consult others about the program, adequate funding, and perceptions that the program would be easy to implement. Other survey studies involving school staff (eg, headteachers, teachers, counselors) in middle and secondary schools have obtained converging results [19-26]. School Mental Health ASSIST, a provincial implementation support team in Ontario that aims to build school capacity to use evidence-based strategies and services, has also identified a “top 10 list” of factors that influence implementation of student mental well-being practices. These factors include commitment, leadership team, assessment of the (initial) capacity and resources, and professional learning [27]. This literature underscores the need to consider factors unique to the school environment that influence the delivery of mental health programs, rather than relying on the more generic implementation literature.

Current Study

To the best of our knowledge, no studies have evaluated the barriers and facilitators to implementing a school-based digitally delivered depression prevention program for students as perceived by school staff. Although insights can be drawn from studies evaluating the implementation of evidence-based face-to-face interventions, there are clearly unique factors to consider in the implementation of digital mental health programs.

The current study explored the perspectives of Australian secondary school staff who are primarily responsible for the adoption and delivery of such programs in the school environment. Integrating the perspectives of principals,

counselors, and teachers will provide a comprehensive picture of the factors that specifically affect the implementation of digital health programs. Based on the available literature [17,18,25,26], anticipated barriers included a lack of time and curriculum constraints, limited staff to support delivery, competing responsibilities, lack of support from the leadership and other staff members, lack of knowledge or skills to facilitate delivery, and lack of perceived fit with school values; anticipated facilitators included appropriate resourcing, a clear program champion, increased school support for staff delivering the program, perceived effectiveness of the program, and knowing what implementation involves. In addition, beliefs and attitudes toward prevention and using technology to deliver mental health programs (eg, effectiveness, safety concerns, inbuilt flexibility) were expected to influence perceptions about the ease, or difficulty, of implementation. This study also explored whether factors identified by school staff act as barriers or facilitators to implementation to the same extent across different school contexts (eg, types of schools, socioeconomic status [SES]). Given the similarities in the experiences of school staff across countries (eg, high workload, burnout, role ambiguity) [28-30], the results are likely to have relevance beyond the Australian context.

Methods

Design and Recruitment

This study involved online surveys of secondary school staff from Australia, including principals and deputy principals, teachers (including librarians, support teaching staff, administrators, and Year Advisors), and school counselors and psychologists. The study procedures received ethical approval from the University of New South Wales Human Research Ethics Committee (HC17468) and the State Education Research Applications Process (SERAP2017339). Recruitment involved convenience and snowball sampling at key times (eg, beginning of school terms) between November 2017 and July 2018. Flyers and emails were sent to the research team's network of school contacts throughout New South Wales, and online flyers were posted on the Black Dog Institute's media channels (eg, Twitter, Facebook, and the Black Dog Institute website). This was an "open survey," and eligible participants were also encouraged to distribute the research opportunity directly to others in their networks.

Interested participants clicked the online link to access the survey that matched their role and were then presented with an information statement. The statement included the names of the investigators, eligibility criteria, purpose of the study, participation requirements (eg, length and nature of the survey), reimbursement, and data storage processes. Before accessing the survey, the participants provided informed consent by ticking boxes corresponding to items such as having read and understood the information statement.

The surveys were completed between 2017 and 2018 alongside recruitment. Participants had the option of providing an email address to receive reimbursement for their time with a \$20AUD electronic gift card. To ensure participant anonymity and confidentiality, email addresses were obtained using a second

survey accessed via a separate URL link that was provided after completing the first survey. Responses to the second survey (ie, email addresses) could not be linked to the participants' responses in the main survey.

Development and Pretesting of Measures

All the three stakeholder surveys (principal, teacher, counselor) included closed and open-ended questions about their demographics, current and previous employment, and current school. Respondents were also asked to rate how responsible they thought schools should be in addressing issues related to physical health, sexual health, mental health, and substance use among students on a Likert scale as follows: 1, very responsible; 2, somewhat responsible; 3, not really responsible; and 4, not at all responsible. A hypothetical digital depression prevention program for high school students was then described to the participants to test their attitudes toward this program. The program was described as a skill-based game, drawing from cognitive behavior therapy, that students would play over 7 20-minute sessions during class time (supervised by school staff). With all the material contained in the program, participants were informed that training or specific mental health knowledge would not be necessary. The description also emphasized that the program was evidence-based and facilitated the reduction of depressive symptoms in secondary school students. A list of barriers and facilitators to the implementation of a program of this nature were then presented. Participants were asked to rate how "challenging" the potential barriers would be for introducing the program at their school on a Likert scale as follows: 1, not at all; 2, not really; 3, moderately; 4, very; and 5, extremely. Using the same scale, they were asked to indicate how "helpful or beneficial" the potential facilitators would be for introducing this program.

For each stakeholder group, the questions were tailored to ensure suitability for their role within the school. To obtain information for developing the surveys, a review of the implementation literature pertaining to evidence-based mental health programs in schools and other relevant settings was carried out. We also consulted a network of professionals within the education, mental health, and research sectors, seeking their input regarding potential barriers and facilitators to implementing mental health programs in schools. Based on all these sources of information, we generated an extensive list of potential barriers/facilitators, which we then grouped into relevant categories, such as logistics, school support, or suitability of the program. Drafts of the surveys were circulated to our network of relevant professionals for feedback, which led to further refinement of the surveys. Once the surveys were presented electronically, they were distributed to several of the research team's contacts within each stakeholder group for testing of the usability, technical functionality, and length before recruitment for the study commenced.

Survey Administration and Procedure

The surveys were administered via Qualtrics, an online survey platform [31]. The surveys were 20-25 pages long with approximately 5-10 questions displayed per page. All questions required a response to progress to the next page. Participants could go back to review/edit responses on earlier pages without

losing information already entered. Participants were also able to save their progress and continue completing the survey during subsequent sessions. A progress bar at the bottom of each page indicated approximately how far through the survey participants were, on a visual scale from 0 to 100%. Cookies were embedded on the first page of the survey, which prevented participants from using the same device to complete the survey more than once. The surveys took approximately 30-45 minutes to complete. All the survey responses were anonymous.

Statistical Analysis

All analyses were conducted using SPSS (version 25, IBM Corporation) or Excel (Microsoft Corporation). All the available participant data were analyzed, including incomplete surveys. The survey completion rate was calculated for each stakeholder group by dividing the number of people who completed the entire survey by the number of people who consented to participate. Completion rates differed between the 3 stakeholder groups, with 55% (6/11) of principals, 83% (77/93) of counselors, and 75% (73/97) of teachers completing the survey.

We calculated the descriptive statistics for each participant sample and cumulative frequencies of the perceived barriers and facilitators. We report the cumulative frequencies for barriers and facilitators rated as “moderate,” “very,” or “extreme.” This decision was taken to focus on the most frequently endorsed, and therefore practically relevant, barriers and facilitators from the perspective of key school stakeholders.

In an exploratory set of analyses, we conducted correlations to identify the relationship between key individual characteristics and beliefs about the helpfulness of online mental health programs in general. We also examined the relationship between

individual characteristics and the willingness of counselors to try different mental health interventions developed by researchers. These questions were designed to assess perceptions about digital mental health programs in general. We conducted chi-square tests of independence, or the Fischer exact test of independence when expected numbers were <5 , to determine whether the selected school variables were associated with perceived facilitators and barriers. The variables included the type of school (government or nongovernment), school location (capital city or rural/regional), and SES (low, medium, high). These variables are related to the availability of mental health staff and other resources in schools and can therefore affect implementation processes [32-34]. For all the analyses, the level of significance was set at $P < .05$ and strength of the association was represented by Cramer's V.

Results

Participant Characteristics

The survey was taken by 97 teachers, 93 counselors, and 11 principals. On average, the teachers were 38.3 years old and had been in the role for 9.8 years. The school counselors were aged 39.5 years, with 6.9 years of experience in their role, and the principals were 50.9 years old, with 10 years of experience in their role. Most teachers (85/96, 89%) and counselors (62/91, 68%) were employed in government schools, whereas less than half (5/11, 46%) of the principals were from government schools. Most participants were employed fulltime (teachers: 78/97, 80%; counselors: 65/93, 70%; principals: 11/11, 100%). The perceived SES and location of employment (eg, capital city vs. rural/regional locations) varied across respondents. [Table 1](#) presents the details.

Table 1. Summary of participant and school characteristics (given that incomplete and complete surveys were analyzed, the sample size for each characteristic may vary).

Characteristics	Teachers (n=97)	School counselors (n=93)	Principals (n=11)
Gender, female, n (%)	73 (75.3)	83 (89)	4 (36)
Age (years), mean (SD)	38.3 (11.0)	39.5 (11.2)	50.9 (7.9)

^aN=96 (for teachers).

^bN=95 (for teachers).

^cN=91 (for school counselors).

^dN=89 (for school counselors).

Perceived Role of the School in Student Mental Health

All the school principals (11/11, 100%) and almost all the teachers (94/95, 99%) and counselors (89/91, 98%) felt they were either “very” or “somewhat” responsible for addressing the mental health of students. Notably, more counselors and teachers felt responsible for student mental health as compared to the number of those who felt responsible for the physical or sexual health of students, or their drug and alcohol use.

Implementation of a Digital Depression Prevention Program

For the teachers and counselors, barriers and facilitators were divided into logistical factors, school support factors, suitability of the program, and other miscellaneous factors. For the principals, to match their roles, logistical factors were conceptualized in terms of costs and resources.

Perceived Barriers

Tables S1 and S2 in [Multimedia Appendix 1](#) display the facilitators to the implementation of a digital mental health program in schools perceived by teachers, counselors, and principals.

Logistical Factors (Including Costs and Resources)

Time was the most frequently reported barrier to program implementation by the surveyed staff, with 77% (70/91) of the teachers, 94% (84/89) of the counselors, and 64% (7/11) of the principals indicating that finding time in the school schedule would be a significant barrier. Frequencies indicated that a greater number of the surveyed counselors relative to the surveyed teachers reported that time, staff, and room availabilities were barriers to implementation. Less than half of the principals (5/11, 45%) indicated that funding for the program would be a major barrier.

School Support

Less than half of the surveyed staff members felt that obtaining school support would be a significant barrier to implementation. However, there were two exceptions for the counselors, who rated obtaining administrative support (54/89, 61%) and teacher support (53/89, 60%) as at least “moderate” challenges.

Program Suitability

Very few members of the surveyed staff were concerned that the program would increase the risk of mental illness (15% [13/88] of the teachers and 7% [6/87] of the counselors), and

fewer than one-third of the teachers and counselors felt that mental health interventions should be conducted face to face rather than online. In comparison, 36% (4/11) of the principals indicated concern about the delivery format. Less than 11% of the teachers, counselors and principals felt that mental health programs were only appropriate to those with symptoms, suggesting acceptance of universal preventive approaches. A noteworthy proportion of the teachers (28/88, 32%) and counselors (40/87, 46%) expressed concerns that student privacy would be a significant barrier to the implementation of the digital program.

Other Factors

Student engagement was reported by more than half of the teachers and counselors as a potentially significant barrier to implementation. Only a small number of teachers felt that delivering this program was not their role (20/87, 23%), but many more (39/87, 45%) expressed concerns that the program would uncover mental health problems that they were not equipped to address. In contrast to the teachers, over a third of the surveyed counselors reported that delivering the program was not their role (32/87, 37%). A similar proportion of the counselors (28/87, 32%) indicated that dealing with student mental health issues and high-risk students identified during the program would be a significant barrier. Compatibility between the program and school values was also identified as a barrier by 27% (3/11) of the surveyed principals.

Perceived Facilitators

Tables S3 and S4 in [Multimedia Appendix 1](#) display the facilitators to the implementation of a digital mental health program in schools perceived by teachers, counselors, and principals.

Logistical Factors (Including Costs and Resources)

Just over 80% of the surveyed teachers (72/86) and counselors (73/87) reported that allowing students to use personal devices to access the mental health prevention program would be helpful or beneficial to implementation. Having the program available at no cost was also rated as an important facilitator by all surveyed teachers (82/82, 100%) and most counselors (83/84, 99%), but only by 70% (7/10) of the principals.

School Support

The surveyed teachers and counselors indicated that all aspects of school support were important facilitators to program implementation. Although results were generally comparable between the teachers and counselors, having support from the principal (83/87, 95%), teachers (84/87, 97%), administrative staff (83/86, 97%), and parents (83/86, 97%) was particularly important for counselors, as was having a staff member responsible for answering concerns (83/86, 97%) and sharing responsibility for implementation with other staff members (84/86, 98%). In contrast, the surveyed principals indicated that

support from counselors/well-being staff was most important (9/10, 90%).

Program Suitability

All or almost all the surveyed staff indicated that knowledge on program efficacy (for academic and emotional outcomes) would be important for implementation in schools.

Flexibility

All the surveyed principals (10/10, 100%) and most teachers (80/82, 98%) and counselors (81/84, 96%) reported that selecting an appropriate time in the school year for program delivery would be an important facilitator. Less than half of teachers (39/82, 48%) and 67% (56/84) of the counselors reported that delivering the program to only those students who might need it would be an important facilitator. Few teachers (18/82, 22%) and counselors (23/84, 27%) indicated that a targeted approach would be “very” or “extremely” important, indicating that universal approaches may be preferred.

Other Factors

The available training and the format of that training were rated by teachers (76/82, 93%) and counselors (77/84, 92%) as potential facilitators to delivery. Most surveyed teachers (76/82, 93%) and counselors (76/84, 90%) and all principals (10/10, 100%) indicated that having a screening component to identify students at risk, with student information being transferred to counselors, would be at least moderately helpful. Most surveyed teachers (72/82, 88%) indicated that aligning the program with the existing school curriculum was important, and this was comparable to the ratings provided by approximately 90% (76/84) of the counselors and principals (9/90). Alignment with the school’s philosophy, knowledge on the efficacy and benefits, and receiving feedback about the impact/success of the program from students were rated as important facilitators by all the groups.

Exploratory Analyses

Correlation analyses showed that for the surveyed teachers, age ($r=0.03$, $P=.79$) and years of experience ($r=0.02$, $P=.88$) were not associated with beliefs about how helpful online mental health programs could be in addressing common mental health problems in young people. A similar pattern of results was found for counselors ($r=-0.06$, $P=.57$ and $r=-0.05$, $P=.67$, respectively). Additionally, for counselors, there was no association between age ($r=-0.16$, $P=.13$) and years of experience ($r=0.007$, $P=.95$) with the reported willingness to try new and different types of therapy or interventions developed by researchers.

Tests of independence showed that the ratings provided for the perceived barriers and facilitators by the surveyed teachers and counselors were generally consistent across different school characteristics. However, there were some exceptions (see [Tables 2-4](#) for descriptive percentages).

Having a training manual to support implementation	55 (68)	26 (32)

^aPDHPE: personal development, health, and physical education.

Teachers

For teachers, logistic and school support varied by subgroup. SES was significantly associated with teachers' perceptions that finding time in the school curriculum ($P=.001$, $v=0.33$) and

computer availability ($P=.004$, $v=0.37$) would be barriers. Analyses of the percentages showed that time and computer availability were perceived as more important by teachers from low and average SES schools compared to high SES schools. The school location was significantly associated with teachers'

perceptions that computer availability ($P=.001$, $v=0.55$) and access to technical infrastructure ($P=.02$, $v=0.52$) would be barriers. These factors were more likely to be barriers for teachers from rural/regional schools compared to schools in capital cities. The type of school was significantly associated with teachers' perceptions that obtaining support from other teachers would be a barrier ($P=.01$, $v=0.56$), with teacher support being as more important in government schools than in nongovernment schools.

Counselors

The school SES was significantly associated with the counselors' perceptions that obtaining support from school administrations would be a barrier ($P=.02$, $v=0.31$). Inspection of the percentages indicated that administrative support was perceived as a greater barrier by counselors from low and average SES schools compared to those in high SES schools.

In terms of facilitators, the school SES was significantly associated with the counselors' perceptions that obtaining principal support ($P=.01$, $v=0.28$), recognition from the principal that program delivery was part of their job ($P=.04$, $v=0.25$), and sharing responsibility for introducing the program with other staff ($P=.04$, $v=0.26$) would be important facilitators. These factors were perceived as more important facilitators by counselors from low and average SES schools compared to those in high SES schools. The type of school was significantly associated with counselors' perceptions that aligning the program to the school curriculum ($\chi^2_2=6.27$ [N=76]; $P=.046$; $v=0.29$) and being able to complete the program on the students' own devices ($\chi^2_2=7.57$ [N=73]; $P=.02$; $v=0.32$) would be important facilitators. For both facilitators, there was a greater importance placed on these factors by counselors in government schools compared to those in nongovernment schools. The same pattern of results was also found for counselors' perceptions about the program being accessible for free, being provided with a training manual, and sharing responsibility for introducing the program, with $P_s < .04$ and $v_s > .29$. Finally, the school location was significantly associated with counselors' perceptions that having support from other teachers would be an important facilitator, with $P=.02$ and $v=0.30$, with teacher support being rated as a more important facilitator by counselors from schools in capital cities than those in rural/regional schools.

Discussion

Summary of Findings

The current study identified barriers and facilitators that must be considered when implementing a digital depression prevention program within Australian schools. The results align with the emergence of conceptual frameworks that outline the influential factors in the implementation of school-based interventions [35]. The results also replicate and extend findings from studies investigating the implementation and use of digital mental health programs in young populations [14,36], as well as mental health programs delivered in schools via traditional methods (eg, face-to-face programs) [17,25,37]. We clarify our results in the context of this prior research in the sections below.

Barriers to Implementation

Overall, teachers, counselors, and principals thought that a digital depression prevention program would be suitable for use within their schools, although certain factors would need to be considered to enable effective implementation. Lack of time and resources (ie, staffing and rooms) were identified as logistical barriers. This is consistent with prior work investigating the barriers for implementing face-to-face mental health programs in schools [17,25,37] and is not particularly surprising given the high workload and demands of school staff. Although endorsed by all the surveyed staff, a novel finding in our study was that these logistical barriers were particularly evident for counselors. Counselors are expected to be more familiar with what is needed to implement mental health programs effectively in schools owing to their experience in their role. Identifying differences in terms of the degree rather than the kind is an important addition to literature, with the implication being that some strategies to boost implementation ought to be tailored to specific staff members.

Teachers and counselors are concerned about information privacy in school-based digital mental health programs. Common concerns about privacy in digital approaches include how personal information about students will be stored, accessed, and used [38]. Some counselors were also concerned about having to address student mental health issues identified through the program (particularly those that are highly risky). These perceived barriers might reflect the uncertainty about how counselors will be ethically informed about students' needs and how they will provide effective care. These issues of privacy require novel solutions that are not currently addressed in face-to-face mental health care programs.

Another result supplementing the current literature was that over a third of the counselors thought that delivering the program was not their role. One explanation is that these counselors had reservations about delivering programs via digital means, and perhaps felt unequipped in terms of technical knowledge. This is an unlikely reason because most counselors (indeed, most respondents) indicated that a digital format was appropriate for students in their schools. Another possible explanation is that because the digital program would deliver standardized mental health content, counselors recognized that delivery would require low levels of support and mental health expertise, which could potentially be delegated to other school staff members such as teachers. This would benefit them in that they can have more time to work with higher-risk students and provide follow-up care. This interpretation converges with our finding that not having support from other administrative staff and teachers would be a major barrier to implementation for counselors. However, some teachers were concerned about having to help students with problems that they were not equipped to address. These results build on previous findings by indicating that new ways of collaborating with other staff might be necessary for successful implementation. Clear implementation guidelines need to be established before digital prevention programs are implemented in schools.

Facilitators to Implementation

Specific to digital programs, teachers and counselors thought that using personal devices was an important facilitator. Allowing students to use their own devices may overcome limitations in terms of school infrastructure/resources. Teachers and counselors also stated that receiving training and a training manual would assist with implementation. Training could increase staff confidence and buy-in to the program by clarifying the rationale and evidence for implementing the program, staff responsibilities, and prerequisite mental health knowledge. Previous research has shown that mental health literacy is an unmet need in school staff, with many wanting additional training to support their professional development [39-41]. Further, we discovered evidence for embedding digital programs into the national curriculum, with many school staff members indicating that existing school subjects (such as health and physical education) could be used as the timeslots for delivery. Integration into the curriculum would not only save time but also help consolidate support from the leadership (education departments, principals) and other staff within schools (eg, administration). Finally, the principals indicated that support from the counselor or well-being staff was the most important facilitator for successful implementation. Having support from staff with mental health expertise will help ensure that suitable programs are selected and that benefits are maximized for students.

Specific characteristics of the program were also identified by the surveyed staff as important facilitators. These characteristics included having an evidence-based, universal delivery, inclusion of a screening component, and clear referral pathways. A large proportion of the teachers, counselors, and principals indicated that knowledge on the program's efficacy would be important for implementation. Very few evidence-based mental health programs are implemented in schools; however, when used, they are not typically implemented as intended [34,42]. Respondents also thought that universal delivery of the program to all students, regardless of their symptoms, would increase the ease of implementation. This approach aligns with meta-analytic data showing that universal prevention programs, including those delivered using technology, are effective when delivered in schools [7].

The staff reported that incorporating a screening component to identify students at risk, with student information then being transferred to a counselor, would be necessary in the school context. Mental health screening in schools has the advantage

of identifying at-risk students early and preventing them from slipping through the cracks [43-45]. In turn, engaging a triaging system would help to allocate school resources based on student needs. Previous research in Australian schools has shown that using an online mental health screening service in schools is an effective way of identifying students in need and providing an appropriate level of care [46].

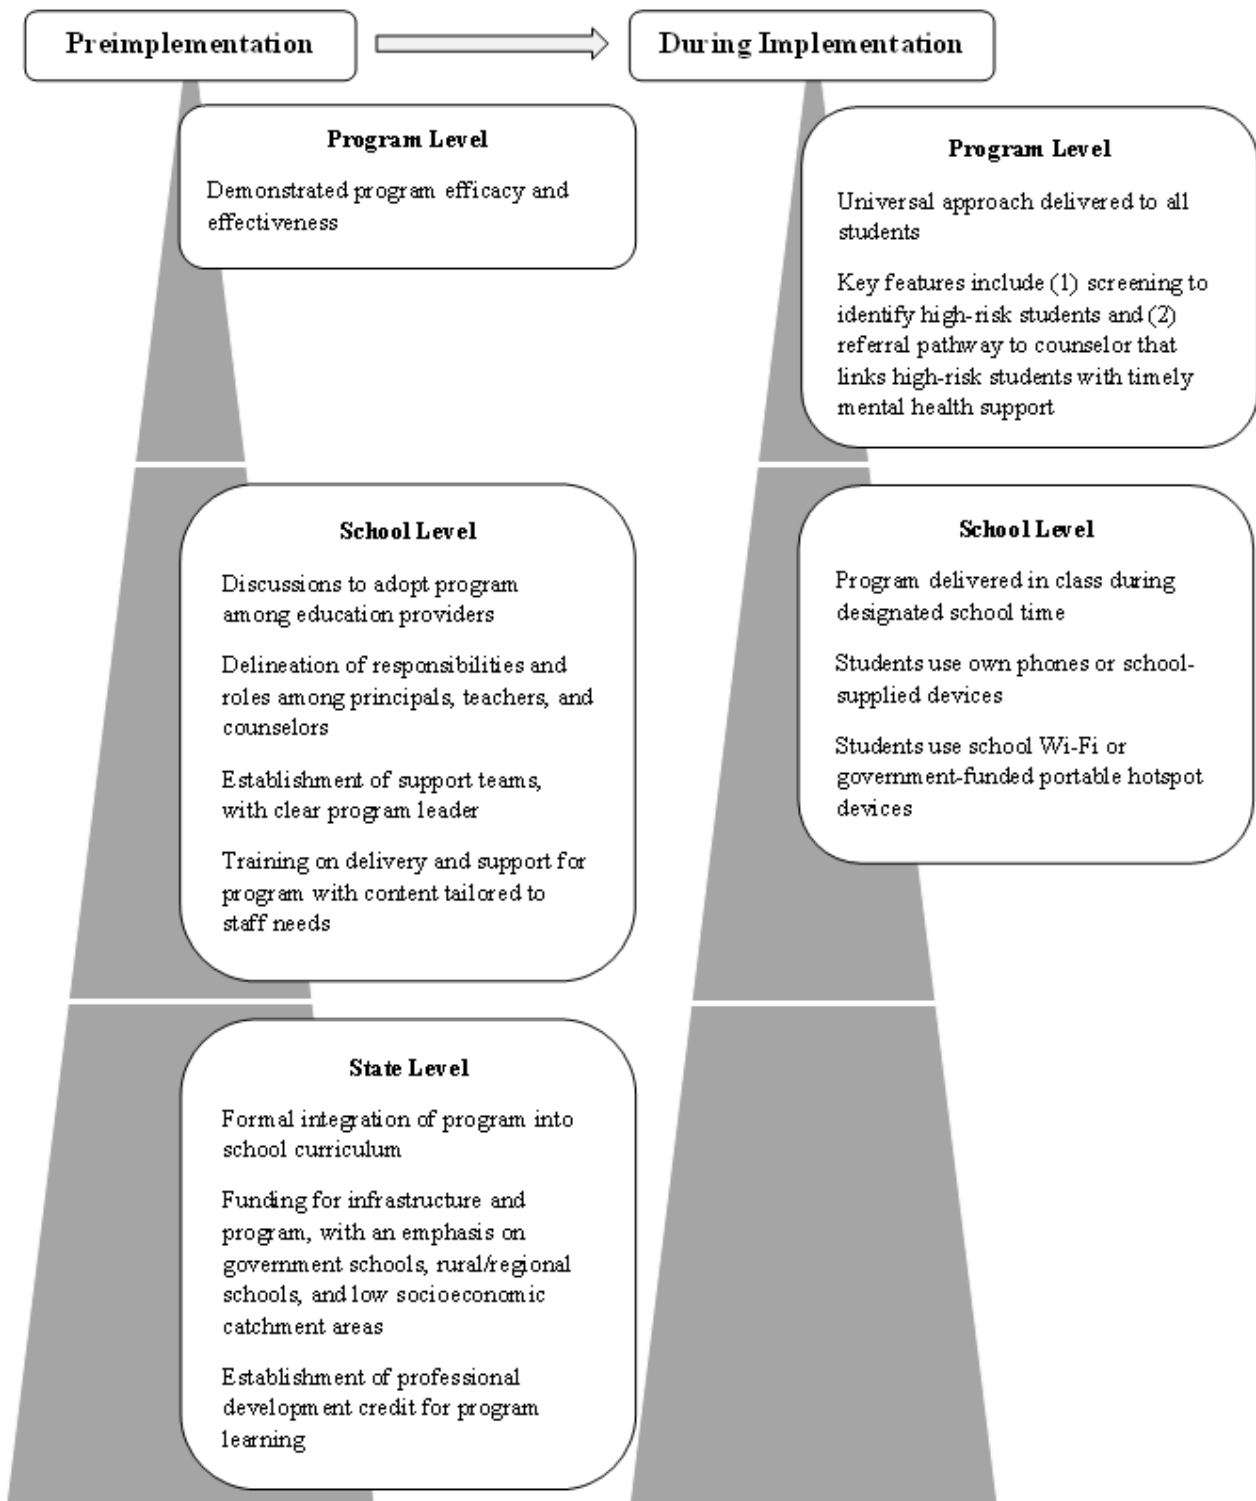

School-Based Factors

There were variations in the perceived implementation barriers and facilitators based on school contextual factors. Similar to previous research [33], the school location, type, and SES played a role in shaping the teachers' and counselors' perceptions regarding which factors would influence the implementation success. The general pattern was that the staff working in government schools, rural/regional areas, and low socioeconomic catchments anticipated facing more logistical and support barriers during implementation. These staff members identified a complementary set of facilitators to maximize implementation in these schools. Emphasis was placed on obtaining support from the other staff members and leadership, sharing responsibility for the program, embedding the program into the personal development, health, and physical education (PDHPE) curriculum, providing the program at no cost, and allowing students to use their own devices. These facilitators can be viewed as ways to reduce the burden on the already limited resources and fit the program within schools.

Implications

Our results indicate that different approaches are needed to target various staff members in different school types. One example is involving counselors in discussions about the program, before implementation, to ensure that they are on-board and can provide support. This might be particularly important in government schools. Another example is tailoring program implementation strategies to school regions and ensuring preparedness in terms of available technology, infrastructure, and support [32]. Our results also highlight the importance of factors that impact decisions related to adopting digital programs ahead of time [47]. Some face-to-face programs are already being developed with school-based barriers and facilitators in mind [48]. Extending this research to digitally delivered programs may help to design and develop school appropriate products. [Figure 1](#) shows the proposed outline of the key implementation factors formulated from the current results.

Figure 1. Key implementation factors to consider in digital mental health program delivery at the program, school, and state levels, with focus on the Australian context.

Limitations

This study is limited in some respects. The sampling processes could have contributed to selection biases and positive self-presentation. School staff who responded to the survey may have already been interested or engaged in the mental health of their students. Staff members who were reached by recruitment but did not consent to participate may have had systematically different perspectives about the anticipated barriers and

facilitators. Further, our study only included a small proportion of the total number of staff members in Australia eligible to participate in the study. However, the teachers, counselors, and principals in our study did represent a variety of school types, locations, and socioeconomic circumstances, which increases the generalizability of our findings. The characteristics of our sample, including the average age and gender proportion, were also consistent with the population characteristics of Australian teachers and principals [49]. Random sampling with more

participants will help to prevent biases in sampling during future studies.

Another limitation is that we only focused on schools in Australia. Although our results may be relevant in other Australian states and countries with similar school systems (eg, United Kingdom), it is unclear how digital programs would be received in places with fewer resources or different staffing roles. Future research could compare the implementation factors in schools on an international level, with particular focus on schools in low- and middle-income countries (LMICs). LMICs are likely to encounter different barriers and facilitators, issues that are important to consider when implementing such programs on a large scale [50]. Finally, given that we examined a hypothetical digital depression prevention program, our conclusions may not be generalizable to the actual implementation of real-world programs. Implementation process evaluations of digital mental health programs will help understand what the most effective approach in schools is,

thereby improving outcomes for students and school communities. One example of such an evaluation is currently underway in Australian schools [16,51].

Conclusions

Our study explored the factors influencing the implementation of a digital depression prevention program within secondary schools from the perspectives of teachers, counselors, and principals. The surveyed staff members thought that a digital program focusing on universal prevention was suitable for delivery in their schools. A range of logistical, support, and program barriers and facilitators were identified, some of which were unique to digital programs. There were also some differences between what teachers, counselors, and principals thought were the most important factors to be considered, as well as among staff members from different schools. Our results highlight the importance of considering multiple perspectives in school-based implementation and tailoring strategies to maximize digital delivery based on staff roles and school types.

Acknowledgments

AW-S secured funding from a New South Wales Health Early-Mid Career Fellowship. The funding body had no role in any aspect of the study design or in writing this manuscript. We would also like to thank Katarina Kikas, who assisted with the development of [Figure 1](#).

Authors' Contributions

AW-S conceived the study. LJ collected the data. JRB conducted the data analysis and wrote the manuscript, with assistance from AW-S. All authors contributed to the methodology, including the development of the survey measures. All authors have read, reviewed, refined, and approved the final manuscript.

Abstract

Background: The rapid growth of social media as an information channel has made it possible to quickly spread inaccurate or false vaccine information, thus creating obstacles for vaccine promotion.

Objective: The aim of this study is to develop and evaluate an intelligent automated protocol for identifying and classifying human papillomavirus (HPV) vaccine misinformation on social media using machine learning (ML)–based methods.

Methods: Reddit posts (from 2007 to 2017, N=28,121) that contained keywords related to HPV vaccination were compiled. A random subset (2200/28,121, 7.82%) was manually labeled for misinformation and served as the gold standard corpus for evaluation. A total of 5 ML-based algorithms, including a support vector machine, logistic regression, extremely randomized trees, a convolutional neural network, and a recurrent neural network designed to identify vaccine misinformation, were evaluated for identification performance. Topic modeling was applied to identify the major categories associated with HPV vaccine misinformation.

Results: A convolutional neural network model achieved the highest area under the receiver operating characteristic curve of 0.7943. Of the 28,121 Reddit posts, 7207 (25.63%) were classified as vaccine misinformation, with discussions about general safety issues identified as the leading type of misinformed posts (2666/7207, 36.99%).

Conclusions: ML-based approaches are effective in the identification and classification of HPV vaccine misinformation on Reddit and may be generalizable to other social media platforms. ML-based methods may provide the capacity and utility to meet the challenge involved in intelligent automated monitoring and classification of public health misinformation on social media platforms. The timely identification of vaccine misinformation on the internet is the first step in misinformation correction and vaccine promotion.

Introduction

Background

Human papillomavirus (HPV) infection is a highly prevalent sexually transmitted infection. HPV infections cause approximately 33,700 cases of cancer every year in the United States, including cervical, vaginal, penile, anal, and head and neck cancers [1,2]. Since 2006, a vaccine against the most common HPV subtypes has been available to prevent associated cancers and genital warts [3]. Despite undeniable evidence of its effectiveness, the HPV vaccine has been controversial among parents, which has contributed to vaccine hesitancy and even refusal [4] and to relatively low national rates of HPV vaccine initiation and series completion [5]. Resistance to the HPV vaccine has been a result of parents' concerns about the vaccine's effect on sexual behavior, because HPV is a sexually transmitted infection, and the safety of the vaccine, as well as inconsistent vaccine recommendations from health care providers [6].

A burgeoning antivaccine movement has affected overall vaccine coverage in the United States and contributed to a resurgence of vaccine-preventable diseases such as measles [7]. Vaccine hesitancy has been found to be driven mainly by concerns about vaccine safety and is propelled by misinformation circulated through social media [8]. The rapid growth of social media as an information channel has made it possible to quickly spread inaccurate or false information and create a platform for antivaccine campaigns to promulgate vaccine-related misinformation [9]. Participants in the antivaccine movement circulate antivaccine sentiments and misinformation through various internet channels and create demonstrable impact on individual and community health [10]. Experts in media communications have suggested that web-based misinformation is becoming unmanageable, even as concern increases about the damage it causes to consumer well-being [11]. Efforts to curtail the phenomenon, such as story-flagging and fact-checking tools, are not enough to suppress the advocates of misinformation [12,13] because the efficiency and scalability of these tools are limited, and misinformation is disseminated much faster and broader than true information.

Mitigation of medical and public health misinformation on social media is important; however, the sheer amount of information makes it challenging to identify these posts efficiently and accurately. Although social media is a convenient way for users to generate, share, receive, and comment on social content [14], there is a need for broad-scale, innovative methods to track and understand the spread of health misinformation on social media outlets [15].

Identifying vaccine-related misinformation presented on social media is an important first step in the timely curbing of the ongoing spread of vaccine misinformation. Given the large volume of social media posts and unique features of social media language (ie, incomplete sentences and misspellings), the use of automated methods for the identification of misinformation is challenging. However, machine learning (ML)-based approaches have been previously applied to identify misinformation on Twitter regarding controversial topic domains [16] and rumors regarding a range of topics [17]. ML involves the use of algorithms and statistical modeling that provide the ability to automatically conduct tasks and learn without using explicit programming [18]. Despite the utility of these ML approaches, there is a dearth of application to medical or health topics. To date, an ML-based system has tracked misinformation about the Zika virus on social media [19] and classified misinformation within specific health forums (eg, MedHelp) [20]. Although there have been efforts to develop ML for sentiment analysis on vaccine topics [21,22], to our knowledge, there is no prior work on *automated identification* of vaccine-related misinformation on social media. Deep learning (DL) is a subset of ML algorithms based on deep neural networks. Although DL has advanced ML algorithms in multiple tasks [23], the utility of DL regarding vaccine misinformation identification is still unclear.

Objective

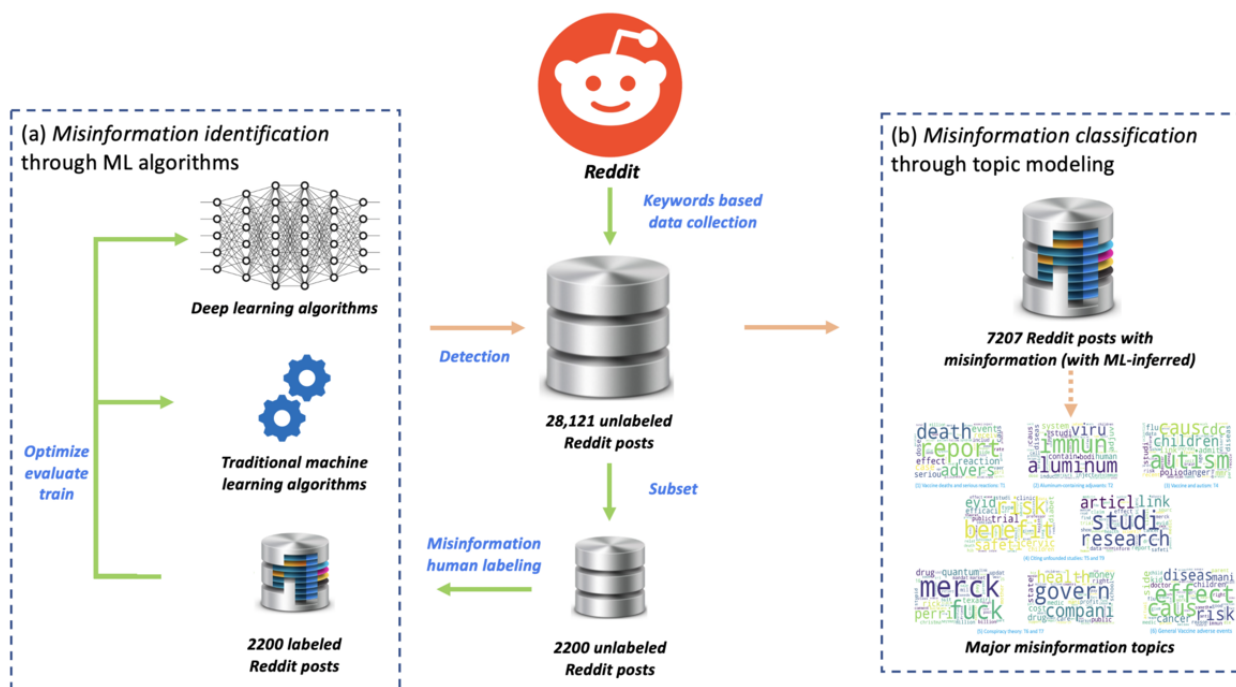

We report the utility of various conventional ML and DL algorithms to automatically identify and categorize misinformation on the HPV vaccine using posts on Reddit, a popular social media platform with more than 330 million monthly active users [24]. Reddit users are primarily anonymous young users below the age of 35 years, and more than half (54%) live in the United States [25]). Studies have revealed that young adults in the United States have low perceived susceptibility of contracting HPV [26], low health literacy pertaining to HPV and the HPV vaccine [27], and are more likely to seek health information on social media than other age demographics [28]. Table S1 in [Multimedia Appendix 1](#) lists ML-related terms in the manuscript and their definitions.

Methods

Overview

We used a hybrid approach for the identification and classification of HPV vaccine misinformation on Reddit ([Figure 1](#)). Our approach can be divided into two steps: (1) evaluation of ML algorithms for vaccine misinformation identification and (2) topic modeling on Reddit posts that contain vaccine misinformation (ML-inferred).

Figure 1. The overview of human papillomavirus misinformation identification and classification on Reddit. (a) Evaluation of machine learning–based misinformation identification and (b) topic modeling. ML: machine learning.

Reddit posts that contain HPV vaccine keywords were first collected, after which random subsets of the posts were labeled as containing *misinformation* or *nonmisinformation*. The labeled Reddit posts served as the gold standard corpus for the training and evaluation of various traditional ML and DL algorithms. The best algorithm, one that achieved the highest area under the receiver operating characteristic curve (AUC) [29], was then selected to infer the misinformation label for the remaining unlabeled Reddit posts. Finally, we applied topic modeling to the Reddit posts that were classified as misinformation to explore the major discussion topics and their prevalence.

Data Set Collection and Labeling

We collected Reddit discussions related to HPV vaccination from 2007 to 2017 (N=28,121) using Pushshift [30]. Submissions (topic starters) and comments (responses to the topic) that contained the case-insensitive expressions of *cervarix* or *gardasil* or the combination of *hpv* or *papillomavirus* with *shot* or *vaccine* were collected.

We selected a random sample (simple random sampling) of the total collected Reddit posts (2200/28,121, 7.82%) and labeled the posts as misinformation or nonmisinformation. The purpose of this step was to build a gold standard corpus (ie, Reddit posts with their expert-assigned labels) that was used for the training and evaluation of the automated ML algorithms. The definition of vaccine misinformation was largely informed by the *Antivaccination Information* class of the Vaccine Misinformation Ontology (VAXMO) [31], a formal ontology to describe vaccine misinformation. Within the VAXMO, the *Antivaccination Information* class includes several subclasses, such as *Vaccine inefficacy*, *Alternative medicine*, *Civil liberties*, *Conspiracy theories*, *Falsehoods*, and *Ideological*. The random sample of the Reddit posts was used to develop a guideline through discussion among the annotators. A priori consensus was reached among 3 of the study annotators to combine the subclasses *Civil Liberties* and *Ideological* and to add two categories: *Vaccine recommendations* and *Other*. The resultant decision rules were that if a Reddit post contained one or more types of vaccine misinformation, it was considered an instance of misinformation (Textbox 1).

Textbox 1. Descriptions of types of vaccine misinformation.

- Vaccine inefficacy: vaccine misinformation related to concerns about the lack of effectiveness of vaccines.
- Vaccine safety: vaccine misinformation related to concerns regarding safety issues and supposed harmful ingredients.
- Conspiracy theories: vaccine misinformation related to accusations of a cover-up, where regulatory bodies purportedly have information about vaccines that they are hiding from the public.
- Vaccine recommendations: vaccine misinformation related to vaccine recommendation or schedule.
- Civil liberties and ideologies: the encroachment on personal and parental legal rights or personal principles influencing individual opinions about antivaccine sentiment based on religion, morality, or other ideological reasons.
- Other: other types of vaccine misinformation or a mixed type of misinformation.

Furthermore, 3 study team members in the fields of biomedical informatics and public health (JD, SP, and HS) were involved in the annotation. The first 100 Reddit posts served as training, with the annotators independently annotating each post and then discussing each post and its annotation as a group. The training ended when the annotators achieved consensus (or took a decision based on a majority vote) on all the posts. After the annotation training, the remaining sampled Reddit posts were split among the 3 annotators for independent labeling. To examine the quality of the annotation, we selected 200 additional posts from the unlabeled Reddit posts, and JD, SP, and HS worked on these posts independently. We calculated the Cohen κ among the 3 annotators [32]. The total labeled Reddit samples were used as the basis of a gold standard corpus that was subsequently used for the training and evaluation of the automated ML algorithms.

Misinformation Identification

Text Classification

Text classification is a fundamental task of natural language processing (NLP) which aims to classify the textual posts into predefined classes [33]. NLP is a subfield of artificial intelligence that allows computers to process and analyze natural language (ie, free text) data. We framed the identification of misinformation from Reddit posts as a binary text classification task. Each Reddit post was assigned one of two exclusive labels (ie, misinformation or nonmisinformation) within the automated ML-based algorithms (described below).

ML Algorithms

We evaluated 5 ML-based algorithms: 3 conventional and 2 DL algorithms. Traditional ML algorithms (ie, nondeep neural network–based algorithms) with feature engineering are widely used for text classification tasks. Altogether, 3 conventional ML algorithms were evaluated in this study: a support vector machine, logistic regression (LR), and extremely randomized trees. Support vector machines have been widely used in text classification tasks [34–36]. LR has achieved favorable performance on many task classification tasks as well but requires substantially less running time [37,38]. Extremely randomized trees is a tree-based ensemble method that has achieved favorable performances in our previous studies on social media text classification tasks [39,40]. Term frequency-inverse document frequency (TF-IDF) was adopted as the feature for these traditional ML algorithms. TF-IDF is a numerical statistic that assesses the relative importance of a word to a document in a corpus [41].

DL is a subset of ML algorithms. We evaluated 2 commonly used DL-based frameworks in this study: convolutional neural network (CNN) [42] and recurrent neural network (RNN) [43]. The effectiveness of traditional ML algorithms depends on task-specific feature engineering [44]. Deep neural networks can take advantage of pretrained word embedding to capture the semantics of words, which saves significant effort in feature engineering by domain experts [45]. DL algorithms have achieved state-of-the-art performance on many text classification tasks [46–49].

As there are frequent occurrences of incorrect spelling in social media posts, both the evaluated DL algorithms contained a character layer and a word-embedding layer to map both in-vocabulary (ie, correctly spelled) and out-of-vocabulary (ie, incorrectly spelled) words to high-dimensional vectors to represent their semantics. GloVe (Global Vectors for Word Representation) embedding (ie, glove.840B.300d) [50] was used to initialize the weights in the word-embedding layer. The CNN model takes word-level embedding as input and feeds it to convolution and max-pooling layers, a fully connected layer and a softmax layer, respectively, for classification [42]. The RNN model follows an architecture that is similar to that of the CNN model by replacing convolution and max-pooling layers with bidirectional long short-term memory layers and attention layers.

More specifically, for both the CNN and RNN models, the learning rate was set at 0.01, the batch size was 64, and the number of epochs was set at 100. The length of the character embedding was set at 50 for both models. For the CNN model, the filter sizes were 1, 2, and 3, and the number of filters was 2048; for the RNN model, the hidden dimension of the long short-term memory unit and attention layer was set to 128. The dropout probability was 0.2 for both models. The model that achieved the best AUC value on the validation set was selected for testing and prediction.

Experiment Settings and Evaluation

The gold standard posts (ie, Reddit posts with expert-assigned labels) were randomly split into train, validation, and test sets in a ratio of 7:1:2. We adopted spaCy *tokenization* [51] to split the post text into separate words, remove punctuations, and convert words and letters in uppercase to lowercase. Sequentially, the train set was used to *train* the algorithms, the validation set was used for hyperparameter selection, and the test set was used to evaluate the performance of the models. To account for imbalance in label distribution, the criterion of reference was the degree of specificity as measured by the optimal AUC. The algorithm with the highest AUC value was selected for the inference of vaccine misinformation from unlabeled Reddit posts.

We further plotted the precision and recall curves of the best-performing model (ie, the CNN model) and selected the optimal cutoff (based on the highest F_1 score) of the algorithm to identify vaccine misinformation in Reddit posts. Precision was defined as the fraction of misinformation posts identified by the labelers among the fraction of misinformation posts identified by the classifier. Recall was defined as the fraction of misinformation posts identified by the labelers that were retrieved by the classifier. The F_1 score is a harmonic mean of precision and recall. The cutoff that led to the best F_1 score for the CNN model was selected. The model was applied to identify vaccine misinformation–related Reddit posts in the remaining unlabeled Reddit corpus.

Misinformation Topic Model

The ML and DL algorithms described above can potentially be used to automatically identify Reddit posts with misinformation, but they do not categorize the types of misinformation. We

adopted a topic model algorithm (ie, Biterm Topic model [BTM]) [52], and we implemented the code from a GitHub repository [53]) to identify and visualize major topics from the misinformation in Reddit posts. Topic models are a type of statistical model designed to cluster the abstract topics that occur in a collection of documents. After using the best-performing ML algorithm to identify Reddit posts that contain misinformation, we then applied the BTM to these posts. We performed stemming for each word to remove morphological affixes (eg, *dies* to *die* and *denied* to *deni*). The number of topics is a hyperparameter for the BTM, which determines the number of topics that will be generated. We evaluated 5, 10, and 20 as the number of topics and selected 10 through a manual review of the topics and associated posts. We then manually reviewed these topics, associated words, and posts to further identify relevant topics associated with vaccine misinformation. The BTM also outputs the prevalence of each identified topic. Word clouds were then adopted to provide a graphic representation of these topics, where the size of each word is proportional to its probability of appearing in posts about that topic [54]. To examine the association of the identified topics, we further performed network analysis among these topics.

Ethics Approval and Consent to Participate

This study received institutional review board exemption from the committee for the protection of human subjects at the

University of Texas Health Science Center at Houston. The reference number is HSC-SBMI-20-0151.

Results

Misinformation Annotation

In total, 28,121 Reddit posts were collected from 2007 to 2017 from more than 16,633 unique users. The statistics of these posts as well as their distributions in subreddits (ie, user-created discussion boards where posts are organized by a subject) are shown in Table 1. There was an increasing trend of HPV vaccine-related discussions (in terms of both the number of posts and number of unique users) during the study period. There were 207,651 upvotes (a user likes the post) and 10,700 downvotes (a user does not like the post) for these posts. Of the 28,121 posts, we manually labeled 2200 (7.82%) randomly selected posts. We measured the annotation agreement by calculating the Cohen κ among the 3 annotators: 0.5578 for JD and HS, 0.5216 for JD and SP, and 0.4685 for HS and SP. The agreement scores are considered moderate according to El Eman [32], which indicates a good quality of our gold standard. Among these 2200 posts, 396 (18%) were annotated as vaccine misinformation, whereas 1804 (82%) were annotated as nonmisinformation. The highly imbalanced label distribution created barriers to achieving high performance for the classification algorithms.

Table 1. The statistics of the human papillomavirus Reddit posts corpus. For statistics regarding Reddit users, we removed the posts if the accounts were unavailable.

Year	Total posts	Total up-votes	Total down-votes	Total unique users	User posts distribution, mean (SD)	Most frequent subreddits ^a (top 3)	Subreddit post distribution, mean (SD)
2007	15	51	1	10	1.00 (0.00)	Reddit, 11; politics, 3; science, 1	5.00 (5.29)
2008	172	335	35	100	1.34 (1.32)	Reddit, 57; science, 54; health, 23	11.47 (18.88)
2009	414	1563	206	249	1.39 (0.93)	Science, 81; AskReddit, 51; Reddit, 47	14.28 (18.96)
2010	546	1655	155	346	1.33 (0.79)	AskReddit, 95; sex, 83; TwoXChromosomes, 72	12.13 (22.37)
2011	2156	12,711	927	1382	1.37 (1.47)	Politics, 298; TwoXChromosomes, 207; AskReddit, 203	19.42 (48.48)
2012	2457	12,812	739	1641	1.32 (1.34)	AskReddit, 457; TwoXChromosomes, 308; sex, 221	13.96 (48.60)
2013	3864	26,623	1416	2540	1.39 (2.44)	Science, 490; AskReddit, 375; sex, 297	15.97 (51.53)

Misinformation Detection and Classification

The LR algorithm demonstrated the highest AUC value (0.7678) among the 3 traditional ML algorithms used to identify vaccine

misinformation in the Reddit posts (Figure 2). Both DL algorithms (CNN and RNN) achieved higher AUC values than the traditional ML algorithms. The CNN model slightly outperformed the RNN model (0.7943 vs 0.7908) in the

identification of misinformation. The CNN model with the optimal cutoff was applied to classify the Reddit posts that contained vaccine misinformation. The precision and recall curves of the CNN model are shown in Figure 2. The optimal cutoff led to a precision of 0.4083, a recall of 0.6202, and an

F_1 score of 0.4925. Together with 1.41% (396/28,121) of the Reddit posts that were manually annotated as misinformation, 25.63% (7207/28,121) of the random subset of posts were classified as vaccine misinformation.

Topic modeling generated 10 topics from 7207 Reddit posts that were classified as vaccine misinformation. Through qualitative analysis of these 10 algorithm-identified topics and a review of their relevant Reddit posts, we condensed them into 7 (6 major topics + *Other*) topics. The word clouds for the 6

identified misinformation topics are shown in Figure S1 of Multimedia Appendix 1. The 6 major topics, the percentage of posts assigned to the topic, and post examples are listed in Table 2.

Table 2. The major topics of misinformation identified by topic modeling (n=7207).

Misinformation topic	Prevalence, n (%)	Explanation	Examples (excerpts)
General vaccine adverse events	2672 (37.07)	Promotion of general misinformation regarding the safety of HPV ^a vaccine	<ul style="list-style-type: none"> “The HPV vaccine is unnecessary and unsafe.” “The HPV vaccination causes retardation.”
Conspiracy theory	1072 (14.87)	Propagation of conspiracy theories about HPV vaccine and fraud by the government and large pharmaceutical companies (eg, Merck)	<ul style="list-style-type: none"> “Rick Perry signed an executive order trying to mandate Gardasil vaccines for young girls. He did this to make money for his buddies at Merck.” “The HPV vaccine is a joke pressed on schools and administrations by greedy pharmaceutical corporations.”
Citing unfounded studies	989 (13.72)	This type of misinformation can be very misleading because it tends to cite and interpret <i>scientific</i> studies from sources that are not scientifically peer reviewed	<ul style="list-style-type: none"> “Flawed safety study on HPV vaccine triggers butterfly effect - leaked e-mails reveal who suppressed info on dangerous particles in vaccine” “We find that HPV vaccine clinical trials design, and data interpretation of both efficacy and safety outcomes, were largely inadequate”
Vaccine deaths and serious reactions	520 (7.21)	Propagation of HPV vaccine-induced death and serious adverse reactions	<ul style="list-style-type: none"> “For instance, the HPV vaccine has caused children to die.” “The shots have killed women. The adverse event reports from the FDA^b about HPV vaccination read like a litany of horrors.”
Aluminum-containing adjuvants	456 (6.33)	Promoting misinformation on safety issues of aluminum-containing adjuvants in vaccines	<ul style="list-style-type: none"> “Another good keyword is for Gardasil adverse drug reactions. That’s how I found this: ‘each 0.5-ml dose of the vaccine contains approximately 225 mcg of aluminum (as amorphous aluminum hydroxyphosphate sulfate adjuvant)’ This study clearly shows that aluminum found in vaccines can cause neurologic damage.” “Brain damage and autoimmune diseases can be caused by aluminum adjuvants. Aluminum adjuvant is in the HPV vaccine.”
Vaccine and autism	198 (2.75)	Promoting misinformation on the discredited links between vaccine and autism	<ul style="list-style-type: none"> “The HPV vaccine causes autism” “Vaccine court awarded millions to two children with autism. CDC^c report creates controversy for Merck’s Gardasil vaccine”

^aHPV: human papillomavirus.

^bFDA: Food and Drug Administration.

^cCDC: US Centers for Disease Control and Prevention.

Misinformation Network Analysis

We further analyzed the network among the identified topics. For each Reddit post, we identified the 2 most associated topics (ranked by probability generated by the BTM). We assume that these top 2 topics were linked for that post, which was considered an undirected edge in the network. Figure S2 in [Multimedia Appendix 1](#) shows the misinformation topic network among these 7 topics. The size of the circle for each topic is proportional to the degree of associations of the topic (ie, the number of connections with other topics). The width of the edge is proportional to the number of connections between the 2 topics.

Discussion

Principal Findings

In this study, we evaluated the use of different ML-based approaches to analyze Reddit discussions related to HPV vaccine misinformation. The CNN and RNN algorithms improved the

AUC value compared with the traditional ML algorithms. A BTM was adopted to further explore the major topics related to vaccine misinformation discussions. Overall, 6 major topics related to HPV vaccine misinformation, including *Vaccine death and serious reactions* and *Aluminum-containing adjuvants* were identified. The *Vaccine adverse effect*, which refers to general misinformation regarding safety issues, is the most prevalent topic within HPV vaccine misinformation.

The highest proportion of vaccine misinformation content on Reddit identified with our approach concerned general vaccine adverse effects (2672/7207, 37.07%), followed by content about vaccine conspiracy theories (1072/7207, 14.87%). These results are consistent with previous analyses of social media-based vaccine misinformation, which found that inaccuracies about vaccine knowledge and risk (37.9%) made up most of the social media posts with negative vaccine sentiments [55]. The same small study also found that 13.8% of the negative posts about vaccines included distrust of government and pharmaceutical

companies, which closely mirrors our findings in a larger sample from Reddit.

We further analyzed the top subreddits among the posts that ML inferred as containing misinformation and nonmisinformation. The subreddits that contain the most misinformation-related posts include *science* (n=653), *AskReddit* (n=604), *conspiracy* (n=593), and *politics* (n=397). On the contrary, the subreddits that contain the most nonmisinformation-related posts include *AskReddit* (n=2040), *sex* (n=1994), *TwoXChromosomes* (n=1652), and *science* (n=1385). Besides general popular subreddits such as *science* and *AskReddit*, misinformation tends to cluster in subreddits such as *conspiracy* and *politics*. There is an increasing trend of discussing HPV vaccine-related topics on Reddit from 15 posts in 2007 to 5878 posts in 2017. There is a decreasing trend in the proportion of misinformation over time on Reddit. The proportion of misinformation ranged from 41.8% (72/172; in year 2008) to 53% (8/15; in year 2007) during the period 2007 to 2009, whereas it ranged from 22.84% (1009/4417; in year 2016) to 33.85% (730/2156; in year 2011) during the period 2010 to 2017. The decrease could be a result of the continuous promotion efforts made by public health professionals, as well as an increase in internet verification skills among users.

The results of our network analysis of the 6 identified vaccine misinformation topics (in addition to *Other*) further reinforce our findings and demonstrate the strength of the connectedness of each topic. Although general concerns about the safety of the vaccine emerged as the main source of hesitancy regarding HPV vaccination, the network analysis indicates that the other prominent topics identified, such as the presence of conspiracy theories, may also be rooted in fears about the side effects of the vaccine. Mere exposure to beliefs that the government and pharmaceutical companies gain or profit from mass vaccination through deception or at the consumers' expense, has strong negative effects on attitudes about the safety and effectiveness of vaccines, consequently affecting choices about whether to vaccinate [56].

Of note, the annotators anecdotally observed that the Reddit posts identified in this study did not seem to be connected to any organized movements; rather, they were by single users advocating their personal views. A potential method to combat these misinformed messages once identified is to counter them with an organized campaign, composed of factual, evidence-based messages, that does not acknowledge disinformation. As other studies have noted, acknowledging and deferring to web-based disputes related to vaccines may cause health information seekers to doubt established evidence regarding vaccine efficacy and safety [57]. In addition, it has been found that attempting to correct misinformation directly often reinforces the sentiments of those holding strong antivaccine views [58].

To the best of our knowledge, this is one of the early efforts to explore the use of *automated* ML algorithms (eg, ML and NLP) to identify and classify HPV vaccine misinformation in social media discussions. We chose the HPV vaccine as the use case for our analysis, but the proposed methodology framework can also be applied to other types of vaccines or other pertinent

health-related topics. The ML-based framework is also scalable to big social media data. Our work could assist policy makers and the industry to accurately understand and address the spread of health misinformation on social media. The methodology framework developed in this study is generalizable to other social media platforms such as Twitter and can be used to identify misinformation in both retrospective and real-time social media feeds. The use of this methodology could be incorporated into social media platforms dedicated to curbing the spread of health-related misinformation on these sites, although the ethical ramifications of such restrictions should be taken into consideration.

Limitations and Future Work

This study should be interpreted in light of limitations and future research needs. Given the unique features of social media language, the accurate identification of misinformation is a very challenging task. The best algorithm achieved an AUC value of 0.7943, and there is some room for improving this performance. Our current ML classifier has a higher recall than precision (0.6202 vs 0.4083). This means that the classifier tends to label both misinformation and nonmisinformation as misinformation. In a real-world scenario, the classifier may serve as a tool to prescreen misinformation, and more rigorous fact-checking methods (eg, human checking) would be needed to label true misinformation posts. The high imbalanced label distribution (ie, only 396/2200, 18%) of the posts were labeled as misinformation in the gold standard corpus) hurt the ML algorithm because most of the ML algorithms used for classification were designed based on the assumption of an equal number of examples for each class. Imbalanced label distribution results in models that have poor predictive performance, specifically for the minority class (eg, misinformation in our case) [59]. As we further refine and expand the gold standard corpus, which is critical for the evaluation and training of ML algorithms, we expect the performance to improve. In addition, we will explore the use of data augmentation techniques [60] and random oversampling methods [61,62] to alleviate the issues caused by imbalanced label distribution. Other emerging advanced DL algorithms such as Bidirectional Encoder Representations from Transformers (BERT) [63] hold promise for improved performance. In addition, we performed annotation at the level of Reddit posts, which may have sacrificed precision. A single Reddit post often contains multiple sentences, allowing a mix of misinformation and nonmisinformation to exist in a single post. Therefore, a Reddit post annotated as *misinformation* could also contain evidence-based facts. Future research can establish the effect of annotation and classification at the sentence level to improve the precision of misinformation identification. In addition, the identification of *abstract topics* from topic modeling is a semiautomated process combined with expert review. However, topic assignment and summarization may be subjective and suffer from biases as well. In future, we can explore the use of supervised algorithms for more precise topic discovery.

Conclusions

Our ML-based approaches demonstrated efficacy in the automated identification and classification of HPV vaccine misinformation in discussions on the social media platform Reddit. The large quantity of web- and social media-based medical and public health information available may make it difficult for those with low health and web literacy to navigate and find authentic and evidence-based information. Although our ML algorithm does not solve the problem of health and

vaccine misinformation single-handedly, we provide an innovative stepping stone that may bridge multiple approaches for combating this invasive and growing public health concern. The accurate and timely understanding of vaccine misinformation on social media can assist vaccine promotion campaigns to prevent such information from misleading the vulnerable public. Our methodology could also be applied to other social media platforms such as Twitter, although new labeled data would be necessary.

Abstract

Background: One of the successful measures to curb COVID-19 spread in large populations is the implementation of a movement restriction order. Globally, it was observed that countries implementing strict movement control were more successful in controlling the spread of the virus as compared with those with less stringent measures. Society's adherence to the movement control order has helped expedite the process to flatten the pandemic curve as seen in countries such as China and Malaysia. At the same time, there are countries facing challenges with society's nonconformity toward movement restriction orders due to various claims such as human rights violations as well as sociocultural and economic issues. In Indonesia, society's adherence to its large-scale social restrictions (LSSRs) order is also a challenge to achieve. Indonesia is regarded as among the worst in Southeast Asian countries in terms of managing the spread of COVID-19. It is proven by the increased number of daily confirmed cases and the total number of deaths, which was more than 6.21% (1351/21,745) of total active cases as of May 2020.

Objective: The aim of this study was to explore public sentiments and emotions toward the LSSR and identify issues, fear, and reluctance to observe this restriction among the Indonesian public.

Methods: This study adopts a sentiment analysis method with a supervised machine learning approach on COVID-19-related posts on selected media platforms (Twitter, Facebook, Instagram, and YouTube). The analysis was also performed on COVID-19-related news contained in more than 500 online news platforms recognized by the Indonesian Press Council. Social media posts and news originating from Indonesian online media between March 31 and May 31, 2020, were analyzed. Emotion analysis on Twitter platform was also performed to identify collective public emotions toward the LSSR.

Results: The study found that positive sentiment surpasses other sentiment categories by 51.84% (n=1,002,947) of the total data (N=1,934,596) collected via the search engine. Negative sentiment was recorded at 35.51% (686,892/1,934,596) and neutral sentiment at 12.65% (244,757/1,934,596). The analysis of Twitter posts also showed that the majority of public have the emotion of "trust" toward the LSSR.

Conclusions: Public sentiment toward the LSSR appeared to be positive despite doubts on government consistency in executing the LSSR. The emotion analysis also concluded that the majority of people believe in LSSR as the best method to break the chain of COVID-19 transmission. Overall, Indonesians showed trust and expressed hope toward the government's ability to manage this current global health crisis and win against COVID-19.

KEYWORDS

large-scale social restrictions; social media; public sentiment; Twitter; COVID-19; infodemiology; infoveillance

Introduction

Social quarantine measures, such as movement control order, shelter in place, and lockdowns, are considered effective methods to curb the spread of COVID-19 [1]. Countries all over the globe affected by this pandemic have at least considered implementing this modus as a national strategy to bring COVID-19 cases down and reduce the burden on their health care system. Until a vaccine can be effectively administered to the public, the only effort that can be done to reduce virus transmission sustainably is by exercising prevention measures and embracing it as the new living norm. This includes restricting movement that reduces social contact and improves physical distancing [2]. Physical distancing is performed to decrease the risk of virus transmission from one who is likely to be infected to other healthy individuals [3]. A study measuring the effectiveness of physical distancing in England found that this method can significantly decrease the contact-level frequency up to 74% and was the key factor in decreasing the total confirmed cases in the country [4]. Effective physical distancing correlates with a gradual decline in the number of cases infected [5].

In most countries affected by COVID-19, national-level physical distancing order such as lockdowns, movement control, and shelter in place are implemented as strategies to bring down the number of coronavirus cases. This regulation has been proven as the most effective strategy to eradicate the spread of the virus in several countries such as Brunei [6], New Zealand, and Vietnam [7]. As a result, those 3 countries have succeeded in flattening the curve since the first wave of infection up until now. A valuable lesson can also be learned from Indonesia's closest neighboring country—Malaysia. Through a study on COVID-19 control measures, Ng et al [8] summarized that the movement control order had managed to suppress the transmission within only 3 weeks after its implementation. Thus, despite difficulties in implementing physical distancing measures in the long run, this method is a critical and effective measure in curbing the spread of infection [9].

After the first case was reported on March 2, 2020, the COVID-19 curve of Indonesia started to show a significant increase at the end of the month with no signs of decline, as the number of infected cases continued to hit a new peak every day. In that month, with 136 deaths out of 1528 total positive cases, Indonesia surpassed China in its case fatality rate (8.90%). China's death rate was at 4% at the time [10]. The implementation of the large-scale social restriction (LSSR) on March 31, 2020, was overdue, as the number of cases was significantly high [11]. At the time, the number of positive cases in Indonesia was still 2 times lower compared with Malaysia, but as of early June 2020, the country had the second highest number of positive confirmed cases in Southeast Asia after Singapore. Indonesia became the country with the highest fatality rate in Asia, with a case fatality rate of 5.94% (n=1573) among the overall confirmed cases (N=26,473) [12]. If social restriction is a reference to the success of a country in handling and suppressing the COVID-19 outbreak, then the high number of daily confirmed cases reported in Indonesia indicates the poor implementation of the policy and government supervision

of the LSSR. According to The Institute for Development of Economics and Finance [13], Indonesia is the least successful country in implementing the movement restriction policy among Southeast Asian countries. The number of confirmed cases in Indonesia is considered the worst compared with neighboring countries.

LSSR implementation in Indonesia indeed has faced many obstacles since its first inception. The success of LSSR is not merely determined by policy execution by the government, but is significantly influenced by public willingness to participate by voluntarily staying at home and not visiting public places. Therefore, it is useful to examine public response toward the implementation of LSSR. However, studies on public response toward LSSR effectiveness are limited. Most prior public-oriented studies have focused on COVID-19 knowledge, attitudes, and behaviors [14-19]. Furthermore, only few studies discussing public response toward social quarantine policy, especially in Indonesia, are available.

Accordingly, this study aims to identify public response toward government policy, specifically the LSSR, in Indonesia. Studies on public response toward policy implementation regarding COVID-19 prevention are imperative, particularly when the government as the policy maker is expected to be sensitive to societal needs and behavior [20]. Utilizing sentiment analysis, this study attempts to identify Indonesian public sentiment and emotions toward the LSSR from a macro perspective. Several studies have examined public response toward government rules concerning COVID-19 prevention in Indonesia using sentiment analysis, for example, Djalante et al [11] and Raamkumar et al in Singapore [21]. However, both studies looked at responses on specific platforms and cannot be generalized to the larger population. Therefore, this study will offer a macro approach by mining and analyzing big data from more than 500 online news portals and social media platforms such as Twitter, Facebook, Instagram, and YouTube. This study is useful to gauge public responses in Indonesia in detail as guidance to improve existing policy.

Methods

Study Design

This study employed sentiment analysis using a supervised machine learning approach to mine COVID-19-related posts on selected media platforms (Twitter, Facebook, Instagram, and YouTube). Machine learning was chosen as the method for classifying sentiment categories considering its effectiveness to accommodate a larger data set. The analysis was also performed on COVID-19 news published in more than 500 online news platforms recognized by the Indonesian Press Council. Online news and social media posts included in the analysis are those posted between March 31 and May 31, 2020. The whole process of supervised machine learning application is described in Figure 1.

The first analysis in this study involved sentiment analysis on data from both online news portals and social media platforms. The second analysis was an emotion analysis conducted on the Twitter platform to identify collective public emotion toward

the LSSR. The whole analysis process on social media and online news portal involved natural language processing (NLP)

on Apache SOLR. Details of the systematic analysis process are as outlined below.

Figure 1. Machine learning workflow.

Data Gathering

This study applied 2 different methods for data collection from each platform. The data from online news portals were collected using Perl Web Crawler, while real-time application programming interface (API) provided by Perl Programming Language, including Net::Twitter, Facebook::Graph, API::Instagram, and WebService::YouTube, was employed for each social media platform. Online news and social media posts obtained were then stored in the Apache SOLR database. Search profiling was accomplished using the terms “Pembatasan Sosial Berskala Besar” (large-scale social restrictions), “Pembatasan Sosial” (Social Restrictions), and “PSBB” (LSSR) as the main keywords to describe the government-implemented social restrictions in Indonesia. These keywords were deemed sufficient to capture public interest in the LSSR as there are no other synonyms in either Bahasa Indonesia or English that refer specifically to the government-implemented restrictions.

Data Preprocessing

Overview

Additionally, a data cleansing process was conducted. The supervised machine learning approach enabled the researchers to sort, select, and also update the data stored in the search engine to ensure that only data associated with the study context will be analyzed. The main purpose of data preprocessing is to clean the data set from all noise and outliers. The details of this phase are described in the following subsections.

Duplicate Text Filtering

This process was done to remove text duplication and ensure only original data were included for analysis. All duplications in social media data (mostly from retweets) and online news were removed to avoid redundancy.

Text Normalization

All usernames, stop words (eg, at, in, on, may, always), URLs, hash symbols (#), punctuation marks, and other nonalphanumeric characters were removed as those entities would have no influence in determining the value of sentiment. Besides, typos and multiple occurrences of certain characters within 1 word were normalized in this stage (eg, “SAAAAAAAAD” becomes “SAD”).

Case Folding

Case folding is a procedure that helps data normalization, in which all texts are standardized to lower case to make it easier for the system to retrieve information more effectively.

Feature Selection (Part-of-Speech Tagging)

The part-of-speech (POS) tagging system is a word processing tool in NLP that refers to the process of tagging text onto a corresponding POS based on its definition and its relation with other words [22]. Commonly, only words that are categorized as nouns, adjectives, verbs, and adverbs were tokenized and tagged by the POS tagger, as those words are considered important indicators of objectivities and opinions [23]. Some studies have been conducted to create an Indonesian Standardized Annotated Corpus by applying a probability statistic approach such as Hidden Markov Model [24] and Maximum Entropy [25]; nevertheless, none of them are accessible for general audiences [26]. Thus, in this study, it was decided that the Indonesian Language Dictionary (*Kamus Besar Bahasa Indonesia* or *KBBI*) would be used as the main lexical database.

Algorithm Selection and Training

The naïve Bayes classifier is a machine learning algorithm that is commonly utilized for text classification based on probabilistic calculations to predict future possibilities by looking at past patterns [27]. Although there is still no exact justification on which algorithm is best in classifying text, the use of naïve Bayes has been proven effective or even more accurate [28] and precise [23,29] than other algorithms in previous studies. Additionally, a recent study discovered naïve Bayes to be more accurate in determining COVID-19 sentiment categories compared with other classifiers such as logistic regression [30]. Therefore, it was decided that this algorithm will be used to classify the sentiment into 3 categories from the training data: positive, negative, and neutral. The use of naïve Bayes algorithm for this study can be described by the following equation:

$$P(X_i|V_c)$$

where V_{MAP} is all examined categories; V_c is the sentiment category; $P(X_i|V_c)$ is the probability of the word i falling into category c ; and $P(V_c)$ is the probability of V_c .

Large amounts of data tokenized into nouns, adjectives, verbs, and adverbs by POS tagging were stored within a training data set and trained using fivefold cross validation to ensure the accuracy of the sentiments. To further improve the accuracy, a system that allows admin intervention in the sentiment labeling process was developed and interannotator agreement was applied involving 3 annotators (from Astramaya) in the review process to ensure the validity of labeling.

In the review process, all unrelated contents were removed as they are not suitable for analysis. Further, this process enabled the researchers to fix the sentiment defined on the machine so that the sentiment tendency would fit to the context and demands of the analysis. After the selection process, we obtained 1,934,575 mentions of the search terms on both online news portals and social media platforms from March 31 to May 31, 2020. The data crawling process placed Twitter as the platform with the highest number of data, in which the keywords were mentioned 1,440,062 times. The use of Twitter for sentiment analysis research is indeed more popular than other platforms. Twitter is accessed by over 330 million users monthly and has 145 million daily active users [31]. The open nature of the microblogging service with numerous daily messages produced and generated has positioned it as the focal point of social media research and NLP [32].

Lexicon-Based Approach for Emotion Analysis

The emotion analysis in this study was performed using a lexicon-based, or specifically a dictionary-based approach, in which the Indonesian Language dictionary *Kamus Besar Bahasa Indonesia (KBBI)* was utilized as the lexical database. The categorization of emotion was derived from the basic emotion concept put forth by Plutchik [33], including joy, trust, fear, surprise, sadness, disgust, anger, and anticipation. There is a slight methodology difference in determining emotion categories for the data collected from both types of platforms. On social media, public sentiment and emotion were identified based on an analysis of the text in each post; 1 post or unit of analysis

could represent 1 or more emotions. Emotion analysis with a lexicon-based approach enables the researcher to conduct pattern matching using the regular expression feature on the Perl application. In addition, emotion analysis was not carried out for online news platform as online news does not represent any form of public conversation trend. Thus, only public sentiment can be obtained on this platform, and not public emotion.

Data Visualization

Visualization is the final part of the NLP process, where the results of the analysis are translated into visuals to support the statistical data. To optimize the data presentation interface, all visual presentations in this study were delivered using Zend Framework (Linux Foundation).

Results

Data Demography

Search using the keywords “*Pembatasan Sosial*” and “*PSBB*” (LSSR) performed on both online news and social media platforms revealed 1,934,596 mentions of these in news sentences and social media posts. Twitter yielded the highest mentions (1,440,062/1,934,596, 74.44%), followed by online news (397,004/1,934,596, 20.52%), Instagram (50,754/1,934,596, 2.62%), Facebook (43,819/1,934,596, 2.27%), and YouTube (2957/1,934,596, 0.15%). Figure 2 presents the data distribution for each platform.

The data distribution showed that discussions related to LSSR on social media mainly took place on Twitter. This justified the use of Twitter to describe the overall sentiment and emotions toward the LSSR on social media. To identify popular topics discussed by the public, the NLP process helped to cluster discourses which were predominantly used and written in online news platforms via topic mapping. However, on Twitter, popular topics were identified based on top tweets during the study period. Figure 3 reports discourses and topic mapping for LSSR in online news platforms.

Figure 2. Data distribution for each platform.

Figure 3. Topic mapping of online news platforms.

The most frequently discussed topics related to LSSR in Indonesia are LSSR policy, the new normal, and the impact of LSSR on the economic sector. The high level of conversation regarding the relaxation of LSSR in online news platforms represents the amplification of various responses from the public and media toward the government’s swift plan to implement new norms.

The discussions about LSSR on both online news platforms and social media are mostly in relation to the new normal. In addition, news crawling found that a number of LSSR-related news are political. Many assumed that the LSSR relaxation in Indonesia was not based on careful consideration but was implemented to reduce the economic burden on the government.

The term “political crisis” was used to describe what would happen if the government did not take any immediate action to ease the economic burden of its society. This assumption is supported by the high number of new reports highlighting the economic impact of LSSR on the nation. Government as the policy maker faced various negative reverberations about LSSR relaxation, as it was seen to be prioritizing the economy over public health.

In addition, to identify LSSR topics with the highest engagement level on Twitter, tweets with the highest number of retweets were ranked. Figure 4 describes 5 tweets with the highest engagement.

Figure 4. Most retweeted tweets.

Overall, it can be assumed that the tweets represented public outburst and resentment toward 2 parties: the government that is considered indecisive to implement LSSR, and those among the public who enjoyed the LSSR relaxation by going out freely.

Public Sentiment Toward Large-Scale Social Restrictions

Sentiment analysis on online news platforms and social media during the period between March 31 and May 31, 2020 (n=1,934,596) showed that public sentiment toward the LSSR tended to be positive. Figure 5 presents the distribution of total mentions of positive, negative, and neutral sentiments in online news and social media platforms.

Figure 5. Total mentions by sentiment.

Based on the statistics in Figure 5, positive sentiment surpasses other sentiment categories (1,002,947/1,934,596, 51.84%) followed by negative (686,892/1,934,596, 35.51%) and neutral (244,757/1,934,596, 12.65%) sentiments. These data suggest that although society in general viewed the government’s LSSR implementation and relaxation as indecisive, the majority still supported and regarded LSSR as the best solution to break the chain of COVID-19 transmission in the country. At the same

time the negative sentiment on LSSR can be considered very high. It is not a good indicator of government performance, moreover, considering that the recovery phase of this health crisis will highly depend on public support and cooperation. Therefore, strategic and proactive efforts are needed to maximize the support from society. To deepen the understanding of public sentiment, a trend analysis was carried out as outlined in Figure 6.

Figure 6. Sentiment trends in all media types.

Figure 6 presents the overall trend in sentiment for both online news and social media. It was observed that overall, positive sentiments were higher than negative and neutral sentiments. There were only 2 days where negative sentiments were higher than positive sentiments, precisely on May 11 and 21, 2020. Tweets with the highest engagement on May 11, 2020, highlighted the flaws in LSSR implementation, wherein the government lacked a firm response toward a mass gathering in Sarinah, Central Jakarta.

The positive and negative sentiments toward the LSSR reached the peak on the same day (ie, May 14, 2020), with recorded mentions of more than 30,000. Interestingly, both positive and negative opinions on that day were referring to a particular tweet, posted by @Jeromepolin, regretting the public’s noncompliance to the LSSR. A detailed analysis concerning the discussion trend revealed that the negative sentiments referred mostly to the indecisive government and noncompliance toward the LSSR. A similar pattern of both positive and negative sentiments with high mentions was also recorded on May 17, 2020 (Figure 7).

Figure 7. Sentiment trends on May 17, 2020.

Similar to the sentiment trends on May 14, 2020, the topic with the highest mentions on May 17, 2020, also referred to skepticism toward the government's implementation of the LSSR. In addition to this, some parties were disappointed with the government's decision to relax the LSSR when positive cases of COVID-19 in Indonesia were still on the rise.

Public Emotions Toward LSSR

Public emotion analysis using a lexicon-based approach and quote extraction was applied to explore collective public

emotion regarding the LSSR. As discussed in the "Methods" section, public emotion was categorized based on the basic emotion concept by Plutchik [33], including joy, trust, surprise, fear, disgust, sadness, anger, and anticipation. Furthermore, this analysis can be used as a parameter to identify how far the government and the LSSR garnered public trust. Public emotions toward the LSSR are shown in Figure 8.

Figure 8. Emotion analysis.

The emotion analysis concluded that although there were many negative opinions toward the government and the LSSR, the public still believed that the LSSR was the best method to break the chain of COVID-19 transmission. The public expected that all members of society would accept and comply with this policy in order to achieve overall success. At the same time, the public

still had expectations that the government would immediately overcome the issue by implementing firmer control. Although the overall public emotion was still "trustful," interesting trends were found in 2 other emotion categories, namely, "fear" and "sadness." Figure 9 depicts public emotion trends during the study period.

Figure 9. Trend of public emotions.

The “sadness” and “fear” emotions showed the most outstanding patterns compared with other emotion categories and were found to reach their peak on April 11, 2020, and May 14, 2020, respectively. On April 11, 2020, the most retweeted post suggested public sadness toward the implications of the LSSR. Moreover, on that date, the number of deaths continued to surpass the total recovered cases in the country. The same trend occurred on 22 May, 2020, which also indicated “fear” of public disobedience toward the LSSR.

Discussion

Principal Findings

This study found Twitter as the most dominant platform used by the public when discussing COVID-19 and LSSR. Public sentiment toward the LSSR was largely positive with expressions of support for the government intervention in combating COVID-19. Even so, negative sentiments were also quite high, especially concerning government’s indecisiveness and public defiance of the LSSR. The emotion analysis revealed that Indonesians were mostly trustful with notable peaks in sadness and fear corresponding to increased COVID-19 death rates.

A closer examination of tweets with the highest level of engagement showed that a majority of the public were dissatisfied with the government and parties that did not obey LSSR regulations. This is supported by the trends observed in the sentiment analysis. Criticisms of government’s indecisiveness and LSSR relaxation dominated the discussion trends regarding LSSR during the study period. Even though the overall public sentiment was positive, the negative and neutral sentiments were still considered high. The fact that almost half of the public did not show positive attitudes toward the government and LSSR implementation can be worrying, particularly in a global health crisis of this magnitude. A

neighboring country, Vietnam, for example, has proven that effective cooperation between the society and the government can successfully allow the country to control the spread of COVID-19 cases. Compliance of Vietnamese to their government instructions such as wearing masks and implementing self-quarantine [34] has made their country one of the victorious in managing the pandemic with less than 60 deaths as of June 2021 [35].

The results also show that the Indonesian government’s inconsistent stance in implementing policies has contributed to the emergence of public emotions such as fear and sadness. The Indonesian media may have played a role in this, as concerns about socioeconomic uncertainty, LSSR, social distancing violations, and economic downturn in all sectors were widely reported in the media from March to early April 2020 [36]. In the earlier phase of the pandemic, negative media reports on issues such as insufficient government response, patient care, and burial of the deceased also caused agitation among the Indonesian public [37]. A previous study on COVID-19 news in Indonesia also suggested that the distortion of news by both online and mainstream media has caused an increase in public fear and anxiety [38].

Analysis of sentiments surrounding COVID-19 has produced similar results in communities across the globe. The health crisis has sparked concerns on the spread of the virus and its containment [39], economic survival [40], and physical and mental well-being [41]. The uncertainty surrounding the pandemic has resulted in expressions of mixed emotions in the public domain. An analysis of Twitter discussions in the early stages of the pandemic found dominant emotions of trust, anger, and fear surrounding COVID-19 cases and deaths [39]. A study in Italy observed a similar pattern; feelings of anger and fear emerged along with trust, solidarity, and hope [42], while in Spain sentiments surrounding the pandemic were that of disgust, fear, anger, and sadness [43].

It is important to note that while these sentiments and emotions were dominant at the beginning of the pandemic in early 2020, there has been much polarity and change in the sentiments since then [44]. COVID-19 should be a lesson for governments to affirm the consequential role of strategic public policy and acknowledge the importance of clear, consistent, and well-targeted public communications in overcoming crisis.

While public trust is still high, the government must be responsive to the needs of its society, considering their outlook as the basis for formulating policies and revising those deemed incompatible with public needs. Economic struggles were one of the biggest drivers of LSSR noncompliance in Indonesia. The large number of violations found in big cities such as Jakarta, Bogor, Depok, Tangerang, and Bekasi [45] is consistent with the findings of Wasdani and Prasad [46], who reported that the implementation of social distancing among the urban poor is very difficult. Therefore, strategic public policy should be introduced to maintain economic resilience, for instance, allocating budget for economic stimulus packages as done by the Malaysian government, which distributed MYR 260 billion (US \$61 billion) to its people in the lower- and medium-income groups [47].

Even so, robust public policy alone may not be sufficient to curb negative emotions surrounding the pandemic. Mohamad et al [48] have highlighted that the delivery of clear, consistent, and credible information is key to control and mitigate the disease. Misinformation resulting from the communication of policies greatly affects public perceptions and trust during the pandemic [49]. To ensure successful communication to the public, authorities must recognize the important role of mass media in delivering quality information, as evidenced by previous studies [43].

Strength and Limitations

The strength of this study is in the variety of platforms analyzed. To obtain more diverse data, analyzing various types of social media and online news platforms with relatively large data sets makes it possible to synthesize diverse results compared with previous studies. Previous studies involving online media often only analyzed a single type of platform such as Twitter [49,50], Sina Weibo, the Chinese version of Twitter [51,52], Facebook [21], and online news portals [53,54]. By contrast, this study has a relatively larger data set collected by optimizing

web-crawling functions on more than 500 online news portals and large amounts of social media data.

However, there were some limitations to this study. The large amount of data analyzed on social media platforms made it difficult for the researchers to determine what topics were dominant on social media, particularly Twitter. The text-based approach used on Twitter requires a relatively longer issue clustering process. Accordingly, the topic mapping could only be used to analyze the data gathered from online news platforms, by applying a clustering method to identify topics that are similar to each other, assisted by paragraph segmentation to deepen researcher understanding of the news context. In addition, this study did not conduct emotion analysis on the comments that appeared in online news. Future research is recommended to explore public emotions by analyzing comments written in response to news items.

Research Implications

The results of this study may assist policy makers in being active observers of public responses in online media, especially on social media. Public communications by the government in this new media era must transform from being mere publicity to observing and analyzing public sentiment.

Social listening is becoming an important way to gauge public opinion and response. Public confusion surrounding the LSSR is a sign that the government must develop a comprehensive communication protocol to emphasize the importance of LSSR in eradicating the spread of COVID-19 in Indonesia.

Conclusions

Overall, this study disclosed Twitter as the most popular platform used by Indonesian public in conveying their thoughts regarding LSSRs. The analysis performed on the major keywords that appeared on social media and online news portals revealed positive sentiment toward the LSSR. However, there were concerns on emerging conversations regarding public skepticism toward effective implementation of the LSSR. In addition, the emotion analysis concluded that a majority of the public still believe LSSR as the best method to effectively slow the spread of COVID-19. This explains why the public still hold high hopes and expectations toward the government as the policy maker in keeping them safe in a health crisis such as this.

Acknowledgments

The completion of this paper could have not been done without outstanding support from our partner, Astramaya, in running the data mining procedure. Therefore, we express our sincere appreciation to and acknowledge the Astramaya team for their contribution. It was an honor to work with the biggest and most reputable data analytics company in Indonesia.

Abstract

Background: Previous studies have suggested associations between trends of web searches and COVID-19 traditional metrics. It remains unclear whether models incorporating trends of digital searches lead to better predictions.

Objective: The aim of this study is to investigate the relationship between Google Trends searches of symptoms associated with COVID-19 and confirmed COVID-19 cases and deaths. We aim to develop predictive models to forecast the COVID-19 epidemic based on a combination of Google Trends searches of symptoms and conventional COVID-19 metrics.

Methods: An open-access web application was developed to evaluate Google Trends and traditional COVID-19 metrics via an interactive framework based on principal component analysis (PCA) and time series modeling. The application facilitates the analysis of symptom search behavior associated with COVID-19 disease in 188 countries. In this study, we selected the data of nine countries as case studies to represent all continents. PCA was used to perform data dimensionality reduction, and three different time series models (error, trend, seasonality; autoregressive integrated moving average; and feed-forward neural network autoregression) were used to predict COVID-19 metrics in the upcoming 14 days. The models were compared in terms of prediction ability using the root mean square error (RMSE) of the first principal component (PC1). The predictive abilities of models generated with both Google Trends data and conventional COVID-19 metrics were compared with those fitted with conventional COVID-19 metrics only.

Results: The degree of correlation and the best time lag varied as a function of the selected country and topic searched; in general, the optimal time lag was within 15 days. Overall, predictions of PC1 based on both search terms and COVID-19 traditional metrics performed better than those not including Google searches (median 1.56, IQR 0.90-2.49 versus median 1.87, IQR 1.09-2.95, respectively), but the improvement in prediction varied as a function of the selected country and time frame. The best model varied as a function of country, time range, and period of time selected. Models based on a 7-day moving average led to considerably smaller RMSE values as opposed to those calculated with raw data (median 0.90, IQR 0.50-1.53 versus median 2.27, IQR 1.62-3.74, respectively).

Conclusions: The inclusion of digital online searches in statistical models may improve the nowcasting and forecasting of the COVID-19 epidemic and could be used as one of the surveillance systems of COVID-19 disease. We provide a free web application operating with nearly real-time data that anyone can use to make predictions of outbreaks, improve estimates of the dynamics of ongoing epidemics, and predict future or rebound waves.

KEYWORDS

Google Trends; symptoms; coronavirus; SARS-CoV-2; big data; time series; predictive models; Shiny web application; infodemiology; infoveillance; digital health; COVID-19

Introduction

COVID-19 is a new entity, and the dynamics of its propagation are difficult to predict. In the absence of compelling evidence, health and political decisions have been strongly driven by a wide variety of statistical models and simulation scenarios to forecast the COVID-19 epidemic. Still, large variations exist among the different models with respect to the predicted number of infected people, time to reach a peak of new cases, course of the epidemic, and identification of outbreaks [1]. One key limitation of such models is that they rely heavily on the number of confirmed infected subjects who usually seek medical attention due to moderate to severe symptoms. However, confirmed cases are most likely only a small proportion of the true number of cases as the vast majority of infected individuals are asymptomatic or mildly symptomatic [2].

There is increasing interest in the potential of “big data” analysis to predict future areas of COVID-19 outbreaks and incidence of cases based on symptom search behaviors. In the past, search query data have been used to facilitate early detection and near real-time estimates of flu and Dengue [3]. A few studies have shown a correlation between Google Trends data of medical term searches and COVID-19 metrics [4], suggesting that incorporating Google Trends data into conventional metrics could lead to better nowcasting and forecasting of the COVID-19 epidemic.

In this study, we systematically evaluate patterns of web queries for COVID-19 clinical manifestations and develop an open-access web application for exploring their correlations with COVID-19 propagation. We implement models integrating conventional COVID-19 metrics with Google Trends data and compare them to those not containing Google Trends data. The aim of this study is to present a framework for digital surveillance of COVID-19 using open-access big data of Google searches of symptoms associated with COVID-19.

Methods

Data Collection

Daily new confirmed COVID-19 cases, the cumulative number of COVID-19 cases, and the number of cases and deaths per million for all available countries were exported from the COVID-19 Data Repository by the Center for System Science and Engineering at Johns Hopkins University [5]. The selected countries used as case studies are given in the results section below. Country choice was arbitrary, and the following principles were adopted: representation of the five continents; inclusion of countries where the COVID-19 epidemic had different levels of severity and different evolutions over time; inclusion of countries where Google is the preferred search engine; exclusion of countries with limited access to the internet; exclusion of countries where one or more Google Trends topic

had only zero or missing values in the selected time frame; and exclusion of countries whose reliability in terms of data reporting has been questioned. As data were fully anonymized and publicly available, no ethical approval was required.

The Google Trends application programming interface (API) was used to extract trends of Google searches for the most common COVID-19 signs and symptoms. For each search term, geographic region, and time frame selected, Google Trends outputs an “interest-over-time” index, which estimates the relative search volume on a normalized scale from 0 (no searches) to 100 (search term popularity peak). A total of 20 topics were identified on the basis of the most frequent signs and symptoms of COVID-19 and included the following: abdominal pain, ageusia, anorexia, anosmia, bone pain, chills, conjunctivitis, cough, diarrhea, eye pain, fatigue, fever, headache, myalgia, nasal congestion, nausea, rhinorrhea, shortness of breath, sore throat, and tearing [6-9]. Google Trends queries were carried out with the “topic” function, which includes all the related terms sharing the same concept in different languages. This approach ensures that the frequency of searches for closely related symptom types are appropriately grouped together.

For each country and search term, data were automatically exported as CSV files for two prespecified time frames: (1) five years of weekly data from July 1, 2015, to July 1, 2020, to study the long-term pattern of search terms, and (2) daily data from January 22, 2020, to December 20, 2020. As Google Trends allows daily data exportation up to 9 months, daily data were reconstructed by means of an overlapping method [10].

Data Analysis

Interest-over-time values for the 5-year interval were used to distinguish topics with a significant deviation from their long-term pattern from the onset of the COVID-19 epidemic. For seasonal queries, trends were isolated from seasonal and random components with an additive decomposition method (Figure S1 in [Multimedia Appendix 1](#)); for nonseasonal queries, trends were extracted by smoothing the time series with a 1-year moving average. Decomposition plots were visually inspected, and topics with no clear change in their 5-year trends from January 2020 were excluded from the subsequent analyses.

The relationship between the daily interest-over-time values for the selected topics and COVID-19 confirmed deaths and new cases were investigated in the shorter time frame indicated above. Relationships between interest-over-time values of each topic and the number of new daily confirmed cases or deaths per million were visually assessed with line graphs. Changes in interest-over-time values over time were visually assessed with streamgraphs. To smooth daily fluctuations in both interest-over-time values and number of new cases, plots were generated using a 7-day moving average.

Time-lagged cross-correlations between COVID-19 new cases and each topic were calculated, using a 7-day moving average of both interest-over-time values and COVID-19 confirmed cases and deaths to blunt the day-by-day fluctuation.

Model Development and Assessment

Principal component analysis (PCA) was used to perform data dimensionality reduction, decrease the number of input variables, and filter out noisy or redundant information. For each country, two PCA models were implemented: one using unprocessed data and the other using 7-day moving average smoothing. PCA was applied to standardized data (ie, with zero mean and unit variance). The PCA model was graphically inspected through PCA score and loading plots. PCA was assessed via 5-fold cross-validation, and the results obtained in each test sample were averaged. The amount of variance explained by each principal component (PC) in the model was inspected with scree plots. Based on the elbow and Kaiser rules, the first two PCs (PC1 and PC2) were subsequently used for time series modelling [11].

A total of three different time series models were fitted on PC1 and PC2 values: error, trend, seasonality (ETS); autoregressive integrated moving average (ARIMA); and a feed-forward neural network autoregression (NNAR) model with one hidden layer [12]. Models were fitted on a 30-day window and used to predict future PC1 and PC2 values up to 14 days. The 14th predicted day was aligned to the peak and base of each wave. The new data scores predicted with the time series models were then reinserted into the model as input variables.

For each country, the three models were compared in terms of ability to predict the PC1 and PC2 using the root mean square error (RMSE) of the predicted values. For each time series model, the predictive abilities of the model generated with raw data and the one generated with 7-day moving averages were compared. To further assess the PCA models based on both Google Trends data and conventional COVID-19 metrics, we also generated predictive models based on conventional COVID-19 metrics only; we then compared the predictive ability of models with and without Google Trends data by means of RMSE for each country.

Web Application

An open-source web application was developed using R Shiny [13]. Data are collected, imported, and updated daily for 188 countries from the sources mentioned above.

The web application allows users to generate line graphs and streamgraphs to visualize interest-over-time values and COVID-19 metrics and view worldwide trends over time in a choropleth map. Relationships between the variables at various lags can be explored with cross-correlations. The web application allows fitting and evaluating PCA models, fitting a time series model (either ETS or ARIMA), predicting PC components or any of the input variables of the model (including numbers of new cases and deaths), and evaluating the model performance graphically and with various metrics, such as RMSE and mean absolute error. The user has operational control of several model features, including the subset of variables to build the PCA model, the time window to fit the time series model, and the time interval to predict.

Data Sharing

Raw data used in this study are publicly available on the COVID-19 Data Repository by the Center for System Science and Engineering at Johns Hopkins University [14] and the Google Trends webpage [15]. All processed data used in this study can be accessed and reproduced on the PredictPandemic website [13]. The code for the current version of the web application is open source and freely available [16].

Results

For this study, three European countries (Italy, United Kingdom, and France), one Asian country (India), one Oceanian country (Australia), one North American country (United States), one South American country (Brazil), one African country (South Africa), and one Middle Eastern country (Iran) were chosen as case studies. The cumulative numbers of cases and deaths in the selected countries are illustrated in [Figure 1](#).

[Table 1](#) summarizes information from the 5-year analysis. Among the 20 screened topics, 13 showed seasonality, while the remaining were nonseasonal. Overall, 11 search topics ([Figures S2-S20 in Multimedia Appendix 1](#)) showed a clear deviation from their 5-year trend: ageusia, anosmia, chills, cough, eye pain, fever, headache, nasal congestion, rhinorrhea, shortness of breath, and sore throat.

Figure 1. Cumulative number of confirmed cases (A) and deaths (B) per million for each country over time.

Table 1. Symptoms screened in the 5-year analysis.

Topic	Seasonality	Deviation from 5-year trend ^a
Abdominal pain	Nonseasonal	No
Ageusia	Nonseasonal	Yes
Anorexia	Seasonal	No
Anosmia	Nonseasonal	Yes
Bone pain	Nonseasonal	No
Chills	Seasonal	Yes
Conjunctivitis	Seasonal	No
Cough	Seasonal	Yes
Diarrhea	Seasonal	No
Eye pain	Nonseasonal	Yes
Fatigue	Seasonal	No
Fever	Seasonal	Yes
Headache	Seasonal	Yes
Myalgia	Seasonal	No
Nasal congestion	Seasonal	Yes
Nausea	Nonseasonal	No
Rhinorrhea	Seasonal	Yes
Shortness of breath	Seasonal	Yes
Sore throat	Seasonal	Yes
Tearing	Nonseasonal	No

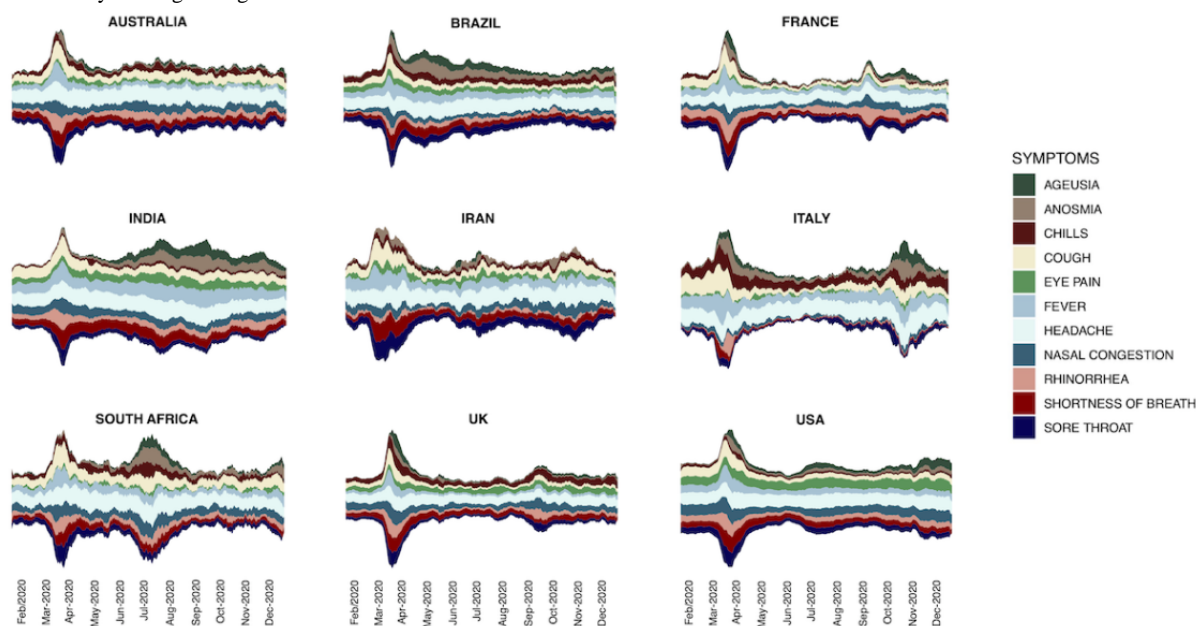

^aTopic categorization into deviating and not deviating from their 5-year trend was determined on the visual inspection of decomposition plots.

The relationships between the number of new cases and each search topic are illustrated in Figures S21-S29 in [Multimedia Appendix 1](#). Several symptoms, including ageusia, anosmia, cough, rhinorrhea, and sore throat were aligned with the COVID-19 epidemic in most countries and were searched on Google well before the number of COVID-19 confirmed cases peaked. On the other hand, other topics showed less evident variations (chills, eye pain) or deviated from their trend only during the first wave (headache, shortness of breath). Additionally, the peak of interest in all symptoms (except eye pain) preceded that of confirmed COVID-19 cases in most countries, and topics increasing earlier reached their highest interest-over-time value before those growing later. Similar patterns were observed for interest-over-time of search terms

when compared to the number of newly confirmed deaths (Figures S30-S38 in [Multimedia Appendix 1](#)).

The interest-over-time change for all topics is illustrated in [Figure 2](#). Overall, the interest-over-time values of the selected topics had a peak in March 2020 in all selected countries. In Italy, France, and South Africa—and, to a lesser extent, Iran, the United Kingdom, and the United States—there was a decrease in the search terms after the first peak, followed by a second peak. In Iran, a third peak in searches was seen, corresponding to the third COVID-19 wave. In India and Brazil, searches of medical terms remained high after the first peak, and no second peak was seen. In Australia, the interest-over-time values of the selected topics returned to the pre-peak values soon after the first peak in March and remained low and stable.

Figure 2. Streamgraphs of the interest-over-time index for each individual country. The x-axis values are given in months. Index-over-time values were plotted as 7-day moving average.

Cross-correlations between each topic and the number of confirmed COVID-19 cases are reported in Tables S1-S9 in [Multimedia Appendix 1](#). Overall, ageusia, anosmia, and headache were most consistently correlated with COVID-19 cases across the selected countries. The degree of correlation and the best time lag largely varied as a function of the selected country and topic, but overall the optimal time lag was 15 days.

The scores and loadings plots for the PCA models are given in Figures S39-S47 in [Multimedia Appendix 1](#). The scores plot represents a summary of the collected data trends over time, while the loadings plot shows how strongly each variable influences a PC. In the month of March 2020, all selected countries deviated considerably from their previous scores and moved toward the PCs directions of the loadings of the Google search terms, preceding the increment in the number of searches of the symptoms related to COVID-19. The latest 14 days show a similar pattern for all selected countries, pointing toward the loadings' directions of deaths and new cases. Specifically, for Italy, France, and South Africa, the latest scores are in the same area of loadings plots corresponding to deaths and new cases, indicating a stable trend in these metrics. On the other hand, the United Kingdom, the United States, Brazil, and India followed a worsening pattern, as their scores kept moving

toward the direction of new deaths and cases. Australia and Iran were the only selected countries showing an improving trend, with the score points moving away from the loadings of COVID-19 deaths and new cases.

[Figure 3](#) illustrates the RMSE for the prediction of PC1 values with the three time series models in the various countries using raw data and a 7-day moving average. Models based on the 7-day moving average lead to considerably smaller RMSE values as opposed to those calculated with raw data (median 0.90, IQR 0.50-1.53 versus median 2.27, IQR 1.62-3.74, respectively). Overall, predictions based on both search terms and COVID-19 conventional metrics performed better than those not including Google searches (median 1.56, IQR 0.90-2.49 versus median 1.87, IQR 1.09-2.95, respectively), but the improvement in prediction varied as a function of the selected country and time frame. Although ETS (median 1.62, IQR 0.87-2.7) led to slightly smaller RMSE than ARIMA (median 1.65, IQR 1.04-2.58) and NNAR (median 1.82, IQR 1.15-3.15) models, none of the tested time series models clearly outperformed the remaining two, and the best model varied as a function of country, time range, and period of time selected. Similar results were obtained when trying to predict PC2 ([Figure S48](#) in [Multimedia Appendix 1](#)).

Figure 3. Root mean square errors of the prediction error for principal component 1 of the various models for the selected countries. MA1 and MA7 indicate analyses performed on 1-day (ie, original data) and 7-day moving averages of data, respectively. GT indicates models based on both traditional COVID-19 metrics and Google Trends data, while NOGT models are based on COVID-19 metrics only. ARIMA: autoregressive integrated moving average; ETS: error, trend, seasonality; NNAR: feed-forward neural network autoregression; RMSE: root mean square error; UK: United Kingdom; USA: United States of America.

Discussion

In this study, we investigated the relationship between Google Trends searches of symptoms associated with COVID-19 and confirmed COVID-19 cases and deaths. We found that some of the search terms showed an unusually high recent online interest that deviated considerably from their expected behavior and preceded the peak of confirmed COVID-19 cases by days to weeks. This pattern was consistent across different countries and of similar magnitude. We developed and validated predictive models to forecast the COVID-19 epidemic based on the combination of Google Trends searches of symptoms associated with COVID-19 and traditional COVID-19 metrics. We found that models incorporating Google Trends data generally performed better than those based solely on traditional COVID-19 metrics. We also developed a web application [13] to translate our approach into action.

Our study identified patterns of Google searches of several symptoms and signs associated with COVID-19 in a consistent way across the studied countries. Overall, Google searches of COVID-19 symptoms followed a similar trend to that of the COVID-19 epidemic and preceded traditional COVID-19 metrics. This behavior can contribute to the early recognition of new waves and epidemic peaks.

The interpretation of symptom search behavior during COVID-19 outbreaks should be carefully considered. Dynamics of online searches may show atypical patterns during pandemics where major restrictions occur, including shutdowns of economic activities, movement restrictions, and health care

overload [17]. Constant media attention may contribute to increasing interest in some of the studied topics [18]. COVID-19 received extensive coverage that might have precipitated unusually high interest during lockdowns [19]. Our findings on online search behavior might be secondary to general media interest in specific COVID-19 symptoms, rather than a primary, and possibly predictive, consequence of people with COVID-19 researching their own symptoms in real time. All the selected countries had a peak in searches of medical terms in or around March and April 2020, including those countries with low numbers of cases at that time, such as South Africa and India. This pattern may indicate that curiosity and media coverage regarding the new pandemic can explain part of the first peak in search terms, in agreement with a previous study [20]. After the first peak, however, Google search behavior followed different patterns across countries and resembled the course of the COVID-19 epidemic. In those countries that had a second wave—such as Italy, France, Iran, the United Kingdom, or the United States—the number of Google searches had a second peak; the height of the second peak of the searches was lower than that of the first peak, despite a higher number of reported cases and deaths, suggesting that individual curiosity regarding the new pandemic could have inflated the first peak in search terms. Iran also had a third peak in searches between October and December 2020, when the country had a third COVID-19 wave. South Africa had a second peak in its searches in July 2020, when the country had its first wave. In India, the first peak in searches was followed by a steady increase from June 2020, after which searches remained stable until October 2020, and then decreased gradually, resembling the shape of the

COVID-19 epidemic in this country. In Australia, which effectively managed the COVID-19 epidemic and had among the lowest infection and death rates in the world, the interest-over-time of the various search terms after the first peak remained low and comparable to pre-peak values.

We observe that not all the selected topics reached their peak searches simultaneously; rather, they had different time patterns, which were fairly consistent across all countries. We believe that the intense and simultaneous media coverage of all the selected topics should have had the same effect at the same date if the media influence entirely caused this search behavior [21]. Ageusia and anosmia showed the highest correlations when lagged by a few days, while cough, fever, nasal congestion, sore throat, rhinorrhea, and shortness of breath preceded increases in COVID-19 cases by up to two weeks. This finding is consistent with the clinical course of COVID-19; in a large multicenter European study, olfactory and gustatory dysfunctions were among the latest and first manifestations in approximately 65% and 12% of patients, respectively [8].

In addition to describing how Google search terms changed over time in different countries and investigating their relationship with the numbers of cases and deaths, we also developed models combining interest-over-time values of searches of COVID-19 symptoms with conventional metrics (eg, number of new cases, number of new deaths) to predict the course of the COVID-19 epidemic, and we compared the prediction ability of these models against that of models based only on conventional metrics. The PCA approach allowed us to reduce dimensionality, summarize information into 2 PCs, and filter out the noisy or redundant information. Another advantage of PCA was to provide visual representations of data patterns, similarity trends, and outliers. The PCA approach is highly flexible and potentially allows accommodating new variables of interest in future versions of our application. As the PCA itself does not make any predictions, we processed the PC computed values with different time series models, and new data scores predicted with the time series models were reinserted into the PCA model. Our approach allows the extraction of the predicted values of any input variable, including the number of new cases and deaths. Models integrating interest-over-time values of the search topics and COVID-19 traditional metrics generally outperformed models based solely on confirmed cases and deaths, leading to improved predictions. There was no single best model in this study, and the best performing time series model varied as a function of the country, time frame, and moving average. Predictions were more accurate, leading to considerably smaller RMSE, when obtained using a 7-day moving average rather than daily data. This result is not surprising as Google Trends data have high daily fluctuations, and COVID-19 reported cases greatly oscillate, reflecting testing and reporting practices and contingencies [22,23].

To translate our results into practice so that the scientific community, agencies, and even curious users could potentially use them, we developed a freely available web application [13]. The application is interactive and updates the data daily, so it

operates in near real time. It allows the user to visualize data for 188 countries, choosing any time frame. In addition, COVID-19 traditional metrics and Google search terms' interest-over-time can be visualized globally on different graphs. The user can explore cross-correlations among selected keywords, generate predictive models with default variables or a user-selected subset of variables, and check model performance.

This study has limitations. The Google Trends algorithm is a "black box," and the exact calculation formula for interest over time and raw data has never been made public. Search results may differ slightly when downloaded by different computers or on different days. However, we conducted search-research reliability, which showed excellent reliability for most of the topics included in this study (data not shown). The exclusion of those symptoms with no significant deviation from their 5-year trend reduced the possibility of spurious correlations, but it was not possible to account for seasonality in the selected topics. In other words, a small proportion of the increasing trend in some topics might be explained by their usual seasonal variations. The results of this study may not apply to countries where Google is not a popular search engine or where Google is censored or limited in its use. However, this approach can be applied to other search engines (eg, Baidu, Yahoo, Naver), as was done in previous studies on different diseases and on COVID-19 in Hubei province, China [24,25]. Previous studies have shown that self-reported symptoms on social media networks, such as Twitter, can provide useful information to track the COVID-19 pandemic and can be used for intelligence along with search engine data [26-28]. Our approach could, in principle, be applied to social media as well. Geographical areas and groups of people (older adults and children) with scarce internet access cannot be studied with this strategy, and our results may not apply to largely rural countries. This study included only the most common clinical manifestations of COVID-19, and only a few selected countries were included as a case study. However, information and models for every country can be found on our web application.

Future work will include increased data granularity, allowing users to access information and make predictions at a regional level. Other metrics of interest, such as hospitalizations, will be included in our analysis as outcomes. Finally, we plan to allow the user to generate a one-page report for each country, summarizing the most relevant information.

In conclusion, the results of this study show that Google Trends searches during the COVID-19 pandemic may precede outbreaks by up to two weeks. The inclusion of digital online searches in statistical models may improve the nowcasting and forecasting of the COVID-19 epidemic and could be used as one of the surveillance systems employed by government agencies and supranational organizations to refine their monitoring of COVID-19. We provide a free web application operating with nearly real-time data that anyone can use to make predictions of outbreaks, improve estimates of dynamics of ongoing epidemics, and predict future or rebound waves.

Abstract

Background: Liver transplantation (LT) is the only curative treatment for end-stage liver disease. Less than 10% of global transplantation needs are met worldwide, and the need for LT is still increasing. The death rates on the waiting list remain too high.

Objective: It is, therefore, critical to raise awareness among the public and health care providers and in turn increasingly acquire donors.

Methods: We performed a Google Trends search using the search terms *liver transplantation* and *liver transplant* on October 15, 2020. On the basis of the resulting monthly data, the annual average Google Trends indices were calculated for the years 2004 to 2018. We not only investigated the trend worldwide but also used data from the United Network for Organ Sharing (UNOS), Spain, and Eurotransplant. Using pairwise Spearman correlations, Google Trends indices were examined over time and compared with the total number of liver transplants retrieved from the respective official websites of UNOS, the Organización Nacional de Trasplantes, and Eurotransplant.

Results: From 2004 to 2018, there was a significant decrease in the worldwide Google Trends index from 78.2 in 2004 to 20.5 in 2018 (–71.2%). This trend was more evident in UNOS than in the Eurotransplant group. In the same period, the number of transplanted livers increased worldwide. The waiting list mortality rate was 31% for Eurotransplant and 29% for UNOS. However, in Spain, where there are excellent awareness programs, the Google Trends index remained stable over the years with comparable, increasing LT numbers but a significantly lower waiting list mortality (15%).

Conclusions: Public awareness in LT has decreased significantly over the past two decades. Therefore, novel awareness programs should be initialized.

Introduction

Background

Liver transplantation (LT) remains to be the only curative therapy for patients affected by end-stage liver disease, cirrhosis with hepatocellular carcinoma, acute fulminant hepatic failure, hepatocellular carcinoma, hilar cholangiocarcinoma, and several metabolic disorders [1,2].

Each year, approximately 12,000 LTs are performed in Europe and the United States, with numbers significantly increasing over time [3]. At present, more than 70% of liver transplant recipients survive for at least 5 years, compared with 20% in the 1980s. Such statistics are especially encouraging, considering that transplanted patients tend to have more severe diseases [4]. Several factors increase the survival of patients with LT, including better control of disease before LT, improved surgical techniques and surgeons specialized in these techniques, improved organ preservation, and advanced immunosuppressive therapy regimens [5]. However, the improved success rate of LT has resulted in substantial organ shortages [4]. Such shortages have led to a prolonged time for patients on the waiting list and increased waiting list mortality [6-8].

In 2017, the median pretransplant waiting time among active waitlisted adults was 10 months in the Eurotransplant region and approximately 9 months in the United States [9]. Mortality on the list was 18.7% in the Eurotransplant region, which is comparable with the United States' 19.8% of listed patient deaths before transplantation. It is important to note that limited donor organs are available from deceased donors after brain death [6].

The discrepancy between available liver allografts and transplant candidates continues to increase globally. Significant efforts have been made to raise the donor pool in Europe and the United States, such as using extended criteria donor organs [10], inventing extracorporeal normothermic or hypothermic organ perfusion systems [11], and accepting liver allografts as donation after circulatory determination of death (DCDD) [12]. Despite these efforts, there remains no significant decrease in waiting list mortality. To close the gap between available organs and the number of patients in need of LT, a higher awareness and acceptance of the transplant and donor program in the general population, as well as among health care providers, is a potentially effective strategy.

Infodemiology is an emerging area of research among health informatics, health care professionals, and patients. Introduced in 2002 [13], the term infodemiology is defined as a new area of scientific research that holds great promise for improving public health by focusing on specific internet searches for user-contributed health-related content [13-15]. These searches track public opinion, behavior, attention, knowledge, and attitudes [16].

Objectives

The first study indicated a correlation between searches on the internet and incidence in the field of *infectious diseases* [17]. The number of infodemiological studies has increased over the past decade, and these studies have used Twitter and Google

[18]. Many researchers have used the infodemiological approach to study various health-related topics, for example, infectious diseases such as influenza or HIV/AIDS, chronic diseases such as multiple sclerosis, or patterns of smoking and tobacco use [19-27]. A particular interest in infodemiology has risen because of the ongoing COVID-19 pandemic [28], as research informs about the speed of misinformation [29], correlation between search behavior and COVID-19 related mortality [30], mental health issues [31], and pressing health care topics such as telehealth capacity of hospitals [32]. In addition, these data are becoming valuable tools for exploring human behavior. The advantage of infodemiology is that metrics are available in real time, which can provide quantitative and qualitative data while being automatically and inexpensively collected.

The analysis of internet search queries offers information on the extent of public attention, thereby reflecting the level of public awareness [33-36]. Google Trends is one of the most widely used tools for this purpose. It is not only used to study public interest in health care topics but also to predict disease occurrence and outbreaks [17,37,38].

In this study, we evaluated public interest in LT over time using Google Trends data and compared them with the number of transplanted livers reported from the United Network for Organ Sharing (UNOS), the Organización Nacional de Trasplantes (ONT), and the Eurotransplant regions.

Methods

Retrieving Transplantation Numbers for UNOS, ONT, and Eurotransplant

Data were retrieved by accessing the respective websites of the transplant organizations UNOS, ONT, and Eurotransplant [39-41]. We extracted information on living and deceased donors over a period of 15 years (2004-2018) for the following countries: the United States (UNOS), Spain (ONT), Austria, Belgium, Croatia, Germany, Hungary, Luxembourg, and the Netherlands (belonging to the Eurotransplant countries). No organs from executed prisoners were used in these transplant organizations.

Retrieving Google Trends Data on LT

The Google Trends tool was used on October 15, 2020, to retrieve data on internet user search activities in the context of LT [42]. Worldwide Google Trends indices were retrieved from January 2004 onward using the search terms, *liver transplantation* and *liver transplant*. We retrieved Google Trends indices for the United States, Spain, and European countries, in part included in the Eurotransplant network, namely Austria, Belgium, Croatia, Germany, Hungary, and the Netherlands. No Google Trends indices could be retrieved for Luxembourg and Slovenia. Whereas the worldwide search was performed in English, individual searches across non-English-speaking countries were performed in their respective official languages. We used individual search terms and combined the search terms yielding Google Trends results in larger queries, as listed in Table 1. On the basis of monthly data, annual average Google Trends indices were calculated for the years 2004 to 2018 and used to generate the line plots with

the ggplot2 package of the statistical software R (version 3.4.1; R Foundation for Statistical Computing). It is important to note that none of the queries in the Google database for this study can be associated with a particular individual. The database does not retain information about the identity, IP address, or

specific physical location of any user. The Spearman correlation coefficient was used to determine pairwise correlations between total liver transplant numbers per country and Google Trends indices.

Table 1. Google Trends search query listing (2004-present).

Region	Language	Google Trends search query
Worldwide	English	<i>liver transplantation and liver transplant</i>
United States	English	<i>liver transplantation and liver transplant</i>
Spain	Spanish	<i>trasplante de hígado, trasplante hígado, and trasplante de higado</i>
Belgium	French	<i>transplantation hépatique and levertransplantatie</i>
The Netherlands	Dutch	<i>Levertransplantatie</i>
Germany	German	<i>Lebertransplantation</i>
Austria	German	<i>Lebertransplantation</i>
Hungary	Hungarian	<i>májátültetés and májtranszplantáció</i>
Croatia	Croatian	<i>transplantacija jetre</i>

Results

Google Trends and Trends for LT Worldwide

The global Google Trends index for LT decreased from 73.8 to 36.6 (–50.4%) between 2004 and 2014. In 2018, there was a slight upward trend in the LT index to 46.3 (+27.5%; [Figure 1](#)).

A similar trend was observed for the UNOS, with the Google Trends index dropping from 59.2 to 38.8 (–34.5%) in 2014 and an upward trend since then to 50.3 (+46.2%) until 2018. Similarly, Google Trends indices in the Eurotransplant region exhibited a decline in numbers in all Eurotransplant countries across the same period ([Figure 2](#); [Tables 2 and 3](#)).

^aTX: number of transplantations.

In the same period (2004-2018), UNOS reported the most significant increase in deceased donor liver transplants from 6642 to 8875 (+34.0%). Conversely, the number of living donor donations remained stable during the same period. The number

of LTs increased by 24.0% and 18.2% in the Eurotransplant and ONT, respectively (Figure 3; Multimedia Appendix 1), and the number of (both deceased and live donor) LTs increased by 24.0% and 18.2% in the Eurotransplant and ONT, respectively (Figure 3; Multimedia Appendix 1).

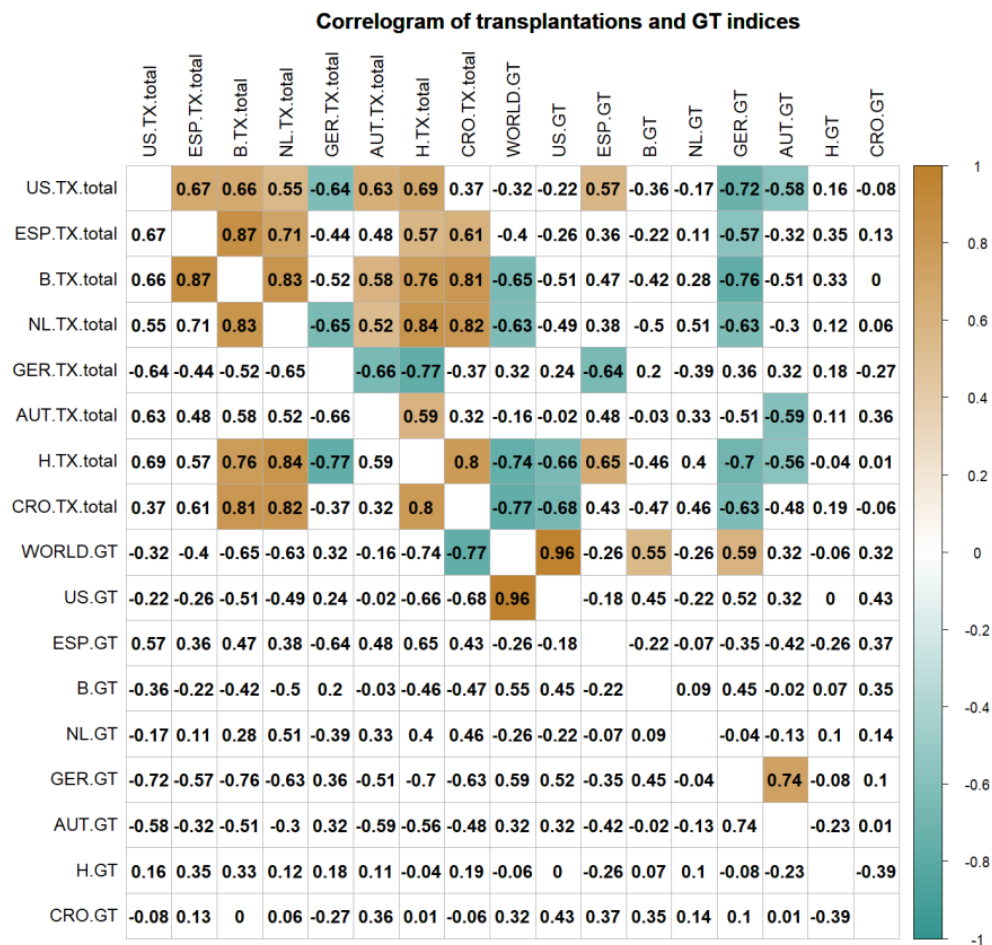

Figure 3. Number of liver transplants in Eurotransplant, United Network for Organ Sharing, and Organización Nacional de Trasplantes. AUT: Austria; B: Belgium; CRO: Croatia; ESP: Spain; GER: Germany; GT: Google Trends; H: Hungary; NL: the Netherlands; TX: number of transplantations; US: United States.

Belgium and the Netherlands were the only 2 countries in the Eurotransplant region with a mild increase in living donor LT; however, in these countries, a significant decrease in the Google Trends index was observed (Belgium: -48.3% ; the Netherlands: -53.3% ; Multimedia Appendix 2). Similar downward trends were observed in all Eurotransplant countries. A correlogram of the total transplant numbers and Google Trends indices of the investigated countries are depicted in Figure 4. Most notably, even in Croatia, a country with 42 transplantations per million and a dissent solution, the Google Trends index significantly

decreased from 7.8 to 2.5 (-75.7%). Google Trends changes and the number of transplants (deceased donor and living donor transplantations) in the respective countries over time are displayed in Figure 2. The number of DCDD donors in the Eurotransplant region and the UNOS area showed a mild increase. In 2018, only 8.08% (145/1795) and 5.71% (537/9412) of deceased donors were DCDD donors for LT in the Eurotransplant and UNOS regions, respectively (Multimedia Appendix 3).

Figure 4. Correlogram of total transplant numbers and Google Trends indices of investigated countries. Correlations are based on the Spearman correlation coefficient. Pairwise correlations between total transplant numbers per country and Google Trends indices were calculated. Significant correlations with *P* values <.05 and <.001 are highlighted by a colorful background in the upper and lower half of the matrix, respectively. AUT: Austria; B: Belgium; CRO: Croatia; ESP: Spain; GER: Germany; GT: Google Trends; H: Hungary; NL: the Netherlands; TX: nuber of transplantations; US: United States.

Google Trends and Waiting List Mortality

The waiting list mortality did not change significantly in UNOS (-5.2%) and Eurotransplant (-6.2%; [Multimedia Appendix 4](#)) regions. Even in Germany, the Eurotransplant country with the highest waiting list mortality (451/1379, 32.7%), the Google Trends index decreased from 40.4 to 21.1 (-48.5%). Furthermore, we analyzed the data of UNOS based on ethnicity. With no significant change over time, Hispanic individuals (2.4%), and American Indians and Alaska Natives (each 4.8%), had a significantly higher mortality on the waiting list than that of all ethnicities ([Multimedia Appendix 5](#)). An overview of changes in Google Trends over time, number of transplants (deceased donor, DCDD, and living donor transplantation) in the respective countries is depicted in [Figure 3](#).

Google Trends and LT Program in Spain

Spain exhibited a distinct Google Trends index pattern compared to other countries. The index slightly decreased until 2011 (the year of implementation of the DCDD program in Spain). A campaign for DCDD donors in the public, as well as in hospitals where potential donors are hospitalized, resulted in an increase in the Google Trends index. In the period of 15 years, we could not find a significant decrease in the Google Trends index

(-1.8%). In fact, the number of transplanted livers increased because of DCDD by 18.1%. Moreover, there was a decrease in waiting list mortality between 2011 and 2012 (-4.7%). The overall waiting list mortality, too sick to transplant, and the dropout rate for other reasons were also significantly lower in Spain (15%) than in UNOS (31%) or Eurotransplant (29%; [Multimedia Appendix 5](#)).

Discussion

Principal Findings

In this study, we found a significant decrease in Google Trends search queries for LT in the UNOS and Eurotransplant regions. As such, public and health care providers' levels of awareness regarding LT are decreasing alarmingly. In Spain, the leading country for transplantation, these findings were not as pronounced. Furthermore, the dropout rate in Spain was significantly lower than that in UNOS and Eurotransplant. Although the need for LT, as the only curative option for chronic liver disease, is increasing, the number of donor organs is also increasing. However, the gap between possible recipients and donors is also increasing. To close this gap, transplant and donor programs, which in part bring awareness to both the public and health care domains, may provide some improvement.

As indicated by the compelling findings presented here, the application of internet data in health care research presents a promising new field. It may further complement and extend the current data sources and foundations [43]. Approximately 90% of US citizens use the internet regularly. According to a data analysis of Pew Research Center (Washington, DC), following an ongoing rapid growth of *going online* and use of social media in the United States over the last decade, it stayed stable over the past 3 years. Comparable data are available in Europe.

Health and *health care* were the number 2 priorities to the US public in 2019. Internet users tend to search for health-related topics accordingly. In fact, more than 80% of all internet users look for health information on the web. Among them, 66% searched for information concerning a specific disease or medical problem (perennially the most popular purpose), and 56% were interested in a certain medical treatment or procedure. After checking emails and using search engines, looking for health topics was the third most frequent activity on the internet. Interestingly, the typical search for health information is on behalf of someone else [44]. The most popular science Facebook group boasts up to 44 million followers [45]. Limited access to internet use, especially internet search for health-related topics, has been found in minorities such as Hispanic, American Indian, and Alaska Native (PEW Research Center). This finding might in part explain the higher mortality and morbidity rates in these ethnicities compared with other ethnicities. Although health care topics on the internet are constantly rising, interest in LT has been decreasing since 2014 all over the world. This trend indicates that the topic LT is underrepresented in the web, despite a small increase seen from 2014 onward. However, the internet (eg, search engines and social media) is the largest platform for awareness programs in the field of liver disease and LT.

To date, very little is published regarding the awareness of LT. This disparity between the low search volumes of the terms relating to LT and the actual increasing number of transplantations may originate in the established low awareness campaigns of LT. Such campaigns are highly useful, as past awareness movements have proved extremely effective. For example, the *Ice Bucket Challenge* promoted awareness of amyotrophic lateral sclerosis. This activity, demonstrated by the dumping of a bucket of ice water over a person's head, went viral in the summer of 2014 and resulted in a nearly 1000-fold increase in the Google Trends index. Subsequently, over US \$220 million in funding has been raised worldwide for this rare disease. Several awareness campaigns related to other health issues in recent years have also proved immensely successful. One of the best known includes the *Red Ribbon* movement to fight HIV infection. Even a *World AIDS Day* was initiated on December 1, 1988 [46]. Other programs, such as those promoting the fight against breast cancer, were followed with significant successes in both awareness and funding. An additional notable example is the *Jade Ribbon Campaign*, which was a great success in hepatitis B virus awareness, screening, and physician follow-ups in Chinese Americans. Conversely, the term *liver disease* is strongly underrepresented in the public awareness and, in turn, the World Health Organization's goal to eradicate hepatitis C by 2030 will most likely not be achieved.

Even in well-developed countries, there is too little awareness of this disease among health care providers and the broad public [47]. The LT field was even more underrepresented. The reasons for this dearth of awareness are two-fold. The knowledge of primary care providers regarding the possibilities of LT remains insufficient. However, patients complain about a lack of information related to the nature of their disease and the potential to undergo LT.

As shown from past promotion campaigns of various other diseases, public awareness should be the key goal to increase organ donation rates. Spain's case offers evidence of such contention. The overwhelming number of 43.4 donors per million population in the country (2016) reflects the increased level of information provided to the public regarding organ donation. Close attention to the mass media is a key point of the Spanish system and serves a preeminent way to inform the public and raise awareness. As a result of Spain's communication policy, journalists have become extremely important in promoting organ donation. This topic is massive and continuously presented in the media. In 2016, a total of 155 Spanish media reports or news on the topic transplantation were on TV, radio, and printed press releases on the European organ donation day in October. The internet and social media were not included in the survey. The estimated audience comprised 24 million people [48]. Thus, the interest in LT in Spain has remained high over the past 16 years.

In addition, it is important to note that the number of DCDD LTs has increased significantly over the last few years in Spain. This increase in LTs, including DCDD, might reflect the success of awareness campaigns by the ONT. The ONT has established awareness programs across the country, subject to the national Spanish health ministry. Hepatologists and anesthesiologists with special training in the field of LT are representatives of transplantation programs [49]. The fruits of this work were visible in our Google Trends analysis. Specifically, there were increased search rates of the topic, *liver transplantation*, in Spain, alongside increased number of donors, transplantations, and a lower mortality rate on the waiting list. Thus, we conclude that a stable Google Trends index, compared with the global trend, reflects the success story in Spain. This underlines our hypothesis that sensitizing people for the topic could close the gap between supply and demand in LT. Furthermore, the worldwide increase of the search terms *liver transplantation* and *liver transplant* since 2014 may be because of more awareness programs, as well as an increasing number of DCDD and living donor transplants worldwide. Indeed, steps to increase awareness are underway. For example, the first National Patient Advisory Committee of America's Liver Foundation was founded. At present, more than 50 diverse members are trained to raise awareness of the field of LT across the United States. In 2015, legislators were educated about LT and liver disease. Such discussions resulted in an annual Advocacy Day, which allowed for more awareness and an increase in search terms in the United States and worldwide.

The impact of web-based research has grown continuously in the past decade [50]. To date, Google Trends is the only unbiased approach that includes millions of users and has been widely used in economics and health issues. In economics,

Google Trends data can help to improve forecasts of the current level of activity for a number of different economic time series such as automobile sales, retail sales, or unemployment [51,52]. Economists have already been at work using Google Trends to make quantitative forecasts [51,53]. Several recent research publications demonstrate that data on web searches from Google Trends can improve the accuracy of forecasts over conventional models. The use of Google data has rapidly spread in the literature to predict other economic indicators, such as analyzing their impact on stock markets and studying bond markets or their impact on commodities [54,55]. Google Trends and the field of infodemiology are being widely used in the field of health-related issues as well. Public attention in different fields of health care has been published recently (eg, osteoarthritis, breast cancer, or chronic inflammatory lung disease) [34,56,57]. Furthermore, infodemiology and Google Trends are used to generate awareness profiles and are suitable substitutes for classical data collection, such as surveys [50]. Thus far, Google Trends has been primarily used to monitor disease control and awareness in cancer, HIV, or stroke and also in rare diseases such as antiphospholipid syndrome or systemic lupus erythematosus [35,58-60]. Google Trends offers a wide range of capabilities, with one being the detection of success rates of awareness programs [61,62].

Limitations

Our data indicate multiple novel aspects in the field of LT, such as those concerning donor and recipient awareness. Nonetheless, as with any study, there are some potential limitations. Data should be interpreted with caution in the context of public health and disease awareness. Rationale is 2-fold. First, there was no information about individual searches for the analyzed topics. A bias related to a high number of search queries by health care professionals, industry, or marketing agencies cannot be excluded. Second, it is to some extent elusive which search queries are summarized in the topics defined by Google Trends algorithms, as detailed information on how Google generates these data is not provided. The selection of spelling or terms might affect the results and conclusions; therefore, we chose to use more accurate spelling by native speakers and provide a

detailed description of our data-gathering approach to facilitate reproducibility. Misspellings, slang words, or different accent use were considered; foreign languages (eg, English and official languages of neighboring countries) were not taken into consideration. Furthermore, some countries (eg, Hungary and Luxembourg) have a lower number of inhabitants, thus resulting in a small sample size for these countries. This may result in huge variations in Google Trends analyses over time. Another limitation may concern rural areas, as they tend to have limited internet access. Moreover, the internet use of the term *liver transplantation* is low in some countries and their official languages. The importance of accuracy in defining search queries is exemplified by searching Google Trends for the topic *immunosuppressants*. Although not specifically representing LT, immunosuppressants are associated with LT. Hence, using the query *immunosuppressant* may be useful to analyze symptom-related interest but does not sufficiently represent LT awareness. Finally, the number of studies based on Google Trends has been increasing, but so far, there is no standardized procedure for data collection. More guidance by Google is warranted to assist researchers in establishing an optimal search strategy [63].

Conclusions

Google Trends provides a powerful tool for evaluating public interest related to LT and associated liver diseases. According to our study, interest in LT has decreased over the last decade in all investigated countries except Spain. The success story in Spain is encouraging, as it confirms that more awareness campaigns in the field of LT are needed to close the gap between increasing demand and a small supply of potential donor organs. Therefore, international awareness programs are required. In the future, the effects of awareness programs could be evaluated using Google Trends. In line with the goal of higher awareness for solid organ transplantation, Google Trends helps to collect, analyze, report, and disseminate LT-related health data. Google Trends may, therefore, not only drive change and track progress but may also help to improve programs to counteract the current lack of public LT awareness.

Abstract

Background: Developing an understanding of the social structure and phenomenon of pandemic information sources worldwide is immensely significant.

Objective: Based on the quadruple helix model, the aim of this study was to construct and analyze the structure and content of the internet information sources regarding the COVID-19 pandemic, considering time and space. The broader goal was to determine the status and limitations of web information transmission and online communication structure during public health emergencies.

Methods: By sorting the second top-level domain, we divided the structure of network information sources into four levels: government, educational organizations, companies, and nonprofit organizations. We analyzed the structure of information sources and the evolution of information content at each stage using quadruple helix and network analysis methods.

Results: The results of the structural analysis indicated that the online sources of information in Asia were more diverse than those in other regions in February 2020. As the pandemic spread in April, the information sources in non-Asian regions began to diversify, and the information source structure diversified further in July. With the spread of the pandemic, for an increasing number of countries, not only the government authorities of high concern but also commercial and educational organizations began to produce and provide significant amounts of information and advice. Nonprofit organizations also produced information, but to a lesser extent. The impact of the virus spread from the initial public level of the government to many levels within society. After April, the government's role in the COVID-19 network information was central. The results of the content analysis showed that there was an increased focus on discussion regarding public health-related campaign materials at all stages. The information content changed with the changing stages. In the early stages, the basic situation regarding the virus and its impact on health attracted most of the attention. Later, the content was more focused on prevention. The business and policy environment also changed from the beginning of the pandemic, and the social changes caused by the pandemic became a popular discussion topic.

Conclusions: For public health emergencies, some online and offline information sources may not be sufficient. Diversified institutions must pay attention to public health emergencies and actively respond to multihelical information sources. In terms of published messages, the educational sector plays an important role in public health events. However, educational institutions release less information than governments and businesses. This study proposes that the quadruple helix not only has research significance in the field of scientific cooperation but could also be used to perform effective research regarding web information during crises. This is significant for further development of the quadruple helix model in the medical internet research area.

Introduction

Background

Since the first reported case of COVID-19 in late 2019, the disease rapidly spread to become a pandemic in March 2020. An infectious disease caused by a pathogen generally spreads to a living host, and it is easily transferable from the infected. As of January 7, 2021, over 87 million people have been infected with the virus in 190 countries and regions worldwide since the outbreak of COVID-19 in February 2020, resulting in a global catastrophe [1].

Social disasters, including infectious diseases, must be controlled through a process of actual data-based analysis [2]. Real-time assessment is critical for disaster monitoring; special attention must be paid to rapid analysis using relevant social and cultural data at both the macro and micro scales. The core of sociocultural data analysis is to understand, identify, and even predict the risk of transmission. Thus, a system needs to be constructed to collect data based on the disaster type or area, and to support the spontaneous decision-making process. Without this system, the public would face an information overload, as they would feel burdened dealing with an enormous amount of information in critical situations [3].

In today's knowledge-based society, information production goes beyond traditional media organizations and involves many entities. In particular, with the increased popularity of smartphones, the amount of online information produced by individuals and organizations has grown exponentially. As the information production process becomes increasingly complex, traditional media companies face a situation in which the so-called legacy media's usage time has decreased and is now competing with various sources [4]. Search engines and web portals are catering to a wider range of user needs than traditional alternatives [5]. Low cost is an important reason that internet information channels have more advantages than traditional information channels [6]. This phenomenon is especially obvious when significant events occur. The same is true for the information about COVID-19. Fear, anger, and other emotions also lead people to believe and spread online information available through nontraditional media, regardless of whether it is fake [7]. This implies that not only individual media and informal organizations but also a large number of formal organizations such as governments, academic institutions, and formal public organizations have started using online media to produce and disseminate information. However, sensitivity to fake news is also often influenced by political ideology [8]. In some countries, citizens do not support direct government control of the news, and are more concerned with information sources in cooperation with the media and other nongovernmental organizations [9]. Therefore, web media represent a strong competitor to traditional media in terms of both production and services.

COVID-19 has had a strong impact on the media system [10-12]. People have created significant numbers of online documents by utilizing new media sources such as Facebook and Twitter [13-15]. In fact, governments in some countries have used these forms of new media to build platforms to help combat the virus [16]. For example, due to the COVID-19 outbreak in Wuhan in February 2020, and the shortage of medical resources and services, Weibo, one of the largest new media companies in China, cooperated with the local government to set up a citizen assistance platform on which citizens with real-name identification could ask for help. This new mode of interaction is difficult to create with traditional media. To deal with the COVID-19 pandemic that is currently threatening the world, it is evident that the greater the number of internet information sources, the stronger the social immune system.

Therefore, in this study, we collected information sources with high online presence through big-data techniques in countries with confirmed COVID-19 cases. Additionally, the information related to COVID-19 in three stages (from February to April to July 2020) was analyzed in detail, and the morphology and trend of the web big data in these first 6 months of the pandemic are discussed. From these large-scale online big data, the information dissemination trends of educational institutes, enterprises, and government, and their contents were analyzed. In the case of an emergency or a disaster, this study can systematically explain the multielement spiral structure of the information transmission source in the cyberspace of major countries, which has high academic and social value.

In general, based on the quadruple helix and network analysis method, this study constructed and analyzed the structure and content of internet information sources of COVID-19 considering time and space. The aim was to determine the status and limitations of web information transmission and online communication structure in public health emergencies. Moreover, based on the content revealed, valuable suggestions are proposed to contribute to the internet communication of future public health events.

Online Information Sources

With the rapid growth of the internet, web data analysis (often called "webometrics") has become important, and its quantitative vastness and content diversity have been increasing accordingly. As mobile phones, tablets, and other mobile terminals have been growing in popularity, people usually use these terminals to obtain information instead of traditional media. Although some mainstream media outlets have their own web feeds, people generally use digital feeds from search engines such as Bing or Google to obtain information. Therefore, the study and analysis of comprehensive network information is often more objective than the study of specific news media, and more comprehensive information can be collated. For example, Thelwall [17] used Wikipedia data collected by Bing to study public interest in astronomy. Park et al [18] used Twitter and YouTube to analyze the spread of the Occupy Wall Street

movement. Park and Lim [19] analyzed North Korean propaganda changes using YouTube media data. Cho and Park [16] used network activity information about the agriculture, forestry, and fishery departments to discuss the use of internet innovation by government organizations. This literature indicates that analysis and research on web sources have drawn useful conclusions in many areas to date.

There has also been substantial research regarding online sources of information at the time a disaster occurs. Jung and Park [20] used webometric methods to track and analyze the information networks of various organizations during the Gumi chemical spill in South Korea. They found that the flow of information between agencies had an impact on mobilizing emergency facilities and planning specific emergency responses. Online sources of information can also help alleviate the damage caused by disasters. Allaire [21] studied the Bangkok floods and found that social media users were obtaining real-time updates that could help to reduce their losses. Park [22] analyzed YouTube social activities during the 2016 South Korean earthquake, and found that YouTube became a channel to raise public crisis awareness and promote safety strategies. Kim et al [23] also elaborated on the role of social media in relaying information during disasters. By studying data from online information sources during the 2017 storms in the United States, it was found that the flow of information across the network was controlled by many types of users. Song et al [24] studied the differences and the range of emotions people felt toward local online channels, including publishing boards, Twitter, cafes, blogs, and news, that delivered information related to MERS (Middle East Respiratory Syndrome) [24]. Some scholars also analyzed the network information source data regarding COVID-19. For example, Park et al [25] collected Twitter data and found that monitoring public dialog and rapidly spreading media news can help professionals make complex and rapid decisions. However, web page data in internet information sources are often more stable than those in a social media environment [26]; therefore, we adopted web page data for analysis.

To grasp and respond to the situation of worldwide disasters such as COVID-19, we collected and analyzed the network information source data of countries with a large number of confirmed cases to understand how the disaster-related information provided by multiple sources changes over time. We identified three time periods (February, April, and July 2020), and performed a detailed analysis of the differences in information sources at these times. We also studied the structure of national cyberspace information sources. Through these analyses, we identified the structural evolution of web information publishers and clearly revealed the dynamic changes of information content in each period.

Research Questions

Our primary research questions were as follows: (1) What are the structures and form of the COVID-19 web-mediated network among countries? (2) Are there differences in the keywords and topics of COVID-19-related online information at different stages?

Methods

Data Collection

Data were collected using Webometric Analyst 4.1 through Bing, which is one of the most widely used search engines that is available in most countries and regions, including Mainland China. In addition to Google, the Bing search engine is also often used to carry out scientific research [27-29]. Although Google is the world's largest search engine, it is not available in some regions, including mainland China. Since web page data from China were very important for this study, we used the Bing platform for data collection. Website and domains obtained through the search application programming interface service of Bing were analyzed. In February 2020, the most widely used COVID-19 keyword in the world was "coronavirus." Therefore, the keyword for the data collected on February 12 was "coronavirus." After February, the terms "COVID-19" and "2019-nCoV" were also widely used. Therefore, we chose "COVID-19 OR Coronavirus OR 2019-nCoV" for the keyword searches performed on April 17 and July 22, 2020. Data were collected in real time, instead of collecting all information during a certain period. In other words, the data for these three time points (February 12, April 17, and July 22, 2020) are the results of real-time relevant searches on Bing for that day. Instant messages were not limited to the time of publication, and they may contain previously published information that is still highly popular. In addition, instant messages can reflect the actual state of the internet data at that time.

The time of the first collection was in the initial stage of the outbreak, the time of the second collection corresponded to the stage at which the number of new diagnoses had leveled off after spreading worldwide, and the time of the third collection corresponded to the stage when the number of newly diagnosed patients increased sharply as a second wave. For February, we collected data for all 28 countries and regions with confirmed cases, with a total of 9149 data points. For April 17, we collected data from 29 countries and regions with over 7000 confirmed cases and obtained 14,768 data points. For July 22, we collected data of over 70,000 people who received a diagnosis in 30 countries and regions, and obtained 14,483 pieces of data. Our data were collected from the top countries with the highest number of diagnoses per stage, not only from English-speaking countries. To ensure consistency, we only analyzed the English data on the webpage.

Quadruple Helix

Quadruple helix is a research method based on triple helix, which was proposed in 1995 [30]. Researchers studied the development of the knowledge-based economic structure through the spiral relationships among universities, industries, and the government. At first, the triple helix model was used to explain the interaction among academia, government, and industries, and was often used in research related to knowledge production [31]. However, with the development of the triple helix theory, more elements were considered. In 2009, Carayannis and Campbell [32] introduced elements representing the public into the spiral model, such as the civil society and

media, thereby forming a quadruple helix model; they added a research method at the level of new technologies and social needs. In 2010, Carayannis and Campbell [33] added the natural environment factor and constructed the quintuple helix model. Based on this factor, the relationship between innovation and sustainable development can be discussed. During cooperation and communication between various organizations, when one kind of organization occupies a dominant position, it can be considered that this organization is separated from the collection of various organizations, and the relationships among different organizations can be studied and explained through the quadruple, quintuple, or n-tuple helix concept [31]. This spiral structure does not always exist only in the academic, government, and industrial dimensions.

We collated the second top-level domain (TLD) data, which were categorized as data from commercial organizations, educational institutes, governments, and nonprofit organizations. A total of 38,399 domains were collected. To better classify the effective levels, we first sorted all of the collected second TLD data. After frequency analysis, the second TLD data that had an occurrence frequency higher than 1% (91/9149; 148/14,767; 145/14,483) were selected for classification. From 15,813 data units, we extracted four levels, namely governments, commercial enterprises, educational institutes, and nonprofit organizations. We used the quadruple helix model to analyze the structural dynamics of the four institutional levels at different periods in detail. For convenience in figures, we abbreviate government domains such as “.gov,” “.gob,” and “.go” collectively as “G” (governments); educational domains such as “.edu” and “.ac” as “E” (educational institutes); commercial domains such as “.com” and “.co” as “C” (commercial organizations); and “.org” and “.or” nonprofit domains as “O” (nonprofit organizations).

Network Analysis

A network analysis method was used to analyze the structure of the quadruple helix in detail. Network analysis is a method of quantitative analysis of nodes and connections in a network. When individuals and organizations act as nodes, the connection between them acts as a link. Through the quantitative results of the structure, the characteristics and nature of the network composed of these entities can be analyzed [34]. Network analysis has been widely used in social science research such as in social media use, knowledge dissemination, and organizational cooperation [35,36]. Although nodes have the same properties in a one-mode network, nodes differ in two-mode networks. Thus, in the one-mode network, nodes are the institutional components of a quadruple helix: government, private/business, educational institutions, and nonprofit organizations. By contrast, the two-mode network focuses on the relationship between the analyzed countries and the four institutional types. Centrality indices are important quantitative indices in network analysis, including degree centrality,

betweenness centrality, eigenvector centrality, closeness centrality, and others [37-40]. The centrality index used in this study was degree centrality. Degree indicates the direct relationship between the nodes [39,40]. In this study, the degree was mainly used to determine whether the governments, education institutions, nonprofit organizations, and commercial organizations of different countries have similar information, and to observe the helix degree of different countries and the four fields. Although betweenness centrality is an important indicator for evaluating the influence of a mediating effect, the link between countries in this study is common information without mediating phenomena; thus, it was not used for this analysis. In addition, the eigenvector centrality is an index to evaluate the importance of each node connected to other nodes. However, in this study, based on the importance of government, education, public authorities, and companies, it was considered to be less important to evaluate the significance of the connected countries' eigenvector centrality. Closeness centrality is an indicator of the shortest distance, and was also considered to be of little significance for this study. However, the degree centrality index can judge the strength of direct connections between countries and domains. In other words, the more countries connected in a field, the stronger the influence of this field. Therefore, only degree centrality was used for this analysis.

We used UCINET6 for network analysis and network visualization, including triple helix network analysis and content analysis. In the content analysis, we used the convergence of iterated correlations (CONCOR) method to cluster the semantic network in which words are regarded as nodes and cooccurrence between words forms a tie. CONCOR is a method of performing repeated cross-node correlation analyses to identify the appropriate level of similarity [41]. In other words, we first organized the relationships among words into matrices, thus forming a network of relationships among words. We then calculated the correlation coefficients between the rows and columns in the matrix and carried out the same calculation for the obtained correlation coefficient matrix. After repeated calculations, a correlation coefficient matrix consisting of only 1 and -1 was obtained, which was thus divided into two categories. We then performed the same calculation for both categories again and obtained four different clusters.

Results

The hit counts and domains for each country (or region) are compiled and listed in Tables 1-3 for the three time periods, respectively. We standardized the number of hits and domain names for the three months (February, April, and July), with the maximum value set to 100 and the rest being the ratio of the original value to the maximum value multiplied by 100.

Table 1. Hit counts and domains for February (N=28).

Country	Hit counts	Domains
Australia	100.00	100.00
Canada	32.46	53.23
Italy	24.69	67.93
United Kingdom	23.93	33.08
Germany	21.05	43.98
France	18.30	33.46
Spain	13.66	44.61
Belgium	10.41	38.91
Japan	7.29	81.62
India	5.99	33.33
Mainland China	5.61	47.40
Singapore	5.34	69.84
Malaysia	4.10	28.77
United States	3.11	64.39
Hong Kong (China)	2.26	68.44
United Arab Emirates	2.22	7.73
South Korea	1.63	32.07
Taiwan	1.29	35.61
Philippines	1.29	29.91
Sweden	1.10	58.17
Sri Lanka	0.83	10.65
Vietnam	0.70	40.18
Finland	0.61	19.90
Russia	0.42	47.02
Thailand	0.18	41.70
Macau	0.16	14.45
Nepal	0.06	5.83
Cambodia	0.02	7.35

Table 2. Hit counts and domains for April (N=29).

Country	Hit counts	Domains
Canada	100.00	81.26
France	69.96	79.83
England	61.98	58.84
Germany	53.23	83.51
Brazil	51.71	88.14
Italy	46.01	75.92
US	32.78	99.88
Sweden	31.67	100.00
Belgium	30.61	44.13
Japan	30.42	61.80
Austria	21.48	41.04
Netherlands	20.95	93.24
Spain	18.17	59.43
Turkey	18.10	49.23
Chile	16.73	55.63
India	16.35	43.06
Switzerland	13.92	67.50
Denmark	13.50	84.82
Russia	9.16	27.05
Portugal	9.13	54.09
Ireland	8.33	45.20
Korea	6.39	46.74
Peru	5.86	31.55
Mainland China	4.18	35.11
Poland	3.84	75.56
Romania	3.31	49.11
Ecuador	2.95	41.28
Israel	2.67	41.64
Iran	0.36	46.38

Table 3. Hit counts and domains for July (N=30).

Country	Hit counts	Domains
United Kingdom	100.00	3.18
Canada	47.74	87.18
France	46.76	81.88
Mainland China	36.35	49.18
Brazil	33.40	92.00
Germany	32.22	4.59
Italy	24.56	94.24
Argentina	15.11	81.06
Mexico	13.67	89.06
Spain	11.00	4.47
South Africa	8.47	57.65
India	7.52	84.82
Turkey	7.43	71.41
United States of America	6.35	3.41
Russia	6.25	81.76
Colombia	4.20	68.00
Peru	4.01	41.18
Sweden	3.61	83.88
Chile	2.85	77.53
Ecuador	1.80	58.59
Indonesia	1.53	100.00
Pakistan	1.07	57.65
Philippines	1.02	61.41
Egypt	0.73	30.59
Iran	0.57	58.47
Bangladesh	0.47	42.47
Kazakhstan	0.26	44.82
Saudi Arabia	0.15	32.94
Qatar	0.05	35.06
Iraq	0.02	25.41

Table 1 shows that the countries with the highest hit counts in February were Australia, Canada, Italy, the United Kingdom, and Germany. **Table 2** shows that the countries with the highest hit counts in April were Canada, France, and the United Kingdom. **Table 3** shows that the countries with the highest hit counts in July were the United Kingdom, Canada, and France. In February, there were more domains in Australia, Japan, and Singapore. In April, more domains were observed in Sweden, the United States, and the Netherlands. In July, more domains were found in Indonesia, Italy, and Brazil.

Following these results, we analyzed publishing organizations. We visualized the countries involved in the high-frequency second TLD data as a two-mode network. The data revealed 23 countries in February, 26 countries in April, and 26 countries in July. The visualization results are shown in **Figures 1-6**. The

large “G” in the figures denotes “group.” For example, G(GEOC) means the group in which G (government), E (education), O (nonprofit organizations), and C (commercial organizations) appear simultaneously.

As seen in **Figure 1**, most of the COVID-19–related messages released in February were from the government, educational, or commercial sectors, with relatively few messages from the nonprofit sector. We divided the countries into several groups based on areas. Among all groups, the countries and regions that received information from these four areas the most included mainland China, Hong Kong, Macao, Australia, and Vietnam. Asian countries accounted for 88% (14/16) of these countries. Information from Italy was primarily from the government and educational enterprises. In Sri Lanka and the United Arab Emirates, information was mainly from the

government and educational institutes. In the United States and Russia, information was from the government and the educational and commercial sectors. In the United States, government agencies were primarily concentrated in California. Spain reported more commercial agencies, whereas Belgium reported the most information from the educational field. In general, Asian countries were more diverse regarding the online information shared on COVID-19 in February than other regions. This could be because most of the confirmed COVID-19 cases were diagnosed during this period in Asia, and various regions of the continent were considered to be more sensitive than others [42].

Figure 2 shows the institutional network diagram of the COVID-19-related information released in February 2020. The connection between nodes represents the simultaneous release of COVID-19-related information by these institutions. The width of the connection line represents the frequency of coreleases, and the wider the line, the more simultaneous the releases. The bold line between G and C indicates that the government and commercial area released the most information simultaneously, followed by the government and educational sector, and then the commercial and educational sector. Within the framework of the quadruple helix model, the government and the educational and commercial institutions were the leading producers of COVID-19-related information, and they played a prominent role.

Figure 1. Two-mode quadruple helix structure in February 2020. Large "G" refers to the group. G: government domains; E: educational institute domains; C: commercial domains; O: nonprofit organization domains.

Figure 2. One-mode quadruple helix structure in February 2020. G: government domains; E: educational institute domains; C: commercial domains; O: nonprofit organization domains.

As seen in Figure 3, April's COVID-19 messages were primarily from the government and the educational and commercial sectors, and relatively little information was provided by the nonprofit sector, as was the case in February. The number of countries and regions that received information from all four areas simultaneously was the largest. The areas in which COVID-19 information was released in these countries were relatively diverse, including mainland China, the United Kingdom, Brazil, and Japan, with Asian countries accounting for less than half. This is significantly different from the situation in February because, at this stage, COVID-19 became a pandemic and was no longer concentrated in Asia. Information from Romania, Peru, and Chile was primarily from the government and the educational and nonprofit sectors. In Spain, information was mostly from the government and the commercial and nonprofit sectors. Portugal, Italy, India, and Ireland received information primarily from the government and educational sector. Countries where commercial and nonprofit agencies released more information included Israel, the United States, Austria, and Sweden. For South Korea and

Poland, government and commercial sectors released more information. In Russia and the Netherlands, most information was shared by government agencies, while in Switzerland and Belgium, educational institutions were the primary sources of COVID-19-related information. In France, the information was primarily shared through the commercial sector. In general, the online information shared about COVID-19 during April and February was quite different in terms of both countries and institutions. Non-Asian countries diversified their fields as COVID-19 became a pandemic.

Figure 4 shows the institutional network diagram of the COVID-19-related information released in April. The government and the educational sector released the most information at this time. The relationship between the government and commercial sector, and that between commercial and nonprofit organizations was also closer. In April, the government and the educational and commercial institutions were still the leading producers of information, playing a prominent role in information dissemination.

Figure 3. Two-mode quadruple helix structure in April 2020. Large "G" refers to the group. G: government domains; E: educational institute domains; C: commercial domains; O: nonprofit organization domains.

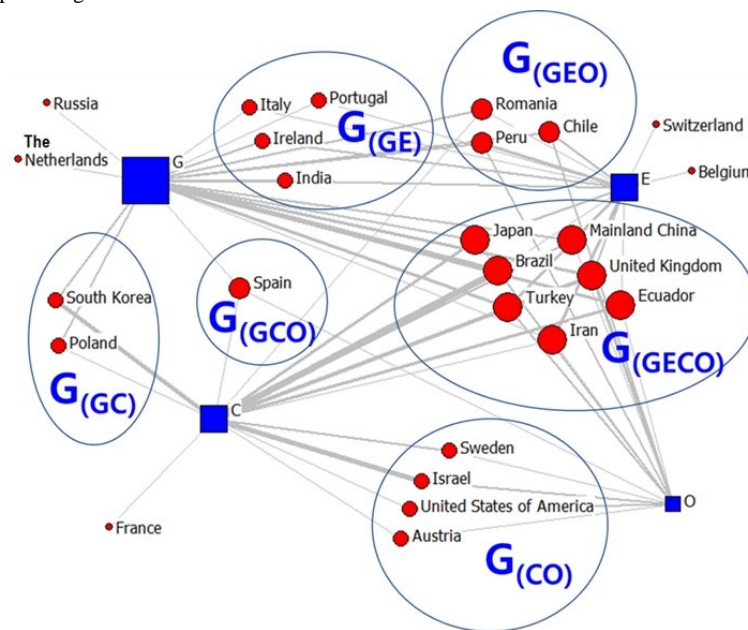

Figure 4. One-mode quadruple helix structure in April 2020. G: government domains; E: educational institute domains; C: commercial domains; O: nonprofit organization domains.

The two-mode diagram of the COVID-19 information release in July shows that most countries were delivering information from a diverse range of sectors (Figure 5). The proportion of individual areas and of countries and regions that received information from only two areas was lower than that in the previous phases. The countries and regions that received information from all four sectors the most included mainland China, Russia, Turkey, and the Philippines. In April, the COVID-19 pandemic continued to spread around the world, and the geographic distribution of information was also seen globally, and not just in Asia. Information from Iraq was primarily from the government and commercial and educational organizations. Information in France was from the government and nonprofit sectors. Government agencies in Chile and Italy provided relatively more information. In the United States, information from the government and educational sector decreased, while information from commercial sectors increased. Less information was collected from Bing in the United States in July. Most regions of the world and many industries were affected by the pandemic in July. The structure of the network for information-publishing organizations also developed from the coexistence of double, triple, and quadruple helices to the main structure of quadruple helices.

Figure 6 shows the institutional network diagram representing the COVID-19-related information released in July. The number of concurrent announcements made by the government and commercial sector remained the highest, followed by the government and educational sector, and then the commercial and educational sectors. In the three stages, the government and the educational and commercial institutions were the leading producers of information and played a prominent role.

We collated the degree centralities in four helices and found that the commercial sector in February had the highest degree, followed by the government and educational sector, and finally the nonprofit organizations (Figure 7). In April, the biggest area of degree centrality was again the commercial sector, followed by the government, nonprofit organizations, and finally educational organizations. In July, the government ranked first, commercial organizations ranked second, educational organizations were third, and the nonprofit sector fourth. Thus, the government and commercial organizations played a significant role in the COVID-19 information network, whereas the role of the nonprofit sector was relatively small.

Figure 5. Two-mode quadruple helix structure in July 2020. Large "G" refers to the group. G: government domains; E: educational institute domains; C: commercial domains; O: nonprofit organization domains.

Figure 6. One-mode quadruple helix structure in July 2020. G: government domains; E: educational institute domains; C: commercial domains; O: nonprofit organization domains.

Figure 7. Degrees of the three stages. G: government domains; E: educational institute domains; C: commercial domains; O: nonprofit organization domains.

We performed a text analysis and CONCOR analysis for the content of the information shared. For the content analysis, we deleted non-English and scrambled characters during data cleaning. There was a total of 9149 documents in February, and 8889 remained after cleaning. There were originally 14,768 documents in April, 14,766 of which remained after cleaning. The number of documents in July was 14,484 and 13,087 remained after cleaning. Word preprocessing was first performed using Python (the Spacy package) and the results were manually collated. We identified the 50 most frequently found words during each of the three months, which are compiled in [Table 4](#).

[Table 4](#) indicates that in February, people paid the most attention to the affected areas (China), health, departments, international, and news. In April, the content was focused on information regarding deaths, health, the pandemic, and public. In July, the content was focused on information regarding the pandemic, health, and news. These remained the top concerns in July 2020, whereas words such as “online,” “service,” “university,” and “government” were also highly ranked at this time. To summarize, the main content in February was dominated by information and news about the outbreak; in April, information was primarily regarding the public and the pandemic; and in July, various online services were used to address the problems caused by the pandemic.

Table 4. The 50 most frequent words of the three stages.

Rank	February		April		July	
	Words	Standardized frequency	Words	Standardized frequency	Words	Standardized frequency
1	coronavirus	100.00	coronavirus	100.00	coronavirus	100.00
2	country	59.30	information	24.96	information	36.79
3	China	30.18	die	21.70	pandemic	24.33
4	novel	28.57	health	12.09	health	22.67
5	health	27.90	virus	9.96	online	18.62
6	Jan	21.14	pandemic	8.22	service	17.20
7	international	19.88	public	7.64	virus	14.21
8	year	19.53	update	6.88	university	12.67
9	department	17.85	country	6.69	government	12.24
10	news	16.35	pour	6.62	news	12.12
11	world	16.00	school	6.60	provide	11.88
12	school	15.91	service	6.58	case	11.28

To further assimilate valuable information, we constructed the semantic network of high-frequency words and used CONCOR analysis for clustering. Furthermore, we obtained a visualization diagram of the clustering network in the three stages.

Group 1 in Figure 8 is named “Ministry and University,” which contains information on services provided by the government

departments, public authorities, and schools. Group 2 is named “Virus Spreading,” which primarily includes confirmed cities, patient symptoms, and the spread of the infection. Group 3 is “Coronavirus and Health” and Group 4 is “Child and Education.” Most of the information in Group 4 is related to “NSW (New South Wales, Australia) education” and “child,” and it showed the highest frequency in February.

Figure 8. Semantic network in February 2020.

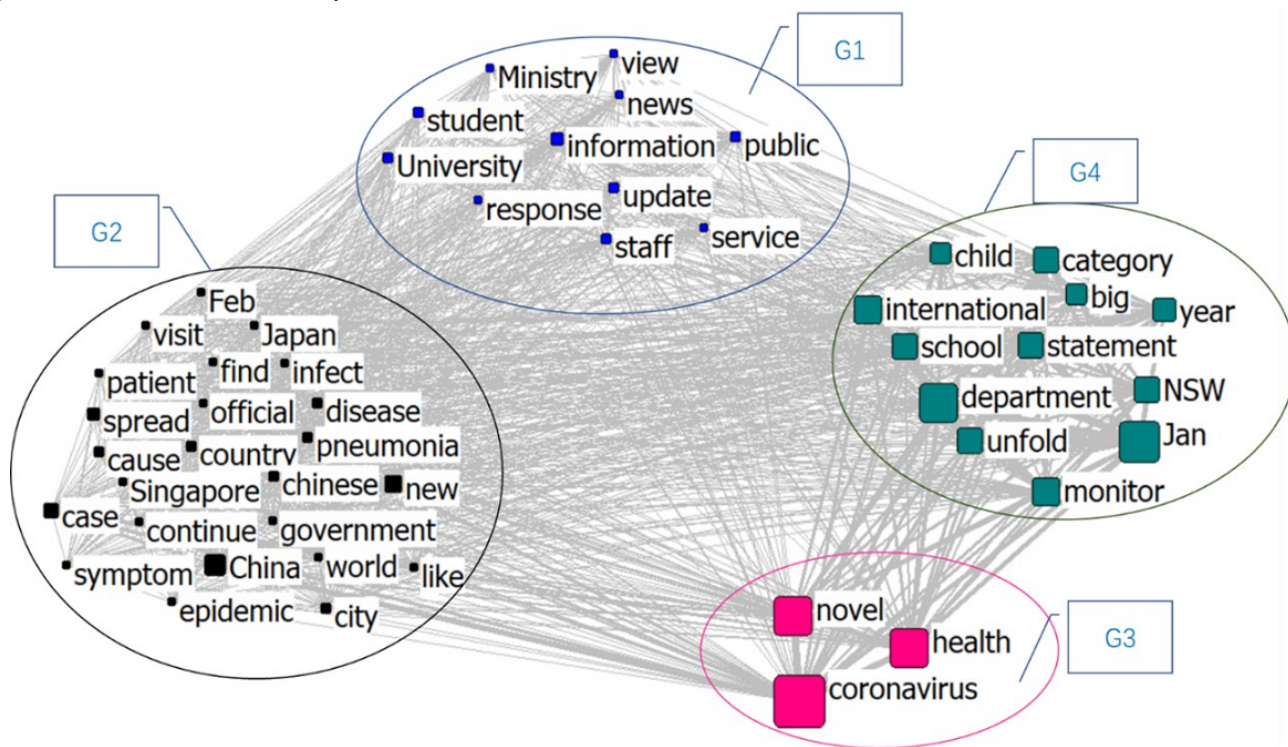

Figure 9 shows the semantic network for April. Group 1 is a school and student-related group named “Education Issue.” Group 2 is “Virus Spreading,” including information about the outbreak and the spread of the pandemic. Group 3 is “Virus Description,” which contains information related to the

characteristics of the virus. Group 4 is “Commercial Issue,” which includes words such as “business,” “government,” “service,” and “help,” and is related to the social change brought about by the pandemic.

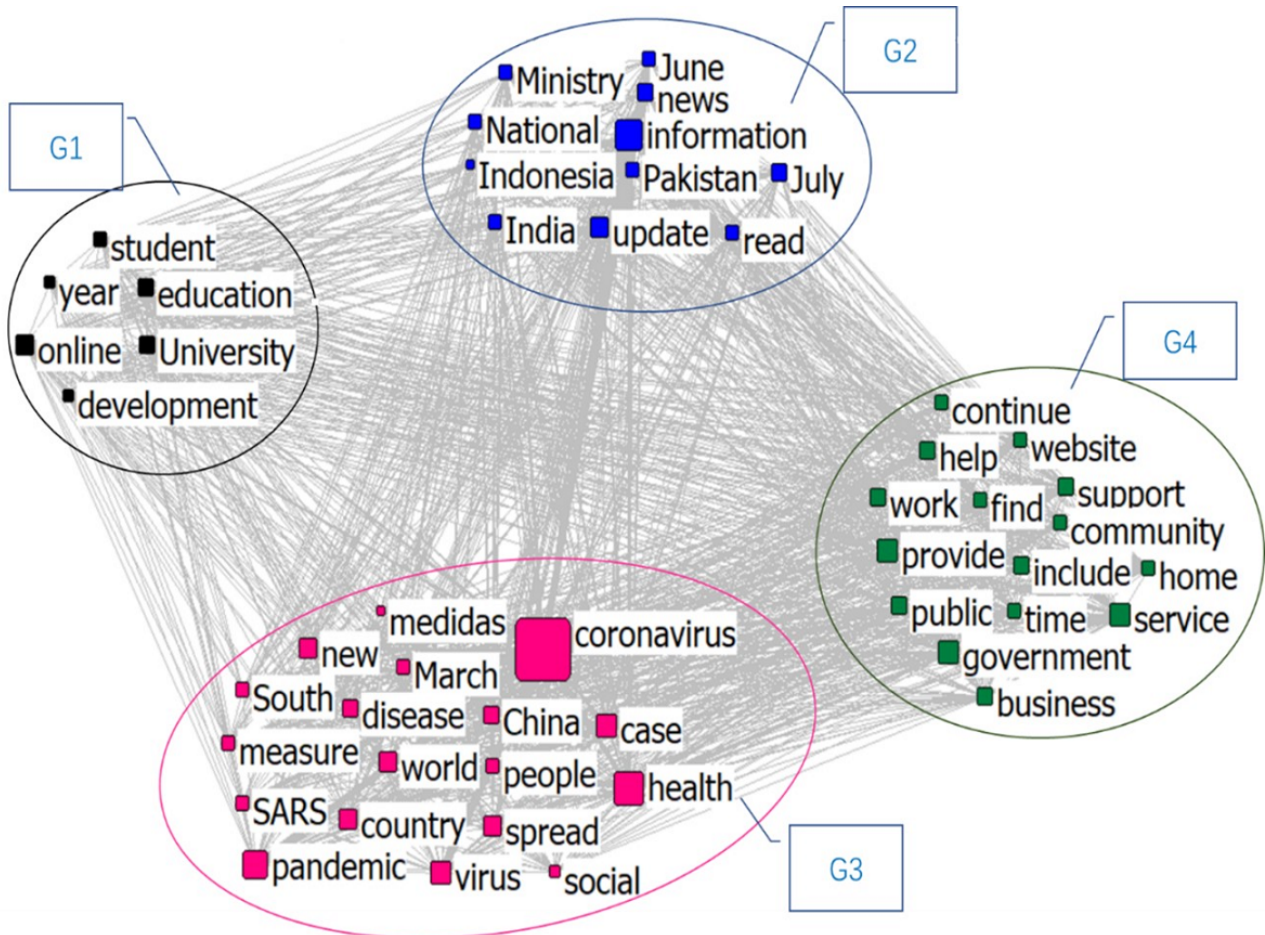

Figure 9. Semantic network in April 2020.

In July, the semantic network was also divided into four groups, as shown in Figure 10. Group 1 is “Distance Education,” which contains information about online education. Group 2 is “City News,” which contains information about the cities affected by the pandemic. Group 3 contains information about the measures

taken, and is therefore named “Measures.” The last group is “Commercial Issues,” which includes information regarding “business,” “services,” “government,” “provide,” “community,” and similar.

Figure 10. Semantic network in July 2020.

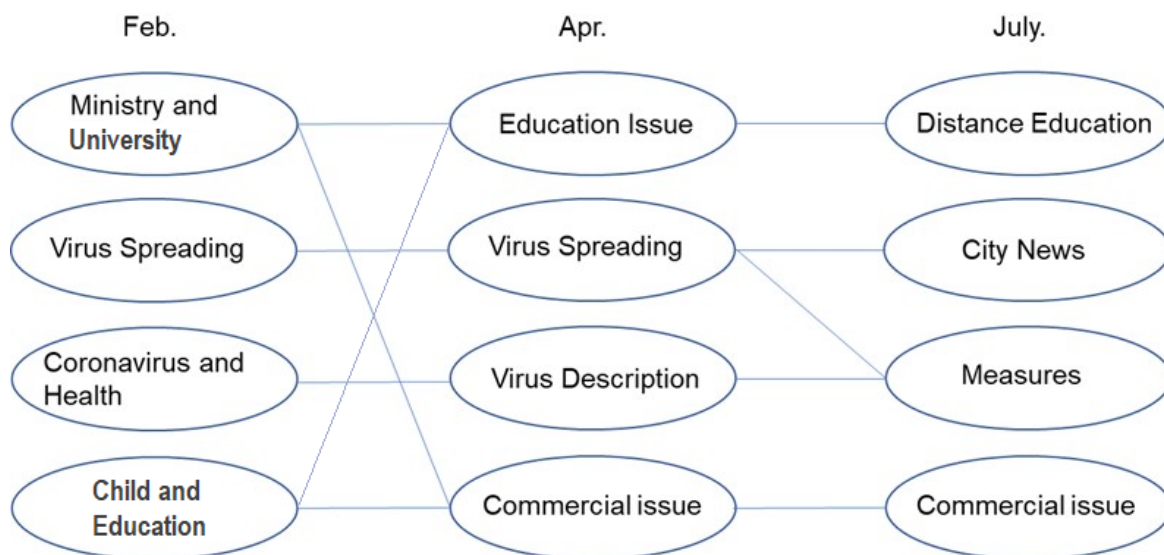

The clustering topics of the three stages are sorted in [Figure 11](#). The results show that the information in February was mainly regarding the response of the government and educational institutes, such as the impact on schools after the virus began spreading, and the spread of the virus and health issues became prominent topics. In addition, since the spread of COVID-19 was at an early stage in February, information reports in some places were also relatively prominent. By April, the disease had become a pandemic. At this stage, besides information, the spread of the virus, the description of the related characteristics of the virus, and the changes of the commercial environment became prominent topics. By July, the focus in education shifted to distance education. As the pandemic could not be fully controlled within a short period of time, most educational institutions began to prepare for or implement online education. By this time, the public had a basic understanding of the virus and how it spreads, and the focus shifted to measures such as how to deal with this spread. The impact of the pandemic on

business and society was still an important topic. Information about cities related to the outbreak also continued to appear in the news.

In general, education became a prominent topic of discussion in all three stages. With time, the basic information regarding the virus and its transmission became popularized, and people began to pay more attention to information about measures to prevent its spread. Since the beginning of the pandemic, the situation has changed in terms of business, government policy, and other public issues. Society has also changed. We compared the results of content analysis with the results of the quadruple helix structure and found that the content analysis also confirmed the form of the quadruple helix structure. In the content analysis, the information groups about business issues and government emerged as relatively large, with a smaller contribution of information about education, although this topic also forms a certain scale of the groups.

Figure 11. Evolution of topic content.

Discussion

Principal Findings

In this study, we analyzed COVID-19 web information sources from a quadruple helix perspective, and found changes in structure and content at each stage during the first 6 months of online information regarding COVID-19. We also found problems in the structure of information sources in the transmission of relevant information. We here provide detailed suggestions, which can contribute to the internet communication of future public health events.

Based on the quadruple helix model, this study collated and analyzed the structure and content of the network information sources about COVID-19 considering time and space. By sorting out the second TLD, we divided the structure of network information sources into four categories: the government, education, companies, and nonprofit organizations. An information source network composed of four levels was obtained. The results of the two-mode quadruple helix analysis of the three stages showed that the major confirmed cases in

February (first stage) occurred in Asia, and the online information sources in Asia were more diversified than those in other regions. As the pandemic spread in April (second stage), non-Asian sources of information began to diversify, and in July (third stage), the sources of web information became globalized. Thus, the impact of the first stage of the pandemic was more sensitive in Asia, and the information from various industries was related to responding to this need. However, only some industries in non-Asian regions paid attention in the first stage, and the information source helix did not form, which also led to the slow response to COVID-19 in some regions and the delay in response measures [43]. Since April, the spiral has intensified in non-Asian regions due to the spread of the pandemic to many areas outside Asia, which has raised concern of various industries.

In general, from the results of the two-mode analysis, the structure of the three stages of web information publishing organization has gradually developed from the coexisting structure of a double, triple, and quadruple helix to the diversified structure centered on the triple and quadruple helix. From this phenomenon, we can find that in the face of major

public health emergencies, most of the local information release sources are not comprehensive. This phenomenon has also led to the failure of many industries to anticipate and respond to the pandemic in a timely fashion [44,45]. Our results suggest that the health care sector can call on the local information sources of various industries to release appropriate and reasonable information about the health and public events in the future to ensure the timely deployment of all sectors of society and avoid more losses. We used a modular quadruple helix structure to analyze the forces of these four levels at various periods in detail. We found that in February, the information shared was the most coincident and closely linked between government and commercial organizations, followed by educational and government organizations. Next, there was a closeness between the commercial and educational sectors. In April, the government and the educational sector simultaneously released the most information about COVID-19. The relationship between the government and commercial sectors, and the relationship between commercial and nonprofit sectors were also closer. In July, the number of concurrent announcements about COVID-19 by the government and commercial sector remained the highest, followed by the government and educational sector, and then the commercial and educational sectors. We collated the centrality of the three stages and four areas, indicating that the commercial area scored the highest in February, followed by the government and educational sectors, and finally the nonprofit organizations. In April, the biggest area of degree centrality was also the commercial sector, followed by the government, nonprofit sector, and finally educational enterprises. In July, during the third stage, the government played a central role in the COVID-19 information network. In all three stages, as a whole, the government and commercial sector played a significant role in COVID-19 network information, and the connection of the nonprofit sector was relatively low. In fact, in the event of major infectious diseases, school is an important aspect that cannot be ignored, and schools often gather dense populations [46]. The communication role of the education sector as an information source is not stronger than that of business and government sectors. However, as educational institutions learn more than any other institutions about the actual school and education situation, they should take on more of a role than the government and businesses to ensure the spread of information. In future infectious disease health events, education and industry organizations, along with others, need to release information more quickly and accurately.

This study included an analysis of the quadruple helix structure and the content of the three stages using dynamic progressive detailed analysis. We carried out content analysis on 36,742 pieces of information in the three stages. The results of frequency analysis showed that the most prominent information in February was news about the pandemic. April was dominated by information about the public and the pandemic. The focus in July was the use of various online services to solve problems caused by the pandemic. We then used CONCOR cluster analysis to classify the topics in the three stages. The changes in trends in the three stages were also sorted. The results indicated that in the early stages, there were more reports about the affected areas, and the response of authorities such as

governments and schools to the virus, and the spread of the virus and health issues were the main points of focus of discussion. The second phase focused on the spread of the virus across the world, which created a global pandemic. At this stage, information about educational hotspots, descriptions of virus-related features, and information about commercial environment changes caused by the pandemic also received attention. In the third stage, the educational hotspots differentiated into the characteristics of distance education. The pandemic made physical face-to-face education difficult. Many educational institutions began to prepare for or implement online education. Public attention at this stage shifted from what the virus was to measures of controlling its spread. In general, education was a prominent topic at all levels. With the change of stage, the information content also changed. In the early stage, the basic situation of the virus and its impact on health attracted most of the attention. Later, the focus was on pandemic prevention measures. The business environment and policy environment have changed from the beginning of the pandemic, and the social changes caused by the pandemic have also become an important discussion topic.

Limitations

Owing to the large amount of data from all countries worldwide, this study has only used the web information for countries with a significant number of diagnosed cases at each stage as the research object. In addition, we only used data from Bing. Although Bing is more widely used than any other search engine in the webometric field, it does not have a strong market share in some parts of the world that rely more on other search engines. For example, Google has the largest market share in the United States, Baidu has the largest share in China, and Naver has the largest share in South Korea. Therefore, the results of different search engines in individual regions may somewhat vary from those of Bing. In addition, there is no ideal description of the web network structure [47]. Search engine properties are considered as more engineering products than mathematical tools [48]. Different search engines often have divergent algorithms and search results, which inevitably produce repeated and mixed results. Since search engines usually consider both quality and efficiency, this could also lead to problems related to Type I and Type II errors, which objectively lead to insufficient coverage [48,49]. These can be considered as limitations of the study.

Conclusions

This study focused on the structure of information sources at each stage of the first 6 months of the COVID-19 pandemic and the development of the network structure through the quadruple helix framework. We found that for public health emergencies, some online and offline information sources were not sufficient. Diversified institutions need to pay attention to public health emergencies, and actively respond to multihelical information sources, which is conducive to implementing a timely and more comprehensive response to public health emergencies. In terms of published messages, the educational sector plays an important role in public health events. However, educational institutions release less information than governments and businesses. In addition, we summarized the

trend of COVID-19 online information dissemination. It is important to understand the communicational structure of pandemic information sources worldwide. Currently, the quadruple helix model is primarily used in the field of scientific cooperation in terms of coauthorship analysis, and research in other fields is insufficient. This study highlights that the

quadruple helix not only has theoretical significance in the scientific innovation field but can be also used to conduct effective research regarding web information. This is significant for further development of the quadruple helix model with respect to the COVID-19 pandemic.

Acknowledgments

This research is partially funded by the Foundation for Broadcast Culture (방송문화진흥회) in the Republic of Korea. The data for February were analyzed and reported from a different scheme for a Korean-language journal. Since then, the data for April and July have been compiled only for this study, as COVID-19 has rapidly become more serious over time.

Abstract

Background: Premature ejaculation (PE) is one of the most described psychosocial stress and sexual complaints worldwide. Previous investigations have focused predominantly on the prospective identification of cases that meet researchers' specific criteria. The genuine demand from patients with regard to information on PE and related issues may thus be neglected.

Objective: This study aims to examine the online search trend and user demand related to PE on a national and regional scale using the dominant major search engine in mainland China.

Methods: The Baidu Index was queried using the PE-related terms for the period of January 2011 to December 2020. The search volume for each term was recorded to analyze the search trend and demographic distributions. For user interest, the demand and trend data were collected and analyzed.

Results: Of the 36 available PE search keywords, 4 PE searching topics were identified. The Baidu Search Index for each PE topic varied from 46.30% (86,840,487/187,558,154) to 6.40% (12,009,307/187,558,154). The annual percent change (APC) for the complaint topic was 48.80% ($P<.001$) for 2011 to 2014 and $-16.82%$ ($P<.001$) for 2014 to 2020. The APC for the inquiry topic was 16.21% ($P=.41$) for 2011 to 2014 and $-11.00%$ ($P<.001$) for 2014 to 2020. For the prognosis topic, the annual APC was 11.18% ($P<.001$) for 2011 to 2017 and $-19.86%$ ($P<.001$) for 2017 to 2020. For the treatment topic, the annual APC was 14.04% ($P<.001$) for 2011 to 2016 and $-38.83%$ ($P<.001$) for 2016 to 2020. The age distribution of those searching for topics related to PE showed that the population aged 20 to 40 years comprised nearly 70% of the total search inquiries (second was 17.95% in the age group younger than 19 years). People from East China made over 50% of the total search queries.

Conclusions: The fluctuating online popularity of PE searches reflects the real-time population demands. It may help medical professionals better understand population interest, population concerns, regional variations, and gender differences on a nationwide scale and make disease-specific health care policies. The internet search data could be more reliable when the insufficient and lagging registry data are completed.

KEYWORDS

premature ejaculation; Baidu Index; infodemiology; public interest; patients' concern; sexuality; sexual dysfunction

Introduction

Premature ejaculation (PE) is one of the most described psychosocial stress and sexual complaint worldwide [1]. The estimated PE prevalence rate is 16% and over 20% in an internet-based survey [2,3]. Characterized with poor controlled and rapid ejaculation, the PE condition negatively impacts both sexual partners with symptomatic psychological problems and humanistic economic burdens [2,4]. However, instead of seeking help from professionals, previous reports revealed that most patients with PE are prone to initiate information-seeking behavior by using the internet due to embarrassment and wrong beliefs [5,6]. The PE prevalence and its actual impact may hence remain unveiled and underestimated.

The quality and liability of online health care-related content have been previously examined and scrutinized. Though the content was mainly acceptable, the amount of misleading content and their impact on the audience cannot be ignored. Currently, *searching before seeing a doctor* has become a trend in patients. The inquiry frequency and concerning problems from the users have been well documented by internet platforms and their demographic data. Using data from these internet platforms, infodemiology research has been successfully practiced in reporting disease incidence [7,8], surveilling pandemic outbreaks [9,10], and analyzing other public health events and related public awareness [11,12]. Previously, public interest and the change over time of the search volume in sexual dysfunction were analyzed [13,14]. It was shown that consulting *Dr Internet* influences the decision-making process of inquisitive people. Additionally, the extent of misinformation penetration could not be neglected [6,13]. However, such data in mainland China is still lacking.

By 2020, the netizens population has reached 940 million in mainland China [15]. With the 766 million users actively seeking medical information and inquiring about symptoms for diagnosis confirmation on the internet, we believe it is crucial to evaluate users search behavior and their interest or beliefs [16]. As the leading search engine in mainland China, Baidu has taken 92.1% of the search volume and 93.1% coverage of the use rate exclusively [17]. Baidu's big data analyzing platform, Baidu Index, enables users to track the popularity change and correlated demand of one specific phrase [7,8]. Therefore, we aim to evaluate the online search trend and user demand related to PE problems and the genuine needs from a *real-world* geospatial and temporal database.

Methods

Keyword Selection and Data Retrieval

This study was mainly referring to the temporal search trends of PE-related terms in Chinese. The PE keyword was identified by referring to the International Society for Sexual Medicine's definition [1]. To reduce the language habit-derived differences and biases, all possible synonyms or complex derivatives were screened and selected as previously described [8,18]. According to the available search keywords, four categories of PE topics were identified. All included PE search keywords were checked

on the Baidu Index platform for their availability and are listed in [Multimedia Appendix 1](#).

In the trend module, the Baidu Search Index (BSI) value is provided for each keyword at the national and subnational scale [8]. The BSI value is a numerical value that represents the sequential search volume on a daily basis. Hence, each keyword's monthly search index values from January 1, 2011, to December 31, 2020, were collected at the national and provincial level from the platform [8,18]. For the terms with multiple available synonyms, the searching value of each synonym was summed [8,18]. In the search-demand module, the top 10 keyword-related phrases were listed and sorted with their BSI value. The user age, gender, and region distribution data were collected from the demographic portrait module. Therefore, the user demand and user geodemographic data were collected from the Baidu database to analyze users' demand and public awareness concerning the PE issue.

Data Analysis

For each PE topic, the corresponding BSI data were plotted sequentially to describe the trend of public attention. The monthly search index of each PE topic was sorted annually, and the overall time trend change for each domain was determined by the annual percent change (APC) model. This model is designed to examine the overtime change of popularity over a specified fixed interval [19]. The APC was calculated by the Joinpoint Regression model, Program Version 4.7.0.0 (Statistical Research and Applications Branch, National Cancer Institute). A $P < .05$ was considered statistically significant.

Statistical Analysis

The database was constructed with Excel 2019 (Microsoft Corporation). We used Prism 8 for macOS, version 8.4.0 (455; GraphPad Software) to conduct statistical analysis and create figures.

Results

Web-Based Data Trends in PE Topics

We summarized the total BSI of PE-related search keywords in the past 10 years. The retrieved 36 search keywords were manually categorized into four topics, complaint, inquiry, prognosis, and treatment, based on search keywords' content by the expert panel of medical professionals with over 5 years of experience. The total BSI value of these PE search keywords was 187,558,154. The BSI for each PE topic varied greatly. The search percentage in treatment ($n=86,840,487$, 46.30%) and complaint ($n=66,387,459$, 35.40%) accounted for the majority of the PE searches, leaving the inquiry ($n=22,320,901$, 11.90%) and prognosis ($n=12,009,307$, 6.40%) topics accounting for less than 20% of the total search ([Table 1](#)).

The monthly time series curves of the BSI for each PE topic and the APC trend lines are demonstrated in [Figure 1](#). According to the average count of the annual BSI for each PE topic, these topic trends shared a similar increase for a period of time and redescended at the end of 2020. The following are the overall time average APC for the topics: complaint (1.18%; $P=.94$), inquiry (-2.9%; $P=.73$), prognosis (-0.32%; $P=.91$), and

treatment (2.13%; $P=.65$). Specifically, the average APC for the topic complaint was 48.80% ($P<.001$) for 2011 to 2014 and -16.82% ($P<.001$) for 2014 to 2020. The average APC for the topic inquiry was 16.21% for 2011 to 2014 ($P=.41$) and -11.00% ($P<.001$) for 2014 to 2020. For the topic prognosis, the average APC was 11.18% ($P<.001$) from 2011 to 2017 and -19.86%

($P<.001$) from 2017 to 2020. For the topic treatment, the average APC was 14.04% ($P<.001$) from 2011 to 2016 and -38.83% ($P<.001$) from 2016 to 2020. The detailed search trend of the summed searches detailed in each topic are listed in [Multimedia Appendix 2](#).

Table 1. Search popularity of each topic in premature ejaculation.

Topic	Baidu Search Index (n=187,558,154), n (%)
Complaint	66,387,459 (35.40)
Inquiry	22,320,901 (11.90)
Prognosis	12,009,307 (6.40)
Treatment	86,840,487 (46.30)

Figure 1. Online interest in premature ejaculation topics over the last 10 years. BSI: Baidu Search Index.

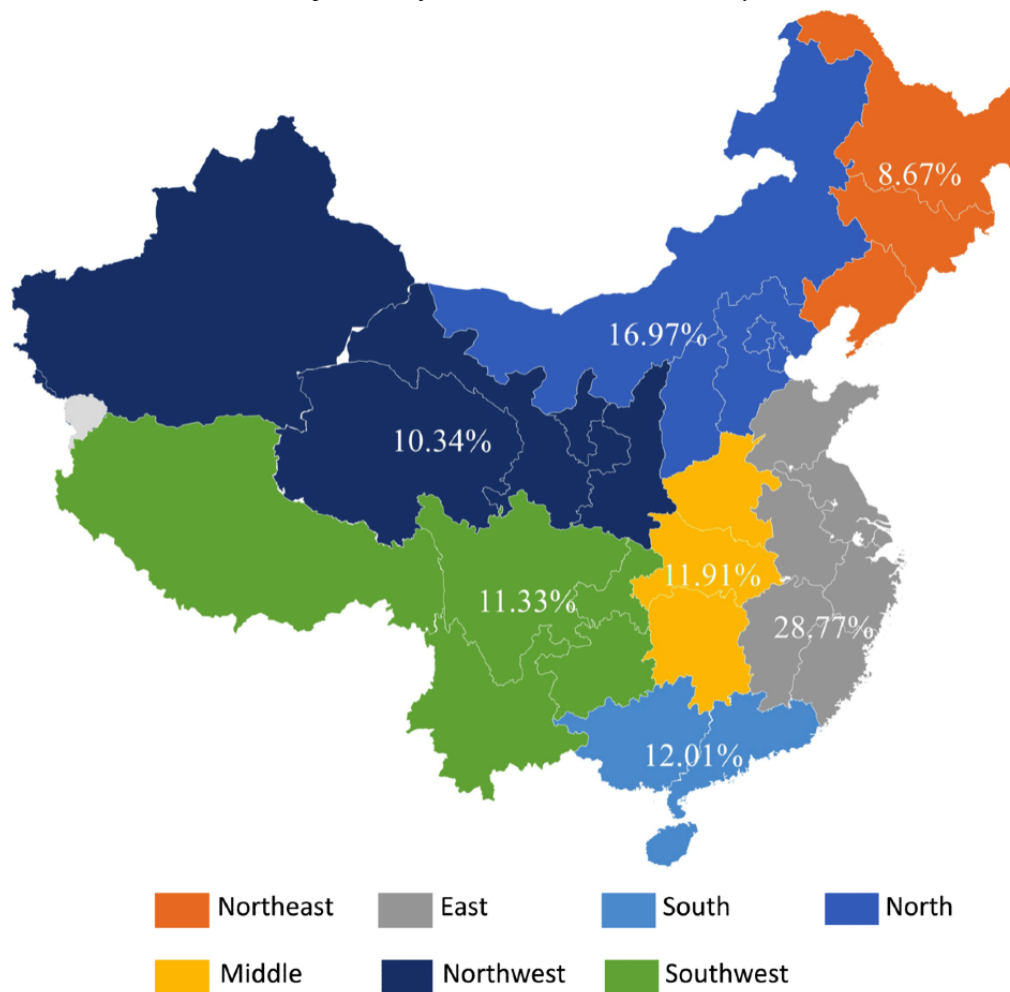

Geographic Differences

The PE BSI geographic distribution was calculated based on provincial data and sorted according to Chinese administrative divisions. The seven regions were as follows: Northeast China, East China, South China, North China, Central China, and Northwest and Southwest China. In [Figure 2](#), the 10-year

regional BSI proportions for all PE topics are presented on a map of mainland China with a valid searching record. Notably, people from eastern China (Northeast, East, and South China) made 57.75% (BSI: 108,317,892/187,558,154) of the total search queries. Nevertheless, the queries from west China (Northwest and Southwest China) only made 21.67% (BSI: 40,645,892/187,558,154) of search queries.

Figure 2. Regional distribution of online interest in premature ejaculation searches over the last 10 years.

Demographic Differences

From the age distribution (Table 2), in total, it was demonstrated that nearly 70.24% (BSI: 131,732,080/187,558,154) of the PE searches was inquired by the population aged 20 to 39 years (20-29 years and 30-39 years), followed by the population aged 40 to 49 years and younger than 19 years. People older than 50

years accounted for 1.87% (BSI: 3,516,547/187,558,154) of the total popularity. A similar pattern was observed in each PE topic subgroup. With regard to gender differences, the total inquiry was mainly dominated by the male group (Table 3). In detail, the treatment topic was the main concern from the male population, followed by the complaint, prognosis, and inquiry topics.

Table 2. Age percentages of search popularity in premature ejaculation topics.

Topic	Baidu Search Index, n (%)				
	≤19 years	20-29 years	30-39 years	40-49 years	≥50 years
General (n=187,558,154)	33,738,405 (17.98)	80,330,533 (42.83)	51,401,547 (27.40)	18,571,122 (9.92)	3,516,547 (1.87)
Complaint (n=66,387,459)	11,590,226 (17.46)	29,134,384 (43.88)	18,625,737 (28.06)	6,048,631 (9.11)	988,481 (1.49)
Inquiry (n=22,320,901)	4,731,811 (21.19)	10,623,644 (47.59)	5,217,263 (23.37)	1,567,679 (7.02)	180,504 (0.81)
Prognosis (n=12,009,307)	3,252,774 (27.08)	4,391,126 (36.56)	3,267,039 (27.20)	975,100 (8.12)	123,268 (1.02)
Treatment (n=86,840,487)	14,163,594 (16.31)	36,181,379 (41.66)	24,291,508 (27.97)	9,979,712 (11.49)	2,224,294 (2.56)

Table 3. Gender percentages of search popularity in premature ejaculation topics.

Topic	Female, n (%)	Male, n (%)
General (n=187,558,154)	46,556,413 (24.82)	141,001,741 (75.18)
Complaint (n=66,387,459)	20,435,182 (30.78)	45,952,277 (69.22)
Inquiry (n=22,320,901)	9,144,492 (40.97)	13,176,409 (59.03)
Prognosis (n=12,009,307)	3,928,248 (32.71)	8,081,059 (67.29)
Treatment (n=86,840,487)	13,048,492 (15.03)	73,791,995 (84.97)

Keyword-Relevant Terms and Search Frequency

In the Baidu Index platform, the user demand data is available for review by sorting the top-searched keyword-relevant terms. The terms were categorized into 14 types to clarify the users' main concerns and sort their popularity according to the content and implied intention. To better explicitly and comprehensively describe users' concerns, these categories were defined as (1) irrelevant, (2) complaint, (3) inquiry of etiology, (4) treatment, (5) health-related information, (6) diagnosis, (7) hospital and product, (8) diagnosis confirmation, (9) test and examinations, (10) prognosis, (11) traditional Chinese medicine (TCM) complaint, (12) TCM inquiry, (13) TCM regiment, and (14) TCM materials. The total BSI for the user demand terms was 1,518,298,328, which is nearly 10 times the requests for PE terms. However, only 43.74% (BSI: 664,107,756/1,518,298,328) of the demand search terms were identified as relevant to PE. Detailed distributions of these relative terms were presented in Figure 3. The categorized users' demand in each PE topic and the detailed treatment inquiries are presented in Figures 4 and 5. Furthermore, the top 3 related terms and their BSI are listed in Multimedia Appendix 3.

(10) prognosis, (11) traditional Chinese medicine (TCM) complaint, (12) TCM inquiry, (13) TCM regiment, and (14) TCM materials. The total BSI for the user demand terms was 1,518,298,328, which is nearly 10 times the requests for PE terms. However, only 43.74% (BSI: 664,107,756/1,518,298,328) of the demand search terms were identified as relevant to PE. Detailed distributions of these relative terms were presented in Figure 3. The categorized users' demand in each PE topic and the detailed treatment inquiries are presented in Figures 4 and 5. Furthermore, the top 3 related terms and their BSI are listed in Multimedia Appendix 3.

Figure 3. Term categories related to premature ejaculation searches in the Baidu Index demand graph. A: relevant ratio of term BSI; B: distribution of term. BSI: Baidu Search Index; TCM: traditional Chinese medicine.

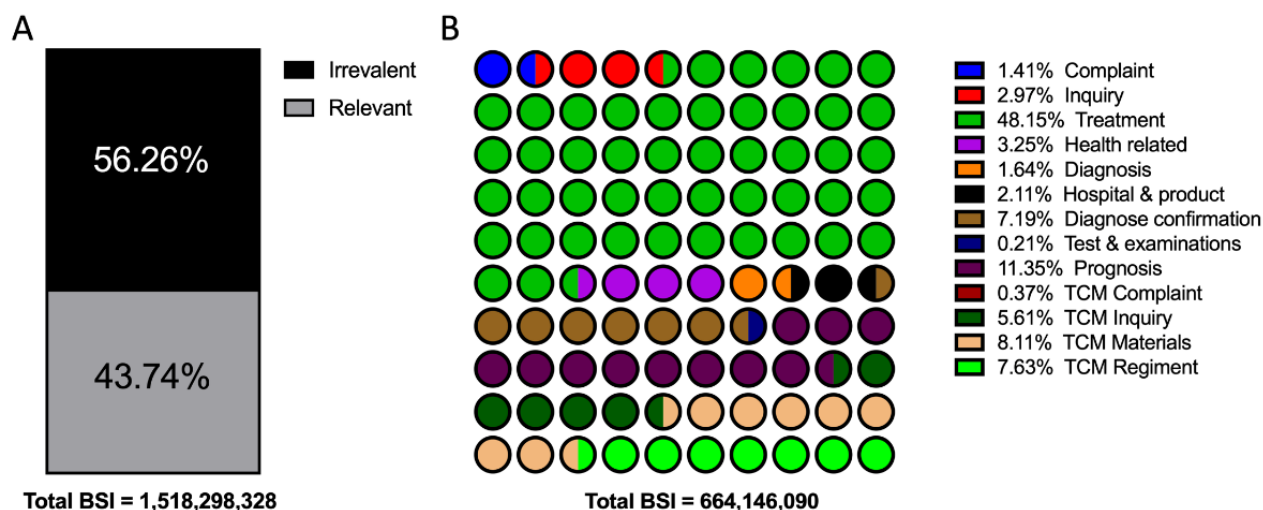

Figure 4. Term categories related to each premature ejaculation topic search in the Baidu Index demand graph. A: topic complaint; B: topic inquiry; C: topic prognosis; D: topic treatment. BSI: Baidu Search Index; TCM: traditional Chinese medicine.

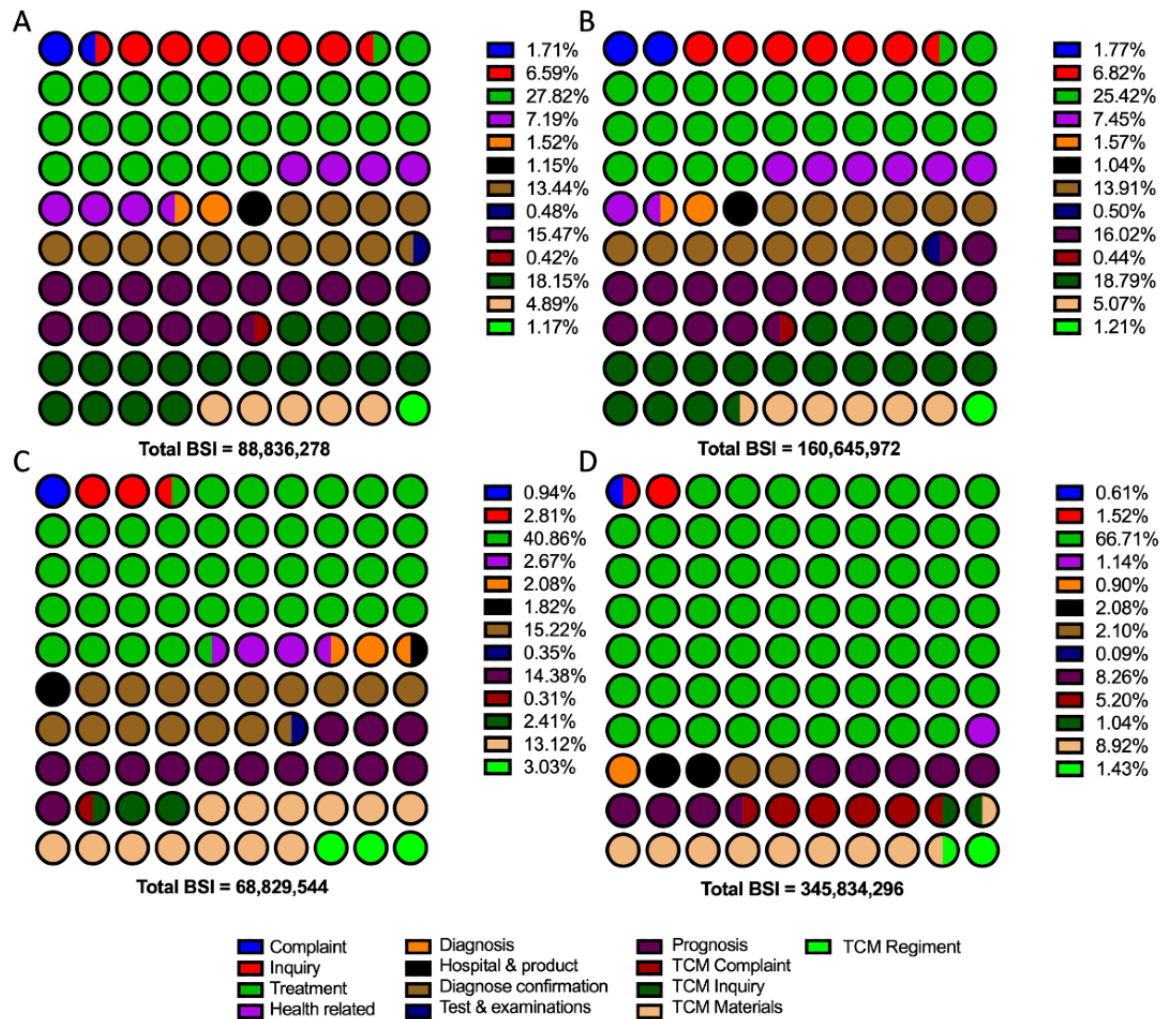

Figure 5. Classification of the detailed options in PE-related treatment search terms. BSI: Baidu Search Index; CPPS: chronic pelvic pain syndrome; ED: erectile dysfunction; PDE5i: phosphodiesterase type 5 inhibitor; PE: premature ejaculation; SSRI: selective serotonin reuptake inhibitor.

Discussion

Principal Findings

In investigating PE online interest in mainland China, 36 PE search keywords were identified as valid and could be categorized into the topics complaint, inquiry, prognosis, and treatment. Information on search trend and the geographic, demographic, and user demand information could be identified based on data from the BSI platform.

Baidu is the leading search platform in mainland China. Every day, over billions of user-initiated information queries are made on this platform. With the substantial amount of user-generated data, the medical professionals were enabled with a new insight into users' information-seeking behaviors and health care problems. Studies have confirmed that the big data from the online platform is capable of assisting with forecasting pandemic outbreaks, identifying population interests, monitoring health education campaigns, and tracking the popularity trend of patients' preferences [20-22]. Our investigation revealed that the PE search trend on the Baidu Index platform reflects the overall public concern of this health issue.

In our research, 36 PE keywords were categorized into four topic categories. Searches for the complaint topic accounted for over 35% (BSI: 66,387,459/187,558,154) of the search popularity for PE inquiries. This high proportion is probably because the PE search keywords are also words describing symptoms. When it was intuitive and simple to express without content restriction, starting a query with these terms could allow users to decide additional queries depending on the retrieved information. The treatment topic included 21 search keywords, describing PE treatment ranging from medication, surgery, or other available options. From these search keywords, the conveyed definition and concept were restricted and specific. Therefore, this result reveals that Chinese users are likely to assume they have a health problem and are more concerned about the availability and options of solving this problem. Despite the lack of basic understanding of this disease, such as its definition, morbidity, etiology, pathology, or diagnostic criteria, the treatment options were users' primary concern in health issues like PE. Though six search keywords concerned PE definition and criteria, the total search popularity of the topic inquiry accounted for only 11.90% (BSI: 22,320,901/187,558,154). Hence, a high rate of online self-diagnosis and treatment was observed. Internet self-diagnosis has caused concern about diagnosis delay and misleading treatments [23]. With unproven or biased information that is frequently presented on the internet, the population is given unrealistic expectations. A distrust of professionals with "objective" reasoning could also exacerbate their anxiety about their own problems [24]. Our findings partly represent these issues. Therefore, improving internet health care and optimizing medicine services relies on elevating service quality and popularizing basic medical concepts [25].

When evaluating the popularity trend, a similar pattern was observed for the four PE topics. For each topic, the sustained growing trends were only observed in the beginning years. This trend pattern reveals that, although the PE incident rate in the

population may remain constant, the users' medical advice-seeking habits may have changed. The medical information from the Baidu platform has always been in public dispute. As the most commonly used search engine in mainland China, Baidu has long been criticized for presenting the top-ranked sites based on higher bids [23]. The biased and inductive information with higher bids are always listed at the top, making high-quality or evidence-based medical information from universities or medical centers more time consuming to obtain [23]. When the Wei Zexi incident broke out in 2016, public critiques of Baidu had reached a peak because the top listed and false advertised treatments claiming to cure synovial sarcoma from this search engine were deemed the leading cause for a 21-year-old student's death [26]. In 2017, Hu et al [23] found that most health information online from the first 100 links for keywords were generally inadequate. Furthermore, from a recent investigation by Chen et al [27], the content available on Baidu were less credible and inferior to those from Google. Consequently, instead of serving as a search engine that presents information on health education and credible content, Baidu more resembles an advertising platform. Therefore, local public health authorities should participate more and make regulations on the internet service industry, encouraging them to provide more qualified and well-produced information, unbiased information, and evidence-based recommendations on their platform. Hence, the trends in our research indicate that, although the PE prevalence may remain stable, the public awareness may change as people change their information-seeking behavior in response to poor quality content, impacting search popularity.

From the geographic data, we discovered that the PE search popularity was dominated by searches from the East China, North China, and South China regions, where the top four Chinese megacities (Beijing, Shanghai, Guangzhou, and Shenzhen) are located. Although national PE epidemiology data are lacking, this geographic distribution was in line with the leading regional economic level and the demographic distribution [28]. Coinciding with the finding from Xu et al [8] and Wang et al [7], the search popularity's interregional gap may also be a result of the differences in socioeconomic status, population structure, healthy concepts, and health care policies [9]. Medical professionals could gain insight into the public concern toward PE and customize their clinical session accordingly.

PE was reported as the most common sexual complaint in males in all age groups in previous epidemiological studies [29]. Though it has long been believed that the PE incidence is correlated with age differences, the existing age PE prevalence data were controversial [30-32]. In our investigation, over 70% of PE online search queries came from males aged 20 to 39 years. This result appears to contradict the Global Online Sexuality Survey, from which the peak PE prevalence was observed in men in their forties [32]. Nevertheless, from an internet-based survey, the highest self-reporting PE incident was for those in their thirties and twenties [30]. The discrepancy between these previous research results may be caused by the screening method, diagnostic standard, and inclusion criteria of risk factors such as age, coitus regularity, circumcision, and

masturbation history [31,32]. We believe the openness in Son et al's [30] investigation resembles the online inquiry on a searching platform. Their discoveries were similar to ours, the results presenting the natural concerns of users and the related popularity distribution [30]. In addition, we noticed the PE inquiry from the female population had reached 24.82% (BSI: 46,556,413) in total and 40.97% (BSI: 9,144,492) in the topic inquiry. Previously, the investigated partners' satisfaction rates were 45% from the individual with PE's perspective [33]. According to Zhang et al [34], although only 21.39% of females tended to report PE as hampering sex satisfaction, females are more adversely experienced with relationship issues, such as arousal difficulty, weak sexual desire, and organism inability [34]. Though the cultural differences may underlie searching preference, as the tip of an iceberg, our results may show the concerns and demands of PE issues troubling females. Hence, PE impact on females should be stressed.

In the user demand section, the top 10 most related terms were used for each keyword search. From this section, practitioners were able to gain insight into the patients' most concerning problems and to confirm individuals' main intentions from these weekly updated data. Generally, these related terms reflected the wide-ranging scope of concerns when searching PE-related content, such as PE comorbidity, PE training practices, PE etiology, and reproductive influences.

We noticed that the most popular term was "The fastest and easiest way to cure PE?" The high prevalence of this term echoes the topic popularity finding in our research, indicating that the users' most concerning issue is related to problem solving. Hence, users' self-diagnosis and self-treatment of issues should be stressed.

The relationship between PE and chronic prostatitis (CP) has been long observed [35]. Suggested as an organic PE cause, the existence of CP in PE is yet to be fully understood. The sexual dysfunction prevalence in males with CP has reached 49% in previous investigations, and the severity of the symptom scoring between these two clinic complaints is well correlated [36,37]. Supporting these investigations, we discovered that "prostate" and "prostatitis" were the most inquired terms from users. This popularity revealed that prostatic problems are the primary concern for patients with PE; also, these people may tend to self-diagnose themselves with prostatitis instead of ejaculatory dysfunction. Whether this concern results from the doctor's instruction or is based on the patient with PE's complaint, it is necessary to screen for PE and CP complications.

Additionally, in investigating the users' demands in treatment, the most queried terms were related to selective serotonin reuptake inhibitors. The followed treatment regimens were phosphodiesterase type 5 inhibitor, topical anesthetic agents, behavior therapy, and tramadol, accounting for over 80% of the search popularity, and these treatment options were either recommended by the sexual dysfunction treatment guidelines

or evaluated for safety and efficacy [38,39]. This information could alert the patients to treatment avoidance and contraindication. In addition, better compliance could facilitate patients' comprehension of the doctor's instructions.

Nevertheless, terms with false information and their popularity are not noteworthy. These terms typically suggest applying homemade regimens from everyday domestic items on to the penis, ranging from vegetable mixtures with ginger, leeks, or onions to toothpaste or the *Fengyou essence* (a type of essential balm). Though patients could not be harmed much from the vegetable mix remedies aside from allergies or mucosal lesions, damages from the toothpaste and the *Fengyou essence* can be more consequential [6], for the main ingredients of *Fengyou essence* and toothpaste are more abrasive and irritative pharmaceutical materials; the improper application of these regimens with the wrong dose could cause severe skin abrasion or even damage the genital organ [6,40].

Some limitations must be addressed in this study. First, the Baidu Index is only available for search data on the Baidu platform. Though Baidu is the most widely used platform and monopolizes the searching requests in mainland China, the users' shift to social media for searching is rising. Therefore, lacking a uniform recording system, data from these growing social media sites are not able to be incorporated or be assessed without bias. In addition, in considering the user privacy security, only the user age, gender, and living region information was available for the demographic research. For an in-depth demographic investigation, data such as socioeconomic status, ethnicity, or educational background are required. Additionally, instead of representing the actual search frequency, the BSI is just a weighted index derivative and cannot manifest real-world disease prevalence. Nevertheless, before a nationally conducted PE prevalence and demographic investigation is available, infodemiology research is practical to investigate the PE problems and users' information-seeking behaviors from the population perspective.

To our best knowledge, this is the first infodemiology study that investigates PE public concerns in mainland China. We chose to examine the PE popularity because its clinical manifestations are intuitive and easy to describe. More importantly, patients with sexual dysfunction are willing to search online due to privacy concerns. Hence, the real-time updated searching data helps to improve practice standards and policy making for medical professionals and health officials.

Conclusion

The fluctuating online popularity of PE searches reflects the real-time population demands. It may help medical professionals better understand population interest, population concerns, regional variations, and gender differences on a nationwide scale and make disease-specific health care policies. The internet search data could be more reliable when the insufficient and lagging registry data are completed.

Abstract

Background: COVID-19 is still rampant all over the world. Until now, the COVID-19 vaccine is the most promising measure to subdue contagion and achieve herd immunity. However, public vaccination intention is suboptimal. A clear division lies between medical professionals and laypeople. While most professionals eagerly promote the vaccination campaign, some laypeople exude suspicion, hesitancy, and even opposition toward COVID-19 vaccines.

Objective: This study aims to employ a text mining approach to examine expression differences and thematic disparities between the professionals and laypeople within the COVID-19 vaccine context.

Methods: We collected 3196 answers under 65 filtered questions concerning the COVID-19 vaccine from the China-based question and answer forum Zhihu. The questions were classified into 5 categories depending on their contents and description: adverse reactions, vaccination, vaccine effectiveness, social implications of vaccine, and vaccine development. Respondents were also manually coded into two groups: professional and laypeople. Automated text analysis was performed to calculate fundamental expression characteristics of the 2 groups, including answer length, attitude distribution, and high-frequency words. Furthermore, structural topic modeling (STM), as a cutting-edge branch in the topic modeling family, was used to extract topics under each question category, and thematic disparities were evaluated between the 2 groups.

Results: Laypeople are more prevailing in the COVID-19 vaccine-related discussion. Regarding differences in expression characteristics, the professionals posted longer answers and showed a conservative stance toward vaccine effectiveness than did laypeople. Laypeople mentioned countries more frequently, while professionals were inclined to raise medical jargon. STM discloses prominent topics under each question category. Statistical analysis revealed that laypeople preferred the “safety of Chinese-made vaccine” topic and other vaccine-related issues in other countries. However, the professionals paid more attention to medical principles and professional standards underlying the COVID-19 vaccine. With respect to topics associated with the social implications of vaccines, the 2 groups showed no significant difference.

Conclusions: Our findings indicate that laypeople and professionals share some common grounds but also hold divergent focuses toward the COVID-19 vaccine issue. These incongruities can be summarized as “qualitatively different” in perspective rather than “quantitatively different” in scientific knowledge. Among those questions closely associated with medical expertise, the “qualitatively different” characteristic is quite conspicuous. This study boosts the current understanding of how the public perceives the COVID-19 vaccine, in a more nuanced way. Web-based question and answer forums are a bonanza for examining perception discrepancies among various identities. STM further exhibits unique strengths over the traditional topic modeling method in statistically testing the topic preference of diverse groups. Public health practitioners should be keenly aware of the cognitive differences between professionals and laypeople, and pay special attention to the topics with significant inconsistency across groups to build consensus and promote vaccination effectively.

KEYWORDS

COVID-19; vaccine; Zhihu; structural topic modeling; medical professional; laypeople; adverse reactions; vaccination; vaccine effectiveness; vaccine development

Introduction

Background

As of April 23, 2021, over 0.14 billion confirmed cases of COVID-19 and nearly 3.1 million deaths have been reported worldwide [1]. The COVID-19 vaccine has been acknowledged as one of the most effective strategies to contain the ongoing public health predicament [2]. However, what needs to be recognized is that the COVID-19 vaccine still requires cautious validation of efficacy and adverse reactions since it is a relatively innovative therapeutic intervention in development [3,4]. Owing to the intrinsic uncertainty, vaccine hesitancy and vaccine-related misinformation pervaded during the COVID-19 vaccination process [5]. Some nationwide and transnational surveys also revealed that the public's COVID-19 vaccination intentions were suboptimal [6-8]. While numerous medical professionals have devoted themselves to vaccine development at a breakneck speed [9] and eagerly promote the massive vaccination campaign, a considerable number of laypeople expressed concerns, hesitancy, and even antagonism toward COVID-19 vaccines [5]. For instance, a recent web-based poll conducted on Twitter disclosed that more than half of the respondents doubted the safety of COVID-19 vaccines [10]. To obtain a deeper insight into the different perceptions between the professionals and laypeople toward the COVID-19 vaccine, the present study endeavors to seek the potential differentiated expressions by adopting a text mining approach on a Chinese social media platform.

The Internet as a Pivotal Communication Space for Health-Related Issues

Web-based communication provides easy and cost-effective access to a broad audience and enables interactivity and collaborative content-sharing [11]. During the past decades, the world witnessed a drastic increase in health information on the internet, along with a pronounced tendency that both patients and caregivers are growing more likely to seek health information on the internet [12]. In the meantime, people are prone to discuss health-related issues in this virtual sphere, especially during a public health crisis [13]. For example, during the COVID-19 era, some people disclosed their disease status on the internet for help-seeking [14], and a more substantial number of people talked about their own and others' symptoms as a mere natural reaction to the threat of illness [15]. Given those features, various internet platforms serve as fertile grounds for examining the public's perceptions of health issues or events [16]. This holds true for the vaccine issue because vaccines and vaccination are buzz topics on the internet and are encompassed by provaccine and antivaccine discourses [17,18].

Recognizing the salient characteristics of the internet, health professionals spare extensive attention to utilizing the internet to launch health campaigns, deliver health knowledge, and

promote behavioral change [11]. Previous studies have summarized relevant experiences in delivering health care and health interventions with the strength of internet technologies. One representative example is that some scholars classified social media into 10 categories and put forward 4 guidelines for medical professionals to better engage in web-based health communication [19]. In reality, a series of public health institutions have implemented web-based communication strategies. The Centers for Disease Control and Prevention in the United States adopted Twitter to disseminate information, interact with the audience, and alert the public throughout the Zika epidemic [20]. In a similar vein, public health agencies in Singapore also made use of Facebook for outbreak communication and communicating the Zika epidemic strategically [21]. To cope with the COVID-19 threat, many public health agencies use social media accounts to rapidly disseminate risk messages to the public to curb contagion [22]. Except for health institutions, many medical professionals practice web-based health communication spontaneously; for instance, some doctors have joined eHealth communities to exchange medical information with patients or peers [23].

Taken together, searching and exchanging health information on the internet are common phenomena nowadays; both professionals and laypeople are critical actors in the web-based health communication environment. Since the internet has prominent advantages, including low cost, easy access, broad reach, and interactivity, it facilitates the lay public to share their health concerns, seek support, enhance their health-related knowledge, and communicate with one another. Meanwhile, professionals can develop health education and interventions on the internet. For public health researchers, diversified internet platforms can be exploited to investigate varying perceptions and expressions toward various kinds of health-related issues, especially emergent ones.

Professionals vs Laypeople in Perceiving Health-Related Issues

An entrenched thought toward the divergence between professionals and laypeople emphasizes the knowledge chasm, which retains an inherent assumption that the laypeople lag behind professionals in their knowledge levels. A professional is always defined as someone who procured special knowledge or skills of a particular subject through deliberate training and practice, while laypeople usually lack formal training or practical experience [24]. Furthermore, an extended viewpoint believes that professionals' judgments and perceptions are more objective and reliable than those of laypeople [24]. In health communication, we particularly underscore 2 additional significant dimensions stemming from the knowledge level disparity when discussing differences between professionals and laypeople: risk perception and attitude.

As a vaccine shrouded in uncertainty, societies worldwide are deluged with suspicions and debates about the COVID-19 vaccine's safety [25]. All concerns are closely connected to risk perception, which denotes people's subjective assessment of a risk's characteristics and severity [26]. Risk perception is a compound of scientific judgment and subjective factors [27]. When it comes to differences in risk perception between professionals and laypeople, one school of thought holds that owing to the differences in knowledge reservation and established mindsets, professionals usually treat risks and uncertainties from an analytical, objective, and rational perspective. Laypeople, however, are favored to rely on hypothetical, subjective, and emotional cues when perceiving risks [28-30]. Moreover, laypeople are accustomed to amplifying risks and more susceptible to psychological factors, while professionals may underestimate the dangers and accentuate the benefits of certain controversial technologies [30,31]. Another school of thought refutes those assertions by demonstrating that professionals and laypeople are unanimously influenced by emotions, worldviews, and values when forming opinions about controversial issues [27,32]. For some medical topics, the scientific literacy advantage of professionals is not more prominent than that of laypeople [33,34].

Another dimension is attitude. According to the knowledge deficit model, the lay public's skepticism toward innovative technologies can be attributed to their deficiency in scientific knowledge [35,36]. Besides, this model hypothesizes that the laypeople's and professionals' divergent opinions on the same issue can be ascribed to the public's insufficient issue-specific knowledge [37]. Therefore, a more supportive attitude toward emerging technologies could be realized by enhancing the public's scientific knowledge level or the so-called scientific literacy [35,38,39]. Although this model has been criticized by a series of empirical studies [40], it still influences health communication and science communication research. Recently, a study on emergency medicine influencers' Twitter use during the COVID-19 pandemic disclosed that medicine influencers' messages contain words with more positive and neutral emotion than those of the general public. The influencer group also has a manifest topic preference for clinical information and COVID-19 news [41].

Using Social Media to Explore Expression Differences

As one of the most burgeoning branches of internet technologies, social media has been invested with plentiful unobtrusive and naturalistic data [42,43], which makes it suitable for examining heterogeneous discussions and perceptions toward specific health-related topics or events [16]. For instance, some pundits employed tweets to gain insights and knowledge of how people discuss the human papillomavirus vaccines [44]. Similarly, Twitter contents have also been applied to excavate public sentiments and opinions toward COVID-19 vaccines [45]. Similar studies have bolstered the notion that social media can offer valuable illumination to infoveillance, promoting vaccine uptake, and altering vaccine hesitancy. Nevertheless, it should be noted that this series of studies have often been conducted in Western contexts. As a country with an increasingly expanded proportion in social media usage, China has not gained enough scholarly attention.

Based on the aforementioned discussion, this research aims to explore expression differences between professionals and laypeople toward the COVID-19 vaccine on social media. This research topic is essential because it affords a basis for understanding perception disparities between professionals and nonprofessionals, which in turn provides insights into devising effective communication strategies between the 2 groups to promote COVID-19 vaccination compliance and coverage. Additionally, there are limited studies systematically examining expressions between laypeople and professionals [46,47]. Whether the abovementioned risk perception divergence and attitudinal difference reflect in expressions is still unknown. Our research endeavors to replenish the present lacuna by offering empirical evidence on how the 2 groups conceive medical technologies in a public health crisis.

Given China's low visibility in the previous research scope, we focused on China. China was one of the first countries severely affected by COVID-19. After implementing a series of strict prevention and control measures, the Chinese government tamed the virus in a comparatively short period; the so-called "China's model to combat the COVID-19" set an example for other countries to combat this global health crisis [14]. Furthermore, China has taken great strides in developing COVID-19 vaccines. For instance, the 2 Chinese pharmaceutical pioneers Sinovac and Sinopharm have undertaken tremendous vaccine production tasks and promoted their products domestically and overseas [48]. As one of the first-tier countries launching vaccines against COVID-19, the COVID-19 vaccine entered the Chinese public discussion sphere early, endowing us a unique opportunity to unravel the possible asymmetric perceptions between medical professionals and the public toward the same issue. In summary, we formulated two research questions: (1) is there any difference in expression between professionals and laypeople when discussing the COVID-19 vaccine in China? (2) What major themes about the COVID-19 vaccine emerged in the 2 groups' expressions in the Chinese context? Do thematic disparities exist? The first question leans to the explicit layer and focuses on the primary text features. The second question leans to the implicit layer and targets the latent thematic structures. We believe that this study could develop an in-depth understanding of the differences between professionals and laypeople by synthesizing the 2 aspects.

Methods

Data Source

We selected a web-based question and answer (Q&A) forum to collect the research data. Zhihu [49], a Chinese equivalent of Quora, is the most popular social Q&A website in China [46]. According to Liang et al [46], Zhihu is an ideal platform to investigate differences between professionals and laypeople for 3 reasons. First, Zhihu amasses a substantial amount of user-generated content about controversial social issues. For example, as of May 12, 2021, the "COVID-19 vaccine" topic on Zhihu has garnered 762 questions. Second, Zhihu has a unique structure that facilitates interactive communication. Users can follow each other, invite others to answer questions, and reply to each other in the comments section. Third,

professionals are highly visible and active on Zhihu. A significant proportion of experts could be easily distinguished by their self-reported personal details (eg, affiliation and working sector) or visual symbols bestowed by the platform (eg, a blue badge after the username) [46]. Those who specialize in particular fields and engage in sharing opinions are more likely to become influencers on Zhihu [50]. These characteristics enable us to discern professionals from laypeople cost-effectively and discover the expression incongruities between the 2 user groups on Zhihu.

To obtain as much comprehensive data as possible, one of the authors designed a Python script to crawl all questions (including extended question descriptions) and their corresponding number of answers under the “COVID-19 vaccine” topic, which is the most relevant and active topic about the COVID-19 vaccines on Zhihu. Since some questions received very few responses, we excluded those questions with less than 10 answers. Next, we adopted another self-written Python script to collect each answer’s concrete content along with each respondent’s public profile. The content serves as the core corpus of the current study, whereas the public profiles are used to determine the identity category of the respondent. Finally, 65 questions were retained for the ensuing analysis with 3196 answers under them. [Multimedia Appendix 1](#) provides details regarding the reserved questions. Data collection was finished on March 23, 2021.

Coding Scheme

Manual coding was applied to differentiate the 2 types of identities and classify the 65 retained questions. According to the Merriam-Webster Dictionary, a professional can be defined as someone who conforms to the technical or ethical standards of a profession [51]. Because of the inherent medical attributes of COVID-19 vaccines, we further narrowed the meaning scope of *professional* by restricting it to medical professionals. Two criteria were set to distinguish the professional identity: (1) users licensed or certified to provide health care services to natural persons (eg, physicians and pharmacists) [52] and (2) users who major or conduct research in medicine or related fields (eg, Chinese pharmacy or life sciences) [46]. Laypeople are also evaluated on the basis of two criteria: (1) users who

explicitly disclose their identities, other than medical professionals and (2) users who do not divulge their identities explicitly. Identification cues are extracted from pertinent information units in the user’s public profile, including self-reported educational experience, working sectors, career history, and authentication information.

With regard to the reserved 65 questions, it is untenable to perform between-group comparisons 65 times. In other words, it is not sensible to compare professionals’ and laypeople’s expressions under each question because it would be difficult to draw a representative and systematic conclusion through repeated small-scale analysis. Therefore, we classified those questions to find out some common underlying characteristics among them. In line with previous experience [53], we carried out semiopen coding to clarify question categories. All authors discussed the classification framework back and forth on the basis of personal understanding after reviewing all questions and their descriptions. Later, we performed a pilot manual coding to confirm the rationality and applicability of the preliminary categories. The final classification comprises 5 categories ([Table 1](#)), which suit all questions well. The mapping relationships between individual questions and categories can also be found in [Multimedia Appendix 1](#). More specifically, the 5 categories in [Table 1](#) resonate with preceding studies. Firstly, people’s COVID-19 vaccination intention primarily hinges on the safety and side effects of the relevant vaccines [54]. COVID-19 vaccines’ efficacy and safety profile are vital for its successful deployment and the achievement of herd immunity [6,9]. Thus, “adverse reactions” and “vaccine effectiveness” are 2 indispensable categories when discussing the COVID-19 vaccine. Secondly, one study about discerning topics regarding vaccines on the internet proposed that disease outbreaks, vaccine development, vaccine studies, and vaccination guidelines emerged in web-based articles on vaccines [55]. Besides, many scholars accentuated vaccines’ nonnegligible role in preventing communicable diseases and indicate the severity and hidden threats resulting from vaccine hesitancy from a societal perspective [2,56,57]. Our remaining 3 question categories ([Table 1](#)) have significant overlap with those findings.

Table 1. Question categories and their meanings.

Category	Meaning
Adverse reactions	Asking about any unintended or dangerous human reactions to COVID-19 vaccines
Vaccination	Asking about COVID-19 vaccination programs, arrangements, intentions, and status quo
Vaccine effectiveness	Asking about the physiological reactions in individuals, such as the effectiveness and success signs of a specific type of COVID-19 vaccine or efficacy comparison between candidate vaccines
Social implications of the vaccine	Asking about the social consequences of the emergence and uptake of the COVID-19 vaccine, such as whether COVID-19 vaccines can achieve herd immunity
Vaccine development	Asking about details regarding the COVID-19 vaccine development process, such as performance indicators in the 3 trial phases

Analytical Strategies

We selected traditional content analysis and automated text analysis as our research methods to address the 2 proposed research questions. Conventional content analysis aimed to

distinguish the identity of each respondent through manual coding. Three authors coded 50 randomly sampled respondents in accordance with the aforementioned designated criteria in the pilot coding stage. Intercooder reliability reached an ideal state (Krippendorff $\alpha=0.93$). The 3 authors then coded the

remaining respondents independently. Similarly, 3 authors coded 20 randomly selected questions to test intercoder reliability for the question category. The reliability coefficient also meets the statistical standard (Krippendorff $\alpha=.91$).

Owing to the large volume of answers, we leveraged automated text analysis to analyze the corpus efficiently. Automated text analysis is a broad terminology for a series of natural language processing methods, including but not limited to frequency analysis, co-occurrence analysis, and topic modeling [58]. This automated approach benefits text miners in alleviating the labor-intensive task of coding texts manually. More specifically, we calculated the fundamental expression characteristics of the 2 user groups, including the answer length, distribution of attitudes, and high-frequency words [46,59]. Attitudinal analysis was completed using the up-to-date TextMind software developed by the Chinese Academy of Science, which can be regarded as the Chinese version of LIWC (Linguistic Inquiry and Word Count) [60]. TextMind is capable of inferring emotional states, intentions, and thinking styles from text through a dictionary-based approach with high reliability and validity [61].

For thematic analysis, we utilized topic modeling to probe into the thematic differences between the 2 identities. Topic modeling can investigate the hidden thematic structure of a given collection of texts [62]. As one of the cutting-edge branches in the topic modeling family, structural topic modeling (STM) allows researchers to estimate a topic model by considering document-level metadata. In other words, STM enables researchers to discover relationships between topics and metadata, such as the topic preference of distinct authors

or topic fluctuation across time [63]. STM assimilates document metadata (eg, authorship and time of publication) as covariates during the generative process; it has previously been used to explore the distinct selective sharing mechanisms of different media outlets [64] and how party identification affects topic prevalence [65]. Before formal modeling, the authors conducted preprocessing to clean the corpus, including discarding punctuation, filtering out stop-words, and pruning highly frequent words. The preprocessing procedure adheres to that of a widely recognized topic modeling study [62]. STM was implemented using the stm package in R [63], while other automated text analyses were accomplished in the Python programming environment.

Results

The first research question asks about the expression differences between professionals and laypeople. Given the 5 predefined question categories, we examine all answers under each question category and performed statistical analysis (Tables 2-5).

Compared to the answers of professionals, those of laypeople are more prevalent (Table 2). Besides, professionals are inclined to write longer answers than laypeople (Table 3). A subsequent series of 2-tailed independent-samples *t* tests confirmed this supposition by revealing that professionals' average answer length was significantly higher in word count than that of laypeople under each question category (adverse reactions: $t_{711}=-2.335$; $P=.02$; vaccination: $t_{958}=-2.401$; $P=.02$; vaccine effectiveness: $t_{415}=-2.240$; $P=.03$; social implications of vaccine: $t_{260}=-2.149$; $P=.04$; vaccine development: $t_{842}=-4.546$; $P<.001$).

Table 2. The number of answers posted by professionals and laypeople under 5 question categories regarding COVID-19 vaccines (N=3196).

Question category	Answers, n (%)
Adverse reactions	
Professional	68 (9.54)
Laypeople	645 (90.46)
Vaccination	
Professional	104 (10.83)
Laypeople	856 (89.17)
Vaccine effectiveness	
Professional	76 (18.23)
Laypeople	341 (81.77)
Social implications of the vaccine	
Professional	25 (9.54)
Laypeople	237 (90.46)
Vaccine development	
Professional	129 (15.28)
Laypeople	715 (84.72)

Table 3. Answer length of professionals and laypeople under 5 question categories regarding COVID-19 vaccines (N=3196).

Question category	Answer word count, mean (SD)
Adverse reactions	
Professional	454.12 (674.09)
Laypeople	251.83 (806.92)
Vaccination	
Professional	510.67 (1191.63)
Laypeople	225.97 (482.32)
Vaccine effectiveness	
Professional	937.03 (2408.93)
Laypeople	310.80 (619.62)
Social implications of the vaccine	
Professional	765.52 (1310.93)
Laypeople	200.10 (331.42)
Vaccine development	
Professional	815.60 (1345.11)
Laypeople	266.18 (609.15)

Table 4. Attitude distribution of professionals and laypeople 5 five question categories regarding COVID-19 vaccines (N=3196).

Question category	Answers with a positive attitude, n (%)	Answers with a neutral attitude, n (%)	Answers with a negative attitude, n (%)
Adverse reactions			
Professional	21 (30.88)	28 (41.18)	19 (27.94)
Laypeople	209 (32.40)	220 (34.11)	216 (33.49)
Vaccination			
Professional	46 (44.23)	28 (26.92)	30 (28.85)
Laypeople	339 (39.60)	276 (32.24)	241 (28.15)
Vaccine effectiveness			
Professional	38 (50.00)	13 (17.11)	25 (32.89)
Laypeople	170 (49.85)	97 (28.45)	74 (21.70)
Social implications of the vaccine			
Professional	10 (40.00)	6 (24.00)	9 (36.00)
Laypeople	96 (40.51)	67 (28.27)	74 (31.22)
Vaccine development			
Professional	53 (41.09)	49 (37.98)	27 (20.93)
Laypeople	336 (46.99)	219 (30.63)	160 (22.38)

Table 5. High-frequency words of professionals and laypeople under 5 question categories regarding COVID-19 vaccines.

Question category	High-frequency words ^a
Adverse reactions	
Professional	RNA, Pfizer, adverse reactions, death, America, side effects, clinical trial, inject, inactivated vaccine, data
Laypeople	America, China, Pfizer, coronavirus, RNA, death, Japan, inject, adverse reactions, country
Vaccination	
Professional	coronavirus, crowd, immune, infect, clinical trial, antibody, country, adverse reactions, disease, emergency
Laypeople	coronavirus, Russia, America, country, China, crowd, inject, clinical trial, infect, research and development
Vaccine effectiveness	
Professional	RNA, coronavirus, data, protein, effective rate, infect, cell, immune, inactivated vaccine, technology
Laypeople	RNA, China, coronavirus, data, inactivated vaccine, America, India, technology, produce, protein
Social implications of the vaccine	
Professional	coronavirus, data, clinical trial, Sinovac, infect, come into the market, China, symptom, effective rate, country
Laypeople	country, coronavirus, price, China, research and development, control, domestic, America, free of charge, crowd
Vaccine development	
Professional	clinical trial, coronavirus, RNA, experiment, research, research and development, China, infect, clinic, data
Laypeople	America, China, RNA, coronavirus, research and development, country, pregnant woman, experiment, infect, company

^aThe 10 most frequent words are listed, and words are translated from Chinese to English. Some Chinese words correspond to more than 1 English word.

Furthermore, statistical analysis revealed that a positive attitude dominated the discussion regarding COVID-19 vaccines (Table 4). A series of chi-square tests were conducted to examine the correlation between attitude and identity. The results revealed nonsignificant relationships under 4 question categories, which suggests that professionals do not differ significantly from laypeople with respect to their attitude distribution when discussing adverse reactions ($\chi^2_2=1.5$; $P=.47$), vaccination ($\chi^2_2=1.3$; $P=.51$), social implications of the vaccine ($\chi^2_2=0.3$; $P=.86$), and vaccine development ($\chi^2_2=2.8$; $P=.25$). However, for vaccine effectiveness, the correlation reached significance ($\chi^2_2=6.3$; $P=.04$). Post hoc analysis based on the adjusted residual (AD) score revealed that laypeople were less likely to express a negative attitude (AD=-2.100), while professionals favor a negative attitude (AD=2.100) under this category.

With respect to the high-frequency words among the 2 user groups, it is evident that laypeople mentioned countries more frequently (eg, *America, China, Japan, Russia, and India*) than professionals. Professionals talked more about medical jargon (eg, *clinical trial, immune, antibody, cell, and effective rate*) than laypeople (Table 5). However, a comparison of high-frequency words barely reveals a general word use preference pattern; the latent semantic structures still require a more in-depth inspection. Thus, we performed subsequent STM to deepen our understanding of the 2 groups' topic preferences.

The second research question makes an inquiry about the latent themes that belong to the 2 kinds of identities under the 5 categories and accompanying possible thematic differences.

For an accurate and robust estimation, we took advantage of the data-driven approach to select the number of topics, which is a built-in function in the stm package [63]. Based on the semantic coherence and residual fluctuation from multiple rounds of automated tests, we determined the topic number of each question category. The detailed indicators are exhibited in Multimedia Appendix 2.

According to a prior study using STM [13], the topic estimation process sticks to some assumptions. First, each document can be regarded as a mixture of latent topics, where each topic is a probability distribution of words. Second, a document is statistically generated by an iterative inference process. A topic is randomly sampled in each process, and a certain word associated with the topic is randomly drawn. The most probable topics and pertinent distributions are estimated on the basis of the given data. Although the probability distribution of words has no intuitive meaning, researchers can interpret the topic's meaning from the relative importance (or the so-called "weight") of words. In the current study, after executing the STM, topics were represented as collections of words. The authors labeled each topic and summarized the topic's meaning by considering the highest-probability words and exclusive words simultaneously [63]. In STM, words with the highest probabilities and the highest frequency and exclusivity (FREX) weights are provided. A high probability implies that corresponding words are highly likely to appear under the given topic [63], while a high FREX score replenishes the high probability indicator by considering word exclusivity and frequency simultaneously [13]. Topics extracted from answers under each question category were depicted (Figure 1). Detailed

topic meanings are shown in [Multimedia Appendix 3](#). Next, we estimated the relationship between user identity and topic prevalence. The stm package illustrates those relationships with forest plots, reflecting the difference in topical prevalence between professionals and laypeople in a more expressive way.

Figures 2-6 delineate the thematic disparities between the 2 user groups under each question category. The horizontal lines represent CIs. If the CIs for each topic overlap with the dotted vertical line (indicates null effect), this implies that at the 95% CI level, professionals and laypeople do not differ from each other in adopting the topic. For the 3 topics under *adverse reactions* (Figure 2), the “safety of Chinese-made vaccine” topic is more likely to be used by laypeople ($\beta=-.032$; $P=.04$). For the 4 topics under vaccination (Figure 3), the two topics “vaccination arrangement for priority groups” ($\beta=.044$; $P<.001$) and “urgent approval and prioritization of vaccines” ($\beta=.052$;

$P<.001$) were primarily associated with professionals. In contrast, the other 2 topics “vaccines in Russia” ($\beta=-.037$; $P<.001$) and “the effectiveness of vaccination in Russia and the U.S.” ($\beta=-.059$; $P<.001$) were more frequently adopted by laypeople. Among the 3 topics under *vaccine effectiveness* (Figure 4), 2 varied significantly across the 2 user groups. “indicators for evaluating vaccine effectiveness” topic ($\beta=-.044$; $P=.003$) was more likely to be mentioned by laypeople, while “medical principles of vaccine effectiveness” ($\beta=.026$; $P=.03$) was more inclined to be mentioned by professionals. Regarding the 4 topics under *social implications of the vaccine* (Figure 5), none of them reached significantly difference levels. Regarding the last category (Figure 6), “principles of vaccine trials” ($\beta=.139$; $P<.001$) was more inclined to be mentioned by professionals. Conversely, “vaccine development process worldwide” ($\beta=-.132$; $P<.001$) was more inclined to be mentioned by laypeople.

Figure 1. Question categories and their related topics under the COVID-19 vaccine issue on Zhihu.

Discussion

Principal Findings

This study aimed to disentangle the expression differences between professionals and laypeople in the context of a somewhat contentious issue. To the best of our knowledge, this is one of the few studies adopting STM to analyze thematic disparities between these 2 user groups, which goes beyond previous studies that mainly relied on the hand-annotated method [46]. Moreover, there is a shortage of studies focusing on the professional-laypeople divide during the COVID-19 pandemic. Our study contributes to comprehending the expression characteristics of the 2 identities and provides us an empirical foundation for facilitating professional-laypeople communication in a web-based Q&A environment, further helps advocate authoritative voices, and corrects misinformation in a time inundated with uncertainties and risks [66].

Per our primary findings, the first arresting finding is the active participation of laypeople in the COVID-19 vaccine issue. This phenomenon, to some extent, gives credence to the previous viewpoint on the communication-facilitating effect of social media. Brossard [67] contended that the new media technologies afford the lay audience more opportunities to participate in and discuss scientific issues in a relatively straightforward way. Similarly, Peters [68] bolsters this assertion by reporting that circumstances for web-based communication substantially challenge the once quasi-monopoly status of intermediary information disseminators (eg, professional journalists and scientists) [68]. Therefore, although laypeople do not possess equivalent professional knowledge as professionals, the former are still guaranteed sufficient opportunities to discuss professional issues with professionals. In other words, the social media platforms characterize equality, openness, and plurality, which lowers the knowledge threshold and entry barrier when discussing medical issues. However, whether this frequent occurrence of laypeople equates to effective communication or fruitful dialogue between these 2 groups needs further investigation.

Aside from the extensive participation of laypeople, our study revealed additional expression differences between the 2 user groups. First, the average answer length of professionals was longer than that of laypeople. Backed with professional knowledge and practical experience, professionals are likely to elaborate their viewpoints by incorporating various evidence. This is especially true for the COVID-19 vaccine topic because COVID-19 is a typical “sudden and unexpected event” [69] with medical puzzles, and the COVID-19 vaccine still calls for rigorous clinical trials and continuous surveillance [4]. According to Zou et al [70], statistical evidence and narrative evidence are 2 major types of evidence adopted to elucidate health-related topics. Professionals are more familiar with quantitative and numerical evidence owing to their professional background and working experience. They can also invoke narrative evidence derived from daily experiences to support their views. However, laypeople lack quantitative arguments and have to depend on narratives to expound their viewpoints. Furthermore, professionals may have a more cautious and

conservative mindset because of the intrinsic features in their vocational training and educational background. One representative example is professionals are not as optimistic as laypeople when talking about vaccine effectiveness on the premise that COVID-19 vaccine development is an ongoing process that requires more reliable evidence, such as the undetermined age-specific adverse effects [71].

Our results also show that professionals and laypeople analyzed the COVID-19 vaccine issue from varying perspectives. Echoing the literature review, 1 long-standing speculation in the public health field and science communication fields is that laypeople’s risk perceptions are always insufficient with regard to scientific assessments [72]. The scientific knowledge deficiency among the lay public hampers their ability to understand specific scientific issues and establish a positive attitude toward them [38,39,73]. Considering risk perception and attitude together, we prefer to believe that laypeople’s knowledge is not quantitatively lesser than or qualitatively inferior to that of professionals. Instead, the 2 user groups share some similarities but hold different thinking angles simultaneously, which is more appropriate to be marked as “qualitatively different.” First, the 2 user groups unanimously paid attention to adverse reaction symptoms worldwide, the vaccine’s effectiveness against the mutant virus, the contribution of vaccination for global disease prevention, and some other topics, which implies overlaps in their perspectives. However, considering issues related to medical expertise, such as the vaccination question category in our study, professionals accentuate arrangement and urgent approval, which are inextricably linked to public policies, and the reasonable allocation of medical resources. Laypeople prefer to care about other countries, presumably driven by the overwhelming media coverage on epidemic situations in other countries. This comparison suggests that the disparities rest in the division between professional and experiential modes of thinking, which act as 2 thinking modes toward controversial issues. The stark contrast also manifests in high-frequency word comparison and other medical-related question categories, including vaccine development and effectiveness. Second, we did not observe clear distinctions between the 2 user groups with regard to attitude under 4 question categories, which further illustrates that the attitudinal difference assumption based on knowledge level disparities is untenable in the Chinese COVID-19 vaccine context. Despite some objective gaps in knowledge acquisition between professionals and laypeople, they were both willing to treat the COVID-19 vaccines positively. Third, the “adverse reactions” category is most closely related to risk. In fact, we did not see laypeople lay excessive stress on the abnormal symptoms. This finding debunks the risk perception disparities that originated from the knowledge deficiency supposition, which implies that laypeople are not always amplifying the risks. They favor countries’ specific situations and think from living experience rather than magnifying vaccine risks or expressing suspicion regarding COVID-19 vaccines.

Regarding the social implications of the vaccines, as a category not closely linked to medical knowledge, the 2 user groups showed no significant differences. This finding indicates that the professional and experimental thinking modes lost their

explanatory power when encountering the abstract issue. The social implications of COVID-19 vaccines can be broad and intricate, related to a wide range of societal dimensions. Hence, it is difficult for professionals or laypeople to lay particular emphasis on merely 1 mode. Combining the topics' similarities and incongruities between the 2 user groups, we conclude that apart from the overlaps, the "qualitatively different" characteristic is also common on the web-based Q&A forum, which reflects different perspectives derived from knowledge background and life experience. In the context of COVID-19 vaccines, the medical-related questions are more sensitive to the influence of the "qualitatively different" feature, while more broad and abstract questions seem impervious to this feature.

Limitations

Our analysis bears several caveats. With respect to the question categories, the COVID-19 vaccine is a multifaceted, intricate, and context-dependent issue associated with copious aspects [5]. Some question categories, such as vaccines and international relations, are omitted in this study and hence need to be further explored in future studies. Besides, the inclusion of longitudinal perspectives in this text mining study would yield more intriguing findings. For instance, with the development of the COVID-19 pandemic, will the thematic differences between these 2 user groups become wider or narrower? A dynamic and longitudinal approach would undoubtedly advance our comprehension of the ongoing COVID-19 vaccine issue and help curb this public health emergency. Furthermore, 1 aspect that cannot be dismissed is that the answers, of both professionals and laypeople, were largely hinged on the characteristics of the questions. Thus, the topic distribution may be confined within the questions' scopes. Future studies could focus on other social media platforms (eg, Twitter and Sina Weibo) to obtain a more holistic discursive landscape, which may be more topic-rich owing to the absence of designated questions.

Conclusions

This study provides an overview of opinion patterns and scrutinizes the expression differences between professionals and laypeople toward the COVID-19 vaccine. In terms of quantity, laypeople are the dominant discussants in the web-based Q&A forum Zhihu. Regarding expression differences, the professionals preferred writing longer answers than laypeople; they also showed a conservative stance in vaccine effectiveness and tended to mention medical

terminologies in their discussions. By exerting the power of STM, as a valuable tool under unsupervised machine learning, we outlined the topics under each question category, along with the topic preference of the 2 groups. In a nutshell, professionals paid more attention to the medical principles and professional standards nested in discourses on COVID-19 vaccines. In contrast, laypeople showed solicitude explicitly for vaccine-related issues at the national and global levels, and to the safety of the Chinese-made vaccine. The 2 user groups shared some common grounds and manifested distinct concerns within the COVID-19 vaccine context.

We believe that this study has some implications and merits. First, public health scholars should be keenly aware of expressions and discussions on web-based Q&A forums, which were comparatively overlooked in prior infoveillance or infodemiology studies [74]. Q&A forums such as Zhihu or Quora make a clear distinction between professionals and laypeople, thus providing researchers with opportunities to explore the professional-laypeople incongruities in discursive styles and core topics. These dimensions may further facilitate addressing the underlying "distance" or "gap" between the 2 user groups [68]. Second, extant studies germane to COVID-19-related topic modeling widely to probe into public concerns and public awareness [75,76]. However, there is a paucity of studies on the thematic differences among various identities. Our attempts using STM provide a viable solution to discover the nuanced differences between distinct identities, unfolding some particular advantages over traditional topic modeling. Third, for public health educators, effective professional-laypeople communication does not need to focus on all underlying topics. Considering the "qualitatively different" characteristic, practitioners should focus on discussing topics that are significantly inconsistent across different identities and strive to mitigate misunderstanding while generating consensus on those topics. For example, some scholars found that popular conspiracies on Chinese social media, which are related to the pandemic's origin, are about whether country actors intentionally developed SARS-CoV-2 in the laboratory or as bioweapons [77]. Since laypeople are highly concerned with COVID-19 vaccines in foreign countries, public health practitioners must closely scrutinize relevant discussions to guard against the emergence of vaccine-related rumors, conspiracies, or hate speech and strive to create an atmosphere for a rational discussion.

Acknowledgments

The authors wish to thank Dr Anfan Chen (postdoctoral researcher, The Chinese University of Hong Kong) for his constructive suggestions in the initial stage of the study.

Abstract

Background: Social inequities affecting minority populations after Hurricane Katrina led to an expansion of environmental justice literature. In August 2017, Hurricane Harvey rainfall was estimated as a 3000- to 20,000-year flood event, further affecting minority populations with disproportionate stroke prevalence. The Stomp Out Stroke initiative leveraged multimedia engagement, creating a patient-centered cerebrovascular health intervention.

Objective: This study aims to address social inequities in cerebrovascular health through the identification of race- or ethnicity-specific health needs and the provision of in-person stroke prevention screening during two community events (May 2018 and May 2019).

Methods: Stomp Out Stroke recruitment took place through internet-based channels (websites and social networking). Exclusively through web registration, Stomp Out Stroke participants (aged >18 years) detailed sociodemographic characteristics, family history of stroke, and stroke survivorship. Participant health interests were compared by race or ethnicity using Kruskal-Wallis or chi-square test at an $\alpha=.05$. A Bonferroni-corrected P value of .0083 was used for multiple comparisons.

Results: Stomp Out Stroke registrants ($N=1401$) were 70% (973/1390) female (median age 45 years) and largely self-identified as members of minority groups: 32.05% (449/1401) Hispanic, 25.62% (359/1401) African American, 13.63% (191/1401) Asian compared with 23.63% (331/1401) non-Hispanic White. Stroke survivors comprised 11.55% (155/1401) of our population. A total of 124 stroke caregivers participated. Approximately 36.81% (493/1339) of participants had a family history of stroke. African American participants were most likely to have Medicare or Medicaid insurance (84/341, 24.6%), whereas Hispanic participants were most likely to be uninsured (127/435, 29.2%). Hispanic participants were more likely than non-Hispanic White participants to obtain *health screenings* (282/449, 62.8% vs 175/331, 52.9%; $P=.03$). Asian (105/191, 54.9%) and African American (201/359, 55.9%) participants were more likely to request *stroke education* than non-Hispanic White (138/331, 41.6%) or Hispanic participants (193/449, 42.9%). African American participants were more likely to seek *overall health education* than non-Hispanic White participants (166/359, 46.2% vs 108/331, 32.6%; $P=.002$). Non-Hispanic White participants (48/331, 14.5%)

were less likely to speak to health care providers than African American (91/359, 25.3%) or Asian participants (54/191, 28.3%). During the 2018 and 2019 events, 2774 health screenings were completed across 12 hours, averaging four health screenings per minute. These included blood pressure (1031/2774, 37.16%), stroke risk assessment (496/2774, 17.88%), bone density (426/2774, 15.35%), carotid ultrasound (380/2774, 13.69%), BMI (182/2774, 6.56%), serum lipids (157/2774, 5.65%), and hemoglobin A_{1c} (102/2774, 3.67%). Twenty multimedia placements using the Stomp Out Stroke webpage, social media, #stompoutstroke, television, iQ radio, and web-based news reached approximately 849,731 people in the Houston area.

Conclusions: Using a combination of internet-based recruitment, registration, and in-person assessments, Stomp Out Stroke identified race- or ethnicity-specific health care needs and provided appropriate screenings to minority populations at increased risk of urban flooding and stroke. This protocol can be replicated in Southern US *Stroke Belt* cities with similar flood risks.

KEYWORDS

environmental justice; urban flooding; stroke; community engagement; education; health disparities

Introduction

Importance of the Problem

Social inequities affecting minority populations after Hurricane Katrina led to an expansion of the environmental justice literature after large-scale floods [1]. In 2017, Hurricane Harvey rainfall over a 4-day period was estimated as a 3000- and 20,000-year flooding event [2]. Studies after Hurricane Harvey in Houston detailed more extensive flooding among racial or ethnic minority households and those of lower socioeconomic status [3,4].

Houston is not only ranked among the most flood-impacted urban centers in the United States but also has some of the highest national stroke mortality rates, significantly affecting minority health [5]. In Harris County, Texas, which encompasses Houston, 4.7% of Medicare beneficiaries have been treated for stroke, placing Harris County in the worst quartile of all counties in the United States [6]. The combined effects of flood impact and cerebrovascular disease disparities are a growing concern for environmental justice. Correlated with the underdiagnosis and undertreatment of risk factors, minorities have a median age of first stroke 10-13 years earlier than non-Hispanic White people [5,7]. The age-adjusted incidence of first ischemic stroke is 179 per 100,000 in non-Hispanic White people, compared with 294 per 100,000 in African American people [8]. Direct medical costs for African American patients with stroke were estimated to reach 16 billion dollars in 2020; by 2030, stroke prevalence is expected to rise the most among Hispanic men, with direct costs of care increasing over 300%, compared with 140% in non-Hispanic White men, since 2012 [9].

Pros and Cons of Multimedia Stroke Prevention in Minority Populations

Minority populations are receptive to the use of mobile health (mHealth) technology for health interventions; however, racial differences in technology use and internet access persist [10]. In a recent study of stroke survivors and caregivers by Naqvi et al [11], the highest number of participants with reported internet access were non-Hispanic White people. Furthermore, studies on stroke risk factor management using mobile apps versus usual care in minority populations have yielded equivocal results [12].

Purpose

Studies have shown that ongoing public education on stroke symptoms improves stroke recognition [13,14]; unfortunately, racial disparities continue to exist regarding stroke literacy [15,16].

There are limited data regarding the practice of community engagement in stroke systems of care in flood-prone areas [17], including the method of delivery and educational activities. Furthermore, the utilization of a hybrid multimedia model—using technology to identify health care needs specific to minority populations, followed by in-person health screenings—has not been evaluated.

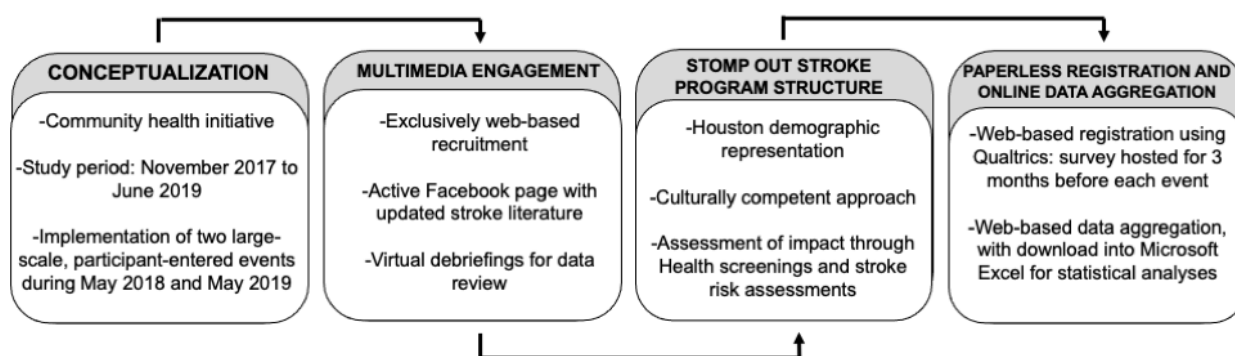

The purpose of this study was to implement Stomp Out Stroke, a hybrid multimedia education and health screening paradigm, serving a population disproportionately affected by Hurricane Harvey flooding. We hypothesize that the Stomp Out Stroke structure identifies and provides targeted health interventions, fulfilling specific needs, stratified by race and ethnicity. Multiple coastal cities in the Southern *Stroke Belt* (New Orleans, Louisiana; Charleston, South Carolina; and Savannah, Georgia) have similar demographics and flood risk, improving the generalizability of this population health intervention.

Methods

Conceptualization

Stomp Out Stroke is a prospective observational study and a collaborative public education initiative, which was implemented by the Vascular Neurology Program at the McGovern Medical School at the University of Texas Health Science Center at Houston (UTHealth) as part of the Joint Commission–Certified Integrated Stroke Healthcare System at Memorial Hermann Health System. Both institutions are located in the 2.1 square mile Texas Medical Center, topographically distributed within the 100-year and 500-year floodplains due to Brays Bayou, a slow-moving river that borders the health care district [18]. Stomp Out Stroke study period was from November 2017 to June 2019, including patient and public involvement, program structure, and implementation of two events: the first in May 2018 and the second in May 2019. Figure 1 details the Stomp Out Stroke flow process.

Figure 1. Stomp Out Stroke flow process.

Multimedia Engagement

Recruitment for participation in Stomp Out Stroke occurred exclusively via web-based platforms. Both the Texas Medical Center and the Texas Heart Institute provided location information, types of activities, and links to the registration website [19-21]. Stomp Out Stroke also has an active Facebook page, which is consistently updated with stroke awareness literature [22]. We used the social media hashtag #stompoutstroke on Twitter, Instagram, and Facebook. Members of the Vascular Neurology program also participated in television, iQ radio, and web-based news interviews to expand our reach.

Evidence-based protocols for primary stroke prevention were followed using the US Preventive Services Task Force Guide to Clinical Preventive Services [23] and the American Heart Association Guidelines for Heart-Health Screenings [24]. The Alzheimer's Foundation of America National Memory Screening program detailed the protocols for cognitive testing [25]. Virtual Stomp Out Stroke debriefings facilitated the review of data on attendee health screenings, volunteer or exhibitor evaluations, and opportunities for growth.

Stomp Out Stroke Program Structure

Houston Demographics

Houston is the fourth largest city in the United States, with a 2018 population estimate of 2.3 million people [26]. The Stomp Out Stroke program structure reflected Houston's racial or ethnic diversity and socioeconomic characteristics. The approximate racial or ethnic makeup of Houston is 45% Hispanic or Latino, 22.09% African American, 24.41% non-Hispanic White, and 6.72% Asian [27]. Overall, 30% of Houston residents were born outside of the United States. Twenty-five percent of people aged <65 years are uninsured and 20% live in poverty.

Content

Stomp Out Stroke was divided into five zones: central, stage and entertainment, healthy brain, stroke recovery, and children's. Each zone had health education and screening stations and was staffed by a volunteer coordinator and co-coordinator. Family-friendly activities and entertainment, including local multicultural dance groups, were included throughout the program (Multimedia Appendix 1).

Culturally Competent Approach

To address disparities in stroke literacy due to language barriers, bilingual health care providers and students were recruited as volunteers to assist in registration or check-in and to conduct health screenings or risk assessments in Spanish, simplified Chinese, and Vietnamese.

Assessment of Impact: Health Screenings or Stroke Risk Assessments

Assessment of impact was determined through the completion of onsite health screenings and stroke risk assessments. Each health screening consisted of vascular risk factor counseling, risk modification strategies, and recommended primary care provider follow-up. At the end of each screening, participants received printed educational materials and a give-away item (value <US \$5). Automated blood pressure monitors (HEM-7222-ITZ; Omron Healthcare, Inc) were used to obtain a single measure. Additional health screenings included bone density, carotid ultrasound, BMI, serum lipids, and hemoglobin A_{1c}. The 10-year stroke risk was calculated utilizing a modified Framingham stroke risk profile assessment tool, which contains age, sex, and baseline measurements of cerebrovascular risk factors, including systolic blood pressure, use of antihypertensive medications, current smoking status, presence of cardiovascular disease, current or prior atrial fibrillation, and diabetes mellitus (Multimedia Appendix 2) [28,29].

Paperless Registration and Web-Based Data Aggregation

Institutional review board approval was obtained at the McGovern Medical School at UTHealth to collect voluntary onsite and web-based registration data (HSC-MS-15-0813—UT Stroke Team Community Outreach Program). The UTHealth Institute for Stroke and Cerebrovascular Diseases has an archive of past Stomp Out Stroke events, detailing the evolution of the program before the study period [30]. During the 3 months before the event, the *Register Here* button on the front page linked participants to a web-based registration form using Qualtrics software, Version March 2020 [31]. No paper registration forms were used. Registration forms (aged >18 years) included sociodemographics, stroke survivorship, caregiver of a stroke survivor, or family history of stroke. Participants' interest in attending Stomp Out Stroke was assessed. On the event day, two check-in stations were available

for preregistrants, and two stations were available for onsite registration through Qualtrics. At the end of both the 2018 and 2019 events, Qualtrics surveys were closed, and participant responses were downloaded into Microsoft Excel spreadsheets for analyses.

Statistical Analysis

Sociodemographic characteristics were summarized using frequency and percentage or median and IQR for nonnormal distributions. Comparisons by racial group or ethnicity (Asian, Black or African American, Hispanic, or non-Hispanic White) were conducted using the Kruskal-Wallis (for age) or chi-square test. A P value of $<.05$ indicated a statistically significant difference between at least two of the four ethnic groups. A

Bonferroni-corrected P value of .0083 (.05 divided by 6) was used to control for multiple comparisons. If the pairwise comparison P value was $<.0083$, there was a statistically significant difference between multiple ethnic groups. All analyses were performed using SAS (version 9.4; SAS Institute Inc).

Results

Overview

Table 1 details the sociodemographic characteristics of Stomp Out Stroke registrants. Data from 1401 Stomp Out Stroke registrants in 2018 and 2019 were analyzed. Less than 5% of the data were missing, and imputation was not used.

Table 1. Summary of sociodemographic characteristics: 2018 and 2019 Stomp Out Stroke registrants (N=1401).

Variable	Value
Age in years (n=1381), median (IQR)	45.0 (36-57)
Sex (n=1390), n (%)	
Female	973 (70)
Male	417 (30)
Marital status (n=1383), n (%)	
Married	770 (55.68)
Not married	613 (44.32)
Race or ethnicity (n=1401), n (%)	
Hispanic	449 (32.05)
Black or African American	359 (25.62)
Non-Hispanic White	331 (23.63)
Asian	191 (13.63)
Other, two, or more races	49 (3.5)
American Indian, Alaska Native, Native American, or Pacific Islander	5 (0.36)
Unknown	17 (1.21)
Hispanic ethnicity (n=449), n (%)	
White	234 (52.12)
Black or African American	9 (2)
American Indian, Alaska Native, Native American, or Pacific Islander	8 (1.78)
Asian	3 (0.67)
Other, two, or more races	136 (30.3)
Unknown	59 (13.29)
Have children (n=1389), n (%)	
No	882 (63.5)
Yes	507 (36.5)
Health insurance (n=1342), n (%)	
Employer based	614 (45.75)
Medicare or Medicaid	251 (18.7)
Private insurance	205 (15.28)
Self-insured	44 (3.28)
Uninsured	228 (16.99)
Education (n=1331), n (%)	
More than high school	1053 (79.11)
High school or less	278 (20.89)
Are you a stroke survivor? (n=1342), n (%)	
No	1187 (88.45)
Yes	155 (11.55)
Are you a caregiver for a stroke survivor? (n=1339), n (%)	
No	1215 (90.74)
Yes	124 (9.26)
Do you have a family member who is a stroke survivor? (n=1339), n (%)	
No	846 (63.18)

Variable	Value
Yes	493 (36.81)

The median registrant age was 45 years; 69.54% (973/1390) were female and 55.68% (770/1383) were married. Overall, 32.05% (449/1401) of registrants self-identified as Hispanic, 25.62% (359/1401) self-identified as Black or African American, 23.63% (331/1401) self-identified as a non-Hispanic White person, and 13.63% (191/1401) self-identified as Asian.

A total of 63.5% (882/1389) of Stomp Out Stroke participants did not have children, 79.11% (1053/1331) had more than a high school education, and 45.75% (614/1342) had employer-based health insurance. Moreover, 155 Stomp Out Stroke participants were self-reported stroke survivors and 124 were caregivers. Nearly 36.81% (493/1339) of the registrants had a family history of stroke ([Table 1](#)).

[Table 2](#) compares the sociodemographic characteristics of Stomp Out Stroke participants by racial or ethnic group. Hispanic participants were significantly younger than African American or non-Hispanic White participants (aged 43 years vs 48 or 49 years). A larger proportion of African American women participants were noted in comparison with Asian or

non-Hispanic White people (274/358, 76.5% vs 124/188, 66% or 216/330, 65.5%).

Hispanic participants were the least likely among the four ethnic groups to have education past high school (274/432, 63.4% vs 269/322, 83.5% non-Hispanic White; 291/338, 86.1% African American; and 164/176, 93.2% Asian participants), and African American participants were the least likely to be married (128/357, 35.9% vs 200/329, 60.8% non-Hispanic White; 274/443, 61.9% Hispanic; and 123/189, 65.1% Asian participants; [Table 2](#)).

African American participants were the most likely to have Medicare or Medicaid insurance 24.6% (84/341), whereas Hispanic participants were the most likely to be uninsured 29.2% (127/435). In total, 19.9% (68/341) of African American registrants were stroke survivors; this group was the most likely to have a family history of stroke 46.5% (158/340) and more likely than non-Hispanic White or Hispanic people to have previously participated in Stomp Out Stroke ([Table 2](#)).

Table 2. Sociodemographic characteristics of Stomp Out Stroke participants by racial or ethnic group (N=1401).

^aExcept for the *P* value in the Age row, which is based on the Kruskal-Wallis test, all remaining *P* values are based on the chi-square test.

^{b-f}Indicate significant differences in pairwise comparisons of either median scores or proportions in different ethnic groups. The presence of the same letter in the columns for two race or ethnic groups (ie, “a” in the Asian and “a” in the African-American race columns) indicate a significant difference between the median scores or proportions between those two respective ethnic groups.

Table 3 compares interest in attending Stomp Out Stroke by racial or ethnic group. African American registrants were more likely to attend Stomp Out Stroke for family fun and entertainment than Asian registrants (173/359, 48.2% vs 66/191, 34.6%). Hispanic registrants were more likely than non-Hispanic White people to attend Stomp Out Stroke for free health screenings (282/449, 62.8% vs 175/331, 52.9%). Asian and African American registrants were more likely to attend Stomp Out Stroke for stroke education than non-Hispanic White or Hispanic people (105/191, 54.9% Asian or 201/359, 55.9% African American vs 138/331, 41.7% non-Hispanic White or 193/449, 42.9% Hispanic). African American participants were more likely to express interest in learning about health care topics other than stroke than non-Hispanic White people (166/359, 46.2% vs 108/331, 32.6%). Non-Hispanic White people were less likely than African American or Asian registrants to speak to a health care provider (48/331, 14.5% non-Hispanic White vs 91/359, 25.3% African American or 54/191, 28.3% Asian).

Table 3. Participant interest in attending Stomp Out Stroke by racial or ethnic group (n=1330).

Variable	Asian	Black or African American	Non-Hispanic White	Hispanic	<i>P</i> value ^a

^aExcept for the *P* value in the Age row, which is based on the Kruskal-Wallis test, all remaining *P* values are based on the chi-square test.

^{b-e}Indicate significant differences in pairwise comparisons of either median scores or proportions in different ethnic groups. The presence of the same letter in the columns for two race or ethnic groups (ie, “a” in the Asian and “a” in the African-American race columns) indicate a significant difference between the median scores or proportions between those two respective ethnic groups.

During the 2018 and 2019 events, 2774 health screenings were completed within a period of 12 hours, averaging four health screenings per minute. These included blood pressure (1031/2774, 37.16%), stroke risk assessment (496/2774, 17.88%), bone density (426/2774, 15.35%), carotid ultrasound (380/2774, 13.69%), BMI (182/2774, 6.56%), serum lipids (157/2774, 5.65%), and hemoglobin A_{1c} (102/2774, 3.67%).

Multimedia Engagement

Before the 2018 event, 27 Facebook posts were displayed between December 21, 2017, and April 23, 2018, reaching 17,975 people, with 782 likes, comments, and shares; 648 post clicks; 339 page likes; and 340 page followers. The hashtag *#stompoutstroke* achieved 51 posts and 951 likes, comments, and shares on Facebook; seven posts and 30 likes, comments, and shares on Twitter; and 36 posts and 2093 likes, comments, and shares on Instagram. The Stomp Out Stroke webpage [21] achieved 18,639 page views and 9316 unique visitors. A total of 20 media placements between March 25, 2018, and April 2, 2018, reached approximately 849,731 people in the Houston area. This included 12 television stories, five web-based news stories, two iQ radio interviews, and one print story ([Multimedia Appendix 3](#)).

Discussion

Principal Findings

This study provides novel insights regarding the implementation of Stomp Out Stroke, using multimedia engagement, followed by in-person stroke education and health screening initiative, among a large minority population disproportionately affected by large-scale flooding events and cerebrovascular disease. Stomp Out Stroke registrants were representative of Houston racial or ethnic demographics, including Hispanic or Latino (449/1401, 32.05%), African American (359/1401, 25.62%), and Asian (191/1401, 13.63%). Our population was young (median age 45 years), largely female, and had received more than a high school education. Overall, 16.99% (228/1342) of Stomp Out Stroke participants were uninsured, and 18.70% (251/1342) of the participants were insured through Medicare or Medicaid.

The low adoption rates of electronic consultations for cerebrovascular risk factors, such as hypertension and diabetes, leave questions about overall use and generalizability [32]. To our knowledge, a substantial number of completed health screenings has not been replicated in the literature; indeed, the frequency of four health screenings per minute speaks to the intervention fidelity and reproducibility of Stomp Out Stroke. The multimedia impact of Stomp Out Stroke is a critical component of our hybrid model; the use of social media, hashtags, our webpage, and strategic television, iQ radio, and web-based news stories reached nearly 850,000 people.

The American Heart Association has recently focused on the use of internet-based recovery strategies for stroke survivors [33]; however, there is a paucity of research on the impact of the health and well-being of the caregiver, who may share cerebrovascular risk factors. Overall, 20.79% (279/1342) of Stomp Out Stroke registrants were stroke survivors or caregivers, a population that is undersupported by the health care system and faces unique barriers to obtaining the needed services [34]. Disabled populations are disproportionately exposed to environmental health hazards and feel abandoned by the health care system due to the marginalization of services and a lack of knowledge or skills to reengage [35]. A 2019 study of stroke survivors and caregivers enrolled in an mHealth intervention showed that female caregivers were more likely to

have unknown or poorly controlled cerebrovascular risk factors [36]. The combination of multimedia engagement, followed by in-person health screening, is a hybrid model that can be used in similar urban settings.

An analysis by the City of Houston estimated that 208,353 of 848,340 households were affected by Hurricane Harvey, with a disproportionate number consisting of racial or ethnic minorities and those of lower socioeconomic status [37]. At the request of the Federal Emergency Management Agency, the National Academies of Sciences, Engineering, and Medicine appointed a committee to hold workshops in Houston post Hurricane Harvey to gain an initial understanding of the impacts of urban flooding [38]. Residents most vulnerable to flooding were again described as minorities and the poor. Houston flood district funding comes from state and federal programs, focusing on capital improvement, structural projects, home buyouts, operations, maintenance, and repairs [39]. Unfortunately, the social aspects of urban flooding are far less studied than the physical aspects; indeed, rebuilding a bridge is tangible, and building health capacity is multifaceted. Data on the intangible impact of flooding on vulnerable populations, such as stroke screenings, provide another layer of urban flood risk assessments. Future data collection and analyses could help residents of flood-prone areas receive support from civic organizations, increasing their social agency and capacity.

Community engagement paradigms focused on stroke literacy help improve the awareness of signs and symptoms [40]. We found that Hispanic populations were more likely to attend free health screenings and that African American participants were more likely to express interest in learning about nonstroke health care topics compared with non-Hispanic White people. We also identified an increased interest in speaking to a health care provider among African American or Asian participants compared with non-Hispanic White participants. Differences in the provision of health care (ie, speaking to health care providers) do not necessarily reflect deficiencies. Our goal was to provide health assessments in multiple formats. By fulfilling specific health promotion and disease prevention needs, future community engagement interventions can be tailored to the needs of culturally diverse populations.

Limitations

This study has some limitations. First, the organization and planning of Stomp Out Stroke is led by the Director of Stroke Community Outreach and Education, a full-time faculty member at the McGovern Medical School at UTHealth trained in Vascular Neurology. Her position is supported by endowment funds; sustaining Stomp Out Stroke requires collaborative efforts from multiple faculty members and neurology departmental support staff. Second, Stomp Out Stroke is funded through sponsorships, educational grants, philanthropy, and in-kind donations. Cost mitigation occurred by leveraging free educational resources at the local, state, and national levels. Third, a formalized emergency medical services and safety plan ([Multimedia Appendix 4](#)) was required for security, lost and found children, lost items, and medical emergencies. This plan was used in 2018 for a participant with transient ischemic attack symptoms. The proportion of female participants in Stomp Out

Stroke (973/1390, 70%) was higher than the female population of Houston (1,162,454/2,320,268, 50.1%), which may increase type I error when addressing the health care needs of male participants. We used the largely accepted convention that ethnicity is self-identified, based on factors such as language and shared culture. Therefore, we did not analyze the differences between the Hispanic and non-Hispanic counterparts of each race. Statistical analyses of registrants detailed the purpose of attendance and health-related needs, with no linkage to cerebrovascular risk factors or health screening data. Finally, registrants were not asked about the extent of individual losses

due to Hurricane Harvey. Future studies will include zip code mapping to identify households in flood-impacted areas.

Conclusions

Stomp Out Stroke combined multimedia engagement with in-person health screenings to improve environmental justice for underserved populations at increased risk of urban flooding and cerebrovascular disease. The next step will focus on the use of mHealth technology to assess behavioral changes among repeat attendees, recurrent stroke among stroke survivors, and objective measures of stroke knowledge and preparedness.

Abstract

Background: Searching the internet for cancer-related information helps patients with cancer satisfy their unmet information needs and empowers them to play a more active role in the management of their disease. However, to benefit from the search, patients need a sufficient level of skill to search, select, appraise, and apply web-based health information.

Objective: We aim to study the operational, navigational, information, and evaluation skills and problems of patients with cancer performing cancer-related search tasks using the internet.

Methods: A total of 21 patients with cancer were recruited during their stay at the rehabilitation clinic for oncological rehabilitation. Participants performed eight cancer-related search tasks using the internet. The participants were asked to think aloud while performing the tasks, and the screen activities were recorded. The types and frequencies of performance problems were identified and coded into categories following an inductive coding process. In addition, the performance and strategic characteristics of task execution were summarized descriptively.

Results: All participants experienced problems or difficulties in executing the tasks, and a substantial percentage of tasks (57/142, 40.1%) could not be completed successfully. The participants' performance problems were coded into four categories, namely operating the computer and web browser, navigating and orientating, using search strategies, and evaluating the relevance and reliability of web-based information. The most frequent problems occurred in the third and fourth categories. A total of 90% (19/21) of participants used nontask-related search terms or nonspecific search terms. A total of 95% (20/21) of participants did not control for the source or topicality of the information found. In addition, none of the participants verified the information on 1 website with that on another website for each task.

Conclusions: A substantial group of patients with cancer did not have the necessary skills to benefit from cancer-related internet searches. Future interventions are needed to support patients in the development of sufficient internet-searching skills, focusing particularly on information and evaluation skills.

Introduction

Background

Searching the internet for cancer-related information enables patients with cancer to satisfy their unmet information needs

and empowers them to play a larger role in the management of their disease. Unmet information needs are one of the most frequently reported unmet supportive care needs of patients with cancer (6%-93%) during the treatment and posttreatment phases [1]. Patients with cancer prefer to receive as much

information as possible about their disease [2,3]. The most common topics of cancer-related information sought on the web are information regarding the diagnosis, prognosis, disease stage, treatment options, or side effects of treatment [4-6].

The percentage of patients with cancer who use the internet to search for cancer-related information is high. In 1 Swedish, 1 American, and 1 Dutch sample, 63%-75% of the participants used the internet to search for cancer-related information or general health information [4,7,8]. The prevalence will continue to rise in the future owing to the increasing use of the internet worldwide [9].

Patients with cancer have various reasons for searching cancer-related web-based information. They use the internet to develop questions to discuss with their physician, verify information given by their physician, or seek alternative treatments [4]. Moreover, they feel that the amount of information they receive from their physician is insufficient [10].

Searching the internet for cancer-related information is positively associated with patient-reported outcomes and socioeconomic characteristics of patients with cancer. Patients with cancer who search the internet for cancer-related information are more involved in medical decision-making [11], feel better informed about their disease [7], have a higher level of self-reported health [12] and quality of life [13], are more likely to have a partner [8], and are younger and more educated [4,8,13] than patients who do not search the internet. In addition, internet health information seeking can improve the patient-physician relationship of patients with acute or chronic conditions, depending on whether the patients discuss the information with their physicians [14].

Nevertheless, to benefit from cancer-related internet searching, cancer-related web-based information must be reliable, and patients with cancer need a sufficient level of skills to search, select, appraise, and apply web-based health information [15,16]. However, the quality of cancer-related web-based information varies widely [17-23]. Information on websites is often incomplete and does not provide a basis for well-informed medical shared decision-making [17-23]. Only half (52%) of the patients with cancer trust the internet as a source of cancer-related information [24]. A total of 3 previous studies [15,25,26] analyzed essential skills to properly search the internet for health-related information. These 3 studies used performance tests and observed participants while executing health-related search tasks on the internet. The essential skills observed during task execution can be divided into 2 categories. First, people need operational and navigational skills to use a computer and web browser, that is, using a keyboard, mouse, or touch screen; navigating forward and backward between websites; and maintaining orientation on a website [15,25]. Second, they need information and evaluation skills to search, find, and assess web-based information, that is, formulate adequate search terms, choose a relevant search result, or check the source of information [15,25]. The results of the first study indicated that approximately one-third of the participants had severe problems in using operational and navigational skills [25]. Similar to the first study, the sample in the second study

had, on average, a sufficient level of these skills [15]. The third study did not evaluate these 2 skills [26]. The levels of information and evaluation skills observed in the 3 studies seemed to be much lower [15,25,26]. Many participants reported problems choosing relevant search terms (14/15, 93%), selecting a reliable search result (13/15, 87%), and not checking the source of information (14/15, 93%) in at least 1 task [25]. Furthermore, none of the participants controlled the source of information, the topicality of the information, or how the information had been compiled [26].

Thus far, research on internet searching skills has focused on general healthy populations [15,26] or patients with rheumatoid arthritis [25]. The internet-searching skills of patients with cancer have not yet been studied.

Objective

Therefore, the primary goal of this study is to gain insight into the operational, navigational, information, and evaluation skills and problems of patients with cancer performing cancer-related search tasks using the internet.

Methods

Study Design

A performance test was conducted to obtain in-depth insight into the operational, navigational, information, and evaluation skills and problems of patients with cancer using the internet to search for cancer-related information on the web. Three qualitative methods of data collection were used: (1) the think-aloud method [27] combined with (2) the study administrator's *real-time* notes and (3) video and audio data of the participants' screen activity.

The report of this study followed the recommendations of the Standards for Reporting Qualitative Research, consisting of 21 items that aimed to improve the transparency of all aspects of qualitative research by providing clear standards for reporting qualitative research (Multimedia Appendix 1) [28].

The study protocol for this qualitative study is freely available at the Open Science Framework [29] and was published before the recruitment of the first participant.

Setting, Participants, and Recruitment

The participants were recruited during the first week of their 3-week stay at a rehabilitation clinic for oncological inpatient rehabilitation. Recruitment was conducted by the medical director (GE) of the clinic who approached the participants during the patient consultations. Patients were included if they had been diagnosed with any type of cancer and if they had sufficient oral and written proficiency in the German language. An appointment for the performance test was scheduled within the following week, and the participants received informed consent forms. Informed consent included information about the study goal, potential risks and benefits of the study, the voluntary nature of participation, and the type and duration of data storage. The participants were instructed to sign the informed consent before data collection. All appointments occurred at the rehabilitation clinic and were conducted by the same researcher (LLD). The sample size in this study was based

on the concept of theoretical saturation [30], which is defined as the point when no new information, themes, or topics emerge from the data. Saturation, in the context of this study, indicates that no new performance problems were observed among the participants.

Procedure and Materials

Each appointment started with a short questionnaire to collect the following data: (1) the participants' socioeconomic characteristics (age, gender, education, and marital status); (2) their medical characteristics (cancer type, time since cancer diagnosis, and self-perceived health status measured using the second-to-last items of the German version of the EORTC QLQ C-30 [European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-30] [31], with response options ranging from 1=very poor to 7=excellent); and (3) their general and cancer-related internet usage characteristics (internet experience, daily time spent on the internet, internet use for cancer-related topics, frequency of health-related internet use,

and self-perceived internet searching skills). The participants had to evaluate their internet searching skills on four 5-point scales (ranging from *very bad* to *very good*) that measured the participants' self-perceived ergonomic skills, navigational skills, evaluating information reliability skills, and determining relevance skills [16].

Performance tests were started when all the items were completed. The patients executed 8 cancer-related internet search tasks (Textbox 1) based on the most common topics of cancer-related information sought on the web [4,5]. The order of the tasks was randomized for each participant because a learning effect was expected to affect the performance of subsequent tasks. The tasks were pilot tested with 4 patients with cancer to ensure comprehensibility and applicability. The participants of the pilot study were recruited from the Outpatient Clinic for Psycho-Oncology of the University Medical Center Hamburg-Eppendorf. The pilot study contained 10 search tasks. Two tasks were deleted because none of the participants were able to complete these tasks independently.

Textbox 1. Description of the cancer-related internet search tasks.

Description of the Cancer-Related Internet Search Tasks

- Imagine that you have noticed the following effects on your physical and mental well-being during your cancer treatment: listlessness, physical and mental exhaustion that does not improve even by sleep or rest. Search the internet for the symptom's name.
- Please search the internet for treatments or methods of treatment for chronic or persistent "fatigue" (this task always came after task 1).
- Please search the internet for various providers who offer psycho-oncological counseling in the Hamburg area (postcode: 22529).
- Formulate a disease-related question you have had in the past and show how you would approach this on the internet.
- Please search the patient guidelines of the German Cancer Society for your specific type of cancer.
- Search for the information sheet of the Cancer Information Service "Cancer on the internet: Surf safely."
- With the help of information from the internet, please name 5 possible side effects or symptoms of the specific cancer therapy (eg, chemotherapy and radiotherapy) that you received.
- With the help of information from the internet, please name possible ways that you could change your diet to promote your well-being or reduce side effects.

The performance tests were recorded using *Open Broadcaster Software* (version 26.1.0), which generated video and audio data. The participants were asked and trained to think aloud while performing the tasks. The verbalization of the participants' thoughts allowed the researcher to gain insight into the participants' cognitive processes while searching for web-based information [32]. In addition, the researcher present observed the participants and recorded real-time notes to identify problems with the hardware operation.

Each performance test was conducted using the same hardware (laptop, mouse, and keyboard) with identical settings. The laptop was connected to an active internet connection and was programmed with the 3 most popular web browsers (Internet Explorer, Mozilla Firefox, and Google Chrome). The participants were instructed to choose the web browser with which they had the most experience. All web browsers began with a blank page. To prevent the participants from being influenced by previous participants' search activities, the web browser was reset after each participant by removing the web browser history and cookies using CCleaner version 5.44 (Avast Software). If the participants were unable to perform the task,

help was offered by the researcher present. The participants received €15 (US \$17.70) for participating in the study.

Data Analysis

Statistical analyses were conducted using SPSS Statistics (version 25, IBM SPSS Inc). The participants' sociodemographic characteristics, medical characteristics, and general and cancer-related internet usage were summarized descriptively.

Video and audio data, as well as the researcher's real-time notes, were analyzed to (1) identify participants' performance problems, (2) evaluate the participants' performance, and (3) identify performance and strategic characteristics of task execution.

To identify participants' performance problems, the researchers followed an inductive coding process [33]. Participants' behavior or statements were initially coded and subsequently grouped into categories and subcategories that were then named. The category names were partly based on categories from previous research [25]. The number of problems encountered per task was then determined.

The evaluation of the participants' performance per task and the difficulty of the tasks were based on two variables: (1) could the participants complete their task *completely independently*, *with help*, or *not able to complete* the task at all, and (2) the time needed to perform the task (the more time needed to complete a task, the higher the difficulty of the task).

The execution and strategic characteristics of task execution were described by six variables: (1) the used web browser (Internet Explorer, Mozilla Firefox, or Google Chrome), (2) the starting point (eg, a specific website or a search engine), (3) the position of the opened website in the Google search listings from top to bottom (the position of the opened website in the search listings is an indicator of whether participants look beyond the first search results), (4) the number of words per search query (the use of a single search term was considered too unspecific; it is more important for the successful completion of a task to use task-related search terms than a large number of search terms), (5) the number of times a search query needed to be adjusted (a higher number of adjustments per task indicated a higher difficulty of the task), and (6) the name of the opened websites (Do the most often opened websites have a good content ranking and a commercial interest?) [21].

The influence of the participants' education (>10 years of school education vs ≤10 years of school education), age (above vs below median), self-perceived internet skills (above vs below median), internet experience (above vs below median), and time since cancer diagnosis (above vs below median) on the participants' average number of problems per task and

percentage of successfully completed tasks were analyzed using 2-tailed *t* tests for independent groups. For additional interpretation, effect sizes were calculated: the values of Cohen *d* for small, medium, and large effects were 0.2, 0.4, and 0.8, respectively [34]. The α level of significance was set at $\alpha=.05$.

Ethics Statement

The study was conducted in accordance with the Code of Ethics of the Declaration of Helsinki and was surveyed by the Ethics Committee of the Medical Association (Hamburg, Germany). Written informed consent was obtained from all the participants before participation.

Results

Participants' Characteristics and Participants' Internet Use

Slightly more women (12/22, 55%) than men participated in the study (Table 1). The participants' ages ranged between 25 and 81 years (mean 57 years, SD 11.9 years). Almost three-fourths of the participants lived with a partner (16/22, 73%). Most (13/22, 59%) of the sample had 10 years or less of schooling, whereas 27% (6/22) had a university degree. Breast (6/22, 27%), colon (4/22, 18%), and prostate cancer (3/22, 13%) were the most frequently reported cancer diagnoses. The participants received their diagnosis, on average, 28 (SD 57.8) months prior. The average self-perceived health status score was 4.5.

Table 1. Medical and sociodemographic characteristics of the participants (N=22).

Participant characteristics	Values
Age (years), mean (SD; range)	56.8 (12; 25-81)
Gender (female), n (%)	12 (55)

Time since cancer diagnosis (months), median (range)	6 (1-207)
Self-perceived health status, mean (SD)	4.5 (1.0)

^aMultiple selection.

The participants' mean internet experience was 15 years (Table 2). Most of the participants (13/22, 59%) used the internet for less than 1 hour per day. The most common cancer-related activities on the internet were searching for cancer-related information (14/22, 64%) and communication with relatives

(14/22, 64%). More than half (14/22, 64%) of the participants used the internet less than once a month for health care reasons. The participants rated their ergonomic skills, evaluating information reliability skills, navigation skills, and determining information relevance skills as *medium to good*.

Table 2. General and cancer-related internet usage of participants (N=22).

Participant characteristics	Values
Internet experience (years), mean (SD; range)	15.4 (7.7; 0-30)

Execution of Cancer-Related Tasks and Problems Encountered

Search Strategy and Effectiveness of Searches

Performance tests of the 21 participants were included in the analysis. The performance of participant 22 was excluded

because the participant could not execute the tasks due to stress. On average, the participants executed 6.8 tasks. Participants 1 and 21 performed only 2 tasks. A total of 57% (12/21) of participants executed all 8 tasks. All data on task execution and performance problems are available in Figshare [35].

None of the participants used medical websites as a starting point. All search tasks were started using the Google search engine. On average, the participants successfully completed 59.9% (85/142) of all the tasks. Task F (Search the information sheet of the Cancer Information Service) had the highest rate of successful completions (14/18, 78%) and took participants, on average, the shortest time to execute (Table 3). Task E (Search the patient guideline for your cancer type) had the lowest rate of completion (6/19, 32%). The longest mean time (mean 323 seconds) to execute a task was observed for task D (retrieve previously searched disease information). A total of 86% (18/21) of participants used the same web browser for all the tasks. Google Chrome was used in 80.2% (114/142) of search queries. The participants opened 192 webpages (the same

website was counted every time it was opened) from 61 different websites during their 142 search queries (Multimedia Appendix 2). The 2 most frequently opened websites were provided by professional associations with generally good content rankings [21]. The participants usually selected one of the first websites from Google search listings. Of the 192 opened webpages, 163 (84.9%) webpages were ranked among the first 5 Google search results. Websites from the second page of Google search listings were opened 4 times (4/192, 2.1%). On average, the participants used 4.2 search terms per task. A single search term was used for 4.9% (7/142) of search queries. In addition, in 27.5% (39/142) of search queries, the participants decided to adjust the search terms to improve the Google search results.

ⁱNumber of participants who experienced this problem during the execution of at least one task.

^jN/A: not applicable.

^kThe problem was task-specific (task 5).

^lVerifying the information was not applicable for this task because participants were instructed to search for a particular website.

Operating the Computer and Web Browser

A total of 62% (13/21) of participants had at least 1 problem using computer hardware (keyboard and mouse) or problems using basic web browser functions.

In total, 33% (7/21) of participants had problems using the keyboard, especially locating keys while typing search terms or searching for the *enter* key. In addition, 38% (8/21) of participants had problems controlling the mouse, mainly the double-clicking of icons (eg, web browser). A total of 14% (3/21) of participants experienced difficulties with the scroll bar. A total of 52% (11/21) of participants had problems operating the web browser. Frequent problems included finding the web browser icon on the desktop and closing and reopening the web browser to adjust the search terms instead of using the web browser's *back* button. Furthermore, 10% (2/21) of participants had problems reading the text of a website because of the small font size.

Overall, the operational problems were not task-specific. Most of the operating problems (94/122, 77%) were experienced by the same 6 participants. After completing several tasks, the present researcher observed that the participants became increasingly frustrated with the recurring operational problems.

In addition, 2 behaviors were observed but were not coded as operational problems. A total of 81% (17/21) of participants closed the web browser after every individual task and reopened the browser for the next task. Furthermore, 71% (15/21) of participants used a single tab for all searches.

Navigating and Orienting

A total of 33% (7/21) of participants experienced at least one problem with navigation and orientation in web browsers and on websites. Problems often occurred when the websites had complex structures, such as different graphical control elements (ie, dropdown lists or anchor links).

A total of 24% (5/21) of participants had problems maintaining their orientation on a website. They lost their orientation for various reasons. Twice, the participants felt confused by the browser's starting page (eg, "This is not where I wanted to be" [Participant 8]). Two other times, the participants did not understand the function of the anchor link at the top of the website, which would have helped them jump to the relevant information in the text. A total of 14% (3/21) of participants could not distinguish an opened PDF file from a website. In total, 10% (2/21) of participants did not find relevant

information on websites because they could not use the websites' dropdown lists. One participant lost orientation due to the Google option *related searches* (eg, "I did not write that" [Participant 8]).

Notably, most of the orientation and navigation problems (94/122, 77%) were experienced by the same group of 6 participants who encountered most of the operational problems.

Using Search Strategies

A total of 95% (20/21) of participants experienced at least 1 problem using search strategies. Most of the problems occurred in the first stage when the participants formulated the search terms.

A total of 24% (5/21) of participants used only single search terms that were too broad to successfully complete the tasks. In total, 90% (19/21) of participants used nontask-related search terms or nonspecific search terms. For example, Participant 5 used the search terms *patient Hamburg* to find the patient guidelines of the German Cancer Society (task 5; nontask-related). Participant 11 searched for *psychological support* instead of *psycho-oncological support* (task 3; unspecific search). In total, 52% (11/21) of participants made spelling or grammatical errors in their search queries. These participants (9/11, 81%) usually did not adapt the search terms, and the Google option *did you mean* was not used to correct the errors.

The use of nontask-related, nonspecific, or grammatically incorrect search terms made the participants adjust their search terms or select a nontask-related webpage from Google search listings. A total of 29% (6/21) of participants experienced problems adjusting the search terms. For example, Participant 9 adjusted the original search query from *side effect of cancer therapy* to *side effect of cancer*, a query that was still not task-related (task 1: identify the symptom fatigue). A total of 52% (11/21) of participants selected nontask-related websites from the search listings. Many of these participants (5/11, 45%) randomly opened one of the first search results ("I am going on a random website; usually I don't like to pick the first website" [Participant 14]; task 2). They did not look at the URL or Google snippet (short description of the website's content) to be informed about the website's content.

To complete task 5, the participants had to find the patient guidelines (PDF file) of their specific cancer type. A total of 38% (8/21) of participants selected clinical practice guidelines

instead of the patient guidelines. Both types of guidelines can be found on the same website.

Evaluating Relevance and Reliability

All participants experienced at least 1 problem while evaluating their relevance and reliability. None of the participants controlled the source or topicality of the information, except for Participant 19. Furthermore, none of the participants verified the information on 1 website with that on another website for each task. Most of the participants only opened a second website when they were not satisfied with the information on the first website. A total of 19% (4/21) participants made critical comments regarding the reliability of commercial websites; for example:

The first search result is an advertisement. Therefore, I will not consider that webpage. [Participant 7]

Nevertheless, 38% (8/21) of participants selected and searched the providers' websites with a commercial interest. In total, 4 of these participants even opened websites marked as ads by Google. A total of 29% (6/21) of participants did not scan the selected websites for relevant information to complete the task. They read the websites' headings and then completed the task because they were convinced that the information they were looking for could be found on the website.

Notably, 71% (15/21) of participants made comments regarding the following: (1) the reliability of certain websites; for example:

I got offers. Here, from yelp.com. I have problems with opening this website because for me that is dubious information. [Participant 17]

(2) the reliability of certain types of websites; for example:

What I would not read are patient forums. Where some laymen write what they did...I would rely on medical tips. [Participant 2]

or (3) the internet as a source of cancer-related information; for example:

The internet in general is way too superficial. I read a book to gather information about that. [Participant 4]

Understanding the Task and Staying Focused

A total of 33% (7/21) of participants experienced problems understanding the tasks ("I don't know what I am supposed to search" [Participant 14]; task 1), usually (10/12, 83%) resulting in nontask-related search queries. A total of 43% (9/21) of participants forgot the task during execution and had to reread it. A total of 24% (5/21) of participants were distracted by other nontask-related information. For example, Participant 3 became distracted by a brochure about *sexuality and cancer* while executing task 6.

Relationship Between Patient Characteristics and Performance Parameters

Participants 1 and 21 were not included in this analysis because they executed fewer than 3 tasks. The participants who were younger (mean 2.7, SD 1.0) and had higher self-perceived internet skills (mean 2.9, SD 1.1), on average, encountered

significantly fewer ($t_{17}=-2.78$, $P=.01$, Cohen $d=1.30$; $t_{17}=-2.33$, $P=.03$, Cohen $d=1.07$) performance problems per task than those who were older (mean 4.6, SD 1.8) and had lower self-perceived internet skills (mean 4.5, SD 1.8; [Multimedia Appendix 3](#)). Both the differences had a large effect size. In addition, participants with higher self-perceived internet skills (mean 75.6, SD 18.1) completed a significantly higher percentage of tasks successfully ($t_{17}=2.65$; $P=.02$; Cohen $d=1.23$) than those with lower self-perceived internet skills (mean 44.9, SD 30.2). In addition, differences with a large, medium, and small effect size can be found: (1) younger participants completed a higher percentage of tasks successfully (Cohen $d=0.87$); (2) participants with more internet experience completed a higher percentage of tasks successfully (Cohen $d=0.87$) and had fewer performance problems (Cohen $d=0.66$) than patients with less experience; (3) participants with higher education completed a higher percentage of tasks successfully (Cohen $d=0.46$) and had fewer performance problems (Cohen $d=0.40$) than participants with a lower education; and (4) participants who had more time since diagnosis completed a higher percentage of tasks successfully (Cohen $d=0.30$) and had fewer performance problems (Cohen $d=0.40$) than participants with a lower education.

Discussion

Principal Findings

This study examined the level of operational, navigational, information, and evaluation skills of a sample of patients with cancer performing 8 cancer-related search tasks using the internet. The results indicate that a substantial group of patients with cancer did not have the necessary operational, navigational, information, and evaluation skills to benefit from cancer-related internet searches. A total of 29% (6/21) of participants had major problems with the operation of the hardware, operation of the computer and web browser, and with navigation and orientation in web browsers and on websites. These participants produced three-fourths (94/122, 77%) of the operational and navigational problems. These problems caused great frustration among the participants and often resulted in tasks not being completed successfully. A total of 6 participants completed only 29% (12/42) of their tasks successfully. Although the operational and navigational skills of most participants (15/21, 71%) seemed to be sufficient for searching the internet, the information and especially the evaluation skills were much lower. Many participants struggled with formulating a task-related search query (19/21, 90%), selecting a task-related search result (11/21, 52%) of a provider without a commercial interest (8/21, 38%), and browsing the website to find the answer to the task (6/21, 29%). Strikingly, only 19% (4/21) of participants verified the information on 1 website with that on another website, and only 5% (1/21) of participant informed himself about the provider of the website. The remaining participants seemed to take no interest in the source or topicality of the information. These findings are alarming because previous research has shown that the quality of cancer-related web-based information varies widely [17-23].

Comparison With Previous Work

Our results are consistent with those of previous studies that used performance tests to analyze the internet-searching skills of healthy participants [15,26] and patients with rheumatoid arthritis [25]. Operational and navigational problems occurred in only approximately one-third of the samples [15,25]. In addition, almost all the participants of this study and three similar studies had problems with information and evaluation skills [15,25,26]. Owing to the similarity of the results, we believe that the identified internet searching problems can also be found in patients with other health conditions and in the healthy population. In addition to the National Action Plans that plan to increase the health literacy of the entire population in the future [36,37], further web-based interventions are needed to increase the internet-searching skills of patients with low skills presently [38-40].

The rate of search queries with single search terms was the main difference between the search strategies used in 2002 [26] and those used in this study. In 2002, 65% of all search queries comprised a single search term [26] compared with 4.9% (7/142) in this study. The longer average internet experience of our sample (15.4 years vs 2.5 years) could be a possible explanation for choosing to use more search terms. However, information skills did not seem to grow with years of internet experience [41].

An exploratory analysis of our data indicated that younger age, higher self-perceived internet skills, more internet experience, and higher education were associated with encountering fewer performance problems and completing a higher percentage of tasks successfully. In addition, more time since diagnosis was associated with fewer performance problems and a slightly higher percentage of successfully completed tasks. The results of our exploratory analysis should be interpreted carefully because our sample size ($n=19$) was too small to make assumptions about the population of patients with cancer. However, previous research on internet-searching skills using performance tests confirmed that younger age, a higher level of education, more internet experience, and higher self-perceived internet skills are associated with more successful task completion [25,41]. Younger participants have higher operational and navigational skills but particularly poor performance regarding evaluation skills [41,42]. Education and self-perceived internet skills are associated with operational, navigational, information, and evaluation skills, whereas internet experience only has a positive influence on operational and navigational skills [41]. In addition, we analyzed the influence of time since cancer diagnosis on the participants' test performance, assuming that patients who had more time looking for cancer-related information on the web may know of more reliable providers of web-based cancer information than patients who recently received their diagnosis. A possible explanation for the lack of a stronger association with participants' performance might be that having more time since diagnosis may only be associated with patients' evaluation skills but not their operational, navigational, and information skills. Future performance tests with larger sample sizes are needed to examine this question.

Limitations

This study had several limitations. First, the participants performed the tasks in an artificial research setting under experimental conditions. They may have felt more nervous than if they had been in a natural setting. For example, Participant 22 did not start the performance test because of stress. In addition, the participants may have felt time pressure to perform the tasks and may have focused less on evaluating the reliability or topicality of the websites. We tried to minimize the pressure to perform and time pressure by explicitly reminding participants to take their time and that there were no right or wrong answers. Second, some participants had to use unfamiliar hardware as they accessed the internet exclusively with their smartphones or tablets [9]. This may have increased the number of operational problems experienced. Asking the participants what type of digital device they use to access the internet would have helped to distinguish among the users. Future performance studies should also consider enabling participants to perform tasks on a smartphone or tablet. Third, to ensure that the tasks were related to the interests and needs of patients with cancer, we formulated search tasks that covered the most common topics of cancer-related information sought on the web [4,5] and pilot-tested the tasks. However, compared with a real setting, answering our cancer-related questions had no direct effect on the treatment or well-being of the participants. Therefore, the participants may have been less motivated to evaluate the website's reliability or to verify the information found on a second website. Fourth, the study sample was small and most likely nonrepresentative. No national or international studies with representative samples have been conducted yet that allow statements on the internet searching skills of entire population groups or patients with cancer [43]. However, we expect that our sample had higher skills than the population of patients with cancer for the following three reasons: (1) the participants volunteered to participate in the study; (2) the participants' average internet experience in years (mean 15.4 years) was high, and operational and navigational skills grew with years of internet experience [41]; and (3) the participants were often highly educated (28% had a university degree), with a high level of education being related to high internet searching skills [41]. Future performance test studies should concentrate on older, lesser-educated patients with cancer with little internet experience. Additional important performance problems may be identified because these patient characteristics are associated with low internet-searching skills [25,41]. Fifth, using the concept of data saturation [30] also captures the risk of missing additional important performance problems [44]. Previous studies have indicated that even if no new concepts emerge, the possibility of further uncovered concepts in the population cannot be excluded [45,46]. We cannot completely exclude the possibility that we missed certain internet searching problems. Nevertheless, by giving the participants sufficient time to express all of their thoughts and the similarity between our results and those of previous performance tests [15,25], we are convinced that we have identified most of the important problems of patients with cancer using the internet to search for cancer-related information on the web.

Conclusions

A substantial group of patients with cancer did not have the necessary skills to benefit from cancer-related internet searches. The problems included operating the hardware, navigation and orientation in web browsers and on websites, and in particular formulating a task-related search query and critically evaluating and verifying web-based content. Given the high number of

participants with higher education and relatively high internet experience, the need for future interventions or programs to increase the internet-searching skills of patients with cancer may be underestimated in this study. Additional important performance problems may be identified in future studies that concentrate on older, low-educated patients with little internet experience.

Acknowledgments

This study was financed with own funds.

Authors' Contributions

LLD was responsible for conceptualization, data curation, formal analysis, investigation, methodology, project administration, resources, validation, visualization, writing—original draft and review and editing. HS was responsible for the investigation, methodology, supervision, validation, and writing—review and editing. CB was responsible for conceptualization, investigation, methodology, supervision, validation, and writing—review and editing. GE was responsible for the recruitment of the sample, project administration, and writing—review and editing. All authors reviewed the final manuscript.

Abstract

Background: Owing to the shortage of medical professionals, as well as demographic and structural challenges, new care models have emerged to find innovative solutions to counter medical undersupply. Team-based primary care using medical delegation appears to be a promising approach to address these challenges; however, it demands efficient communication structures and mechanisms to reinsure patients and caregivers receive a delegated, treatment-related task. Digital health care technologies hold the potential to render these novel processes effective and demand driven.

Objective: The goal of this study is to recreate the daily work routines of general practitioners (GPs) and medical assistants (MAs) to explore promising approaches for the digital moderation of delegation processes and to deepen the understanding of subjective and perceptual factors that influence their technology assessment and use.

Methods: We conducted a combination of 19 individual and group interviews with 12 GPs and 14 MAs, seeking to identify relevant technologies for delegation purposes as well as stakeholders' perceptions of their effectiveness. Furthermore, a web-based survey was conducted asking the interviewees to order identified technologies based on their assessed applicability in multi-actor patient care. Interview data were analyzed using a three-fold inductive coding procedure. Multidimensional scaling was applied to analyze and visualize the survey data, leading to a triangulation of the results.

Results: Our results suggest that digital mediation of delegation underlies complex, reciprocal processes and biases that need to be identified and analyzed to improve the development and distribution of innovative technologies and to improve our understanding of technology use in team-based primary care. Nevertheless, medical delegation enhanced by digital technologies, such as video consultations, portable electrocardiograms, or telemedical stethoscopes, can counteract current challenges in primary care because of its unique ability to ensure both personal, patient-centered care for patients and create efficient and needs-based treatment processes.

Conclusions: Technology-mediated delegation appears to be a promising approach to implement innovative, case-sensitive, and cost-effective ways to treat patients within the paradigm of primary care. The relevance of such innovative approaches increases with the tremendous need for differentiated and effective care, such as during the ongoing COVID-19 pandemic. For the successful and sustainable adoption of innovative technologies, MAs represent essential team members. In their role as mediators between GPs and patients, MAs are potentially able to counteract patients' resistance toward using innovative technology and compensate for patients' limited access to technology and care facilities.

Introduction

Background

The current health care systems are facing major challenges. Several shortcomings are prevalent with regard to the availability of medical professionals and facilities, which impedes the provision of comprehensive care. In particular, rural areas are undergoing a rapid demographic change, leading to higher patient numbers and increased occurrences of age-related health issues, which results in a higher health care demand [1]. Simultaneously, the numbers of general practitioners (GPs) and specialized physicians have been decreasing in these areas [2], in part because they often find it more attractive to establish themselves in bigger cities [3]. Thus, doctors often struggle to find successors who are willing to take over their practice, which in turn leads to higher workloads for the remaining GPs who must meet the growing demand [4]. Consequently, an inequitable distribution of health care services has emerged that disadvantages rural areas that are often structurally weaker [5,6]. Nowadays, these disadvantageous trends are further complicated by the ongoing COVID-19 pandemic, which has led to governmental decisions restricting personal contacts among society as well as between patients and health care providers [7]. Therefore, a transition away from in-person treatment can be observed, evoking novel challenges that need to be addressed to maintain comprehensive access to care [8,9], such as privacy and cybersecurity concerns [10,11], the potential conduct of inaccurate examinations, or the undermining of patient-physician relationships [8].

As a reaction and countermeasure to these challenges, new care models have emerged that alter the structures and delivery processes in health care and seek to free up resources and enable GPs to cope with increasing demands and contemporary restrictions [12]. One example of a novel way of organizing comprehensive ambulant patient treatment is the deployment of medical assistants (MAs) who are entitled to an advanced set of permissions and responsibilities [13-15]. MAs are meant to take on some of the GP's tasks, such as conducting home visits or adjusting medications (which are done in collaboration with the GP). Accordingly, these new structures and processes call for new ways of communicating, documenting, and practicing care that account for the multiple actors [16]. Although GPs need to be empowered to delegate some of their duties to the assistants to free up their own capacities and thus be able to cope with increasing demands, MAs must form ways to warrant their work, align it with medical standards and routines, and thus contribute to effective and safe treatments. Hence, new collaborative forms of care emerge, and responsibilities are partially disseminated across professionals [13]. However, this multi-actor approach also presents challenges, such as patient compliance with these novel processes. In addition, the importance of effective communication increases within team-based primary care, as MAs are not allowed to treat patients autonomously because of legal boundaries. In this regard, treatment errors and communication problems between actors can occur that call for generating digital competencies at an early stage [17] and the willingness to participate in this digital transformation.

In addition to approaches dealing with the prevalent issues in health care that involve innovative changes in personnel management and delegation, the application of digital technologies within care delivery and treatment processes has also been shown to be effective under specific conditions. Technologies such as telemedical video consultation systems for efficient patient-physician communication [18], body-worn sensory equipment that allows for patient-sided collection of vital data [19], and telemonitoring systems that render in-person contact unnecessary [20] have been applied to bridge gaps in patient treatment and in the availability of medical professionals in the workforce. In this context, the emerging internet of things brings together a variety of data collected by users and ubiquitous connected devices such as biosensors and smart meters [21,22]. Further applications of these technologies include virtual home visits [23], remote examinations [24], digital prescriptions [25], and scheduling appointments [26] and the provision of information on diseases, symptoms, and possible treatments that can be easily accessed on the web [27]. In addition, internet of things apps can be used to support older or chronically ill patients at home, thus contributing to an independent way of life [21]. In particular, with regard to the ongoing COVID-19 pandemic, telemedicine (such as video consultations and telemonitoring) has been shown to enable spatially independent treatment while ensuring quality of care and patient safety [28]. Nevertheless, research has also shown that the digitalization of primary health care processes might lead to contrary effects and requires careful consideration of underlying conditions. Research argues that digital-first approaches to general practice might lead to an increase in workload without sufficient differentiation of patients and their needs [29].

Drawing a synopsis of these two perspectives, the integration of digital technologies and new care delivery structures holds the potential to further improve health care quality and comprehensiveness, with the ultimate goal of maintaining or even improving the safety, satisfaction, and overall health of the patient. Research delivers initial insights in that regard, showing that the integration of technologies into multi-actor health care processes can yield higher allocative efficiency and organizational outcomes (eg, lower hospitalization rates) [30]. These targeted benefits are of particular interest when looking at rural areas and the prevailing circumstances, such as a lack of work force and resulting per capita demand [31]. Here, the application of digital technologies within multi-actor health care processes holds the potential to address the challenges and issues that are vital to address, such as more complex communication and delegation paths or the need for dispersed and transparent accountability [32]. Using digital technologies, GPs and MAs alike are potentially able to collect richer data on their patients based on measured vital parameters or user inputs. It can be assumed that the augmentation of innovative, multi-actor care delivery models with supportive digital technologies represents a promising and more holistic strategy, which calls for dedicated studies examining whether prevalent challenges in health care and structural disparities, such as in rural and remote areas, can be approached in a beneficial and feasible way.

Multi-Actor Approaches in Modern Health Care

The shortage of medical professionals in Western countries has led to the development of multiple strategies to counter the difficulties related to the provision of medical services in primary care [33], especially through shifting from clinical to ambulant care [34] and through medical task delegation, that is, the transfer of medical interventions from a doctor to another medical professional [33]. Although task delegation in Western countries normally involves the transfer of medical interventions from doctors to nurses [35,36], GPs also delegate tasks to MAs in several countries [37]. Although *medical assistant* is a general term for several professionals with different medical skills and training, MAs are usually part of a GP's staff [15]. The former role of MAs in physicians' offices was focused on administrative tasks and the provision of isolated clinical measures under the direct supervision of physicians [38]. Currently, MAs are qualified to visit patients at home and manage different tasks, for example, monitoring a patient's health status, taking blood samples, or supervising and adjusting the intake of prescribed medication. Although MAs are usually not permitted to diagnose patients or adjust medical treatments on their own, the role of MAs increasingly comprises the more complex task of continuously assessing and evaluating a patient's health status to ensure optimal case management together with primary care physicians [39]. Undertaking tasks including patient education, health promotion, or monitoring the social and psychological well-being of patients, the role of MAs and primary health care nurses share specific similarities and might converge in the future [40]. Nevertheless, the differentiation and definition of the roles MAs and nurses take for primary care require further investigation and are not always clear [12,41]. Through the delegation of tasks in ambulant primary care to MAs, GPs are able to better distribute and structure their workload, resulting in a more effective and satisfactory work routine [33]. Therefore, the success of multi-actor approaches in health care depends on specific structural, organizational, and outcome-associated conditions, for example, efficient communication between team members [42] or patient satisfaction [43].

Bridging Gaps in Primary Care Through Digital Technologies

Considering these challenges of multi-actor approaches in primary care, the digitalization of health care technologies improves the ability to catalyze team-based, multidisciplinary, and resource-sensitive processes. Considering the uniqueness of multi-actor approaches in primary care, the technologies that are relevant are those that are capable of enhancing collaboration, communication, documentation, and patient intervention. Information and communication technologies (ICTs) in particular have the potential to optimize multi-actor care processes [44], for example, by enabling remote access to patient information or documenting care through digital platforms [45]. For digitally mediated delivery of care, a wide range of telemedicine systems provide different services, from audiovisual applications for digital appointments (video consultation) [46,47] to sensory-enhanced systems for auscultation (listening to the internal sounds of the patient, usually with a stethoscope) [48]. In addition, body-worn sensors or other monitoring devices allow autonomous and continuous

measurements to generate more accurate, rather than isolated, medical data [19,49]. For digitally mediated health care, it is of great interest to differentiate between the potential of different types of digital technologies and to explore factors that are crucial for their adoption and sustainable integration into existing work routines [50]. Therefore, the role of digital technologies in multi-actor approaches is bound to the evolving informational gaps that are caused by new structures and processes in primary care.

Objectives

To date, the literature lacks studies that shed light on the potential and benefits of combining multi-actor care processes and supportive digital technologies in primary care. Hence, this study seeks to investigate the attitudes, perceptions, expectations, and needs of medical professionals located in a rural area, who play a role in multi-actor patient treatment processes. To accomplish this, our research draws upon qualitative results gathered from semistructured interviews as well as results from a web-based survey that was completed by both GPs and MAs. Both interviews and surveys were conducted in a region characterized by rural conditions and associated challenges. This mixed methods approach allows for a triangulation of findings and delivers richer insights into the target groups' attitudes and perceptions regarding the use of digital technologies in health care, thus shedding further light on how these health care actors cope with increasing efforts provoked by the rural environment. Consequently, the objectives of this study are to investigate (1) the technologies that are suitable and effective for application in multi-actor care delivery and delegation processes in rural care and (2) the factors underlying the professionals' use and perception of identified technologies that are already in use or exhibit future applicability.

Methods

Study Design

We conducted a three-step, mixed methods approach to thoroughly investigate the phenomena of interest. As part of a regional project in Rhineland-Palatinate, Germany, with 11 different primary care physicians' offices, this study empirically explored the potential of various digital technologies for enhancing delegation processes in rural primary care. Following our initial research objectives, we (1) collected and analyzed qualitative data from 19 interviews with GPs and MAs from 11 different primary care physicians' offices participating in the project. Through our process of analysis, we discovered that the perceived differences between technologies that were already being used by medical professionals and new innovative technologies seemed to be important factors for the hypothetical adoption or rejection of innovative technologies. Therefore, to expand our understanding of the perception of innovative digital technologies by GPs and their MAs, we (2) conducted a web-based survey within the same population and used multidimensional scaling (MDS), which will be further explained later within this section, to reveal underlying patterns of technological preferences. GPs and MAs from our sample confirmed the results of our MDS in a subsequent workshop.

Finally, we achieved a richer and deeper understanding of the investigated phenomena by (3) triangulating the results of both data sets [51,52].

Interview Study

Overview

As part of a regional project on the digitalization of delegation processes in German primary care, we conducted 19 qualitative interviews with GPs and MAs in 11 different rurally situated offices (we ensured to conduct at least one interview with

participants from each office). All MAs that participated in this study underwent basic nonacademic clinical training for 3 years and had a supplementary qualification enabling them to undertake clinical tasks in ambulant care, comprising 190-270 hours of training. Originally, we had planned to conduct individual interviews only. Nevertheless, some offices asked us to conduct group interviews because of the high workload and time pressure. Therefore, we conducted 13 individual interviews and 6 group interviews with comparable characteristics. [Table 1](#) provides an overview of the interviewees' characteristics.

Table 1. Summary of interviewees' characteristics.

Characteristic	Type of interview		
	Group	Individual	Total
Interviews, n (%)	6 (32)	13 (68)	19 (100)
Duration (minutes), mean (SD)	77 (23.4)	59 (16.0)	68 (20.0)
Participants, n (%)	13 (50)	13 (50)	26 (100)
Age (years), mean (SD; range)	43 (11.2; 26-59)	49 (9.2; 31-61)	46 (10.5; 26-61)
Job experience (years), mean (SD; range)	20 (9.1; 7-35)	26 (7.3; 9-37)	23 (8.6; 7-37)
Profession, n (%)			
Medical assistant	8 (57)	6 (43)	14 (100)
General practitioner	5 (42)	7 (58)	12 (100)
Gender, n (%)			
Male	4 (57)	3 (43)	7 (100)
Female	9 (47)	10 (53)	19 (100)

In addition to demographic characteristics and general questions about their profession, we asked participants about (1) their current organizational processes of delegating medical services in ambulant care, the role of (digital) technologies for these processes, and possible solutions for emerging difficulties; (2) their relationship to patients and how (digital) technologies shape or affect them; and (3) the reciprocity of self-perception and the use of (digital) technologies, that is, how participants' own understanding of their professional role affects their attitude toward (digital) technologies. The full interview guidelines can be found in [Multimedia Appendix 1](#). Note that not every question was asked during each interview. If a direct or indirect answer was given before the respective question was asked, it was skipped by the interviewer. In this way, we were able to reduce redundancy in the data and provide a more streamlined interviewing experience. Through these semistructured interviews, we intended to recreate the daily routines or processes of GPs and MAs regarding medical delegation and their use of technology to moderate or facilitate these routines. Subsequently, participants were asked about hypothetical scenarios involving the use of innovative digital technologies in the near or distant future, for example, video consultation or automated monitoring of medical parameters, such as blood pressure, blood coagulation, or blood glucose levels. Following previous theoretical and empirical work, we plan to outline insights into the use of innovative technologies to facilitate and assist delegation processes, as well as insights into the GPs'

and MAs' subjective perspectives and understanding of technological effectiveness.

Interview Data Collection and Analysis

The regional project in Germany, which included this study, involved 11 GPs' offices in rural areas. Following a purposeful sample [53], we included all 11 offices by conducting at least one interview (group or individual) with GPs or MAs from each office. The participating staff members from each office were contacted and interviewed by 2 different members of the research group (MK and MM). As identifying the differences between the perspectives of GPs and MAs on the use of innovative digital technologies in primary care was considered an important goal of this study, we focused on individual interviews with representatives of each profession. All interviews were conducted face to face between August and October 2019. In addition, we conducted a smaller number of focus group interviews. We did not change our aforementioned guidelines to ensure comparability throughout all interviews. Interviews were audio recorded, transcribed nonverbatim, and translated into English. As we were primarily interested in content-related insights, we did not conduct a sequential analysis and left out pauses and emotional or nonverbal sounds (such as sighs or laughter) from the transcription. The interviewees signed an informed consent form before the start of their interview.

To analyze the qualitative data, we followed a three-fold approach that was applied in a previous study in the health care domain [31]. First, 2 authors from the research group (MK and MM) independently coded each interview. On the basis of the grounded theory methodology proposed by Strauss and Corbin [54], the coding process comprises open, axial, and selective coding, which is described subsequently. This approach is particularly useful in this study because it performs well when inductively analyzing qualitative (unstructured) data with little or no previous knowledge. Hence, the highly explorative approach chosen in this study, combined with the lack of pre-existing research and insights about the phenomenon under investigation, qualified the grounded theory methodology as a fitting analysis paradigm. Following this procedure, each author started with open coding by intuitively assigning *in vivo* codes to the interview texts. Where possible, the first categories were formed by subsuming related open codes. Then, after going through each interview, axial codes were formed by categorizing open codes into broader schemes, thus achieving a higher level of abstraction. Next, superordinate, selective codes were formed that representatively subsumed related or redundant axial codes, which represented the theoretical core findings on a top level of abstraction. Therefore, two independent coding schemes emerged, each comprising selective, axial, and open codes. Second, in a process of comparison, the 2 authors discussed their coding schemes with regard to the research objectives and dissolved disagreements in code formulation and categorization, meaning, and code-to-text assignments. This step produced a reconciled coding scheme consisting of three overarching categories (ie, selective codes) that represent the essential findings of our qualitative analysis. In the third and final step, both authors each recoded the data by applying the novel scheme, followed by a conclusive discussion and approval of the coding procedure.

Survey Study

Overview

Owing to inconsistencies in the findings from the qualitative study, which are discussed later in the *Results* section of our qualitative findings, we decided to conduct a second data collection to explore latent dimensions of subjective technology valuation by GPs and MAs. Research shows that the combination of semistructured interviews and MDS appears to be a valuable approach to gain a deeper understanding of the differences in participants' subjective perceptions or underlying beliefs [55,56]. Therefore, we reached out to participants through a web-based survey conducted in March 2020. The survey consisted of demographics and a sorting question that asked participants to bring 10 different digital technologies into a hierarchical order following their perception of how relevant these technologies are or would be for their everyday work. The named technologies were derived inductively from our qualitative study and represented technologies that are already used for medical delegation by all offices or discussed purely for future use within our sample of 11 different offices. Therefore, these 10 technologies represent a combination of innovative digital technologies for primary medical care and technologies that were already in use by GPs and MAs. Table 2 lists the included technologies along with a short definition. Please note that the status of use in Table 2 (*technologies already in use*) reflects the time before or just at the beginning of the COVID-19 pandemic. Status of use was determined by the findings of our qualitative study and is defined by the categories *Yes* (technologies are used by all offices) or *No* (technologies are not used by any office).

To visualize and analyze nonmetric sorting data to build clusters and interpret the latent dimensions of valuation, we used MDS. Through this approach, we were able to further examine the aforementioned contradictions from our qualitative findings.

Table 2. Definition and summary of technologies used in the web-based survey to explore general practitioners' and medical assistants' latent dimensions of technology use.

Type of technology	Abbreviation used for analysis	Characteristics	Technologies already in use
Telemedical electrocardiogram (12-lead)	TeLECG	Records electronic signals of a patient's heart to assess the cardiac health status of a patient with the same quality as a stationary 12-point ECG ^a , but allows remote operation at a patient's home through MAs ^b and real-time data transmission to a physician	No
Electronic medical record	EMR	Collects and stores patient data electronically; helps to organize and structure medical care in clinical settings	Yes
Blood pressure monitor	BPM	Measures the blood pressure of a patient to assess information about a patient's cardiac or general health status; can be either electronic or manual	Yes
Blood coagulation monitor	BCM	Measures the coagulation level of a patient's blood; often used on patients taking medication to thin their blood after cardiac or neurological incidents	Yes
Telemedical stethoscope	TelSteth	Instrument to auscultate heart, lungs, or other body parts of a patient like a stethoscope, but allows remote operation at a patient's home through MAs and real-time data transmission to a physician	No
Mobile venoscope	MobVen	A mobile instrument to detect veins and venation through transillumination; facilitates the puncture of veins	No
Smartphone	SP	Mobile phone with computer-like functions, including verbal and text-based communication, internet access, camera use, navigation, and its own operating system	Yes
Blood glucose monitor	BGM	Measures the level of glucose in patient's capillary blood; mainly used on patients with metabolic diseases, especially diabetes	Yes
Digital appointment	DA	Audiovisual appointment (video consultation) between patient and general practitioner or patient and MA to digitally assess a patient's health status	No
Infrared thermometer	InfTherm	Measures the body temperature of a patient; indicates inflammatory processes in a patient's body, for example, infections	Yes

^aECG: electrocardiogram.

^bMA: medical assistant.

Survey Data Collection and Analysis

As this study aimed to determine the underlying dimensions of perception participants had to judge the value of a specific technology for their work, we contacted participants from our qualitative study and asked them to participate in our additional web-based survey. Therefore, we ensured a purposeful sampling approach within the same population of participants to draw conclusions from both data sets appropriately. Therefore, 2 members of the research group (MK and MM) contacted participants from the qualitative study who were then asked to participate in the survey study. The participants started the survey by providing their consent. From the initial 26 GPs and MAs participating in our qualitative interviews, 14 (54%) responded to our web-based survey, from which three data sets

had to be removed because of incomplete data. The demographics of the remaining 11 participants are summarized in [Table 3](#).

MDS originates from psychological research, which has been used as an explorative approach for determining latent dimensions of nonmetric or metric data. It has been applied in different contexts regarding technology use, such as to differentiate between types of e-marketplaces [57] or to address technology-related phenomena in organizational research [58,59] and, more recently, to explore latent dimensions for context-specific technology use, such as cyberdeviance [60]. Owing to its applicability to behavioral phenomena and its ability to operate with small sample sizes [61], MDS was selected as an applicable statistical method to enrich our insights from the qualitative interviews.

Table 3. Demographic information about participants from the web survey.

Characteristics	Values
Gender, n (%)	
Male	4 (36)
Female	7 (64)
Profession, n (%)	
Medical assistant	5 (45)
General practitioner	6 (55)
Age (years), mean (SD; range)	45 (12.3; 27-62)
Job experience (years), mean (SD; range)	21(9.1; 9-34)
Patient size of physician's office (number of patients treated per year), mean (SD; range)	4940 (1876.3; 1000-7600)

In an MDS configuration, objects are represented as points in a multidimensional space (usually 2D or 3D). The distances between the points correspond to the empirical dissimilarity of the objects [62]. Therefore, MDS transfers dissimilarity data into a geometrical configuration with m dimensions ($m \in \mathbb{N}$). Thereby, dissimilarity data can be represented by pairwise ratings of objects, intercorrelations, or hierarchically sorted preferences [62]. Through a specific mathematical algorithm, dissimilarity data are then used to generate an optimized one- or multidimensional configuration representing the starting point for theoretical reasoning. For our second data set consisting of technologies that participants sorted by their subjective perception of relevance for their daily work routines, we used a special type of MDS called multidimensional unfolding (MDU) [62,63]. MDU creates an optimized geometrical representation of participants, together with their subjective perceptions of technologies, enabling a visual interpretation of the latent dimensions of these perceptions. We used the R Foundation's statistical software R [64] with the package smacof [65] for statistical analysis. The geometrical configuration was calculated using the Euclidean distance function to define the distances between included objects. Euclidean distances were calculated using the formula for Minkowski distances $d_{ij}(X)$ while setting the distance's order $p=2$.

Euclidean distances allow an intuitive interpretation of geometrical configurations, as they represent our natural understanding of distances [63]. For instance, the Euclidean distance between two points in a 2D space is determined by a direct line between these points. In an MDU configuration, small distances represent high similarities between objects and vice versa. The dimensional suitability of our statistical solution was evaluated by comparing the *stress-I* values for different numbers of dimensions [62,66]. *Stress-I* values yield a normed indicator for the differences between the distances within the actual configuration $d_{ij}(X)$ and a function $f(p_{ij})$ with distances p_{ij} , called disparities, representing the ideal model for the empirical data [63].

Compared with error functions from other statistical methods, such as regression analysis, a minimization of the *stress-I* value (convergence toward 0) is desirable. Furthermore, we evaluated the number of iterations required to calculate the configuration.

Results

Results From Semistructured Interviews (Interview Study)

Overview

From our qualitative interviews with GPs and MAs, three main categories emerged for discussing the potentials of digital technologies in facilitating delegation processes: direct patient treatment, documentation and communication of treatment, and contrast of personal interaction and telemedicine. The main categories represent the highest level of content-related interpretation, following our approach for qualitative data analysis.

Direct Patient Treatment

Our first category reflects participants' perspectives on the important role of digital technologies for medical diagnosis and treatment through delegation. While recreating their daily work routines, GPs and MAs primarily described technologies that they already use to take direct measurements of medical parameters (mainly blood glucose levels, blood pressure, and blood coagulation levels) of patients in ambulant medical care. When considering the ongoing digitalization of the measurement of vital parameters (eg, continuous automated monitoring of blood glucose levels or the automated data transfer of blood pressure measures to a patient's GP), participants evaluated present and future scenarios based on accuracy and instantaneousness of measurement, as well as the usability of technologies. For the measurement of blood pressure, GPs and MAs primarily use a combination of blood pressure cuff and stethoscope, both manual technologies. As digital versions of these measurement tools are easier to use but do not provide the same accuracy, GPs and MAs continue to use manual technology:

Sometimes, a patient has horrible blood pressure measurements [while using a digital blood pressure monitor], so you go to visit him. Then you measure it [blood pressure of the patient] yourself and tell the patient to put a new battery in it or something like that, so maybe it will take a better measurement next time. [Interview 16, GP]

Concerning the measurement of blood coagulation levels, both GPs and MAs mentioned the importance of technological innovation for the feasibility of delegation processes in ambulant care and time-efficient treatment processes. In the past, GPs or MAs had to take blood samples through venous punctuation and send them to a medical laboratory to determine a patient's coagulation level. Digital versions of blood coagulation monitors can now instantly and accurately measure the parameters using capillary blood. Therefore, digital coagulation monitors are currently used almost exclusively for ambulant care:

In the past, . . . GPs had to visit the patients and had to take blood samples for coagulation, even before consultation hours. In the afternoon they had to see the patients again . . . it was very complicated, and now it's easy, isn't it? [Interview 15, MA]

Similar to blood coagulation levels, the blood glucose levels of patients are also usually measured with digital equipment, as only capillary blood is needed for an instant analysis and accuracy does not vary much in comparison to venous sampling. GPs mentioned that MAs were competent enough to assess whether a patient's blood pressure, blood glucose level, or blood coagulation level necessitated notifying the GP about the patient's health status. While discussing potential digital innovations for these kinds of technologies, such as automated data transfer or push notifications in case of an unusual deviation in a patient's vital parameters, GPs preferred receiving the subjective interpretation from an MA through a direct phone call, as GPs were likely to ask additional questions about a patient in a potential emergency case:

They [MAs] give me a call when something's wrong. . . . and they're very quick—quicker than some typed message that I maybe wouldn't hear. In this situation, automated data transfer isn't of any use. When a patient has a blood glucose level of 60 [hypoglycemia], they know what to do; they know it's too low and they have to do something. [Interview 14, GP]

Aside from already familiar technologies, participants discussed in detail the potential of two innovative digital technologies for ambulant medical care: mobile telemedical electrocardiograms (ECGs) and telemedical stethoscopes. In contrast to monitors for blood glucose levels, blood pressure, and blood coagulation levels, the interpretation of ECGs or auscultation sounds is highly complex and is usually not delegated to MAs. However, MAs are competent in recording patient data for the GP:

I can't evaluate it [ECG], that's the doctor's business . . . I can put it on a patient . . . and then I bring it to the office. There it's evaluated and the doctor decides what to do with it. [Interview 15, MA]

Therefore, a mobile version of an ECG that is able to transfer an ambulant patient's data in real time to the GP's office (hereafter called a telemedical ECG) was discussed in the interviews as an innovative technology that could be used in daily work. Mostly, GPs and MAs believed that this technology would be helpful in recording and analyzing a patient's ECG data remotely. Especially when an ambulant patient's medical issues occur spontaneously, MAs liked the idea because they could reassure themselves and the patient through a direct evaluation of the ECG data:

To transfer ECG data, that would be great. I'd like that a lot, I could imagine, to somewhat delegate medical problems . . . [Interview 2, GP]

Nevertheless, accuracy remained an important factor for GPs and MAs in deciding to actually use a telemedical ECG, as they emphasized the necessity of a telemedical ECG to generate a quality of medical data that are comparable with state-of-the-art stationary ECGs (12-lead). Although participants found the idea of a telemedical ECG highly interesting and relevant, the GPs were especially pessimistic about the cost-effectiveness. Owing to the high purchase prices and the lack of reimbursement by social health insurance, numerous GPs formulated resistance to actually purchasing a telemedical ECG:

If I had one [telemedical ECG], that would be really helpful, but you have to consider that I couldn't even charge something for the use of it. . . . So alas, it's a cost-benefit analysis once more. [Interview 18, GP]

Similarly, the opportunity to auscultate ambulant patients from a distance by instructing qualified MAs on how and where to put a digital stethoscope on the body of a patient seemed to be of high interest for GPs. By enabling the collection of medical data and real-time transfer to a GP's office, telemedical stethoscopes were seen by GPs as a likely way to save time:

Well, it surely would make my work easier, if I don't need to visit every older patient with a cold anymore, if I could just auscultate them remotely. [Interview 19, GP]

GPs and MAs mentioned that a telemedical stethoscope could be practical because of its variety of uses. Telemedical ECGs are used solely for medical issues involving functional cardiac abnormalities. Telemedical stethoscopes' indications include cardiac, pulmonic, and unspecific medical problems.

Documentation and Communication of Treatment

Our second category contains the participants' discussions of the potentials arising from digital documentation and communication. GPs and MAs emphasized the importance of mobility and ubiquity of information, but also mentioned hindrances for the sustainable use of digital technologies. While discussing the digitalization of communication about patients and their treatment processes, GPs and MAs pointed out the role of direct contact between GP and MAs in daily work routines. As MAs might unexpectedly encounter a patient with severe medical issues, all of the included GPs' offices provided an emergency call system. Thus, MAs can talk to a GP at any time if they think it is necessary. In addition, participants talked about the use of private messaging systems for cases in which

communication was not urgent. As one of the most recent widely discussed innovations in primary care, digital telemedicine systems that enable audiovisual communication (video consultation), combined with the remote transfer of medical data in real time (eg, telemedical stethoscopes) were perceived as helpful for delegation processes by GPs and MAs. Three different benefits were primarily associated with telemedicine systems: replacing a GP's home visit through digitally mediated delegation, improving (ad hoc) diagnostics in ambulant medical care, and reassuring MAs in ambulant medical care. Although GPs were skeptical about fully replacing direct bilateral contact with a patient through telemedicine, telemedicine-mediated interactions involving MAs were considered helpful in some situations:

If I could actually have a look at the patient, like in a video conference, and our medical assistant asks some additional questions and I got some relevant parameters, I could really imagine saying, "Well, the patient's all right; he's stable, so there's no need for me to visit him." [Interview 2, GP]

In addition, GPs mentioned that they would not rely on a patient's ability to use a telemedicine system for diagnostic purposes on their own; for example, as the use of telemedical ECGs might be complex, and potential misuse might lead to misleading information. Therefore, the medical competence of MAs was discussed as an important factor for using digital technologies to potentially improve ambulant medical care and overcome a patient's lack of competence in adequately using such technology. Telemedicine systems were considered by MAs to be useful as an innovative channel of communication that can help to better determine the potential diagnosis of a patient after they initially assess the patient's health status:

If I could send some data directly to the doctor, that would make things easier. So that telemedicine, when I put on an ECG, the doctor might tell me from his desk, if it's alright or not, if we have to call an ambulance or if he needs to visit the patient by himself. [Interview 10, MA]

Through telemedicine systems, MAs saw the possibility of contacting a GP regarding a medical situation that they were not fully able to assess. Closely related to the improvement of the quality of a diagnosis in delegation processes, telemedicine seemed to provide a feeling of security and reliability:

When facing a critical situation, I think it [video consultation] could help me to feel safe. Because I'm usually alone on-site . . . I think I would be more confident when I think the patient's not looking good, I better turn it on and the doctor sees what I see. [Interview 6, MA]

Although telemedicine systems, therefore, appear to be helpful for direct communication in ambulant medical care, health records are used to collect and sort patient information and data over a longer period of time. Participants discussed the use of mobile electronic health records (EHRs), and MAs especially pointed out the importance of having access to relevant patient health records in ambulant medical care. As direct contact with a GP is usually reserved for critical situations, MAs discussed

their need for a medium through which to collect relevant information about a patient's health status. Although all participating offices installed some type of EHR in their systems, remote access to patient information seemed to be difficult, as mobile versions of EHR were not installed on suitable devices or their actual use was impractical. Nevertheless, participants emphasized the potential benefits of easy-to-use mobile documentation that could make manual documentation obsolete:

. . . and then I write it down, write it all down and sometimes I can't figure out my handwriting afterwards and therefore it [mobile EHR] would be useful. So you can write it down directly and be connected to a patient's entire medical history. [Interview 18, MA]

Although some participants mentioned that manual documentation was carried out very quickly while making home visits, most participants reported the necessity for double documentation later:

. . . here [doctor's office], you're sitting for hours to write down everything you did on home visits. It takes a lot of time. So, if you could just make your documentation while you're still on home visits, that would save a lot of time. [Interview 9, MA]

Furthermore, GPs remarked on the lack of interoperability, not only between mobile software apps and applications in their office but also between their own documentation software and the software used by hospitals, nursing homes, or other GPs. Especially when patients move from clinical to ambulatory care, GPs pointed out that transferring the patient's clinical data or updating medication takes a lot of time because the inability to transmit records electronically means that it must be done manually:

When a patient comes to me with his clinical reports, that's a catastrophe. You get hand-written reports, . . . you have to transfer into the EHR. Also, it doesn't work with ambulant nursing care, it doesn't work with nursing homes. [Interview 8, GP]

Communication and documentation technologies seem to be essential factors for a dynamic and uninterrupted workflow, from the perspectives of GPs and MAs. Although telemedicine systems enabling audiovisual communication between the GP, MA, and patient or real-time remote transfer of medical data (ECG and auscultation sounds) are recognized as helpful digital innovations, the digital technologies that are already in use (EHR) do not seem to have reached their full potential because of a lack of interoperability and user-friendly mobile apps.

Contrast of Personal Interaction and Telemedicine

In our third category, we subsumed participants' discussion of the risks and limitations of digital technologies concerning team-based primary care and the interaction between them and patients. Aside from considerations about the usefulness of digital technologies regarding direct patient interventions or superordinate processes of medical care, participants perceived the use of technology as contextual, that is, directly or indirectly embedded in a specific social interaction. Although the positive aspects of telemedicine system use were discussed, most

participants were skeptical about replacing direct physical interaction with digitally mediated interaction:

It makes a difference . . . It's not the same. I think the gold standard is a direct encounter, to be in the same room; that's just different to [audio-visual telemedicine]. [Interview 4, GP]

Participants further differentiated the limitations of telemedicine use into those resulting from a perceived restriction of relevant patient data (eg, skin conditions, walking behavior, or general appearance) and those resulting from the absence of bodily contact itself. In particular, GPs emphasized their need to use multiple sensory inputs to correctly diagnose a patient:

Well, I don't know how he [the patient] smells, I can't have a look at his skin. Is he sweating? Is his skin cold not supplied with enough blood? I want to examine him [physically]. And these are things that are most relevant for the diagnosis you find, in the end. For me, it plays an important role. [Interview 7, GP]

Some MAs argued that not only is the ability to evaluate the physical conditions of a patient reduced by digitalized home visits but also the ability to evaluate environmental factors, such as the general condition of a patient's home or the presence of objects that could potentially increase the fall risk in older patients:

Also, it's about fall risk; I have an eye on that. There might be a new carpet, causing a risk or cables lying in a patient's way. I talk to the patient about these things, or his relatives. [Interview 8, MA]

Aside from more objective limitations, GPs and MAs discussed the meaning of bodily contact with a patient as a part of the social interaction itself. Participants mentioned the importance of direct contact with patients, not just to medically treat them correctly and comprehensively but also to form a relationship with them. Participants were not able to completely explain what underlying assumptions lead them to the impression that a direct, nondigitally mediated interaction is preferable to the use of telemedicine for the purpose of social interaction. Nevertheless, they emphasized the advantage of direct contact with the patient to build a relationship in which trust can be created and patients feel safe to talk about personal problems:

The bodily presence. The contact . . . , especially for older patients. My job is especially about old people. They need it. Or maybe some joking or something like that. You won't do that when you're on the computer. When you're sitting directly with each other, then some things are discussed. And that's missing while using telemedicine. If everything was to be digital, something would be missing. [Interview 10, MA]

In contrast, participants also considered the social effects that the use of technology itself has on patients, for example, the feeling of security and control when blood pressure or blood coagulation are being monitored. In particular, GPs compared the positive effect of technological use on patients with the placebo effect known from medication:

The patient has a good feeling, then. Technology is always great. Something beeps, some additional measurement for some specific symptoms. Technology has something like a placebo effect. [Interview 5, GP]

In addition, participants assumed that technology adoption by patients was highly affected by the attitude of the attending GP or MA. Participants reasoned that the technological adoption of patients might depend on the formulated medical necessity and the explanation given by the GP or MA:

But they don't really ask many questions about it [long-term blood pressure monitor or ECG]. We tell them how it is done, how it works. And then it's all right, so it's very uncommon that someone asks questions about it. They rely on what we said about it. [Interview 10, MA]

In summary, GPs and MAs were aware of the factors that influence the relationship between them, the patient, and the use of technology. Participants reflected on the potential effects of innovative technologies on social interaction and discussed the limitations from their point of view. Interestingly, our three main categories, therefore, represent three different dimensions of technological use in ambulant medical delegation: (1) an interventional dimension involving direct patient contact, defining the action of care; (2) a superordinate dimension of communicating and documenting care; and (3) a reflective social dimension in which participants discussed contextual and relational factors of technology use.

In the process of analyzing and summarizing the qualitative findings from the focus group and individual interviews, contradictions were identified between the interviewees' perceptions of innovative technologies and technologies that were already in use. Several times during the interviews, participants seemed to reject innovative technologies (eg, telemedicine systems used to contact patients from a distance) while using specific arguments (eg, risk of private data misuse) that they did not apply to technologies that were already in use (eg, smartphone use to communicate patient data). As the underlying mechanisms of subjective technology valuation must be considered an important factor for technology use [67], in an effort to answer our initial research questions, we decided to conduct our survey study to explore latent dimensions of subjective technology valuation by GPs and MAs.

Results From MDU (Survey Study)

By applying MDU, we explored the underlying dimensions of the GPs' and MAs' perceptions of the usefulness of relevant technologies in facilitating the process of delegation in medical ambulant care. Qualitative results suggest the various categories and factors that GPs and MAs use to evaluate different types of technologies; the subjective motivation and individual perception of technologies help to fully understand and explain the behavioral intention and the actual use of technology by medical professionals. By merging the results from both the qualitative and survey studies, we intended to contribute to a comprehensive understanding of the role of digital technologies in primary care delegation processes.

To determine the number of dimensions that are appropriate for interpretation, we analyzed the *stress-1* values as well as the number of iterations for different MDU configurations (Table 4). Although values for *stress-1* decreased with greater numbers of dimensions, iterations for dimension *m=4* reached its maximum of 10,000 and were excluded after visualization from potential solutions because of its obvious triviality. For all calculated configurations, we followed the suggestions of de Leeuw et al [65] and Busing et al [68] to avoid degenerate solutions.

As it showed the lowest *stress-1* value, we selected the configuration with *m=3* for further analysis and interpretation. As a *stress-1* value of 0.18 represents an approximately correct solution, we tested the reliability of the configuration in relation

to the data by calculating a random solution for *m=3* (number of iterations=1) and compared it with the initial configuration [63]. The random solution had a *stress-1* value of 0.38. As the *stress-1* value of our initial 3D configuration appears to be much smaller [63], we considered our result to be satisfactory. Figure 1 shows a 3D depiction of the resulting configuration.

To provide a possible interpretation of our results, we changed the angles of our selected configuration and fixed one dimension after another (Figures 2-4) using the R package *scatterplot3d* [69]. Demographic control variables (eg, age or gender) did not lead to a sufficient explanation of the following dimensions and were therefore not discussed as potential criteria for interpretation.

Table 4. Summary of different configuration characteristics.

Dimension	Number of iterations	<i>stress-1</i> value
1	12	0.41
2	62	0.24
3	113	0.18
4	10,000	0

Figure 1. 3D configuration of technologies and participants to visualize the perceived technological relevance for daily work routines (numbers represent participants, words represent different technologies). BCM: blood coagulation monitor; BGM: blood glucose monitor; BPM: blood pressure monitor; DA: digital appointment; EHR: electronic health records; InfTherm: infrared thermometer; SP: smartphone; TelECG: telemedical electrocardiogram; TelSteth: telemedical stethoscope.

BCM: blood coagulation monitor; BGM: blood glucose monitor; BPM: blood pressure monitor; DA: digital appointment; EHR: electronic health records; InfTherm: infrared thermometer; SP: smartphone; TelECG: telemedical electrocardiogram; TelSteth: telemedical stethoscope.

Figure 4. 3D configuration with fixed third dimension (numbers represent participants, words represent different technologies). BCM: blood coagulation monitor; BGM: blood glucose monitor; BPM: blood pressure monitor; DA: digital appointment; EHR: electronic health records; InfTherm: infrared thermometer; SP: smartphone; TelECG: telemedical electrocardiogram; TelSteth: telemedical stethoscope.

In Figure 2, we propose the underlying dimension *hypothetical* and *actual frequency of use*: innovative digital technologies that were not yet in use at the time of data collection, such as telemedical stethoscopes and ECGs or video consultation, are sorted to the left of the dimension *frequency of use*, whereas

frequently used technologies, such as blood pressure or blood glucose monitors, are sorted to the right. Notably, the venoscope appears to be near innovative digital technologies that were not yet in used at the time of data collection, as GPs and MAs of our sample usually do not use it in ambulant medical care.

Therefore, the perceived relevance of technological use seems to be strongly associated with daily work routines and the possible incorporation of specific technologies. Although most of the participants are sorted to the right, meaning that they tend to find the technologies that they already use to be relevant, participants 1, 7, and 8 are sorted near innovative digital technologies. Therefore, most participants take into account their current behavioral routines when evaluating the relevance of a specific technology, whereas a minority of participants forecast a frequent use of innovative technologies whose characteristics and benefits they only assume but do not have experience with.

Considering [Figure 3](#), we propose *technological objectivity* as an explanation for the second dimension. Except for the infrared thermometer, technologies sorted on the right, such as telemedical ECG or blood coagulation monitor, measure a patient's more objective medical parameters, whereas technologies to the left, such as smartphones or EHR, are not used to directly assess a specific medical parameter, but rather to facilitate the communication and documentation of care. Participants are distributed more equally among the second dimension than among the first dimension, indicating that the perceived relevance associated with *technological objectivity* is a more subjective factor and that participants have a relatively ambivalent perspective on *technological objectivity*. Furthermore, an accumulation of most participants in the middle could indicate that *technological objectivity* might not directly increase the subjective relevance of technology use but that it depends on the specific context in which the technology is used. Overall, this dimension might represent the individual perspective of participants regarding the relevance of objective medical data.

Finally, we propose *benefit for a patient's health status* as an explanation for our third dimension. Considering the technologies that appear at the bottom of [Figure 4](#), for example, blood coagulation monitoring or telemedical stethoscope, participants might connect the characteristics of these technologies with the benefits they could have for a patient, especially in critical medical situations, as blood coagulation levels or auscultation sounds are strong indicators of a patient's health. Seemingly distorting our interpretation of the third

dimension, the arrangement of smartphones and EHRs toward the bottom of our configuration might be explained by the smartphone's ability to connect the user to other medical professionals, especially in a medical emergency. Meanwhile, an EHR could be essential for GPs or MAs in interpreting or classifying specific symptoms of a patient with regard to their medical history and, therefore, essential in arriving at an appropriate diagnosis, especially in critical situations. Participants accumulate in the middle of the third dimension, indicating that the perceived benefit from a patient's perspective can be seen relatively within a specific range of interpretation. Therefore, the third dimension of our configuration partially represents the professional identity of GPs and MAs and their motivation to use (digital) technologies arriving at a specific treatment objective to create a benefit for patients.

In accordance with the initial objective of our survey study, our results suggest three latent dimensions of subjective technology valuation by GPs and MAs. First, participants appear to assess the (potential) value of a technology by its extent of practical implementation, that is, the *hypothetical* and *actual frequency of use*. Second, the purpose of a specific technology appears to be another major reference for participants to decide whether a specific technology is relevant to their daily work routines or not. Here, participants differentiated between technologies primarily assessing objective medical parameters and those primarily used to communicate or document, that is, *technological objectivity*. Finally, the subjective valuation of technology appears to be dependent from the participants' impression of whether it creates values from the perspective of patients and their treatment, that is, *benefit for a patient's health status*. [Figure 5](#) represents the final 3D configuration, including our interpretations.

To ensure that the dimensions of participants' perceptions are valid, we discussed and reflected our findings from MDU with 17 physicians and MAs from our sample, as recommended by the literature [[56,57](#)], during a project-related workshop in November 2020. Participants confirmed our results from their professional perspective by emphasizing that our derived dimensions are plausible factors for their perception of technological relevance and effectiveness.

Figure 5. 3D configuration with interpreted dimensions (numbers represent participants, words represent different technologies). BCM: blood coagulation monitor; BGM: blood glucose monitor; BPM: blood pressure monitor; DA: digital appointment; EHR: electronic health records; InfTherm: infrared thermometer; SP: smartphone; TelECG: telemedical electrocardiogram; TelSteth: telemedical stethoscope.

Discussion

Overview

Reflecting the results from both the semistructured interviews and the survey study, we discussed the role of medical delegation for future primary care and the preconditions for a sustainable and effective implementation. Thereafter, we reasoned about specific aspects that are worth considering in the process of digitalizing primary care through mediated delegation and are needed to reflect possible (unintended) changes regarding the interaction between patients and medical professionals, that is, the subjectivity of medical data and the key role of MAs. Finally, we discussed possible challenges in the process of digitalizing primary care through mediated delegation and implications for theory and practice.

Mediated Delegation

As it is an essential prerequisite for multi-actor care processes, our data show that GPs attribute high degrees of competence and expertise to MAs when it comes to assessing a patient's health status and interpreting symptoms and parameters. Hence, MAs can pre-evaluate patient data and communicate it to the GP. In this process, both sides benefit from the integration of telemedical tools, such as digital measurement equipment and sensors, as the objective data they produce better inform the assessment of MAs. As a result, these tools expand the scope of what a GP can delegate and what an MA can actually do on site with the patient. As proposed by the diffusion of innovations model [70], the adoption of a technology also depends on the type of decision-making process. In particular, collective evaluations and decisions as they are made in multi-actor networks can facilitate higher adoption rates once required attributes, such as compatibility, are universally perceived. Here, compatibility plays a major role as the MA's competencies and working styles as well as the technology used need to fit the delegated task and requirements—both on an organizational and medical level—that come with it. Accordingly, the symbiosis of an MA gathering subjective and valuable impressions of the patient and technologies collecting objective data enables a more holistic image of the patient to be given to the GP, as our findings indicate that data of both subjective and

objective nature are essential to arrive at a proper diagnosis and successful treatment protocol.

Demands and Requirements on Digital Technologies for Telemedicine

Another important factor that underlies the GPs' and MAs' perceptions of the use of technologies in direct patient care is the accuracy and instantaneousness of the applied sensors, the devices, and the resulting data. The participants stressed that the accuracy and quality of data is a major prerequisite for using digital technologies. For the evaluation of practicability and usefulness, GPs and MAs seem to consider the quality of medical data generated from a specific technology. Although usability might be relevant for technology use in general, participants rejected easier-to-use digital technologies because of their perceived lower precision. Furthermore, the objectiveness of technology is associated with participants' subjective perceptions of technological relevance, implying that the development of digital technologies for measuring medical parameters should address not only innovative ways to measure but should also ensure at least a constant quality of data compared with already elaborated technologies and procedures. Moreover, the consideration of legal frameworks or boundaries at an early stage in the development process might increase the adoption of innovative digital technologies because of the GPs' desire for cost-effectiveness, as the reimbursement of technology-mediated treatment by (social) health insurance companies seems to be an important factor for medical professionals when assessing a technology's usefulness [71]. In addition, financial support for the implementation of innovative technologies by public institutions might be a vital measure to counter the increasing workload and complexity of primary care. These findings align with current research on the success of eHealth interventions, identifying limited financial resources as a major obstacle [72].

Subjectivity of Medical Data

When it comes to the interpretation of medical data, our results suggest that GPs and MAs consider several subjective and environmental factors to be highly relevant, such as the state of a patient's home, medical history, or complex sensory impressions. Although common telemedical solutions such as

video consultation systems enable practitioners to derive an initial picture of the patient based on what the camera captures and what the patient verbalizes, such technologies are still perceived as limited [73], particularly by hindering the continuance of care [74]. With digital technologies enabling the remote evaluation of a patient's health, the importance of combining or merging different technological characteristics becomes apparent, that is, the development of multichannel systems to provide not only quantified data but also a comprehensive image of a patient as well as platforms or opportunities for social interaction between the GP, MA, and patient. Consulting the diffusion of innovation model [70], it becomes apparent that a high level of complexity that comes with introducing a novel technology into multi-actor processes, paired with a lack of observability due to subjective assessments, highly individual routines, and tacit knowledge of involved actors, can further hamper the comprehensive adoption of telemedicine in multi-actor environments. Here, the complementary approach consisting of multi-actor care services and digital technologies facilitates the holistic assessment of the patient's health status and symptoms, as subjective impressions are augmented with digital measurements. As a result, the limitations of telemedicine are partially mitigated by the personal interaction of an MA with the patient, which in turn can lead to higher use intentions and adoption rates in the medical domain. Nevertheless, our findings show that a simple replacement of physical interaction between patient and MAs or GPs with digital interaction might lead to decreasing quality of care, because of a restriction of sensory information (eg, the state of a patient's environment, odors, or mobility) and the absence of physical contact to suggest caring [73]. At worst, a strategy of digitalizing primary care only from the perspective of economical effectiveness might lead to the discrimination of vulnerable groups, such as older, chronic, and immobile patients treated through ambulant primary care.

Telemedicine and the Key Role of MAs

The findings further indicate that the degree of responsibility and accountability with regard to actions performed by MAs when visiting a patient at home increases through the application of supportive telemedical tools. The data show that an MA, who is equipped with digital technologies such as telemedical stethoscopes or telemedical ECGs, is empowered to conduct a broad spectrum of diagnostic measures in a more autonomous and deliberate way. As a side effect, the presence of a supportive technology provides additional assurance to the MA as it augments the MA's subjective assessments with objective data, for instance, in the form of vital parameter measurements and visualizations. Furthermore, digital ICTs are able to reassure MAs by providing an enhanced amount of information about a patient, for example, mobile apps of EHRs or an enhanced remote interaction between the GP, MA, and patient by bridging spatial and temporal limitations [75]. Another interesting implication drawn from our results is that an MA potentially possesses high degrees of both medical and technical competence. Hence, in multi-actor treatment settings involving GPs, MAs, and patients, an MA who is skillful in using, understanding, and explaining digital technologies and their purpose is able to bridge gaps in technology competence and

adoption behavior that occur on both the side of the care provider (ie, GP) and the side of the consumer (ie, patient).

Considering the major challenges that arise from the individual use of telemedicine, such as the insecurity of patients (and their relatives) to assist in a remote examination by manipulating technology [76], our findings suggest that technology-mediated delegation might be a suitable way to improve workflows of primary care physicians and address issues that arise from remote consultations. In general, the literature has shown that practitioners, as well as patients, have certain reservations when it comes to forming attitudes and use intentions toward digital health care technologies. On the professional side, empirical results indicate that some GPs think that a large portion of their patients, especially older patients, are not able to operate digital technologies, which hinders the effectiveness and progress of treatments [77]. On the patient side, low technology adoption rates can occur, *inter alia*, because of the desire to maintain a personal and direct relationship to their GP or the lack of familiarity with the respective technologies [71]. In many cases, patients do not see the benefit that digital technologies can have on their treatment and, thus, also on their health status and progression, because of their preuser status and unfamiliarity with innovative digital health care technologies [78,79]. Therefore, the integration of factors related to technology adoption in multi-actor settings, such as external perceptions of technological competence, might provide theoretical insights that could explain variations in the explanatory power of elaborated acceptance models with regard to health care technologies [47]. In this regard, our results indicate that the approach of combining multi-actor treatment settings with supportive digital technologies can bridge structural and perceptual gaps as well as a possible digital divide. As telemedicine becomes increasingly important for primary care, older patients may face disadvantages with regard to the delivery of vital care because of the underutilization of internet use and digital technologies [74,80]. Patients are no longer obliged to adopt technologies themselves and can stick with familiar treatment patterns while maintaining direct personal contact with the treating person. Especially for older patients or patients with chronic diseases lacking competence or interest in digital technologies [74,81], technology-mediated delegation might be an essential step to adopt innovative digital approaches to primary care. In addition, GPs are more likely to integrate technological tools into their working routines, as they trust their MAs to use them efficiently. Hence, the perceived lack of willingness and the ability to adopt digitalized treatments can be resolved.

Challenges Regarding Telemedicine Adoption

Furthermore, our results suggest that the adoption of digital technologies by GPs and MAs may be partially explained by the theoretical concept of bounded rationality. Considering the assumption that human decisions are not entirely based on a rational balancing of costs and benefits, but on heuristics and cognitive simplifications as well [82], the tendency to prefer familiar technologies, called the status quo bias, is known to have a powerful effect and could explain user resistance [83]. Most participants in our studies found the technologies that they had already learned how to integrate in their daily work routine

especially relevant and, therefore, potentially assessed the subjective relevance of unfamiliar digital technologies, such as telemedical applications, from the perspective of their status quo. While anchoring their subjective perception of usefulness and relevance to familiar technologies [84], technologies containing innovative characteristics that are dissimilar to elaborated ones are possibly rejected. Thus, considering that the evaluation and adoption of technologies partially depend on heuristics in decision-making that are often applied subconsciously and are thus difficult to externalize and become aware of [85], additional barriers occur that potentially hamper the comprehensive adoption of telemedicine in multi-actor care. Therefore, to increase the attraction of innovative technologies in primary care, providers might consider the importance of the integrability of their products into the existing routines and communicative structures of their customers. The possibility of using digital technologies without an obligation to eventually buy them might hold an opportunity for customers, that is, GPs and the staff of their practices, to experimentally incorporate a new technology to overcome the status quo bias and the anchoring effects to which they are subject. On the contrary, as the aforementioned heuristics serve the goal of making fast and efficient decisions and in the light of lacking information regarding the application and performance of a given technology [86,87], it should be further taken into account that in some specific cases, digitally complementing treatments in multi-actor care do not represent a feasible and effective way of making things better, but instead introduces new forms of overhead and uncertainty.

Theoretical and Practical Implications

Through our empirical findings, we provide insights into digital technologies and their potential for multi-actor delegation processes in primary care in relation to research, medical practice, and the development and design of technology. For theoretical reasoning, our paper points out several factors that are relevant for expanding the understanding of technology use by medical professionals. Within the context of multi-actor approaches to delegation in primary care, the results suggest that MAs facilitate the use of and access to health care technology for patients. There, MAs might even be able to compensate for a possible lack of technological competence or skills and for the resistance of patients bypassing obstacles related to usability [88]. In this regard, our results may be used to expand or contextualize theories concerning technological adoption used for telemedicine [47], such as the Technology Acceptance Model or the unified theory of acceptance and use of technology. Technology adoption and use appear to be reciprocal processes involving external perceptions of patients and their hypothetical reactions to the use of digital technologies by medical professionals, which might be considered to enrich theoretical models. In addition, we explored an anchoring effect [84] concerning the adoption of unfamiliar technologies by GPs and MAs, indicating that the adoption of digital technologies in health care might comprise cognitive biases that need to be further differentiated and operationalized to improve the predictive power of elaborated theoretical models.

From a practical point of view, our findings indicate a strong potential and benefit of using digital technologies, especially

those used for telemedical examinations and video consultation for delegation processes in ambulant primary care. This holds not only for GP-MA interaction but also between GPs and nurses or registered nurses and nursing assistants. Owing to a shift in the organization of health care that can be noticed in North and Middle European, or North American countries, the relevance of team-based primary care increases [89-91]. Our study suggests that technology-mediated delegation and care processes might be a suitable way to ensure comprehensive personal care and effectively deal with the challenges of time pressure, increasing case complexity, and shortage of medical professionals. In this regard, our results are valuable for the strategic alignment of health care providers, health insurance companies, companies developing telemedicine applications, or politics. Moreover, the potential discharge of health care systems' resources through differentiated and needs-based care has become increasingly important with respect to the ongoing COVID-19 pandemic. The ability to guarantee adequate care for patients at home through MAs utilizing telemedicine might increase time-efficient treatment and accurate monitoring of patients while decreasing inequalities concerning personal technological competence or affinity between younger and older patients. Within the multi-actor processes of primary care, digital technologies can enrich the subjective assessment of a patient by optimizing the objective measurements of medical data and by providing a more effective way to communicate and document. By comprehending the subjective interaction between MAs and patients, specific prerequisites for innovative digital technology use might change or be omitted because of the medical and technological competence of MAs. Nevertheless, our study suggests that the accuracy and reliability of the technology remain an important factor for medical professionals.

Limitations

The results of our paper were bound to relatively small sample sizes. Although the explorative nature of our research objective matched our chosen methods of data collection and analysis, a potential bias might emerge from the fact that both studies were drawn from the same sample. In addition, data from our survey study represent only a part, but not the entire sample of our interview study, resulting in limited generalizability within the respective sample. Although GPs and MAs ensured the validity of our results from our survey study, our findings might partially reflect the tendency to confirm existing knowledge (from our interview study), rather than disprove them, known as confirmation bias [92]. Therefore, our selected method for data analysis (MDU) generally implies the risk of subjective interpretation and needs to be discussed in future research. Furthermore, as all participants in our studies were associated with a regional project on the digitalization of health care technologies for delegation processes in ambulant medical care, participants might represent opinions and perceptions that tend to be more optimistic and interested in the ongoing process of digitalization. In addition, we concentrated on a sample related to specific characteristics, that is, GPs and MAs in rural German areas. To extend the validity of our findings, a quantitative approach with a large sample size might provide insights into the generalizability of our findings and optimize the representativeness of our MDU model. As our study provides

insights into the process of technology adoption through incorporation and shows the importance of practical experience for technology adoption, an interventional pre-post study might further enrich our findings.

Conclusions

Our study explores the potential of using digital technologies in primary care delegation processes. Interviews with GPs and MAs revealed the complex situational role of technology within these delegation processes. Although the results suggest that the importance of ICT is increasing because of its ability to remove spatial and temporal limitations, telemedical solutions appear to be promising, as they enable video consultation or automated transfer of medical data. In addition, telemedical solutions have the potential to facilitate direct patient treatment by merging medical and social competence to overcome

demographic and structural changes, as well as to overcome deficits in patients' technological competence. Therefore, digital technologies assist in finding innovative, case-sensitive, and cost-effective methods of treatment in primary care. Nonetheless, our study revealed the contextual nature of technology use in primary care. The adoption and implementation of technology underlie reciprocal processes involving different attitudes and perceptions within multi-actor settings. Furthermore, the results suggest that these attitudes and perceptions might be biased because of the underlying needs for action that are unique to medical treatments. Consequently, our study provides a foundation for further investigation of relational characteristics within multi-actor settings in primary care. Finally, practical suggestions are made to improve the development and distribution of innovative technologies for medical delegation processes.

Abstract

Background: In rural communities, there are gaps in describing the design and effectiveness of technology interventions for treating diseases and addressing determinants of health.

Objective: The aim of this study is to evaluate literature on current applications, therapeutic areas, and outcomes of telehealth interventions in rural communities in the United States.

Methods: A narrative review of studies published on PubMed from January 2017 to December 2020 was conducted. Key search terms included telehealth, telemedicine, rural, and outcomes.

Results: Among 15 included studies, 9 studies analyzed telehealth interventions in patients, 3 in health care professionals, and 3 in both patients and health care professionals. The included studies reported positive outcomes and experiences of telehealth use in rural populations including acceptability and increased satisfaction; they also noted that technology is convenient and efficient. Other notable benefits included decreased direct and indirect costs to the patient (travel cost and time) and health care service provider (staffing), lower onsite health care resource utilization, improved physician recruitment and retention, improved access to care, and increased education and training of patients and health care professionals.

Conclusions: Telehealth models were associated with positive outcomes for patients and health care professionals, suggesting these models are feasible and can be effective. Future telehealth interventions and studies examining these programs are warranted, especially in rural communities, and future research should evaluate the impact of increased telehealth use as a result of the COVID-19 pandemic.

KEYWORDS

telehealth; telemedicine; rural health; health outcomes; social determinants of health; eHealth; health care accessibility

Introduction

Health care is increasingly becoming a technology-driven environment. Telehealth is a remote health care service delivery method and allows for real-time communication between a patient and health care provider [1]. Telehealth is an alternative model of health care service delivery; specifically, it provides

opportunities to expand treatment access and reduce barriers to care in underserved and rural areas. Telehealth has been used to promote healthy behaviors and condition management, and there have been promising effects observed, including increasing patient participation and satisfaction and reducing rates of chronic illnesses. In one study, ter Huurne et al [2] conducted a web-based technology study to improve health care service

for individuals with chronic eating disorders. In their study, which used a web-based treatment program to improve health care service, 54% of participants completed all program tasks and assignments, and the program significantly improved BMI, body dissatisfaction, quality of life, and physical and mental health [2].

Telehealth is a convenient approach for patients to access health care in the comfort of their own home. Kruse et al [3] conducted a literature review to examine the association of telehealth and patient satisfaction in terms of efficiency and effectiveness. The review concluded that telehealth decreases travel time, improves communication with providers, increases access to care, increases self-awareness, and empowers patients to manage their chronic conditions [3]. From a health care system and provider perspective, benefits include decreased missed appointments, decreased wait times, decreased readmissions, improved medication adherence, and improved quality and timeliness of patient care; in addition, telehealth is a good modality for education [3]. Physician shortage and burnout are common and significant issues in rural areas that can be alleviated by telehealth. Ward et al [4] found that 75% of family physicians in rural areas were covering local emergency departments (ED) as a condition of their practice or hospital privilege. Mandating these conditions discourages physicians from practicing in rural areas; however, the study concluded that telemedicine may help improve the chronic rural workforce shortage by improving physician recruitment and retention [4].

Residents of rural communities across the United States include some of the most vulnerable populations, including individuals with low socioeconomic status, Indigenous communities, children and older adults, and individuals with disabilities [1]. People living in rural communities have limited access to health care, travel long distances to receive care, and/or delay care until after they have a health emergency. Limited access to health care can result in poor health outcomes and is a social and economic burden for both the patient and the health care system. The cost associated with traveling for medical care places an additional burden on the patient, including incurring additional costs for traveling to visits, lost work hours, lower productivity, and increased costs associated with caregiver or childcare support [1]. Telehealth extends the reach of health services and provides the opportunity to reduce barriers to care in rural communities.

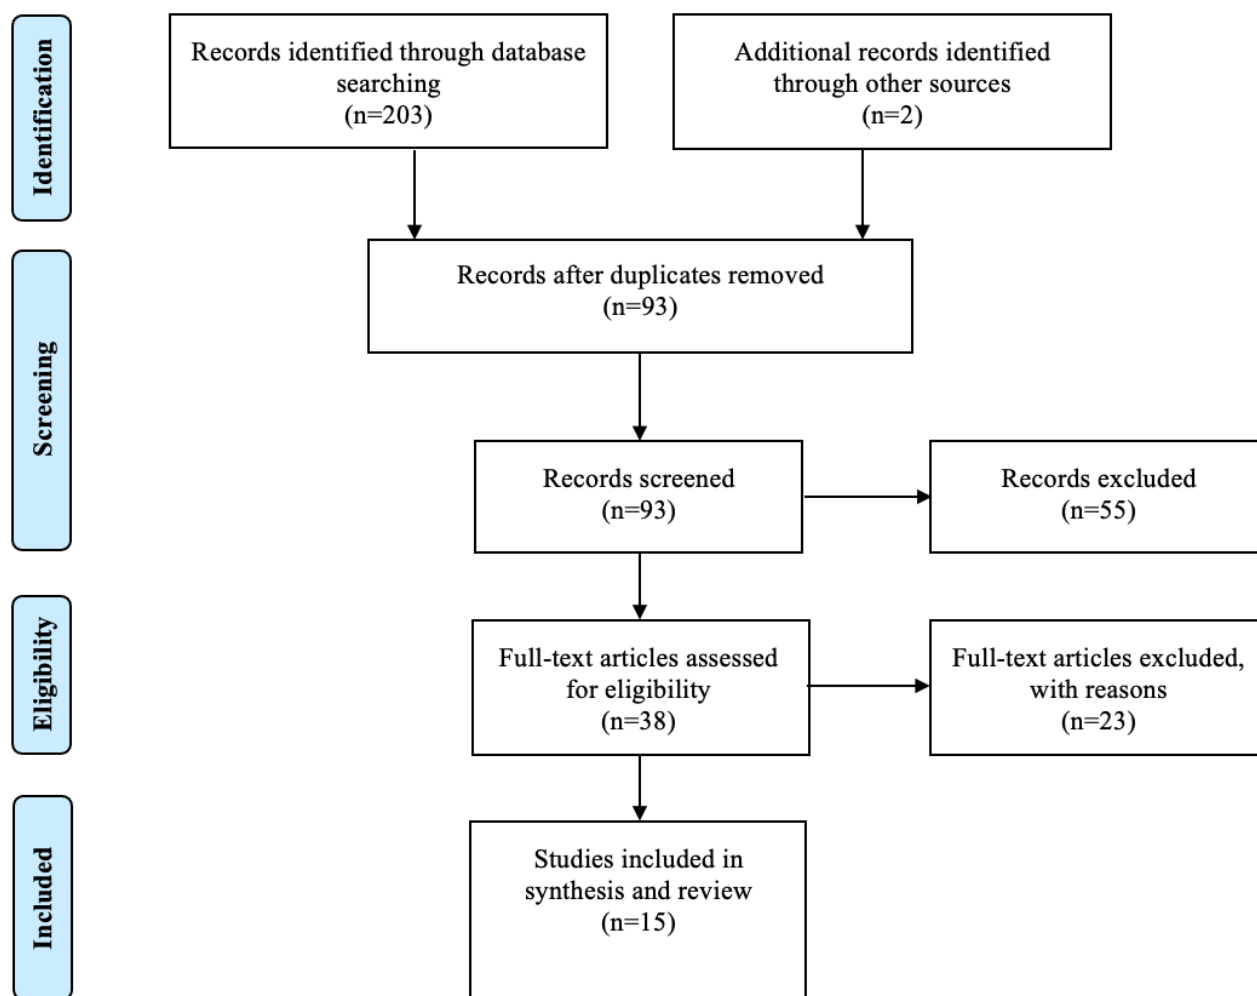

The literature assessing the effectiveness of telehealth practices remains ambiguous and many technology interventions are unverified. In rural communities, there are gaps in describing the design and effectiveness of technology interventions and best practices for preventing and treating specific diseases and addressing determinants of health. Synthesizing the current scope and application of telehealth is critical for guiding future interventions and policies. For this article, we defined telehealth as both telehealth and telemedicine and will include mobile

health and digital health solutions: electronic health, telemedicine, artificial intelligence, electronic medical record/portal technology, videoconferencing, wearables and biosensors, and remote monitoring tools. The objective of this study was to review and evaluate literature published on the current applications, therapeutic areas, and outcomes of telehealth interventions in rural communities in the United States.

Methods

For this narrative review, we searched PubMed MEDLINE from January 2017 to December 2020. Key search terms included (“telehealth” AND “telemedicine”), “rural” AND “outcomes.” Filters were applied to identify free full-text studies published in English over a 4-year period to include the most recent evidence available in this research area. We included randomized controlled trials, mixed methods studies, qualitative studies, post hoc analyses, and prospective and retrospective cohort studies. Included studies contained at least one type of telehealth service and one primary measurable outcome and were assessed in rural communities/settings. We excluded systematic reviews, meta-analyses, editorials, conferences, unpublished studies and abstracts, studies outside the United States, and articles that were missing criteria based on the Critical Appraisal Skills Programme criteria. The Critical Appraisal Skills Programme has developed a set of 8 critical appraisal tools to assess the quality of evidence-based research; they have been widely used in previous studies [5].

To organize our review of the literature, we used Covidence, a review management tool, to conduct a review of titles and abstracts, and a full review of the articles. We used Covidence to exclude duplicate records. Both authors screened studies for relevance based on titles and abstracts. Both authors reviewed the full-text articles of relevant articles for study inclusion. Article discrepancies on study inclusion were resolved through formal discussion and consensus between the two authors. The Critical Appraisal Skills Programme checklists [6] were used to assess the quality and content of the articles. Additionally, we examined the reference lists of all included articles for other relevant references. Figure 1 outlines the article review process. We excluded articles due to irrelevance (n=13), wrong study design (n=8), wrong intervention (n=1), and wrong outcomes (n=1). We extracted the following information from each article: study design, telehealth type, therapeutic area, population, risk of bias, key message, and the primary outcome. We grouped the articles according to study population into the following categories: health care professionals, patients, and health care professionals and patients. This narrative literature review was exempt from ethics review as no human participant protection was required because no human participants were involved in this research.

Figure 1. PRISMA flow diagram. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Results

Overview

A total of 38 eligible articles were identified, of which 15 reported telehealth intervention outcomes and were included. The therapeutic areas examined included mental health (n=3), HIV (n=2), reproductive care/women's health (n=3), osteoporosis (n=1), orthopedics (n=1), acute ischemic stroke (n=1), cancer (n=1), substance use disorder (n=1), ophthalmology (n=1), and emergency medicine (n=1). The majority of the studies (n=9) analyzed telehealth interventions

in patients, followed by health care professionals (n=3) and both patients and health care professionals (n=3). Of the patient-centered studies, two studies were specific to veterans, two to Medicare beneficiaries, and one to Medicaid beneficiaries. [Table 1](#) outlines the characteristics the studies included in this review. The outcomes of these studies were focused on the following main themes: feasibility and acceptability of telehealth, diagnostic and treatment validation of telehealth, patient satisfaction and self-confidence, education and training, and telehealth design features including prevalence and access, type of service, and therapeutic area.

Table 1. Characteristics of the studies included in the review.

Study	Study design	Telehealth type	Therapeutic area	Outcomes	Risk of bias
Ward, 2018 [4]	Mixed methods	Tele-ED (emergency department)/telemedicine	Emergency medicine	Feasibility and acceptability	Medium
Hicken, 2017 [7]	Randomized	Internet and telephone-based care	Mental health	Feasibility and acceptability	Low
Stringer, 2018 [8]	Mixed methods	Electronic adherence monitor	HIV	Feasibility and acceptability	Low
Uscher-Pines, 2019 [9]	Randomized	Telelactation/telehealth	Reproductive care/women's health	Feasibility and acceptability	None
Huskamp, 2018 [10]	Retrospective	Tele-substance use disorder/telemedicine	Substance use disorder	Telehealth use	None
Mehrotra, 2017 [11]	Retrospective	Telemental/telemedicine	Mental health	Telehealth use	None
Sinha, 2019 [12]	Qualitative	Telemedicine	Orthopedics	Patient satisfaction	Low
Brechel, 2018 [13]	Retrospective	Telestroke Network	Acute ischemic stroke	Diagnostic validation	Low
Kapinos, 2019 [14]	Post hoc analysis	Telelactation	Reproductive care/women's health	Design and demand	None
Talbot, 2019 [15]	Retrospective	Telehealth	Mental health	Prevalence, diagnosis, and type of service	Low
Lewiecki, 2017 [16]	Prospective	TeleECHO	Osteoporosis	Acceptability and self-confidence	Medium
Moeckli, 2017 [17]	Mixed methods	Extension for Community Health Outcomes (ECHO)/telemedicine	HIV	Application and acceptability	Low
Gilbertson-White, 2019 [18]	Mixed methods	Oncology Associated Symptoms and Individualized Strategies (OASIS)	Cancer	Patient needs and satisfaction	Low
Liu, 2019 [19]	Qualitative	Teleophthalmology	Ophthalmology	Feasibility and acceptability	None
Demirci, 2018 [20]	Qualitative	Telelactation/telemedicine	Reproductive care/women's health	Feasibility and acceptability	Low

Patients

Of the nine studies that analyzed telehealth interventions in patients, three (33%) of them examined the feasibility and acceptability of telehealth. These studies demonstrated that internet, electronic adherence monitors, and telelactation are feasible and accepted in rural, underserved populations and

improve access to care (Table 2). The disadvantages were the following: comparative effectiveness outcomes were not different between caregivers receiving technology interventions and those receiving telephone-delivered support, results were not statistically significant in detecting differences in breastfeeding duration and exclusivity, and technological difficulties, such as loss of connectivity [7-9].

Table 2. Key messages from included studies.

Study	Key message
Ward, 2018 [4]	Telemedicine led to decreased staffing costs and improved physician recruitment and retention.
Hicken, 2017 [7]	Technology demonstrated feasibility and acceptability for delivering caregiver support to a group of largely older, rural, spousal caregivers of veterans with dementia.
Stringer, 2018 [8]	Electronic adherence monitor is acceptable and feasible in a rural US setting, but technological difficulties were present and may impede effectiveness.
Uscher-Pines, 2019 [9]	Telelactation participants were breastfeeding at higher rates and telelactation can be implemented in a rural underserved population.
Huskamp, 2018 [10]	There were low use rates of tele-substance use disorder (Tele-SUD) overall. Future studies should evaluate the effect of Tele-SUD on access and outcomes.
Mehrotra, 2017 [11]	States with a telemedicine law and a pro-telemental health regulatory environment had significantly higher rates of telemental health use.
Sinha, 2019 [12]	Telemedicine visits decreased indirect and direct costs, reduced travel time, and resulted in similar patient satisfaction.
Brechthel, 2018 [13]	Telestroke provides less restrictive criteria for clinical risk factors associated with the inclusion of hypertensive patients with stroke for thrombolysis.
Kapinos, 2019 [14]	Telelactation showed both demand for and positive experiences with telelactation in an underserved population.
Talbot, 2019 [15]	Rural Medicaid beneficiaries were more likely to use telehealth services than their urban counterparts, but absolute rates of telehealth use were low.
Lewiecki, 2017 [16]	TeleECHO showed substantial improvement of self-confidence in 20 domains of osteoporosis care and can improve osteoporosis care with greater convenience and lower cost than referral to a specialty center.
Moeckli, 2017 [17]	There was limited uptake of HIV Extension for Community Health Outcomes (ECHO) telemedicine in settings where veterans traveled to distant specialty clinics. Other telemedicine models should be considered for HIV care.
Gilbertson-White, 2019 [18]	Oncology Associated Symptoms and Individualized Strategies (OASIS) is easy to use, contains relevant content, and has pleasing graphics. Rural stakeholders perceived OASIS positively.
Liu, 2019 [19]	Patients and primary care providers have limited familiarity with teleophthalmology for diabetic eye screening and primary care providers reported difficulties with use.
Demirci, 2018 [20]	Telelactation was convenient and efficient, was accepted in rural areas lacking breastfeeding support services, increased maternal breastfeeding confidence, and showed several advantages over in-person and telephone-based support. Telelactation appears to be an acceptable delivery model for lactation assistance in rural areas.

A total of two studies examined the outcomes of telehealth use in Medicare patients with substance use disorder (SUD) and mental health disorders, designated as Tele-SUD and telemental, respectively. Huskamp et al [10] concluded that Tele-SUD has low use rates and is primarily used to complement in-person care and is disproportionately used by those with relatively severe SUD. Mehrotra et al [11] concluded that beneficiaries who received a telemental visit were more likely to be younger than 65 years old, be eligible for Medicare because of disability, and live in a relatively poor community; in addition, states with a pro-telemental health regulatory environment had significantly higher rates of telemental health use than those that did not.

The outcomes of the other four patient-centered studies included patient satisfaction, diagnostic validation, design and demand, and prevalence, diagnosis, and type of service. The advantages of telemedicine visits found in these studies included the following: decreased indirect and direct costs, lower travel costs and travel times, similar patient satisfaction compared to onsite visits, and patient satisfaction among telelactation users [12-14]. In addition, telestroke technology provides less restrictive criteria for clinical risk factors associated with the inclusion of hypertensive patients with stroke for thrombolysis [13]. Talbot et al [15] concluded that rural Medicaid beneficiaries were more likely to use telehealth services than their urban counterparts,

psychotropic medication management was the most prevalent use of telehealth, the proportion of users who accessed nonbehavioral health services through telehealth was significantly greater as rurality increased, and significantly higher proportions of telehealth users received services to address attention deficit hyperactivity disorder. There were no direct disadvantages reported in these four studies.

Health Care Professionals

A total of three studies analyzed telehealth interventions in health care professionals and reported outcomes. Lewiecki et al [16] examined the acceptability of TeleECHO and found that self-confidence in 20 domains of osteoporosis care showed substantial improvement. In addition, they determined that TeleECHO can contribute to alleviating the osteoporosis care crisis by leveraging scarce resources; providing motivated practitioners with the skills to provide better skeletal health care, closer to home, with greater convenience; and being lower cost than referral to a specialty center. Additionally, TeleECHO can be applied to any location worldwide with internet access, allowing access in local time zones and a variety of languages [16].

Another study examined the application and acceptability of a telemedicine intervention called HIV ECHO. Moeckli et al [17]

showed a limited adoption of ECHO, which was attributed partly to shifting ownership of care from HIV specialists to primary care providers (PCPs) and low HIV prevalence and long treatment cycles that prevented rapid learning loops for PCPs. More specifically, there was limited uptake of HIV ECHO telemedicine programs in settings where veterans historically traveled to distant specialty clinics [17]. The third study evaluated the feasibility and acceptability of a technology intervention for emergency departments, Tele-ED. Ward et al [4] concluded that Tele-ED hospitals tended to have decreased ED staffing costs—while the hospitals not applying this policy showed continually increasing staffing costs over time—and improved physician recruitment and retention. The only disadvantage to the study was limited uptake of Tele-ED (7/19 hospitals, 37%); however, these results conclude that more hospitals will likely use telemedicine to provide physician backup for advanced practice providers staffing the ED [4].

Patients and Health Care Professionals

A total of three studies analyzed telehealth interventions in patients and health care professionals. Gilbertson-White et al [18] examined patient needs and satisfaction with an electronic health tool, Oncology Associated Symptoms and Individualized Strategies (OASIS), and concluded that the web application is easy to use, contains relevant content, has pleasing graphics, and was perceived positively. There were infrequent users of OASIS in the group; however, both frequent and infrequent internet users positively evaluated the web application [18]. Liu et al [19] tested the feasibility and acceptability of teleophthalmology and concluded that patients and PCPs have limited familiarity with teleophthalmology for diabetic eye screening. A major disadvantage to teleophthalmology was that PCPs reported significant difficulty identifying when patients are due for diabetic eye screening and could not sufficiently initiate referrals [19].

Another study examined the feasibility and acceptability of telelactation. The advantages of telelactation were as follows: convenient and efficient, provided a needed service in rural areas lacking breastfeeding support services, and increased maternal breastfeeding confidence [20]. The barriers to use included maternal reluctance to conduct video calls with an unknown provider, preference for community-based breastfeeding resources, and technical issues, including limited Wi-Fi in rural areas [20].

Discussion

Principal Findings

This review of the literature indicates telehealth is used for a variety of disease states and rural populations across the United States. Health technology interventions are a critical component of health care services in rural areas; they decrease staffing costs, travel costs, and travel time, and increase the ability of residents to seek care (including specialty care) that they otherwise would not be able to access in remote locations. This review explored telehealth in a broad sense and included technology models for clinical use, education and training of health care professionals and patients, and preventive and primary care services. All of these included models have shown

feasibility and acceptability in rural populations, validating their importance and potential to improve outcomes and access to care.

Overall, the included studies reported positive outcomes and experiences of telehealth use in rural populations, including acceptability and increased satisfaction; in addition, the technology was considered convenient and efficient. Other notable benefits included decreased direct and indirect costs to the patient (travel cost and time) and health care service provider (staffing), lower onsite health care resource utilization, improved physician recruitment and retention, improved access to care, and increased education and training of patients and health care professionals.

Disadvantages of telehealth interventions included having tele-visits with unknown providers and technological issues such as loss of connectivity and limited Wi-Fi access in rural areas. Several studies reported that comparative effectiveness outcomes between telehealth and traditional visits were not statistically significant; however, these studies also noted telehealth technology was well accepted and implemented in rural, underserved populations and described the importance of testing additional technology interventions in these populations to identify which telehealth programs are most effective.

Feasibility and acceptability are the foundation for implementing new health technologies in any environment or setting. This validation shows that rural populations and underserved communities have the capability to implement telehealth, report satisfaction with telehealth interventions, and describe the interventions as both convenient and effective. Even in articles where telehealth programs did not show statistical significance, these programs have demonstrated feasibility and acceptability. Limitations often associated with technologies (eg, lack of Wi-Fi in remote locations, connectivity issues, and inability of persons to use technology successfully) were reported at low rates, much lower than common perceptions about using these technologies in rural communities. This shows these technologies can be implemented successfully and supports the extension of telehealth programs in rural communities throughout the United States.

A key additional finding of this review regards the appropriate types of telehealth programs. Although these technologies have been verified, these studies consistently highlight the need to test various telehealth programs in specific communities to validate which models are most effective; for example, diagnostic telemedicine versus telehealth video calls will have greater benefits in different settings and populations. It is important that we go beyond the scope of feasibility and acceptability to make sure we use telehealth programs to their full benefit and effect. The benefits have been established but the possibility of expansion of telehealth programs does not rely solely on testing just one model for a population but finding which model fits the community the best.

Additionally, while no articles with a primary outcome of telehealth use for COVID-19 met the criteria for inclusion in this review, the landscape of telehealth and digital health care has changed dramatically since the start of the pandemic. The acceptance of telehealth during the pandemic has accelerated

to the point that many of the barriers to telehealth use may have disappeared. To our knowledge, no reviews have been published on this topic in PubMed MEDLINE. Future reviews should focus on the changes in and outcomes of telehealth use in rural communities across the United States due to the COVID-19 pandemic.

The administrative regulations behind telehealth programs, especially in areas where reimbursement for telehealth programs is not enforced by the state, should be highly considered. Requiring insurance companies to provide telehealth services to their patients is key to providing access to health care services in rural communities. Rural communities lack the resources, staff, and expertise to be able to positively affect health care outcomes, health care quality, and health equity. This review highlights the need for additional telehealth program studies and research into long-term real-world outcomes. Evidence-based studies have the potential to establish significance and comparative effectiveness against traditional health care (ie, onsite services). Additionally, state, federal, and local policy should be updated to cover the use of these programs and provide grants and funding for researchers to implement and test these programs in rural, underserved communities to improve access and quality of care.

Limitations

There are several limitations to this narrative review. Publication bias is possible within this study as we leveraged only PubMed MEDLINE and omitted grey literature such as reports, government documents and releases, working papers, white papers, and evaluations. Searching additional databases would

potentially provide additional articles to be included in this review. Additionally, limiting our search time frame to the past four years excludes earlier publications and data on health technology interventions and outcomes; however, the objective of this review was to report the most recent information on telehealth programs as they have advanced and expanded greatly over the past several years. Lastly, this review only included rural communities in the United States and would not be generalizable to non-US territories or domestic, urban communities, and populations affected by COVID-19. This study is generalizable to rural, underserved populations and potentially to the clinical settings and specific therapeutic areas studied in the included articles.

Conclusion

This review highlights the current scope of using telehealth interventions in rural populations across the United States. Telehealth models were associated with positive outcomes for patients and health care professionals, suggesting these models can be effective for continuing education and training in the workplace. The findings of this review are limited to rural, domestic communities and are concentrated in specific therapeutic areas of disease. The findings support the existing literature on the need to increase and validate telehealth interventions and further update and implement policies to increase access and provide high-quality telehealth programs. Future telehealth interventions and studies examining these programs are warranted, especially in rural communities, and future research should evaluate the impact of increased telehealth use as a result of the COVID-19 pandemic.

Authors' Contributions

MB was the principal study investigator and conducted the article search. MB and YC reviewed all articles for inclusion. MB wrote the first draft of the article with input from YC. Both authors were involved in the study design, contributed to the interpretation of the results, contributed to the writing and revision of the manuscript, and approved the decision to submit the article for publication.

Conflicts of Interest

Abstract

Background: Telestroke has developed rapidly as an assessment tool for patients eligible for reperfusion therapy.

Objective: To investigate whether vascular neurologists can diagnose intracranial large vessel occlusion (LVO) as quickly and accurately using a smartphone application compared to a hospital-based desktop PC monitor.

Methods: We retrospectively enrolled 108 consecutive patients with acute ischemic stroke in the middle cerebral artery territory who underwent magnetic resonance imaging (MRI) within 24 hours of their stroke onset. Two vascular neurologists, blinded to all clinical information, independently evaluated magnetic resonance angiography and fluid-attenuated inversion recovery images for the presence or absence of LVO in the internal carotid artery and middle cerebral artery (M1, M2, or M3) on both a smartphone application (Smartphone-LVO) and a hospital-based desktop PC monitor (PC-LVO). To evaluate the accuracy of an arterial occlusion diagnosis, interdevice variability between Smartphone-LVO and PC-LVO was analyzed using κ statistics, and image interpretation time was compared between Smartphone-LVO and PC-LVO.

Results: There was broad agreement between Smartphone-LVO and PC-LVO evaluations regarding the presence or absence of arterial occlusion (Reader 1: $\kappa=0.94$; $P<.001$ vs Reader 2: $\kappa=0.89$; $P<.001$), and interpretation times were similar between Smartphone-LVO and PC-LVO.

Conclusions: The results indicate the evaluation of neuroimages using a smartphone application can provide an accurate and timely diagnosis of anterior intracranial arterial occlusion that can be shared immediately with members of the stroke team to support the management of patients with hyperacute ischemic stroke.

KEYWORDS

stroke; infarction; teleradiology; smartphone; telehealth; reperfusion; neurology; mHealth; application; mobile health; mobile applications; diagnosis; diagnostics

Introduction

In acute stroke management, early initiation is the most important factor in successful reperfusion therapy for both

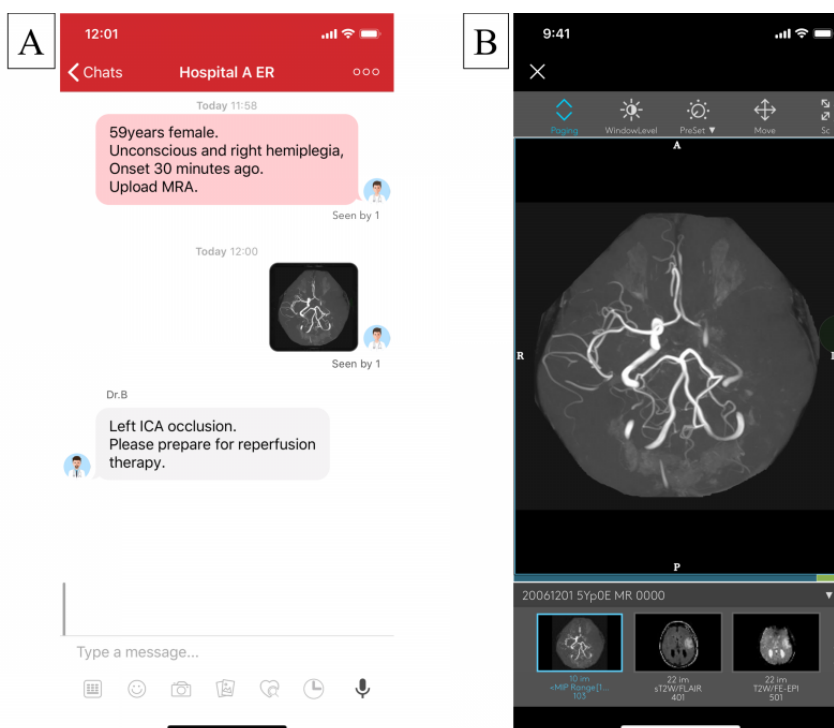

intravenous tissue plasminogen activator (IV-tPA) and mechanical thrombectomy (MT) [1,2] because the patient loses 1.9 million neurons every minute that a stroke is untreated [3]. The selection of appropriate candidates for reperfusion therapy

requires neurological evaluation and neuroimaging studies to be obtained immediately after admission. Accurate diagnostic information must be shared promptly within the multidisciplinary stroke team (comprising of emergency physicians, vascular neurologists, neuroradiologists, neurosurgeons, anesthesiologists, and ward nurses) to progress the decision-making process.

Because “time is brain” in acute stroke treatment, the appropriate use of information and communication technology (ICT), particularly telemedicine for stroke or “telestroke,” has become a valuable method for reaching out to patients who are eligible for IV-tPA and MT administration. Telestroke is continually

undergoing development, specifically in the United States and the European Union. The JOIN smartphone application enables the multidisciplinary stroke team to share clinical information and imaging data securely. Through JOIN, the intrahospital network system sends medical images from the hospital server to a shared chat room accessible to stroke team members only, similar to modified teleradiology and teleconferencing (Figure 1). Over 200 medical institutions in Japan and more than 11 other countries, including the United States, Germany, and Brazil, use JOIN. It is complementary to the telestroke system, particularly as an image evaluation tool [4]. In addition, the COVID-19 epidemic has increased the importance of teleradiology.

Figure 1. A. The JOIN smartphone application utilizes the easy-to-use interface of the social networking communication environment. B. The JOIN smartphone application displays diagnostic medical images, such as magnetic resonance imaging. ICA: internal carotid artery; MRA: magnetic resonance angiography.

Because the evaluation of large vessel occlusions (LVO) is vital for successful MT [5-7], the accurate and rapid diagnosis of LVO is clinically relevant. ICT can play an essential role in this regard by providing intranetwork and internetwork support. At our stroke center, the patients with acute ischemic stroke are initially examined via magnetic resonance imaging (MRI) rather than computed tomography (CT) due to hyperacute ischemic stroke being easily diagnosed on an MRI. LVO can be assessed via magnetic resonance angiography (MRA) without the use of a contrast agent. Although a previous study has reported favorable interdevice agreement between smartphone applications and desktop PC monitoring systems for evaluating CT images [8] and diffusion-weighted imaging on MRI [9], interdevice agreement for LVO on MRI is unknown. This study compares the speed and accuracy of LVO diagnosis by vascular neurologists between the JOIN smartphone application (Smartphone-LVO) and a conventional hospital-based image viewer using a desktop PC monitor (PC-LVO).

Methods

Patients

Consecutive patients admitted with ischemic stroke to Jikei University Hospital, Japan, between January 2016 and September 2017 were retrospectively enrolled in the study. The subtype of ischemic stroke was classified according to the TOAST (Trial of ORG 10172 in Acute Stroke Treatment) [10]. Stroke severity on admission was assessed using the National Institutes of Health Stroke Scale score [11]. After reviewing patients' medical records, 108 patients with ischemic stroke in the middle cerebral artery territory identified on MRI within 24 hours of onset were enrolled in the study. Patients who did not undergo MRI upon admission or for whom imaging was not available were excluded from the study.

JOIN Smartphone Application

The JOIN (Allm, Tokyo, Japan) smartphone application enables teleradiology of medical images, including MRI, CT,

ultrasonography, and angiography (Figure 1). Using JOIN, medical information can be shared immediately among the stroke team via SMS. Images from the initial MRI brain examination are sent immediately from the picture archiving and communication system (PACS) on the hospital server to each smartphone on which JOIN is installed. Users can enlarge and evaluate the images through a simple touch sequence on the screen of their smartphone.

MRI Protocols

All patients underwent routine 3D time-of-flight (TOF) MRA of the intracranial arteries and fluid-attenuated inversion recovery (FLAIR) of the brain on a 1.5T scanner (MAGNETOM Avanto and MAGNETOM Symphony). The imaging parameters were TOF MRA: repetition time (TR)/echo time (TE) = 23/7.15 ms, flip angle = 20°, section thickness = 0.6 mm, matrix = 320 × 288, field-of-view (FOV) = 18 cm; FLAIR: TR/TE = 9000/94 ms, flip angle = 160°, section thickness = 5 mm, section gap = 1.5 mm, matrix = 256 × 256, FOV = 21 cm.

Image Review

The image review process is shown in Figure 2. Prior to the review, 2 readers (TK and KS, Readers 1 and 2 with 8 years and 10 years of experience in vascular neurology, respectively) installed JOIN on a Jikei University Hospital iPhone (version 7; Apple). After they confirmed the operation of the application,

a radiologist transmitted the MRA and FLAIR data to the application. Patient image sets were presented randomly, and the readers were blinded to all background and clinical information. Both readers evaluated all the images from all patients. After receiving the MRA and FLAIR images, the readers independently assessed them on the JOIN application for the presence or absence of intracranial arterial occlusion; in the case of LVO, the site of arterial occlusion was identified. In patients with acute stroke, it is important to check for hyperintense vessel sign (HVS) on FLAIR, which suggests the presence of LVO [12]. HVS occurs because of slow flow due to LVO but is not an indicator of infarction. Therefore, the 2 readers evaluated the MRA images for LVO and evaluated the FLAIR images for HVS. The arterial occlusion site was classified as internal carotid artery (ICA), the horizontal segment of the middle cerebral artery (M1), or insular or cortical segments of the middle cerebral artery (M2 or M3, respectively). The diagnosis accuracy of arterial occlusion was defined as interdevice variability between Smartphone-LVO and PC-LVO. We recorded the interpretation time (minutes), defined as the time between receiving the MRI data to completing the interpretation. We used 1 to 4 min to interpret times in segments of 0 to 1 min, 1 to 2 min, 2 to 3 min, and 3 to 4 min. The 2 readers evaluated all MRI data using the hospital desktop PC monitor in the same manner 2 weeks later.

Figure 2. Flow diagram of the study design. LVO: large vessel occlusion, MRI: magnetic resonance imaging.

Statistical Analysis

Interdevice agreement for evaluating the presence of arterial occlusion was analyzed between Smartphone-LVO and PC-LVO via kappa statistics. Kappa scores for agreement were rated as follows: poor (<0.20), fair (0.21-0.40), moderate (0.41-0.60), favorable (0.61-0.80), almost perfect (0.81-1.0).

Wilcoxon signed-rank test was used to compare image interpretation times between Smartphone-LVO and PC-LVO.

P values <.05 indicated statistical significance. All analyses were performed using SPSS for Windows (version 22.0; BM-ARmonk).

Standard Protocol Approvals and Registrations

The Regional Ethics and Hospital Management Committee of the Jikei University School of Medicine approved the study (approval No. 29-197). The board waived the need for patient consent by giving patients from whom data had been collected the opportunity to opt-out of the study.

Results

Patient Characteristics

Table 1 lists the patient characteristics. We enrolled 108 patients with a median age of 69 years and a median NIHSS score of 4 upon admission, of whom 72 (66%) were male.

Table 1. Patient characteristics.

Variable	All patients (n=108)
Age (years), median (IQR)	69 (61-80)
Sex (male), n (%)	72 (67)
NIHSS ^a score on admission, median (IQR)	4 (2-7)
TOAST^b classification, n (%)	
Large-artery atherosclerosis	8 (7)
Small-vessel occlusion	14 (13)
Cardio-embolism	35 (32)
Other determined etiology	9 (8)
Undetermined	42 (39)
Modified Rankin scale at 3 months, median (IQR)	1 (1-3)

Interdevice Agreement Between Smartphone-LVO and PC-LVO

Interdevice agreement for evaluating the presence or absence of intracranial arterial occlusion was almost perfect between Smartphone-LVO and PC-LVO (Reader 1: $\kappa=0.94$, 95% CI 0.82-0.97; $P<.001$ and Reader 2: $\kappa=0.89$, 95% CI 0.77-0.92;

$P<.001$; **Table 2**; **Figure 3**). Regarding detection of lesions in individual arteries, interdevice agreement was almost perfect for ICA and M1 occlusion (**Tables 3 and 4**; **Figure 3**). For analyzing M2 or M3 occlusion, interdevice agreement by Reader 1 was almost perfect ($\kappa=0.89$, 95% CI 0.77-0.93; $P<.001$), and that by Reader 2 was favorable ($\kappa=0.75$, 95% CI 0.60-0.80 $P<.001$; **Table 5**; **Figure 3**).

Table 2. Comparison of evaluation of the presence or absence of intracranial arterial occlusion between Smartphone-LVO and PC-LVO.

Smartphone-LVO ^a	PC-LVO	
	Occlusion	No occlusion
Reader 1 (TK)		
Occlusion	33	2
No occlusion	1	72
Reader 2 (KS)		
Occlusion	42	5
No occlusion	1	60

^aLVO: large vessel occlusion.

Figure 3. Interdevice agreement for evaluation of intracerebral arterial occlusion and for the 3 vessel categories. The degree of interdevice agreement was almost perfect in the evaluation of the arterial occlusion sites and was higher for proximal than distal arterial occlusion sites. ICA: internal carotid artery.

Interpretation Time Between Smartphone-LVO and PC-LVO

Wilcoxon signed-rank test (2-tailed) revealed that the interpretation time was significantly longer for Smartphone-LVO than PC-LVO (Reader 1: $z=-3.547$; $P<.001$ and Reader 2: $z=-2.921$; $P=.003$). However, the median

interpretation time was the same between Smartphone-LVO and PC-LVO for each reader (Reader 1: 2 min for each method and Reader 2: 1 min for each method; [Table 6](#)). The interpretation time difference between Smartphone-LVO and PC-LVO was less than 1 min in 98% of the patient data sets in our series ([Figure 4](#)).

Table 6. Comparison of interpretation times between Smartphone-LVO and PC-LVO.

	Interpretation time of Smartphone-LVO ^a	Interpretation time of PC-LVO
Reader 1 (TK)		
Median minute (IQR)	2(2-2)	2(1-2)
Standard deviation	0.64	0.68
Min minute	1	1

Figure 4. Difference in interpretation times between Smartphone-LVO and PC-LVO for Readers 1 and 2. The difference in interpretation time between Smartphone-LVO and PC-LVO was <1 min in 98% of all patient datasets. Reader 1, left; Reader 2, right. LVO: large vessel occlusion.

Discussion

Principal Findings

The study results show that the smartphone application yielded an accurate diagnosis of anterior intracranial arterial occlusion in times similar to diagnoses completed using the hospital-based desktop PC monitor. Several studies have reported the use of smartphone applications for the management of stroke [4,13-15]; however, no study has reported their use for assessing LVO. To the best of our knowledge, this is the first article to examine interdevice agreement and compare interpretation times for MRA and HVS on FLAIR imaging between a smartphone application and a hospital desktop PC monitor.

The JOIN smartphone application shows promise for use in acute stroke management for several reasons. JOIN provides a platform for simultaneously sharing important clinical information among the entire stroke team via PACS, whether on duty or on call. Because the information shared within the team is secured, JOIN can seamlessly support intrahospital teleradiology for MT in the “drip and ship” acute stroke management model. Conventionally, after receiving a stroke call, the vascular neurologist must immediately access a desktop PC and log into the network and server before browsing images sent via PACS. The neurologist’s interpretation of the neuroimaging examinations is then shared over the telephone with one person in the stroke team. JOIN can substantially improve the speed of this process by reducing the time taken to evaluate neuroimaging, particularly in situations where the neurologist is not near a desktop PC or is not at the hospital at the time that treatment for hyperacute stroke is being decided. The utilization of the JOIN application should simplify and shorten the MT decision-making process.

Regarding the telestroke system, while peer-to-peer network protocols are standard, they are limited in that the sender communicates only with one receiver in the stroke team, much like a closed circuit loop. In contrast, the JOIN application enables multicasting communications from one sender to many

receivers. The team leader pre-authorizes which stroke team members participate in the secure group chat, and all of the patient’s data are centralized to the group chat. The entire stroke team can then receive notifications of the stroke patient’s arrival, view neuroimaging examinations, and review the medical plan via JOIN. Thus, important information is shared immediately among all members. JOIN also enables messaging among the team and displays neuroimaging files at a high resolution. Because the decision-making process is tracked via messages displayed on JOIN, the application plays a role in avoiding errors. Thus, combining the conventional telestroke system with JOIN would be desirable for arranging hyperacute stroke care in a complex and time-sensitive environment.

Finally, the telestroke system, comprising the 3 components of teleconsultation (doctor to patient), teleconferencing, and teleradiology, is confronted with developmental challenges in Japan. It is difficult for hospitals in Japan to introduce the real-time interactive video conference systems required for tele-examination using a hub and spoke model because there is no legal or regulatory provision for doctors on the hub side regarding patient examinations or a provision for medical decisions [16]. In addition, the Japanese government only approves medical practice via conventional encounters with a unique patient in emergency settings. Therefore, teleconsultation is only allowed under strict conditions (ie, for monitoring chronic disease after a second visit). In contrast, teleradiology is commonly used in Japan because of national insurance coverage. The advantages of using JOIN for acute stroke care include its portability, quick accessibility of target neuroimages, and its financial viability. In the near future, the Japanese Stroke Association plans to expand their practical guidelines for telestroke to include ICT solutions, under which JOIN would be considered for use.

Limitations

Our study has several limitations. First, the MRA images were evaluated by only 2 vascular neurologists, both of whom were experienced. In a future study, more evaluators should be used,

including less experienced evaluators. Second, the study did not directly prove that the smartphone application was useful for early reperfusion therapy. Finally, the study only evaluated anterior circulation ischemic stroke; its applicability to posterior circulation ischemic stroke has yet to be investigated.

Conclusions

A smartphone application yielded an accurate diagnosis of anterior intracranial arterial occlusion in times similar to

diagnoses completed using the hospital-based desktop PC monitor. It also enabled access to all patient information regardless of the user's location. Thus, this system can play an important role in organizing the stroke team to manage patients with hyperacute ischemic stroke.

Abstract

Background: Food insecurity is a global public health challenge, affecting predominately the most vulnerable people in society, including older adults. For this population, eHealth interventions represent an opportunity for promoting healthy lifestyle habits, thus mitigating the consequences of food insecurity. However, before their widespread dissemination, it is essential to evaluate the feasibility and acceptability of these interventions among end users.

Objective: This study aims to explore the feasibility and acceptability of a home-based eHealth intervention focused on improving dietary and physical activity through an interactive television (TV) app among older adults with food insecurity.

Methods: A pilot noncontrolled quasi-experimental study was designed with baseline and 3-month follow-up assessments. Older adult participants with food insecurity were recruited from 17 primary health care centers in Portugal. A home-based intervention program using an interactive TV app aimed at promoting healthy lifestyle behaviors was implemented over 12 weeks. Primary outcomes were feasibility (self-reported use and interest in eHealth) and acceptability (affective attitude, burden, ethicality, perceived effectiveness, and self-efficacy), which were evaluated using a structured questionnaire with a 7-point Likert scale. Secondary outcomes were changes in food insecurity (Household Food Insecurity Scale), quality of life (European Quality of Life Questionnaire with five dimensions and three levels and Functional Assessment of Chronic Illness Therapy-Fatigue), physical function (Health Assessment Questionnaire, Elderly Mobility Scale, grip strength, and regularity of exercise), and nutritional status (adherence to the Mediterranean diet).

Results: A sample of 31 older adult individuals with food insecurity was enrolled in the 12-week intervention program with no dropouts. A total of 10 participants self-reported low use of the TV app. After the intervention, participants were significantly more interested in using eHealth to improve food insecurity (baseline median 1.0, IQR 3.0; 3-month median 5.0, IQR 5.0; $P=.01$) and for other purposes (baseline median 1.0, IQR 2.0; 3-month median 6.0, IQR 2.0; $P=.03$). High levels of acceptability were found both before and after (median range 7.0-7.0, IQR 2.0-0.0 and 5.0-7.0, IQR 2.0-2.0, respectively) the intervention, with no significant changes for most constructs. Clinically, there was a reduction of 40% in food insecurity ($P=.001$), decreased fatigue

(mean -3.82 , SD 8.27 ; $P=.02$), and improved physical function (Health Assessment Questionnaire: mean -0.22 , SD 0.38 ; $P=.01$; Elderly Mobility Scale: mean -1.50 , SD 1.08 ; $P=.01$; regularity of exercise: baseline $10/31$, 32% ; 3 months $18/31$, 58% ; $P=.02$). No differences were found for the European Quality of Life Questionnaire with five dimensions and three levels, grip strength, or adherence to the Mediterranean diet.

Conclusions: The home-based eHealth intervention was feasible and highly acceptable by participants, thus supporting a future full-scale trial. The intervention program not only reduced the proportion of older adults with food insecurity but also improved participants' fatigue and physical function.

food insecurity; eHealth; television app; elderly people; vulnerable population; cognitive behavioral strategy; health innovation; multidisciplinary program

Introduction

Background

Food security is an essential prerequisite for a population to be healthy, active, and well-nourished. According to the World Health Organization, food security exists “when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life” [1]. As a comprehensive concept, food security depends on four essential dimensions: physical availability of food, economic and physical access to food, food use and maximization of consumption, and stability at all times [1]. When one or more of these dimensions are compromised, people or households are assumed to have food insecurity.

The multidimensional and self-perceived nature of food insecurity makes quantification challenging. Among the various instruments, the Household Food Insecurity Scale developed by the United States Department of Agriculture (USDA) is the most widely used tool in epidemiological studies [2,3]. This instrument classifies the food insecurity status of an entire household while considering multiple dimensions using a simple, easy, and validated approach [3].

Food insecurity is a global public health problem. Despite mainly affecting low-income countries, increasing evidence suggests that food insecurity is also highly prevalent in high-income countries [4]. For example, in the United States, one of the richest nations in the world, a USDA report states that 10.5% of households were facing food insecurity in 2019 [2]. Although this represents a lower prevalence since the Great Recession of 2008, the economic downturn caused by the COVID-19 pandemic may trigger an unprecedented food insecurity crisis [5,6]. National estimates in March and April 2020 indicate that the prevalence of this problem has more than tripled to 38% , which is the highest level of food insecurity ever measured in the United States [7].

In Europe, particularly Portugal, a country still recovering from an economic crisis, the impact of the COVID-19 pandemic is uncertain. The current economic, political, and social instability in this country may have overwhelming consequences, especially for individuals who are physically, economically, and socially vulnerable, such as older adults. Indeed, the

prevalence of food insecurity among older adults is remarkably high, with a study from our group reporting that 23% of older Portuguese people experienced food insecurity in 2015 and 2016, which is higher than the prevalence among adults [8,9].

The consequences of food insecurity among older adults present major challenges to the society. The aging of this population, which has a poor overall health status, physical comorbidities, limited family contact or assistance, and low income, can compromise the motivation of older adults to adopt health behaviors that are compatible with an active and healthy lifestyle, particularly those related to a healthy diet and physical activity. For this population, which has special nutritional needs, food insecurity is associated with a poor nutritional status, physical disability, muscle weakness, depression and anxiety symptoms, and lower health-related quality of life (HRQoL), which in turn increases vulnerability to other conditions, hospitalization, and death [9-14].

Developing strategies to mitigate the consequences of food insecurity among older adults is essential for increasing their quality of life and well-being. However, the unique characteristics of this population make it difficult to conduct an experimental study, leaving this particularly vulnerable and growing population with low access to health care innovation.

The promotion of healthy lifestyle habits and the resulting increase in well-being and quality of life among older adults could be addressed by eHealth interventions, which are defined as the use of information and communication technologies (ICTs) for health [15]. These interventions are low-cost, personalized approaches capable of increasing the autonomy of older adults and their access to quality health care [16-18]. Emerging evidence shows that eHealth interventions for older adults have delivered promising results in terms of improving nutritional status [19] and physical activity [20,21] and have positive clinical outcomes for specific conditions such as fragility fracture [22] and cardiovascular disease [23]. However, unique characteristics of the lifestyle of older adults should be acknowledged to overcome the associated barriers before the wider implementations of eHealth interventions [18,19,24].

Among the available ICTs, television (TV) is the device mostly used by older people [25]. As most older people's houses have a TV, this device could present an opportunity to successfully design and implement eHealth interventions aimed at promoting

healthy lifestyles with their daily life. By improving the nutritional status and physical activity levels, a TV home-based program might slow the decline in physical function and increase the well-being and quality of life among older adults experiencing food insecurity.

To promote healthy lifestyles among older adults with food insecurity, we designed a home-based intervention program using an interactive TV app [26]. Following the new Medical Research Council's guidance for developing and evaluating complex interventions [27], a multidisciplinary team of health

professionals (ie, physicians, nurses, nutritionists, and physiotherapists), physical exercise experts, telecommunications companies, stakeholders, and end users collaboratively developed the conceptual framework of the program (Figure 1). In this development process, 11 older adult participants in a focus group reported high app usability, adherence intention, and the expected impact of the program on behavior modification [26]. All aspects of program conception considered ethical, social, economic, cultural, and environmental implications for all stakeholders, as suggested by the Responsible Innovation Framework [28].

Figure 1. Conceptual framework of the program. TV: television.

Objectives

After the conclusion of the TV app development process [26], the next step was to analyze the feasibility and acceptability of this intervention program in a pilot study. The primary aim of this pilot study is to test the feasibility and acceptability of a multidisciplinary 12-week home-based intervention program focused on improving dietary and physical activities through an interactive TV app among older adults with food insecurity. The secondary aim is to assess changes in the key clinical outcomes at the 3-month follow-up. The results of this pilot study are crucial for understanding end users' interest and use of the TV app along with the suitability of the program to their needs.

Methods

Research Design

This pilot study used a noncontrolled quasi-experimental design with before and after measurements. Program feasibility, acceptability, and key clinical outcomes were evaluated at baseline and at the 3-month follow-up after the completion of the eHealth intervention. Older adult participants aged 60 years or above were recruited from 17 primary health care centers in the *Lisboa e Vale do Tejo* health region in Portugal.

Participants

A convenience sample of older adults with food insecurity from 17 primary care centers in *Lisboa e Vale do Tejo* health region was used in this study. Individuals were included if they (1) were aged 60 years or above, (2) were classified as having food insecurity during recruitment [29], (3) were able and willing to give written informed consent and a phone number contact and comply with other requirements of the study protocol, (4) were a Portuguese speaker or able to understand Portuguese, (5) were noninstitutionalized and living in a private household in Portugal, (6) had electricity at home, and (7) had cable TV with a box at home. Individuals were excluded if they (1) were unable to comply with the study protocol (eg, hearing or visual loss and cognitive impairment), (2) had an absolute contraindication to exercise, (3) had cable TV operated by a company other than MEO, Vodafone, or NOS, and (4) had a household member involved in the study. Participants were recruited between November 2015 and May 2016. During the recruitment phase, all older adults who attended health services in the selected primary health care centers were invited to complete an initial screening questionnaire, which included a food insecurity scale [29]. Participants who agreed to complete the questionnaire were asked to provide their consent for further contact. All participants who identified as having food insecurity were invited to participate in this study. In case of acceptance, the first baseline assessment appointment was scheduled. This

occurred during an appointment in a primary health care setting with a multidisciplinary team that included a physician, nurse, nutritionist, and physiotherapist. The physician asked for informed consent and checked the eligibility criteria.

Intervention

A detailed description of the intervention can be found in a previous study [26], which briefly comprised a 12-week home-based intervention focused on the innovative use of an interactive TV app. The design of the intervention program was based on a transtheoretical model of behavior change [30] and aimed to promote lifestyle behavior changes among older individuals with food insecurity by (1) providing education on the importance of a healthy diet and physical activity among older adults, (2) demonstrating that low household income is not a barrier to healthy lifestyle habits and that it is possible to have a healthy diet and practice physical activity at low cost, and (3) providing motivation for adopting a healthy diet and physical activity habits to reduce noncommunicable diseases. The pillars of program content were divided into nutrition and diet tips for healthy eating, low-cost healthy recipes, and physical exercise programs. Different contents were specifically structured based on the thematic weeks. The themes for each week and the respective content of each video were developed by considering the different types of food most frequently used in daily life routine (eg, vegetables, water, and milk). Nutrition and diet tips were based on the explanations of the benefits and harms of eating certain foods, especially regarding their relationship with risk factors for noncommunicable diseases and nutritional requirements for older adults [31-34]. Low-cost healthy recipes were specifically designed for our program using a popular Portuguese TV chef and a nutritionist. Finally, the physical activity program was developed by physical exercise experts with the specific objective of promoting the practice of physical activity at home for at least 30 minutes thrice a week [35].

All program content was disseminated on a dedicated TV channel via the interactive TV app and delivered on a scheduled basis on specific days of the week for developing a program access routine. To increase the participants' motivation, interactive TV reminders, including tips about healthy lifestyle habits, were sent on a weekly basis. In addition, participants had at their disposal the teams' telephone numbers and options to contact them whenever necessary. The research team also made frequent contact with the participants to increase their adherence and overcome difficulties. The TV app software included the delivery of small questionnaires aimed at assessing participants' compliance and learning during the intervention program. These questionnaires were delivered on a weekly basis and could be answered using TV remote control buttons. Any participant who opened the TV app fewer than 2 times during the intervention period was excluded from the data analysis.

Outcomes

Overview

The primary outcomes were feasibility and acceptability of the intervention program. Secondary outcomes were changes in

food insecurity, quality of life, physical function, and nutritional status after the intervention.

Data were collected using a structured questionnaire administered at two time points: before the intervention at study enrollment (baseline) and 3 months after the intervention (follow-up). The baseline assessment was performed by a multidisciplinary team (ie, physicians, nurses, nutritionists, and physiotherapists) at the primary care centers involved in the study using a computer-assisted personal interview system. At the 3-month follow-up, the assessment was performed by telephone using a computer-assisted personal interview system by a team of trained research assistants.

Baseline Characteristics

During baseline assessment, information was collected regarding sociodemographic (ie, gender, age, years of education, and marital status), socioeconomic (ie, employment status, household composition, household monthly income, and income perception), clinical (ie, food insecurity, BMI [kg/m²], anxiety and depression symptoms measured using the Hospital Anxiety and Depression Scale [36], and self-reported noncommunicable chronic diseases), and lifestyle characteristics (ie, alcohol intake profile, smoking habits, PREDIMED [Prevención con Dieta Mediterránea] score, perceptions of the importance and difficulty of healthy eating, frequency of watching TV, frequency of computer, videogame, tablet use, and frequency of internet use).

Feasibility and Acceptability of the Intervention Program
